> *My fear is that when the self-exclusion disappears, I have not come so far that I will not get stuck in gambling again…I think it is important that you try to solve your problems when you are self-excluded.* [Male participant, 43 years old]

Peer support groups, counseling services, and psychotherapy were deemed vital complements to self-exclusion. However, participants expressed reluctance to seek out support independently, underscoring the importance of proactive outreach and integrated support systems from within Spelpaus. Some of the participants who considered themselves to be more at risk of developing a gambling problem expressed that Spelpaus alone was enough for them.

> *If you take a year, and you have the opportunity to end it, then there needs to be some kind of dialogue before, and some kind of amount limit.* [Male participant, 55 years old]
>
> *I think it should be combined with a guaranteed CBT [cognitive behavioural therapy] or diary where you write what you feel, what you can do and what you think you should be able to do. Then of course, in the best of worlds, group therapy is perhaps even better than being digital.* [Male participant, 55, years old]

Addressing Loopholes

Participants raised concerns regarding the efficacy of Spelpaus in preventing access to overseas gambling sites. The absence of coverage for nondomestic operators posed a significant loophole, enabling some individuals to circumvent self-exclusion measures. Suggestions for improvement included enhanced international cooperation and stricter regulations on gambling advertisements.

Practical Enhancements

Participants proposed various technical and logistical improvements to Spelpaus, including more flexible and expanded self-exclusion options, longer time intervals, and a more deliberative process for ending self-exclusion periods. Mainly, participants asked for time intervals longer than 12 months. Several participants saw it as problematic to be able to gamble immediately after the end of a self-exclusion period. Additionally, participants advocated for heightened demands on gambling operators to deter relapse and streamline the self-exclusion process.

> *The self-exclusion service should be able to be developed so you cannot access overseas sites…when*

> *you select it, it should be covering all sites within the EU [European Union] or something like that…that you have a self-exclusion service for all of Europe when you choose it.* [Male participant, 62 years old]
>
> *The best thing would have been if there was a self-exclusion site where you are self-excluded from all gambling…that you have some kind of cooperation with other countries and everything and that it will be a stop everywhere.* [Female participant, 35 years old]

Several respondents stated that the possibility of returning to gambling after the self-exclusion period should still be hindered or slowed down in order to prevent impulse-related relapses even after the predetermined self-exclusion period is over. Some examples of this was an "embargo" period during which gambling still could not be reopened. Some participants found themselves waiting to gamble immediately after the self-exclusion period ended, so they suggested there be some kind of deposit limit for all clients coming back from self-exclusion, a mandatory telephone call or other message to individuals for whom self-exckusion is ending, prohibition of direct advertising to individuals immediately after a self-exclusion period, or mechanisms making the risk of gambling during alcohol influence smaller (eg, through prohibition of gambling during the night).

One respondent described the need for an embargo period:

> *After 12 months, you should not be able to cancel it on the same day; it should be 1, 2, 3 months notice…otherwise, when 12 months have passed, you can just gamble without any restrictions.* [Male participant, 32 years old]

Other respondents described the need for other possible measures to apply in the policy of self-exclusion:

> *After the self-exclusion ended, the advertising started coming again. It becomes like a reminder. So one could simply get going and gamble again!* [Male participant, 31 years old]
>
> *There should be some time to think it over when a client has asked to come back to gambling again. Some time should elapse, and then the person should be asked again. After some time, you should be asked about whether you really want to gamble again. There are people who get a kick, but after some time, that feeling migh pass again.* [Male participant, 44 years old]

Discussion

Principal Findings

This study aimed to deepen the understanding of the user experience of a nationwide, multioperator self-exclusion service, beyond what is known from recent quantitative research studies with web panel members and clinical data from patients in treatment for a gambling disorder. The potential challenges of a multioperator self-exclusion service have been demonstrated in surveys, showing that primarily among individuals with highly intense gambling practices, self-exclusion is popular but often breached by its users [13,14]. However, advantages of being self-excluded, and a deeper understanding of how this is related to the challenges of the method, largely remain to be understood.

Here, this qualitative study resulted in the description of 3 overarching categories that provide a deeper understanding of the problem: the main reasons for the decision to self-exclude, the advantages perceived by the users of this method, and the users' suggestions for improvements.

The decision to self-exclude from gambling platforms is often prompted by a sudden realization of escalating gambling behavior and a subsequent desire to regain control. Although the development of a disordered gambling pattern or financial difficulties were reported to have contributed to the decision to self-exclude, it was also reported, less expectedly, that self-exclusion may also be triggered by a wish to prevent another person from gambling on one's account. This may be a less expected reason for self-exclusion and will merit further investigation, especially in relation to the role of gambling in criminal behavior. Gambling or conducting financial transactions using somebody else's identity may represent one of the features of a severe gambling problem and also constitutes a criminal act [26].

Importantly, the role of the gambler's concerned significant others emerged as one of the reasons for self-exclusion. This highlights the importance of further addressing the interplay between individuals with gambling problems and their close ones and may also facilitate treatment processes if families of the affected individual are actively involved. This finding is consistent with previous research indicating that concerned significant others can favor treatment seeking and a favorable treatment outcome in their near ones with gambling problems [27,28]. In addition, the active participation of partners in the treatment of patients with a gambling disorder can be beneficial, both to the outcome of the affected patients and to the well-being of patients and their partners [29]. Thus, altogether, concerned significant others appear to play an important role through different phases of help seeking in individuals with problem gambling, even in the earlier harm-reducing interventions that self-exclusion is meant to represent.

Furthermore, the data showed that one reason for self-exclusion may be the intention to demonstrate one's willingness to quit gambling when formally applying for a public service where this is either required or believed to have an effect favoring the application process. This type of instrumental decision to self-exclude in order to obtain specific services or to fulfill expectations of external decision makers rarely has been reported in this context before. Whether this happens as part of an individual motivational process or entirely based on the requirements from others remains to be studied.

When external factors are cited as a reason to self-exclude, whether it be the concern of family members or the requirements from a treatment setting or authority, it can be argued that the choice to self-exclude does not represent the same decisive step in a motivational process as it does when an individual self-excludes based on their own decision to stop gambling in order to prevent or alleviate symptoms of addiction. Thus, the

possibly different levels of personal commitment associated with self-excluding will be relevant to include in the theoretical framework of self-exclusion in the future.

Overall, many favorable effects from self-exclusion were cited, despite previous experience where research has highlighted some major limitations of this service. Previous studies have been conducted using quite different methodologies, relying on larger quantitative data sets from online surveys [13,14] and clinical documentation [16], and where the findings were primarily the high rates of breaching one's self-exclusion within this service. This paper, importantly, adds to the literature regarding the present type of multioperator, nationwide self-exclusion service; in previous publications from this setting, it has been highlighted that the rate of breaching of one's self-exclusion is high in people with a gambling disorder [16] or with intensive online gambling patterns [14]. Here, several respondents described a large favorable impact on life after having self-excluded. Therefore, the description of more favorable experiences from this study provides a valuable experience, which contributes to the overall picture of this model, and strongly deepens the understanding of how this service fairs in affected individuals, over and above previous analyses conducted with quantitative methodology.

Although self-exclusion offered a respite from gambling-related stressors, several suggestions for improvements of the system emerged from the interviews. Participants emphasized the importance of holistic support systems and regulatory measures to augment its efficacy as a harm reduction tool. Suggestions for improvement partly followed what could be expected from previous web survey studies on gamblers; as many individuals who self-exclude also struggle with the risk of relapsing on overseas and nonlicensed gambling sites, users desired further legislative efforts making it possible to also self-exclude from other services, including those that are registered outside the present jurisdiction. Gambling in unlicensed, overseas online casinos has been reported to be the most common means of breaching one's self-exclusion period, as reported in the online surveys previously conducted here in this setting [13,14]. Thus, one major implication of this is the political process of how to exclude unlicensed gambling operators from the gambling market or to prevent financial transactions to gambling companies operating abroad. The legal framework and technical boundaries of this go beyond the scope of this study, but these findings highlight the need for gambling regulations to stretch beyond the controlling of the land-based gambling opportunity within each geographical jurisdiction.

One important and relatively novel suggestion was the linking between a mere harm-reducing self-exclusion service and actual therapeutic efforts against the addictive disorder. Importantly, this would move the purpose of the self-exclusion service from being an anonymous electronic support tool to actually providing a conduit to treatment. Treatment seeking in gambling disorder is known to be low, with several barriers reported [18]. Importantly, it has been reported that despite perceived barriers against treatment seeking, individuals with gambling problems may use more informal ways to seek help and not necessarily formal enrolment into psychotherapeutic treatment. For example, this may involve access to online advice or other online tools to facilitate a behavioral change [10]. In that aspect, any degree of referral from self-exclusion to different degrees of online support, advice, or treatment may be a way forward to improve the outcome of a person with gambling problems, over and above the effect of self-exclusion per se.

Such a system of transferring self-excluding clients to addiction treatment has not, to the best of our knowledge, been described in previous literature, and this may suggest a new area of research. For example, in such a system, it would have to be considered whether there is a potential barrier against enrolling in a self-exclusion service if it may, under some conditions, trigger a personal contact from a gambling operator, from a public authority, or from a treatment provider. However, it has been demonstrated that unsolicited motivational telephone calls to people displaying hazardous gambling habits may be a way to lower wagering and increase harm-reducing measures [30,31] and that acceptability of such motivational efforts appears to be high [32]. Thus, if self-exclusion from gambling would trigger an outreach effort aiming to improve the individual's gambling, it could be argued that this would not require a formal therapist-guided treatment but possibly may involve a brief, personalized intervention but with the capacity to refer individuals to further treatment when needed. Such individualized, personalized normative feedback has been suggested to be effective in other treatment or harm reduction interventions in problem gambling [33,34] and can initiate or enhance an internal motivational process in affected individuals, over and above the effects from the sole self-exclusion.

Likewise, another expansion of the self-exclusion tool, as suggested by this study, would be to slow down the procedure of opening up gambling opportunities after the self-exclusion period is terminated. This would also be a novel strategy that would require further study, but potentially, given the loss of the control component in gambling disorder, a more gradual onset of gambling after the self-exclusion period may provide further possibility to consider one's choice to gamble and may reduce the harm potentially associated with a sudden onset of high-risk gambling. Likely, any tool that slows down access to online gambling may potentially have a harm-reducing and relapse-preventing effect [35].

Overall, including the considerations made by interviewees in this study and their suggestions for improvement, a self-exclusion service generally appears to be promising and possible to increase even further. However, the major obstacle to this method, the risk of breaching one's self-exclusion through the use of gambling sites outside of the system, may remain. Here, one also has to consider the fact that the choice to self-exclude may cause the gambling patterns upon a potential relapse to happen on an unlicensed market and thereby with a lower degree of control than inside a licensed market. Previous experience, however, has pointed out that in individuals with extremely intense gambling patterns, such gambling patterns may happen on many operators, and a limit set upon one's gambling in one setting may be followed by gambling on another site. Still, even when this happens, such as during a deposit limit imposed during the COVID-19 pandemic in Sweden, still many clients report such a limit to be favorable and to have decreased their gambling pattern, rather than the

opposite [36]. Thus, although a method such as self-exclusion cannot hinder all types of gambling, it may still have motivational effects that limit the money lost and limits some of the consequences even in a high-risk gambling behaviour.

Strengths and Limitations

This study has a number of potential limitations, but given the novelty of the research topic and the merits of an in-depth qualitative study design, it also has considerable strengths. Recruitment via social media advertisements and digital interviews can be considered as both a strength and a limitation. The recruitment method enabled recruitment without any geographical limitations, therefore enabling a wide sample of individuals with different backgrounds, gambling habits, and experiences. However, it is possible that advertisements in social media attract interviewees with slightly different views on and experiences of self-exclusion from gambling than help-seeking individuals or individuals currently attending some type of land-based or online-based gambling venue. In contrast, the capacity of a qualitative design to identify a range of different aspects of a behaviour may benefit from this type of broad recruitment.

Digital interviews may represent another limitation, as these cannot readily be compared with physical interviews. Small changes in tone and body language are easily overlooked when the interview is held online. Meanwhile, the use of digital interviews in this study substantially facilitated data collection, widened the possibility to participate from the whole country rather than only locally, and may have facilitated recruitment of affected individuals who may not readily disclose their personal suffering and show up in person in a mental health–and addicion-oriented research unit. Indeed, challenges, but also potential advantages, of online qualitative research interview have been discussed in the research literature in recent years [37], pointing to the fact that such online interviews can play an important role in qualitative research.

Another potential limitation is the time aspect; some of the participants had recent or even ongoing experiences of Spelpaus, while others had been using it further back in time. Although this may be seen as a limitation, their information about their Spelpaus-related experience still is of great value (ie, as their ongoing or previous experience).

Additionally, the absence of a diagnosis of gambling gisorder as an inclusion criterion means that assessments of participants' gambling problems relied solely on self-reported statements and estimations, which may not capture the full spectrum of gambling-related issues. This limitation underscores the possibility that experiences with Spelpaus may vary based on individuals' level of gambling problems.

However, this study addressed a novel research issue and has strengths in a number of aspects. This is, to the best of our knowledge, the first qualitative study centered around the users' experiences of the relatively novel and unique nationwide self-exclusion service. Consequently, it offers updated and in-depth insights into gamblers' experiences with Spelpaus, elucidating its advantages and challenges as a harm reduction tool.

Conclusion

This qualitative study aimed to deepen the knowledge about and understanding of a novel nationwide service for self-exclusion from gambling. This includes the experience of individuals who have a history of being self-excluded, including their reasons for self-exclusion and their experience of the system's merits and challenges. Based on the interviews, this study suggests that although breaching one's self-exclusion remains a challenge, users of this service also report major advantages from being self-excluded. Users suggest further improvements to the self-exclusion model, such as international collaboration in order to prevent overseas gambling operators offering gambling outside of the self-exclusion system and also structured links from self-exclusion to further help and support, possibly also involving formal treatment. The study provided new information about self-exclusion and about a broader ranges of reasons for self-excluding, over and above the reporting of severe gambling problems (eg, the role of self-exclusion in the relationship with concerned significant others or to prove willingness to quit gambling). Several favorable effects from self-excluding were reported, in addition to a need for clearer obstacles against going back to gambling once self-exclusion ends.

Conflicts of Interest

AH has research funding for other projects from AB Svenska Spel, which is the state-owned gambling operator of Sweden, and from Svenska Spel's independent research council, as well as from the research council of Systembolaget, the Swedish alcohol monopoly. None of these organizations had any role in, or influence on, this project. The project itself was carried out thanks to funding from the research council of Svenska Spel. The funder did not have any influence on the procedures of this research or on the interpretation and reporting of results.

Abstract

Background: Peer support groups or web-based chats for young people offer anonymous peer support in judgment-free spaces, where users may share their thoughts and feelings with others who may have experienced similar situations. User engagement is crucial for effective web-based peer support; however, levels of engagement vary. While moderation of peer support groups can have a positive impact on the engagement of young people, effective moderation can be challenging to implement.

Objective: This study aimed to identify barriers and facilitators to user engagement with, and moderation of, web-based peer support groups among young people aged 16 to 25 years and to provide recommendations for enhancing this service.

Methods: Drawing upon the Theoretical Domains Framework (TDF) and the Behavior Change Wheel (BCW), this study conducted qualitative interviews and gathered open-ended questionnaires from service users and moderators of The Mix, the United Kingdom's leading web-based mental health platform providing peer support groups for young people. Semistructured interviews were conducted with 2 service users and 8 moderators, and open-ended questionnaires were completed by 7 service users. Themes were coded using the Capability, Opportunity, Motivation, and Behavior (COM-B) model and the TDF. The BCW tools were then used to identify relevant behavior change techniques to improve user engagement in, and moderation of, the service.

Results: Thematic analysis revealed a total of 20 inductive themes within 10 TDF domains—9 (45%) for engagement and 11 (55%) for moderation. Of these 20 themes, 3 (15%) were facilitators of engagement, 7 (35%) were facilitators of moderation, 4 (20%) were barriers to moderation, and 6 (30%) barriers to engagement. Results suggest that skills, knowledge, beliefs about consequences, intentions, emotions, and the social and physical environment are important factors influencing service users and moderators of group chats. In particular, supporting the improvement of memory, attention, and decision-making skills of those involved; adapting the physical environment to facilitate effective interactions; and reducing negative emotions are suggested to optimize the value and effectiveness of peer support groups for young people's mental health for both the service users and moderators of these services.

Conclusions: The study demonstrates the effectiveness of the BCW approach and the use of the TDF and COM-B model to understand the influences on behavior in a systematic manner, especially for mental health and well-being interventions. The findings can be applied to design structured interventions to change behaviors related to the engagement with, and moderation of, web-based peer support groups and, in turn, improve mental health outcomes for young people.

Introduction

Background

Young people aged 16 to 25 years are particularly vulnerable to mental health difficulties [1]. Recent evidence shows an increase in reported mental health problems for young people aged 16 to 25 years, particularly following the COVID-19 pandemic [2,3]. For example, in young people aged 17 to 19 years in England, rates of probable mental disorders rose from 17.7% in 2020 [4] to 23.3% in 2023 [5]. Nevertheless, health care systems and support often overlook the needs of young people [6]. In the United Kingdom, 75% of young people experience delays in accessing mental health support, leading to a worsening of their condition [7].

Web-based mental health communities are a viable option to bridge the mental health service gap for young people. They offer anonymous peer support in judgment-free spaces, where users may share their thoughts and feelings with others who may have experienced similar situations [8]. Web-based peer support can be asynchronous or synchronous, providing online support in a group format, with or without moderation [9,10]. Synchronous or real-time support, such as web-based chats, provides users with in-the-moment assistance without the delays that can occur within asynchronous services [11,12]. Notably, studies have shown the efficacy of web-based peer support platforms compared to in-person talk therapies [13]. They offer clinical effectiveness [14] and scalability for public health impact, enabling outreach to a larger population [13]. Therefore, there is a strong argument for the use of web-based peer support platforms for young people as they address key barriers and hold the potential to enhance mental health treatment by providing a safe, accessible, and effective means of support.

Despite numerous benefits, studies have also highlighted challenges to web-based peer mental health support that limit its effectiveness [15], including varying engagement rates [14]. Low rates of engagement can lead to negative outcomes, such as perceived exclusion and isolation [16], whereas high rates have been found to improve young people's mental health [17]. Effective moderation of web-based, user-led mental health services has been found to improve user engagement [18]. However, there are few studies examining user engagement in, and moderation of, synchronous web-based peer support groups, especially capturing the perspectives of both service users and moderators [11,19]. Service users, with their lived experience of giving and receiving support, can offer valuable insights and suggestions for improving these platforms. Moderators, due to their proximity to users and responsibility for supporting positive interactions, safety, and engagement [14], may have practical insights to enhance platform effectiveness [20]. A systematic examination of these behaviors from different viewpoints would enable the identification of tailored intervention strategies to improve moderation of web-based peer support services and enhance user engagement. Using the Behavior Change Wheel (BCW) [21], this qualitative research study investigates the barriers and facilitators to user engagement and moderation for web-based peer support groups among young people aged between 16 and 25 years and then proposes tailored strategies for optimization.

User Engagement in Web-Based Peer Support

Digital health research has defined user engagement as the extent and subjective experience (characterized by attention, interest, and affect) of use [22]. Studies measure engagement in terms of use time, log-ins, or module completion [23,24], with approximately 60% of studies measuring attendance alone to assess engagement [25]. However, although passive involvement or observational participation in web-based peer support groups has recognized benefits [26], considering only attendance falls short as it omits active participation and interaction, which fosters the sense of community and support unique to this service. Therefore, this study considers engagement in the broader sense, incorporating any observable written contribution, such as comments expressing thoughts and feelings or support for others. This inclusive approach captures subjective experience, aids barrier and facilitator identification, and can inform interventions for enhanced meaningful engagement.

Previous research highlights key barriers and facilitators to young people's engagement with digital mental health interventions and services [27,28]. Barriers include interventions that are perceived as unappealing or unhelpful, technical issues, privacy concerns, and young people lacking time or remembering to use the intervention. Facilitators include the personalization and flexibility offered by digital interventions, along with effective design, usability, opportunities to build connections, and the potential for a rewarding user experience [27,28].

However, there is a gap in research examining influences on young people's engagement in synchronous web-based peer support groups for mental health. Barriers and facilitators are likely to differ from those in other digital mental health services, as peer-to-peer support is viewed as less stigmatizing and more relatable [29]. In addition, synchronous interactions have a different pace compared to other formats [11]. Recent research focusing on peer-to-peer chats has centered on moderators' roles without including service user voice [30].

Moderation of Web-Based Peer Support

Moderation involves managing content, safeguarding, and providing support to users when needed [18]. It can be carried out by health professionals or trained volunteers [19]. Effective moderation has been found to have a positive effect on user engagement and has also been helpful in preventing "toxic" web-based settings [18]. Negative effects of web-based platforms such as trolling and stalking may also be prevented by effective moderation [16]. In web-based chat groups and

discussion forums, moderators ensure adherence to group guidelines to enhance user safety and prevent service users from becoming overly dependent on one another [31,32].

There has been limited research on the moderation of web-based mental health interventions [19]. Synchronous group settings pose distinct challenges as they require real-time monitoring of the chat and interaction between peers and moderators. In a recent study, Deng et al [30] explored moderation of peer support for a web-based mental health community. In this study, although moderators were qualified mental health professionals, they experienced challenges, such as dealing with emotionally triggering problems or hostile users. In a similar environment, Saha et al [33] highlighted challenges, such as a lack of concern for moderators' well-being and moderators' uncertainty about when to intervene. However, the services examined in these studies were not specifically designed for young people. Thus, there is a need to understand moderation and, importantly, how to enhance it, particularly in the context of real-time group chats for young people moderated by young volunteers, in a way that is structured and rooted in theory.

To address these research gaps, this study triangulates moderator and service user perspectives using a theoretically based behavior change approach, providing a comprehensive examination of user engagement and the moderation process in synchronous web-based mental health peer chats. The BCW provides a systematic and comprehensive framework to enhance understanding of behavior and support the identification of linked, relevant behavior change techniques (BCTs) to address the identified barriers and optimize group chat engagement [21].

BCW Framework

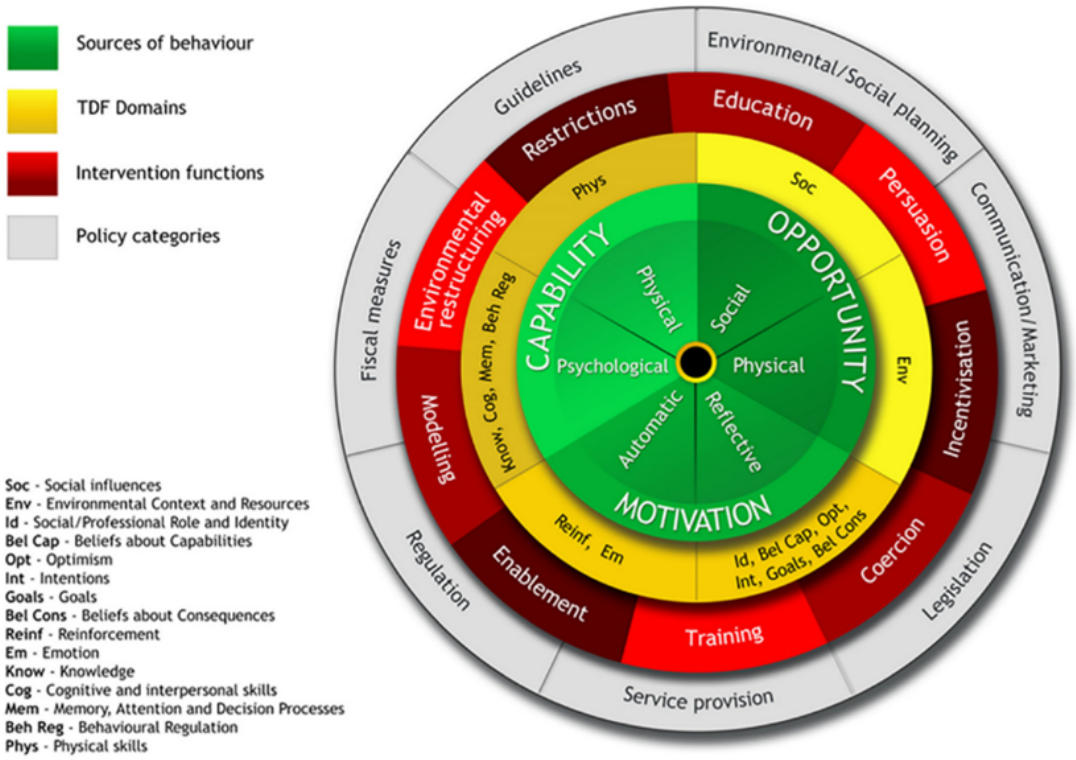
The BCW comprises interconnected tools to guide decision-making and facilitate the systematic development and evaluation of behavioral interventions [21]. At its center lies the capability, opportunity, motivation, and behavior (COM-B) model of behavior, which supports the identification of the barriers and facilitators to a behavior (Figure 1 [21]). Capability refers to an individual's physical as well as psychological capacity to perform a specific activity. Motivation is the cognitive processes that drive human behavior. Finally, opportunity refers to external factors that are outside the individual and may facilitate behavior.

The components of COM-B can be further elaborated into 14 domains using the Theoretical Domains Framework (TDF), providing a more granular understanding of the influences on behavior [34,35]. In the next layer of the BCW are intervention functions, which are the broad categories of means by which an intervention can change behavior. The outer layer consists of policy categories to support long-term, system-wide implementation.

The Behavior Change Techniques Taxonomy (BCTT) comprises 93 observable and replicable BCTs. The BCTT is a reliable method for specifying, interpreting, and implementing BCTs, which are considered "active ingredients" to facilitate behavior change either alone or in combination [36]. Expert consensus allows for mapping of the COM-B and TDF domains to intervention functions and corresponding BCTs, guiding appropriate strategies for change [37].

The BCW approach has been successfully applied in previous research to understand the barriers and facilitators to the use and delivery of digital mental health platforms for young people, including webchat counseling [28,38] and moderation of self-harm content in web-based discussion boards [39].

Figure 1. The Behavior Change Wheel and Theoretical Domains Framework (TDF) (adapted from Michie et al [21]).



This Study

Given the lack of research in this area, this qualitative study systematically explores the barriers and facilitators to the user engagement and moderation of synchronous web-based peer group chats for young people and proposes evidence-based strategies for improvement. Data were gathered from open-ended questionnaires and in-depth, semistructured interviews with young service users and moderators of The Mix, a web-based mental health support service for young people aged <25 years. Using the BCW [21], the following research questions were addressed:

1. Using the COM-B and TDF, what are the barriers and facilitators to young people's engagement in web-based peer support groups?
2. Using the COM-B and TDF, what are the barriers and facilitators to moderation of web-based peer support groups?
3. Using the BCTT, what strategies can be used to improve user engagement in, and moderation of, web-based peer support groups for young people's mental health?

Methods

Participants

This study collected data from service users and moderators of The Mix, the United Kingdom's leading digital mental health support service for young people aged <25 years. The Mix offers free mental health support, including a helpline, phone and webchat counseling, crisis support, discussion boards, and moderated live group chats. These synchronous group chats are freely available for young people aged 13 to 25 years. Table 1 summarizes the peer-to-peer mental health group chats of The Mix analyzed in this study.

The Mix circulated a poster to moderators (total population of 52) and service users to promote participation. Interested participants contacted the researcher through email, and their involvement was entirely voluntary. As shown in Table 2, a total of 2 service users were interviewed, and a further 7 service users completed an open-ended questionnaire about their engagement. A total of 8 moderators (n=5, 63% staff and n=3, 38% volunteers) participated in interviews about moderation. Of these 8 moderators, 4 (50%) staff members and 1 (13%) volunteer also completed a separate interview about user engagement. As this was a qualitative study, it aimed to gather rich and detailed data from participants, similar to previous studies in a similar context [38,39], rather than to achieve a representative sample.

All moderators were women, while most of the service users were either women or did not self-identify their gender, with the exception of 1 man and 1 nonbinary service user. Moderators were aged between 19 and 30 years, and service users were aged between 18 and 24 years (Table 2). Moderators were involved with The Mix ranging from 6 months to as long as 8 years and worked for 1 to 2 hours per week.

Semistructured interviews, based on the TDF, were conducted via the Microsoft Teams platform and transcribed for analysis. The interviews lasted between 30 to 60 minutes each and were designed to gain in-depth service user and moderator insights into experiences of group chats regarding peer interactions, structure of the chats, and feelings about contributing. Questions included, for example, "How long do you spend on The Mix's chat per week?" and "How do other people in the group chat

make it easier or more difficult for you to share your thoughts, feelings and experiences or support others with theirs?" Questions for moderators only included the following: "How do other people influence how you contribute to the moderation of posts on the group chats?"

For user engagement only, participants were offered the alternative option to complete an open-ended Microsoft Forms questionnaire to combat any difficulties young people felt in expressing themselves in an interview and may have hindered participation [28]. The questionnaire included 5 open-ended questions, exploring what made it easier or harder for users to share their experiences, what influenced their decision to participate or not, and what changes they would make to the chat if given the opportunity.

Table 1. The Mix's peer-to-peer mental health chat groups.

Group chat type	Description	Participants, n	Structure	Participation	Privacy	Moderation
Support chat	Peer support for mental health struggles	Variable	Open discussions	Active participation	No sign-up required, no password protection	Moderated by trained young volunteers and staff
Support circle	More intimate setting, where everyone takes turns to obtain support while the rest of the group listens	≤5	Rotating support and sharing	Sign up to receive support or as a "listener"	Password protected, full session attendance	Moderated by trained young volunteers and staff

Table 2. Participant information.

Participant	Data	Age (y)	Gender
SU1[a]	Interview	24	Man
SU2	Interview	18	Nonbinary

Data Analysis

Data were thematically analyzed using the 6-phase process developed by Braun and Clarke [40]. NVivo (Lumivero) and Excel (Microsoft) were used as analytical tools. The initial stage involved gaining familiarity with the transcribed interviews. A deductive coding approach was adopted initially, which involved reviewing items of data from the transcripts and questionnaires and organizing them into the TDF domains, providing a "start list" [41,42] of themes to be categorized as barriers or facilitators. The process was repeated using an inductive analysis to generate specific subthemes within each TDF theme. These subthemes were then reviewed, defined, and included in the codebook [43]. A codebook was developed to facilitate coding and was iteratively updated. As new data were added to TDF domains, facilitators and barriers were modified, expanded, or recategorized using the constant comparison method to identify patterns and variations within the dataset [44]. Triangulation

was completed with data from both service users and moderators to explore consistencies and contradictions in influences on young people's engagement with group chats. Reflexivity was prioritized to ensure openness and challenge in interpretations [45]. To ensure coding reliability and validity, 2 researchers independently cross-coded 1 transcript; a reliability check was conducted, and agreement was reached on any discrepancies.

Following data analyses, the coded TDF barriers were mapped to corresponding intervention types, using the BCW, and then specific BCTs were selected using the links specified in Cane et al [46] as well as the more recently developed Theory and Techniques Tool [47,48]. The selection of the relevant and appropriate intervention types and BCTs was informed by an appraisal of the affordability, practicability, effectiveness and cost-effectiveness, acceptability, side effects, and equity criteria [21]. This approach has been used in a multitude of studies [49,50] to evaluate intervention strategies. The selection of policy options was out of scope because the study was focused on a single organization rather than system level. Finally, the BCTs were operationalized, and intervention strategies were proposed based on a review of previous literature.

Ethical Considerations

Low-risk ethics approval was obtained from the University College London Ethics Committee (Z6364106/2023/03/149 social research, 25069/001). Participant information and a consent form were provided to interested parties to sign digitally and confirm consent. Participants were advised that participation was completely voluntary and they could withdraw at any time, up to 4 weeks after their data were collected. As reimbursement for the interviews, participants were given a £10 (US $12.45) voucher. Questionnaire respondents could opt into a lottery prize draw to win 1 of 2 £10 (US $12.45) vouchers by providing their email address. To protect participant privacy and confidentiality, data were fully anonymized.

Results

Overview

Table 3 sets out the themes identified as both barriers and facilitators to user engagement and moderation. These are set out according to both COM-B and TDF frameworks.

Table 3. The COM-B[a] and TDF[b] themes and subthemes for user engagement and moderation.

COM-B and TDF themes	User engagement subthemes	Moderation subthemes
Psychological capability		
Cognitive and interpersonal skills	• Difficulty expressing feelings and needs (barrier) • Skills to listen and validate (facilitator)	• Developing skills (facilitator)
Knowledge	—[c]	• Understanding the guidelines (facilitator)
Memory, attention, and decision-making	• Memory recall of guidelines (barrier)	• Responding quickly in complex situations (barrier)
Behavioral regulation	—	• Holding back on advice (barrier)
Reflective motivation		
Beliefs about consequences	• Judgment and confidentiality concerns (barrier)	• Impact of moderation (facilitator)
Social and professional role and identity	—	• Congruence between social and professional identity (facilitator)
Intentions	• Wanting to support others (facilitator)	• Intending to shape young people's perceptions (facilitator)
Automatic motivation		
Emotions	• Fear and anxiety (barrier)	• Distressing subject matter (barrier)
Physical opportunity		
Environment, context, and resources	• Overload and lack of structure (barrier)	• Organizational resources (facilitator) • Lack of visual cues (barrier)
Social opportunity		
Social influences	• Similarity and familiarity (facilitator) • Integration of new users and gaps in support (barrier)	• Support offered (facilitator)

[a]COM-B: Capability, Opportunity, Motivation, and Behavior.

[b]TDF: Theoretical Domains Framework.

[c]Not applicable.

Young People's Engagement

As shown in Table 3, a total of 9 barriers and facilitators were identified as subthemes across 7 domains of the TDF. Themes were mainly consistent across support chat and support circle responses, but a small number of differences arose between the 2, and these are indicated, where relevant, in the following subsections.

Cognitive and Interpersonal Skills (Psychological Capability)

Difficulty Expressing Feelings and Needs

Several service users and moderators described the difficulty users face in expressing their emotions and thoughts, which can prevent them from opening up in the chat. Subthemes are described below, together with illustrative quotes. Service user quotes are indicated by "SUX," volunteer moderator quotes are indicated by "MVX," and staff moderator quotes are indicated by "MSX," where "X" is the participant number, to identify each participant as per Table 2. One user commented the following:

> *[What makes it more difficult to open up is] not being able to express myself about feelings.* [SU8]

Moderators also noted that vague statements about one's emotional state without specific requests for support may be a barrier to others' engagement, as they provide insufficient guidance for other users to offer relevant support. For example, one user stated the following:

> *I think it depends on how someone phrases the question...if they're sort of saying, "And I'm feeling really low today" or "And I can't do this anymore," like some of those trickier comments.* [MV5]

Skills to Listen and Validate

Both moderators and users identified that having skills to effectively validate and listen to others facilitated peer support and engagement. One moderator noted the following:

> *The people that tend to offer the most peer support are those that...know how to validate someone's experiences.* [MS1]

Users described how they did this, with one user stating the following:

> *Everyone listened and waited their turn...I listened to others, and they encourage people waiting their turn to help others.* [SU6]

Personal experiences that related to others' struggles made it easier to connect and offer support, but 1 user stated the following:

> *There are some situations where I can't exactly relate...so I stay quiet.* [SU5]

Memory, Attention, and Decision Processes (Psychological Capability): Memory Recall of Guidelines

Difficulties in absorbing, retaining, and applying guidelines posed a significant barrier to a couple of users. Users indicated that they struggled to remember guidelines due to content volume, distractions, and cognitive limitations, impacting their ability to engage. Even long-term users found it challenging, with 1 individual expressing the following:

> *I can't actually remember what [the guidelines are]. They're very basic from what I do remember.* [SU1]

Mental health crisis situations further exacerbated guideline oversight, leading some users to unintentionally deviate from the chat's intended mode of engagement in the moment. Moderators noted that this issue was worsened by some users, particularly regular ones, who found the guidelines unengaging and tended to ignore them.

Beliefs About Consequences (Reflective Motivation): Judgment and Confidentiality Concerns

This was a barrier revolving around young people's apprehensions about being judged, misunderstood, or facing negative reactions when sharing personal thoughts and experiences, particularly in the presence of new members. One participant stated the following:

> *Some people feel like a new person may judge more or less or may be offended more or be offended less. So [withdrawing] very much sort of safeguarding themselves, protecting themselves, and protecting others.* [SU1]

This could also lead users "to not give too much information" (SU7). Similarly, a moderator highlighted concerns about users fearing judgment, with 1 moderator stating the following:

> *...judging that person for talking about that cause I think that's probably what they worry about quite a lot.* [MV5]

Both moderators and users mentioned concerns about confidentiality, giving examples of where their privacy was violated by other members, leading to negative consequences. As a result, they became hesitant to share. One moderator stated the following:

> *Some members also worry confidentiality will be broken so they don't open up in fear of the police being called.* [MS2]

Intentions (Reflective Motivation): Wanting to Support Others

Overall, the intention to create a supportive environment was a facilitator, which motivated users to engage to support others. One user expressed the following:

> *Most of the time, I try my best to offer support and be there for the person too. I just want people to be able to open up to me, and when they do, I try to be a good friend.* [SU2]

However, moderators were concerned that some users may prioritize self-support, limiting their involvement in supporting others and welcoming newcomers. One moderator stated the following:

> *Often times, the young people are so busy sharing their own experiences that they don't make enough space to support others who may be going through a similar thing.* [MS1]

Emotions (Automatic Motivation): Fear and Anxiety

A frequently mentioned barrier by both users and moderators related to the user's fear of being perceived as a burden by sharing their thoughts, feelings, and experiences. One user expressed the following:

> *As for not opening up so much that's more when I feel like I'm a burden and not wanted, but that's me not The Mix.* [SU4]

Users identified that "Worrying what people think" (SU7) in terms of oversharing or repeating themselves caused them to hold back or stop sharing altogether. Another user shared similar sentiments, noting that opening up more "doesn't really make me feel better, it just makes me anxious and guilty" (SU2). These feelings of self-doubt and anxiety hindered users from fully opening up and receiving the support they needed.

Environmental Context and Resources (Physical Opportunity): Overload and Lack of Structure

A barrier identified by almost all participants was the lack of structure and organization within the support chat, especially during busy times. This could result in confusion, overwhelm, and a sense of disorganization. Users sometimes struggled to fully engage and provide or receive support effectively because, as 1 user said, "When you have a lot of people, you do get to a point where you do have like five, ten different conversations going on, all different levels of importance so it does get a bit confusing" (SU1) and "It can be hard to type that fast" (SU6). One moderator added the following:

> *It can be hard for someone to post, and their message may get missed.* [MV5]

Another user highlighted the following:

> *Support Chat needs to be more organized...The way it currently is...stresses me out, I find myself leaving midway most of the time.* [SU9]

Social Influences (Social Opportunity)

Similarity and Familiarity

The presence of individuals who had experienced similar situations or who were known to each other was highlighted by moderators and users as helping foster a sense of belonging and encouraging engagement. One user noted the following:

> *It helps that there are people who know what you've been through, so you don't feel alone. It makes you feel more comfortable to open up.* [SU1]

It was seen to be "Easier to have people with similar problems and get ideas surrounding mental health teams etc." (SU3). Several long-term users also highlighted that regular participation by both users and moderators builds trust and familiarity, facilitating engagement. One user stated the following:

> *Because we've been with [the moderators] for some time, they understand our situations a little bit more so it makes it easier for us to open up to them and...we can trust them.* [SU5]

Moderators shared similar insights, noting that regular users "feel quite attached to the moderators, so they'll leave support circle and join support chat for a bit and then come back" (MV5).

Integration of New Users and Gaps in Support

A frequently mentioned barrier by several members and most moderators related to how some regular users tended to chat among themselves or with the moderators, making it difficult for new users to integrate into the group. This could lead to new users feeling like outsiders and being less likely to engage. One user stated the following:

> *When I first started coming to circle, it was very awkward for me because the other people in there had been doing it a lot longer and I felt like a bit of an outsider.* [SU5]

New users described not receiving responses to messages, which seemed to have a notable impact on them. One of them stated the following:

> *What prompts me to withdraw is when some of my messages get ignored. I know it's not on purpose but it kind of makes me feel unwanted.* [SU4]

This was a theme that was also recognized by multiple moderators as a deficiency in social support.

Moderation

As shown in Table 3, a total of 11 barriers and facilitators were identified as subthemes across 10 domains of the TDF. The following paragraphs describe the themes in more detail, along with selected quotes.

Cognitive and Interpersonal Skills (Psychological Capability): Developing Skills

Most moderators discussed how they developed their skills over time through a continuous learning process, which helped them become more effective and refine abilities such as active listening and conflict management:

> *But it's like a continuous learning process, so I wouldn't say they give you kind of training at the beginning of you know, how to be an active listener and how to give that specific type of support.* [MS1]

Observing and practicing moderating also helped develop the necessary skills for moderation. One moderator expressed the following:

> *I think a lot of it is just sort of the exposure and just sort of the repeated attendance of chats and you sort of build, you work out sort of what things you've said have gone down well.* [MS7]

Knowledge (Psychological Capability): Understanding the Guidelines

Knowing and understanding the guidelines and procedures laid out by The Mix was a recurrent enabling theme of moderation, mentioned by all moderators, facilitating the identification of what is and is not deemed inappropriate. One moderator expressed the following:

> *And then the handbook also has things around the tech side of things, so using the platform how to use the moderator functions as well, so we're able to mute people. We're able to freeze them and then remove them from the room as well.* [MS3]

The guidelines were also particularly helpful for directing individuals at risk through appropriate safeguarding procedures. One moderator stated the following:

> *"It's got things from and sort of managing young people that come in who are in crisis. So many kinds of questions to ask safely within the room and the kind of signpost we can give.* [MS2]

Memory, Attention, and Decision Processes (Psychological Capability): Responding Quickly in Complex Situations

The complexity of group chats acted as a barrier for most moderators, presenting challenges by their fast-paced nature and situations that moderators may not have come across before. Attentively responding to the chats becomes challenging. One moderator expressed the following:

> *But there's only so fast you can type, and only so many conversations you can kind of have going on at once that you can't talk to everybody.* [MS8]

In addition, dealing with novel or gray situations caused confusion about what is acceptable in the chat and what is not, making decision-making difficult. One moderator stated the following:

> *There's still some situations that catch me off guard. You know, some people saying things that I've not come across before, experiencing things that I've not come across before.* [MV5]

Behavioral Regulation (Psychological Capability): Holding Back on Advice

Having a natural inclination to offer advice made it difficult for some moderators to self-monitor their responses. Going against instincts and refraining from giving advice when young people shared their problems required self-monitoring of behavior. One moderator expressed the following:

> *It is like to go against that nature and leave it open to the room to support each other and not give advice.* [MS1]

As moderators found it difficult to hold back, effective moderation became challenging. One moderator stated the following:

> *We can't give medical advice, it's tough...we shouldn't really be saying (giving advice) to someone.* [MV5]

Belief About Consequences (Reflective Motivation): Impact of Moderation

Overall, the perceived outcome of moderation for young people, as understood by moderators, facilitated their moderation. Moderators had different beliefs on the impact that moderation had on young people. Some believed that moderation helped create a safe space. One moderator expressed the following:

> *I think young people find it really reassuring to have, like, moderators there because there's a lot of online support spaces, but they're not always moderated or kept safe.* [MS2]

Some moderators felt that young people could feel left out and unsupported. One moderator stated the following:

> *And sometimes the young people can feel like the moderators are not responding to them.* [MS3]

The vast coverage of the impact of moderation was also highlighted by moderators. One moderator expressed the following:

> *I think you do notice the impact because it covers everything OK, like mental health is the main domain. But it's also like everything like education, careers, drugs and alcohol. Just like everything that someone could be going through. So I think you do notice a wider impact.* [MV4]

Social or Professional Role and Identity (Reflective Motivation): Congruence Between Social and Professional Identity

The alignment of personal values and social identity with the professional role of a moderator facilitated moderation for all moderators. One moderator expressed the following:

> *I love volunteering and I love working in a church in the voluntary sector and working with charities. So and I like working with young people. A lot of my work has been with young people. So and yeah, I think it does. It does fit in that respect personally.* [MS3]

The role of a moderator aligned with the identity that moderators had built for themselves. One moderator stated the following:

> *I also work in mental health in my 9 to five job, so that really helps and that's why I wanted to start it in the first place because I started the chat at university and I was trying to broaden my experience working with people with mental health conditions.* [MS7]

Intentions (Reflective Motivation): Intending to Shape Young People's Perceptions

Some moderators expressed a deliberate intention to shape and manage young people's perceptions and expectations of the chat. One moderator expressed the following:

> *I've tried over the years to change the young peoples' perception of what the chat should be used for, I think that in the spirit of trying to make it more of a group conversation like a group chat.* [MS1]

This intention served as a strong facilitator for moderators. One moderator stated the following:

> *So I guess how we manage those situations, yeah, we can warn community members like, we encourage them to take a step back and let the moderators manage the situation. And yeah, we always let them know like they might be removed from the room if they don't like, listen to us.* [MS2]

Emotion (Automatic Motivation): Distressing Subject Matter

Most moderators identified that topics discussed in group chats, such as self-harm and suicidal thoughts, could take an emotional toll on moderators and cause stress and exhaustion. One moderator stated the following:

> *The topics that are being discussed are quite distressing. Examples are feeling very, very low and sometimes it becomes a bit of an echo chamber of you know, they're all talking about feeling like they want to end their life or feeling like self-harming.* [MS1]

These topics also gave way to discussions about the larger mental health ecosystem and evoked concern among the moderators for the young people. One moderator expressed the following:

> *Hard when you see them struggling. And so yeah, I think when that happens, you like worry quite a lot and it does kind of be on your mind for like a few days.* [MS2]

These distressing thoughts and related feelings inevitably acted as a barrier for moderators.

Environmental Context and Resources (Physical Opportunity)

Organizational Resources

The multitude of resources provided by The Mix was appreciated by all moderators. These encompassed guidelines, debrief forms, newsletters, and more, helping them moderate effectively. One moderator stated the following:

> *It really helps to have that handbook there to walk you through those guidelines and how to respond.* [MS3]

Moderation was facilitated through the ready availability of these resources, providing moderators with content that could be used in the chat. One moderator expressed the following:

> *And we have our Mod handbook which is really helpful in terms of giving us like example messages to pop in the group chat and to manage certain situations.* [MS7]

Lack of Visual Cues

Working in a web-based environment meant that moderators had to work without any visual cues, such as facial expressions. One moderator stated the following:

> *I think moderating is quite a unique task...especially when it's online.[MS2]*

This absence made it difficult for moderators to gauge the intensity of young people's emotions and thus required extra effort and attention, which could be a barrier for some moderators. One moderator expressed the following:

> *I guess you have to put a bit of extra effort into that because you don't have the visual cues of like, nodding and all that stuff.* [MS1]

Social Influences (Social Opportunity): Support Offered

Support offered during and after moderation (eg, support from supervisors and emails checking up on moderators) acted as an enabling influence. All respondents had an overwhelmingly positive response toward the support that they received from their supervisors and believed that this support helped them moderate. A respondent stated the following:

> *[The Mix] never makes you feel unappreciated. Like we get quite regular emails of just a reminder that you're all doing really good things...and I think yeah, when you have had a difficult chat and sort of things, they're feeling a bit hard, just things like that really make a difference.* [MS7]

In addition, volunteers reported that the presence of a supervisor in the chats made moderation easier. One moderator stated the following:

> *The moderator would flag it to the supervisor on shift and just say you know ohh it looks like these two are having a bit of a disagreement. What should we do?* [MS1]

One moderator expressed the following:

> *They are really understanding about wanting someone else to step in with a conversation that hits too close to home or needing 5 mins to yourself during the session. There is also a debrief form and if I say anything I felt unhappy with, they always chase it up to check on me or ask if I want more training in the area.* [MV6]

BCTs to Address Barriers

To optimize user engagement, Table 4 presents the BCTs identified to address the core barriers and enhance the facilitators, along with examples.

Table 5 shows the potential intervention types along with the corresponding BCTs to overcome the identified barriers to moderation.

Table 4. Barriers to engagement and strategies for change.

TDF[a] domain	Barrier	Intervention types	Potential BCTs[b]	Operationalization of BCTs
Cognitive and interpersonal skills	Difficulty expressing feelings and needs	Training	Instruction on how to perform a behavior (4.1[c]); behavioral practice/rehearsal (8.1)	Self-reflection worksheets: provide optional worksheets with guidance on identifying emotions and the support needed before users' participation in the group chat.
Memory, attention, and decision processes	Memory recall of guidelines	Enablement	Commitment (1.9)	Group agreement (in the support chat): collectively agree to abide by principles and behaviors aligned with the guidelines at the start of the support chat.
Memory, attention, and decision processes	Memory recall of guidelines	Education	Prompts/cues (7.1)	Reminders: implement periodic reminders or prompts about the chat guidelines to reinforce their importance and improve memory recall.
Beliefs about consequences	Judgment and confidentiality concerns	Education	Information about emotional consequences (5.6)	Share success stories: highlight success stories or testimonials from other young individuals who have benefited from engaging in peer-to-peer group chats.
Emotions	Fear and anxiety	Enablement	Reduce negative emotions (11.2)	Clarify burden misconceptions: provide information and resources from peers about the value of sharing and supporting each other, and share examples of challenges discussed by previous service-users in groups chats to address misconceptions that sharing is a burden and facilitate engagement.
Environmental context and resources	Overload and lack of structure	Environmental restructuring	Restructuring the physical environment (12.1)	Group similar topics and establish topic rotation: encourage moderators and members to brainstorm and group similar topics together either during the support chat (eg, via a poll website such as Slido) or before the chat (eg, via a poll on the discussion boards), allowing for more focused and meaningful discussions instead of fragmented conversations (alternative: create more themed chat sessions).
Environmental context and resources	Overload and lack of structure	Environmental restructuring	Restructuring the social environment (12.2)	Limit chat size: implement a cap on the number of members allowed in the support chat at 1 time to maintain a manageable and supportive group size.
Environmental context and resources	Overload and lack of structure	Environmental restructuring	Adding objects to the environment (12.5)	Emoticons: consider moving to a new chat software that enables members to offer immediate reactions to others' messages via emoticons rather than messages.
Social influences	Integration of new users and gaps in support	Enablement	Social support (unspecified; 3.1) and social support (practical; 3.2)	Buddy system: assign new users a designated "welcoming buddy" (peer) whose role is to encourage or practically facilitate interactions during their initial sessions; grouping or pairing system: pairing or grouping members in the chat as each other's dedicated "supporters" for the session to enhance peer support and encourage more engagement.

Table 5. Barriers to moderation and strategies for change.

TDF[a] domain	Barrier	Intervention types	Potential BCTs[b]	Operationalization of BCTs
Memory, attention, and decision processes	Responding quickly to complex situations	Training	Behavioral practice/rehearsal (8.1[c])	Practice sessions: create practice moderation sessions that simulate the quick nature of group chats, which could help moderators to enhance their attention and decision-making processes.
Behavioral regulation	Holding back on advice	Training	Self-monitoring of behavior (2.3)	Diaries: ask moderators to make a note of situations and monitor when they feel instinctively inclined to offer advice to avoid it in the future.
Emotion	Distressing subject matter	Enablement	Reduce negative emotions (11.2)	Positive messaging: providing information about the positive impact of moderation through regular updates (eg, weekly or biweekly emails such as "Here's the impact that you helped deliver!") to increase moderators' positive emotions and reduce concerns about young people.
Environmental context and resources	Lack of visual cues	Environmental restructuring	Prompts/cues (7.1)	Phrase book: prompts or cues may be provided to compensate for the lack of visual cues. A booklet of phrases or "words to look out for" may be provided such that moderators may look out for these words to gauge if an individual is at risk, which may otherwise be missed.

Discussion

Principal Findings

This study addresses a research gap by investigating the influences on engagement with, and moderation of, synchronous web-based peer support group chats to support young people's mental health. Using the BCW framework, thematic analysis revealed a total of 20 themes, 9 (45%) for engagement and 11 (55%) for moderation. Of the 20 themes, 3 (15%) were facilitators of engagement, 7 (35%) were facilitators of moderation, 4 (20%) were barriers to moderation, and 6 (30%) were barriers to engagement. The following discussion focuses on the COM-B and TDF themes that were prominent and common across both user engagement and moderation. The findings of this study are discussed in relation to previous research, and the potential BCTs to address the identified barriers to engagement and moderation are contextualized.

Facilitators Common to Moderation and Engagement

Cognitive and interpersonal skills and knowledge (psychological capability) enabled users to express their feelings and needs. Both moderators and users benefitted from having the skills to listen and respond to other users. Moderators developed these skills through practice and were supported by a strong knowledge and understanding of the chat guidelines. Similar themes have been found in other modes of web-based mental health support [39].

Intentions (reflective motivation) were also core themes for moderators and users—both were driven by their desire to help others and ensure that the chat was a valuable resource for users. This sentiment is echoed elsewhere in the literature on web-based support groups, where listeners aimed to create a "safe and warm" space for their clients [51]. Similarly, moderators in this study consciously resolved to provide a safe and nonjudgmental space for young people. This is a theme that can be seen elsewhere in the literature, relating to other web-based peer mental health communities [30].

Finally, for both engagement and moderation, social influences (social opportunity) was another facilitator, where other users, moderators, or supervisors were seen as understanding, supportive, and appreciative of others' needs. For users, this meant being able to share experiences in a safe environment, and moderators felt valued, appreciated, and encouraged in their moderation. Such support also promotes moderators' mental health. As has been previously suggested by Aldamman et al [52], perceived organizational support was positively related to mental well-being, reduced emotional exhaustion, and reduced stress among humanitarian volunteers. This aspect is also linked to the potential of moderators to contribute to the enhancement of the mental well-being of service users, as demonstrated by Perry et al [19].

Barriers Common to Moderation and Engagement

Group chats present a complex environment due to their dynamic and fast-paced nature, with multiple users. Users could find it difficult to remember and adhere to the guidelines, especially in pressurized situations (eg, crises). Although moderators were familiar with the guidelines, they found it challenging to make real-time decisions, particularly during busy chats when many users were interacting rapidly with one another. This inherent complexity can function as a barrier to effective moderation and engagement. With a continuous inflow of new messages in group chats, it becomes challenging to focus on messages and identify any specific theme, as noted by Li et al [53]. Moderators in this study also encountered difficulties in promptly and accurately assessing messages for potential at-risk situations, under time pressure, while simultaneously

ensuring that all the young people in the chat felt supported. The BCT of "Behavioral practice" can help equip moderators to handle novel situations quickly as they arise. This BCT has been successfully used to "positively influence" behavior in the context of user training [54] and in interventions supporting shared decision-making [55].

The challenges with rapid decision-making of how to respond partly resulted from the chat environment being unstructured and uncontrolled in terms of the volume and speed of message exchanges; this was a barrier for moderators and users. Implementing emoticons (BCT "adding objects to the environment") could offer an alternative and rapid way of engaging with messages, helping to express emotions while reducing message overload [56]. Previous studies have also highlighted participants of a Cognitive Behavioral Therapy-based peer support platform feeling overwhelmed and stressed due to message volume and unfamiliar dynamics [57]. This underscores the need for accessible and well-organized chat platforms. One promising BCT is "restructuring the physical environment." Similar topics could be grouped within the platform or support chat sessions could be themed to allow users to explore and self-organize into groups based on shared characteristics and pain points, as has been implemented elsewhere [58].

Another aspect of the environment that was highlighted in previous studies was the lack of visual clues to support decision-making. This was a particular barrier for moderators, impeding connection and relationship building [39,59]. The BCT "prompts/cues" has been previously suggested in a similar context to improve moderation [39]. These could be in the form of electronic prompts or suggested phrases that pop-up when a young person writes a phrase that may need to be flagged. Such prompts may support moderators to identify individuals at risk and compensate for the lack of visual cues. This BCT has been successfully used to prompt action by the user in various contexts [60] and can also be used to simultaneously address barriers related to memory difficulties.

Given the sensitive nature of the discussions within web-based peer support chats, it is perhaps unsurprising that emotions can constitute another barrier. The BCT of "reduce negative emotions" can help address this. For users, the fear and anxiety associated with disclosure can prevent them from sharing in the chats, hindering their access to the help they need. Previous interventions report participants finding it helpful to know that others were undergoing similar emotions, reducing feelings of isolation [61]. Therefore, providing information and resources from peers about the value of sharing and supporting each other, and sharing examples of challenges discussed in group chats by previous service users may facilitate engagement. This could further build a sense of a supportive and friendly community on the platform, which facilitates willingness to share feelings and difficulties in other contexts [57]. Dealing with distressing topics such as mental health issues, suicidal thoughts, and other issues that young people are dealing with often becomes emotionally exhausting for moderators. In this case, the BCT "reduce negative emotions" could involve providing moderators with information about the positive impact of their moderation, to counter any negative emotions. A scoping review highlighted that this BCT has frequently been used in the development of mental health interventions [62]. Resilience-building training may also be helpful in equipping moderators to deal with the "emotional cost" of content moderation [63].

Barriers Specific to User Engagement

The barrier of "difficulties expressing feelings and support needs" experienced by users aligns with a prior study on webchat counseling engagement among young people, which found users lacking self-expression skills [28]. "Constructive emotional sharing" is a skill that can be improved with practice [64]. Promising BCTs to address this barrier include "instruction on how to perform a behavior" and "behavioral practice/rehearsal." For example, self-reflection worksheets could encourage users to identify their feelings and practice written statements before participating in group chats [64]. Statements such as "I feel...when...because" could be shared, leading to more personalized responses [65]. These BCTs could prove particularly beneficial for newcomers or individuals less familiar with the dynamics of group chat interaction, also creating positive spillover to a further barrier "integration of new users and gaps in support." A barrier identified here aligns with a previous study, which found that receiving empathic comments initially has a significant cascading effect, motivating individuals to reciprocate and offer support to others [66]. To further encourage integration and support for new users, the BCT "social support" could be introduced by assigning a designated "welcoming buddy" whose role is to support new members during their initial sessions or pairing members in the chat as each other's "supporter" to enhance peer support and encourage more engagement. Prior research has shown that shared interests encouraged conversation between new pairs in a peer support intervention, who were strangers when they were initially paired [67].

Having judgment and confidentiality concerns constituted another barrier. Overcoming such concerns can contribute to more fluid communication in web-based peer support and are a core component of building trust [67]. The BCT "information about emotional consequences" may address this barrier through sharing success stories, statistics, or personal narratives. Within the recovery model, this increases a sense of acceptance, understanding, and authenticity, particularly for new service users who tend to experience these fears more than long-term users [68].

Barriers Specific to Moderation

Moderators found it difficult to hold back on offering advice. Rooted in the logic of care [69], moderation is contextualized and involves an empathetic dialogue or interaction between moderators and users [70]. In such an open-ended process, holding back, given the natural flow of an interaction, proved a challenge for moderators. "Self-monitoring of behavior" could be a potential BCT that may help moderators to keep their behavior in check and change it. This could be achieved by encouraging moderators to note when they instinctively offer advice or feel like they want to do so, allowing them to reflect and monitor their own behavior if such situations arise again. This technique has proved effective in many behavior change

interventions in different contexts [71,72], particularly for health behaviors [73,74].

Limitations

The findings of this study need to be considered in light of certain limitations. The sampling of this study was reliant on self-selection, which may have introduced bias and favored participation by more confident users and moderators, potentially influencing the barriers and facilitators identified [75]. Although the participants were assured that their responses would remain confidential and would not have any consequences with respect to their relationship with The Mix, they may nevertheless have given socially desirable responses, whether intentionally or subconsciously [76]. Furthermore, it is noteworthy that the study participants were predominately women, making the sample relatively homogeneous. However, the overall population of moderators and group chat users at The Mix is also mainly women (>70% of users and 95% of moderators). Finally, the study's findings are grounded in the data obtained from a single mental health group chat forum, which could limit the generalizability of the results to other chat contexts operating under different circumstances.

Conclusions

Group chats are an increasingly popular form of digital mental health intervention, and this study contributes to building the evidence base, which can help optimize them as a safe and timely form of mental health support for young people. It is particularly valuable as it examines synchronous group chats, which are characterized by in-the-moment empathic interactions and emotional connections. Through using the COM-B and TDF, the study found that skills and knowledge, beliefs about consequences and intentions, emotions, and the social and physical environment are important factors influencing both the users and moderators of group chats. In particular, supporting the improvement of memory, attention, and decision-making skills of those involved; adapting the physical environment to facilitate effective interactions; and reducing negative emotions are suggested to optimize the value and effectiveness of group chats for young people's mental health support for both the users and moderators of these services. The intervention types and BCTs proposed serve to emphasize the importance of training and support, particularly for moderators, in this important role. The study also further demonstrates the effectiveness of the BCW approach and the use of the TDF and COM-B to understand the influences on behavior in a systematic manner, especially for mental health and well-being interventions.

A natural progression of this work would be to implement and evaluate the interventions proposed in the study and gauge to what extent the suggested BCTs reduce the identified barriers. In addition, the fidelity of the BCTs could also be assessed to understand the nuances of intervention delivery [77] to facilitate contextualized tailoring of the intervention. In an environment where digital mental health interventions for young people continue to grow in significance, this study and future suggested studies can contribute toward ensuring that they are evidence based and consider the voices of young people themselves.

Abstract

Background: The literature around the safety of digital mental health interventions (DMHIs) is growing. However, the user/patient perspective is still absent from it. Understanding the user/patient perspective can ensure that professionals address issues that are significant to users/patients and help direct future research in the field.

Objective: This qualitative study aims to explore DMHI users' experiences, views, concerns, and suggestions regarding the safety of DMHIs.

Methods: We included individuals aged 18 years old or older, having experience in using a DMHI, and can speak and understand English without the need for a translator. Fifteen individual interviews were conducted. Deductive thematic analysis was used to analyze the data.

Results: The analysis of the interview transcripts yielded 3 main themes: Nonresponse: A Concern, a Risk, and How Users Mitigate It, Symptom Deterioration and Its Management, and Concerns Around Data Privacy and How to Mitigate Them.

Conclusions: The results of this study led to 7 recommendations on how the safety of DMHIs can be improved: provide "easy access" versions of key information, use "approved by..." badges, anticipate and support deterioration, provide real-time feedback, acknowledge the lack of personalization, responsibly manage access, and provide genuine crisis support. These recommendations arose from users' experiences and suggestions. If implemented, these recommendations can improve the safety of DMHIs and enhance users' experience.

KEYWORDS

digital mental health; safety; user perspective; patient perspective; qualitative; risks; risk mitigation; deterioration; nonresponse; data safety

Introduction

Digital mental health interventions (DMHIs) are mental health interventions that are delivered through digital platforms such as mobile apps, websites, or virtual reality [1]. Some of the added benefits of mental health interventions that are delivered digitally are improved accessibility, scalability, convenience, and the potential for anonymous engagement [2]. To realize these benefits, users need to trust that these interventions are effective and safe [2]. The evidence shows that DMHIs can be as effective as traditional face-to-face therapies, especially for common mental health disorders such as depression and anxiety

[3,4]. However, the safety of DMHIs is still an evolving field [1,2,5,6].

DMHI's users face similar risks to those in face-to-face therapy, such as deterioration in symptoms, novel symptoms (experiencing new mental health symptoms during treatment), and nonresponse [1]. Deterioration of symptoms, observed in approximately 3%-10% of psychotherapy cases [7,8], signifies a phenomenon where patients' conditions worsen during therapy. Deterioration is the most common side effect of mental health therapies (face to face and digital) [1]. There is a debate in the literature about whether deterioration is a normal and integral part of therapy or an unnecessary side effect [9,10]. A recent experts' consensus study concluded that short-term deterioration that occurs during therapy is part of therapy and should not be considered a safety concern; however, deterioration still needs to be monitored to ensure that it is not chronic, severe, and does not lead to an adverse event such as the patient dropping out of treatment [11]. Nonresponse occurs when the therapy is not effective in relieving the target symptoms [12]. It is considered a negative outcome as it hinders access to more effective treatments, spontaneous remission, and may prolong or even increase distress [12]. Additionally, the digital nature of DMHIs introduces additional risks to mental health therapies such as technical issues and privacy concerns [5,13].

The expanding body of literature addressing the safety of DMHIs is noteworthy [1,5,6]. While considerable attention has been devoted to exploring the safety of DMHIs (how it is assessed, analyzed, and reported), a notable gap exists in the qualitative understanding of individual perspectives on the topic. Existing qualitative studies in this field have either focused on the viewpoints of health professionals and medical students [14,15] or have sought user opinions on specific digital innovations usually as part of a wider program of development work. A few studies have sought service users' views on digital interventions more generally [16-18], but no work to our knowledge has investigated user/patient perspectives specifically about the safety of these technologies [19,20]. Understanding the user/patient perspective on safety can help direct future research in the field to ensure professionals focus on issues significant to users/patients; identifying users' concerns can help professionals address these issues, leading to higher rates of adherence and engagement. For that reason, this qualitative study aims to explore DMHIs users' experiences, views, concerns, and suggestions regarding the safety of DMHIs.

Methods

Design and Aim

This qualitative study utilized individual interviews to explore users' experiences, views, concerns, and suggestions about the safety of DMHIs. The Consolidated Criteria for Reporting Qualitative Research (COREQ) was used to report the results of this study [21].

Recruitment

The study included individuals aged 18 years or older, with previous experience using a DMHI, and speaking and understanding English without the need for a translator. The DMHI needed to be a mental health intervention that was provided via a tech-based medium (eg, app, website, virtual reality) and targeted a specific mental health condition. Participants were recruited using nonpurposive sampling by posting advertisements on authors' own professional social media platforms, such as X (formerly Twitter; X Corp.) and LinkedIn (Microsoft Corporation), an online participant recruiting platform (MQ; MQ Mental Health Research), the university's (King's College London) research volunteering circular email, and through DMHI trials whose participants consented for their details to be shared for future research. A total of 54 potential participants reached out; 15 (28%) were eligible and participated in the study, 7 (13%) did not complete the online eligibility form, and 32 (59%) were ineligible. Eligibility was determined through screening questions asked of potential participants to gather further details about the specific intervention used. The main reasons for ineligibility were that the intervention used was telehealth (eg, face-to-face therapy conducted via video call) or did not target a specific mental health condition (eg, mindfulness apps).

Participants

A total of 15 participants were recruited to participate in this study. Researchers initially estimated a sample size of 6-16 participants based on pragmatic recommendations from the literature, suggesting that 6-16 interviews provide sufficient information power [22]. Then the final sample size (15 participants) was determined based on the richness of the data and their ability to sufficiently answer the research question [23]. Of the 15 participants, 12 (80%) were females and 3 (20%) were males. All participants lived in the United Kingdom at the time of the interviews. Participants had an average age of 30 years (SD 6.43 years; range 19-42 years). On average, participants had used a DMHI for 8 months (SD 10.51 months; range 1-36 months). The DMHIs used by participants in this study were Beating the Blues, Calm Harm, FREED-M, Happify, Molehill Mountain, Moodkit, Silver Cloud, Sleepio, STOP app, Woebot, Youper, and an online intervention for Bulimia. See Table 1 for more information on the interventions used by participants in this study. Some participants used the DMHI for both anxiety and depression. Other than that, no other participants used the DMHI for more than 1 target symptom or condition.

Table 1. The DMHIs[a] used by participants in this study (N=15).

DMHI	Values, n (%)	Duration (months) of use, mean (range)
DMHI's target symptom/condition		
Depression and anxiety	5 (33)	3.4 (1-6)
Depression	2 (13)	19.25 (2.5-36)

[a]DMHI: digital mental health intervention.

[b]N/A: not applicable.

Materials

Individual interviews with participants were conducted and recorded online via Microsoft Teams (Microsoft Corporation). Interviews were semistructured. See Multimedia Appendix 1 for the topic guide. The interviewer (RT) used prompts to facilitate and guide the discussion. RT has experience conducting individual interviews for research purposes.

Procedure

Participants viewing the study advertisement were asked to email the researcher if they were interested. The researcher replied to introduce them to the study, share the participant information sheet (PIS), and request that they complete an online (Qualtrics) questionnaire to check eligibility. The same researcher contacted eligible participants to check that they had read the PIS, answered any questions that they had, and asked if they were interested in participating in the study. Those expressing a desire to participate were emailed an online form that includes a few questions (details below) and an e-consent form (using Qualtrics) to sign and a link to book a 1-hour slot for the interview. The online form asked for demographic details such as gender and age, details about the intervention (name and intended purpose), and how long they used the intervention for. All interviews were audio recorded. At the end of the interview, participants were sent a thank you email and a £20 (US $25) voucher as compensation for their time. Interviews lasted on average 40 minutes. Recordings were automatically transcribed by Microsoft Teams and were verified for accuracy by RT. Once transcription was complete all recordings were deleted.

Analysis

Thematic Analysis Process

The 15 transcripts were uploaded onto NVivo (Lumivero, LLC) for analysis [24]. We used deductive thematic analysis to analyze the data. Thematic analysis is a process used to identify

patterns or themes within qualitative data to answer or explore a research question [25,26]. The analysis was conducted collaboratively by 2 researchers (RT and JY), who followed Braun and Clarke's [25] step-by-step guide to conduct a thematic analysis by familiarizing themselves with the 15 transcripts and coding the data. They then organized the codes based on relatedness, reviewing them, and defining and naming them as subthemes and themes [25]. The thematic analysis acknowledges "the researcher's reflective and thoughtful engagement with their data, and their reflexive and thoughtful engagement with the analytic process is essential" [25]. It recognizes the potential benefits of using multiple coders, such as achieving richer interpretations, however, it does not view this as a requirement [26]. Researchers are discouraged from attempting to provide accounts of "accurate" or "reliable" coding or pursuing consensus among multiple coders [26].

Given the research question and acknowledging that participants' experiences and perspectives on safety may vary in this study, the analysis was used to reflect the range of experiences of participants and highlight how these might differ, rather than attempting to merge these experiences into a single, unified interpretation [25]. Once the results of the study were ready, they were shared with all 15 participants to review and ensure that they were representative of their experiences. Three participants responded and said that they agreed with the results and did not offer any additional insights or suggest any alterations.

Researcher Reflexivity

A critical realist epistemology was adopted for this study, where the researchers aimed to explore participants' subjective experiences, acknowledge them as "real," and recognize the researchers' inability to fully access that reality [25]. The researchers were aware of their reflexivity [27]; at the time of this study, they all worked on a separate clinical trial that aimed to assess the efficacy and safety of a specific DMHI. The first author (RT) was completing her PhD on the safety of DMHIs. This study was 1 of 4 separate pieces of work for the PhD (other work comprising a systematic review, a methodology paper, and an experts' consensus study). This study was not directly related to or in any way part of the clinical trial that researchers were working on. As a team, the researchers were invested in learning how users/patients experience risks, react to them, and what risks matter to them in order to contribute to the field and improve their approach to safety.

Ethical Approval

Ethical Clearance was provided for this study by the King's College London (reference number LRS/DP-22/23-35403).

Results

Overview

The analysis of the data using deductive thematic analysis led to 3 major themes:

- Nonresponse: A Concern, a Risk, and How Users Mitigate It
- Symptom Deterioration and Its Management
- Concerns Around Data Privacy and How to Mitigate Them

Theme 1: Nonresponse: A Concern, a Risk, and How Users Mitigate It

Assessing the Effectiveness of DMHIs

Under this theme, participants spoke about their concerns regarding the DMHI being ineffective, experiencing ineffectiveness/nonresponse as a risk, and the methods they used to assess whether a DMHI was safe and effective.

Concerns Around Nonresponse

Users of DMHIs were concerned about the potential ineffectiveness of these interventions. Will these interventions be able to help them? Are these interventions evidence-based? One important area of concern is illustrated as follows:

> *Umm, I was concerned with like how helpful it would actually be, being that it is an online thing and like I'm not actually talking to a person you know...I was even actually concerned when I started the first session, whether the program would have lasting effects on actually helping me or supporting my mental health.* [Participant 6, used a DMHI for depression for 2.5 months]

It is likely that participants were doubtful about their interventions' effectiveness because they were struggling and in such emotional pain that they were unsure how a technology with no human could alleviate their pain and improve their mood.

Nonresponse as a Risk

Participants also spoke about the risk of the DMHI being unhelpful and ineffective, and how that at times led to further frustration, deterioration, and self-blame, for example:

> *I found it ineffective, if I'm honest. I think it was the set of six or eight weeks...I remember that the second week I burst into tears. It just felt so pointless. I can't remember what set me off, but it just felt so pointless.* [Participant 9 used a DMHI for an eating disorder for 1.5 months]

Another participant explained how the ineffectiveness of the DMHI led to a deterioration in her symptoms and feelings of isolation and self-blame. She said:

> *So, it's sort of added to that frustration when it was making the situation worse...So now, I felt like it would lead me to do sort of negative coping strategies...I'd be like get angry and irritable with people, or I'd go and overeat....it definitely sort of furthered the thoughts that there was like no one to help me...It made low moments even worse...It almost triggered sort of thoughts of like, oh, something's wrong with me. Why can't the program help me?* [Participant 14 used a DMHI for post-natal depression for 24 months]

Users' Method for Assessing Safety and Effectiveness

Users used 2 main methods to assess whether they thought a DMHI was safe and effective: (1) social proofing, which refers

to the tendency to follow the behavior of others as a guide for one's own actions [28]; and (2) assessing the contribution of experts or a trusted body. Some participants opened up about finding it difficult to assess the safety of a DMHI, and not knowing how to do that.

Participants wanted to know that professionals were involved in the development of the DMHI and that scientific research has been conducted to assess it, saying:

> *I suppose I would want to know how it was developed and in partnership with mental health practitioners...so I think with credibility, I guess things like whether they have worked with the university or with kind of recognized academics and done any kind of scientific research and rather than just user testing.* [Participant 11 used a DMHI for insomnia for 1.5 months]

In this participant's case in particular, knowing that the intervention was evidence-based was very important because she had struggled with insomnia for more than a decade and had tried many things (face-to-face therapy and medication) that were not helpful for her. Users also relied on other users' experiences. They checked reviews, ratings, and social media groups to find out more about the DMHI. The following quote is an example of this:

> *Uh, I have this habit of looking up these things online, so I would look up reviews of the app online. Maybe even check out any details about how helpful it has been. If people have had good experiences, bad experiences, they've had negative experiences, what have they been about and how I could avoid them. I would maybe even like look at Facebook groups.* [Participant 6 used a DMHI for depression for 2.5 months]

Some participants were honest about not knowing how to check the safety of the DMHI, and needing the support of professionals to be able to do so, they said:

> *I mean, unless it was like referred by my GP or kind of, you know, promoted through kind of official channels like the NHS website or something, I don't know how I would even check that an app has all the right checks, and you know safeguarding approvals or whatever.* [Participant 13 used a DMHI for depression and anxiety for 2 months]

Other participants suggested that the DMHI needs to assess users' suitability, saying:

> *I guess before someone's able to access the app kind of going through, I don't know, some sort of risk assessment on like who would find it useful.* [Participant 7 used a DMHI for paranoia for 3 months]

Another participant thought that this could be achieved by the DMHI clearly stating its intended use and target population:

> *I think the app would need to be really explicit about the limitations and sort of say up front like this is not for severe mental health issues or this is for maintenance.* [Participant 14 used a DMHI for post-natal depression for 24 months]

Theme 2: Symptom Deterioration and Its Management

Addressing Symptom Deterioration in DMHIs

Under this theme, participants spoke about experiencing symptom deterioration. Participants also gave their feedback on one of the methods used to support them when experiencing or struggling to cope (referral to other services and crisis support) and their suggestions on how deterioration can be managed.

Deterioration of Symptoms

Participants talked about how using a DMHI and dealing with their mental health struggles at times led to a deterioration in their mental health symptoms because it made them think about things that were upsetting. One participant who was struggling with sleep said:

> *I did find thinking more closely about my trouble with sleep did initially make me more anxious about sleep and made it harder to sleep. So, like the kind of tracking and then realizing that actually that was a really bad night...sometimes makes it harder to sleep the next night, by bringing it to the forefront.* [Participant 11 used a DMHI for insomnia for 1.5 months]

It is important to note that this participant found her intervention effective in helping her manage her insomnia and improve her sleep quality. This aligns with recent findings from an expert consensus study, which concluded that symptom deterioration is not a safety concern of DMHIs but rather a normal part of therapy [11].

In some cases, the inflexibility of the predetermined content in the DMHI and its inability to cater specifically to each user's needs (ie, lack of personalization) meant that the DMHI was unable to relate to users' emotional state and could lead to a deterioration in symptoms, for example:

> *So sometimes the AI (chatbot) like would give me suggestions that didn't really fit my situation. So, I'm like, you know what? Forget it. I'm not even going to do it, and I would feel worse afterwards because I wanted to express it. And then I'm just sitting here typing things, and it's not helping. It wasn't really built to recognize that CBT isn't effective for certain situations.* [Participant 14 used a DMHI for post-natal depression for 24 months]

Managing Deterioration

As deterioration is the most common negative effect of DMHIs [1], the authors asked participants how they think DMHIs could support them through it. Some participants said that normalizing deterioration would be very helpful. Participant 1 explained how that could be done in a hybrid model:

> *I think one way to support...is to have a video call therapy session. With an agent for example to make me understand that these things are normal. So, at that I would be reassured that I'm getting back to*

normal. [Participant 1 used a DMHI for depression for 36 months]

Another participant explained how that could be done in a nonhybrid model:

> *Uh, maybe you know if the app had a mood tracker. The algorithm could check if you're feeling low right after therapy. It might just send them a message "Hey, if you're feeling down, you just check, you just had therapy. This could be normal" and that would be like, uh, fair enough.* [Participant 5 used a DMHI for depression and anxiety for 1 month]

Another participant suggested using regular check-ins to detect deterioration and provide users with support accordingly, saying:

> *Umm, I think the biggest thing is regular check-ins. That's quite an important thing about how they're finding it and what particularly is so difficult, maybe even not slowing it down, but having a bit of flexibility around kind of OK, you found this section of the app pretty difficult.* [Participant 10 used a DMHI for self-harm for 1.5 months]

Signposting to Other Services for Support

Most participants (11/15, 73%) were provided with emergency numbers, within the DMHI, to call in case they felt that they could not cope and needed further support. Some participants shared that they found this support helpful:

> *They gave me the contact numbers of like mind and Samaritans in case I needed urgent help. I'm using an online service. If I did need help, I could contact these services, which is actually really helpful because once or twice when I really felt like I was troubled at night, this did come in handy.* [Participant 6 used a DMHI for depression for 2.5 months]

However, other participants felt that the signposting to crisis support within the DMHI was tokenistic, sharing:

> *It's hard to feel like it's a genuine thing. It feels almost like a boilerplate that they put in every conversation. It doesn't really feel like there's thought going into it like "Ohh I recognize that the program can't help you with this. This would be better for a psychiatrist.* [Participant 14 used a DMHI for post-natal depression for 24 months]

Further analysis of these data highlighted that the participants who had a positive experience with the DMHI (ie, found it helpful) experienced the referral to crisis support information positively. By contrast, participants who found the DMHI unhelpful and were frustrated with it found the crisis support information unhelpful and ingenuine. Thus, users' relationship with the DMHI and their feelings toward it informed how they felt about being referred to other services. Users who found the DMHI helpful were likely to view the information about other services as a helpful bonus, whereas those who found their DMHI unhelpful were likely to doubt its genuine concern for them and thus viewed such referrals as a mere box-ticking exercise.

Theme 3: Concerns Around Data Privacy and How to Mitigate Them

Participant Perspectives on Data Privacy

Under this theme, participants spoke about their concerns around data privacy and their suggestions on how to help ease these concerns.

Concerns Around Confidentiality and Data Privacy

Participants were concerned about their data. Was the DMHI confidential? If not, who is it sharing their data with? Participants talked about their concern that the data might be shared with their health care team without their consent:

> *I had concerns about the information that I was putting in, and the kind of data that might have been collected. It's kind of that worry that what you're writing isn't actually confidential or you know that it could go back to someone else. I think one of the biggest worries for me was that what I was inputting in the app might have been given to my psychologist or somehow, you know, connected with the NHS or something like that.* [Participant 10 used a DMHI for self-harm for 1.5 months]

It is worth noting that, given the sensitivity of participant 10's struggle with self-harm, it is understandable why they were particularly concerned about their data being shared—even with their health care provider.

A User-Friendly Data Policy

Participants expressed their frustration with the vagueness and complexity of how DMHIs present their data protection policy and had suggestions on how that can be improved. Some thought that DMHIs should make key data protection information available in a simpler and more readily accessible format:

> *Maybe just share more information...like make it clear what you do to protect users' data. I don't want to have to go through, you know, all of your Terms and conditions, privacy policies and things like that to find out what it is. I mean, nobody's actually going to do that. I would never actually do it, so it would be helpful if it was just clearly mentioned somewhere.* [Participant 6 used a DMHI for depression for 2.5 months]

Another participant said that all they wanted from a DMHI is to be honest about what data they are storing and why:

> *They could kind of like emphasize maybe that your data isn't stored under an identifiable name that leads to you. Or say we are storing the data, but it is confidential and we're doing it to help more people. That's all...just being open about it.* [Participant 8 used a DMHI for an eating disorder for 3 months]

It is worth noting that the data from this study did not show any association between duration of use and participants' experiences. Participants had mixed responses to the DMHI when they used it for a short period (1.5 months, eg, participants 10 and 11), and those who used the DMHI for a long period (24 months; eg, participant 14) did not necessarily have a good

experience. However, Table 1 does show that the DMHIs that were targeting low mood–related areas were used for the longest period, such as depression (on average 19.25 months), self-harm (on average 12.75 months), and postnatal depression (on average 24 months). It is also noted that self-administered interventions were used for longer periods compared with hybrid interventions (on average 9.33 months vs 1.66 months). This is expected given that self-administered interventions require fewer resources and clinician time.

Discussion

Advancing Knowledge on DMHI Safety

This research was successful in exploring and understanding users' experiences, views, concerns, and suggestions regarding the safety of DMHIs. Until now, such findings have been absent from the literature. These findings contribute to advancing the field of digital mental health safety by providing valuable evidence of the viewpoints and experiences of its target population.

Principal Findings

Overview

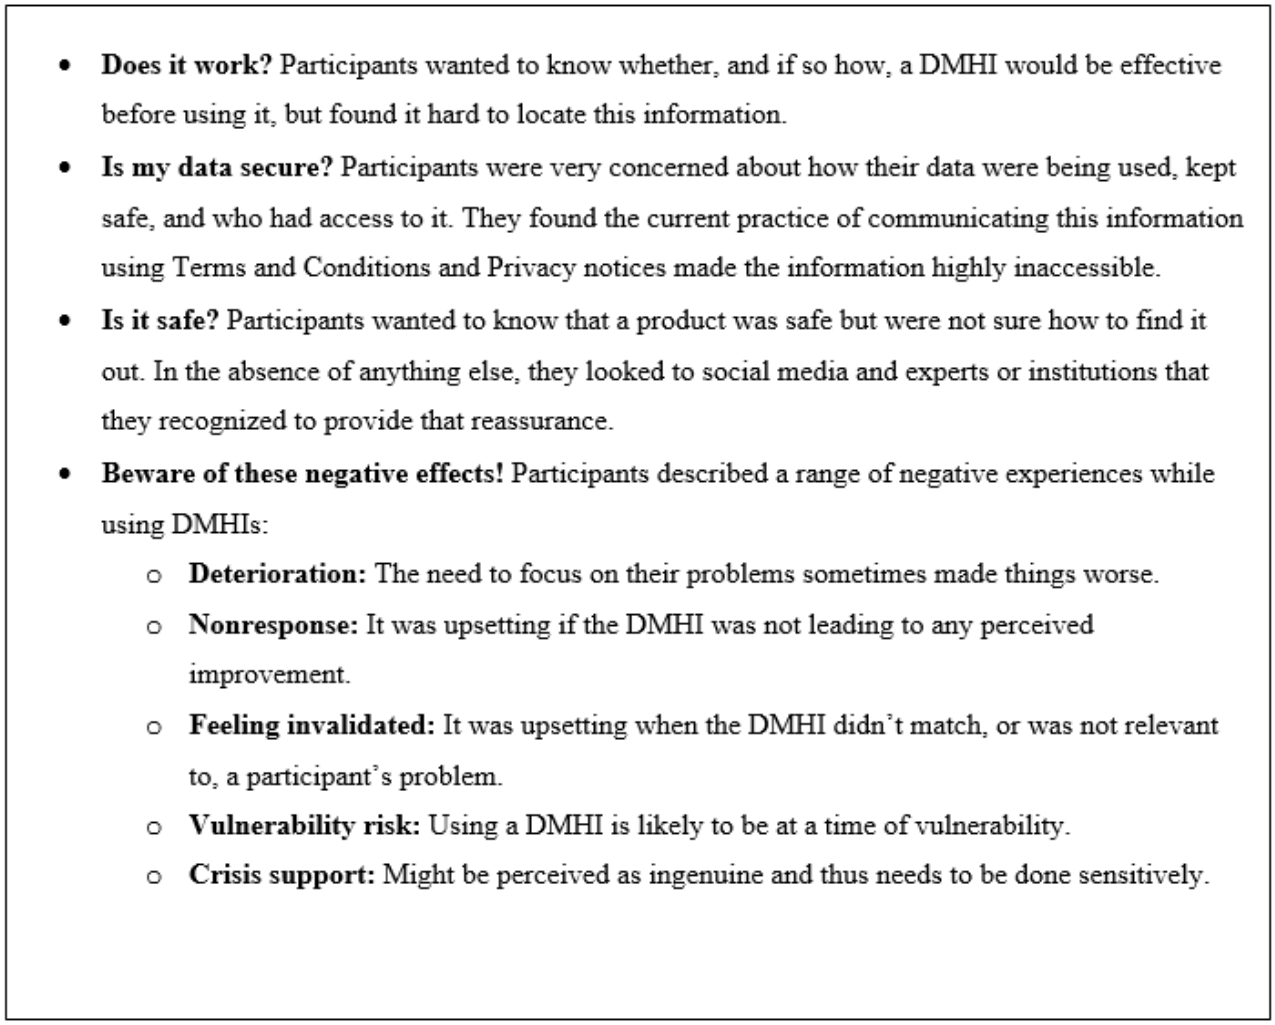
The main findings of this study are presented in Table 2 (also see Figure 1) using user-friendly language and in the form of recommendations.

Table 2. User-informed recommendations to improve DMHI[a] safety.

Recommendations	Description
1. Provide 'easy access' versions of key information	Ensure that DMHI product manufacture and approval include a requirement to provide readily accessible, easy-to-read lay summaries of key information. At a minimum, these should cover (1) evidence of effectiveness; (2) data usage, security measures, and access (ie, who can access the data); and (3) potential negative effects.
2. Use 'Approved by...' badges	Introduce a sectorwide, widely recognized, branded badge to provide top-level reassurance of the quality and safety of any DMHIs bearing that badge.
3. Acknowledge the lack of personalization	DMHIs should flag to users their inability to be fully personalized and adaptable to an individual user's needs to mitigate feelings of invalidation and disappointment.
4. Anticipate and support deterioration	Before using a product, users should be alerted to possible mood or symptom deterioration, given normalizing information, and signposted to relevant support to help mitigate these effects should they occur.
5. Provide real-time feedback	DMHIs should internally track users' progress and provide feedback on whether they are benefiting as expected. Where there is no individual benefit, despite the appropriate use of the product, users should be automatically advised to seek alternative support.
6. Provide genuine crisis support	Content should include an acknowledgment of the DMHIs' limitations and a summary of each crisis service's support. It is recommended to consult the target population on wording to ensure genuine concern for users is communicated.
7. Responsibly manage access	DMHIs should incorporate an assessment of suitability focusing on risk levels and the appropriateness of the intervention for users' specific mental health conditions and severity. This could be done with a simple set of initial built-in questions which output a recommendation to use, or not use, the product based on the user's response.

[a]DMHI: digital mental health intervention.

Figure 1. Key findings (in lay language). DMHI: digital mental health intervention.



Users' Concerns Around the Safety of DMHIs

In this study, users expressed 2 primary concerns regarding the safety of DMHIs: (1) whether a product would be effective and (2) whether their data would be secure and confidential. Evidence around the effectiveness of DMHIs is usually disseminated in academic peer-reviewed articles. This poses an accessibility challenge for the typical users, which is only slightly tempered by recent initiatives toward making open-access publications the norm in academia. It has been documented that uncertainty around the effectiveness of a DMHI is a key barrier to its use [15]. To address users' concerns about effectiveness, it is crucial to translate scientific findings into lay language and publish them in user-friendly formats to improve accessibility (recommendation 1). This dovetails well with the increasing requirements placed upon academics to evidence the impact of their work.

Regarding users' second major concern, data safety and confidentiality, participants in this study suggested that DMHIs provide their users with clear and concise information on how their data are used, stored, and who has access to it. Recognizing that users often overlook traditional lengthy privacy policies and terms and conditions [29], DMHIs could supplement these by providing users with a layperson's summary of how their data are being used, kept safe, and who has access to them (recommendation 1). Clear and transparent communication about data and privacy would help build trust, a key component of the therapeutic relationship [30]. The evidence to date suggests that the digital therapeutic alliance is both relevant and important in DMHIs [19,20].

Assessing a DMHI's Safety From Users' Perspective

It is important to understand how users assess the safety of DMHIs, as this will inform professionals about where users look for safety information and so where and how best to provide it. Participants in this study described methods for assessing the safety of a DMHI that reflected social proof, a concept first attributed to Robert Cialdini [31,32]. Social proof refers to situations where people use opinions and information from others similar to themselves to influence personal choices, decisions, and behaviors, especially if uncertain [31,32]. In the present context, this involved reading online product reviews on websites and mobile app stores. Other participants expressed that they did not know how to assess the safety of a DMHI. In a different qualitative study, medical students shared a similar experience, expressing difficulty in identifying which DMHIs were evidence-based [15]. These students also criticized the lack of guidance available for users on how to find evidence-based DMHIs [15].

There are already regulatory bodies equipped and responsible for assessing the efficacy and safety of DMHIs and making recommendations for use. In the United Kingdom, this includes NICE (The National Institute for Health and Care Excellence) and the MHRA (Medicines and Healthcare Products Regulatory Agency). The NHS (National Health Service) previously had a health app store called the "NHS Health Apps Library," but it was decommissioned in 2021 due to the increasing complexity of maintaining the library and ensuring the safety and effectiveness of the listed apps. An alternative to this has emerged through the Health App Library provided by the Organization for the Review of Care and Health Apps (ORCHA), in collaboration with health providers such as NHS Trusts. This library offers a list of mobile apps that have been reviewed by ORCHA for effectiveness and safety. One effective way to demarcate a product's safety and efficacy status would be for regulators to introduce a branded, recognizable stamp or badge to be displayed by products achieving prespecified minimum safety and efficacy requirements (recommendation 2). What those requirements should be, however, would entail significant additional research to achieve a consensus across industry, regulatory bodies, academia, developers, and users. Nevertheless, this approach would capitalize on users' existing tendency to seek safety information via the product's mobile app page or website and is therefore likely to ultimately be an effective means of disseminating key information on which end users can base their decisions. A notable advancement in this direction is Google's revision of their app store's health policy, which mandates that starting from May 31, 2024, all health apps posted on their app store must prove compliance with relevant laws and regulations (privacy policy, ethics approval, and certification when required) [33].

Risks Experienced by DMHIs' Users and Their Suggestions on How to Mitigate Them

Participants in this study spoke about 3 risks they had experienced as a result of using a DMHI: feeling invalidated by the DMHI, deterioration in their symptoms, and nonresponse. Users noted that, unlike a human therapist, the DMHIs' inability to be fully responsive, personalized, and adaptable to each user's needs left them feeling invalidated and unheard. Such experiences undermine the therapeutic relationship. There is evidence that personalization in a DMHI fosters therapeutic alliance [20], and thus the lack of it is likely to undermine this alliance. The weaker the digital therapeutic relationship, the more this is likely to undermine the effectiveness of the DMHI [30]. In a qualitative study involving Australian psychologists and their experiences with DMHIs, the psychologists expressed the view that DMHIs are inferior to face-to-face therapy due to their limited capacity for personalization [14]. In another qualitative study, medical students made the same comparison between DMHIs' and health professionals' ability to provide personalized therapy [15]. This is a limitation of current technologies, which might change with the future advances of artificial intelligence. However, for now, it is important for DMHIs to acknowledge and communicate this limitation to users to mitigate feelings of invalidation (recommendation 3).

Participants suggested that DMHIs can support users experiencing deterioration by informing them about the possibility, normalizing it, and providing pathways to relevant support when it occurs (recommendation 4). These suggestions align with those made by digital mental health professionals in a recent consensus statement [11]. Other studies have suggested implementing an automated process within DMHIs to monitor and flag when participants' symptoms deteriorate beyond a predefined threshold [5]. Although that threshold would be subject to individual conditions and clinical opinion within any specific context, a useful starting point would be to adopt the clinical "rule of thumb" that considers a 20% change in symptoms as a meaningful variation [34].

"Nonresponse" is a documented potential side effect of DMHIs [1,12]. It was interesting to see how nonresponse from users' perspective was almost a compound negative effect that led to a cascade of unwanted effects including feelings of frustration, hopelessness, deterioration, isolation, and self-blame. One way to address this would be for DMHIs to track users' clinical outcomes, identify those experiencing nonresponse, and provide them with targeted pathways to further support as a way of mitigating these possible adverse consequences (recommendation 5).

The Risk Mitigation Methods Experienced by DMHIs' Users

When discussing how DMHIs mitigate risks and safeguard users, users highlighted the importance of signposting to other sources of support. The majority of users (11/15) were provided with details of emergency numbers and other mental health services; however, not all users found these helpful. Some users felt that this was a checkbox exercise that DMHIs needed to complete and that the crisis support provided was ingenuine. Users of DMHIs may feel this way because of their experiences with mental health services, and because most mental health services/interventions tend to provide crisis support information. Signposting to a different service needs to be done delicately to ensure that the user feels cared for. For that, DMHIs need to be careful about how they present crisis support details. Including an acknowledgment of the DMHI's limitations, a concern for the user, and a description of the support that each crisis service provides might help make users feel that the intention to provide support is more genuine (recommendation 6). Soliciting user input on how such information is phrased and presented would also be of benefit (recommendation 6).

Only 1 user among our sample of 15 was informed of the potential side effects of the DMHI that they were using. A recent systematic review on the safety of DMHIs found that only one-third of the interventions informed their users of their adverse events or possible side effects [1]. The even lower level of side effect awareness in our study might be due to the commonplace practice of embedding side effect information within inaccessible or often unread documentation (eg, terms and conditions or instructions for use) [6]. Indeed, as reported above, our participants told us that they found these documents particularly impenetrable, suggesting some may have missed out on important side effect information. To ensure user safety, it is important to improve the visibility and accessibility of side effect information by adopting new methods of communication (recommendation 1). This might include a digital equivalent of

listing possible side effects on medication labels. Existing regulations already require a digital product label to be displayed within the product itself and this label includes "Cautions" and "Warnings." It would be a relatively simple matter to add a section "Possible Side Effects" as a further requirement.

However, simply adding information is unlikely, on its own, to meet users' needs as identified by our study. In addition (and as already discussed earlier), serious consideration should be given to adopting the practice of requiring "easy read" or "lay summary" versions of key information which is provided alongside full and formal versions. This is now standard practice in domains such as academia, governmental, and other public sector organizations. Our study suggests that, as a minimum, this should apply to information on data security and side effects.

Finally, to minimize this risk, our sample of participants/users recommended that DMHIs should evaluate each user's suitability, with a focus on assessing risk levels and determining the appropriateness of the intervention for their specific mental health condition and severity. These assessments can be included as a standard procedure before onboarding a user onto a DMHI, similar to how patients are screened before they receive face-to-face therapy (recommendation 7).

Limitations

There are a few limitations to this study. The participants in this study were mostly female (12/15, 80%). The DMHIs used by participants were mostly self-administered (12/15, 80%), and thus results might be biased by their experiences. Additionally, recruiting for a study to explore users' perspectives on the safety of DMHIs might have attracted individuals who have experienced such issues. It is important to be aware of how the sample of participants in this study could have shaped the results. This is expected in qualitative studies, which aim to explore and understand the experiences and opinions of a sample of the population [35].

Conclusions

The results of this study led to 7 user-informed recommendations on how the safety of DMHIs can be improved. These recommendations arose from users' experiences and suggestions. The key findings (Figure 1) and recommendations of this paper could improve the safety of DMHIs, enhance users' experience, address some of their concerns, and foster a more trusting therapeutic relationship between the user and the DMHI.

Acknowledgments

We are grateful to all our participants for taking the time to participate in our study and share with us their valuable experiences and opinions. We also would like to express our gratitude to the National Institute for Health and Care Research (NIHR) Biomedical Research Centre hosted at South London and Maudsley NHS Foundation Trust in partnership with King's College London. The views expressed are those of the author(s) and not necessarily those of the NHS, the NIHR, the Department of Health and Social Care, the ESRC, or King's College London.

Conflicts of Interest

None declared.

Abstract

Background: Many youth with significant mental health concerns face limited access to mental health services. Digital programs, such as mobile apps designed to address mental health issues, have the potential to expand access to strategies for managing these conditions. However, few mental health apps are specifically designed for youth experiencing severe concerns, such as suicidal ideation. BritePath is a new app developed to enhance communication and interaction between providers and youth at risk for suicidal behavior.

Objective: This study aims to explore health care providers' opinions and concerns regarding the use of mental health apps for youth at significant risk of suicidal behavior.

Methods: We conducted individual semistructured interviews with 17 providers across 7 states. Interviews were conducted via video, recorded, and transcribed. Codes were developed using a team-based approach, with discrepancies resolved through team discussions.

Results: Most providers were aware of mental health apps in general and expressed interest in trying the BritePath app with patients experiencing depression, suicidality, or both. Analyses identified 4 key themes related to mental health apps: (1) almost all providers viewed mental health apps as an adjunct to, rather than a replacement for, psychotherapy visits; (2) most providers were concerned about the cost of apps and youth access to them; (3) providers noted the challenge of maintaining patient engagement with apps over time; and (4) providers were concerned about patient privacy, in terms of both data shared with app developers and data privacy within families. Analyses of providers' opinions specifically about the BritePath app identified 4 additional themes: (1) providers believed that access to safety plans within BritePath could be beneficial for youth at risk for suicidal behavior; (2) providers reported that BritePath's interactive features could enhance communication between providers and youth; (3) providers appreciated BritePath's flexibility and the ability for both youth and providers to tailor its content to individual needs; and (4) providers expressed concerns about integrating BritePath into clinical workflows within health systems.

Conclusions: The use of mental health apps is expanding, yet there is limited understanding of how to effectively integrate these tools into mental health treatment. Providers are increasingly referring patients to mental health apps, and most expressed interest in trying the BritePath app for patients with depression, suicidality, or both. However, providers also identified several concerns, particularly regarding privacy and safety.

KEYWORDS

depression; adolescent; suicidality; safety plan; mental health; apps; suicide

Introduction

Background

Adolescent suicidal behavior, suicide ideation, and depression are major public health problems that have increased significantly over the past 20 years [1-3] and have been exacerbated by the COVID-19 pandemic and its sequelae [4-8]. For example, between 2019 and 2021, the number of female high school students reporting that they had seriously considered attempting suicide increased by 6% [3]. These increases in suicidal ideation, behavior, and depression have disproportionately affected youth from historically minoritized racial and ethnic groups [2-4]. Once youth are identified as having a significant risk of suicidal behavior, they are typically treated in emergency departments or urgent care settings or hospitalized for stabilization before beginning outpatient treatment [9]. However, many youth remain at high risk of suicidal behavior even after acute treatment or stabilization in intensive settings. Managing youth with high levels of suicidal risk requires close communication between patients and clinical providers, such as psychiatrists or mental health therapists (referred to collectively as providers hereafter). Evidence-based care for these youth includes regular monitoring of depression symptoms, suicidal ideation, and suicidal behavior [9-11]. However, most health systems fall short of maintaining this level of close communication due to barriers such as lack of time and resources, as well as difficulties in staying in touch with at-risk youth after they leave intensive settings or acute treatment.

To address these concerns, researchers are developing new mobile apps aimed at improving both the efficiency of communication with youth at risk for suicidal behavior and shared decision-making between providers and adolescent patients. These tools are increasingly promoted to address mental health concerns in general and depression in particular [12-16]. Empirically based apps for depression range from cognitive behavioral self-help programs [15,16] to screening [16,17] or mood-tracking apps [18]. Recent research indicates that these tools are generally acceptable to providers [13,17]. However, there are several limitations to their use in clinical practice. Much of the evidence comes from surveys asking providers about the acceptability of apps [19] or studies that have not focused on specific concerns about particular apps [13]. Few studies have examined the use of apps within the context of mental health treatment [15]; instead, most have focused on patients' use of apps independent of providers [13]. To date, no prior research has examined the acceptability of apps designed to support shared decision-making between providers and youth at high risk for suicidal behavior. While some experts have raised potential ethical and safety concerns about using digital interventions with high-risk populations [19,20], improving connections to treatment after nonfatal suicidal behavior has the potential to enhance the treatment trajectory and long-term outcomes for these youth.

Study Goal

The aims of this study were to characterize providers' (1) opinions on the barriers and benefits of using apps in mental health care in general, (2) perspectives on the use of apps with adolescents with depression or suicidal thoughts and young adult patients, (3) interest in and willingness to use a recently developed app (BritePath) intended for use with adolescents with suicidal thoughts or young adult patients, and (4) barriers to implementing the BritePath app in routine clinical practice.

Methods

Implementation of BritePath: Benefits and Barriers

This qualitative study was conducted as part of the Center for Enhancing Treatment and Utilization for Depression and Emergent Suicidality (ETUDES Center), an ALACRITY Center funded by the National Institute of Mental Health (NIMH P50MH115838), aimed at helping providers better support youth experiencing severe depression, suicidality, or both. This study explores issues related to the use of mental health apps in general with this population and examines potential benefits and barriers to implementing an already developed app, BritePath, in health systems that have not participated in the research studies developing BritePath and are not affiliated with the ETUDES Center. To date, all information regarding the acceptability of the BritePath app has been gathered within the institutions that developed it.

The BritePath App

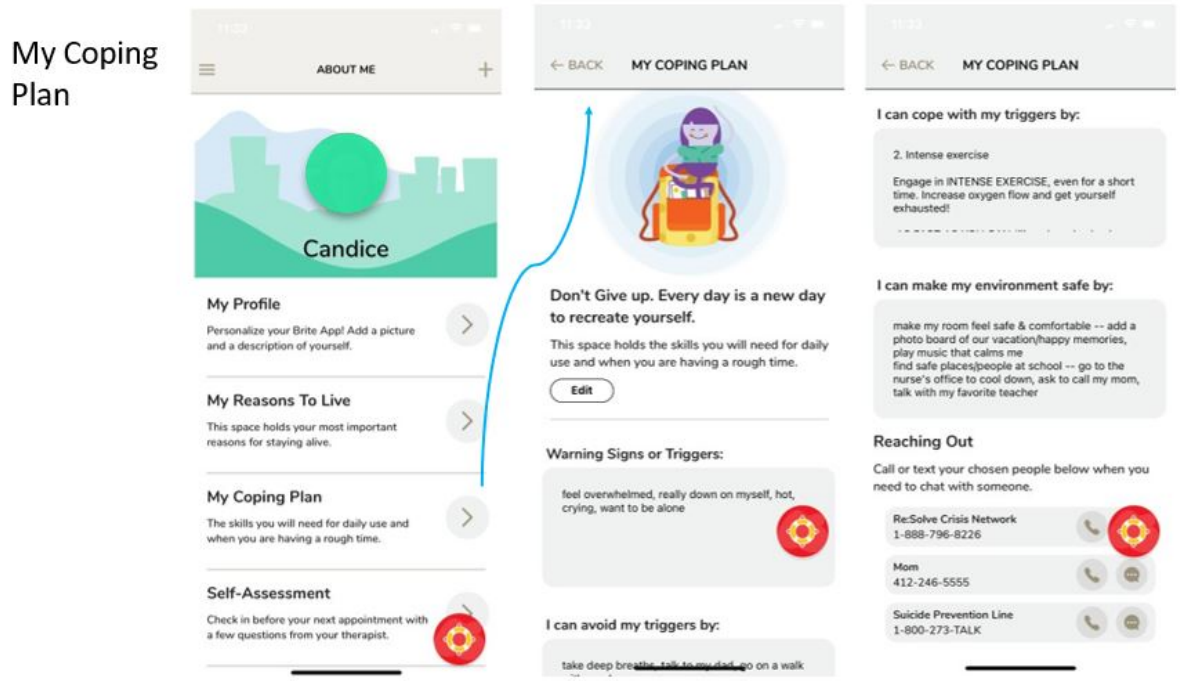
The BritePath app was developed to improve communication between providers and youth with depression or suicidal thoughts. It consists of 3 integrated components: (1) *Guide2BRITE*, an electronic guide for mental health providers that includes step-by-step instructions for onboarding a patient's safety plan into the app, as well as guidance on discussing key treatment components such as emotion regulation and distress tolerance skills; (2) the *BRITE app*, a personalized and interactive safety plan and self-monitoring tool for youth; and (3) the clinician dashboard, *BRITEBoard*, which allows providers to track youth's app use, distress levels, and treatment progress while facilitating communication and collaboration among mental health and primary care providers.

BritePath promotes self-monitoring and self-management through personalized strategies to avoid or cope with triggers for suicidal urges [21]. It is based on BRITE, a patient-facing safety planning app developed by researchers in psychiatry and psychology at the University of Pittsburgh and the University of Texas Southwestern Medical Center [21]. To our knowledge, BritePath is the first smartphone-based safety planning app to be tested in clinical trials involving adolescents with severe depression or suicidal thoughts. BritePath provides providers

with tools to onboard their adolescent and young adult patients to the app. This includes assisting youth in developing and personalizing a safety plan, incorporating distress tolerance and emotion regulation strategies, and monitoring symptomatic progress for at-risk youth in their care. Figure 1 provides a screenshot from the BritePath app for a mock patient.

BritePath was first tested for clinical effectiveness in a pilot randomized trial that evaluated BritePath in combination with a related intervention. The study found that the combined intervention reduced the rate of suicide attempts by 50% in the 6 months following hospital discharge [21]. This pilot study also suggested that more frequent use of BritePath increased reasons for living. However, the small sample size did not allow for comprehensive testing of BritePath alone. A more recent, larger randomized trial found that BritePath is as effective as usual care for youth hospitalized for suicidality. Additionally, youth who received BritePath were less likely to have a subsequent suicide attempt and had a longer time until a repeat attempt [22].

Figure 1. Example of the safety plan in the BritePath app.



Sampling and Recruitment

We identified a convenience sample of mental health and primary care providers who have cared for patients with mental health concerns. Providers were recruited through health systems participating in the Mental Health Research Network [23] and via snowball sampling [24,25], in which interviewed providers recommended additional potential participants. No specific level of digital experience or skills was required for participation in the study.

Ethical Approval

All study procedures were approved by the Institutional Review Board of the Kaiser Permanente Center for Health Research (KPCHR) at Kaiser Permanente Northwest (approval ID: MOD20050381-003), where the study was conducted. Interviews were conducted via KPCHR Teams, and digital recordings and transcripts were securely stored within the primary organization's firewall-protected file service.

Data Collection

Semistructured interviews were conducted remotely via Microsoft Teams. The interview guide (Multimedia Appendix 1) was developed by our medical anthropologist expert (NV) in coordination with the principal investigator (FL). Additionally, a qualitative investigator from the larger BritePath team reviewed the guide for content. The interviewer (FL) used a semistructured interview guide (Multimedia Appendix 1) to ensure consistency across interviews. The framework that guided the design of our qualitative interview guide focused on usability and concept testing. We examined whether providers from different backgrounds and training would consider using BritePath. The included questions aligned with several frameworks for adopting new technology, such as the Diffusion of Innovation theory [26,27]. The interviews assessed providers' opinions on using apps with patients and their impressions of the benefits and barriers of mental health apps in general. Participants were then shown a series of visuals (screenshots) depicting what a user would see while interacting with the BritePath app. These prompts ensured that participants had a clear and consistent understanding of the app's features and user interface. During this portion of the interview, participants were asked about their initial impressions of the BritePath app, as well as the barriers and potential benefits of using it in their practice. They were also given the opportunity to suggest features they would like to see in future app developments. Each interview lasted 30-40 minutes and was audio recorded and transcribed by an independent transcriptionist. Transcripts were entered into Atlas.ti [28], a qualitative analysis software program

used for coding and managing data. Atlas.ti was then used to generate reports for the analysis of interview transcripts.

Analysis

Thematic analysis, a method for analyzing patterns of meaning in a data set, was used to interpret the data by identifying themes and their interconnections [29-32]. Following established thematic analysis procedures [30], members of the research team (JC, LF, and NV) first familiarized themselves with the data and, together with FL, developed an initial code list consisting of a priori codes reflecting the interview questions. JC and LF coded the first interview using this initial code list and identified additional codes while reviewing the transcripts. The full team met to review coding consistency between reviewers and to evaluate the need for new, emergent codes. Modifications to the code list were made based on discussion and consensus. This process was repeated, with 2 team members coding 2 additional transcripts each. The full team met to discuss differences between coders for these additional transcripts and found minimal discrepancies in the codes applied. Upon confirming sufficient consistency in code usage and identifying no additional emerging codes, a master code list was finalized and used to code the remaining transcripts. After coding all transcripts, the full study team individually reviewed reports of coded interview segments to identify themes. The final themes were then derived through discussion and consensus. This formal, team-based analysis procedure was used to enhance the credibility and trustworthiness of the findings.

Results

Providers' Perspectives on Mental Health Apps and the BritePath App for Youth at Risk of Suicidal Behavior

We conducted semistructured interviews with a convenience sample of 17 providers from 7 states in the United States (Table 1). Our goal was to understand providers' opinions on the use of apps for youth with mental health concerns in general and the use of the BritePath app for youth at risk of suicidal behavior. First, we asked providers about their experiences using mental health apps with patients. Next, we gathered their opinions on a specific app, BritePath, designed to improve patient engagement and communication with providers for youth at risk of suicidal behavior. The interview guide is available in Multimedia Appendix 1.

Table 1. Provider demographics (N=17).

Characteristic	Values, n (%)

Providers' Opinions About the Use of Apps for Mental Health Concerns in General

Overview

All providers reported familiarity with mental health apps, and most stated that they had referred at least one patient to a mental health–focused app—for example, to help patients learn a skill such as relaxation. However, none of the providers reported regularly using any mental health app during treatment visits or in an interactive manner with patients. Each theme is discussed in more detail below.

Theme 1: Mental Health Apps Have the Potential to Be Valuable as an Adjunct to Therapy Visits

Providers reported that they felt mental health apps could add value to the therapeutic relationship as an adjunct or complement to face-to-face or video-based psychotherapy sessions. However, most did not believe that mental health apps could serve as a substitute for psychotherapy visits. Several providers noted that these apps can offer access to exercises for learning new skills or encourage the use of tools discussed in therapy, making them a useful complement to treatment sessions.

> *I think they can be really great adjuncts if you have the time to utilize those as a clinician. I am always interested for my patients of course for them doing things in the many hours outside of therapy, so I see you from 1:00 to 2:00 and then there are all these other hours that in theory you're doing the things that we were practicing in that one hour. If there are apps that can promote, engage, and promote the use of those strategies, whether it's thought records or sleep diaries or mood meters, things like that. And then they can bring that back in and we can look at it together and that facilitates the conversation, I think that would be great.* [P5]

> *And this way as a clinician I am teaching a skill, but I want it to be reinforced by this tool that mainly my client really loves but eventually is a way to train the brain to think a new and different way.* [P4]

Providers also noted that this approach to learning skills may be particularly useful for teenagers, who frequently engage with their phones.

> *I think they're a great compliment to therapy. I think they're really useful as a tool. I am not a huge fan of the app-based therapies you know. Like text therapy and stuff like that, I think it's not a good fit for everybody of course. But I think the apps themselves as far as tools and teaching and reinforcing skills I think are really helpful. And I would imagine for teenagers, I am assuming most of them are on their phones quite a bit. So that might be kind of a really easy transition or way to incorporate into something they're already doing. I think it would be cool especially for teens if there was a way to have some sort of feedback or back and forth with their therapist so they could actually share what they're doing, that would be neat. I think there's a lot of potential there for younger people.* [P14]

Although providers generally expressed support for mental health apps, most also raised several concerns. They described issues from both the provider and patient perspectives.

Theme 2: Cost/Access to Tool

The cost of purchasing an app was noted as a potential barrier. Providers suggested that they would only consider recommending apps with relatively low fees or a 1-time payment rather than ongoing costs.

> *Obviously free is best. Especially for teens, even young adults that are trying to make ends meet. If not then maybe something that's a one-time fee. If it was a subscription that would be harder for that population. I think that's something that older adults could possibly swing, but unless the parents are paying for it, it doesn't seem like that would be a good match.* [P13]

> *On the patient side yeah I think it would depend on how expensive the app would be. If they've got to pay $50/month that certainly could be prohibitive for folks.* [P5]

In addition, providers expressed concern that some youth, particularly those from low-income backgrounds, might lose phone service or have limited minutes, which could hinder access to the app and reduce engagement with its tools. They also noted that youth might have only intermittent access to mental health apps for various reasons, such as an inability to consistently pay for phone service or depleting their data or minutes. This loss of access could be frustrating for youth trying to use mental health apps and could interfere with their engagement with the app's content.

> *Most of our patients do have smart phones so that's usually not a barrier. But sometimes getting their cell phones shut off has happened before. So whether or not they'll have continuous access I think has been a barrier in the past.* [P8]

Theme 3: Engagement

Many providers expressed concern that a common barrier to using mental health apps is a lack of patient engagement. Several participants shared experiences of patients downloading apps but never using them beyond the initial session. Others noted that apps often lose their appeal quickly, making sustained engagement a challenge.

> *Yeah, and I think the literature is pretty clear that if you send patients off to use some sort of behavioral health app, they'll use it once or twice. They'll check it out and then use drops of precipitously.* [P1]

> *I think patients often download and forget about them which is probably the biggest one is the engagement with some of these apps is low. After a short amount of time they might forget about it and then they don't really come back to it. So in the context of therapy that was less of an issue because I would be there and be encouraging that use. So that's one of the barriers if people were just using it out in the real world.* [P9]

Providers described challenges in getting youth to engage with an app at all. Several noted concerns that apps must be visually appealing and up-to-date to attract teens, who are often highly tech-savvy. Based on their experience, if an app was not engaging enough, usage would decline, similar to what they had observed with other patient-focused apps.

> *I think we all know that teens are very sophisticated with apps and tech so I think having it be interesting and up to date is I think if they're going to use it, it's got to be flashy in some way.* [P3]

Theme 4: Patient Privacy

Most providers expressed concern about patient privacy. Some noted that their patients had raised concerns about the privacy of data collected by apps, which could make them hesitant to use mental health apps. Providers also emphasized that health systems would need to ensure patient privacy before integrating an app into treatment.

> *I know so many patients just in general are very concerned about their privacy. So I think that would be at the top of my list is just knowing that I could have confidence in saying to this person this app has*

> *been vetted in these different ways. This is the security that it offers. Maybe it's even password protected when you sign in so that way if your mom picks up the phone and she can't get into that particular app. I feel like that's a deeply personal thing. And I would want to make sure that I am protecting my patient's confidentiality and I can speak to how this app does that.* [P2]

> *I think always a concern is privacy and making sure the data is secure and HIPAA compliant. Especially working in health systems we're always concerned about technology and the privacy of patient information.* [P9]

Some providers also discussed concerns about patient privacy at home. Before recommending an app, they wanted to be confident in their understanding of how patient data were being protected.

> *On the other hand, if their parents are checking their phone and they don't feel like they have privacy they might not be able to use it in the same way that they might have otherwise had they had more privacy.* [P8]

Providers' Opinions About the Use of the BritePath App

Overview

All of the themes providers discussed regarding mental health apps in general were also reported in relation to the BritePath app. For instance, providers expressed privacy concerns both broadly and specifically in the context of BritePath. After hearing a description of BritePath, all but one provider expressed interest in trying this type of app for patients with depression, suicidality, or both. In addition to the general themes identified for mental health apps, several additional themes emerged specific to BritePath.

Theme 1: May Make Visits More Efficient

Providers described several ways in which an app such as BritePath could make therapy visits more time-efficient. Some noted that BritePath could help patients gain insight into the relationship between their mood and the activities they engage in between visits.

> *I think such a common thing with younger teens is being able to reflect back on how their week went or how their time went. And often times having something that is kind of tracking in the moment gives so much more actual information of when there were any spikes in anxiety or in distress in some way to help be like oh I saw this happened on this day, what happened then. To help anchor them into being able to talk about some things. So I can see that being a real benefit.* [P15]

> *I think it's so important for people to be able to see visually what the distribution is of the moods throughout the week. And also to remember that they're not always in that low point. So having some check ins throughout and maybe not only on their really bad days, right, but check ins every day would be helpful probably so they could be able to track down only the downs but maybe the ups or the little bit better.* [P14]

BritePath was also seen as a tool for providers to gather information on patient moods and their use of techniques between in-person sessions. Providers noted that access to this information via the app could make sessions more focused and productive by reducing the need to collect it during visits and allowing for better session preparation. Additionally, real-time patient-reported data on the app were perceived as more complete and valid than recalled information shared during a visit.

> *If you had the time to review what someone did or didn't do since you last saw them before they even walked in the door...I've saved at least 10 minutes of the precious 45 that we have together. I can launch straight into hey your mood meter was great over the last week. Or I see you check in on your safety plan on Tuesday, tell me a little bit about that? I don't have to say so how did the last week go? Oh Tuesday was bad. Tell me more about Tuesday and then wait for them to bring up the fact that they had to use their safety plan on Tuesday. We can just get straight to it. And it helps...not only the time saver, but hopefully not having to deal with retrospective recall.* [P5]

> *I think too if we have a session with a patient and they're just in that moment trying to recall their week is not as impactful as if you can actually go back and see what they're feeling in any particular time and probably would really help with recall bias.* [P8]

Providers also discussed how the BritePath app could facilitate communication with youth and enhance their engagement in the treatment process.

> *I think...leveraging digital health tool...I think another place this can be helpful is if kids engage in it, it gives you more to talk about in the session. You know doing sessions with teenagers a lot of times it's pulling teeth to get them to say anything. At least this would provide them with one, another way to keep them engaged and two, more fodder for talking to someone that may not be interested in filling 45 minutes' worth of talking.* [P5]

Theme 2: Provides Access to Safety Plans

Most providers noted that a key benefit of BritePath was giving patients convenient and consistent access to their safety plans through the app. They believed that because most youth carry their phones, they would be more likely to have their safety plan readily available in a crisis—unlike a paper version, which could be easily misplaced.

> *I think the nice thing about it, is it's all in one place. It's easily accessible on our phone. If they're in distress at any given moment they can pull it out and it's all right there. That makes it much more likely that they're going to use their skills in the moment, versus us giving them a piece of paper or emailing*

> *them or whatever else technology that would be used in the past. So I think that's a huge advantage.* [P13]

> *So patients can have a safety plan in the EHR but if they can't access it. We print it out and who knows where they left it. This gives them something, most people are pretty good about not leaving without their phone. So, it's a way that's there, it's accessible.* [P1]

However, providers also had questions and concerns about the functionality of storing the safety plan on a youth's phone. Some wondered whether the safety plan could be easily integrated into the patient's electronic health record. Another concern was whether providers would be notified when a patient accessed or used their safety plan.

> *Would the provider be alerted if there was a change? For example, if someone were to use the program or use part of their safety plan would that then ping me as a provider? Or would I just need to go and check on the patient status every so often to know those sorts of things? Another thing I might be curious about is how it might communicate with my EHR, if there was a way to import the information or download, even the safety plan for example so that way I could then upload it into the patient's chart. I think that would be important for me too.* [P2]

Theme 3: Offers an Additional Way to Communicate With Patients

Providers noted that BritePath could serve as an alternative communication tool for patients. Some recounted experiences with teens who struggled to express themselves and suggested that BritePath could offer these youth another way to connect with their providers. One provider also noted that this feature could enhance engagement in treatment for some patients.

> *Obviously, someone who is busy, if they're actually busy or just having issues with talking with a clinician face to face, this is a way to avoid that stress of direct interpersonal interaction. So that's a positive. And adolescents have all sorts of reasons why they sometimes don't want to engage with care. This is a way for them to get some care even if they're not feeling like interacting with their clinician that week. That I see as a benefit. Asynchronous so it can be on their time rather than someone else's time.* [P12]

> *If you think about teenagers, they are much more comfortable with technology and sometimes that's a great place to start for therapy or treatment with them because they might not feel comfortable talking to a professional.* [P9]

Several providers valued BritePath's 2-way communication feature, noting that it could facilitate shared decision-making and provide real-time updates to the treatment plan.

> *I think there's a real value in that shared decision-making component that can go into an app like the one you're describing. And it also becomes an important way of sort of communicating.* [P1]

> *I think that two-way communication is what I think could be the most useful if it's going between the patient and the therapist and you're able to interact back and forth. So in terms of modifying treatment plan or knowing what is resonating with the person.* [P3]

Theme 4: Flexibility and Personalization of the BritePath App

A number of providers expressed enthusiasm for BritePath's flexibility and personalization features. Several noted that allowing youth to customize the app with photos, videos, motivational reminders, or prompts for coping strategies could help sustain engagement, increase usage frequency, and accommodate diverse patient needs.

> *I think that's definitely a bonus. Sometimes the out of the box app works just fine. But the more you can tailor it or personalize it to someone's specific needs, the more likely they are to use it, so I think that that could definitely be useful!* [P9]

> *I love that there can be general tools but also some really individualized personal things in there in too. I just love the idea of having names and photos of people, loved ones and pets and things like that.* [P14]

One provider highlighted BritePath's potential to empower youth by allowing them to personalize their treatment and safety plan.

> *The place a teen usually goes to for soothing support regulation is the phone. But it often feels like the phone is just riddled with pitfalls of things that could make things worse. Maybe don't go on Instagram and compare your life to other people. So the fact that there's something right next to it potentially on their phone for them to dive into instead of something that could be potentially more disregulating or harmful I think is fabulous. The more opportunity I think there is to customize what's happening in that app the more I'd be inclined to really empower my client to tap into a wise place, tap into wiser parts of themselves, have those places and parts load what's in the app. So then they have access to it in those harder moments. I could see that being a particularly empowering thing.* [P11]

The collaborative functionality of the app was also seen as a benefit, as it enables providers to modify the app's content in collaboration with patients over time as their needs change.

> *I think that two-way communication is what I think could be the most useful if it's going between the patient and the therapist and you're able to interact back and forth. So in terms of modifying treatment plan or knowing what is resonating with the person.* [P3]

Theme 5: Concerns About Integration of BritePath Into Clinical Workflow

Providers expressed additional concerns specific to BritePath, beyond those related to mental health apps in general. One

concern was its impact on clinical workflow. For instance, providers questioned how well the app would integrate with existing electronic medical record systems. They also expressed concerns about its ease of use for busy clinicians.

> *Another thing I might be curious about is how it might communicate with my EHR, if there was a way to import the information or download, even the safety plan for example so that way I could then upload it into the patient's chart. I think that would be important for me too.* [P2]

> *Do I have to have a certain log in? Do I see a list of patients that I have that are using it? How cumbersome is it to get into that? And what's the patient's understanding and expectations for me, either monitoring that data or accessing that data or is there even some sort of portal to do that? Or is it more that the patient brings in their phone with their smart phone app and sort of shows me what they've been up to?* [P1]

In some cases, these concerns amplified existing worries about mental health apps in general, such as what might happen if a patient experiences a crisis. Additionally, several providers raised concerns about managing patient expectations regarding 24/7 access to their provider and ensuring that patients understood how to handle crises when providers were unavailable.

> *The only thing that has come up before... as far as cell phone and texting technology is somebody trying to text you in crisis while you're off work. You're not checking, so if there's something that presents in the app that is alarming or suggests that this client is in danger of harming themselves and you haven't checked the app in whatever amount of time, that would be I guess the concern for me too.* [P13]

> *I would want to make sure that whatever the app is that it stays within the boundaries of how I am available to the client or not. And I'd want it to be clear, it's tricky because if I can get a report about where they're at conceivably I could get a report when they're having a moment of increased distress and does that require me to then reach out to them too? So, I'd want it set up to be like hey either this app only releases this data to me X amount of times, so if you put in that you're having a hard time I am not going to see it.* [P11]

Discussion

Principal Findings

The focus of this qualitative study was to gain a deeper understanding of provider opinions on the use of mental health apps in general and the BritePath app specifically for treating teen and young adult patients with depression, suicidality, or both. Providers in this study had no prior exposure to the BritePath app. Most were aware of mental health apps in general and expressed interest in trying the BritePath app with patients with depression, suicidality, or both. Nearly all providers viewed mental health apps as a complement to other mental health treatments rather than a replacement for psychotherapy visits.

Mental Health Apps in General

Most providers were supportive of mental health apps, recognizing their potential to provide access to information and skills that could improve youth mental health. Key benefits included their availability at any time—particularly when providers were not accessible, such as late at night—and their ability to reinforce skills such as stress reduction between sessions. However, providers differed in their level of comfort with these tools. Some frequently recommended resources such as online cognitive behavioral therapy programs or anxiety management apps, while others were less enthusiastic. Most providers noted that mental health apps might be particularly useful for younger individuals, as they frequently use phones and other digital devices. These findings align with existing research on provider and patient perspectives, which indicate broad support for digital mental health tools [13,17,33-35]. However, most providers emphasized that apps alone were not sufficient for youth with significant mental health concerns. Many explicitly stated that these tools should complement, rather than replace, psychotherapy.

All providers expressed concerns about patient privacy. They discussed potential risks related to data collection by apps, including unauthorized access by individuals other than the youth (eg, parents) and uncertainties about how app providers might use collected data. While privacy concerns are common with app usage in general [13], providers emphasized that data collected by mental health apps are particularly sensitive and require high standards of privacy and protection. Several providers noted that app usage has become so commonplace that privacy policies are often overlooked, which may be especially problematic for youth. One provider specifically highlighted the difficulty in determining how commercial apps safeguard data privacy, which they found concerning.

Many providers also raised concerns about maintaining youth engagement with apps. Difficulty in sustaining engagement with digital tools has been noted in prior studies [36,37]. Several providers pointed out that they currently have little to no insight into how engaged their patients are with mental health apps. This uncertainty tempered some providers' optimism about the potential of these tools as a strong aid in treatment.

Providers also identified several logistical barriers to the effective use of mental health apps. The cost was a common concern, particularly the potential inaccessibility of apps that require ongoing payments (eg, monthly fees). Additionally, several providers noted that youth often experience inconsistent access to phones due to service suspensions, late payments, or lack of internet access. While these concerns have been raised in studies on app use in general [13], they may be especially critical for youth with mental health concerns, as intermittent access could disrupt their ability to use these tools as a coping mechanism.

BritePath App

Each of the potential benefits and concerns providers expressed about mental health apps in general were also raised in relation

to BritePath, including data privacy, patient engagement, and cost-related concerns. In some cases, providers expressed stronger opinions—both positive and negative—specifically regarding BritePath. For example, concerns about patient privacy were heightened due to the app's inclusion of sensitive information on symptoms and suicidality. By contrast, providers strongly supported BritePath's potential to enhance psychotherapy visits by facilitating more in-depth collaboration between providers and patients on skill development.

Providers raised several additional themes regarding BritePath. Many highlighted the value of the app's personalization features, noting that these could enhance patient engagement. Most providers expressed enthusiasm for BritePath's ability to facilitate communication between sessions and help providers prepare more effectively for upcoming appointments.

Providers also raised concerns about ensuring that safety issues were thoroughly addressed if BritePath were to be used in practice. While they appreciated the idea of having a safety plan integrated into the app, they emphasized the need for built-in safeguards, such as pop-up messages directing patients to emergency services when necessary. Additionally, providers wanted to ensure that patients understood that communication through the app would not guarantee a 24/7 response from providers.

Practical Implications for Research and Clinical Practice

Providers suggested several ideas for future research on apps addressing suicidality in youth. Integrating ambient phone data, such as activity tracking, could enable more timely and accurate recording of safety plan activities, reducing reliance on self-reporting. Additionally, visually linking mood and activity data, along with incorporating pop-up mood assessments, could enhance patient awareness of the relationship between mood and behavior. Increasing personalization in mood tracking and allowing patients to annotate their mood data may further improve engagement with the app.

Although providers were enthusiastic about the potential benefits of a customizable, readily accessible safety plan on a patient's phone, many also raised concerns about ensuring the security of this information. From a clinical perspective, safeguarding safety plans on the device would be essential for successful implementation within health systems. Additionally, embedding a clear and transparent patient consent process into the app—one that explains who will have access to their data and why—would be crucial in helping patients understand the risks associated with using a tool such as BritePath. Furthermore, ensuring that BritePath is compatible with different phone operating systems and can integrate with various electronic health record systems would be key to facilitating widespread adoption in clinical practice.

Strengths and Limitations

This study provides new insights into providers' perspectives on the use of mental health apps for youth at risk of suicidal behavior. We acknowledge the potential for sampling bias. To address this, we aimed to recruit a diverse range of providers from different health systems affiliated with the NIMH Mental Health Research Network [23]. While this sample may not be fully representative of providers across all health systems, participants were drawn from health systems in 7 US states. Although the sample is not fully representative of all providers in the United States, it includes a variety of geographic areas, organizational arrangements, and provider types, ensuring a diverse range of perspectives. In designing our qualitative interview guide, we focused on usability and concept testing rather than adhering to a specific technology adoption theory, such as the Technology Acceptance Model [26] or the Diffusion of Innovation Model [27]. However, our interview questions covered many of the key domains included in these models. We invited providers who delivered mental health services within these health systems to participate, without requiring a specific level of experience with apps or other digital tools in their practice, as we aimed to capture a broad range of experience levels. It is possible that providers with a greater interest in app use were more likely to participate.

One goal of this study was to explore providers' opinions about the BritePath app, which was developed for use with youth at risk for suicide. Specifically, we sought feedback from providers with no prior clinical experience or knowledge of BritePath to assess its potential for future implementation in health systems. Our focus was on understanding the broader applicability of mental health apps, with a particular emphasis on BritePath. While we collected limited demographic data on providers, it is possible that unmeasured factors influenced their perspectives on the use of mental health apps. For example, although respondents represented a range of age groups, most were younger providers, who may have been more comfortable with apps in general than older providers. Despite these limitations, this study offers new insights into providers' perspectives on mental health apps, including the BritePath app, and highlights key concerns regarding their use with young patients at risk for suicide.

Conclusions

The use of mental health apps is expanding, yet more research is needed to determine how they can be most effectively integrated into mental health treatment. Most providers expressed interest in using the BritePath app for patients with depression, suicidality, or both; however, concerns about privacy and safety remain.

Acknowledgments

This study was supported by the National Institute of Mental Health: The Center for Enhancing Triage and Utilization for Depression and Emergent Suicidality in Pediatric Primary Care (grant P50MH115838). The development and testing of BritePath have been funded by the National Institute of Mental Health (grants R34 MH100451 and P50MH115838), the American Foundation

for Suicide Prevention (AFSP), and a clinical use version institutional review board protocol (STUDY20050047) for collecting usability data. The authors thank Ms. Jill Pope for editorial assistance, Dr. Megan Hamm for feedback on the interview guide, Ms. Brandie George-Milford for editorial support, and Dr. David Brent for leading the P50 grant.

Conflicts of Interest

The authors have an SBIR proposal with Ksana Health to commercialize the BRITE app.

Abstract

Background: As technology is integrated into health care delivery, research on adoption and acceptance of health technologies leaves large gaps in practice and provides limited explanation of how and why certain technologies are adopted and others are not. In these discussions, the concept of legitimacy is omnipresent but often implicit and underdeveloped. There is no agreement about what legitimacy is or how it works across social science disciplines, despite a prolific volume of the literature centering legitimacy.

Objective: This study aims to explore the meaning of legitimacy in health and technology as conceptualized in the distinctive disciplines of organization and management studies, science and technology studies, and medical anthropology and sociology, including how legitimacy is produced and used. This allows us to critically combine insights across disciplines and generate new theory.

Methods: We conducted a critical interpretive synthesis literature review. Searches were conducted iteratively and were guided by preset eligibility criteria determined through thematic analysis, beginning with the selection of disciplines, followed by journals, and finally articles. We selected disciplines and journals in organization and management studies, science and technology studies, and medical anthropology and sociology using results from the Scopus and Web of Science databases and disciplinary expert–curated journal lists, focusing on the depth of legitimacy conceptualization. We selected 30 journals, yielding 796 abstracts.

Results: A total of 97 articles were included. The synthesis of the literature allowed us to produce a novel conceptualization of legitimacy as a form of social infrastructure, approaching legitimacy as a binding fabric of relationships, narratives, and materialities. We argue that the notion of legitimacy as social infrastructure is a flexible and adaptable framework for working with legitimacy both theoretically and practically.

Conclusions: The legitimacy as social infrastructure framework can aid both academics and decision makers by providing more coherent and holistic explanations for how and why new technologies are adopted or not in health care practice. For academics, our framework makes legitimacy and technology adoption empirically approachable from an ethnographic perspective; for decision makers, legitimacy as social infrastructure allows for a practical, action-oriented focus that can be assessed iteratively at any stage of the technology development and implementation process.

Introduction

Background

Technological innovations and health care delivery have become increasingly intertwined in recent decades [1,2]. With each promising innovation, new questions are raised about how to integrate the technology into health domains and the social implications of doing so [2-8]. This problem has given rise to evaluation processes such as health technology assessment [9] and a range of government institutions, such as the National Institute for Health and Care Excellence in the United Kingdom, to help make decisions about the appropriate use of technologies in various health care contexts [10].

Questions of legitimacy are implicit in debates about embedding technologies in health care, and these implicit questions about legitimacy permeate the literature about health and technology. While there is limited conceptual work on legitimacy in health and technology specifically, within the small body of work that exists, legitimacy is explored through a wide range of theoretical lenses and conceptualizations. However, there is no consensus about what legitimacy is or how it works nor is there much conversation among different branches of the literature. Across social science disciplines and medicine, legitimacy is affiliated with many concepts, including "acceptability" [11], "reasonableness" [12], and "transparency" [3,4]; these terms are sometimes conflated with legitimacy itself. Definitions of legitimacy range just as widely, especially among different disciplines: in organization and management studies (OMS), legitimacy is often defined as "normative appropriateness" [13,14], although science and technology studies (STS) and medical anthropology and sociology (MAS) include definitions such as "the acceptability of claims to authority" [15,16] and "accountability for reasonableness" [10] when the term is defined. Some disciplines, such as OMS, follow a strong tradition of explicit theorization of legitimacy, while others, such as medicine, usually do not explicitly problematize or define the word "legitimacy," although legitimacy and similar concepts may play a substantial role in discussions in the field. Within the same discipline, some authors use legitimacy interchangeably with other concepts [6], while others focus on a single subcategory of legitimacy developed from a narrow line of theoretical thought [17]. Given the breadth and depth of the literature on legitimacy in health and technology, it is clearly an important topic. A cross-disciplinary conceptualization of legitimacy that can be applied to questions about embedding technologies in health care would allow for a deeper understanding of these processes.

We chose to focus on legitimacy for several reasons. Legitimacy specifically is widely used but poorly defined within multiple fields studying health and technology and points toward social and organizational processes. Even though legitimacy is clearly important in studies of health and technology across many disciplines, it is abstract and there is very little cohesion both within and across social science disciplines around how it is produced and how it is used.

To understand the role of legitimacy in relation to the embedding and governance of technology in health care, we fleshed out the different ideas and underlying assumptions authors bring to the OMS, STS, and MAS literature. This paper explores three research questions: (1) What does legitimacy mean in the context of health and technology? (2) How is legitimacy produced? (3) How is legitimacy used to explain the challenges of embedding technologies in health care? On the basis of a synthesis of the literature, we developed a novel conceptualization of legitimacy as social infrastructure. This allowed us to focus on the aspects of legitimacy related to norms, materialities, semiotics, and specific relationships among stakeholders and larger systemic contexts.

Existing frameworks guiding policy intentions around technology adoption in health care often do not reflect the realities of everyday practice nor do they focus on the social processes of embedding technologies in health care [18]. Current models and frameworks for embedding technologies (in health care), such as the Unified Theory of Acceptance and Use of Technology [19] and the Technology Acceptance Model (TAM) [20,21], provide useful information about the judgments and perceptions of various actors in relation to a specific technology. While these models provide useful insights into actors' *intention* to adopt, as well as the ethical considerations they may perceive and institutional norms they may face, they do not often explain how and why certain technologies are or are not adopted or accepted *in practice* among particular groups and thus can provide only limited governance support [22]. Most technology adoption and acceptance models deal primarily with behavioral intention [20,21]. These models attempt to explain individual behavior intentions (as a proxy for actual behavior) through an analysis of a variety of factors, which can include beliefs, attitudes, perceived control, and perceived norms. This leaves substantial gaps, including the lack of attention to external factors impacting the embedding process [20] and any difference between behavioral intention and practice. Focusing on the impact of legitimacy within technology embedding processes can help fill these gaps by allowing for more comprehensive and nuanced conversations about technology adoption and acceptance.

A Cross-Disciplinary Legitimacy Conceptualization

The goal of this review is to produce a theoretical synthesis of how the legitimacy of health and technology is conceptualized. We aim to generate theoretical insights that will allow for a cross-disciplinary approach to legitimacy. To do this, we used the critical interpretive synthesis (CIS) review method to produce a cross-disciplinary understanding [23] of how legitimacy is produced and maintained without privileging one discipline's theoretical traditions over another's [24].

We used OMS, STS, and MAS as a disciplinary framework to understand the different strands of reasoning within legitimacy studies. OMS includes the most clearly developed theorization of legitimacy as a concept and several of the best-known review articles [14,25]. Legitimacy studies is a well-defined subarea of OMS research that explores legitimacy in the context of management, entrepreneurship, and institutional endeavors. OMS primarily focuses on how legitimacy works at the level of organizations and institutions, rather than among individual people or through technologies.

STS explores the social and cultural implications of science, technology, and technology development [26,27]. STS tends to focus on controversies, the unforeseen implications of technology development and adoption, and "black box" technologies [28] that inhibit full understanding. This contributes to a strong disciplinary interest in legitimacy, particularly of technology and medicine. STS centers interactions with technologies and technical change in legitimacy discussions, rather than separating the motivations of human actors from technologies and practices.

Although MAS developed from different traditions, they have partially converged in the study of medical cultures and interactions from a qualitative perspective [29], which is also the focus of legitimacy studies in MAS. MAS generally takes a skeptical view of taken-for-granted institutions. Many studies explore the impact of this taken-for-grantedness on people who are harmed by or left out of these institutions and systems. This leads to a natural questioning of legitimacy and deeper exploration of baseline assumptions, particularly in a health care context. Together, these disciplines explore health and health technologies with less focus on institutions and more focus on humans and connections among them. We hope that greater synthesis of different conceptualizations of legitimacy could provide a more holistic perspective about how and why technologies are or are not embedded in health care that integrates ideas from outside current frameworks based on adoption, acceptance, and implementation.

This review does not focus on ethics, although some articles that deal with ethics are included in this review. Within ethics, there is general consensus that legitimacy in health and technology is produced through ethical judgments and values-based reasoning [30-33]. While there is more cohesion in ethics than in other disciplines that deal with legitimacy, the scope of the literature is narrower and generally limited to moral or ethical legitimacy [3,34]. Legitimacy is often defined in ethical terms across several disciplines, including management, STS, and health policy. Articles with an ethical focus on health care technology adoption usually prioritize normative and moral dimensions of legitimacy, which may or may not be related to other aspects that contribute to overall legitimacy, such as utility or social acceptability [35]. While moral legitimacy is an important dimension of the subject, it has also already been studied and reviewed extensively and is far more clearly defined within the literature than other dimensions of legitimacy. Therefore, we chose to focus on other aspects of legitimacy to fill gaps in the existing social science literature. In addition, our review does not center legal approaches. Legal literature defines legitimacy according to principles of a participatory democracy [36]. Because the focus of this review is on social processes rather than democratic principles, we have chosen to center other means of legitimacy production and thus other branches of the literature, while acknowledging that democratic principles can play an important role [15,37].

Methods

Overview

In a research landscape that increasingly encourages and necessitates interdisciplinary collaboration, a CIS [24] allows us to develop a richer conceptual frame that can bring these different disciplines into conversation with one another [23,38]. The CIS method specifically addresses the limitations of conventional systematic reviews in cases where the objective is to generate a critical analysis of a body of the literature [24]. It draws on a tradition of qualitative inquiry: rather than summarizing the literature using preidentified key concepts, CIS uses an inductive, iterative process to interpret data, develop key concepts, and synthesize concepts with data through the process of the review itself [39]. Therefore, CIS produces a critical interpretation of the data reported in literature, which allows questioning of taken-for-granted assumptions [24].

We found CIS to be a particularly appropriate review style for an exploration of legitimacy in health and technology because, unlike traditional review styles, CIS is adept at dealing with "a large, amorphous, and complex body of literature" [24]. CIS synthesizes findings in a way that is both conceptually valuable to researchers and useful in informing policy. Furthermore, the CIS review style can manage the abstract nature of legitimacy across 3 disciplines without reducing the complexity of existing literature.

CIS is methodological and rigorously structured. However, it is also labor intensive compared to other review styles and deprioritizes transparency and full replicability available through systematic reviews. As in other kinds of interpretive research, different researchers using the same materials may have come to different conclusions, and full transparency of analysis cannot be expected at the same level as quantitative studies. We chose the CIS method in service of greater interpretive flexibility and conceptual depth and because it allowed us to account for the diversity of qualitative research without privileging a small range of studies that met specific and, here, less-relevant methodological standards.

Despite many empirical papers that address some aspects of legitimacy in relation to health and technology, there is a much more limited number of articles dealing with legitimacy in the domains of health and technology at a conceptual level. Therefore, we adopted broad definitions of both technology and health, including as many articles with strong legitimacy theorization as possible. "Health" in this paper refers to "human health and well-being"; "technology" includes "any devices, machinery, or equipment developed for the application of scientific knowledge that may impact human health." We acknowledge that there are potentially many other ways to operationalize these concepts that could be relevant to this review and health care in general [40]. Given the broad, conceptual focus of the review, as well as the wide range of distinctive technologies considered, we introduced 2 measures that allowed us to provide a clear focus. First, we zoomed in on conceptualizations of legitimacy; it was outside the scope to examine the specific empirical contexts and details of these conceptualizations (ie, the use of specific technologies within

specific health practices). Second, looking at specific disciplines proved helpful to demarcate boundaries around our topic. We used academic disciplines as the basis of our theoretical categories to give structure to a broad and abstract review, following in a strong disciplinary synthesis tradition established by other CIS researchers [23,38].

Our review was conducted in 4 cycles [38]. In the first cycle, we conducted an exploratory search in relevant journals with many articles on legitimacy in the context of health and technology. Using this search and subsequent iterations, we refined inclusion criteria (for instance, a threshold for legitimacy theorization) to determine a list of disciplines, journals within each discipline, and articles within these journals that would be a part of our review (see Multimedia Appendix 1 for details). In the second cycle, we read and coded included articles directly from the text, then grouped codes into thematic areas. Third, we analyzed legitimacy in health and technology within each discipline through interpretive disciplinary summaries. Finally, we developed a synthesizing argument across all 3 disciplines, based on these interpretive summaries.

Search Strategy

Journals within each discipline were selected for the review manually. Given the interdisciplinary nature of this review, we sought to include relevant journals within each discipline from a wide range to ensure diversity of perspectives.

The first author ran an initial search in Google Scholar and the Web of Science (WoS) database using the terms “legitimacy,” “health,” and “technology.” However, it became clear that regardless of how specific the search criteria became, most records returned through a database search would not include deep conceptualizations of the term “legitimacy.” This is because this term is commonly used across many disciplines as an unproblematic descriptor of technologies, legal processes, narrative choices, medical decisions, policies, and institutions. Therefore, we switched to a more iterative, manual strategy for discipline and subsequently journal selection (Textbox 1). The first author searched through a few of the major journals (based on impact factor or prior knowledge of the review team) in depth to understand whether studies addressing questions of legitimacy in a specific discipline generally included deeper conceptualization. This method allowed us to narrow down the disciplines to be included (see Multimedia Appendix 1 for details).

- Sociology-The Journal of the British Sociological Association
- Sociological Theory

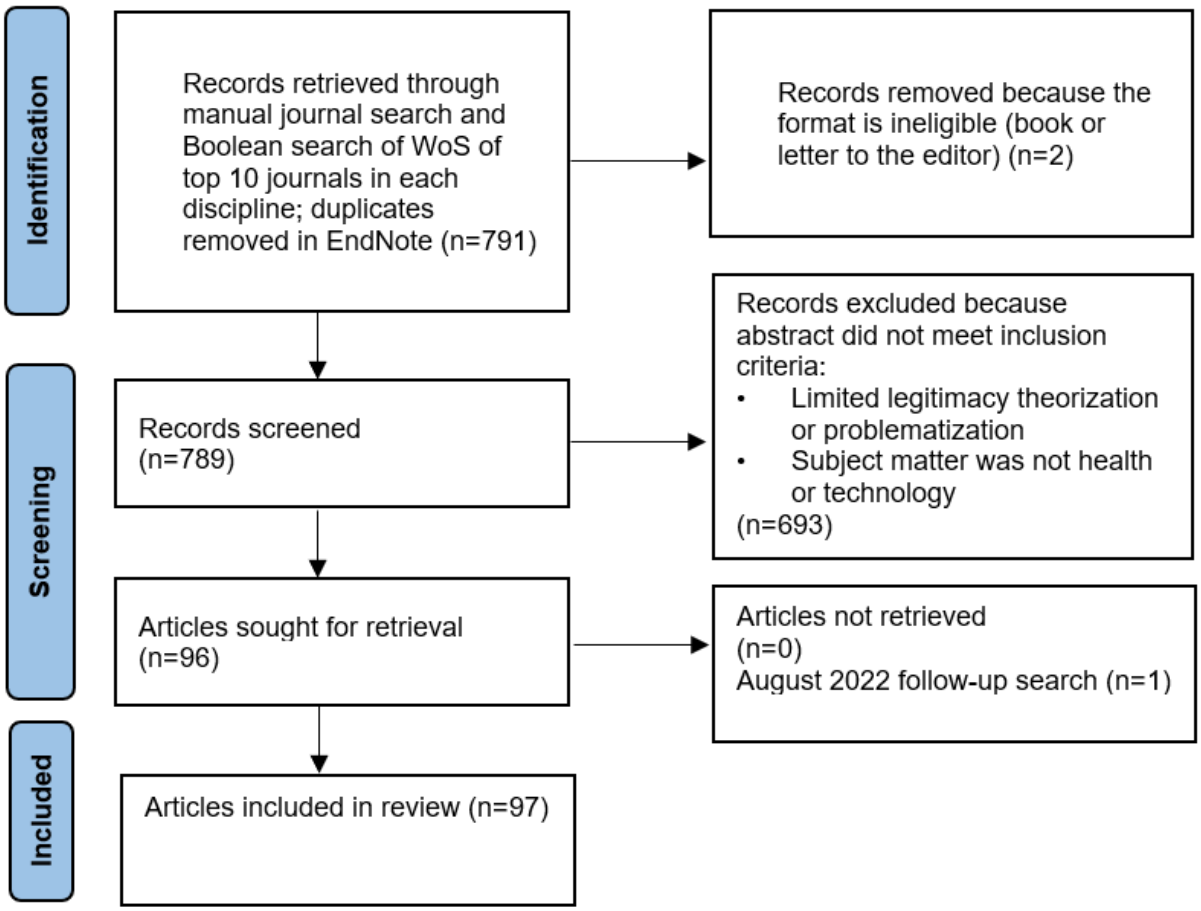
Upon the selection of disciplines, journals were first included based on impact factor: the top 10 journals in each discipline according to the WoS formed the base of the list. Then these journals were screened for topical relevance, and lower-ranked journals were excluded when the topic was not relevant. Finally, journals were added from library guides created by universities that are well-known in the field, especially if no definitive rankings were available from the WoS (STS) or there was too much disciplinary overlap in the rankings (MAS). This resulted in a list of approximately 20 journals per discipline. We then screened all journals for legitimacy, health, and technology results to produce the final list, prioritizing journals that contained significant theorization and conceptual work around legitimacy (see Multimedia Appendix 1 for details).

Selection Process

Overview

A total of 791 abstracts were selected for initial review in April 2021 (Figure 1). Articles were sorted based on inclusion criteria: an article was included if there was evidence of explicit theorization or problematization of legitimacy in the abstract and the subject of the article was health or technology or both. A final search for more recent articles was run in August 2022, resulting in 1 additional inclusion. Multimedia Appendix 1 gives more information about the inclusion criteria.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of inclusions. WoS: Web of Science.



Triangulation

The first author (SH) read all 791 abstracts and categorized them according to the inclusion criteria as "include," "exclude," or "review." The last author (RW reviewed 79/791, 10% of the total articles' abstracts at random (every 10th article when arranged in alphabetical order by author name). The resulting inclusion list closely matched SH's selection. In the 7 disagreements, the 2 reviewers came to a joint decision about each contested article and edited the inclusion criteria. SH then reviewed the abstracts again. With no disagreements following this protocol, the literature list of 96 articles was finalized in March 2021, with an addition of 1 article in August 2022, bringing the total to 97, including, by discipline, 48 for STS, 29 for OMS, and 20 for MAS [4-8,10,12,13,15,16,37,41-126].

Synthesis Methods

The goal of our initial analysis was to develop "synthetizing constructs" for each discipline, which "build on the explanations and interpretations of the constituent studies and are simultaneously consistent with the original results while extending beyond them" [24]. To accomplish this, SH first coded themes across a random selection of 30 articles spread equally across the 3 disciplines in Atlas.ti (ATLAS.ti Scientific Software Development GmbH). Inductive coding began with words taken from the article text. We made an exception for deductive codes relating to assumptions made as part of our "critical and reflexive approach" to this review [24]; for instance, coding whether articles discussed legitimacy as a process, perception, or asset based on our background understanding of existing legitimacy theorization across multiple disciplines. SH grouped codes by theme within each discipline. This thematic analysis was performed with the help of tables of code co-occurrences, generated in Atlas.ti, which showed overlap of unique codes within each document; this allowed us to understand when codes could be combined into a theme. We also used network visualizations, which helped us understand how different aspects of legitimacy may relate to one another on a broader scale (see Multimedia Appendix 2 for an example of one of these visualizations). This process allowed reviewer SH to maintain a differentiated perspective on each discipline and acted as a memory aid for the reviewer given the volume of the literature. SH then wrote summaries of the approach to

legitimacy within each discipline, which were discussed with RW. SH coded the remaining articles using Excel (Microsoft Corporation) while editing the disciplinary summaries as necessary. Multimedia Appendix 1 provides an example.

SH developed a synthesizing argument that could connect constructs of legitimacy across all 3 disciplines. SH tested the fit of different conceptualizations with the disciplinary summaries and then explored the development of these metaphors with RW. After SH had read 90% (87/97) of the articles, no further edits or additions to the disciplinary summaries or synthesizing argument were necessary, likely indicating data saturation.

Results

Organization and Management Studies

What Does Legitimacy Mean?

The basis of legitimacy epistemology in OMS can be traced to the highly influential paper by Suchman [14]. His definition of legitimacy still forms the basis of most subsequent theorizing in this field: "Legitimacy is a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions" [14].

This definition builds from and expands on Weber's [127] understanding of legitimate authority, among other conceptualizations [41], focusing on the application of Weberian legitimacy concepts such as "tradition, affectual attitudes, value, and legality" [127] within a "socially constructed system of norms, values, beliefs, and definitions" [14]. Bitektine and Haack [128] further expanded on the Weberian connection to Suchman [14] with a multilevel legitimacy theory that differentiates among legitimacy judgments at the individual and collective levels [42]. Because of strong theoretical cohesion in this discipline, authors draw generously from these theoretical traditions, and most legitimacy subtypes are variations of normative legitimacy. Normative legitimacy deals with the norms, systems, and underlying assumptions that result in an institution, technology, or system being considered legitimate, and is generated through systems and social processes that may not be made explicit until there is a legitimacy crisis [41].

This definition is notable for its understanding of legitimacy as a perception of actions based on socially constructed norms and implicit conceptualization of legitimacy as a taken-for-granted state. However, perhaps more important is what is left out: because legitimacy is "generalized," it is not dependent on materialities or physical space, nor does the definition of legitimacy change specific to relationships among institutions or individuals. Our critical interpretive analysis shows that these kinds of assumptions seem to help determine the lines of reasoning for most OMS legitimacy scholars included in this review.

Our analysis shows that OMS legitimacy studies constitute a cohesive body of literature in which theoretical contributions are made incrementally. For instance, most authors outline exactly how they are adding to the existing literature (usually based on the definition by Suchman [14]) in a specific way. For instance, articles often divide legitimacy into ever more granular categories such as "network legitimacy" [43] and "actional legitimacy" [44] or focus on a particular aspect of the definition by Suchman [14] to explore in more depth, such as "normative appropriateness" [129]. Therefore it is easy to trace the lineage of theory. However, because every article adheres to the same framework, there is less diversity of thought. In light of this, a division could be made between technology literature and health care literature. Technology literature, usually with an entrepreneurship bent, tends to focus on audience perception and innovation framing through discourse, by teaching entrepreneurs how to appeal through discourse to different kinds of funding audiences [45]. For example, entrepreneurs seeking crowd-based funding are advised to make "contribution claims" emphasizing identity and added value to the funding community, rather than institutional ties or the significance of potential scientific or social advancements that may legitimate the entrepreneur to other audiences [45]. Health care literature focuses mainly on institutional legitimacy, for instance, by examining the negotiations involved in academic health center mergers [46] or the role of physician executives in institutional contexts [47]. For example, Kitchener [46] emphasizes that even as new sources of legitimacy for an academic health center became necessary in the wake of both a merger and a changing environment, the aim was to create an "aura" of legitimacy within a new institutional logic; in other words, even though the source of legitimacy changed, it was still defined through institutions.

How Is Legitimacy Produced?

On the basis of the literature reviewed for this study, conceptualizations of legitimacy production in OMS fall into 3 categories. Legitimacy-as-process, or legitimation, is "an interactive process of social construction" [25], often with clearly delineated steps toward generating legitimacy [48,130]. Articles using this conceptualization tend to track change over time [13,49,50], for instance, by examining the legitimation journey of a single innovation over decades [50]. Legitimacy as perception or "a social judgment, an evaluation, a socio-cognitive construction" [25] is used most frequently in relation to audiences or the question "legitimate to whom?" usually when examining innovations within larger organizational contexts [45,51,52]. Finally, a legitimacy-as-property conceptualization, in which legitimacy is viewed as an asset to be gained, increased, or lost [25], emphasizes how an entity gains legitimacy rather than differences between legitimate or illegitimate entities; this conceptualization appears to play a smaller role in more recent work. Legitimacy as a process and legitimacy as a perception are often used simultaneously within the same paper; there is an acknowledgment that both perspectives can offer valuable insights. For instance, McKnight and Zietsma [53] describe the process through which new ventures can achieve "optimal distinctiveness" (a perception) through framing and collaboration strategies (a process). Similarly, Garud et al [54] discuss entrepreneurial storytelling as a legitimation process that relies on audience perceptions, thereby promoting an understanding of audience perceptions

as part of analyses of different narrative techniques, which are framed as processes of legitimation [53].

How Is Legitimacy Used?

Within the literature reviewed, we noted that legitimacy is often assumed in OMS to be necessary for resource acquisition and is mostly relevant in an institutional setting. Because resource acquisition is the *raison d'être* of business in capitalism, legitimacy is considered essential. All literature included in our review aims to explain legitimation journeys or to advise institutions and entrepreneurs on how to move toward legitimacy. The stated goal is often to advance legitimacy theory within OMS, rather than explore empirical evidence beyond specific case studies.

Our analysis shows that nearly all legitimacy problems in OMS are framed as problems of categorization: either an institution or innovation has been miscategorized by its intended audience, or it has not yet been categorized [51]. Because of this, there are several articles that deal with the paradox of legitimacy for disruptive innovations: the innovation must conform to a category to be seen as legitimate, but it will not be seen as necessary unless it also distinguishes itself within the category [45,53,54]. Articles often describe how entrepreneurs can strike this balance or analyze how an older innovation navigated the paradox. For instance, Ruef and Scott [41] produced a multidimensional model of legitimacy designed to help hospitals use knowledge of legitimacy norms and categorization to "attract managerial legitimacy." Other authors provide articles that, while academic, can also be interpreted as how-to guides for entrepreneurs attempting to formulate narratives for different audiences. Articles in this category posit that entrepreneurs must fit the narrative to the correct category of both the legitimacy problem [54] and the audience's perspective [45].

Articles discussing specific innovations often explore problems of categorization through "institutional logics" [45,46,55] or the forms normative legitimacy may take within a particular institution. These articles acknowledge that different institutions have different norms, and therefore, entrepreneurs and innovators must adapt their storytelling to "fit" with the institution. Our analysis of the OMS literature showed that institutions that are taken for granted have no narrative flexibility. This means that any changes made not only require buy-in from professionals but also immediate practical implementation of changes (such as shifting patient education responsibilities from physicians to nurses) to avoid becoming mired in default institutional processes [56]. However, an entrepreneurial venture wrestling with liability of newness [53] has nearly endless opportunities for narrative reframing and limited risk of stagnation in nonexistent institutional processes [45].

Summary

In short, OMS seems to heavily theorize granular definitions of legitimacy, derived mostly from normative legitimacy. Most articles describe how organizations can move from illegitimate to legitimate status. Legitimacy must be negotiated at multiple levels and can be conceptualized as a process, perception, and asset. On the basis of our initial analysis, legitimacy in OMS rests on taken-for-grantedness and categorization according to institutional logics; it is hampered by liability of newness [51] and difficulties fitting into an institutional logic or other category.

We now move on from the critical interpretation phase of CIS methodology and toward synthesis. We develop synthetic constructs to metaphorically unite major themes within each discipline. While the OMS line of reasoning is somewhat homogeneous, our interpretive analysis shows that there is acknowledgment that different institutions use different systems of thought, or institutional logics, to judge and negotiate legitimacy. Stakeholders must navigate these different systems by fitting themselves into clear categories. However, the system by which legitimacy is judged and negotiated is rarely fully navigable to any one stakeholder.

In this way, navigating legitimacy in OMS is like using a highway system. The roads themselves (in this case, pathways to legitimacy) are clear and concrete but can only be used by particular categories of vehicles in particular locations, in the same way that, for instance, entrepreneurs must use particular discourses (ie, roads) to legitimate their invention to certain audiences (locations) [45,50,54]. The metaphor of the highway system allows us to capture OMS' conceptualization of legitimacy as a rule-bound system of connections, driven by institutions. The highway system metaphor shows us that the OMS perspective on legitimacy is unusual for how fully theorized and comprehensive it is. However, in the same way that mapping a highway system alone does not describe everything that happens on the road, this metaphor also helps us articulate gaps in OMS theorization. OMS focuses on pathways to legitimacy, institutional involvement, and categorization; however, it can be difficult to explore the moments of legitimacy breakdown, unexpected contradictions within legitimacy journeys, and the influence of materialities on legitimacy within the concrete and bounded pathways that make up legitimacy conceptualization in OMS.

Science and Technology Studies

What Does Legitimacy Mean?

Within the legitimacy literature reviewed, nearly all STS articles dealt with health care or science practices on the edge of scientific validity or public acceptance, usually by focusing on controversial technologies. Authors seemed to pay significant attention to the audience for these controversies. Innovations explored within STS also include changes in health care and scientific systems or discourses, for instance, the process of creating new institutions within an academic environment [57].

In this way, it seems that legitimacy in STS can only be discussed easily when it is in question. This may be linked to STS's longstanding focus on controversies as strategic locations of research and the STS tendency to "stay with the trouble" [131]. Taken-for-grantedness may be considered such an integral part of legitimacy that it raises red flags in a discipline that is highly sensitive to unintended consequences.

However, in the STS literature reviewed, legitimacy itself is rarely the subject of an article. Our interpretive analysis shows that legitimacy is still undertheorized in STS, in that many

articles do not reference other legitimacy literature or define the term. When legitimacy is explored in depth, authors tend to deal with it as a type of knowledge coproduced at the site of controversy between human and nonhuman actors. For instance, 2 articles examine the demarcation of boundaries in discourse about future-facing technologies; in these articles, narratives about nanotechnology and forensic science both impact and are impacted by developments in the technology [16,58]. For instance, Selin [16] demonstrates that even if a single vision of the future of nanotechnology is accepted by scientists over all others, competing visions may still have an impact on the direction of technological development via other avenues, such as governance and funding. We interpret this as evidence that legitimacy is coproduced between the narrative around new scientific disciplines and concrete innovations within those disciplines.

A consequence of the focus on disputed boundaries that we observed in the STS literature seems to be that STS scholars treat legitimacy as mutable. Boundary work [59] articles conceptualize legitimacy as a process that happens through negotiation within relationships among people and institutions. Boundary work deals with how people and institutions negotiate changing roles, limits, and responsibilities, often in relation to knowledge practices [59]. Within our review, most authors seem to use boundary work only as an explanatory framework for discursive strategies, but some articles include writing and practices as instances of boundary work [60]. For instance, Granja and Machado [58] describe how forensic scientists clearly demarcate their expertise and the limits of their role in the justice system through both discursive strategies and practical performances of accountability such as fastidious record keeping as a strategy to maintain their legitimacy. While perception can play a role in this process, we found no STS boundary work articles within the literature reviewed that consider legitimacy to be merely an asset. We interpreted this as possible evidence of the STS disinclination to consider any relationship or object to be fixed and a general disciplinary focus on processes of knowledge production.

How Is Legitimacy Produced?

We found that processes of legitimacy coproduction of new technologies in health care are described in relationships among a variety of human and nonhuman actors [28]. STS seems to resist explanations that pin legitimacy's presence or absence on a single explanation or strategy. Instead, by examining the influence of nonhuman actors, STS encourages readers to embrace complexity in legitimacy relationships. For example, Barker [61] discusses how a drug marketing campaign legitimated a contested illness; McLevey [62] details how legitimacy goals for policy recommendations change how think tanks make knowledge; and Greco [63] uses the concept of "scientific ideology" to explore how the placebo effect threatens the legitimacy of scientific rationality in biomedicine. In these examples, the influence of unexpected nonhuman actors shapes legitimacy in a porous way; this influence adds complexity to legitimacy relationships. These examples thus turn the "expected" legitimacy relationship upside down. Barker shows that a treatment can make an illness legitimate (rather than an illness becoming legitimate and then treatment being developed). McLevey [62] demonstrates that knowledge may be made to legitimize policy recommendations (rather than knowledge first being created and then informing policy decisions). Finally, Greco [63] posits that a biomedical effect can threaten the legitimacy of biomedicine (rather than biomedicine creating biomedical effects that reinforce its legitimacy).

How Is Legitimacy Used?

Through our critical interpretive analysis, legitimacy in STS appears to be yet another "two-faced Janus" [28], in that it is coproduced by both taken-for-granted processes and unexpected assemblages, which may appear contradictory. For instance, Brown and Michael [64] note that the institutional mechanisms for validating scientific discovery play a part in legitimizing medical use of pig organs. However, the authors also find that these taken-for-granted institutional processes are not enough to legitimate transspecies transplantation. Rather, porcine donor organs are legitimated in their interpretation through an unexpected assemblage of institutional processes and scientific and cultural judgments about pigs. While anatomical similarities between humans' and pigs' organs exist from a scientific perspective, human-pig differences legitimate porcine donor organs (over, for instance, monkey organs) from a cultural perspective [64]. These apparent contradictions do not threaten the legitimacy of porcine donor organs; instead, the authors interpret these contradictions as necessary to establish legitimacy for a controversial innovation in medicine.

While most articles in the reviewed STS literature use the concept of legitimacy to explore complexity in relationships among technologies, ideas, people, and institutions, a small subset of the literature consists of discourse analyses focusing on language as the only vehicle of legitimation [4,62]. In these articles, there is no room for other means of legitimation, such as nondiscursive practices, language-free materialities, or physical space. In addition, policy-oriented articles about discourse-based legitimation strategies tend to view these strategies as mutually exclusive: "legitimacy can only be achieved if complexity is reduced via language" [65]. This appears to be a radical departure from the assembled view of legitimation present in most STS articles, in that legitimacy is produced by specific arguments designed to convince one party that another is legitimate, rather than *through* the complexity of negotiation among people, technologies, ideas, and institutions. However, both STS subgroups use legitimacy as a relational concept, whether relationships are implied through arguments or complex negotiations.

Summary

Our analysis demonstrates that STS approaches legitimacy through controversy and contestation. Because of its empirical orientation and wide variety, the way legitimacy is approached in STS cannot be viewed as theoretically cohesive. We found that STS explores legitimacy as an artifact of knowledge coproduction, centering nonhuman actors and complex legitimacy processes through discourse, practices, or both. In one conceptualization, legitimacy is viewed as a constant and complex negotiation among actors and their contexts. However, discourse analyses often view the complexity of these relationships as a problem for legitimacy rather than an integral

aspect of the concept. Despite this divergence, nearly all STS literature reviewed seems to assume that legitimacy is relational and includes nonhuman actors, contexts, and practices of knowledge production.

Moving toward our synthetic constructs, we posit that in STS, the coproduction of legitimacy through both taken-for-granted processes and unexpected assemblages functions such as the mutable infrastructure of a computer operating system. The hardware of the computer does not change (much), even though the overall capacity of the computer relies on constant updates of existing software. New operating systems build on what came before while adding something new to stay relevant. Similarly, the legitimacy of technologies in health care is viewed predominantly as being built on underlying infrastructures, such as evidence-based medicine (EBM) and laboratory protocols. However, it is also considered to be shaped by unexpected influences, such as the coexistence of traditional medicines with EBM standards [66] and popular conceptualizations of new technologies that do not align with the use of those technologies by experts [58]. Furthermore, legitimization of a technology may have unexpected consequences, such as a medicine legitimizing an illness [61]. Legitimacy, according to STS scholars, must be constantly negotiated among nonhuman actors through an iterative process that is most visible at the boundaries. Through the metaphor of computer operating systems, STS emphasizes a dualistic perspective of legitimacy. Legitimacy in STS depends on the mutability and unexpected creativity of practices, actors, and context (ie, software); simultaneously, this "software" of legitimacy must be built on top of preexisting systems that are much more rarely changed in substantial ways (ie, hardware). Without these preexisting systems, the knowledge production practices delineated by STS scholars have nowhere to operate.

Medical Anthropology and Sociology

What Is the Meaning of Legitimacy?

On the basis of our critical interpretation of the MAS literature under review, we found that MAS tends to center relationships among people within larger systems and physical spaces, rather than the nature of the systems or institutions themselves. Similar to STS, the MAS literature reviewed usually discusses controversies rather than strategies of legitimation.

Because few articles use concrete definitions of legitimacy or conceptualizations that reference any other body of literature, even if they discuss legitimacy issues in depth using empirical evidence, we found legitimacy to be undertheorized within MAS as a discipline. Several articles use terms such as "medical legitimacy" [6] or "narratives of legitimation" without definitions [67]. Some define legitimacy only in relation to another concept [12,68,69]. More than any other discipline, MAS seems to veer toward legitimacy definitions that are limited by subject and narrow [59] in scope: for instance, "being legitimately on sick leave requires both a certified illness and the inability to perform one's work as a result of that illness" [70]. In our interpretation, this appears to allow for more empirical grounding but prevents conversation with other literature about legitimacy as a larger concept. Within the MAS literature reviewed, legitimacy is always relative, in that there is no universal legitimacy that works across all contexts.

However, there is still some cohesion visible among a subset of articles in the discipline. Several authors frame legitimacy as a form of "symbolic capital" in the Bourdieuvian sense [69,71,132] that can be used for resource acquisition. These articles and others also use boundary work [59] to describe the legitimacy of professional roles as a negotiation of boundaries mostly through discourse [72]. In combination with the disciplinary tendency to focus on the disenfranchised, these framings paint legitimacy as a power issue [37].

The literature reviewed seems to prioritize nuanced accounts of both social processes in contested situations and the spaces and materialities that shape the contestation of a technology. For instance, in an exploration of medical quackery in South Africa, Hornberger [68] shows that even when using medically useless technologies, providers of these technologies can construct legitimacy for their patients because of contextual elements, such as lower education levels, local beliefs, and problems accessing proven medical treatments. Spaces, materialities, and relativity appear to be especially important in articles about disconnects between policy and practice in professional settings [73]. For example, Perrotta and Geampana [7] explore how in vitro fertilization (IVF) professionals navigate the disconnect between the standards of EBM and the enthusiasm of patients for the latest technologies. In another account of IVF, Barnreuther [84] notes that because the research took place in a physician private home in India, as opposed to an institutional setting in a Western country, the resulting technical success was deemed illegitimate and went unrecognized in both medicine and research for decades. We find that these kinds of nuanced accounts present a deeper and more empirically grounded understanding of the meaning of legitimacy in context, despite a lack of theorization.

How Is Legitimacy Produced?

Our critical interpretation of the MAS literature emphasizes the intertwined nature of practices, discourses, social processes, and materialities in the production of legitimacy. Authors often seem to assume these are impossible to separate from each other without losing meaning. For instance, in a study of the use of restraint in a hospital psychiatry ward, McKeown et al [74] examine how boundaries of space (ie, office or patient area), identity (ie, health care professional or patient), and diagnosis work together to legitimize or delegitimize the use of force in context. In this way, legitimacy is defined, not merely influenced, by the environment in which it is generated [75].

When legitimacy is conceptualized as a power problem, categorization seems to solidify the standing of already-legitimate actors. Meanwhile, power appears to become less accessible for the illegitimate when professional boundaries are unclear [69,76-78] or impermeable to outsiders [8,79,80]. Common MAS topics include contested illnesses and attempts of patients to receive treatment [70,80,81] and role negotiations of nonmedical practitioners within the medical establishment [69,79,82-84]. In both cases, power imbalance is usually framed as the primary obstacle to legitimacy, which is necessary for a more egalitarian redistribution of power. Although some authors

argue it is possible to have some power without legitimacy [72,82,84], the physical location of institutions, people, and technologies still defines flows of resources, manifesting in, for instance, differential treatment of patients at a rural hospital that would be unlikely at an urban hospital due to differences in hospital conditions rather than patient deservingness [85]. On the basis of these examples, our interpretation is that MAS and OMS have some overlap in this area in that both disciplines seem to approach legitimacy as an issue of access to resources.

How Is Legitimacy Used?

MAS literature reviewed often examines how legitimacy can flow through the taken-for-granted artifacts of professionalism. These artifacts include prescriptions [78] and complicated-looking fake medical machines [68]. Because the object itself is imbued with legitimacy through specific qualities in the professional context (eg, an appearance of being "official" or "high tech"), artifacts in these articles seem to reinforce the legitimacy of the pharmacist writing the prescription or the practitioner using the machine. Material artifacts may also include larger systems such as old IT infrastructures or preexisting contracts that impede desired change within institutions [73], implicitly reinforcing the legitimacy of institutional systems. While these materialities impact potential changes in legitimacy, they are usually not the subject of debate in the MAS literature. Therefore, it seems that the legitimacy of the prescription-writing pharmacist may be contested, but the prescription itself usually is not [78].

Summary

Our critical interpretation of the MAS literature is that legitimacy in this discipline is a relative and context-dependent concept. Legitimacy is often understood to be intertwined with power relations, but authors disagree about the nature of this connection and its implications. Finally, MAS articles center sites of controversy in which the subject has already been deemed illegitimate by focusing on space, materialities, and relationships. MAS authors appear to use these lenses to question "default" narratives of legitimacy in favor of exploring how and why a technology, system, group, or experience came to be viewed as illegitimate.

Here we develop our final disciplinary synthetic construct. Our interpretive analysis found that in MAS, legitimacy is physical, material, and always relative. Therefore, we employ the metaphor of a building's plumbing: each part of the system, from the pipes to the faucets, performs a different function, which defines both their physical form and location. No two buildings can have identical plumbing systems, because no two buildings, even if constructed similarly, are situated in exactly the same location—thus, they must connect to the local environment in different ways. In much the same way, the materialities of health and technology, and how these materialities interact with spaces and actors, are considered to define the legitimacy of health and technology in MAS. A "quack" technology reads as legitimate instead of "fake" because of both its physical form and the spatial context it inhabits [68]; an innovation such as IVF in the "wrong" space may never be recognized as innovation at all [84]. In both cases, if we understand legitimacy to be an infrastructure that is dependent on both space and materialities, we can better connect the different underlying systems and elements that comprise legitimacy for health technologies. A sink connected to a sewer line requires multiple specific parts, arranged in a particular way, running through a particular location, to function. In the cases noted earlier, materials, the spaces in which they are developed, and the spaces in which they are used must be arranged in particular ways for technologies to be considered legitimate, whether the audience is the international scientific establishment [84] or residents of a rural South African community [68]. The metaphor of a plumbing system emphasizes the categorical importance of context and physical materials in the construction of legitimacy: in MAS, legitimacy cannot exist without these. Therefore, this metaphor also helps us understand why MAS generally avoids comprehensive definitions or theorization of legitimacy; other than a few basic building blocks, systems of legitimacy for MAS are essentially viewed as nontransferrable between contexts.

Synthesizing Argument: Legitimacy as Social Infrastructure

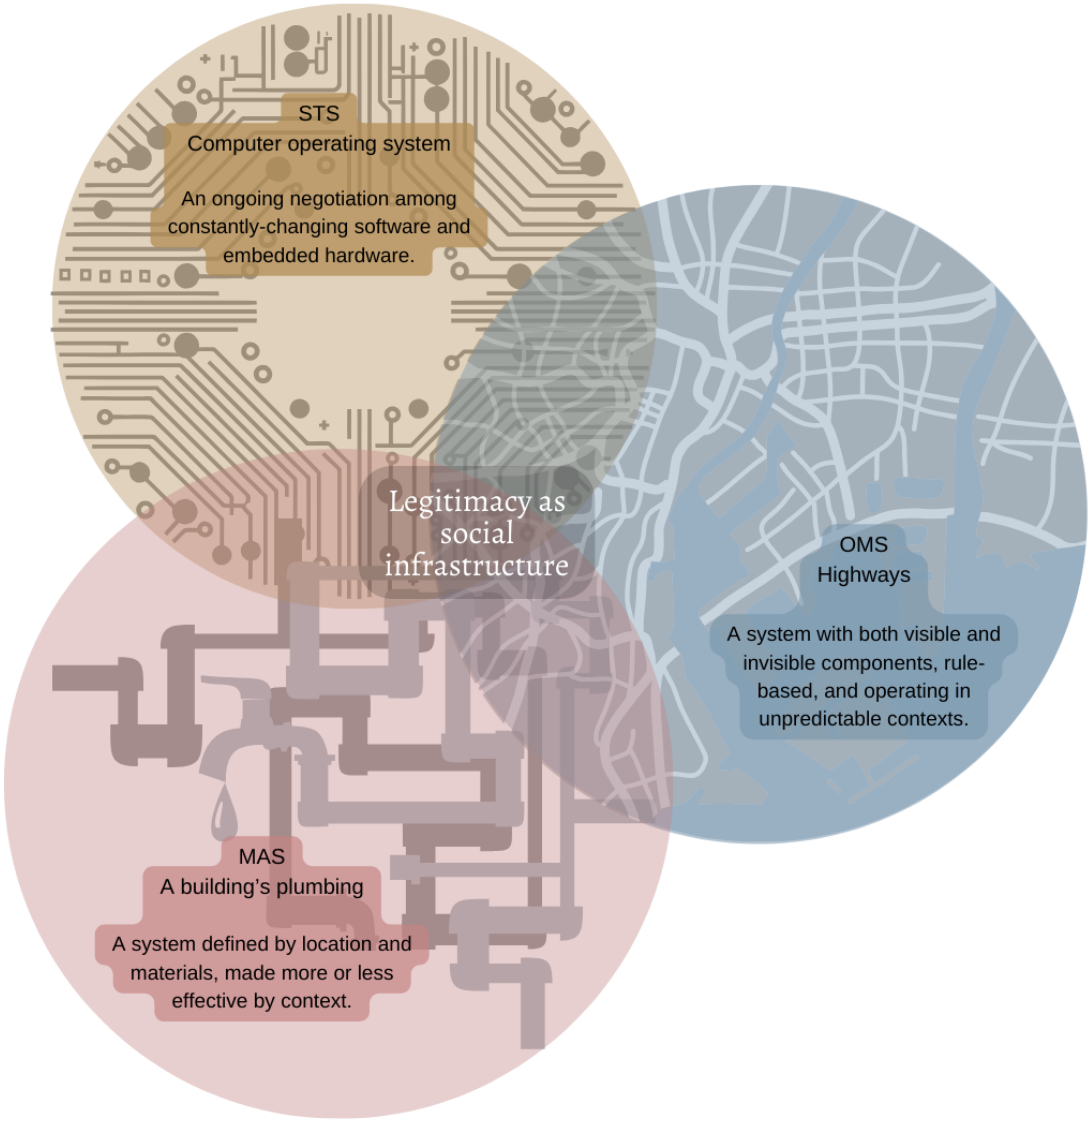
Legitimacy is omnipresent and important within all 3 disciplines. However, it is often undertheorized and the subject of many implicit assumptions across MAS and STS literature. In OMS, conversely, increasingly detailed theorization results in the proliferation of "subtypes" of legitimacy with limited empirical support (see Table 1 for more details). Our synthesizing argument allows us to bring these different disciplinary traditions into conversation with each other through a new conceptual framework for legitimacy.

Using the 3 disciplinary metaphors we developed, we propose that legitimacy can be conceptualized as a social infrastructure, based on the criteria for an infrastructure by Star and Ruhleder [133]. If we combine the metaphors of a highway system (OMS), computer operating system (STS), and plumbing system (MAS), we begin to see the building blocks of an infrastructure that can support an entire city (Figure 2). Each metaphor shows a particular element of city infrastructure (ie, understanding of legitimacy) clearly. However, similar to a layered map of a city's interconnecting infrastructures, we gain a fuller picture of how legitimacy works in health and technology when we layer the metaphors to view their intersections and divergences. Knowing how computer systems monitor traffic and manage stoplights helps us better understand both computer systems and highways; similarly, an STS understanding of how unexpected assemblages may work with taken-for-granted processes can help us better understand how these unexpected assemblages may impact theory about taken-for-granted processes in practice within OMS. Therefore, such a layered map allows for a richer conceptualization in which there is room for different approaches to legitimacy without denying the validity of any single conceptualization.

Table 1. Disciplinary characteristics: legitimacy in organization and management studies (OMS), science and technology studies (STS), and medical anthropology and sociology (MAS).

	OMS	STS	MAS
Theoretical foundations	Major focus on theory, granular definitions of legitimacy common; normative legitimacy most prevalent	Some theoretical exploration but limited theoretical cohesion	Limited theoretical exploration, reliance on granular definitions based on empirical evidence
Conceptualized as	A process (of negotiation); perception; or asset, and sometimes as several of these at once.	A product of knowledge coproduction; a negotiation among human and nonhuman actors, contexts, and epistemic cultures	A relative and context-dependent concept intertwined with power relationships
Purpose of literature	Describe how organizations can move from illegitimate to legitimate status	Investigate instances of controversy and contestation	Explore how and why a subject came to be viewed as illegitimate
Most important related concepts	Taken-for-grantedness; categorization and standardization	Relationships, taken-for-grantedness, and unexpected assemblages	Materialities, relationships, and space

Figure 2. Disciplinary metaphors. MAS: medical anthropology and sociology; OMS: organization and management studies; STS: science and technology studies.



Similar to a physical infrastructure, legitimacy can be understood as a binding fabric that makes possible certain types of relationships among people, institutions, and technologies. In our conceptualization, legitimacy is an inherently relational concept: it can only exist between two or more entities, rather than within the perceptions of a single person or institution. The notion of social infrastructure makes space for legitimacy to exist outside of human judgments, without devaluing the importance of perception in the production of legitimacy. Just as infrastructures consist of both materialities and abstract systems (eg, roads are made of concrete, but their use is facilitated by traffic laws), social infrastructure melds semiotic,

material, and normative aspects of legitimacy and explores how they might work together. Infrastructure thus allows for the integration of disparate and seemingly contradictory aspects of making legitimacy. While Star [134] has emphasized that infrastructure is inherently a "relational property," we use the word "social" to focus on how legitimacy supports specific types of relationships among people, institutions, and technologies; in particular, how these relationships are shaped by implicit and intangible norms and values [135]. For instance, understanding the nuances and norms of pharmacists' relationships with both physicians and health care institutions reveals why a simple policy change allowing pharmacists to prescribe medication legally is not enough to legitimize the practice [78]. This moves us away from conversations about legitimacy as a conduit for resources and toward more clarity about how legitimacy acts as a binding fabric within social relationships.

Descriptions of legitimacy across all 3 disciplines fit the criteria for an infrastructure by Star and Ruhleder [133]. For instance, legitimacy is usually only visible "upon breakdown" [133]. Contestation and controversy are the only sites of legitimacy exploration in MAS and STS; in OMS, legitimacy is discussed in terms of desired change in legitimacy status (ie, moving from illegitimacy to legitimacy), and contestation is captured explicitly through concepts such as "liability of newness" [53,54]. In addition, maintenance of this social infrastructure happens through continued adherence to legitimizing protocols and norms within relationships; deviations can result in a crisis of legitimacy. In this sense, legitimacy is characterized by a strong fit with predefined categories and "standards" [133] in many articles [45,53,65,85], even when legitimacy itself is not defined. In our conceptualization of legitimacy, norms and values make up the "installed base" into which legitimacy is embedded [133] and are responsible for legitimacy's taken-for-granted nature.

Legitimacy also acts similar to infrastructure, in that it can be used to invisibly support the work of organizations, technologies, or people [55,86,133], often by allowing for acquisition of resources or power [69,87]. In fact, values and norms are often so deeply entrenched and invisible that even the infrastructure supporting them (ie, legitimacy) becomes taken-for-granted and invisible itself. This combination can make it extremely difficult for any contradictory experiences or knowledge to find expression within a society's taken-for-granted, unquestioned truths [85,88,89,132]. Therefore, it is understandable why the moments of crisis when legitimacy is "visible upon breakdown" usually occur when norms and values clash with each other. For example, in the exploration of IVF by Perotta and Geampana [7], new reproductive technologies are a site of legitimacy crisis because they are heavily desired by patients but cannot adhere to standards of EBM. In this situation, physicians must navigate among the medical value of providing patients with the care they seek, the medical value of providing evidence-based care, and the medical norm of adhering to preset medical standards that may not have kept up with available care options.

Finally, the origins of legitimacy parallel those of any other infrastructure. Legitimacy is built on existing social systems: it "wrestles with the inertia of the installed base" [133] and borrows both strengths and weaknesses from that base, resulting in legitimation by once-functional mechanisms that are now relics. For instance, Sheard et al [73] show how desired changes in practices in a hospital setting are stalled by existing social, technical, and bureaucratic systems and entrenched social practices, despite a lack of effectiveness of these entrenched systems and a desire for change among the people acting within them. Overcoming this systemic inertia requires the integration of new practices and systems into the installed base, regardless of the current utility of that base; attempts to completely overhaul entrenched institutional practices or technologies without attention to the installed base rarely succeed.

In all 3 metaphors, infrastructure serves as a system through which different elements that contribute to legitimacy can negotiate with one another. A social infrastructure conceptualization reflects the nature and parameters of these negotiations. Thus this lens allows us to see where different perspectives on legitimacy could provide a more holistic picture of how legitimacy works in practice, encouraging a collaborative approach to conflicting views on legitimacy.

We hope this conceptualization can provide a useful lens to better understand how legitimacy is produced and how it works among institutions, technologies, and people. We aim to move the conversation toward a more holistic perspective on embedding technologies in health care that goes beyond models based primarily on judgments and perceptions.

Discussion

Principal Findings

Our conceptualization of legitimacy as social infrastructure allows for deeper analysis and understanding of the meaning, production, and uses of legitimacy when embedding technologies in health care. Our review contributes to the OMS literature by bringing in outside perspectives. Cross-fertilization among the 3 disciplines reigns in the proliferation of legitimacy theory in OMS while providing a better connection with empirical research. STS and MAS literature benefit from grounding empirical exploration within a more cohesive theoretical framework. Our review also helps contextualize studies of legitimacy that are more limited in scope; for instance, while discourse analyses of legitimacy are useful, this review demonstrates that discourse comprises just one aspect of legitimacy production [67,90,91]. By allowing for many definitions of legitimacy, the notion of legitimacy as social infrastructure is adaptable enough to produce meaning across disciplines while providing ways to explore relational, material, and semiotic aspects. By providing a framework through which to explore many conceptualizations and understandings of legitimacy, we hope LSI can facilitate fruitful cross-disciplinary collaborations of legitimacy researchers. Specifically, LSI allows different conceptualizations to coexist without competing with one another, providing a framework in which researchers can build on the work of other disciplines without having to disregard the traditions of their own discipline. In addition, this framework provides value to acceptance, adoption, and implementation researchers and other stakeholders interested

in better explaining how technologies are embedded in health care. Through an interdisciplinary understanding of legitimacy and a focus on relationships and moments of breakdown, LSI provides a mechanism to study technology embedding both contextually and over time. In this way, LSI produces a more comprehensive understanding of how the interconnected social, medical, environmental, and institutional elements surrounding a technology may interact in ways that impact legitimacy for a given technology, and thus, whether a technology will become embedded in health care.

Embedding Beyond Current Frameworks

Legitimacy as social infrastructure provides an alternative to current models describing how technologies are embedded in health care. We can use this conceptualization to account for gaps between policy intentions and practices when embedding technologies. Social infrastructure produces a more comprehensive understanding of the issues underpinning technology adoption than frameworks that hinge on trust [136,137], transparency [4,137], and acceptability [19], especially when those frameworks are based on behavioral intention [20,21,138]. Articles included in this review have shown that the complexities of embedding technologies in health care often clash with the best-intentioned policy choices because these frameworks generally do not account for the full scope of legitimizing processes within health care delivery systems. This is particularly evident in articles that focus on contested illnesses [80,89,92] and professional boundary work negotiations in light of new policies or collaborations in health care [47,56,77,78,93,94]. For example, Weiss and Sutton [78] demonstrate that even though policy changes explicitly allow pharmacists to prescribe medication, actually doing so in practice involves a more complex negotiation of roles and hierarchies to legitimize pharmacist prescribing activities. The new prescribing policy, based on notions of trust and acceptability, is not enough. For patients whose contested illnesses do not meet EBM criteria [80], negotiations and individual relationships are essential to access any kind of medical care [95]. Here, EBM criteria designed to increase transparency and trust in medicine prevent patients with real symptoms from accessing necessary care.

The many technology acceptance and adoption frameworks available currently have difficulty explaining adequately how and why some technologies are embedded in health care but others are not; in other words, “the literature does not specify the conditions for full use to be achieved” [138]. Similar to legitimacy, these terms are not clearly defined across the literature [138]: “acceptance” and “acceptability” generally are defined in terms of perceptions of potential users [138,139] and separate from both “adoption” and “appropriation,” which deal with the processes and practices of using the technology [138]. Other models aim to identify factors contributing to acceptance of new technologies. TAM is the most well-known example; it has been adapted and added to by numerous authors since its inception [20,21,138,140]. However, similar to most adoption and acceptance frameworks, TAM is based on behavioral intention, which has limited utility in predicting actual behavior [141,142] and does not generally attempt to integrate other systemic or relational aspects of technology acceptance. Within this review, Reay et al [56] demonstrated that gaining discursive buy-in, the focus of behavioral intention models of technology adoption, “is not enough” to legitimize new practices in a clinical setting without action and interpersonal, structural support.

Other frameworks have attempted to integrate sociocultural aspects of technology acceptance, specifically in low- and middle-income countries, although acceptance still generally focuses on individual users rather than systemic or relational factors [143]. More unusually, the nonadoption, abandonment, scale-up, spread, and sustainability framework by Greenhalgh et al [22], which is explicitly directed at health technologies, attempts to fill gaps left by TAM and other models by focusing on nonadoption and abandonment of technology instead of acceptance. This framework incorporates norms and values to some extent but does not focus specifically on legitimacy and the impact of norms and values on technology development.

The legitimacy as social infrastructure framework (LSI framework) is different from these models: rather than starting with adoption and acceptance of technologies, our conceptualization focuses on the relationships and negotiations that result in adoption and acceptance or not. If we take legitimacy as a necessary element in technology adoption and acceptance, conceptualizing legitimacy as social infrastructure allows us to understand how adoption, acceptance, and implementation frameworks may work together to explain the process of embedding technologies in health care. For instance, rather than conducting acceptance, adoption, and implementation studies separately in a health technology development project, researchers could use the conceptualization of legitimacy as social infrastructure as a framework to iteratively explore the binding fabric of relationships and legitimacy narratives that make up the landscape in which a new technology is being developed and provide advice to decision makers based on these findings. This focus would also allow project stakeholders to contextualize the results of a traditional acceptability or adoption study to better support the end goal of successfully embedding a technology in health care. Doing so would move conversation beyond simple adoption and acceptance and toward a more holistic perspective about this embedding process based instead on an analysis of legitimacy.

Focus on Relationships and Narratives

Momentum for embedding technologies in health care often fades due to unforeseen complexities [144] when moving technologies from laboratories to real-world environments. Particularly for mobile health technologies in which social and relational elements play a heightened role, the LSI framework could prove extremely useful in both anticipating and navigating complexity in the real world by describing changing relationships and narratives. Legitimacy as social infrastructure could provide a better blueprint that takes contextual factors into account earlier and avoids some of the acceptance and adoption bottlenecks that develop in linear models.

The struggles and unintended consequences of embedding technology in practice have been well-documented in STS and OMS [58,61,93,96]. The LSI framework conceptualizes how these documented struggles impact legitimacy and, thus,

technology adoption and acceptance. STS understands new technologies (including those designed for health care) to be both directional and open-ended [23]. Technologies are embodied with certain scripts and ideas, produced both through the development process and purposely in the minds of developers and other stakeholders, impacting how they can be used and when. However, the scripts managing this directionality never completely determine how a technology is used in practice [23,145]. Integrating technologies into real-world environments necessarily involves tinkering [22,23,144] by users, developers, and other stakeholders, often contradicting a technology's directionality entirely. For instance, as Perrotta and Geampana [7] demonstrate, new medical technology may be used in ways that contradict its original EBM-derived script, given a particular set of circumstances generated by patients, economics, and the pace of technology development. What happens next is a negotiation that determines how real-world context, practices, and technology scripts interact to generate a legitimacy relationship. Conceptualizing legitimacy as social infrastructure allows us to both understand the nature of these interactions and how they may or may not lead to technology adoption and acceptance in a health care setting. For instance, Sheard et al [73] discuss the complex systems and legitimacy relationships that impact the ability of care providers in the United Kingdom to act on patient feedback; this feedback is solicited in the first place to increase trust in and acceptability of the medical system. If we view patient feedback frameworks as a form of health care technology, legitimacy as social infrastructure helps us better understand and anticipate the relative importance of backgrounded relational and structural systems [73] that determined whether patient feedback was incorporated successfully in the health care institutional systems under study. An infrastructural understanding reveals how the 3 issues identified (ie, normative legitimacy, structural legitimacy, and organizational readiness [14,73]) work together to support or deter change in a complex organizational setting. A binding fabric of relationships ties all of these issues together and clarifies why the quality of certain relationships is more important than others. This focus also adds to understanding of the phenomenon of "institutional entrepreneurs." Relationships likely play a role in how institutional entrepreneurs avoid being "confined by the status quo," allowing them to change organizations from within despite legitimacy challenges for others [73].

Future Research and Applications

Given the utility of this conceptualization in bringing together 3 very different disciplinary traditions around legitimacy, future research could expand on this work to incorporate perspectives from disciplines, such as ethics and law, that we could not include here. In addition, it is possible that legitimacy is usually not explicitly conceptualized in medicine and psychology due to an implicit discipline-wide understanding of the values that underpin the concept. In other words, norms and legitimacy in medicine and psychology may be so closely intertwined with the goal of providing care that legitimacy may not be contested or questioned from these disciplinary perspectives. These kinds of taken-for-granted assumptions make it important to explore the origins, production, and meanings of legitimacy more thoroughly in the psychology and medical fields. Our conceptualization could allow for such investigation in fields in which the language describing legitimacy is either absent or perceived to be self-evident.

Potential applications of legitimacy as social infrastructure in practice have a wide range thanks to the flexibility and adaptability of the conceptualization. For example, to manage risks appropriately, regulators and others must have knowledge and understanding of the subject of regulation, in this case, health care technologies. This includes not only technical knowledge, but epistemological understanding of what is seen to constitute valid forms of knowledge, what is being left out, and "system knowledge of the context regulation is operating in" [146]. By approaching the embedding of technologies in health care as a result of knowledge coproduction, the notion of legitimacy as social infrastructure can provide deeper understandings of the systems and context of health technologies. It can then help regulators differentiate valid from invalid forms of knowledge in context. Regulators also experience legitimacy concerns themselves, in that regulation must be legitimate to function [9,147]. An understanding of legitimacy as social infrastructure could provide regulators with clarity about the practices, decisions, and structures that may impact their own legitimacy. For instance, knowing more about how their relationships with various stakeholders contribute to their legitimacy could help regulators take stakeholders' viewpoints into account at the most impactful moments and more appropriately narrate their decisions for different audience needs.

Limitations

Given the broad focus of our topic "legitimacy in health and technology," we included a heterogenous collection of empirical topics within each discipline. While this allowed for a broad discussion of legitimacy in health and technology, we did not produce one overarching definition of legitimacy; rather, we developed a conceptualization that can be used as a framework with the diversity of definitions already available. Similarly, the disciplinary boundaries are somewhat "fuzzy" [24]: OMS is a subdiscipline of sociology, STS overlaps with both MAS and OMS, and MAS is a combination of 2 disciplines with similar approaches. We found these disciplinary constructs useful because, despite their overlap, they highlight substantial differences among social science approaches to legitimacy.

In addition to the legal and ethical boundaries previously described, in this review, we did not engage with several other topics related to the legitimacy of technologies in health care. While the word "legitimacy" is used frequently in medicine and health economics, very few articles in these fields define the concept or explore it in any depth. Rather, the vast majority use the word uncritically within a surface explanation of the importance of a problem, either by claiming without evidence that legitimacy is an asset held by organizations, technologies, or people [148-150] or by mentioning that the legitimacy of a technology is under threat but without fully discussing why or how [151,152]. When legitimacy is defined, it is often reduced to a series of related concepts, such as "expertise, reciprocity, and trustworthiness," without discussing how these interact to

create legitimacy [153], although there are a few exceptions [9]. Due to the general lack of critical exploration, medicine and health economics were excluded as disciplines. This is an area that would benefit from further research using the LSI framework.

For similar reasons, we focused our search strategy within journals known to provide deep conceptualization of legitimacy (see Multimedia Appendix 1 for further details). Given the abstract and conceptual nature of our subject, a database search proved inadequate for finding all relevant articles; however, searching only within specific journals, despite rigorous selection, may have biased study findings. We feel the benefits of closely adhering to CIS protocol in this manner outweighed this issue due to our study's interpretive goals and the abstract subject matter.

Conclusions

The notion of legitimacy as social infrastructure provides a deeper understanding of how and why technologies are or are not embedded in health care. Social infrastructure focuses on the aspects of legitimacy related to norms, semiotics, materialities, and specific relationships among stakeholders and institutional contexts without excluding or privileging one form of knowledge production over the other. Through this conceptualization, the production and use of legitimacy can be studied ethnographically by following the social infrastructural networks and relationships that constitute and maintain legitimacy. By moving beyond judgment- and perception-based frameworks, legitimacy as social infrastructure approaches the problem of embedding technologies in health care through the lens of knowledge coproduction. The LSI framework enables empirical data collection and analysis that transcends disciplinary boundaries without negating the discrete lines of theoretical thought of any one discipline.

Given the interdisciplinary nature of health care policy and practice and the wide range of stakeholders involved, clearer and deeper communication around legitimacy could have far-reaching impacts. This could include new frameworks explaining technology adoption and acceptance, greater consensus about what makes a health care technology or policy decision legitimate, and strategic direction for decision makers working with disruptive health care technologies within entrenched systems.

Abstract

Background: Digital health technologies, particularly mobile health (mHealth) apps and wearable devices, have emerged as crucial assets in the battle against hypertension. By enabling lifestyle modifications, facilitating home blood pressure monitoring, and promoting treatment adherence, these technologies have significantly enhanced hypertension treatment.

Objective: This study aims to explore the perspectives of health care professionals (HCPs) regarding the perceived benefits and barriers associated with the integration of mHealth apps into routine hypertension care. Additionally, strategies for overcoming these barriers will be identified.

Methods: Through qualitative analysis via semistructured interviews, general practitioners (n=10), cardiologists (n=14), and nurses (n=3) were purposefully selected between October 2022 and March 2023. Verbatim transcripts were analyzed using qualitative content analysis.

Results: The results unveiled 3 overarching themes highlighting the benefits of mHealth apps in hypertension care from the perspective of HCPs. First, these technologies possess the potential to enhance patient safety by facilitating continuous monitoring and early detection of abnormalities. Second, they can empower patients, fostering autonomy in managing their health conditions, thereby promoting active participation in their care. Lastly, mHealth apps may provide valuable support to medical care by offering real-time data that aids in decision-making and treatment adjustments. Despite these benefits, the study identified several barriers hindering the seamless integration of mHealth apps into hypertension care. Challenges predominantly revolved around data management, communication contexts, daily routines, and system handling. HCPs underscored the necessity for structural and procedural modifications in their daily practices to effectively address these challenges.

Conclusions: In conclusion, the effective usage of digital tools such as mHealth apps necessitates overcoming various obstacles. This entails meeting the information needs of both HCPs and patients, tackling interoperability issues to ensure seamless data exchange between different systems, clarifying uncertainties surrounding reimbursement policies, and establishing the specific clinical benefits of these technologies. Active engagement of users throughout the design and implementation phases is crucial for ensuring the usability and acceptance of mHealth apps. Moreover, enhancing knowledge accessibility through the provision of easily understandable information about mHealth apps is essential for eliminating barriers and fostering their widespread adoption in hypertension care.

Introduction

Hypertension is a significant health problem affecting millions of people worldwide [1]. In Germany, too, hypertension is one of the most common diseases affecting a large proportion of the population. Prevention and effective treatment of hypertension are therefore crucial to prevent associated serious complications such as ischemic heart disease, strokes, and renal disease, and to improve the quality of life of those affected [2-4].

In recent years, the development of digital health technologies has experienced a considerable upswing, opening up promising perspectives for the prevention and management of hypertension [5]. Mobile health (mHealth) apps, wearables, and other digital tools enable patients to monitor their blood pressure levels, track lifestyle changes, and set health goals. These technological advances also offer health care professionals (HCPs) new opportunities to improve patient care and promote healthier lifestyles [6]. mHealth apps in particular have been shown to improve the treatment of hypertension [7].

In Germany, the following professional groups are primarily involved in the treatment of people with hypertension. General practitioners play a central role in the diagnosis, treatment, and long-term care of patients with hypertension. They are often the first point of contact for patients with hypertension and coordinate further care. Cardiologists specialize in the diagnosis and treatment of heart disease, including hypertension. They can treat complex cases of hypertension and offer specialized diagnosis and treatment options. Internists can also play a role in the care of patients with hypertension, especially if there are comorbidities or complex medical problems. Nursing professionals (nurses, nursing assistants) play a crucial role in the care of patients with hypertension. They help implement blood pressure control measures, educate patients, and help monitor symptoms and side effects [8]. In October 2020, physicians in Germany were allowed to prescribe digital therapeutics (DiGA [Digitale Gesundheitsanwendungen]) in standard care for the first time [9]. DiGAs can be prescribed by physicians for a 3-month use period and is fully reimbursed by the statutory insurance companies. To obtain approval, mHealth providers must demonstrate the safety, functionality, quality, data security, and a fundamental benefit in a clinical study to obtain DiGA status. Patients receive a written prescription for a DiGA based on respective indications (eg, depression) and have to send it to their insurance company.. At the time this study was conducted, there was no DiGA that is specific for the prevention of hypertension. In perspective, however, it is expected that mHealth apps for the prevention of hypertension will obtain DiGA status and will be made available to patients. In their recent study, Dahlhausen et al [10] pointed out the significant role of HCPs, specifically physicians, in promoting mHealth use among patients. In order to understand the implementation of mHealth into hypertension care, it is necessary to understand the perspectives of physicians, nurses, and medical assistants and their perception of benefits and challenges, as well as their information needs, in order to best integrate mHealth into hypertension care.

Nevertheless, a certain frustration is noticeable among physicians in Germany. Not least because there have been repeated technical problems in the past with the connection to the German telematics infrastructure (TI). The TI comprises a range of technical components that are relevant for operation in medical practices. These include the practice management system (Praxis Verwaltungssystem), which supports the organization and documentation of practice tasks, and the connector, a piece of hardware that enables access to the TI and communicates with the eHealth card terminal and the Praxis Verwaltungssystem via a secure network. The eHealth card terminal is used to use the electronic health card and to check practice ID cards. Other components include mobile card terminals, practice or institution ID cards, a virtual private network access service, and the electronic health professional card, which is required for various applications such as the electronic doctor's letter and prescriptions [11]. However, half of the physicians have to struggle with technical problems at least once a week, compared to 36% in 2020. Overall, frustration with the digitization process has increased [12].

While there is a wealth of research focusing on the patient perspective regarding digital health tools [13-15], there remains a lack of comprehensive evidence on how physicians perceive and integrate these technologies into their clinical practice. Despite the promising potential of digital health tools, the potential obstacles and barriers to widespread adoption of these technologies in the clinical setting have not been thoroughly explored. A deeper understanding of the structural and individual factors that influence the implementation and adoption of digital prevention approaches is imperative. Integrating digital prevention approaches into the health care system requires a clear delineation of the role and positioning of these technologies within the broader health care landscape. A thorough investigation of how digital health tools can be effectively integrated into the existing health care infrastructure and how they are perceived by the various stakeholders in the health care sector is crucial.

Addressing these research gaps can contribute significantly to a more nuanced understanding of how digital health and specifically mHealth apps can be optimally used for hypertension prevention. It can also identify potential barriers and pave the way for strategies to improve clinical adoption and seamless integration of these technologies. In this study, we explore the following research questions: Which benefits

do HCPs see in mHealth apps for prevention? What are possible structural and individual barriers to the use of mHealth apps? How can the challenges be met?

Methods

Study Design

This paper reports on our exploration of the HCPs' perspectives regarding mHealth apps in hypertension prevention. We conducted in-depth interviews with general practitioners, cardiologists, and nurses. This study is part of the DiPaH project [16], which examines structural and individual factors in different stakeholders that influence the use of digital preventive measures in patients with arterial hypertension in Germany.

Ethical Considerations

This study was approved by the Ethics Committee of the Brandenburg Medical School Theodor Fontane (E-02-20220620). All experimental protocols were approved by a named institutional or licensing committee. All methods were carried out in accordance with relevant guidelines and regulations. Participants were informed verbally and in writing about the purpose, the procedure, the significance of the study, and the benefits and risks that may be associated with it and had the opportunity to ask questions. They were also informed that they had the right to withdraw their consent to participate in the study at any time, either verbally or in writing, without giving reasons. They were also informed that personal data would be recorded and stored, whereby the data would be pseudonymized, but that no data would be published that could be used to identify the person. For security reasons, the data received from the participants were always stored in a password-protected folder on a secure desktop computer. Written consent was obtained after participants were given the opportunity to ask questions. Patients were not involved in designing this study. Participants were offered €75.00 (approximately US $77.89) as an incentive for their participation in the study.

Recruitment

Participants were selected using purposive sampling [17]. We included HCPs who were currently actively involved in the treatment of people with hypertension, such as general practitioners, cardiologists, and nurses. The participants were selected according to defined categories, aiming to generate a heterogeneous sample with the broadest variety of different perspectives [18]. The following categories were included: region of practice (rural vs urban), main area of practice (outpatient vs inpatient), and gender (male vs female). A further inclusion criterion was interest and willingness in participating in an interview. Participants were recruited both by systematic invitation and by snowball sampling. The following sources were used for recruitment (Textbox 1).

Textbox 1. Sources used for recruitment.

- Social media accounts of the university (Brandenburg Medical School Theodor Fontane), such as Facebook, Instagram, and Twitter
- Association of Statutory Health Insurance Physicians Brandenburg (KVBB): newsletter
- General practitioners' association Brandenburg: information study participation at events
- Personal contacts among colleagues (snowball sampling)
- Interested persons contacted the study team by telephone or e-mail, and it was checked in advance whether they could be included before an interview was conducted

Data Collection

A preliminary semi-structured interview guide was drafted by a multiprofessional team (SM, FM, DB, and SSp). The semistructured interview guide consisted of open-ended questions that explored how the participants are attuned to digital applications and mHealth apps, what benefits and barriers they see in digital technologies for prevention, what information needs they have, and how these can be met. The focus was on hypertension apps with the following functions: educating about hypertension, monitoring blood pressure, and promoting adherence, although no specific apps were offered or recommended to participants. Sample interview questions included: Which mHealth apps in the context of hypertension treatment are used in your practice, or what experiences have you had with it? What benefits do you see in the use of mHealth apps? What barriers do you see in the use of mHealth apps? How well informed are you about mHealth apps, and where are knowledge deficits? In addition, sociodemographic data were collected, including profession, gender, age, number of inhabitants of the place of practice, duration of professional activity, and setting. To ensure clarity and relevance of the questions, we did a pilot test of the interview guide with 5 eligible participants recruited from clinics and outpatient physicians in the study's catchment area (refer to Multimedia Appendix 1).

All interviews were conducted via telephone during October 2022 to March 2023. The interviews were recorded and transcribed verbatim in accordance with data protection guidelines. Data collection continued until no substantially new findings emerged and saturation of content was reached. Saturation of content is defined as code saturation, when no additional issues are identified, and meaning saturation, when no further dimensions, nuances, or insights of issues can be found [19]. We chose to conduct 27 interviews, as this number has proven to be adequate in previous studies to reach theoretical saturation in the exploration of digital approaches [20,21]. Field notes (a short summary of the interview) were taken following each interview to ensure better comprehensibility of the interview situation. The field notes themselves were not included in the analysis.

Data Analysis

Qualitative analysis of the interviews was performed iteratively by the study team (SM and FM) based on Kuckartz's structured qualitative content analysis [22] using MAXQDA Analytics Pro 2022, Release (version 22.1.0; Verbi GmbH). After transcription of the audio material, the analysis began with a screening of the interview texts, whereupon the interviews were coded. Relevant text passages from the interview material were coded according to a deductive-inductive procedure. Main categories and subcategories were formed inductively from the codes. Until a common understanding of all the emerging categories was achieved, consensus discussions were held continuously in the research group. Other categories were developed deductively based on the research questions and merged into the coding tree. By then, the process of gathering data had already concluded. Two researchers (SM and FM) separately applied the established category system to analyze the complete data set, ensuring that the process could be traced and replicated. The data was analyzed in German. To present the findings, significant excerpts from the transcriptions were chosen as representative quotes. These quotes were translated into English by native speakers and incorporated into the manuscript. The manuscript has been compiled in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research; refer to Multimedia Appendix 2) [23].

Results

In total, 27 interviews were conducted and analyzed until theoretical saturation was reached. The mean duration of the interviews was 42 (range 33-56) minutes. The mean age of the participants (N=27) was 50 (range 35-74) years. Most participants were female (14 female/13 male). A total of 14 cardiologists, 3 nurses, and 10 general practitioners participated. In total, 9 persons worked in the inpatient setting and 17 persons worked in the outpatient setting. One person worked in both settings. Four of the HCPs had already had experience with digital applications in daily practice or were also working with them. Detailed characteristics of study participants are shown in Table 1.

Table 1. Detailed characteristics of study participants.

Characteristics	Participants (N=27), n (%)
Professional group	
General practitioner	10 (37)
Cardiologist	14 (52)
Nurse	3 (11)
Duration of professional activity	
>10	9 (33)
10-20	8 (30)
21-30	7 (26)
31-40	3 (11)
Gender	
Female	14 (52)
Male	13 (48)
Age (years)	
>40	2 (7)
40-50	11 (41)
51-60	11 (41)
<60	3 (11)
Number of inhabitants	
>10,000	2 (7)
10-100,000	11 (41)
100,001-1 million	4 (15)
<1 million	10 (37)
Setting[a]	
Inpatient	10 (37)
Outpatient	18 (67)

[a]One participant works in both the inpatient and outpatient settings.

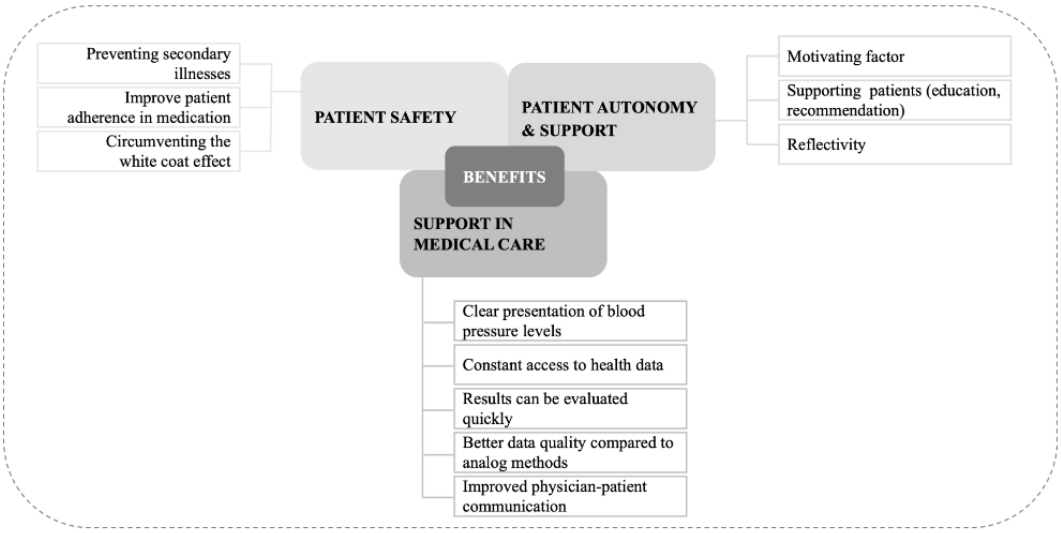
Themes

The analysis explored 7 key themes, categorized into benefits and barriers. Themes identified as benefits included (1) patient safety, (2) patient autonomy and support, and (3) support in medical care. Themes identified as barriers were organized by the following context: (4) handling of data, (5) in the context of communication, (6) in daily routines, and (7) in dealing with the systems.

Benefits

Although few of the HCPs use or have used mHealth apps in their daily practice, they were able to mention benefits they expected to gain from using mHealth apps. In the context of benefits, 3 overarching themes could be identified: potential to increase patient safety, patient autonomy, and support in medical care (Figure 1 and Multimedia Appendix 3).

Figure 1. Coding tree of the benefits regarding mHealth apps in hypertension prevention. mHealth: mobile health.



A different number of subcategories could be assigned to the 3 main categories. The following 3 subcategories were assigned to the “Patient safety” category: preventing secondary illnesses, improving patient adherence in medication, and circumventing the white coat effect. The following 3 subcategories were assigned to the category “Patient autonomy and support”: motivating factor, supporting patients, and reflectivity. The following 5 subcategories were categorized under the category “Support in medical care”: clear presentation of blood pressure levels, constant access to health data. Results can be evaluated quickly, better data quality compared to analog methods, and improved physician-patient communication.

Patient Safety

Respondents see the potential of mHealth apps primarily in the prevention of secondary diseases. In addition, participants see the potential of mHealth apps to improve patient adherence to treatment in terms of medication adherence, which in turn has an impact on patient safety.

The respondents attribute a better representation to the blood pressure levels measured at home and subsequently documented. The interviewees hope that through the use of mHealth apps, patients will consistently document their blood pressure and thus always have an overview of their blood pressure levels. This is because, in contrast to the blood pressure levels measured in the practice, they seem to correspond more closely to the reality of life. The “white coat effect” is thus circumvented.

Patient Autonomy and Support

An mHealth app can offer a variety of features that serve as a motivating factor for patients from the perspective of health care providers. Gamified elements, progress tracking, and reward systems can provide incentives for developing and maintaining health-promoting behaviors, strengthening patients' self-motivation, and fostering engagement in their health.

From the HCP’s perspective, an mHealth app can be a valuable addition to medical care by providing support to patients in several ways. First, the mHealth app can provide personalized advice based on the patient's individual needs and health goals. This can include dietary recommendations, lifestyle changes, or stress management tips. Second, mHealth apps can act as reminders, reminding patients to take their medication, which could improve adherence to therapy.

An mHealth app can also include reflectivity and help patients comprehend information about their blood pressure to their behaviors, which can support them reduce or avoid unfavorable behaviors.

Support in Medical Care

By using mHealth apps, the HCPs assume that blood pressure levels can be presented in a clear and understandable way. mHealth apps allow patients to access their levels on their smartphones or other digital devices. Patients can track the development of their blood pressure over time and identify possible trends or abnormalities so that they can seek medical help timely if necessary.

Patients have constant access to their current health data. This enables real-time tracking of their health status, even if they are not undergoing immediate medical treatment.

mHealth apps provide quick results that can be evaluated immediately. Physicians can thus make timely decisions about the treatment and care of their patients.

HCPs attribute better data quality to mHealth apps compared to analog methods.

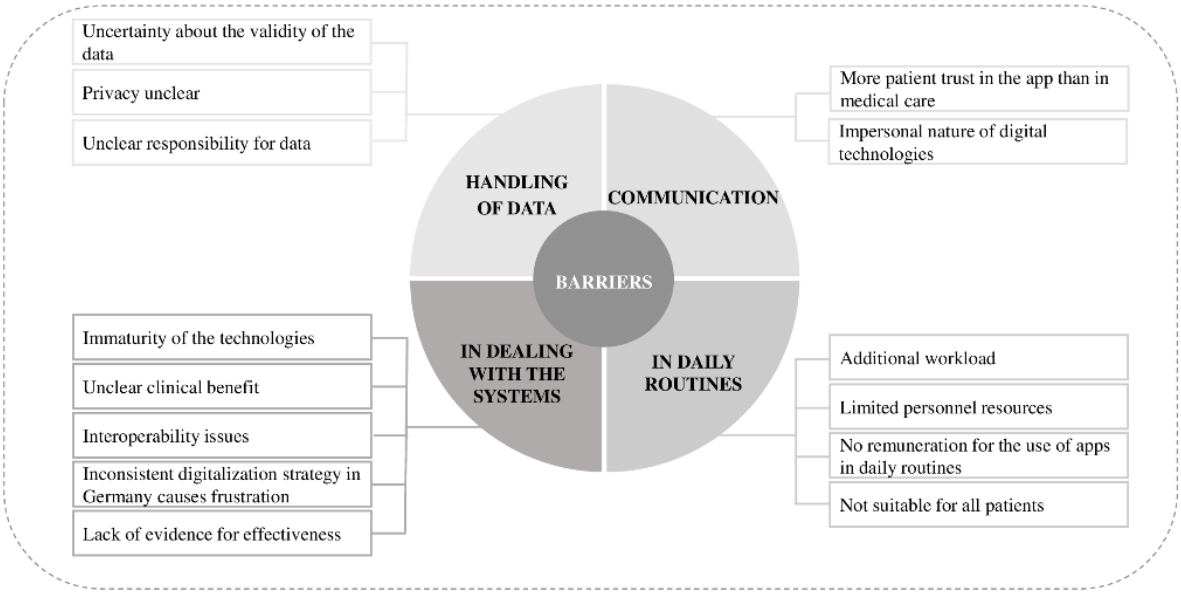
Using mHealth apps, patients can send the data they collect in their daily environment directly to the medical facility before visiting the physician. This allows the physician to check the blood pressure levels in advance and prepare specifically for the conversation with the patient. The time saved helps to make the physician-patient conversation more efficient and targeted so that relevant questions and concerns of the patient can be better addressed.

The benefits initially included constant access to health data, which was particularly mentioned by participants in the outpatient sector. This group also appreciated the motivating factor that the apps could provide to support them in their health routines. Participants in large cities also preferred the app's clear display of their blood pressure readings, which helped them to better understand their health data. The time saved in doctor-patient communication was also mentioned as a benefit by the outpatient participants.

Barriers

We identified barriers in 4 different aspects of the HCPs work life: handling of data, in the context of communication, in daily routines, and in dealing with the systems (Figure 2 and Multimedia Appendix 4). A different number of subcategories could be assigned to the 4 main categories. The following 3 subcategories were assigned to the category “Handling of data”: uncertainty about the validity of the data, privacy unclear, and unclear responsibility for data. The following two subcategories were assigned to the category “in the context of communication”: more patient trust in the app than in medical care and the impersonal nature of digital approaches. The following 4 categories were assigned to the category “in daily routines”: additional workload, limited personnel resources, no remuneration for the use of apps in daily routines, and not suitable for all patients. The following 5 subcategories were assigned to the category “in dealing with the systems”: immaturity of the technologies, unclear clinical benefit, interoperability issues, and inconsistent digitalization strategy in Germany, which causes frustration and lack of evidence for effectiveness.

Figure 2. Coding tree of the barriers regarding mHealth apps in hypertension prevention. mHealth: mobile health.



Handling of Data

One of the main barriers to the use of apps for blood pressure monitoring is uncertainty about the validity of the data collected. Concerns about the accuracy of data documented by patients can undermine HCPs’ confidence in the data and willingness to use such tools.

Another important concern related to the use of mHealth apps in the treatment of hypertension is privacy. Fear of data breaches or unauthorized access to patient information may limit the use of such tools.

Unclear responsibility for data presents another hurdle. Physicians and nurses feel uncertain about who is responsible for managing and interpreting the data they collect. The wealth of data generated by mHealth apps can be overwhelming, and the lack of clear structures and policies for appropriate use of the data can be challenging.

In the Context of Communication

The HCPs expect that a potential barrier to communication when using mHealth apps is the tendency of some patients to trust the mHealth app more than their medical care. This misconception could lead to patients relying solely on the mHealth app for solutions or seeing its advice as better than that of their physician. This could hinder communication with HCPs and lead to a lack of collaboration between patients and physicians.

Another barrier perceived by HCPs is the impersonal nature of mHealth apps. In contrast to direct interaction, the use of mHealth apps could lead to a lower intensity of exchange between patients and HCPs. In addition, mHealth apps may be perceived as less empathetic and less tailored to the individual needs of patients.

In Daily Routines

The HCPs apprehend that introducing mHealth apps in medical practice can initially lead to an additional workload for them. The introduction of new technologies requires training, the adaptation of workflows, and integration into existing IT systems, which can initially lead to time and resource constraints.

In many health care settings, resources are lacking in order to engage HCPs in the active use of mHealth apps in practice. Adoption and integration of new technologies requires time, training, and technical support, which can be challenging in an already strained health care system. Limited capacity impedes readiness to use mHealth apps for hypertension care.

At present, the use of mHealth apps is not sufficiently reimbursed in everyday health care in Germany. HCPs do not receive additional compensation or incentives for the use and deployment of digital tools in the care of hypertensive patients. This lack of compensation may cause some HCPs to be hesitant to use digital tools, as it may entail additional tasks without financial compensation.

Although mHealth apps offer many benefits, they may not be suitable for all patients. Older people or those with limited digital capabilities may have difficulty using digital applications. In addition, some patients, especially those with hypertension, may overmeasure their blood pressure, which can negatively impact their blood pressure levels. According to HCPs, digital tools for monitoring blood pressure may be less appropriate for such patients.

In Dealing With the Systems

A major barrier to the use of mHealth apps in hypertension care is the immaturity of the technologies. HCPs suspect that mHealth apps do not work reliably, have bugs, or do not have all the necessary features to meet the demands of medical practice. As a result, they may be reluctant to recommend digital technologies for fear that the systems will not exist at a later date.

Another barrier to the use of mHealth apps in hypertension care is the unclear actual utility and clinical effectiveness of such tools from the perspective of HCPs.

The diversity of mHealth apps and their interfaces is another barrier for HCPs. The incompatibility or lack of interoperability between systems can hinder smooth data exchange and integration.

The insufficient as well as inconsistent digitalization strategy in Germany is a source of frustration for HCPs. There is often a lack of a clear, long-term vision and of a structured approach to drive the integration of digital technologies in health care. The development and implementation of digital health solutions is often fragmented and inconsistent, leading to confusion, ineffective solutions, and a return to analog methods. These negative experiences are a significant barrier to the adoption of digital tools.

The actual effectiveness and long-term impact of mHealth apps in treating hypertension are poorly researched or demonstrated from the perspective of HCPs. The lack of evidence on the clinical effectiveness of such tools raises doubts and influences their willingness to use them.

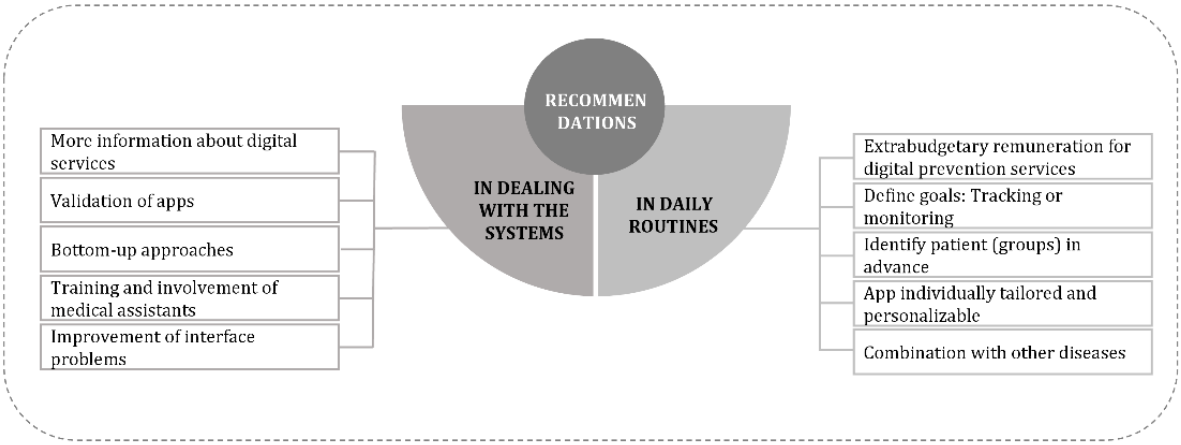
Specific Aspects in Various Subgroups

Participants from the outpatient sector in particular pointed out interoperability problems that could hinder the smooth exchange of data. In addition, the unclear clinical benefits of the apps were not recognized by everyone, especially not by the participants from the outpatient sector. It was also noted from the outpatient sector that not all apps are suitable for every patient. Concerns about data protection were also expressed by participants in the outpatient sector, who were worried about the security of their personal health data. Finally, the lack of reimbursement for the use of health apps from the outpatient sector was cited as a further barrier. Women expressed concerns about the validity of the data collected by the apps.

Recommendations for Successful Integration of mHealth Apps Into the Health Care Landscape From HCPs' Perspective

In the context of recommendations, 2 themes could be identified: in daily routines and in dealing with the systems (Figure 3 and Multimedia Appendix 5). A different number of subcategories could be assigned to the 2 main categories. The following 5 categories were assigned to the category "in daily routines": extrabudgetary remuneration for digital prevention services, defining goals: tracking or monitoring, identifying patient (groups) in advance, app individually tailored and personalizable, and combination with other diseases. The following 5 subcategories were assigned to the category "in dealing with the systems": more information about digital services, validation of apps, bottom-up approaches, training and involvement of medical assistants, and improvement of interface problems.

Figure 3. Coding tree of the recommendations for successful integration of mHealth apps into the health care landscape. mHealth: mobile health.



In Daily Routines

One of the fundamental challenges in integrating hypertension mHealth apps into routine medical practice is that the time spent using and counseling patients is not adequately compensated. To address this problem and increase HCPs' motivation to use digital prevention services, extrabudgetary reimbursement for the implementation and support of these apps in HCPs' practices should be considered. According to the participants, such remuneration would ensure that HCPs are appropriately compensated and thus create an incentive to increasingly integrate mHealth apps into their daily work.

It is crucial to define clear goals for the use of mHealth apps in hypertension prevention. HCPs should work with patients to determine which parameters or data should be collected by the mHealth app and which specific health goals are being pursued. The HCPs assume that a distinction can be made between tracking and monitoring approaches. While tracking helps patients to collect data on their blood pressure, lifestyle, and other relevant parameters themselves, monitoring enables the physician to regularly monitor and analyze the collected data. The clear definition of goals facilitates the use of the mHealth apps and ensures that the collected data can be used meaningfully and effectively.

The HCPs mentioned that not all patients benefit equally from mHealth apps. It is important to identify in advance which patients or patient groups could benefit most from a hypertension prevention mHealth app. Some patients may already be well informed and motivated to use digital health technologies on their own, while others may need more support and guidance. By identifying those patients who could best benefit from mHealth app use, clinicians can target their mHealth services more effectively and efficiently.

Another important improvement is that hypertension apps should be customized and personalizable. Each patient is unique, and the mHealth app should therefore be customizable to each individual's specific needs, health goals, and preferences. Personalization options could include selection of relevant health goals, medication reminders, or customization of the app interface to the user's personal preferences. By tailoring the app to each patient's individual needs, the user experience is likely to be enhanced and the likelihood of long-term use increased.

Hypertension often occurs in combination with other conditions, such as diabetes or obesity. To improve the care of multimorbid patients, mHealth apps for hypertension could be combined with other health applications to provide comprehensive and integrated care.

In Dealing With the Systems

It is important that HCPs have access to comprehensive and reliable information about the functionalities, efficacy, safety, and privacy policies of the various hypertension apps. A transparent and evidence-based presentation of this information can help to address concerns about the quality and reliability of the apps and stimulate physicians' interest in using these digital tools.

Careful validation of mHealth apps is essential to ensure that hypertension management apps actually deliver the promised benefits and provide medically robust data. HCPs need reliable information about the scientific evidence and clinical validity of the apps in order to effectively integrate them into their clinical practice.

To improve the adoption and integration of apps for hypertension, it is crucial to promote bottom-up approaches. This means including the user perspective, including physicians and medical staff, in the development and implementation of mHealth apps from the very beginning. Involving users in the development process makes it possible to adapt mHealth apps to the specific needs and requirements of physicians and ensure high usability.

Successful integration of hypertension apps requires not only training of physicians but also the involvement of other HCPs, especially medical assistants. Medical assistants play an important role in helping physicians use mHealth apps and interact with patients. Extensive training of medical assistants on how the mHealth apps work and are useful, as well as how to effectively use the data collected, can help ensure that the integration of the apps is seamless in the practice workflow.

Interoperability and compatibility between different mHealth apps and existing practice IT systems are critical. Often,

physicians and medical assistants face the challenge that the interfaces between the mHealth apps and existing IT systems are not sufficiently optimized, which can lead to technical difficulties and data inconsistencies. Targeted improvement of the interface issues enables physicians to work smoothly with the mHealth apps and seamlessly integrate the captured data into their practice workflows.

Discussion

Principal Results

This qualitative study is the first to explore the factors that enable or hinder the use of mHealth apps for the prevention of hypertension from the perspective of general practitioners, cardiologists, and nurses in Germany. Until now, mHealth apps for the prevention of hypertension are only fragmentarily used in the care of hypertensive patients. From the perspective of the caregivers, the main potentials of mHealth apps lie in increasing patient safety, patient autonomy, and support in medical care. However, the presented results point to major challenges in data handling, patient-HCP communication, integration into standard care, and interoperability. Measures such as extra-budgetary remuneration for digital preventive services, setting targets through tracking or monitoring, identifying patient groups in advance, adapting and personalizing mHealth apps, and combining them with other diseases could, in the view of the HCPs, help to overcome the barriers. In dealing with the systems, the HCPs mention aspects such as more information about digital services, validation of mHealth apps, bottom-up approaches, training and involvement of medical assistants, and improvement of interface problems.

Comparison With Prior Work

Our results are in line with earlier research in mHealth and beyond: physicians and nurses recognize the added values and positive potential of mHealth apps in supporting patients, fostering patient autonomy, and improving medication adherence [24,25]. The attributed benefits are supported by evidence: for instance, Li et al [26] report improvements in self-management behavior and medication adherence in adults using mHealth. Furthermore, self-monitoring of hypertension-related behaviors via smartphone apps combined with tailored advice has a modest but potentially clinically significant effect on blood pressure reduction [27].

Despite the advantages of mHealth, as of yet the barriers hinder their integration into the medical routine. One of the main concerns is the handling of data. Physicians frequently doubt the validity of data collected by patients and have concerns regarding data privacy and security. This can impede trust in the data and willingness to use such mHealth apps.

The mode of communication between physicians and patients can also be influenced by the use of mHealth apps. Some patients may tend to place more trust in the instructions provided by the mHealth app than in the recommendations of their medical caregivers. This could hinder communication with HCPs and impede collaboration between patients and physicians. However, studies have already demonstrated that there are contrary findings to the presumed concerns: findings of a systematic, narrative review show a generally positive influence of mHealth apps on physician-patient communication and relationships, which at times was correlated with better health outcomes [28]. And perhaps the use of apps can make visits more efficient, because blood pressure levels can be transmitted to the practice in advance, and conversations can be focused on essential aspects.

In the interviews, it is stated that mHealth consumes more resources and deteriorates patient communication. In rheumatology, digital health and especially mHealth are considered resource-saving. Digitization creates more time for patient interaction, which enhances the quality of care. If questions have already been answered beforehand, there may be extra time in the conversation with the patient to focus on essential aspects, which can positively impact the perceived quality of care [29]. Furthermore, it is emphasized in rheumatology care that this would allow more time for patient consultations. This is a contradiction. However, rheumatology is more digitized compared to hypertension care because of the greater shortage of personnel and disease burden.

Furthermore, apps can initially mean additional workload for HCPs. The introduction of new technologies requires training, adaptation of workflows, and integration into existing IT systems, which can lead to time and resource constraints. In addition, due to limited resources, many medical facilities may not be adequately prepared to actively integrate digital technologies into their practice. To be able to use digital technologies in their daily routine, physicians also need the appropriate digital skills [30]. In a recent measurement of physicians' professional digital health literacy, they scored 53.1 out of a possible 100 points [31]. For nurses, this figure is only slightly higher at 54.5 points. The most difficult task for physicians and nurses is “helping patients assess the trustworthiness of the digital health information they find,” followed by “helping patients find the digital health information that is relevant to them.” In the future, physicians and nurses will need support especially in this area so that the digital transformation in health care can be driven forward.

A lack of integration of digital tools into the reimbursement structure of the health care system in Germany is also a barrier to the use of such applications. Currently, physicians only receive remuneration for prescribing DiGAs, which does not translate to monitoring apps that have not obtained the DiGA status. There are ongoing discussions about which remuneration model is suitable for mHealth. Labinsky et al [32] reported that only 13% of patients that were prescribed a DiGA completed the whole program. This may also be due to a lack of incentives for physicians to ask if the apps are being used. Considering the low adherence with DiGA, performance-based compensation appears to be appropriate.

Implications

Several recommendations for the integration of mHealth apps into medical practice can be derived from the results. It is important to provide HCPs with low-threshold access to comprehensive and reliable information about available mHealth apps to address their concerns about quality and privacy. Validation of mHealth apps for effectiveness and clinical

validity is critical to convince physicians that these apps provide real value [33]. Bottom-up approaches or participatory study designs that include the user perspective, including physicians and medical assistants in the development process, can help ensure that apps are better tailored to the needs and requirements of medical practice and have a higher usability.

Involving HCPs, especially medical assistants, is also important as they play a key role in helping physicians use mHealth apps and interact with patients. Extensive training of medical staff on how the apps work and their benefits can help ensure that the integration of the apps is seamless in the practice workflow.

Our results underline the importance of staggered use of the mHealth app for effective blood pressure control in patients with hypertension. A high frequency of use at the beginning of treatment helps both patients and health care providers to quickly identify and implement individualized strategies to lower blood pressure. Once the target values have been stably achieved, the frequency of use can be gradually reduced so that the mHealth app can serve as a monitoring tool without unnecessarily increasing the time required by medical staff. This flexible handling could allow the mHealth app to be optimally integrated into everyday clinical practice while minimizing the burden on health care providers in terms of data management.

In addition, it is important to improve the interface issues between digital health apps and existing IT systems. Interoperability and compatibility between different digital apps and medical practice software systems are critical to ensure smooth integration and use of the apps. Targeted improvement of the interfaces can enable physicians to work smoothly with the apps and seamlessly integrate the collected data into their practice workflows.

The use of digital care services could be beneficial if the goal of use were addressed in advance in physician-patient communication. For example, use in the sense of self-tracking would not necessarily require medical intervention. Whereas the use in the sense of monitoring is associated with a control function, and physicians are actively involved in the process. Further studies are also needed to analyze the benefits and effectiveness of digital care services.

Based on the current findings and recommendations made by the HCPs, various stakeholders (eg, policy makers, health insurance companies, physicians' associations, associations of the scientific medical societies, patient organizations, health care researchers, or app developers) in different fields of the health care system should take action to push the integration of mHealth app in daily practice (Textbox 2).

Textbox 2. Recommendations for the integration of mobile health (mHealth) apps into medical practice.

Structural conditions

- Extrabudgetary remuneration for digital prevention services
- Improvement of interface problems
- Training and involvement of medical assistants
- More information about digital offers

App development

- Bottom-up approaches and user experience design
- App individually tailored and personalizable
- Combination with other diseases
- Validation of mHealth apps

Use in patient care

- Assessment of patients' eligibility to use mHealth
- Identify patient (groups) in advance
- Define goals: tracking or monitoring

Strength and Limitations

Our study is the first to investigate the benefits and barriers of using mHealth apps in preventing hypertension in Germany. We drew closely on the reality of care and the perspectives of the physicians and nurses. The qualitative interviews allowed for obtaining an in-depth understanding of the experiences with or without apps in preventing hypertension and expected advantages and disadvantages. However, there are certain limitations to our study. The results might be subject to a selection bias because perhaps people who were more interested in the topic took part in the study. Due to the sampling strategy, we may not have been able to reach everyone and did not record important aspects. A generalization of the results is therefore impossible. In addition, patients were not interviewed at this time.

The authors are aware that this general exploration can only be a first step given the breadth and diversity of the topic "hypertension mHealth apps." Further studies must be conducted in the context of specific health care situations to build upon these findings. These limitations directly translate into opportunities for further research: We are planning to extend

the study to a larger sample in Germany [16] and to validate the qualitative results with a questionnaire survey.

Further research should also focus on how to identify patients who may or may not be eligible for mHealth apps in hypertension care; how HCPs can be effectively informed about mHealth and digital health in general, as well as what reimbursement strategy will reinforce the effective use of mHealth in the care of chronic conditions.

Conclusions

HCPs recognize the benefits of mHealth apps for patient safety or to support disease management. However, at present, best practices for implementing mHealth apps in preventing hypertension do not exist. In order to be able to use digital tools such as mHealth apps efficiently, the barriers, such as information needs, interoperability issues, uncertain remuneration, and vague clinical effectiveness, need to be overcome. Above all, users need to be involved in design and implementation processes. Furthermore, low knowledge needs to be eliminated by offering access to low-threshold information on mHealth apps.

Acknowledgments

The authors would like to thank all interview partners and participants for their valuable contributions and time. We would like to express our special thanks to the Association of Statutory Health Insurance Physicians Brandenburg (KVBB) and the General Practitioners' Association Brandenburg for their support during the recruitment process. This work was supported by the Innovation Committee at the Federal Joint Committee (Innovation Fund, grant number 01VSF18014).

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files). For further questions regarding the reuse of data, please contact the corresponding author (susann.may@mhb-fontane.de).

Authors' Contributions

SM made substantial contributions to the design of the work, the data acquisition and analysis, and the interpretation of the data; drafted the manuscript and had full access to all the data in the study; and takes responsibility for the integrity of the data and the accuracy of the data analysis. FM made substantial contributions to the design of the work, the data acquisition and analysis, and the interpretation of the data; drafted the manuscript and had full access to all the data in the study; and takes responsibility for the integrity of the data and the accuracy of the data analysis. EW made substantial contributions to the design of the work and the data acquisition and analysis and substantively revised the manuscript. FS made substantial contributions to the data analysis and substantively revised the manuscript. MH made substantial contributions to the data acquisition and analysis and substantively revised the manuscript. DB made substantial contributions to the design of the work, obtaining funding, and data acquisition and analysis, and substantively revised the manuscript. SSp made substantial contributions to the design of the work, obtaining funding, and data acquisition and analysis, and substantively revised the manuscript. All authors have approved the submitted manuscript. In addition, the authors have agreed both to be personally accountable for the author's own contributions and to ensure that questions related to the accuracy or integrity of any part of the work, even ones in which the author was not personally involved, are appropriately investigated, resolved, and the resolution documented in the literature. SM and FM contributed equally to this work (shared first authorship). DB and SSp contributed equally to this work (shared last authorship).

Abstract

Background: Telehealth is a recognized and rapidly evolving domain in the delivery of emergency medicine. Research suggests a positive impact of telehealth in patients presenting for emergency care; however, the regional challenges of acute telemedicine delivery have not been studied. The WA Country Health Service (WACHS) established the Emergency Telehealth Service (ETS) in 2012 to provide telehealth and other technology-enabled services to regional Western Australian hospitals and clinics. The WACHS ETS supports 87 rural and remote WACHS-operated hospitals as well as 10 non-WACHS health clinics via high-definition audio-visual equipment installed in the resuscitation bay of the emergency department (ED) at each site. This 12-year practical application of emergency telemedicine offers a unique opportunity to explore the experiences and perceptions of clinicians delivering virtual care to rural and remote communities.

Objective: This study explores the perceptions of ETS clinicians regarding acceptability, appropriateness, and clinical decision-making when delivering emergency telemedicine in rural and remote settings.

Methods: This qualitative study used semistructured interviews to explore the perspectives of ETS clinicians regarding the factors influencing their clinical decision-making. It explored how ETS clinicians determine and modify clinical risks associated with using audio-visual equipment to deliver care. Emerging themes were compared with the concepts arising from the interim guidance of the Medical Board of Australia, and both the Australian and New Zealand, and American Colleges of Emergency Medicine.

Results: Overall, 16 doctors, 4 clinical nurse coordinators, and a nurse educator from WACHS ETS provided their experiences and perspectives. Accurate clinical decisions, especially regarding patient disposition, were crucial to virtual care. Timeliness and accuracy were enhanced through a mutual learning model grounded in the local context. Mitigation strategies such as improvisation and flexible technology use compensated for technological barriers. Nonmodifiable risk factors included patients' presenting complaints, clinical urgency of presentation, ED capability, clinician scope of practice, and, if a transfer was required, the distance between the ED of original presentation and the hospital of definitive care.

Conclusions: Telehealth can enhance clinical decision-making in rural and remote EDs, and ETS clinicians can prioritize patient safety through a lens incorporating both local hospital capabilities and community contexts. Even for the most experienced

clinicians, telehealth was not comparable to face-to-face communication in all circumstances. The impact of the ETS on the scope of the regional emergency medicine practice and on the building of clinical skills warrants further study in relation to its overall effectiveness and cost-effectiveness in rural and remote EDs. These findings identify areas for further qualitative research while providing a rich contextual background for rigorous quantitative analysis of the effectiveness of the ETS.

Introduction

Background

Telehealth has rapidly emerged as a means of providing health advice and care to people at sites where health providers at the hospitals of initial presentation (presenting hospitals) may lack capability or require assistance with the diagnosis and treatment of presenting clinical conditions. In recognition of the rapidly evolving domains of telehealth in the delivery of emergency medicine (EM) in the United States [1] and Australia and Aotearoa (New Zealand) [2], the Australasian College of Emergency Medicine (ACEM) [2], American College of Emergency Physicians [1], and Medical Board of Australia [3] deliberated on interim principles, considerations, and minimum standards to guide emergency telemedicine ("the interim guiding principles from the Colleges of Emergency Medicine"). Telehealth in the emergency department (ED) aspires to improve the quality of health care for patients in remote and other settings by increasing access to specialists and optimizing health service utilization and disposition coordination, including timely access to definitive care [2].

Guiding Principles on Emergency Telemedicine Implementation

These interim principles provide minimum standards for telehealth practice in the ED. As the Colleges of Emergency Medicine have identified, the use of telehealth in EM is in the formative stage and currently lacks a strong evidence base for clinical practice in the context of emergency care.

The ACEM and Australian New Zealand Fellow of ACEM (FACEM) Telemedicine Community of Practice (ANZFTCOP), superseded by a formal ACEM Emergency Telehealth Network, raised the importance of local context and the unplanned and exigent nature of emergency care [3]. The ANZFTCOP distinguished the nature of emergency medical practice from the broader telehealth discussion as it involves the provision of acute care without an ongoing clinical relationship either in-person or virtually [3]. The Community of Practice also pointed to circumstances where it may not be possible to access emergency physician expertise without recourse to telemedicine [3]. This is common for many rural and remote Australian EDs. The ANZFTCOP suggested that the decision regarding the appropriateness of conducting a telemedicine session instead of an in-person consultation should be based on individual clinical circumstances and expert clinician judgment [3]. Table 1 provides an amalgamated summary of the key guiding principles from these position statements and guidance documents.

Table 1. Amalgamated summary of the interim guidance on emergency telemedicine implementation.

Key themes	What is emergency telehealth and what should it do?	What is not emergency telehealth and what should it not do?
Locally grounded	• Should be an important complement for locally and regionally provided comprehensive health care. • Should be part of regional models of emergency care delivery validated by all relevant stakeholders across the public health system. • Should have regard for the local context and be grounded in the relationship with local clinicians including but not limited to knowledge of the local population, service availability, and patient pathways. • Should have appropriate escalation procedures in place to activate emergency services.	• Should not replace local care. • Should not be considered as a substitute for face-to-face consultations. • Should not involve low-value care that would not have otherwise been provided. • Should not be a stand-alone solution to address health workforce capacity and maldistribution.
Of similar quality and standard to ordinary care	• Assessments and consultations: (1) should be thorough within the limitations of telehealth and virtual consultations, (2) should replicate the components of an emergency medicine consultation, and (3) should be cognizant of the peculiarities or distinctive requirements of specific conditions. • Should implement quality assurance programs to monitor clinical performance, patient outcomes, and integrated ongoing care.	—[a]
Timely care	• Should ensure that definitive care is not delayed.	• Should not create additional barriers to accessing emergency medical care.
Appropriateness of care	• Should ensure that the patient's presenting problem is suitable to be assessed and managed remotely.	• Not appropriate for all clinical consultations.

[a]Not applicable.

Study Setting

The WA Country Health Service (WACHS) is one of the largest country health services in the world in terms of geographical coverage (2.55 million square kilometers, 96% of the land mass of Western Australia), with a population of 531,934 (18% of the Western Australian population; population density of 0.21 per square kilometer). It is organized into 7 distinct and diverse regions with 118 health facilities, accounting for 41% of the total number of emergency presentations across Western Australia (over 40,000 presentations per year) [4]. Most hospitals outside the large regional centers are staffed mainly by nursing staff supported by a resident general practitioner (GP) credentialed to provide medical services at the hospital. There are variable numbers of consultant specialists providing services at the larger regional resource centers. The majority of WACHS hospitals do not have on-site access to emergency medicine physicians (FACEMs).

The WACHS established the Emergency Telehealth Service (ETS) in 2012 to provide telehealth and other technology-enabled services to regional Western Australian hospitals and clinics. The ETS is the earliest and most established service stream of the WACHS Command Centre, which supports 87 WACHS hospitals and 10 additional non-WACHS facilities through high-definition videoconferencing services [5]. The Command Centre is a 24/7 virtual clinical and operational hub including services for general medical inpatients, mental health, midwifery, after-hours palliative care, and transfer coordination. It supports clinicians in regional hospitals and nursing posts by providing ready access to specialist clinicians who use technology, videoconferencing, and real-time data to assist in delivering quality patient care [6].

In addition to over 38,000 clinical consultations per year, the ETS supports rural and remote clinicians to maintain skills and knowledge through an education program and opportunities for professional development [5]. The consulting clinicians are located across multiple geographical areas (Perth, across regional Western Australia, other Australian jurisdictions, and internationally). Most medical practitioners are FACEMs complemented by EM-credentialed GPs and emergency nurse practitioners. The central hub of the Command Centre is based in Perth, and referrals are coordinated by a team of clinical nurses and clinical nurse consultants.

Referrals to the ETS vary across hospital types but are mainly from small hospitals (81.5%), nursing posts (9.7%), and integrated district health services (8.2%), and the ETS is least used by regional resource centers (0.7%) [4,7]. The proportions of ED presentations involving the ETS also vary across hospital types, with nursing posts and small hospitals involving the ETS in 21.3% and 23% of all ED presentations, respectively. Between July 2018 and April 2023, the uptake for nursing posts ranged from 2.8% for nonurgent presentations to 62.1% for emergency presentations that must be attended within 10 minutes. For small hospitals, the uptake ranged from 5.3% for nonurgent presentations to 47.9% for presentations requiring resuscitation. The more remotely located EDs appear to have greater reliance on the ETS especially for the management of more urgent cases [4,7].

Evidence on Telehealth Implementation in Rural and Remote EDs

Studies have identified factors that negatively influence the experiences of regional clinicians in rural and remote EM practices. These include [8,9] the lack or absence of medical backup or resources, the geographical and social isolation of

rural communities, poor health system coordination, the loneliness experienced by regional clinicians, and the challenges of health care provision in geographically isolated locations [10-12].

The challenges these conditions pose are community specific [8], and studies found that rural and remote EM physicians drew on the strength of professional relationships to improvise, solve problems, and create systems of support to meet local needs in order to survive and thrive in the middle of rural and remote challenges [8,9].

Published studies on the use of telehealth in EM suggested positive impacts on patient care, including benefits such as cost reduction, improved quality of care, reduced mortality rate, reduced patient treatment time, and reduced time between first contact and treatment [13]. Moreover, in the rural and remote context, studies have reported reduced patient transfers from rural facilities to major centers [10-12,14-16] and improved capability of rural centers [10,17,18]. However, studies have not discussed the complexities of rural and remote EM practices in depth or taken them into account in their analyses.

The use of telehealth in rural and remote EDs to help alleviate these regional EM practice challenges has not been studied. Whether or how emergency telemedicine in rural and remote settings improves patient health outcomes and the factors influencing the clinical decisions of emergency telehealth clinicians remain uncertain. There is a need for quality evidence to better understand these factors to help identify the gap in the effectiveness of emergency telehealth [12,14,15,17,19-27].

Studies have, however, identified challenges in the implementation of virtual care, and emergency telehealth is one of the practice areas considered [14,22,23]. These include technical difficulties [11,12,23,25-27], factors impeding the process of care [10,14,16,19-21,24-26], and factors impacting patient privacy, confidentiality, and data security [24-26].

It has been proposed that to understand the factors influencing job satisfaction, the complex environments around rural and remote EM practices must be considered [8]. However, the impact of environmental factors on clinical decision-making in rural ED practice has not been considered.

The clinicians' perceived clinical risks have been identified as a challenge in rural and remote EM practices [8,9]; however, how individuals perceive the risks in rural and remote emergency telehealth practices and the impacts on their clinical practices have not been explored previously. In rural and remote EDs, it is possible to assume that when the perceived clinical risk is high, the approach to diagnosis and treatment may change, leading to increased rates of transfer. The distinctions between these perceived clinical risks when delivering face-to-face versus virtual EM services warrant investigation.

To the best of our knowledge, specific links between the challenges of clinical reasoning and decision-making in virtual emergency care and the rural and remote context have not been identified. However, these factors are critical for understanding the effectiveness of implementing telehealth in rural and remote EDs.

Study Aims

From the perspective of WACHS clinicians delivering the ETS, this study explored the perceptions of emergency telehealth clinicians regarding the acceptability, appropriateness, and determinants in clinical decision-making when delivering emergency telehealth in rural and remote settings. This study aims to understand the following: (1) the factors influencing clinical decisions during an emergency telehealth consultation; (2) the impact of involving emergency telehealth clinicians in rural and remote ED consultations on the health workforce and the safety of clinical service delivery; and (3) how the clinical risks associated with emergency telehealth consultation can be modified, including whether improving the status of factors that are amenable to change can positively influence the safe and effective delivery of the ETS.

Methods

Overview

This qualitative study used semistructured interviews to explore the perspectives of ETS clinicians regarding the factors influencing their clinical decision-making. It explored how ETS clinicians determine and modify associated clinical risks. Emerging themes were compared with the concepts arising from the interim guidance of the Medical Board of Australia and both the Australian and New Zealand, and American Colleges of Emergency Medicine. The WACHS ETS was used to examine contextual factors influencing the quality and perceived effectiveness of emergency telehealth in rural and remote areas.

Sampling Techniques and Study Participants

A combination of convenience, snowball, and purposive sampling was used to obtain a diverse perspective on the ETS model of care. Convenience sampling was required given the nature of ED work and participant availability to recruit FACEMs, GPs, ETS nurse coordinators, and clinical nurses. A purposive sampling of WACHS ETS physicians who were interstates or overseas occurred toward the end of the participant recruitment.

On December 17, 2020, an invitation email was sent to all ETS doctors and nurses by one of the FACEM members of the research team. This was followed by individual follow-up emails on January 22, 2021, to ETS doctors, as well as emails and in-person follow-ups by one of the ETS clinical nurse consultants in the research team.

Interview Guide Development

The interview protocol (guide) was developed in collaboration with the clinical researchers at the Command Centre. This interview guide was then distributed to the full research team for review.

After piloting the interview protocol with a select leadership group, the protocol was updated to include probes on whether an electronic stethoscope would help provide confidence in clinical decision-making, as well as adding questions related to the clinical governance, service legitimacy, and legality of the ETS practice. Minor changes were also made to the wording and ordering of the content areas and probes within each content

area. The final version of the interview protocol is presented in Multimedia Appendix 1.

Simultaneous Data Collection and Analysis

Semistructured in-depth interviews explored the experiences and opinions of the clinicians involved in ETS implementation and the factors considered in clinical decision-making.

Participants were given the option to participate in an interview via MS Teams (Microsoft Corp) or phone, from a place and at a time of their choosing. Interviews were audio recorded, automatically transcribed, and repeatedly played back in the open-coding phase of the analysis to validate the accuracy of the transcription. Due to the nature of emergency work, the recruitment and conduct of the interview occurred opportunistically to catch moments when the clinicians were available. This meant that interviews sometimes occurred outside rostered work times, with some conversations interrupted by work-related demands.

Data analysis proceeded simultaneously with data collection and issues arising from information [28]. The early phase of the analysis included open and axial coding [29], identifying the emerging themes with open coding from clinician interviews. The emerging themes were then compared with the guiding principles identified from the interim guidance documents of the Colleges of Emergency Medicine and Medical Board of Australia. The key guiding principles were introduced as axial codes to place the open codes within the context of EM practice. In the final phase of the analysis, risk factors considered by clinicians in their clinical decision-making during an emergency telehealth consultation were extracted and classified into technology related, presenting hospital/location related, or EM related. The modifiability of each of the factors was assigned by the lead author and confirmed by co-authors based on author experience, the rural and remote context of Western Australia, the public health service landscape, and the resources available to the WACHS. The factual findings reported in this paper were discussed with and confirmed by the WACHS Command Centre.

Ethics Approval

This research obtained ethics approval from the WACHS Human Research Ethics Committee (approval number: RGS0000003076) and reciprocal ethics approval from the Curtin University Human Research Ethics Committee (approval number: HRE2019-0740-09). Site access was governed by the WACHS research governance policy and procedures. A participant information and consent form was attached to individual email invitations to the participants to review, sign, and return before the scheduled interview. For participants who attended the interview but were unable to sign the consent form, verbal consent was obtained before the commencement of the interview. Interview recordings were transcribed verbatim by the first author. The transcripts and recordings were allocated a participant code and stored in a password-protected electronic folder that is separated from the folder where the participant register is stored.

Results

Interviews and Participants

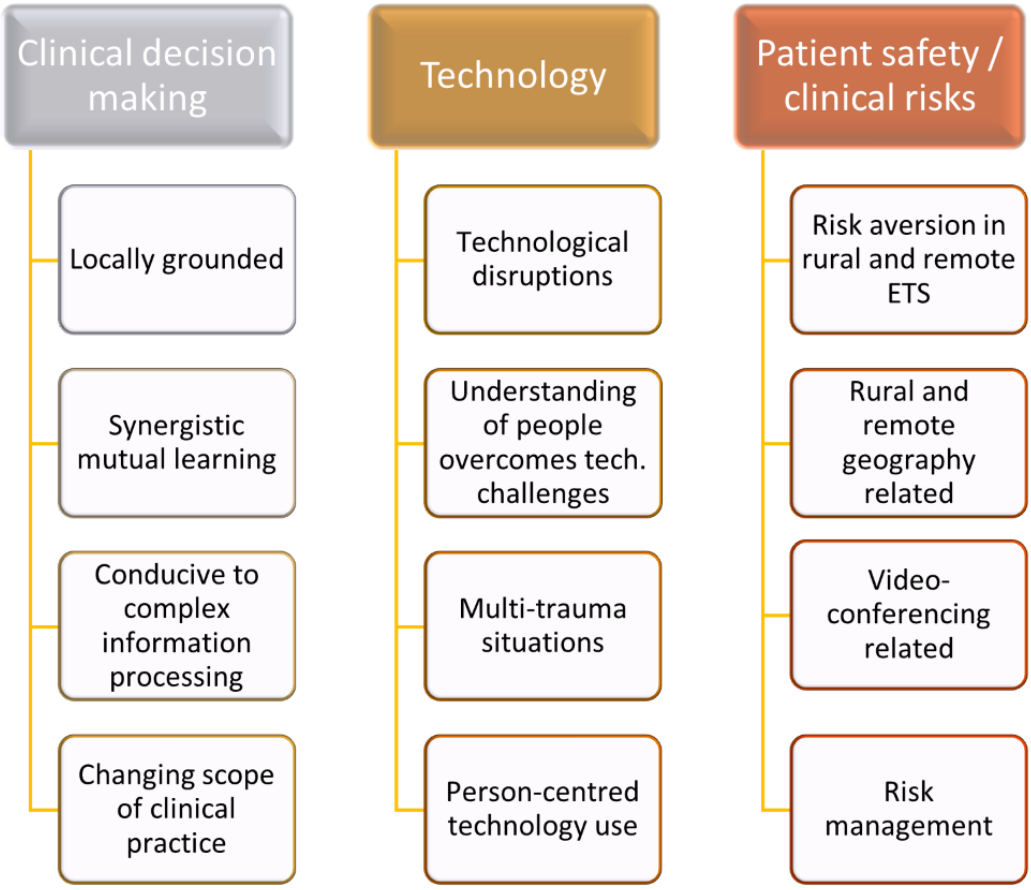
Most interviews were conducted via MS Teams (17/21, 81%), and the remaining were conducted by phone (4/21, 19%). Participants were in their private homes, a dedicated home office space, or Western Australian health facilities.

Sixteen WACHS ETS doctors and 5 ETS nurses participated in the interviews. There were 9 FACEMs, 5 GPs, 2 ED registrars, 4 clinical nurse coordinators, and 1 nurse educator. All participating ETS nurses were based at the Command Centre in Perth, while 5 of the ETS medical practitioner participants were based in Perth, 6 were based in regional Western Australia, 4 were overseas, and 1 was interstate. Two senior rural GPs provided their perspectives from both the receiving and provisioning ends of the ETS (as GPs working in regional locations). Around a quarter of ETS doctors and 16% of ETS nurses in the Command Centre participated in the interviews. All ETS nurses, except 1, were recruited by the same clinical researcher through face-to-face invitations, while 83% (15/18) of the ETS doctors who participated in the interviews responded to the initial invitation to participate. The purposive recruitment yielded 2 additional ETS participants to add weight to the perspectives of overseas or interstate doctors. Multimedia Appendix 2 lists the details of the participants, including home base, professional designation, gender, ETS role, and perspectives they contributed to this study.

Domains That Emerged From the Simultaneous Data Collection and Analysis

The major thematic domains identified in this analysis were clinical decision-making, technology, and patient safety or clinical risk. The themes and subthemes have been outlined below. Figure 1 provides a representation of the domains and themes.

Figure 1. Thematic domains and subthemes that emerged in this study. ETS: Emergency Telehealth Service; Tech.: technology.



Clinical Decision-Making: Benefits of Involving the ETS to Support Clinical Decisions

Participants identified 3 key benefits of ETS involvement in rural and remote clinical services. Hospital clinicians reported that having the ETS improved the willingness and confidence of regional clinicians to practice in remote locations. The ETS enabled synergistic mutual learning through the collaborative patient management of site-based and ETS clinicians. Further, ETS FACEMs experienced the benefit of ETS practice over site-based practice as it allowed them to be more cognitively focused when processing complex information. Participants touched on the changing scope of clinical practice as part of their discourse on clinical decision support.

Locally Grounded Clinical Decisions

Participants described timely and appropriate disposition (admission, discharge, or transfer) of patients as the most significant clinical decision for rural and remote EDs. Disposition of ED patients, especially from less-resourced remote EDs, has significant patient safety and clinical risk implications. Clinical decisions pertaining to patients presenting to small and remote EDs differed from those of better-resourced urban or regional center EDs as site-related factors needed to be considered.

All participants commented that multiple interacting factors were at play when deciding to transfer a patient for ongoing management. Table 2 lists the factors they considered in their clinical reasoning, and only 1 was related to technology. The predominant consideration was the resources available locally within the presenting hospital and in the local community. The next consideration was the distance to a destination site of definitive treatment if a patient's condition deteriorated. The final consideration was the timing of transfer and its appropriateness according to an individual patient's health condition.

Table 2. Thought processes in clinical decisions including patient disposition considerations via rural and remote emergency telehealth.

Thought processes of decision-making clinicians	Technology related	Hospital/location related	Patient related	Emergency medicine related
Normal diagnostic decision-making: what is wrong with the patient?	No	No	No	Yes
Can the patient be adequately assessed for all relevant possibilities at the site? What [differential diagnosis] am I potentially missing and is that putting the patient at risk?	Yes	Yes	No	No
Is this patient safe to go home medically and socially?	No	Yes	Yes	No
Is there a local GP[a] in town to care for the patient the next day?	No	Yes	No	No
Am I happy for the patient to wait till the next day for follow-up in a community?	No	Yes	Yes	Yes
Considering the patient's location, the weather conditions, and the local resources available, is the patient safe to stay at this site and/or be admitted locally for observation?	No	Yes	No	No
Does the patient need to be retrieved earlier [compared to the standard of a tertiary center or regional center ED[b]]?	No	Yes	No	No
Where and how do I transfer them? Is this patient safe to go somewhere with private transport or road ambulance, or do they require aeromedical transfer?	No	Yes	Yes	No
What does the patient want? (some patients do not want to leave their community)	No	No	Yes	No

Synergistic Mutual Learning With Joint Clinical Decision-Making

ETS physicians were reliant on the local knowledge of hospital clinicians at the site of patient presentation to facilitate and consider community, social, and resource factors in clinical decisions for regional patients. Rural-based hospital clinicians reported benefits from the assistance of ETS clinicians in making clinical decisions, especially their support in connecting to appropriate and available resources.

Regional-based participants reported that the involvement of ETS colleagues supported them in answering the questions listed in Table 2, with increased speed and confidence. An ETS physician who also worked at a site based on a WACHS ED stated:

> *It makes certain that we make the best decisions for our patients. ETS does make the decision-making process much easier in the region. I've got somebody else online who can call me if I'm looking after somebody who's critically ill. They can help organize transfers and ICU admission, they can help me with drug doses, so I can…crack on and do what I need to do. And I know that I'm working in a safe environment.* [ETS Doctor #3]

Participants also stated that they acquired a different skill set working in a supportive role to clinicians in remote facilities, including ways of communicating instructions to presenting hospital clinicians (mainly nursing staff), gathering medical history, prescribing medications, and efficiently analyzing and synthesizing presenting complaints.

For ETS clinicians who were FACEMs mainly based in metropolitan hospitals, participation in ETS consultations provided a new and unfiltered experience in the rural and remote clinical practice. Many reported that this changed the way they practiced in their substantive role on the floor of tertiary EDs:

> *I think [the learning has been] in both directions, one, it makes me realize how resource rich we are in a tertiary hospital. Two, it makes me realize that the nurses and other staff out there [in regional WA] are often just as competent, just as knowledgeable, and just as skillful and often braver than we are in tertiary hospitals. It certainly helps me stay grounded when I'm accepting referrals. [Tertiary hospital] has a big catchment, we receive a lot of these people from peripheral hospitals and nurse run clinics. And one that certainly helped me know where all these places are, when I'm on the receiving end of the phone…I'm able to explain to other staff exactly how resource limited, a lot of these clinics are. And there is a reason they haven't had blood tests and haven't had imaging. And in fact, there's no doctor there. So they have just been seen by nurses must come to be seen by us, we don't have to be difficult about accepting them. I think that's been quite useful.* [ETS Doctor #43]

Conducive to Complex Clinical Information Processing

Participants reported that their ability to control and prioritize their consultations in the virtual environment assisted their efficiency in processing complex information and enabled more objective assessment than working in person on the ED floor, given their distance from the patient. Participants reported the

benefits of providing virtual care compared to working on an ED floor:

> *If you're on an ED floor you are interrupted constantly because you're physically there…one of the most frustrating things is you're constantly distracted, and you can't finish a task from A to B, I think that adds hugely to burnout. …But you are focused here [at ETS], …we can only see one camera…one patient at a time. …And the chaos is more manageable… you can choose to not be interrupted. So I feel that it's very satisfying, because you're so cognitively focused. And I think that can potentially lead to better quality care… because you can just make better decisions.* [ETS Doctor #6]

With the ability to control the environment they practice in, ETS FACEMs found the virtual environment conducive to them being more cognitively focused.

Changed Scope of Clinical Practice

The impacts on the scope of practice of regionally based clinicians, especially nurses, were dichotomously reported. Most participants reported an increasing scope of site-based clinical practice with ETS doctors guiding local nurses to perform procedures that they otherwise would not have the confidence to do on their own. A contrary perspective was the engagement of ETS clinicians in treatment and procedures or clinical decisions, which local clinicians would have performed independently through a local process in place prior to ETS implementation. For example, regarding giving a tetanus booster, 1 participant commented:

> *…we'll get consults of patients who need a tetanus booster, they've had a small wound a few days ago, …I don't know what they would have done before, I think they would have done it and had a process in place to do it.* [ETS Doctor #2]

The changing scope of practice was noted by the participants. This reflected policy changes to increase medical practitioner involvement in ED consultations and was an emerging theme that warrants further in-depth exploration.

Technology

The second thematic domain was technology, which included technological (digital) disruption and mitigation strategies in emergency telehealth consultations.

Participants were of the view that the WACHS ETS had already made most of the technological and process improvements and considered that any further changes on the technological front would have incremental benefits in effectiveness for improving patient health outcomes. One FACEM participant stated:

> *A lot of the system problems are the fact that we have a hundred places that are tiny and it's hard to get [for example] a pathologist, or experienced nurses for long stays. A lot of it is system problems that are difficult to modify.* [ETS Doctor #43]

> *We probably made the easy gains and the incremental changes you can make to improve things from here are big and costly, and difficult. For example, attracting and keeping people in remote communities and providing enough staffing to let GPs take holidays and do professional development and be replaced by someone, rather than leaving the community to rely on telehealth because there is no one else to cover.* [ETS Doctor #43]

Participants described the ways in which they modify how they use the telehealth technology or adjust the process of care to improve the quality of ETS consultations.

Technological (Digital) Disruptions

A commonly expressed view among ETS physician participants was that during videoconferencing, one is expected to lose nonvisual cues and some verbal cues due to technological (digital) disruptions. Clinicians reflecting on the videoconference consultation experience suggested that the amount and quality of information a clinician could gather through video came down to their level of understanding of people as individuals. They referred to the nuances of patients' expressions observable during videoconferencing and being able to relate to the regional context of the patients. Table 3 provides a summary of the circumstances around the technological barriers during an ETS consultation and the mitigation strategies participants used to overcome these technological disruptions.

Table 3. Technology-related issues of Emergency Telehealth Service technology and mitigation strategies.

ETS[a] technology-related issues	Technology barrier			Mitigation strategy		
	Barrier	Circumstances	Participants	Strategy	Incompatibility	Participants
Positioning of the monitor where the image of the ETS physician appears (ie, at the foot of the ED[b] stretcher)	• Sending the wrong message that the doctor is looking down on the patient. • Abrupt appearance does not allow ETS to ease into the scene as in the case of an in-person ED floor.	When people on the floor are not adequately prepared and people are unaware why the ETS clinician is appearing on the screen, there can be disruptions in the actions already taking place in the ETS bay.	ETSD[c] #1, 4, 6, 7, 10, and 13; ETSN[d] #3	• Prepare patients before the VC[e] link is up; explain the process before and after VC consultation, including the steps leading up to transfer when interhospital transfer is indicated • ETS physician is identified as not from Perth and thus does not appear as "someone from Perth talking down on us"	• In a critical encounter, there is no time and space to prepare patients and people in the room. • Only available to regional-based ETS clinicians.	ETSN #3; ETSD #7
Talking into an open space; broadcasting of sound from the VC setup into the ETS bay	• Impersonal, with privacy and confidentiality potentially compromised; concurrent private conversations can occur from adjacent ED bays, which can create distracting noise during the consultation process.	Especially when multiple parties are involved in the conversation	ETSD #1, 4, 7, 10, and 13; ETSN #3	• Mute VC sound and use a telephone directly with site-based clinicians or patients for audio to ensure private conversations. • Transition to telephone only after an initial meet and greet with VC. • Clinicians on the floor are encouraged to wear headphones to enable switching voice channels between different target audiences.	• If children are involved, communicate with parents or carers	ETSN #3 and 4
The ETS clinician's visual field of the ETS bay is restricted by the camera's visual field	• ETS clinicians are not aware of others in the room.	Consulting before realizing a family member or another patient is in the room; knowing who is in the room and their relationship with the patient can change the dialogue and alter the instructions given regarding the next steps.	ETSD #1 and 6	• Use a telephone before screen appearance, find out who is present, and clarify the purpose of involvement. • Self-introduction, role of ETS consultation, and a name shown at the base of the screen.	—[f]	ETSD #2, 4, 8, 9, 12, 13, 15, and 43
Zoom in or out function adjusted locally without the ETS clinician's awareness	• Unable to zoom in to see what needs to be seen.	Significant (disastrous) impact in critical situations.	ETSD #5	• Having a reliable camera that the ETS doctor can control.	—	ETSD #4 and 14

[d]ETSN: ETS nurse.

[e]VC: videoconferencing.

[f]Not applicable.

The videoconferencing equipment setup and the restriction of the camera's visual field created technological barriers affecting the quality of ETS consultation. Physical distance was the perceived distance between either side of the high-definition audio-visual equipment installed in the resuscitation bay of the ED at each site.

Participants experienced constraints of the camera setup made consultations impersonal and visual cues easily missed or distorted, and they shared how they adapted in their ETS practice to ensure effective visualization. One doctor said the technical issues and logistics of commencing a consultation with sudden appearance on a screen and sound broadcasting as key differences to working on the floor:

> *…, you got to spend time to dial in, and, then suddenly just appear on the screen in front of the patient… sometimes they're a bit shocked because you're big and loud on the screen… especially if they're drunk, confused that can exacerbate that [shock]. And sometimes I don't know what the volume is, sometimes I'm absolutely booming. And then everybody can hear me in the ED… they got to find the mute button, unmute me and decrease the volume…* [ETS Doctor #6]

A few participants suggested that adding a reliable remote-control pan or zoom would considerably improve the quality of the ETS physical assessment:

> *…great history and reading the cues if someone is lying very still, are they squirming around, are they making reasonable eye contact, are they coherent when they talk, all of that sort of stuff... you know looking for facial droop, obvious distal neurological deficit can be done really well [with reliable and high resolution camera].* [ETS Doctor #14]

Understanding of People Can Overcome Technological Challenges

Through reflective practice, participants redefined and modified their practice over the ETS to mitigate the shortcomings of the videoconference equipment setup. There were varied responses to technological (digital) disruptions in interpersonal communications. ETS doctors gave examples of how they used visual and imperfect auditory cues to assist with formulating their working diagnosis when direct eye contact was not possible via videoconferencing. Visual cues, such as closing hands and fidgeting, were used to the clinician's advantage to help with diagnosis. Humor and a nonjudgmental approach were helpful in getting patients to reveal their alcohol issues and to work collaboratively with patients over videoconferencing to reach the best outcome for them. These human approaches made a notable difference in the virtual physical assessment process.

Multitrauma Situations With One Videoconference Bay

In a multitrauma situation when only 1 doctor was available on site, teamwork was required. For example, when the site-based doctor was busy with hands-on procedures in collaboration with an ETS FACEM, a local nurse stepped up to perform the team leader tasks under the guidance of ETS clinical nurses. When there were multiple casualties, all casualties would need to rotate to be in front of the cameras (typically 2 perpendicular pan/tilt/zoom cameras), and by using headphone channel switching, ETS clinicians could converse with each of the site clinicians individually. When there was a requirement to "shuffle" beds in and out of the camera visual field, adequate explanation ahead of the action was noted as an indispensable component of patient-clinician communication.

Person-Centered Technology Use

Facing variations in the quality of the internet connection, fixed positioning of cameras, and the broadcasting of sound into an open space of the ETS bay at regional EDs, ETS clinicians developed approaches to work with and via the presenting hospital clinicians to improve the quality of videoconference consultation while also protecting the privacy and confidentiality of patients. Overcoming technological limitations required users to troubleshoot and adapt to circumstances, requiring flexibility to ensure the effectiveness of virtual care. This finding pertains more to the exigent nature of EM and less to the rural and remote context of ETS delivery.

Patient Safety and Clinical Risk Considerations

The final thematic domain was related to the perceived risks of virtual care identified by the study participants (Table 4). The central aim was to ensure patient safety when using telehealth. If the ETS team perceived that patient safety was compromised by remaining at the local facility (particularly if there was no on-site medical practitioner), they would strongly consider transferring patients to an appropriate hospital for ongoing management. ETS clinicians who had higher levels of perceived clinical risk had a lower threshold to transferring their patients. Participants were confident that with experience (both at the site and virtually), some transfers could be avoided. The modifiability of risks as assessed in this study identified areas for potential improvement and the factors to consider in the effectiveness dialogue.

Table 4. Factors that make emergency telemedicine clinicians risk averse in rural and remote areas in Western Australia.

Clinical risks and sources of risks in the Emergency Telehealth Service practice	Technology related	Hospital/location related	Emergency medicine related	Is it modifiable?
Insufficient or lack of local resources				
Nature of ED[a] cases: sudden deterioration not always predictable	No	No	Yes	Not modifiable
Distance/time required to transfer to a location with more resources against the risk of deterioration	No	Yes	No	Not modifiable
No short-stay unit: cannot keep the patient after hours	No	Yes	No	Potentially
Local workforce capacity and capability				
Clinicians on the ED floor are unable to perform the required physical assessment	No	Yes	No	Limited
Procedural (IV[b] access and treatment procedures)	No	Yes	No	Potentially
No doctor or insufficient nurses onsite to admit the patient	No	Yes	No	Potentially
No GP[c] in town to follow-up on the next day	No	Yes	No	Limited
Unable to secure a clear diagnosis				
Unable to access required testing or imaging	No	Yes	No	Not modifiable
Unable to fully examine: chances of missing a clinical cue are greater	Yes	No	No	Limited
Not 100% confident with the clinical picture despite full complement of clinical information	No	No	Yes	Not modifiable
Variable internet quality: disrupts physical assessment	Yes	No	No	Limited
Camera is not always reliable	Yes	No	No	Modifiable
Individual factors				
Physician personality and approaches to risk	No	No	Yes	Not modifiable
Physicians are less comfortable with the reliability of their own physical assessment over VC[d] compared to face-to-face evaluation	Yes	No	No	Potentially
Patient preference (to stay closer to home)	No	No	Yes	Not modifiable
Patients and family members are risk averse to telehealth consultation	Yes	No	No	Potentially

Concept of Risk Aversion in the WACHS ETS

Risk aversion impacts transfer rates from the site of presentation. The level of risk ETS clinicians were willing to take in keeping patients locally depended on 4 broad categories risk considerations. The first and second considerations of risks were related to the presenting hospital capacity and capability (ie, the health service resources and workforce). Risk aversion was associated with increasing remoteness of the presenting hospital. The third category of risk was unanimously reported by all the ETS physician participants. They reported that they were not able to examine the patient adequately or be completely confident with the clinical information relayed by site-based clinicians. This concern reflected how well ETS clinicians felt they could apply strategies to mitigate technological (digital) disruptions. The final category reflected individual clinician factors, such as their personality and their own tendency to be risk averse, and was present in EM generally, irrespective of whether it was place based or virtual. Factors related to the nature of EM and patients presenting to EDs would not have changed this risk even if managing clinicians were able to be "teleported" to the scene in person, and these aspects have not been discussed further in this paper.

Risk Aversion Associated With the Hospital of Presentation and the Rural and Remote Geography

Of 17 risks, 8 emerged from the ETS risk-aversion discussion related to the hospital of presentation and the rural and remote geography. These were less readily modifiable than the videoconference-related risks. The least modifiable risk was related to the inability to access the required tests or imaging, and this was reported by multiple clinicians. If point-of-care testing and the pathological approach available locally were not adequate to reach a clear diagnosis, the patient would be

transferred for further investigation. The extent to which this was considered an issue varied, with 1 participant (ETS doctor #3) having a view that point-of-care tests, routine pathology, and x-ray imaging available locally were generally satisfactory and sufficient for many of the presentations, and this view differed from that of many other participants.

Another factor associated with the presenting health facility was related to the regional workforce capacity and capability to perform the required physical assessment or procedure, or to keep patients locally for observation onsite or in the community. This mainly applied to sites where there were no medical practitioners. These factors had limited modifiability at the time of the consultation but were potentially adaptable. When the ETS clinician was unable to work with the clinician onsite to overcome the limitations of physical assessment over videoconferencing, the workforce capacity at the presenting hospital impacted the ability to secure a clear diagnosis and manage the patient adequately. Workforce capability was also related to the inability to perform required procedures ranging from establishing vascular access, inserting an intraosseous needle, and simple suturing to performing more complicated procedures, which could have avoided transfer. Generally, this is related to nursing-only facilities staffed by clinicians with limited scope of practice. Even when a diagnosis was made and the required procedures are performed, a patient might still be transferred if there was no doctor or insufficient nursing capacity to keep the patient on site for further observation, including if there was no GP in town the next day to follow-up in the community.

The final factor adding to the risk aversion of ETS clinicians was related to resources available at the hospital of presentation. The key issue raised here was the absence of a short stay–type inpatient unit to keep patients in the hospital for overnight observation. The distance and time required to transfer patients to a location with higher levels of capacity and capability were considered against the risk of deterioration of the patient's condition and the assessment of clinical risk. These factors were not modifiable and subject to the treating clinician's judgment of the patient's health condition.

Videoconference-Related Risk Aversion

Of the 4 categories of ETS clinical risk, 2 included factors that were related to the inability to secure a clear diagnosis and were related to videoconferencing. Many participants discussed the need to transfer patients because they were not confident with the clinical assessment via video. These included their perception of missing significant clinical signs, due to being unable to directly palpate or examine the patient, which impeded reaching a clear diagnosis. For example, 1 FACEM participant commented as follows:

> *…spending a lot more time thinking about exactly what I'm going to do and why… you don't have any of the nice reassurance normal investigations you would normally have. You are putting yourself more at risk by doing telemedicine because the chances of missing something are greater because you don't have access to all the little things that would make you much more comfortable.* [ETS Doctor #14]

ETS physician participants also reported issues with internet connectivity and speed, and many made comments on issues associated with the reliability of the camera affecting their ability to formulate a clear diagnosis. As discussed above, issues related to the camera were associated with the way it was physically positioned in the allocated treatment bay; operational limitations with pan, tilt, or zoom; and the camera technology itself. The internet speed and connectivity were more challenging as they were impacted by the internet provision where both the patients and ETS clinicians were physically based (nationally and internationally).

Finally, user acceptance of videoconference consultation differed among participants. Not seeing patients face-to-face made some clinicians more cautious and risk averse, with treating clinicians also reporting that some patients or family members were risk averse to telehealth consultations due to a lack of experience or understanding of this alternative modality of clinical service delivery. Several ETS clinicians reported that they spent more time second-guessing their observations and decisions, suspecting that they are less reliable over videoconferencing compared to a face-to-face meeting.

Risk Management for Patient Safety Instead of Risk Aversion

Complementing the higher level of potential and perceived risk associated with videoconference consultations, participants shared a range of perspectives on the perception of clinical risk:

> *…am I risk averse? I am probably less. It's not my personality. My personality is not risk averse. And I think most emergency physicians are not risk averse. That's not the nature of our business. There's risk everywhere we are risk managers.* [ETS Doctor #2]

Despite observing the potential risks associated with videoconference consultations, participants believed that those who were overly risk averse would not participate in telehealth, and it was a matter of finding a balance between the perceived benefits of ETS and the expected risks associated. A pragmatic view was that ETS physicians were no more cautious on camera compared to being on the ED floor; however, due to incomplete data points to inform an evidence-based clinical decision, interhospital transfer may be suggested for the required investigations. In terms of confidence in their decisions, some participants reported that they felt comfortable with their clinical decision-making as FACEM training helped balance relatively scant information in undifferentiated patients, and this was no different from the decision they would make in a face-to-face meeting:

> *Well, that's my job. It's not so much about being confident. Well, you've got to be confident in your decision because otherwise you can't afford to be in the [emergency medicine] business. I mean, you know, if you if you're worried about the patient, then you do something to alleviate that worry… Occasionally, there are times when it is difficult… for example, if a patient has a communication problem in either they are deaf, or they can't speak properly, and so my interaction is sufficiently degraded but otherwise, for*

> *[most] times, I don't think it does make a particular difference to be honest. The difference between me not being there and being there is far more evident in the skills that are brought face-to-face. And those are nearly all procedurals.* [ETS Doctor #5]

Discussion

Overview

The experiences and perspectives of WACHS ETS clinicians contributed to an in-depth understanding of the factors influencing clinical decision-making during an emergency telehealth consultation in rural and remote settings. The study progressed the understanding of the mutual learning opportunities presented during the joint decision-making process, the perceived clinical risks of emergency telehealth practice in the rural and remote context, and the technological barriers imposed on clinical decisions and the modifiability of these perceived risks.

Principal Results: Meeting the Principles of the ETS Practice

This research described the mutually beneficial effects of ETS consultation recognized by the participants in their clinical practice. These were in line with the principles and interim standards stipulated by the Colleges of Emergency Medicine that telehealth should complement and be part of the regional model of emergency care delivery validated by all stakeholders [1-3]. This finding also aligns with previous research, which highlights how rural and remote ED clinicians rely on the support and expertise of their colleagues to navigate and succeed in the unique challenges of rural and remote settings [8-10,17,18]. It further explored how this dynamic operated when colleagues provided support through a virtual presence. This research provides additional insights into how collegiality during emergency telehealth consultations supports various aspects of practice. These include enhancing confidence in rural and remote clinical practices, advancing the practice of virtual EM, and incorporating the rural and remote context into collaborative clinical decision-making involving stakeholders on both sides of the technology.

Clinical Decision-Making

The participants described clinical decision-making mediated by a complement of ordinary technologies. Considerable regard was given to the context of the hospital of initial ED presentation, the community where the patient is from, and the regional Western Australia health service delivery landscape. ETS clinicians were reliant on the local knowledge of presenting hospital clinicians, the patients, and their family members to incorporate these local contexts into collaborative decision-making. The capacity building was mutually beneficial for regionally based clinicians and ETS clinicians. Their complementary skills and synergies in what they were able to contribute to patient care became apparent during ETS consultations. In this paper, we have referred to this phenomenon as “synergistically mutual learning.”

Many participants described their experience of improved efficiency in processing complex clinical information through better focus. This reflected the time-sensitive nature of the ED, especially when the hospital of definitive treatment was hours away, and the organized chaos in multitrauma situations. This finding represents a novel contribution from the perspective of emergency physicians conducting virtual ED consultations. The quality of clinical reasoning was reported to be superior in ETS practice where there was greater reliance on synthesizing medical history, reviewing clinical records, and carrying out focused processing of multiple sources of information. In situations where there was a heavy reliance on physical examinations and complex laboratory or imaging investigations, clinicians were cognizant of the peculiarities and distinctive requirements of the specific conditions and replicated, as much as possible, the components of an EM consultation. This was in line with the guiding principles stipulated by the Colleges of Emergency Medicine to deliver a service of similar quality and standards as ordinary care [1,2].

The perspectives of ETS clinicians highlight a critical aspect of improvement in the overall efficiency of emergency care delivery not previously reported in studies of the efficiency of emergency telemedicine within receiving hospitals [10-12,14-16].

Clinical Use of Technology

At the forefront of technological change is how humans personalize technologies. The way technologies are used is a significant part of the innovation in the EM practice in rural and remote settings. This study extended past findings of technological difficulties impeding care processes [10,14,16,19-21,24-26], patient privacy, confidentiality, and data security [24-26] by explaining how emergency telehealth practitioners introduced human factors to the innovative use of emergency telehealth through their understanding of people and tailoring the use of the same technology to the needs of patients on the other side of the camera as described in Table 3. To the best of our knowledge, this is the first description of how human users innovate to close the distance across technological barriers in an emergency telehealth scenario.

Modifiability of Patient Safety and Clinical Risks Identified

Risk factors related to ETS technology were modified through upgraded camera resolution, fixed camera positioning, increased user experience, improvisation, and consumer preparation. The quality of physical examinations was generally considered unlikely to match the quality of face-to-face examinations, especially when examinations of hard-to-visualize areas of the body or procedural interventions were indicated. However, emergency telemedicine using videoconference facilities has been considered to have reached a plateau and might be sufficient to cover a great majority of presentations. Additional investment in other examination equipment will need to be carefully evaluated as the benefits of further equipment upgrades are likely to be incremental against the costs of purchasing the equipment.

To meet the standard of replicating components of an EM consultation stipulated in the interim guidance [1,2], the need for an appropriately skilled and competent local workforce

cannot be overlooked. Workforce capabilities were potentially modifiable through education, including pre- and postvocational training opportunities; however, modifiability was offset by the ongoing issue of the turnover of clinical staff in rural and remote hospitals. This said, participants provided examples of how inter- and intraregional movement of clinical staff helped to retain the necessary skill sets within Western Australia. The extent to which clinical skills acquired through ETS involvement in ED consultations benefited the overall capability of the regional clinical workforce in WA fell outside the scope of this paper; however, this is an area of significant importance and relevance to the effectiveness of the ETS.

The pivotal but nonmodifiable consideration in clinical decision-making was the physical distance from definitive treatment locations and presenting hospitals. Local hospital resources, capacity and capability were beyond the scope of this study, but it was acknowledged that these had limited modifiability, at least in the short term.

This paper did not explore the impact of the ETS on the quality and standard of care in larger regional EDs, and the dominant view that EM specialists are risk managers is of significance. Any manifested risk aversion is likely related to patient safety considerations given that rural and remote contextual factors are nonmodifiable or have limited modifiability. Despite the dominant view that the ETS added value to presenting hospital clinical decisions, there were also concerns that pre-existing processes and capacity had been disrupted by the care processes now available through the ETS. The change in the scope of practice in presenting hospitals, particularly regarding nursing staff, because of ETS involvement is a subject for further detailed exploration to reach an optimal balance.

Novel Contributions of This Study

Prior work has paid considerable attention to advocating for telehealth policy reform [30] and identifying the barriers and enablers of telehealth implementation in rural and remote EDs. This is the first study to systematically detail the complex interrelationships between technological and human interfaces. The barriers to quality and safety of emergency telehealth consultations and mitigation strategies used by the WACHS ETS clinicians when collaborating with rural and remote EDs were detailed. These perceived clinical risks and risk mitigation strategies added new insights into the contextual factors influencing the effective implementation of rural and remote ETS.

Findings around technological challenges were consistent with the findings of previous studies that pointed to variations in usability, depending on the setting and situation. Unlike previous studies that compared the approach of different types or combinations of telehealth technologies (eg, videoconferencing, store and forward, and telemonitoring) [21], this study embraced the use of available technology as a norm in rural and remote ETS practices in Western Australia. The focus on the strategies used in WACHS ETS delivery to overcome technological barriers in this study makes a novel contribution to advancing our knowledge on the modifiability of the risks associated with rural and remote virtual care and helps to inform future quantitative analysis and interpretation of findings on the effectiveness of rural and remote ETS.

Limitations and Future Research

The findings reported in this paper are subject to several limitations. Clinical nurse coordinators are the first contact points for accessing the ETS, and this triaging (referred to as ETS prioritization to distinguish from the Australasian Triage Scoring system) plays a pivotal role in case review order and selection. The ETS prioritization process ensured that the presenting hospital and community context were incorporated into timely and appropriate care from the first point of ETS contact. This paper focused on regional context considerations influencing clinical decisions around the disposition of ED patients during a virtual consultation and did not examine regional context factors already incorporated during the process of ETS prioritization. Future reports on ETS prioritization would be an essential addition to the body of knowledge on emergency telehealth implementation in the rural and remote context.

Telehealth, especially emergency telehealth, is a relatively new area in clinical practice with evolving clinical governance standards. Medical indemnity issues were discussed during the interviews but did not emerge as a dominant theme in the data analysis. WACHS ETS physicians are particularly focused on patient safety. However, based on available data, it is difficult to conclude the extent to which medicolegal considerations are at play in the response to the risks associated with the ETS practice.

The financial viability or cost-effectiveness of virtual care is best explored quantitatively. It is worth noting that participants were value conscious in evaluating disposition options. However, they were not able to comment on the financial viability of the service as it was not within the role of most of these clinician participants. The implementation factors identified inevitably influence the effectiveness of telehealth in rural and remote EDs but are insufficient to determine the effectiveness of the ETS. This study represents a step toward determining the effectiveness of ETS delivery and is an area for future research.

The recruitment of participants may have been subject to social desirability bias, and some nonresponders may have had an alternative opinion about the service, which they felt did not align with the health service's official position. The presenting health condition is one of the central tenets in this research, although the data collection did not focus on specific health conditions. Our intention in this paper was to capture the overarching themes of clinical decision-making and how they affect the safe and effective delivery of rural and remote ETS to improve patient health outcomes. There were no comparisons between the treatments of urgent and nonurgent presentations because formative analysis showed the tendency of using the ETS for more urgent cases. This focus was due to the higher proportion of FACEMs among the study participants, who were more likely to encounter urgent cases.

Conclusion

Telehealth has the potential to improve the processes of clinical decision-making in rural and remote EDs. The participants, all

of whom participated in delivering the ETS, perceived improved accuracy, confidence, and speed of clinical decisions. The reach and effectiveness of the ETS in addressing the identified health needs remain to be tested.

Patient safety was central to all clinical decisions, which were grounded in the capability of presenting hospitals and the local community context. The risks of delay in definitive care for those patients requiring transfer for ongoing management associated with the geographical distance to the hospital for definitive treatment and the presenting hospital capability were not amenable to change. The importance of social and geographical contexts for appropriate telehealth delivery was highlighted in this study.

Technological barriers to the safe and effective delivery of the ETS were amenable to improvisation and improvements to infrastructure, but overall, participants were aware that they could not reach the same reliability as that in face-to-face consultation for all presenting conditions. Although the ETS was an acceptable and feasible option for ED consultation, the maintenance and sustainability of the ETS as part of routine practice and policy are dependent on presenting conditions.

Investment into rural and remote telehealth has the potential to support regionally based clinicians both directly in patient care and indirectly by promoting their (health workforce) longevity in regional areas through the ongoing development of the virtual care network. The effect of the ETS on the scope of the regional ED practice and the building of clinical skills within the region warrants further in-depth exploration including its potential implications for the overall effectiveness and cost-effectiveness of telehealth services in rural and remote EDs.

Acknowledgments

This research was initiated by the WA Country Health Services (WACHS) and Curtin University, and received financial support from both institutions as well as the Digital Health Collaborative Research Centre (DHCRC) in the form of PhD scholarships. The WACHS also contributed in-kind support in the form of clinician time, industry supervision, and administrative and research infrastructure support. This research received further in-kind contributions from the School of Population Health at Curtin University, WA Centre for Rural Health at the University of Western Australia, WACHS Command Centre, and WACHS Country Health Innovation Project Support Office in the form of academic supervision, industry mentorship, and knowledge exchange.

Abstract

Background: Commercial wearable and mobile wellness apps and devices have become increasingly affordable and ubiquitous. One of their aims is to assist the individual wearing them in adopting a healthier lifestyle through tracking and visualizing their data. Some of these devices and apps have a wheelchair mode that indicates that they are designed for different types of bodies (eg, wheelchair users with spinal cord injury [SCI]). However, research focuses mainly on designing and developing new condition-specific self-tracking technology, whereas the experiences of wheelchair users with SCI using self-tracking technology remain underexplored.

Objective: The objectives of this study were to (1) provide a comprehensive overview of the literature in the field of self-tracking technology and wheelchair users (as a basis for the study), (2) present the self-tracking needs of wheelchair users with SCI, and (3) present their experiences and use of commercial self-tracking technology.

Methods: We conducted semistructured interviews with wheelchair users with SCI to understand their experiences with self-tracking and self-tracking technologies, their self-tracking needs, and how they changed before and after the injury. The interviews were thematically analyzed using an inductive approach.

Results: Our findings comprised three themes: (1) being a wheelchair user with SCI, (2) reasons for self-tracking, and (3) experiences with self-tracking technologies and tools. The last theme comprised 3 subthemes: self-tracking technology use, trust in self-tracking technology, and calorie tracking.

Conclusions: In the Discussion section, we present how our findings relate to the literature and discuss the lack of trust in commercial self-tracking technologies regarding calorie tracking, as well as the role of wheelchair users with SCI in the design of commercial self-tracking technology.

Introduction

Background

Every year, up to 500,000 people experience spinal cord injury (SCI) and, as a result, become wheelchair users [1]. This population must adjust to their new body, learn to use a wheelchair, and sustain an active lifestyle. An active lifestyle is vital for their independent living and quality of life. If they are not active, their shoulders can be injured because they are overused in their daily life without being trained for specific activities (eg, getting in and out of the wheelchair). Another risk is that they can gain weight, which requires them to change to a wider wheelchair, thus rendering more places inaccessible.

As commercial self-tracking technology (eg, smartwatches) becomes increasingly common, wheelchair users can access and benefit from its advancements. Some of this technology (eg, Apple Watch and Runkeeper) has already implemented accessibility settings for wheelchair users. Up to now, research on self-tracking technology has focused on (1) chair-ables, artifacts placed on or in the wheelchair to promote a healthier lifestyle [2-4]; and (2) studies on wheelchair users' experiences with self-tracking technology that was provided or introduced to them [5-7]. However, the everyday lived experience of self-tracking and related technology (ie, self-tracking technology) of wheelchair users with SCI is underresearched. This can result in the exclusion and underrepresentation of this specific group in the research and development of commercial wearables. Excluding part of the population as "special users" is an ethical and social issue [8,9]. In addition, more commercial technologies are anticipated to become accessible to a broader audience once the European Accessibility Act (EAA) is applied. This act focuses on digital products and services, underlining the importance of mainstream technology being accessible to people with disabilities and older adults [10].

The objective of this study is to build on previous research on self-tracking and self-tracking technology among wheelchair users with SCI [5-7,11] to include lived experience of self-tracking and self-tracking technology. Through an interview study, we aimed to answer the following question: How do wheelchair users with SCI experience self-tracking and commercial self-tracking technology in their everyday lives?

This section first provides an overview of SCI and the impact of the injury on people's lives. This is followed by a short overview of existing research on wheelchair users and self-tracking technology for health and well-being. Finally, we position our research in the context of contemporary society and technological research focusing on the role of wheelchair users with SCI.

SCI Overview

Worldwide, approximately 90 million people live with SCI, many of whom are either underage or part of the working population [1,12]. Each year, between 250,000 and 500,000 people sustain an injury to their spinal cord [1]. The average lifetime costs of an SCI starting at the age of 25 years range from €0.45 million to €2.1 million (US $0.49 million-$2.3 million), which exceeds those related to dementia, multiple sclerosis, and cerebral palsy [1]. Poor quality of life for people with SCI, their families, and caregivers—in combination with the socioeconomic burdens caused by the injuries—make it imperative to find solutions for this condition.

A motor-complete SCI leads to complete muscle mass loss in the legs and, thus, life as a wheelchair user. For a walking person, the muscles in the legs are the main consumers of energy both in an active state (eg, when the person exercises or moves) and in a rest state (eg, sleeping or sitting) [13,14]. In addition, an injury above thoracic level 6 provokes an altered (physiological) autonomic response during both rest and activity [15]. This results in an altered metabolic response, leading to reduced energy burn in both states [13-15]. Body weight balance is partly explained as caloric balance based on calorie intake and output [16-18]. After an SCI, the total energy burn (ie, calorie burn) is much lower than before. Generally, after the initial acute phase, people with SCI lose weight due to the loss of muscle mass and the healing process. During rehabilitation, most people get used to their light body weight and narrow wheelchair, facilitating an active and independent daily life. Throughout the rehabilitation phase, body weight tends to increase (approximately ≥2 kg during the first year) [19]. This relates to the lack of compensatory caloric intake due to the lower metabolic demands (total daily energy burn), which leads to energy imbalance with higher calorie intake than energy burn [19]. Increased body weight can have many consequences, such as higher stress on shoulder muscles due to extra weight being carried each time the person transfers to and from their wheelchair [20]. Moreover, it becomes more difficult to manage daily activities such as self-care. The resulting shoulder pain and reduced independence are often devastating [20]. Thus, calories are extremely important for people with SCI. Maintaining an appropriate calorie balance becomes much more achievable when energy burn and calorie intake can be monitored.

Wheelchair Users With SCI and Self-Tracking Technology for Health and Well-Being

Overview

Self-tracking is a voluntary, reflexive practice in which people collect data about themselves to enhance self-awareness and understanding by observing, noting, and interpreting various aspects of their lives [21]. Self-tracking technology is any technology that supports people in self-tracking practice. This technology can include apps—where the user registers information about their health and well-being—smartwatches or other wearable technology (wearables), or sensors embedded in assistive technology such as a wheelchair (chair-ables). Self-tracking technology is not assistive technology as it does not aim to improve the functional ability of people with disabilities or enable and enhance their participation and inclusion in different domains of life [22]. However, self-tracking technologies can offer inclusivity through adjusting functionality to include people with disabilities.

In this study, we focused on the experiences of people with SCI with mainstream technology as we aimed to contribute to an inclusive design. However, we recognize the importance of

understanding and learning from assistive technology for our target demographic. This understanding could direct inclusive design research and practice as it provides insights into adjusting or expanding the mainstream technology to be more inclusive.

Assistive Technology

Chair-ables have been researched in terms of tracking specific behaviors and self-care–related injuries. Let us take the case of pressure releases, which are vital for wheelchair users in avoiding pressure ulcers potentially contributing to premature death [23]. A chair-able can support wheelchair users with pressure release exercises. Sensors can be placed on the wheelchair to measure in-seat movement, classify the activity from the sensors into weight shifts, and inform the user with their data as well as sending push notifications upon achieving goals related to pressure releases [2]. In 2021, Ahad et al [4] developed and evaluated the reliability of an algorithm and a chair-able that could support people on wheelchairs in doing their pressure release exercises. The year after, design considerations for supporting electric wheelchair users with SCI on their pressure releases were published [24]. The authors [24] implemented context-aware and unobtrusive reminders delivered by the wheelchair for incomplete or incorrect pressure release exercises. The interaction with the wheelchair in this context [24] was preferable to an interaction with an app. Similarly, but in the context of self-tracking apps, Amann et al [25,26] used participatory design to design, develop, and evaluate an evidence-based app that uses a smart camera to prevent pressure injuries.

As for self-care, Büyüktür et al [3] presented requirements for semiautomated tracking to support people with SCI in their self-care by interviewing patients and health care professionals. Their main findings were that the patients' routines change from the clinic to the home environment and each patient decides to focus on what they value the most (eg, sleeping instead of waking up to change position during their sleep). Each patient and their informal caregivers try different routines in the home environment until they find one through which they can track the behavior and with which they can comply. Thus, Büyüktür et al [3] recommended a highly tailored and flexible system that can follow the patient's routines as they change and give them feedback. In general, a systematic literature review [11] showed that there is research on self-management of SCI in the home environment and clinic as well as the promotion of physical activity and a healthy lifestyle (eg, wellness and fitness). For example, one of the articles reviewed [27] presented that an intervention that tracked the activity of wheelchair users with SCI and motivated them through just-in-time messaging had the potential to improve physical activity for wheelchair users with SCI. Similarly, an interview study [28] explored the barriers that people with SCI face to staying physically active: (1) lack of tailored physical activity forums with wheelchair users with SCI and (2) lack of personalized fitness-tracking technology tailored to wheelchair-based activities.

Mo et al [29] explored the information needs of wheelchair users, and they identified a lack of tailored, accurate, and affordable tracking for wheelchair users both commercially and academically. Even though they argued for inclusive technology, the start of filling this gap could be in the assistive technology literature. Li et al [30] introduced WheelPoser, a system that tracks and identifies wheelchair users' on-the-move activity. They argued that they could do that by using 4 small sensors. Their dataset, code, and models are available for everyone to use, which allows mainstream technology to become more inclusive by using the same system as an add-on to their trackers or only the dataset to train their own systems. Huang et al [31], recognizing the lack of data on wheelchair users for training artificial intelligence algorithms on pose estimation, developed and evaluated a dataset to fill that gap. Their dataset is publicly available as well. Another article published in a disability forum explored the relationship between the successful completion of activity guidelines for people with SCI and the fitness or health status of the person with SCI [32]. This paper referred to activity guidelines [33,34] for people with SCI and an understanding of how mainstream technology can tailor its features (eg, daily goals) to a specific SCI group.

Inclusive Technology

Research underlines the need for inclusive and accurate commercial technology for wheelchair users through studies [35] and literature reviews [36,37]. The participants in the study by Li et al [35] showed interest in tracking their activity, but they did not trust the accuracy of contemporary commercial technology, understanding that those using powered wheelchairs could track some data on their activity that were relevant to them, such as distance. A literature review explored how academic publications in the personal informatics field address the information needs of wheelchair users [36]; it consolidated recommendations to tackle the design challenges that researchers and practitioners may face when attempting to design for including wheelchair users' activity tracking and information needs. In 2019, Moon et al [37] conducted a literature review of studies on the inclusivity of contemporary digital technology. They advocated for inclusive and universal design to become an integral part of commercial digital technology's development process and consolidated methods that can support the process.

Another systematic literature review [11] published in 2023 examined the use of mobile health in supporting people with SCI to maintain or improve their health. It showed that research lacked results regarding the role of commercial self-tracking technology for health and wellness to support people with SCI. The authors [11] attributed this gap in research to the fact that commercial self-tracking devices are inaccurate in their calculations for wheelchair users. However, in 2021, a study [38] evaluated the accuracy of the Apple Watch Series 1, showing that the watch was accurate for high-frequency strokes on a wheelchair (eg, a treadmill) but not for low-frequency strokes (eg, walking). Even though the research was published recently, the results of this research may not correspond to the current version of the Apple Watch (Series 7).

Related to commercial trackers and their use by of wheelchair users with SCI or their preferences, there is research limited to commercial technology given to them for a specific amount of time. For example, Ungurean and Vatavu [7] published a study in 2022 exploring the needs of wheelchair users related to activity trackers regarding different self-tracking technologies

(eg, rings, watches, armbands, and chair-ables). The researchers [7] interviewed participants after letting them watch videos of 2 different self-tracking technologies (eg, ring and armband) to understand their perceptions, preferences, and willingness to use wearables. Some of their participants were already wearable technology users, and the researchers mentioned that this could have supported them in answering the interview questions [7]. However, the study's results focused on the videos that the participants watched.

Malu and Findlater [5] based their research on the work by Carrington et al [6]. Carrington et al [6] tracked variables of wheelchair basketball players and presented the variables to the athletes to understand their needs and potential data use. In addition, Malu and Findlater [5] included wheelchair users who were not necessarily athletes. Their participants were interviewed, participated in design workshops, and tried 2 commercial technologies. Specifically, they used 3 fitness trackers for 30 minutes before they compared them and participated in a design session for designing a fitness tracker. Finally, both studies agreed that the values that people in wheelchairs may want to see are energy burned (calories), distance, GPS data, and pulse. The participants in the study by Malu and Findlater [5] added that calorie intake is equally important to energy burned. Finally, Malu and Findlater [5], unlike Carrington et al [6], showed that commercial self-tracking devices using GPS and comparing mobility in steps between different dates were acceptable and of value to their participants.

In 2019, Helle and Rosenbeck Gøegb [39] conducted a focus group interview study with 7 wheelchair users who were members of a basketball team. The study aimed to explore wheelchair users' experiences with current self-tracking devices and future requirements. Their key results showed that their participants only found the distance and time parameters useful and perceived calorie consumption, pulse, steps, and training intensity as inaccurate [39]. Their study participants commented that "some activity trackers provide reminders that assume that the user can walk" [39]. The authors concluded that accurate activity trackers designed for wheelchair users are needed. It is not obvious from this publication whether the participants were daily users of the technology or whether the technology was given to them for study purposes, and we do not know whether they were professional athletes.

To summarize, research on self-tracking and self-tracking technology and its use by wheelchair users with SCI is primarily focused on either building technology for them or gathering requirements and their opinions on contemporary commercial self-tracking technology, with which they may have limited experience [5-7,11,25,39]. Our research enriches this body of knowledge [5-7,11,25,39] with lived experience of people who track or tracked their activity or use or used commercial self-tracking technology. This study also increases the body of knowledge of everyday lived experiences with self-tracking devices and self-tracking for an often underrepresented community in technological research—wheelchair users with SCI [40].

More Reasons for Inclusion in the Design of Commercial Technology

People with disabilities are often considered users of "special" products designed explicitly for them instead of active participants in the mainstream market [41]. "Special" targeted products would have a smaller share in the market, and they may be more expensive and, therefore, inaccessible for many people with disabilities as people with disabilities—at least in the European Union (EU) [42]—tend to be at a higher risk of financial challenges. According to Eskyte [41], dividing the market into "average" and "vulnerable" users is an obstacle to incorporating accessibility requirements into general consumer product development. In 2025, all digital services and products in the EU market need to be accessible according to the EAA [10], which will urge practitioners to design digital products and services with a diverse audience in mind.

Publications in technological fields support that building things for people with disabilities often means building better things for everyone [9], and a systematic literature review [11] shows that research on technology for people with SCI tends toward user-centered design. Even though user-centered design focuses on the user by collecting information about them, building empathy—often by simulating their health conditions [43]—and potentially involving them in key stages of the design and development process, it does not seem to be enough. Bennett and Rosner [44] argued for a more participatory way of designing; instead of designing for the person who is different from the designers (eg, wheelchair users), we should design *with* them as part of the design team. Their research indicates that, by trying to simulate their life experiences, we do not treat them as equals but as something different from us, different from the norm [44]. While the solution to the limitations of current empathy-building methods seems to be the participation of the specific user group in the design process, participation does not guarantee technology acceptance [26] and may be hard to achieve [40]. For example, in the case of SCI, Kabir et al [40] support that, due to the impact of the condition on the user, for example, speaking or fatigue issues may have been excluded from the research because the collection methods of the designers and researchers are inaccessible. Kabir et al [40] describe that the methods need to be adjusted based on each participant's abilities, something that some publication forums and reviewers may consider a methodological weakness of a study.

This paper does not argue about replacing the involvement of people with SCI in research or user research. However, it gives an idea of how current people with SCI experience commercial self-tracking technology and describes some of their needs. Even though researchers and practitioners will need to involve people with SCI when designing accessible products, this study can act as a starting point to understand some people's experiences with SCI, their self-tracking habits, and their use of self-tracking technology.

Methods

We will first present the research context and then how the data collection and analysis were conducted.

Context of the Study

This research was conducted as part of a long-lasting cooperation among researchers in the human-computer interaction field; a researcher in physiotherapy focusing on wheelchair users with SCI; and a center for SCI in Gothenburg, Sweden. This cooperation aims to explore the use of affordable commercial wearables and build an application that uses the wearables' data to accurately calculate the collected variables specifically for wheelchair users with SCI. The project is based on research exploring the energy outtake for wheelchair users with SCI on specific exercises [21-24]. Within the scope of this project, we conducted interviews to understand *how wheelchair users with SCI experience self-tracking and the use of commercial self-tracking technology in their everyday lives*.

Ethical Considerations

At the start of the cooperation, the planned research was reviewed and evaluated for its ethical integrity following the process of the Department of Applied IT at the University of Gothenburg, Sweden. This qualitative study interviewed people with SCI on their tracking habits and use of commercial self-tracking technology. This type of research does not fall under any of the categories described by the Riksdag (the supreme decision-making body of the Kingdom of Sweden) as research requiring ethical clearance as no sensitive personal data or other personal data were collected or published [45]. The study did not have access to or collect interviewees' personal information prior to, during, or after interviews. The participants were informed about the study through an informed consent form and could ask questions before taking part. The information sheet also included details on how they could withdraw. The data of the participants were handled according to the Swedish implementation of the European General Data Protection Regulation. Participants received no compensation.

Recruitment, Data Collection, and Data Analysis

We conducted 9 semistructured interviews [46,47] with wheelchair users with SCI. Knowing from the literature [40] that we may face challenges in recruiting participants for interviews, we used nonprobability convenience sampling using the network of the SCI center in Gothenburg, Sweden, and personal connections. Eligible for participation were people aged >18 years who had SCI for more than a year and who used a wheelchair to move. If participants did not fulfill all the aforementioned criteria, they were excluded. The aim was to have a deep understanding of the experiences of the people who contacted us rather than having a certain quantity of data.

Due to the geographical distribution of the participants and to accommodate the interviews at any time the participants wanted (even if it was on short notice), we conducted the interviews and recorded them over Zoom video call (Zoom Video Communications). In that way, the participants could also show us how they tracked themselves if needed. The interview guide had three groups of questions: (1) introductory and background questions, aiming to get to know the interviewees and their habits concerning daily life and exercise activity, including mobility; (2) questions about experiences of self-tracking and self-tracking technologies before and after their injury, aiming to understand the relationship of the interviewee with self-tracking and self-tracking technologies before and after their injury; and (3) closure of the interview questions, aiming to allow the interviewees to add anything they wanted us to know and understand their interest in the results of the study. We did not collect any actual measurements of their physical activity, nor did we try to evaluate their physical activity based on any tool as the focus of this study was to understand their experiences with self-tracking and self-tracking technologies.

The average duration of the interviews was 45 (SD 12.9) minutes, with the shortest being 30 minutes long and the longest being 69 minutes long (390 min; 6.5 h of video recordings in total). All participants were Swedish; 89% (8/9) of the interviews were conducted in English, and 11% (1/9) were conducted in Swedish. The participants interviewed in English could communicate clearly and fluently in English. The interviews were transcribed, and the first author analyzed them through inductive thematic analysis [48] following the steps by Braun and Clarke [49]. The first author familiarized themselves with the data and found codes and initial themes (steps 1-3). All authors reviewed, defined, and named the themes (steps 4-5). In our qualitative and explorative study, we focused on providing a rich description of our participants' experiences with self-tracking and self-tracking technology rather than the frequency with which they talked about each theme. The quotes used were modified to remove repetitions and for grammatical correctness. The quotes taken from the Swedish-language interview were translated into English.

Methodological Limitations

To invite the participants, we used the connections mentioned previously. In the invitation, we informed participants that it would be an online interview; thus, participants who had difficulty speaking due to their injury or other reasons may have been excluded [40]. We expected a small sample who would have the time and energy to participate. To counteract this, we invited people with SCI to participate regardless of whether they were current or past users of self-tracking technology as long as they had tracked something related to their injury or physical activity at some point. We focused on analyzing and obtaining a deeper understanding of the experiences of the 9 people rather than on collecting more data.

Results

Overview

A total of 22% (2/9) of the participants were female, reflecting the gender ratio of SCI at 20% female [50]. In total, 22% (2/9) of the participants had never used self-tracking technology, but they had all tracked some variables. Apart from participant P5, no one was currently an athlete. All the participants (9/9, 100%) were well past their first year of living with SCI, characterized as phase 3 or the chronic phase [40]. No participant had any serious issues with breathing or speaking during the interview regardless of their level of injury. More details about each participant's sex, age, years with SCI, and use of self-tracking technology, as well as the code used to refer to them in the following sections, can be found in Table 1.

Table 1. Demographics of the participants, including their use of self-tracking technology.

Participant code	Sex	Age group (y)	Years with SCI[a]	Use of self-tracking technology
P1	Male	50s	35	Yes
P2	Female	40s	31	Yes
P3	Male	30s	5	Yes
P4	Male	≥65	29	No
P5	Male	30s	12	Yes
P6	Male	40s	13	Yes
P7	Female	≥65	40	No
P8	Male	60s	6	Yes
P9	Male	50s	—[b]	Yes

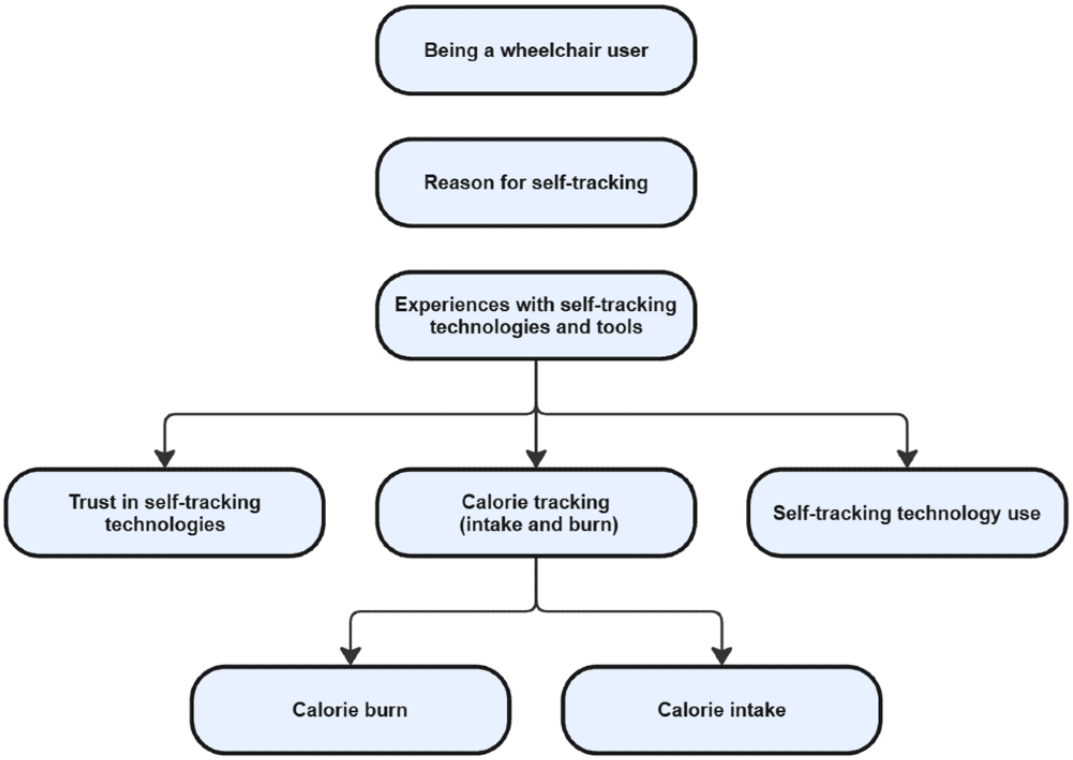
[a]SCI: spinal cord injury.

[b]Not applicable.

In total, 78% (7/9) of the participants had extensively experienced self-tracking technology; however, this high level of engagement with technology should be considered within the context of the study. People living in Sweden use IT daily for mundane things (eg, mobile payment is common; 92% of the population) [51]. In addition, Sweden is among the 7 countries in the EU with the lowest gap in employment between people with and without disabilities, which may have allowed our participants to have enough income [52] to purchase self-tracking technologies.

The thematic analysis resulted in 3 themes, one of which had 3 subthemes. The first theme, *being a wheelchair user with SCI*, included codes relevant to the participants' descriptions of their activity levels, themselves, and their lives. The second theme, *reasons for self-tracking*, included codes related to the participants' self-tracking habits. The third theme, *experiences with self-tracking technologies and tools*, included subthemes related to self-tracking technology use, calorie tracking (intake and burn), and trust in self-tracking technologies. Figure 1 provides a more illustrative understanding of how the themes are structured. The figure is designed to be read from top to bottom and left to right. A tabular form of the figure can be found in Multimedia Appendix 1.

Figure 1. The final themes that resulted from the thematic analysis in a diagrammatic representation. Multimedia Appendix 1 shows the representation of the themes in a tabular form with a summary of the main findings.



Being a Wheelchair User With SCI

This presentation of the participants aims to increase our empathy and understanding of how they experience their lives as wheelchair users and as former walking persons. Wheelchair users with SCI experience life first as walking people and then as wheelchair users. This means that they must adjust to their new body and develop new skills and often see themselves and their life divided into 2 periods—before and after the injury. For example, P8, who had a physical job and changed to a desk job after becoming a wheelchair user, mentioned that "before the injury, I did not track [my activity]. You could see I was physically in a good place. I was very masculine. After the injury, it is another story...you need to train, of course, a lot of rehabilitation." The various SCIs can influence people's bodies and lives differently, widening the diversity of their bodies.

Our participants dealt with the change in their skills in five ways: (1) adjusting their previous knowledge to the new situation, (2) giving up old habits, (3) being challenged to keep old habits, (4) reflecting on the behavior of their body, and (5) acquiring new skills. For example, regarding item 1, P3 adjusted his previous knowledge to the new situation in the following way:

> *I knew what because of my experience before the injury. I knew how to train, [but] I had to adapt to the situation I got into. I could not do everything in the same way, but I got some tips from the rehabilitation clinic, and I tested them myself.*

Others had advanced skills as non–wheelchair users that they lost when they became wheelchair users. For example, regarding item 2, P9 preferred to give up old habits "since I know that I have been playing badminton at a certain [high] level, it is frustrating to find myself being bad at it in the wheelchair. So maybe I would rather play tennis or basketball," whereas others saw their new life as a challenge to keep doing what they used to do. For example, regarding item 3, P1, who used to ski before his injury, felt that sit skiing would not be a challenge. When he tried it and realized how difficult it was for him, he was challenged to keep skiing:

> *I tried [sit ski], then it was so super hard.... So somewhere, it triggered me that I need to practice to get better at it.*

Regarding item 4, P9 reflected that his body did not react the same while running. As now he was not using his legs but his arms to move the wheelchair, it was harder for him to raise his pulse and feel the effects of exercise before his arms got tired. All of them had to learn to use a wheelchair, and the learning experience differed from person to person (item 5). For example, P4, one of the main organizers of a wheelchair community, mentioned that, when he started using a wheelchair, there was not much support but, in his community, they support others with basic wheelchair skills:

> *[W]e [practice] with balancing the wheelchair [on the back wheels] without dropping it back. [It] is very useful and hard skill.... It is very dangerous [as] you can hit your head.*

Everyday activities take more time based on the level of the injury and how it has influenced the body. For example, P7 mentioned that "I have to take care of myself and then work...it takes a lot of time," so she did not have much time to dedicate to exercising. P6, who worked at a rehabilitation center where people stayed for several weeks, said the following:

> *[R]ehabilitation is a lot about...you come here for 4, 6, 8, 10 weeks and you lay a foundation, but to get to be autonomous/independent. You need to continue when you get home because that's where you really need to put in the effort. And I tried to be clear with patients that this is the beginning. When you come home, that's where the struggle or the real-life starts.*

P6 underlined that, when one is in the rehabilitation clinic, they are free from daily responsibilities that may increase when they return to their daily life and take time from the exercise levels they need to sustain. Finally, P4 and P8 pointed out that, in addition to SCI, one develops more chronic conditions due to aging (eg, P8 kept track of his diet due to type 2 diabetes, and P4 tracked his blood pressure and related medication because he had a myocardial infarction).

To summarize, wheelchair users with SCI need to learn to know and adjust to their new bodies—bodies that are diverse by nature combined with the type of injury. When they learn basic wheelchair skills, they must deal with everyday life, which of course takes time for everyone, but for them, it can take time from their exercise. Exercise is a vital part of the high level of activity they need to sustain to be independent and healthy.

Reasons for Self-Tracking

Habitually, inpatients in rehabilitation clinics are told to document their activities or have them tracked during any type of rehabilitation or training related to their injury. However, few of our participants described this as tracking. For example, P9 mentioned the following:

> *If one is in rehab, one should keep track so they can see that the exercise is working...*

P7 remembered tracking during her injury-related training:

> *[Y]ou get a mentor that you can check up to after a couple of weeks, then you must make a new measure and see how you are doing. That was very useful.*

P8 reflected on the lack of technology and feedback during rehabilitation:

> *I think I get the idea [of tracking] from having to fill out all those forms when I was in the rehab center. Every week I have to write on paper, my weight, how much I lost when I went to the toilet, how much I ate on a particular day...and then the doctor concluded...[what I should change]...with the technology we have today just putting that on paper was not doing anything to me...I was just waiting for the outcome from the doctor.*

Our participants had different motivations for tracking. A total of 44% (4/9) of them (P1, P2, P5, and P9) mentioned that they had started tracking as they were practicing a sport. They tracked because their coach had told them to, or their coach did the

tracking for them. However, all of them kept tracking their behavior even after stopping exercising. P2 tracked variables related to swimming (eg, swimming style, time, and meters) as she was training for the Paralympics; nowadays, she tracks the activities she does through her Apple Watch as "it's so simple...the watch does it for me" and also uses it as a motivation to move—"it kind of reminds me to move" and "it keeps track, and it tells me you did a good [job] today." P1 mentioned his reaction the first time he was asked to track variables related to skiing (eg, weather conditions, exercise type, and timing) and how he came to keep tracking his activities:

> *Well, it was the trainer who said, you need to keep track on what you do. Why I've already done it. That was my answer. But then I started to do it. And then I realized that let's say after one season, I looked in the diary [and thought] oh, I need a lot of those things and [those things] didn't pay off. Maybe I should do less of those things since they don't pay off so much and maybe I should increase the things that pay off.*

P9 continued reflecting on his motivation for tracking his activities using his Apple Watch:

> *[I]t is not so much that I want to be in a national team or anything, it is more important that I can stay healthy and be a part of family activities and continue to do that. That is the most important thing to me.*

P3 mentioned keeping track of his training, especially when making changes to his training activities:

> *When you gonna train intensively for a month or something, I think it's interesting to keep track of your training. If you have a goal or race as well, which I don't right now.*

He reflected the following:

> *Yeah, I think most parts of tracking is for motivation for me at least, and then also, it's just interesting to see some data.*

P2 and P3 mentioned that they used tracking to increase motivation, as did P6:

> *[I]t's mostly motivation to see that to give myself a pat on the shoulder.*

Some participants (P1, P5, P6, and P9) tracked their activity before their injury as they were practicing different sports or participating in competitions. On the other hand, P4, P7, and P8 were not interested in tracking or were motivated to track only after their injury. P4 tracked his activity only as part of a game his colleague created—a point system that considered activities one did (eg, walking) and measurements of weight, waist, and chest. The person with the most points won. The point system was adjusted for P4 as he was in a wheelchair. P4 mentioned this game:

> *It was like, a challenge, you know...we challenge ourselves and even checked together "now I'm up to 2000 points" or whatever.*

P7, who had a higher level of injury, mentioned that she was never interested in tracking but that she kept track of her weight and the time it took her to move between places in her house:

> *[I]f you go to the bathroom, I got to make it in 10 minutes, [to] compete with myself to do with it as quickly as possible.... The only thing I track is my weight. My heart rate is no use because I can't get [much variation]*

P8 mentioned that he started feeling the need to track after his injury; before, he could simply see that he was muscular.

Summarizing, our participants performed a lot of tracking during their rehabilitation period to support the health care professionals following them, but the tracking was done on paper. Those training before their injury had a habit of tracking different variables and found value in tracking, but not everyone felt the need to track. In any case, the injury changed the way in which our participants tracked, either from not needing to track to needing to track or by changing the reasons for tracking and the variables they tracked.

Experiences With Self-Tracking Technologies and Tools

In this section, we will present the experiences of our participants with self-tracking technologies and tools through three subthemes: (1) use of self-tracking technologies, (2) tracking calories, and (3) trust in self-tracking technologies.

Self-Tracking Technology Use

The participants had experience using the Apple Watch, Runkeeper, Polar Beat, Pulse Polar Watch, and Nike+. While these technologies automate tracking and keep score of data, the participants also used manual means of tracking data about themselves. They mentioned using Microsoft Excel, a stopwatch, Lifesum, and paper as examples of manual means of self-tracking. One participant (P5) also mentioned that they "track in my mind." However, the most recurrent technologies in the responses were Apple Watch and Runkeeper.

Before their injury, only P6 and P9 used technology (Nike+ Running App) to track their activity. P1 kept a logbook with ski-related variables (he continued after the injury until he bought his Apple Watch), and P5's coach tracked his activity and gave him a schedule or advice accordingly. After their injury, participants P3, P5, P6, and P9 started using the Runkeeper app, which includes a wheelchair user mode. P3 and P5 used it to measure their speed and the distance they ran, and P6 and P9 used it to train for marathons or similar events. However, P9 mentioned that he had given up on Runkeeper because it did not work well with his Apple Watch:

> *Nike, that's actually what I used when [training for the] world run because it's, it's pre-installed in my Apple watch. So, when I got the Apple Watch, the first thing I did was download RunKeeper on my Apple watch. But I noticed that it wasn't attached to it with all its [features]. But there was also already a running up called Nike.*

P1, P2, and P9 were using Apple Watch to track their activities. Apple Watch includes an option for wheelchair users. In the

default mode, the Apple Watch tracks many activities (eg, biking, swimming, and skiing). However, if one sets it to the wheelchair user mode, only 4 activities become available: wheeling in- or outdoors and walking or running speed. P2 preferred to track her activities separately and used the default mode:

> *So most of the time I use the activities that are in the watch. I'm aware that they [calories] are not adapted for me and my muscle mass. That is not the important thing to me. For me, the important thing is that kind of keeps track and tells me that—okay, you did a good job.*

For P2, it was more important to track her activities and obtain positive feedback than to have access to accurate measurements of some of her activities.

The Apple Watch also displays 3 concentric rings: the inner blue ring shows how many times in the day one has moved (ie, changed position), the middle green circle shows how many minutes of brisk activity one has had, and the outer red circle indicates the active calories burned throughout the day. When P2 referred to the positive feedback she received, she meant how full these rings were. P1 and P9—who used the wheelchair mode on their watches—also looked at those rings for a quick daily overview. P9 mentioned the following:

> *[I] look at it but I don't pay too much attention to it.... I can see that I have done my full day's work and that's kind of the analysis I do, not so much else.*

Some of our participants used other apps and devices. For example, P8 had tried the Samsung Health app, but the measurements provided were not relevant to him. P1, one of the Apple Watch users, used a digital food diary (Lifesum) compatible with his watch to track his diet. P5, who was using Runkeeper, also used Polar Beat when training to measure his heart rate; however, he also considered the limitations of the technology. Specifically, he said the following:

> *I don't know if it's correct, but they mean that if you're a tetraplegic [injury level], your heart rate can't go over 120 Mm. And you can push as hard as you can. And you can't get over 120 But on the Polar-Beat that I [wear around the arm], I have been up to 136, I don't trust the one you put around [the chest] like this.*

This section shows that our participants were familiar with self-tracking tools. Many used or tried digital self-tracking technology after their injury, and some had done it even before. They tracked variables that could influence their sports performance or support them in understanding their body (eg, pulse and diet). They also tracked in less quantifiable ways, for example, what activities they did (eg, skiing or swimming) or the completion of goals set on their Apple Watch, which provided motivation. However, all participants mentioned calories and their measurement and consumption. Some expressed the need for a "lifestyle app" supporting them in healthy living as a whole—both in activity and diet tracking.

Tracking the Calories

Overview

When our participants talked about their experiences with self-tracking technology, the discussion always turned to calorie tracking or similar variables (such as weight and diet). Keeping a healthy lifestyle and not gaining weight is an issue for wheelchair users, and the impact of gaining weight on their life quality is tremendous. P9 was the most descriptive on how gaining weight could influence his life quality:

> *I just want one thing; I don't want to have to change my wheelchair into a wider one. If I get fatter, for example, it would be harder to make all these movements that I have to do in and out of the car every day, in and out of my bed every day in and out of the shower every day, or maybe every other day. Also, if because I'm getting fatter, if I have to get a wider wheelchair, I wouldn't get into certain doors, for example, in hotel rooms because my wheels are wider apart...I don't want that to happen and I'm ready to try any mechanical device to help me from not having to do that.*

This quote illustrates the potentially more serious consequences of gaining weight for wheelchair users and the need to track the calorie burn and, if possible, intake. P5 mentioned that "in our world, calories are very important," and P1 commented on weight gain and aging:

> *[W]eight is a problem all the time, especially now when I am getting a bit older, and it is easier to gain weight than losing it.*

Even P7, who seemed uninterested in tracking her activities and did not use any self-tracking technology, mentioned that "tracking it's not so important for me" but "I track weight because it is important for us." When our participants discussed tracking their calories, they mostly talked about calorie burn (P1, P2, P3, P5, P6, P8, and P9). Only 44% (4/9) of the participants (P1, P3, P4, and P5) mentioned calorie intake or diet, and only 11% (1/9; P7) mentioned weight (which can be perceived as a balance between calorie intake and burn).

Calorie Burn

As wheelchair users with SCI have less muscle mass than a walking person, they consume calories differently. P1 mentioned the following:

> *It is really hard for a paraplegic [injury level] to burn calories. It takes so much more time to burn the same amount as you [a full-muscle ability person]. If you're out jogging for one hour, I must wheel maybe for three.*

Therefore, to burn enough calories, they need to spend more time exercising.

Few commercial self-tracking technologies have their features adjusted to wheelchair users. Runkeeper and Apple Watch were 2 technologies mentioned by our participants that consider wheelchair users in some of their features. Our participants did not trust the self-tracking technology they used regarding calories and, instead, used other variables as a proxy for calorie

burn. Consequently, they managed their calories by staying active or using self-tracking technology as a motivation to stay active. P6 used self-tracking technology (FitNotes and Runkeeper) to keep a high level of activity in addition to motivating himself:

> *[One session] wasn't good enough, next week, I'm doing two sessions. And I'm taking the time [for an extra session] by putting something else out of my schedule. Or if, last week, I trained five times. I tell myself I did something good. Continue!*

P5, who used the Runkeeper app, underlined that he checked the distance and speed provided by the app but not the calories despite mentioning that calories were very important to him. He also discarded the calories that his wearable showed (Polar Beat, which measures heartbeat and calories), saying that "I don't care about the calories because I know...the calories are all wrong." P3 also mentioned heartbeat as an indicator for understanding that his training had an impact:

> *[H]eartbeat is always good because if your heartbeat races, you're doing something.*

He also reflected on a noncommercial smartwatch he had tried as part of another study that measured steps, finding steps not to be a good indicator or proxy for understanding his activity levels:

> *I do not know if I am moving a lot, I have more steps on my watch, but I do not know how it works and I do not know what it reduces it and what it does not.*

Similarly, P8 reflected that the visualization of steps in commercial self-tracking technology as an activity proxy was irrelevant to him:

> *Samsung health (smartphone) counts my steps which is not connected with the reality...Like FitBit.*

Apple Watch is one of the self-tracking technologies that has adjusted some of its features for wheelchair users (eg, wheeling in- or outdoors and walking or running pace); however, only P1 trusted and followed their calorie burn. In contrast, P9 pointed out the following:

> *I have my Apple Watch on when I do [strength exercises]. I guess it's not smart...it tracks some of the movements I make as a push in my wheelchair. It was the same with that would that pole pooling...it doesn't track it as something else than kind of push with the wheelchair.*

Thus, the watch counted his calories based on the strokes he did to move his wheelchair, and he argued that, regardless of what exercise he did, the watch would always measure only wheeling in- or outdoors and walking or running pace but not the actual exercise. Therefore, the calories could not be estimated based on a different activity but only on the strokes he did, so he did not pay attention to them but used the watch mainly for motivation. P2, another Apple Watch user, said the following:

> *[A]ll other activities are in there, but they are not adapted for people with no full muscle ability. With that said, I had kind of decided that it doesn't really matter if I spent 300 calories or 500 calories.*

She added that she used the watch to motivate herself to move. Thus, she preferred to use the Apple Watch in the default mode rather than in the wheelchair mode, favoring the ability to track different activities over a more accurate calorie estimation.

Some participants also used nontechnological means to measure their calories manually. For example, P1, who was part of a medical research project on SCI, became aware of the connection between his energy consumption and his pulse and took action based on that:

> *[B]efore being part of the project about energy consumption for a disabled person, I had no way to determine how much energy I consume during the day but after that, I made charts because I have a really strong correlation between pulse and how much energy I consume.*

To summarize, a person with SCI consumes calories at a slower pace than a full-muscle, able-bodied person and needs to be more active to burn the same amount of calories. Most commercial technology currently in the market does not account for this difference, which leads to apps incorporating the wheelchair symbol without adjusting the calorie burn for this type of user or apps calculating the calorie burn correctly but only for limited activities. Thus, our participants estimated their calorie burn based on how many exercise sessions they did or their heart rate increase. Self-tracking technology was used mainly for motivation, and steps were not perceived as a good proxy for activity tracking or calorie burn.

Calorie Intake

Weight is impacted not only by calorie expenditure but also by calorie intake. For example, P4 said that "Exercises are good but if you don't stop eating too much, you will never lose weight." Just like P3 adjusted his exercise knowledge to the new situation, P5 needed to adjust what he knew about diet. Before the injury, P5 had a personal trainer who planned his weekly exercise and diet, for example, to gain muscle. However, P5 mentioned that he found that he could no longer follow what he had learned from his trainer after the injury:

> *When I ended up in a wheelchair, I was used to having the [diet and exercise] paper in the back of my head. But every other person in a wheelchair said you can't eat as much as you did before. So today I'm eating small portions but more often. I don't do breakfast, lunch, dinner.*

P5 had to adapt his weight management after becoming a wheelchair user by avoiding the traditional food distribution throughout the day.

Even though participants were interested in counting their calorie intake, only P1 used a dietary app, called Lifesum. He mentioned that the intake of calories was also important and that it would be interesting to have a daily calorie goal and take note of the type of diet one follows, if applicable. P1 said the following:

> *An app that could measure what I eat, and I can put in parameters like, [amount of] calories [that] are ok for the day, and any kind of diet I follow.*

Another participant, P7, felt that she had control over her diet owing to a course organized for people with SCI that she took after her injury:

> *[In this course] you start tracking everything, they check your weight and height, how you train and exercise, how you feel—everything. And then you get a plan and learn a lot [about] bad calories, and you know exactly how much you are going to eat and how to change...you get a mentor that you can check in with after a couple of weeks, then you [must] make a new measure or everything and see how you are doing. That was very useful.*

Here, instead of using a tracking tool, the user learned how to manage their calorie intake in an educational setting, when episodic measurements were made, and then made sense of them with the support of their mentor.

The participants expressed that calorie intake was as important as calorie burn. They described that they had to adjust their eating habits after the injury to fit their new bodies. Even though only P1 used self-tracking technology to track their diet, other participants mentioned that they had to undergo training or go through an adjustment period to learn how much they could eat by tracking their diet.

Trust in Self-Tracking Technology

P1, P2, P3, P5, P6, and P9 used self-tracking technology to track their activities but did not trust this technology, especially regarding the calories. P1 trusted his Apple Watch because "Apple bought a survey conducted in the US that was about paraplegics, working [out], and how much calories [they burn] with which workload. And they put that algorithm in the watch. For example, let's say a paraplegic person has a 30% slower or lower metabolism compared to able-bodied, that is in consideration in this app." He compared his watch to Runkeeper:

> *I'm out wheeling with 100 pulses; I get depressed because it's like 210 calories. But if you go to RunKeeper, and you have been jogging for one hour, you have 700 calories. So, if you use that app, you will be so fooled and tricked by it. Because it is hard for a paraplegic to burn calories.*

P1 made a comment on commercial apps using the wheelchair symbol deceptively:

> *[Y]ou have apps on the market RunKeeper, or whatever, you download it because it has a wheelchair symbol [thinking] Oh, yeah, this is a cool company, they even bother to [consider] wheelchair [users]. Yeah, but people don't understand. That's a chart with calories from an able-bodied person. They just replace the running person symbol with the wheelchair symbol.*

P2 was dissatisfied that, as a wheelchair user, she could only track 4 activities on the Apple Watch. Therefore, she preferred to use the watch without the wheelchair user setting to keep track of the different activities rather than accurately tracking the calories—as the quote in the previous theme shows. Despite this, P2 stated that they were an "Apple family" and that she trusted Apple because "it's people I know that are interested in technology that buy all the gear and try all the gear out that's Apple Watch is good I'm buying kind of trusted them Yeah. And my husband recommended and said that it would be worth it [now] that I had already started to add more exercise into my life, and I thought that could be a good fun thing to try." In this case, what made the technology more trustworthy was not the actual technological features but the social context. On the other hand, P9 did not trust his Apple Watch to accurately calculate the calories because it tracked everything as strokes on a wheelchair regardless of the type of activity—as his quote in the previous theme showed. However, he mentioned that he trusted his Apple Watch more than an app on his phone as he could not see how an app could track accurately:

> *[T]here was a wheelchair feature that I can put [in the RunKeeper], instead of running or cycling, I put it on the chair. But for example, it didn't track my pushes, because it can't track my pushes, it seems it's only on the phone. So, I think it helps that it's on my Apple watch on my hand to be able to keep track of [the pushes]. So, if I only have the phone in my, pouch that I have on my sitting pillow, or I have it on my arm higher, it doesn't track my movement in the same way.*

P9 expressed his distrust of Runkeeper because it did not provide the user with an explanation of how the app measures the calories of a wheelchair user.

Similarly, P3 and P5 mentioned that they did not trust the technology they used (Runkeeper and Polar Beat) regarding the calories it presented them with. Specifically, P5 mentioned the following:

> *Now it's like, if I go for a walk, it shows how far and the pace and even it [RunKeeper] shows the calories. But I do not think the calories are exact, so I don't care so much about the calories.*

He explained that, apart from calories, "I trust just the RunKeeper because it's like a map, a GPS. You have walked three kilometers. You got the pace for each kilometer." This quote illustrates that, despite P5 distrusting some features of the app (calories), he trusted others that were more easily understandable. He added the following:

> *So for now, I'm pretty happy with the Polar-Beat it is just the calories are not...and it's not reliable.*

Although the user considered himself satisfied with the Polar Beat use, he chose not to rely on the calorie measurement.

Summarizing, trust in self-tracking technology (or the lack of it) is influenced by the perception of the participants regarding how the technology works and how the development company accounts for different bodies related to calorie burn.

Discussion

Principal Findings

This section recaps our contribution followed by a short discussion on trust and transparency related to self-tracking technology. Then follows a section with the implications of commercial self-tracking technology, which concludes with directions for future research.

To address the question of how wheelchair users with SCI experience self-tracking and commercial self-tracking technology in their everyday lives, we interviewed 9 wheelchair users with SCI who had experience with self-tracking or self-tracking technology. The last theme, *experiences with self-tracking technology and tools* in Figure 1 divided into 3 subthemes, shows that current self-tracking technology fails to accommodate wheelchair users' needs concerning calorie management in 2 ways. First, the current commercial technology calorie calculation is based on a body with full muscle ability and, therefore, is inaccurate for people with SCI (subtheme: *calorie tracking*), and second, the users do not trust the calories in the self-tracking technology (subtheme: *trust in self-tracking technology*). Nevertheless, the wheelchair users we studied continue to use self-tracking technology to motivate them to stay active and to monitor variables such as heartbeat, speed, and activity schedule as proxies for their energy consumption (subtheme: *self-tracking technology use*).

This research has limitations due to the small number of interviews and the positioning of the research in a technologically advanced country (Sweden), which also has 1 of the 7 lowest gaps in unemployment between people with and without disabilities in the EU. If the study had been conducted in a different context with, for example, lower technological literacy and use or lower employability of people with disabilities, the results may have differed, particularly on the number of people who have used self-tracking technology. Finally, all of our participants (9/9, 100%) were White. If our participants had had a darker skin tone, the results may have differed, particularly in relation to the *trust in self-tracking technology* theme as self-tracking technology is even less accurate on darker skin [53]. Nevertheless, this study adds to the body of knowledge by validating previous studies on the different variables that wheelchair users want to see. It expands the current body of knowledge by focusing on long-lived experiences of self-tracking and contemporary commercial self-tracking technology, especially on calorie management—the most important factor influencing the life quality of wheelchair users with SCI.

Our research contributes to the scientific community as follows. It extends the work by Malu and Findlater [5] on fitness trackers on wheelchairs by interviewing wheelchair users with SCI who had lived, daily experience with tracking their activity or self-tracking technologies. In line with the work by Malu and Findlater [5], our findings in the *calorie tracking* subtheme indicate that one of the most important values to be measured is calories (intake and burn), followed by distances, GPS data, and pulse, as indicated by the *self-tracking technology use* subtheme. However, our findings in the *calorie burn* subtheme indicate that steps are not a good variable to measure for wheelchair users, which contradicts the study by Malu and Findlater [5] but is in line with the work by Carrington et al [6] and Helle and Rosenbeck Gøegb [39].

Our research, specifically the *self-tracking technology use* subtheme, is in line with the work by Helle Rosenbeck Gøegb[39] regarding the tracking of distance and time. In addition, the *trust in self-tracking technologies* subtheme is partially in line with the results of Helle and Rosenbeck Gøegb [39] showing a lack of trust in technology related to some variables (calorie burn and training intensity). Our participants, similarly to those in the study by Helle and Rosenbeck Gøegb [39], trusted the self-tracking technology regarding their speed measurements and were interested in these measurements; however, neither the participants in the aforementioned study nor our participants trusted calorie burn tracking (see the *trust in self-tracking technology* subtheme). Some of our participants showed a lack of trust in training intensity as well (similarly to those in the study by Helle and Rosenbeck Gøegb [39]); for example, smartwatches counted every activity as a stroke on a chair without distinguishing it from upper-body strength training (see the *trust in self-tracking technology* subtheme). Finally, our findings in the *reasons for self-tracking* theme suggest that being able to track different activities and calorie burn and keep track of exercise schedules, as well as seeing activity goals being reached, was motivational for our participants to keep the active lifestyle they needed, which is in line with the findings of past research [27,28,54].

Trust and Transparency

Participants' trust in self-tracking technologies was heavily influenced by their understanding and perception of how these devices worked. For example, Apple Watch users often trusted the device more than phone apps, believing that the watch's ability to track arm movements made it inherently more accurate than a phone carried in a pocket. However, this trust was conditional and limited; participants expressed confidence in the calorie estimates only for the 4 wheelchair-specific activities provided by the device. Regarding other activities in which calorie expenditure was approximated using these predefined categories, they expressed skepticism about accuracy. This led to varying strategies—some participants attempted to fit all their activities into 1 of the 4 wheelchair-specific categories to achieve more reliable calorie estimates, whereas others discarded calorie tracking entirely and used the watch in nonwheelchair mode to access a broader range of features.

Previous work on trust in self-tracking technology has revealed that users often have a *mental model* of how apps or devices work and calculate data [55]. Trust in self-tracking technologies, particularly in the context of wheelchair users with SCI, hinges significantly on the transparency of how data are collected, processed, and presented. Participants in our study exhibited a nuanced understanding of their devices, often forming mental models to rationalize the data's validity. However, the perceived "black box" nature of calorie calculations—whether on the Apple Watch or Runkeeper—fostered skepticism. This reinforces previous findings that transparency regarding algorithms and data processing is critical for trust [56]. On the

basis of this, we suggest that designers prioritize user education by including detailed explanations of their algorithms, especially when adapting generic metrics such as calorie burn for niche user groups, such as wheelchair users. This aligns with broader calls [57,58] for designing technologies that foster informed trust.

Furthermore, trust in technology is not isolated from social factors [59]. Apple Watch users' trust was partially rooted in social recommendations and previous brand experiences. This suggests that trust may extend beyond technical accuracy to include the brand's perceived reliability and commitment to inclusion. Investigating the interplay between social networks, brand trust, and technology adoption among wheelchair users could provide further insights into how collective validation influences individual trust decisions.

Distrust in calorie tracking was not merely technical but also emotional, linked to fears of inaccuracy impacting critical life decisions (eg, managing weight to maintain mobility). This illustrates that trust is not just a cognitive process but a deeply affective one. Incorporating participatory design with wheelchair users at every stage of the design and development process—testing, iteration, and after launch—can mitigate such emotional concerns. By co-designing solutions, developers can address both the technical and psychological dimensions of trust.

We observed how distrust often led participants to bypass calorie metrics altogether, choosing instead to focus on other variables or manual methods. This self-empowerment reflects resilience but also signals a failure of the technology to deliver on its promise. Therefore, tools must enhance user agency by aligning design goals with real-world constraints and expectations.

Finally, we observed a mismatch between representation and actual design. Runkeeper users appreciated the app's reliance on GPS and speed data, which they found straightforward and comprehensible. However, despite this, they distrusted the app's calorie calculations even when using its wheelchair mode and described feeling misled by its implied inclusivity. The use of wheelchair symbols created an initial perception of inclusivity but, ultimately, resulted in feelings of deception among participants due to inaccurate calorie calculations. This reflects a broader issue in which symbols and icons signaling accessibility and inclusiveness are in fact merely superficial. Misrepresentations such as these can diminish trust but also risk alienating the very communities that the technologies claim to support. Implications such as these are discussed further in the next section.

Implications for Commercial Self-Tracking Technology for Wheelchair Users With SCI

The most important need and valuable variable for our participants (subtheme: calorie tracking), and of the participants of previous research with wheelchair users, was the accuracy of calorie consumption [6,39,60]. Previous research [6,39,60] and our participants indicated that commercial fitness and wellness technology that uses the wheelchair symbol does not necessarily calculate accurately the calories burned by wheelchair users (subtheme: *trust in self-tracking technologies*). Research [6,39,60] also indicates that specific technology for wheelchair users needs to be developed, personalized, and tailored to their needs, which underlines the importance of tailoring mainstream self-tracking technology to the user group that it intends to include [61]. Furthermore, there is extensive research on wheelchair user–specific technology for self-tracking health and well-being [27,28,54], as well as exploring current technology with wheelchair users to inspire designs of wheelchair user–specific fitness and wellness technology [5]. Even though a big part of the aforementioned literature focuses on assistive technology or technology specifically for wheelchair users, mainstream self-tracking technology that aims to be inclusive toward wheelchair users can take advantage of what assistive technology research can offer (eg, databases and artificial intelligence models) [30,31], as well as what the medical field offers, which already has some physical activity guidelines for wheelchair users [14,32,34,62].

On the other hand, the production of new wheelchair-specific self-tracking technology (which is not assistive technology) divides the market into wheelchair users and non–wheelchair users. Recent research [41] indicates that, by excluding specific populations from the development of commercial products, the incorporation of accessibility requirements into general consumer products comes to a halt. In addition, special technology could cost more as it targets a specific population. Regarding wheelchair users, special technology may not be a financially viable solution as they have a higher risk of financial issues [42]. Working with affordable materials to create new technology for a specific population can also lead to them not using it because it could be stigmatizing [63]. From 2025 onward, digital services and products in the EU market should be accessible according to the EAA [10,49]. Our findings show that the self-tracking technology currently in the market is not prepared to be accessible to wheelchair users with SCI. This technology is not trusted when it comes to calorie calculation. Our participants described how they used proxy variables to estimate their calorie consumption and activity level. They expressed the need for a self-tracking technology that accurately calculates their calorie intake and burn during a variety of activities. Many of the issues with self-tracking technology that uses the wheelchair symbol can be solved by involving wheelchair users in the design and development phase. This involvement will make the technology more relevant to the people it aims to include (ie, wheelchair users) and open the market to broader audiences [64-66].

On the basis of the literature presented in this paper and our findings, we see a need for future research and development regarding inclusive self-tracking technology for wheelchair users with SCI supported and inspired by assistive technology literature.

First, there is a need to explore ways to make affordable technology already used by wheelchair users closer to their needs and make it more accurate regarding calorie burn (ie, track a variety of activities and calorie intake). Our study can be seen as a starting point for this exploration of commercial fitness self-tracking technology and its use by wheelchair users with SCI, complementing previous literature on similar subjects [5-7,11].

Second, we argue that there is a need to confront and acknowledge the limitations of the methods used to conduct similar research and alternate them for the research and practice to be more inclusive. According to Kabir et al [40], data collection and design methods may be inaccessible to some populations, leading researchers to exclude them as they perceive them as "difficult to reach and research." Instead, they suggest having a palette of methods and adjusting them based on the participants' abilities [40]. Similarly, Moon et al [37] provide a comprehensive toolbox for more inclusive user research when designing with wheelchair users in mind. In addition, Li et al [30] and Huang et al [31] provide freely available concrete tools (ie, databases and code) for developing an inclusive self-tracking technology to be used by anyone wanting to make self-tracking technology more inclusive.

Third, regardless of all the support that this paper and the literature provide, the inclusion of wheelchair users as an integral part of the design process of the self-tracking technology targeting this demographic should be seen as mandatory for the product to be relevant to the new audience (ie, wheelchair users) [65,66].

Future Research

Our next steps are a series of participatory workshops in which we—together with people with SCI and the support of the SCI center we partnered with—identify further tracking needs and co-design a first version of an app that could support them in learning about their new body in different stages of their postinjury phase. In the workshops, we plan to include the physiotherapist who cooperates with us to include the health care perspective without compromising the power balance. His participation will also create an environment in which the participants can learn more about SCI and how the health care system perceives SCI and them as patients. To create a link for the communication between health care professionals and people with SCI, we will use the connections of our partner at Karolinska Institute to investigate the needs of health care professionals (ie, which of the data tracked by people with SCI are relevant to the health care professionals and in what form to fit their practice when consulting with their patients).

Acknowledgments

The authors thank all the people who dedicated their time to participate in the interviews. Without their contribution and their rich experiences, this study would have been impossible. The authors thank their collaborators from the spinal cord injury center that supported this research and helped them find participants for this study.

Authors' Contributions

VM led the research and the writing process of the paper. VM designed and conducted the interviews and the initial thematic analysis with support from KC. AW and MR participated in the later stages of the thematic analysis and contributed to the overall writing of the paper. TH contributed to the writing of the paper and was responsible for the medical accuracy of the paper regarding spinal cord injury.

Conflicts of Interest

None declared.

Multimedia Appendix 1
The final themes resulting from the thematic analysis in a tabular form.

Abstract

Background: Digital health competence is increasingly recognized as a core competence for health care professionals. A comprehensive evaluation of knowledge, skills, performance, values, and attitudes necessary to adapt to evolving digital health technologies is essential. DigiHealthCom (Digital Health Competence) is a well-established instrument designed to assess digital health competence across diverse health care professionals.

Objective: This study aimed to translate and culturally adapt DigiHealthCom into simplified Chinese (Mandarin) and verify its reliability and validity in assessing digital health competence of Chinese health care professionals.

Methods: DigiHealthCom was translated into Chinese following the guideline proposed by its original developers. The cultural adaptation involved expert review and cognitive interviewing. Internal consistency, test-retest reliability, content validity, convergent validity, discriminant validity, and factor structure were examined. Item analysis tested item discrimination, item correlation, and item homogeneity. Internal consistency was assessed using Cronbach α, and test-retest reliability was measured using the intraclass correlation coefficient. Content validity was assessed through both item and scale content validity indices. Convergent validity was measured by the Average Variance Extracted and Composite Reliability, while discriminant validity was measured by the heterotrait-monotrait ratio. A five-dimension model of DigiHealthCom was confirmed using confirmatory factor analysis.

Results: The finalized Chinese version of the DigiHealthCom was completed after addressing differences between the back-translations and the original version. No discrepancies affecting item clarity were reported during cognitive interviewing. The validation process involved 398 eligible health care professionals from 36 cities across 15 provinces in China, with 43 participants undergoing a retest after a 2-week interval. Critical ratio values (range 16.05 - 23.77, P<.001), item-total correlation coefficients (range 0.69 - 0.89), and Cronbach α if the item deleted (range 0.91 - 0.96) indicated satisfactory item discrimination, item correlation, and item homogeneity. Cronbach α for dimensions and the scale ranged from 0.94 to 0.98, indicating good internal consistency. The intraclass correlation coefficient was 0.90 (95% CI 0.81 - 0.95), indicating good test-retest reliability. Item content validity index ranged from 0.82 to 1.00, and the scale content validity index was 0.97, indicating satisfactory content validity. Convergent validity (average variance extracted: 0.60 - 0.79; composite reliability: 0.94 - 0.95) and divergent validity (heterotrait-monotrait ratio: 0.72 - 0.89) were satisfactory. Confirmatory factor analysis confirmed a well-fit five-dimension model (robust chi-square to df ratio=3.10, comparative fit index=0.91, Tucker-Lewis index=0.90, incremental fit index=0.91, root-mean-square error of approximation=0.07, standardized root-mean-square residual=0.05), with each item having a factor loading exceeding 0.40.

Conclusions: The Chinese version of DigiHealthCom has been proved to be reliable and valid. It is now available for assessing digital health competence among Chinese health care professionals. This assessment can be used to guide health care policy makers and educators in designing comprehensive and implementable educational programs and interventions.

KEYWORDS

competence; digital health; health care professionals; instrument; reliability; validity

Introduction

The World Health Organization (WHO) defines digital health as the field that involves the development and use of digital technologies to improve health outcomes [1]. In 2019, the WHO released the world's first guidelines for digital health interventions, outlining 10 ways to use digital health technologies to enhance health and primary services [2]. This concept extends beyond eHealth to include a wide array of smart devices and connected equipment, encompassing digital technologies such as the Internet of Things, big data, artificial intelligence, and robotics [2]. The release of these guidelines was followed by the Global Strategy for Digital Health (2020 - 2025), which emphasizes prioritized digital health strategies for global health care development [1]. China has incorporated measures for the development of a digitally healthy nation in the 14th Five-Year Plan [3]. With the global market projected to grow from US $211 billion in 2022 to US $809.2 billion by 2030 [4], digital health care is recognized as a rapidly expanding sector. Digital health has emerged as a significant trend in the evolution of global health care services. The digital transformation that the health care sector is currently undergoing is redefining the roles and responsibilities of health care professionals [5,6], creating an urgent need for digital health competence among them.

Given increasing prominence of digital health in global health care landscape, it is critical for health care professionals to possess sufficient digital health competence. Digital health competence is increasingly recognized as one of the core competencies for health care professionals, which would enable them to design and evaluate the impact of digital solutions on patient care and determine the best way to implement digital solutions in their work [7,8]. Although patients are becoming more accepting of and motivated to use digital health care services and tools, health care professionals face a digital skills shortage that impedes the adoption of digital solutions [9-11]. Inadequate digital health competence may lead to negative experiences and frustration with technology adoption among these professionals [12]. There is a strong association between health care professionals' digital health competence and their willingness to use such tools [13,14]. Studies have highlighted that the acceptance of digital health technologies by health care professionals significantly influences the adoption of digital solutions and emphasizes the critical role of digital health competence in ensuring patient safety [12,14]. Therefore, assessing digital health competence is essential to effectively providing digital health care solutions to the public.

Previous studies have attempted to explore digital health competence among health care professionals but have struggled to define it comprehensively due to the evolving nature of digital technologies [15]. Existing assessment tools primarily focus on informatics competence, digital health literacy, or skills related to the application of digital technologies. Examples include the Digital Health Literacy Instrument (DHLI, 2017) [16], the eHealth literacy questionnaire (eHLQ, 2018) [17], and the Nursing Digital Application Skill Scale (NDASS, 2024) [3]. The eHLQ is designed for eHealth user, especially individuals with low digital health literacy and those with chronic conditions [17]. The NDASS targets nurses' digital application skills in clinical settings [3]. Digital health literacy reflects users' knowledge and skills within their cultural, social, and institutional context [17]. Competence entails an integrative understanding of the knowledge, skills, performance, values, and attitudes essential for the effective execution of a given task [18]. Therefore, it is crucial to comprehensively evaluate the knowledge, skills, performance, and attitudes required for various health care professionals to adapt to the evolving digital health technologies.

Developed and validated among Finnish health care professionals in 2022, the DigiHealthCom (Digital Health Competence) instrument offers a more comprehensive scope than existing tools and is applicable to a wide range of health care professionals. In addition to assessing competence in using digital solutions and information and communication technology (ICT), it also explores previously unaddressed domains that reflect future requirements, such as acceptance of digital solutions, human-centered remote counseling, and ethical competence concerning digital solutions [19]. Furthermore, the instrument has been used to explore digital health competence profiles and associated factors in 817 health care professionals from 9 organizations in Finland [20]. It has been translated into 15 languages, and a large-scale international cross-sectional study on the digital health competence of health care professionals is currently in progress. Our team is part of this collaborative research effort. This study aimed to culturally adapt and validate the Chinese version of DigiHealthCom for Chinese health care professionals.

Methods

Study Design

A cross-sectional study was conducted.

Participants

Participants were recruited between May 2023 and April 2024 via convenience sampling. Recruitment posters with QR codes were disseminated on social networks specific to health care professionals. In addition, health care professionals attending local academic conferences were invited to participate. The inclusion criteria for participants were (1) employment within a health care organization and (2) consent to participate. The exclusion criteria were (1) individuals who were retired or had less than 1 year of work experience; (2) health care students; (3) individuals who completed the questionnaire in less than 150 seconds, as this indicated random clicking; or (4) individuals who displayed erratic response patterns.

According to the thumb rule, the sample size should be 5 to 10 times the number of items. With an anticipated 10% rate of invalid responses, a minimum of 231 samples was necessary. Finally, a total of 398 cases were included in the study. To assess the test-retest reliability of the instrument, 43 participants who provided contact information completed the questionnaire again after a 2-week interval.

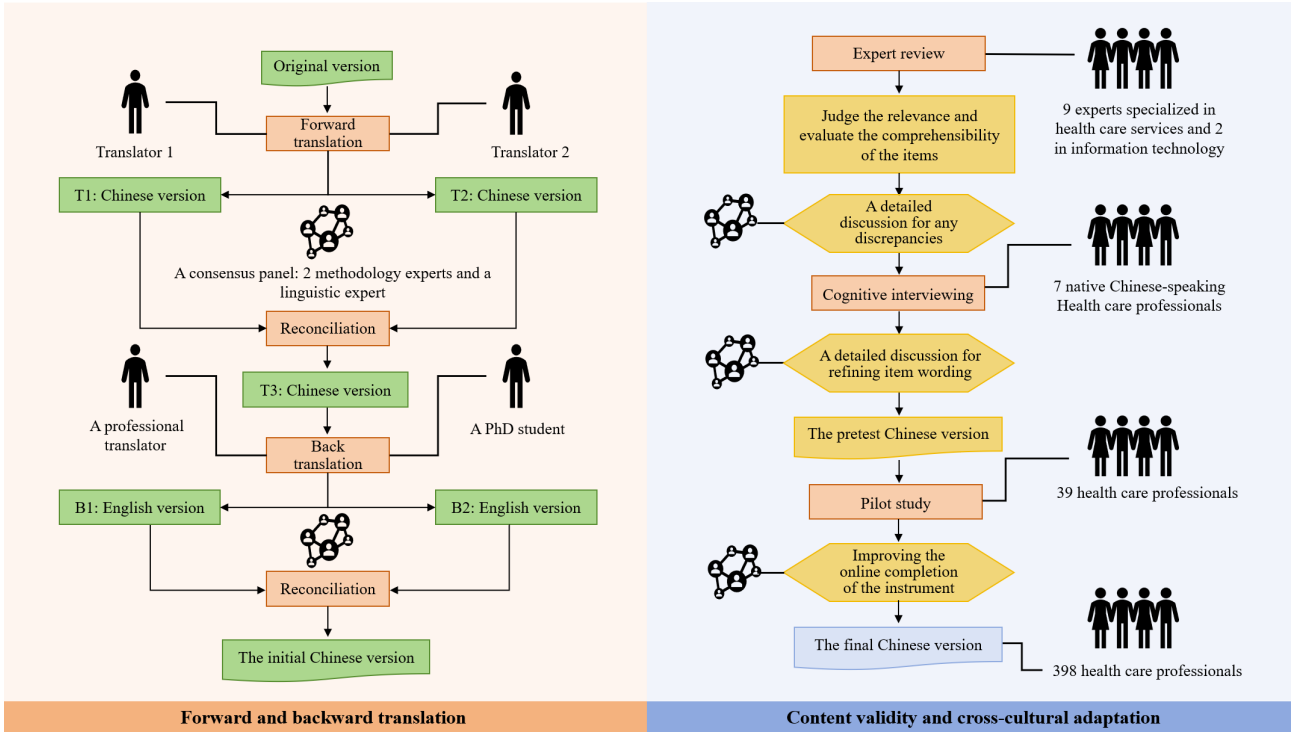
Instrument

The DigiHealthCom instrument comprises 5 domains, comprising a total of 42 items—competence in human-centered remote counseling (16 items), digital solutions as part of work (9 items), competence in ICT (5 items), competence in using and evaluating digital solutions (8 items), and ethical competence related to digital solutions (4 items). Each item was rated on a 4-point Likert scale (1=completely disagree, 2=partially disagree, 3=partially agree, and 4=completely agree). For each domain, a mean value of ≤2.49 indicated low competence, 2.50 - 3.49 indicated intermediate competence, and ≥3.50 indicated high competence [20]. DigiHealthCom has been validated among health care professionals across tertiary, primary, and private health care settings (n=817), demonstrating satisfactory internal consistency (Cronbach α=0.80 - 0.97) and content validity (item content validity index [I-CVI]: 0.77 - 1.00; S-CVI/Ave: 0.94) [19].

Translation and Cross-Cultural Adaptation

To ensure a high-quality Chinese translation of DigiHealthCom, a rigorous translation and cross-cultural adaptation process was followed [21]. Figure 1 illustrates the translation and cross-cultural adaptation process.

Figure 1. The translation and cross-cultural adaptation process of developing the Chinese version of the DigiHealthCom (Digital Health Competence) instrument.



Forward and Backward Translation

In total, 2 bilingual nursing professionals, who are native Chinese speakers (a nursing expert and a nursing graduate student), independently translated the English version of DigiHealthCom into Chinese, resulting in 2 forward translations (T1 and T2). A consensus panel reviewed these translations for conceptual equivalence, clarity, and comprehensibility, producing a reconciled version (T3). Subsequently, the T3 version was back-translated into English by a professional translator and a PhD student unfamiliar with the original version, both knowledgeable about Chinese and English-speaking cultures. The consensus panel reviewed and resolved discrepancies between the back-translations and the original version, finalizing the initial Chinese version. The consensus panel comprised 2 nursing researchers experienced in scale development and a linguistic expert.

Expert Review

To assess the content validity of the Chinese version of DigiHealthCom, 11 experts were invited to evaluate the relevance of its dimensions and items using a 4-point ordinal scale (1 [not relevant], 2 [weakly relevant], 3 [strongly relevant], and 4 [very relevant]). The expert panel consisted of 9 health care specialists and 2 IT experts. In addition, expert evaluated the comprehensibility of the items. The consensus panel, initially involved in the translation process, conducted a detailed discussion to resolve any potential discrepancies.

Cognitive Interviewing

Cognitive interviewing was used to evaluate the clarity and cultural suitability of the initial Chinese version. A total of 7 native Chinese speakers, including 2 doctors, 4 nurses, and 1 IT technician, were recruited. Participants were briefed on the study's objectives and methods before interviews, and their consent was obtained.

The first author, trained in qualitative research methods, conducted the interviews in a meeting room. Participants completed the Chinese version of DigiHealthCom independently and engaged in cognitive interviews. Interviewers evaluated whether participants found the items relevant to their condition and if they encountered any understanding difficulties. Field notes were taken. Modifications were deemed necessary if at

least 1 participant (1) found an item difficult to understand, (2) demonstrated mostly or completely inaccurate comprehension of an item, or (3) provided feedback indicating the need for improvements, especially regarding cultural relevance. The consensus panel determined whether to retain or alter item wording following expert review and cognitive interviewing. Discrepancies affecting item clarity were resolved to create the pretest version of the Chinese DigiHealthCom version. Specific item modifications were detailed in Table S1 in Multimedia Appendix 1.

Pilot Study

A pilot study was conducted with 39 health care professionals from a general hospital in Guangzhou, China. The pilot study confirmed that no further modifications were required. The final Chinese version of DigiHealthCom consists of 5 dimensions and 42 items.

Data Collection

Data were collected using the Wen Juan Xing (a Chinese web questionnaire platform) [22]. Respondents accessed the questionnaire by scanning a QR code or clicking a link, with 1 response allowed per IP address to prevent duplicates. The questionnaire platform performed completeness checks before submission. The Chinese version of DigiHealthCom was presented alongside a sociodemographic questionnaire. The questionnaire consisted of 2 pages and 73 items. Sex, age, education, service area, professional license, work experience, type of organization, and frequency of patient work were collected. Participants who voluntarily chose to provide contact information participated in a retest after a 2-week interval. An introduction outlined the study's purpose and provided questionnaire instructions.

Statistical Analysis

Item analysis was used to evaluate item discrimination, item correlation, and item homogeneity. For item discrimination, respondents were classified into high-score (top 27%) and low-score (bottom 27%) groups based on their total scores. An independent *t* test determined whether each item could significantly distinguish between these groups. Items with a critical ratio ($|t|$) less than 3.0 were considered for exclusion [23]. In addition, item homogeneity and item correlation were tested using Cronbach α if the item was deleted and corrected item-total correlation coefficient. Items with a corrected item-total correlation coefficient below 0.40 were considered for exclusion [23]. Cronbach α and Intraclass correlation coefficient (ICC) were used to assess the internal consistency and test-retest reliability of the instrument. A Cronbach α≥0.70 indicated good internal consistency, while ICC>0.70 indicated good time stability [23]. The I-CVI and the Scale CVI/Average (S-CVI/Ave) were used to evaluate content validity of the instrument. I-CVI≥0.78 and S-CVI/Ave≥0.90 indicate satisfactory content validity [24].

Construct validity was evaluated using confirmatory factor analysis (CFA) with a robust chi-square to df ratio (χ^2/df) less than 3, Tucker-Lewis Index (TLI), Incremental Fit Index (IFI), and Comparative Fit Index (CFI) greater than 0.90, and root-mean-square error of approximation (RMSEA) and standardized root-mean-square residual (SRMR) less than 0.08, indicating an acceptable data-model fit [25]. The average variance extracted (AVE) and composite reliability (CR) were used to assess convergent validity, with AVE greater than 0.50 and CR greater than 0.70 indicating good convergent validity [26]. Discriminant validity was performed using the heterotrait-monotrait ratio (HTMT), with a correlation matrix value <0.90 considered good [26].

Furthermore, participants were divided into 2 groups based on geographic location for the sensitivity analysis. The DigiHealthCom scores were compared to evaluate potential selection bias. The absence of a significant difference in digital health competence between the groups indicates that selection bias is unlikely in the study sample. Statistical analysis was conducted using IBM SPSS (version 27.0), IBM AMOS (version 29.0), and Smart PLS (Version 4.1.0.0; GmbH Corp). A *P* value of less than .05 was considered statistically significant.

Ethical Considerations

Ethical approval was obtained from the Ethical Committee at Nanfang Hospital, Southern Medical University, China (NFEC-2023 - 165). This research adhered to the principals of the Declaration of Helsinki. All participants provided informed consent and voluntarily completed the web questionnaire. Participants had the option to skip questions, review, and delete their responses. Participants had the right to withdraw from the survey at any time. Those who completed it received a random monetary reward ranging from CNY 2 to 5 (US $0.28 to 0.69). Participants' rights and researcher's contact information were provided on the first page of the web survey. Minimal sociodemographic was collected to maintain ethical standards. Participant information was kept confidential and anonymous. The CHERRIES (Checklist for Reporting Results of Internet E-Surveys; Checklist 1) was used to enhance the transparency of the study [27].

Results

Characteristics of the Participants

Initially, 431 participants were recruited for this study. Furthermore, 33 participants were subsequently excluded due to not meeting the inclusion criteria (n=7), having less than 1 year work experience (n=4), completing the questionnaire in under 150 seconds (n=2), and exhibiting erratic response patterns (n=20). Finally, 398 eligible health care professionals were included. Figure 2 illustrates the participant enrollment flowchart. The participants enrolled from 36 cities across 15 provinces, as identified by IP addresses. Among the participants, 249 (62.6%) were recruited from Guangzhou, a megacity in Guangdong province that contains 6125 registered medical facilities. As shown in Table 1, 364 (91.5%) participants were female, 386 (97%) worked in health care services, and 357 (89.7%) were nurses. The participants had an average of 13.7 (SD 9.4) years of work experience, with 281 (70.6%) working directly with patients for at least 5 days per week. Participant characteristics are summarized in Table 1.

Figure 2. The flowchart for the enrollment process of health care professionals.

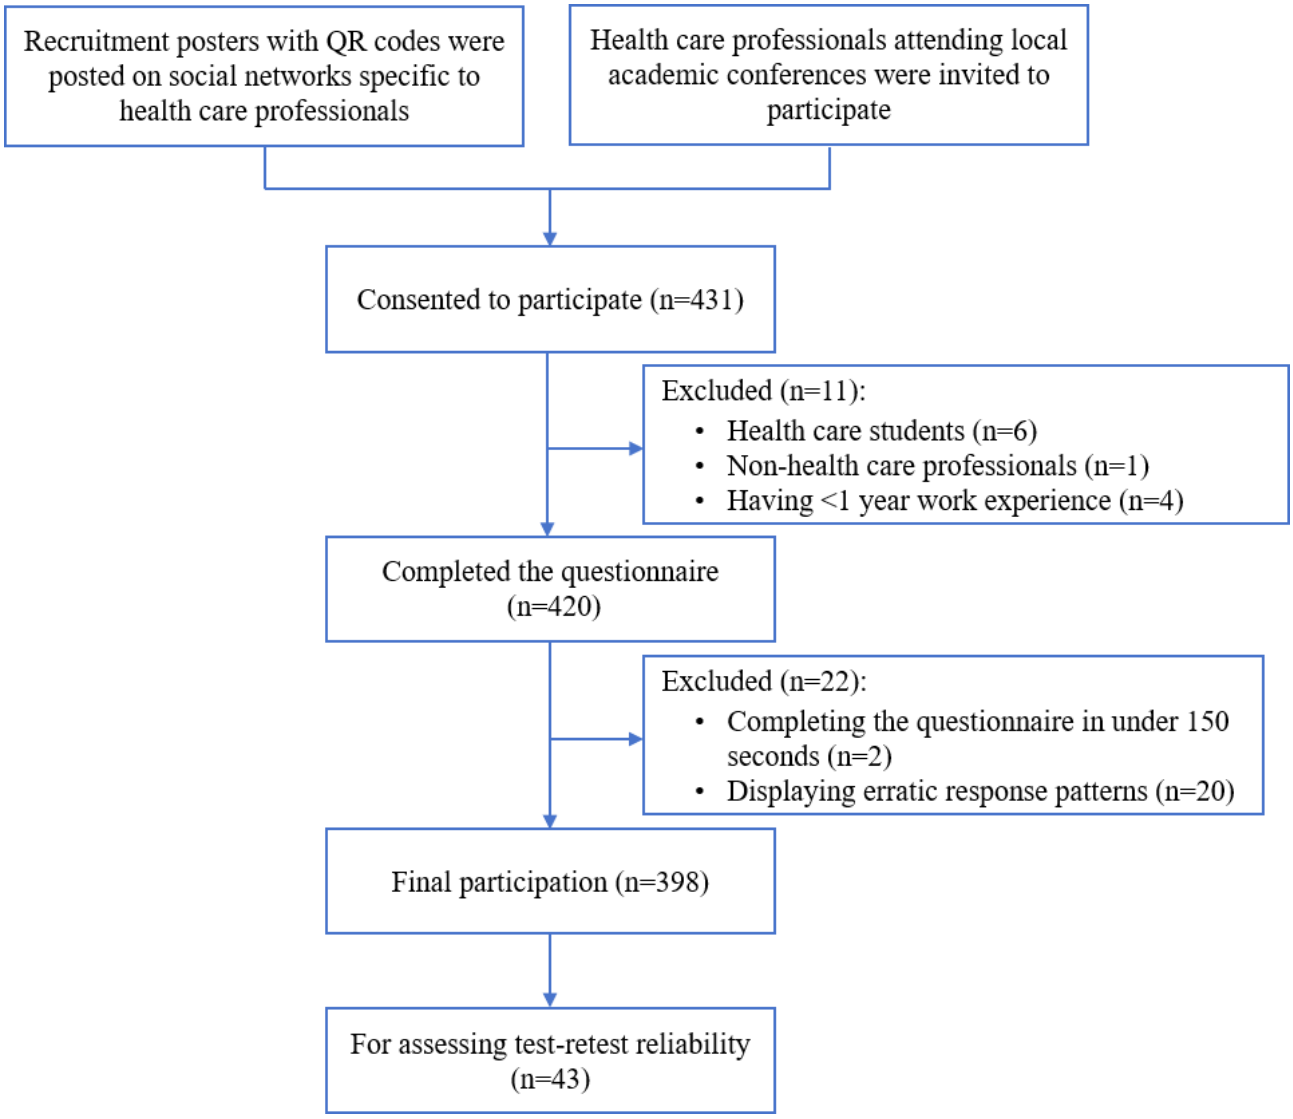


Table . Demographic characteristics of the participants (N=398).

Variables		Value
Sex, n (%)		
	Female	364 (91.5)
	Male	34 (8.5)
Age (years), mean (SD)		36.1 (8.8)
Education, n (%)		
	Junior vocational qualification	58 (14.6)
	Bachelor's degree	273 (68.6)
	Master's degree	53 (13.3)
	Doctoral degree	14 (3.5)
Service area, n (%)		
	Health care service	386 (97)
	Social service	4 (1)
	Rehabilitation service	7 (1.8)
	Others	1 (0.3)
Location, n (%)		
	Southern China	351 (88.2)
	Northern and Western China	47 (11.8)
Type of organization, n (%)		
	Tertiary hospital	248 (62.3)
	Secondary hospital	36 (9)
	Community health care center	76 (19.1)
Professional license, n (%)		
	Nurse	357 (89.7)
	Doctor	24 (6)
	Midwife	10 (2.5)
	Others[a]	7 (1.8)
Working experience (years), mean (SD)		13.7 (9.4)
Patient work, n (%)		
	Daily (at least 5 days a week)	281 (70.6)
	Weekly (1-4 days per week)	62 (15.6)
	Monthly (a few times a month)	17 (4.3)
	Rarely (a few times in several months)	23 (5.8)
	I do not currently work with patient	15 (3.8)
Full-time, n (%)		398 (100)

[a]Including physiotherapist, paramedical technician, and pharmacist.

Results of Item Analysis

Item analysis showed a significant difference between high-score and low-score groups. The critical ratio values for all items were above 3.0 (range 16.05 - 23.77, P<.001; Table 2), indicating excellent item discrimination. All corrected item-total correlation coefficients exceeded 0.4 (Table 2). The Cronbach α if the item deleted (range 0.91 - 0.96) were acceptable (Table 2).

Table . Item analysis and content validity of the 42 items in the DigiHealthCom (Digital Health Competence; N=398).

Item	Critical ratio	CITC[a]	CID[b]	I-CVI[c]
RC1[d]	16.05	0.69	0.96	1

Item	Critical ratio	CITC[a]	CID[b]	I-CVI[c]
EC4	21.44	0.86	0.91	1

[a]CITC: corrected item-total correlation.

[b]CID: Cronbach α if item deleted.

[c]I-CVI: item content validity index.

[d]RC: human-centered remote counseling competence.

[e]DS: digital solutions as part of work.

[f]ICT: information and communication technology competence.

[g]UE: competence in using and evaluating digital solutions.

[h]EC: ethical competence related to digital solution.

Internal Consistency and Test-Retest Reliability

As shown in Table 3, internal consistency (Cronbach α=0.94 - 0.98) and test-retest reliability were good (ICC=0.90; 95% CI 0.81 - 0.95).

Table . Internal consistency and test-retest reliability of the Chinese version of the DigiHealthCom (Digital Health Competence).

Dimension	Cronbach α (N=398)	ICC[a] (N=43)	95% CI of ICC
RC[b]	0.96	0.80	0.63-0.89
DS[c]	0.96	0.90	0.81-0.95
ICT[d]	0.94	0.79	0.62-0.89
UE[e]	0.96	0.80	0.63-0.89
EC[f]	0.94	0.81	0.65-0.90
Total	0.98	0.90	0.81-0.95

[a]ICC: intraclass correlation coefficient.

[b]RC: human-centered remote counseling competence.

[c]DS: digital solutions as part of work.

[d]ICT: information and communication technology competence.

[e]UE: competence in using and evaluating digital solutions.

[f]EC: ethical competence related to digital solutions.

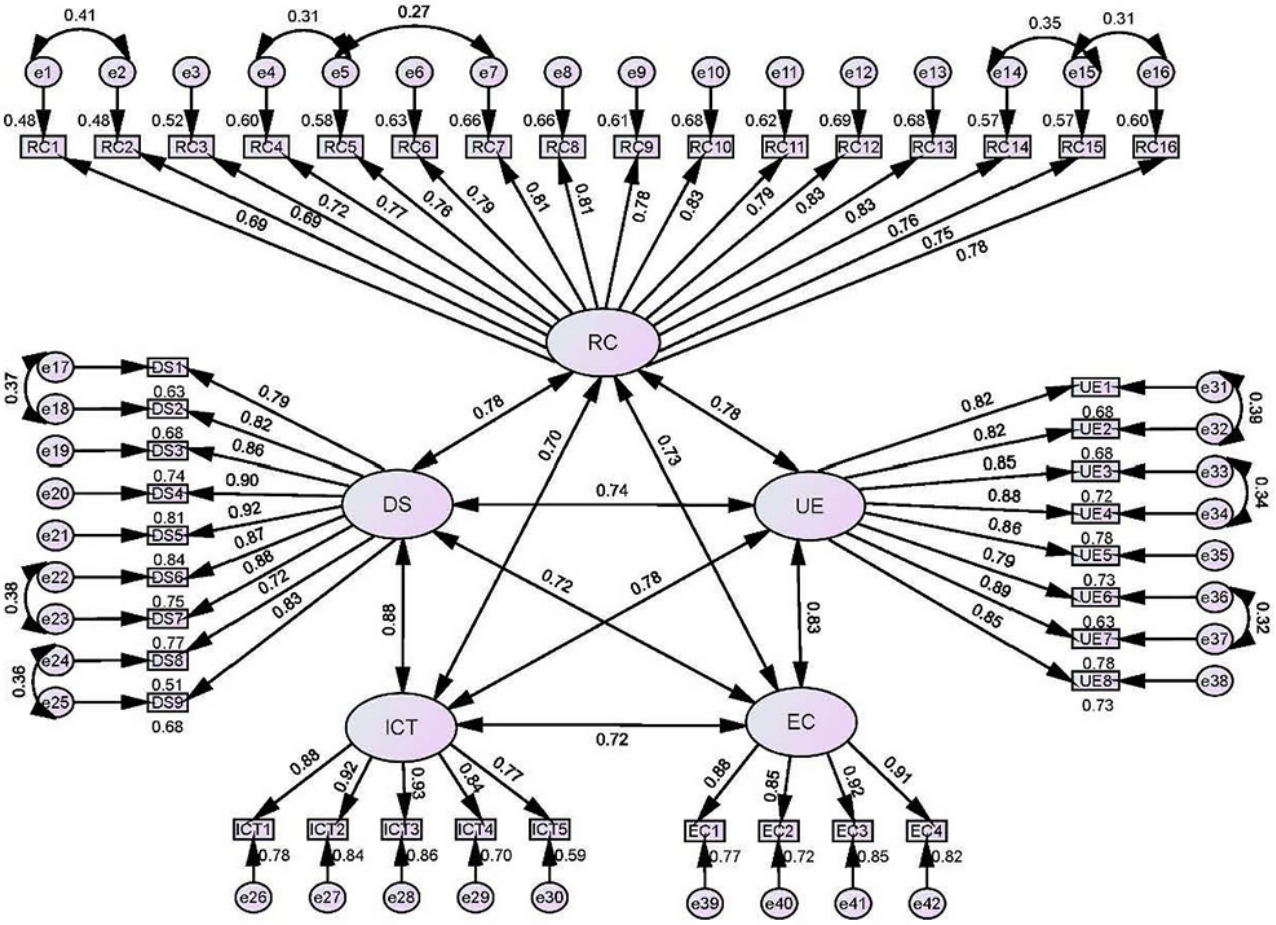
Content Validity

To test content validity, 11 experts evaluated the relevance of the items. The S-CVI/Ave for the instrument was 0.97, and the I-CVI ranged from 0.82 to 1.00 (Table 2), indicating satisfactory content validity.

Construct Validity

As illustrated in Figure 3, the results of CFA supported the 5-factors structure (digital solutions as part of work; ethical competence related to digital solutions; ICT competence; human-centered remote counselling competence; competence in using and evaluating digital solutions). The indices, including χ^2/df (3.10), CFI (0.91), TLI (0.90), IFI (0.91), RMSEA (0.07), and SRMR (0.05), indicated an acceptable model fit. The factor loadings of items ranged from 0.69 to 0.93 (Figure 3). The AVE values for each dimension exceeded 0.50 (range: 0.60 - 0.79), with the CR values >0.70 (range: 0.94 - 0.95), indicating excellent convergent validity. The HTMT values within the matrix were less than 0.90 (range: 0.72 - 0.89), indicating good divergent validity. These results collectively demonstrated satisfactory construct validity of the instrument.

Figure 3. The confirmatory factor model of the Chinese version of the DigiHealthCom (Digital Health Competence; N=398). DS: digital solutions as part of work; EC: ethical competence related to digital solutions; ICT: information and communication technology competence; RC: human-centered remote counselling competence; UE: competence in using and evaluating digital solutions.



Sensitivity Analysis

Participants were divided into 2 groups based on geographic location: Southern China and Northern and Western China. The DigiHealthCom scores were compared to evaluate potential selection bias. As illustrated in Table S3 in Multimedia Appendix 2, no significant difference was found in DigiHealthCom scores between the 2 groups (P>.05), indicating that selection bias is unlikely in the study sample.

Discussion

Principal Findings

In this study, we translated and culturally adapted the DigiHealthCom instrument into Chinese and assessed its reliability and validity among Chinese health care professionals. The Chinese version of DigiHealthCom demonstrated satisfactory internal consistency, test-retest reliability, content validity, and construct validity. To our knowledge, this study represents the first effort to validate a comprehensive Chinese tool for measuring digital health competence among health care professionals.

In this study, each item of the Chinese version of DigiHealthCom was translated and back-translated strictly following the dual direct-to-back translation model [21] to ensure alignment in semantic, conceptual, and content with the original English version. And then, we conducted expert review involving 11 experts in nursing and IT to examine content validity of the Chinese version. High content validity indices imply that the instrument provides a broad enough range of content to allow conclusions about the targeted construct. We also conducted cognitive interviewing and a pilot study to ensure its clarity and comprehensibility [28]. Issues related to semantic validation and understanding identified in the initial Chinese version were addressed after receiving feedback from the expert review and cognitive interviewing, leading to improvements such as clarifying complex terms and vague definitions. Item analysis revealed good differentiation and high correlations between the items in this study. Furthermore, this instrument underwent rigorous testing for internal consistency, test-retest reliability, and construct validity, exhibiting excellent internal consistency, time stability, and construct validity, resonating with the original study [19]. The types of reliability and validity assessed in this study represent essential psychometric properties for a measurement instrument.

Discrepancies between existing instruments largely stem from differing conceptual frameworks. The DHLI measures 7 individual skills: operation, navigation, information searching, evaluating reliability, determining relevance, adding self-generated content, and protecting privacy [16]. The eHLQ comprises 7 dimensions, addressing users' attributes, their interaction with technologies, and their experience with systems

[17]. Our CFA findings confirm a 5-factor structure, consistent with the exploratory factor analysis findings of the initial study [19]. Beyond competence in using and evaluating digital solutions and ICTs, the DigiHealthCom instrument addresses additional essential domains that were previously unaddressed, that is acceptance of digital solutions, human-centered remote counseling, digital interaction skills with patients and interprofessional teams, and ethical competence related to digital solutions [19]. Notably, acceptance of digital solutions significantly influences health care professionals' adoption of digital solutions [13,14]. Competence in person-centered remote consultations is crucial for fostering patient engagement and improving accessibility to equitable digital health services [8]. Furthermore, proficient digital interaction skills facilitate effective coordination in digital settings, thereby supporting decision-making and optimizing treatment plans [8]. As digital solutions become more prevalent, attention to data privacy and information security has intensified [29,30]. Ethical competence related to digital solutions ensures appropriate management of patient information, fostering trust in digital health technologies and enhancing the safety of digital health services [20,31]. These domains provide a unified theoretical framework for comprehensively measuring digital health competencies among various professionals [8,9,19], which are essential for delivering high-quality digital health services to meet future demands.

The Finnish health care system is renowned for its universality, robust public funding, and centralized digital infrastructure [32]. Regional variations exist in Finland; for example, northern districts have fewer professionals specializing in remote counseling and the integration of digital solutions compared with southern areas [20,33]. Strategies have been implemented to enhance health care professionals' digital health competence and improve education related to health care digitalization, including technology to support client engagement, digital services integrated into nursing work, and considerations of safety and ethics in the digital environment [20,34]. In contrast, China experiences regional disparities in digital health infrastructure and access to digital health services, especially in rural areas, despite the rapid growth of digital health services [35]. In addition, system compatibility across hospitals remains an unsolved issue [35]. These factors may influence the development of digital health competence among health care professionals. A cross-sectional study conducted in a central Chinese province reported that 49.9% (1690/3386) of clinical nurses demonstrate low telehealth readiness [36]. Consequently, evaluating, addressing, and reducing regional disparities in health care professionals' digital health competence is vital for promoting equity in health care service provision. Validating a comprehensive digital health competence measurement instrument for health care professionals is imperative to address challenges posed by diverse health care environments, such as China's. The Chinese version of DigiHealthCom is now ready for application in a wide range of settings and various health care professionals. Researchers, educators, health care providers, and policy makers can use it to evaluate digital health competence among diverse health care professionals, and develop digital health training curricula and policies based on the assessment.

Limitations

This study acknowledges several limitations. First, the primary participants were nurses. Future research should involve a broader spectrum of health care professionals. Second, although recruited from diverse health care institutions, the participants mainly came from southern China, which may introduce selection bias due to regional disparities in digital health infrastructure. To address this, participants were divided into 2 groups (Southern China versus Northern and Western China) for sensitivity analysis, and their DigiHealthCom scores were compared. We did not find significant differences in digital health competence between the 2 groups, indicating that selection bias is unlikely in the study sample. Future studies could benefit from employing a stratified sampling method. Third, the absence of a standardized method for assessing digital health competence among health care professionals hindered the evaluation of criterion validity. Assessments of digital health competence predominantly rely on subjective self-reports, which might be susceptible to response bias. However, relying exclusively on performance-based assessments or other objective measures to evaluate competence also presents challenges. Therefore, using a more holistic combination of methods could offer a viable solution. Future research should consider larger sample sizes and multicenter external evaluations to address these limitations.

Conclusions

In conclusion, we have successfully translated, culturally adapted, and validated DigiHealthCom for Chinese health care professionals. Our findings demonstrate that the Chinese version of DigiHealthCom is a reliable and valid instrument for assessing digital health competence among these health care professionals.

Acknowledgments

The authors would like to acknowledge all the participants who participated in this study; in particular, Dr Donglan Ling for help with the translation process. XL is supported by the National Natural Science Foundation of China (grant 82171202). The funding agents had no role in the study design; collection, analysis, and interpretation of the data; writing of the manuscript; or decision to submit the paper for publication.

Data Availability

The dataset collected in this study is available from the corresponding author on reasonable request.

Authors' Contributions

XL and LG had full access to all the data in this study and takes responsibility for the integrity of the data and the accuracy of the data analysis. Concept and design were contributed by XL. Acquisition, analysis, or interpretation of data were contributed by LG, MC, and JW. Drafting of the manuscript was handled LG and XL. Critical revision of the manuscript for important intellectual content were contributed by XL, LG, JW, MC, and JW. Administrative, technical, or material support were contributed by JW. The authors read and approved the final manuscript.

Abstract

Background: The accuracy of the *ICD-10-CM* (*International Classification of Diseases, Tenth Revision, Clinical Modification*) procedure coding system (PCS) is crucial for generating correct Taiwan diagnosis-related groups (DRGs), as coding errors can lead to financial losses for hospitals.

Objective: The study aimed to determine the consistency between an artificial intelligence (AI)-assisted coding module and manual coding, as well as to identify clinical specialties suitable for implementing the developed AI-assisted coding module.

Methods: This study examined the AI-assisted coding module from the perspective of health care professionals. The research period started in February 2023. The study excluded cases outside of Taiwan DRGs, those with incomplete medical records, and cases with Taiwan DRG disposals *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision)* PCS. Data collection was conducted through retrospective medical record review. The AI-assisted module was constructed using a hierarchical attention network. The verification of the Taiwan DRGs results from the AI-assisted coding model focused on the major diagnostic categories (MDCs). Statistical computations were conducted using SPSS version 19. Research variables consisted of categorical variables represented by MDC, and continuous variables were represented by the relative weight of Taiwan DRGs.

Results: A total of 2632 discharge records meeting the research criteria were collected from February to April 2023. In terms of inferential statistics, κ statistics were used for MDC analysis. The infectious and parasitic diseases MDC, as well as the respiratory diseases MDC had κ values exceeding 0.8. Clinical inpatient specialties were statistically analyzed using the Wilcoxon signed rank test. There was not a difference in coding results between the 23 clinical departments, such as the Division of Cardiology, the Division of Nephrology, and the Department of Urology.

Conclusions: For human coders, with the assistance of the *ICD-10-CM* AI-assisted coding system, work time is reduced. Additionally, strengthening knowledge in clinical documentation enables human coders to maximize their role. This positions them to become clinical documentation experts, preparing them for further career development. Future research will apply the same method to validate the *ICD-10* AI-assisted coding module.

diagnosis-related group; artificial intelligence coding; International Classification of Diseases, Tenth Revision, Clinical Modification; ICD-10-CM; coding professionals

Introduction

The *International Statistical Classification of Diseases* (*ICD*) system was set up by the World Health Organization (WHO) for the purpose of tracking diseases globally. Over the past several decades, the WHO has made significant changes to both content and structure. It accompanies a new scientific understanding of diseases and new structures for organizing *ICD* codes to accommodate enhanced use and extensibility [1]. The WHO introduced the *ICD* in 1948, and it is a universal language used to categorize diseases or causes of death. The use of it is attributed to health care–related units in 194 countries and is generated by professional coders based on discharge records, with countries adjusting the *ICD* to their circumstances. In 2016, Taiwan adopted the international trend of switching from *ICD-9-CM* (*International Classification of Diseases, Ninth Revision, Clinical Modification*) to *ICD-10-CM* (*International Classification of Diseases, Tenth Revision, Clinical Modification*) procedure coding system (PCS) for coding hospital patient diagnoses, procedures, analysis and reimbursement. The National Health Insurance Administration (NHIA) under the Ministry of Health and Welfare has adopted the 2014 edition of *ICD-10-CM* PCS, with approximately 71,900 diagnosis codes and 78,500 procedure codes.

The use of the *ICD-10-CM* PCS involves coding and classifying morbidity data from health records, reimbursement claims, and administrative databases. Improving health care quality, monitoring public health, and conducting research are all benefits of the *ICD-10-CM* PCS in Taiwan and involves converting the physician's discharge diagnosis into *ICD-10-CM* codes by following the primary diagnosis selection principle announced by the NHIA. The diagnosis-related group (DRG) provides information such as health insurance reimbursement, relative weight, presence of comorbidities, and complications for the current hospitalization.

The accuracy of *ICD-10-CM* PCS coding is crucial for generating accurate Taiwan DRGs, as coding errors can lead to financial losses for hospitals [2,3]. According to the coding principles set forth by the NHIA and the Taiwan Society of Medical Records Management, coding is based on the inpatient and emergency room records of patients. In the past, this task was undertaken by trained and certified clinical coding professionals (referred to as coding professionals hereafter), but with the rapid advances of medical technology, the rules of disease classification have also evolved, and coding professionals must regularly accumulate relevant training hours to update their disease classification skills [4].

In recent years, artificial intelligence (AI) and natural language processing have shown exciting potential in the field of automatic clinical coding. In 2021, the disease coding scales in the United States were worth approximately 18 billion US dollars. Several technology companies in the United States have developed AI-assisted coding systems, and scholars believe that interdisciplinary collaboration and feedback from clinical coding professionals are essential to further refine the modules [5,6]. Research on AI-assisted coding consistently conclude that it improves quality and reduces error rates while saving costs [7,8]. AI-assisted *ICD-10-CM* PCS coding can be considered as a text classification task within the field of machine learning [9]. In recent years, studies in the machine learning text classification field have predominantly proposed using deep learning–based neural networks [10]. Many research papers have focused on AI assistance in *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision)* coding [11-14], but few have examined the results of coding implementation from the perspective of disease classification personnel. The development and validation process of the AI-assisted coding model requires the involvement and feedback of clinical coders to enhance accuracy and correctness, aligning with user needs [15].

In Taiwan, several hospitals have also ventured into the development of AI-assisted coding for disease classification. However, due to variations in physicians' documentation of medical records across different hospitals, the AI-assisted coding systems developed are not universally applicable [11], necessitating the development and validation of customized AI-assisted coding systems. Medical coding personnel must review the discharge records meticulously and then translate the discharge diagnoses and procedures (interventions) recorded in the medical records into *ICD-10* codes. In the past, the most significant factor contributing to coding errors was handwritten medical records by physicians, which were difficult to decipher or included abbreviations, leading to mistakes [16]. In recent years, most medical centers in Taiwan have adopted electronic health records, resulting in a significant reduction in coding errors caused by handwritten records. Clinical coding personnel also encounter various pressures, including the need to accomplish all inpatient coding tasks within specified deadlines, optimize Taiwan DRGs assignment coding, enhance and maintain coding reliability and validity, and engage in discussions with clinical physicians regarding the content of medical record writing.

Recently, the global trend in AI coding has been on the rise [11,13,17-19]. In this study, we have developed an exclusive *ICD-10-CM* AI-assisted coding module. Coding professionals took part in the research and offered suggestions to improve the efficiency of coding operations. Consequently, this study focuses primarily on the following two research aims: (1) to verify the consistency between the AI-assistant coding module and a coding professional in encoding, based on the MDC results in Taiwan DRGs and (2) to find the clinical departments within the medical center that can benefit from using the developed AI-assisted coding module.

Methods

Data Description

This study used a total of 136,841 unstructured discharge summaries of patients who were hospitalized, recorded in Kaohsiung Medical University Chung-Ho Memorial Hospital from April 1, 2019, to December 31, 2020, as the primary data source. Textbox 1 displays an example of a discharge summary from the Kaohsiung Medical University Chung-Ho Memorial Hospital.

Textbox 1. Example discharge summary.

Chief complaint:

Abdominal pain for 1 day

Impression on admission:

Sepsis, focus on retroperitoneal abscess

Discharge diagnosis:

Sepsis, focus on retroperitoneal abscess due to surgical site infection

History on admission:

This time, according to the patient's statement, he suffered from recurrent abdominal dull pain after discharge. The pain was serious by jejunostomy feeding, and there was no relieving factor. The pain suddenly progressed...

This study verified the AI-assisted coding from the perspective of coding professionals. Since the AI-assisted coding system was introduced in the medical center in February 2023, the study period began in February 2023. The subjects of this study were selected based on the following exclusion criteria: non–Taiwan DRGs cases, cases with procedures (*ICD-10* PCS) in Taiwan DRGs, and cases with incomplete medical records. According to the study conditions, there were approximately 700 to 1000 cases per month. The coding by both the AI-assisted coding module and coding professionals were based on the electronic discharge summaries of a certain medical center each month.

Research Design

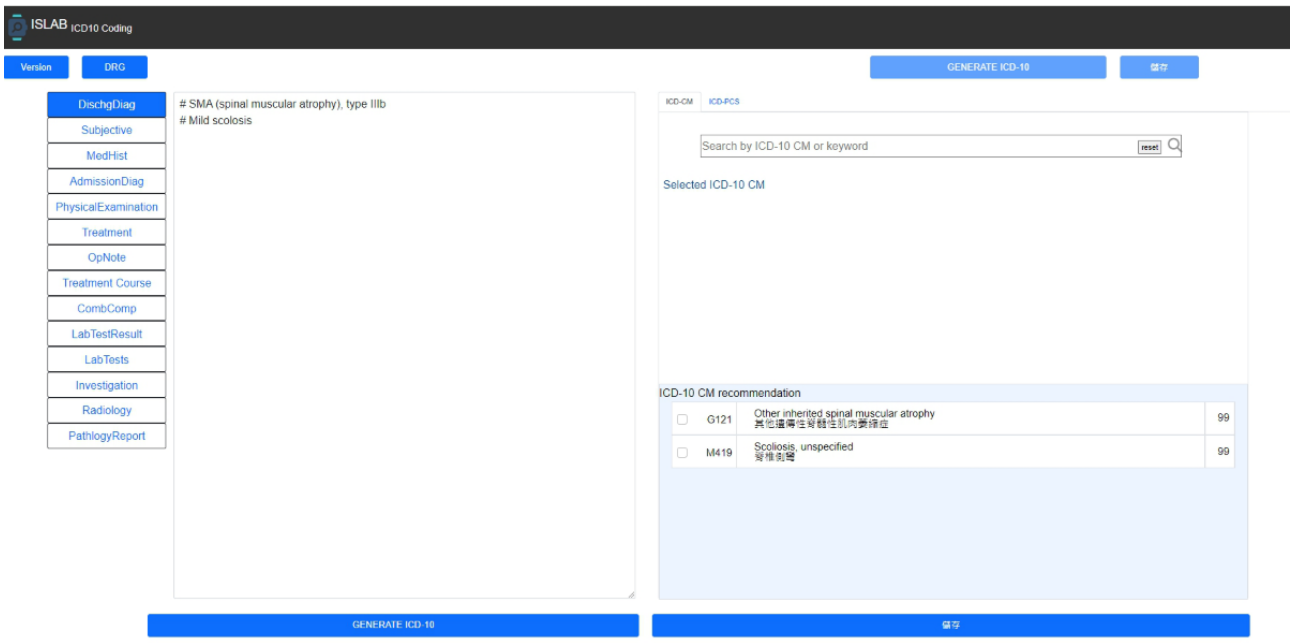
After each data entry was encoded by the AI-assisted coding module and verified by a coding professional, it was transmitted to a certain university's database. The results of both the AI-assisted coding and coding professional were compared using an Excel (Microsoft) file. Following the linkage to the NHIA's DRG calculation software, separate datasets for Taiwan DRGs were obtained for both the AI-assisted coding and coding personnel, with the consistency of the primary diagnosis coding between these two groups being examined. In cases of discrepancies, the medical records were scrutinized again by the coding professional to determine if the AI-assisted coding results met the criteria for primary coding as per the coding professional; the consistency results of the Taiwan DRGs data for both the AI-assisted coding and coding professional were adjusted accordingly.

AI-Assisted Coding Construction Process

The AI-assisted *ICD-10-CM* coding system was developed by CSL, CHL, and BTS, based on approximately 110,000 discharge summaries collected from April 1, 2019 to December 31, 2020, in a medical center. The deidentified summary data were processed by segmenting sentences and filtering out meaningless delimiters and prefix symbols (eg, # or "") by using a clinical natural language processing tool [20]. The data were categorized into 21 groups based on the first 3 codes of the *ICD-10-CM*, and models were built using bidirectional encoder representations from transformers (BERTs) [21] and hierarchical attention networks (HANs) [22]. The results favored HANs, leading to the decision to adopt the HAN module. The precision, recall, and F1 scores of the developed HAN model were 0.55, 0.82, and 0.66, respectively. For the top 50 most frequent codes, the F1 score of the developed HAN model was 0.818.

Aside from module modeling, another time-consuming task was the design of the user interface for the coding professionals, as it needed to present discharge summaries, laboratory data, and imaging reports, as well as the *ICD-10-CM* codes predicted by the AI-assisted coding module. Coding professionals were actively involved in providing feedback during the interface design process. Figure 1 provides an illustration of the designed user interface, which provided suggestions automatic *ICD-10-CM* recommendation and fields for coding professionals to input the final codes. The developed AI-coding system was integrated into a medical center's hospital information systems in November 2022 and operated in February 2023.

Figure 1. User interface screenshot.



Ethical Considerations

This study was approved by Kaohsiung Medical University Ching-Ho Memorial Hospital (institutional review boards number: KMUHIRB-E(II)-20230214). The institutional review board approval covered secondary analysis without additional consent. Data was anonymized or deidentified. There was not any compensation provided to participants.

Statistical Analysis

The study involved an analysis incorporating descriptive statistics for exploration, as well as inferential statistics for investigating MDCs and relative weight. Statistical computations were conducted using SPSS version 19. Research variables consisted of categorical variables represented by MDC, and continuous variables were represented by the relative weight of Taiwan DRGs.

Results

Distribution of *ICD-10* Codes

The distribution of the *ICD-10* codes seen in the collected training dataset is shown in Multimedia Appendix 1. The first digit of the *ICD-10-CM* code consisted of English letters, so the alphabetical characters on the horizontal axis of the log data were the first digit of the *ICD-10-CM* code, showing diseases pertaining to different systems. According to Multimedia Appendix 1, data starting with codes C, E, and I in *ICD-10-CM* had the highest volume, with C representing neoplastic diseases; E for endocrinal, nutritional, and metabolic diseases; and I for diseases of the circulatory system. These were the body systems with the highest learning volumes for the AI-assisted coding module.

Descriptive Statistics

In the period from February to April 2023, a total of 15,756 discharges were recorded. Excluding cases with interventions, non–Taiwan DRG cases, and cases with incomplete medical records, there was a total of 2632 cases. The primary diagnosis was the key factor in deciding the main disease category, while secondary diagnoses only affected the distribution of Taiwan DRGs within the same primary disease category. According to disease classification rules, the primary diagnosis was based on the reason for the patient's admission, but only one disease could be selected as the primary diagnosis. If multiple diseases were treated during admission, selecting any one of them as the primary diagnosis was not considered an error. Therefore, the coding professional (author ATL) manually examined the discharged cases' notes to categorize the output of the AI-assisted system into one of the following categories. The results are shown in Table 1.

Table . Frequency distribution and percentage analysis of primary diagnoses.

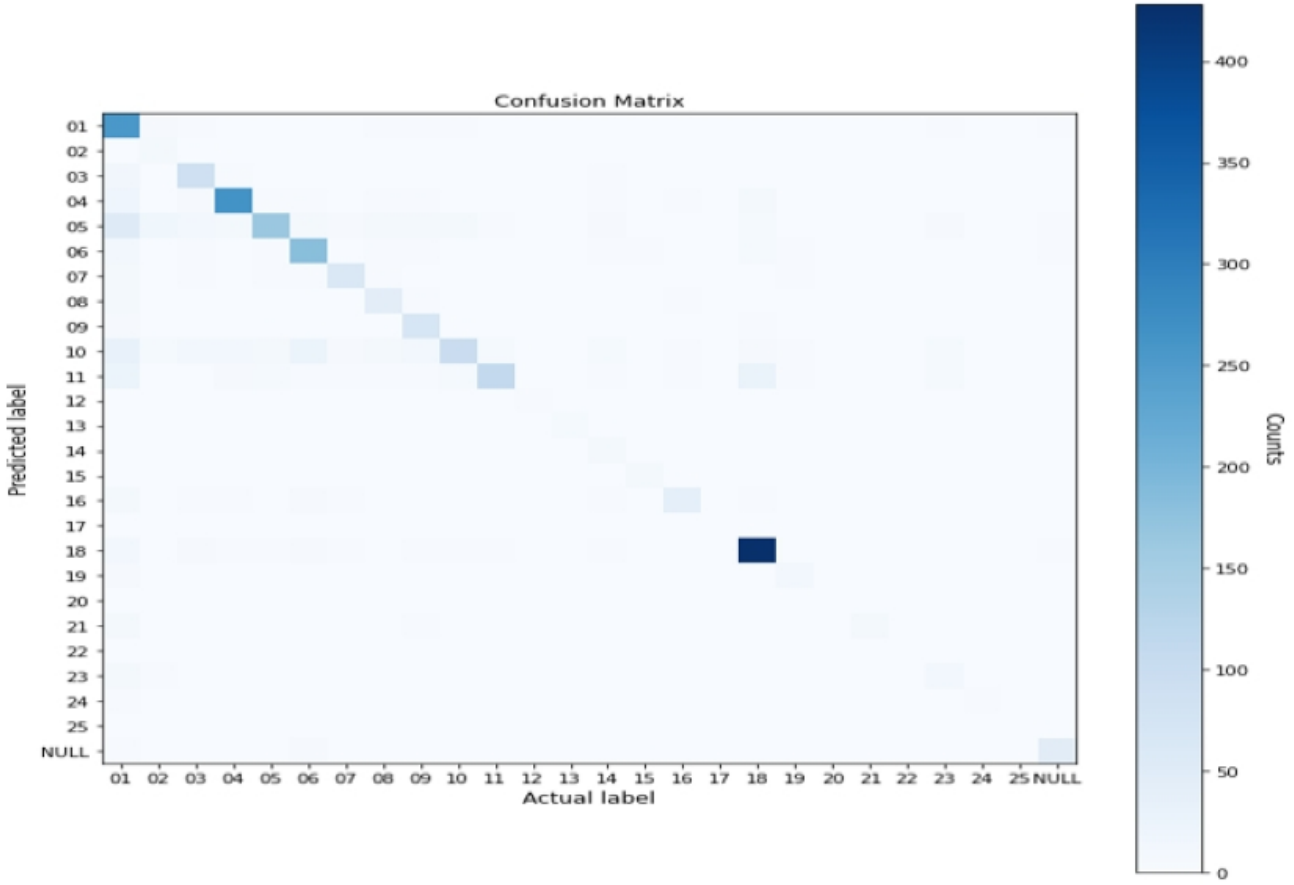
Variable	Month of case, n (%)		
	February (n=748)	March (n=991)	April (n=893)
No primary diagnosis	181 (24.2)	277 (28)	285 (31.9)
Incorrect secondary diagnosis with a primary diagnosis	462 (61.8)	477 (48.1)	369 (41.3)
All correct	79 (10.6)	181 (18.3)	177 (19.8)
All incorrect	26 (3.5)	56 (5.7)	62 (7)

Operational definitions were as follows:

- No primary diagnosis: in comparison to the coding professional, a single hospitalization's predicted diagnosis codes did not include a primary diagnosis.
- Incorrect secondary diagnosis with a primary diagnosis: in comparison to the coding professional, a single hospitalization's predicted diagnosis codes included a primary diagnosis, but there was at least 1 error in the secondary diagnoses.
- All correct: all predicted diagnosis codes for a single hospitalization perfectly aligned with those given by the coding professional.
- All incorrect: in comparison to the disease classification personnel, none of the predicted diagnosis codes in a single hospitalization were the same.

In Figure 2, we analyzed the agreement of MDC classification between the AI-assisted coding module and the coding professional through a heat map analysis. The vertical and horizontal axes in Figure 2 represent MDCs coded by the AI-assisted coding module and MDCs coded by coding professionals, respectively. The intensity of color in the figure indicated a higher number of agreed MDCs between the AI-assisted coding module and professionals. As shown in Figure 2, MDC 1 (diseases and disorders of the nervous system), MDC 4 (diseases and disorders of the respiratory system), and MDC 18 (infectious and parasitic diseases and disorders) had the highest agreements.

Figure 2. MDC heat map analysis between AI-coding module and professionals.



The κ Coefficient Test

Furthermore, we assessed the MDC agreement between the AI coding module and coding professionals using the κ coefficient test. The κ values were broadly categorized into 5 groups based on various levels of agreement: extremely low agreement (0.00-0.20), fair agreement (0.21-0.40), moderate agreement (0.41-0.60), high agreement (0.61-0.80), and almost perfect agreement (0.81-1.0).

When analyzing the cumulative data for February to April 2023 (Table 2), the MDCs with the highest consistency were MDC 4 (diseases and disorders of the respiratory system) and MDC 18 (infectious and parasitic diseases and disorders), followed by MDC 1 (diseases and disorders of the nervous system), MDC 3 (diseases and disorders of the ear, nose, mouth and throat), MDC 6 (diseases and disorders of the digestive system), MDC 7 (diseases and disorders of the hepatobiliary system and pancreas), MDC 9 (diseases and disorders of the skin, subcutaneous tissue and breast), MDC 11 (diseases and disorders of the kidney and urinary tract), MDC 13 (diseases and disorders of the female reproductive system), MDC 15 (newborn and other neonates), and MDC 16 (diseases and disorders of the blood and blood forming organs and immunological disorders).

Table . Kappa tests for aggregation of major diagnostic category in the total counts for February to April 2023 (κ=0.592).

No.	Major diagnostic category	AI-assisted case coding (n=2362), n (%)	Cases coded by human coders (n=2362), n (%)	Kappa value
1	Diseases and disorders of the nervous system	280 (10.6)	509 (19.3)	0.670[a]
2	Diseases and disorders of the eye	9 (0.3)	38 (1.4)	0.300
3	Diseases and disorders of the ear, nose, mouth, and throat	113 (4.3)	132 (5)	0.689[a]
4	Diseases and disorders of the respiratory system	309 (11.7)	302 (11.5)	0.845[b]
5	Diseases and disorders of the circulatory system	310 (11.8)	184 (7)	0.607
6	Diseases and disorders of the digestive system	217 (8.2)	229 (8.7)	0.775[a]
7	Diseases and disorders of the hepatobiliary system and pancreas	90 (3.4)	84 (3.2)	0.710[a]
8	Diseases and disorders of the musculoskeletal system and connective tissue	66 (2.5)	87 (3.3)	0.576
9	Diseases and disorders of the skin, subcutaneous tissue, and breast	83 (3.2)	116 (4.4)	0.692[a]
10	Diseases and disorders of the endocrine, nutritional, and metabolic systems	237 (9)	132 (5)	0.505
11	Diseases and disorders of the kidney and urinary tract	205 (7.8)	120 (4.6)	0.648[a]
12	Diseases and disorders of the male reproductive system	7 (0.3)	3 (0.1)	0.362
13	Diseases and disorders of the female reproductive system	8 (0.3)	8 (0.3)	0.749[a]
14	Pregnancy, childbirth and puerperium	11 (0.4)	41 (1.6)	0.419
15	Newborn and other neonates (perinatal period)	9 (0.3)	15 (0.6)	0.635[a]
16	Diseases and disorders of the blood and blood forming organs and immunological disorders	64 (2.4)	57 (2.2)	0.624[a]
17	Myeloproliferative diseases and disorders (poorly differentiated neoplasms)	3 (0.1)	2 (0.1)	0.399
18	Infectious and parasitic diseases and disorders	465 (17.7)	505 (19.2)	0.870[b]
19	Mental diseases and disorders	23 (0.9)	0 (0)	—[c]
20	Alcohol or drug abuse or induced mental disorder	2 (0.1)	0 (0)	—
21	Injuries, poison, and toxic effects of drugs	24 (0.9)	21 (0.8)	0.404
22	Burns	0 (0)	1 (0)	—

No.	Major diagnostic category	AI-assisted case coding (n=2362), n (%)	Cases coded by human coders (n=2362), n (%)	Kappa value
23	Factors influencing health status and other contacts with health services	24 (0.9)	42 (1.6)	0.366
24	Multiple significant trauma	6 (0.2)	4 (0.2)	0.599
25	HIV infection	2 (0.1)	0 (0)	—
—	None	65 (2.5)	0 (0)	—

[a]High agreement (0.61-0.80).

[b]Almost perfect agreement (0.81-1.00).

[c]Kappa value was not calculated when there were 0 cases in a coding group.

Inferential Statistical Analysis: Wilcoxon Signed Rank Test

The κ coefficient test was used for a broad-scale analysis of MDCs. However, under the same MDC, it was possible to further classify the data into numerous Taiwan DRGs, with each having its own code and relative weight. Even within the same MDC, this might result in different Taiwan DRGs. Furthermore, some diseases could be treated across departments. Therefore, for the statistical analysis of relative weight, we first conducted a normality analysis of the relative weights obtained from both AI-assisted coding and coding professionals. The statistical results based on the Kolmogorov-Smirnov analysis yielded a significance level of less than .05, showing a nonnormal distribution. Given that the research sample consisted of paired data, the nonparametric Wilcoxon signed rank test was used to analyze whether there were differences in relative weight between AI-assisted coding and coder-assigned coding; the null hypothesis assumed that there was no difference in relative weight between AI-assisted coding and coder-assigned coding.

The Wilcoxon signed rank test, with clinical departments as the unit of analysis, identified differences in relative weight in the following 12 departments: Division of Endocrinology and Metabolism, Division of Hematology and Oncology, Division of General Internal Medicine, Division of Geriatrics and Gerontology, Division of Trauma, Division of Neurosurgery, Division of Cardiovascular Surgery, Division of General and Digestive Surgery, Division of Pediatric Neurology, Department of Otorhinolaryngology, Department of Neurology, and Department of Rehabilitation Medicine. As shown in Table 3, the overall statistical result with a *P* value of <.001 showed that there were still differences between AI-assisted coding and coder-assigned coding in this study.

Table . Wilcoxon signed rank test results across various clinical departments (P<.001).

Clinical department	Frequency of cases (n=2632), n (%)	Relative weight (95%CI)		*P* value
		AI[a] coding	Human coding	
Division of Gastroenterology	61 (2.3)	0.66 (0.58 - 0.74)	0.70 (0.63 - 0.77)	.12
Division of Hepatobiliary and Pancreatic Medicine	81 (3.1)	0.69 (0.63 - 0.75)	0.74 (0.69 - 0.79)	.07
Division of Cardiology	177 (6.7)	0.69 (0.65 - 0.73)	0.72 (0.68 - 0.75)	.39
Division of Chest Medicine	181 (6.9)	0.90 (0.85 - 0.93)	0.90 (0.87 - 0.94)	.50
Division of Nephrology	64 (2.4)	0.71 (0.65 - 0.78)	0.71 (0.64 - 0.78)	.91
Division of Endocrinology and Metabolism	36 (1.4)	0.62 (0.54 - 0.71)	0.68 (0.59 - 0.77)	.03
Division of Hematology and Oncology	42 (1.6)	0.79 (0.69 - 0.88)	0.87 (0.80 - 0.94)	.006
Division of Rheumatology, Immunology, and Allergology	36 (1.4)	0.68 (0.58 - 0.79)	0.71 (0.64 - 0.79)	.33
Division of Infectious Diseases	78 (3)	0.91 (0.85 - 0.98)	0.94 (0.90 - 0.99)	.39
Division of General Internal Medicine	205 (7.8)	0.69 (0.65 - 0.73)	0.73 (0.69 - 0.77)	.005
Division of Geriatrics and Gerontology	54 (2.1)	0.92 (0.85 - 0.99)	0.99 (0.94 - 1.04)	.003
Division of Trauma	16 (0.6)	0.43 (0.21 - 0.65)	0.64 (0.46 - 0.83)	.04
Division of Neurosurgery	151 (5.7)	0.53 (0.48 - 0.58)	0.68 (0.63 - 0.73)	<.001
Division of Cardiovascular Surgery	24 (0.9)	0.67 (0.54 - 0.80)	0.94 (0.82 - 1.06)	.002
Division of Chest Surgery	14 (0.5)	0.56 (0.43 - 0.69)	0.60 (0.45 - 0.75)	.40

[a]AI: artificial intelligence.

Discussion

Principal Results

For clinical coders, it is clear from the MDCs that AI-assisted coding can serve as a reference for disease systems. However, hospital administrators may require detailed statistical results from clinical departments to make judgments. In the individual clinical department analysis based on the Wilcoxon signed rank test, the Division of General Internal Medicine, the Department of Neurology, and the Division of Neurosurgery had the highest number of cases studied, but the statistical results were inconsistent with coder-assigned coding. However, in the κ coefficient test, the statistical results for the nervous system MDC were highly consistent. This is because patients admitted to the Department of Neurology and Neurosurgery do not exclusively have neurological conditions. According to further analysis shown in Table 4, the AI model's predictions for neurological system diseases were still highly consistent with those of the disease classification staff in the neurology department. However, respiratory and urinary system conditions have affected the AI model's coding performance for neurology and account for the discrepancies seen in both the Wilcoxon signed rank test and the κ coefficient test.

Table . Analysis of major diagnostic category for 366 neurology patients admitted from February to April 2023.

No.	MDC[a]	AI[b]-assisted case coding (n=366), n (%)	Cases coded by human coders (n=366), n (%)	Kappa value	*P* value

[a]MDC: major diagnostic category.

[b]AI: artificial intelligence.

[c]Analysis was not performed when there were 0 cases in a coding group.

In the circulatory system, the statistical results for the Division of Cardiology and Division of Cardiovascular Surgery in the Wilcoxon signed rank test were also markedly different. Upon closer examination of the data from the exploratory study, it was discovered that in the Division of Cardiovascular Surgery, half of the cases helped by AI-coding modules did not have the main diagnosis coded, which could be attributed to differences in how physicians document medical records. For example, after carefully reviewing the 24 cases of data collected by the Cardiac Surgery Department, it was found that 12 Taiwan DRGs were inconsistent. All of these did not follow the disease classification coding rules and did not include the main diagnosis (Table 5).

Table . Discussion on writing medical records in the Division of Cardiovascular Surgery.

Number	Excerpt of discharge diagnosis	Cause analysis
Case 1	"Chest tightness for a week Acute heart failure with reduced ejection fraction * 2023/04/24 Thallium 201 (Stress SPECT (single-photon emission computed tomography) imaging): mild myocardial ischemia in inferolateral wall of LV (left ventricle)"	The examination results were attached to the discharge diagnosis, leading to coding confusion.
Case 2	"Type A aortic dissection - post TEVAR (Thoracic endovascular aneurysm repair)+ stenting grafts in the ascending to descending aorta, left common carotid and subcalvian arteries on 2023/02/07 # Suspect gastroparesis related to relative gastric malperfusion"	The discharge diagnosis showed coding confusion with previously treated conditions.
Case 3	"Type B dissection, intramural hemorrhage - 2023/03/10 Chest CT (computed tomography) angiography:1) Suspect intramural hematoma in the descending aorta.2) Suspect thrombus formation in the bilateral femoral arteries.3) Suspect a thrombosed aneurysm in the right internal iliac artery"	The anatomical location was not clearly documented, making correct coding impossible.

Furthermore, in MDC 14 (pregnancy, childbirth, and puerperium) and MDC 21 (injuries, poisonings, and toxic effects of drugs), there are specific coding rules. Clinical coders need to synthesize the entire medical record information and apply the coding rules, which could result in diagnoses different from those presented in the discharge summary.

Limitations

The AI-coding module was trained on inpatient data from April 2019 to December 2020. Advancements in medical care might lead to variations in the diseases of admitted patients. Taken together, these show situations where the AI-coding assistance module might not capture the main diagnosis, as observed in the Dermatology Department.

Conclusions

With the rapid advancements in global medical technology and the evolving challenges of diseases, the development of DRG-based hospital payment systems in various countries is also meeting significant challenges. Key areas for future research include determining the flexibility of DRG payments, balancing payment structures, and aligning with disease management goals [23]. The Taiwan DRGs system, like those in other countries, aims to prevent medical institutions from delivering excessive services and causing unnecessary waste, all while safeguarding patient rights. It looks to strengthen management mechanisms to improve the quality and efficiency of care and ensure fair payments among peers.

In this context, AI-assisted coding emerges as a powerful tool [24]. A recent study used cross-random control methods to prove that AI-assisted coding reduces the coding workload [25]. The focuses of our research were the practical applications of AI models, with two main goals. The first was to investigate the consistency between the AI-assisted coding module and coding professionals and the second was to find the departments suitable for using the AI-assisted coding module. The research results showed that the highest consistency in MDC classification was seen in diseases of the respiratory system, as well as infectious and parasitic diseases. In the analysis of various inpatient specialties, departments such as the Division of Cardiology, Division of Nephrology, and Department of Urology showed no significant difference from coder-assigned coding results; accordingly, consideration could be given to integrating the AI-assisted coding module into the hospital information system, allowing physicians to reference Taiwan DRGs assignments for hospitalized patients, thus effectively controlling medical expenses.

However, upon analyzing the entire hospital department, discrepancies were observed in alignment with disease categorizations and personnel coding, so the research team is actively working on continuous improvements. Nevertheless, AI-assisted coding indeed served as a valuable reference by reducing human errors, as during the research period, it was found that the error rate detected by human coders (number of coding errors by human coders/total cases) was 1.9% (50/2632). Given the regular updates to the tool book by the Department of Health and the revisions in coding rules, the coding assistance module undoubtedly proves to be a powerful tool.

The development of AI-assisted coding for the *ICD-10-CM* PCS is just the beginning for intelligent health care in disease classification. Many operational aspects of hospitals are closely related to the *ICD-10-CM* PCS, including inpatient coding monitoring, discharge preparation services, and infectious disease surveillance, among others. For hospital administrators, the goal of AI-assisted coding is to achieve best operational revenue. For human coders with the assistance of an *ICD-10-CM* AI coding system, work time is reduced. Additionally, strengthening knowledge in clinical documentation improvement enables human coders to maximize their role, positioning them to become documentation experts [15] and preparing them for further career development.

Abstract

Background: Language acquisition is a critical developmental milestone, with notable variability during the first 4 years of life. Developmental language disorder (DLD) often overlaps with other neurodevelopmental disorders or simple language delay (SLD), making early detection challenging, especially for primary caregivers.

Objective: We aimed to evaluate the effectiveness of the Gades platform, an adaptive screening tool that enables preschool teachers to identify potential language disorders without direct support from nursery school language therapists (NSLTs).

Methods: The study took place in a nursery school and an early childhood educational and psychopedagogical center in Madrid, Spain, involving 218 children aged 6 to 36 months, 24 preschool teachers, and 2 NSLTs. Initially, NSLTs conducted informational sessions to familiarize teachers with DLDs and how to identify them. Following this, the teachers used the Gades platform to conduct language screenings independently, without ongoing support from NSLTs. The Gades platform was enhanced to collect detailed profiles of each child and implemented an adaptive screening model tailored to account for variability in language development. This setup allowed preschool teachers, who are not language experts, to observe and assess language development effectively in natural, unsupervised educational environments. The study assessed the platform's utility in guiding teachers through these observations and its effectiveness in such settings.

Results: Gades identified language difficulties in 19.7% (43/218) of the children, with a higher prevalence in boys (29/218, 13.3%) than in girls (14/218, 6.4%). These challenges were most frequently observed in children aged 15 to 27 months. The platform demonstrated a high accuracy rate of 97.41%, with evaluators largely agreeing with its recommendations. Teachers also found Gades to be user friendly and a valuable tool for supporting language development observations in everyday educational settings.

Conclusions: Gades demonstrates potential as a reliable and accessible tool for early detection of language disorders, empowering educators to identify DLD and SLD in the absence of NSLTs. However, further refinement of the platform is required to effectively differentiate between DLD and SLD. By integrating Gades into routine preschool assessments, educators can facilitate timely interventions, bridging gaps in early childhood education and therapy.

Introduction

Screening and Prevalence of Developmental Language Disorder

Communication plays a fundamental role in children's cognitive development. Through communication, children acquire knowledge, express their thoughts and emotions, develop their cognitive ability, and establish relationships with others. Adequate communication development enables them to learn and participate in various social contexts. Therefore, language acquisition during childhood is one of the most critical developmental milestones but with the most substantial interindividual variability in the first 4 years of life. Children start consolidating their language learning process from the age of 4 to 6 years [1-7].

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*), published by the American Psychiatric Association, introduced a new category known as neurodevelopmental disorders (NDDs) that groups different conditions that emerge early in child development before starting elementary school. These conditions eventually persist throughout adulthood [8-12].

The NDDs include communication disorders related to language, speech, and communication impairments. Developmental language disorder (DLD) is classified as a communication disorder. Children with DLD experience challenges in the acquisition and use of language. Language proficiency depends on receptive and expressive abilities. Therefore, children diagnosed with DLD encounter difficulties in both domains [12]. Thus, vocabulary is more limited than expected, and sentences are shorter and less complex with grammatical errors or with speech alterations in narration and comprehension or production of sentences. In addition, they may appear shy or prefer to communicate only with their family members. Children with DLD not only have symptomatology in communication skills but also have difficulties in cognitive and sociocultural processes [5,13-16].

Moreover, a family history of language disorders is often present, and DLD occurs with other disorders, such as autism spectrum disorder and attention-deficit/hyperactivity disorder (ADHD), in 30% of cases [5,17,18]. This makes early detection of DLD in these children more challenging for primary care pediatricians due to the significant comorbidity and similar symptoms with other NDDs [19].

On the other hand, early detection of DLD can be masked by misidentifying it as simple language delay (SLD). DLD is a persistent disorder with a slow rate of improvement and significant variability. This differentiates it from SLD [1,5,20]. However, this indicator does not allow for early detection of DLD, as we cannot identify whether the child has a one-off delay or is showing symptoms of DLD. To differentiate among them, difficulties must be identified in other areas, such as semantics, pragmatics, morphosyntax, and phonology [3]. Therefore, language difficulties manifest through the aforementioned skills that are measurably below what is expected for age, significantly impacting academic achievement, work performance, communication, and socialization [8-11].

DLD is diagnosed at the age of 4 years and is usually stable over time, as interindividual differences in language ability are reduced [1]. However, there may be warning signs that manifest themselves earlier. A study carried out by Vall d'Hebron Hospital Universitari in Barcelona, Spain, highlights a significant portion of children aged 5 to 17 years who exhibit clear symptoms of NDDs but have not been previously diagnosed with DLD [21]. Moreover, communication disorders are one of the significant NDDs with more prevalence in Spanish schools (1.05%-3.42%), along with ADHD and learning disorders [21,22]. Other studies estimated that the population prevalence of language disorders, without any relation to other intellectual disabilities, is 7.58% for children aged 4 to 5 years [17] and 6.4% at the age of 10 years [23]. To summarize, within a preschool setting of 30 children, it can be anticipated that about 2 children may exhibit DLD manifestations [17]. In total, 10% of preschool children present difficulties in language acquisition, of whom 5% to 7% end up being diagnosed with DLD, and the rest are diagnosed with SLD [5].

Before the detection and diagnosis of DLD, there is a prevention phase. Here, the nursery school plays a key role, as it is within this environment that the child spends most of their time and is involved in different interactions [1]. These interactions contribute to developing their communicative skills (communicative intention, nonverbal communication, imitation, waiting, etc) with peers of a similar age and teachers. Research has demonstrated a correlation between children with DLD and their academic performance. In fact, 88% of these children fail to meet the necessary curricular standards during their first year of school [14,17]. Hence, there is a pressing need to support education professionals with enough training and knowledge to identify early indicators of potential language disorders [1,24-27].

In the detection phase, the aim is to identify early whether a child is suspected of having some NDDs. To achieve adequate detection, tools such as screening forms and questionnaires allow information to be compared with previously defined risk indicators [20,28-32]. Some regions, such as Madrid (Spain), have early childhood educational and psychopedagogical guidance teams supporting nursery schools' detection phase. These teams engage in preventive actions and collaborate to detect developmental issues during the initial years of a child's life. If an educational case is identified, it is referred to the early intervention centers responsible for the assessment and intervention phase [33].

The assessment and intervention cover different aspects. During the assessment phase, it is necessary to analyze the family environment through interviews with relatives. In addition, hearing tests should be administered to eliminate potential associated psychological disorders. Evaluation of communication, playing with peers, comprehension, language production, and psychomotor skills are also essential. Finally, this information is correlated with medical history [6,14,15,20]. The intervention phase for DLD should be multidisciplinary, involving teachers, occupational therapists, speech therapists,

and psychologists skilled in children's language development techniques [7,24,27,34].

Gades: A Screening Tool for DLD

Gades functions as a clinical decision support system designed to grant expert knowledge regarding language disorders to preschool teachers. It offers a screening form to assess the language acquisition process during the early stages of a child's development. Gades allows the implementation of screening systems in natural environments for the child, thereby embracing the principles of pervasive therapy [35].

Pervasive or ubiquitous therapy is a therapeutic approach supervised by professionals that aims to promote engagement in activities focused on improving the individual's life within their natural environment through the support of information and communication technologies. It aims to be person centered instead of focusing on a specific clinical pathology. It especially seeks to identify how a problem impacts and manifests across various contexts [18,36]. This approach has the same phases of prevention, detection, assessment, and intervention as normative therapy. Moreover, using information and communication technologies ensures consistency and continuity of the therapeutic process within the person's natural setting [32,37-39].

For children's pervasive therapy, its application extends beyond the clinical center to environments like the child's school or home. Nursery schools are included in these settings. Being places where children spend much of their time, they are crucial for the early detection of DLD [24]. During this educational phase, teachers or educators and specialists in therapeutic pedagogy, such as nursery school language therapists (NSLTs), are typically involved. However, many nursery schools lack NSLTs, and even when they are available, fewer than half of the children suspected of having a language disorder are referred to or receive support from these specialists [1,7,17,23,27].

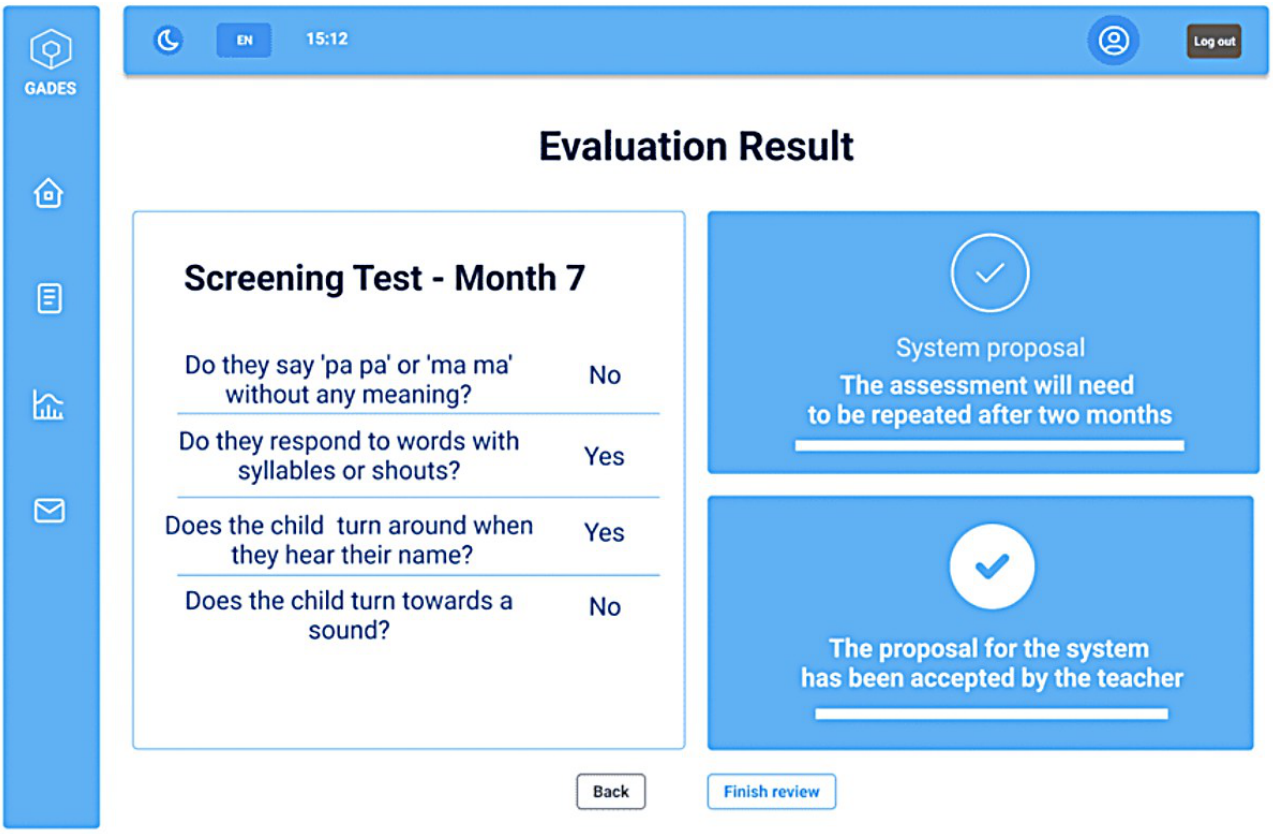
Martín Ruiz et al [35] developed and evaluated a previous version of Gades. The platform's cornerstone is a knowledge base (KB) that includes 106 milestones related to children's language acquisition based on age, defined and agreed upon by language experts. The previous version of this KB covered children aged 1 month to 72 months [35]. Building upon the findings of the previous experiment, increased instances of suspected DLD were identified in children aged 0 to 3 years. Consequently, in the current experiment, we focus on prioritizing the implementation of Gades during this developmental period. To extend this goal, Gades has undergone modifications and enhancements to its functionalities to gather additional pertinent information concerning language acquisition in children. These adaptations include integrating inquiries specific to the bilingual context of the children and their family backgrounds and evaluating results from the Gades across different language areas.

When using Gades, the corresponding milestones, tailored to the child's condition, are incorporated into a screening form through questions that education professionals use to assess a child's language development level. The milestones are categorized into 2 main types: "warning milestones," which prompt a reevaluation, and "alarm milestones," indicating the need for direct referral to health professionals. Gades' KB assesses 4 areas of speech and language development: sensory reception, speech perception, production, and pragmatic.

After the form adapted to the child is completed, Gades generates an evaluation result, including a suggestion for action if deviations from typical child development stages are detected. Therefore, it provides education professionals with expert knowledge on language acquisition, enhancing the early detection of DLD. Furthermore, this screening form acts as a psychopedagogical report for early intervention health professionals. Gades can aid in identifying the language development profile of a child suspected of having DLD through the assessment of processing-oriented and performance-based tasks.

Figure 1 depicts the graphical user interface of Gades, showcasing the evaluation results of consultation for a child aged 7 months. The platform displays the outcomes of the screening form, including the posed questions and the teacher's responses. Response options include "yes" if the child performs the specified action, "no" if not, and "do not know/no answer" for unknown answers. This form is completed based on the preschool teacher's observations of the child without direct interaction. After review, the system recommends that the assessment be repeated in 2 months, a suggestion that the overseeing teacher has validated. Gades also features additional tools for child registration, language evaluation, and user profile management.

Figure 1. Gades' evaluation result page for a child aged 7 months. In total, 4 questions were asked based on the child's age, and the system suggested repeating the evaluation in 2 months. The preschool teacher concurred with the system's recommendation.



Goal of This Study

For effective early detection and intervention of DLD, it is essential to offer sufficient services to these children to minimize the impact on their social, emotional, and educational development. Thus, language disorders often require a multidisciplinary approach among professionals from diverse fields such as education, speech-language therapy, and medicine to extend their reach into various settings [17,18,24]. Supporting training programs and systems for health and education professionals fosters collaboration. This collaboration facilitates the creation of adequate evaluation and intervention plans that meet the diverse needs of individuals with language difficulties, enhancing the quality of care and inclusivity [22,26,30,31,38,40].

Within this collaboration, the early detection of warning signs, which are potential indicators of language disorders in children, should be an integral part of the daily work of those interacting with children [1,7]. Supporting early childhood education professionals is crucial to ensure that they possess adequate knowledge and tools for preventing and detecting early language development issues in children aged 0 to 3 years because behaviors and warning signs related to language disorders can be identified from the age of 2 years onward [1,3,4,24]. It facilitates appropriate early diagnosis of DLD or SLD through subsequent assessment at early intervention centers. Moreover, given the absence of an NSLT in some schools, preschool teachers must have access to these resources.

Considering the higher incidence of suspected DLD observed in children aged 0 to 36 months in the previous experiment [17,23], this paper aims to emphasize the use of Gades during this period, targeting kindergarteners aged 6 to 36 months in a nursery school and an early childhood educational and psychopedagogical center. Gades has been adapted and expanded to gather more relevant information on language acquisition, including questions tailored to bilingual contexts and family backgrounds. Therefore, our primary goal is to evaluate Gades' ability to differentiate between typical and atypical language development for the target ages with these minor adjustments.

As the previous experiment consisted of a controlled environment, this paper also presents the relationship between preschool teachers and the Gades platform. Specifically, how Gades serves as a valuable tool for guiding nonexperts, such as preschool teachers, in conducting language observations. Therefore, it evaluates Gades' effectiveness in a real setting and its adherence to clinical criteria without direct supervision or intervention of language experts or technical staff. A potential challenge is also associated with integrating these technological tools into unsupervised educational settings to support therapeutic interventions [41].

Moreover, this screening process aims to identify the patterns indicative of a child with problems in language development, including SLD or DLD. Considering the updated *DSM-5* criteria, language development in children occurs within heterogeneous and dynamic contexts. Hence, it is imperative to use screening tools to identify significant patterns and milestones in the language development of a child with DLD, facilitating early detection and intervention. To accomplish this, the screening

tools must be intersectional, considering influential parameters, such as clinical conditions and the sociocultural and linguistic environment surrounding the child. Consequently, the final goal is to outline the framework for an adaptive screening model for language disorders that reflects the child's current developmental and social context. This approach ensures a comprehensive and nuanced understanding of each child's unique situation, enhancing the accuracy and effectiveness of early detection methods. Therefore, this study hypothesizes that the Gades platform can effectively support preschool teachers in the early detection of language development difficulties, including DLD and SLD, within natural educational settings, achieving high accuracy rates and providing actionable insights without requiring direct supervision from language disorder specialists.

Methods

Overview

This study used a prospective observational design to evaluate the updated Gades platform in real-world educational settings. The design involved monitoring children aged 6 to 36 months and their evaluators—preschool teachers and early childhood educators—over a defined period, collecting data as they naturally occurred during regular classroom activities. This approach was selected to ensure that the platform's performance could be assessed in authentic, uncontrolled conditions, reflecting its practical application. By focusing on how educators integrated Gades into their daily routines, the study aimed to capture unbiased insights into its usability and effectiveness in identifying early signs of language development difficulties.

Requirement Analysis

Individuals encounter varied communicative situations involving diverse entities and methods in everyday life. Current diagnoses and treatments for various disorders frequently overlook key characteristics, such as diversity, heterogeneity, and the role of socialization. The *DSM-5* and numerous studies highlight the necessity to consider interindividual differences in language acquisition early on. These sources suggest that assessments of language, speech, and communication should consider sociocultural aspects, linguistic context (including dialects), and socioeconomic status, as these aspects directly influence language development [1,12,16,17,19,21,31,32,42-44].

Bosch et al [21] demonstrated that 1.05% of the participants had communication disorders, with the most significant factors being foreign origin, genre, socioeconomic status, and age. Consequently, the diagnosis of language impairment should consider the individual's background, bilingual context, direct clinical observations in settings such as home or school, and results of standardized tests to assess the severity of the disorder.

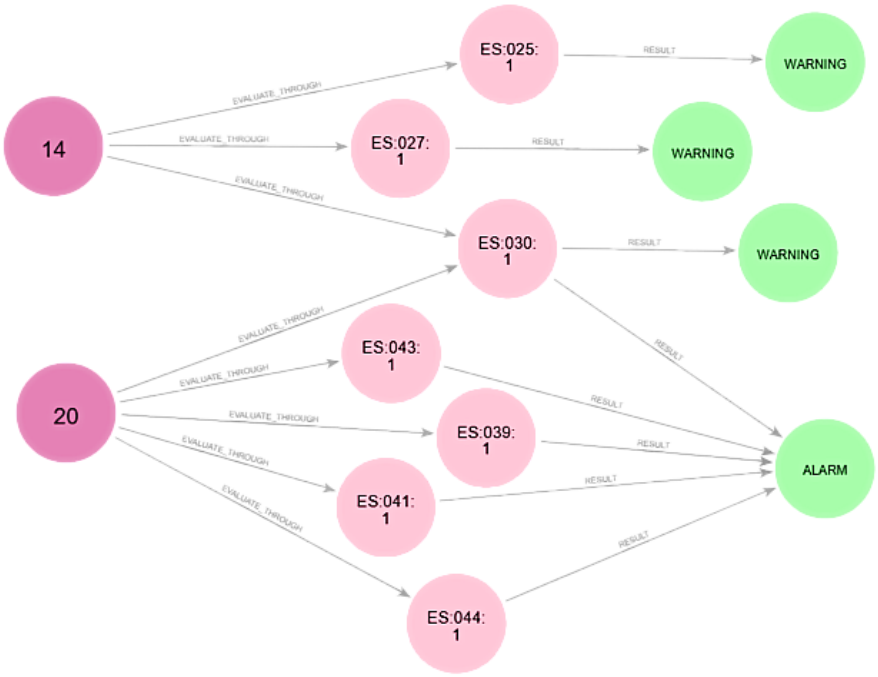
The New Gades Platform

Building on the previous experiment with the Gades platform [35], we updated it with new technologies and features. These enhancements enable the collection of additional information from children to conduct more accurate and suitable assessments of a child's language development. This includes gathering details about the child's family background, linguistic environment, and medical history, all of which contribute to a more comprehensive understanding of each child's unique developmental context. Therefore, incorporating these minor adjustments delineates the structure of an adaptable screening model that considers the variability in language development. This methodology guarantees a thorough and nuanced comprehension of each child's individual circumstances, enhancing the precision and efficacy of techniques for identifying potential issues in language development.

Implementing Neo4j (Neo4j Inc), a graph database technology, is crucial in optimizing our Gades platform, specifically in enhancing the accuracy of language disorder detection. Neo4j allows for a more natural and flexible representation of complex data and interconnected relationships between them, which is essential for modeling the intricate interactions and dependencies observed in child language development [45]. In the context of Gades, Neo4j facilitates the dynamic integration and analysis of large volumes of data related to language development milestones, assessment responses, and individual characteristics of children. For example, the graph structure enables us to directly link children's responses to specific questions with language development patterns and automatically flag connections that indicate potential delays or deviations from typical development.

Therefore, the KB has also been migrated to Neo4j graph databases. As illustrated in Figure 2, each milestone is represented through a month (dark pink node) with several questions (pale pink nodes) and a final suggestion (green nodes). Thus, in the figure, a dark pink node is represented each month, corresponding to different questions designed to evaluate the child's language proficiency, depicted by pale pink nodes. Notably, some questions are linked to multiple months, reflecting the dynamic nature of language development assessment. Different action suggestions can be generated based on the answers to these questions, such as confirming typical development, recommending reassessment, or advising referral to early childhood care services (green nodes represent these). This graph-based approach facilitates a nuanced analysis of the child's language development, allowing for tailored interventions sensitive to each child's unique progression.

Figure 2. Gades' knowledge base in Neo4j: milestone months (dark pink node), questions identifiers (pale pink nodes), and suggestions (green nodes). Each month has various questions to evaluate language acquisition (for a child aged 14 months or 20 months) with suggestions such as typical development, repeat evaluation, or advising referral to early childhood care services.



With the updates to Gades, the system has addressed feedback from educators seeking more information on DLD. Previously, questions were categorized by language development areas and were only accessible to the system's technical staff. However, with the recent improvements, information about various skills is now accessible to the evaluation staff. This improvement means that by using Gades, preschool teachers and other professionals can gain deeper insights into the specific language development areas being assessed. Such transparency not only empowers educators with a better understanding of language development but also enables them to contribute more effectively to detecting warning signs.

Table 1 illustrates the classification and number of questions across different categories. The sensory reception category is administered in the earliest months of life, primarily to assess for hearing issues, and gradually transitions into language perception. This aspect entails the capacity to receive, process, and comprehend linguistic information through sensory channels, whether auditory or visual. Pragmatics includes conversational skills, coherence, cohesion within discourse, and the functional and social use of the language. Finally, language production encompasses phonology, morphosyntax, semantics, and nonverbal communication. This structured approach allows for a comprehensive assessment of a child's language development, targeting specific areas crucial for early detection and intervention of language disorders.

Table 1. Classification of questions according to language category [35].

Language development domains	Number of questions
Sensory reception	3
Language perception	32
Production	48
Pragmatics	25

Hypothesis and Experiment

We aimed to validate the reliability and effectiveness of the new Gades platform in a real setting without the direct supervision or intervention of language experts or technical staff. We explored the interaction between preschool teachers and the Gades platform, highlighting how Gades functions as a valuable tool for facilitating language observations to detect warning signs of language difficulties by nonexperts. The Gades platform is specifically designed to assist in detecting early language difficulties that may signal potential DLD. By focusing on these early warning signs, Gades supports the early detection and monitoring of language development challenges in real-world educational settings.

The Gades KB was established in a previous study [35] and is grounded in standardized tests commonly used to assess DLD. This ensures that Gades relies on validated methodologies to identify and interpret potential language difficulties.

The study's population sample consisted of 218 children aged 6 to 36 months from 2 educational centers in the city of Madrid: a preschool center and an early childhood educational and

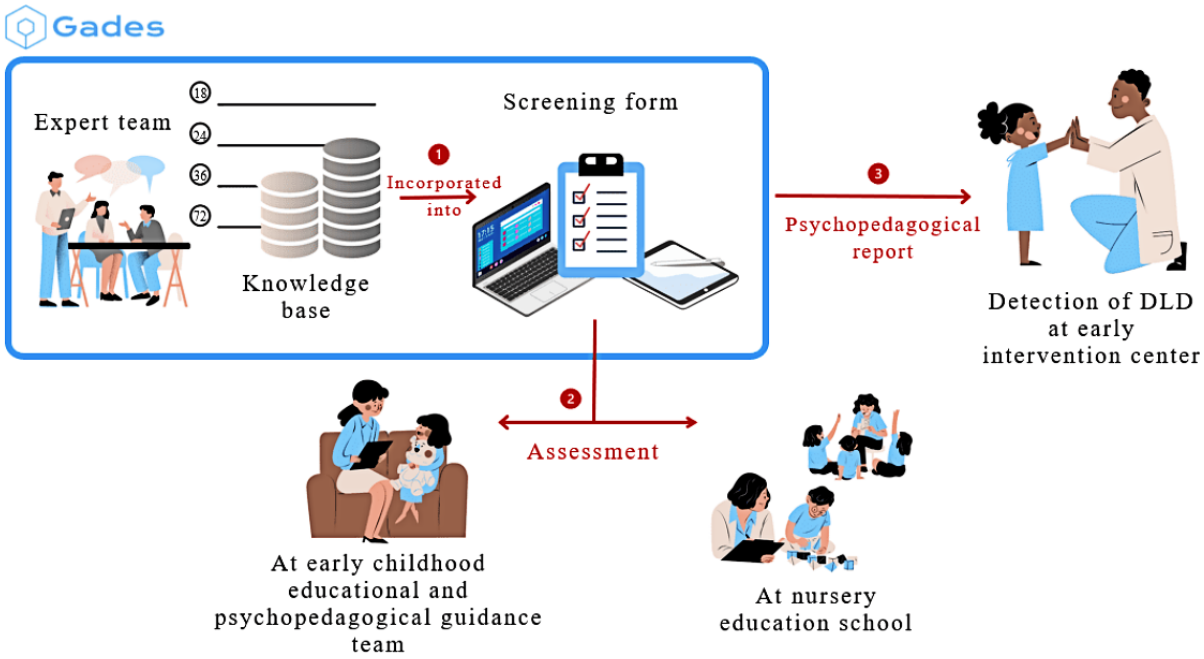
psychopedagogical center. All children enrolled in the first cycle of early childhood education, which aligns with this age range, participated in the study. This selection was based on recent evidence highlighting the critical importance of identifying language difficulties during this developmental period [1,3,4,24]. The screening data were collected from March to June 2023, providing an initial assessment of Gades' effectiveness in a real-world educational setting. Notably, access was limited to Spanish-speaking and some bilingual children.

The screening assessments for DLD involved the active participation of 24 nursery school educators and preschool teachers and a clinical professional from the early childhood center. Throughout this study, we will refer to them as evaluators. Hence, 2 categories of evaluators were involved in the experiment. The initial cohort consisted of professionals from early childhood centers, who, while not specialized in DLD, possessed adequate knowledge of NDDs. The second group comprised nursery school educators and preschool teachers, who may lack specialized language expertise but possess valuable insights into the children's competencies under their care. Before starting the experiment, the evaluators received training from qualified professionals affiliated with the Specific Language Disorder Association of Madrid. This training aimed to deepen their understanding and expertise regarding DLD and its identification with children aged 6 to 36 months. The training, delivered in a concise 2-hour format, was designed to ensure efficiency while providing comprehensive insights. By the session's conclusion, it was anticipated that the educators would have developed a more nuanced understanding of typical language milestones and a heightened capacity to discern early indications of language difficulties in children under their care.

During the evaluations, they operated without direct assistance from the training professionals or the Gades technical support team. Consequently, the experiment was conducted in an uncontrolled setting, relying exclusively on the evaluators' direct observation of the children's behavior for further evaluation through Gades. The evaluations were conducted following the guidelines recommended by Gades, aiming to ensure that the process was as effective and informative as possible within the constraints of the study's design.

Figure 3 outlines the Gades' framework, starting with an initial phase where a series of meetings were conducted to review and validate the KB established in the previous experiment. This phase involved experts in language disorders and the technical personnel from Gades to ensure the KB's relevance and accuracy. The panel of experts, who were also involved in constructing the KB as part of a previous study [35], recommended that including 3 to 6 questions per month would constitute an adequate measure for detecting language development issues. In the context of this study, the same experts conducted a review and confirmed the continued validity and applicability of the content of the KB. Once the KB was validated, the second phase, the screening process, began.

Figure 3. Gades' detailed framework. The process starts with expert validation of the knowledge base, integrated into a screening form with control and language questions. Evaluators assessed the children, and Gades provided recommendations, such as reassessment or referral, forming the basis of a psychopedagogical report. DLD: developmental language disorder.



The assessments were carried out by experienced female educators and professionals proficient in using digital platforms and information technologies. They used mobile devices and workplace computers to conduct evaluations, strategically scheduling them during the children's nap time around midday to minimize distractions. This approach involved each evaluator conducting assessments of the children under her care, which consisted of 2 parts. The first part included control questions related to the child's medical history and linguistic context, serving as a baseline for understanding each child's unique background. The second part consisted of the language difficulties screening questions. These questions were

meticulously developed in collaboration with experts to cover risk parameters for the early detection of DLD.

After the screening form was completed, the Gades system generated a recommendation to the evaluator, such as suggesting a repeat assessment in the upcoming months or indicating the need for a referral to an early intervention center. If a referral was recommended, nursery schools in Madrid forwarded the result to the expert through a psychopedagogical report. The designated expert, a language professional, was responsible for conducting a standardized evaluation tailored to the child's needs. Meanwhile, the educator played a supportive role by closely observing the child's progress in class and paying particular attention to areas of difficulty. Regular communication between schools and the expert was maintained with biweekly visits to ensure follow-up and support.

The application of the Gades platform was deliberately structured to be as nonintrusive as possible, allowing evaluators to focus on their primary duties while still contributing to the study. On average, each child underwent 1.24 (SD 0.49) assessments, indicating a consistent approach to the number of evaluations. The average duration of an assessment was 70 (SD 41.8) seconds per child, demonstrating the platform's efficiency in collecting data within a brief timeframe. To validate the Gades platform, both quantitative and qualitative analyses were conducted.

Quantitative validation focused on assessing the platform's accuracy and reliability. Descriptive statistics were used to summarize the duration and frequency of assessments. Agreement between the system's recommendations and evaluators' decisions was measured using concordance rates, calculated as the proportion of evaluations where the evaluators accepted Gades' recommendations. Statistical significance was set at $P<.05$. In addition, the platform's accuracy rate (97.41%) was determined by dividing the number of accepted suggestions (n=263) by the total number of evaluations (N=270). Instances of disagreement were analyzed qualitatively to identify patterns or recurring issues.

Qualitative validation focused on the integration of Gades into educational settings and its usability as perceived by preschool teachers. Evaluators were asked to provide feedback via a standardized questionnaire, following a validated system usability scale [41]. Responses were anonymized and collected outside the Gades platform to reduce potential bias. Evaluators also provided open-ended feedback to capture their experiences and insights, highlighting the platform's strengths and areas for improvement. The qualitative data were analyzed thematically to identify trends and recurring themes.

This combination of statistical and thematic analyses ensured a comprehensive validation of Gades. By comparing the platform's outcomes against educator feedback and established clinical criteria, the study aimed to validate Gades' ability to aid in the early detection of language development issues, such as SLD or DLD. Furthermore, comparisons between the initial version of Gades (2014) [35] and the current version highlighted improvements in adherence to clinical standards and system usability.

Ethical Considerations

This study, including the validation of the Gades platform and the experiment conducted through it, received ethics approval from the Ethics Committee of the Polytechnic University of Madrid in October 2023 GYGSDAALTD-MLMR-DATOS-20231010 and GYGSDAALTD-MLMR-HUMANOS-20231010). This approval ensures that both the use of the Gades platform and the specific experimental protocol comply with ethical standards, including data protection, participant rights, and research transparency.

For this study, an opt-out consent model was implemented. Participants were informed in advance about the study's objectives, the nature of the data collection, and the measures taken to ensure anonymity. They were given the opportunity to decline participation or withdraw their data at any point without providing a justification. Consent was implied by the participants' choice to continue with the evaluations, as no identifiable personal data were collected. Anonymized data were securely provided to the research team.

The professionals overseeing the evaluations maintained confidentiality in accordance with professional secrecy standards. Only the principal investigator had access to the evaluation results, which were securely stored in an encrypted database, accessible solely through authorized credentials.

Results

Sample Summary

The sample size for this study was calculated using a finite population correction formula to ensure adequate representation and statistical power. On the basis of demographic data from Madrid, the estimated population of children aged 6 to 36 months was approximately 150,000 [46]. With an assumed prevalence of DLD of 7%—a conservative estimate derived from epidemiological studies [17]—a 95% CI (Z=1.96), and a margin of error of 5%, the required sample size was calculated. The formula incorporates the finite population adjustment to account for the limited size of the target population, yielding a minimum required sample size of approximately 100 participants. This calculation also considered the variability in language development within the population.

The study's population sample comprised 218 Spanish-speaking children aged 6 to 36 months, more than double the calculated minimum sample size, ensuring robust statistical power and enhancing the reliability of the results. It featured a control group of 134 children from the nursery school (center 1) without any previous diagnosis or visible language difficulties and an experimental group of 84 children from the early childhood educational and psychopedagogical center (center 2), suspected of NDDs. Both groups were matched by gender to maintain homogeneity. Each child was assigned a random identifier for data anonymization and to facilitate subsequent analysis by the research team.

In Madrid's nursery schools, for each child, the evaluations were conducted by 2 assigned preschool teachers, also called an "educational pair." The concept of an "educational pair"

refers to 2 professionals sharing responsibilities and collaborating for the children's development and well-being, enabling the distribution of evaluation tasks between them. Therefore, in classrooms with children aged <12 months, each teacher evaluated an average of 4 (SD 0) children. For groups with children aged from 13 to 24 months, the responsibility increased to an average of 6.75 (SD 0.577) children per teacher. For those aged >24 months in the classroom, the average was 5.9 (SD 6.610) children per preschool teacher. Evaluations at the early childhood educational and psychopedagogical center were conducted by the teacher specializing in therapeutic pedagogy (NSLT).

Table 2 presents an overview of the study's sample, detailing the distribution of the children by age and gender: 45.4% (99/218) of the girls and 54.6% (119/218) of the boys participated. Within this group, 36% (36/99) of the girls and 40.3% (48/119) of the boys came from the early childhood center, initially identified with potential NDD concerns. Specifically, for participants aged >3 years, the study included 4 boys and 2 girls, all aged 37 months, except for 1 girl who was aged 38 months. The second year of the initial preschool cycle had the highest representation, with the largest number of children aged between 18 and 28 months, averaging 10 (SD 3.045) children per month. The average age in months per grade was distributed as follows: up to 12 months, the average age was 10.020 (SD 1.136) months; from 13 to 24 months, the average age was 20.331 (SD 1.108) months; and from 25 to 36 months, the average age was 31.578 (SD 1.094) months.

Table 2. Distribution of children by center, gender, and age range[a].

Grade	Up to 12 mo (n=26), n (%)	13-24 mo (n=102), n (%)	25-36 mo (n=84), n (%)
Children from center 1			
Female	10 (38.4)	22 (21.6)	31 (36.9)
Male	8 (30.7)	24 (23.5)	39 (46.4)
Children from center 2			
Female	5 (19.2)	22 (21.6)	9 (10.7)
Male	3 (11.5)	34 (33.3)	11 (13.1)

[a]Center 1 is the nursery school, and center 2 is a psychopedagogical center. The age ranges align with the preschool grades. The second year of the initial preschool cycle had the highest representation (102 children).

The screening form's initial section included questions regarding the child's medical history and linguistic context. Birth complication cases were more prevalent in center 1, particularly among male participants. Results indicated that 8.2% (11/134) of the children with no previous diagnosis of NDD experienced birth complications, including prenatal, perinatal, and preterm risks. 2.9% (4/134) were reported among females while among males, 5.2% (7/134) were observed. In center 2, only 2% (2/84) cases were reported in males and no cases in females. Notably, 3 children faced more than 2 of these risks, such as family history combined with perinatal risk. The mean gestational weeks remained relatively consistent across both centers and genders, with slightly more variation among girls. The average gestational age was 39.518 (SD 5.363) weeks, female children had an average of 38.984 (SD 2.36) weeks in center 1 and 40 (SD 0) weeks in center 2, while males had 39.563 (SD 1.29) weeks in center 1 and 39.791 weeks (SD 1.44) in center 2. A baby is considered premature if born before the 37th week of pregnancy. According to the study, only 3.7% (8/218) of the children were born preterm, highlighting specific early life factors that could influence developmental outcomes. Instances with a family history or bilingual cases were limited. Among the 218 cases studied, only 2 reported a family history of other NDDs such as autism spectrum disorder. Information regarding the bilingual context was exclusively available for children from center 1 (N=134). 7 (5.2%) cases were found among females, and 3 (2.2%) cases were recorded in males. It suggests that the language development impact of being raised in a bilingual environment could not be thoroughly assessed across the entire sample.

Overview of the Obtained Health Results

This section presents the results obtained from the evaluations that were conducted. A total of 270 assessments were completed, accounting for instances where children underwent multiple assessments. Retaining only the latest assessment conducted for each child (218 evaluations), there were 19.7% (43/218) children, which resulted in a suggestion to refer them to an early intervention center for a specific assessment by a professional. These types of suggestions were classified as alarms. That was the most severe system decision. Table 3 shows the results of the final assessments. The system has recommended repeating the remaining assessments in subsequent months to further evaluate and discard language issues. Suggestions that indicate repeat evaluation are classified as warning type.

Table 3. Distribution of Gades' final suggestionsa (N=218).

Description	Distribution, n (%)
Typical developmental	117 (53.7)
Refer to early childhood care	43 (19.7)
Repeat assessment (within 3 mo)	28 (12.8)
Repeat assessment (within 2 mo)	19 (8.7)
Repeat assessment (within 1 mo)	11 (5)

[a]More than half of the sample (n=117, 53.7%) were identified as typical language development. However, 19.7% (43/218) of assessments identified language difficulties as indicative of possible simple language delay or developmental language disorder.

Table 4 displays the distribution of assessment types by gender. It reveals that more alarm cases were identified in boys (29/218, 13.3%) compared to girls (14/218, 6.4%). In addition, both genders had a similar frequency of warning assessments and neurotypical results.

Table 4. Distribution of evaluations by suggestion type and gender. More alarm cases were identified in boys (29/218, 13.3%) compared with girls (14/218, 6.4%). Both genders had a similar rate of warning assessments and neurotypical results (N=218).

Gender and evaluation	Evaluations, n (%)
Female	
Alarm	14 (6.4)
Warning	29 (13.3)
No findings	56 (25.9)
Male	
Alarm	29 (13.3)
Warning	29 (13.3)
No findings	61 (27.9)

Gades identified more cases of alarm and warning in children already undergoing evaluation by specialists than from the center (alarm: 29.7%; warning: 32.1%), but we do not know whether these children had language disorders. Hence, among children already experiencing some difficulties, it identified that there may be some indication of language difficulties (ie, DLD or SLD).

Table 5 shows the distribution of evaluations that were classified as an alarm because it was detected that the assessed child did not meet the language acquisition milestones expected for their age. The incidence of language impairment from center 2 was comparable between boys and girls (15:10) and 30% (25/84) of the cases were detected as alarms. Meanwhile, for children without a suspicion of NDD coming from nursery school (center 1), difficulties in language and communication were detected in 13.4% (18/134) of the cases. However, a notable discrepancy was observed between boys and girls (14:4).

Table 5. Distributions of alarm evaluations by gender, month, and center[a].

Month	9	10	11	14	15	16	18	19	20	24	25	26	27	28	30	32	37	Total
Children center 1																		
Female	0	1	1	0	0	0	0	0	1	1	0	0	0	0	0	0	0	4
Male	0	1	0	1	0	0	4	0	0	1	1	2	1	0	1	1	1	14
Total	0	2	1	1	0	0	4	0	1	2	1	2	1	0	1	1	1	18
Children center 2																		
Female	1	0	0	0	2	0	1	3	0	0	0	1	1	1	0	0	0	10
Male	0	0	0	0	3	1	4	2	2	2	1	0	0	0	0	0	0	15
Total	1	0	0	0	5	1	5	5	2	2	1	1	1	1	0	0	0	25

[a]For children coming from center 1, language issues were detected in 13.4% (18/134) of the cases. The incidence of language issues from center 2 was comparable between male and female participants (15:10), with alarms detected in 30% (25/84) of the cases.

Notably, most of the suspected cases were detected in months 15, 18, 19 and 24. All these months correspond to the second year, encompassing children aged between 1 and 2 years. Upon thorough analysis of the evaluations during these months,

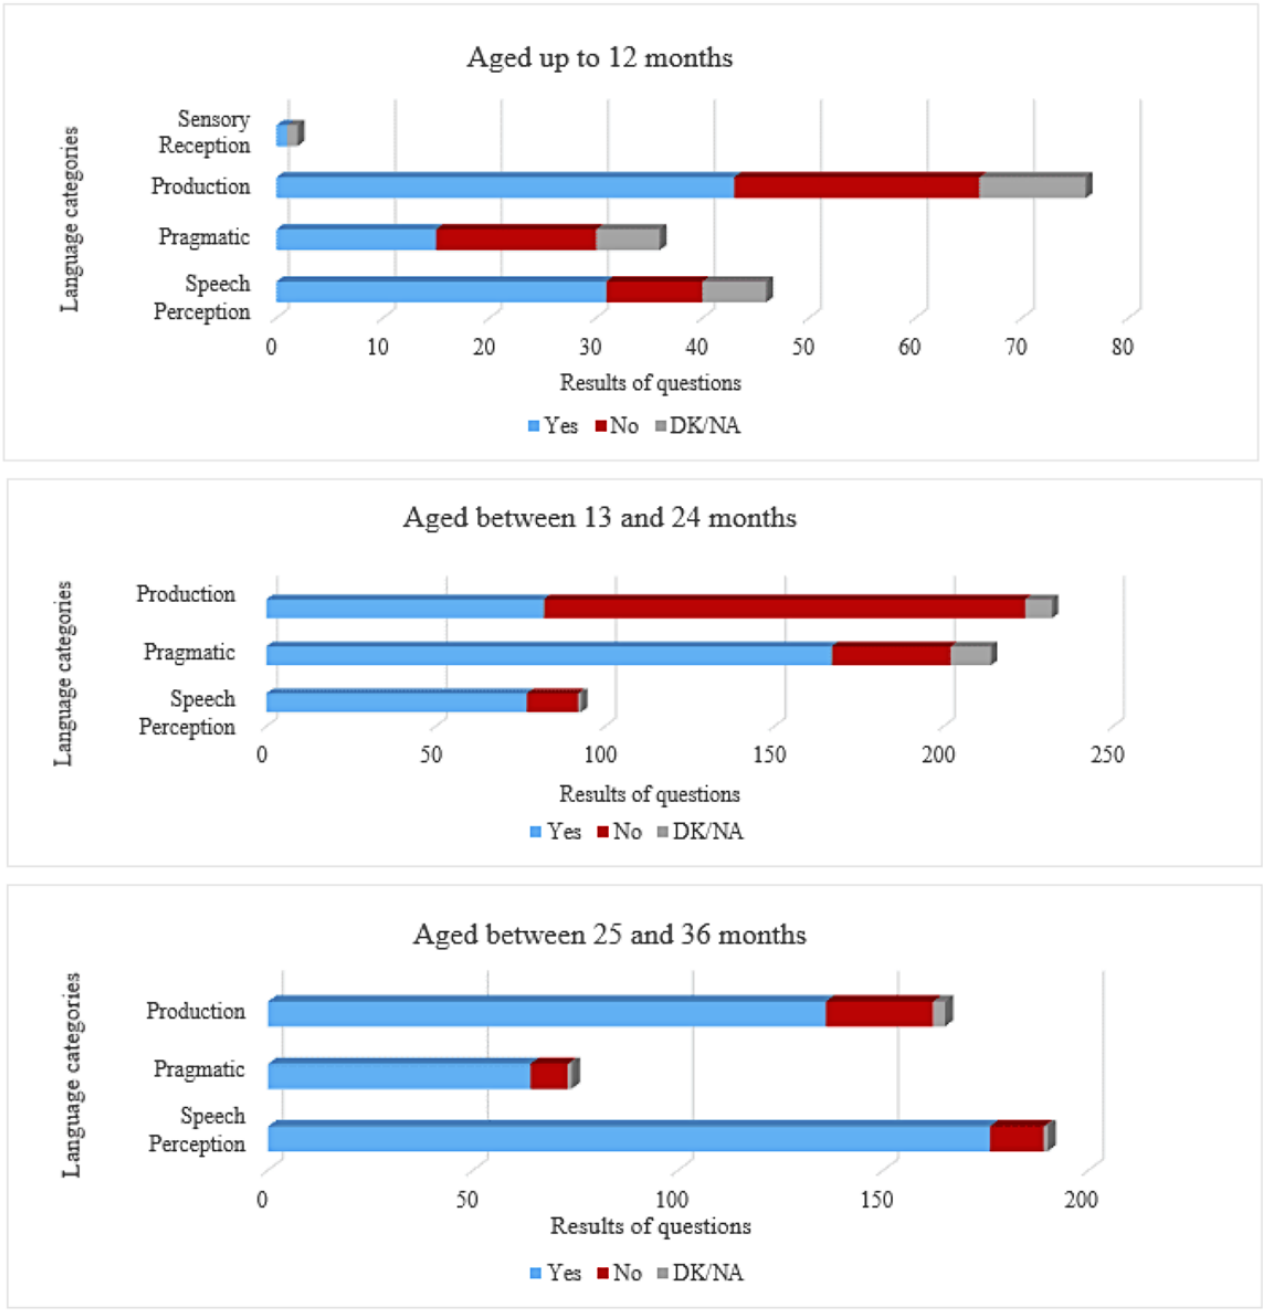
difficulties were discerned in the language production category for month 15. Half (23/40, 50%) of the children resulted in alarms. When compared to assessments from previous months, several observations emerged. First, most questions in this category were not been asked in previous months, as the child's age renders them too young to possess these competencies. Second, only 1 question, "first disyllables (one word in addition to dada and mama)?" was repeated in months 12 and 14, with half (8/14, 57%) of the assessed children answering negatively in both months. For month 15, all respondents answered negatively.

Month 18 had the highest number of detected suspected cases (9/11, 82%). During one of the meetings, educators expressed that they had observed more issues in language production, citing example, such as the child's inability to articulate certain words. In addition, similar questions asked in previous months also resulted in alarms. For instance, the one with the most error answers was "first bisyllables (two words in addition to dada and mama)?" In subsequent months, specifically month 19, identical pragmatics and language production questions were asked, and negative responses were received.

In month 24, 40% (4/10) of the evaluations raised alarms. Upon analyzing the questions, 3 were related to pragmatics and language comprehension, which were previously asked in earlier months. Most children satisfactorily answered these questions, indicating alignment with their current developmental stage. Therefore, the cases prompting alarms may signify potential instances of children with SLD or DLD.

Figure 4 depicts the results of questions categorized by language development areas. The sensory reception category was evaluated only for children aged up to 12 months to discard hearing issues. Children aged <12 months encountered more challenges in the production and pragmatics categories. Furthermore, there were no cases of hearing problems. The pragmatics category showed an equal balance between successes and failures. Conversely, children in the second year demonstrated notable difficulty in answering questions within the language production category, with a higher-than-average rate of incorrect responses. Other categories showed satisfactory performance.

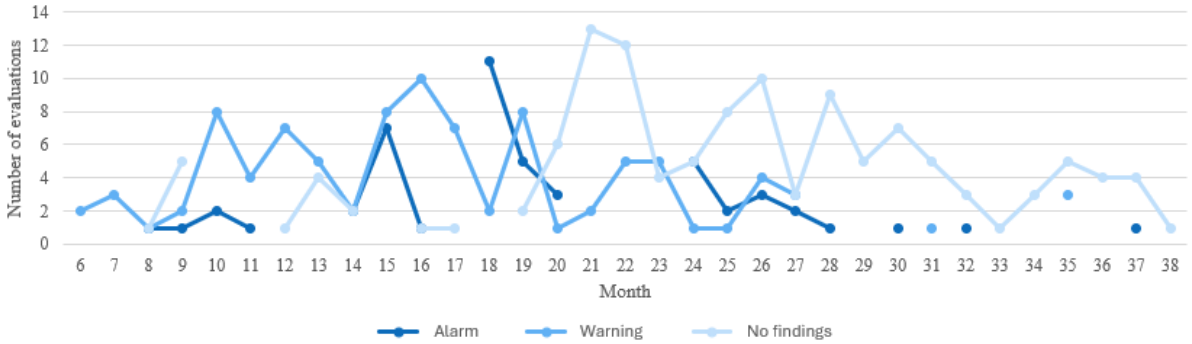
Figure 4. Distribution of results based on language-category questions. Each question is categorized according to language category (refer to Table 1 for more information) and can be answered with a yes, no, or do not know/no answer (DK/NA). Children aged from 13 to 24 months demonstrated notable difficulty in production questions. Children aged >24 months exhibited positive responses across most categories.



Finally, children aged >24 months exhibited predominantly positive responses across most categories. Hence, it becomes evident that children aged <24 months exhibit a higher frequency of errors, attributable to the inherent variability in language acquisition during this developmental stage. Consequently, there is a pressing need for greater flexibility in language milestones and extending their coverage across months.

As illustrated in Figure 5, this distribution reveals that instances of children with difficulty in language development are prevalent between months 15 and 27, gradually decreasing in the final months until 3 years of age.

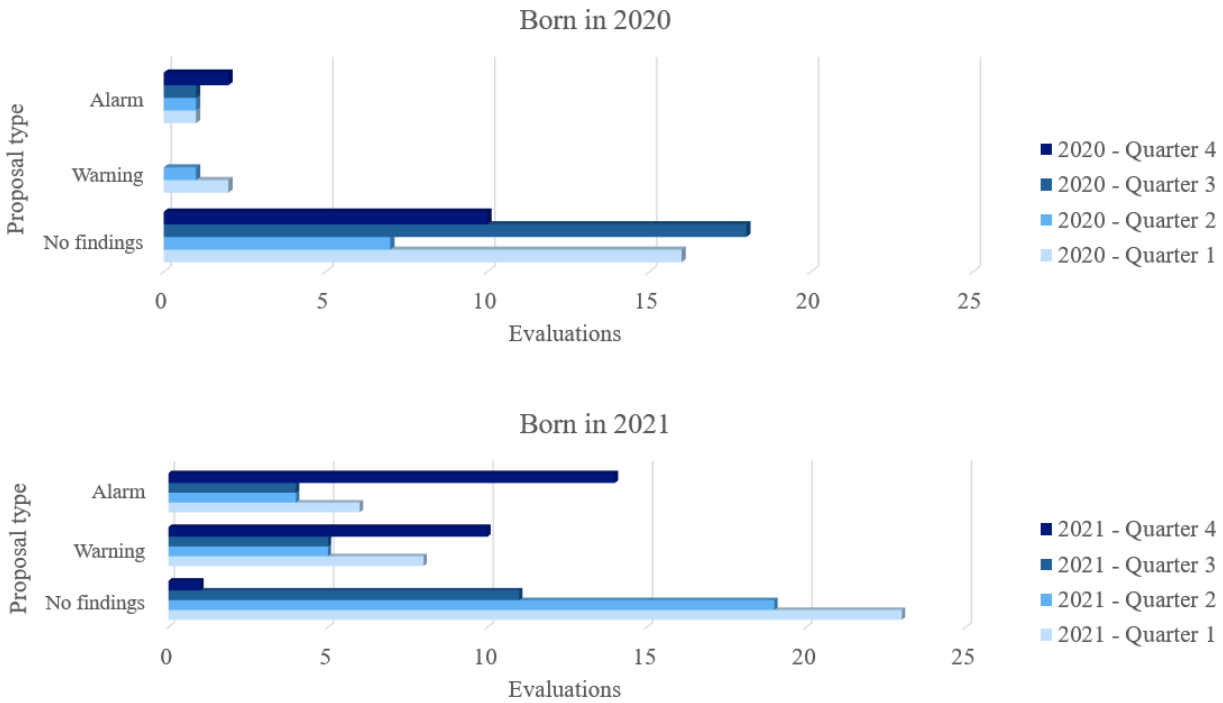
Figure 5. Distribution of suggestion type per month. Cases of children with language development issues were prevalent between months 15 and 27 (dark blue). The graphic reveals a gradual decline during the final months, with more typical development cases (pale blue).



In contrast, the evaluations were analyzed considering the control questions asked and the correlation between language development and the child's date of birth. In Madrid's nursery school classes, children were grouped based on their birth year. Consequently, at the beginning of the school year in September, a significant age gap existed between children born in the first quarter and those born in the last months. The latter group comprised the youngest in the class, resulting in a notable developmental difference between them.

The assessment outcomes for the youngest children in each class are presented in Figure 6. The youngest children were defined as those born from October to December 2020 for the age range of 25 to 36 months and from October to December 2021 for the age range of 13 to 24 months. This categorization was not applicable for children aged <12 months, as we did not have children from the last trimester. Hence, upon comparing the alarm for children born in 2020 and those born in 2021, it consistently appeared higher for those in the previous quarter. The youngest children tend to yield poorer results using Gades, as language development differs.

Figure 6. Assessment results by school quarter and suggestion type. For children born in 2020 (age between 25 and 36 months) alarm cases were more prevalent among children from quarter 4. However, these results are tempered by many more typical development cases at the same age. By contrast, for children born in 2021, the youngest children (quarter 4) tended to have alarm suggestions using the Gades platform.



The results of the assessment outcomes in relation to the control questions can be observed in Table 6. It is noteworthy that the 2 children who disclosed a family history of other NDD in the control questions were identified as cases with difficulties in language development (ie, SLD or DLD cases). Among cases with reported issues during pregnancy (ie, perinatal, prenatal, or premature), a notable percentage resulted in difficulties in language development (9/13, 69% including warnings). In the case of preterm children, only 8 (3.7%) of the 218 cases were identified as cases with difficulties in language development. Only one of these preterm cases, a girl, was assessed as an alarm. The 3 cases of preterm boys without previous NDD

demonstrated typical development. The remaining alarms in boys corresponded to cases of prenatal (3/218, 1.4%) and perinatal (4/218, 1.8%) risks. A similar scenario extended to bilingual cases, where only 1 child exhibited an alarm of language development difficulties.

Table 6. The child's evaluations were distributed by control information, gender, and suggestion typea (N=218).

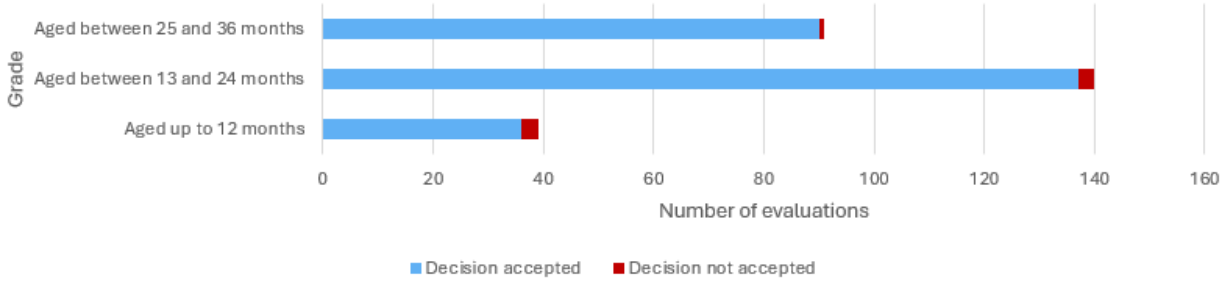
Gender and evaluation	Birth complications, n (%)		Family history, n (%)		Bilingual cases, n (%)	
	Center 1	Center 2	Center 1	Center 2	Center 1	Center 2
Female						
Alarm	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Warning	3 (1.4)	0 (0)	0 (0)	0 (0)	3 (1.4)	0 (0)
Typical development	1 (0.5)	0 (0)	0 (0)	0 (0)	4 (1.8)	0 (0)
Male						
Alarm	4 (1.8)	2 (0.9)	1 (0.5)	1 (0.5)	1 (0.5)	0 (0)
Warning	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Typical development	3 (1.4)	0 (0)	0 (0)	0 (0)	2 (0.9)	0 (0)

[a]Among children with birth complications, 69% (9/13) of them showed language development difficulties. Those with a family history of neurodevelopmental disorder also faced challenges, while only 1 bilingual child showed an alarm.

Gades' Performance

Gades' performance is assessed by the extent to which the system's decisions align with the perspectives of evaluators who support its recommendations. If there was disagreement with a recommendation, evaluators were prompted to justify dissent. Evaluators based their agreement or disagreement with the system's decision on their understanding of the child, considering factors such as age, family environment, and communicative intent. According to the results, Gades exhibited an accuracy rate of 97.4% (263/270). Out of 270 evaluations, only 7 (2.6%) suggestions were declined by evaluators. Figure 7 shows a higher disagreement rate with the system's decisions in children aged <24 months. Specifically, the accuracy rate was 92.3% up to 12 months, compared to 97.8% in the second grade (aged between 13 and 24 months) and 98.9% in the third grade (aged between 25 and 36 months).

Figure 7. Gades acceptance per grade. Out of 270 evaluations, only 7 proposals were declined (ie, 3 for evaluations of the first and second grades and 1 for evaluations in children aged >24 months). Even so, the acceptance of Gades remains above 90% in all courses.



Considering the total of 270 assessments conducted, including those where children were evaluated twice, the accuracy of Gades' decisions is depicted in Table 7. Among the suggestions provided by the Gades system, where evaluators disagreed (7/270, 2.6%), some suggested referring the child to early intervention for a specialized assessment (5/270, 1.9%).

Table 7. Gades' accuracy by the suggestion typea.

Suggestion description	Accepted suggestion, n (%)	
	No (n=7)	Yes (n=263)
Refer to early childhood care	5 (1.9)	45 (16.7)
Typical development	0 (0)	125 (46.3)
Repeat assessment (within 2 mo)	2 (0.74)	29 (10.7)
Repeat assessment (within 3 mo)	0 (0)	44 (16.3)
Repeat assessment (within 1 mo)	0 (0)	20 (7.4)

[a]Evaluators did not agree with Gades' suggestion in 2.6% (7/270) of evaluations. Most of these unaccepted suggestions were for the most severe cases identified by Gades ("refer to early childhood care"). Gades exhibit an accuracy rate of 97.41%.

When the evaluator disagreed with the Gades' decision, they were required to provide a comment stating the reason for nonacceptance. Thus, several reasons explain why the evaluators did not accept Gades' decision (Table 8). In 4 instances (ie, for months 10, 12, 15, and 18), they noted that the questions were not tailored to the child's developmental stage. In 2 cases from 18 months, the evaluator rejected the suggestion. Moreover, in case "The questions do not align with the child's developmental stage," the assessor disagreed with the suggestion and conducted an immediate reassessment. This subsequent assessment issued a warning (ie, to repeat the evaluation in the next months). In addition, in 2 cases involving 2 boys, the evaluators intended to continue observing the child's progress as they had identified other communicative skills. Finally, there was no disagreement for typical development cases.

Table 8. Evaluator's reasons for rejecting the final suggestion from Gadesa.

Reason	Children's gender	Evaluation month
Refer to early childhood care		
"We will monitor the situation closely. If necessary, we will consult the Early Assessment Team for guidance."	Male	26
"There are alternative forms of communication besides verbal language, and he demonstrates proficiency in them. We will observe his development and see how it progresses."	Male	18
"The questions do not align with the child's developmental stage."	Female	10
"The questions do not align with the child's developmental stage."	Male	10
"The questions do not align with the child's developmental stage."	Female	15
Repeat assessment (within 2 mo)		
"The questions do not align with the child's developmental stage."	Female	12
"We consider that it is not necessary at this stage."	Male	18

[a]The suggestions that were not accepted relate to "refer to early childhood care and repeat assessment (within 2 months)". Most of the reasons were that the assessment conducted by Gades was not aligned with the child's developmental stage.

Overview of the Obtained Functional Results

Numerous interviews were conducted with the evaluation staff, and they completed a web-based form assessing the usefulness and practicality of the Gades tool in uncontrolled educational settings, following the guidelines outlined in the referenced study [41]. None of the evaluators had previous experience using this specific platform. It was noted that preschool educators and professionals in early childhood educational and psychopedagogical centers found Gades highly acceptable. Most (18/24, 75%) of the evaluators found the system easy to use, although it required dedicated time. They experienced occasional technological issues such as student search processes or time sessions. A quarter felt previous technological knowledge was necessary.

The educators used an observational methodology during the school day to respond to the form's questions, considering it noninvasive and conducive to respectful support within an appropriate environment for the child. They suggested that implementing the Gades assessment during the first term of the school year, particularly during the adaptation period, could be challenging due to their limited familiarity with the child. In addition, they proposed conducting evaluations every 3 months for cases initially indicating "typical development" to ensure ongoing progress.

While control questions were valuable for accurate results from the Gades system, access to certain information, particularly related to birth difficulties, was limited for many children. Regarding the comprehension and appropriateness of the KB questions, educators encountered comprehension difficulties in only 2 out of the 108 questions, which they resolved by consulting the Gades' technical staff. They noted that some questions were unsuitable for the child's developmental stage. They highlighted the absence of questions about family context, communication dynamics, and disruptive behaviors in the second and third years.

Regarding recommendations, 75% (18/24) of the evaluators reported that they would suggest Gades to other nursery schools, emphasizing the need for previous DLD training to observe children effectively. They reported high knowledge acquisition and insight into their students' language development. For instance, they had observed that girls aged <12 months initiated communication earlier and more fluently.

Discussion

Principal Findings

This study's core findings underscore the Gades platform's effectiveness as a robust tool for screening language disorders in preschool environments, successfully identifying language difficulties in 19.7% (43/218) of the children assessed. This rate, with a notable prevalence in boys (29/218, 13.3%) compared to girls (14/218, 6.4%), is significantly higher than the traditional prevalence estimates of 2% to 7% for DLDs [8,17,21,23,43]. This discrepancy suggests that Gades may be particularly sensitive to early signs of language difficulties or may also capture cases of SLD. As a screening tool rather than a diagnostic system, Gades aims to identify children at higher risk for DLD or SLD, which might lead to elevated detection rates compared to studies focused strictly on diagnosis. Comprehensive assessments by specialists at early intervention

centers are required for a definitive diagnosis, highlighting the necessity of further evaluation following initial screening outcomes.

The study validated Gades' technical and functional capabilities in uncontrolled educational settings without direct intervention by an NSLT. The platform's utility in guiding nonexpert users, such as preschool teachers, through the screening process was particularly noteworthy. Teachers could use Gades effectively to observe and assess language development, reflecting its potential to empower educators with limited specialized training in language disorders.

Moreover, Gades demonstrated a high accuracy rate (97.41%) in aligning with the educators' assessments, underscoring its reliability and the robustness of its underlying algorithms and KB. The discrepancies between the system's recommendations and the educators' judgments were minimal, indicating a high level of agreement and trust in the platform's diagnostic suggestions.

The findings also illuminated specific age ranges (between 15 and 27 months) where language difficulties are most prevalent, reinforcing the importance of targeted early intervention during this critical developmental period. The ability of Gades to adapt its screening approach based on the child's age and specific educational context was a key factor in its effectiveness.

These promising results suggest that integrating Gades into regular preschool assessments could significantly enhance the early detection of language disorders, potentially leading to more timely and effective interventions.

Extending Detection to Natural Environments

This study highlights the importance of checking for developmental disorders similar to DLD in natural settings, such as preschools, where children naturally spend much time. DLD, similar to autism and ADHD, is among the most common developmental challenges but often goes unrecognized because its symptoms may resemble simple speech delays or overlap with other developmental disorders, leading to delayed diagnoses. Equipping educators, teachers, and school professionals with the right knowledge and support is crucial because they can spot early signs of these disorders. Early detection, significantly enhanced through collaboration with a multidisciplinary team, is key to improving a child's prospects for developing language skills effectively.

Applicability and Scalability

The Gades platform is designed to be versatile and scalable, making it a valuable tool for educators worldwide, especially in regions with limited access to specialized language disorder services. This flexibility is crucial for adapting to diverse linguistic and cultural environments across global educational systems. To effectively implement Gades in these diverse settings, developing training programs sensitive to local languages and educational standards is essential. These programs should equip educators with the skills to use the platform effectively and to recognize early signs of language disorders, even without specialized training.

Considering the technological limitations in different regions, Gades should be designed to operate in low-bandwidth environments and comply with local data protection regulations. This will make the platform accessible and trustworthy. Enhancing the platform's database to support multiple languages and reflect cultural specifics can make Gades a more inclusive tool that accurately reflects diverse child development patterns.

Practical implementation strategies include collaborating with local educational authorities to incorporate Gades into routine screening processes. This might involve tailoring the platform to meet local developmental benchmarks and language nuances. Partnering with local educational institutions can provide continuous support and feedback, helping to refine the platform.

Gades could offer versions that range from sophisticated, high-tech applications to more basic, web-accessible formats to accommodate varying technological capabilities. Establishing a community of practice among Gades users would encourage sharing best practices and provide essential peer support, enhancing the platform's overall effectiveness and user experience.

Limitations

One significant limitation of the Gades system is its reliance on the accuracy of the input provided by educators, who may not have specialized training in identifying language disorders. This dependency can introduce biases or inaccuracies in the screening process, as nonexpert interpretations of language development may vary widely, affecting the reliability of the outcomes. To mitigate these potential biases, it is essential to implement comprehensive training programs for educators using the platform. These programs should focus on familiarizing them with common language development milestones and the specific signs of language disorders. In addition, incorporating automated prompts and guidelines within the Gades system can help standardize recorded observations, reducing subjective interpretation errors.

Further refining the interface and feedback mechanisms of Gades can also enhance the accuracy of the data collected. For instance, the platform could include illustrative examples or short training videos on typical versus atypical language behaviors to guide educators' assessments before they input data. Regular updates and calibrations based on user feedback and new research in language development could further improve the system's precision and adaptability to real-world educational environments.

The study's limitations extend beyond the technical aspects of the Gades platform to include concerns about the sample size and the uncontrolled implementation settings. The small sample size may not adequately represent the broader population of preschool children, limiting the generalizability of the findings. In addition, while providing real-world insights into the use of Gades, the uncontrolled setting might introduce variability in how the platform is used across different environments, potentially influencing the consistency and applicability of the results. These factors could lead to higher variability in outcomes, which might not fully indicate the platform's efficacy under different or more controlled conditions.

Future Directions

Future research should include larger and more diverse populations to address the limitations mentioned to ensure that findings are robust and widely applicable. Controlled trials, where variables can be more tightly managed, would also help understand the platform's effectiveness across varied educational settings and populations. This would allow for more reliable validation of the platform's capabilities and identify specific conditions under which it performs best, guiding more targeted improvements.

To enhance Gades' effectiveness and reliability, it is imperative to refine the tool by expanding the KB to better differentiate between DLD and SLD at earlier stages. Adapting the system to align more closely with the actual ages of children rather than their academic year will provide more accurate assessments. Implementing educator training modules will equip them to effectively recognize early signs of language difficulties. Future versions of Gades should include a nuanced approach for assessing the youngest children in the class, considering their specific developmental stages and potential delays without prematurely recommending specialist evaluations. These improvements will ensure that Gades supports early detection and integrates smoothly into regular preschool assessments, potentially enhancing the effectiveness of interventions for language disorders.

Conclusions

This study confirms that DLD remains a commonly overlooked condition with significant variability and potential overlaps with other developmental disorders. Importantly, our findings reinforce the critical nature of age-specific screenings, with the most alarms for language difficulties arising in second-year grades, supporting the hypothesis that this period is crucial for detecting DLD risk factors. Despite the conservative and generic screening process, which identified language difficulties in 19% of cases—higher than the 7% prevalence typically noted in other studies—some of these instances may represent SLD. This suggests a need for refining language milestones within the Gades system to more effectively distinguish between DLD and SLD.

The qualitative outcomes from the Gades platform demonstrate its value in designing tailored educational programs and therapeutic interventions. By integrating such tools without the need for direct support from NSLT, Gades facilitates a deeper understanding of individual language development patterns. This insight enables educators, particularly those without specialized training in language disorders, to identify and address developmental challenges more effectively and earlier. The platform has been well-received in terms of usability and practicality, enhancing educators' ability to actively monitor and support language development.

Moreover, implementing Gades has provided substantial learning opportunities for preschool teachers. Educators with no previous expertise in DLD have gained significant knowledge and skills in informal screening processes, which has had a transformative impact on their ability to recognize and respond to language development issues. This empowerment of teachers underscores the potential of Gades to serve as a foundational tool in early education settings, enhancing early detection and intervention strategies.

To extend the utility of Gades beyond this study context, it is crucial to provide practical recommendations for its implementation in various educational settings. Tailoring the platform to accommodate different regional educational standards and linguistic backgrounds can maximize its effectiveness and reach. In addition, the successful deployment of Gades is contingent upon comprehensive training programs for educators. These programs should focus on enhancing understanding of language milestones, screening techniques, and the specific functionalities of the Gades platform. Effective training could be implemented through web-based modules, workshops, and ongoing support systems to ensure educators can proficiently use the tool.

In conclusion, the Gades platform represents a significant advancement in the field of educational technology for screening language disorders. By facilitating detailed observation and reporting of language development, Gades supports educators in their daily interactions with children and contributes to a broader strategy for addressing DLDs in early childhood education. The adoption of such tools, accompanied by adequate training and tailored implementation strategies, holds the promise of significantly improving outcomes for children at risk of DLD and SLD across diverse educational landscapes.

Acknowledgments

The authors would like to thank the team of educators and preschool teachers from Escuela Infantil Sabina and Patricia Calcerrada Muñoz from Equipo de Orientación Educativa y Psicopedagógica de Atención Temprana de Parla (Madrid, Spain) for their collaboration in performing the experiment presented here. In addition, the authors give special thanks to Esther González Dávila and Elena Jambrina Prieto from the Asociación del Trastorno Específico del Lenguaje de Madrid for their support in this study.

Abstract

Background: The global increase in the Internet of Things (IoT) adoption has sparked interest in its application within the educational sector, particularly in colleges and universities. Previous studies have often focused on individual attitudes toward IoT without considering a multiperspective approach and have overlooked the impact of IoT on the technology acceptance model outside the educational domain.

Objective: This study aims to bridge the research gap by investigating the factors influencing IoT adoption in educational settings, thereby enhancing the understanding of collaborative learning through technology. It seeks to elucidate how IoT can facilitate learning processes and technology acceptance among college and university students in the United Arab Emirates.

Methods: A questionnaire was distributed to students across various colleges and universities in the United Arab Emirates, garnering 463 participants. The data collected were analyzed using a hybrid approach that integrates structural equation modeling (SEM) and artificial neural network (ANN), along with importance-performance map analysis to evaluate the significance and performance of each factor affecting IoT adoption.

Results: The study, involving 463 participants, identifies 2 primary levels at which factors influence the intention to adopt IoT technologies. Initial influences include technology optimism (TOP), innovation, and learning motivation, crucial for application engagement. Advanced influences stem from technology acceptance model constructs, particularly perceived ease of use (PE) and perceived usefulness (PU), which directly enhance adoption intentions. Detailed statistical analysis using partial least squares–SEM reveals significant relationships: TOP and innovativeness impact PE (β=.412, *P*=.04; β=.608, *P*=.002, respectively), and PU significantly influences TOP (β=.381, *P*=.04), innovativeness (β=.557, *P*=.003), and learning motivation (β=.752, *P*<.001). These results support our hypotheses (H1, H2, H3, H4, and H5). Further, the intention to use IoT is significantly affected by PE and usefulness (β=.619, *P*<.001; β=.598, *P*<.001, respectively). ANN modeling enhances these findings, showing superior predictive power (R^2=89.7%) compared to partial least squares–SEM (R^2=86.3%), indicating a more effective identification of nonlinear associations. Importance-performance map analysis corroborates these results, demonstrating the importance and performance of PU as most critical, followed by technology innovativeness and optimism, in shaping behavioral intentions to use IoT.

Conclusions: This research contributes methodologically by leveraging deep ANN architecture to explore nonlinear relationships among factors influencing IoT adoption in education. The study underscores the importance of both intrinsic motivational factors and perceived technological attributes in fostering IoT adoption, offering insights for educational institutions considering IoT integration into their learning environments.

Introduction

Background

The use of Internet of Things (IoT) applications has been implemented in medical education projects [1]. IoT has the ability to completely transform the educational landscape by offering a more adaptable and quantifiable educational system that unites teachers and students under a single technological roof [2]. IoT innovation plays a significant role in transforming training at all levels, from school and college to university education [3]. Everyone, including students, instructors, and college campuses, can benefit from this innovation. Educators and administrators can leverage the power of IoT to connect people with devices and data, enabling them to gain valuable insights that have not been previously used in education. The traditional human-centered educational system has been transformed into an IoT-based one [4-6] using IoT. IoT has been leveraged to change the conventional personalized schooling system to an IoT-based system [4-6]. Figure 1 illustrates a cohort of university students actively engaging with IoT technology within an academic context. These individuals are adorned with sophisticated wearable devices, including smart glasses and smartwatches, which project information into their visual field, indicative of a digital and augmented educational milieu. The students are depicted with a palpable focus, using a portable electronic apparatus, likely for the manipulation of or interaction with the data overlay provided by their IoT devices.

The IoT has the potential to transform institutional practices and enhance learning capabilities across various levels and domains. University lecturers, students, and support staff can leverage large IoT platforms successfully. However, there is room for improvement in the utilization of IoT technology across different educational institutions. Researchers, scholars, and students can collaborate to develop IoT systems, devices, applications, and services, leading to the evolution of the educational environment as an increasingly dynamic and globally relevant subject. Better IoT deployments in colleges and universities have significantly improved positively to the creation of efficient and useful educational resources [7,8].

Figure 1. Students using augmented reality and Internet of Things technology (generated by Openart AI).

This research aims to explore how IoT technology is adopted and used by educators and students in universities across the Middle East. By integrating the technology acceptance model (TAM) and additional external factors, the study seeks to evaluate the effectiveness of IoT as an educational tool from the perspectives of both students and educators. Using the TAM as a metric, along with external variables, the research intends to identify and analyze the factors that influence the acceptance and use of IoT in medical education. The analysis uses a hybrid framework that combines structural equation modeling (SEM) and artificial neural networks (ANN) to examine how intrinsic motivational factors and perceived technological attributes affect IoT adoption. The SEM-ANN approach was specifically chosen to leverage the strengths of both methodologies [9,10]. SEM is highly effective in assessing the relationships between observed and latent variables, providing clarity on both the direct and indirect effects within the hypothesized model [11]. This method allows for robust statistical analysis capabilities, making it ideal for hypothesis testing and understanding the structural relationships among the theoretical constructs [12]. Conversely, ANN is used for its superior ability to model complex nonlinear relationships between variables, which are often not adequately captured by traditional linear models like SEM. ANN's data-driven nature allows it to directly learn and adapt to these relationships from the data, thereby enhancing the model's predictive accuracy and robustness. By integrating SEM with ANN, the study not only validates the theoretical framework through SEM's rigorous statistical analysis but also enhances the predictive power and generalization capabilities of the model with ANN's computational intelligence. This hybrid approach is particularly effective in exploring deeper, nonlinear interactions within the data, offering a more comprehensive understanding of the factors influencing IoT adoption. Given the complexities of modern datasets, which often exhibit nonlinear and digital behaviors among variables, this methodological integration is well-suited to achieving the research objectives and provides a justified, robust approach for the study.

The proposed hypotheses are: (1) intrinsic motivational factors like technology optimism (TOP), innovation, and learning motivation (LMT) significantly impact students' intention to adopt IoT; (2) perceived ease of use (PE) and perceived usefulness (PU), fundamental components of the TAM, strongly predict IoT adoption intentions among students in the United Arab Emirates.

This paper is organized as follows: "Literature Review" section delves into the existing research related to the adoption of IoT technologies, highlighting key theories and previous findings that set the groundwork for this study. Section "Methodology" details the research design, sampling methods, data collection procedures, and analytical techniques used to investigate the hypotheses. Section "Findings" presents the results of the data analysis, offering quantitative insights into the factors influencing IoT adoption. Section "Discussion" interprets the findings in the context of the existing literature, discussing the implications for theory and practice. Finally, the section "Conclusions" summarizes the study's main contributions, outlines its limitations, and suggests directions for future research. This structure is designed to provide a clear and logical progression through the topics covered, facilitating a comprehensive understanding of the study's scope and conclusions.

Related Work

The review of existing literature on the topic of IoT has explored both practical and theoretical aspects, suggesting a correlation between IoT and other factors such as self-efficacy, technology utilization, motivation, security, privacy, training, and more [13-19], indicating a relationship between the IoT and other elements including self-reliance, technological use, inspiration, safety, privacy, schooling, and beyond [13-19]. Likewise, research has examined the impact of IoT in conjunction with TAM and other external factors, and IoT with the help of TAM and external factors [20,21].

As IoT applications become more intricate, they can significantly impact learning. The difficulty is the IoT technology's quick development, which requires diverse skills ranging from developing IoT applications to incorporating devices into management systems that analyze device-generated data [14,22]. Previous research has highlighted the significance of IoT in addressing challenges students encounter when using modern IoT apps and gadgets. Potential solutions include focusing on computational thinking education, assisting students in solving challenges, and providing clear instructions and training to facilitate the integration of new students with IoT devices and encourage training in it.

A different approach was taken in another study, where a workshop was offered to address the importance of IoT. The results showed that students found the workshop highly satisfactory for learning about IoT, improving problem-solving skills, and enhancing problem-solving capabilities, while also finding it enjoyable [13-15].

Several outside variables, including drive, contentment, ease of use, effectiveness, involvement, and interest, have been investigated to explore the relationship between IoT and students' attitudes. The most significant factors are motivation and enjoyment regarding IoT technology, which are essential for its acceptance among students. While satisfaction and performance indirectly affect the application of IoT, greater contentment levels are not proportional to higher interactions [18,19]. Recent studies have used qualitative and quantitative methods to examine the uptake of IoT and have identified favorable attitudes, ease of use, contentment, affordability, basic knowledge, security, and privacy as crucial factors that influence its adoption. Apart from motivation and enjoyment, training and experience are also crucial in uptaking IoT devices, and educational training workshops can significantly improve the learning curve, digital learning, real-life applications, and problem-solving skills [16,17,23].

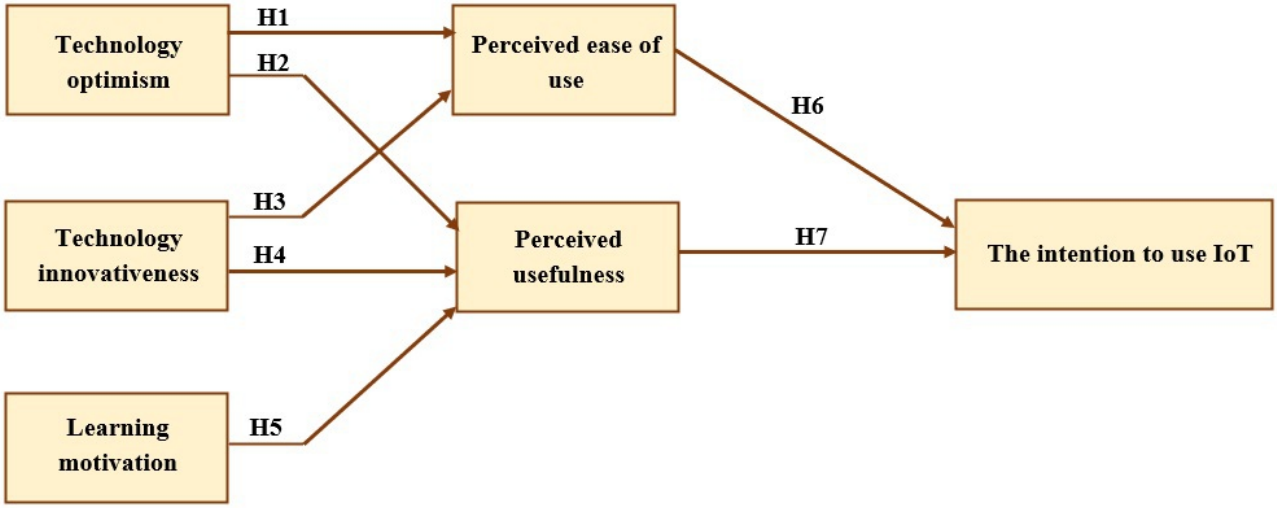
Previous research has explored the various benefits of implementing IoT technologies in educational settings, including the ability for teachers to gain insight into students' performance and knowledge levels, as well as the potential for improved teaching quality. As a result, the use of IoT has the potential to greatly impact learning environments, leading to a more

advanced educational landscape. This could also lead to changes in how we interact and collaborate as a society, as IoT technology continues to connect us in new ways [24,25]. While previous studies have investigated students' attitudes toward IoT from different angles [14,22,26], there has been limited research on the importance of IoT technology from the perspective of teachers' knowledge of the significance of IoT innovation from the educational viewpoint of instructors and how it impacts pedagogy in the classroom. Therefore, this study aims to address this gap by developing a model that combines both students' and teachers' attitudes to examine the effectiveness and efficiency of IoT in educational environments. By creating a framework that incorporates the viewpoints of learners and educators, this research intends to close this imbalance by analyzing the usefulness and efficacy of IoT in classrooms.

Developing Hypotheses and Theoretical Framework

The study paradigm shown in Figure 2 describes how the inspiration for learning, technological exuberance, and technological advancements influence learners' perceptions of the PU and ease of use (PE) of IoT devices. Such concepts have not yet been looked into in relation to IoT devices and applicability. Although earlier research has examined how these factors may affect IoT adoption plans [27], their individual effects on students' attitudes toward this technology have not been analyzed before.

Figure 2. Research model. IoT: Internet of Things.



LMT is a crucial factor impacting students' behavior in conventional and digital educational settings. It is an outside variable of the suggested approach and can be influenced by multiple factors, including the learning environment, expectations, and social values. Research has shown that LMT significantly impacts students' academic achievements [28]. Students must therefore be driven to acquire knowledge in order to achieve the suggested intended goals [29,30]. Highly motivated learners can achieve their learning goals spontaneously and willingly. Social cognitivism emphasizes the significance of requirements, conducts, and ideologies in education.

Researchers are investigating the influence of TOP and innovation on students' adoption of IoT in the education sector. The study aims to understand students' attitudes and behavior toward technology by using 3 theoretical concepts: inventiveness, technological exuberance, and learning incentive. The researchers have combined the (TAM) constructs with the aforementioned variables to accomplish their study's objectives. Several researchers have used the TAM model to evaluate the effectiveness of IoT technology and its applications [31,32]. The model explains why people accept technology based on their attitudes and beliefs and how these beliefs impact their behavioral intention toward technology use [33,34]. It is an established concept that supports embracing technology in various settings and strongly links it to technological progress [35-37]. The TAM model can forecast variables like technology elation and inventiveness that influence how well a certain technology is received [38,39]. TOP refers to users' favorable perception of technology, while technology innovativeness (TIN) refers to users' willingness to adopt technology early and lead to its use.

The PE and PU constructs of TAM are closely related to TOP and TIN. In the academic setting, students' perceptions of technology can be influenced by their peers and instructors. If the student's immediate academic circle has a positive view of a particular technology, the student will likely also develop a favorable opinion. Similarly, tech-savvy students tend to have a positive self-perception. Early on in the acceptance of technology, students are usually eager to pioneer using advanced technologies [40-44].

Furthermore, a student's optimism about technology is linked to their level of involvement in guiding its use. Similarly, technological optimism can significantly impact a student's attitude. IoT acceptance is greater for learners who are enthusiastic about experimenting with novel innovations. Technological innovators infrequently perceive new innovations as being challenging or outside their comprehension. Individuals are more inclined to regret not having the freedom to play around with novel technologies [45]. As a result, a number of hypotheses are put forth:

- H1: TOP affects positively the PE.
- H2: TOP affects positively the PU.
- H3: TIN affects positively the PE.
- H4: TIN affects positively the PU.
- H5: LMT affects positively the PU.
- H6: PE affects positively the intention to use Internet of Things (INT).
- H7: PU affects positively the INT.

By evaluating the association between TAM and its connected factors, this research seeks to add to a collection of current work. It has been said that it is important to measure these variables and analyze their relationship to TAM to assess the efficiency of IoT in classrooms. Past research and literature have mostly focused on preservice teachers, and there is a need to conduct more studies involving in-service teachers to enhance the practicality of the TAM model [46,47]. Thus, this study investigates the correlation between teachers' levels of TAM and their attitudes toward IoT acceptance when working with teachers from different fields.

Methods

Data Collection

The data collection for this study was carried out between January 20 and March 20, 2023, throughout the academic year 2023 - 2024's winter semester, at educational institutions in the United Arab Emirates. The research team used web-based surveys to collect data, with 500 questionnaires randomly distributed. Of these, 463 surveys were answered, resulting in a response rate of 93%. Some questionnaires were rejected due to missing values. Since a few surveys had no responses, they were discarded, leaving 769 usable questionnaires, which is considered an appropriate acceptable sample size according to Krejcie and Morgan [48]. Although the sample size exceeded the minimum requirements, the research team used SEM SmartPLS (version 3.2.7; SmartPLS GmbH) and SPSS Statistics (version 23; IBM Corp) to evaluate the hypotheses and confirm the relationship between variables. It is important to note that the hypotheses were based on previous theories related to IoT, which formed the foundation of this study.

Ethical Considerations

Ethical considerations were meticulously adhered to throughout the research process. All procedures involving human participants were approved by the institutional review board of the host universities in the United Arab Emirates (#RAREC00065), ensuring compliance with ethical standards. Informed consent was obtained from all participants before data collection, and they were informed of their rights to withdraw from the study at any time. Privacy and confidentiality were strictly maintained, with all data being anonymized and securely stored to prevent unauthorized access. Participants were not compensated for their participation, as the study involved minimal risk and was conducted as part of educational activities within the institutions involved.

Student's Personal Information

The demographic data of the respondents (N=463) are presented in Table 1. The data showed that 70% (n=325) of participants were female and 30% (n=138) were male. In terms of age, 42% (n=193) of participants were between 18 and 29 years, 35% (n=163) were between 30 and 39 years, 21% (n=99) were between 40 and 49 years, and 2% (n=8) were between 50 and 59 years. Regarding education, 80% (n=372) of participants held a bachelor's degree, 14% (n=62) held a master's degree, and 6% (n=29) held a doctoral degree. To obtain participants' willingness to participate, the research team used a purposive sampling approach. The participants came from various universities, academic levels, and programs relevant to this research. SPSS Statistics was used to analyze the demographic data.

Table . Demographic data of the respondents (N=463).

Category	Value, n (%)
Sex	
Female	325 (70)
Male	138 (30)
Age (years)	
Between 18 and 29	193 (42)
Between 30 and 39	163 (35)
Between 40 and 49	99 (21)
Between 50 and 59	8 (2)
Educational qualification	
Bachelor's degree	372 (80)
Master's degree	62 (14)
Doctorate	29 (6)

Study Instrument

This research proposed a survey instrument for validating the hypotheses. To assess the 6 constructs of the questionnaire, an additional 18 questions were included in the survey. The origins and histories of these constructs are presented in Table 2. To make the research more relevant, the researchers modified the questions from previous studies.

Table . Measurement items.

Constructs	Items	Definition	Instrument	Sources
TIN[a]	• TIN1 • TIN2 • TIN3	The term "technology innovativeness" describes a user's perception that they are at the forefront of technology use. Users who are pioneers in adopting new technologies typically do not view them as complicated or difficult to comprehend. Such users may feel a sense of regret if they miss the chance to experiment with new technologies.	• I accept IoT[b] technology to be used in my daily classes. • I am the only one. There is only me prepared to use IoT technology among my fellow students. • I am ready to use. I am prepared to use and experiment with the latest information technologies.	[45]
TOP[c]	• TOP1 • TOP2 • TOP3	A person's readiness to use technology is known as technological optimism.	• I am ready to test. Prepared to take the test IoT technology. • To complete my assignments to finish my homework, I will be using IoT. • I will learn more with the help of my preparedness to use IoT.	[2,49]
LMT[d]	• LMT1 • LMT2 • LMT3	The concept of learning motivation is used to measure the behavioral intention to use technology. Motivation learning is composed of 4 key components, which are attention, relevance, confidence, and satisfaction. These components have been identified in previous studies [50,51].	• I can improve my focus by using IoT for my daily classes. • Using IoT makes me feel more confident. • Using IoT for study purposes satisfies me.	[50,51]
PE[e]	• PE1 • PE2 • PE3	The TAM[f] was introduced by Davis [52] as a means of assessing the effectiveness and acceptance of technology. The model includes the concept of PE, which refers to the user's perception of how effortless it is to use the technology.	• IoT technology being simple will polish my skills. • I can improve my learning achievements by using IoT technology. • IoT is simple and easy to use.	[52]
PU[g]	• PU1 • PU2 • PU3	Usefulness refers to PU that the users of technology may see.	• IoT technology will hugely benefit me. • IoT will make my abilities and skills better. • Using IoT for my daily classes is beneficial.	[52]
INT[h]	• INT1 • INT2 • INT3	An individual's view of what others think about a certain behavior is known as a behavioral intention to use.	• IoT will be my go-to for daily tasks. • In the future, I will be using IoT. • IoT technology will be my recommendation to every student.	[53]

[a]TIN: technology innovativeness.

[b]IoT: Internet of Things.

[c]TOP: technology optimism.

[d]LMT: learning motivation.

[e]PE: perceived ease of use.

[f]TAM: technology acceptance model.

[g]PU: perceived usefulness.

[h]INT: intention to use Internet of Things.

Survey Structure

The questionnaire survey given to the students has 3 sections. Three components make up the survey that is provided to learners: (1) personal data is the focus of the first section, (2) the general question related to the "Intention to Use IoT" is the second section, and (3) 15 items that deal with TIN, TOP, LMT, PE, and PU is present in the third section.

A 5-point Likert scale was used to assess the 18 items, with response options ranging from 1=strongly disagree to 2=disagree, 3=neutral, 4=agree, and 5=strongly agree.

Results

Data Analysis

In this study, the gathered data were analyzed using SmartPLS (version 3.2.7) software through the partial least squares–structural equation modeling (PLS-SEM) technique [54-56]. The evaluation consisted of 2 stages: the measurement model and the structural model [57,58]. PLS-SEM was selected for this research after considering several factors.

The selection of PLS-SEM for this study was based on several reasons. First, PLS-SEM is preferred when the study aims to build on an existing theory [59]. Second, PLS-SEM is effective in handling complex models in exploratory research. Third, PLS-SEM analyzes the entire model as a single entity rather than dividing it into components [60]. Finally, PLS-SEM allows for the simultaneous analysis of structural and measurement models, leading to more accurate results [61].

Convergent Validity

Hair et al [57] suggested that to assess the measurement model, it is important to examine the construct reliability (including Cronbach ɑ and composite reliability) and validity (including convergent and discriminant validity). Table 3 shows that the Cronbach ɑ readings are greater than the suggested criterion of 0.7, and vary from 0.797 to 0.858 [62], indicating good construct reliability. Similarly, the proposed criterion is also greater than the composite reliability numbers, which vary from 0.735 to 0.858 [63]. Factor loading and average-variance extracted (AVE) analysis are required to evaluate convergent validity [57]. The factor loading values in Table 3 are higher than the recommended threshold of 0.7, and the AVE readings are greater than the suggested limit of 0.5, spanning from 0.556 to 0.712. These results suggest that there is convergent validity.

Table . Convergent validity results which assures acceptable values (factor loading, CA[a], CR[b], Dijkstra-Henseler's ρ ≥0.70, and AVE[c] >0.5).

Constructs and items	Factor loading	CA	CR	AVE

[g]PE: perceived ease of use.

[h]PU: perceived usefulness.

[i]INT: intention to use Internet of Things.

Discriminant Validity

To assess discriminant validity, 2 criteria were recommended: the Heterotrait-Monotrait ratio and the Fornell-Larcker criterion [57]. According to Table 4, the Fornell-Larcker criterion is met, as the AVE and its square root for each construct exceed its correlation with other constructs [64]. Table 5 displays the Heterotrait-Monotrait ratio results, which demonstrate that each construct's value is below the threshold value of 0.85 [65]. This suggests that discriminant validity exists, and the measurement model's reliability and validity were confirmed without any issues. As a result, the collected data can be used for analyzing the structural model.

Table . Fornell-Larcker scale.

	TIN[a]	TOP[b]	LMT[c]	PE[d]	PU[e]	INT[f]
TIN	0.864[g]	—[h]	—	—	—	—
TOP	0.675	0.883[g]	—	—	—	—

Hypotheses Testing Using PLS-SEM

To assess whether the theoretical constructs of the structural model are interconnected, the study used Smart PLS with maximum likelihood estimation to create a structural equation model [66]. The proposed hypotheses were then analyzed using this model. The results indicated a high level of predictive power for the model, with 86.3% of the variance in INT being accounted for, as shown in Figure 3 and Table 6.

Table 7 provides information on the β values, *t* values, and *P* values of all developed hypotheses based on the findings produced using the PLS-SEM technique. The researchers have confirmed each hypothesis. The empirical data supported H1, H2, H3, H4, H5, H6, and H7 following the data analysis hypotheses. This study demonstrates that TOP and TIN have a noteworthy influence on PE with respective regression coefficients (β=.412, *P*=.04), and (β=.608, *P*=.002), supporting H1 and H3. Moreover, the results indicate that PU is significantly impacted by TOP (β=.381, *P*=.04), TIN (β=.557, *P*=.003), and LMT (β=.752, *P*<.001), supporting hypotheses H2, H4, and H5, respectively. Finally, the study reveals that the relationship between PE and PU significantly affects INT with respective regression coefficients (β=.619, *P*<.001) and (β=.598, *P*<.001), supporting H6 and H7.

Figure 3. The path coefficients of the research model. IoT: Internet of Things. *P<.05; **P<.01; ***P<.001.

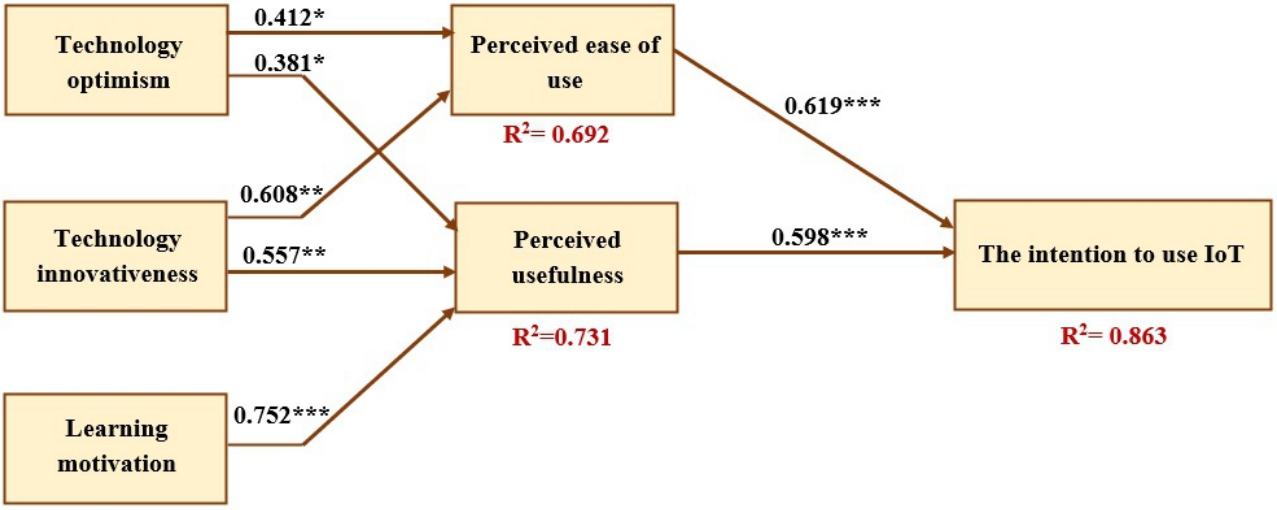

Table . The R^2 values for the endogenous latent variables.

[e]LMT: learning motivation.

[f]INT: intention to use Internet of Things.

ANN Results

The predictors identified during the PLS-SEM analysis are further investigated through ANN analysis using SPSS software. The PLS-SEM analysis identified TIN, TOP, LMT, PE, and PU as critical factors; therefore, ANN analysis also considers these 3 factors only. The structure of the ANN model is based on behavioral intention as an output neuron and TIN, TOP, LMT, PE, and PU as input neurons (Figures 4-6). ANN model supported deep learning in all the output neuron modes through its 2-hidden layer deep structure [67,68]. The researcher applied the activation function of the sigmoid function to hidden neurons, as well as output neurons, keeping the values of input and output neurons between [0, 1]; this allowed the researcher to obtain better performance from the research model [69,70]. He also applied the 10-fold cross-validation method to training

and testing data in the ratio of 80:20 to ensure that there is no overfitting in the ANN model [71]. The researcher evaluated the root mean square of error (RMSE) to test the neural network model for accuracy. The training data showed an RMSE value of 0.1388 for the ANN model while the testing data showed an RMSE value of 0.1439. The training and testing data showed only slight variance in the RMSE values and SD values (ie, 0.0043 and 0.0096). Hence, we can infer that using the ANN model enhances the accuracy of the research model.

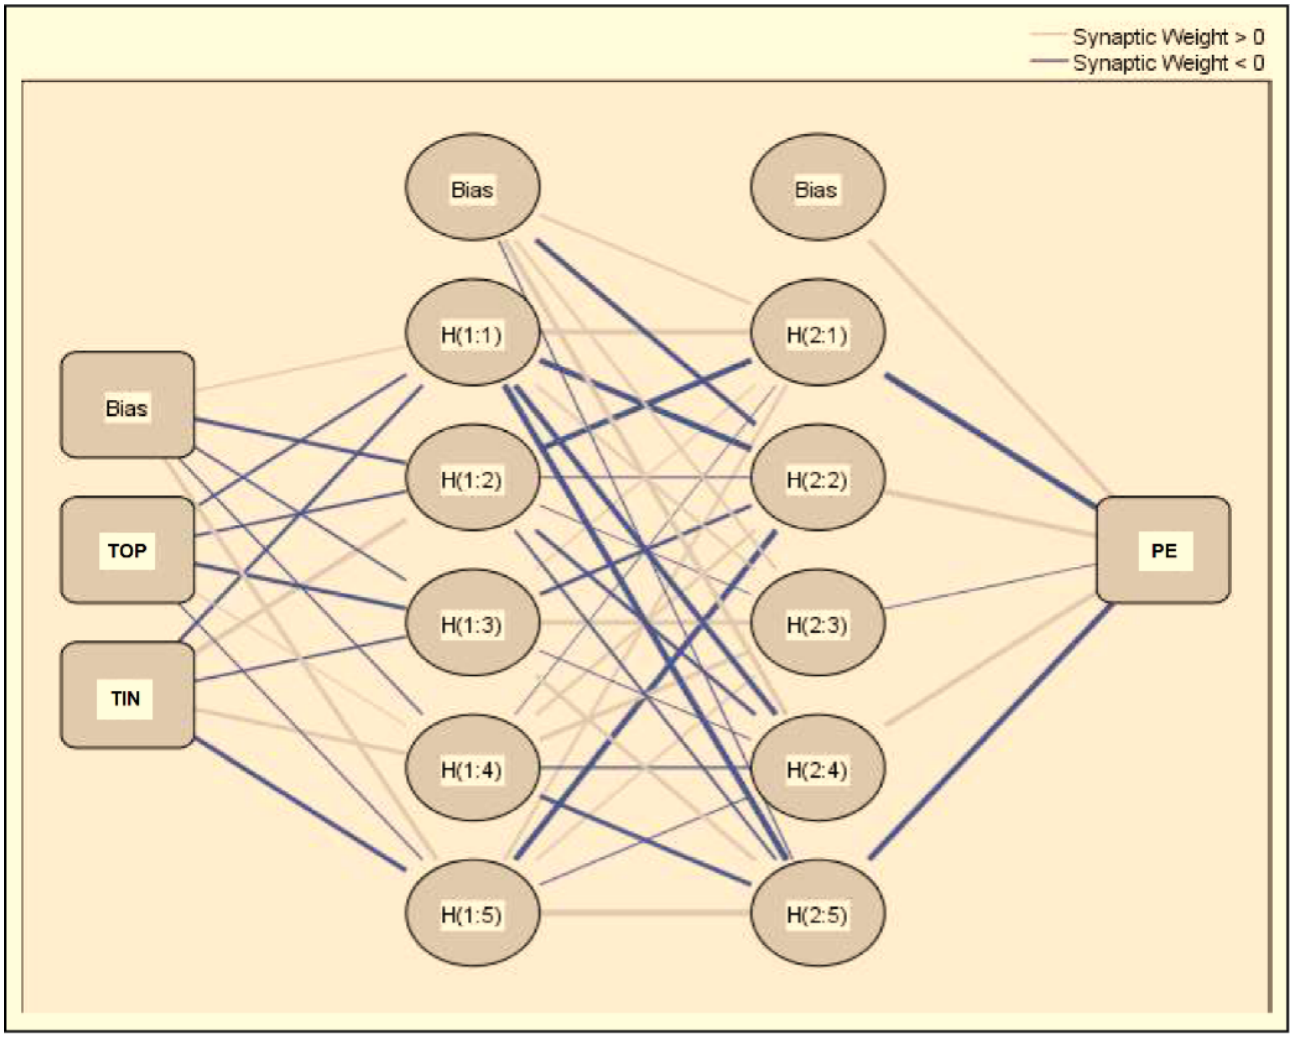

Figure 5. ANN model for predicting PU. ANN: artificial neural network; LMT: learning motivation; PU: perceived usefulness; TIN: technology innovativeness; TOP: technology optimism.

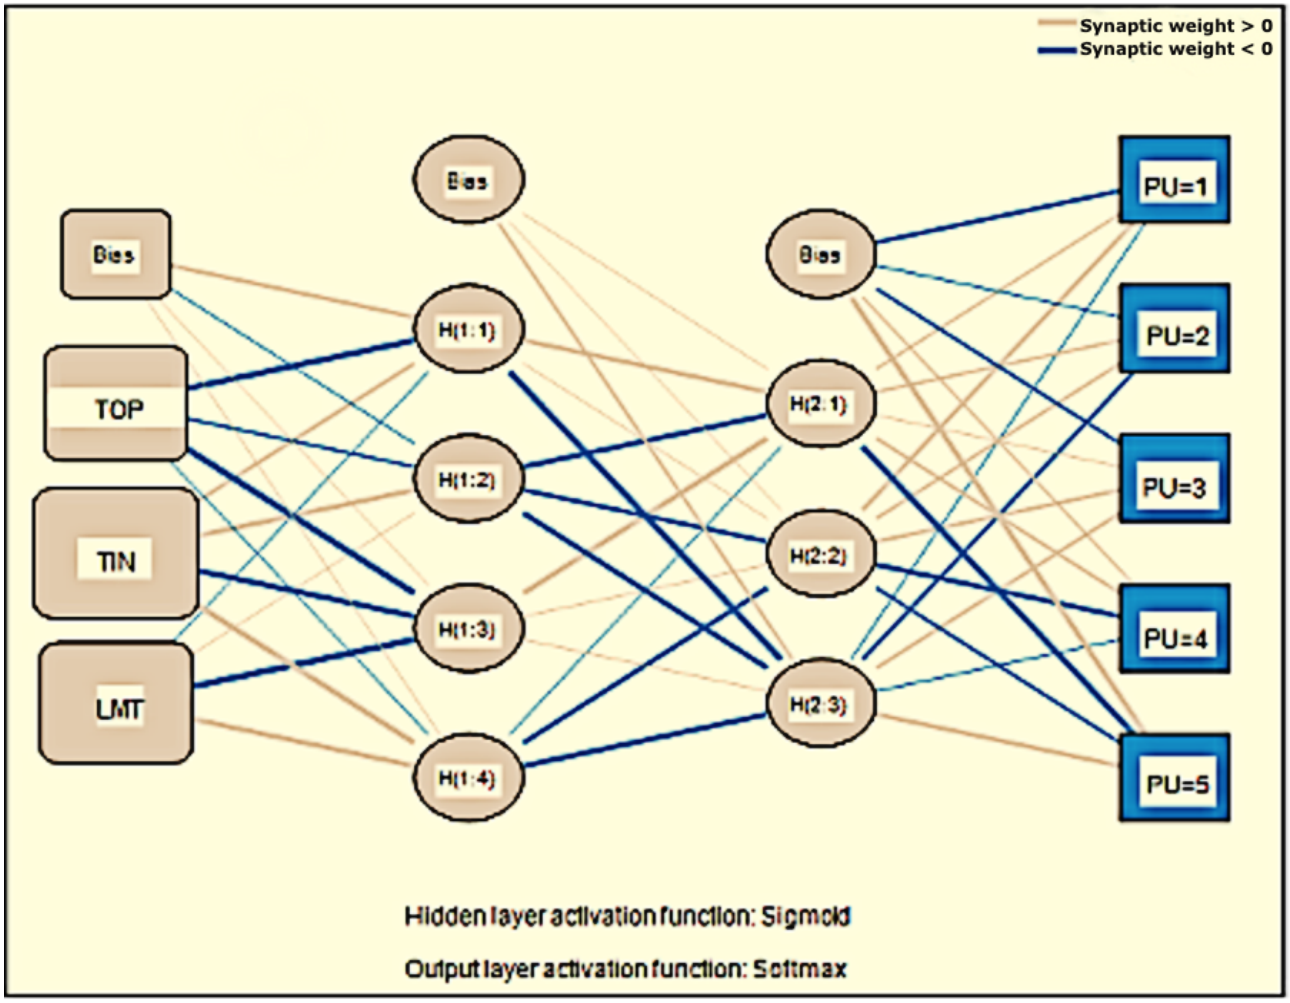

Figure 6. ANN model for predicting INT. ANN: artificial neural network; PE: perceived ease of use; PU: perceived usefulness; INT: intention to use Internet of Things.

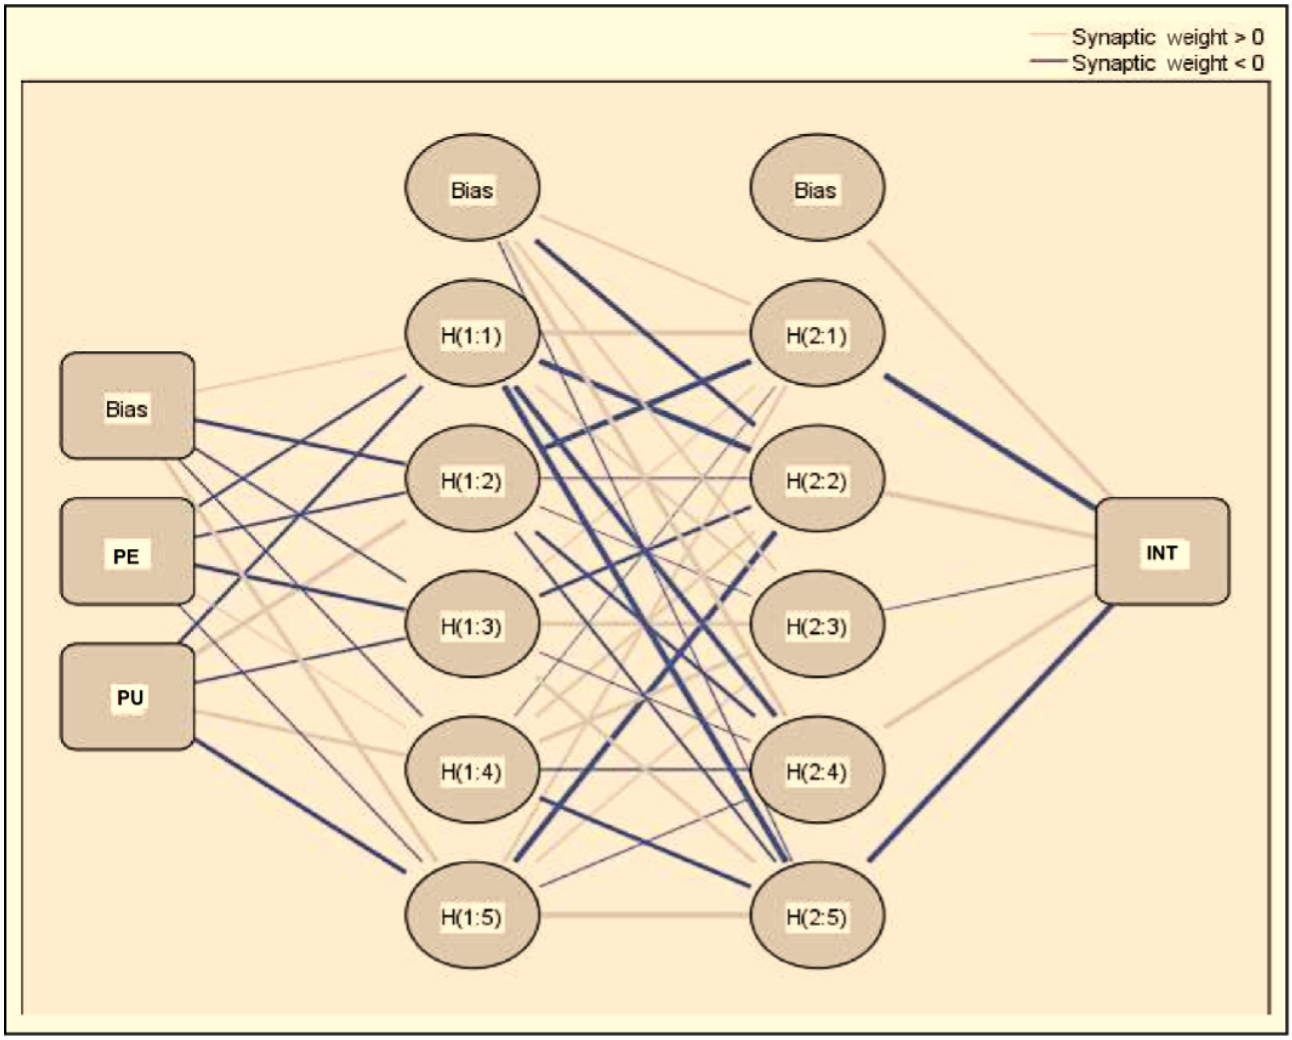


Sensitivity Analysis

The researcher estimated the value of normalized importance by comparing each predictor's average value with the maximum mean value depicted among all predictors stated in percentage form. The values of normalized importance and mean importance computed for the predictors involved in ANN modeling are recorded in Table 8. This table also depicts the outcomes of the sensitivity analysis which identifies the predictor of PU to have the most significant impact on behavioral intention; the second most significant impact was imposed by TOP while the least impact was imposed by PE. ANN application was additionally assessed for its accuracy and performance by computing the goodness-of-fit for authentication and validation of the application. The ANN application uses goodness-of-fit just as PLS-SEM analysis uses R^2 [72,73]. The predictive powers of both the applications are compared where ANN analysis outperforms the other one with a predictive power of (R^2=89.7%) against the PLS-SEM predictive power of (R^2=86.3%). Hence, ANN analysis can explain endogenous constructs more effectively than PLS-SEM. Moreover, ANN analysis is based on deep learning and has the potential to better identify nonlinear associations among constructs which results in variances in the predictive powers of the ANN and PLS-SEM methods.

Table . Independent variable importance.

	Importance	Normalized importance (%)
TIN[a]	0.335	83.1
TOP[b]	0.463	94.8
LMT[c]	0.361	77.5
PE[d]	0.118	19.2
PU[e]	0.539	100

[a]TIN: technology innovativeness.

[b]TOP: technology optimism.

[c]LMT: learning motivation.

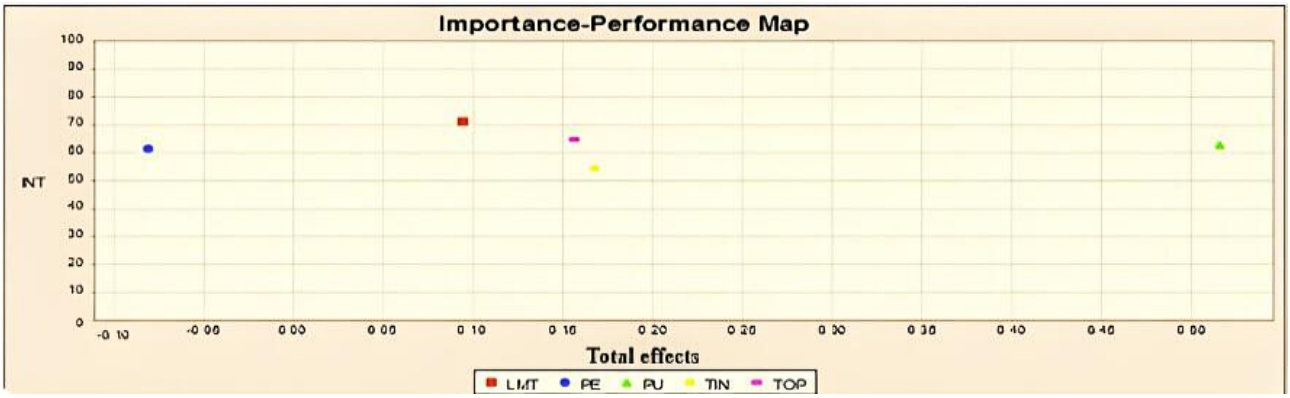
[d]PE: perceived ease of use.

[e]PU: perceived usefulness.

Importance-Performance Map Analysis

This study has used importance-performance map analysis (IPMA) as an advanced approach in PLS-SEM, which used behavioral intention as the main variable. As suggested by Ringle and Sarstedt [74], a better interpretation of the results of PLS-SEM is possible by using IPMA. A substitute way to only test the path coefficients (ie, importance measure), the average value of the latent constructs, and their indicators (ie, performance measure) are also included in the IPMA [74]. According to IPMA, the total effects reflect the predecessor factors' importance in developing the target factor (ie, behavioral intention), while the average of latent constructs' values is a reflection of their performance. The IPMA findings are reported in Figure 7. The estimation of the importance and performance of the 5 factors (ie, TIN, TOP, LMT, PE, and PU) has been shown in this table. According to the findings, the PU has been reported to have the largest values in terms of both importance and performance measures. Furthermore, it can be clearly seen that TIN has the second largest values in terms of both importance and performance measures. The third largest value was reported in the case of TOP in terms of the importance measure; however, it has the smallest value on the performance measure. Relatively, the opposite scenario was reported in the case of PE, as it had the lowest value on the importance measure.

Figure 7. Importance-performance map analysis results. INT: intention to use Internet of Things; LMT: learning motivation; PE: perceived ease of use; PU: perceived usefulness; TIN: technology innovativeness; TOP: technology optimism.



Discussion

Principal Findings

The main findings of this study indicate that the intention to adopt IoT technologies is positively influenced by both intrinsic motivational factors and TAM constructs. Specifically, TOP, innovation, and LMT play crucial roles at the initial level of influencing IoT adoption. At a secondary level, the perceived ease of use and PU, core elements of the TAM, directly enhance the INT technologies. Further analysis using ANNs and IPMA highlighted PU as a particularly significant predictor of IoT use intentions.

Based on these results, it is evident that technology features are critical in shaping users' PE and PU toward IoT applications and tools. The positive influence of TOP, innovation, and LMT is reflected across all model variables, suggesting that well-designed technology features can significantly boost IoT acceptance. The TAM framework effectively provides a user-friendly experience that meets users' value expectations and fosters positive emotional responses, which in turn, positively impacts their INT. Additionally, the significant positive impact of technology features on TOP boosts users' trust in the system's quality, further influencing their willingness to engage with IoT systems. The social aspect of technology use, where familiarity influences adoption, also plays a pivotal role in the INT features. Technology innovation contributes

significantly to perceived ease and usefulness, enhancing trust and satisfaction during the user experience, thus fostering a conducive environment for IoT adoption.

The confirmation of hypotheses H1-H5 supports the proposed conceptual model and the proposed hypotheses [75-77]. Previous research has also produced results that are consistent with these findings. However, other studies have shown that the lack of sufficient security and privacy are major challenges that may hinder the deployment of IoT in education [63,64], and to reduce these obstacles, future efforts to implement IoT in education must consider these factors. Although IoT has not been widely adopted in resource-limited countries, scholars need to examine the factors affecting its adoption to enable effective deployment. Therefore, scholars need to investigate the use and adoption of these technologies in other domains.

Managerial Implications

The adoption of IoT in educational settings demands that administrators and educational leaders ensure their faculty is proficient in using IoT technologies effectively in the classroom. This includes competencies in handling relevant technology tools, understanding pedagogical integration, and applying these technologies within various teaching scenarios. To support this, institutions should offer targeted professional development that focuses on both the technical and educational aspects of IoT. Additionally, management should consider the infrastructure upgrades necessary to support IoT technologies, such as improved wireless networks and enhanced security measures to protect student data [78,79].

Practical Implications

The practical applications of this study highlight the necessity for educational curricula to evolve alongside technological advancements. Institutions offering programs in computer science and engineering should integrate IoT courses to prepare students for the demands of the workforce, which increasingly relies on IoT technologies. Moreover, schools should align their IoT strategies with real-world applications, providing students with hands-on opportunities to work with IoT in context. This could include partnerships with IoT companies or practical projects that allow students to solve real problems using IoT solutions [80,81].

Theoretical Implications

This study contributes to the academic understanding of technology adoption by confirming the significant role of intrinsic motivational factors and TAM constructs in the adoption of IoT technologies. By highlighting the dual influence of personal motivation and perceived technological attributes, this research extends existing models of technology acceptance. Furthermore, the use of advanced analytical methods such as ANN and IPMA provides a deeper insight into the nonlinear relationships among the constructs, offering a nuanced perspective that can inform future research in technology adoption theories. This could encourage scholars to explore how different educational contexts or cultural backgrounds influence the adoption and effective use of emerging technologies like IoT [82,83].

Conclusions

IoT technology has fundamentally altered the tech and business industries, laying the groundwork for the creation of intelligent societies and advancing social and economic development. The IoT has advanced quickly and significantly. The research team developed the PE and PU frameworks for Arab customers using path estimation and modeling of structural equations depending on their responses to analyze individuals' acceptance of IoT. In addition to additional factors including technology exuberance, advancements in technology, and academic drive, the research additionally looked at the effects of TAM components on these factors. These factors and TAM components were found to be directly related to the study. According to the research, the incentive to learn, technological advancement, and technological positiveness all had a substantial influence on PE and PU. While earlier research has demonstrated that TAM components affect the motivation to use IoT, this research has investigated how other external factors, including social factors like LMT, can affect these constructs. The study used a conceptual model to examine users' attitudes toward IoT adoption, with 2 levels of analysis. The first level focused on social attitudes, particularly the impact of the incentive to learn as a standalone factor. The second stage looked at how personal traits influenced technological positivism and inventiveness, influencing customer needs and IoT interactions. Subsequent research could look at how individual characteristics affect incentives to learn and look at extra technological aspects that affect IoT uptake. Subsequent research could improve the assessment and give more insight into the value of IoT by including mediating factors between personal characteristics and technological attributes. The theoretical framework could also be used with cutting-edge technology like metaverse systems and artificial intelligence.

Abstract

Background: Electronic health records (EHRs) offer a valuable resource for research and health care improvement. However, public acceptance of sharing personal health data is critical to the success of such initiatives. In Germany, automatic data sharing via EHRs will be implemented unless people opt out.

Objective: This study aims to assess the willingness of the German population to share health data via EHRs and to explore the role of trust in influencing these attitudes.

Methods: A computer-assisted telephone interview study was conducted in December 2023, with 1004 respondents aged 18 years and older, representative of the German population. Descriptive statistics and multivariate linear regression models were used to analyze the data.

Results: The survey shows that 43.4% (n=432) of respondents would be willing to share their health data via EHR, and a significant 34% (n=338) remain undecided. While the population is open to adoption of the EHR for personal health issues (n=483, 53% show interest in using it), the opt-out model for data sharing is viewed critically, with 44.7% (n=438) of respondents rejecting it. Socioeconomic status significantly influences the willingness to share data, with higher income, education, and digital literacy being associated with greater openness to data sharing. However, trust emerged as the most significant factor. Additionally, experiences with digital technologies increase the willingness to share personal health data.

Conclusions: The German population shows general openness toward EHRs and data sharing. Trust plays a critical role in promoting willingness to share health data. The findings highlight challenges in Germany's transition to an opt-out system.

Introduction

Legislative Context and Research Questions

Health data stored in electronic health records (EHRs) are considered an extremely valuable source for advancing medical science and health care. EHRs have the potential to provide high-quality longitudinal data from a broad spectrum of the population. It is therefore not surprising that many countries are implementing data-sharing options to make use of these data. In Germany, the EHR ("elektronische Patientenakte") was introduced on January 1, 2021, and is available to all legally insured persons through their health insurance company. It can be used to store and manage medical diagnoses and treatment data. The use of the EHR also allows control over who can view and access data. However, by 2024, only 1% - 2% of the eligible population have an EHR. To increase the prevalence and benefits of the EHR, the German Bundestag passed the Digital Act ("Digital-Gesetz") and the Health Data Use Act ("Gesundheitsdatennutzungsgesetz") on December 14, 2023. This means that starting in 2025, for all people with statutory health insurance in Germany, an EHR will be automatically created unless they opt out. The Health Data Use Act further allows for the use of pseudonymized health data for research purposes by public and private institutions by amending §303e SGB V. That means data stored in the EHR will be available for research purposes including commercial purposes unless people opt out. The data will be made available through the German Health Research Data Center ("Forschungsdatenzentrum"). The legislative changes mark a paradigm shift in the way health data are handled: the creation of electronic patient records and the sharing of health data will be automatic unless people actively opt out. The German federal minister of health, Karl Lauterbach, stated that the paradigm shift will be a "gamechanger" for the development of health [1]. The new legal framework marks a step toward digitization

that many experts have been calling for for a long time [2]. At the same time, the extensive and passive sharing of health data has been criticized by various stakeholders.

This paradigm shift raises some serious questions about the social implications. There are a number of challenges to the "data is gold" perspective [3]. Some social scientists criticize that digitization in health bears potential for "panoptic surveillance" [4]. Other critics [5] have highlighted data security issues that can harm citizens in many ways. Furthermore, the risks, but also the opportunities to benefit from digital health, are unevenly distributed across society. There is ample empirical evidence of a so-called "digital divide," meaning that people with lower socioeconomic status have lower chances of using digital (health) services and face higher risks [4,6,7]. The digitization of health therefore needs to be critically monitored. Citizens should be aware of the potential benefits as well as the potential dangers of sharing personal health data. This becomes even more urgent with the implementation of an opt-out mechanism. Opt-out is an instrument of nudging [8]. It aims to increase the use of EHRs and the acceptance of data sharing by "choice architecture" [9]. Citizens retain their freedom of choice but are nudged toward using the EHR. However, an opt-out mechanism relies on informed citizens to take deliberative action, especially when data sharing can be harmful. The policy of choice architecture and the use of EHR data for health research make clear that health data sharing cannot be reduced to an individual action but must be analyzed in its social context. It raises questions of legitimacy, social inequality, and the diffusion of knowledge among citizens.

This paper focuses on public opinion on EHR data sharing in Germany. It answers three research questions: (1) Is there sufficient willingness in society to share health data that justifies the introduction of an opt-out scheme? (2) Does the willingness to share data differs with socioeconomic status? (3) How can individual willingness to share EHR data be explained?

State of the Art

This section summarizes the research on data sharing and evidence on EHR adoption. International research finds widespread support for the idea of EHRs among citizens and institutions in the health care sector [10-12]. However, "evidence indicates that consumers who have been offered access to PEHRs have not widely used them and the number of active users has remained low" [12]. For example, a recent study shows that in the United States, the number of active users of the EHR is about 26% (2019), despite its increasing integration in medical practice [13]. In Germany, until 2024, according to data from public health insurance, less than 2% of the insured actively requested an EHR [14]. At the same time, only about half of the population is even aware of the EHR [15]. Several studies have shown that interest and use of the EHR show a digital divide. Younger and more digital literate people show a higher probability of using EHRs, while older and low-income groups have less often access [12,16,17]. Regarding socioeconomic factors, lower educational and employment status, as well as belonging to an ethnic minority, have a negative impact on individuals' desire to access and use EHRs [12,18].

Several studies have examined citizens' motivations for using EHRs. The perceived advantages and disadvantages strongly influence the intention to use and the actual use. Key factors here are concerns about data protection and the fear of being discriminated by health insurers or employers on the one hand, and the benefits of better information and experience with the portals or providers on the other [12,19,20]. Data protection concerns are a key factor because health issues are relevant in many areas of daily life [10,12,19]. This can be seen directly when respondents report fears of stigmatization as a result of digitally disseminated health information from the EHR [21,22]. For people with chronic diseases, the balance of advantages and disadvantages seems to be clearly in favor of the advantages. Several studies have reported higher levels of interest in providing data due to the hope of treatment progress [23,24]. For people with chronic diseases, there are already care programs in place that people can benefit from, such as disease management programs [25].

While the research literature stresses that EHRs are potentially an important tool to transform "passive recipients of treatment to empowered consumers" [12], the empirical findings are rather disappointing. Several international studies have shown that the overall use of EHRs by patients remains low [12]. Furthermore, there is little evidence of empowerment effects [12]. Even people who have an EHR often do not know which data are stored in the health record and how to interpret the information [12,26]. When users experience that they do not understand the EHR or the information stored in it, their willingness to use it decreases significantly [23]. Thus, we can expect a significant gap between interest in EHRs and actual use. This gap is likely to be even more pronounced in Germany, with its high standards for data security and complicated routines for accessing the EHR.

Data sharing is an essential part of EHRs. Many EHR systems allow anonymized health data to be used for scientific research. While this can lead to progress in the health system, there is no clear-cut advantage for an individual sharing its data, since anonymization makes individual feedback regarding new health insights hard. That might be the reason, why in public discourse, data sharing is often labeled as "data donation" [27]. Research regarding data sharing has shown that a considerable part of the population (often exceeding 50%) is willing to share its health data [27-30]. There are considerable differences between different countries. For example, the Scandinavian countries show the highest willingness to share health data, while people in Southern Europe are rather skeptical about it [31]. For Germany, recent research suggests that 8 of 10 citizens are willing to share their health data for scientific purposes [15,32,33]. Notably, this high approval rate also seems to hold true for the planned opt-out regulation [33]. However, these high approval rates have to be interpreted with caution, since limited knowledge about health data sharing is widespread and some studies have methodological limitations. Like many other surveys in this area, the high approval rates rely on web-based surveys that have proven to be of less quality regarding the research results compared to face-to-face or telephone interviews [34]. One reason is that they show a higher tendency to produce biased results [35]. Since there is an empirical correlation

between digital literacy and the willingness to share health data, the results are likely to be too optimistic. Furthermore, some questionnaires tend to highlight the positive impacts of data sharing and thereby inflating the approval rate (The question of the survey conducted in Germany was [15,32]: “Assuming that in the future your personal health data, such as your medical history, examination results, X-ray images, etc. can be stored online in a digital health record. Would you agree that your personal health data is used anonymously and free of charge for the purpose of medical research so that in the future diseases can be better recognized and new treatments developed?” And “At present, the use of patient data for medical research requires the consent of patients. However, it is often difficult or even impossible to obtain such consent. Therefore, there are considerations in Germany to legally allow medical research without consent on encrypted patient data after an independent review of the research project. In return, it should be possible for every citizen to simply object to this so-called ‘data donation’ How would you find such a legal regulation ... for publicly funded research?”).

Empirical studies have revealed that the willingness to share data differs among different groups. The findings are comparable to the overall use of EHR: among those with higher age, educational level, and income, a higher willingness to share data can be observed [30,36-39]. Some studies investigate potential individual causes for the willingness to share health data for scientific purposes. These studies find that concerns about confidentiality breaches and data misuse are important factors that prevent data sharing [28,29]. Unsurprisingly, privacy protection, anonymization, and transparency have proven to be key factors for data sharing [29,40]. Furthermore, people are motivated by potential benefits, including more altruistic ones, like advancements in science and public health [29,40]. Another key factor is the use of health data. While international research has shown relatively high public support for the secondary use of health data, this support decreases significantly when shared data can be used by the private sector [41-43].

Another source of insight comes from studies that focus on the social contexts in which data are shared. They have identified 2 other relevant aspects: digital literacy and trust. Health data sharing relies on digital tools. Therefore, people who are more familiar with digital tools may be less reluctant to share data. In addition, technology companies such as Google and Apple have created many services that make use of data sharing in everyday life. Hence, digitally literate people are more involved in data sharing in general. In line with this argument, empirical studies show a higher propensity to share health data among the more digitally savvy people [36,37,40,44,45]. On a more abstract level, it can be argued that trust plays an essential role in health in general [46] and in data sharing in particular. Since the sharing of data is a socially highly indeterminate constellation for social action, trust is a crucial resource. The risks taken by data donors as well as the potential benefits depend strongly on other actors and can hardly be known in advance. For example, the question of anonymizing health data can only be answered in relation to existing knowledge and techniques. The benefits of data sharing are particularly uncertain because there is no guarantee of medical progress, and even if progress does occur, it is unclear whether data donors themselves benefit. Given these theoretical arguments, it is not surprising that empirical studies show an important influence of trust. They can show that trust in the institutions involved in data sharing is relevant, as is general trust in science [15,29,36,37,40,44,45].

Methods

Ethical Considerations

Ethics approval was obtained from the ethics department of the German Aerospace Center (21/23) before the interviews were conducted. Participants gave verbal informed consent to participate in the study. Anonymized interview data were provided to the author by the survey institute. No compensation was given to the interviewees.

Survey Design and Sample

The analysis is based on a dedicated telephone survey (computer-assisted telephone interview [CATI]) about health data conducted between December 7 and 21, 2023. The sampling was carried out by the survey institute drei.fakt (Erfurt) on behalf of the Ernst Abbe University of Applied Sciences Jena. For the study, a representative randomized stratified random sample was drawn based on randomized landline and cell phone numbers (30/70) [47]. Random landline numbers were called based on regional quotas. The mobile phone numbers were sampled and stratified by telephone provider. A total of 11,451 residential numbers were called. In total, 1004 respondents aged 18 years and older participated in an interview. In contrast to many web-based surveys in this area, CATI allows people without internet access to be able to take part in the survey. To ensure the quality of the sample, it was compared with the population for age, gender, and region during the field period. Statistics from the 2019 German microcensus served as a data basis for comparing the distribution of the sample with the distribution of the characteristics in the population. Compared to population statistics, the unweighted sample underrepresents immigrants and slightly overrepresents people with higher education. This selection bias of telephone interviews is well-known from survey research. Therefore, all analyses use a weighting variable in order to adequately represent the population in terms of demographic and socioeconomic characteristics.

Questionnaire

The questionnaire comprised 32 questions regarding various topics about health data sharing. The questionnaire included information on digital skills, the willingness to share personal health data in general, motives for and against data sharing, questions regarding trust and data protection, as well as attitudes toward the EHR and socioeconomic characteristics. The CATI lasted approximately 20 minutes. Most questions were based on a 5-point Likert scale or binary response options and included multiple response categories. The final questionnaire included feedback from 2 separate pretests. In this pretest, the survey instrument was tested for its practical suitability in the field and potential misunderstandings. The full questionnaire and survey data are available in German via the GESIS repository [47].

Data Analysis

Descriptive statistics and multivariate linear regression models are used for analysis. The dependent variable in the multivariate regression models is the attitude toward sharing health data via EHR. People were asked on a 5-point scale (1=yes, definitely and 5=no, definitely not): "Would you be willing to share your health data from your EHR anonymized for medical research purposes?" To minimize potential misunderstandings about the EHR, the question was preceded by a brief explanation of EHRs ("Since January 1, 2021, all people with statutory health insurance can use the EHR via an app of the insurance provider. The EHR contains medical findings and information from previous treatments."). It is important to note that this question is hypothetical, as only a small fraction of people actually had an electronic personal health record at the time of the fieldwork (see Introduction section). However, in order to measure the willingness to share personal health information and to take into account the new legal framework, the question was phrased in a hypothetical manner. This makes it possible to measure the willingness to share extensive and potentially sensitive personal health information rather than actual planned behavior. Therefore, the question is also analyzed for respondents without an EHR in order to reflect overall opinions about the new legislative approach.

Results

The first step is to analyze the approval rates for the use of the German EHR. In general, the population is very open to the EHR. In total, 53% (n=483) of the population who claim to have no EHR yet show interest in using it. At the same time, 8.9% (n=89) of the sample state that they already have an EHR, in comparison to the 1% reported in official statistics. Therefore, it has to be assumed that some people lack a proper understanding of the EHR (see Limitations and Further Research Questions section). Only a minority of 17.1% (n=156) refuse to use it. The proportion of people with no clear opinion (partly partly or do not know) is significantly higher (n=272, 29.9%).

The legislative proposals also introduce the sharing of health data from the EHR for research purposes, as long as individuals do not actively object. Figure 1 summarizes whether respondents would be willing to share their personal health data stored in an EHR. The figure summarizes the attitudes of respondents with and without EHR. Respondents are more cautious about data sharing compared to the interest in using the EHR. In total, 43.4% (n=432) of respondents are willing to share their health data (yes, definitely or rather yes). Nearly 1 in 4 (n=225, 22.6%) respondents oppose data sharing. In addition, a large proportion of respondents are undecided (partly or not at all or do not know). A high interest in using the EHR corresponds empirically with a high willingness to share health data via EHR (no figure). The bivariate correlation is considerably large with 0.56 (Spearman).

The attitude toward health data sharing varies considerably with the data user respondents have in mind (Figure 2). The survey included a question regarding health data sharing with different institutions. It has to be noted that this question did not mention the EHR directly but addressed the willingness to share health data more generally. While 28.7% (n=285) and 18.8% (n=186) do not want to share data with public research institutions or public health insurances, about 38% (n=377) object to share their personal health data with private research institutions.

In the next step, the interest to use the EHR and the willingness to share health data for research purposes are measured for different socioeconomic groups. Table 1 shows the percentage of respondents in each group who intend to use the EHR and how many would agree with data sharing (yes and rather yes). In addition, respondents were asked for their opinions on different consent mechanisms. Figure 1 shows the proportion of people who explicitly reject the opt-out procedure as it will be introduced by law in 2025—compared to those who agree or are undecided (do not know).

Figure 1. Opinions about the use of electronic health record (EHR) and data sharing for research purposes (in percentages). Own calculation and weighted results for the following questions: "Would you like to use the EHR to view and manage your digital health data?" (n=911; nonresponse and people with EHR excluded) and "Would you be willing to share your health data from your EHR anonymized for medical research purposes?" (n=995; nonresponse excluded).

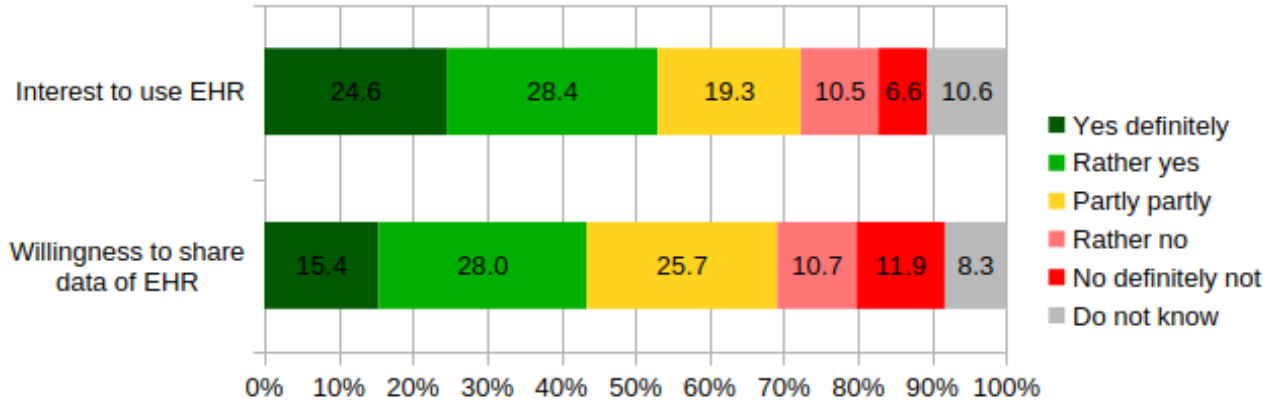

Figure 2. Willingness to share personal health data by data user (in percentages). Own calculation, weighted results for the question, “Would you be willing to share your health data anonymously for medical research purposes with the following institutions?” (nonresponse excluded; n=993).

Total sample	483 (53)	432 (43.4)	438 (44.7)
Total respondents, n	911	995	980

[a]Own calculations, weighted percentages for columns 1 and 2 (share of a sample with statement yes definitely and rather yes) and column 3 (share of a sample who disagrees opt-out) in response to the question: “The German government is planning to use data from the electronic health records for medical research, eg, for research on new diseases and therapeutic approaches. Which of the following consents do you agree with? ... My data will be shared until I object.” Options to answer: agree or disagree or do not know or nonresponse; nonresponse excluded; do not know is interpreted as no interest to use EHR, not in favor of data sharing and agree with opt-out.

There are clear socioeconomic differences in interest in using the EHR and willingness to share health data, which are similar for both variables. The higher a person’s socioeconomic position (like income or education), the more open respondents are to using the EHR and sharing their personal health data for research purposes. Older people and men also tend to be more open. There are pronounced differences by migration status. The final column summarizes attitudes toward the opt-out process. First of all, it is striking that the procedure implemented by the legislator is explicitly rejected by a significant part of the population. In the entire sample, 44.7% (n=438) say that they are against an opt-out. Additional analyses not presented here show that the remaining respondents either agree (n=400, 40.8%) or have no opinion (n=142, 14.5%). Interestingly, the opt-out model is mainly rejected by people in a higher socioeconomic position. There are hardly any differences with regard to the other socioeconomic variables, except for a lower level of rejection in the eastern part of Germany. Overall, the descriptive statistics suggest that citizens are open to EHR and data sharing but want a high degree of autonomy in dealing with their health data. Additional analyses not shown here indicate that active consent is supported by over 80% (n=788) of respondents.

In the next step, the willingness to share data via the EHR is examined in a multivariate linear regression model (Table 2). The dependent variable is the willingness to share personal health data expressed on a 5-point scale (Figure 1). To prevent an excessive reduction in the sample, people who answered “do not know” were assigned to the “partly partly” category. The findings presented here remain stable even with a smaller sample. The determinants identified in the State of the Art section are added as independent variables to the model. Special

attention is given to the role of trust. The first model includes socioeconomic parameters. As shown in Table 1, the multivariate model confirms socioeconomic differences. However, some more differentiated statements can be made. Controlling for other parameters, there is a curvilinear relationship between age and willingness to share. The positive squared age term indicates that the willingness to share is highest among the very young and the very old. The willingness to share is lowest among people in their 50s. On a 5-point scale, their willingness is about 0.5 points lower than that of 20-year-old people. Income has a positive significant influence on willingness to share, which confirms the descriptive findings. The level of education also has an influence. However, when controlling for income, medium levels of education are associated with the highest willingness to share. Women and people born abroad show no different opinion regarding health data sharing after controlling for income and education. The model also includes a dummy variable indicating the presence of chronic diseases. On the one hand, people with chronic diseases may be at a higher risk of data misuse, but on the other hand, they may be more likely to benefit from digitally supported medical progress. In fact, interest in sharing data appears to be 0.2 points higher for people with chronic physical diseases.

The second model adds comfort with digital technologies. As in comparable studies from other countries, there are significant effects. People who find it easy to use digital technology are more open to sharing their health data. However, the effect disappears when the trust variables are included (model 3). Trust turns out to be a very strong influencing factor. Trust in science has the strongest influence. This is particularly noteworthy because the trust indicator does not specifically address the EHR or the institutions behind it but science as a whole. Controlling for socioeconomic parameters, a person who mistrusts the scientific system has a willingness to share that is more than 2 points lower on a scale of 5 than a person who fully trusts the scientific system. In addition, trust in the big technology firms also has a highly significant influence on the hypothesized direction. The strong influence of trust can be seen directly in the sharp increase in the fit of the model (R^2). The model also includes a proxy for altruistic tendencies in the form of a general willingness to donate (eg, money). The dummy for people who donate on a regular basis is significant. In the last model, motivations and concerns that may be associated with data sharing were included. However, the last model should be interpreted with caution. Because the wording of the questions in the independent variables refers to data sharing, the coefficients may be biased by self-reference (eg, if you care about doing good for society by sharing your data, you will more be willing to share). Nevertheless, the coefficients provide important clues about the motives that drive data sharing. The multivariate results show an interplay between altruistic motives (doing good for society) and cost-benefit considerations (potential benefits for personal and fear of data breaches that expose personal health data to the public).

[n]I am worried that my data will be made public (0=disagree or 1=agree 1).

Discussion

Principal Findings

The results of this study shed light on attitudes toward the use and sharing of EHRs for research purposes in Germany, particularly in the context of the new legislation based on the opt-out mechanism. Overall, the study reveals a nuanced picture of the German population's attitudes. The empirical results show an openness to EHRs (about half of the nonusers express a desire to use their EHR, signaling significant potential for increased adoption). At the same time, a significant share of the population remains skeptical or undecided. The overall openness is in line with international research regarding interest in EHR [12]. Given these high levels of interest, the introduction of an opt-out model does not seem unjustified. However, especially a large fraction of undecided people need to be properly informed about the consequences of having their health data stored electronically. While there is general support for sharing health data, with 43.4% (n=432) of respondents indicating a willingness to do so, a significant portion (n=225, 22.6%) remain opposed, and a large number are undecided. The results indicate a significantly lower willingness to share health data than has been measured in comparable studies in Germany [15,33]. Possible explanations for these differences are (1) different timing: other studies collected their data at a time when there was no legal framework for health data sharing and therefore risks, etc, had not yet been widely discussed in public. (2) Methodological: this study is based upon a telephone survey rather than web-based and explicitly allows people to have no specific attitude by including categories like refuse to answer, do not know, and neither nor. Last but not least, the comparatively low willingness to share health data in this study compared to international research [27,28] may be due to the emphasis on the personal character of the data potentially shared. The ambivalent results highlight the need for careful consideration of how the opt-out mechanism is implemented and communicated. Although there is openness in principle, "soft paternalism" must be viewed critically precisely because of the high proportion of undecided citizens. In contrast to the principle of informed consent, in which the processes and risks of data sharing have to be explained before citizens allow data sharing, an opt-out solution presupposes that the population is sufficiently informed in other ways. This becomes even more clear after considering attitudes toward the opt-out mechanism, which 44.7% (n=438) disapprove. Especially people who are positive about EHRs and the sharing of their health data reject the opt-out mechanism proposed by the legislator more often. Presumably, "choice architecture" is seen as too much interference in their own decisions.

The study also confirms a digital divide, as socioeconomic factors significantly influence both the willingness to use EHRs and the willingness to share personal health data. The results are in line with international research findings [16,30]. Higher income, education, and digital literacy are associated with greater openness, while those with lower socioeconomic status are more reluctant. However, socioeconomic factors are not the most important in explaining openness to data sharing. Trust plays a critical role in determining the willingness to share health information. While other studies have pointed to the role of trust as a significant factor [15,40,44,45], this study shows that institutional trust has a decisive influence compared to other factors. The influence of socioeconomic variables, as well as other factors such as digital literacy, diminishes when trust variables are taken into account, highlighting trust as a fundamental element in the acceptance of digital health initiatives. The observed socioeconomic disparities reinforce the need for targeted interventions and information to ensure equitable access and participation in digital health.

Policy Implications

The paradigm shift to an opt-out system is expected to increase participation rates because it relies on passive inclusion rather than active consent. However, this comes at the cost of potentially creating a population of uninformed and passive citizens who are enrolled in the system without fully understanding the implications. This raises critical concerns about consumer autonomy and challenges the notion of the autonomous consumer who actively engages with—and consents to—data-sharing practices. With a large portion of the population still undecided about EHR adoption and data sharing, the need for population-wide education becomes even more apparent. Ideally, all citizens, regardless of their socioeconomic background, should be able to make informed and autonomous decisions about their participation. The study also shows the complex mechanisms of the digital divide, with those in higher socioeconomic positions being more open to the adoption of EHRs but also more likely to oppose the opt-out system. This suggests that the paradigm shift is perceived as a restriction of autonomy. Those with greater resources and digital literacy want to make informed choices and therefore resist mechanisms that limit their freedom of choice. While those with greater resources are likely to be able to opt out if they perceive the risks of data sharing to be too high, they could trigger serious political resistance to the opt-out mechanism. In contrast, individuals with lower socioeconomic status may be less able to navigate these systems and therefore are more vulnerable to passive inclusion.

The transition to an opt-out system for EHRs in Germany marks a significant policy shift with the potential to transform the health sector. However, for this shift to be successful, it is essential to address the underlying concerns of the population, particularly around data security, autonomy, and the digital divide. Continuous monitoring of the implementation of the opt-out system will be crucial to keep and build trust within the population.

Limitations and Further Research Questions

In contrast to web-based surveys, which are often used in EHR research, the CATI method used here avoids many problems of self-reporting, sample bias, and inference [48,49]. However, the quality of data collected through telephone interviews also experiences low response rates. It seems highly plausible that nonresponse is not random. People with lower levels of trust and willingness are supposedly less likely to participate in the survey. Thus, despite the weighting procedure applied, the sample may be biased toward more trusting people. This problem is common to other data used in comparable research.

Another limitation concerns the correct understanding of the EHR in Germany. During the field phase, little more than 1% of the insured population opted for the EHR. It is possible that many respondents do not have a proper understanding of the EHR or have no knowledge at all. The survey provides some evidence in this direction. A question about knowledge of the EHR reveals that 13.9% (n=139) have never heard of it. For this group, the evaluation of data sharing is probably less substantiated. However, at the same time, a large fraction says that they have heard of the EHR (n=720, 71.7%) or even use it (n=89, 8.9%). On the one hand, these results support the assertion that a large proportion of the sample has a basic understanding of the EHR. During the field phase, there was also an extensive media discourse about the EHR, as the Gesundheitsdatennutzungsgesetz was being discussed in parliament in December 2023. On the other hand, the self-reported use of the EHR does not match the official statistics. Some respondents probably confused the EHR with other apps provided by their health insurance. This problem of overreporting has also been observed in other studies [15].

The study focuses on the interest in using the EHR and the willingness to share health data. At the time of the field phase, EHR adoption was very low, and a legal framework for health information exchange was in its formative stages. Research has already shown that there is a gap between attitudes and actual behavior [12,42]. So the results have to be interpreted with some caution. In addition, the high proportion of undecided respondents indicates that reported attitudes are not very salient and therefore susceptible to survey effects. However, other studies share this disadvantage. Moreover, the consequences of limited interest in EHR do not only affect surveys but also have far-reaching practical implications, especially when using opt-out regulations.

Future research should focus on the gap between interest in using the EHR and actual behavior. With a focus on Germany, the potential burdens of adoption should be analyzed in more detail. With regard to trust, the potential ways to build trust within the health care system without relying too much on general institutional trust also point to new research directions. Furthermore, there are interesting research questions regarding self-responsibility in a system that becomes largely based on passive consent (opt-out).

Acknowledgments

This work was supported by the German Federal Ministry of Education and Research and the European Union—Next Generation (grant 16KISA015). The funded project is called AVATAR ("Anonymisierung persönlicher Gesundheitsdaten durch Erzeugung digitaler Avatare") and consists of several research institutions that aim to develop new methods for anonymizing patient data for research. The funding agency had no role in the design, conduct, analysis, interpretation, or approval of the study. The content is the sole responsibility of the author. The author would like to thank Elias Kühnel, Julia Berghäuser, Sven Bock, and Anna Weber for their thorough work on the questionnaire.

Abstract

Background: Cases of the occupational lung disease silicosis have been identified in workers processing artificial stone in the stone benchtop industry (SBI). In the Australian state of Victoria, the Regulator commissioned a screening program for all workers in this industry.

Objective: To facilitate systematic data collection, including high-quality exposure assessment, an electronic data capture tool (EDCT) was developed.

Methods: A multidisciplinary team developed an EDCT using Research Electronic Data Capture (REDCap; Vanderbilt University). The needs of the EDCT were (1) data entry by multiple clinicians and the workers attending for screening and (2) systematic collection of data for clinical and research purposes. The comprehensibility and utility of the tool were investigated with a sample of workers, and the EDCT was subsequently refined.

Results: The EDCT was used in clinical practice, with capacity for data extraction for research. Testing of comprehension and utility was undertaken with 15 workers, and the refined version of the Occupational Silica Exposure Assessment Tool (OSEAT) was subsequently developed.

Conclusions: The refined OSEAT has been determined to be comprehensible to workers and capable of collecting exposure data suitable for assessment of risk of silicosis. It was developed for workers in the SBI in Australia and is adaptable, including translation into other languages. It can also be modified for SBI workers in other countries and for use by workers from other industries (mining, construction) at risk of silica exposure, including in lower-income settings.

Introduction

Silicosis is an incurable, potentially life-threatening, form of fibrotic lung disease caused by inhalation of respirable crystalline silica (RCS) [1]. The disease has been recognized globally for over 100 years, and lung disease screening is recommended for high-risk industries, including mining and construction [2]. Cases of silicosis were identified in 2010 among workers in the stone benchtop (countertop) industry (SBI) working with artificial stone (AS; Textbox 1) [3-12]. Subsequently, a number of cases of artificial stone-associated silicosis were diagnosed in Australia [3,13]. AS has a very high crystalline silica content, often over 90% [14]. Processing AS by drilling, polishing, cutting, or grinding generates fine particles of dust containing RCS, which can cause silicosis when inhaled [15].

Textbox 1. Timeline of artificial stone (AS) and silicosis in Australia

Early 2000s: AS introduced to Australia
2010: First case of silicosis associated with AS reported in Italy
2015: First case of silicosis associated with AS reported in Australia (conference abstract)
2017: First case of silicosis associated with AS reported in Australia
2019: Screening program of stone benchtop industry workers begins in Victoria, Australia (paper-based data collection)
2021: Screening program first incorporates electronic data capture tool (EDCT)
2021-2023: Refinement of EDCT informed by data cleaning and evaluation study with workers

An investigation of the effects of RCS exposure in the SBI was commissioned by the Victorian regulator, WorkSafe Victoria [16], and developed into a screening program by Monash University. It included (1) exposure assessment from a detailed occupational history; (2) collection of respiratory symptoms; (3) recording of investigations including spirometry, chest x-ray, and high-resolution CT of the chest; (4) screening for comorbidities associated with silica exposure, including autoimmune diseases and tuberculosis [4,17]; and (5) a mental health instrument.

The initial paper-based questionnaire was developed by a multidisciplinary team, including respiratory physicians, an occupational hygienist, and occupational physicians [16]. Simplicity was prioritized, as many industry workers were born outside Australia and spoke English as an additional language [18].

Up to 6 jobs in the SBI could be recorded in the occupational history. The proportion of time spent on specified *tasks* in each job and the proportion of time spent on dry cutting of stone and working near someone doing dry cutting were recorded. *Exposure control measures* (ventilation and respirator use) were identified for each job. Other information collected included the country, start and (if relevant) finish date; days per week worked; number of people in the organization; and type of stone predominantly worked with (AS or natural stone). Other silica-associated occupations (eg, mining, quarrying) and any non-occupational activities that involved dust exposure (including hobbies and home repairs, eg, tiling, plastering) were also recorded.

Data were collected from multiple users, including respiratory physicians, multidisciplinary team, workers, and administrative staff, and capture all the elements listed earlier. The data were cleaned and entered into an electronic data capture tool (EDCT) held on the secure REDCap platform [19,20]. The data were used for both clinical and research purposes. In 2021, screening was centralized and carried out at a single site, which led to a need for direct data entry to the EDCT by the worker.

Exposure calculations from the occupational data have been used to identify roles within the SBI with greater RCS exposure, such as factory machinists and installers, and that exposure intensity and cumulative exposure were associated with dyspnea and radiological abnormalities consistent with silicosis [21]. The screening program data has also been used to describe the numbers of cases of silicosis diagnosed to date [18], the rates and determinants of psychological distress, and the psychometric properties of the mental health instrument [22,23].

The aim of this study was to describe the development of the EDCT, present its refined content, and describe the results of an audit of its clinical utility undertaken with a sample of workers.

Methods

Overview

The original team reviewed the exposure questionnaire, which overall had been well understood, and identified items that required substantial data cleaning. The team redeveloped the questions, which included, for example, adding illustrations of dry and wet cutting examples and the types of respirator and ventilation options that were sourced from workplace health and safety organizations [24-26]. Further, additional optional responses were added from free text replies, for example, water jet cutting.

In the first draft questionnaire, participants were asked to apportion their tasks (Figure 1).

The percentages seldom added to 100%, as shown in the example in Figure 1, so in the revised questionnaire, a sliding bar was provided that provided visual input of the proportions (Figure 2). A pop-up trigger was included if the task proportions were out of range, as shown in Figure 2.

Figure 1. Original paper questionnaire asking workers to estimate proportions of work time spent doing specific tasks in their workplace. CNC: Computer Numerical Control____.

15.	What do you do in this job? (Tick all that apply)	
TASK		Estimate percentage of time in a typical week undertaking this task (e.g. 10%)
Shaping e.g. with powered hand tools	☑	20
Sawing e.g. with bridge saw	☑	50
Using CNC machine	☐	
Polishing/Finishing	☑	50
General labouring	☑	50
Maintenance	☑	40

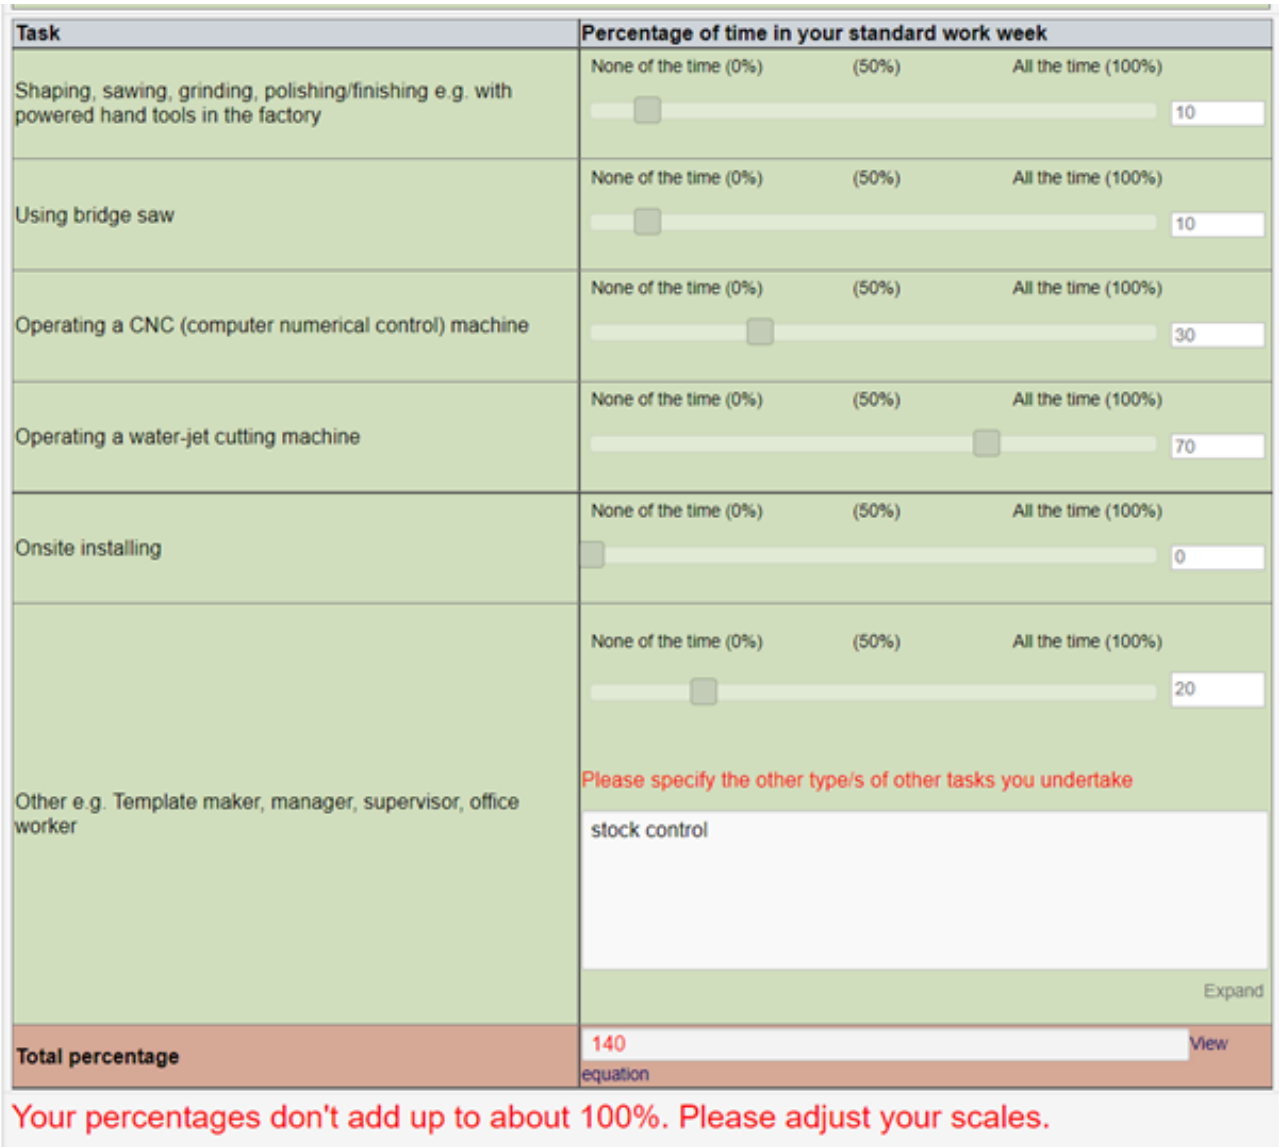
Onsite Installing	☑	100
Other eg Template maker, manager, supervisor, office worker	☐	
If other, specify:_____		

Figure 2. EDCT (electronic data capture tool) version of the task estimation section of the occupational history with a total that adds to a proportion of >100% of the time and the warning message provided to the worker.



Prior to attending for screening, workers were emailed a link to the EDCT containing the revised questions in order to

complete their occupational history. The final page completed by workers included optional electronic consent for sharing data with Monash University.

Other data collected during screening included medical history, smoking status, respiratory symptoms, physical examination findings, diagnosis, return-to-work assessment, and results of all relevant investigations, including chest x-ray, high-resolution CT, pathology, and spirometry.

In 2023, an investigation of the comprehensibility, feasibility, and face validity of the occupational history section of the EDCT was completed with workers.

A total of 15 workers participated in the investigation, which was conducted between February and May 2023. Workers were interviewed about their responses on the EDCT, using a pre-developed proforma to prompt feedback. They were asked: "Were there any words you did not know?" "Did you understand what was meant by 'dry work'" "Are there any other tasks in your workplace that expose you to dust?" and "Did the list of ventilation options include what you use in your workplace?" For all questions, respondents could reply yes or no and provide additional comments. If a worker reported no dry cutting in their current or most recent job but had exposure to dry cutting from previous jobs, they were asked to respond to questions referring to their former job.

Ethical Considerations

Workers were eligible to participate if they had completed their occupational history using the EDCT, did not require an interpreter for their appointment, and had provided electronic consent to share data with Monash University. All participants were provided with a written information sheet and asked to provide verbal consent for participation. Responses were deidentified, and workers did not receive compensation for their participation. Approval was granted by the Alfred Hospital Research Ethics Committee as a substudy of project 292/21.

Results

The demographics of the workers are presented in Table 1. Most participants were male, and they covered a range of ages and years of employment in the SBI. They included machinists, installers, and office workers.

Table . Demographics of participants.

Characteristics		Values
Males, n (%)		14 (93)
Age (years), mean (SD)		38.1 (10.9)
Years in stone benchtop industry, mean (SD)		9.6 (7.85)
Born in Australia, n (%)		5 (33)
Language other than English spoken at home, n (%)		6 (40)
Most recent SBI job held, n		
	Director	3
	Installer	4
	Stonemason	5
	Foreman	2
	Other	1

All participants were asked to report about their *comprehension* of an introductory statement, and one worker commented that it took a while to read and understand, and did not feel like he understood it fully. All workers reported that they comprehended what was meant by "dry work." When asked about *tasks* that exposed them to dust that were not already listed on the EDCT, 2 workers identified new relevant tasks: emptying bins containing benchtop fragments and cleaning of the final benchtop product, onto which the dust-containing water used in wet cutting had dried. In total, 4 workers reported that their *ventilation* option was not included in the list on the EDCT, nor was it pictured. However, after discussion, the alternative options they were describing were "air conditioning," "garage door," "no ventilation," and "ventilation in the wall," all of which were listed.

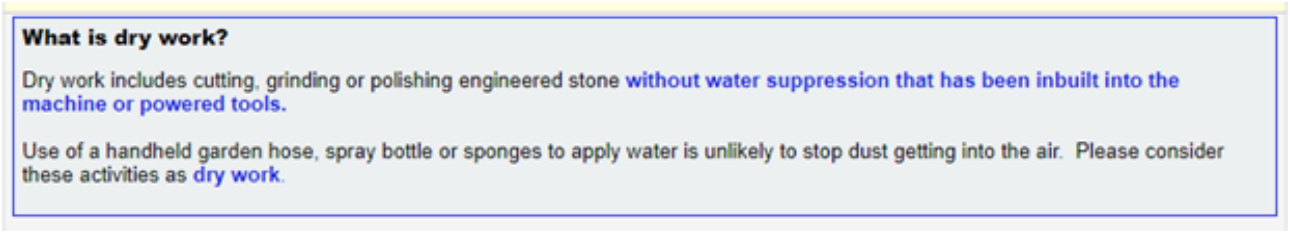
For *respirators*, 14 workers identified the type they used from the descriptions and pictures in the EDCT, and the only worker that did not see their device described use of one similar to that depicted. Of 8 workers who were asked if they could easily remember and estimate the percentage of time they spent wearing a respirator, 7 responded in the affirmative. One worker had worn his respirator for 6 hours out of an 8-hour shift (approximately 75%), but had estimated that he wore it for 35% of the day. One worker commented that he wore his respirator all day, regardless of the task, whilst another pointed out that each job was different, with some jobs being "perfect" (ie, not requiring any adjustments), whereas others required adjustments onsite, adding to the difficulty of responding to this question accurately.

If a worker reported dry cutting in their current job, they were asked whether or not practices around dry cutting had changed (this was because dry cutting without suitable protection had been officially banned recently in Australia). Of the 11 workers who completed this question, 10 understood the question and were able to complete it accurately, but one worker expressed some confusion around the wording of the question. Workers

also described measures other than ventilation and respirators that their employer had introduced including changing clothes at work and using water systems for dust suppression when loading stone.

Subsequently, modifications were made to improve accessibility for the workers: simplification of the language used in descriptive statements and instructions, modification of the color scheme to improve readability, and addition of commonly reported responses (eg, "home maintenance," "tiling," and "plastering") as a prompt on the non-occupational (eg, hobby) dust exposure history section. One of the simplified statements was an introductory statement that defined "dry work" (Figure 3). An image accompanied the text with examples of dry and wet cutting [26]:

Figure 3. Refined EDCT for clarification of the definition of dry work.



The current version of the Occupational Silica Exposure Assessment Tool from the EDCT is presented in Multimedia Appendix 1.

Discussion

Principal Findings

Since 2019, over 1000 SBI workers have undergone screening for silicosis in Victoria, Australia, through a protocolized screening program. In this study, we described the development of the screening questionnaire into an EDCT, the Occupational Silica Exposure Assessment Tool, and have described how it was refined as a result of our experiences and after assessment of its acceptability and comprehension among this worker population. The results of the investigation suggested that the usability and comprehension of the refined EDCT are acceptable among English-speaking workers.

The benefits of EDCTs for improving patient care [27]; improving accuracy of data collection compared to paper methods [28]; and facilitating data collection from multiple users, including patients and health care providers [29], have been established in many settings. Moreover, EDCTs are able to capture and retain large volumes of data, maximizing cost- and time-efficiency in clinical and research settings [29,30]. As demonstrated, the development of this EDCT has already provided all of these benefits and enabled us to create a streamlined and efficient screening program for workers in the artificial stone benchtop industry.

Benchtops made from AS are a popular kitchen product globally, and there are concerns that cases of silicosis among workers who produce them are underreported in the literature [31,32]. Globally, silica deaths were estimated to be more than 12.9 thousand in 2019 [33], and the highest rates were recorded in low- and middle-income countries [33,34]. Silicosis has been seen in a range of industries, including construction, jewelry production, quarrying, tunneling, dental material manufacturing, denim jean production, and ceramic and pottery manufacturing [35]. There is therefore an urgent need for occupational screening for large numbers of workers exposed to RCS, for which reliable instruments are needed. The Occupational Silica Exposure Assessment Tool can be deployed in settings in which workers are exposed to RCS, whether for workers in the SBI or modified for other occupational settings.

In addition to assessing SBI workers at risk of silicosis, the data collected from the Occupational Silica Exposure Assessment Tool (OSEAT) can be used to estimate an individual's level of RCS exposure. In previous work, occupational history data collected using the OSEAT were used to group SBI workers by extent of silica exposure, using a combination of the proportion of time working with AS and the proportion of time spent dry cutting [21]. Both cumulative exposure and exposure intensity were found to be associated with symptoms of dyspnea and chest x-ray abnormalities [21]. This illustrates the ready utility of having added the e-consent function to the EDCT within REDCap, facilitating extracting data from the OSEAT to use for research purposes.

One consideration when introducing a REDCap-based EDCT in a clinical setting is its reliance on workers having adequate internet connection. This has been a limiting factor for the utilization of similar instruments, in which open-source software that was not reliant on internet connection was preferred [28,36]. In some resource-poor settings, REDCap was the preferred platform [37,38], and REDCap has now developed a mobile app that can be used offline that may overcome internet connection limitations [20].

A limitation of this study was the small number of workers included, none of whom required interpreters. Its comprehensibility is therefore unknown among those who require interpreters. Furthermore, these workers were recruited consecutively and recently from the clinic and consequently are not necessarily representative of the wider workforce. Another limitation was that the original instrument was not co-designed with consumers (workers in the SBI), something that we addressed in this study. We were unable to investigate floor or ceiling effects within the scope of this work, which would be a necessary step if the tool is to be used in translated versions.

A strength of the OSEAT is that it has been used and improved for close to 3 years with demonstrably good comprehension by SBI workers.

Future development of the OSEAT will include its translation into other languages using the REDCap multilanguage module.

The commonest languages other than English among the workers attending screening at our center have been Vietnamese, Persian, Chinese, and Arabic, and are therefore a priority for translation and inclusion into the module.

Conclusions

This study has presented the development, comprehension, utility, and refinement of the OSEAT, a purpose-built EDCT for use among SBI workers undergoing assessment for silicosis that included input from workers and has the capacity for modification and use within other silica-exposed occupational settings.

Acknowledgments

This project was funded by WorkSafe Victoria, and FHL was supported by a PhD project stipend from WorkSafe Victoria. The manuscript was prepared by the Monash Centre for Occupational and Environmental Health, Monash University. The opinions, findings, and conclusions expressed in this publication are those of the authors and not necessarily those of WorkSafe Victoria.

Data Availability

The datasets generated and analyzed during the current study are not publicly available for ethical and privacy reasons. Patient consent did not include sharing of data external to Monash University. If data need to be shared, additional approval from Monash University HREC and Alfred Hospital HREC would be required.

Authors' Contributions

FHL provided the concept and study design. Input into study design was provided by KWB and DCG. The EDCT was built by CD with input from RH, DG, FHL, MRS, JJM, and KWB. Data acquisition was performed by FHL. Data analysis was completed by FHL, with interpretation by FHL, KWB, and DCG. The manuscript was drafted by FHL, with significant contributions by KWB, RFH, and DCG, and additional editing provided by MRS, JJM, CD, and JF.

Conflicts of Interest

FHL was supported by a PhD project stipend from WorkSafe Victoria. The authors have no further interests to declare.

Abstract

Background: A smart medication dispenser called "spencer" is a novel generator of longitudinal survey data. The patients dispensing medication act as a survey panel and respond to questions about quality of life and patient-reported outcomes.

Objectives: Our goal was to evaluate panel persistency, survey response rates, reliability, and validity of surveys administered via spencer to 4138 polychronic patients residing in the United States and Canada.

Methods: Patients in a Canadian health care provider's program were included if they were dispensing via spencer in the June 2021 to February 2024 time frame and consented to have their data used for research. Panel persistency was estimated via discrete survival methods for 2 years and survey response rates were computed for 1 year. Patients were grouped by mean response rates in the 12th month (<90% vs ≥90%) to observe differential response rate trends. For reliability and validity, we used a spencer question about recent falls with ternary responses value-coded −1, 0, and 1. For reliability, we computed Pearson correlation between mean scores over 2 years of survey responses, and transitions between mean score intervals of [0, 0.5), [−0.5, 0.5), and [0.5, 1]. For validity, we measured the association between the falls question and known factors influencing fall risk: age, biological sex, quality of life, physical and emotional health, and use of selective serotonin reuptake inhibitors or serotonin-norepinephrine reuptake inhibitors, using repeated-measures regression for covariates and Kendall τ for concomitant spencer questions.

Results: From 4138 patients, dispenser persistency was 68.3% (95% CI 66.8% - 69.8%) at 1 year and 51% (95% CI 49% - 53%) at 2 years. Within the cohort observed beyond 1 year, 82.3% (1508/1832) kept surveys enabled through the 12th month with a mean response rate of 84.1% (SD 26.4%). The large SD was apparent in the subgroup analysis, where a responder versus nonresponder dichotomy was observed. For 234 patients with ≥5 fall risk responses in each of the first 2 years, the Pearson correlation estimate between yearly mean scores was 0.723 (95% CI 0.630 - 0.798). For mean score intervals [0, 0.5), [−0.5, 0.5), and [0.5, 1], self-transitions were the most common, with 59.8% (140/234) of patients starting and staying in [0.5, 1]. Fall risk responses were not significantly associated with sex (P=.66) or age (P=.76) but significantly related to selective serotonin reuptake inhibitor or serotonin-norepinephrine reuptake inhibitor usage, quality of life, depressive symptoms, physical health, disability, and trips to the emergency room (P<.001).

Conclusions: A smart medication dispenser, spencer, generated years of longitudinal survey data from patients in their homes. Panel attrition was low, and patients continued to respond at high rates. A fall risk measure derived from the survey data showed evidence of reliability and validity. An alternative to web-based panels, spencer is a promising tool for generating patient real-world data.

KEYWORDS

real-world data; real-world evidence; patient-reported outcomes; longitudinal studies; survey methods

Introduction

Background

The use of patient data collected in real-world settings has never been more impactful. The US Food and Drug Administration's Real-World Evidence (RWE) Program has elevated real-world data (RWD) as a tool to support new indications for already approved drugs [1-3], the European Medicines Agency has published their RWE framework [4], and Canada's Drug and Health Technology Agency has published their guidance document [5].

RWD may take the form of claims records, electronic health records, registries, or patient-generated data, with patient-reported outcomes (PROs) as an important subset. Longitudinal surveys, where patients are surveyed at 2 or more points in time, generate data that allow for the analysis of within-unit change as well as aggregations over time [6]. This results in greater "causal leverage" than cross-sectional surveys [7] and is ideal for submissions to regulatory bodies.

Web-based panels, or "registered persons who have agreed to take part in online studies on a regular basis," rose in attractiveness with the proliferation of the web [8]. Recently, however, shortcomings of longitudinal studies based on web-based panels have undermined their reputation as a high-quality data source. Panel attrition, where subjects in earlier waves cease to respond in later waves, has become worse since the 1990s [7,9-11]. While web-based panel data are also prone to quality problems (eg, false answers, careless responses, and multiple panel memberships [12]), these problems have been exacerbated by innovations in automation and improvements in large language models, where human reviewers are unable to consistently detect automated responses [13]. This has become a corrupting force in web-based survey sampling [14].

Amazon Mechanical Turk (MTurk) was considered a representative and convenient source of web-based longitudinal survey data [15] but has seen its reputation deteriorate within the last decade. For example, a study that used MTurk to build a diabetes panel failed after only 5.8% (13/224) were deemed eligible for future survey research [16]. Researchers noted declines in MTurk data quality starting around summer 2018, as evidenced by degraded psychometric properties of well-understood metrics [17]. A warning was issued in the journal *Perspectives on Psychological Science* after an exercise revealed that only 2.6% (14/529) of MTurk samples were valid [18].

Alternatives to web-based panels exist in populations of patients using web-connected hardware, also known as "smart" products. One interesting subset is the population of patients using smart medication dispensers, as these products sit in the home amidst a public health need for digital adherence solutions [19]. A 2023 review of smart medication adherence products reviewed the features of 51 products without mention of survey administration capabilities [20]. One of these products, a dispenser named "spencer" [21,22] (manufactured by Spencer Health Solutions, Inc), has a touch screen display that allows it to administer survey questions following on-time medication dispenses (Figure 1).

At the time of writing, in-home spencer devices have generated more than 3 million longitudinal responses from more than 4000 unique patients to quality of life and PRO measures from a polychronic population residing in the United States and Canada. These are patients of Canadian health care provider Custom Health, Inc, a company offering "a personalized, connected service that goes beyond medication management and ensures medications are working as they should" [23]. Patients or caregivers can express interest directly via a collection of sign-up forms [24,25] or they may be directed to spencer via their health plans that have partnered with Custom Health [26]. When a health plan partners with Custom Health, their services are provided to members "who require a high degree of clinical oversight, those managing multiple medications or those experiencing medication adherence challenges" [27].

Figure 1. Key components of the spencer smart medication dispenser.

Objectives

The study's aim was to evaluate the spencer smart medication dispenser as a longitudinal survey platform for a polychronic patient population. Panel persistency, survey response rates, and measurement reliability and validity were assessed.

Methods

Recruitment

Patients of Custom Health were included if they met the criteria enumerated in Textbox 1.

Textbox 1. Inclusion criteria for patients in the study.

1. The patient entered Custom Health's intake process either by self-selection or based on the recommendation of a health care provider.
2. Custom Health professionals decided to pair the patient with a spencer smart medication dispenser.
3. The patient agreed to the Custom Health consent form.
4. The patient agreed to the Spencer Health Solutions End User License Agreement, permitting his or her deidentified data to be used for research purposes. This occurred on the spencer unit's touch screen.
5. The patient's first scheduled medication dose was between June 3, 2021, and February 14, 2024.
6. The patient dispensed a medication dose by March 14, 2024. In this paper, dispensing medication refers to dispensing multidose packs containing oral solids.

After completing Custom Health's intake process, spencer devices were shipped to patients' homes. Once set up, the devices displayed both current local time and the scheduled time of the next medication dispense via a touch screen display. Refills containing medication strips (multidose adherence packaging) prepared by a pharmacy were shipped to the patients' homes and were inserted by the patient or care nurse into the top of the unit via an electronically controlled door. At scheduled dosing times, the unit alerted the patient through sound, light, and a message on the touch screen display. After the patient pressed the dispense button on the touch screen, the unit dispensed 1 or more medication pouches. After an on-time dispense, a question was presented to those patients who had not explicitly opted out of surveys.

Data Generation and Processing

The question and response mechanism is further elaborated here. If a dose was dispensed on time and the patient had not opted out of surveys, 1 question was displayed on-screen. To answer, a single button press was needed to select from a multiple-choice answer set. This was followed by a review step (also serving as the completeness check) where the patient could confirm the selection or go back and change the answer. If a patient did not make the confirmation in the review step, the questionnaire would not be submitted to the database and later analyzed as an instance of nonresponse. If left attended to, a question would remain on the screen until the next scheduled dose.

In collaboration with health care professionals at Custom Health, 35 survey items were designed to measure the spencer experience, quality of life, and PROs. To avoid copyright infringement, these questions were not taken from any existing validated scale. Questions were scheduled one-to-one with doses in a predefined sequence that repeated indefinitely. Response options were consistently listed from most positive sentiment (eg, "Excellent") toward the top of the screen to least positive sentiment (eg, "Poor") toward the bottom of the screen. Questions were manually answered on test devices in a quality assurance laboratory before being released to patients, and patients could call into a support line to provide feedback regarding the questions or to request that they be turned off.

As is typical of web-based panels, the panel formed by the selection criteria in Textbox 1 constitutes a convenience sample. The target population best described by the sample is polychronic patients taking multiple medications daily. Since the surveys were administered as part of routine patient monitoring, no institutional review board (IRB) approval was needed.

Survey responses were sent to the application database through either cellular connection (the default) or Wi-Fi. In cases where the spencer lost connectivity, a store and forward mechanism sent data to the cloud database once connectivity was reestablished. The database is managed by Spencer Health Solutions that has received both ISO27001 [28] and Data Privacy Framework [29] certifications.

Date of birth, biological sex, and residential postal code were entered into a web-based portal by health care providers when patients were recruited. These fields were retrieved from the application database March 4, 2024. Dates of birth that were within 2 years of the database entry date were replaced with missing values, and age was computed as the difference between the first dispense date and date of birth. Within the United States, 5-digit postal codes were converted into US states via the *zipcodeR* R package. For Canadian postal codes, a function was written that maps the first letter of the postal code to the associated province. Prescription information was created by the pharmacies at the time of refill creation and sent to the database.

Statistical Analysis

Panel Attrition

Patients may leave the spencer dispensing platform for multiple reasons, including life transitions to higher care services or natural death. Leaving the dispensing platform is the primary mechanism of spencer panel attrition. To estimate dispenser persistency, we used the discrete survival analysis framework described by Allison [30], where the periods start on the first

day a patient is scheduled, are 30 days in length, and an attrition event occurs when a patient is not scheduled during an entire 30-day period. There is a *resurrection* mechanism: when a patient is scheduled in a later period after previously meeting the definition for an attrition event, the attrition flag is reset for all previous periods.

For readability, we will refer to a 30-day period as a *month*, 12 thirty-day periods as a *year*, and so on. Furthermore, we will refer to the time in years between the first scheduled dose via spencer and the analysis date as *tenure*. A patient's tenure represents the amount of experience a patient has had with the spencer platform as of an analysis date.

Beyond dispenser attrition, the second source of panel attrition is when patients request that their questions no longer appear on-screen following a dispensing event. To study this phenomenon, we computed rates of requested question discontinuation for the first 12 months of tenure for patients who remained dispenser persistent for more than a year.

When pursuing the subset of patients who were dispenser persistent for more than a year, the subset taken was patients who remained on the spencer platform through the 14th month. In addition to our operational month being shorter on average than a calendar month (by a fraction of a day), the 2 additional months of persistency provided a buffer against the decreased interaction with the device that often precedes full platform discontinuation.

Survey Response Rates

On the survey platform, nonresponse occurs when patients do not enter a response after a question is displayed and the question is cleared. We computed rates of nonresponse by month and plotted the resulting series. We knew from prior analyses that some patients consistently respond to the questions, and we wanted to observe this phenomenon. For patients who were still receiving surveys in the 12th month, we created 2 groups: those with 12th-month response rates of <90% and those with 12th-month response rates of ≥90%. For both groups, we computed the frequency of patients, plotted response rates by month, and provided a qualitative description of the patterns observed.

Psychometric Analysis

Reliability

A reliability analysis in the context of a platform requires a narrowing of focus to a specific measure, as both reliable and unreliable measures may be generated from any platform. Inspired by the Falls Efficacy Scale-International, a reliable measure of fear of falling known to be related to both past and future falls [31,32], we chose an existing question from our rotation that asks the patient about recent falls. Hereafter referred to as Q_FALL, the question text read "Have you experienced a fall in the past month?" The response options were "No," "Not Sure," and "Yes" (a 1-letter variation in capitalization occurring after September 2022, where "Not sure" was replaced with "Not Sure"), which were value-coded as 1, 0, and −1, respectively.

One conceptualization of reliability is test-retest reliability and can be quantified using Pearson correlation between a measure's values at 2 time points [33]. For a comparative baseline in the literature, Falls Efficacy Scale-International measurements taken by the same patients at different time intervals had Pearson correlations ranging from 0.66 to 0.83 for measurements taken up to a year apart [34].

The Pearson correlation coefficient is known to suffer bias when distributional assumptions are violated, a concern because Q_FALL has only 3 response levels and there were different response counts between patients and years. The use of averages and bootstrap resampling were thus employed to address these factors. First, we limited attention to a subset of 234 patients from the persistency analysis who answered Q_FALL at least 5 times in both a full first year and a second year of tenure, hereafter referred to as year 1 and year 2. Second, we used the bootstrap to obtain a bias-corrected estimate of the Pearson correlation along with a nonparametric 95% CI [35]. This allowed us to perform inference on the coefficient of determination (R^2) for the equivalent regression of the year 2 means regressed on the year 1 means.

Averaging the ternary scores allowed us to work on a continuum where rare fallers and never fallers appear close together on the resulting scale, a notion supported by similarities between these groups in a 1-year cohort study [36]. To circumvent the limitations of a linear correlation analysis, we performed an additional discrete state transition analysis. We examined the frequency of transitions to and from mean Q_FALL scores of [−1, −0.5), [−0.5, 0.5), and [0.5, 1.0] in year 1 and year 2, expecting self-transitions to be the most frequent.

Validity

To assess the convergent validity of the recent falls question administered via spencer, the mean scores for year 1 and year 2 were compared with the following established risk factors of fall risk: increased age, biological sex, previous fall frequency, low quality of life, depressive symptoms, physical impairment, and medication use [31,34,37]. Many patients in this population were prescribed selective serotonin reuptake inhibitors (SSRIs) or serotonin-norepinephrine reuptake inhibitors (SNRIs), and these are associated with falls in the older adults [38,39]. A meta-analysis found that 95% (70/74) of studies reported gender or sex differences in fall-related outcomes with females at a higher risk than males [40]. Canonically, increased age is a risk factor for falls [41]. The validity analysis was split into 2 parts, each based on the 234-patient subset from the reliability analysis.

We first conducted an analysis of the relationship between raw Q_FALL values and covariates age, sex, and SSRI or SNRI usage, as these were known before any responses were received (medication can be discontinued but medication classes tend to be stable within patient). To accommodate the repeated measures received from each patient, we used a generalized estimating equation approach to model the relationship between the coded value of Q_FALL and an exchangeable working correlation structure. This was accomplished with the *geepack* package in R, which reports SEs that are robust to both the choice of working correlation structure and nonnormality of the response. For age and SSRI or SNRI usage, we expected to see negative

relationships. For biological sex, we expected that female patients would be associated with lower mean Q_FALL than male patients.

For evidence of association between Q_FALL and other relevant variables, including quality of life, depressive symptoms, and hospital visits, we selected the questions listed in Table 1 as contemporaneous survey-based measures that had face validity for concepts of interest. Their responses are integer-coded and arranged by sentiment, and thus we expected positive correlations with Q_FALL.

The robust Kendall τ measure was used to test for associations, as the sample sizes of the questions from Table 1 may be arbitrarily small within patient. Kendall τ is more appropriate for ties and has an accompanying 2-sided nonparametric test for testing the null hypothesis of zero association [35]. For a nonparametric 95% CI on τ, we used the *kendall.ci* function from the R package *NSM3* [42], which provides a bootstrap CI.

Table . Standard spencer questions relating to known risk factors of falling.

Question text	Possible responses	Values coded	Construct[a]
Rate your recent quality of life.	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Quality of life
How is your emotional health today?[b]	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Depression
How would you rate your physical health today?	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Physical health
Rate your ability to perform activities today.	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Ability or disability
Are you able to accomplish what you have planned today?	Completely | Mostly | Moderately | A little | Not at all	5 | 4 | 3 | 2 | 1	Ability or disability
Hospital, ER[c], or urgent care in the past month?	No | Not sure | Yes	1 | 0 | −1	ER visits from falls

[a]Construct is based on face validity of the spencer standard questions.

[b]This question has been in rotation for multiple years, but in September 2022, the number of responses changed from 3 (“Poor,” “Good,” and “Excellent”) to 5 (“Poor,” “Fair,” “Good,” “Very good,” and “Excellent”). We coded the 3-response set as 1, 3, and 5, and the 5-response set as 1, 2, 3, 4, and 5, respectively.

[c]ER: emergency room.

Ethical Considerations

This study used operational data collected from a commercial medication dispensing system used in routine patient care and was not subject to IRB review requirements, so IRB approval was not pursued. Users of the spencer device provided consent for data collection through the End User License Agreement, which covers the collection of medication adherence data and responses to quality of life and PRO surveys as part of the system’s standard operation. No additional compensation was provided to users beyond the normal terms of their device usage agreement. All data analyzed in this study were deidentified prior to analysis. Spencer Health Solutions has achieved both ISO27001 [28] and Data Privacy Framework [29] certifications, and the system uses industry-standard encryption and security measures.

This research analyzed data collected during standard clinical care and device usage. All results are presented as anonymous aggregate statistics. The original data collection occurred as part of routine clinical practice, with patients providing consent for research use through the device terms of service and care management agreement. Under Canadian TCPS 2 Article 2.4, research ethics board review is not required for research that relies exclusively on secondary use of anonymous information where the process does not generate identifiable information. Under US regulation 45 CFR 46.104(d)(4)(ii), IRB review is not required when information is recorded by the investigator in such a manner that subjects cannot be identified, directly or through identifiers linked to the subjects, the investigator does not contact the subjects, and the investigator will not reidentify subjects.

Results

Patient Population

The patient population was majority female (2552/4133, 61.7%), with 0.1% (5/4138) of the biological sex fields missing. The mean age was 54.4 years (SD 19.9, range 5-104 years). Most patients (3736/4138, 90.3%) resided in Canada, with 1 address unmapped at the country level. Patients were scheduled to take multiple drugs per day (mean 9.6, SD 5.1). Of the 2805 unique compounds scheduled during the observation window, 70.2% (1970/2805) were mapped to an Anatomical Therapeutic Chemical classification system second-level code, with a modified “Vitamins & Supplements” that included dietary supplements. Table 2 contains the 20 most frequently observed subgroups observed during the observation window.

Table . Patient demographics, geographic distribution, and medication usage among the 4138 patients studied.

Section and variable	Patients (N=4138)
Patient demographics, n (%)	
Sex

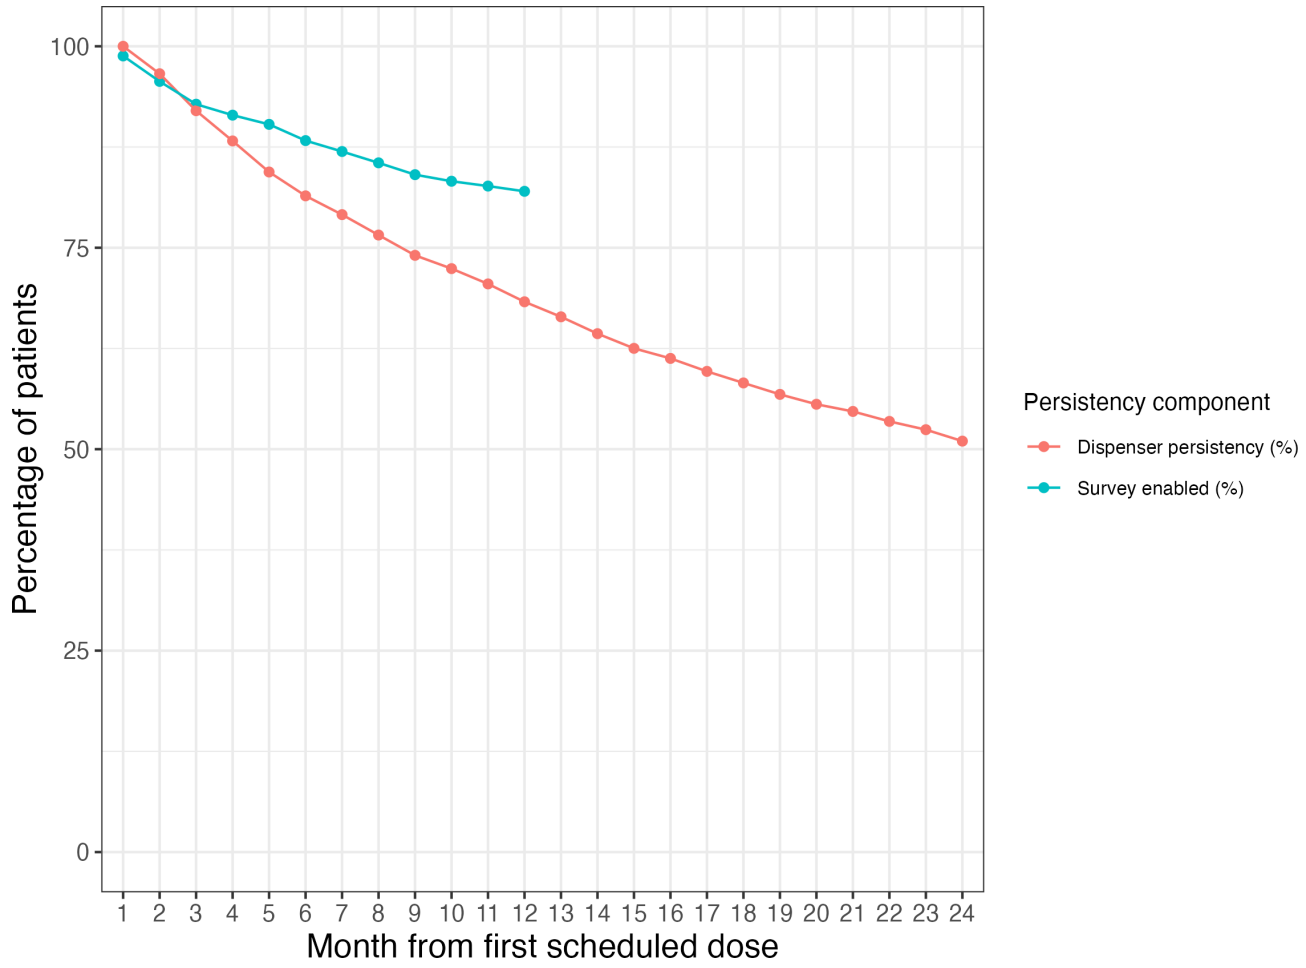
Drugs for constipation	295 (7.1)
Antihistamines for systemic use	289 (7)

Panel Attrition

From 4138 patients, dispensing persistency was estimated to be 68.3% (95% CI 66.8% - 69.8%) at year 1 and 51% (95% CI 49% - 53%) at year 2. Among the patients who stayed on the dispensing platform past year 1, 82.3% (1508/1832) kept surveys enabled through the 12th month. The rates of question opt-out slowed during the year, as can be seen in Figure 2.

Figure 2. Dispenser persistency and percentage of patients with surveys enabled by month on platform.



Survey Response Rates

Among the 1508 patients who kept their surveys enabled through year 1, the mean response rate was 95.6% (SD 11.9%) in the first month and 84.1% (SD 26.4%) in the 12th month, with the rate of decline slowing in the second half of the year (Figure 3). For patients with surveys enabled in the 12th month, 67.9% (1024/1508) had response rates at or above 90% and 32.1% (484/1508) had response rates below 90%. Figure 4 shows the trajectories of both groups, where the high-response group maintained near perfect response rates while the low-response group experienced a substantial decline by the 12th month.

Figure 3. Mean survey response rate (%) for patients with enabled surveys by month on platform.

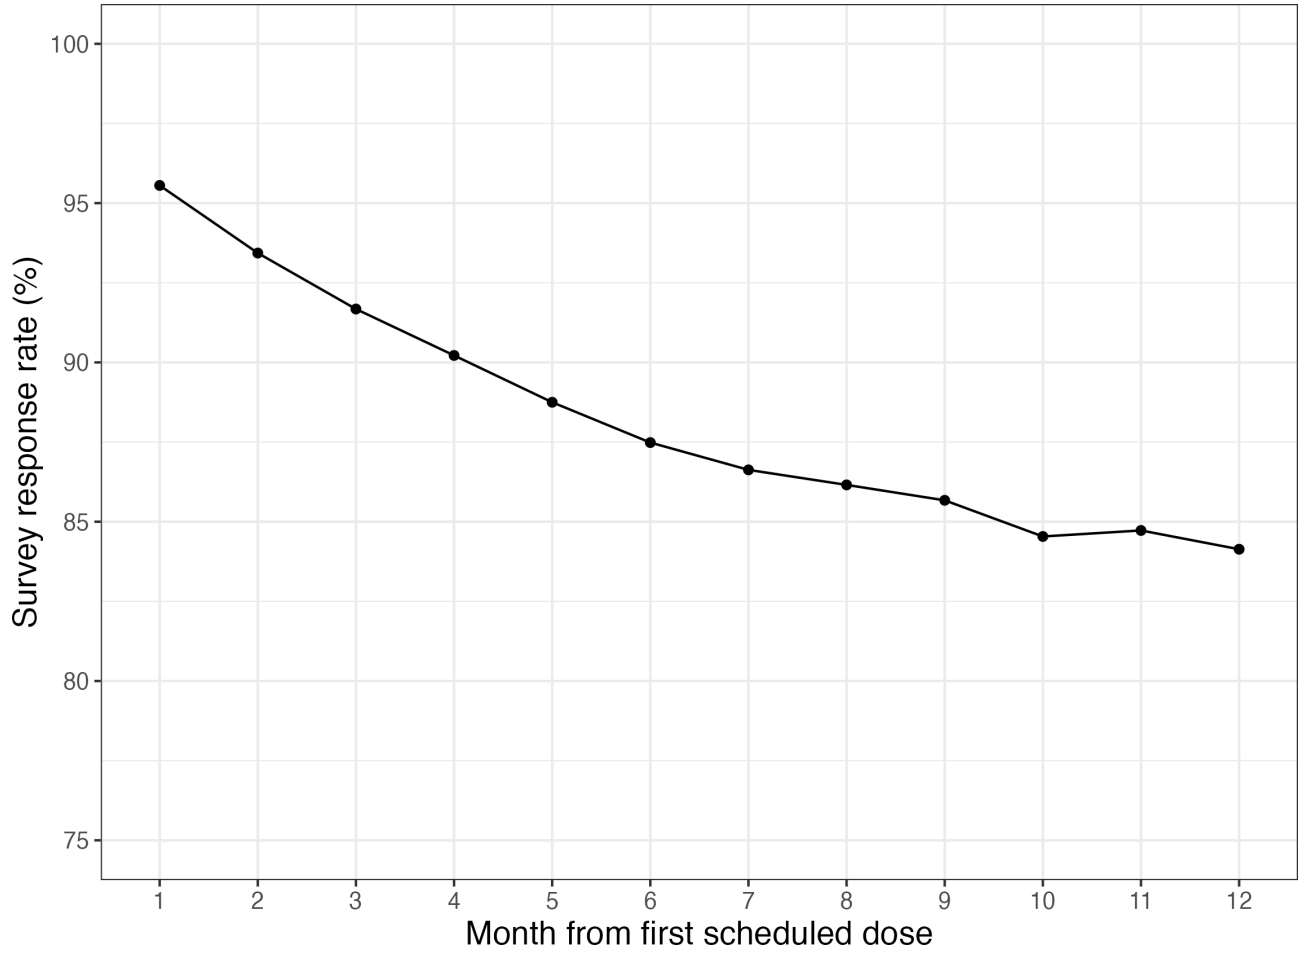


Figure 4. Mean survey RR by month on platform, grouped by RR in the 12th month. RR: response rate.

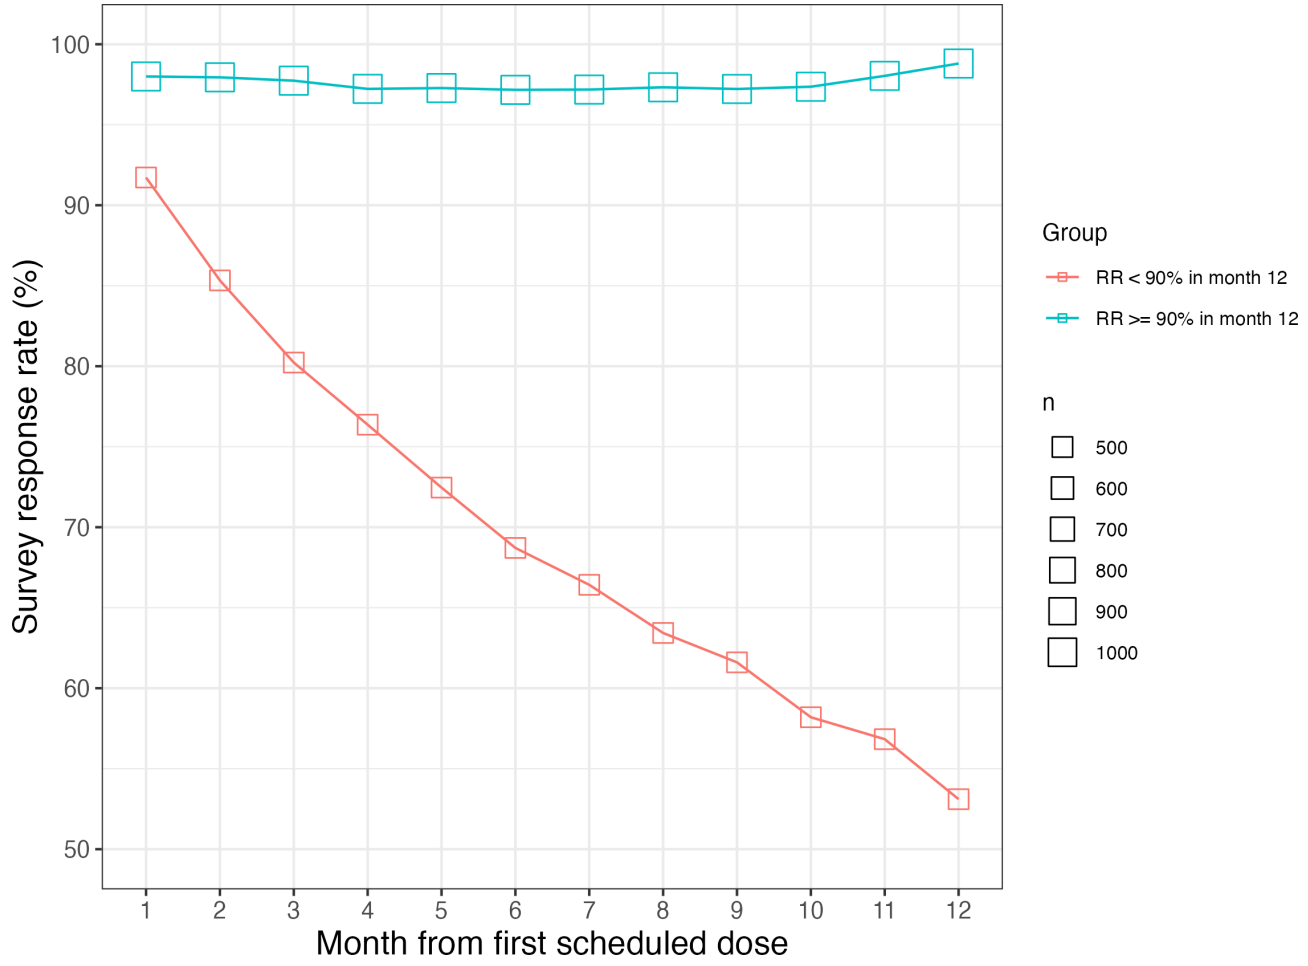

Reliability

Among 234 patients, the bootstrap estimate of the Pearson correlation between the year 1 and year 2 mean Q_FALL was 0.723 (95% CI 0.630 - 0.798), and the estimate of R^2 for the equivalent regression on year 2 versus year 1 means was 0.523 (95% CI 0.397 - 0.637).

Mean Q_FALL interval transitions from year 1 to year 2 are shown in Table 3. As hypothesized, self-transitions were the most common, with 59.8% (140/234) of patients starting and staying in [0.5, 1]. These rare fallers in the [0.5, 1.0] interval in year 1 remained in this interval during year 2 in 83.8% (140/167) of cases. For the frequent fallers in the [−1.0, −0.5) interval during year 1, 66.7% (12/18) remained during year 2.

Table . Mean score range transitions from year 1 to year 2[a].

Year 1 and year 2 (n=234)		Frequency, n (%)
Frequent fallers [−1.0, −0.5) (n=18)		
	[−1.0, −0.5)	12 (66.7)
	[−0.5, 0.5)	5 (27.8)
	[0.5 to 1.0]	1 (5.6)
Occasional fallers [−0.5, 0.5) (n=49)		
	[−1.0, −0.5)	5 (10.2)
	[−0.5, 0.5)	24 (49)
	[0.5 to 1.0]	20 (48.8)
Rare fallers [0.5, 1.0] (n=167)		
	[−1.0, −0.5)	1 (0.6)
	[−0.5, 0.5)	26 (15.6)
	[0.5 to 1.0]	140 (83.8)

[a]A mean score of +1.0 would be a “perfect score” of no reported falls, a mean score of −1.0 indicates that all responses indicated that a recent fall had occurred, and scores in between span the interval (−1.0, 1.0). One patient who moved from [−1.0, −0.5) to [0.5, 1.0] had a score of exactly 0.5 (the boundary), with only 6 measurements in year 2.

Validity

Covariates

For 232 patients, the generalized estimating equation model results of Q_FALL on these covariates are shown in Table 4. The coefficients associating biological sex and age to Q_FALL were not significantly different from zero; this was unexpected. However, the coefficient indicating the presence of an SSRI or SNRI medication was negative and highly significant, indicating more falls in the SSRI or SNRI group adjusted for sex and age.

Table . Generalized estimating equation linear model summary for sex, age, and whether the patient was prescribed a selective serotonin reuptake inhibitor or serotonin-norepinephrine reuptake inhibitor during the observation window.

Coefficient	Estimate	SE	Wald	*P* value
Intercept	0.684	0.127	28.857	<.001[a]
Sex (male)	−0.030	0.069	0.195	.66[b]
Patient age	0.001	0.002	0.092	.76[b]
SSRI[c] or SNRI[d]	−0.232	0.062	14.092	<.001[b]

[a]The *P* value corresponding to the hypothesis of the intercept being zero is included by convention but is not a meaningful statistic.

[b]These *P* values correspond to the 2-sided test of the hypothesis of a zero regression coefficient.

[c]SSRI: selective serotonin reuptake inhibitor.

[d]SNRI: serotonin-norepinephrine reuptake inhibitor.

Contemporaneous Outcomes From the Spencer

The analysis of correlations between Q_FALL and other contemporaneous spencer questions, based on Kendall τ, is shown in Table 5. Interpretation of correlation coefficients varies, for example, 0.2 may be characterized as either “weak” or “poor,” and 0.3 as “weak,” “moderate,” or “fair” [43], and in the bivariate normal case, a τ value of 0.200 corresponds to a Pearson correlation of 0.309 [44]. While the strength of association between mean Q_FALL and the contemporaneous response outcomes was consistently weak to moderate, *P* values were uniformly small, indicating positive relationships of these questions with the measure of recent falls.

Table . Contemporaneous association between survey questions administered via spencer.

Question	Patients, n[a]	Average responses per patient, n	Kendall τ	95% bootstrap CI for τ	*P* value[b]
Rate your recent quality of life.	233	14	0.15	0.058-0.244	<.001
How is your emotional health today?	233	54	0.21	0.120-0.293	<.001
How would you rate your physical health today?	164	8	0.18	0.071-0.296	<.001
Rate your ability to perform activities today.	232	35	0.23	0.140-0.316	<.001
Are you able to accomplish what you have planned today?	197	9	0.18	0.083-0.276	<.001
Hospital, ER[c], or urgent care in the past month?	192	9	0.20	0.096-0.299	<.001

[a]Number of unique patients who responded to each question at least once and also responded at least 5 times to Q_FALL in year 1 and year 2.

[b]Derived from Kendall τ test, a nonparametric hypothesis test used to measure the ordinal association between 2 variables.

[c]ER: emergency room.

Discussion

Principal Findings

Although its primary function is dispensing medication, the spencer platform doubled as a web-based longitudinal panel where polychronic patients answered survey questions at high rates and exhibited low panel attrition over years of platform tenure. Measures generated from the responses where stable through time (ie, evidence of reliability) and were associated with other theoretically related variables (ie, evidence of validity). For polychronic patients residing in the US and Canada, the home medication dispenser is a promising source of reliable and valid measures of important health constructs.

As with all survey panels, there was attrition and nonresponse. Panel attrition could be decomposed into attrition from the dispensing platform and survey opt-outs for patients remaining on the dispensing platform. These losses were cumulative. Based on the estimates presented, starting with 100 patients, 68 would still be dispensing via spencer by the end of the first year, with 56 still receiving questions following their dispenses.

In our literature review, persistency was often a serious issue in the context of longitudinal patient studies. For 8 remote digital studies conducted between 2014 and 2019, researchers found that more than half of all participants discontinued their participation within the first week of the study [9]. In a web-based study during the COVID-19 pandemic, of 2734 participants who completed wave 1, only 964 participated in wave 3 [10]. In a study of smartphone app usage to improve oral anticoagulation adherence, a retention rate of 27% at 6 months was reported [11]. Considering these results, keeping more than half of the initial patients actively participating in surveys at the end of the first year represents favorable retention.

The rate of new survey opt-outs also decreased substantially through the year, setting up milder losses in year 2.

By the end of first year, the average survey response rate for patients taking surveys on spencer was 84%. While 80% has been considered excellent in the context of primary care research studies [45], multi-item surveys administered at a single point in time are an imperfect benchmark. Ecological momentary assessment, a survey methodology that addresses phenomena as they occur, typically sees compliance rates from 50% to 90% [46]. By either standard, the response rates observed in spencer surveys were good.

We can speculate on why some patients responded to fewer spencer questions over time than others. Survey fatigue is a well-known phenomenon that occurs when respondents become weary of repeated survey tasks [47], and although surveys administered via spencer are brief, they are frequent. In addition to fatigue, some patients may not have been aware of how the questions were being used to monitor their well-being. Developing interventions to improve survey response rates is a topic for future research.

Noncoverage in web-based surveys, often defined as lack of access to the web, is thought to be a more serious problem than nonresponse, which is an unwillingness to participate [48]. Since every participant has a connection to the web through the device itself (the spencer units have both cell and Wi-Fi connections), there is no noncoverage in the sense of lack of web access, although machines do go offline for varying durations.

With sufficiently high panel persistency and response rates, attention focuses on the quality of the data that are generated. We showed that a measure about recent falls generated from a spencer question exhibited temporal stability, a form of reliability. The measure showed expected associations with most theoretically related variables. One exception was the

demographic factors of age and biological sex, which failed to achieve significance in a regression where medication use was significant ($P<.001$). While additional data may reveal the expected relationships, we surmise that in a polychronic population taking many medications, demographic factors may be weaker predictors of falling than in the general population.

Limitations

First, since the patients studied in this paper were polychronic patients enrolled in a care management program and residing in the United States and Canada, inferences to other populations may not be warranted.

Second, our validity analyses were limited to data collected entirely within the spencer ecosystem. While correlations between spencer survey responses suggest meaningful patterns, these questions, although having face validity, lack validation against established instruments. The observed correlations might partly reflect the consistent presentation format on the device, where responses are always ordered from most to least positive sentiment. Our validity arguments would be substantially stronger with independent measurements, particularly comparisons between spencer responses and validated traditional instruments measuring the same constructs.

Third, this study did not consider sensitivity to change, which is important in the context of RWE because it allows researchers and clinicians to detect change resulting from a minimal intervention [49]. While we focused on reliability by treating fall risk as a stable construct, and although fall risk is sufficiently stable to support our reliability analysis, treating it as static was a limitation of this research. Future research could explore methods for estimating changing states from longitudinal survey data, building on established approaches in the literature [50,51].

Conclusions

Administering longitudinal surveys via spencer, a smart medication dispenser, effectively generated high-quality RWD from patients in their homes. Patients persisted on the platform for years and maintained high response rates. A measure derived from longitudinal surveys assessing fall risk demonstrated both reliability and validity. The performance of spencer as a longitudinal survey platform offers a promising alternative at a time when web-based survey data quality is deteriorating.

Because medication dispensing is a fundamental component of the survey-generating mechanism, RWD from the spencer platform offers an ideal opportunity to study medication effectiveness and health outcomes, providing evidence to support new drug indications and demonstrate relationships between health outcomes and economic factors.

Acknowledgments

This work was funded by Spencer Health Solutions, Inc, a private corporation headquartered in Morrisville, North Carolina. The authors wish to thank University of Maryland professor Greg Hancock for his perspective on presenting this new source of patient-reported outcomes. The authors thank Devi Kodavanti, a member of the data team at Spencer Health Solutions, for computing many reliability coefficients in the past that gave them confidence to do this research. Their resident designer Lew Wilson created the table of contents image. Finally, the authors thank Alan Menius, the scientist behind the evolution of the spencer standard questions.

Data Availability

The dataset analyzed during this study is not publicly available to protect patient privacy and comply with health care privacy regulations, since it contains patient-reported outcomes collected through medication-dispensing devices. While the data are deidentified, they represent longitudinal health-related information of single patients alongside demographic information; it is difficult to guarantee that reidentification, however unlikely, is impossible. However, controlled access to specific portions of the data are available from the corresponding author on reasonable request, which should include (1) a brief research proposal outlining their intended use of the data, and (2) documentation of their institution's data security protocols.

Authors' Contributions

All authors participated in the conceptualization, review, and revision of the final manuscript draft for submission. BO proposed the methodology, performed the formal analysis, and wrote the original draft. TR supervised the research through all stages and performed validation activities.

Conflicts of Interest

Authors BO and TR are current employees of Spencer Health Solutions, Inc, the developer of the spencer platform. Author ES was employed at Spencer Health Solutions during the initial research and manuscript development phase.

Abstract

Background: The integration of health care and social welfare services together with the consolidation of health care information systems (HISs) and client information systems (CISs) has become a timely topic. Despite this development, there is a scarcity of systematic research on physicians', registered nurses' (RNs) and social welfare professionals' (SWPs) experiences of participating in the development of HISs and CISs.

Objective: This study aimed to examine how physicians, RNs and SWPs experience collaboration with HIS or CIS vendors, and what kinds of end users have participated in HIS or CIS development.

Methods: National cross-sectional usability surveys were conducted in Finland among RNs and SWPs in 2020 and physicians in 2021. Questions concerning participation experiences were analyzed by professional group, working sector, managerial position, and age.

Results: In total, 4683 physicians, 3610 RNs, and 990 SWPs responded to the surveys. In all 3 professional groups, those working in nonmanagerial positions and the youngest respondents participated least in HIS or CIS development, and 76% (n=3528) of physicians, 78% (n=2814) of RNs and 67% (n=664) of SWPs had not participated at all. When comparing the groups, physicians were least aware of feedback processes and least satisfied with vendors' interest in end-user feedback and the manner and speed of HIS development. Those who had dedicated working time for HIS or CIS development were less critical of vendors' interest and responsiveness to development ideas than those who had not participated at all. In all 3 professional groups, the youngest were most dissatisfied with HIS and CIS vendor collaboration.

Conclusions: Experiences of participation in HIS and CIS development were relatively negative across all 3 professional groups, with physicians being the most critical. Dialogue and collaboration between developers and end users—also the youngest ones and frontline workers—need improvement; simply increasing allotted working time is unlikely to produce more positive participation experiences.

Introduction

Background

The increasing collaboration between health care and social care and the consequent need for integrated information systems (ISs) warrants studies on the end-user participation viewpoints of all major user groups. Physicians [1-5], nurses [1,2], and social welfare professionals (SWPs) [6] are not satisfied with the usability or daily work support of health care information systems (HISs) and client information systems (CISs) [7]. Furthermore, these professionals experience collaboration with HIS and CIS vendors and developers to be unsatisfactory. However, the majority would be willing to participate in

information system development, but suitable means are lacking [1,2,6,8-11].

End users' participation in IS development is considered to lead to a better user experience and increased user acceptance [12,13]. However, the characteristic inherent complexity of HISs and CISs complicates the implementation of many user participation methods [14,15]. Although end-user participation is regarded as essential in HIS and CIS development [16], without careful management throughout the software development process, participation alone does not guarantee system success [17-19]. End-user participation may even cause more problems than benefits, particularly if the ISs are expected to solve organizational problems [20]. Users may experience that their participation does not affect IS functionalities in a desired manner [1,4,6,16]. In addition, emphasizing administrative information needs and wishes instead of the needs of frontline professionals can complicate work processes by increasing the requirements for data entry and thus impair the workflows [21]. IS users in leadership positions have different needs for ISs than frontline professionals [22].

Comprehensive HISs and CISs are complex ISs used by dozens of user roles in a wide variety of use contexts [23,24]. Many countries, including Finland, are integrating health and social welfare services and consequently ISs [25-27]. One of the rationales behind this development is that those with high numbers of visits to health care often need social welfare services and vice versa [28]. From the point of view of patients and clients, treatment and service packages often include both health care and social services [29-33], which emphasizes the need for fluent information exchange between professional groups to guarantee high-quality and safe care. Consequently, end users from the major professional groups are needed in the IS development processes.

Context of the Study: Health Care, Social Welfare and HISs and CISs in Finland

Until 2023, municipalities (n=309 in 2022) were responsible for organizing social welfare services and primary health care (health centers) in Finland. A total of 20 hospital districts, jointly owned by the municipalities of the region, organized specialized medical care; 5 university hospitals provided tertiary care. Although one-third of outpatient visits to physicians are to private providers (eg occupational health care), the variety of services provided by the private sector is narrow; for example, there are no private intensive care units (ICUs) or labor and delivery units [34]. In social welfare, municipalities or federations of municipalities often purchase some services from private service providers and non-governmental organizations (n=3971 in 2017) [27]. In 2018, there were 19,627 working-age physicians, 70,198 RNs, and 34,523 SWPs in Finland [35-37].

In Finland, the first HISs and CISs were implemented in the 1970s [27]. While only every tenth US hospital used electronic health records (EHRs) as late as in 2010 [38], in Finnish public health care, HIS coverage had already reached 100% by 2007, and by 2014 CISs covered almost all public social services [39,40]. By contrast, in 2020, a quarter of nonpublic social welfare organizations still operated on paper [27,41].

All public hospitals and health centers had joined the Kanta services (national patient data repository and electronic prescription system) by 2015 [42,43], but implementation of the national data repository for social welfare services only began in 2020 [44]. This has required considerable resources from both health care and social welfare organizations and IS vendors over the years [45].

During 2020‐21, in public health care, 2 leading specialized care and 2 leading primary care EHR brands were in wide use. In addition, 4 EHR brands covered both primary and specialized care, of which 1 also covered tertiary care (including functionalities for eg, operating rooms, ICUs, radiology, and emergency departments) and 6 out of the 7 nationally defined social welfare service lines. In addition, 1 EHR brand covered most private sector health care. In public social welfare, 2 CIS brands were in use in most municipalities [46]. In addition, EHR brands were also used in social welfare [41]. In 2018‐21, a new IS was deployed in Southern Finland with 47,000 end users.

Research Questions

In this study, we examined the experiences of physicians, registered nurses (RNs) and SWPs of participating in HIS or CIS development. The data were gathered in 3 large Finnish national surveys in 2020 and 2021. The research questions were as follows:

1. What experiences do physicians, RNs and SWPs have of collaboration with HIS and CIS vendors?
2. Do participation experiences vary by managerial position, employment sector, or age?
3. What types of physicians, RNs and SWPs have participated in HIS and CIS development?

Methods

Survey

This study was part of large national cross-sectional HIS and CIS usability surveys conducted among SWPs and RNs in 2020, and physicians in 2021 [47]. The survey questionnaires and data are available online [47]. The surveys were based on the validated National Usability-Focused HIS Scale [48] and included a section on end users' experiences of participation in HIS or CIS development (Table 1). The statements were originally created and piloted for the national physician survey in 2010 [4,5], and the same statements have been used in later surveys for physicians [1], for RNs [8,49], and SWPs [6]. The survey method and the questionnaire have been described in detail previously [4,5,48].

Table . Questionnaire statements.

Questions and statement/option designations		Statements and options
Question (1) What has been your experience of providing feedback on the information systems you use and their development? please assess the following statements based on your experience. Response options: Fully agree / Somewhat agree / Neither agree nor disagree / Somewhat disagree / Fully disagree		
	Statement A	I know how and to whom I can send feedback about the system if I wish to do so.
	Statement B	The system vendor is interested in feedback about the system provided by the end users.
	Statement C	The system vendor implements corrections and change requests according to the suggestions of the end users.
	Statement D	Corrections and change requests are implemented within a reasonable time frame.
Question (2) Have you participated in information systems development work?		
	Option A	Yes, some of my working time has been allocated for such development work
	Option B	Yes, in addition to my work
	Option C	No

The link to the survey questionnaire was sent to the members of the Finnish Medical Association (FMA) (>90%) (email address available, n=19,142), RN members of the Finnish Nursing Association, the National Association of Health and Welfare Professionals, and the National Professional Association (n=58,276), and SWPs with at least a Bachelor's degree who were members of the following trade unions: the Union of Professional Social Workers, the Trade Union for the Public and Welfare Sectors, or the Social Science Professionals union (n=12,471) [9,50,51] .

The section addressing end-user participation experiences in HIS or CIS development (Table 1) was identical for the physicians and the SWPs with 5-point Likert scale response statements (fully agree; somewhat agree; neither agree nor disagree; somewhat disagree; or fully disagree). However, for the 2020 RNs' survey, a sixth option "Prefer not to respond / Don't know" was added. Furthermore, unlike in the physicians' and SWPs' surveys, it was not possible for RNs to not respond at all. Up to 25% of RNs chose this sixth option. To make the surveys more comparable, we formed a sixth category also for physicians and SWPs of those who had not responded to the statements. In addition, for the descriptive statistics in Figures 1-4 and Table S1 in Multimedia Appendix 1, we combined the responses "Fully agree" and "Somewhat agree" to form a new category "Agree" and included those from the sixth category in the denominator.

The statement on having allocated time to participate in IS development was identical in all 3 surveys, and the background questions included in this study were all optional in all 3 surveys, so nonrespondents were not included in these numbers.

Figure 1. Participation experiences of Finnish physicians, RNs and SWPs by leadership position (leaders versus others). RN: registered nurse; SWP: social welfare professional.

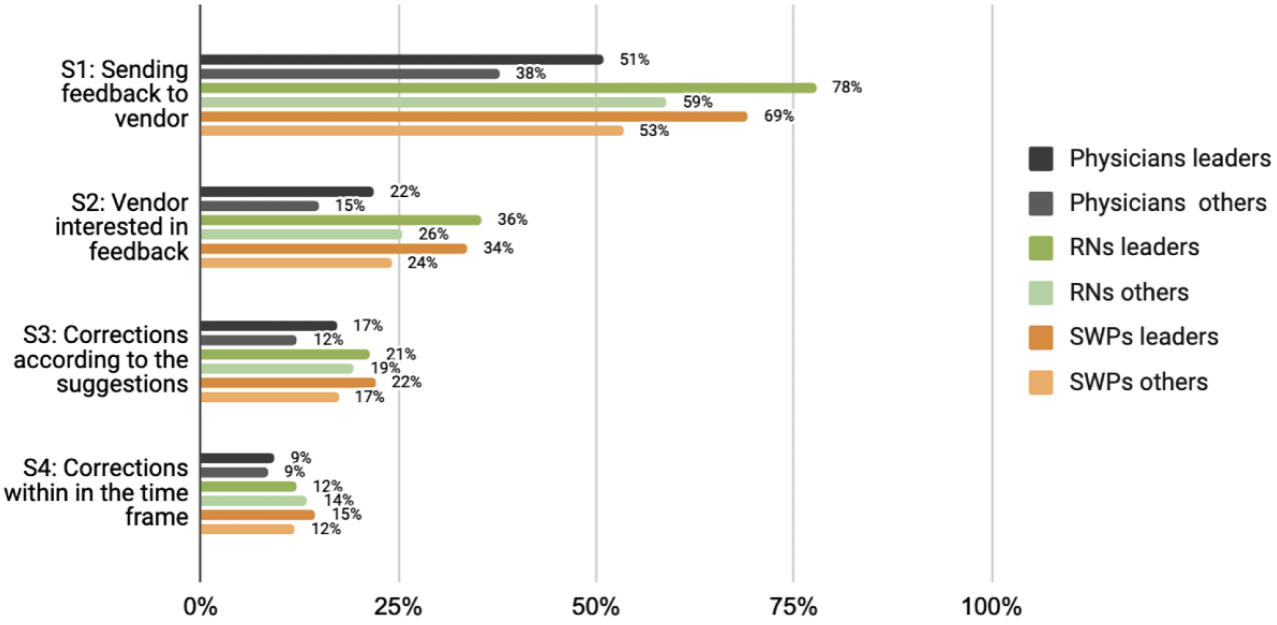

Figure 2. Participation experiences of Finnish physicians, RNs and SWPs by working sector. RN: registered nurse; SWP: social welfare professional.

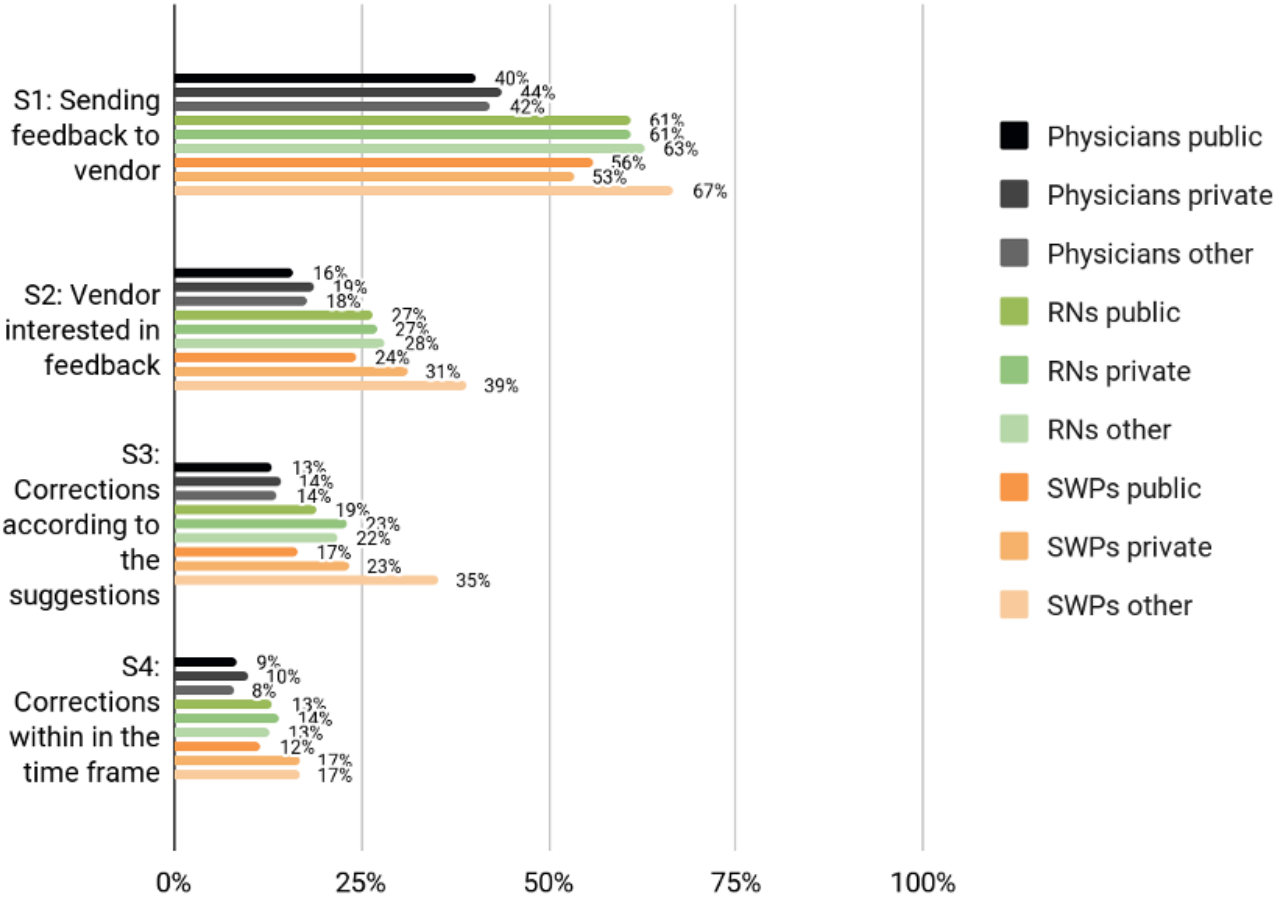

Figure 3. Participation experiences of Finnish physicians, RNs and SWPs by age group. RN: registered nurse; SWP: social welfare professional.

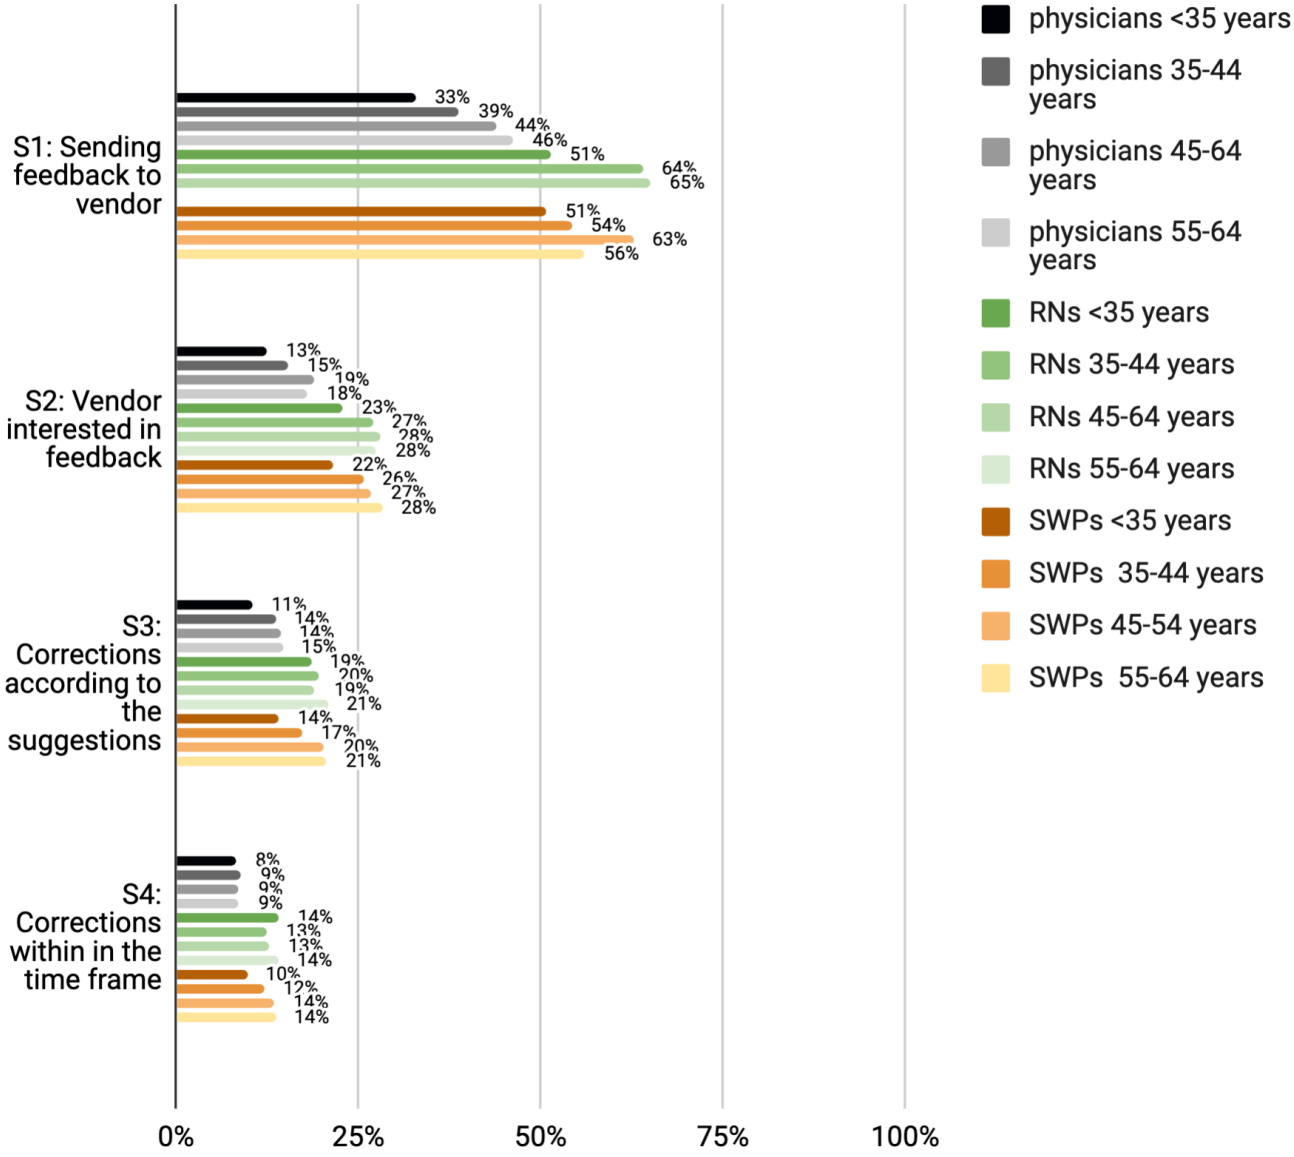

Figure 4. Participation experiences of Finnish physicians, RNs and SWPs by working time allotted for participation. RN: registered nurse; SWP: social welfare professional.

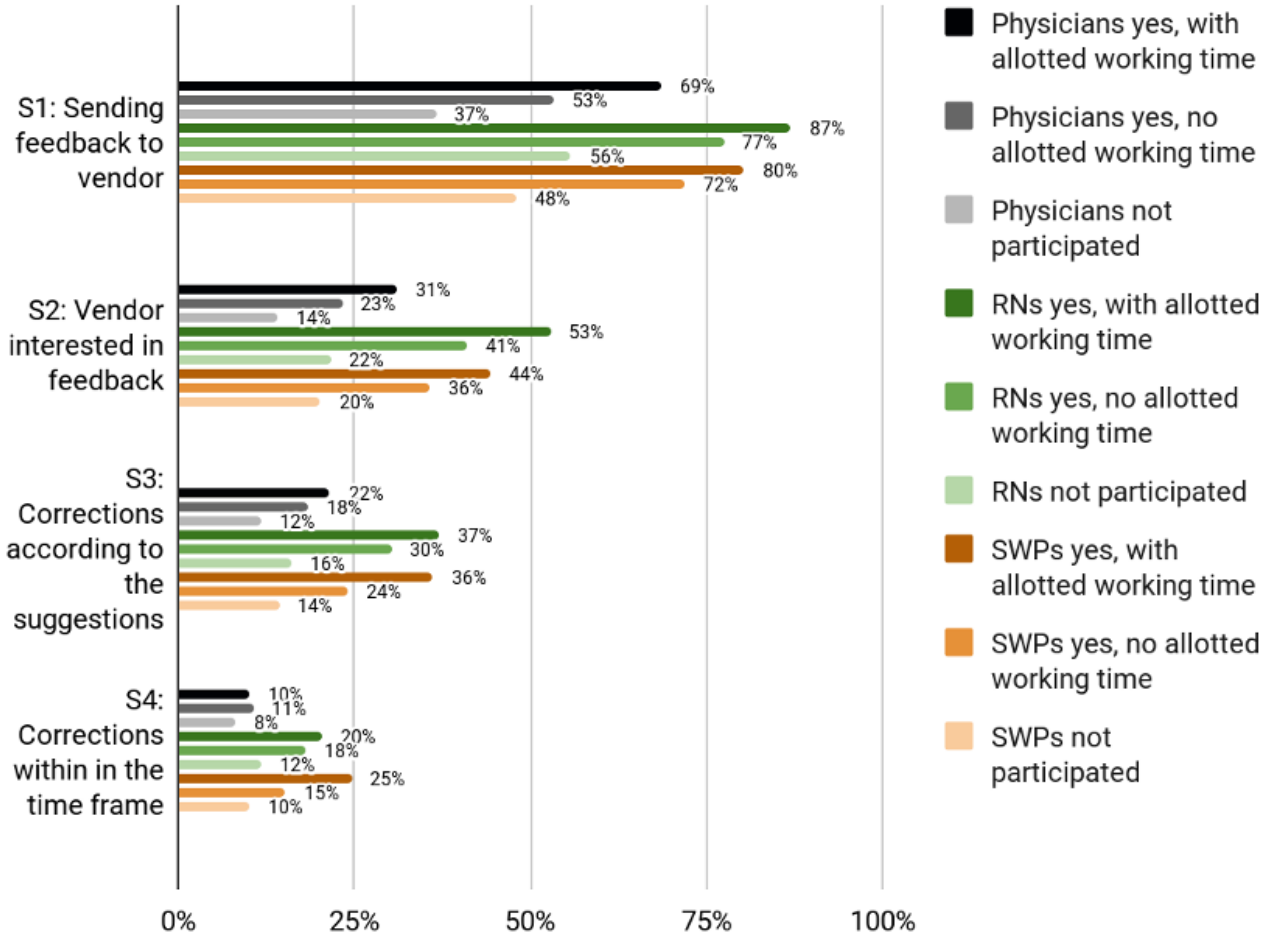

Statistical Analyses

Statistical analyses were carried out with SPSS 28 (IBM Corp). The χ^2 test or Fisher exact test was used as appropriate. Statistical significance was determined as $P<.05$.

Ethical Considerations

According to the national ethical instructions for research, the studies did not require ethical approval (Finnish Advisory Board on Research Integrity 2023) [52].

The autonomy of research subjects was respected, there was informed consent, no harm was possible to the participants and confidentiality of the subjects, and research data were protected. The researchers were not able to identify individual respondents. However, as the data for the RN and SWP studies were collected by a national authority (Finnish Insititute for Health and Welfare), the ethical approval (THL482/6.02.01/2020) was provided by its institutional review board.

Results

Respondent Characteristics

The demographics of the respondents to all 3 surveys are provided in Table 2. In 2021, 4683/19,142 physicians (24.5% of email invitation recipients) participated in the survey, and in 2020, 3610/58,276 RNs (6.2% of email invitation recipients) and 990/12,471 SWPs (7.9% of the theoretical target group) participated in the survey [35-37].

Table . Respondent characteristics.[a]

	Physicians (n=4683), n (%)	Registered nurses (n=3610), n (%)	Social welfare professionals (n=990), n (%)
Working sector			
Public sector	3654 (78)	3076 (85.2)	846 (85.5)
Private	775 (16.5)	456 (12.6)	90 (9.1)
Other	253 (5.4)	78 (2.2)	54 (5.5)
Age group (years)			
<35	949 (20.3)	739 (20.5)	185 (18.7)
35 - 44	1215 (25.9)	833 (23.1)	346 (34.9)
45 - 54	1161 (24.8)	1108 (30.7)	260 (26.3)
55 - 64	1315 (28.1)	921 (25.5)	198 (20)
Leadership position			
Works in a leading or managerial position	1139 (24.3)	406 (11.2)	172 (17.4)
Works in other positions	3543 (75.7)	3204 (88.8)	818 (82.6)

[a]The email invitation was received by 19,142 physicians, 58,276 registered nurses, and 12,471 social welfare professionals. Of these, 4683 (24.5%) physicians, 3,610 (6.2%) registered nurses, and 990 (7.9%) social welfare professionals responded to the survey.

Participation Experiences of the 3 Professional Groups

Physicians appeared to be least knowledgeable of how and where to send feedback, with only 41% (1920/4683) agreeing with statement 1, as compared to 61% (2204/3610) of RNs and 56% (556/990) of SWPs (Figure 5). In terms of vendors' interest in end-user feedback and the manner and speed of IS development, physicians were also least satisfied, with 16% (776/4683), 14% (672/4683), and 9% (407/4683) of them, respectively, agreeing with statements 2, 3, and 4, as compared to 26% (960/3610), 19% (707/3610), and 13% (481/3610), respectively, of RNs and 25% (225/990), 19% (180/990), and 13% (122/990), respectively, of SWPs (Figure 5). In total, 76% (3528/4683) of physicians, 78% (2814/3610) of RNs and 67% (664/990) of SWPs had not participated at all in HIS or CIS development (Figure 6).

Figure 5. Experiences of physicians, RNs and SWPs of collaboration with health care information system and client information system developers. RN: registered nurse; SWP: social welfare professional.

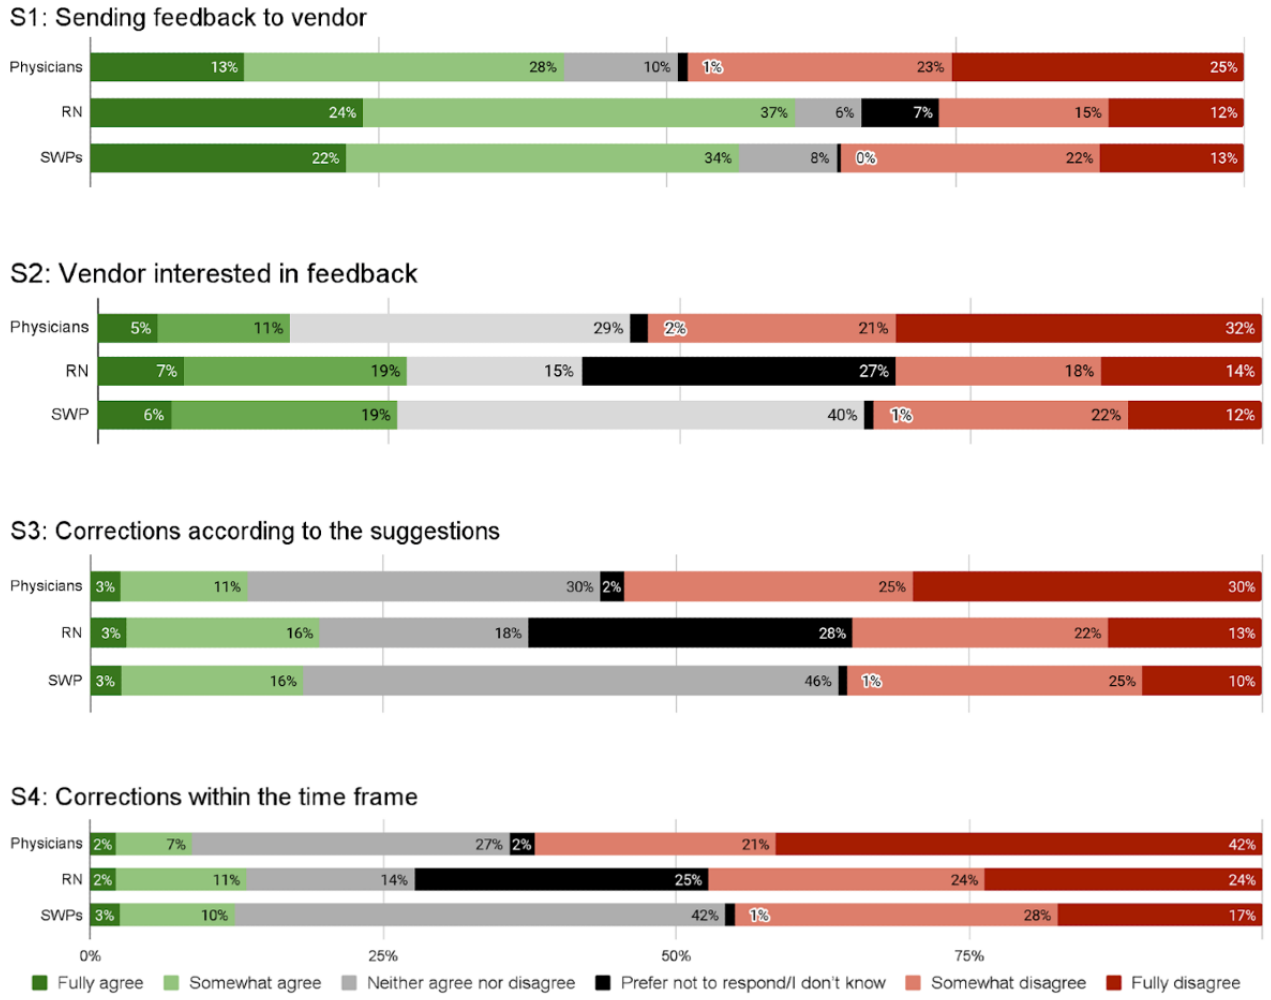

Figure 6. Participation in information system development work by professional group. RN: registered nurse; SWP: social welfare professional.

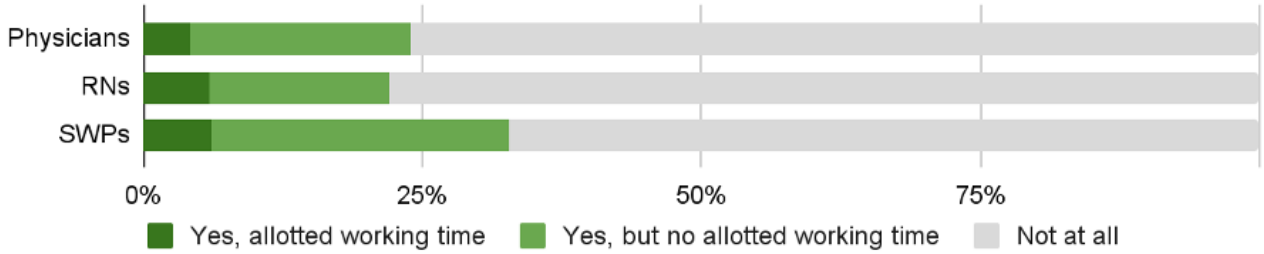

Factors Associated With Participation Experiences

Leaders, particularly among RNs, were more aware of how and where to send system feedback (statement 1) than those working in nonmanagerial positions (Figures 1-4). Leaders in all 3 professional groups were more satisfied with the system vendor collaboration (statements 2 - 4) than the others. The working sector did not impact end users' experiences. In all professional groups, the youngest appeared least aware of how and where to send feedback and least satisfied with the collaboration. Those who had participated in HIS or CIS development considered IS vendors more interested in feedback and were more satisfied with the manner and speed of system improvements and corrections.

Factors Associated With Having Participated in HIS or CIS Development

In all 3 professional groups, leaders had participated more in IS development than their colleagues in nonleadership positions (Figure 6).

Among physicians and RNs, but not SWPs, those working in the private sector had participated less than their public sector colleagues (Table 3). In all 3 professional groups, the youngest had participated the least (Table 3).

Table . Participation in development by allocated working time.

Participated in development	Yes, allotted working time, n (%)[a]	Yes, but no allotted working time, n (%)[a]	Not at all, n (%)[a]
Leadership position			
Physicians			
Leaders	85 (7.5)	403 (35.7)	640 (56.7)

Discussion

Overview

To our knowledge, this is the first study to assess how the major professional groups in the health care and social welfare sector, that is, physicians, RNs, and SWPs, view HIS and CIS development participation. The responses were analyzed by managerial position, employment sector, and age group. Furthermore, we examined which types of professionals have participated in HIS and CIS development.

RNs and SWPs Highly Aware of to Whom and How to Send Development-Related Feedback

The majority of RN (2204/3610, 61%) and SWP (556/990, 56%) respondents knew how and to whom to send development-related feedback; the respective proportion for physicians was 41% (1920/4683). The difference may be explained by mentoring or superuser and training programs during and after HIS implementations among RNs [9,53]. On the other hand, since the response rate among RNs and SWPs was relatively low, those who responded were probably more interested in ISs and thus more aware of HIS and CIS development than those who did not. The findings concur with our earlier studies, which have shown that physicians tend to be more critical towards their HIS compared with RNs and SWPs [2,5].

Leadership and its competence play an important role in the implementation of ISs and investment of resources in digitalization [22,54].

In this study, leaders in all professions and those with allotted working time for HIS or CIS development were more aware of feedback processes than others. These are usually responsible for the orientation of personnel, furthermore, they are often the ones to whom other personnel report development ideas or problems with HIS or CIS use. In all 3 professional groups the youngest were least aware of the feedback processes; whereas the youngest often have mentors who also help with HIS or CIS related problems, it is also probable that the currently available means are not suitable for the younger generations.

Leaders Critical About Cooperation

Although leaders had more often dedicated working time and participated more often in the development of HISs or CISs than the others, they were critical about cooperation with vendors. Their information needs, informatics competencies, and partly also the ISs differ from those working in nonmanagerial positions [55]. The particularly negative viewpoints of physician leaders may be impacted by most of them regularly using HISs for direct patient care, unlike RN or SWP managers who mainly use HISs or CISs for managerial purposes [56]. The most recent study shows that RN managers are able to use HISs for their managerial duties. Due to poor system integration, they need to gather data from different systems for management, which wastes resources inefficiently [22].

Those With Dedicated Working Time Less Dissatisfied With Vendor Cooperation

Those who had dedicated working time for HIS or CIS development were less dissatisfied with vendors' interest and responsiveness to development ideas than those who had not participated at all. They are likely to be more aware of the development processes and timelines of their respective HISs or CISs. Furthermore, since they have been chosen by their respective organizations as participants in HIS or CIS development, their ideas are more likely to become realized. Earlier studies have also found that user participation increases acceptance and active use of HISs contributes to the acceptance and increased active use of HISs [57]. Although not all development ideas are suitable for execution and not all end users can be expected to spend considerable working time on HIS or CIS development, to achieve better engagement in the use of ISs, users need to experience that they are heard and understood [57].

The Youngest Least Satisfied With Vendor Cooperation

Similar to the findings of our previous studies [1,4,6], the youngest were the most dissatisfied with vendors' interest in feedback. This is a particularly important finding as it suggests that the current ways of engaging professionals will not become more suitable or even acceptable to future generations. Barchielli et al [58] also found that younger nurses rely on their colleagues' opinions of health technology use, while older nurses rely on their own experiences.

What Kinds of Users Have Participated in HIS or CIS Development?

Previous studies have shown that impactful participation in IS development requires dedicated working time [58]. Of those working in nonmanagerial positions, 72% - 82% responded that they have not participated at all in HIS or CIS development, whereas the respective proportion for leaders was 45% - 57%. Physician and RN leaders were most likely to have allotted working time for HIS development. Our findings agree with several studies suggesting that managerial viewpoints are likely to become overrepresented in IS development [59,60]. Although the data produced by the ISs is essential for leadership and management purposes, if the participating leaders are not engaged in clinical work or practice the solutions may end up not supporting the needs of frontline workers [61,62].

Health care professionals working in the private sector participated less than their public sector colleagues, among SWPs the differences were minimal. As the majority of Finnish private sector physicians work as private practitioners, their participation would usually result in decreased earnings. It is also likely that the lack of most complex patients in private healthcare reduces the need for HIS development.

In all 3 professional groups, the youngest participated the least. This may be because they are at the stage of learning the clinical content of their work and their employers may not want to invest their time in HIS or CIS development. Khairat et al [62] also

report underrepresentation of physicians in specialization training in HIS development groups. Although not possessing advanced professional skills, the youngest are not burdened with old, often paper-based workflows, which could assist in redesigning processes and enhance the use of newer technologies [62].

How to Improve Satisfaction in HIS and CIS Development

The development processes of large-scale complex systems such as HIS and CIS are typically dominated by cooperative activities involving multiple stakeholders [63-65]. Different information needs must be identified, prioritized, and communicated clearly enough to the IS designers and developers [65].

It remains challenging to increase user input and select appropriate participants and human-centered design methods through the different phases of the participatory development cycle [15,20]. Identifying other factors that influence user experiences, such as decisions made by regulators, policymakers, and administrators, may assist in developing better HISs and CISs [66]. Previous studies have recognized the importance of clinical informaticists who also use HISs or CISs in clinical work in communicating end users' needs and feedback to designers and developers [6,67-75]. From the organizational perspective, the benefits can be seen beyond the IS implementation phase [76]: informatics competent social and health care professionals have been found to be able to improve patient safety and patient care outcomes [67]. In social welfare, however, this role is still being developed [74,75].

Limitations

Our study has some limitations. First, compared with physicians, the lower response rates among RNs and SWPs are likely to have resulted in the selection of more involved and interested participants among these professional groups.

Second, the response rates were highest for physicians. The FMA, which was responsible for collecting the physician data, has a long history of conducting surveys among physicians, the results of which are used in FMA policies. However, the number of participating professionals from all 3 professional groups in the national level studies can be considered high compared to other similar studies [50].

The RNs questionnaire respondents, comprising nurses from various sectors including hospitals, health centers, private practice, and social care, were found to align with the target population according to Statistics Finland's employment data for nurses, midwives, and community nurses [9].

During data collection with SWPs questionnaire, incomplete contact information in membership registries limited survey outreach. To compensate, survey invitations were distributed also through sector networks and social media. The study's final sample comprised 990 SWP respondents, with an estimated response rate of 8%. It's important to note this limitation when interpreting findings. Nonetheless, the sample size was considerable and exhibited diversity in age, service backgrounds, and geographical representation across Finland [51].

Third, our questionnaire did not cover how end users were involved in HIS or CIS development and whether the means of participation would impact satisfaction with the process and the end results. Further research is needed on best practices of user participation in the development of complex HIS and CIS systems.

Conclusion

The fluent use of HISs and CISs is a prerequisite for efficient and safe health care and social welfare, as currently professionals spend a considerable part of their working time with ISs and rely on them as their primary source of information. User participation of all major professional groups—physicians, RNs and SWPs—and their involvement in development are essential for the success of complex HIS or CIS. Compared with RNs and SWPs, physicians appeared to be more critical towards IS vendors and the success of participatory HIS development. As even those with allotted working time were mostly dissatisfied with vendor cooperation, it is evident that simply allocating more end users' working time for HIS and CIS development will not guarantee satisfaction; rather, dialogue between end users and developers needs improvement. New means are needed to better engage all end-user groups, particularly the youngest ones and those working in nonmanagerial positions.

Acknowledgments

This study was part of larger projects supported by the Strategic Research Council of the Academy of Finland (projects 303607 and 327145) and the Ministry of Social Affairs and Health (project 112241). We thank the Finnish Medical Association, the University of Oulu, University of Eastern Finland, the Union of Health and Social Care Professionals in Finland, the Finnish Nurses Association, the National Association of Health and Welfare Professionals, the National Professional Association, the Union of Professional Social Workers, the Trade Union for the Public and Welfare Sectors, and the Social Science Professionals Union for their collaboration. We would also like to thank the respondents to the questionnaires. According to the local and national ethical instructions for research (Finnish Advisory Board on Research Integrity) instructions, this study did not require ethical approval.

Authors' Contributions

SM was responsible for the main supervision, writing and visualization of the research output. TL was mainly responsibile for the statistical analysis. All authors contributed to the analysis and writing of the research output. In addition, SM, JV, and TL

contributed to the design of methodology of all 3 studies, SS to the design, data curation and investigation of the SWP study, and UMK to the design of the registered nurse study.

Conflicts of Interest

SM has been previously employed by 2 of the health care information system (HIS) and client information system (CIS) software vendors included in the study. SS has been previously employed by a publicly owned in-house HIS and CIS vendor included in the study. TL has been previously employed by a publicly owned in-house HIS and CIS software vendor included in the study. The employers did not provide any support, financial or otherwise, to the study. Furthermore, these vendors were not involved in the design of the study or in the collection, analysis or interpretation of the data.

Abstract

Background: Through third party applications, patients in the United States have access to their electronic health record (EHR) data from multiple health care providers. However, these applications offer only a predefined organization of these records by type, time stamp, or provider, leaving out meaningful connections between them. This prevents patients from efficiently reviewing, exploring, and making sense of their EHR data based on current or ongoing health issues. The lack of personalized organization and important connections can limit patients' ability to use their data and make informed health decisions.

Objective: To address these challenges, we created Discovery, an experimental app that enables patients to organize their medical records into collections, analogous to placing pictures in photo albums. These collections are based on the evolving understanding of the patients' past and ongoing health issues. The app also allows patients to add text notes to collections and their constituent records. By observing how patients used features to select records and assemble them into collections, our goal was to learn about their preferred mechanisms to complete these tasks and the challenges they would face in the wild. We also intended to become more informed about the various ways in which patients could and would like to use collections.

Methods: We conducted a think-aloud evaluation study with 14 participants on synthetic data. In session 1, we obtained feedback on the mechanics for creating and assembling collections and adding notes. In session 2, we focused on reviewing collections, finding data patterns within them, and retaining insights, as well as exploring use cases. We conducted reflexive thematic analysis on the transcribed feedback.

Results: Collections were useful for personal use (quick access to information, reflection on medical history, tracking health, journaling, and learning from past experiences) and clinical visits (preparation and raising physicians' awareness). Assembling EHR data into reliable collections could be difficult for typical patients due to considerable manual work and lack of medical knowledge. However, automated collection building could alleviate this issue. Furthermore, having EHR data organized in collections may have limited use. However, augmenting them with patient-generated data, which are entered with flexible richness and structure, could add context, elevate meaning, and improve actionability. Finally, collections might produce a misconstrued health picture, but bringing the physician in the loop for verification could increase their clinical validity.

Conclusions: Collections can be a powerful tool for advancing patients' proactivity, awareness, and self-advocacy, potentially facilitating patient-centered care. However, patients need better support for incorporating their own everyday data and adding meaningful annotations for future reference. Improvements in the comprehensiveness, efficiency, and reliability of the collection assembly process through automation are also necessary.

KEYWORDS

mobile health; patients; electronic health records; sensemaking; data organization; collections; awareness; proactivity; self-advocacy; patient–health care provider communication

Introduction

Background

Digital technologies play a pivotal role in facilitating patient-centered care that focuses on understanding patients' needs and fostering shared decision-making with their health care providers [1]. However, this approach relies heavily on well-informed patients and on effective patient-provider communication [2]. In the United States, a major step toward meeting these requirements was enabling patients to access their medical records from multiple providers through third-party applications [3,4]. While this is a significant achievement, enabling patients to engage in making sense of these data and turn the insights they gain from this process into actionable steps remains a challenge. Consequently, many patients lack a satisfactory understanding of their health, feel discouraged to self-advocate, and have mediocre communication with their providers, which is at odds with the core values of patient-centered care. Therefore, addressing the challenges around sensemaking and the usability of health data will be important to advancing patient-centered care and empowering patients to take an active role in their health journey.

Making sense of data, or *sensemaking*, is a cyclic process that involves cognitive activities for answering complex questions [5]. These activities involve repeated access to artifacts, identifying relevant information, finding information relationships, and presenting the answers in an understandable format [6]. Patients face a plethora of sensemaking challenges to manage their health. They need to assemble health information from different providers and identify outliers, correlations, and trends to become educated on health topics, drive decision-making, and formulate discussion points with health care providers [7]. Unfortunately, robust platforms to support patients in making sense of their clinical data are lacking.

Several commercial mobile apps such as Apple Health Records [8], iBlueButton [9], OneRecord [10], and 1upHealth [11], along with the academic web application Discovery [12], advance patient sensemaking by offering data visualizations and specialized views for data exploration. These views help patients uncover interesting patterns related to prevalence, periodicity, co-occurrence, and pre-post analysis of medical events. Typically, these solutions organize electronic health record (EHR) data by type, time stamp, or provider. However, such approaches provide very little support for patients in finding deeper connections between their medical records that are required for understanding health issues, reflecting on medical history, or preparing for clinical encounters.

Moreover, these apps do not allow patients to annotate their medical records or save their sensemaking progress, forcing them to remember findings or record them elsewhere. This necessitates patients to revisit the same data repeatedly to refresh inferences and recreate mental notes. Such work is typically tedious and frustrating, leading to anxiety and missing crucial information. Consequently, patients can form skewed health impressions, resulting in poor decisions or risky actions. In clinical visits, the inability to communicate the sensemaking insights to physicians may hinder optimal treatment, leading to repeated tests or medical errors.

To address these limitations, we explored an alternative solution that organizes EHR data into collections based on health issues and ongoing problems [13]. Inspired by findings that a problem-based view of EHR data improves clinician awareness, prioritization, and decision-making in the intensive care unit [14], we adapted a similar approach for patients anchored in the *data-frame* sensemaking theory [15]. Data frames (ie, structured mental models) or *collections* of health data, as we refer to them in our previous work [13], systematically break down problems and help in answering complex questions. These capabilities of the collections hold significant potential for managing health data effectively for all sorts of patients, particularly those with complex medical histories or multiple comorbidities [13]. By organizing abundant data around health issues, collections help patients avoid fragmented health impressions, a common challenge for those with multiple comorbidities. Patients who see multiple specialists can use collections to track the development of specific issues and share insights across providers, raising awareness and improving care coordination.

More precisely, our proposed concept of *collections* allows patients to dynamically organize, adapt, and explore their health information based on evolving needs and available data. For example, a patient managing cardiovascular issues might create a Blood Pressure collection to consolidate related records, which could later branch into more specific collections such as Extreme Blood Pressures or Blood Pressure Lab Work. These refined groupings help uncover patterns and dependencies among factors such as BMI, diet, cholesterol levels, and blood pressure, enhancing understanding and facilitating proactive management of health conditions. Gathering insights from the collections may also help patients have more productive discussions with their providers.

In our study, we extended the capacity to transform EHR data into collections and facilitated reasoning regarding them. As patients' sensemaking of health data is driven by finding outliers, correlations, and trends [7,16], we enabled capabilities to identify data patterns within the collections. In addition, we supported the assembly of relevant medical records for the collections by helping patients visually explore, find temporal patterns [17-20], and make sense of their EHR data within a single, context-preserving view [12]. Acknowledging patient requests for automation [13], we offered manually assembled and system-assembled collections. We also allowed for personal data input through free-text notes, fulfilling previously identified patient needs [13].

A notable advancement in our work is moving from mock-ups [13] to a fully functional mobile app, Discovery. The app

provides patients with a realistic platform to interact with collections, uncovering deeper insights into preferred mechanisms for creating, refining, and using these collections. Moreover, we intended to motivate patients to see collections as tools for self-advocacy during clinical visits, which was identified as a key use case in our earlier research [13].

Objectives

In this study, we used the Discovery app to explore patients' needs, preferences, and desired interactions for organizing EHR data and delve into potential use cases. More concretely, we asked the following research questions (RQs):

- What are the needs and feature preferences for organizing EHR data from multiple providers? (RQ 1)
  - What are the patients' experiences with creating and building collections?
  - How effectively does our app allow patients to organize their EHR data using the concept of collections?
  - How can we better meet patients' needs for meaningful EHR data organization?
- What purpose would organizing the EHR data in collections have? (RQ 2)

To answer these RQs, we conducted a qualitative evaluation study with 14 participants.

Methods

Description of Discovery

General Overview

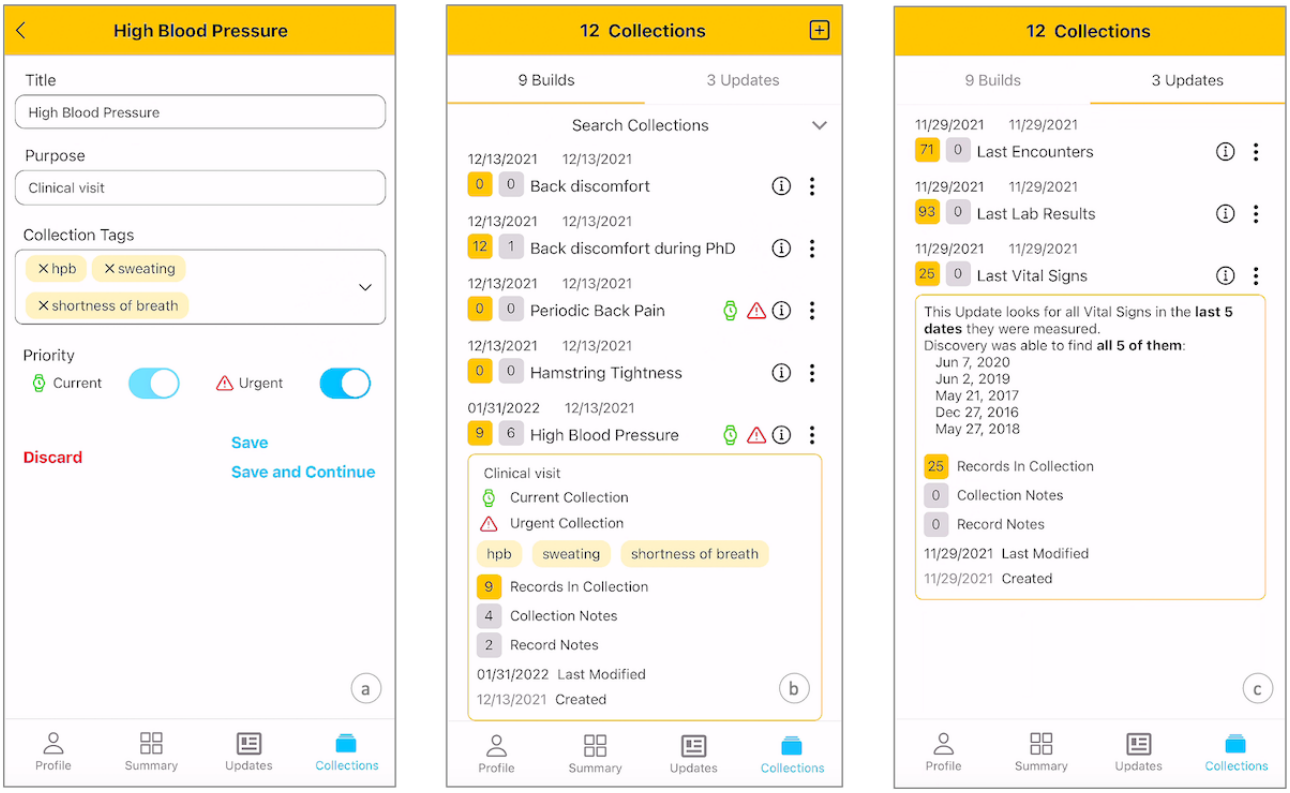
Discovery is a noncommercial iPhone app designed to help patients make sense of their EHR data. It introduces a novel concept that organizes EHR data into personalized, problem-based collections. In addition, it allows patients to add their own observations and insights, providing context and complementing their medical records with patient-generated data (PGD).

For this study, the app was restricted to accessing synthetic EHR data through a Fast Healthcare Interoperability Resources (FHIR) format [21] from the SMART Health IT repository [22]. Discovery accesses only structured EHR data and relies on a 2-level hierarchy. At the highest level, there are the record categories ("Conditions," "Immunizations," and "Vital Signs"). Each record category has multiple record types ("Vital Signs: Body Height," "Body Weight," and "Blood Pressure"), and each record type can have multiple instances ("Blood Pressure: systolic: 125, diastolic: 90," and "date: 02/01/2022"). Each instance of data in our app is called a record and corresponds to an FHIR resource with standardized attributes.

Organizing Records in Collections

The manually created collections are called Builds (creation shown in Figure 1A and list shown in Figure 1B), whereas the app-assembled collections are called Updates (Figure 1C).

Figure 1. (A) Creation of a new collection; (B) list of patient-built collections—Builds; (C) list of system-generated collections—Updates.



Patients can manually create a new collection (Figure 1A) by entering a name and additional metadata. To prioritize and distinguish the collections, we introduced descriptors: purpose, tags, and priority. For example, in Figure 1A, the patient created a High Blood Pressure collection with the purpose Clinical Visit for an upcoming appointment. They also added tags such as

hpb, sweating, and shortness of breath for reference. The priority descriptor indicates that the collection addresses a current and urgent issue. Patients can modify any of this information as the collection develops and changes.

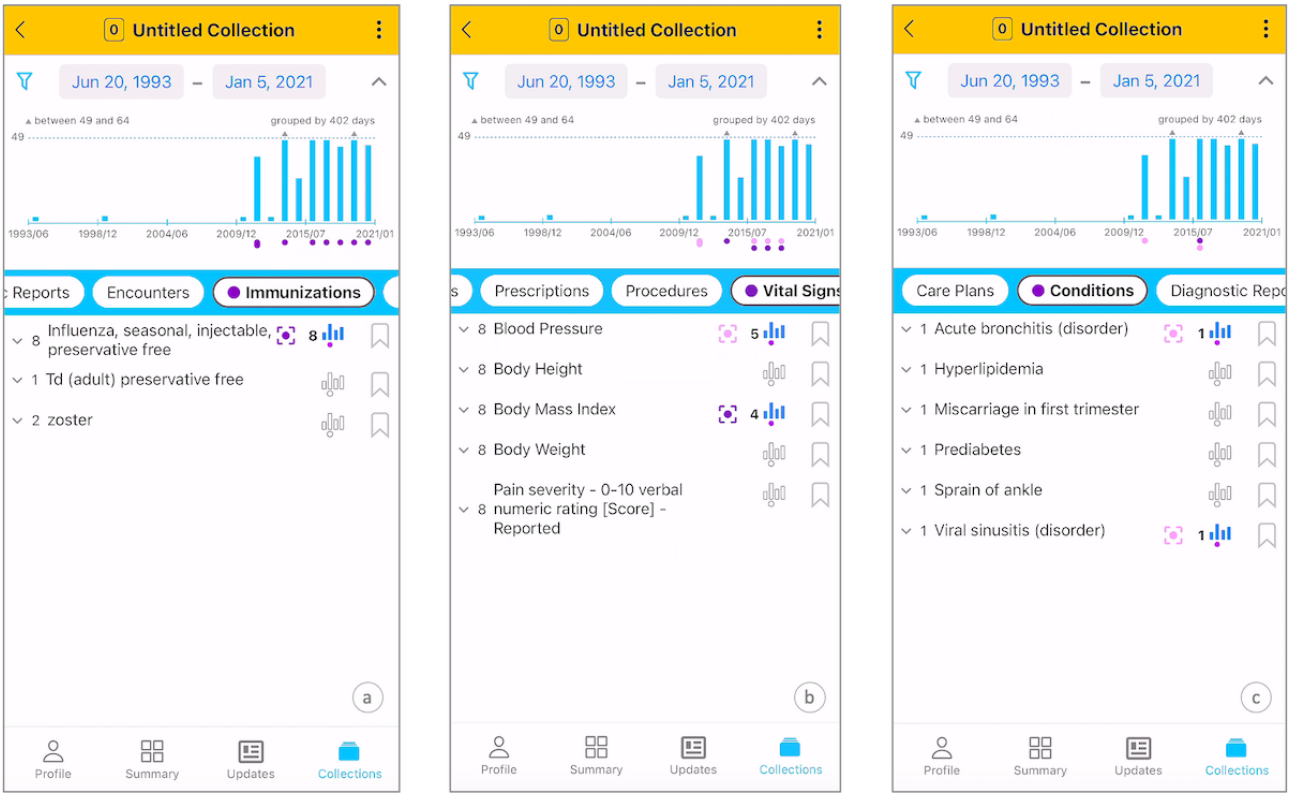
As patients repeatedly create collections, their EHR data transform into a problem-based list, as shown in Figure 1B, which includes health issues such as back discomfort, hamstring tightness, and high blood pressure. Collections are displayed with their name, creation and last modification dates, record count, number of patient-added notes, and labels for current (green clock) and urgent (danger sign) issues. An information button provides a summary with explanations. For example, the High Blood Pressure collection was created on December 31, 2021, and last modified on January 31, 2022. An information panel summarizes its contents: 9 records, 6 notes (4 for the collection and 2 for individual records), and tags for detailed search (hpb, sweating, and shortness of breath).

Updates automatically familiarize patients with the latest relevant events without requiring any action on their part (Figure 1C). The app scans all records and matches predefined templates, such as recent encounters, laboratory test results, and vital signs. In Figure 1C, 3 Updates are listed—Last Encounters, Last Lab Results, and Last Vital Signs—based on the last 5 dates when corresponding records were logged by the provider. The list entry follows the same structure as that of the Builds without the labels for currency and urgency. Although records in an Update cannot be changed, patients can add and remove notes. Patients can also clone an Update into a new Build and rename it if needed, allowing them to reuse and customize the assembled records for specific purposes. The reason for having this distinction between Updates and Builds is to delineate what the system and the user have produced and which entity is responsible for the collection that might have led to certain actions.

Identifying Relevant Records and Patterns for Collections

Discovery offers an interactive visualization to find patterns within records. The Timeline depicts record counts in equal time intervals, showing the prevalence of medical events. A dotted horizontal line marks the threshold above which the volume of records is considered abnormal, corresponding to the mean record count per interval. Gray triangle glyphs indicate values between the mean and 2 SDs, whereas red triangles highlight values of >2 SDs. By highlighting individual records or entire record types, patients can explore patterns that may be saved in existing collections or trigger the creation of new collections. For example, Figure 2A shows periodicity of influenza shots (when and how frequently influenza shots were administered), Figure 2B shows the co-occurrence of high blood pressure and high BMI, and Figure 2C shows the absence of respiratory conditions after an amoxicillin prescription.

Figure 2. Finding medical event patterns: (A) periodicity of influenza shots (showing when and how frequently influenza shots were administered), (B) co-occurrence of high blood pressure and high BMI, and (C) absence of respiratory conditions after an amoxicillin prescription.



The FHIR resources (ie, medical records) are represented with Record Cards, which display the clinical information in human-readable format. Patients can use a Filter and Date Picker to narrow down record categories and time frames for displayed records. Selected record categories appear in a Sliding Tabs control, allowing patients to swipe left or right for immediate access. Clicking on a record category in the Sliding Tabs organizes it by record type, represented with Accordions (eg,

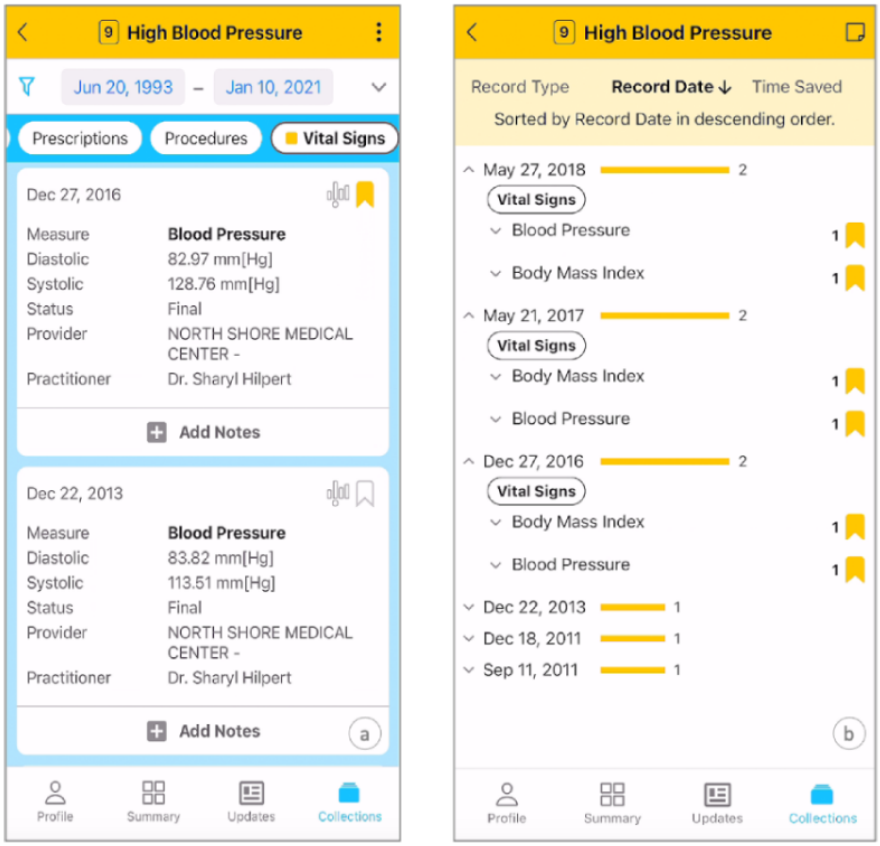
the Accordion for Immunizations category will have 3 sections for the Flu shot, Tdap, and Zooster record types). Patients can expand the Accordion sections to scroll through individual Record Cards. For example, Figure 2A shows 8 Record Cards for the influenza shot under the Immunization Accordion section. Accessing and revisiting records involves swiping the Sliding Tabs and selecting record categories, with Accordions retaining their expanded or collapsed state and scrolling position. This method is more context preserving compared to existing solutions, which require repeated back-and-forth navigation through different views for each record category and record type.

Producing Insights for the Collection

Patients can save individual records or entire record types by tapping the bookmark icon in the corresponding Record Card or Accordion section. Figure 3A demonstrates adding individual Blood Pressure records to a collection using a Record Card. Records can be removed from collections by tapping the selected bookmark again.

To identify data relationships and produce insights, patients can inspect a collection in the Collection Review (Figure 3B). Here, records can be viewed by type, date recorded in the provider's EHR system, or time added to the collection. When sequence matters, records can be ordered chronologically. Patients can also remove records in the Collection Review by tapping the selected bookmark. For example, in Figure 3B, the patient views records grouped by recording dates in descending order, with yellow bars indicating record counts by date. They observe high blood pressure and high BMI co-occurring 3 times, suggesting a pattern that may need further investigation or discussion with a physician.

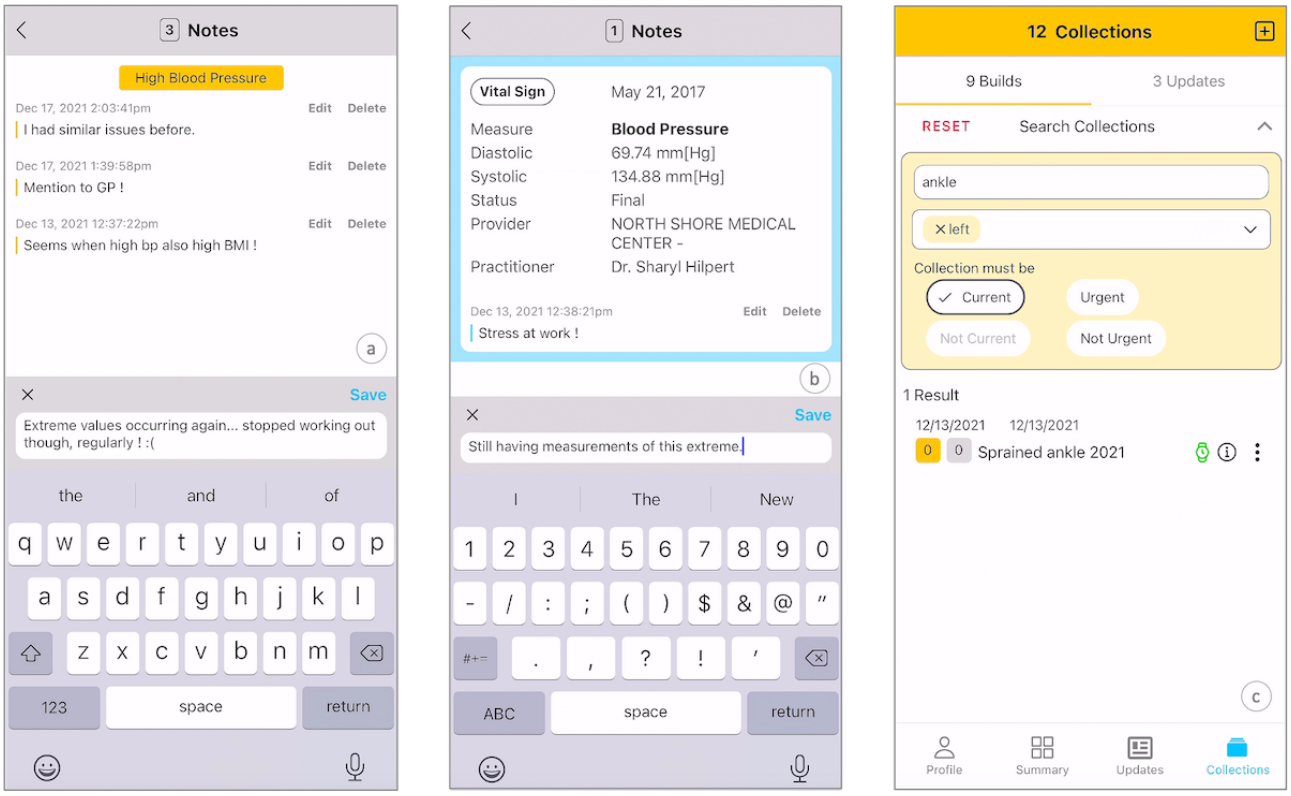
Figure 3. (A) Saving a record to a collection and (B) reviewing the collection and inspecting data patterns.



Supporting PGD

Patients can enter notes for a collection (Figure 4A) or individual records within it (Figure 4B) to add personal insights, progress, observations, details, or disease journal entries. Notes can be modified or removed at any time. In Figure 4A, the first note provides context on past high blood pressure experiences. The second note serves as a reminder to mention occasional high blood pressure to the general practitioner. The currently created note adds context about noticing changes in blood pressure after stopping regular workouts. In Figure 4B, the patient contextualizes a high blood pressure measurement taken during a stressful period at work and notes the recurrence of high values.

Figure 4. (A) Adding a note to a collection, (B) adding a note to a record, and (C) searching the collections.



Searching the Collections

Free-text search targets the collection name, purpose, and notes (Figure 4C), as well as tags and priority. Results dynamically update as the search query is constructed.

Study Design

Participants

We recruited 14 participants from our email list compiled from previous recruiting efforts and Craigslist. This number is sufficient to uncover usability issues and provide rich findings as per current design research practices [23] and literature on user feedback quality [24]. We balanced the sample by age, gender, and medical history (including healthy individuals, those with acute episodes, and those with chronic illnesses). Eligibility criteria included adults fluent in English; possessing an iPhone (iPhone 6 or above) and a laptop or desktop computer (screen size of 13“ or more) with a stable, fast internet connection for both devices; and with normal or corrected vision, no color blindness, and medical records from one or more providers. Medical history was self-reported.

Table 1 illustrates the detailed participant demographics collected using the questionnaire from Table S1 in Multimedia Appendix 1. Our 14 adult study participants included 10 (71%) women and 4 (29%) men aged 24 to 61 years (mean age 35.6, SD 12.6; median 30.5 years). All had some college experience: half (7/14, 50%) held bachelor’s degrees, 14% (2/14) had some graduate experience, and 14% (2/14) had completed master’s degrees. Participants had between 2 and 15 health care providers, with half (7/14, 50%) having ≥6. The 29% (4/14) of the participants who were healthy saw physicians a few times a year. Those with chronic illnesses had been managing their diseases for 1 to 20 years.

All participants were comfortable with daily technology use, and 21% (3/14) had work experience in data analytics. Most (11/14, 79%) used third-party apps to track mental health, weight loss, sleep, and exercise. All but 1 (13/14, 93%) used provider-patient portals to review test and laboratory results, refill prescriptions, and schedule appointments. However, participants found it cumbersome to remember multiple passwords and difficult to find specific information due to interface issues. Data sharing among providers was often slow or impossible, forcing participants to print and assemble records for clinical visits.

Table 1. Participant demographics.

Participant ID	Age (y)	Sex	Educational level	Medical issues	Health care providers, N
P1	61	Male	2-year college	High blood pressure, sleep apnea, fatty liver (stage 3), and liver transplant	7-8
P2	45	Female	Some college	High blood pressure, prediabetes, obesity, and hypothyroidism	6-7
P3	51	Male	Some graduate school (incomplete degree)	Hypertension and gout	2
P4	24	Male	Bachelor's degree	Childhood asthma, recent hernia surgery, and mental health therapy	5
P5	24	Female	Bachelor's degree	No chronic issues	2
P6	27	Female	Bachelor's degree	No chronic issues	3-4
P7	28	Male	Graduate degree	Physical and mental (20 years)	Approximately 13
P8	37	Female	Master's degree	Thyroid condition (many years)	3-5
P9	29	Female	3 years (incomplete degree)	Chronic migraines (10 years) and hemiplegic migraines (1 year)	≥12
P10	59	Female	Bachelor's degree	Yes—5 years	10-15
P11	25	Female	Bachelor's degree	No chronic issues	3-5
P12	33	Female	Master's degree	Anemia (2 years) and IBS[a] (10 years)	3
P13	19	Female	Some college (incomplete degree)	Asthma (since she was a baby) and EDD[b] (10 years)	>5
P14	32	Female	Master's degree	No chronic issues	3

[a]IBS: irritable bowel syndrome.

[b]EDD: eosinophilic digestive disease.

Procedures

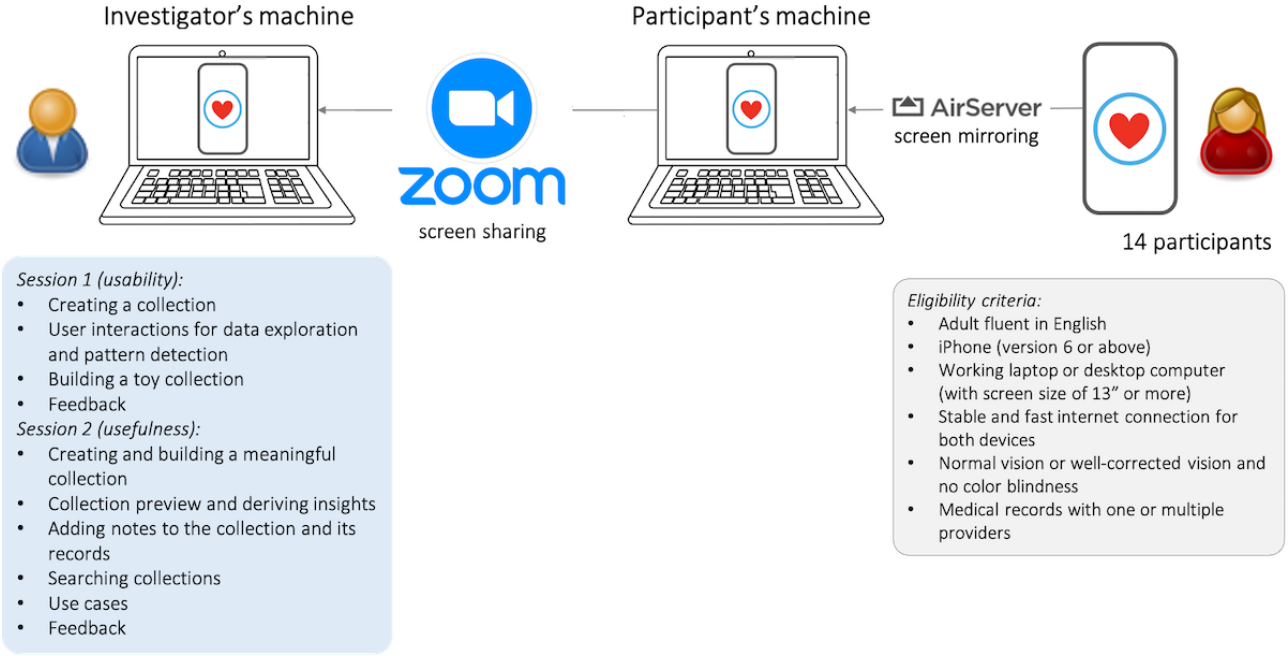
Inspired by existing patient portal usability studies, the study procedures were tailored to our RQs [23,25,26] and are presented in Figure 5. The study was conducted remotely via Zoom (Zoom Video Communications) meetings. Participants downloaded our app on their iPhone using Apple TestFlight for beta testing [27] and mirrored their iPhone screen on their laptop using AirServer (App Dynamic ehf.) [28]. The laptop screen was then shared with the researcher for observation.

Participants attended an initial 60-minute session (session 1) and a follow-up 45-minute session (session 2). Both sessions used the concurrent think-aloud protocol to gather rich qualitative data on user needs, perceptions, and preferences efficiently [29]. Textbox 1 illustrates 2 example topics and detailed tasks for creating a toy collection and realistic collection from sessions 1 and 2, respectively. The full set of 13 topics for both sessions and their detailed tasks that follow a similar structure are shown in Tables S2 and S3 in Multimedia Appendix 1.

In session 1, the researcher first collected demographics and digital health consumer information from participants (Table S1 in Multimedia Appendix 1). The session then evaluated the usability of the app (RQ 1). Participants were introduced to the app's key concepts and features and were then given tasks to learn the interactions for creating and assembling relevant records in collections. After each task block, participants provided feedback. Tasks included creating a toy collection, adding descriptors, exploring scoping mechanisms for record categories and time ranges, navigating records using the Sliding Tabs, and inspecting the interactive Timeline visualization. Participants also completed tasks related to finding periodicity, co-occurrence, and pretest-posttest analysis of medical events using the Timeline; saving records to a collection; and reviewing it. The session concluded with feedback on the intuitiveness, usability, and usefulness of creating, building, and reviewing collections, as well as data exploration and pattern detection features (Textbox 2).

Session 2 focused on the usefulness of collections in real-life settings (RQ 2). Participants performed tasks involving creating a collection tied to a specific issue (eg, high blood pressure) and purpose (eg, clinical visit). After each task block, participants provided feedback. Tasks included creating a High Blood Pressure collection, adding descriptors for a clinical visit, selecting records related to high blood pressure, identifying patterns in selected records, adding notes to the collection and specific records for clinical context, and using the search feature to find other collections. The session concluded with feedback on the usefulness of collections, brainstorming real-life use case scenarios, and suggesting potential improvements (Textbox 2).

Figure 5. Study design—14 participants for 2 one-on-one sessions with a researcher. Session 1 focused on usability, and session 2 examined usefulness. Feedback was collected on how participants would use collections for their own data and needs.



Textbox 1. Example tasks from sessions 1 and 2.

Session 1: creating a collection (5 min)

- For the purposes of learning the basic mechanics around building a Collection from scratch, first Create a new Collection and name it "Toy Collection."
- Now, let's add some descriptors about the Collection.
  - Please add a purpose to the Collection, something related to learning about this app.
  - Now, add a couple of tags to further describe, summarize or annotate the Collection for future quick access.
  - Finally, specify the priority of this Collection by marking it as urgent.
- What was your experience with creating the new Collection?
  - How intuitive was it? Have you seen similar interactions elsewhere?
  - How useful do you find the descriptors for the Collection?
- Now, let's go back to the list of Collections. Let me know how can you see the details about the Collection you just created?
  - How intuitive was it?
- What are possible improvements?

Session 2: building a collection (15 min)

- You will now create a Collection that is more realistic and meaningful for use in a real-life scenario. We will assume that you are preparing for an upcoming visit to your physician's office related to potential issues with high blood pressure. Create a collection called "High Blood Pressure."
  - Add the purpose for the Collection
  - Add a few tags
  - Mark its priority
- Add the Records with blood pressure with systolic value over 120 and BMI over 30.
- What was your experience with assembling the Records for the Collection?
  - How laborious was it?
  - What are some ways in which we can make this assembling process more efficient?
  - How do you feel about having the system prepopulate the Collection for you and let you modify it afterwards?

Textbox 2. Feedback collected at the end of the study sessions.

Session 1 example tasks

- What was your impression of this app?
  - What did you like?
  - What did you dislike?
- How intuitive was the app?
- How easy or hard was it to explore the data?
- How useful were the features in the app to identify patterns in the data?
- How did you like the mechanism for saving Records in the Collection?
- What are some improvements you would like to see?

Session 2 example tasks

- How useful do you think the Collections can be for you?
- What are some use cases for the Collections that you can think of?
- What are some improvements you would like to see for the Collections?
  - Automatic support for building Collections?
  - Automatically finding data patterns in the Collections?
  - Patient-generated data?

Data Collection

We recorded the Zoom meetings for audio and video capture of the entire interaction. The first author also took notes during the meetings.

Data Analysis

Audio recordings were transcribed using Rev (Rev.com, Inc). We analyzed video recordings for additional context and a deeper understanding of participant comments during the think-aloud protocol. Video annotations were added to the transcripts and session notes [23] for reflexive thematic analysis [30]. The first author began by open coding the textual data. Emerging categories were reconciled in meetings with the second and last authors to identify use cases and detailed approaches to organizing and annotating EHR data. These themes were validated in a group meeting with researchers unfamiliar with the collection concept and with our app.

Ethical Considerations

The Harvard Faculty of Medicine Institutional Review Board approved this study (protocol IRB20-1757). Participants signed a consent form, which also allowed them to opt out of the study at any point. Each participant received a US $40 Amazon gift card as compensation. The data obtained from the study sessions did not include any identifiable information about the participants and were stored on a password-protected computer with encryption. Only the research team had access to these data.

Results

Overview

The results from our study are organized and analyzed around five qualitative themes, two applicable to RQ 2 and three applicable to RQ 1: (1) using collections for personal benefit (RQ 2), (2) using collections in a clinical setting (RQ 2), (3) creating and building collections (RQ 1), (4) enhancing collections (RQ 1), and (5) accessing collections (RQ 1). In the remainder of the Results section, we characterize the participants and report on these themes using 16 quotes from 11 different participants. The participants are labeled as P1 to P14.

Purposes for Organizing the EHR Data in Collections

Using Collections for Personal Benefit

Quick Access to Information

Participants perceived the Collections feature as a way to index information at a suitable level of granularity for health issues, topics of interest, or conditions to monitor. They expected that this would give them quick access to current or urgent problems that were being managed:

> *Personally I would like to monitor my asthma because I am using medication for that, the typical inhaler, but I would like to monitor, these days I had certain attacks or shortness of breath, so collections, having it back for that specific condition is very useful to me, because I wouldn't have to speculate about when my last attack was or when my last appointment date was, it's right here for me to access.* [P13]

Reflection on Medical History

Participants viewed collections as a tool to construct and understand their medical history. They expected collections to serve as a repository for the health issues they faced, aiding in reflecting on the existence, prevalence, and development of their health conditions:

> *This will be able to find what happens when I have, in my case, headaches related to my high blood pressure and nothing else, or if you're sick for the flu, influenza and you have fever, it's just related to the influenza, not to the COVID.* [P1]

Keeping Track of Health Status

Most participants envisioned using collections to track their health status proactively. This included monitoring urgent issues needing immediate attention, unstable conditions requiring frequent observation, and treatments needing careful monitoring. Participants also wanted collections to track abnormal laboratory test results and vital sign values across various health issues:

> *Well, for me, it's kind of good [to have medical records organized in collections], especially, for example, blood samples, especially those with high triglycerides or something. Maybe I can collect them and see whether there's a trend for this month, or for January, I'm high in this one. Then second month, I'm also high, so maybe I can lower it down...For collections, just categorize those. Which are high, which are low.* [P5]

Journaling Daily Events

Most of the participants envisioned using collections as a personal diary for coping with diseases and logging measurements and their effects on lifestyle. They wanted to track challenges, successes, and progress toward finding solutions and monitor disease developments:

> *What I've done is I've taken all of my videos and stuff since February. Like I said, I've been to eight different doctors and I've shown them, this is the progress of what's happened from...I've had two surgeries before this surgery where they lanced it, cut it, drained it. Nothing happened. The cyst came back and then it went into my bone. So I'm able to bring these photos, I'm able to bring this timeline, I'm able to bring my frustrations and show this doctor within 30 seconds [using a collection], look, this is what it looked like. And this is my own diary, my own history. It's very important because they're a doctor. They don't know me, they don't know what it looked like on day one.* [P10]

Learning From Past Experiences

Nearly all participants wanted to use collections to identify trends and patterns in their ongoing health experiences, including co-occurring symptoms and treatment effects. They also intended to log food intake, sleep, activity, or stress factors to find triggers for symptoms:

> *I think I could definitely use them there. It's a lot easier now because I could highlight the certain event, and put like my triggers down with it, like migraine on the third was this, you could even put what you took with it. So for me, I would look back and be like, "Oh, I can tell my doctor that, I've had 10 migraines. I took a medication with these three. What's my options." So I think that would be great, it's a great tool that I can actually do that with this app.* [P9]

Using Collections in a Clinical Setting

Preparation for the Clinical Visit

Most participants would use collections to prepare talking points for clinical visits combining personal measurements and notes with medical records from other providers (eg, laboratory and test results). This was crucial because their physicians often did not have access to external data:

> *For collections, I would say that if I'm meeting with multiple providers about one health issue, I could see myself combining all my records there so that multiple providers can see each other's records...I would probably [use the notes], if I needed to jot down a certain time that I took a measurement, or if my doctor told me keep track of what you ate that day, or kind of anything that I would want to have the details for the next time that I go and see the provider.* [P6]

Relying on Collections During Clinical Visits

All participants wanted to share collections with their physicians during clinical visits to establish ground truths, raise awareness of other providers' information, and provide transparent talking points. They believed that adding PGD to collections could describe what happened between visits and raise their physicians' awareness:

> *If you have a condition, you need to check on your blood pressure. You need to communicate that with your doctor, so you can add a note [in the collection] saying like, "Latest, highest blood pressure from this week," from a date.* [P14]

In addition, most participants felt that taking in-visit notes and saving them in a collection could help them understand care plans and take appropriate actions afterward:

> *Maybe [taking notes in the collection for the clinical visit] just for your own personal reference or if you wanted to bring it up later on in another appointment or something, or just maybe, I guess, just general recording of something that happened during that visit.* [P11]

All participants saw physicians as essential partners in reviewing collections and deciding on actions based on their contents. This was primarily because most participants doubted their expertise in determining what should go into collections or which collections to create. While they were very open to include their physicians in the collection curation, some feared that they might overburden physicians with verification inquiries:

> *I guess I would definitely do that [look for patterns in the data and store them in a collection] just*

> *because I can actually consult the doctor. Is this actually correlated or will I have to change my diet because it affects this? At least you can ask the doctor, or confirm whether that is true or not.* [P5]

Needs and Feature Preferences for Organizing EHR Data in Collections

Creating and Building Collections

Manual Workflow for Creating and Building Collections

Overall, all participants expressed satisfaction with the clarity and simplicity of the mechanics to create collections and save records in them. However, those with less medical knowledge and disease experience (relatively healthy and recently diagnosed individuals) thought that initiating and building collections was challenging. For them, it was not always clear what issues deserved separate collections, what records to include in a collection due to delicate dependencies, and why they should invest substantial time and effort in assembling collections. In contrast, the more experienced (chronic) patients were relatively confident in their ability to carve a personalized view of their EHR data. However, some did acknowledge that they might not be as exhaustive and reliable in their data organization.

Participants quickly mastered using the Sliding Tabs with Accordions and appreciated the context-preserving record exploration. However, most of the participants found it challenging to assess the relevance of individual records due to unexplained clinical language and attribute values. Participants requested explanations, prominent visual cues for abnormal values to attract their attention, and time-series visualizations for additional context and noticing trends. They also wanted to be able to sort by date or attribute value, with filtering capabilities that also included adding the filtered records in bulk to a collection.

Some participants desired collections with richer internal structures, recognizing the need to identify subsets of records and their importance within a collection. They suggested linking groups or individual records using specific annotations for easy identification during visual inspection or search:

> *...maybe if certain records are related to each other. So I would want to mark that. And then maybe just have a way of sorting down based on certain labels.* [P8]

Automatic Support for Building Collections

Participants were highly receptive to discussing ideas that could automate building collections. They were interested in seeing their records automatically put into collections based on provenance (provider, physician, hospital, location, and date) and clinical meaning (condition, disease, organ, organ system, and abnormality of the values across records). Some also suggested grouping records into collections based on personal annotations. For all these groupings, they wished to be able to edit the collection manually:

> *If I had neurological problems, neurology collection. If I had urological problems, urology collection. I think that for me at least would seem a more straightforward way to categorize them. But from the categories I've already seen, I find those useful.* [P4]

Several participants suggested using a "seed" to automate collection building, such as naming a collection, adding keywords, or including a few records:

> *And I think a lot of patients don't know where to start, what data to begin with. So if it's something that's already preset, they say, "Okay, I'm suffering from depression or I have diabetes." And the system pulls the different data points that they would need to look at for someone who's diabetic or someone who's dealing with depression, I think that's helpful. Because sometimes, the problem is you don't know where to start and you don't know what to look for.* [P11]

Finally, most of the participants wanted to receive automated help to add or remove records for a collection that had already been created. Few described wanting to choose from a list of suggested records based on the existing content of a collection, revealing records and record patterns otherwise invisible to them. Others saw this automated record offering more as an idea generation approach—needing some follow-up validation, including taking it up with their physicians:

> *When I work, I want to listen to some music and then I'm like, okay. I just don't know what's next. I need something similar to this, the same vibe, but I just can't think about that. And then there is suggestions. And yes, some of it's weird. But maybe like the doctor can also have some help here, and when you review the collections together, they might say, "Hey, listen, this is what the system gave you and that's great. Let's remove a few things. I would suggest you add a couple others. And whatever you put there, it's also fine. And let's keep it that way."* [P6]

Enhancing Collections Through Personally Provided Data

Making Collections Complete

Participants strongly expressed the need to complement their EHR data with daily entries from sensors; self-monitoring devices; and manual measurements of symptoms, treatments, and outcomes in various formats (text, photos, videos, and scanned documents):

> *Actually, I think you can sort of restructure the whole core of the collections on top of two main pillars. The first one would be all of the doctor's data, which is basically hard data, which allows you to diagnose, allows you to run statistical analysis...That could be part of the core data, but all of the context, maybe I'm getting this shortness of breath in my home, watching my TV, might be added by the notes. You have these two types of data. By adding the user data, would allow me to get context, give context, which is important and will allow me to, on a daily basis, keep a record, which in case of data like shortness of breath, I'm having, I'm not having. Would allow the*

> *doctor to have a really unbiased input on symptoms I'm having.* [P7]

Participants wanted to log detailed observations and measurements, pairing treatments with outcomes and symptoms with triggers. They suggested dedicating a special PGD record category for these data, with some preferring complex structures and others favoring simple data entry options:

> *I would probably use the notes quite often just to maybe outline the symptoms I was experiencing and the steps I took to alleviate those symptoms or which doctors I contacted.* [P13]

Making Collections Distinguishable

Participants liked the existing collection descriptors and suggested additional ones. They wanted labels for clarity (clear, unclear, or potential issue), stability (stable or unstable), progress toward resolution, development stages (nonthreatening or threatening), and a list of involved providers and physicians. When collections were related to clinical visits, participants wanted to specify the targeted physicians.

Making Collections Actionable

Participants believed that organizing medical records by health issues in collections was a good start but thought that actionability could be improved with specific insight notes and annotations applied to entire collections:

> *And then as far as the purpose of adding a note to the whole category, I would say that, like you said, if you happen to notice any patterns when you're looking at the data, or basically I would use it for any general or bigger-picture takeaway that I wanted to tell my doctor, "Hey, I noticed this" or something and I wanted to bring it to their attention.* [P6]

Participants envisioned using collection-wide notes to summarize contents or purpose, track progress, describe issue development, and highlight special events. They also wanted notes representing care plans and actions prioritized in a to-do list. Participants intended to use collections to prepare for clinical visits with questions, reminders, and critical measurements. They also saw value in adding collection notes about visit outcomes, key takeaways, and next steps.

Some participants wanted to annotate and highlight keywords or add tags to free-text notes for organized review and pattern identification.

Accessing the Collections

All participants emphasized the importance of fast, reliable access to collections and their contents. They primarily relied on collection descriptors but also desired a deep search feature that would scan through individual records, notes, and annotations within collections.

Discussion

Principal Findings

We identified 3 principal findings of our study. First, participants embraced the collection concept. Unrestrictedly organizing EHR data into collections that map medical records to health issues and track ongoing concerns gave participants a sense of ownership. They felt empowered by developing personalized health narratives that could aid in self-management and communication with their physicians, enhancing their self-advocacy. Second, while participants easily mastered the interface for initiating and adding records to collections, they found the process laborious. They lacked confidence in selecting appropriate records due to limited medical knowledge and requested additional visual cues, explanations, and automatic collection features. There was concern about potential self-misguidance without physician verification. Third, collections would need richer PGD capabilities for adding contextual information not found in participants' EHR data, logging observations, and labeling data. This would enhance the comprehensiveness and accuracy of their health narratives and support foraging, sensemaking, and action taking.

Interpretation of the Findings and Contributions

Overview

On a broader scale, this work contributes to patient-centered care. This is achieved by demonstrating potential to enhance patients' grasp of their health, encourage self-advocacy, and improve patient-provider communication. More accurately, there are several concrete contributions of our work that can be considered as proxies toward achieving the aforementioned objectives: (1) encouraging patient ownership of their EHR data by organizing them into personalized, health issue–based collections; (2) understanding patients' perceptions and preferences for creating, building, and using these collections; and (3) offering design insights for automating collections, integrating rich PGD, enhancing access to collection contents, and using collections to facilitate patient-provider communication.

Going forward, we will situate our findings within a sensemaking framework and discuss contributions related to 3 key patient needs: increasing awareness through independent health sensemaking, proactivity through efficient action taking, and self-advocacy through incorporating evidence-supported patient perspectives into patient-provider communication. We will elaborate on how collections can meet these needs and offer design implications to enhance their capabilities.

The Role of the Collections in Supporting Sensemaking

To explain the collections' role in sensemaking, we used the model by Pirolli and Card [6], which divides the sensemaking process into 2 subcycles: the foraging loop and the sensemaking loop. On the basis of this model, collections can be described as a space for assembling relevant data about a topic, finding relationships between them, and storing outcomes from the sensemaking. In the foraging loop, patients gather relevant records to answer questions such as the following—"Is there a relationship between my weight and blood pressure?"—and save them in a collection, such as Weight vs. Blood Pressure. In the sensemaking loop, patients identify information relationships within the collection that they capture in notes, such as instances where there was co-occurrence of high blood pressure and high body mass. These notes help argue hypotheses such as the following: "My blood pressure is high when I'm

overweight." The outcome of this sensemaking process could be a comprehensive note for a clinical visit.

While, in their current form, collections respond to the needs of the sensemaking model by Pirolli and Card [6], improvements can be made to make this more efficient. This study revealed that medical records alone are not enough for reliable sensemaking. Adding PGD such as symptoms, measurements, outcomes, and everyday events is essential for creating comprehensive collections. The foraging loop can be made less laborious and time-consuming if there are additional visual cues, medical explanations, filtering capabilities, and automatic support to improve the relevance and reduce the effort of assembling collections. The sensemaking loop could be improved by adding more schematization capabilities such as annotating medical records and PGD to identify patterns later (eg, symptom triggers, medication effects, and correlations) and grouping records within collections, labeling those groups, and establishing group relationships with explanations (eg, linking "cholesterol lab results" with "food intake" as "food effects on cholesterol" in a High Blood Pressure collection).

Reliability of Collections

According to our study, there are 4 main factors that can influence the reliability of the collections: robust coverage of health issues, provision of PGD, grouping and linking of medical records and PGD within a collection, and verifying the contents of the collections. This reliability is related to collections' capability to aid in creating personalized but realistic health issue narratives, support self-management, and stimulate awareness and proactivity.

Robust Coverage of Health Issues: Relevance Assessment

Collections should ensure that patients can create collections for their most important health issues to support awareness and proactivity. Participants desired visual cues, explanations, and automatic support to determine which collections to create and what records to include.

While participants found the context-capturing data exploration using Sliding Tabs and Timeline convenient, they needed more to identify relevant records quickly. Future tools could incorporate Accordions that summarize record types, graph values over time, and highlight abnormal or extreme values. In addition, patients should be able to expand individual records to see explanations of clinical terms and clinical meaning interpretations. While there is existing work related to visualizing time series of EHR data [17-20] and automatic provision of short explanations [31], this study shows the need for combining them in a new way to support relevance assessment for a novel purpose—constructing collections. Finally, patients should be able to order and filter records by attribute for quicker browsing and bulk addition to a collection.

Automatic support should also be provided for creating and building collections to save time and ensure robust, reliable coverage of health issues. Our previous work highlighted the need for automating collections [13], and this study highlights a clear preference for automatically grouping medical records by clinical meaning—whether *thematically* or *guided by patient input*. Thematic collections would be those that tie records together based on conditions (bronchitis or diabetes) and procedures (stent placement or appendix removal) or with respect to organs (heart or kidneys) or organ systems (cardiovascular or renal). Alternatively, patients could specify a seed by setting parameters such as the collection's name, tags, or initial records. The system can offer candidate records to include or delete with confidence scores and explanations. Patients could then refine these system-generated collections by adding or removing records, PGD, and tags.

Addressing automatic support for collections may be challenging due to subtle relationships between medical records [32-34]. However, starting with easier constructs such as *time stamps* (eg, medical records from the same day, week, or month), *FHIR links* (eg, medical records from the same encounter or physician), *abnormal values* based on well-established clinical guidelines (eg, high or low blood pressure or cholesterol), *test findings* (eg, positive and negative), and *patient tags* (eg, triggers or pivotal events) is a feasible approach.

Provision of PGD: Sensemaking Data Completeness

Collections should include PGD to improve data completeness for sensemaking. Previous research has suggested that maintaining consistent PGD logging over time is difficult [35]. However, this should not be considered a barrier or a prerequisite for the collections' success. Patients' motivation and preferences for PGD logging intensity vary based on their disease self-management state [36]. When setting goals and learning strategies, patients prefer meticulous data collection. Once goals and strategies are in place, logging intensity decreases. In addition, if physicians require PGD logging for treatment planning, patients are motivated to engage in it [36,37].

Thus, collections should enable flexible and efficient PGD logging. Disease-specific contexts such as irritable bowel syndrome [38], diabetes [7], and migraine [39] have explored health sensemaking without focusing on diverse data types. This contrasts with patients' desire to log PGD for various medical issues within a single application [40,41] using a universal logging model for different observations [42,43]. To address this issue, we propose a straightforward workflow where patients initiate free-text entries and use tags to specify the type, quality, or other details. This mechanism allows for quick data capture and embellishment at convenient times.

Tags can classify PGD as *clinical observations*, *everyday life events*, or *notes*. Further specification can be added using tags such as *symptom*, *measurement*, *treatment*, and *outcome* for observations; *meal*, *exercise*, *meeting*, and *deadline* for life events; and *context*, *personal note*, and *visit note* for notes. Additional tags such as *absent*, *normal*, *high*, *low*, *extreme*, *improvement*, *deterioration*, *pivotal event*, *trigger*, or *relaxer* can be used for further detail that captures the quality and importance of the logged data. In addition to these system-offered tags, patients can also create their own custom tags for better personalization.

Grouping and Linking Within Collections: Schematization Capabilities

Patients need to connect medical records and PGD within collections for easier sensemaking. Future tools should add structure by enabling record grouping and linking of groups or individual records. This helps highlight important subsets of records and trace major conclusions as collections grow.

We recommend using a simple yet powerful tagging concept. Records sharing the same tag can form a group, whereas links between groups can be specified using related tags. The same mechanism can link individual records with other records or groups, providing nuanced sensemaking. This approach aligns well with the proposed PGD tagging model that can be applied to medical records as well.

Collection Verification

Collections represent the patient's personalized perception of their health and issues. As such, they should undergo occasional verification by the patient's physician for safe decision-making and action taking. While collection verification may add to the physician's workload, it can inspire and enable patients to manage health issues more independently. That said, patients should consider the physician's workload before requesting verification [44].

Future tools could allow for the conversion of a collection into a well–laid-out PDF document capturing all its contents. This document can be printed for review during a clinical visit or shared as a PDF attachment in the patient portal for verification at the physician's convenience.

Taking Actions Based on Collections

While annotating PGD is known to aid learning and disease self-management [7,45], our findings reveal that annotations can also enhance EHR data, creating synergy with PGD. Participants expressed a desire to annotate their data for various purposes: identifying triggers to avoid or encourage certain behaviors, marking pivotal events to remind them of shifts in health attitudes and management, and labeling outcomes as desired or undesired to evaluate treatments and strategies. These capabilities can be easily implemented using the previously elaborated tag-based design for linking records.

To increase the awareness and prioritization of collections, we previously proposed *collection descriptors* such as topic, urgency, currency, and sentiment [13]. Participants found value in these descriptors but expressed a need for additional ones that can be classified as *patient specified* and *data driven*. Future tools may include patient-specified descriptors for *clarity* (eg, is the diagnosis clear?), *stability* (eg, is the treatment working consistently?), *severity* (eg, is there a significant medical risk?), and *progress markers* (eg, is the issue substantially resolved?). Data-driven descriptors could be derived from the collection data, indicating the *time span* (from the oldest to the latest record) or listing the *physicians involved* (the providers and physicians the records came from). Both types of descriptors should be optional for patients to use as needed.

Providing an inner structure, enabling annotations, and describing collections can improve information access and expedite decision-making. Powerful search engines can use these metadata to allow patients direct and easy access not only to individual collections but also to their specific contents.

While these features can enhance collections' actionability, it is important to note that collections are not meant for making independent clinical decisions by patients. Collections should be verified by a physician to serve as reliable tools for sensemaking and health self-management. However, collections can always be invaluable tools for patients to understand their health; organize thoughts, hypotheses, and insights; and communicate effectively with their physicians.

Collection Use for Patient-Provider Communication

As observed in our findings, patients can use collections to prepare for a clinical visit by devising checklists and organizing thoughts supported by evidence. During the visit, collections can be used for *note taking* and, afterward, for *recording reminders* and *follow-up actions*. These uses indicate how collections can start addressing known challenges during clinical visits, such as problem presentation [46], information retention [47], setting common ground, aligning goals, and understanding instructions [48]. To effectively tackle such challenges, the Collections feature should support richer note capturing and collaborative data analysis in a collocated setting [49,50].

Future improvements in capturing PGD could make collections more appealing to physicians. For physicians, PGD play a crucial role in understanding the boundaries and context for accurate diagnosis and optimal treatment [51]. However, physicians often face problems with PGD, such as incomplete data, inconsistent data structures, and insufficient time for reviewing due to poor organization [52]. These issues arise because patients use disjointed platforms to log their data, lacking consistent models for logging different types of data [52,53], and face challenges in efficiently using these platforms [42,52]. Collections can help overcome these issues by providing a single platform for logging PGD for various health issues in a simple, universal way that allows for flexibility, organization, and standardization.

An alternative approach to enhancing collections as a communication tool and fostering physician collaboration in their creation and verification is to introduce them as a *shared resource* similar to Google Docs [54,55]. While this may seem unconventional, it builds on the principles of OpenNotes [56]. OpenNotes provides access to and transparency regarding clinical notes, enabling patients to improve their treatment and EHR data quality by taking an active role in detecting errors, raising concerns, asking questions, or seeking clarifications [56,57].

Similar to OpenNotes, *shared collections* would follow the principle of asynchronous communication and transparency. However, shared collections could eliminate the expressiveness constraints and lack of efficient ways to provide granular and tailored context observed in existing messaging systems [58,59]. In addition, shared collections would enable direct editing of underlying data in collaborative ways, minimizing communication overhead.

Moreover, shared collections would introduce a new communication channel between patients and providers outside the traditional patient portal. Synchronizing the digital traces of care in collections with the provider's EHR system to avoid discrepancies and legal issues should be a top consideration in future design iterations of the shared collection concept.

A Glimpse Into the Future: Collections and Generative Artificial Intelligence

In the future, we should explore the potential of generative artificial intelligence (GenAI) models to support patient sensemaking through collections. Tools such as ChatGPT [60] and Med-PaLM [61], which have demonstrated substantial medical knowledge [62-64], can replace the need for custom-made machine learning algorithms for knowledge-intensive tasks.

In particular, GenAI tools can aid in automatic and iterative collection construction with explanations and guidance. They can analyze the data within collections for insights, including medical records, PGD, notes, and tags. In addition, GenAI can assist in composing case narratives and talking points for clinical encounters. By offering this level of automation, GenAI can help tackle the significant knowledge challenges while lowering the labor barrier for patients' sensemaking activities.

Using GenAI models, collection construction could rely on natural language instructions such as the following: "Group my EHR data by condition," "Find all records related to my bronchitis," or "Identify records that don't belong to this collection and those that are missing." GenAI models could also deliver context, explaining why certain records are included or excluded and providing educational material such as term definitions and clinical implications.

In addition, patients can issue commands for identifying relationships within their annotated data, such as "List all triggers for my headaches over the last year." Finally, they can ask for help in constructing case presentations for clinical visits (eg, "Based on my 'High Blood Pressure' collection notes, write a 100-word summary").

To be useful for sensemaking, GenAI tools do not need to achieve complete accuracy. While still striving for maximum reliability, their main value should come from providing an environment that enables and encourages patients to refine artificial intelligence–generated outputs. As such, the contribution of GenAI toward sensemaking would be evaluated on its ability to help the patient efficiently produce a satisfactory solution with minimal physician input.

Finally, existing approaches for supporting sensemaking through search and interactive visualizations should not be disregarded. Exploring the integration of GenAI, search, and visualization is a prudent strategy as different sensemaking tasks related to collection assembly, editing, and analysis may require diverse approaches based on complexity, patient skills, and artificial intelligence reliability.

Limitations

This study has several limitations. First, the cohort skewed younger, likely due to recruitment via Craigslist (less popular with older adults) and the complexity of the remote setup. Second, participants used data from a fictitious patient, which may have reduced their motivation to learn the app and their ability to suggest real-life use cases. Third, participants had limited time to learn how to interact with collections, possibly affecting their perceptions of usability and utility. Future studies should have participants use their own data with automatic interaction logging. Despite these limitations, this study provided valuable insights into designing patient-facing sensemaking tools for organizing and augmenting EHR data.

Conclusions

Collections can potentially improve patient-centered care by involving patients more in decision-making and encouraging self-advocacy. Current assumptions often expect patients to have the necessary skills, tools, and motivation. We believe that collections can lower these barriers, encouraging patients to *increase engagement* with their health data, better *educate themselves*, and *communicate more effectively* with their care providers.

Our study suggests that EHR data can be better used and more useful for patients through *improved organization* and *annotation*. This approach can incentivize patients to engage more deeply with their EHR data, develop insights, and reflect on their experiences. Patients felt that this empowered their awareness, resourcefulness, and proactivity regarding health issues, making them more prepared and better informed for clinician interactions.

These findings support our premise that collections are a crucial step toward *patient empowerment* and *self-advocacy*. With appropriate improvements, collections can enhance patients' expertise by facilitating sensemaking activities and enabling insightful discussions with their physicians. First, collections motivate patients to construct health models based on their issues and ongoing problems. Second, patients gain medical education by actively participating in the evolution of collections through independent or system-assisted assembly and editing. Finally, patients acquire additional medical knowledge by engaging in meaningful discussions with their physicians and considering their feedback on collection verification.

Our study highlighted the importance of integrating PGD with EHR data. We envision a synergy in which patients use clinical data as a foundation, augmenting them with their observations, notes, and annotations to create personalized health narratives that support better health management and provider communication.

In the future, we should explore GenAI models to support patient sensemaking through collections. These models could help patients build collections, analyze the data within them, and produce health narratives more efficiently. Such enhancements may also reduce physicians' workload for verifying collection contents, leading to more focused, evidence-driven discussions during visits.

Promising ideas from this work should be advanced carefully, with gradual design improvements tested in real-life settings. Respecting existing clinical practices and workflows can facilitate quicker adoption and more significant changes in the

future. We believe that collections can revolutionize how patients interact with their medical records and communicate with their providers.

Abstract

Background: In response to the COVID-19 pandemic, the United States extended regulatory flexibilities to make telemedicine more accessible to providers and patients. Some of these flexibilities allowed providers to intake patients over telemedicine and prescribe certain scheduled medications without an in-person visit.

Objective: We aim to understand providers' parameters for their comfort in prescribing over telemedicine and report on solutions providers have adopted in response to potential barriers and challenges in prescribing via telemedicine.

Methods: As part of a larger mixed methods study between February and April 2024, we conducted 16 semistructured interviews with mental health providers who prescribe via telemedicine within the United States. We used the results of a web-based, cross-sectional survey to develop a codebook and support recruitment. We analyzed a subsection of the 16 interviews using content analysis to capture comfort, barriers, and workarounds in telemedicine prescribing. We reported codes by frequency and by provider.

Results: Participants were typically male (11/16, 69%), provided care mostly or completely over telemedicine (11/16, 69%), and were psychiatrists (8/16, 50%) or other physician (3/16, 19%). Providers' primary states (10/16, 62%) of practice included Oregon, Texas, New York, and California. The content analysis yielded a total of 234 codes, with three main codes—comfort (98/234, 41.9%), barriers or challenges (85/234, 36.3%), and workarounds or solutions (27/234, 11.5%)—and two subcodes—uncomfortable prescribing (30/98, 31%) and comfortable prescribing (68/98, 69%) over telemedicine. Participants reported being comfortable prescribing over telemedicine as long as they could meet their main parameters of working within their expertise, having access to needed patient health information, and being compliant with rules and regulations. Participants reported frustrations with e-prescription workflows and miscommunications with pharmacies. Solutions to ease frustrations and alleviate discomforts in prescribing over telemedicine included developing workflows to help patients complete laboratory tests and physical examinations and directly communicating with pharmacies.

Conclusions: By applying content analysis to the semistructured provider interviews, we found that physicians are comfortable prescribing via telemedicine when they feel they are practicing within their personal parameters for safety. While many providers experience frustrations such as miscommunication with pharmacies, these barriers appear to not prevent them from telemedicine prescribing. With expected changes in 2024 and 2025 to the US laws and regulations for telemedicine prescribing, we may see changes in provider comfort in prescribing.

Introduction

During the height of the COVID-19 pandemic, health care visits moved to telemedicine when possible to help stem the spread of infection [1]. In the United States, the public health emergency (PHE) and regulatory flexibilities were instrumental in streamlining this effort by waiving specific requirements, such as the providers' ability to see patients outside the states where they are licensed and to prescribe over telemedicine with fewer restrictions [2,3]. Due to these temporary changes, providers could prescribe via telemedicine less restrictively and determine what level of care they felt comfortable providing over telemedicine.

The US Drug Enforcement Administration extended prescribing flexibilities past the May 11, 2023, PHE deadline and is in the process of finalizing a rule regarding telemedicine prescribing [4,5]. There has been concern that waiving elements of the Ryan Haight Act, which previously required providers to meet with patients in person before prescribing certain controlled substances, would adversely impact patient outcomes [6,7]. The concurrent opioid epidemic has also provided a new level of scrutiny in the space of telemedicine and prescribing scheduled medication for the treatment of substance use disorder (SUD) [8-10]. As US providers await the promulgation of this final rule, evidence continues to grow regarding positive patient outcomes via mental health prescribing over telemedicine [11]. One Medicaid data study following over 90,000 patients showed remarkable positive outcomes from telemedicine initiation of buprenorphine treatment, including better odds of 90-day treatment retention than if initiation occurred in person [12]. In a scoping review from 2008 to March 18, 2021, reviewers found that telehealth technology in SUD treatment increased access and adherence to buprenorphine and generally showed higher patient satisfaction and comparability to in-person retention rates [11]. Especially within the space of buprenorphine prescription, evidence supports that telemedicine offers comparable treatment to in-person care and can be an effective method for increasing patient access to mental health treatments [8,11].

With the flexibilities, providers can now choose the extent to which they use telemedicine. One study reported psychiatrists felt telemedicine use in a hybrid scenario allowed for treatment adaptation based on client needs and access [13]. The study's participants emphasized their need to consider each patient's unique case in determining whether they could successfully leverage telemedicine to initiate care or ensure continued visits over time [13]. For example, one psychiatrist in the study noted the following:

> *When you have these patients who are at risk for falling out of care, if you don't offer them telemedicine, but [they] are also at risk for getting slightly suboptimal care when you do offer them telemedicine, it is a very case-by-case judgment call in terms of the risks and benefits of enabling the telemedicine.*

Such sentiments support the call for greater provider autonomy and options, as well as the focus on including telemedicine as part of the holistic health care model [13-15].

Though there is evidence supporting the safety of prescribing certain scheduled substances over telemedicine (even without an initial in-person visit) [8,11,12], there is a need for greater insight into mental health providers' experiences in prescribing scheduled medications during and after the PHE. A better understanding of providers' perspectives, experiences, and comfort in prescribing for their patients over telemedicine would build a more accurate understanding of what providers view as actual challenges and limitations. This knowledge would add to the discourse regarding updates in policy and guidelines, especially necessary for policy makers as they deliberate over proposed rules and regulations [16]. To the best of our knowledge, no previous studies have focused on mental health providers' experiences regarding general prescribing—including scheduled medications—over telemedicine. In early 2024, we conducted a mixed methods study that included a web-based, cross-sectional survey and semistructured interviews of mental health providers who prescribe via telemedicine. The survey aimed to assess provider perceptions, experiences, comfort, and perceived patient safety in prescribing medications over telemedicine [17]. The interviews aimed to get a better understanding of providers' general telemedicine use, challenges and solutions specific to prescribing over telemedicine, and providers' knowledge and experiences regarding compliance with prescribing over telemedicine. In this study, our objectives were (1) to understand better providers' parameters for safe prescribing over telemedicine and (2) to report practices or workflows providers have adopted to accomplish safe prescribing via telemedicine. The results of the study will help stakeholders reassess long-standing policies—made at the beginning of these technological advances—that may now be causing unintended harm as the technology has improved and become more accessible to laypeople.

Methods

Study Design

We performed exploratory content analysis of semistructured interviews with tele–mental health care providers as part of a larger, mixed methods study. We used an explanatory sequential design, building upon a previously reported, web-based, cross-sectional survey [17].

Interview Development

After an initial literature review, we developed the semistructured interview guide with consultation and pretesting from 5 providers. We estimated that interviews would take 60 minutes. The interview attempts to capture context regarding what factors affect providers' views and comfort in prescribing medications via different scenarios and combinations of in-person and telemedicine visits. The interview guide covers the topics of (1) the provider's practice, such as specialty, telemedicine use, patients, and general difficulties with telemedicine; (2) challenges and solutions concerning prescribing over telemedicine; and (3) knowledge pertaining to laws and regulations of prescribing to telemedicine (see Multimedia Appendix 1 for the interview guide). This study focuses specifically on answers to the challenges and solutions concerning prescribing over telemedicine (Multimedia Appendix 1).

Participants and Recruitment

We recruited participants for the semistructured interviews from among participants in a research survey. The survey sampling, recruitment, and results are reported elsewhere [17]. In brief, we recruited a sample of US tele–mental health care providers from a telemedicine research panel, TelehealthEngage [18]. A total of 115 participants fully completed the survey. Participants were predominantly White (83/115, 72.2%), non-Hispanic or Latino (97/115, 84.3%), female (66/115, 57.4%) providers who were physicians (69/115, 60%) seeing their clients most to all of the time (50%-100% of visits) over telemedicine (82/115, 71.3%) [17].

Participants who agreed to be contacted at the end of the survey were invited to participate in follow-up interviews. Of the 115 completed surveys, 59 (51.3%) participants showed interest in being interviewed. Research team member JI (a White, immigrant female individual with a background in medical anthropology, psychology, and biomedical informatics) sent out interview invitations and completed interviews between February and April 2024. We aimed to complete 20 interviews or until we reached content saturation [19].

Data Analysis

One author (JI) performed an exploratory content analysis of 6 interviews. The codebook for content analysis, consisting of three main codes and two subcodes, was specified on the basis of prior survey findings (Table 1) [17]. The codebook was developed to test our expectations that providers will feel comfortable when their personal parameters for patient safety have been met and when the telemedicine visit is within the scope of provider practice and expertise. We used content analysis of the interviews to identify codes related to personal parameters for comfort in prescribing over telemedicine, named barriers and challenges of telemedicine prescribing, and the types of workarounds providers have found useful within those situations [19].

Table 1. Demographics as reported by providers during the interview[a].

Demographics for content analysis	Value, n (%)
Sex (n=16)	
Male	11 (69)
Female	5 (31)
How often telemedicine is used (n=16)	
None to seldom	1 (6)
Fairly often (about half the time)	4 (25)
Mostly or completely	11 (69)
Provider type (n=16)	
Psychiatry	8 (50)
Family medicine or general practice physician	3 (19)
Nurse practitioner	3 (19)
Physician assistant	2 (13)
Type of practice (n=21)	
Private practice	12 (57)
Statewide health system	4 (19)
Community health center	2 (10)
Solo practice	1 (5)
City-run program	1 (5)
Outpatient rehabilitation center	1 (5)

[a]Some demographic values sum to more than 16 as some providers worked in multiple practices.

We transcribed and deidentified completed interviews using Dovetail software (Dovetail). We confirmed transcripts for accuracy prior to deleting video data of interviews and uploaded transcripts to MAXQDA 2024 software (MAXQDA) for analysis. A single author (JI) coded the interviews over three iterations using the previously developed codebook, and coauthor HS (an Asian, immigrant female individual with a background in biomedical informatics and human factors research in behavioral health) reviewed the codes and codebook for validity and accuracy. We resolved discrepancies through consensus to ensure consistency and accuracy in the qualitative method [20,21]. The unit of analysis was meaningful phrases. Although we calculated the total frequency of code instances, we primarily focused on the frequency of codes by individual participants [19]. Additionally, contextual subtopics within the main reported codes were often double coded—as participants provided multiple examples, explanations, and reasoning—resulting in percentages over 100. We reported participant characteristics in the aggregate to ensure participants' confidentiality. For context, we included participants' numbers (1 through 16) after each quote.

Ethical Considerations

This study was reviewed and approved by the BRANY Institutional Review Board (IRB00010793). We attained verbal informed consent for the interviews in addition to the written informed consent from the survey protocol. Participants had the opportunity to opt out of our research. Participants were compensated with a US $75 e-gift card for their time. While there is always a risk of selection and other compensation-related biases, the amount was deemed appropriate for US mental health professionals who were the focus of recruitment. We use deidentified data for the purposes of this research.

Results

Demographics

We completed 16 semistructured interviews between February 22 and April 26, 2024. There were 11 (69%) male and 5 (31%) female participants (see Table 1 for demographics). Participants primarily practiced in the following states: Oregon (n=3, 19%), Texas (n=3, 19%), New York (n=2, 12%), Illinois (n=2, 12%), California (n=1, 6%), Florida (n=1, 6%), Michigan (n=1, 6%), Washington (n=1, 6%), Indiana (n=1, 6%), and Tennessee (n=1, 6%). The majority (n=11, 69%) provided care mostly or completely over telemedicine (75%-100% of visits), 4 (25%) providers reported an even mix (40%-60% of telemedicine and in-person visits) in their hybrid practice often depending on the weather, and 1 (6%) provider reported almost complete in-person care except for emergencies. Providers included psychiatrists (n=8, 50%), family medicine or general practice physicians (n=3, 19%), nurse practitioners (n=3, 19%), or physician assistants (n=2, 12%). Providers reported working in private practice (n=12, 75%), statewide health systems or clinics (n=4, 25%), community health centers (n=2, 12%), a solo practice (n=1, 6%), a city-run program (n=1, 6%), and an outpatient rehabilitation center (n=1, 6%). Some providers worked in multiple positions or practice types.

Content Analysis

A total of 234 code instances were identified, corresponding to three main codes and two subcodes. Table 2 shows the frequency of code instances corresponding to each main code and subcode. Frequencies of instances of *generally uncomfortable* and *generally comfortable* subcodes add up to the total frequencies of the *comfort* main code instances.

Of the 98 (41.9%) out of 234 total code instances under *comfort* in prescribing medications over telemedicine, 69% (68/98 code instances) were related to describing positive comfort in prescribing from all 16 providers. However, the majority of providers (10/16, 62%) also reported varying discomfort (30/98, 31% code instances) in prescribing over telemedicine even though it was less frequently mentioned.

Providers reported (85/234, 36.3%) varied barriers and challenges (85 code instances, 14 providers), providing information regarding problems that both providers and their patients face when prescribing medications over telemedicine. Providers reported fewer (27/234, 11.5%) workarounds and solutions (27 code instances, 11 providers).

Table 2. Content analysis results with the frequency of instances by main codes and subcodes[a].

Name	Frequency of code instances, n	Definition	Example
Comfort (main code)	98	Any direct discussion regarding feelings of comfort or ease in prescribing over telemedicine	"I just don't wanna like, yeah, miss something. And like, actually probably more so with the Benzos than with, than with stimulants because I feel like the stimulants you can: see if people are kind of like … when people are on Benzos they might be more drowsy, that you're just not picking up with, on the, the, the, the virtual…" [Participant 1]
Generally uncomfortable (subcode)	30	Any direct discussion regarding feelings of discomfort or unease in prescribing over telemedicine	"I feel less comfortable with over telemedicine because sometimes just like the cadence of a conversation is hard. Sometimes if there's a lag in telehealth or like whatever it may be. As for prescriptions, I would say, like your level twos and level threes are ones that I would not consider prescribing unless I'd at least seen them once in person…" [Participant 3]
Generally comfortable (subcode)	68	Any direct discussion regarding positive feelings of comfort or ease in prescribing over telemedicine	"And I would say that it's really about the same, the actual prescribing is pretty darn smooth. So, I feel like the mechanics of the prescribing are the same. I do not prescribe differently because I, I've got a sense, I don't know this person as well because I'm not me. No, I feel like I know my patients really well. Certainly, before I'm gonna be prescribing, I know what the story is in my mind. I may be wrong, but I've got that level of certainty. So, I don't think the telehealth platform impacts my decision-making or the mechanics around prescribing significantly." [Participant 6]
Barriers and challenges (main code)	85	Any direct discussion where a provider mentions a problematic situation that affects their decision-making to prescribe over telemedicine or affects a patient's ability to receive treatment	"But I would say, yes, it's difficult to feel comfortable, directing someone in another state to something that they may need without really knowing where that resource, who that resource is." [Participant 7]
Workarounds and solutions (main code)	27	Any direct discussion where the provider describes a way they adapt their process or decision-making due to a barrier or challenge	"So, a lot of times I give them information on how to find a particular how to vet another practitioner, but that's about the best [I can do]." [Participant 7]

[a]Main code and subcode definitions were developed based on survey analysis.

Parameters for Comfort in Prescribing Over Telemedicine

Overview

Providers brought up three main parameters as they contextualized their comfort or discomfort with prescribing medications over telemedicine: (1) limits of telemedicine and personal expertise, (2) knowledge of patients and access to their relevant health information, and (3) liability concerns.

Limits of Telemedicine and Personal Expertise

Five (31%) of the 16 providers established that they felt comfortable when the interaction stayed within their perceived limits of telemedicine and occurred within their realm of expertise. One provider pointed out that these parameters essentially establish criteria for a successful telemedicine visit:

> *So the direct answer to the question is I feel very comfortable [prescribing over telemedicine]. But I think the reason that I feel very comfortable has to do with the patients: who I see and who I won't see on telemedicine. So again, doing this is like a philosophical thing. I'm a big believer in getting people to the right place. And a lot of times that's me and a lot of times that's not me when it comes to mental health and telehealth, I try to, there are things that I, I don't personally feel comfortable or think would be appropriate to, to treat. So in general, if someone is like in a manic state, if they're psychotic, if they're actively suicidal, like suicidal with a plan intending to act on it, that sort of stuff, I won't see them through telehealth or if I have a patient who starts to experience those things, I will refer them for a higher level of care and we'll be pretty insistent on it. Not that I'm not gonna see them anymore, but it's just I want to get you to the best place.* [Participant 13]

Regarding the parameter of experience and expertise, 3 (19%) providers reported feeling uncomfortable prescribing over telemedicine when they thought they did not have the expertise to treat a particular diagnosis. One provider described feeling nervous about such a scenario:

> *I don't have anybody that I'm treating for narcotic abuse or opiate stuff. So I, not that I wouldn't, but I don't have anybody and I don't have a lot of experience with that. So that would make me nervous, especially over telemed. I just because I don't do it much in person either.* [Participant 9]

In this case, the provider notes they would feel uncomfortable treating such a patient in person and that seeing such a case over telemedicine would increase that feeling.

Knowledge of Patients and Access to Their Relevant Health Information

This parameter encompassed several topics including working with established patients and accessing needed patient health information such as labs or physical exams. A total of 4 (25%) providers identified knowledge of a patient's history—especially in regard to them being an established patient—as a crucial element of feeling comfortable prescribing for them.

> *So, certain medication that requires good monitoring for that level that may make me not want to prescribe medications on this platform. But I don't think it has anything to do with virtual platforms, any providers or psychiatrists would do so in, in person also. So I'm not, I'm trying to think if, unless the only time I don't prescribe is if someone makes the first appointment and say I'm on this medicine and I need refill, I don't do that because that's not a good practice. It's like, OK, unless I have some data or previous records or not a very strong medication, then you can continue. But if someone comes with a specific request for medicines that are not appropriate, then I wouldn't consider that as an OK to do it as a virtual practice.* [Participant 10]

This provider noted that in the scenario provided, they would need more information about the patient before prescribing, regardless of whether the visit is in person or via telemedicine. Meanwhile, one of these providers mentioned the importance of generally knowing their patients and their health status as they determine whether telemedicine visits are sufficient for care:

> *...If you have somebody who's a fragile diabetic, you need to have a different level of observation for that person. But if you have a stable diabetic, then you can just continue to prescribe that whatever it might be…* [Participant 15]

Inherent in this explanation is that the provider felt they have sufficient knowledge regarding a patient's current and past health status and feeling personally able to diagnose and treat in the presenting situation.

A total of 4 (25%) providers commented on the importance of having established patients in a scenario to make providers feel more comfortable prescribing over telemedicine. One of these providers underlined the importance of having such a relationship, especially when seeing patients for SUD treatment, as they may be able to pick up on potential concerns requiring more oversight via telemedicine or in person:

> *I mean, people with substance use problems. Now that brings a whole host of challenges itself because of confidence in, in history, you know, and confidence of just general reporting ... So I have a special, I have a different kind of relationship with [specific patient with SUD]. I can tell when somebody's bullshitting. And I can call them pretty well on it. I rarely get blindsided because I've been doing this for a long time. So I come with enough experience, I think also that allows that to happen. But suffice to say that if I have an issue with someone there, I'll put more controls over it, and we'll go to task if needed. If they need to come in, I need to see them in person...* [Participant 15]

In this case, the provider leveraged not only their years of experience in the specific field (expertise parameter) and having known the patient for a long time but also their hybrid practice, as they can have the patient come for an in-person visit.

A total of 3 (19%) providers mentioned they feel comfortable prescribing over telemedicine because they have such an option. In addition to this, 4 (25%) providers also pointed out that having a way to check on their patient's safety, whether it be having local resources for the patient or being able to view a Prescription Drug Monitoring Program, influences their comfort positively. One of these 4 providers described that knowing they can get patient health information quickly and seamlessly made them comfortable prescribing for an individual:

> *If they have established care, either someone who can update me on their vitals or regular monthly visits and have some kind of formal evaluation for me to backtrack the diagnosis. And then there is a way to order urine drug screens to make sure they're not abusing any other drugs on the top of. So, if that makes it an easy flow for us, then, yeah. Yeah. I think that's not a big problem. It's just how to coordinate that care sometimes makes it harder...* [Participant 10]

Additionally, 4 (25%) providers stated the importance of developing and adhering to a protocol with their patients. Providers discussed this concept within the patient information parameter in everything from the formal quality of care processes to simply expecting to see a patient in person for all intakes. Adhering to protocols appears to be driven by the need for patient health status and history, as providers often discussed continuity of care and procurement of labs and exams.

> *So, I think patients who are, really complex, I feel less comfortable with prescribing over telemedicine because sometimes just, like, the cadence of a conversation is hard. Sometimes if there's a lag in telehealth or whatever it may be. As for prescriptions, I would say, your level two's and level three's are ones that I would not consider prescribing unless I'd at least seen them once in person. I know personally, our clinic does random drug tests on our patients...* [Participant 3]

Liability Concerns

A total of 5 (31%) providers noted that they maintain their comfort in prescribing over telemedicine by simply refusing to prescribe certain controlled substances or not accepting specific diagnoses in their practice, especially due to their wariness of laws and regulations. One of these providers explained that while they treat SUDs, they do not prescribe certain medications and are aware of prescribing barriers:

> *...I do see a lot of patients with substance use disorder...just the fact that it's [buprenorphine] more accessible now is amazing for these patients. I've heard there are still some barriers with methadone in particular...it hasn't been an issue for me because I don't prescribe that medication in particular.* [Participant 16]

Indeed, 2 (12%) providers indicated they avoid prescribing over telemedicine unless they feel they have to for the patient.

> *I generally refrain from prescribing anything scheduled over telemedicine ... just because of the, the insane liability with it ... the unbalanced liability, I would say that physicians shoulder in this industry.* [Participant 7]

Here, the provider also touched on the issue of compliance and liability inherent in this situation.

Barriers and Workarounds in Prescribing Over Telemedicine

Of the 85 (36.3%) out of the 234 total code instances that describe barriers (14 providers), 37 (44%) of the 85 instances specifically mentioned that the e-prescription platform and the pharmacies caused challenges in prescribing medicines or picking up medicines (13 providers). There were 17 (20%) instances of providers describing difficulties with the actual e-prescription platform they use.

> *But Epic, they started putting in all these like hard blocks like you need to click this before you can do what you're trying to...I think the way that they went about it sometimes, it was really like a hassle for the workflow when you add it all together.* [Participant 2]

Providers also often noted their patients' prescription order was not received or not fulfilled by the pharmacy due to shortages in medicines or misunderstandings in prescribing over telemedicine (20/85, 24%). One provider noted how such a situation acted as a barrier for patients receiving their necessary prescriptions:

> *But I had a pharmacy once, call me that said that...they weren't going to allow my patient to fill a pack of the prescription because I hadn't provided an estimated glomerular filtration rate or creatinine clearance with my prescription. But like that's because they now have the ability to prescribe that on their own. But I sent the prescription. I'm assuming the responsibility. I already checked that all you're doing is throwing up another barrier to this patient, getting their medication when you do that, which I get. You don't want to be audited or whatever, but you're not the one prescribing it. I am, you know what I mean? I just like the pendulum has swung so far the other way since the opioid epidemic that they're really trying to tighten the noose and on all this stuff, and I just think it's going to end up harming patients who are calling for their beta blockers or, you know, whatever.* [Participant 2]

Providers reported shortages of certain medicines, usually stimulants, in pharmacies, requiring patients to find pharmacies with stock and providers to resend prescriptions. Providers' complaints regarding the e-prescription platforms and pharmacies' inability to provide the medications ranged from workflow nuisances to concerns that their patients could not receive necessary medications promptly.

Other mentioned barriers (49/85, 58%) were related to general telemedicine concerns and issues such as patient health concerns (17/85, 20% codes; 11/16, 69% providers), rules and regulations (16/85, 19% codes; 7/16, 44% providers), and reimbursement concerns (9/85, 11% codes; 2/16, 13% providers). Patient safety concerns mainly touched on worries that patients are not having their follow-up appointments, exams, and labs in a timely manner, which can affect patient health outcomes, as well as the ability of providers to prescribe medications for them.

> *I will put a child on a medication and I'll say I need to have you call me in two or three days because this medicine doesn't take a long time to start working. And I need to know so we can make adjustments. And invariably 99% of the time they wait till the next month, scheduled appointment and we could have made some, you know, needed changes. And that was difficult even when we were in the office...* [Participant 11]

Concerns regarding rules and regulations more closely align with providers seeing patients across state borders. Some providers felt such regulations hindered their ability to treat patients but also created unnecessary frustrations.

> *So, yeah, it's interesting navigating all of that because, and honestly, I think it's just so stupid having state-dependent licensing system when they all use the same criteria.* [Participant 7]

While providers recognized the need for laws and regulations, their current struggles often placed them in positions having to choose between seeing their (often established) patients or complying with regulations.

> *It reminds me of another patient, he's in college in North Carolina and, he had really good, he had a psychiatrist through his school but then the school had canceled the contract with that [psychiatrist] and he's like, what now am I supposed to do? And like, he wasn't exactly, he wasn't unstable but he wasn't stable. Like, you know, in that gray zone and he's like, can't you see me?...And I would love to see you. I feel my heart goes out to you, but like, you're in North Carolina, like, I...I, I will see you all through Christmas break, summer break. But like, I don't know what to do. Like, if you're having a crisis, definitely call me like, and I will, you know, I will just override it. But like, if you're going there and, you know, like you need the help, like you gotta, I don't know, I don't know what to tell you. Like, I feel terrible if you.* [Participant 1]

Providers often reported that mobile patients such as college students are the ones most strongly affected by these types of laws and regulations.

Providers reported far fewer workarounds or solutions (27/234, 11.5% codes; 11/16, 69% providers) to mentioned barriers relating to prescribing over telemedicine. Direct responses to barriers and challenges included—as subtopics—streamlining how they receive patient health data (8/27, 30%), finding new pharmacies for patients to use (5/27, 19%), using reminders and new ways to connect with patients quickly (5/27, 19%), responding to regulatory pressures (3/27, 11%), and making individual adaptations in their practice (6/27, 22%; due to double coding of subtopics, percentages add up over 100) The most common solution providers reported was finding an easier way to receive laboratory tests, examinations, and vitals from their patients (8/27, 30% codes; 5/16, 31% providers). While providers were able to direct their patients to local laboratories or request that their patients invest in a blood pressure cuff, one provider noted their practice found certain tests to be beneficial for telemedicine visits:

> *Hm, we do drug screens online. So, we do saliva testing online and drug screens. And so that's if we don't always have to have people go pee somewhere or go to the lab, they can do those at home. So, I guess that's something that we found just as a, not really a workaround, well, kind of a workaround, and I guess to allow them to stay at home, but just to incorporate it as something that's a little bit more convenient.* [Participant 5]

Providers further noted the emphasis on streamlining patient processes by using novel ways to communicate with them regarding simple questions or requests. For example, one provider noted the following:

> *[Patients] can just text me a question...A few patients of mine have learned that they come and sit in the waiting room if they have a question. And so, I see them sitting in my waiting room, and sometimes I'm done. I'm like, "What's up?" And they say, "Yes, you know, hey, I need a refill.*" [Participant 12]

In this case, the provider sought to have secure, simple messaging with a patient. Other solutions related to streamlining processes with patients included actively talking with pharmacies in the patients' area (5/27, 19%), moving to a new e-prescription platform (1/27, 4%), and creating a protocol for helping their out-of-state patients find health resources (1/27, 4%).

Providers mentioned two differing approaches to handling the barriers created by laws and regulations in prescribing over telemedicine. Some (2/16, 13%) providers chose to unequivocally adopt the strictest state and federal regulations within their practice, and another explained that they would continue with a process that works for their patients but was admittedly in the gray zone legally.

Content analysis of barriers affecting provider comfort in prescribing over telemedicine identified 85 code instances over 16 interviews. With 27 code instances of workarounds and solutions directly relating to these noted barriers, the qualitative analysis identifies areas in telemedicine where progress still needs to be made.

Discussion

Principal Findings

By leveraging the results of our more extensive mixed methods study [17], we framed our content analysis to provide needed context for understanding mental health providers' comfort in prescribing over telemedicine. This qualitative study identified vital parameters that constitute comfort for mental health providers who prescribe via telemedicine. Our results show that providers feel most comfortable prescribing over telemedicine when they are practicing within its inherent limitations and their own professional expertise, with access to patients' relevant health information, and within clearly defined legal and regulatory confines. In addition, we identified related barriers that affect these parameters and the potential solutions that providers have used to alleviate these challenges. Content analysis revealed providers found the e-prescription platforms and the miscommunications with pharmacies receiving prescriptions as substantial sources of frustration and concern in the prescribing process. Ultimately, providers prescribe medications over telemedicine within the bounds of their perceived comfort parameters but would like to see changes in streamlining the prescribing workflow, assurance of timely patient examinations and laboratory tests, and clarity in the laws and regulations surrounding prescribing over telemedicine.

Overall, even while providers reported feeling comfortable prescribing over telemedicine, they were aware their comfort was due to practicing within their established personal parameters. Providers noted their comfort in prescribing over telemedicine was attributable to their specialty and providing care to patients who require specific types of medications that providers may be generally hesitant to prescribe. Research using claims data between 2020 and 2023 shows that certain specialties (ie, psychiatry) were seen to initiate treatment for alcohol use disorder over telemedicine more than others (ie, primary care physicians) [22]. Within the same study, researchers observed a different rate of telemedicine initiations dependent on the types of medications being prescribed (eg, naltrexone at 14.6% vs topiramate at 11.8%). Our results support these findings as psychiatrists are better versed in treating mental health disorders and have tacit knowledge regarding certain medications and patient symptoms. Unsurprisingly, in this study, some providers emphasized that their comfort in prescribing decreased when faced with diagnoses they have little experience treating. From a 2023 review of pandemic-era research on telemedicine use in SUD treatment in the United States, authors noted providers would vary the number of days (supply) of prescribed medication based on their judgment of each patient interaction and context [23-26]. These findings are supported by our results as providers work within their personal parameters and determine how to proceed with prescribing based on their interaction with each patient.

Additionally, providers' personal parameters likely echo current guidelines regarding telemedicine use and limitations [27,28].

Such guidelines proffered protocols and practices based on earlier telemedicine research and stricter rules and regulations [29]. Considering that guidelines emphasize compliance with state and federal laws and regulations, we may be seeing providers' personal parameters reflecting these policies even when they feel comfortable and capable of prescribing over telemedicine [30]. Updates of such guidelines would help reframe providers' understandings of telemedicine prescribing limitations and liabilities; however, lagging legal progress limits the ability for such revisions [31,32]. With the loosening of laws and regulations regarding telemedicine prescribing, new evidence has shown that providers can care for their patients effectively while maintaining positive patient outcomes [29].

Providers also emphasized the importance of access to patient's health information, especially timely updates of exams and labs needed to prescribe certain medications such as stimulants. Certainly, the content analysis showed multiple workarounds focused on streamlining the process of accessing patient health information. Understandably, providers also noted that they feel more comfortable working with established patients, where patient health history and a personal repertoire with the patient can provide context to a telemedicine visit. Interview results suggest that an established patient—via telemedicine or in-person visit—is a central factor in how providers view their needs for timely patient health updates. This parameter is relevant for in-person and telemedicine visits. Nevertheless, with the inflated fear of liability when using telemedicine, providers show increased concern when operating outside their parameters for comfort in telemedicine prescribing [33]. Similar findings show providers may feel that additional assessment, such as physical examination, reinforces their decision-making and allays liability fears [34].

Our content analysis shows that the ultimate tipping point in whether providers prescribe via telemedicine is whether the clinical situation falls within the provider's personal parameters for comfort in prescribing. The obstacles we identified in the study, such as the e-prescription platform errors, were predominantly situations that caused frustrations in the prescribing process but were insufficient reasons for providers to discontinue prescribing medications. Of course, particular barriers, such as miscommunications with pharmacies and not receiving patient examinations or laboratory tests promptly, directly impact patient safety and outcomes. Our results support prior research showing that providers and patients faced challenges with e-prescriptions where pharmacies faced a dearth of certain medications such as buprenorphine [23,35,36]. Providers emphasized the importance of patient safety with their noted solutions: the most frequently mentioned solutions revolved around streamlining the receipt of patient health information and ensuring patient access to needed medications. Given the current, typical support infrastructure in the United States, telemedicine is not as effective for treating disorders that require laboratory examinations [37]. However, telemedicine is becoming a permanent mode of health care delivery, and successful solutions for assessment, such as diagnostic testing and information access, will be a priority for providers and other stakeholders. As a result, there is a growing support infrastructure including at-home laboratory options ranging from technicians coming to your home to home tests that can be done during a telemedicine visit [38,39]. While large health institutions such as Yale School of Medicine may have such resources available for their patients [38], small clinics or solo providers face difficulties in connecting their patients to these resources, especially in relation to an individual patient's insurance coverage [39].

Our results show that providers prescribe within the scope of their personal parameters determined by perceived limitations of telemedicine and professional expertise, provider access to relevant patient health information, and liability concerns. Once providers met their individual parameters, they expressed higher comfort in prescribing over telemedicine. With an increase in legal clarity and simplification of prescribing over telemedicine, providers may feel more capable and comfortable with the process, as guidelines would reflect the loosening of restrictions [30]. These personal parameters exist in the context of current legal and regulatory considerations; therefore, making PHE telemedicine-related policy flexibilities permanent may help expand the situations in which providers feel comfortable prescribing. Such progress may also improve patient access to mental health care services—providers may feel more comfortable expanding their patient base for telemedicine, thus alleviating access and inequity issues for mental health care treatment [40].

Limitations

This study used interviews from providers recruited through nonprobability convenience sampling via the TelehealthEngage research panel. Our findings are not generalizable to all US mental health providers. It reflects the view of interview participants, including providers from solo, small private practices; statewide health systems and clinics; and other types of mental health care settings. Additionally, as we included all prescribing mental health providers, the prescribing challenges, workarounds, and level of comfort we captured in the study may differ for other providers based on their practice focus. Future research should include a larger sample of participants including those practicing in larger health systems and academic health sciences centers, who were underrepresented in our sample.

Conclusions

Through content analysis of semistructured provider interviews, we determined that the participating providers feel comfortable prescribing over telemedicine when they practice within perceived limits of telemedicine and their own expertise, with sufficient access to patient health information, and when they do not have liability concerns. Providers mentioned multiple hindrances to prescribing over telemedicine. However, the ultimate reason they refer patients to other providers or convert encounters from telemedicine to in-person visits is that their comfort parameters are not met, and thus, patient safety is at risk. Future research, including inductive-deductive qualitative analysis of the interviews, will help create a more robust understanding of provider perspectives on telemedicine prescribing and inform future implementation and policy of prescribing over telemedicine.

Acknowledgments

We gratefully acknowledge Beju Shah for his assistance in developing the interview guide. Funding for this research was provided through Doxy.me, Inc.

Conflicts of Interest

BMW is a shareholder, and JI, HS, TO, BEB, EL, and MRC are employees of Doxy.me Inc, a commercial telemedicine company.

Abstract

Background: The rising demand for advanced home care services, driven by an aging population and the preference for aging in place, presents both challenges and opportunities. While advanced home care can improve cost-effectiveness and patient outcomes, gaps remain in understanding how eHealth technologies can optimize these services. eHealth tools have the potential to offer personalized, coordinated care that increases patient engagement. However, research exploring health care professionals' (HCPs) perspectives on the use of eHealth tools in advanced home care and their impact on the HCP-patient relationship is limited.

Objective: This study aims to explore HCPs' perspectives on using eHealth tools in advanced home care and these tools' impact on HCP-patient relationships.

Methods: In total, 20 HCPs from 9 clinics specializing in advanced home care were interviewed using semistructured interviews. The discussions focused on their experiences with 2 eHealth tools: a mobile documentation tool and a mobile preconsultation form. The data were analyzed using content analysis to identify recurring themes.

Results: The data analysis identified one main theme: optimizing health care with eHealth; that is, enhancing care delivery and overcoming challenges for future health care. Two subthemes emerged: (1) enhancing care delivery, collaboration, and overcoming adoption barriers and (2) streamlining implementation and advancing eHealth tools for future health care delivery. Five categories were also identified: (1) positive experiences and benefits, (2) interactions between HCPs and patients, (3) challenges and difficulties with eHealth tools, (4) integration into the daily workflow, and (5) future directions. Most HCPs expressed positive experiences with the mobile documentation tool, highlighting improved efficiency, documentation quality, and patient safety. While all found the mobile preconsultation form beneficial, patient-related factors limited its utility. Regarding HCP-patient relationships, interactions with patients remained unchanged with the implementation of both tools. HCPs successfully maintained their interpersonal skills and patient-centered approach while integrating eHealth tools into their practice. The tools allowed more focused, in-depth discussions, enhancing patient engagement without affecting relationships. Difficulties with the tools originated from tool-related issues, organizational challenges, or patient-related complexities, occasionally affecting the time available for direct patient interaction.

Conclusions: The study underscores the importance of eHealth tools in enhancing advanced home care while maintaining the HCP-patient relationship. While eHealth tools modify care delivery techniques, they do not impact the core dynamics of the relationships between HCPs and patients. While most of the HCPs in the study had a positive attitude toward using the eHealth tools, understanding the challenges they encounter is crucial for improving user acceptance and success in implementation. Future development should focus on features that not only improve efficiency but also actively enhance HCP-patient relationships, such as facilitating more meaningful interactions and supporting personalized care in the advanced home care setting.

Introduction

Advanced Home Care

Advanced home care, also known as advanced health care in the home, involves providing medical care or treatment directly at a patient's home, serving as an alternative care to inpatient care. The World Health Organization defines home care as "an array of health and social support services provided to clients in their residence. Such coordinated services may prevent, delay, or be a substitute for temporary or long-term institutional care" [1]. According to a study by Barakat et al [2], the components of home care include preventive actions and assessments, postdischarge actions, and evaluations, with objectives focused on enhancing or maintaining the quality of life, optimizing functional health status, and promoting independence. The composition of health care professionals (HCPs) providing home care varies depending on the patient's needs and the extent of services they require. This team may involve various HCPs, such as physicians, nurses, assistant nurses, physical therapists, occupational therapists, speech-language pathologists, home health aides, home infusion nurses (specialized nurses who administer intravenous medications in patients' homes), hospice caregivers, and medical social workers [3]. Patients receiving home care may have a wide range of health conditions and diseases, including chronic conditions, such as diabetes, hypertension, and heart disease; neurological conditions, such as Parkinson disease, dementia, and stroke; respiratory conditions, such as chronic obstructive pulmonary disease, asthma, and sleep apnea; cancer; individuals requiring wound care; and those in need of palliative care [3].

The increasing demand for home care services is driven not only by an aging population but also by the growing preference among many individuals to age in place, remaining in their own homes. The primary goal of advanced home care is to enhance patients' quality of life and clinical outcomes while simultaneously reducing health care costs and hospital readmissions [4].

Use of Electronic Health in Advanced Home Care

Organizational suppliers of health care are increasingly delivering medical care directly to patients' homes, which has created a growing reliance on medical technologies and eHealth tools [1] to support health care staff in managing not only older people care but also palliative and end-of-life care and patients with multiple comorbidities or complex diseases. The increased presence of eHealth tools also highlights the importance of considering the competencies and requirements of HCPs for using eHealth tools in older people care [2].

eHealth's vital role in advanced home care includes using telehealth, remote patient monitoring, and mobile health apps to deliver health care services to patients with complex medical needs in their homes [5]. eHealth tools facilitate communication between patients and HCPs, support medication management, monitor vital signs and symptoms, and offer educational resources to patients and caregivers. Furthermore, integrating eHealth into advanced home care can also enable organizational suppliers of health to deliver personalized and coordinated care, increase patient engagement and self-management, and improve overall patient satisfaction [2].

In Sweden, the national policy emphasizes home assistance and home care over institutionalized care, with various programs supporting long-term care for older people, assistance for people with disabilities, end-of-life care, palliative care in hospitals or hospices, and advanced palliative home care administered by municipalities. In 2017, home care met 72% of long-term care needs, while institutions served the remaining 28% [6]. Given the substantial reliance on home care for health care delivery, there is a significant need for resources, making eHealth services, such as those mentioned earlier, highly beneficial [7].

A study by Rydenfält et al [8] outlined the implementation of eHealth services in Swedish home care nursing, listing national patient summaries, mobile documentation, digital locks, digital medical lists, digital security alarms, and camera supervision as the most commonly used services. Organizational suppliers of health care had implemented mobile documentation most widely among these services at the time of the study, with plans for its continued use in the future for home care nursing.

Traditional Documentation

Health care staff have long used traditional methods, such as pen-and-paper notes, to document patient encounters, including observations, assessments, signs, symptoms, and communications during clinic consultations and home care visits. While some remnants of this traditional documentation method may persist in current practices, health care organizations have adopted information and communication technology solutions [9] and notable mobile communications [10] to address the inherent challenges of traditional documentation. Traditional documentation methods occasionally lead HCPs to omit crucial information inadvertently, record data inaccurately, produce illegible handwriting, and misunderstand patients' accounts, while requiring significant time for documentation [11].

Patient Experiences With eHealth

Researchers have extensively explored patient experiences with eHealth, particularly in home and palliative care settings, and have revealed a range of benefits and challenges. Steindal et al [3] found that telehealth applications in palliative home care enhance access to HCPs, helping patients feel more secure and safe. Similarly, Widberg et al [4] highlighted that eHealth applications facilitate better communication between patients and HCPs in palliative care. Karlsen et al [12] focused on older adults' use of telecare in home care services and emphasized their desire to age in place. These studies show that patients view technology as a valuable tool to achieve this goal, although

some resist adopting new technologies, struggle with digital proficiency, and worry about privacy and security [5].

Older patients face notable challenges when using eHealth tools. These include their preference for direct contact with HCPs, age-related cognitive decline, the stigmatization of telemonitoring devices, and the potential loss of social interactions, which are essential for well-being [5,13]. Experts emphasize the importance of balancing in-person care with eHealth use for certain populations, such as older patients with chronic conditions. Despite these obstacles, studies highlight that eHealth improves care accessibility and patient autonomy [3,5,12].

Specific eHealth applications directly benefit patients. For instance, an eHealth app tested in home care settings allowed patients to report health concerns and increased their sense of security [10] by reducing the frequency of phone calls to nurses, enabling them to prioritize care based on the app's alerts. However, frequent reporting through the app led HCPs to perceive minor health issues as significant, which increased their workload [10]. These findings illustrate the nuanced impact of eHealth on patient experiences and underline the need to carefully address patients' needs and contexts.

The Acceptance and Perspectives of HCPs on eHealth

HCPs play a pivotal role in adopting and successfully implementing eHealth solutions, as their acceptance and perspectives directly influence outcomes. Li et al [14] identified key factors that affect HCPs' acceptance of eHealth. These factors include HCP characteristics, voluntariness of use, performance and effort expectancy, and how organizational conditions either support or hinder eHealth adoption. HCPs emphasize patient autonomy, personalization, and continuity of professional support as facilitators of eHealth adoption, while they note advanced patient age as a primary barrier [15].

Qualitative studies offer additional insights into HCPs' attitudes toward eHealth. In an interview study, general practitioners expressed positive attitudes toward eHealth as a means to promote healthy lifestyles for patients and themselves [16]. They showed confidence in transitioning from traditional paper-based approaches to digital solutions, particularly those incorporating patient-reported outcome measures. Similarly, Das et al [17] examined the impact of an eHealth portal on HCP-patient interactions and reported that HCPs value the portal for its ability to provide comprehensive patient information, foster accountability, and serve as a clinical tool. However, they also identified organizational challenges, such as a lack of incentives and time constraints, which hinder eHealth integration.

Understanding HCPs' experiences and perceptions is essential for optimizing eHealth tools. While eHealth enhances health care quality, efficiency, and accessibility, its success depends on addressing the barriers that HCPs face. Targeted training and strategies to overcome organizational constraints can improve HCP satisfaction and ensure seamless integration of eHealth into clinical practice [18].

Aim of the Study

Despite extensive research in eHealth, there remains a limited understanding of how eHealth tools affect the relationship between HCPs and patients in advanced home care settings. While some studies have explored patient perspectives, fewer researchers have focused on HCPs' experiences and perceptions.

The aim of this study is to explore HCPs' perspectives on using eHealth tools in advanced home care and their impact on HCP-patient relationships. This research is particularly relevant in the context of Sweden's robust home care system.

Methods

Methodology Overview

This study used qualitative research methods, collecting data through semistructured interviews with HCPs working in advanced home care at Aleris in Sweden. Aleris is one of the major private organizational suppliers of health care in Sweden, offering a range of medical services, including advanced home care and other specialist medical treatments [19]. This approach suited the study's objective, which aimed to gain a deep understanding of HCPs' perspectives on using eHealth tools in advanced home care and their impact on relationships with patients. The flexibility of qualitative research allowed nuanced meanings to emerge from participants, captured through direct quotations from interview transcripts. The study adopted an exploratory design to further explain the role of eHealth tools in advanced home care as perceived by HCPs and examined how these tools influence their interactions with patients. This design proved beneficial in uncovering connections between ideas that were either underrepresented or not previously demonstrated in the literature [20]. An inductive approach [21] analyzed the data, aligning with the study's objectives.

The eHealth Tools

The eHealth tools used in the study are part of the SwipeCare health care process management system, which partially integrates into TakeCare, the electronic health record (EHR) system used by HCPs in their daily practice. TakeCare serves as the main repository for patient information and is used for routine clinical documentation. SwipeCare functions as an overlay on TakeCare, enhancing the existing EHR system by adding functionalities, such as iPad (Apple Inc)-based questionnaires, calculations, creating and sending questionnaires to patients, and patient reminders [22]. SwipeCare controls and coordinates the patient care process from diagnosis and treatment to aftercare and follow-up. It allows the organizational suppliers of health to define and manage the entire health care process, initiating actions within that process, some performed by SwipeCare itself (like sending out questionnaires) and others by HCPs or other units. SwipeCare interacts with TakeCare only when it needs to read from or write to the patient's record, thus complementing rather than replacing the EHR.

The 2 tools chosen for the evaluation were a mobile documentation tool and a mobile preconsultation form. The tools were chosen for their complementary nature and potential to capture a wide range of HCP-patient interactions. While the mobile documentation tool was used by the HCP, or

collaboratively by HCP and patients, during in-person visits, the mobile preconsultation form was completed independently by patients at home. This diversity in tool use allowed a comprehensive exploration of eHealth's impact on HCP-patient relationships across different contexts.

The iPad-based mobile documentation tool consists of different predefined standardized forms, which HCPs, either themselves or together with the patient, fill in. Such a form could, for example, cover the required information related to the admission of the patient to a ward or a checklist for evaluating the patient's physical status after an adjustment in the treatment. The questions in the form consist of predefined categories designed to guide HCPs in documenting patient information. Caregivers have the discretion to determine which answers are available for HCPs to fill in. In some cases, there is a designated "comments" section where HCPs can provide additional explanations or insights. However, in other instances, caregivers may choose to limit responses to predefined alternatives. This limitation mirrored traditional documentation methods, such as pen-and-paper systems, where options were similarly restricted. In addition, certain calculations, such as the Mini Nutritional Assessment (MNA) [23] or the National Early Warning Score 2 (NEWS2) [24], necessitate numerical input and cannot accommodate text responses. This further underscored the importance of predefined answer alternatives within the tool. In addition, the forms ensure no relevant aspects are missed, as questions can be made mandatory to answer.

The second tool, the mobile preconsultation form, is part of the patient portal in the system, which enables the patient to access their own portal, or web page, on their mobile or equivalent digital device. The patient first receives an SMS text message with a link to their patient portal. The patient logs in using a secure method and can then access the preconsultation form. The patient answers the questions at their own pace and time and finally sends the answers back to the caregiver. This enables HCPs to review the status of the patient before traveling to the patient's home, avoiding the time spent on questioning and filling in answers. Instead, it allows that time to be spent caring for the patient where the patient has its needs, for example, pain in the foot or problems with digestion. The intention is to free HCPs from administration to devote time to the care of the patient and encourage patients to take a more active role in their own care.

Data Collection and Participant Selection

The recruitment process involved contacting selected participants via email, facilitated by managers from each of the 9 participating clinics in Stockholm, Sweden. Clinics were selected to ensure geographic diversity across the Stockholm region, including clinics from the north, south, and other areas. Clinic heads collaborated in identifying suitable participants with experience using the eHealth tools. This selection strategy aimed to capture a comprehensive range of perspectives, strengthening the validity of the findings. Inclusion criteria for participants comprised individuals aged ≥18 years, officially employed at these clinics, and experienced in using the eHealth tools in their professional roles. The diversity in HCPs' roles and experience levels allowed for capturing a broad view of eHealth tool use in advanced home care.

Interviews took place between March and May 2023. Participants received the informed consent form via email before the interviews, which they reviewed and signed in person at the beginning of the interview session. Audio recordings and notes documented each 30- to 45-minute interview. A structured interview guide provided consistency while allowing the interviewer flexibility to explore topics relevant to HCPs' perspectives further. For example, one question from the interview guide asked participants to describe how they adapted their use of eHealth tools based on individual patient needs, providing deeper insights into their experiences and perceptions regarding the patient-HCP relationship.

The characteristics of the 20 HCPs who participated in the interviews varied across the 9 clinics. Each clinic contributed between 1 and 4 HCPs, with a median of 2, ensuring a good spread of perspectives across the clinics involved. Participants were aged between 24 to 59 years, with a mean of 45 (SD 9.3; IQR 41-52) years.

Table 1 presents participants' characteristics, categorized by profession, years of practice, duration of using mobile documentation tools, and duration of using mobile preconsultation forms. All (20/20, 100%) participants used the mobile documentation tool, while only 60% (12/20) of them used the mobile preconsultation form. This difference in tool use reflects the phased implementation approach common in health care settings, allowing for the gradual adoption and refinement of new technologies. The relatively short duration of eHealth tool use for many participants (0-2 years) illustrates the dynamic nature of health care staffing, characterized by a high turnover rate [25]. HCPs joining from other organizational suppliers of health care or units typically lacked previous experience with these specific eHealth tools. This limited experience duration accurately represents the reality found in many health care units and provides valuable insights into the initial adoption phase of eHealth tools in advanced home care.

These factors—the selection process, varied tool familiarity, and relatively short use duration—shaped the findings by offering a realistic snapshot of eHealth tool adoption in health care units where staff turnover is common. While this scenario limits observations on long-term impacts, the study offers a pragmatic view of eHealth tool implementation, helping stakeholders set realistic expectations and develop strategies that account for the realities of staff turnover and varying levels of tool familiarity in health care settings.

Table 1. Participant characteristics.

Participant	Duration of clinical practice[a] (y)	Duration of the use of mobile documentation tools (y)	Duration of the use of mobile preconsultation form (y)

[a]Clinical practice: total time spent as health care professionals across all settings, including advanced home care clinics.

[b]Not applicable.

Data Analysis

The interview, recorded in audio format, underwent verbatim transcription and subsequent review for accuracy and completeness. Following the transcription of the data, participants' responses were systematically organized and categorized. The analysis was conducted using a content analysis approach grounded in the methodology described by Graneheim and Lundman [26]. The process began with a thorough data familiarization. To gain a deep understanding of its content, we immersed ourselves in the material, reading it carefully multiple times. Once a comprehensive understanding of the data was achieved, we identified *meaning units*—specific segments of text that conveyed key information relevant to the study's objectives. These meaning units were then condensed to retain their core meaning while eliminating unnecessary details. Each condensed meaning unit was assigned a code, which served as a concise label capturing its essential message. The codes were reviewed and grouped into *subcategories* based on shared patterns and similarities, providing a more detailed and refined understanding of the data. These subcategories were subsequently combined into broader *categories* that represented the distinct dimensions of our study. We then merged related categories and identified key subthemes. Ultimately, we consolidated these findings into an overarching theme. This theme captured the core insights from the data, highlighting both the benefits and challenges of eHealth tool use in advanced home care from HCPs' perspectives.

Ethical Considerations

This research was conducted in Sweden. According to the Swedish Ethical Review Act (SFS 2003:460) [27,28], this study does not require ethics approval as it does not involve the handling of sensitive personal information, as defined by the European General Data Protection Regulation (GDPR), Regulation (EU) 2016/679 [29]. However, we acknowledge that ethical principles still apply and have been followed in accordance with relevant regulations and research guidelines.

Prospective study participants received an invitation email outlining the study's purpose. Those who agreed to participate were contacted via email, SMS text messages, or phone calls to schedule interviews according to their preferences. Before beginning the interviews, participants were provided with a comprehensive explanation of the study objectives, interview procedures, and their rights. Both verbal and written consent were obtained from each participant, with informed consent signed by the participant and the researcher. The consent form included information regarding the aim of the study, potential risks and discomforts, potential benefits, how confidentiality would be handled, the right to withdraw, and consent

procedures. It also assured participants of their confidentiality. All participants were informed of their right to withdraw from the study at any stage. Furthermore, no monetary or nonmonetary compensation was provided to any participants. Finally, they were assured that all raw data, comprising audio recordings and interview notes, would be stored on a secured laptop with biometrics log-in (fingerprint) for enhanced data security.

Results

Overview of Data Analysis

The data analysis identified one main theme—*optimizing health care with eHealth: enhancing care delivery and overcoming challenges for future health care*. Two subthemes emerged: (1) enhancing care delivery, collaboration, and overcoming adoption barriers and (2) streamlining implementation and advancing eHealth tools for future health care delivery. Five categories were also identified: (1) positive experiences and benefits, (2) interactions between HCPs and patients, (3) challenges and difficulties with eHealth tools, (4) integration into the daily workflow, and (5) future directions. Table 2 shows the subcategories, categories, subthemes, and themes that emerged after coding.

The overarching theme highlighted the study's central focus on the HCPs' perspectives on the use and integration of eHealth tools in their daily practice. It emphasized how these tools impact the dynamics of health care delivery, including their influence on the relationships between HCPs and patients, and how they shape the overall patient care experience.

Table 2. Overview of the *optimizing health care with electronic health: enhancing care delivery and overcoming challenges for future health care* theme, subthemes, categories, and subcategories.

Subtheme and categories	Subcategories
Enhancing care delivery, collaboration, and overcoming adoption barriers	
Positive experiences and benefits	• Efficiency • Better documentation and enhanced patient safety
Interactions between HCPs[a] and patients	• Unaffected HCP-patient relationships • Enhanced patient engagement • Communication barrier
Challenges and difficulties with eHealth tools	• Technical and resource challenges • Patient-related factors
Streamlining implementation and advancing eHealth tools for future health care delivery	
Integration into the daily workflow	• Ease of use • System integration and application
Future directions	• Staff recommendations • Continuity of use

[a]HCP: health care professional.

Enhancing Care Delivery, Collaboration, and Overcoming Adoption Barriers

Positive Experiences and Benefits

The participants highlighted several benefits of using the mobile documentation tool. One significant advantage was the decreased documentation time during patient consultations. The mobile tool allows HCPs to document directly during patient encounters, which increase *efficiency* by eliminating the need for double documentation [30] and reducing the time spent on paperwork. Approximately two-thirds (13/20, 65%) of the HCPs indicated that the mobile documentation tool helped them save time on documentation:

> *I think it [the mobile documentation tool] decreases my work time [taking clinical notes during consultation].* [Nurse 6]

> *It saves me time because I document while I am at the patient's house.* [Nurse 9]

Another benefit mentioned was the standardization of content for clinical note-taking. The use of standardized templates within the mobile tool ensured that all relevant information was captured consistently, which is crucial for effective patient care. Participants also expressed an enhanced sense of safety and security for patients when using the mobile documentation tool. This improvement was attributed to more accurate and timely documentation of health status, which contributed to better patient outcomes. The time saved through efficient documentation potentially translated to improved patient care quality. With reduced administrative burden, HCPs could devote more time to meaningful patient interactions, allowing more in-depth discussions about health concerns and treatment plans.

While most (13/20, 65%) participants perceived the mobile documentation tool as beneficial, some noted challenges. A few (7/20, 35%) participants reported that it disrupted their routine workflow by prolonging consultation times. They found that carrying the iPad during home care visits added to their equipment load, making it inconvenient:

> *I think it [the mobile documentation tool] increases my work time. My usual consultation is about 20-30 minutes, with it [the mobile documentation tool], it can take 45-50 minutes. We carry a lot of equipment during home care visits, including a laptop, and it can be heavy. The iPad is an additional weight.* [Nurse 1]

> *Because we cannot do everything we need in the [mobile documentation] tool, it kind of doubles the work for us.* [Nurse 4]

Among users of the mobile preconsultation form, participants highlighted several advantages, including knowing the patient's medical concerns in advance and saving time on preparations. This previsit work done by patients reduced the administrative workload on HCPs, allowing for a more efficient use of consultation time.

Standardizing documentation through the mobile documentation tool and preconsultation form may lead to more consistent and thorough patient assessments across different HCPs. This standardization ensures that all relevant information is captured systematically, potentially improving the continuity of care and reducing the risk of overlooking critical patient data.

The use of eHealth tools in advanced home care led to *better documentation practices while enhancing patient safety*. The majority (13/20, 65%) of the participants found the standardized content of the mobile documentation tool beneficial, noting that it ensured they would not overlook critical information:

> *It is kind of nice that the [mobile documentation] tool has a lot of information that can help with taking notes. Also, the setup is the same for everyone, so I think the note-taking is sort of standardized.* [Nurse 1]

This standardized approach to documentation not only improved consistency across different HCPs but also potentially enhanced the quality of patient care. By ensuring comprehensive data collection, the tool might lead to more informed clinical decision-making and improved continuity of care. The structured format guided HCPs through specific assessment points, helping to ensure that all relevant aspects of patient care were addressed during consultations. Improved documentation through eHealth tools contributed to patient safety and security. Participants noted that accurate information recorded in EHRs reassures patients, helping them feel more secure in their care:

> *When we use [the mobile documentation tool], we can check the necessary things we have to ask the patient. We will not forget anything because we have a guide, I think that is good for the patient...it can increase patient security.* [Nurse 13]

> *I think they [patients] feel safer when I can write everything in the [mobile documentation] tool while I am with them, and they can check what I write.* [Nurse 8]

The ability for patients to review clinical notes during consultations further enhanced their confidence, fostering a sense of transparency in the health care process and further strengthening the relationship. This aligned with the principle of "equal care" in Sweden, which emphasizes the importance of providing consistent quality care to all patients, regardless of their location or the HCPs they encounter [31].

By standardizing documentation practices, eHealth tools contributed to this principle by ensuring that all relevant patient information is consistently captured and accessible to different HCPs. This standardization not only improved continuity of care but also enhanced trust between patients and HCPs. The structured format of the mobile documentation tool facilitated comprehensive data collection, allowing HCPs to focus on critical issues during consultations. This approach optimized patient interactions and strengthened the overall quality of care provided, aligning with Sweden's commitment to equitable health care access.

Interactions Between HCPs and Patients

All (20/20, 100%) participants indicated that their *relationship with patients remained unaffected* by the implementation of both the mobile documentation tool and the mobile preconsultation form. This finding suggested that HCPs were able to maintain their interpersonal skills and patient-centered approach while integrating eHealth tools into their practice:

> *I think nothing has changed in how I interact with patients when using it [the mobile documentation tool].* [Nurse 5]

The consistency in relationships despite introducing new technology highlighted the adaptability of HCPs in maintaining effective communication with patients. While the eHealth tools introduced new elements to patient interactions, such as the physical presence of devices, HCPs appeared to successfully navigate these changes without compromising the quality of their patient relationships. Furthermore, the mobile preconsultation form may have enhanced patient engagement by allowing patients to provide more comprehensive information before consultations. This previsit work could potentially lead to more focused and in-depth discussions during face-to-face interactions, without negatively impacting the HCP-patient relationship.

The mobile preconsultation form emerged as a tool that potentially *enhances patient engagement* in their care. Some (3/12, 25%) participants noted that certain patients provided more comprehensive information through written responses on the mobile preconsultation form than during face-to-face interactions with the HCPs. This suggested that the tool may lead to more informed and collaborative interactions during consultations:

> *If you send out the form, I think you can get more information from the patients because they [patients] have more time to think about it rather than when we ask them in person.* [Nurse 7]

The previsit work done by patients allowed them to elaborate on both current problems and positive aspects of their health status. This more comprehensive written information might shift the dynamics of face-to-face interactions, potentially allowing more focused and in-depth discussions during consultations. Furthermore, the mobile preconsultation form's ability to highlight patients' medical concerns in advance

enabled HCPs to prepare more effectively for consultations. This preparation may contribute to more efficient and patient-centered interactions, as evidenced by one participant's comment:

> *We send out the form once every four weeks for when we do the team rounds, it can help us in doing the team rounds, making it faster and more efficient, in my experience.* [Nurse 5]

By facilitating more comprehensive information gathering and allowing HCPs to focus on critical issues, the mobile preconsultation form may enhance patient engagement and potentially improve the quality of HCP-patient interactions in advanced home care settings.

Participants mentioned *communication barrier* as a challenge. While the eHealth tools offered numerous benefits, 20% (4/20) of the participants observed noted challenges in their use during patient interactions. These HCPs noted that the iPad (mobile documentation tool) could sometimes be a barrier to effective communication:

> *When I am holding the iPad in front of the patient, it kind of becomes a barrier between us.* [Nurse 6]

> *When using the iPad, you tend to look down instead of looking at the patient directly.* [Nurse 9]

> *Maybe some patients find it rude [using an iPad during consultation], but most of them understand that we do it to get everything right. Also, I think sometimes I have a less open conversation with patients.* [Nurse 10]

Most (16/20, 80%) participants did not report communication issues, suggesting that the majority of HCPs were able to integrate the eHealth tools without significant impact on patient interactions. Compared to traditional pen-and-paper methods, the eHealth tool presented both advantages and challenges for patient-HCP communication. While pen-and-paper notes may feel less intrusive during patient interactions, the eHealth tool offers improved legibility, standardization, and ease of data retrieval, potentially enhancing the quality of information shared with patients. However, the physical presence of the device could create a perceived barrier for some HCPs and patients. The eHealth tool's structured format ensures comprehensive documentation, potentially reducing the risk of omitting crucial information compared to freeform paper notes. This standardization may lead to more consistent and thorough patient assessments across different HCPs, indirectly benefiting patient care and communication. However, this structure might sometimes limit the flexibility in capturing nuanced patient narratives.

Regarding focus on issues and medical decision-making, the eHealth tool's ability to provide instant access to patient history and standardized assessments can potentially enhance HCP's ability to focus on critical issues during patient interactions. However, as noted by some participants, the tool might occasionally divert attention from direct patient interaction. These observations highlighted the need for balanced use of eHealth tools, combining their benefits with maintaining effective patient communication. HCPs may need to develop strategies to integrate these tools seamlessly into their patient interactions, ensuring that technology enhances rather than hinders the HCP-patient relationship.

Challenges and Difficulties With the eHealth Tools

While most (14/20, 70%) participants reported no technical issues, some HCPs encountered *technical and resource challenges* when using eHealth tools in advanced home care. Specifically, 30% (6/20) of the participants faced technical problems with the mobile documentation tool, including log-in difficulties, frequent software updates, and issues importing clinical notes to the patient's EHR:

> *First, when you come in to work, you have to log in to the [mobile documentation tool]. Sometimes, it's a problem. Now, with the frequent updates—they do updates like every week—there is often something wrong after each update...* [Nurse 3]

Notably, 100% (12/12) of the participants who used the mobile preconsultation form reported no technical issues at all. Resource limitations were a more widespread concern. All (20/20, 100%) participants noted the need to share iPads among staff members, potentially limiting access and flexibility in documentation:

> *The staff has to share iPads [with the mobile documentation tool] within the team.* [Nurse 9]

These challenges highlighted the importance of robust IT infrastructure and adequate resource allocation in eHealth implementation. While technical issues affected only a minority (6/20, 30%) of users, device sharing impacted all (20/20, 100%) participants, potentially influencing HCP efficiency and, consequently, patient care quality.

Patient-related factors, such as patient characteristics, influenced the adoption and use of eHealth tools in advanced home care. Approximately 55% (11/20) of the participants noted that the patient's age and health conditions affected receptiveness to eHealth tools, particularly the mobile preconsultation form:

> *Not all patients are open to using the [mobile preconsultation] form. Usually, older patients or those with difficult diseases are not open to it.* [Nurse 12]

HCPs demonstrated adaptability by adjusting their approach based on patient characteristics. This flexibility was crucial for maintaining quality care across diverse patient populations. However, it also raised concerns about potential disparities in care delivery between technologically proficient patients and those less comfortable with eHealth tools. Some patients expressed skepticism about using the mobile preconsultation form, particularly due to privacy concerns:

> *There are patients who are skeptical about using it [the mobile preconsultation form], as it involves using their [personal information] BankID [a Swedish electronic identification system].* [Nurse 11]

On the other hand, a subset of patients, predominantly younger individuals, demonstrated an openness to using eHealth tools, according to 55% (11/20) of the participants. This varying receptiveness highlighted the need for a personalized approach in implementing eHealth tools in advanced home care settings,

ensuring that all patients receive appropriate care regardless of their technological proficiency.

Streamlining Implementation and Advancing eHealth Tools for Future Health Care Delivery

Integration Into the Daily Workflow

Regarding *ease of use*, 75% (15/20) of the participants found the mobile documentation tool easy to use. The initial introduction and demonstration of these eHealth tools to HCPs lasted an hour and was perceived as sufficient by all the 12 (12/12, 100%) participants who received it. Some (4/20, 20%) participants had the opportunity to familiarize themselves with the tool beforehand as part of the implementation team, while 12 (12/20, 60%) participants received information during introductory seminars at their clinics. Some (4/20, 20%) participants only underwent introductory training after using the mobile documentation tool:

> *I have tried it [the mobile documentation tool], honestly, without any training... I tried to use it... I think it is easy.* [Assistant Nurse 2]

> *My colleague taught me how to use it [the mobile documentation tool].* [Nurse 8]

In addition, 25% (5/20) of the participants reported that the log-in process and navigating through all the components of the mobile documentation tool required some time to become familiar with, but they gradually improved with more use:

> *As I continue to use it [the mobile documentation tool], I learn more about it, which makes me better at using it.* [Nurse 2]

Regarding *system integration and adaption* all (20/20, 100%) participants highlighted challenges in integrating eHealth tools into existing systems and their practical *application* in advanced home care. A key limitation was the incomplete integration of the mobile documentation tool with the existing EHR system, TakeCare. While clinical notes could be uploaded to the patient's journal, other crucial data remained inaccessible through the mobile tool, requiring staff to rely on computers for a complete view of patient information:

> *It [the mobile documentation tool] doesn't have all the functions that you have in the EHR.* [Nurse 7]

> *[B]ecause with the computer, I can do and see everything on the patient's EHR, but not with the iPad.* [Nurse 4]

The lack of full system integration disrupted seamless workflows and raised concerns about potential inconsistencies in documentation and delays in accessing critical information during consultations. Participants expressed a strong desire for improved interoperability to ensure that all necessary data are accessible on the mobile device.

Regarding practical application, HCPs generally found the mobile preconsultation form useful for integrating into their existing workflows. However, its applicability was perceived as limited for certain patient groups and care scenarios. For example, HCPs noted that sending the form before every consultation was unnecessary for patients with chronic conditions requiring long-term care as their primary clinical concerns often remained consistent:

> *For example, I have had this patient for a very long time, and the patient has a chronic condition. I don't need to send the form [before] every visit because the status is still the same.* [Nurse 11]

Despite these limitations, participants acknowledged the value of the preconsultation form for new patients or those with changing health conditions. It allowed HCPs to gather detailed information in advance, facilitating more focused consultations. These findings underscored the importance of improving system integration to enhance workflow efficiency while adapting eHealth tools to meet diverse patient needs in advanced home care settings.

Future Directions

HCPs shared *recommendations* on enhancing the effectiveness of the eHealth tools in their daily workflow in advanced home care. Most (16/20, 80%) participants expressed that completely integrating the mobile documentation tool with the patient's EHR system would improve efficiency. They suggested that accessing the same information as in the patient's EHR directly on the mobile device would eliminate the need to switch between the iPad and the computer for clinical documentation, improving their workflow:

> *Lab results and checking off the to-do list, that is what is still missing, I think...and an easier login.* [Nurse 9]

All (12/12, 100%) HCPs who used the mobile preconsultation form found it adequate. However, 17% (2/12) of the participants suggested further enhancements to the interface, including languages other than Swedish:

> *The [mobile preconsultation] form does not look very good, in my opinion. It can be better.* [Nurse 11]

Regarding equipment use, half (10/20, 50%) of the participants expressed that having sufficient iPads for all staff members would be advantageous, reducing the need for frequent logging in and out.

Approximately two-thirds (14/20, 70%) of participants anticipated *continuity of use* of the 2 eHealth tools in advanced home care, acknowledging the emergence of the new technologies. In addition, 45% (9/20) of the HCPs expressed optimism regarding the increased patient acceptance of technology in health care:

> *I think they [patients] will use them [eHealth tools] more and more in the future.* [Nurse 7]

Discussion

Principal Findings

The aim of this study was to explore HCPs' perspectives on using eHealth tools in advanced home care and their impact on HCP-patient relationships. In total, 20 HCPs from 9 different advanced home care clinics participated in the interviews, leading to the identification of five categories: (1) positive experiences and benefits, (2) interactions between HCPs and

patients, (3) challenges and difficulties with the eHealth tool, (4) integration into the daily workflow, and (5) future directions.

Overall, most (13/20, 65%) HCPs expressed a positive perspective regarding the 2 eHealth tools used in the study: the mobile documentation tool and the mobile preconsultation form. The results showed that HCPs identified several benefits for themselves and their patients. Notably, 65% (13/20) of the participants reported that the mobile documentation tool allowed them to document directly during patient encounters, eliminating double documentation and saving time. Standardized templates within the tool ensured consistency in clinical note-taking, which participants believed enhanced patient safety by reducing errors and omissions.

While most (13/20, 65%) HCPs reported increased efficiency, 35% (7/20) experienced the opposite, suggesting that user acceptance of eHealth is multifaceted. These participants reported that the mobile documentation tool disrupted their routine workflow by prolonging consultation times and adding to their equipment load during home care visits. This highlights the importance of considering individual user experiences in eHealth implementation. The ease of use of the eHealth tools was a significant factor in their integration into daily workflows. Most (15/20, 75%) of the participants found the mobile documentation tool easy to use, indicating successful integration. This high level of usability likely contributed to the overall positive reception of the tools and suggested that well-designed eHealth solutions can be effectively adopted in advanced home care settings.

However, HCPs noted challenges, both tool-related and patient-related. Some (6/20, 30%) of the participants faced technical problems with the mobile documentation tool, including log-in difficulties and issues importing clinical notes to the EHR. These technical challenges highlight the need for robust IT infrastructure and ongoing technical support in eHealth implementation. Resource limitations were a widespread concern, with all participants noting the need to share iPads among staff members. This sharing potentially limits access and flexibility in documentation, impacting workflow efficiency. Future eHealth implementations should consider resource allocation to ensure adequate device availability for all HCPs.

Patient characteristics influenced the adoption of eHealth tools, particularly the mobile preconsultation form. Approximately 55% (11/20) of the participants noted that patient age and health conditions affected receptiveness to these tools. This finding underscores the importance of tailoring eHealth implementations to diverse patient populations and considering alternative approaches for patients less comfortable with technology. The mobile preconsultation form emerged as a tool that potentially enhances patient engagement. Some (3/12, 25%) of the participants using this tool noted that certain patients provide more comprehensive information through written responses than face-to-face interactions with HCPs. This previsit work allows for more focused and efficient consultations, potentially improving the quality of HCP-patient interactions.

Regarding the HCP-patient relationship, all (20/20, 100%) participants reported that the use of eHealth tools had no significant impact on the relationship with patients. This suggests that HCPs successfully maintained their interpersonal skills and patient-centered approach despite introducing new technology. However, 20% (4/20) of the participants noted that using devices such as iPads could occasionally act as a communication barrier during consultations, highlighting the need for strategies to seamlessly integrate technology into patient interactions.

Looking to the future, 70% (14/20) of the participants anticipated continued use of the eHealth tools in advanced home care, reflecting their perceived long-term value despite existing challenges. In addition, 45% (9/20) of the HCPs expressed optimism about increased patient acceptance of technology in health care. While participants did not report changes in HCP-patient interactions, they emphasized that current eHealth tools successfully maintain existing relationships without negatively impacting communication or rapport.

Comparison With Prior Work

Mathijssen et al [32] highlighted a similar finding of positive perception of eHealth by HCPs in home care. Despite recognized challenges such as inadequate training and support, data privacy concerns, and the necessity for more user-friendly technology, eHealth in home care is seen as a promise to enhance care quality. A study focusing on a specific eHealth tool, electronic medication administration records, emphasized the importance of cautious implementation due to potential unintended consequences [33]. Participants noted that the electronic medication administration records introduced new tasks alongside existing nursing tasks. In contrast, our study found no perceived changes in the workflow or work situation due to eHealth tools, potentially contributing to their overall positive reception.

Carlqvist et al [34] conducted a qualitative interview study examining how an eHealth application can serve as a value-creating resource from the perspective of HCPs. Their findings indicated that while such applications can enhance proactive communication and support patient engagement in self-care, challenges remain. Notably, patients' difficulties in using the application or performing measurements sometimes led to value destruction, requiring time-consuming recovery efforts by professionals. This contrasts with our study, where HCPs reported no significant workflow disruptions due to eHealth tools, potentially contributing to their positive acceptance.

Nakrem et al [35] explored the introduction of digital medicine dispensers in home health care services and their influence on patient-caregiver relationships. They found that while such technologies can improve efficiency and enhance patient independence, they may also strain patient-caregiver relationships if not aligned with patients' needs and safety concerns. However, in our study, HCPs did not perceive eHealth tools as affecting their relationships with patients, suggesting that the specific type of technology and its implementation context play crucial roles in acceptance and impact.

Furthermore, Ramachandran et al [36] conducted a review examining the impact of eHealth on patient-HCP and HCP-HCP relationships in primary care. They found that eHealth can have

both positive and negative effects on relationships and trust, influenced by factors, such as technology design, patient demographics, and organizational implementation strategies. This aligns with our findings, where the successful integration of eHealth tools without perceived workflow disruptions may be attributed to effective implementation strategies and user-centered design.

Future Research

Future studies could explore strategies for seamlessly integrating eHealth tools into patient interactions without compromising communication quality. In addition, research into personalized eHealth solutions that accommodate diverse patient needs and preferences could address challenges related to patient characteristics. Investigating the long-term impacts of eHealth tools on care quality, patient outcomes, HCP-patient relationships, and HCP job satisfaction would provide valuable insights for future implementations.

Another important area for investigation is the development and implementation of features that actively enhance HCP-patient relationships in advanced home care environments. For instance, improving patient education modules or creating shared decision-making tools tailored to home care settings could address some of the gaps identified in this study, such as maintaining meaningful interactions while using eHealth tools.

Furthermore, exploring the role of relatives in supporting patients with eHealth tools could offer new avenues for enhancing patient engagement and care delivery [37]. Relatives could assist with completing preconsultation forms or managing digital tools for patients who face challenges due to age or health conditions. Recognizing relatives as key stakeholders alongside HCPs may improve overall patient support in advanced home care settings [38].

Limitations

This study focused specifically on advanced home care settings in Sweden, which may limit the applicability of findings to other health care contexts. The unique characteristics of advanced home care, such as the need for mobile documentation and remote patient monitoring, shaped the experiences reported by HCPs. In addition, the exclusive focus on HCPs' interviews represents another limitation. Incorporating patients' perspectives could offer valuable insights and contribute to a more comprehensive understanding of the implementation of eHealth tools in advanced home care.

Conclusions

HCPs in advanced home care recognize the value of eHealth tools in their daily work while maintaining the quality of their relationships with patients. The study provides insights into both the experiences of HCPs using eHealth tools and how these tools influence their interactions with patients in advanced home care settings. Positive experiences related to eHealth use and the level of integration of eHealth tools into daily work motivate staff to use these tools, potentially allowing for more time and focus on patient interactions. By contrast, negative experiences with the eHealth tools limit their use and acceptance.

Notably, HCPs reported no perceived changes in their relationships with patients when using the mobile documentation tool and the preconsultation form tool. This suggests that eHealth tools can be integrated into care delivery without compromising the personal aspect of HCP-patient interactions. Although most of the staff in the study had a positive view of their use of the eHealth tools, understanding the challenges they encounter is essential to increase acceptance and success in implementation further. Future development should focus on features that not only improve efficiency but also actively enhance HCP-patient relationships in the advanced home care setting.

Acknowledgments

The authors would like to thank all the health care staff members who participated in this study for their time and valuable insights. Artificial intelligence was used for writing assistance. ND was funded by the Health Informatics Center at Karolinska Institutet. The funding did not influence the study's design, data collection, analysis, or manuscript writing.

Authors' Contributions

EVR, ND, and UL participated in the study design. Data collection was conducted by EVR. EVR performed the initial analysis, which was then reviewed and refined through discussions with ND. The first draft of the manuscript was prepared by EVR, with all authors contributing to subsequent writing and review processes.

Conflicts of Interest

During this study, UL was employed by the medical technology company providing the eHealth tool. Therefore, UL did not participate in the data collection, analysis, and manuscript writing of the study and was limited to the initial part of the design phase and preparing and reviewing the manuscript.

Abstract

Background: Current health care education methods in Pakistan use traditional media (eg, television and radio), community health workers, and printed materials, which often fall short of reach and engagement among most of the population. The health care sector in Pakistan has not yet used social media effectively to raise awareness and provide education about diseases. Research on the impact social media can have on health care education in Pakistan may expand current efforts, engage a wider audience, and reduce the disease burden on health care facilities.

Objective: This study aims to evaluate the perceptions of health care professionals and paramedic staff regarding social media use to raise awareness and educate people about diseases as a potential means of reducing the disease burden in Pakistan.

Methods: The study used two-stage structural equation modeling (SEM). Data analysis used AMOS 26.0 software, adopting scales from previous literature. Four-item scales for each social media usefulness and health awareness construct and 8-item scales for health care education constructs were adopted on the basis of their higher loading in alignment with psychometric literature. A 7-point Likert scale was used to measure each item. Data collection used convenience sampling, with questionnaires distributed to more than 450 health care professionals and paramedic staff from 2 private hospitals in Lahore, Pakistan. There were 389 useful responses received. However, 340 completed questionnaires were included in the data analysis.

Results: The study found that all the squared multiple correlation (SMC) values were greater than 0.30. Furthermore, convergent validity was measured using (1) standardized factor loading (found greater than 0.5), (2) average variance explained (found greater than 0.5), and (3) composite reliability (found greater than 0.7). The confirmatory factor analysis (CFA) of the measurement model indicated the fitness of the constructs (Chi-square minimum [CMIN]=357.62; CMIN/degrees of freedom [DF]=1.80; Goodness of Fit [GFI]=0.90; Adjusted Goodness of Fit Index [AGFI]=0.89; Buntler-Bonett Normed Fit Index [NFI]=0:915; Comparative Fit Index [CFI]=0:93; Root Mean Square Residual [RMR]=0:075; Root Mean Square Error of Approximation [RMSEA]=0:055). Moreover, the structural model fitness was also confirmed (CMIN=488.6; CMIN/DF=1.85; GFI=0.861; AGFI=0.893; NFI=0.987; CFI=0.945; RMR=0:079; RMSEA=0.053). Hence, the results indicated that social media usefulness has a positive and significant effect on health awareness (hypothesis 1: β=.669, *P*<.001), and health awareness has a positive and significant effect on health care education in Pakistan (hypothesis 2: β=.557, *P*<.001).

Conclusions: This study concludes that health care professionals and paramedic staff in private hospitals support the use of social media to raise awareness and provide health care education. It is considered an effective tool for reducing the disease burden in Pakistan. The study results also revealed that young health care professionals are more inclined toward social media usage and express the need for legislation to support it and establish a monitoring process to avoid misinformation.

Introduction

Background

In Pakistan, the health care system is resource-strapped, leading to challenges in preventing infectious diseases. The country has a high maternal mortality rate (186 deaths per 100,000 live births) and a high infant mortality rate (56 deaths per 1000 live births) [1]. Many complications arise from a lack of awareness and education about prenatal care, safe delivery practices, and postnatal care [2]. Moreover, poor understanding of nutrition has led to widespread malnutrition among children and pregnant

women in Pakistan [1,2]. Malnutrition in children leads to stunted growth, weakened immunity, and impaired cognitive development [2]. The prevalence of stunting in Pakistan is among the highest in the world, affecting approximately 38% of children under 5 years of age [3].

In this context, health awareness and education campaigns potentially lead to behavioral changes and alleviate the burden on health facilities [4]. Public health campaigns, particularly those focused on preventive measures like vaccination, hygiene, and lifestyle changes, have substantially reduced the incidence of various diseases [3,5]. For example, handwashing campaigns alone have reduced respiratory infections by up to 23% [6]. Awareness campaigns aimed at managing chronic conditions, such as diabetes and hypertension, through education on medication adherence and lifestyle modifications have reduced complications and hospital visits [7]. These interventions have been shown to improve health outcomes and reduce health care costs by up to 25% [8].

Among various tools and health interventions, social media has attained the most global attention to enhance health awareness and education to a wider population and discovered its significant impact in addressing health care issues [9,10]. According to social media statistics, social media users worldwide reached 5.04 billion in January 2024, representing 63% of the world's population, with users growing 6% annually [11]. On average, social media users spend 2 hours and 23 minutes daily on social media platforms and see various content [11,12]. Social media tools, such as Facebook (Meta), TikTok (ByteDance), Twitter (subsequently rebranded as X), Instagram (Meta), and YouTube (Google), facilitate health care professionals in educating and influencing perceptions, including networking, sharing ideas, disseminating information, demonstrating, coaching, consulting, and advertising [12,13]. Existing literature in the health care sector has exhibited the transformative potential of social media and its usefulness in spreading health awareness and education [9,10,12,13].

However, the existing literature lacks comprehensive insights into the role of social media in fostering health awareness and education within developing countries, particularly Pakistan. This study addresses this gap by applying Innovation Diffusion Theory to examine the mediating effect of health awareness and empirically testing the impact of social media on health care education among health care professionals.

Therefore, the primary objective of this study is to investigate the role of social media in enhancing health awareness and its subsequent impact on health care education in Pakistan. By addressing the gap in the literature concerning the adoption of social media for health care communication in developing countries, this research aims to provide empirical evidence and practical insights for leveraging digital platforms to improve health outcomes.

This section comprehensively reviews existing literature on social media usefulness, health awareness, health care education, and health care sector challenges in Pakistan.

Social Media Usefulness

The global adoption of social media platforms has led to scalable public health interventions, increased precision and effectiveness, and improved resource mobilization [14]. Social media has encouraged healthy behaviors and enabled informed choices through sharing tips, challenges, and success stories [9]. Health care professionals can provide accurate, evidence-based information as trusted sources [11]. Their involvement is vital due to their expertise, credibility, and ability to reach a wide audience. Campaigns through social media on vaccination, hygiene practices, mental health awareness, and other preventive measures have been helpful in countries like Germany and France [9,10].

Moreover, social media has been effectively used to combat the pandemic and other diseases during the COVID-19 pandemic [15]. The social media data were instrumental in tracking the spread of the COVID-19 virus and disseminating accurate information [16]. Campaigns on platforms such as Facebook and Twitter have been used to promote vaccination, leading to increased uptake in various regions [12]. Tailored messaging on HIV prevention for at-risk populations has shown to be more effective than generalized campaigns [13]. Moreover, existing literature has shown examples of successful public health campaigns, such as:

1. #SmearForSmear Campaign: this social media campaign aimed to raise awareness about cervical cancer screening and successfully increase screening rates by leveraging the reach of platforms such as Twitter and Instagram [17].
2. Truth Initiative: an antismoking campaign that effectively used social media to reduce teen smoking rates through engaging content and interactive platforms [18].

Health Awareness

Health awareness is termed as "Enhancing the ability of individuals to understand and use health information to make informed decisions about their health" [13]. Efforts for health awareness are varied and multifaceted, encompassing a wide range of activities aimed at educating the public about health issues, promoting healthy behaviors, and preventing diseases [16]. Health awareness campaigns lead to early detection and timely intervention, which benefits individuals by lowering their health care expenses and reducing the financial burden on the health care system [18]. Health awareness is generally performed using mass media, social media, posters, billboards, workshops, seminars, local outreach programs, influencers, and public figures [12]. However, social media is most useful in the current era due to its cost-effectiveness and wider audience engagement [17]. Social media allows targeted messaging based on demographics, interests, and online behavior [19]. This ensures that health messages reach the people most likely to benefit from them. Moreover, the effectiveness of health awareness through social media can be measured in a few easy ways, such as the number of impressions, likes, shares, comments, hashtag usage, and so on [18,19]. Hence, medical professionals can analyze the efficacy of their awareness messages. There have been several successful health awareness campaigns conducted through social media that have achieved significant outcomes (Textbox 1).

Textbox 1. Health care awareness campaigns.

- **ThisGirlCan (2015)**
  - Objective: Encourage women of all ages and backgrounds to be more physically active, regardless of their shape, size, or fitness level [20].
  - Execution: The campaign featured real women participating in various physical activities, promoting the message that women should feel confident about being active regardless of societal pressures or body image concerns.
  - Platforms used: Instagram, Twitter, Facebook, and YouTube.
  - Outcomes:
    - Widespread engagement: The hashtag #ThisGirlCan was used millions of times, with significant engagement from women sharing their own stories and photos.
    - Behavioral change: The campaign was credited with encouraging over 2.8 million women in the United Kingdom to become more active.
    - Long-term impact: The campaign continued beyond its initial phase, evolving into a broader movement that still influences public attitudes towards women and fitness.
- **#BellLetsTalk (Ongoing)**
  - Objective: Raise awareness about mental health issues and reduce stigma around mental illness in Canada [21].
  - Execution: For every tweet using the hashtag #BellLetsTalk, every text message sent by Bell customers, and every Facebook video view, Bell Canada donates 5 cents to mental health initiatives.
  - Platforms used: Twitter, Facebook, Instagram, and Snapchat.
  - Outcomes:
    - Record participation: The 2021 campaign saw 159 million interactions, raising nearly CAD $8 million (equivalent US $5.56 million) in a single day.
    - Sustained impact: Since its inception, the campaign has raised more than CAD $121 million (equivalent US $84.5 million) for mental health initiatives.
    - Increased conversations: The campaign has significantly increased public dialogue about mental health in Canada, contributing to reducing stigma and promoting mental wellness.

Health Care Education

Health care education refers to a deeper understanding of specific health topics, including the causes, symptoms, prevention, and treatment of diseases and how to maintain or improve health [20]. It involves having factual information and comprehension of health-related subjects [17]. Health care education encourages regular check-ups, screenings, and vaccinations, leading to early detection of diseases and more effective prevention strategies [19]. For those with chronic conditions such as diabetes, hypertension, or asthma, health care education is essential for managing symptoms, adhering to treatment plans, and avoiding complications [13].

In resource-limited economies, insufficient health care education has been reported among the population, which impedes individuals' ability to understand, access, and apply health information effectively [21]. Moreover, low-income individuals may have less access to health resources, education, and information, which hinders their ability to acquire and apply health education [22]. Addressing these barriers in resource-limited countries requires targeted strategies such as improving health literacy, offering culturally sensitive health care education, increasing access to technology, and combating misinformation [21].

Among these targeted strategies, social media has gained the most attention in the high-income world [20]. Health care education through social media has become an increasingly effective method for reaching diverse audiences with health information. Studies suggest that health care education campaigns on social media can achieve behavioral change success rates ranging from 20% to 40% [16,17]. For instance, social media campaigns promoting COVID-19 vaccination have seen varying success, with some countries reporting a 15% to 25% increase in vaccine uptake attributable to social media efforts [15]. Moreover, some campaigns that promote health services (eg, vaccination drives or mental health counseling) report conversion rates (actual service uptake) of 5% to 20%, depending on the call to action and the ease of access to the service [18]. The existing literature has discussed a few notable health care education campaigns executed through social media and validated their impact. One such campaign for spreading health care education is The Amyotropic Lateral sclerosis (ALS) Ice Bucket Challenge (Textbox 2).

Textbox 2. Health care education campaigns through social media.

1. The ALS Ice Bucket Challenge (2014)

- Overview: Participants dumped buckets of ice water over their heads, shared videos on social media, and nominated others to do the same, all to raise awareness and funds for Amyotrophic Lateral Sclerosis (ALS) research [23].
- Impact:
  - Financial: Raised over US $115 million for the ALS Association in just a few months.
  - Awareness: Dramatically increased global awareness of ALS, with millions participating worldwide.
  - Research Advancement: Funds contributed to significant research advancements, including the discovery of new ALS genes.

Pakistan Context

In Pakistan, the Federal and provincial governments jointly administer 60% of the health care system, with the private sector contributing 30%. Autonomous bodies support the remaining 10 percent [24]. The diverse structure and the country's economic challenges pose unique obstacles to effective health care delivery. The country's health care spending is at 2.95% of its Gross Domestic Product, and the Pakistani government always disregarded the economic survey data and faced criticism from the apex medical organization as it necessitated health allocations in line with global guidelines [25]. To provide quality health care, the Pakistan Medical Association (PMA) expressed the need for 6% of the country's Gross Domestic Product allocation, as recommended by the World Health Organization [17], which the country is unable to meet due to economic challenges [26].

Due to these financial limitations, there are reported disparities in health awareness, with urban areas generally having better access than rural regions [2]. Thus, communicable diseases, such as waterborne diseases and vector-borne diseases, remain a more significant concern in rural regions [1,3]. Moreover, with limited access to maternal health care and family planning services, Pakistan witnesses high maternal and child mortality rates [2]. Diseases such as malaria, tuberculosis, and hepatitis are prevalent, which exacerbates the situation [24]. Moreover, stigma about sexually transmitted infections results in inadequate prevention and treatment efforts that result in a psychological attack on patients [25]. Poor sanitation and hygiene contribute to outbreaks of diseases like cholera and dysentery in Pakistan and many preventable diseases, such as polio and measles, persist due to low vaccination rates [23].

Amid financial crises, health care awareness and education are known to be effective in reducing the disease burden rate [8]. There are several traditional efforts made by the Government of Pakistan Ministry of Health in the past to improve disease awareness and reduce the patient burden [24]. These include the following:

1. Engaging community health workers in disseminating health information, especially in rural areas. However, the number of community health workers to cover the target population is very limited and requires substantial spending [24].
2. Use of radio and television for health awareness programs, public service announcements, and talk shows but requires financial resources [27].
3. Newspapers, magazines, and pamphlets are also used to spread health information, but considering the low literacy rate and cost of print media, these are not found to be much effective for the target population [27].

However, among the modern techniques, social media has gained much attention from health care communities globally [7,10]. Pakistan has also witnessed the widespread of social media but in academics, e-commerce, entertainment, media, politics, sports, and religious sectors. In Pakistan, 29.5% of the population is on social media, whereas 77.8% has active mobile connections, meaning these users also have access to social media platforms [28].

The health care sector is structured to depend on government approval for any initiative [29]. The government has not devised any legislation to promote the use of social media for awareness [24,27]. This mainly restricts the government's health departments and health care professionals from using this tool to publicize health messages. Some efforts have been made to digitalize the health care sector using the eHealth concept and implement a few apps to initiate telehealth and telemedicine [30]. Also, mobile messaging and caller voice tunes are found to be significant in health care services awareness [30]. However, the interpretation and usage of social media tools are still scarce [31]. For this reason, it is imperative to investigate the social media usefulness among health care professionals in Pakistan and to identify whether these health care professionals support the use of social media for health awareness and education.

Theoretical Foundation

A few theories explain the behaviors toward acceptance of any new digitalized tool and address their attitude [32], including the innovation diffusion theory proposed by Rogers in 1962, the Theory of Reasoned Action proposed by Fishbein and Ajzen in 1967, the Self-Efficacy Theory proposed by Bandura in 1977, the Theory of Planned Behavior proposed by Ajzen in 1985, the Social Cognitive Theory proposed by Bandura in 1986, and the Technology Acceptance Model proposed by Davis in 1986 [32]. Among these various behavioral theories, the Innovation Diffusion Theory (IDT) offers a framework for understanding how new ideas, behaviors, or innovations spread within a population [33].

In public health, innovation diffusion theory helps explain how new health interventions, practices, or policies are adopted and disseminated within communities [33]. The theory identifies 5

stages individuals and communities pass when adopting an innovation: knowledge, persuasion, decision, implementation, and confirmation [34]. Figure 1 explains these five stages of the innovation-decision process.

To understand social media acceptance for health awareness and education, the theory has categorized individuals within a population into subgroups based on their readiness to adopt innovations. Innovators and early adopters are likely to adopt innovations early, while most of the population follows suit over time. Laggards are the last to adopt [33]. Figure 2 explains these subgroups of individuals.

Figure 1. Innovation diffusion process.

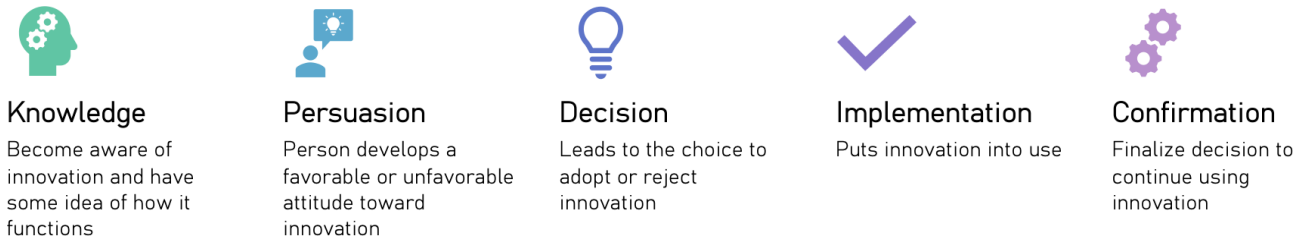

Figure 2. Adopter categories.

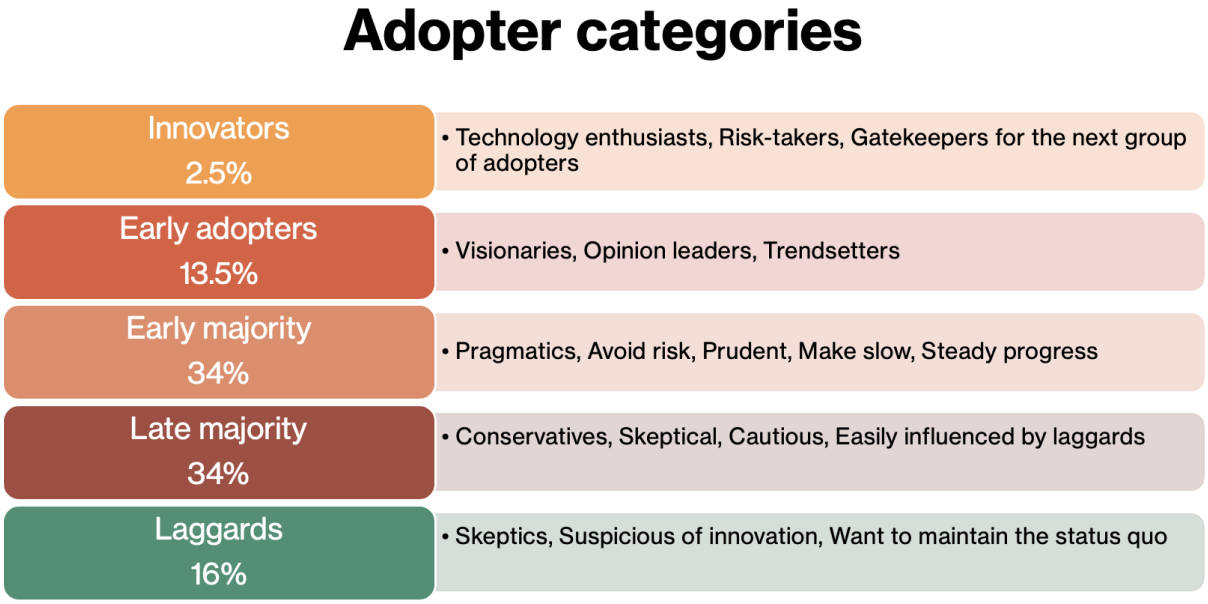

In health care education and awareness, the diffusion of innovation is used to fast-track the acceptance of crucial public health digitalized interventions that ordinarily intend to influence the behavior of a social system [34]. Thus, this theory provides the foundation for understanding social media usage and its adoption attitude in a particular community.

In Pakistan, the ineffective innovation management approaches and deprived diffusion of innovation strategies are hurdles to realizing the importance of social media and its usage for health care education [24,25]. The deprived diffusion of innovation is a significant factor in the inability to attain the desired output. Even for digitalized hospital tools other than social media, the country needs more innovative and user-friendly equipment in the hospital sector [25]. The notion of consistent health care challenges and inadequate health resources in Pakistan is also evident from the recent Joint External Evaluation report [24].

For this reason, it is imperative to investigate the impact of social media's effective use on health awareness and health care education in Pakistan using IDT. This may result in highlighting and understanding the effectiveness of social media tools in reducing the disease burden in the country.

Figure 3 explains the theoretical framework of the current study.

Figure 3. Conceptual framework of the study.

Hence, the current study hypotheses are:

1. Hypothesis 1 (H1): social media usefulness positively and significantly impacts health awareness in Pakistan.
2. Hypothesis 2 (H2): health awareness has a significant positive impact on health care education in Pakistan.

Methods

Instrument Development

A quantitative technique was applied to test the study hypothesis and validate the proposed model using the structural equation modeling (SEM) technique [35]. SEM is deemed the most suitable due to its ability to simultaneously test complex relationships among multiple variables and validate the proposed conceptual model. Data analysis was carried out using AMOS 26.0 software (IBM Corp) [36]. Since the study aims to identify social media's impact on health awareness leading to health care education and uses the IDT as a theoretical foundation, scales from previous literature have been adopted. The main advantage of adopting these scales is that they have already been validated in the health industry's acceptance behavior of new technological tools. For instance, the measurement scale for Innovative Technology (social media) usefulness was adopted from a previous study [37], and measurement scales for health awareness have been adopted from another study [38]. Aligning with the psychometric literature, 4-item scales for each construct based on their higher loadings have been adopted [37]. The modified 8-item scale for measuring health care education was adopted based on the questionnaire of Ho et al [39]. For the measurement of each item, a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree) was used [38].

Data Collection

A questionnaire was designed based on the variables of the present study, utilizing the aforementioned scales, which are provided in Multimedia Appendix 1. A personally administered questionnaire was used for data collection [32]. For data collection, the current research to eliminate targeted health care professionals and paramedic staff of 2 private hospitals in Lahore, Pakistan. The questionnaire was distributed to more than 450 health care professionals and paramedic staff using convenience sampling and requested their valuable feedback. However, only 389 useful responses were received.

Ethical Considerations

As a matter of ethical concerns, prior permission from the hospital management was obtained, and the purpose of the study was explained to all respondents through "informed consent." It was assured that respondents' privacy would be ensured through confidentiality. Ethical approval was not required for this study as it did not involve identifiable personal data, or interventions falling under the scope of institutional or national ethics review requirements. In accordance with the Declaration of Helsinki (World Medical Association, 2013) research ethics policy, studies that do not involve sensitive data are exempt from formal ethics board approval.

Results

Primary Data Screening

Initial screening was carried out among 389 useful responses to eliminate unusual responses, mainly incomplete questionnaires and respondents who marked similar scores on all items. Furthermore, questionnaires with more than 4 missing values were also excluded. The remaining missing values were replaced with the series mean/average for the rest of the responses. Therefore, the final useful sample was reduced to 340.

Table 1 provides the demographics of the study respondents. Among 340 respondents, 58% (197/340) were male, and the rest were female (143/340, 42%). A total of 91% (309/340) of the respondents were between 25 and 35 years of age, which may lead to the fact that most health care professionals and paramedic staff in private hospitals in Lahore are young. However, we may be unable to neglect the 6% of the population under 25 years old and more eager to start their career in the health care sector. The remaining 3% were more than 35 years of age and had extensive health industry work experience.

Table . Sociodemographic characteristics of study respondents (N=340).

Characteristics	Values, n (%)
Sex	
Male	197 (58)
Female	143 (42)
Age (years)	
<25	21 (6)
25-35	309 (91)
>35	10 (3)
Social media experience (years)	
<1	34 (10)
2-5	207 (61)
>5	99 (29)
Monthly income[a]	
Less than PKR[b] 40,000 (US $142.98)	101 (30)
PKR 40,000-80,000 (US $142.98-US $285.97)	197 (58)
More than 80,000 (US $285.97)	42 (12)
Education	
Less than secondary school	63 (18)
Secondary school to graduation	259 (76)
Medical (MBBS[c]/BDS)[d] or Masters degree	18 (6)
Health services experience (years)	
<3	21 (6)
3-6	225 (66)

[c]MBBS: Bachelor of Medicine, Bachelor of Surgery.

[d]BDS: Bachelor of Dental Surgery.

Data Analysis

An exploratory factor analysis was initially performed on the 16 measurement items to confirm the underlying relationships [36]. For sample adequacy, the KMO value (0.850) was greater than the recommended value (0.60), and the significance value of *P*0.001 confirmed the Bartlett test of sphericity, as shown in Table S1 in Multimedia Appendix 2. All those factors were retained for data analysis, with factor loading greater than 0.50 and Eigenvalue greater than 1.0. Hence, this technique provided 3 factors that explained 72.2% of the variance after varimax rotation. Furthermore, scale reliability coefficients were greater than the acceptable value (0.70) [40], and Shapiro-Wilk tests were conducted to check the data normality [40], as shown in Table S2 in Multimedia Appendix 2 . The results of both tests were significant, meaning there was no normality issue in the data.

For further data analysis, a two-stage structural equation modeling (SEM) technique was used [36-38]. This approach allows researchers to evaluate the measurement and structural models separately using two dissimilar subsamples. For this reason, a sample of 340 participants was divided into two parts: a sample of 170 individuals was used for the measurement model, and a similar sample size was used for the structural model assessment to attain impartial results.

Reliability and Validity Measures

According to Hair et al [35], finding the reliability of each item and construct in the research study is essential. Therefore, squared multiple correlation (SMC) was used to find the reliability of each reliability item of each measurement item. SMC represents “the amount of variance explained by an individual indicator/construct of its respective factor and measured by the square of its (indicator’s) standardized factor loading” [40].

Hair [35] indicated that the cutoff value of SMC is 0.30. Hence, it is evident from Table 2 that all the SMC values are greater than 0.30. For measuring the reliability of each variable, the

Cronbach alpha value was used. As suggested in the literature, the cutoff value of Cronbach alpha is 0.70 [36,37]; it is evident from Table 2 that all variables' Cronbach alpha values are more than 0.70. Furthermore, Hair et al [35] also highlighted that for measuring the convergent validity, there are three common approaches: (1) standardized factor loading (0.5 or greater), (2) average variance explained (0.5 or higher), and (3) composite reliability (0.7 or above).

Table . Measurement of reliability and validity.

Constructs and item	Values, mean (SD)	Standardized factor loading	Squared multiple correlation	Composite reliability	Cronbach alpha	Average variance explained
Social media usefulness (SMU)						
SMU1	5.19 (1.65)	0.781	0.607	0.788	0.774	0.589
SMU2	5.33 (1.71)	0.780	0.687			
SMU3	5.01 (1.12)	0.777	0.671			
SMU4	5.05 (1.32)	0.787	0.646			
Health awareness (HA)						
HA1	5.45 (1.56)	0.859	0.677	0.769	0.773	0.592
HA2	5.98 (1.45)	0.874	0.681			
HA3	5.39 (1.43)	0.881	0.675			
HA4	5.51 (1.39)	0.867	0.654			
Health care education (HED)						
HED1	5.23 (1.77)	0.719	0.651	0.783	0.789	0.678
HED2	5.22 (1.74)	0.775	0.629			
HED3	5.60 (1.64)	0.721	0.622			
HED4	5.41 (1.49)	0.739	0.637			
HED5	5.22 (1.15)	0.787	0.663			
HED6	5.11 (1.23)	0.772	0.654			
HED7	5.09 (1.43)	0.759	0.691			
HED8	5.32 (1.59)	0.768	0.609			

Hence, each standardized factor loading was statistically significant (P<.001), and values ranged from 0.719 to 0.881, thus validating adequate convergent validity as shown in Table 2. In addition, the average value explained (AVE) values and construct reliability were also more than their cut-off level of 0.5 and 0.7, respectively, and were statistically significant. Therefore, these measures confirm sufficient convergent validity.

A comparison of shared variance between factors with the average variance explained by individual factors was ensured for measuring the discriminant validity. The diagonal value should be greater than the non-diagonal value to confirm adequate discriminant validity [40]. Hence, results given in Table S3 in Multimedia Appendix 2indicates the correlation matrix of constructs, where non-diagonal elements are correlated among constructs and diagonal elements are the square root of average variance explained (AVE) by that construct and clearly explain that all three constructs differ.

Measurement Model

Using statistical software AMOS 26.0, the measurement model's confirmatory factor analysis (CFA) was performed [40,41]. This provided a passable model fit for the primary measurement model (CMIN=1220.23; CMIN/DF=1.98; GFI=0.72; AGFI=0.80; NFI=0.81; CFI=0.826; RMR=0.089; RMSEA=0.082); however, the number of indicators per item was large; for instance, the number of indicators for health care education were 8. Consequently, 2 items were deleted for further refinement to obtain an adequate model fit through the CFA of the measurement model. This refinement was conducted by deleting items one by one, based on their standardized residual; that is, that item was first deleted, which had a larger error variance than their measurement items. Each item was carefully reviewed before deleting it to ensure that, from a theoretical viewpoint, its error variance also seemed rational. The refinement and assessment process for every construct was first evident by Churchill [41]. Churchill defined this process as; "Though this application may be satisfactory during the early stages of research on a construct, the use of factor analysis in a confirmatory fashion would seem better at later stages." Furthermore, Gerbing and Anderson's [42] study also provided support to Churchill's argument and stated that; "to demonstrate that an explicit evaluation of Unidimensionality is accomplished with a confirmatory factor analysis of the individual measures as specified by a multiple-indicator measurement model. Coefficient alpha is important in assessing reliability but does not assess dimensionality. Although item-total correlations and exploratory factor analysis can provide useful preliminary

analyses, particularly in the absence of a sufficiently detailed theory, they do not directly assess unidimensionality. The reason is that a confirmatory factor analysis assesses the internal consistency and external consistency criteria of unidimensionality implied by the multiple-indicator measurement model.

Hence, this refinement process provided an adequate model fit (CMIN=357.62; the ratio of χ^2 to degree of freedom value (1.80) is remarkably less than its recommended value (5.0). CMIN/DF=1.80; GFI=0.90; AGFI=0.89; NFI=0:915; CFI=0:93; RMR=0:075; RMSEA=0:055) as shown in Table 3.

Table . Structural equation modeling fit indices for the confirmatory factor analysis model.

Fit indices	Cut-off criteria	Results obtained
Absolute fit indices		
Chi-square (*df*)	N/A[a]	357.62 (170)
χ^2/df (CMIN/DF)	<5.00	1.800
Root Mean Square Error of Approximation	<0.06	0.055
Goodness of Fit Index	>0.85	0.900
Adjusted Goodness of Fit Index	>0.85	0.890
Incremental fit indices		
Buntler-Bonett Normed Fit Index	>0.90	0.915
Comparative Fit Index	>0.93	0.930
Tucker Lewis Index	>0.90	0.941
Incremental Fit Index	>0.90	0.932
Parsimonious fit indices		
Parsimony Goodness-Fit Index	>0.50	0.798
Parsimony Normed Fit Index	>0.50	0.848

[a]N/A: not applicable.

Structural Model

The research hypotheses were tested through structural model estimation [40]. Therefore, a second subsample (n=170) was used and provided the adequate structural model fit (CMIN=488.6; CMIN/DF=1.85; GFI=0.861; AGFI=0.893; NFI=0.987; CFI=0.945; RMR=0:079; RMSEA=0.053) as shown in Table 4.

Table . Hypothesized structural model fit indices.

Fit index	Cut-off criteria	Results obtained
Absolute fit indices		
Chi-square (*df*)	N/A[a]	488.6 (170)
χ^2/df (CMIN/DF)	<5.00	1.850
Root Mean Square Error of Approximation	<0.06	0.053
Goodness of Fit Index	>0.85	0.861
Adjusted Goodness of Fit Index	>0.85	0.893
Incremental fit indices		
Buntler-Bonett Normed Fit Index	>0.90	0.987
Comparative Fit Index	>0.93	0.945
Tucker Lewis Index	>0.90	0.976
Incremental Fit Index	>0.90	0.943
Parsimonious fit indices		
Parsimony Goodness-Fit Index	>0.50	0.680
Parsimony Normed Fit Index	>0.50	0.609

[a]N/A: not applicable.

Moreover, the significance of the hypothesis is shown in Table 5. Testing of H1 revealed that social media usefulness has a significant effect on health awareness (H1: β=.669, *P*<.001), supporting the IDT proposed by Rogers. Testing of H2 also supplied similar significant outcomes to the current research model (H2: β=.557, *P*<.001), confirming the findins of prior work.

Table . Hypothesis testing results.

S.no.	Impact of	Impact on	Hypothesis	Path coefficient	*P* value	Outcome
1	SMU[a]	HA[b]	H1[c]	0.669[d]	.001	Significant impact
2	HA	HED[e]	H2[f]	0.557[d]	.001	Significant impact

[a]SMU: social media usefulness.

[b]HA: health awareness.

[c]H1: hypothesis 1.

[d]*P*<.001.

[e]HED: health care education.

[f]H2: hypothesis 2.

Discussion

Principal Findings

This study examined the impact of social media on health awareness and its role in health care education, using IDT as the theoretical framework in Pakistan. A conceptual model was developed to assess the mediating effect of health awareness on the relationship between social media usage and health care education. The hypothesis testing results demonstrated significant relationships, with social media positively influencing health awareness (H_1: path coefficient=0.669, *P*<.001) and health awareness positively impacting health care education (H_2: path coefficient=0.557, *P*<.001). These findings highlight the potential of social media as an effective tool for promoting health care education when strategically leveraged by health care stakeholders.

The study also revealed that younger and more educated health staff are more inclined to use social media, while older groups, though recognizing its usefulness, engage less actively. This demographic insight underlines the need for tailored engagement strategies to maximize participation. Limited research in developing countries, including Pakistan, has tested the application of IDT to health care professionals' adoption of social media for health care education. The standardized direct effects from hypothesis testing affirm the significant relationship between social media usefulness, health awareness, and health care education in the Pakistani context.

Given that developing countries are often classified as late adopters of technology, according to IDT, the findings emphasize the importance of region-specific social media content on platforms, such as Facebook, WhatsApp, or locally developed alternatives, for health care interventions. IDT further suggests that simplifying innovations can facilitate broader adoption, making it easier for health care professionals and the general population to engage with digital health initiatives. These insights highlight the need for cost-effective, user-centric solutions to enhance healthcare outcomes in Pakistan.

The government of Pakistan can also play a significant role in spreading health awareness. They can use social media to run campaigns on maternal health, child nutrition, and disease prevention. The health care professionals in private hospitals also indicated that live sessions and webinars on platforms like Facebook Live and Instagram Live to educate the patients and hospital staff on various health issues and answer their real-time questions have been very useful.

Using social media for health care education in Pakistan could be a game-changer, surpassing the expectations of spreading awareness regarding health needs in a particular community. This potential is not just theoretical; it has been proven in developed countries, such as the US, Jordan, the United Kingdom, and Europe, where social media was used during the COVID-19 pandemic to combat the pandemic and other notable diseases [15]. Moreover, social media platforms have been used to promote telemedicine services, enabling health care professionals to connect with patients remotely for consultations, follow-ups, and monitoring of chronic conditions [16,30].

Overall, this study validates the use of social media to improve public health care education through public awareness. Therefore, the study concludes that health care professionals should use social media tools to inform the wider public and address healthcare issues in Pakistan.

Conclusion

The findings of this study underscore the significant role that social media plays in enhancing health care awareness and education among various populations in developing countries like Pakistan. With their wide reach and interactive features, social media platforms have proven to be effective tools for disseminating health-related information and engaging individuals in meaningful health conversations. Social media breaks down geographical barriers, allowing health information to reach a global audience instantly. This broadens the scope of health care awareness campaigns and makes information accessible to a diverse demographic, including those in remote or underserved areas. The interactive nature of social media facilitates active engagement between health care providers and the public. This interaction fosters a sense of community, encourages the sharing of personal health experiences, and allows for immediate feedback and clarification of health information. Also, social media platforms enable the

dissemination of personalized health information tailored to specific audiences' needs. Moreover, the real-time nature of these platforms ensures that information is up to date, which is crucial during health emergencies or outbreaks.

Health care education through social media can help understand how to prevent common diseases such as malaria, tuberculosis, hepatitis, and polio through vaccination, sanitation, and hygiene in Pakistan. Awareness campaigns can encourage healthier lifestyles, reducing the incidence of chronic diseases such as diabetes, hypertension, and heart disease. Educating women about prenatal and postnatal care, safe delivery practices, and child nutrition can significantly lower maternal and infant mortality rates. Awareness through social media about proper nutrition, immunization, and hygiene practices helps improve children's health and development in the rural outskirts of Pakistan. Also, awareness about communicable diseases and their transmission can help in preventing outbreaks of diseases like HIV/AIDS, tuberculosis, and waterborne illnesses.

Governmental policies provide a framework for regulating the content shared on social media, ensuring that the information disseminated is accurate, reliable, and in line with public health guidelines. Information shared by government-endorsed social media accounts is more likely to be trusted by the public. Official policies lend credibility and legitimacy to health messages, increasing the likelihood of public acceptance and compliance. All active organizations (govt and private) working in the health industry of Pakistan seek prior permission or ethical clearance to initiate any new work. Without government support, the organizations lack the confidence to spread and advertise any health-related content due to fear that they may be subject to local resistance.

Despite its benefits, the use of social media in health care awareness also presents challenges, such as the spread of misinformation and the need for privacy and data protection. Health care organizations must implement strategies to verify information and ensure the credibility of the content shared. Hence, the study suggests that Pakistan's health care organizations should continue leveraging social media to enhance health communication strategies and education. Ongoing research is also needed to explore new ways to maximize social media's benefits while mitigating its risks.

In conclusion, social media is a powerful tool for health care awareness, offering unprecedented opportunities to reach and engage with a wide audience. By harnessing its potential in developing economies, health care organizations can improve public health literacy, promote healthy behaviors, and ultimately contribute to better health outcomes. Collaborative efforts between health care professionals, social media platforms, and policymakers will be crucial in leveraging social media's full potential for public health advancement.

Future Research

Future research should move beyond compliance with existing social media policies to explore strategies and variables that demonstrate tangible improvements in the health care sector. This could include investigating how social media can influence enhanced patient outcomes through better communication and engagement, broaden health awareness campaigns by targeting diverse and underserved populations, and improve access to health care services through innovative digital solutions. Additionally, longitudinal studies examining the long-term impact of social media interventions on public health indicators would provide valuable insights. Identifying and analyzing these variables will contribute to a more comprehensive understanding of social media's transformative potential in health care beyond mere policy adherence.

Acknowledgments

The authors would like to thank Mr Nabil Ahmed, Director at Integral Global Consulting LLC, Tucker, GA, US for providing the necessary resources and facilities that enabled the successful execution of this research. The authors also want to extend their special thanks to all the respondents and hospital management in Lahore, Pakistan, for their feedback and the collaborative environment that fostered productive discussions and the exchange of ideas.

Abstract

Background: Telemedicine represents an essential tool with the potential to reduce health costs, thus avoiding patient displacement and improving patient care outcomes, positioning it as a significant social technology.

Objective: This study aims to analyze the implementation of a telehealth cabin at BP Hospital (A Beneficência Portuguesa de São Paulo), focusing on the evaluation of the experiences of both patients and health care professionals, as well as the acceptability of this tool.

Methods: A mixed methods study was conducted with 229 participants, divided into 2 phases. The first phase involved 40 apparently healthy individuals to assess the usability, experience, and satisfaction of this group for the later safe application in the group with clinical complaints. The second phase included 189 participants, with complaints to assess the usability, experience, and satisfaction of patients and doctors. In both phases, participants completed screening questionnaires (to assess the eligibility criteria), a socioeconomic demographic questionnaire before using the cabin, and a questionnaire including the System Usability Scale and the Net Promoter Score (NPS) after using the cabin.

Results: The data analysis of the first phase showed high acceptance of the telehealth cabin, which supported the progression to the second phase. In the second phase, a high usability score was observed among participants with clinical complaints (mean System Usability Scale score of 85.97, SD 15.50) and a high favorability rating (NPS score of 9.4). Health care professionals also reported favorable results, with a usability score of 67.8 and an NPS of 8.0.

Conclusions: The results of this study reinforce the potential for scaling up this practice based on usability outcomes, and highlight its relevance for the development of public policies aimed at expanding access to quality health care in Brazil. This approach improves the interaction of patients with the health care system, while providing professionals with an extended view of clinical conditions through integrated devices, particularly in areas with limited access to medical care.

KEYWORDS

telemedicine cabin; telehealth; teleservice; e-health; connected offices

Introduction

Health is a fundamental right of the population and must be guaranteed to everyone. It is even included in the Universal Declaration of Human Rights of 1948, in Article 25, which defines that everyone has the right to a standard of living that ensures health, well-being, and health care [1]. Although access to health is often presented as a goal in the health policy, there are several challenges to ensure that right into the Brazilian reality, such as inequalities related to the access and use of health services, discontinuities in the geographical distribution of services, especially of medium and high complexity, in addition to the articulation between health systems of several care levels [2,3].

Among the various proposals developed to improve health care at the national level, the use of technological and telecommunication resources for the exchange of information across different levels of health care, between health professionals, and between doctors and patients, has gained prominence.

According to the Ministry of Health, telehealth uses information and communication technologies to promote the expansion and improvement of medical services. Telemedicine is included in telehealth, related only to remote care through technology. According to the World Health Organization, telemedicine is defined as the "delivery of health services where distance to health professionals is a critical factor, through the use of information and communication technologies to the exchange of valid information for the diagnosis, treatment, and prevention of disease and injuries, research and assessment, and to the continuing education of the providers of healthcare and patients."

Telehealth has been used in Brazil since the 1990s, emerging in a decentralized and fragmented way in the health sites [4]. Telemedicine has the potential to reduce health costs, avoid patient displacement, and even improve patient care outcomes [5-7]. Although many studies are being published, especially as a consequence of the COVID-19 pandemic, the implementation of telemedicine can still be challenging, mainly due to technological barriers and poor computer knowledge, and even due to resisting change and the patient's education level [8]. Despite the increasing interest in telehealth, a significant part of the research focuses on the technological aspects rather than on the tool's adoption and acceptance.

One of the limitations of telemedicine is the lack of possibility to monitor the patient throughout medical care, and some telemedicine platform initiatives have been developed for this purpose. However, today, they provide more complete solutions through a digital health ecosystem, which offers medical instruments to be used by the patient, such as a temperature sensor, stethoscope, dermatoscope, oximeter, otoscope, sphygmomanometer, scale, and height sensor. These new functionalities aim to create resources that can improve even more access and affect the quality of life by bringing doctors and patients closer together.

This research aimed to assess the human aspects of the experience and usability when using telehealth cabins with built-in medical devices, thus expanding the diagnostic and interventional capacity of health professionals in clinical, diagnostic, and interventional capacity practice in its remote format.

To this end, the socioeconomic and demographic profile of the population, the experience and usability of the population in the cabin, the doctor's experience in providing care through telehealth cabins, and compliance in handling the equipment available in the self-examination cabin were evaluated.

Methods

Recruitment

This is a mixed methods study using (1) the System Usability Scale (SUS), (2) the Net Promoter Score (NPS), and (3) a thematic analysis based on participant' perceptions. The aim was to assess the usability and favorability of health care provided in a connected cabin for symptomatic and asymptomatic employees of the BP Hospital (Beneficência Portuguesa de São Paulo).

Ethical Considerations

Ethics approval (CAAE: 58070622.9.0000.5483) for this study was provided by the institutional review board of the BP Hospital (Beneficência Portuguesa de São Paulo) on January 31, 2023. All eligible patients signed an informed consent form for this research protocol.

The data was collected on the RedCap platform, which has access control to ensure the security of the data collected in the research. In addition, all data was anonymized to ensure the privacy of the participants.

Sample Size

The Binomial test was used to calculate the sample size for both parts of the study. For the sampling of asymptomatic individuals (phase 1), an 80% test power was stipulated, a 70% acceptance rate of the cabin under the null hypothesis, and a 90% expected in the sampling rate were specified, resulting in 41 asymptomatic patients.

For the sampling of symptomatic individuals (phase 2), we opted for a conservative scenario. Thus, we set a power of 90%, an acceptance rate of 80% under a null hypothesis, and a 90% expected proportion in the sampling, resulting in 169 patients. Anticipating the possibility of a 12% sample loss, the researchers decided to increase the sampling to 190 symptomatic patients.

Inclusion and Exclusion Criteria

Phase 1: Asymptomatic Patients

The study's first phase involved 40 apparently healthy individuals with no clinical complaints or decompensated chronic diseases (exclusion criteria for the first phase) to assess the safety and usability of the cabin.

During this phase, all hospital staff received an email with information about the study, inviting asymptomatic individuals to participate. Interested individuals could schedule an appointment by phone to use the cabin.

Phase 2: Symptomatic Patients

The second phase included 189 individuals who could be with clinical complaints but did not meet the exclusion criteria, which were: inability to understand and answer the screening questionnaire; patients with signs and clinical symptoms indicating the need for urgent medical care, such as cardiac arrest, shock of any origin, reduced level of consciousness, focal neurological signs, epileptic seizure, chest pain, deep wound, and heavy bleeding.

During this phase, individuals who sought medical care at the institution's employee health center and who met the inclusion criteria were invited to participate. Those who agreed to participate were enrolled in the study.

Telemedicine Cabin

The telemedicine cabin Diagnostica, manufactured in Argentina, was used. It is made of plastic and fiberglass and measures 250×150×230cm dimensions. It has a forced air ventilation and filtering system, environmental lighting with intensity and color control, and an audio and video system for videoconferences (Figure 1).

Figure 1. Telemedicine cabin at the location of the research project.

The participant used his cell phone or the device available in the cabin to receive care and to interact with the person through the app developed for Android and IOS. The patient was accommodated in the cabin and selected the self-examination devices according to their needs.

The following devices were available in the cabin: an otoscope, a digital dermatoscope, and a high-definition camera, all manufactured by Firefly Global in 2021; a stethoscope Riester manufactured in 2021; and an oxyhemoglobin saturation monitor (oximeter), an electrocardiography, a heart rate and temperature monitor, and a sphygmomanometer, models PM6100, all manufactured by Berry, 2021. The patient was instructed to use the app on his cell phone, and the light signals in the cabin were added to a video display to operate the devices for the self-examination.

The cabin recorded the measurements taken by the available devices. The patient had the option, at their discretion, to join the medical consultation at any time during the use of the cabin, even if he did not use the devices. During the synchronous service, the doctor could request that the patient use any of the medical devices to obtain additional clinical information.

Doctors were recruited through direct invitations sent to professionals associated with the hospital. Selection criteria included previous experience with similar technologies and availability to participate in all stages of the study.

Data between the patient and the doctor was transmitted via the Doc24 telehealth platform, implanted in the data processing centers, and connected to the internal service network.

Study Procedure

Before starting the service, a nursing technician applied the informed consent form. After the participant's agreement, a screening questionnaire focusing on the inclusion and exclusion criteria and a questionnaire to collect demographic and socioeconomic data before using the cabin were administered. Individuals who met the exclusion criteria or had acute alterations requiring face-to-face assessment were sent to the Employee Health Center for immediate medical care.

The cabin was equipped with a Wi-Fi network and the patient should download an app to access the cabin and the interface (application) which was customized for the project.

During the appointment, the patient, seated in the cabin, can choose between selecting devices for self-examination or opting for a consultation with a doctor. At the patient's discretion, they have the option to join the medical consultation at any time during the use of the cabin, even without having used the devices.

If the participant chooses to attend a medical consultation during the service, the doctor may ask the patient to use some of the equipment to collect clinical information, or to reuse some of the equipment due to observing poor quality results initially measured by the patient.

Equipment-assisted measurements were available for medical assessment, if required, or later, in the outpatient treatment.

At the end of the service, the research participant was invited to answer the usability questionnaires translated and validated including the SUS, which is a method to measure the usability of several products and services through 10 questions answered on a scale of 1 to 5, where 1 is total disagreement and 5 is total agreement [9], and the NPS, which aims to analyze the patient's experience and satisfaction [10].

After assigning the NPS score, participants were asked to explain their ratings. Inductive thematic analysis was used to identify a rating [11]. Two authors carefully read each response individually and grouped the responses. Any disagreement was discussed with the first author, and then the response was labeled into 6 categories: "service," "usability," "difficulty of use," "innovation," "technology resistance," and "unspecific." The final step was to group the responses into potential themes.

In order to check the usability of health professionals, the participating doctors also completed the same questionnaires at the end of the daily sessions.

Statistical Analysis

Study data were collected and managed by an electronic data capture tool, REDCap (Research Electronic Data Capture), and hosted on the BP server [12,13]. REDCap is a secure software web-based platform designed to support data collection for research studies, providing (1) an intuitive interface for the validated data collection, (2) audit trails to track data manipulation and export procedures, (3) automated export procedures for further data downloads to standard statistical packages, and (4) procedures for data integration and interoperability with external sources. Once collected, data were described considering the mean and SD for the numerical variables and the absolute and relative frequencies to the categorical variables. SUS scores were interpreted using the Sauro and Lewis Curved Grading Scale [14].

Patients were classified into 2 groups according to the SUS scale score "Acceptable usability" (SUS ≥68) and "Usability issues" (SUS <68), and the percentage of patients was compared with 70% (for the Symptomatic sample), and 80% (for the Symptomatic sample) by the Binomial test. The cut-off point of 68 was selected because, despite variability in acceptability, this is the threshold at which the technology is considered to have acceptable usability.

The chi-square test or Fisher exact test was used to compare the groups' qualitative characteristics, and the Mann-Whitney Test was used for the numeric characteristics. The significance level of 0.05 was used throughout the study, and the analyses were performed using SPSS software (version 25; IBM corporation). Graphs were generated using R (version 4.3.2; R studio Team) software and the *ggplot2* package.

Results

Overview

The study was divided into 2 phases: the first occurred from March 6, 2023, to March 16, 2023, and 40 asymptomatic patients were included. The second occurred from March 17, 2023, to June 1, 2023, and 189 symptomatic patients were included.

Assessment of Asymptomatic Patients

The demographic distribution of the asymptomatic patients is shown in Table 1. Most were female, White, married, university-educated, and of higher socioeconomic status.

Concerning the use of the cabin, most of the patients requested support to use the cabin at some point during use. Only 3 patients described the reasons for requesting assistance as difficulties in using the equipment. The appointment had a duration between 10 and 52 minutes.

Upon assessing the satisfaction (Figure 2), we observed that the SUS had a mean value corresponding to Grading A+ (Table 2). When defining the cut-off point for SUS, we identified that only 5 (12.5%) patients had a score of <68 points, whereas 35 (87.5%) had a score of ≥68 points. Thus, the acceptability of 87.5% was statistically different from 70% (P=.009) and had a 95% CI 75.5%-100%, justifying the acceptability of the asymptomatic sample and allowing the study to proceed with the sampling of symptomatic patients.

Table . Distribution of demographic variables for the sampling of asymptomatic patients.

	Values (N=40)
Sex, n (%)	
Male	15 (38)
Female	25 (63)
Ethnicity and race, n (%)	
Asian	2 (5)

SUS[b], mean (SD)	84.9 (13.0)

[a]NPS: Net Promoter Score.

[b]SUS: System Usability Scale.

Figure 2. Distribution for asymptomatic patients for the variables: (A) “How likely is it that you would recommend it to a friend or colleague.” (B) Final SUS Score upon graduation using the Curved Grading Scale. NPS: Net Promoter Score; SUS: System Usability Scale.

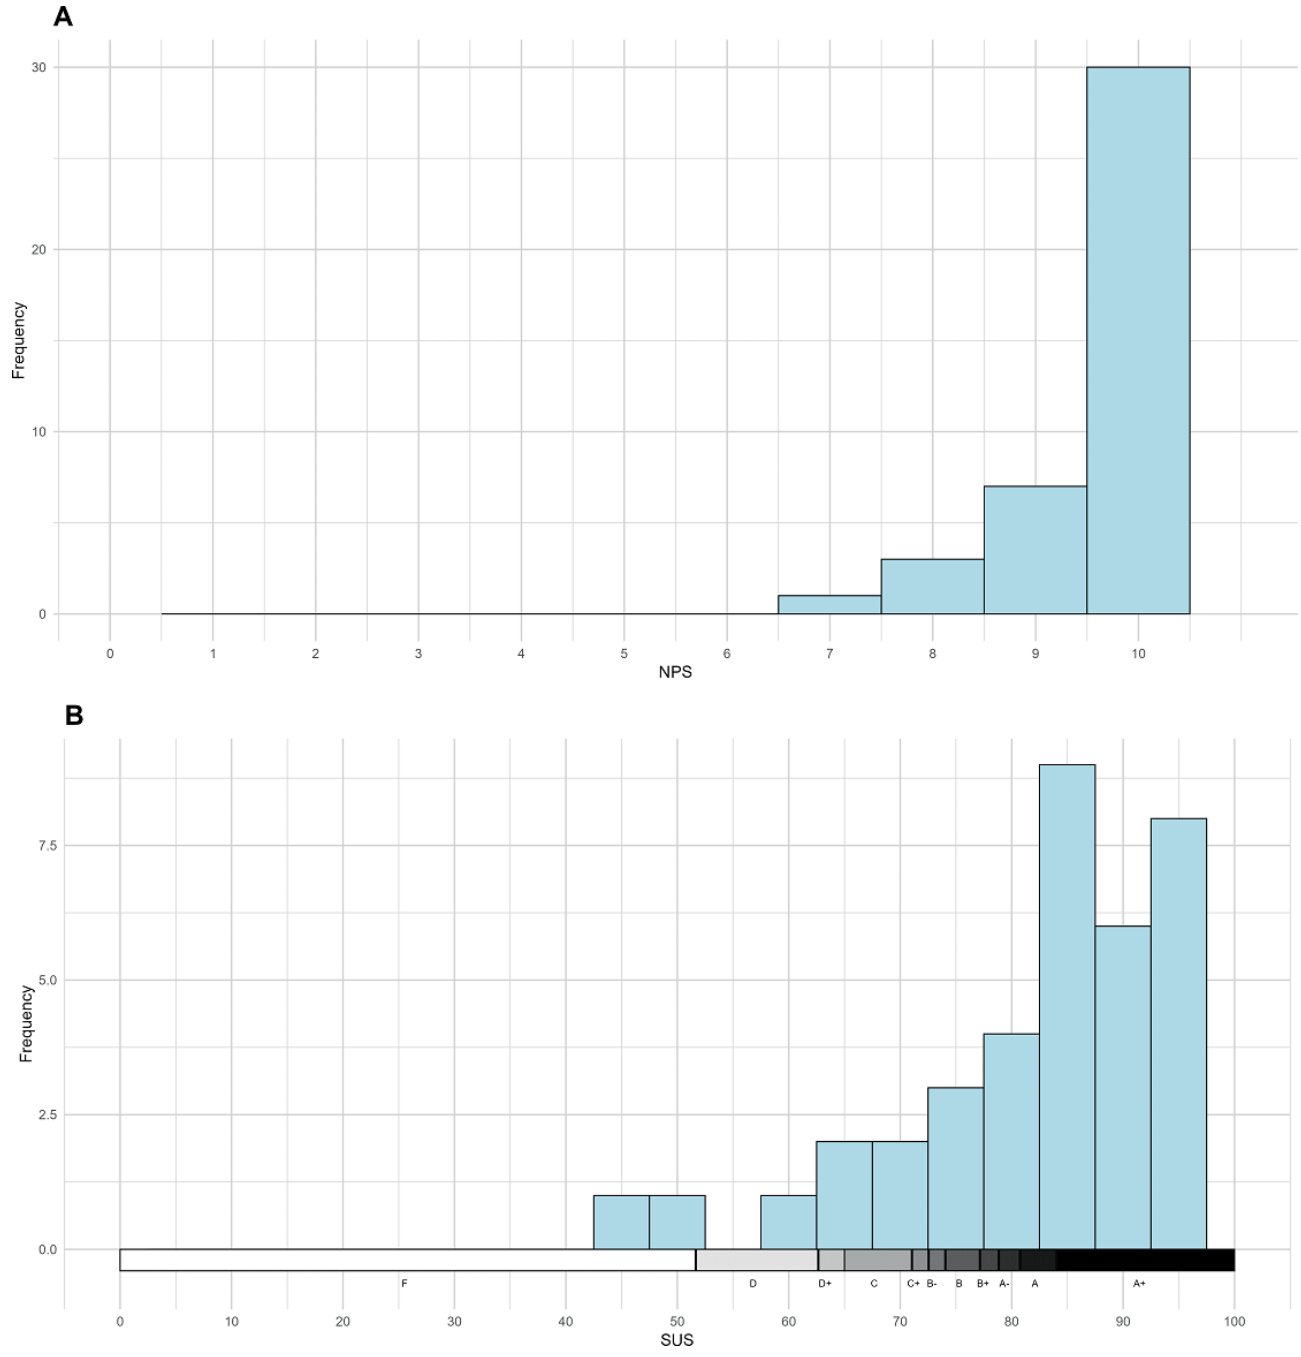

Table . Distribution of patients by Curved Grading Scale grades of asymptomatic and symptomatic groups.

SUS score range	Grading	Asymptomatic (n=40), n (%)	Symptomatic (n=189), n (%)
84.1 - 100	A+	26 (65)	128 (68.1)
80.8 - 84.0	A	3 (7.5)	8 (4.3)
78.9 - 80.7	A−	1 (2.5)	3 (1.6)
77.2 - 78.8	B+	1 (2.5)	11 (5.9)
74.1 - 77.1	B	2 (5)	8 (4.3)
72.6 - 74.0	B−	0 (0)	0 (0)
71.1 - 72.5	C+	1 (2.5)	2 (1.1)
65.0 - 71.0	C	3 (7.5)	11 (5.9)
62.7 - 64.9	C−	0 (0)	0 (0)
51.7 - 62.6	D	2 (5)	6 (3.2)
0.0 - 51.6	F	1 (2.5)	11 (5.9)

Assessment of Symptomatic Patients

The demographic distribution of the symptomatic patients is shown in Table 2. Most were female, white, single, had a college degree, had a household income up to 3 minimum wages, did not perform care functions, and had a mean age was 35.1 years.

Only 5 (2.7%) patients requested support to use the cabin outside the previously established times. The 3 reasons described for requesting support were inconsistencies in performing the cabin and difficulties in using the instruments (otoscope and oximeter) available in the cabin.

The most of participants requested medical orientation and performed the measurement under medical orientation. The duration of the appointment ranged from 2 to 58 minutes. Regarding satisfaction (Figure 3), the variable SUS mean corresponds to Grading A+ (Table 2). When assessing the participants' score in relation to the cut-off point of the SUS scale, we found that only 21 (11.1%) patients had scored <68 points, while 167 (88.8%) had scored ≥68 points. Thus, 88.8% acceptability was statistically different from 80% (P=.001) and had a 95% CI 84.3%-100%.

The 21 patients with a score of 68 or less on the SUS were considered in the group "Usability issues" at the cabin. Eleven (52.4%) were female, 13 (61.9%) self-declared White, 11 (52.4%) had a college degree, 13 (61.9%) were single, 5 (45.5%) were married, 7 (63.6%) earned up to 3 minimum wages, 8 (72.7%) did not carry out welfare activities, and had a mean age of 32.64 years (SD 8.43).

Regarding the use of the cabin by these participants, none of them required assistance from the nursing technician, 8 (38.1%) participants requested medical instruction to perform the tests, 7 (33.3%) participants requested medical orientation and made the tests under medical orientation, while 6 (28.6%) participants did not request medical orientation.

The mean appointment duration was 20.38 (SD 10.29) minutes, ranging from 6 to 40 minutes. When comparing the characteristics of patients with SUS ≥68 related to SUS <68, all of them were not statistically significant (attaining a value equal to or higher than P=.05) (Table 3), meaning that we did not identify characteristics that could have influenced the difference in the SUS score.

Figure 3. Distribution for asymptomatic patients for the variables: (A) “How likely is it that you would recommend it to a friend or colleague.” (B) Final SUS Score upon graduation using the Curved Grading Scale. NPS: Net Promoter Score; SUS: System Usability Scale.

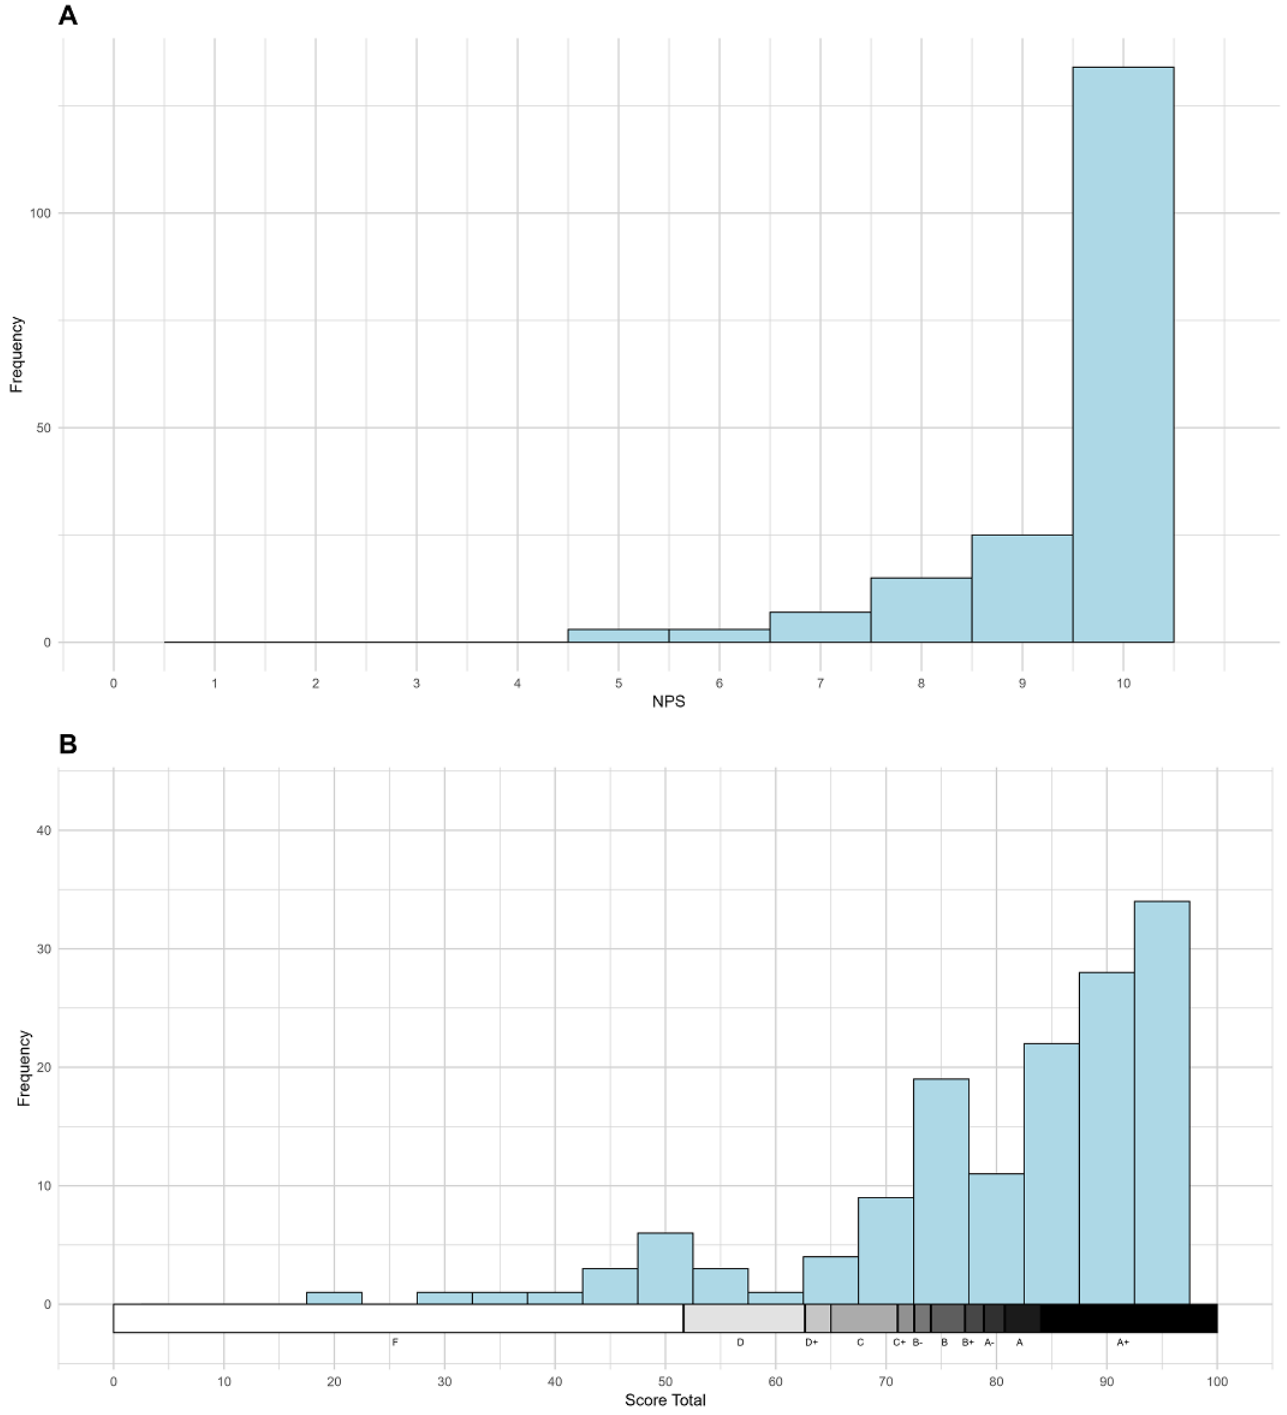

Table . Distribution of the variables for sampling symptomatic patients and comparison System Usability Scale (SUS) <68 versus ≥68.

		Patient's number	SUS[a]		*P* value
			<68	≥68	
Sex, n (%)					.05[b]
	Male	55 (29.1)	10 (47.6)	45 (26.9)

		<68	≥68	
NPS[d], mean (SD)	9.4 (1.3)	7.7 (2.5)	9.6 (0.8)	<.01
SUS, mean (SD)	86.0 (15.5)	51.2 (11.5)	90.3 (9.1)	<.01

[a]There was 1 missing value for the variable "SUS" and 1 missing value for the variable "Has the patient requested support to use the cabin outside the previously set times?".

[b]Chi-square test.

[c]Fisher exact test.

[d]NPS: Net Promoter Score.

Regarding the reasons for their ratings, only 3 participants chose not to answer this question. After careful reading of each response by 2 researchers, the answers were grouped according to the following categories:

- Service: assessment of the interaction between the cabin's professionals and the patient, considering the attention to the needs, clarification of doubts, and resolution of problems. Examples: (1) "Doctor's attention and understanding of my problem"; (2) "The speed and attention of the professionals who cared for me"; and (3) "Spectacular service. All my questions were answered. I thought it was excellent."
- Usability: an assessment of the ease of use of both the interface and the equipment. Examples: (1) "The experience was excellent; I enjoyed doing the tests myself and talking to the doctor about them"; (2) "Super practical, efficient, easy to use the equipment to diagnose, and talk to the doctor afterwards. Loved it!"; and (3) "I found it practical, accessible, and easy to use."
- Difficulty of use: difficulty in using equipment and tools to locate and understand the functions. Examples: (1) "Difficulty in accurately showing images and pain sites to the professional and the client's lack of affinity with the equipment can make it difficult to reach a diagnosis"; (2) "Some people may have difficulty with technology"; and (3) "Conflicting instructions between the cell phone and the screen at the self-diagnosis."
- Innovation: considerations about new products and technologies that can be aggregated to a business or project to bring about improvements. Examples: (1) "Great technology"; (2) "Very advanced technology"; and (3) "For being an innovative, versatile, and practical project."
- Technology Resistance: resistance to technological change. Example: "In no way does it replace the personal contact with the doctor, as there is no way of knowing for sure what you are feeling."
- Nonspecific: answers that were not intended or that did not belong to a predetermined group or situation, in this case, to classes of sentences mentioned above. Examples: (1) "Ok"; (2) "I loved it"; and (3) "Top."

The distributions of the classifications are shown in Table 4.

Most opinions are classified as related to "Usability." When comparing the classes of sentences of those who scored SUS equal or less than 68 (usability issues) with the remaining (acceptable usability), we found statistical differences in the class "Difficult Usability." In the group "Usability issues," 5 (27.8%) scored in this class, while 8 (4.8%) scored in the group "Acceptable usability."

Table . Distribution of the classes of sentences.

	Patient's number, n (%)	System Usability Scale (SUS), n (%)		*P* value
		<68	≥68	
Service				.06[a]
No	106 (57)	14 (77.8)	92 (55.1)

[b]Fisher exact test.

Medical Assessment

At the end of the day's work, the doctor performing the appointments was oriented to answer the NPS and SUS, evaluating his or her day's work. The assessment was performed by 2 doctors, reducing the variability of the influence of the medical service on usability; 89% of the services were performed by one of the doctors, and 11% were performed by the other. The distribution of the NPS and SUS is shown in Table 5.

The main difficulties were related to technical difficulties, such as software updates and network connection problems, besides difficulties in adjusting the cabin's technology (problems with the sensors for measuring the weight and height; problems with the image or screen in the cabin).

Figures 4 and 5 show the evolution of the allocation of medical grades over time.

Table . Distribution of the Net Promoter Score (NPS) and System Usability Scale (SUS) values answered by the doctor at the end of each day of service.

	Patient's number (N)	Mean (SD)	95% CI	Min[a]	1oQ[b]	Medium	3oQ[c]	Max[d]
NPS	41	8.0 (1.4)	7.6-8.4	5.0	7.0	8.0	9.0	10.0
SUS	41	67.8 (13.6)	63.5-72.1	45.0	57.5	65.0	72.5	95.0

Discussion

Principal Findings

The assessment of the implementation of the telehealth cabin in this study aimed to observe the level of favorability and usability of users (doctors and patients) to the cabin and the self-examination devices available, added to their experience of remote service through the technologies available.

The analysis of the results showed that the participants of the first phase of the research (asymptomatic patients) had a different socioeconomic profile than those of the second phase (symptomatic patients), with higher education and monthly income, probably due to the new technology, which attracted leaders and directors of the institution to the research. Although this group was only used to assess the acceptability of both the cabin and the self-examination devices in order to continue the study with symptomatic patients, the outcomes of the favorability and usability were similar between the groups.

Therefore, despite the disparity in access to technology among populations of different economic levels, such a result suggests that the telehealth cabin may have broad applicability for several publics due to the increasing availability and use of mobile devices among the whole population, thus promoting health the equity and reducing social inequalities.

A study with similar equipment performed with French students also concluded that the personal relationship with the technology did not influence the intended use of the telemedicine cabin [15].

A significant portion of the participants did not work in the hospital care sector and therefore did not routinely use the self-examination devices, suggesting that lack of familiarity with the use of the self-examination devices may not impact the use of the cabin. However, this study was performed with professionals working in a hospital, which may bring a certain level of familiarity with those devices, even for those not directly working in the care sector.

Still, we observed that more than half of the patients requested an interview with the doctor, either before or after self-examination, indicating the relevant role of the doctor in such a kind of service.

High favorability and usability were observed for both patient groups (symptomatic and asymptomatic). No statistically significant differences were found when comparing the socioeconomic and cultural profile of those patients with the group of symptomatic who considered the cabin to have acceptable usability, which shows that the usability and favorability of the cabin are unrelated to socioeconomic and cultural factors. However, concerning comments from this group show that some aspects were considered positive even in this group. Furthermore, only one patient described a comment that could be classified in the category "Resistance to Technology," suggesting that most of the population tested is interested in learning and adopting technologies that improve their routines and experiences.

The findings of this study support the work by Scott Kruse et al [8], asserting that the principal barriers to telemedicine are technology specific. They can be overcome by continuous improvement of these technologies, adequate training of technology users, and personal interaction between the patient and the care provider [8].

Concerning the favorability and usability of doctors who performed the cabin services cabin, we found that the answer was also positive, but with a slightly lower level of usability than that of the patients. This fact seems to agree with other studies that assert that some health professionals may be reluctant. However, this resistance may be related to the difficulty of the technology. Therefore, both the favorability and usability can improve with the advancement of technology and the due training of doctors in web-based physical tests [16,17]. This phenomenon highlights the importance of training programs as a strategy to improve user experience and expedite the adoption of this technology.

A limitation of this study is the participation of only individuals without respiratory symptoms (a consequence of the COVID pandemic) or without symptoms that could indicate a medical emergency. Another limiting factor is the poor accessibility of the cabin for people with disabilities. Furthermore, because the total sampling included people employed at the hospital, and so, in the productive age group and predominantly female [18], along with workers in the day shift, this study may have introduced a bias in the perception of favorability and usability of the participants (for instance, older men are less prone to participate in several telehealth activities [19]).

Finally, we emphasize that the results obtained from health professionals should also be interpreted with caution due to the limited number of professionals who provided care for the study.

It should also be noted that no studies using this type of technology were identified in South America to compare the results obtained. In addition, the fact that this study was conducted after the pandemic may have influenced the results given the impact of the COVID-19 pandemic on people's lives, which may have affected perceptions.

Based on the favorable assessment of the technology by the participants in this study (patients and doctors) new studies that extend its use to different populations, without any link to the hospital and from different sectors of activity, different work shifts, sex, and different age groups, may bring new inputs to the application of such technology, expanding the service types and favoring the inclusion of the service in remote locations and for diverse populations.

Conclusions

The authors conclude that the telehealth cabin had good usability and favorability by patients, regardless of the socioeconomic and cultural profile of the population. Doctors who performed the cabin services attested to the cabin's good usability cabin but with a usability index slightly lower than patients. Most patients used the devices for self-examination, with little need for technical assistance. However, a SUS score greater than 68 does not necessarily mean that there are no usability issues to be addressed.

The outcomes of this research allow us to assess as feasible the expansion of this kind of practice from the point of view of usability and that this study can contribute as a subsidy to the construction of public policies to expand the access of the Brazilian population to qualified medical care, promoting the engagement of patients in their health, providing health professionals with an extended view of the clinical conditions through embedded devices even in areas with a shortage of this type of assistance.

Acknowledgments

All authors would like to thank the Votorantim Institute for subsidizing the possibility of this project and for partnering with DOC24 and Diagnóstica, which brought a new way of experiencing the health of the future through innovative equipment.

Abstract

Background: Transgender and nonbinary (TGNB) individuals are increasingly intentionally becoming pregnant to raise children, and hospital websites should reflect these trends. For prospective TGNB parents, a hospital website is the only way they can assess their safety from discrimination while receiving perinatal care. Cisnormativity enforced by communication gaps between medical institutions and TGNB patients can and has caused delays in receiving urgent care during their pregnancy.

Objective: The aim of this study was to evaluate the current prevalence of gender-inclusive terminology among labor and delivery services in the New York tristate area.

Methods: The labor and delivery web pages of 189 hospitals from New York, New Jersey, and Connecticut were examined for gender-inclusive language. “Fully inclusive” websites explicitly acknowledged lesbian, gay, bisexual, transgender, queer, intersex, and asexual plus other gender- and sexual-oriented (LGBTQIA+) parents, “inclusive” websites did not use gendered terminology for parents, and “noninclusive” websites used gendered terms at least once in the text reviewed. The hospitals’ web pages were further stratified by Healthcare Equality Index scores and population classifications defined by the 2013 National Center for Health Statistics Urban-Rural classification given to the county that each hospital was located in.

Results: Of the 300 hospital websites reviewed, only 189 websites met the criteria for inclusion. Overall, only 6.3% (n=12) of labor and delivery web pages were “inclusive” or “fully inclusive.” No geographic areas (*P*=.61) or Healthcare Equality Index scores (*P*=.81) were associated with inclusive or fully inclusive language.

Conclusions: Hospitals need to use inclusive language to help TGNB people identify hospitals where their existence and needs are acknowledged and thus feel more comfortable in their transition to parenthood.

Introduction

Within the last 2 decades, as transgender and nonbinary (TGNB) people have gained greater legal and social recognition, those in the TGNB community who want to become pregnant have become increasingly more common, as have the number of families with same-sex, transgender, or nonbinary parents [1]. Despite this trend, the field of medicine has mostly maintained the heteronormative model of a “mother” and “father” as opposed to a more fluid, freeform reality that accompanies the rise of lesbian, gay, bisexual, transgender, queer, intersex, and asexual plus other gender- and sexual-oriented (LGBTQIA+) couples who raise children.

As pregnant TGNB people attend numerous prenatal visits, they make repeated contact with heterosexist health care systems without the ability to hide their transgender status. Pharr [2] explains that heterosexism is not an active form of discrimination but rather “a belief that the world is and must be heterosexual.” According to the heterosexist worldview, every couple contains—or should contain—only 2 gender-conforming people of the opposite sex [3].

Heterosexism works with homophobia to make health care inaccessible for LGBTQIA+ populations. Current literature has

found that these parents and couples are often invalidated and marginalized throughout the health care process through obstacles like registration forms, comments from ancillary staff, and physicians who are unprepared to deal with LGBTQIA+ couples [4-6]. These experiences can take a deep mental and emotional toll—doubly so during the sensitive transition to parenthood [7].

Beyond these mental health impacts, the invisibility of TGNB parents can negatively affect pregnancy outcomes. LGBTQIA+ patients were less likely to trust providers and divulge important medical information when they received heteronormative medical treatment [8,9]. Patients may also experience delays receiving urgent pregnancy care due to the systematic heterosexism built into the health care system.

For example, Parker et al [6] discuss the experiences of a transmasculine patient who was delayed in seeing the doctor because the receptionist argued that he was not the intended person. These patterns are not limited to individual heterosexist health care workers but also integrated into hospital software. Berger et al [10] describe another scenario where a transmasculine patient's care was delayed, this time because the hospital's electronic medical record required that he reregister as female to document the pregnancy, regardless of his actual gender identity. A delay in care to circumvent cisnormative systems can be dangerous for all pregnant TGNB people. Ultimately, discrimination has often necessitated that prospective TGNB parents discern a "safe" hospital before seeking care.

Historically, LGBTQIA+ people have relied on word of mouth from their personal social circles to find safer health care [11]. However, younger LGBTQIA+ people, especially ones without LGBTQIA+ support networks, also rely on the internet to search for health information and providers that are inclusive of LGBTQIA+ people [12,13]. This vetting of hospitals, along with the increase of patient choice and consumerism for perinatal care in general, has prompted hospitals to advertise their unique benefits, such as low cesarean rates, "baby-friendly" designations, and private rooms [14-19]. Hospitals have tailored their advertisements for other demographics around them, but there is a dearth of literature showing how hospitals advertise their services for LGBTQIA+ populations, who rely on publicly available information to find inclusive care and preserve their health and safety [20].

Purdie-Vaughns et al [21] point to purposeful word choice as one safety cue that, when recognized, signals protection from identity-based discrimination. Hospitals might therefore attract pregnant LGBTQIA+ parents by crafting more inclusive obstetrical web pages. These pages could signal inclusivity by explicitly referencing LGBTQIA+ care or by avoiding gender-exclusive language like "mother and baby," "mom," or presumptive she/her pronouns for parents. Through the words chosen on these public-facing web pages, hospitals thus enable parents to choose to give birth in places where their existence is actively supported during the physically dangerous and psychologically difficult transition to parenthood.

The states surrounding New York City—New York, New Jersey, and Connecticut—boast an exceptionally high population density of LGBTQIA+ individuals, who make up between 3% to 5% of the total adult population [22]. This geographical region is viewed as more inclusive towards LGBTQIA+ people than average, so hospitals may have more incentive to provide inclusive care [23,24]. This study aims to evaluate the current prevalence of LGBTQIA+ inclusion and gender-inclusive terminology among labor and delivery (L&D) service web pages in the New York tristate area.

Methods

Study Design

The targeted words used to assess gender-inclusiveness for this study were largely adapted from the Jennings et al [25] study of gender-inclusive language on National Health Service websites.

The official public-facing obstetric web pages of nonfederal, short-term, acute-care hospitals from Connecticut, New Jersey, and New York were analyzed (n=300). Hospitals without L&D services or web content describing these services were excluded (n=189). Websites were reviewed from late November 2022 to January 2023.

Hospitals were categorized by state, 2013 National Center for Health Statistics Rural-Urban classification, and Healthcare Equality Index (HEI) score. The National Center for Health Statistics Rural-Urban classification is a tool used to identify urban and rural areas of the United States. It was used to analyze any association between urbanization and hospital-based inclusiveness of LGBTQIA+ people. The HEI score is the national LGBTQIA+ benchmarking criterion that assesses health care facilities' policies and practices regarding equity and inclusion of LGBTQIA+ patients, visitors, and employees. It was also used to identify if there was any association between a hospital's publicly perceived LGBTQIA+ inclusivity and word choice on the web pages.

For each hospital, at least 1 web page was examined alongside up to 2 additional pages as supplementation for language analysis. The gendered language used was recorded and analyzed by a single reviewer. The complete L&D-related text was analyzed and the types of gendered language used were recorded. (Explicit discussion of related services, such as chestfeeding, within the same site was excluded.) Any non–gender-inclusive descriptors for the name of the building or third-party services were also excluded from analysis, as these are often not controlled by hospital administration.

Language Analysis

Each web page was reviewed independently by the chief reviewer to minimize any discrepancies. Each hospital's L&D web page was rated as "fully inclusive," "inclusive," or "noninclusive." "Fully inclusive" websites explicitly acknowledged LGBTQIA+ or TGNB parents. "Inclusive" websites did not use gendered terminology or pronouns for prospective parents. "Noninclusive" websites used the terms "woman" or "women"; "mom" or "mother"; other terms for women; "father" or "dad"; or she/her pronouns at least once in the text reviewed.

Statistical Analysis

Categories were analyzed using χ^2 tests presented as frequencies with percentages. *P* values <.05 were considered statistically significant, and all tests were 2-sided.

Ethical Considerations

Ethics and insitutional review board approval were not required since the study did not include human or animal subjects and all data were collected from publicly available websites.

Results

Of the 300 hospital websites reviewed, 111 hospital websites did not have a L&D web page or did not have content describing their L&D services (Multimedia Appendix 1). Of the remaining 189 websites analyzed, 12 (6.3%) of them used fully inclusive or inclusive language (Table 1). Only 1 hospital (0.5%) was considered fully inclusive because it acknowledged “same-sex” couples in its L&D content. The most common noninclusive terms used were “mom” or “mother” (n=166, 87.8%) and “woman” or “women” (n=94, 49.7%). No geographic areas (*P*=.61) or HEI scores (*P*=.81) were associated with inclusive or fully inclusive language (Tables 2-4).

Table . Labor and delivery web pages that used each type of language (N=189).

	Fully inclusive, n (%)	Inclusive, n (%)	Noninclusive, n (%)	Total, n (%)
Websites	1 (0.5)	11 (5.8)	177 (93.7)	189 (100)
Language used				
woman or women	1 (1.1)	0 (0)	93 (49.2)	94 (49.7)
mother or mom	0 (0)	0 (0)	166 (87.8)	166 (87.8)
she/her (parent)	0 (0)	0 (0)	42 (22.2)	42 (22.2)
she/her (staff)	0 (0)	0 (0)	9 (4.8)	9 (4.8)
synonyms for women (ladies, etc)	0 (0)	0 (0)	1 (0.5)	1 (0.5)
father or dad	0 (0)	0 (0)	33 (17.5)	33 (17.5)

Table . Summary of HEI[a] scores and gender-inclusive language used on L&D[b] web pages .

	Fully inclusive (n=1), n (%)	Inclusive (n=11), n (%)	Noninclusive (n=177), n (%)	Total (N=189), n (%)
HEI score=100%	0 (0)	5 (45.5)	60 (33.9)	65 (34.8)
HEI score <100%	0 (0)	1 (9.1)	25 (14.1)	26 (13.9)
HEI score not applicable	1 (100)	5 (45.5)	92 (52)	98 (52.4)

[a]HEI: Healthcare Equality Index.

[b]L&D: labor and delivery.

Table . Summary of gender-inclusive language used on labor and delivery web pages and population data.

	Fully inclusive (n=1), n (%)	Inclusive (n=11), n (%)	Noninclusive (n=177), n (%)	Total (N=189), n (%)
Large central metro	0 (0)	6 (54.5)	53 (30.6)	59 (31.2)
Large fringe metro	0 (0)	3 (27.3)	65 (37.6)	68 (36)
Medium metro	1 (100)	1 (9.1)	31 (17.9)	33 (17.5)
Small metro	0 (0)	0 (0)	7 (4)	7 (3.7)
Micropolitan	0 (0)	1 (9.1)	17 (9.8)	18 (9.5)
Noncore	0 (0)	0 (0)	4 (3.9)	4 (2.1)

Table . Examples of suggested gender-inclusive language [19,25].

Non–gender-inclusive language	Gender-inclusive language
“Mothers”	“Birthing parents” OR “women and birthing parents”
“Pregnant woman”	“Pregnant patient” OR “pregnant person”
“Mother and baby unit”	“Maternity unit” OR “birthing unit”

Discussion

Principal Findings

These results demonstrate that there is a large barrier for TGNB parents to search for and identify potentially inclusive pregnancy care. Out of the 12 inclusive and fully inclusive L&D web pages, 92% were inclusive not because they included gender-additive language or LGBTQIA+ topics but rather because they omitted the pregnant person's gender altogether by addressing the reader in the second person. The websites may have been inclusive not by intention but by coincidence. In stark contrast, there are multiple private reproductive endocrinology and infertility clinics that specifically target LGBTQIA+ couples using specific gender-inclusive language on their websites [26]. TGNB parents who are accustomed to a purposefully inclusive experience during their fertility journey and early pregnancy may be caught off guard by the sudden invisibility of their identities as they progress further through their pregnancy.

Interestingly, none of the hospitals that are acknowledged for their excellence in LGBTQIA+ care in other specialties discussed serving prospective TGNB parents for L&D care on their websites. This likely reflects a wider societal trend of "repronormativity," by which society at large does not recognize reproductive sex between TGNB parents as possible or legitimate [27].

The accessibility of websites and web-based platforms is important for TGNB people to find services and connect to similar parents. Our above findings suggest less than 10% of hospitals use gender-inclusive language when representing their services. Thus, TGNB parents who are not connected to a wider LGBTQIA+ community may struggle to find inclusive prenatal care and delivery services due to the lack of representation.

Limitations

The use of multiple surrogate end points may limit this study. The analyzed web pages, while used as a proxy for the culture in L&D departments, may not fully represent institutional attitudes and practices once parents start using their providers. This is exacerbated by delays between institutional attitude changes and hospital website updates. HEI scores were ineffective in predicting the LGBTQIA+ inclusivity of hospitals' web pages because HEI scores are determined purely through institutional measures like nondiscrimination policies; they do not directly address subtler, underlying heterosexism that hopeful TGNB parents try to avoid in their health care. Finally, the methodology used in this study makes it impossible to establish a causal link between gendered terminology and the quality of LGBTQIA+ inclusive care.

Additionally, it is important to note that individual TGNB people may feel varying levels of dysphoria around maternal terms; some TGNB parents may not consider the words "mom" or "mother" to be exclusively for women. However, using gender-inclusive language and terminology is an important step towards providing a more welcoming and inclusive environment for TGNB parents, regardless of those individuals' personal dysphoria triggers.

Conclusions

Using gender-inclusive language and terminology is the first step towards providing a more welcoming and inclusive environment for pregnant TGNB parents. Hospitals that want to be recognized as more inclusive towards LGBTQIA+ people can integrate gender-additive language into their L&D web pages (eg, "mothers and birthing parents") rather than omit mentions of gender entirely [28]. US hospitals should consider expanding this language to meet the needs of a growing group of people who are having children. Future research should be done including LGBTQIA+ patient advocate groups on the use of inclusive language within health care providers' obstetrical and gynecology departments, specifically in L&D units and on how this language impacts TGNB parents' health outcomes and rapport with physicians.

Conflicts of Interest

None declared.

Abstract

Background: Telemedicine has been utilized in the care of patients with COVID-19, allowing real-time remote monitoring of vital signs. This technology reduces the risk of transmission while providing high-quality care to both self-quarantined patients with mild symptoms and critically ill patients in hospitals.

Objective: This study aims to investigate the application of telemedicine technology in the care of patients with COVID-19, specifically focusing on usability, effectiveness, and patient outcomes in both home isolation and hospital ward settings.

Methods: The study was conducted between January 2022 and December 2022. More than 800 cases were monitored using the QOCA remote home care system, a telemedicine platform that enables remote monitoring of physiological data—including heart rate, blood pressure, temperature, and oxygen levels—through Internet of Things devices and a 4G-connected tablet. Of these, 27 patients participated in thie study: the QOCA remote home care system was deployed 36 times in the isolation ward and 21 times to those in home isolation. The QOCA remote care system monitored isolated cases through remote care packages and a 4G tablet. Case managers and physicians provided telemedicine appointments and medications. Innovative methods were developed to enhance usage, including online health education, remote care equipment instructions via QR core links, and video consultations for patients without smartphones.

Results: A clinical nurse satisfaction survey revealed that most respondents found the content of the remote care package comprehensive and the interface easy to learn. They expressed a desire to continue using the system. The majority also agreed that using the remote care system and package would reduce their workload and that patients and caregivers could easily learn to use the package. While some respondents expressed concerns about network and Bluetooth connectivity, the majority (24/27, 89%) agreed to include the remote device as part of their routine equipment, with an average score of 84.8 points.

Conclusions: The integration of telemedicine technology improves the quality of care while reducing the workload and exposure of health care workers to viruses.

Introduction

COVID-19, a global pandemic, has posed significant challenges to health care systems worldwide [1,2]. While Taiwan has achieved success in epidemic prevention, the reopening of borders raises concerns about potential gaps in prevention measures and strains on health care resources. Addressing these

challenges, this study identifies critical needs in the context of COVID-19 care.

The need for home quarantine and home medical care is vital. National Taiwan University Hospital Yunlin Branch has pioneered a telecommunication-based remote consultation model [3], providing video consultations for individuals under home quarantine. This initiative has not only met their basic health care needs but also minimized the risk of infection by reducing hospital visits. However, with the majority of cases being mild or asymptomatic, and a higher proportion of symptomatic cases among middle-aged and older individuals [4], it is crucial to develop a comprehensive telemedicine model for continuous medical care during home quarantine or isolation and for patients with mild COVID-19 undergoing home treatment [5-7].

During the COVID-19 pandemic, home monitoring of patients has gained popularity. There are two main research designs: (1) assessing patients before hospital admission to reduce virus exposure and identify deterioration and (2) postdischarge monitoring to provide continued care [8]. Monitoring methods include online platforms, paper-based operations with telephone interviews, or wearable devices [9-11]. Paper-based operations with telephone interviews are more inclusive due to limited digital literacy among the target population [12,13]. Most studies focus on vital signs rather than psychological issues. Wearing a pulse oximeter is important for monitoring, but it may cause anxiety and has limitations for certain patients [14-16]. Home monitoring during COVID-19 has benefits and can reduce health care costs [17]. Improving accessibility and convenience is key for future adoption.

Due to the pandemic, health care providers are unable to provide patients with the usual standard of care during hospitalization, leading to various challenges and impacts. Health care workers face psychological stress and staffing shortages, while patients experience isolation and mental health issues. Family members are unable to visit their loved ones in critical condition [18,19]. Technology can offer some assistance in addressing these issues, such as self-monitoring of blood oxygen levels and the integration of vital sign monitoring [20]. Collaboration between technology companies and health care providers is crucial, especially as the pandemic becomes normalized in the community. The development of information-assisted solutions is urgent in order to improve health care delivery [21].

There is a need for low-contact health care for hospitalized, isolated patients. To mitigate the risk of infection among patients with confirmed COVID-19 infection or those at high risk of being infected in dedicated isolation wards, the integration of smart ward solutions and telemedicine is proposed. Real-time remote physiological monitoring can minimize exposure risks and reduce the workload of health care staff, optimize management processes, and preserve valuable isolation rooms and personal protective equipment. Furthermore, obtaining real-time patient information enables early intervention and improves work efficiency, thereby enhancing the safety of patients with confirmed COVID-19 infection.

The study was conducted as a collaboration between National Taiwan University Hospital Yunlin Branch and Quanta Computer, utilizing their expertise in big data analysis and telecommunication telemedicine technology. The project focuses on the COVID-19 response hospitals, with the National Taiwan University Hospital Yunlin Branch serving as the testing ground. Specifically, it aims to provide assistance to patients with confirmed COVID-19 infection or those at high risk of being infected in the dedicated isolation ward, using advanced telemedicine equipment for clinical care. By implementing real-time remote physiological monitoring, the project aims to reduce the exposure risk and workload of health care personnel, simplify management processes, and optimize the utilization of valuable isolation rooms and personal protective equipment. Furthermore, by promptly assessing patient conditions and intervening as needed, the project seeks to enhance work efficiency and ensure the safety of patients with confirmed COVID-19 infection.

Methods

Ethical Considerations

The Institutional Review Board (IRB) of National Taiwan University Hospital approved this study (202009106RIPA). Questionnaires were collected after obtaining informed consent.

All participant data were anonymized or deidentified to ensure privacy. Participants voluntarily provided informed consent, and no personal identifiers were included in the analysis or dissemination. Additionally, anonymous surveys were used to ensure there were no risks of information leakage.

Participants in the study were not compensated monetarily or otherwise. Their involvement was voluntary, and all necessary support for participation, such as the provision of remote care packages and telemedicine tools, was offered free of charge. This ensured equitable participation without financial coercion.

Study Design, Data Sources, and Population

The study was conducted at the National Taiwan University Hospital Yunlin Branch. The inclusion criteria comprised individuals diagnosed with COVID-19, while exclusion criteria included moderate to severe COVID-19 cases, patients unwilling to participate in telemedicine monitoring, and individuals deemed unsuitable for telemedicine evaluation by physicians. Participants were required to be 20 years of age or older and provide informed consent approved by the IRB. The study enrollment period spanned from January to December 2022.

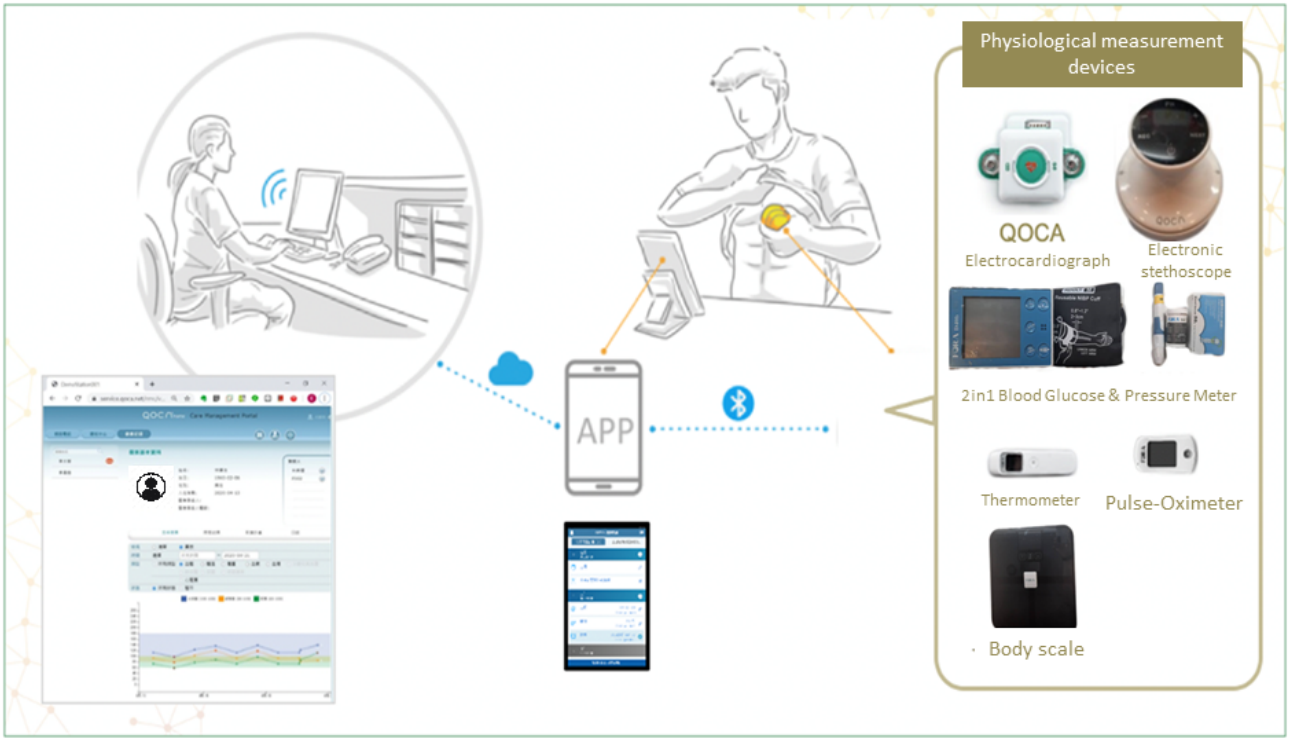
Home Quarantine and Home Medical Care

This study included individuals who have tested positive for COVID-19 and were classified as mild cases or have been determined by the Center for Disease Control, Taiwan, to not require immediate hospitalization due to severe conditions. These individuals can undergo self-isolation monitoring and were either required to quarantine or be monitored at home or quarantine hotels.

The QOCA home system, developed by Quanta Computer, is the core of the remote health care platform. It utilizes a 4G-connected tablet computer for patients, offering features like remote video communication, physiological signal measurement transmission, and remote physical examination (Figure 1). Home monitoring occurs at the patient's residence

or quarantine hotel, providing audiovisual communication and simple consciousness assessment. Vital signs, such as heart rate, blood pressure, temperature, and oxygen level, are measured and transmitted using Internet of Things (IoT) devices. A remote physical examination system, including electronic stethoscope devices, captures and uploads important findings like lung and heart sounds. An interactive care app records visual aspects and clinical conditions, which can be uploaded for health care providers. An online questionnaire system tracks COVID-19 symptoms, comorbidity control, and psychological well-being. Medication assessment and personalized care planning are provided. The hospital-side system manages home isolation quarantine and home-based COVID-19 care. Case managers track patient conditions through a dashboard, maintain daily health logs, and determine if hospital treatment is needed. Information and communication technology–based remote health care ensures continuous medical care and psychological support for individuals in home quarantine or isolation and home-based patients with COVID-19. Remote care packages enable self-isolated individuals to monitor and report symptoms and vital signs, with data transmitted back to the hospital. Dedicated care managers communicate with patients, report to physicians, and provide necessary support in case of discomfort or abnormalities.

Figure 1. The QOCA home system by Quanta Computer is central to the remote health care platform. Utilizing a 4G tablet, it enables remote communication, physiological data transmission, and virtual exams. Monitoring occurs at homes or quarantine locations, allowing audiovisual contact and basic assessment. IoT devices measure and send vital signs, while an electronic stethoscope captures and uploads lung and heart sounds. An interactive app records visual and clinical data for health care providers. An online questionnaire tracks COVID-19 symptoms, comorbidity control, and psychological well-being and includes medication assessment and personalized care planning. IoT: Internet of Things.



Smart Hospital Ward

Patients with COVID-19 admitted to negative pressure isolation wards or intensive care units at National Taiwan University Hospital Yunlin Branch were monitored using the QOCA home system developed by Quanta Computer. Tablet computers, IoT physiological monitoring devices, and video cameras were installed in patient rooms for remote monitoring. Patient physiological data, including heart rate, respiration, body temperature, blood pressure, and blood oxygen levels, were automatically recorded and uploaded to the cloud. The care team accessed these data without entering the rooms. The smart ward included an electronic stethoscope device for recording heart and lung sounds. A central monitoring module and a patient dynamic dashboard were established at the nursing station, providing alerts for abnormal conditions. Patient laboratory reports and images were integrated, enabling health care providers to interact with patients through the video system. The study aimed to utilize information and communication technology, including 4G-connected tablets and IoT monitoring platforms, to facilitate remote health care for patients with COVID-19 in isolation units. This system enabled continuous medical care, psychological support, and remote consultations with physicians; nursing care; psychological counseling; and rehabilitation therapy. It allowed for monitoring of vital signs and COVID-19 symptoms, promoting patient well-being without direct contact.

Satisfaction Survey for the QOCA Smart Ward Remote Care System: Clinical Nursing Staff and General Population

This questionnaire aimed to understand the relevant settings of the remote care system and its clinical application in dedicated wards for COVID-19. The information gathered will be used for future improvements and optimization. This survey was anonymous, and there were no concerns about personal

information leakage. The questionnaire included aspects of communication quality, user-friendliness, overall satisfaction, and suggestions. Each option consisted of strongly agree, agree, neutral, disagree, and strongly disagree (Multimedia Appendix 1).

Results

Overview

Before officially enrolling patients in the monitoring care package, thorough explanations and assistance were provided to each individual in the isolation ward to ensure their understanding and obtain their consent to participate in the research study. Following this, every isolated patient was equipped with a set of remote care packages. This became standard practice in the ward, significantly reducing the frequency of health care personnel entering patient rooms to don and remove isolation garments. Patients were empowered to self-measure their vital signs whenever they felt unwell, providing immediate access to physiological data that could alert health care professionals to any discomfort or changes in their condition. This approach not only alleviated patients' psychological anxiety about their disease progression but also allowed health care staff to spend less time in isolation garments while maintaining a real-time understanding of the patients' current status, ultimately improving the quality of clinical care.

Enhancing Hardware Infrastructure for Remote Care System in Isolation Ward

To enhance the hardware aspect of the remote care system implemented in the isolation ward, the original 7-bed negative pressure ward was expanded to accommodate the installation of 32 sets of care packages, with one set allocated to each bed. Additionally, the nursing treatment cart and the nursing station computer were equipped with the QOCA remote care system platform and individual nursing staff accounts. This setup empowered the nursing personnel to monitor the patients' vital sign data in real time, which were automatically uploaded by the system after patient measurements. Continuous monitoring of vital signs was made possible throughout the patients' entire hospitalization and isolation period. Moreover, the QOCA system facilitated real-time video communication when necessary, enabling consultations with psychiatric physicians to address any illness-related anxieties that the patients may have. By extending the focus of care beyond the patients' physiological needs, the hospitalization and treatment process also addressed their psychological well-being.

Remote Home Care Package for Individual Who Are COVID-19 Positive Under Self-Isolation

For individuals who have tested positive for COVID-19 and can self-isolate at home without requiring hospitalization, a comprehensive remote home care package was provided. This package enabled individuals to independently monitor their health, even without monitoring devices at home. It included daily self-observation of symptoms and measurement of vital signs, with the numerical data automatically transmitted to the hospital through a tablet computer connected to 4G.

To ensure prompt attention to any discomfort or adverse conditions, a dedicated care manager was assigned to each patient. The care manager promptly reported any concerns to the responsible physician and maintained regular contact to inquire about the patient's condition throughout the home isolation period. If individuals experience symptoms, they could also schedule telemedicine appointments to closely monitor changes in their condition.

In cases where symptom management was necessary, the responsible physician could prescribe appropriate medications to help alleviate symptoms. This comprehensive remote home care package aimed to provide effective care and support to individuals with COVID-19, ensuring their well-being while minimizing the risk of further transmission.

Advancing Care Through QOCA Telecare System for COVID-19 Monitoring and Isolation

The number of cases monitored using the QOCA remote home care system exceeded 800. Among them, 29 individuals voluntarily participated in this research study and provided their consent by signing the IRB consent form. The QOCA remote home care system was deployed 36 times in the isolation ward and 21 times to those in home isolation, as indicated in Table 1. In the ward, patients primarily monitor themselves or receive assistance from family members for monitoring, while a small number of individuals without family support or hired caregivers receive help from nursing staff for measurements.

The participants in this study represented a diverse range of age groups, with the majority being aged 41-60 years (13/29, 45%), followed by the 61-80 years age group (9/29, 31%), and the fewest participants in the 21-40 years (3/29, 10%) and 80+ years age groups (4/29, 14%). The sample was predominantly male, with 27 (93%) male participants and only 2 (7%) female participants. Regarding the need for assistance, 11 (38%) participants required help during the study, while 18 (62%) managed independently. The participants' education levels varied, with most having elementary or junior high education (20/29, 69%), while a smaller number had completed high school or higher education (9/29, 31%). In terms of technology usage, 21 (72%) participants used digital devices daily, while 8 (28%) reported no prior experience. Health engagement levels were mixed, with the majority (20/29, 69%) not actively seeking information about their conditions, while some participants regularly consumed health-related content. Additionally, 17 (59%) participants had prior experience with health monitoring devices, further illustrating the range of familiarity with telecare technology among the group.

In contrast to traditional inpatient monitoring methods, the ward implemented a specialized remote home care system designed specifically for the isolation care required during the COVID-19 pandemic. This system enables patients to independently measure their vital signs and automatically transmit the data to the nursing staff. To ensure effective utilization of the remote home care system by patients and their accompanying family members, innovative care methods have been developed, including the following:

1. Online health education materials: With the widespread use of smartphones due to technological advancements, disease-specific health education materials are provided through QR codes during hospitalization. This allows patients to access relevant information whenever needed.
2. Guidelines for operating remote care devices: Some individuals may be unfamiliar with monitoring devices. Even after receiving instructions from health care professionals, patients may require repeated practice. To facilitate practice sessions without overwhelming the nursing staff, instructional videos demonstrating device operation can be accessed through QR codes. Patients can practice as many times as necessary to ensure accurate measurements.
3. Tablet-based video consultations for remote care: Patients without smartphones can still access important information through tablet-based video consultations offered by the remote care system.

The ward continues to fully utilize the remote home care system for clinical monitoring, and the number of users continues to grow. Health care professionals not only provide personalized care to patients but also make adjustments to the care process based on the implementation of the remote home care system. This approach reduces the risk of viral exposure and eases the workload for health care staff, streamlines management procedures, and ultimately enhances the quality of care provided.

Clinical Nursing Staff Satisfaction Survey

This survey aimed to assess the satisfaction and experiences of the clinical nursing staff in using the telecare system in the dedicated COVID-19 isolation wards. The questionnaire was divided into 3 main categories: *communication quality*, *user-friendliness*, and *overall experience*. The objective was to identify and analyze the challenges and difficulties faced by users in relation to equipment, signals, and interface operations.

A total of 27 questionnaires were collected exclusively from nursing staff working in the dedicated COVID-19 wards, specifically Ward 7A and Ward 7B. Regarding the transmission signals of the equipment, 44% (n=12) of the respondents believed that the internet connection of the telecare system was stable, while 37% (n=10) found the Bluetooth connection between the tablet and the devices in the package to be stable. When using the telecare system for video calls, 56% (n=15) stated that the image quality was clear, and 56% (n=15) stated that the sound quality was clear (Table 2).

In terms of usability, following training on the telecare system's interface, 89% (n=24) of the respondents found it easy to learn, and an equal percentage (n=24, 89%) expressed their willingness to continue using the telecare system to assist in clinical care. Furthermore, 67% (n=18) believed that patients or caregivers could quickly grasp the usage of the telecare package. Moreover, 81% (n=22) of the respondents indicated that the telecare package contained all the necessary components and fulfilled the requirements for clinical monitoring. Additionally, 89% (n=24) agreed that the use of the telecare system and package could help alleviate the burden of clinical care (Table 3).

Overall, 89% (n=24) of the respondents agreed to incorporate the telecare device as a regular piece of equipment in isolation wards, with an average satisfaction score of 84.8. The majority (24/27, 89%) of the responses highlighted the short monitoring time of the device and the instability of signal transmission. They expressed a desire for improved stability in wireless internet and Bluetooth signals, as it would lead to a smoother user experience (Table 4).

Table . Communication quality survey responses regarding the telemedicine system.

Question	Score[a] (n=27), n (%)				
	1	2	3	4	5
I think the network connection of this telecare system is stable	1 (4)	11 (41)	12 (44)	3 (11)	0 (0)
The Bluetooth connection between the tablet in the care bag and the instrument is stable	2 (7)	8 (30)	12 (44)	5 (19)	0 (0)
When using the nursing system, the image is very clear.	3 (11)	12 (44)	6 (22)	5 (19)	1 (4)
When using the nursing system, the sound is very clear.	2 (7)	13 (48)	8 (30)	3 (11)	1 (4)

Discussion

Principal Findings

The enhancement of the hardware infrastructure for the remote care system in the isolation ward has significantly improved the quality of care and patient outcomes [22,23]. By expanding to accommodate more care packages, each patient receives continuous monitoring and support. The integration of the QOCA remote care system into nursing carts and computers allows real-time access to vital sign data, enabling prompt interventions and ensuring patient well-being. The system also facilitates video consultations with psychiatric physicians, addressing patients' anxieties and holistic needs. This approach benefits both patients and nursing staff, who can efficiently monitor multiple patients, respond promptly to changes, and access patient data remotely, thus saving time and reducing errors.

The implementation of a remote home care package for individuals who are COVID-19 positive in self-isolation offers effective care and support while reducing transmission risk [24]. Patients can independently monitor their health by observing symptoms and measuring vital signs, actively participating in their care. A tablet connected to 4G enables real-time transmission of data to health care providers, facilitating informed decisions. Dedicated care managers provide personalized support, regularly checking in on patients and promptly reporting concerns. Telemedicine appointments allow close monitoring, adjustment of treatment plans, and direct access to medical professionals, thus reducing anxiety. Remote prescription of medications ensures symptom management without visiting a health care facility. However, challenges include subjective self-reporting and disparities in internet access and technological skills [23,25]. Education and efforts to address disparities are essential for equitable care.

The implementation of the QOCA remote home care system for COVID-19 monitoring and isolation has been successful in advancing care and improving patient outcomes. With over 800 cases monitored, the system allows patients to independently measure vital signs and transmit data to nursing staff, reducing the need for frequent in-person monitoring. Innovative methods, such as online health education materials and instructional videos, ensure optimal utilization of the system. Tablet-based video consultations cater to patients without smartphones. By fully utilizing the remote home care system, the ward provides personalized care, streamlines management procedures, reduces viral exposure, and eases the workload for staff, ultimately enhancing care quality [26]. Ongoing monitoring and evaluation are crucial for system refinement, and its success in COVID-19 care opens doors for its application in other health care settings, showcasing the transformative potential of technological advancements in patient care.

During the COVID-19 pandemic, nursing professionals have made substantial achievements in delivering adequate patient care by utilizing telehealth [8,12,24]. The results of the clinical nursing staff satisfaction survey regarding the telecare system in COVID-19 isolation wards provide valuable insights into their experiences and challenges [27]. The majority of respondents found the telecare package to be usable and to have met the requirements for clinical monitoring. After training, the respondents stated that the interface was easy to learn, and they expressed their willingness to continue using the system. A substantial percentage believed that patients and caregivers could quickly grasp its usage, and that the use of the telecare system helped alleviate the burden of clinical care [12]. Regarding transmission signals, opinions were mixed. While a portion of respondents found the internet connection stable, others highlighted issues with Bluetooth connectivity. In terms of video calls, a majority found the image and sound quality to be clear. Overall, the survey indicates high satisfaction with the telecare system, with a majority of respondents expressing their support for incorporating it as a regular equipment in isolation wards. The average satisfaction score was positive [13]. However, feedback emphasized the need for improvements in signal stability, particularly in wireless internet and Bluetooth connections [24]. The short monitoring time of the device was also a concern.

The difficulties and obstacles in telemedicine for COVID-19 care include insufficient hardware environment and the short monitoring time of equipment [28]. The negative pressure isolation environment in the ward, with multiple walls and controlled doors, leads to weak signals. Installing signal amplifiers, as suggested by the hospital's IT department, can improve signal stability. The monitoring time of the equipment is too short, but through discussions with engineers and the manufacturer, it is believed that adjusting the monitoring time according to individual patient needs can align it with clinical requirements, enabling more accurate monitoring of values. Addressing these challenges will enhance the effectiveness and reliability of telemedicine in COVID-19 care.

One potential limitation of this study is the relatively small sample size, which may affect the generalizability of the findings. With only 36 deployments in the isolation ward and 21 deployments in home isolation, the results may not fully represent the broader population of patients with COVID-19 or other health care contexts. Additionally, the voluntary nature of participation could introduce selection bias, as those who agreed to participate may differ from those who declined in terms of health status or access to technology. Another limitation is that the study was conducted within a single hospital, potentially limiting the applicability of the results to other settings with different resources or patient demographics. Lastly, the short-term focus of the study may not capture the long-term effectiveness or sustainability of telemedicine interventions, warranting further research in this area.

Conclusion

The implementation of the QOCA telemedicine system demonstrated significant benefits in managing patients with COVID-19 who have mild symptoms, both in isolation wards and home quarantine settings. By enabling continuous remote monitoring of vital signs and offering real-time communication between patients and health care providers, the system not only improved the quality of care but also reduced the workload and exposure risk for medical staff.

However, the study had some limitations, including a relatively small sample size and the potential for selection bias, which may affect the generalizability of the findings. Additionally, the short-term nature of the study may not fully capture the long-term impacts of telemedicine in patient care.

Despite these limitations, our findings suggest that telemedicine systems like QOCA can play a crucial role in pandemic response and future health care delivery. Further research with larger, more diverse populations and extended follow-up periods is recommended to fully explore the potential of telemedicine in improving patient outcomes and health care efficiency.

Acknowledgments

We sincerely thank Quanta Computer for their invaluable support in establishing the following health care systems: the Smart Ward Cloud Care System, QOCA Home, Intelligent Remote Health Care System, and Remote Home Care Package. This study was supported by the National Science and Technology Council, Taiwan, for the research (MOST 109－2823－8－002－013-CV).

Abstract

Background: Telehealth is an increasingly important component of health care services. Telehealth services may present an opportunity to increase the equity, accessibility, and effectiveness of health care. As such, it is critical that telehealth design focuses on reducing the barriers to access and usability that may impair some telehealth users.

Objective: Our goal was to identify different demographic characteristics, behaviors, or opinions that may predict groups who are likely to face a barrier to using telehealth services.

Methods: We used data from the National Health Interview Survey and multiple logit regression models focused on different aspects of telehealth to examine three different avenues of telehealth service: looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider through email using the internet in order to consider the ways in which different telehealth services may face different barriers.

Results: Our results suggest that middle-aged (36-55 years old) and older adult (56-85 years old) respondents were significantly less likely to look up health information using the internet or schedule an appointment using the internet versus younger individuals (18-35 years old). Specifically, our analysis found that middle-aged adults were found to have a higher odds ratio than older adults (0.83 vs 0.65) for looking up health information using the internet. We also found that there were differences in age groups for using technology to perform health care–related tasks. In terms of searching for health information using the internet and scheduling appointments using the internet, we found differences between men and women, with women being significantly more likely than men to look up health information using the internet, schedule an appointment using the internet, and communicate with a care provider through email using the internet. Across all the investigated variables, we found that the rates of using the internet for looking up health information, scheduling an appointment, and communicating with a care provider over email increased substantially across the study period. The impact of costs was inconsistent across the different models in our analysis. We also found that there is a strong correlation between respondents' collaboration in their personal health and the likelihood that they would use telehealth services to meet these needs.

Conclusions: This analysis provides an exploratory look at the data to highlight barriers that may impact a user's ability to access telehealth services in the context of other potential predictor variables to account for the real-world variability that these may present. Future work should examine the complex relationships of those variables and understand how these interactions are correlated with the respondents' use of telehealth.

Introduction

Background

With the advancement of digital technologies, the use of technology in health care has grown [1,2]. While there have been several attempts to better understand the use of digital technologies in health care, much of the work has been done in silos and is sometimes limited in scope [2,3]. Generally, telehealth refers to health care communication through technology, often used in conjunction with telemedicine and eHealth [3-5]. Mobile health is an additional term that describes telehealth services in the context of mobile devices [6]. Telehealth is increasingly being used in growing populations, offering distinct advantages and potential barriers for different patient populations and their care.

Benefits Associated With Telehealth

The increased adoption of telehealth services has allowed for its impacts to be examined on actual patients receiving telehealth care [7]. It has been shown that when telehealth is implemented with current best practices, it may help to balance the health care supply and demand disparity [8], improve patient access to care [8,9], and reduce the cost of care [8,9]. Due to increasing demand with changes in population sizes and demographics, as well as decreasing supply as care providers retire or change careers [8], telehealth services and telehealth programs have helped bridge this gap [10,11]. Telehealth also has been shown to improve patients' ability to access care, thus enabling patients to receive efficient and cost-effective care [8,10] by reducing the impacts of geographical barriers [12] and cost barriers to care [13]. Telehealth may also improve the cost-effectiveness of care, with [14] finding that the "all-cause" cost of providing care to older patients (older than 65 years) decreased from US $937.25 to US $491.52 with the inclusion of telehealth services. Telehealth can also offer support for individuals seeking mental health care where mental health specialties are distant or when there may be patient privacy issues in obtaining mental health care [15].

Barriers to the Use of Telehealth Services

There are several potential barriers that have been identified related to the use and effective implementation of telehealth services [7]. A notable barrier to telehealth services is patients' health literacy [16-18]. Individuals with lower levels of health literacy have shown lower comfort levels with using telehealth technologies [17,19]. Older people are using as well as providing telehealth services [20]. Yet, it has been suggested that older patients (older than 60 years) might have greater difficulty using telehealth services [21]. Additionally, technological infrastructure issues (low-quality, limited internet access) may reduce the ability of individuals to access telehealth services [22]. Individuals' access to electronic devices (ie, smartphones, computers, and tablets) may also be a barrier to engaging in telehealth services [22]. In addition to the access issues, the time and costs required to engage in the services (both for the patients as well as clinicians) may be a barrier to rolling out large programs or integrating them into the workflow processes for clinical staff [23].

Changes in Health Care Populations Over Time

There are several factors that have been shown to impact the use of web-based resources for health care and other telehealth services [24]. A 2018 study suggests that demographic factors, such as living in rural areas, age, and insurance types, impact telehealth implementation and use in health care facilities [24]. There have also been racial and ethnic discrepancies reported in the literature, with Black and Hispanic patients preferring emergency departments to telemedicine compared to White patients [25]. Age is also an important factor as the use of telehealth differs among different age groups [14,25]. In addition, health insurance access, and having internet access also influence the use of telehealth [14].

It is important to consider how user needs with telehealth change over time [26]. Changing population demographics, such as age, have major impacts on the use and function of health care [27]. Other additional factors, such as socioeconomic factors and changes in the prevalence of different health conditions, also impact the function of the health care system [27]. Over time, population demographics, access, and technology can change significantly, leading to incorrect conclusions or missed critical trends due to observing only one moment. It is important to consider all these elements when examining which predictors may indicate barriers to telehealth access. The objective of this research is to examine how individuals used the internet to support their health care over 7 years (2012-2018) using the National Health Interview Survey (NHIS) data. Specifically, we examined how different demographic variables and respondents' perspectives influenced how individuals looked up health information using the internet, scheduled appointments using the internet, and emailed to communicate with a care provider using the internet.

Methods

Ethical Considerations

An ethics board review was not required for this analysis as this study used publicly available data.

Overview

Each year the Centers for Disease Control and Prevention (CDC), a government agency assigned to monitor the general public's behavior and health status conducts the NHIS, which is an annual cross-sectional survey designed to gather data on a variety of health-related topics throughout the United States with oversampling of certain demographic groups in a way that is nationally representative [28]. The survey weighting variable is poststratified based on the US Census data to represent national population characteristics [28]. These survey weights are identified for all combinations of persons within the variable WTFA_SA in the NHIS data. Due to the complex survey sampling strategy, the survey person weights must be used in analyzing the data to avoid substantial bias in the results [28].

For this analysis, the NHIS sample adult files for each year from 2012 to 2018 were used. For the files from 2012 to 2014, the American Standard Code for Information Interchange data file was combined using the stringr, stringi, foreign, and RCurl packages in R (R Foundation for Statistical Computing) to run

the associated Statistical Analysis System statements to produce a .csv version of the sample adult file. For the years 2015-2018, a csv file was provided for the sample adult survey data. We created a single file by combining responses for each year using the R functions rbindlist from the data.table package to match each survey year on the corresponding variable columns. Only identical questions related to our research objectives were included in the combined data set.

All responses recorded as the option "not ascertained" were recoded as NA for all variables. All the variables were recoded by assigning binary values or group responses to facilitate the data analysis. The variables used as outcome variables were recoded to become binary variables: health information seeking using the internet (HIT1A), scheduling health care appointments using the internet (HIT3A), and communication with health care providers through email using the internet (HIT4A). Demographic variables were also recoded, including the respondent's race (RACERPI2), Hispanic ethnicity (HISPANI_I), sex (SEX), region (REGION), marital status (R_MARITL), internet use (AWEBUSE) and the frequency of using the internet (AWEBOFNO and AWEBOFTP), email use (AWEBEML) and the frequency of using email (AWEBMTP), whether a respondent would go to a clinic or doctor's office (AUSUALPL and APLKIND), and where a respondent goes to seek preventative care (AHCPLKND). Additionally, whether a respondent skipped medication doses to save money (ARX12_1), whether a respondent took less medication to save money (ARX12_2), if a respondent had delayed filling a prescription (ARX12_3), preferred low-cost medication (ARX12_4), reported buying prescription drugs from another country to save money (ARX12_5), used alternative therapies to save money (ARX12_6), affordability of prescribed medication (AHCAFYR1), affordability of mental health care or counseling (AHCAFYR2), affordability of dental care (AHCAFYR3), affordability of eyeglasses (AHCAFYR4), and worries about paying medical bills (AWORPAY).

All responses where the data were coded as "not ascertained" or "missing" were recoded as "NAs" for all of the variables and were dropped from the analysis. Whether or not a survey respondent had looked up health information using the internet in the last 12 months was recoded to a binary response of 1 to indicate if the respondent had looked up health information on the internet or 0 if they did not indicate looking up health information on the internet (all other responses). Similarly, all binary variables were recoded in the same manner. A survey respondent's race was identified within the data by the RACERPI2 variable from the NHIS data. The variable was recoded to indicate if the survey respondent reported their race as being White, Black or African American, American Indian or Alaska Native, Asian, or multiple races. A survey respondent's Hispanic ethnicity was recoded to indicate if the survey respondent reported being Hispanic, multiple Hispanic, Puerto Rican, Mexican, Mexican-American, Cuban or Cuban American, Dominican (Republic), Central or South American, other Latin American (type not specified), other Spanish, Hispanic or Latino or Spanish (nonspecific type), Hispanic or Latino or Spanish (type refused), or were not Hispanic (a response of 12, not Hispanic or Spanish origin). A survey respondent's region was identified within the data using the variable REGION from the NHIS data. The variable was recoded to indicate if the survey respondent reported residing in the Northeastern, Midwestern, Southern, or Western United States. A survey respondent's marital status was recoded to indicate if the survey respondent reported living with a spouse or partner or not living with a spouse or partner (all other responses). A survey respondent's internet use was identified in the data using the AWEBUSE variable from the NHIS data. The variable was recoded to indicate if the survey respondent reported using the internet, or not. Additionally, a survey respondent's internet use frequency was identified in the data using the AWEBOFNO and AWEBOFTP variables. The variables were recoded to indicate frequently using the internet (responses of once per day or more frequently) or not using the internet frequently (all other response combinations). The variable APLKIND was recoded to indicate if a respondent goes to a clinic or doctor's office (a response of clinic or health center, or doctor's office or health maintenance organization) or somewhere other than a clinic or doctor's office (all other responses). These variables were combined to indicate if a respondent goes to a clinic or doctor's office when sick, goes somewhere other than a clinic or a doctor's office when sick, or does not indicate going anywhere when sick. Where a respondent goes to seek preventative care was identified using the variable AHCPLKND in the NHIS data. The variable was recoded to indicate if a respondent goes to a clinic or doctor's office for preventative care (a response of clinic or health center, or doctor's office or health maintenance organization) or does not go to a clinic or doctor's office for preventative care (all other responses).

We used logit regression models to examine the relationship between our predictor variables and each of our 3 separate questions about the survey participants' use of telehealth: looking up health information using the internet, scheduling an appointment with a health care provider using the internet, and communicating with a provider over email using the internet. In the field of machine learning and statistics, a wide range of computer models can be used for predicting clinical outcomes such as logit regression, decision trees, artificial neural networks, and Bayesian networks. We have selected Logit regression because it is a well-known statistical fitting model that is frequently used for modeling medical problems where it is needed to identify the relation between a binary response variable and a set of independent predictor variables [29]. The models were built using the svyglm function within the survey package in R version 4.2.1 (R Foundation for Statistical Computing) in R Studio 2023.03.0+386 (Posit PBC). The svyglm function includes the ability to account for a weighting variable in the data to facilitate population estimates. The stepAIC function within the MASS package was used to identify the best-fit model for this data.

Results

Overview

Young adults (18-35 years old) made up between 32.1% (n=10,140, unweighted) and 31.26% (n=6902, unweighted) of

weighted survey respondents in 2012 and 2017, respectively, as shown in Table 1, while older adults (56-85 years old) accounted for 32.37% (n=12,662, unweighted) in 2012 and 35.63% (n=11,483, unweighted) in 2018. Women made up between 51.72% (n=13,867, unweighted) and 51.87% (n=19,252, unweighted) of the weighted survey respondents over the years.

Table 1. Demographic information broken down by year; given as count of response and percentage of weighted totals[a].

Parameter	2012	2013	2014	2015	2016	2017	2018
Age, n (%)							
Younger adult	10,140 (32.10)	10,183 (31.92)	10,431 (31.85)	9230 (31.73)	8662 (31.68)	6902 (31.26)	6177 (31.34)

[a]The table shows the unweighted sample size for each variable and the related percentage once the weights are applied to the data.

[b]AIAN: American Indian or Alaska Native.

The percentage of frequent internet users increased from 58.77% (n=18,016, unweighted) in 2012 to 73.15% (n=17,153, unweighted) in 2018. The percentage of email users increased from 64.46% (n=20,038, unweighted) in 2012 to 74.37% (n=17,635, unweighted) in 2018. The number of individuals who reported living with their spouse or partner ranged from 48.07% (n=14,160, unweighted) of weighted survey respondents in 2016 to 48.89% (n=11,031, unweighted) in 2018.

As shown in Figure 1A, older adult respondents tend to look up health information less than the middle-aged or younger adult groups over the years, while the percentage of the respondents looking up health information using the internet grew at similar rates for all groups. As shown in Figure 1B, men tend to look up health information using the internet less than women across all years of the study. Older adult respondents tended to report scheduling an appointment using less than younger adults or middle-aged respondents (Figure 2A). Across the years included in this study, the proportion of younger and middle-aged respondents tended to grow at similar rates. As shown in Figure 2B, men tended to report scheduling an appointment using the internet less often than women. As shown in Figure 3A, a higher percentage of middle-aged adults tended to report communicating with their care provider through email than older adults; a higher percentage of older adults tended to report it than younger adults. As shown in Figure 3B, men tended to report communicating with their care provider through email less often than women.

Figure 1. Percentage of respondents that looked up health information using the internet (A) for each age group and (B) by sex.

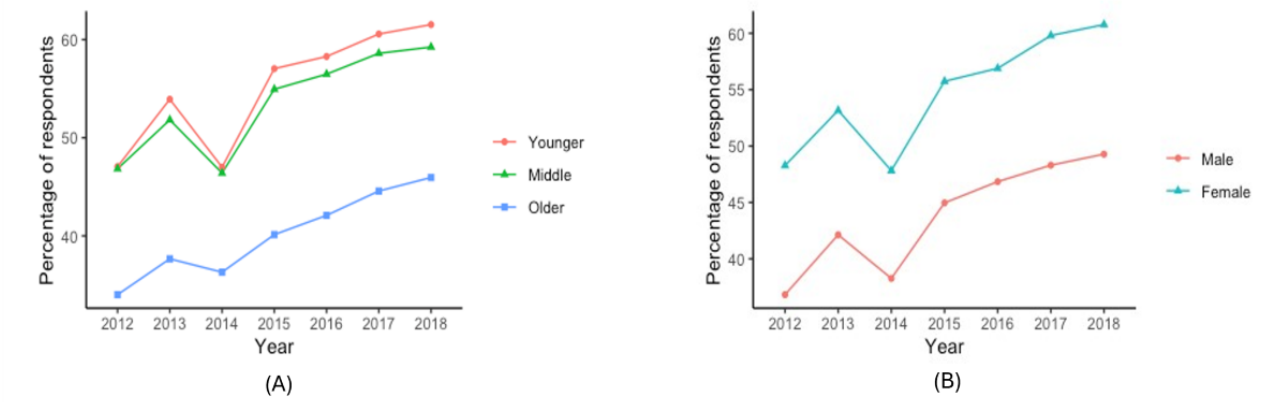

Figure 2. Percentage of respondents that scheduled an appointment using the internet (A) for each age group and (B) by sex.

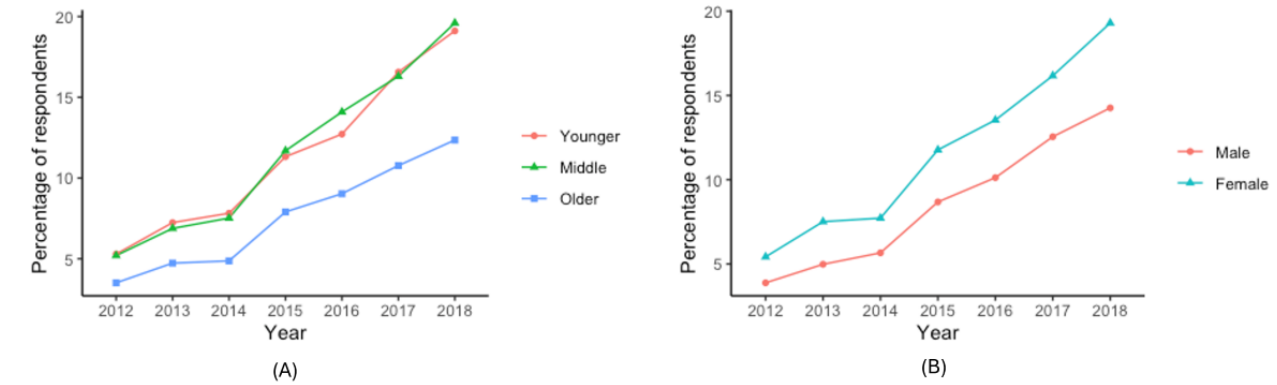

Figure 3. Percentage of respondents that emailed their care provider using the internet (A) for each age group and (B) by sex.

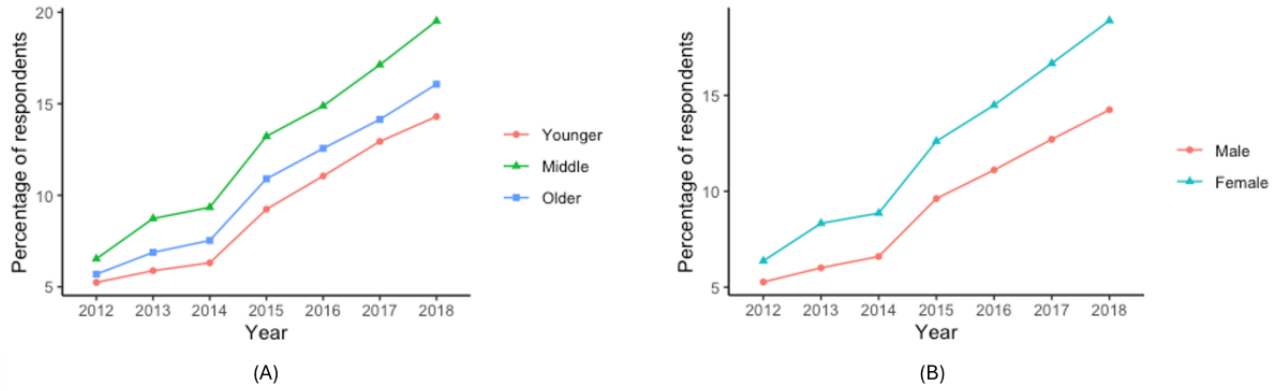

The number of respondents who accessed health information by using the internet increased from 42.76% (n=13,621, unweighted) in 2012 to 55.22% (n=13,677, unweighted) in 2018 (Table 2). In 2018, the percentage of respondents who scheduled an appointment using the internet rose from 4.68% (n=1463, unweighted) in 2012 to 16.86% (n=3962, unweighted). The number of respondents emailing their provider using the internet increased from 5.84% (n=1800, unweighted) in 2012 to 16.65% (n=4176, unweighted) in 2018. The number of respondents seeking medical care who visited a clinic or doctor's office increased from 79.95% (n=27,085, unweighted) in 2012 to 82.03% (n=21,092, unweighted) in 2018. The number of respondents seeking preventive care who visited a clinic or doctor's office increased from 35.96% (n=2706, unweighted) in 2012 to 45.16% (n=2133, unweighted) in 2018. The number of respondents concerned about paying medical bills decreased from 50.24% (n=17,267, unweighted) in 2012 to 43.54% (n=10,637, unweighted) in 2018. The use of alternative therapies to save money increased from 4.07% (n=1454, unweighted) in 2012 to 5.14% (n=1294, unweighted) in 2018.

Table 2. Response variables broken down by year; given as the count of responses and percentage of weighted totals[a].

Parameter	2012	2013	2014	2015	2016	201	2018
Uses internet frequently (>daily), n (%)	18,016 (58.77)	19,699 (63.28)	21,463 (65.04)	19,380 (67.12)	21,013 (69.45)	17,596 (71.05)	17,153 (73.15)
Uses email, n (%)	20,038 (64.46)	21,255 (67.51)	22,697 (68.24)	20,008 (68.84)	21,873 (71.44)	18,198 (72.51)	17,635 (74.37)

[a]The table shows the unweighted sample size for each variable and the related percentage once the weights are applied to the data.

Looking Up Health Information Using the Internet

We constructed a model to examine the relationship between the predictor variables and whether or not the survey respondent accessed health information using the internet (Table 3). With each successive year, respondents were more likely to look up health information using the internet (odds ratio [OR] 1.12, 95% CI 1.10-1.15). Middle-aged adults (OR 0.83, 95% CI 0.75-0.93) and older adults (OR 0.65, 95% CI 0.57-0.73) were less likely in comparison to younger adults to look up health information using the internet. Women were more likely to look up health information using the internet in comparison to men (OR 1.69, 95% CI 1.54-1.85). Black or African American respondents were less likely to look up health information in comparison to White respondents (OR 0.77, 95% CI 0.67-0.89). The survey respondents in the South region were less likely to look up health information using the internet compared to those in the

North region (OR 0.73, 95% CI 0.63-0.85). A frequent internet user was more likely to look up health information (OR 3.40, 95% CI 3.00-3.85). Similarly, respondents who used email regularly were more likely to look up health information using the internet than those who reported not using email frequently (OR 3.88, 95% CI 3.41-4.42). Respondents who reported asking their clinicians for lower-cost medications in order to save money were more likely across all years to look up health information (OR 1.55, 95% CI 1.38-1.75). Respondents using alternative therapies in order to save money were almost twice as likely to look up health information using the internet (OR 1.92, 95% CI 1.57-2.36). Respondents who reported going to a clinic or doctor's office when they were sick were more likely to look up health information using the internet than those who did not report going there (OR 1.21, 95% CI 1.08-1.36). Respondents who reported going to a clinic or doctor's office as part of preventative care were also more likely to look up health information using the internet than those who did not seek out preventative care at a clinic or doctor's office (OR 1.18, 95% CI 1.07-1.31).

Scheduling an Appointment Using the Internet

We constructed a model to examine the relationship between the predictor variables and whether or not the survey respondent scheduled an appointment using the internet (Table 4). With each successive year, respondents were more likely to schedule an appointment using the internet (OR 1.30, 95% CI 1.26-1.34). Older adults were less likely in comparison to younger adults to schedule an appointment using the internet (OR 0.63, 95% CI 0.51-0.78). Women were more likely than men to schedule an appointment using the internet (OR 1.61, 95% CI 1.40-1.85). Respondents who use the internet frequently were more likely to schedule an appointment than those not using the internet frequently (OR 2.75, 95% CI 2.02-3.74). Survey respondents using email were more likely than respondents not using email to schedule an appointment using the internet (OR 3.92, 95% CI 2.78-5.53). Respondents who used alternative therapies in order to save money were more likely to schedule an appointment using the internet than those who did not report using alternative therapies to save money (OR 1.70, 95% CI 1.34-2.16). Respondents who were worried about paying medical bills in the last 12 months were less likely than those who did not report being worried about paying medical bills to schedule an appointment using the internet (OR 0.77, 95% CI 0.66-0.89). Respondents going to a clinic or doctor's office for preventative care were more likely to schedule an appointment using the internet than those who did not report going to a clinic or doctor's office for preventative care (OR 1.55, 95% CI 1.33-1.82).

Communicating With a Care Provider Through Email Using the Internet

We constructed a model to examine the relationship between the predictor variables and whether or not the survey respondent communicated with a care provider through email using the internet (Table 5). With each successive year, respondents were more likely to communicate with a care provider through email using the internet (OR 1.24, 95% CI 1.20-1.28). Women were more likely than men to communicate with a care provider through email using the internet (OR 1.48, 95% CI 1.28-1.71). Respondents who use the internet frequently were more likely to communicate with a care provider through email than those not using the internet frequently (OR 2.08, 95% CI 1.56-2.76). Survey respondents using email were more likely than respondents not using email to communicate with a care provider through email (OR 5.56, 95% CI 3.84-8.05). Respondents who could not afford mental care in the last 12 months were more likely to communicate with a care provider through email using the internet than those who could afford mental care in the last 12 months (OR 1.92, 95% CI 1.39-2.66). Respondents who reported going to a clinic or doctor's office when they were sick were more likely to communicate with a care provider through email using the internet than those who did not report going there when sick (OR 1.32, 95% CI 1.12-1.55). Respondents who reported going to a clinic or doctor's office as part of preventative care were also more likely to communicate with a care provider through email using the internet than those who did not seek out preventative care at a clinic or doctor's office (OR 1.57, 95% CI 1.34-1.85).

Table 5. The best-fit model predicting the likelihood that an individual communicated with a care provider through email using the internet.

Discussion

Principal Findings

This study used NHIS data, which is weighted to represent national characteristics, to examine the use of technology for performing some health care–related tasks over time: looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider over email using the internet. Across all our models, we found that middle-aged and older adult respondents were significantly less likely to use technology to look up health information using the internet or schedule an appointment using the internet versus younger individuals. It has been shown that some older adults may need additional special usability requirements due to their inexperience in the use of technology [21], yet this population is a growing user of technology [30]. This also reaffirmed the results found in the existing literature [26]. Across all of the variables we investigated, we found that the rates of looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider over email using the internet increased substantially across the study period. This demonstrates that there is an increasing use and need for these

services to support larger populations of users including devices and abilities to engage with technology.

Specifically, our analysis found that middle-aged adults were found to have a higher OR than older adults (0.83 vs 0.65) for looking up health information using the internet. We also found that there were differences in age groups for using technology to perform health care–related tasks. In terms of searching health information and scheduling appointments using the internet, we found differences between men and women, with women being significantly more likely than men to look up health information using the internet, schedule an appointment using the internet, and communicate with a care provider through email using the internet. There are conflicting results in the literature related to sex differences in the use of the internet and technology associated with health-related tasks. Newhouse et al [31] found that men were more likely to use email communication for health care than women; however, Baumann et al [32] found that women were more likely to use the internet and technology for health-related tasks such as scientific literature review, communicating with their physician or medical team, and interpreting the diagnostic test results and medications used in treatment. These sex differences may be related to the social construction and perceptions of technology [33]. Future research needs to explore why these trends are occurring and what factors are associated with the differences between men and women especially since there are conflicting results in the literature about use but also about the factors associated with the differences in use.

The impact of costs was inconsistent across the different models in our analysis. With respect to looking up health information using the internet, there was a significant association with using lower-cost medications and alternative therapies to save money. For individuals scheduling a health care appointment using the internet, respondents who indicated using alternative therapies to save money were more likely to schedule appointments using the internet, and surprisingly those who indicated being worried about paying for medical bills were less likely to schedule appointments using the internet. Individuals using email to communicate with a care provider had two different cost-related variables that were significant. Respondents who reported not being able to afford mental care were more likely to email, while those who indicated not being able to afford dental care were less likely to email. In some ways, the included cost-related variables did not seem to indicate a consistent response around cost. This reinforces the notion that determining the extent to which the cost of care is a barrier is challenging and unclear [34]. By examining the results across several cost-of-care–related variables and different elements of health care, it appears that there may be other barriers whose interaction with cost impacts the effect of cost as a barrier. As suggested by Clarke et al [34], and supported by our results, telehealth research should continue to investigate the ways in which different types of costs are intertwined with the use of telehealth; especially as it relates to different avenues of care.

Going to a clinic or doctor's office for preventative care was associated with a greater likelihood of looking up health information using the internet, schedule a health care appointment using the internet, and communicate with a care provider through email using the internet. Going to a clinic or doctor's office when sick was associated with using technology to look up health information and communicating with a care provider through email. This suggests that there is a strong correlation between respondents' collaboration in their personal health and the likelihood that they would use telehealth services to meet these needs. In fact, Sawesi et al [35] found that information technology platforms can enhance patient engagement and improve health outcomes. It is crucial that telehealth research investigate ways in which telehealth can be used to either support individuals in developing an engagement in their own health or identify ways to encourage users to develop an engagement in their own health.

Limitations and Future Work

There are several factors that limit the generalizability of our analyses. One notable limitation of this research is that it relies on self-reported survey data and may not fully capture specific perspectives and opinions about the "why" for some of the activities reported in the NHIS. Yet, the NHIS data collected and maintained by the US CDC is widely used [36-38] and the data, the data design, and the imputation for national representation are widely documented [39,40]. Future research should expand on these results to try to identify if these trends continue or what factors may be driving the differences identified over time.

This research uses responses from specific questions from 2012 to 2018, as those were the only consecutive years where these questions were consistent. As a result, being able to project current and future use of technology for telehealth is limited. Additionally, the COVID-19 pandemic had a major impact on health care as it presented a unique situation that resulted in overcoming many of the traditional barriers to telehealth adoption [41]. COVID-19 also emphasized the use cases of a variety of different technological tools that can be used in telehealth such as chatbots [42]. As our data was limited to data collected before the COVID-19 pandemic, it is important that future work examine the impact that the pandemic has had on the use of telehealth services and if these effects have been sustained in the following years. Future research should also investigate the ways in which the pandemic might have impacted or altered the trends and barriers examined in this research. For example, it may be interesting to evaluate if the exposure and use of these tools during the pandemic have had lasting impacts on the use of the internet tools. To do this, we need similar data from 2020-2023 or later from the NHIS on the use of telehealth services to be able to apply time series modeling techniques to evaluate specific trends in how using telehealth services have changed over time. Interestingly, some initial work has suggested that there is a decline in the use of telemedicine between 2021 and 2022 in the United States, [43] and future work should evaluate if that trend continues or if the trend prior to the COVID-19 pandemic continues.

In order to develop a fundamental understanding of the important barriers, this research did not examine the complex relationships between demographic and response variables. Future research should focus on understanding how these interactions (eg, older women vs middle-aged women vs

younger women) might be correlated with the respondents' use of telehealth. Our models also did not investigate telehealth use for specific socioeconomic levels. Instead, it includes questions regarding a respondent's ability to afford different health care services, which is different from financial security or socioeconomic conditions [44].

Conclusions

As telehealth is increasingly becoming an important component of health care services, it is important to focus on different aspects of telehealth to determine the demographic characteristics, behaviors, or opinions that may predict or influence groups that are likely to face a barrier to using telehealth services. This study used NHIS data to examine the use of technology for performing some health care–related tasks over time: looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider over email using the internet. From this analysis, we have found some potential barriers that may impact a user's ability to access telehealth services, as well as differences in the use of these tools for different groups. Understanding those who are using the internet for health care–related activities and the barriers that they may face is important for the design and implementation of these systems to be as effective as possible. Systems and technology designers, as well as health care providers, should be aware of these differences and the impacts they may have on engaging individuals in their health care.

Abstract

Background: Cardiac pain has been widely considered to be the primary indicator of coronary artery disease. The presentation of cardiac pain and associated symptoms vary in women, making it challenging to interpret as cardiac, possibly cardiac, or noncardiac. Women prefer to consult with family and friends instead of seeking immediate medical care.

Objective: This study aimed to assess the user performance (ie, ease of use, efficiency, and errors) and user satisfaction (System Usability Scale; SUS) of a progressive web application for women with cardiac pain.

Methods: Following ethics approval, a purposive sample of women aged >18 years with cardiac pain or associated symptoms lasting >3 months and able to speak and read English was recruited to participate in 2 iterative usability testing cycles. The first cycle assessed the performance of and satisfaction with *at heart* using a web application, and the second cycle assessed the performance of and satisfaction with *at heart* across various Android and iOS devices. In total, 2 investigators recorded user comments and documented problems. At the end of the testing session, the participants completed the SUS and 4 semistructured interview questions.

Results: In total, 10 eligible women participated in usability testing from March 31, 2020, to April 17, 2020 (cycle 1), and from November 17, 2020, to November 30, 2020 (cycle 2). Women across usability testing cycles had a mean age of 55.6 (SD 7.3) years, and most (9/10, 90%) were well educated. In total, 50% (5/10) were employed full or part time, and 60% (6/10) earned >CAD $70,000 (US $48,881.80) annually. Participants across 2 testing cycles reported the overall usability of the *at heart*

progressive web application as highly acceptable (mean SUS score 81.75, SD 10.41). In total, 90% (9/10) of participants rated the user-friendliness of *at heart* as good or excellent. All participants (10/10, 100%) thought *at heart* was easy to use and efficient. Only 2 testing errors were noted as high priority; these were low contrast or small font and clarification that the chatbot was not a real person. User satisfaction was assessed using themes that emerged from the debrief and 4 semistructured interview questions; *at heart* was engaging, comprehensive, understandable, credible, relevant, affirming, personalized, and innovative.

Conclusions: This study provides initial support for the *at heart* progressive web application for women living with cardiac pain and symptoms. Ongoing evaluations in phases 3 and 4 should aim to examine the feasibility and acceptability of and the extent of engagement with the *at heart* core feature set: Heart Check, Wellness Check, and the library. In addition to assessing effectiveness in the phase-4 effectiveness-implementation hybrid trial (type I), describing and better understanding the context for implementation (eg, race and ethnicity and geography) will be necessary.

Introduction

Background

Cardiovascular diseases constitute the leading cause of mortality worldwide, exerting a substantial economic burden on the health care system [1-4]. As the most prevalent form of cardiovascular disease, coronary artery disease (CAD) is estimated to be associated with 8.93 million deaths annually worldwide across all ages [1]. CAD is a complex condition that varies in clinical presentation across sexes, with both obstructive (macrovascular) and nonobstructive (microvascular) CAD being associated with cardiac pain and other symptoms [5]. Although cardiac pain has been widely considered to be the primary indicator of CAD [6], cardiac pain and associated symptoms reported by women with CAD differ markedly from those reported by men [7,8]. The presentation of cardiac pain and associated symptoms may vary in frequency, pattern, and distribution in women [8], making it challenging to interpret as cardiac specific [9]. Similarly, women that undergo a percutaneous coronary intervention or cardiac surgery report higher prevalence of persistent pain of moderate to severe intensity after treatment as compared to men [10-12]. This cardiac pain is often described by women as sharp and burning and may present with varying extent of dyspnea, fatigue, anxiety, and discomfort that may radiate to the jaws, shoulders, back, and arms [6,8,13]. The manifestations of cardiac pain and associated symptoms contribute to substantial morbidity and impairments in health-related quality of life (HRQoL) in women [14,15].

The complex presentation of CAD in women poses a challenge for timely recognition and management of symptoms. Recent data have shown that women often delay seeking medical care when experiencing acute cardiac pain or associated symptoms, with time between symptom onset and emergency department arrival being 85 to 320 minutes [16]. Women report experiencing difficulties in interpreting, understanding, and attributing their cardiac pain or symptoms to CAD, preferring to consult with family and friends instead of seeking immediate medical care [17]. Moreover, women often hesitate to seek medical care for cardiac pain or associated symptoms as a result of their gendered roles as caregivers [17,18]. Women describe having gendered roles that they are unable to delegate, such as providing care for dependent family members [17,18]. The cumulative effect of symptom underrecognition and hesitancy in women leads to delayed care-seeking behaviors and an increased risk of major adverse cardiac events or mortality as compared to men [6]. As such, it is imperative to promote proper recognition, assessment, and management of symptoms in women to improve health outcomes and HRQoL.

Self-management programs are designed to engage users as active participants in the management of their conditions; they are key predictors of successful behavior change [19,20]. These interventions generally use educational strategies designed to assist users in achieving optimal knowledge, understanding beliefs, and skills, as well as providing meaningful social supports [21]. Digital health–based self-management programs have been developed and effectively used to help women manage weight [22-25], increase physical activity [26], monitor for perinatal depression, and assist with postpartum smoking cessation [27]. Many women describe digital health interventions as being novel and supportive [22] and effective in motivating healthy behaviors, reducing symptoms [28], and improving HRQoL [23]. However, there is a lack of evidence-informed digital health self-management programs specifically for women with CAD living with cardiac pain and associated symptoms [7], demonstrating a clear need for a digital self-management program.

At heart (formerly HEARTPA♀N) [29], a self-management progressive web application, was developed for women with CAD using a sequential phased approach recommended by the Medical Research Council (MRC) [30-32]. In phase 1, an integrated mixed methods systematic review was conducted to evaluate the current evidence related to the self-management of cardiac pain and associated symptoms (eg, dyspnea and fatigue) in women [7,29]. The results of the review suggested that self-management interventions could reduce cardiac pain and associated symptoms if they targeted a greater proportion of women (standardized mean difference [SMD]=−0.01; SE 0.003; *P*=.02), goal setting (SMD=−0.26, 95% CI −0.49 to −0.03), and collaboration or support from a health care provider (SMD=−0.57, 95% CI −1.00 to −0.14) [33]. The review also identified a lack of self-management interventions targeted specifically for cardiac pain and associated symptoms in women

[33]. In phase 2A, the content and core feature set, chatbot, and symptom triage algorithms were co-designed with health care professionals and women with CAD [29]. In phase 2B, the usability of *at heart* was evaluated to ensure that the platform was intuitive and acceptable for women with cardiac pain, and it is the focus of this paper. In phase 3, a process and preliminary efficacy evaluation using a 2-group parallel pilot randomized controlled trial (RCT) will be undertaken, and then a phase-4 effectiveness-implementation hybrid trial is planned (Figure 1).

Figure 1. Phases of the *at heart* progressive web application development.

Objectives

The objectives of this study were to assess the user performance (ie, ease of use, efficiency, and errors) and user satisfaction (interviews and System Usability Scale [SUS]) of a progressive web application for women with cardiac pain.

Methods

Participant Selection

Following ethics approval, a purposive sample of women was recruited from (1) an ambulatory care hospital focused on women's health, (2) an adult tertiary care transitional pain clinic; (3) the Alberta Provincial Project for Outcome Assessment in Coronary Heart Disease registry; (4) the CorHealth Ontario Cardiac Registry; (5) established strategies through the Canadian Pain Coalition; (6) the Ontario Women's Health Network's listserve, which reaches >1900 women and community organizations in Ontario, Canada; and (7) social media. The Ontario Women's Health Network regularly brought women who lived in rural and remote areas together, including women who were disabled, women of color, women with a low income, and Indigenous and older women. Women were eligible to participate in the usability testing if they (1) were aged >18 years, (2) had been diagnosed with obstructive or nonobstructive CAD pain or pain after a percutaneous coronary intervention or cardiac surgery lasting >3 months, (3) were able to speak and read English, and (4) had not previously used or tested the *at heart* progressive web application. Women were excluded from the study if they had (1) severe cognitive impairment, assessed using the Six-Item Screener administered via telephone; or (2) a major comorbid medical or psychiatric condition that would preclude their ability to participate in the usability testing. The Six-Item Screener is a brief instrument for identifying individuals with cognitive impairment, and its diagnostic properties are similar to those of the Mini-Mental State Examination [38,39].

Usability testing is an important phase in the development of digital health interventions [34,35]. End users test a prototype in iterative cycles; they provide feedback about what works, what does not work, and where gaps might exist in the information and functionality [34,35]. These factors contribute to the frequency of use, understanding, and acceptability and enhance the likelihood that users will use the end product [35,36]. Testing the usability of the intervention also serves to assess the suitability of the platform interface and content [37].

Ethical Considerations

The phase-2B usability testing was approved by the Health Sciences Research Ethics Board (REB; 36415) at the University of Toronto on November 26, 2018, and the Health Sciences and Affiliated Teaching Hospitals REB (6026830) at Queen's University on June 20, 2019. An amendment was granted by the Health Sciences REB (36415) at the University of Toronto on March 26, 2020, to use secure video- or web conferencing (Zoom; Zoom Video Communications) for the usability testing sessions due to COVID-19 pandemic restrictions, which prohibited in-person participant contact. Informed consent and a demographic and clinical information form (Multimedia Appendix 1) were obtained from participants before each iterative cycle. Participants were identified using a study ID, and data were stored on a secure OneDrive folder (Microsoft Corp) accessible only to the principal investigator and research officer. All participants were compensated with a user-identified CAD $25 (US $17.52) gift card.

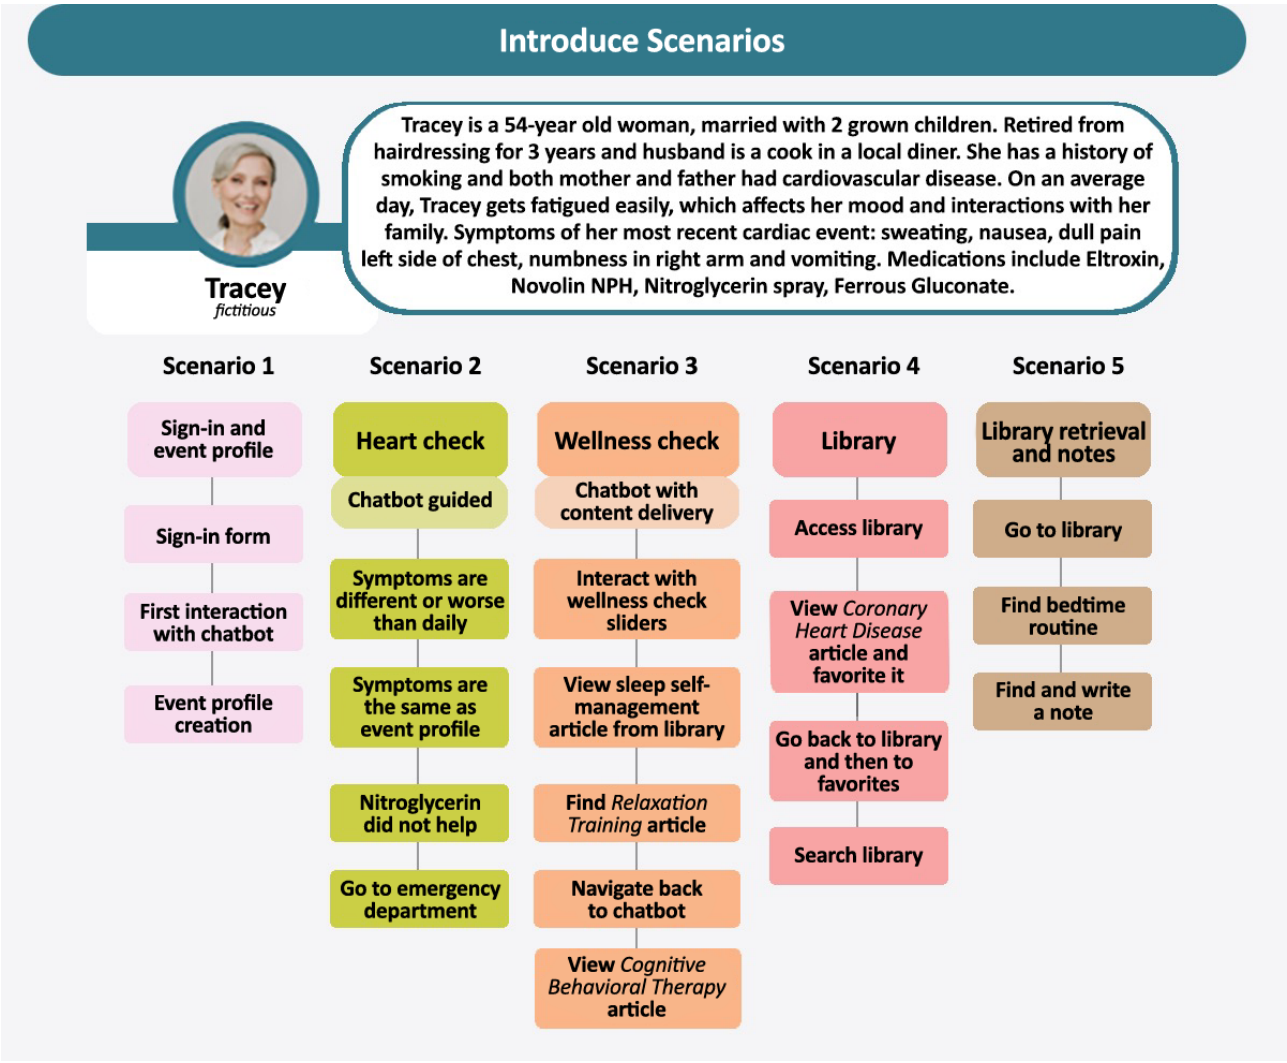
Study Design and Procedures

The usability of the *at heart* progressive web application focused on a think-aloud scenario-based approach to assess user performance (ie, ease of use, efficiency, and errors) and user satisfaction with *at heart's* content and functionality assessed qualitatively through the short scenario debrief questions and the interviews and quantitatively using the SUS [40]. This multi-method approach to usability testing is supported by a recent scoping review [41]. A sample of 10 eligible women was recruited to participate in the iterative usability testing cycles (n=5, 50% of the women participated in each of 2 testing cycles). This sample size was based on the experience of others [42-44], as well as recommendations that usability testing by 3 to 5 users can find approximately 85% of interface usability problems [45,46]. The first cycle tested user performance and satisfaction on a desktop computer, and the second cycle assessed user performance and satisfaction across various Android and iOS devices (ie, smartphones and tablets). Participants were provided with a brief explanation of the study and the *at heart* progressive web application before undergoing a 60- to 90-minute one-on-one observation period conducted and recorded through

the Zoom videoconferencing platform. Participants were introduced to a case of a woman aged 54 years with symptoms that were "possibly cardiac" [47] and asked to sign in, complete an event profile (scenario 1), and then progress through a set of standardized scenarios that incorporated each core feature of *at heart*: Heart Check, Wellness Check, and the library (scenarios 2-5; Figure 2).

The "think-aloud" approach was used to capture users' thought process and problem-solving as they progressed through *at heart's* core features in a systematic manner. After each scenario, the participants answered two short debrief questions: (1) "What did you like about the content and functionality of this specific scenario?" (2) "What did you dislike about the content and functionality of this specific scenario?"

Figure 2. Usability testing workflow.



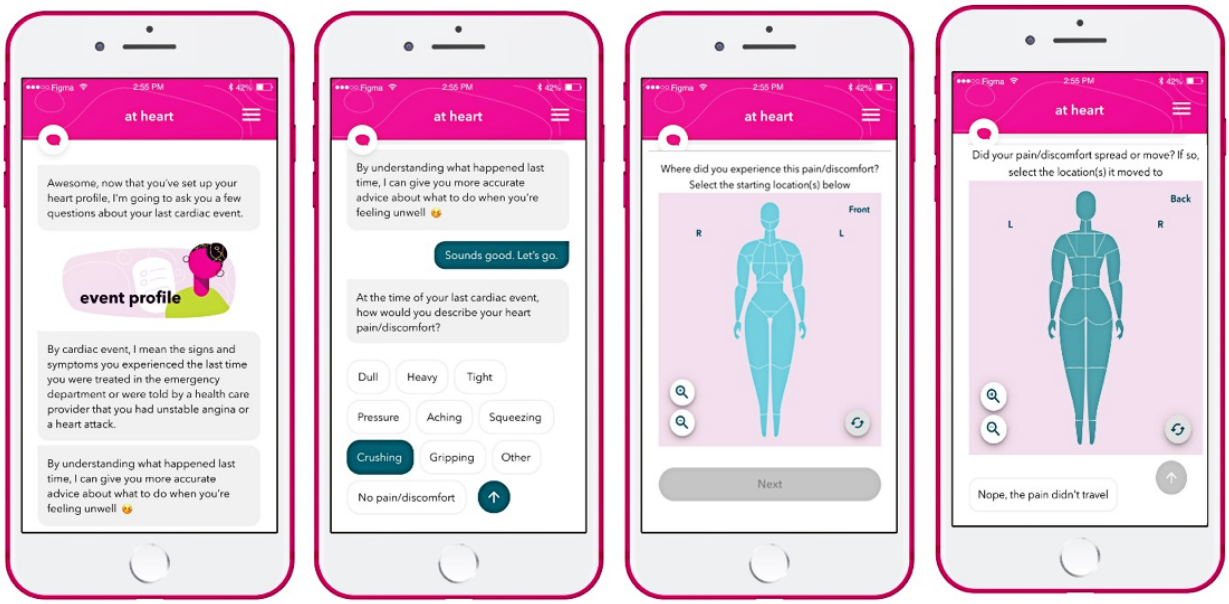
In total, 2 investigators also recorded user comments and documented any problems encountered during each scenario using the usability testing error and efficiency documentation form (Multimedia Appendix 2). Three error types were captured on this form: (1) navigation errors (ie, failure to locate a function or follow the recommended screen flow), (2) presentation errors (ie, selection errors due to labeling ambiguities), and (3) control use errors (ie, improper entry field errors). Four semistructured interview questions were posed following the think-aloud scenarios to assess the overall satisfaction with *at heart's* content and functionality: (1) "What was your overall impression of the *at heart* progressive web application?" (2) "What did you like or dislike about the *at heart* progressive web application?" 3) "Is there anything that could be improved or changed?" (4) "Is there anything missing from the *at heart* progressive web application?" Participants then completed the SUS on the web using REDCap (Research Electronic Data Capture; Vanderbilt University), a secure web application. The SUS is a widely used scale that quantifies the usability of digital health applications. It consists of 10 questions with Likert scales that range from *strongly agree* to *strongly disagree*, and it has been validated across a range of interfaces, including web pages and web applications [40,48,49]. Scores range from 0 to 100, with an accepted benchmark mean SUS score of 68 (SD 12.5) [40]. One 7-point adjective-anchored Likert scale was added to the bottom of the SUS so that participants could rate the overall user-friendliness of *at heart* as *worst imaginable*, *awful*, *poor*, *ok*, *good*, *excellent*, or *best imaginable*. This adjective rating scale helps inform the absolute usability of a product [50-52], such as the *at heart* progressive web application. Numerical equivalents of 1 (*worst imaginable*) to 7 (*best imaginable*) were assigned to the adjectives for scoring. After the first cycle,

revisions were made to the prototype, and the revised prototype was tested in a second usability testing cycle.

At Heart Progressive Web Application

At heart is a novel progressive web application that consists of 3 core features: Heart Check, Wellness Check, and a library. Users are guided through the core feature set by a rule-based chatbot that manages content and conversations. An Event Profile is created on the initial log-in to the progressive web application (Figure 3). The Event Profile contains individualized or personalized data that include the quality and location of cardiac pain or associated symptoms experienced at the time of the participant's last heart event (ie, treated in the emergency department). Female front and back full-body maps were specifically developed for *at heart* using the chest pain or associated symptom locations most commonly described in the literature [6,8,13,47,53].

Figure 3. Screenshots of the *at heart* feature Event Profile prototype.

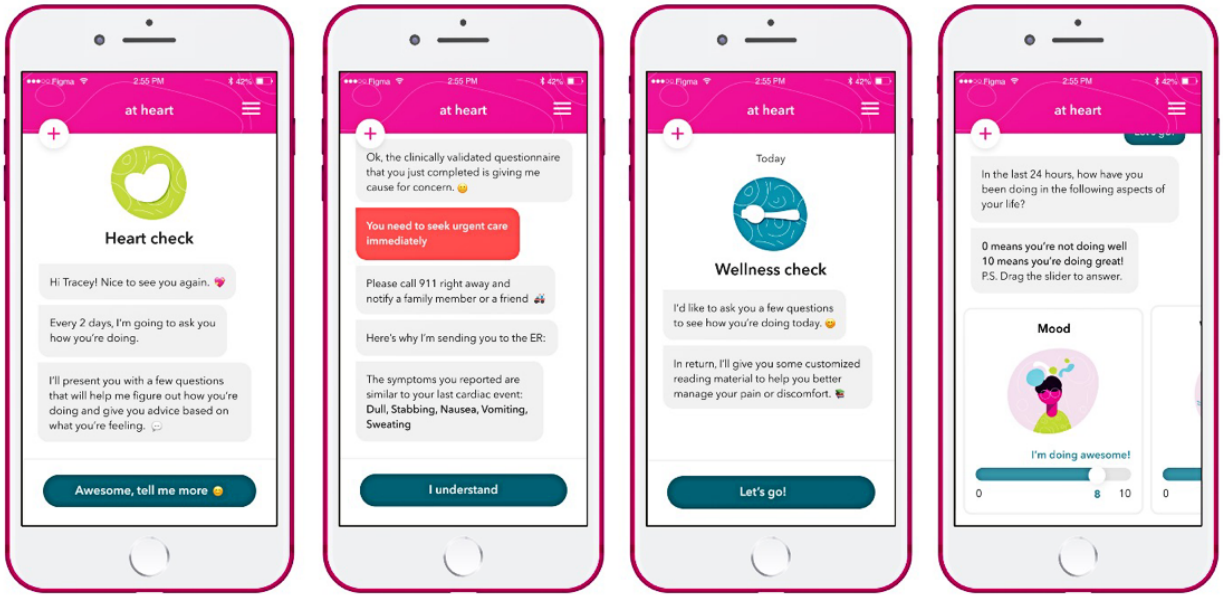


Chatbot Holly asks women the same series of cardiac pain and symptom assessment questions in the Heart Check, which is programmed into the *at heart* progressive web application to occur every 3 days (Figure 2). The Heart Check can occur more frequently simply by asking chatbot Holly for a Heart Check. Rule-based symptom triage algorithms compare each Heart Check to the individually stored Event Profile to make recommendations on an appropriate level of care. Level of care recommendations are based on the similarity and timing of current cardiac pain or discomfort to that stored Event Profile, noting similarities between the current and previous descriptions of the quality (ie, heavy, tight, or pressure), location, radiation, and associated symptoms. Recommendations are assigned to one of three categories: (1) *red* or high risk (ie, similar or high-risk symptoms that have occurred within 24 hours), (2) *yellow* or moderate risk (ie, similar or high-risk symptoms that have occurred beyond 24 hours but within 7 days), and (3) *green* or low risk (ie, no similar or high-risk symptoms). Women who are categorized as *red* are encouraged to notify a family member of their current symptoms and call 911 (ie, to seek appropriate and urgent assessment of their symptoms). Women who are categorized as *yellow* are encouraged to see their primary care provider within 48 hours, and women who are categorized as *green* are permitted access to the *at heart* progressive web application. High-risk symptoms are defined as ≥3 new typical symptom features (ie, dull, heavy, or tight chest pain) [53] or any new associated symptoms, including shortness of breath; palpitations; a racing heart rate; or feeling lightheaded, faint, or dizzy [47].

Women complete the Wellness Check, informed using features of the Brief Pain Inventory–Interference Subscale [54], to indicate the degree to which cardiac pain or associated symptoms interfere with 7 domains of life, which include general activities, paid and unpaid work, walking, mood, relations with others, sleep, and overall enjoyment of life (Figure 4). Wellness Checks are programmed to occur every 7 days at a minimum, and if the score in any domain is below a threshold, the chatbot uses rule-based algorithms to deliver educational content from the library.

The library contains scientific papers, each with a lay summary, covering educational content about CAD in women, with self-management advice to promote good health and well-being [29]. The library also contains videos and podcasts from women with lived experiences of CAD. *At heart* was evaluated by Health Canada and deemed not to be a medical device as defined in the Guidance Document: Software as a Medical Device (SaMD): Classification Examples [55]. *At heart* provides self-management support to women who have CAD and, through a chatbot, guides women to the most appropriate form of assessment (ie, primary care and emergent care) based on their medical symptoms.

Figure 4. Screenshots of the Heart Check and Wellness Check features of the *at heart* prototype.



Data Analysis

Quantitative descriptive data from the demographic and clinical information form and the SUS were analyzed using SPSS Statistics (version 29; IBM Corp). Debrief feedback from each of the 5 scenarios with data from the usability testing error and efficiency documentation form was reviewed after each of the 2 iterative usability testing cycles. Conventional content analysis as outlined by Sandelowski [56] was used to analyze qualitative data obtained from the interview questions. In total, 2 researchers independently assigned codes to label key actions, thoughts, and ideas. Related codes were grouped into categories, and any disagreements were discussed between the 2 researchers. A list of prototype issues was generated and prioritized based on risk to patients and ease of improvement [57]. Modifications were communicated to the website design and development team. Prototype changes made after the first cycle were evaluated in the second cycle, and prototype changes following the second cycle were completed before the phase-3 RCT.

Results

Participant Characteristics

A total of 10 women meeting the eligibility criteria were invited to participate in the usability testing from March 31, 2020, to April 17, 2020 (cycle 1), and from November 17, 2020, to November 30, 2020 (cycle 2). Women across the usability testing cycles had a mean age of 55.6 (SD 7.3) years, and most had a diploma (5/10, 50%), an undergraduate degree (2/10, 20%), or a graduate degree (2/10, 20%). Most of the women were employed full (3/10, 30%) or part time (2/10, 20%) and earned >CAD $70,000 (US $48,881.80) annually (6/10, 60%); 50% (5/10) lived with a disability, 50% (5/10) were the primary household earners, and 80% (8/10) were the primary persons responsible for housework in the home. The women reported cardiac pain or associated symptoms for 1 to 2 years (3/10, 30%), 2 to 5 years (3/10, 30%), or >5 years (3/10, 30%). The most common comorbid conditions included depression (4/10, 40%) and anxiety (4/10, 40%), and 40% (4/10) of the women had had a previous myocardial infarction. Participant demographics by usability testing cycle are reported in Table 1.

All women (10/10, 100%) had a computer at home and were comfortable (3/10, 30%) or very comfortable (7/10, 70%) using a computer, comfortable (1/10, 10%) or very comfortable (9/10, 90%) using the internet, and comfortable (3/10, 30%) or very comfortable (7/10, 70%) using smartphone or tablet apps. Participants' comfort levels and use of the computer, the internet, and smartphone or tablet apps are reported in Table 2. All women selected their own devices for usability testing. Women in the first cycle used only the Google Chrome browser (5/5, 100%), and women in the second cycle used an iPad mini version 9.3.5 (1/5, 20%), Samsung Galaxy S10e (1/5, 20%), iPhone 8 (2/5, 40%), and iPhone 11 (1/5, 20%).

Table 1. Participant characteristics.

Characteristic	Cycle 1 (n=5)	Cycle 2 (n=5)
Age (y), mean (SD)	58.4 (4.827)	52.8 (8.872)
Gender identity (woman), n (%)	5 (100)	5 (100)

Smartphone or tablet app hours per week, mean (SD)	6.4 (2.302)	7 (1.414)
Comfortable using smartphone or tablet apps, n (%)		
Comfortable	1 (20)	2 (40)
Very comfortable	4 (80)	3 (60)

User Performance

User performance was assessed through ease of use, efficiency, and observation of testing errors (ie, navigation, presentation, and control use errors) through each scenario and cycle of usability testing. Testing errors included those related to navigation (difficulties moving through or locating content), presentation (selection errors due to labeling), or control use (improper entry field errors) across the 5 scenarios in 2 usability testing cycles (Figure 2). In scenario 1 of cycle 1 (sign-in, chatbot, and Event Profile), participants reported a low contrast between the text and the background and small font at sign-in. Participants also wanted clarification that the chatbot was not a real person. These were flagged as high priority, and subsequent revisions included larger font and chatbot and user text boxes identified using different colors, and a page was added to the *at heart* progressive web application to describe the chatbot, including its development and function. Specific text included the following: “let me tell you a little more about myself. I’m an educated chatbot, thoughtfully designed by a group of women’s heart health experts. I’ll be here to help you understand more about your heart pain/discomfort through regular check-ins, and I’ll send you tips and tricks for managing that pain. If you want to learn more about my makers, the same ones who named me Holly, go to the menu above...” A summary of suggestions and subsequent changes made to the progressive web application during usability testing cycle 1 is shown in Table 3.

The scenarios were repeated in the second cycle to assess user performance and user satisfaction across various Android and iOS devices (ie, smartphones and tablets). In scenario 1 of cycle 2 (sign-in, chatbot, and Event Profile), participants requested clarification on the terminology used in some of the questions at sign-in, so descriptors and more answers were added to these questions. Participants also had difficulty choosing specific areas on the body map, so the body maps were subsequently amended. In scenario 2 of cycle 2 (chatbot-guided workflow for the Heart Check), participants appeared confused with the order and speed of the questions delivered by the chatbot. The chat time stamp was subsequently increased for desktop, Android, and iOS devices. This allowed women ample time to read and respond appropriately to the Heart Check questions, especially those with longer messages and prompts. Finally, the Heart Check button was reported to be too small and gray, so the size and contrast were adjusted. The chatbot-guided workflow for the Wellness Check (scenario 3, cycle 2) required minor adjustments to ensure that the chatbot selected appropriate resources from the Wellness Library based on wellness scores of ≤4. One participant suggested that “anaphylaxis” be added to the Share My Data section and related articles be added to the library. As a result, lay summaries were generated, and scientific papers were added to the library for Kounis syndrome (n=3) and mast cell activation syndrome (n=2). Kounis syndrome is a complex multisystem arterial condition caused by mast cell activation and T-lymphocyte and macrophage interactions [58]. The resulting allergic, hypersensitivity, and anaphylactic reactions cause coronary symptoms (ie, cardiac pain), and this is referred to as Kounis syndrome [59]. A summary of suggestions and subsequent changes made to the progressive web application during usability testing cycle 2 is also shown in Table 3.

Table 3. Summary of suggestions and subsequent changes during usability testing.

Suggestions	Changes
Cycle 1 (n=5)	
Scenario 1—sign-in, chatbot, and Event Profile	
There was a low contrast between the text and the background and small font at sign-in.	Larger font and chatbot and user text boxes identified using different colors were implemented.
Clarification that the chatbot is not a real person was requested.	A page was added to the *at heart* progressive web application to describe the chatbot, including its development and function.
Participants selected only 1 descriptor on the body map and reported lack of clarity that more than one descriptor could be selected.	Directions for completing the body map were enhanced.
Scenario 2—Heart Check	
None	None
Scenario 3—Wellness Check	
None	None
Scenario 4—library	
Participants had difficulty locating the Favorites section of the library.	The Favorites section was moved to the top of the screen and identified with a larger icon that represented a heart.
Scenario 5—library retrieval and notes	
None	None
Other	
None	None
Cycle 2 (n=5)	
Scenario 1—sign-in, chatbot, and Event Profile	
Participants requested clarification on the terminology used in some of the questions at sign-in.	Descriptors and more answers were added to the questions for clarity.
Participants had difficulty choosing specific areas on the body map to describe their symptoms.	The body maps were subsequently amended to include axillae and body map descriptors.
Scenario 2—Heart Check	
Participants appeared confused with the order and speed of the questions delivered by the chatbot.	The chat speed was reduced for desktop, Android, and iOS devices.
The Heart Check button was reported to be too small and gray.	The size and contrast of the “Heart Check” button were adjusted.
Scenario 3—Wellness Check	
The chatbot says the following: “based on what you’ve told me, here are some topics...” However, the chatbot presented all topics even for wellness scores that were excellent (ie, the readings from the library did not appear tailored to the needs of each participant).	Minor adjustments were made to the rules to ensure that the chatbot selected appropriate resources from the wellness library based on wellness scores of ≤4.
Scenario 4—library	
None	None
Scenario 5—library retrieval and notes	
None	None
Other	
Add anaphylaxis to the Share My Data section.	This was added.
Add anaphylaxis articles to the library as they related to women and heart disease.	Lay summaries were generated and scientific papers were added to the library for Kounis syndrome (n=3) and mast cell activation syndrome (n=2).
Participants requested to have a more robust Share My Data section, with opportunity to record medications and other comorbid conditions.	The introduction and the content of the Share My Data section were enhanced.

User Satisfaction

Overview

User satisfaction was assessed using the SUS and the 4 semistructured interview questions. Overall, 10 participants across 2 cycles of testing reported the overall usability of the *at heart* progressive web application as highly acceptable (mean SUS score 81.75, SD 10.41). There was no difference in SUS scores between cycle 1 (mean SUS score 81.5, SD 8.59) and cycle 2 (mean SUS score 82.0, SD 13.04; t_8=−0.72, 95% CI −16.6 to 15.6). A total of 90% (9/10) of the participants rated the user-friendliness of *at heart* as good or excellent. All participants (10/10, 100%) thought that *at heart* was easy to use (SUS question 3; ie, most women could learn to use *at heart* very quickly):

> *I think everything was pretty straightforward. It was overall really, really good.* [Cycle 2; participant 3]

None of the participants indicated that they would need the support of a technical person to be able to use *at heart* (SUS question 4), and 80% (8/10) of the participants found the various functions in *at heart* well integrated (SUS question 5) with minimal inconsistencies (SUS question 6):

> *Well...I was a bit worried it might be confusing, but it's not confusing at all. It's very intuitive, it, you've built it so it's similar to a lot of other apps out there, right? So, clicking here, you know, submitting the button. So, it seems to be pretty normal as far, it looks, the same look and feel as other apps that are out there which are good. It seems to be easy. I'm not a tech person, so I wanted to make sure that—I was nervous that I wasn't going to be able to manage it because I, I'm not great with technology, but it was easy. So, yeah. I mean, I think it's a great tool.* [Cycle 2; participant 5]

A total of 8 themes emerged from the interview data (ie, engaging, comprehensive, understandable, credible, relevant, affirming, personalized, and innovative) and can be found in Multimedia Appendix 3.

Engaging

Participants commented on the layout, visual appeal, language, and name and logo of the progressive web application. They found the content easy to read and maneuver. Important content was highlighted, and participants reported this to be helpful. Article summaries were presented in larger font and used lay language. At the outset of this study, the progressive web application was named HEARTPA♀N [29]. Participants recommended a name change to one that was less focused on pain as many women describe their cardiac pain as discomfort and have other associated symptoms (eg, dyspnea and fatigue). They felt that the name *at heart* was more personally welcoming and less focused on pain. The heart logo was simple yet distinctive and recognizable.

Comprehensive

Participants indicated that the progressive web application provided necessary information for helping them make decisions about their cardiac symptoms. They liked that it was specific to women and that they could search through the library to improve their knowledge about wellness and women's heart health. Participants also commented that the chatbot assisted them in making decisions:

> *...the bot kind of identifies for me what the big blind spots are that I am perhaps not noticing.*

Understandable

Participants indicated that *at heart* was intuitive, the content made sense, and it flowed well. The tone and the language were suitable and clear. Participants commented on the appropriateness of the associated symptom descriptors included in the Event Profile and Heart Check.

Credible

Participants liked that *at heart* was developed as a living progressive web application. They particularly liked the breadth and depth of scientific articles and lay summaries included in the *at heart* library. Participants valued having an evidence-informed digital health self-management program specifically designed for women with CAD living with cardiac pain and associated symptoms.

Relevant

Participants commented on the relevance and accessibility of content in the *at heart* library. The chatbot asked relevant questions and was able to use rule-based algorithms to provide advice to women about timely assessment in the emergency department. They particularly noted the relevance of having their Event Profile and Heart Check information stored so that they could refer to it when visiting their health care providers. The content was applicable to their everyday lives.

Affirming

Participants looked for affirmation from *at heart's* chatbot when they were having cardiac symptoms. They indicated that they would have otherwise consulted with family members or Facebook group members for guidance. Affirmation of symptoms was important to women, and they appreciated the high-alert messages to seek urgent care immediately.

Personalized

Participants liked the chatbot. They found it to be personal, immediately interactive, accessible, calming, and friendly. They commented that the chatbot may help make them feel less alone if they went to the emergency room because it checked in with them to see how they were doing. The chatbot provided comfort at times when participants felt scared. Participants also valued the videos and podcasts as they also helped them feel that they were not alone in their experience with heart disease.

Innovative

Participants felt that *at heart* provided an opportunity for further research focused on women's heart health. They were willing to share anonymized data on socioeconomics, risk factors, gynecological or obstetrics history, lifestyle, medications, and other conditions (eg, arthritis or depression) to improve outcomes for women at risk of or with heart disease. Participants also valued the ability to journal and take notes in the

progressive web application. They valued the opportunities that *at heart* could provide to women who live in more isolated areas or those who live alone. The *at heart* progressive web application was described as all-encompassing, covering necessary content to improve knowledge and decision-making, with a chatbot to ask questions and deliver information in a comforting manner.

Discussion

Principal Findings

There is growing support for the importance of usability testing for mobile health and eHealth innovations [60-62]. Usability testing incorporates an iterative process of testing and refining to meet end-user needs [63]. The objectives of this study were to assess the user performance (ie, ease of use, efficiency, and errors) and user satisfaction (SUS) of a progressive web application for women with cardiac pain. User performance was assessed through ease of use, efficiency, and observation of testing errors (ie, navigation, presentation, and control use errors) through 5 brief scenarios and 2 cycles of usability testing.

The overall usability of the *at heart* progressive web application was rated highly by 10 participants who completed the usability testing cycles; the progressive web application was easy to use and efficient. However, 2 high-priority testing errors were identified during the usability testing cycles. The first involved small font at sign-in and low contrast between the text and background, and these were corrected by enlarging the font and making alterations to the text and background colors. The second was to clarify that the chatbot was not a real person. A significant amount of time was committed to addressing potential language challenges during the development of the chatbot, and there were no technical, design, or language challenges identified during the usability testing cycles. In fact, the design and language or conversation of the chatbot appeared to mimic human-to-human interaction so closely that participants requested confirmation that the chatbot was actually nonhuman.

The *at heart* chatbot is a simple rule-based conversational agent designed to mimic human-to-human interaction at sign-in and creation of an Event Profile and during completion of the Heart Check and Wellness Check. Our previous systematic review and meta-analysis indicated that self-management programs were more effective in reducing cardiac pain and associated symptoms (eg, dyspnea and fatigue) in women if they included collaboration and support from health care providers [33]. Chatbots are conversational agents able to promote health and provide education and support [64]. Their use in health care is still in a developmental stage; they could improve access to care and health care provider–patient communication, but more evidence is needed. Technical, design (ie, lack of empathy), and language challenges [65] can impede the integration of chatbot technologies into health care [64]. Adopting user-centered and theory-based designs, optimizing user experiences, and addressing patient concerns can improve chatbot uptake and use [64]. Our chatbot relies on scripted computational algorithms, with specific rules for its text-based conversations [66]. More advanced human-machine conversation is now based on natural language processing and large language models that use artificial intelligence methods to learn, understand, and produce structured language content [66,67]. Health care delivery is rapidly changing and is driven by social, scientific, and technological change; our future chatbot may need to emulate person-to-person conversation through dialogue and body movements, with appropriate expressions of empathy and compassion [68]. We are really at a cusp in health care; growth in chatbot use will be driven by a desire for health and wellness and 24-hour access to care, with a growing number of platforms from which to build an intelligent and emotive chatbot in the future [69].

At heart is the first of its kind; no smartphone- or web-based self-management program has been co-designed and systematically developed with women who have lived experience (phase 2A) and then tested with women who have cardiac pain (phase 2B). We used the individual and family self-management theory [70,71], mobile device functionality, and the pervasive information architecture of mobile health interventions [72] and followed the MRC's guidance for developing complex interventions [30-32]. *At heart* was designed as a progressive web application aimed at delivering nativelike user experiences regardless of the browser or the mobile device [73]. This study identified that the comprehensiveness and credibility of the information was important to women. The information helped them understand more about CAD and wellness and provided them with guidance in decision-making. At inception, women clearly articulated the need for a web application that was accessible across Android and iOS operating systems, including computers, smartphones, and tablets. In phase 1, women identified the need to access the library anytime and anywhere (eg, while waiting for dental appointments). As women were involved at the outset in co-design, no other significant user performance or satisfaction–related issues were identified. Female front and back full-body maps were specifically developed for *at heart* using the chest pain or associated symptom locations most commonly described in the literature [6,8,13,47,53]. These required only minor refinements during usability testing (ie, more precise identification of the axillae). Importantly, participants also viewed *at heart* as a way to contribute to the future of women's heart health. Women feel "stopped at the gate," and they want to take charge and advocate for better awareness, education, diagnosis, and management [74].

Limitations and Strengths

First, usability testing was conducted on a predominantly affluent sample of participants, which limits the generalizability of our results. A total of 60% (6/10) of the participants who took part in usability testing earned >CAD $70,000 (US $48,881.80) annually. They were also well educated, and most (8/10, 80%) were White. Canada is known for its diversity in race and ethnicities— over 450 ethnic or cultural origins were reported in the 2021 census [75]. A total of 1 out of 5 people in Canada is born elsewhere; the 3 largest visible ethnic groups are South Asian, Chinese, and Black individuals, representing 60% of the Canadian racial and ethnic populations [76]. Although this was a limitation in the sample for the usability testing, this is not a limitation specific to the *at heart* progressive web application. In fact, the *at heart* library contains heart

disease and heart wellness scientific papers and lay summaries related to South Asian and Indigenous people. These include risk and traditional practices such as drumming and healing and talking circles. However, it will be necessary to include a more diverse sample of women that encompasses those in less populous areas where age-standardized cardiovascular-related deaths in women are highest [77]. It will also be important to target recruitment of women from South Asian and Afro-Caribbean races and ethnicities, those with disabilities, those of a lower socioeconomic status, and those across age and gender identities who also experience greater risk of cardiovascular disease [77-79].

In addition, heterogeneous use of platforms and devices may also be a limitation to the usability testing. Progressive web applications are designed to work across platforms, eliminating the cost, fragmentation, and need to develop the same application several times for multiple platforms. They are designed to behave like mobile apps, working seamlessly across Android and iOS devices. However, past research indicates that progressive web applications may not be as smooth as mobile apps on Android devices [80]. Our sample size was limited, and only 10% (1/10) of the participants used an Android device for testing. Further research is needed to evaluate the usability of the *at heart* progressive web application across various platforms and devices. The phase-3 pilot RCT will determine the feasibility of implementing the *at heart* intervention, including the *feasibility* of randomization, recruitment, and retention; *acceptability* and barriers to implementing the intervention; and the extent of engagement with the intervention. The phase-4 effectiveness-implementation hybrid trial (type I) will investigate the effectiveness and implementation of *at heart* among women living in Canada using the practical, robust implementation and sustainability model [81]. The MRC [30-32] discusses 4 phases of complex intervention research (eg, development, feasibility, evaluation, and implementation) and the importance of refinements with each phase transition depending on the context [70,71] in which the intervention is evaluated and implemented. The practical, robust implementation and sustainability model [81] aligns contextual needs with intervention design using an inequity, systems thinking, and cocreation engagement approach. Context will be addressed by considering the individual perspectives on the intervention, external environment, characteristics of those receiving the intervention, and supports and resources needed to deliver the intervention [81]. Recruiting representative populations can be improved through strengthened community partnerships in governance and decision-making [82-84], and this will be a focus in subsequent phases of this research.

Second, remote usability testing methods were used during the COVID-19 pandemic. Testing a technology's usability remotely has inherent advantages as well as limitations. While participants can prefer remote testing to in-person testing, it can take longer for participants to complete tasks during remote testing, more errors can be made compared to in-person testing sessions, and context and indirect cues can be missed during remote testing sessions [85]. However, the approach taken to usability testing in this study was iterative, comprehensive, and aligned with methods used by others recently reported in a scoping review [41]. Of 133 articles included in this scoping review, 105 used questionnaires, 45 used a think-aloud approach, and 37 used interviews in their usability testing methods [41]. Moreover, many studies used a combination of 2 (n=46) or 3 (n=30) methods of testing, and the SUS was the most reported and validated questionnaire used to assess satisfaction and usability [41]. Finally, the *at heart* chatbot is rule based and designed for specific functions within the progressive web application. It is not led by artificial intelligence technologies (ie, natural language processing or large language models) and, therefore, may have inherent limitations that were not identified during the 2 cycles of usability testing (ie, personality, flexibility, dialogue structure, and conversation complexity or flow) [65].

Conclusions

This study does provide initial support for the *at heart* progressive web application for women with cardiac pain. Participants rated the performance of and satisfaction with this progressive web application as high. Ongoing evaluations in phases 3 and 4 should aim to examine the feasibility and acceptability and the extent of engagement with the *at heart* core feature set: Heart Check, Wellness Check, and the library. In addition to assessing effectiveness in an effectiveness-implementation hybrid trial (type I), describing and better understanding the context for implementation (eg, race and ethnicity and geography) will be necessary.

Acknowledgments

The authors thank the women who were participants in this study. They also thank the women with lived experience who collaborated in the co-design of *at heart* and the Heart and Stroke Foundation of Canada for their partnership. Phases 2 and 3 of the *at heart* program of research are supported by the Canadian Institutes of Health Research (389044) Project Grant: Fall 2017 competition.

Abstract

Background: Chronic pain is among the most common conditions worldwide and requires a multidisciplinary treatment approach. Spinal cord stimulation is a possible treatment option for pain management; however, patients undergoing this intervention require close follow-up, which is not always feasible. eHealth apps offer opportunities for improved patient follow-up, although adherence to these apps tends to decrease over time, with rates dropping to approximately 60%. To improve adherence to remote follow-up, we developed a remote follow-up system consisting of a mobile app for patients, a website for health care professionals, and a remote support center.

Objective: Our objective was to evaluate patient adherence to remote follow-up using a system that includes a mobile app and a remote support center.

Methods: After review of the literature and approval of the design of the follow-up system by a multidisciplinary committee, a team of experts developed a system based on a mobile app, a website for health care professionals, and a remote support center. The system was developed in collaboration with health care professionals and uses validated scales to capture patients' clinical data at each stage of treatment (ie, pretreatment phase, trial phase, and implantation phase). Data were collected prospectively between January 2020 to August 2023, including the number of total surveys sent, surveys completed, SMS text message reminders sent, and reminder calls made.

Results: A total of 64 patients were included (n=40 women, 62.5%) in the study. By the end of the study, 19 (29.7%) patients remained in the pretreatment phase, 8 (12.5%) patients had completed the trial phase, and 37 (57.8%) reached the implantation phase. The mean follow-up period was 15.30 (SD 9.43) months. A total of 1574 surveys were sent, along with 488 SMS text message reminders and 53 reminder calls. The mean adherence rate decreased from 94.53% (SD 20.63%) during the pretreatment phase to 65.68% (SD 23.49%) in the implantation phase, with an overall mean adherence rate of 87.37% (SD 15.37%) for the app. ANOVA showed that adherence was significantly higher in the earlier phases of treatment (P<.001).

Conclusions: Our remote follow-up system, supported by a remote support center improves adherence to follow-up in later phases of treatment, although adherence decreased over time. Further studies are needed to investigate the relationship between adherence to the app and pain management.

Introduction

Chronic pain is one of the most common conditions globally and is associated with reduced quality of life, increased medical expenses, and significant economic costs [1]. Its prevalence ranges between 2% - 40% [1-3], and annual health care costs due to pain amount to US $300 billion in the United States [1] and €12 billion (US $12.3 billion) in Norway [2].

The treatment of chronic pain requires a multidisciplinary approach, with spinal cord stimulation being a potential treatment option. This technique is safe and effective [4] and has also shown benefits in management of other chronic pain conditions, such as complex regional pain syndromes, low back

pain, and other forms of pain. However, ensuring consistent follow-up for these patients is challenging, as they require close monitoring, which is not always feasible.

New technologies have opened up a lot of possibilities to address this challenge. The World Health Organization defines eHealth as the cost-effective and secure use of information and communication technologies to support health and health-related areas, including health services, health monitoring, health literature, health education, and knowledge and research [5].

There are numerous tools designed to facilitate medical care, including mobile apps, websites, and other platforms. While there is limited evidence to support their use, preliminary results are promising. For example, mobile apps used alongside conventional treatments have shown better results in the management of chronic pain than conventional interventions alone [6,7].

eHealth apps also offer an opportunity for closer patient follow-up, although adherence to treatment tends to decline over time, dropping to approximately 60%, as previous studies have shown [8,9]. To address this challenge, we have developed a system that includes a mobile app for patients, a website for health care professionals, and a remote support center.

The aim of this study is to assess patient adherence to follow-up care using a mobile app supported by a remote support center.

Methods

Overview

In 2019, researchers at the Department of Pain Surgery at Hospital Virgen de las Nieves in Granada, Spain, initiated approaches to improve the remote monitoring of patients implanted with epidural spinal cord stimulators for chronic pain management. The aim was to reduce the number of face-to-face consultations or hospital visits while providing additional support to these patients. Therefore, we decided to develop an app complemented by a support center to improve patient monitoring as much as possible. After reviewing the relevant literature, we adapted the tool kit published by Marvel et al [10] to suit our needs, following the four key steps outlined in Table 1. As we already had a multidisciplinary group, we sought the agreement of existing team members and assembled a group of experts. Instead of accelerating the project, we adapted our current workflows and protocols to the new working framework. We also developed the follow-up system after adapting the protocols already in place and enrolled patients only after the system was finalized.

Table . Project phases.

Johns Hopkins tool steps[a]	Project workflow (current study)
Define the problem and the digital tool	Define the problem and the digital tool
Creation of a multidisciplinary group	Creation of an expert team, approval by a multidisciplinary group
Seeking opportunities to accelerate the project	Adaptation of the existing clinical and educational protocol into the framework of the remote follow-up system
Involving professionals	Designing the follow-up system, considering the needs of the involved professionals, and subsequent enrollment of patients
Consulting different partners	Performing quality assessment
Conducting a clinical validation	Conducting a clinical validation

[a]Marvel et al [10].

The concept of a remote follow-up system was presented to a multidisciplinary committee composed of anesthesiologists, neurologists, neurosurgeons, neurophysiologists, and rehabilitation specialists. This committee meets monthly to assess patients with chronic pain who may benefit from interventional therapies such as spinal cord stimulation when conventional treatments have failed. The target population was identified as patients who could benefit from spinal cord stimulation and had not yet started the trial phase, to enable data collection before and after implantation.

The inclusion criteria for patients eligible for spinal cord stimulation system implantation at our center are shown in Textbox 1.

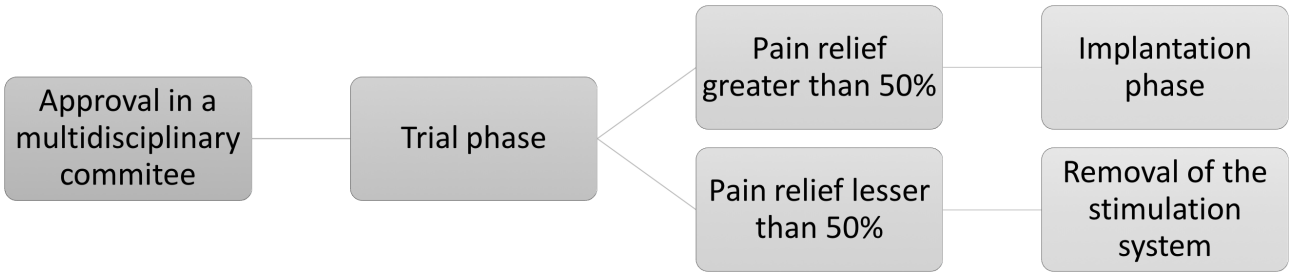
Textbox 1. Inclusion criteria.

- Chronic pain in a specific area of the body (patients experiencing diffuse pain were not accepted)
- Failure of conservative treatments, including rehabilitation and local infiltration
- A favorable psychological evaluation confirming that the patient can wear a spinal cord stimulation system
- No contraindications to surgery or allergies to system components
- No history or current substance use, especially opioids

Once the committee had approved the implantation of a spinal cord stimulator, the procedure was performed in 2 phases, as shown in Figure 1. In the trial phase, one or more electrodes were implanted in the epidural space and connected to an external stimulator. The efficacy of the system was then assessed over a 4-week period using the verbal numerical rating score

(VNRS). The intervention was considered effective if the patient's reported subjective perception of pain relief was at least 50%. If the trial phase was successful, it was followed by the implantation phase, in which a permanent stimulator was implanted in the adipose tissue of the abdomen or lower back. If the 50% threshold was not reached, the system was removed completely.

Figure 1. Algorithm used to evaluate the implantation of the spinal cord stimulation system.



Ethical Considerations

Ethics approval was obtained from the Comité de Investigación Provincial de Granada (study: NC-D-01; ethics committee reference: SICEIA-2020 - 000438), and informed consent for the procedure and follow-up system was obtained from all included patients. To maintain privacy, each patient was assigned a code with a number so that only health care professionals could access the personal data. The platform meets all the standards of Regulation (EU) 2016/679 of the European Parliament and of the Council of April 27, 2016, and has been approved by local and state authorities. This ensures that only health care professionals can access all the data collected and that data security is contractually guaranteed. The study participants have not been compensated in any way.

Design of the Follow-Up System

The remote follow-up system consists of 3 main components: a mobile app for patients, a website for health care professionals, and a remote follow-up center. The mobile app was designed to ensure close monitoring during all phases of treatment, using feedback from all health care professionals involved. The app was developed in collaboration with Clinical Care Connect (Persei) and customized by our team to meet our specific needs. It offers various features including educational content such as brochures and videos, questionnaires with validated scales, pop-up notifications, and a form to contact the remote support center. The validated scales used include Doleur Neuropathique 4 (DN4) to assess neuropathic pain, Oswestry Disability Index/Neck Disability Index (ODI/NDI) to assess back pain, VNRS to assess pain, and 36-item Short Form Survey (SF-36) to assess quality of life. In addition, patient-reported experience measures were used to assess experience and satisfaction with the app. Since pain is a subjective perception, the use of validated scales can help to measure it and compare it between patients.

The website designed by Persei (Vivarium S.L., Spain) can be accessed from anywhere with the necessary authorizations. It also provides alerts using different colors depending on the urgency of the detected problem: red for infection, yellow for insufficient pain relief, and blue for low battery. These alerts are monitored by the remote support center, which contacts the specialist by making a telephone call if necessary, such as, in the event of an infection. For nonemergency issues, such as insufficient pain relief, the support center contacts the patient to analyze the cause, and a priority appointment for treatment is scheduled. This remote support center was set up to increase the efficiency of treatment and improve pain management. The aim was to maximize treatment adherence and ensure the sustainability of the remote follow-up system. Previously, follow-up was carried out 1 month after implantation, 1 year after implantation, and subsequently, as required.

Data Collection and Analysis

We collected data from all patients who were approved for spinal cord stimulation between January 2020 and August 2023 and enrolled in the remote monitoring program. If the committee approved the patient for spinal cord stimulation, informed consent for the remote follow-up system was obtained in addition to consent for implantation. Data were collected automatically and prospectively through surveys completed via the app. The questionnaires were distributed according to the protocol shown in Textbox 2.

Textbox 2. Protocol used to send validated scales.

Validated scales used in the protocol used by the Virgen de las Nieves Hospital

- Pretreatment phase: Doleur Neuropathique 4 (DN4), verbal numerical rating score (VNRS), Oswestry Disability Index/Neck Disability Index (ODI/NDI), 36-item Short Form Survey (SF-36)
- Trial phase: Daily VNRS and patient-reported experience measures (PREMs) at the end of the trial phase
- Implantation phase: DN4, VNRS, ODI, and SF-36 after 1 and every 3 months; the PREMs survey was also distributed after 12 months

The support center sends a notification each time a survey needs to be completed, for a maximum of 3 times. If the questionnaires were not completed, a notification was sent to the hospital so that a specialized caregiver can contact the patient. One of the biggest challenges was ensuring privacy. To achieve this, each patient was coded with a number so that only health care professionals had access to the personal data and that data security was contractually guaranteed.

The data were collected automatically when a survey was answered via the app and stored in a private cloud. This allowed us to minimize potential errors. In addition, the support center guaranteed that the data collected via the app belonged to our hospital's patients and was only accessed and analyzed when a specialist at our center requested it. Demographic information was collected for data analysis. Adherence was measured by calculating the percentage of completed surveys relative to the total number of surveys sent. We analyzed adherence rate during each treatment phase and for the overall study, and compared adherence by demographic variables using ANOVA, adjusting for gender, age, diagnosis, and phase. Age was categorized into 2 groups, with 40 years as the cutoff point, since previous studies have found significant differences in prevalence rates for chronic pain and quality of life [11]. Regarding completeness, we only considered a survey as answered if it was completed. If data were missing, a notification was sent to the patient to complete the survey.

Results

Between January 2020 and August 2023, a total of 64 patients were enrolled in the study, comprising 24 (37.5%) men and 40 (62.5%) women. While identifying the cause of pain, 32 (50%) patients had complex regional pain syndromes, 18 (28%) had failed back syndrome, and 14 (22%) had other diagnoses such as phantom limb syndrome, adhesive arachnoiditis, coccydynia, and axonotmesis. Before the onset of pain, 19 (28%) patients had no fixed occupation, while 10 (18%) were involved in nonphysical and 35 (55%) in physical occupations such as farming or construction (Table 2).

Table . Summary of epidemiological data.

Variables	Patients (N=64), n (%)
Gender	
Men	24 (38)
Women	40 (63)
Age interval	
<40 years	9 (14)
≥40 years	55 (86)
Diagnoses	
CRPS[a]	32 (50)
FBS[b]	18 (22)
Others	14 (18)
Occupation	
Physical occupation	35 (55)
Nonphysical occupation	19 (18)
No fixed occupation	10 (28)
Phase	
Pretreatment	19 (30)
Trial	8 (13)
Implantation	37 (58)

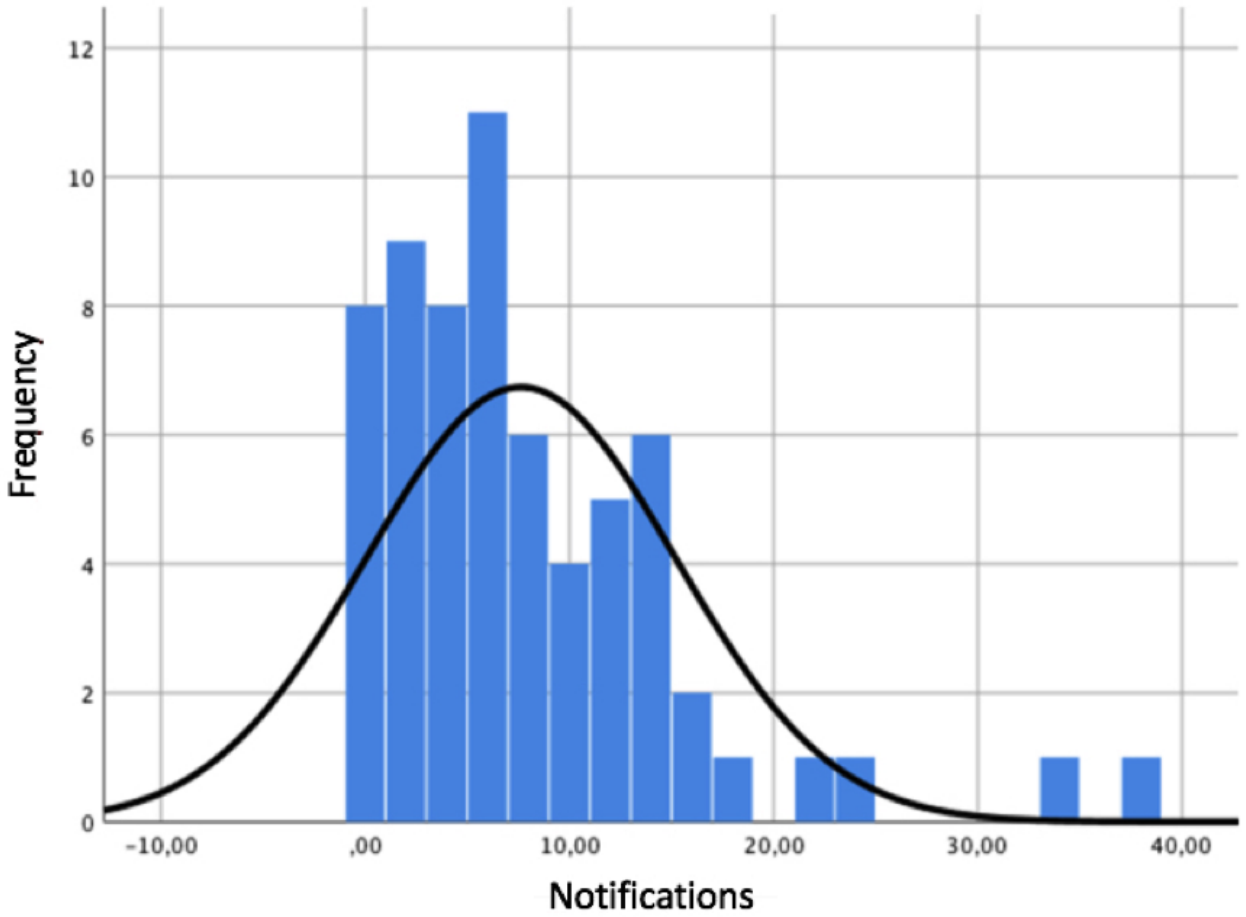
[a]CRPS: chronic regional pain syndrome.

[b]FBS: failed back syndrome.

At the end of the study, 19 (30%) patients were in the pretreatment group, awaiting the start of the trial phase. A total of 8 (13%) patients reached the trial phase but were not transferred to the implantation phase due to insufficient improvement in pain management. Further, a total of 37 (58%) patients advanced to the implantation phase (Table 2).

A total of 1586 surveys were distributed during the study. SMS text message notifications had to be sent to the patients 488 times, which corresponded to a mean of 7.62 (SD 7.57) SMS text messages per patient. However, 8 (13%) patients did not require SMS text messages notifications, while the remaining (n=56, 88%) patients required at least one notification (Figure 2). It was observed that several patients required more than 30 notifications. In addition, a total of 53 phone calls were made to remind patients to complete the surveys; however, 43 (67%) patients did not require any reminder calls.

Figure 2. Histogram with a normality curve showing the number of patients in groups (frequency) based on the number of required notifications (notifications).



The mean follow-up time was 15.38 (SD 9.43) months. A total of 12 (19%) patients were lost to follow-up, and 3 (4%) patients discontinued using the app (ie, 1 during the pretreatment phase and 2 patients during the implantation phase). For patients who discontinued using the app, any surveys not answered by them were considered failures.

Adherence was analyzed for each phase and overall, as shown in Figure 3, which represents the total number of surveys sent and answered in each phase, as well as the adherence rate in each phase. During the pretreatment phase, 256 surveys were sent, of which 242 were completed, corresponding to a mean adherence rate of 94.53% (SD 20.63%). During the trial phase, 645 surveys were sent, of which 499 were answered, corresponding to a mean adherence rate of 77.36% (SD 37.01%). During the implantation phase, 624 surveys were sent, of which 422 were answered, corresponding to a mean adherence of 65.68% (SD 23.49%). A total of 61 satisfaction surveys were sent (excluding 3 patients who discontinued using the app), of which 55 were answered, corresponding to a mean adherence rate of 92.11% (SD 18.47%). The overall mean adherence rate for using the app was 87.37% (SD 15.37%) across all phases (Table 3).

Figure 3. Surveys and adherence rate.

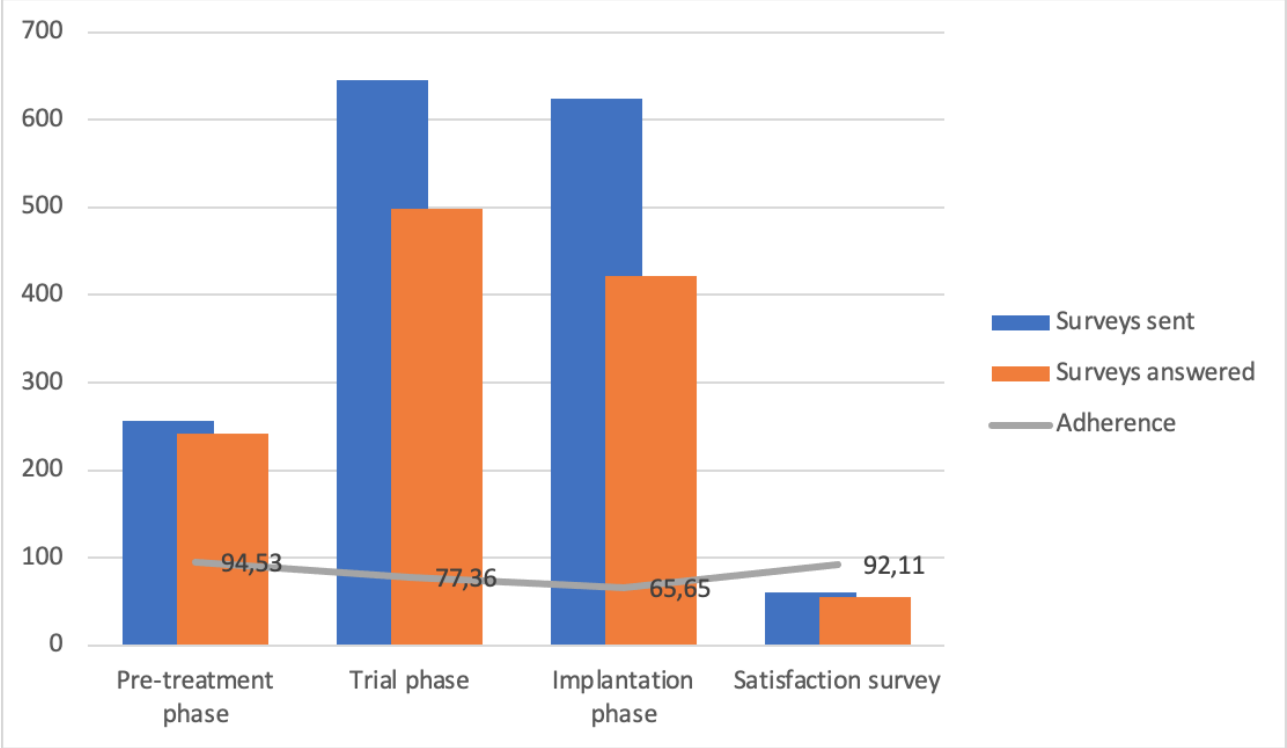


Table . Summary of surveys sent and answered and adherence in each phase.

Phase	Surveys sent, n[a]	Surveys answered, n[a]	Adherence rate[b] (%), mean (SD[c])
Pretreatment phase	256	242	94.53 (20.63)
Trial phase	645	499	77.36 (37.01)
Implantation phase	624	422	65.68 (23.49)
Satisfaction survey	61	55	92.11 (18.47)
Total adherence	1586	1218	87.37 (15.37)

[a]Number of surveys during each phase.

[b]Adherence rate was defined as the total surveys answered x 100/total surveys sent.

[c]The SD represents the variability of adherence rates among individual patients.

ANOVA revealed that adherence rates were significantly higher in the earlier phases of treatment (P<.001). There was also a trend indicating that women were more likely to complete satisfaction surveys (P=.17) and surveys in general (P=.64). However, women also required more SMS text message reminders (P=.70) and phone calls (P=.71). No significant differences in treatment adherence were found when comparing younger patients versus patients older than 40 years or when comparing adherence to treatment based on the cause of pain or type of occupation (Table 4).

Table . Summary of the ANOVA results.

Variables	Pretreatment phase adherence (%; n=64), mean (SD)	*P* value	Trial phase adherence (%; n=43), mean (SD)	*P* value	Implantation phase adherence (%; n=38), mean (SD)	*P* value	Satisfaction survey adherence (%; n=38), mean (SD)	*P* value	Global adherence (%), mean (SD)	*P* value

Discussion

Comparison With Previous Research

In recent years, there has been increasing interest in the use of pain control apps for various purposes, such as postsurgical follow-up, pain self-management, and chronic pain management [6-10,12-14]. However, many of these tools have not been as effective as expected, often due to inadequate planning and a lack of preliminary studies to anticipate necessary roles [15]. However, some studies have demonstrated that these apps can outperform traditional follow-up methods [6,14]. Our study introduces a remote support center, a feature that we believe is not yet widely adopted internationally. The aim of this study is to determine whether the inclusion of a support center improves adherence compared to other systems.

An analysis of the medical apps across various app stores shows that approximately 86% of these apps were developed without the involvement of medical professionals [16]. Lalloo et al [17] examined 1019 apps developed for postoperative pain management or education and found that only 10 apps met the established criteria. When evaluating apps developed with the involvement of health care professionals, only 5 (0.49%) of them were deemed suitable. Similarly, Bhattarai et al [16] examined 373 apps focused on arthritis pain self-management with only 4 apps meeting the Stanford criteria for pain self-management. Portelli and Eldred [18] evaluated 195 apps for pain management against the guidelines for cognitive behavioral therapy. Of these, only 6 (3%) of these apps met the standards, leading to the conclusion that neither health care professionals nor patients were involved in their development. Despite these limitations, a recent meta-analysis of 4767 patients in 22 randomized trials found that these apps offer a small but significant improvement in long-term pain management [19].

For patients undergoing spinal cord stimulation, close follow-up is required to adjust the type and parameters of stimulation, which usually necessitates face-to-face visits. This increases the time and cost burdens for patients and caregivers, especially for those who live far from specialized centers [20]. Our remote follow-up system was developed to overcome these challenges and ensure optimal patient monitoring. The mobile app in combination with the remote support center reduces the need

for in-person examinations while ensuring a high standard of care. The app's alert system helps to detect problems at an early stage, such as infections or low battery levels so that immediate action can be taken.

In addition, the use of validated scales during an in-person consultation is challenging due to the limited time available. Consequently, this system has allowed a better understanding of the patient's condition. Furthermore, some patients have found that expressing themselves via the app helps them [20] in experiencing privacy and without any time pressure.

Adherence to medical app use is crucial as studies show that 75% of users stop using an app within 48 hours of downloading, and 15% delete it after initial use [21]. A review by Wikström et al [9] found that none of the studies focused on improving adherence or motivating users to continue using medical apps. The easiest way to increase motivation is through notifications, which is why our study focused on the role of the remote support center. We consider this as a key factor in the success of our study. However, numerous motivational elements in medical apps have been analyzed in previous studies, as summarized in Table 5.

Table . Motivational elements in eHealth apps.

Studies	Motivational elements								
	Tablet lent to the patient	Chat	Involvement of relatives	Educational texts, pictures, and/or videos	Follow-up of auto evaluation and graphic results	Personalized follow-up	Sharing media elements	Notifications and reminders	Alerts

[a]Element analyzed in the corresponding study.

Our remote follow-up system was developed based on relevant literature to maximize adherence and achieved an overall mean adherence rate of 87.37% (SD 15.37%). Comparison of this rate with previous studies is difficult, as most of these focused on adherence to a treatment or intervention rather than the use of an app. For example, Gomis-Pastor et al [34] showed that the use of an app significantly improved adherence to treatment and medication regimen, which led to significantly better symptom control, as found in a 2022 review [35]. However, Wikström et al [9] have shown that adherence to app use decreases over time, potentially due to improvement in health status or loss of interest [29], among other factors [26,29,32]. Our study aligns with these findings and shows a decrease in adherence from 94.53% in the pretreatment phase to 77.36% in the testing phase and 65.58% in the implantation phase [36-38].

Limitations

The main limitation of our study is the specificity of the target population, as spinal cord stimulation is a specialized treatment for patients experiencing chronic pain. These patients often display a significant emotional component that can influence the outcomes of the interventions, posing challenges during designing this study and its remote follow-up system. In addition, these systems rely on new technologies that can be challenging for older patients, potentially limiting their ability to fully benefit from them. By using self-reported data, we also acknowledged that omissions or misunderstandings in the surveys may be introduced, which we attempted to minimize using validated scales. Finally, setting up a system similar to this study requires a significant financial investment.

Conclusions

Digital systems are a part of medical care, and it is important that health care professionals are involved in the development of tools to ensure the achievement of desired standards. We have developed a remote monitoring system for patients undergoing spinal cord stimulation, based on scientific evidence and supported by a remote support center that improves treatment adherence. This system also provides us with detailed information about each patient. However, there is a tendency for patients to abandon the app usage over time, which could be related to long-term pain control. Further studies are needed to investigate the relationship between adherence and pain control.

Conflicts of Interest

We have received financial support from Medtronic IHS CareConnect Pain to cover publication costs for this article. However, we declare no conflicts of interest as we implant spinal cord stimulation systems from different brands and treat all equally. In addition, none of the authors work for Medtronic IHS CareConnect Pain or receive economic compensation from Medtronic IHS CareConnect Pain.

Abstract

Background: Aging brings physical and life changes that could benefit from eHealth services. eHealth holistically combines technology, tasks, individuals, and contexts, and all these intertwined elements should be considered in eHealth development. As users' needs change with life situations, including aging and retirement, it is important to identify these needs at different life stages to develop eHealth services for well-being and active, healthy lives.

Objective: This study aimed to (1) understand older adults' everyday lives in terms of well-being and health, (2) investigate older adults' needs for eHealth services, and (3) create design recommendations based on the findings.

Methods: A total of 20 older adults from 2 age groups (55 to 74 years: n=12, 60%; >75 years: n=8, 40%) participated in this qualitative interview study. The data were collected remotely using a cultural probes package that included diary-based tasks, sentence completion tasks, and 4 background questionnaires; we also performed remote, semistructured interviews. The data were gathered between the fall of 2020 and the spring of 2021 in Finland as a part of the Toward a Socially Inclusive Digital Society: Transforming Service Culture (DigiIN) project (2019 to 2025).

Results: In the daily lives of older adults, home-based activities, such as exercising (72/622, 11.6% of mentions), sleeping (51/622, 8.2% of mentions), and dining and cooking (96/622, 15.4% of mentions), promoted well-being and health. When discussing their needs for eHealth services, participants highlighted a preference for a chat function. However, they frequently mentioned barriers and concerns such as the lack of human contact, inefficiency, and difficulties using eHealth systems. Older adults value flexibility; testing possibilities (eg, trial versions); support for digital services; and relevant, empathetically offered content with eHealth services on short-term and long-term bases in their changing life situations.

Conclusions: Many older adults value healthy routines and time spent at home. The diversity of older adults' needs should be considered by making it possible for them to manage their health safely and flexibly on different devices and channels. eHealth services should adapt to older adults' life changes through motivation, personalized content, and appropriate functions. Importantly, older adults should still have the option to not use eHealth services.

Introduction

Background

Aging involves physical and life changes [1-4], where eHealth services have the potential to provide support and benefits [4-7]. The prevalence of many diseases increases with age [8,9], and multimorbidity is common among people aged ≥65 years [10,11]. Conversely, healthy behaviors can extend people's lives [12-14].

eHealth can help people nurture their health and well-being, potentially extending their lives. eHealth can also make treatment more accessible, promote treatment continuity, enhance communication, help shared decision-making, and enable patient self-management [10]. Older adults seem to be generally positive toward eHealth in a health management context [15]. They can benefit from eHealth services, as they often have complex health issues and engage in many self-management tasks supporting their health and well-being [1,5,16].

However, older adults sometimes face challenges with eHealth services [5,16,17], including a lack of skills and interest [3,16,18]. Hirvonen et al [19] reported that some older adults find the content or functionalities of eHealth services irrelevant (eg, [20,21]). Sometimes, older adults might even feel that digital services are not "meant for them" (eg, [20,22]). Thus, older adults might have a risk of exclusion from digital services [16,18,23,24] and society [16,23].

Older adults have not always been involved in technological development, especially in mainstream technology [25-27]. At the same time, the older population is growing [28], and health care costs are rising [29]. Stephanidis et al [30] encourage understanding emerging new technology possibilities and context-based user needs when designing digital solutions for the health and well-being (hereafter, *eHealth services* or *eHealth*) of older adults and a better understanding of the role of technology in older adults' lives [30]. Ideally, the technology should be harmonized with these adults' lives [15].

European older adults regularly engage in work, household chores, exercise, cultural activities, and tourism [31]. On the basis of the literature, many older adults in Europe live in rural areas, where they have easy access to nature and can engage in refreshing activities [31]. On the other hand, older adults with urban lifestyles access a variety of services [31]. For example, in Finland and Sweden, rural areas are in the north and distant from health care services, and eHealth services offer a promising option for taking care of one's health [32]. Physical activities might support older adults' health situation during aging. In 2017, in total 43.2% of Europeans aged 50 to 64 years and 44.5% of those aged 65 to 74 years old spent >3 hours per week engaging in physical activity [31]. On the other hand, older adults' daily routines differ. Older adults are a heterogeneous group of people, and aging is a process, not a static state [33]. Therefore, it is important to obtain qualitative insights into older adults' activities. These could help inform the idea and role of eHealth services and harmonize it with older adults' routines [15,30]. We know that older adults use eHealth services, for example, depending on their digital devices, capabilities, interests, or education [31,34]. Statistically, 100% of Europeans have, at least in theory, access to eHealth services or health information [35].

The best approach to eHealth service development means selecting the optimal approach case by case [36]. In eHealth, technology, tasks, individuals, and contexts are holistically combined, which should all be considered in developments [36-39]. eHealth services should genuinely support people pursuing healthier lifestyles and be accessible to all [10], although older adults may perceive the technology differently from other generations [1,40]. Humanity is needed alongside IT. Therefore, design decisions should also help ensure that as a part of eHealth services development, the human touch of personal care will not be removed [30,41].

Mapping user needs is important because without understanding needs, designing high-quality solutions is challenging [42]. User needs can be defined as the problems that prevent users from reaching their goals or possibilities to support them in reaching these goals [43]. User needs can be personal or more social in nature, and they can be related, for example, to available information or technology functions [44]. Poor understanding of users, user needs, and use contexts increases the risk of failure in eHealth service development [39]. On the other hand, user needs are not a stable phenomenon; they might change with age or the use of technology [45]. However, not much is known about what kind of user needs for eHealth services arise in older adults' lives, which is unfortunate because understanding user needs is a great innovation source [46]. In addition, Hirvonen et al [19] recommend further investigation into older adults' eHealth service use as a part of their daily lives.

Goal of This Study

We aimed to understand older adults' everyday lives in terms of well-being and health and their needs for eHealth services. We investigated 2 life stages: working at an older age and life after retirement, possibly with a chronic disease. We were interested in the health and well-being practices of 2 age groups to understand older adults' needs for eHealth services. Investigating these aspects allows developers and designers to better understand how eHealth services can meet older adults' needs and support their healthy living.

Users' needs change with life situations, including aging [47]. Therefore, if we want to harmonize eHealth services with older adults' everyday use, as is recommended by Cabrita et al [15], and to support technology development for well-being and an active, healthy lifestyle, it is important to identify user needs at different stages of life and daily routines in different life situations. The research questions were as follows:

1. What is everyday life like for older adults?
2. What kind of needs do older adults have for eHealth services?

Prior Work

Qualitative Methods for Investigation of Needs

User needs can be explored in many ways. In the human-computer interaction field [48,49], designers and

researchers have several methods for investigating user needs. Soraghan et al [50] and Dickinson et al [51] encourage researchers and designers to step into older adults' homes to assess technology use and empathize with respondents' lives, for example, through in-home interviews and observations. Understanding of older adults can be collected through remote, semistructured interviews [52]. Projective techniques, such as cultural probes [53-57] or sentence completion tasks [58], in which the participants provide information about themselves (instead of the researcher asking them direct questions), can be fruitful methods for gaining a deeper understanding of end users when the topic is challenging to verbalize or includes sensitive aspects [42]. For example, the sentence completion technique can be used to gather both an understanding of end users' values and needs as well as inspirational data for design and discussion activation [42,59,60].

Cultural probes are designed to trigger older adults to provide inspirational information about their lives to designers [53]. Following development, they have been widely used for various purposes, including collecting information about caregivers [56], investigating patient experiences with an eHealth service [54], and in other health care contexts [55,57]. Cultural probes are packages or toolkits of various tasks that end users complete and document [53]. While cultural probes show potential as a projective technique for gathering user needs [42], they appear to be underused in identifying older adults' needs for eHealth services.

Older Adults' Needs and Attitudes Toward Technology

Older adults' needs and attitudes toward technology vary. For example, some older adults do not trust computers and find the terminology and content of computers and digital services confusing [17,18,61]. They might even fear computers [61]. Their self-confidence with computers is sometimes fragile, and usability issues can be disastrous for their self-confidence [61]. In addition, older adults as a user group are much more diverse than many traditional user groups; they may have problems such as sensory loss, challenges with language, and attitudes to technology [61].

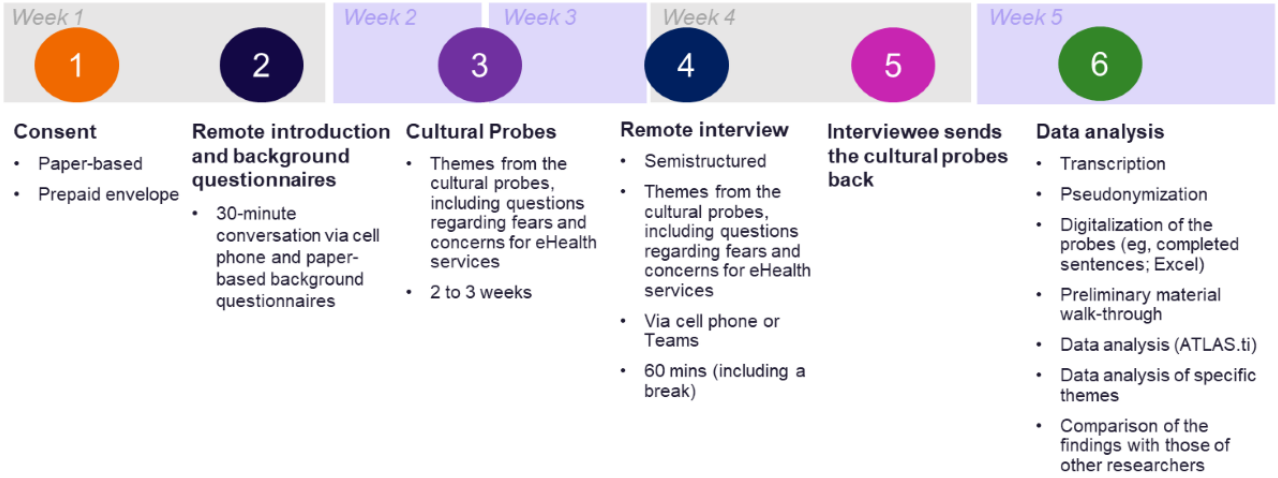
Many older adults appreciate easy access to eHealth services and their medical records, which should be offered in an easy, understandable, and secure way [5,52]. When medical information has compact and clearly labeled contents in well-organized menus [62], clear interface language, and linear navigation [20], this can assist older adults. Backonja et al [47] recommend eHealth services that adjust functionality and content based on the user's needs. Similarly, Cabrita et al [15] recommend personalization of design and functionality, thus lowering older end users' fears toward technology by allowing it to support its users and even offer empathy and sympathy to them.

Methods

Overview

This empirical qualitative study consisted of cultural probes [53,63], which included 4 background information questionnaires (*background questionnaires*), sentence completion tasks [42,58,59], and a diary-based exercise [64-66], and remote interviews [52]. Data collection included 6 phases, which all played an important role (Figure 1). Data collection started with filling out a consent form. After that, background information was collected, and a short remote interview was conducted. Then, the participant had time to respond to the cultural probe package (ie, sentence completion tasks and diary-based exercise). Participation ended with a long remote interview and the return of the probes package to the researcher. Finally, the data were analyzed.

Figure 1. Research procedure.



Sampling and Recruitment

The research was conducted in Finland between the fall of 2020 and the spring of 2021 (ie, during the COVID-19 pandemic) as part of the DigiIN project (2019 to 2025).

Defining an older adult purely by age is somewhat complex [67]. Generally, they are people in late adulthood. In line with the study by Ware et al [5], this study focused on older age groups associated with a higher risk of chronic disease, with participants from 2 age groups (those aged between 55 and 74

years and employed and those aged >75 years and retired). Group 1 participants (ie, those who were still working) were relevant because aging includes preparing for retirement [68].

The participants were selected through purposive sampling (digital survey) and snowball sampling [69]. Group 1 participants (12/20, 60%) were recruited via a digital survey [70]. Group 2 participants (8/20, 40%) were recruited in 2 ways: via the digital survey and snowball sampling. To ensure a diverse and engaged sample for this long-term study, participants' interest in digital services was assessed in advance. The groups were formed according to the life situation: group 1 participants were still working, and group 2 participants were retired. The age category of group 1 was between 55 and 74 years (later, 55-74 years). The age category of group 2 was between 75 and >90 years (later, >75 years). Participants in group 1 had different professions, such as yoga teacher, director, project manager, or entrepreneur. The participants were from different parts of Finland but did not fully cover the whole country.

After participants expressed potential interest in participating in the study, the researcher explained the study in a telephone call. This call lasted for 15 to 30 minutes, depending on the participant's questions. If the participant was still interested, the researcher mailed or emailed the information letter that described this study in detail and a consent form to the participants for their signature.

Ethical Considerations

The empirical study was conducted as part of the DigiIN project (2019 to 2025). The study protocol was reviewed and approved by the Ethical Review Board of Aalto University (95_03.04_2019_DigiIN). All participants provided their voluntary, informed, and written consent. Patients' ability and willingness to participate in the study were confirmed through a phone conversation before they signed the consent form. During the call, the study process was explained, and it was emphasized that participation was voluntary, with the option to withdraw at any time. This was also mentioned in the written consent form.

Research Procedure

The study comprised six phases (Figure 1):

1. First, the study purpose and research procedure were introduced.
2. Second, the cultural probe packages, including 4 background questionnaires, were delivered. The study procedure and contents of the package were explained again in detail by phone or Teams (version 1.6.00.11166; Microsoft Corporation).
3. Third, the participants filled out the cultural probes for 2 weeks, during which the researcher made 2 short phone calls to the participants, being present for possible questions and collecting specific day-based information about the participants' routines and activities related to health and well-being.
4. At the end of the study, the participants were interviewed remotely.
5. Then, they returned the probes package to the researcher in a prepaid envelope. The data collection took a maximum of 5 weeks. When the researcher received the probes package, the participants were sent a small thank-you gift.
6. Data were analyzed.

Cultural Probes

Overview

In this study, cultural probes made data collection of older adults' everyday lives possible in research environments, where remote data collection was important for safety reasons [52]. It helped in collecting data indirectly, as the participants themselves completed the cultural probes at their own pace as part of their everyday lives [42,52,53]. It also helped the participants prepare for the interview [52].

The cultural probe package, recruitment questionnaire, and recruitment letter were tested with 2 nonparticipating members of the target group. The probes, questionnaires, and letter were revised based on the feedback. The research materials were then tested again with another target group member. Finally, the entire study setup with semistructured interviews was tested with 2 target group members.

Background Questionnaires

Among other tasks, the cultural probe package included 4 questionnaires: a background information questionnaire, the Health Confidence Score (HCS) [71], the eHealth Literacy Scale (eHEALS) [72], and the European Health Literacy Survey Questionnaire (HLS-EU-Q16) translated into Finnish by Eronen et al [73]. The other questionnaires were translated into Finnish by the authors. Questions 3 to 10 in the eHEALS questionnaire were used in this study with the added option of "I don't know" [72].

In addition to demographic questions, the background information questionnaire asked about the participant's internet and device use, the eHealth services they had used, and how useful they found them. The purpose of the HCS, eHEALS, and HLS-EU-Q16 questionnaires was to obtain an overview of the participants' capabilities (or perceived skills) to understand health information and use eHealth services.

Diary-Based and Sentence Completion Tasks

The cultural probe package (1) motivated participants to notice and document their actions related to health and well-being as a part of their everyday lives and (2) worked as a triggering element for remote, semistructured interviews. In this remotely conducted study, cultural probes and their exercises helped make the researcher appear more relatable to the participant. This was especially important given the sensitive and personal topics, such as everyday life around health and well-being, discussed in the study, both from the researcher's perspective, and more importantly, from the participant's perspective [74]. The cultural probe tasks included sentence completion tasks [59] and a diary-based task [64-66]. In the diary-based task, participants were asked to make notes regarding their health routines, decisions, and actions for 5 days. In addition, 13 incomplete sentences were formulated following the best practices explained by Nurkka et al [42] and included in the

pretesting phase. In the sentence completion task, participants were asked to complete sentences (Multimedia Appendices 1 and 2) with 4 themes (Table 1).

Table 1. Themes of the sentence completion tasks.

Theme	Included in group 1	Included in group 2
eHealth services now	Yes	Yes
eHealth services in the future	Yes	Yes
Concerns and fears for eHealth services	No	Yes
Informal caregiver's eHealth services (excluded from the data)	Yes	Yes

The cultural probe packages had differences regarding incomplete sentence themes between the group 1 and group 2 participants. The study started with the younger participant group. As data began to accumulate, additional questions addressing concerns and fears were incorporated into the sentence completion tasks, as shown in Table 1. This could support the participants in preparing for the interview as well [52]. However, the interview covered the theme with both participant groups.

Remote, Semistructured Interviews

The themes of the cultural probes were investigated in more detail in remote, semistructured interviews [52], which took 1.5 hours maximum to complete with group 1 participants and 1 hour maximum with group 2 participants. If an interview took longer, the participants were offered the opportunity to continue the interview the next day. The researcher made phone calls using either the Teams call function or a mobile phone, making it easier for participants to take part. Two researchers conducted the interviews, but only 1 conducted each interview for trust-building purposes. The interviews were audio recorded and documented with field notes.

The interviews comprised different perspectives regarding the participants' everyday lives and activities concerning health and well-being. The interview structure (Multimedia Appendix 3) was created based on the themes of the cultural probes. The participants were asked to describe the contents of their cultural probes. The idea was to empower the participants and let them decide how much or in how much detail they were willing to express their thoughts on their well-being and everyday lives. In the interview design, the interview checklist by Tong et al [75] was followed.

Analysis

Overview

After the data were transcribed and pseudonymized, the background questionnaire was analyzed using descriptive statistics, and the qualitative data were analyzed following the inductive content analysis process [69,76,77]. User needs were formulated based on the content analysis of the interviews and the analysis of the cultural probe data. The cultural probe data included the participants' diary notes of their daily well-being activities and completed sentences. The data were analyzed according to data type. The different analysis phases are explained in the subsequent sections.

Preliminary Material Walk-Through

During the interviews, a researcher (PV) identified the preliminary content-based categories and, after each interview, categorized each participant's direct quotes in Excel (version 2208 Build 16.0.15601.20644; Microsoft Corporation). Due to the richness of the data, an additional preliminary review was necessary. The researcher (PV) manually reviewed the entire dataset through after receiving the cultural probes package, using traditional pen-and-paper data analysis methods [78].

After this preliminary data analysis phase, the analysis needs for the next phases were recognized. The analysis needs were identified, keeping in mind that the purpose was to understand user needs. Similar to the data analysis process proposed by Nielsen et al [79], the preliminary material walk-through process needed both systematic and circular practices.

Content Analysis for Interview Data

Afterward, 2 researchers (PV and KS) read the pseudonymized interview transcripts and coded the data in ATLAS.ti 9 (version 9.1.5.0; Scientific Software Development GmbH; Multimedia Appendix 4) to understand the data as a whole and to support the analysis of the cultural probes data later. The process proposed by Mayring [76] was followed in the analysis. When approximately 30% (11/40) of the transcripts were coded, the researchers (PV and KS) revised and compared their categories and agreed on common ones. Finally, the results were discussed again by 2 researchers (PV and KS), and the findings were reported.

Analysis for Background Information Questionnaire Data

The background information questionnaires were analyzed to understand the participants' characteristics and their internet and IT use habits. These questionnaires provided preliminary information about the sample. The questionnaire analysis was done in collaboration between 2 researchers (PV and SK). The means were calculated for the data from each of the 3 questionnaires (PV), and the results were discussed (PV and SK). Owing to the qualitative nature of the study and the small sample size, detailed quantitative analysis was not performed.

Content Analysis for Cultural Probe Data

The data from the cultural probe package were analyzed in collaboration between 3 researchers. Each sentence's main content was analyzed by a researcher (PV), and the results were discussed with 2 other researchers (KS and SK) to ensure the quality of the analysis. The diary analysis focused on the

participants' descriptions of their well-being activities. Activities were written on sticky notes, 1 per note, with the participant code and time of day. After 2 researchers (PV and KS) created the notes for 1 participant, their consistency was checked: a researcher (KS or PV) read the findings and another one (KS or PV) wrote the findings down. The analysis included 644 grouped sticky notes. The sticky notes were grouped by 2 researchers. The notes were taken during the analysis process.

Results

Overview

The results are discussed in three parts: (1) participant information; (2) description of older adults' everyday lives; and (3) user needs, which were expressed based on the findings from the sentence completion and remote, semistructured interview data.

The data comprised 19 cultural probe packages and 329 pages of transcripts of 20 interviews (in Verdana font, 11-point font size, single spaced). One participant did not return the cultural probe package.

Participants

The study included 20 participants (Table 2). The participants were divided into two groups: group 1, those who were still employed, and group 2, those who were retired. Both groups included active computer users with many different devices, but compared to group 1, group 2 included more participants who did not routinely use the internet and IT. However, the variation in device types was greater in group 2 compared to group 1. The results suggest that perhaps retired people use health and well-being services less frequently in general than those who are working.

Table 2. Participant background information (N=20).

	Group 1 (n=12)	Group 2 (n=8)
Age (y)	55 to 74	>75
Gender, n (%)		
Women	9 (75)	6 (75)
Men	3 (25)	2 (25)
Internet activity, n (%)		
Internet use daily or many times in a day	11 (92)	6 (75)
Internet use on a weekly basis	1 (8)	1 (12)
Do not know to use or do not use the internet	0 (0)	1 (12)
Internet habits, n (%)		
Most popular devices for internet use		
Computer	12 (100)	5 (63)
Cell phone	12 (100)	4 (50)
Tablet	9 (75)	4 (50)
Place of internet use		
At home	12 (100)	7 (88)
Outside home	10 (83)	3 (38)
The most popular reasons to use the internet		
Searching information	12 (100)	7 (88)
Banking	12 (100)	6 (75)
Health and well-being services	12 (100)	4 (50)
eHealth use, n (%)		
Most popular digital public health care services used		
Patient portal: checking health information and receipt renewal	12 (100)	4 (50)
Appointment booking	11 (92)	4 (50)
Chat, email, or SMS text message to health care professionals	8 (67)	—[a]
Visiting a health center's web pages	—	2 (25)

[a]Data not available.

All group 1 participants (12/12, 100%) and half (4/8, 50%) of the group 2 participants checked their health information and renewed their prescriptions via eHealth services. Internet users used it for banking and information searches, and 80% (16/20) of them also used it for health services.

Multimedia Appendix 5 presents the background questionnaire results. The eHEALS results (20/20, 100%) show the participants' familiarity with using digitally offered health information, with differences between the participant groups. The results of the HLS-EU-Q16 (19/20, 95%) on health literacy indicate that the participants seemed to have at least basic health literacy skills. One participant did not send the questionnaire back to the researchers. The HCS results (20/20, 100%) on patients' confidence in taking care of their own health show that the participants had at least a basic understanding of their health situation and how to operate in case of health challenges [63].

Everyday Life of Older Adults

The analysis of the data from the diary-based task and the interviews resulted in 15 themes in the participants' everyday activities. The themes were spending time at home, dining and cooking, routines, hobbies or exercising, sleep, mundane activities, work-related activities, medical treatment, cottage or nature, friends, pets, pampering and rest, communication with a relative, planning and controlling everyday life, and weather.

The most common activity was spending time at home, often watching television (102/622, 16.4%); spending time at home and dining and cooking (96/622, 15.4%) were the most popular regular activities of the participants. The importance of food for well-being was often mentioned in the data. Exercising was also popular (72/622, 11.6%), with walking and jogging being commonly practiced, including Nordic walking and climbing stairs. Walking could also be a social activity with a partner or a dedicated group. Sleep was mentioned in the data 51 out of 622 times (8.2%), as were mundane activities, such as going to the post office or having lunch or a coffee (51/622, 8.2%). The repetitive nature of routines, including spending time at home, the importance of food, and the variety of exercises, is reflected in the following quotes (the quotes are translated from Finnish):

> *From Monday to Friday, I wake up 5.50 am on two mornings, and on other mornings 6.50 am. And that 5.50 am means, that I go swimming. And on other mornings I eat my breakfast normally at home and go to work. I drink my morning coffee at the office.* [Group 1, participant U2]

> *There have been such beautiful days lately. Today it seems it is not so beautiful, or at least the sun is not shining yet. I feel I'm privileged that I'm able to live in my hometown, because this is such a beautiful city. I started with 30 min walking exercises, and now I do my walking exercise two times in week. Each walking exercise takes one and half hours nowadays. I explore those different terrains, and we have here a lot of a lot of stairs and a lot of small hills, which I use to improve my fitness.* [Group 1, participant U12]

> *I start my work at 9 am, then I eat breakfast, and walk with my dogs. I normally work at my computer until 6–8 pm. I eat, and drink coffee during short work breaks. At 4 pm I give food to my dogs. In the evening, I don't meet anybody else than other dog owners. I also meet new employees during my workday.* [Group 1, participant U6]

> *I eat breakfast in the morning, and at the same time, I read news from my iPad. My husband and I have not ordered any paper newspapers.* [Group 2, participant HX4]

> *I might visit quite often to meet my neighbor, but not on an everyday basis. But it is a part of my everyday life. ...And then, I go quite often after 6 pm a short walk, and at the same time, visit at my friend, who has two cats. ...Then I make some dinner and watch TV News. I do not usually follow any TV series, but I might sometimes watch something from TV. I go to sleep at around 12 am.* [Group 2, participant HX5]

> *I don't have so many meetings anymore, but my week starts with English lessons every Monday at 10 am. At 4 pm I go to an hour's outdoor exercise. In the evening, I often go to German language speaking exercise group. Next day, I go to aqua jogging, and after that we take a cup of coffee with the members of that group. Next day I participate in outdoor walking exercise group, with which we normally walk an hour together. And at the end of the week, I often do some housework, a little bit cleaning home or something.* [Group 2, participant U7]

Watching television was emphasized in both groups, and activities related to cleaning and housekeeping were popular. Overall, participants in both groups seemed to like routines. The everyday life activity themes are detailed in Multimedia Appendix 6.

The Needs of Older Adults for eHealth Services

Overview

The older adults' needs for eHealth services were collected based on the main findings from remote, semistructured interviews and sentence completion tasks. The themes discovered from the interviews, the main findings under each theme, and the participants' needs based on those findings are provided in Multimedia Appendix 7. In addition, sentence completion revealed the participants' wishes and needs for eHealth services in the future (Multimedia Appendices 1 and 2). The needs described in the following sections were expressed based on the data.

The Need for a Carefree Mind

Older adults need a carefree mind when taking care of their health and regarding their current health and well-being situation, which can be supported with eHealth services. They need to understand the safety of eHealth service use and be able to manage health-related matters well regardless of the channel (eg, mobile phone, chat, or remote appointment). Users' technical skills vary, and some use technical devices versatilely. Support and training possibilities help with this need. Feedback

on one's current health and well-being situation via eHealth services is appreciated. The safety needs are evident in the following quotes:

> *I avoid using all parts [of the user interface] that have even a little bit of a foreign language to me. Because it might happen there that I don't understand something and make a wrong choice somehow [in the user interface].* [Group 1, participant U2]

> *I think managing my health-related affairs should be safe.* [Group 1, participant U6]

The need to obtain health care service regardless of the service channel is reflected, for example, in the following comments:

> *I would like to be able to use eHealth services in parallel with other service channels in the future.* [Group 1, participant U1]

> *I look for information on the internet every day. I use all possible medical and health services that are available digitally. And the same thing with public services: everything that is possible, I do them in digital channels.* [Group 2, participant H3]

On the basis of the data, people's diversity is emphasized: being able to use the eHealth service can be a big challenge for one person, but for another, it brings benefits and ease. Owing to older adults' varying technology skills and device availability, health self-management was desired in varying ways and different channels, either face-to-face or digitally. In addition, group 1 participants seemed to be experienced or very experienced with technology and felt very comfortable using eHealth services. The clear variations between the participant groups should be considered in all design decisions regarding eHealth service development.

Varying skills and comfort levels with using eHealth services are demonstrated, for example, in the following quotes:

> *For me, using eHealth services is natural and easy.* [Group 1, participant U6]

> *For me, using eHealth services is easy and self-evident.* [Group 2, participant HX4]

> *eHealth services do not help me because I have neither the equipment nor the skills.* [Group 2, participant S8]

> *Learning something new [about digital services] is difficult because of the tricky terminology. I've never studied English at school, and systems use a special system language. ...Then these jungles of safety encryptions and passwords: remembering them is almost the most difficult part of it.* [Group 2, participant S9]

The Need for eHealth Service Adaptation Based on Current Life Situation, Use Contexts, and Everyday Life

Regarding different life situations, the participants needed support via eHealth with their health and well-being in changing situations, such as when retiring, regardless of their current technology skills or devices. eHealth could help them, for example, with mental well-being or keeping physical activity levels high enough. The changing situations are evident in the following quotes:

> *My working years are in the final phase. It's sure that I have a couple of years left until I retire officially. After that, my children are already adults as well. But currently, my life is quite work-oriented, long workdays, and I'm all the time busy.* [Group 1, participant U1]

> *I have done more or less work [in my life]. And now I'm retiring. That's a pretty big change.* [Group 1, participant U4]

> *I'd like to use eHealth services in the future even after I retire.* [Group 1, participant U12]

> *I have a little bit tricky stage of life. My son went to heaven two weeks ago, and I am currently going through grief. Five years ago, my husband died. So, that kind of stage of life I have now.* [Group 2, participant H2]

> *Yes, it was easier when I was healthy. After all, then I could do what I wanted and run if I liked and, in every way. ...That life was completely different then. I can't say, however, that none of these moments in this life have been completely unpleasant. ...When I think about this end of life, yes, I have had a good life the whole time, no matter what era it was. They have all been part of life that was then, and it was good at that moment.* [Group 2, participant S7]

Older adults desired eHealth services that could adapt to their current and evolving life situations, such as retirement or changes in health. These services should be tailored to their lives in terms of both content and functionality, including the user interface, and should be flexible enough to adjust according to the season, regardless of their location. Older adults want to take care of their health and well-being regardless of location (from places other than home or a clinic, such as a summer cottage). Service adaptation to everyday life makes eHealth services relevant.

However, the ease of use of an eHealth service becomes relevant only after it has been ensured that it can be accessed at all. One's health state affects everyday life and the ability and willingness to use eHealth services. For example, when a health situation improves due to following healthy daily routines, the content of the eHealth service should follow this new health situation and its user's new needs for the eHealth service. eHealth services should be adaptable to changes in life and health situations as well as fluctuations in motivation to use eHealth, both in the short and long term. eHealth service's role and value as a part of changing life situations and user needs regarding eHealth service's adaptability are reflected in the following quotes:

> *eHealth services help me very well in my health situation.* [Group 1, participant U12]

> *eHealth services help me plan schedules flexibly.* [Group 1, participant U7]

> *For me, the most important thing with eHealth services is that I don't have to commit to a specific time.* [Group 1, participant U10]

For me, the most important thing in eHealth services is the right information at the right time. [Group 2, participant S9]

For me, the most important thing with eHealth services is that I get information immediately without waiting. [Group 2, participant HX4]

Using them [eHealth services] saves time. [Group 1, participant U8]

The Need for a Holistic Perspective

Older adults need content that supports their health and well-being holistically. eHealth services should, for example, include perspectives on their current everyday lives and health situations. Group 1 members often wished that eHealth services would be one service among others, smoothly integrated into everyday life. For group 2 members, more research is needed to investigate their perspectives on a suitable package of service channels and content so that they receive the same holistic support as group 1 members. The example quotes behind the need for holistically offered health and well-being support as a part of older adults' everyday lives are as follows:

I fill in crosswords, and I read when I like to. I cook, but not every day now. Things like that I get pleasure from. After all, all in all, the fact that there are not so many financial worries is a part of that balance. Everything you need is here and now. Everyone can ask themselves the question whether they are happy. [Group 1, participant U11]

For me, the most important thing in eHealth services are the right health goals considering the right information; based on researched and measured information. [Group 1, participant U7]

eHealth services help me to plan flexible schedules. [Group 1, participant U7]

eHealth services help me take care of things related to my health at once. They save time. I get e.g., lab results through a digital service. [Group 1, participant U13]

eHealth services help me get an overall picture of my health. [Group 1, participant U1]

I read a lot. Now that I've been here sick and the moments, I've been awake, I'm reading something all the time. [Group 2, participant HX6]

And then jogging with the dog. It keeps me in balance. All my social interaction now takes place there, walking the dog, because there are many dogs here, and we have lived here 45 years, so there are so many people who know dogs. [Group 2, participant S8]

The Need to be Able to Avoid Using eHealth Services But to Use Specific eHealth Functions

Older adults, especially group 2 members, need to be able to select the service channel: eHealth services or face-to-face. On the other hand, there was a need for eHealth functions. For example, group 2 members often appreciated the opportunity to look at laboratory results without having to go anywhere. The COVID-19 pandemic era might have affected this result. The following example quotes bring insights into the older adults' needs for specific functions and the possibility of obtaining health care services via service channels other than eHealth services:

In principle, they [service providers] accept to do business [face-to-face], but if you ask for some advice there, they recommend that you "go to do it online or look it up online." They don't understand that not everything works perfectly on the internet for them either. I think it's pointless for them to guide you to do business online when it can't be done there online. [Group 1, participant U8]

Or you can use a video connection to contact the nurse! They are certainly good additions to the healthcare service. [Group 1, participant U1]

It's embarrassing that I don't know how to book appointments [digitally]. I don't know how to book a time for our laboratory or X-ray. I don't know how to make an appointment. And you should know that, but when there was no need, you didn't learn. [Group 2, participant HX6]

When I imagine myself retired, and when I no longer have a work computer, and if it is difficult to get from one place to another, then of course, they [eHealth services] will be useful. And then the chat service, where you can easily ask for help or advice!

I think managing my health-related affairs should be possible in person. [Group 2, participant S8]

This means that eHealth services should be accessible: (1) devices should be available and (2) the network connection should be stable enough, and the service must be available regardless of time. The service should be offered in a multichannel manner, including personal contact, phone service, or in writing (eg, chat).

Operations related to health and well-being, such as appointment booking through eHealth services, must be clear and easy to use for all user groups. The operations and the eHealth service should support long-term and short-term health and well-being planning in terms of the content and functions available to both end users and health care professionals. It should work reliably in all situations and support older adults' empowerment in managing and controlling their current and future health situations. This is evident, for example, in the following quotes:

I think operations related to my health and well-being should be easy. [Group 2, participant HX5]

eHealth services do not help me at all. [Group 2, participant HX6]

User Needs Regarding User Experiences

The completed sentences revealed that the older adults' experiences with eHealth services varied, with some finding them easy to use and others finding them challenging. The use of eHealth services was felt to be part of everyday life and routines, and it did not produce many "peak experiences," which are the most memorable experiences producing positive

emotions [70,80]. The variation in user experiences from eHealth use is apparent in the following example quotes:

> *For me, using eHealth services is easy, and a routine.* [Group 1, participant U13]
>
> *Using them [eHealth services] makes me a little irritated.* [Group 1, participant U1]
>
> *I think managing my health-related affairs should be confidential, and the response quick and empathetic.* [Group 1, participant U11]
>
> *Using them [eHealth services] puts me in a bad mood.* [Group 2, participant HX6]

Two (25%) out of 8 participants in group 2 had worrying experiences, such as a loss of self-confidence in the use of eHealth services and an increase in concern about the use of eHealth services. These worries are reflected in the following example quotes:

> *Using them [eHealth services] makes me feel insecure.* [Group 2, participant S7]
>
> *The thing that worries or scares me the most about eHealth services is that soon you won't be able to see a doctor anymore when everything will be done digitally.* [Group 2, participant S8]

However, eHealth services especially brought peace of mind to group 1 participants, seeming to improve their well-being. For both groups, eHealth services produced important information about their current health situation. eHealth services seemed to be used in both age groups, not only out of necessity but also to obtain information and improve the flexibility of taking care of their health. eHealth services provided longer-term insights into their own health status, and information obtained through eHealth services was highlighted at different points. Finding out about their own health status seemed important. With the help of eHealth services, the level of concern about their own health condition improved. Group 2 members had more negative views of eHealth services, and they also mentioned a lack of equipment as a barrier to eHealth service use. eHealth service's role in offering information, flexibility in taking care of one's health, or role as a calming factor is reflected in the following example quotes:

> *I use eHealth services if I book an appointment with my doctor, or check my health information* [Group 1, participant U12]
>
> *I use eHealth services whenever possible.* [Group 1, participant U6]
>
> *Using them gives me peace of mind when I can book appointments and find out about health-related issues at a time that suits me.* [Group 1, participant U13]

Other barriers to eHealth services were lack of human contact, inefficiency, and challenges with its use. eHealth services divided participant opinions regarding its benefits: group 1 participants did not have as many helpful experiences with eHealth services as group 2 participants. Both groups included individuals who felt that eHealth services did not provide holistic support during life changes. At the same time, group 2 participants felt that eHealth helped them acquire information about health-related issues, supported them in planning health-related issues, and helped them commit to lifestyle changes. On the other hand, they lacked competence and felt that eHealth services (use processes and user interfaces) was too complicated. The negative experiences and use barriers are evident in the following quotes:

> *With eHealth services, I am saddened by the lack of consistency and aimlessness, as well as the lack of genuine and cheerful support.* [Group 1, participant U7]
>
> *With eHealth services, I am frustrated by delays and waiting.* [Group 1, participant U6]
>
> *With eHealth services, I am saddened by my laziness and lack of time available to study the use of eHealth services.* [Group 2, participant H3]
>
> *With eHealth services, it saddens me that I don't know how to use them.* [Group 2, participant HX6]

The most important things in eHealth services use were efficiency, ease and smoothness of transactions, access to information, planning (where group 1 members had diverse answers), and support for well-being. Participants in group 2 had the same eHealth needs as those in group 1 but they were more skeptical (Multimedia Appendix 8).

The efficiency, ease, and support for well-being via eHealth services are apparent in the following quotes:

> *Using them [eHealth services] saves my time.* [Group 1, participant U6]
>
> *Using them [eHealth services] makes me think about my health based on researched information.* [Group 1, participant U10]
>
> *For me, the most important thing about eHealth services is that I don't have to commit to a specific time or date.* [Group 1, participant U10]
>
> *eHealth services help me renewing my medicine prescriptions.* [Group 2, participant S7]

Discussion

This qualitative exploratory study aimed to gain a more in-depth understanding of older adults' needs for eHealth services as part of their everyday lives in different life stages. The data were collected with interviews and a cultural probe package, including 4 background information questionnaires, sentence completion tasks, and a diary-based exercise.

Principal Findings

Everyday Life of Older Adults

Both participant groups valued time spent at home and home-based activities as part of their everyday lives. Healthy eating habits were an especially important aspect of the participants' well-being from their own perspective. These older adults enjoyed different activities, such as jogging and Nordic walking, which is in line with other literature [31].

Older adults generally appreciated bringing health and well-being into everyday life. They had weekly or daily

activities or hobbies that supported them to reach their long-term health targets. These routines varied greatly, including exercise, good night sleep, personal hygiene, repetitive food, pet care, and housework-related morning routines. Group 1 participants reported routines and activities that partly differed from those of group 2 participants. For example, all the routines related to the gym or exercising while commuting were reported by group 1 participants. Interestingly, the only mention of reading newspapers with a tablet was reported by a participant from group 2. Furthermore, a mention of doing morning exercise with television was reported by a group 2 participant. Cleaning routines were mainly mentioned by participants from group 2.

The eHealth service can both support health self-management on a long-term basis and activate and support older adults in ad hoc type of activities and operations related to health and well-being, for example, by offering information based on the current health situation or reminding them of a (daily or weekly) hobby.

The Needs of Older Adults for eHealth Services

On the basis of the interviews and sentence completion tasks, four needs for eHealth services were identified: (1) the need for a carefree mind; (2) the need for eHealth service adaptation based on the current life situation, use contexts, and everyday life; (3) the need for a holistic perspective; and (4) the need to avoid using eHealth services but to use specific eHealth service functions. These needs should be considered when designing eHealth services that support older adults' healthy living. In addition, they generally apply to both user groups but may be emphasized differently depending on the group.

On the basis of our findings, the older adults seemed to have generally positive attitudes toward eHealth, aligning with those identified by Cabrita et al [15] and Mielonen et al [28]. The infrastructure behind eHealth services must be stable; then, eHealth services can be offered in an accessible way and without limitations for everyone, assuming that end devices are available. Owing to varying end devices among older adults, eHealth services should be scalable regardless of the service channel or devices. Therefore, the design should support the reliability of eHealth services so that they work in all situations, supporting older adults' health self-management [15,70]. Our study adds the perspective of changing time spans: the service must function smoothly for both short-term and long-term use, accommodating variations in use duration.

Well-being, sickness, health, and illness seem to be subjective personal experiences. The need for eHealth services changes due to the user's current health and well-being situation: eHealth services become unnecessary when health and well-being increase. Therefore, it must be possible for older adults to easily try out whether eHealth services will benefit them. An eHealth service may also be used less frequently at times.

eHealth services can support older adults' health and well-being, particularly when the content of the service aligns with their everyday lives and interests. Therefore, we recommend that the eHealth service work as part of an older adult's healthy routines, which might include, for example, encouraging attitudes and functions for housework and other activities.

Comparison With Prior Work

Our results show that understanding the user's life stage and the key interests at that stage is important, as found in other literature [47]. Owing to older adults' changing health and life situations [1-3,10,11,47], an individual eHealth service should function as part of a wider service offering so that the service supports and adapts to changing life situations and health statuses. For example, in this study, it was recognized that both those who are still working and those who are retired use IT and eHealth services. IT use at work might support learning new skills and sometimes even updating them [70]. In addition, eHealth service flexibility is valued [4]. The need for eHealth services to adapt to the older adult's current life and health situation is in line with the study by Reiners et al [81].

Earlier research recognized a large variation in activities that support older adults' well-being, in line with our findings: exercising; cooking; and hobbies, such as language courses [82]. Even with poor health, older adults achieve well-being and positive effects from daily activities [82,83]. In addition to physical activities, daily activities, such as reading books or watching television, can also offer relaxation [81]. Owing to the differing routines and daily activities, the need for eHealth adaptation based on the current life situation, use contexts, and everyday life was recognized in this study, and we recommend that eHealth services work as a part of older adults' daily living smoothly. Previous research supports our results behind this user need: older adults are a heterogeneous group whose activity possibilities vary regarding their living conditions or current health situation [31]. However, the importance of studying the use of eHealth service as part of everyday life has been recognized [19].

The devices with which the eHealth services are used should be considered when designing these services. Given the possible effect of the small sample size, it can be seen from the data that group 2 participants seemed to use eHealth services somewhat less than group 1 participants. One reason for that could be that older adults who are still employed might use eHealth services for work reasons, as well [70]. On the other hand, it can probably be expected that, nowadays, older adults who are retired have used at least some IT at work.

Understanding the safety of eHealth services use was important to older adults, as in earlier research [4,5,10,18]. In line with previous literature [18,70], they needed available support and training for eHealth service use. In particular, the older participants in this study also needed not to be forced to use the eHealth service. However, this varied considerably between participants, which supports earlier research results [18].

In line with an earlier study [15], one of the most important design functions is to ensure that the eHealth service conveys empathy to older adults. This can be offered via an empathic tone of voice in the services and by offering them through service channels that are especially suitable to each older adult's current situation. The whole life span, including transitions to different life phases, such as retirement, should be considered in design decisions [2,47,70]. This can be done, for example, by offering relevant content related to health and well-being to

different older adult groups and by making sure that the content is relevant to each end user's unique life and health situation.

On the basis of our findings, both those still working and those who have already retired have suitable devices and sufficient technical skills, as also reported by Mielonen et al [28]. However, eHealth services were used only by half (4/8, 50%) of the older participant group. Our findings support the observations of Kruse et al [3] regarding common barriers to eHealth use among older adults: a lack of self-confidence, a fear of making irreversible mistakes, and content that does not meet their needs. Fear can be dispelled with a clearer service concept, implementation support, user support, and instructions, as well as reassurance, such as by highlighting safety both in the service content and in the presentation of the service. In addition to minimizing fear, strengthening the self-confidence of the end user of the service plays an important role. Another phenomenon that emerged from the data was that well-being, health, and illness seem to be subjective, personal experiences.

The need for eHealth services changes due to the user's current health and well-being situation; eHealth services become unnecessary when health and well-being improve. Therefore, it should be possible for older adults to easily try out whether the eHealth service will benefit them. This can be done, for example, by offering trial versions of services, which other research [15,18,84] recommends. Being able to safely try out an eHealth service could help reduce fears, build self-confidence, and better identify the current need for the service. Another helpful option would be to group service functions into easier basic functions and possibly other more complex functions that are recommended to be familiarized with time, as is recognized in the literature [15,47]. However, based on the study findings, the end user's age or life situation does not appear to be a decisive factor in determining the need for user interface content. That said, older adults who are retired may face slightly more challenges in using eHealth services compared to those who are still working.

As also found in other literature [18,70], individual eHealth service should function as part of a wider, multichannel service package so that it adapts to changing life situations and changes in health status. It should work as a channel for end users to receive empathy in challenging health situations. This could be done with effective but sensitive communication possibilities and with empathic content. Because eHealth services should support older adults' health and well-being, it is important to look at and connect their well-being in the IT context [84]. This can be done according to content and with easy and logically functioning user interfaces. In addition, this study's participants wished for an option to not use eHealth services or specific eHealth functions. This need is in line with other research findings [85].

Limitations

This qualitative exploratory study aimed to gain a more in-depth understanding of older adults' needs. The sample was small; the participants were from 1 country, and they were likely to be more interested than average in eHealth services. Older adults are a diverse group from the perspective of, for example, cognitive, motor, or technology use abilities [61]. Therefore, completely covering the population with a representative sample was not possible. This has potentially biased the results. In addition, the COVID-19 pandemic era could have influenced the results, but this was not especially followed as a part of this study.

Regarding the adaptation of eHealth services to different life and health situations, we do not know whether the service should always be the same or differ depending, for example, on whether the health situation has changed, in which case the role and meaning of the service changes from supporting well-being to treating illness. We recommend this as a future research area, especially in long-term studies. More research is needed on the best service channel combinations for older adults to obtain sufficient holistic health and well-being support. In the future, it would be worthwhile to test the design recommendations with representatives of the designer community and older adults, for example, in co-design workshops. In this study, the older adults' needs in different life situations were not compared to those of other age groups. However, this would be valuable to study in the future.

From a methodological perspective, the cultural probe package, including diary-based and sentence completion tasks, combined with remotely conducted semistructured interviews seemed to be effective in collecting information about participants' everyday lives and in mapping user needs for eHealth services. This is interesting because, as far as we know, not many cultural probes studies on this topic are available. The working participants completed more handwriting-based sentences. Therefore, cultural probes including many handwriting exercises might fit better for them. On the other hand, the data were collected using several methods, which confirmed the findings of the study and helped identify user needs. The methods seemed to work well in remote conditions during the COVID-19 pandemic era.

Conclusions

In this qualitative study, we collected information about the everyday lives of older adults in different life situations and identified their related needs for eHealth services. The results helped us understand how older adults see and experience health care with the help of eHealth services as part of everyday life. The older adults in this study often preferred a consistent routine in their daily practices including healthy eating and exercise. eHealth services could offer time saving and flexibility within these routines. A lack of devices or skills was often mentioned as a use barrier. On the basis of the results, four main needs of the older adults for eHealth services were identified: (1) the need for a carefree mind, in which older adults could receive status information on their current health and well-being situation via eHealth services; (2) the need for eHealth service adaptation based on the current life situation, use contexts, and everyday life; (3) the need for a holistic perspective, in which older adults wished to receive support for health issues from many perspectives and through several different service channels; and (4) the need to avoid using eHealth services but to use specific eHealth service functions, in which face-to-face support for their health was especially appreciated. On the basis of the results, eHealth services should be designed such that

they fit well in older adults' everyday lives and adapt to users' everyday practices and health statuses according to content. eHealth services should be accessible and reliable.

Acknowledgments

The authors would especially like to thank the study participants. The authors would also like to thank Marina Broman for completing 3 of the interviews and Marjaana Kanervo, Annetta Kurvinen, Tytti Natunen, Kirsi Pitkälä, Sanna Pussinen, Semra Räikkönen, Reija Saarinen, Sanna Solala, Arja Sunila, and Iina Vartia for the help with the research arrangements and collaboration. The work was supported by the Strategic Research Council at the Academy of Finland (grants 352501 and 352503) and NordForsk (project 100477).

Data Availability

The datasets generated and analyzed during this study are not publicly available due to the sensitive nature of the data, but the numeric data are available from the corresponding author on reasonable request.

Authors' Contributions

The study was conceptualized by PV, SK, and RRH. PV was involved in the methodology, investigation, project administration, data curation, visualization, and formal analysis of the study. KS contributed to the formal analysis and validation of the study. PV, KS, and SK were involved in preparing the original draft of the study. SK contributed to the methodology, resources, data analysis, validation, supervision, and funding acquisition of the study. RRH also contributed to the resource collection of the study. All authors were involved in writing, reviewing, and editing the manuscript.

The visualizations used in the cultural probes were under creative commons licenses. The creators' nick names were OpenClipart-Vectors, Emmie_Norfolk, Buntysmum, Clker-Free-Vector-Images, bibin9363pbr, 1,820,796, ArtsyBee, and b0red.

Abstract

Background: The World Health Organization estimates that 1 in 4 people worldwide will experience a mental disorder in their lifetime, highlighting the need for accessible support.

Objective: This study evaluates the integration of digital peer support (DPS) into an employee assistance program (EAP), testing 3 hypotheses: (1) DPS may be associated with changes in EAP counseling utilization within a 5-session model; (2) DPS users experience reduced sadness, loneliness, and stress; and (3) DPS integration generates a positive social return on investment (SROI).

Methods: The study analyzed EAP utilization within a 5-session model using pre-post analysis, sentiment changes during DPS chats via natural language processing models, and SROI outcomes.

Results: Among 587 DPS chats, 432 (73.6%) occurred after business hours, emphasizing the importance of 24/7 availability. A matched cohort analysis (n=72) showed that DPS reduced therapy sessions by 2.07 per participant (P<.001; Cohen d=1.77). Users' messages were evaluated for sentiments of sadness, loneliness, and stress on a 1-10 scale. Significant reductions were observed: loneliness decreased by 55.04% (6.91 to 3.11), sadness by 57.5% (6.84 to 2.91), and stress by 56.57% (6.78 to 2.95). SROI analysis demonstrated value-to-investment ratios of US $1.66 (loneliness), US $2.50 (stress), and US $2.58 (sadness) per dollar invested.

Conclusions: Integrating DPS into EAPs provides significant benefits, including increased access, improved emotional outcomes, and a high SROI, reinforcing its value within emotional health support ecosystems.

digital peer support; peer support; EAPs; cost-effectiveness; SROI

Introduction

Background

The World Health Organization estimates that 1 in 4 people globally will experience mental disorders in their lifetime [1], stressing the need for a readily available treatment ecosystem. Relatedly, the increasing popularity of remote work post–COVID-19, along with work- and workplace-related stress—stemming from long hours, high workloads, an inability to disconnect, and, in particular, isolation—has contributed to a rise in mental health problems such as anxiety and depression, musculoskeletal pain, sleep deprivation, and stress [2]. These stressors impact not only employees' well-being but also presenteeism, absenteeism, and work-life balance [2-4]. Burnout, in particular, arises from chronic stress characterized by emotional, physical, and mental exhaustion, leading to reduced productivity, increased absenteeism, and higher turnover rates [3].

While the Centers for Disease Control and Prevention's National Center for Health Statistics reports a notable increase in treatment-seeking behaviors between 2019 (19.2%) and 2021 (21.6%), a significant majority of working adults may still suffer alone [5]. The proportion of working adults aged 18-44 years receiving mental health treatment grew significantly from 18.5% in 2019 to 23.2% in 2021 [5], with women (23.8% to 28.6%, respectively) continuing to outpace men (13.1% to 17.8%, respectively) [5]. By 2021, adults aged 45-64 years (21.2%) and those aged 65 years and over (18.9%) ranked second and third, respectively, in seeking treatment [5].

Employee Assistance Programs

Mental and emotional health–focused employee assistance programs (EAPs), which are confidential, voluntary, organization-sponsored, and low-cost services for employees, offer personal or work-related counseling and support. The purpose of EAPs is to help employees manage stress, enhance problem-solving abilities, and, in turn, improve work productivity, reduce absenteeism, and promote overall well-being [6]. Counseling-based EAPs provide psychoeducation, teach coping strategies, and assist users in setting achievable personal goals that build confidence and self-efficacy [7-12]. Additionally, EAPs offer training in communication skills, such as assertiveness, to improve relationships and help users navigate challenges effectively. Patient activation, which refers to an individual's knowledge, skills, confidence, and willingness to manage their health and well-being [7,8], is further supported by connecting users to resources and support networks, including health care providers and peer support groups. Finally, EAPs empower users with self-management tools, such as digital apps and resource libraries, that allow them to track their progress and independently manage their well-being [12]. Together, these strategies foster self-reliance, enhancing users' ability to manage their mental health and overall well-being [7]. Depending on the EAP, a significant return on investment (ROI) may be observed, with some organizations seeing US $3-US $10 for every dollar spent [13], largely due to positive impacts on absenteeism, productivity, and employee turnover and retention [6,13]. EAPs are well-established assets to organizations, delivering emotional benefits to employees and productivity and financial benefits to employers [6,13].

Digital Peer Support

While counseling-based EAPs are known for their advantageous returns, not every emotional concern requires counseling support. A tiered support system for individuals who are mentally well but experiencing lower-acuity emotional distress may be necessary. Simultaneously, the US health care system currently faces a shortage of mental health professionals, limiting access to adequate support [14,15]. In 2021, 5930 areas were designated as health professional shortage areas, leaving 129.6 million people without access to affordable and accessible care [15]. President Biden's 2022 White House brief highlighted this issue and called for efforts to "strengthen system capacity," including the increased use of peer support specialists and paraprofessionals [16].

Peer support interventions involve individuals with similar lived experiences offering mutual support [17]. While expert-based professional support may evoke feelings of shame, failure, and mental health stigma, peer support can normalize emotional struggles and foster connection, validation, and empathy through shared experiences [18]. This "mutual empowerment" from peer-driven interventions grants individuals greater autonomy and competency [18]. However, some Americans may not have access to digital peer services due to a lack of universal internet access and low health literacy. Approximately 24 million people in the United States lack reliable broadband service or high-speed internet [19]. Historically, lower rates of high-speed internet use have been observed in households where the owner is 65 years or older, Hispanic, African American, American Indian, or Alaska Native [19]. Furthermore, in 2021, only about 5 in 10 households with incomes below US $25K used high-speed internet [19]. Additionally, approximately 90 million American adults struggle to understand and navigate complex health- and text-based tasks accurately and consistently, exhibiting low health literacy [20]. By addressing these disparities, digital peer support (DPS) services could become even more inclusive by expanding support to those currently excluded from traditional services.

Self-determination theory, as articulated by Ryan and Deci [21], offers insight into key features that make peer support impactful. The theory states that self-determination and emotional growth are driven by 3 core elements—autonomy, competence, and relatedness [21,22]. Autonomy refers to the ability to self-direct and control one's actions, competence involves mastering new skills, and relatedness is about forming meaningful connections with others [21,22]. Peer support provides a nonjudgmental, nonstigmatizing space that fosters autonomy, as there is no professional expert directing treatment. Competence is strengthened through the normalization of mistakes shared via lived experiences, as well as the application and practice of coping strategies. Relatedness is reinforced through the verbal and emotional connections formed with similar peers [18]. Research has consistently shown that relatedness in supportive relationships contributes significantly to emotional regulation, motivation, and the overall success of interventions. By reinforcing relatedness through peer-to-peer interactions, peer support programs address a fundamental psychological need that complements autonomy and competence, further validating their essential role in the model [17,18]. The interrelatedness of these dynamic factors is believed to enhance mental health and well-being [17-22]. The introduction of DPS platforms extends these benefits by offering accessible, mutually supportive communities to help alleviate feelings of loneliness and isolation [23]. Numerous studies have demonstrated the effectiveness of these digital interventions in addressing mental health needs [23-30].

Confirmed benefits of peer support interventions are evident through self-determination theory and digital platforms [23-30]; however, a significant gap remains in understanding the ROI, particularly when integrated into counseling-based EAPs. Studies suggest that peer support may lead to direct health care savings by equipping individuals with coping mechanisms and providing emotional support, which, in turn, reduces the risk

of crises and costly subsequent interventions (eg, inpatient hospitalization, emergency room use) [31-33]. Specifically, current research does not adequately address how incorporating 24/7 DPS into EAPs translates into measurable cost-effectiveness for organizations. Traditionally, cost-effectiveness and cost-benefit analyses are used to assess the value for money of health and social interventions, but the value derived from participating in 24/7 DPS can be subtle and difficult to measure [34]. As a result, there is a paucity of research on the broader social, economic, and environmental value. This gap underscores the need for a focused study to evaluate the social return on investment (SROI) of integrating 24/7 DPS into a counseling-based EAP, assessing both the economic impact and the efficiency of these interventions.

Social Return On Investment

SROI has become a recognized method for measuring the impact, outcomes, and value created by social-emotional–focused organizations [35,36]. Broadly, SROI uses a mixed-method design to assess the value of an intervention relative to the cost of enabling it. Beyond financial metrics, which may assign limited value to a program, SROI captures social, environmental, and economic elements to generate a comprehensive "social value."

Study Aim and Hypotheses

For this study, a 24/7 US-based DPS service was integrated with a US-based counseling-based EAP firm to explore potential changes in utilization, sentiment, and the SROI of the 24/7 DPS for the EAP's clientele. The following study hypotheses were examined: (1) The introduction of the 24/7 DPS service may lead to changes in the utilization of EAP counseling services within a 5-session model; (2) participants who utilize the DPS service will experience significant changes in sentiment (eg, reduced sadness, loneliness, and stress) over the course of their engagement with the service; and (3) the integration of DPS into the EAP will produce a positive SROI, reflecting the added value of peer support services for EAP clientele. Through these key objectives, the study aims to assess the effects of DPS on EAP utilization, emotional well-being, and the social and economic value added to the EAP.

Methods

Pre- and Post-DPS Integration: EAP Services and Implementation

Using aggregated participant data, pre- and postanalyses of adding DPS to EAP services were conducted. Pre-DPS was defined as the routine care provided within the EAP, including an initial intake, screening for clinical concerns, and offering service options such as counseling, legal resources, psychoeducation, and coaching. Before the introduction of DPS, participants either accessed the EAP provider's website using a company code to explore available services or completed an initial online or phone intake. They were screened for clinical concerns, including substance use and suicidal or homicidal ideation, by licensed clinicians or clinically supervised paraprofessionals. The EAP offers a comprehensive suite of behavioral health and wellness services designed to support mental health, work-life balance, and overall well-being. These offerings include free and confidential counseling, legal and financial benefits (including Medicare and Social Security consultation), wellness coaching, work-life referral services, and an online resource library. Additional services include virtual reality programs, as well as parenting, life, career, and work performance coaching. The EAP provides managed care 24/7, with crisis support delivered by licensed mental health professionals.

An anonymous US-based DPS service that provided 24/7/365 moderated, synchronous peer group chats was integrated into the US-based EAP's client support ecosystem. The DPS service utilized artificial intelligence (AI)–driven natural language processing to match users with peers facing similar issues in small groups, each facilitated by a trained human moderator who ensured a safe environment and directed users to professional services in crises. The DPS model allows for unlimited sessions, in both duration and frequency, while the EAP's 5-session model was selected for further analysis due to the prevalence of 5-session models over other session formats.

Participants

DPS: Peer Support Users

Nonidentifying participant data from the DPS provider, collected between June 2023 and May 2024, were used to evaluate the research objectives. DPS service participants had access to unlimited peer support chats and were included in the data analysis if they utilized the chat service at least once.

EAP: Counseling Service Participants

Inclusion Criteria

Pre-DPS (June 2022 to May 2023) and post-DPS (June 2023 to May 2024) participants were selected based on having active access to the 5-session EAP model. For the analysis of total utilization, no demographic factors were matched between the pre- and post-DPS groups. However, for the utilization analysis of the 5-session EAP model and to ensure comparable groups, participants in both the pre-DPS and post-DPS cohorts were matched based on demographic and emotional concern variables. Matching was conducted using propensity score matching, adjusting for potential confounders such as age, gender, and emotional concerns (eg, anxiety or depression). Participants who had utilized the full 5-session model in both groups were selected, with efforts made to capture diverse client trajectories by including multiple participants matched on these same variables. EAP participants were employed across a wide range of sectors, including health care, education, professional services, manufacturing, construction, building trades, nonprofits, technology, service industries (eg, restaurants), unions, mining, government, and others.

Cohort Exclusion Criteria

Participants were excluded from the analysis if they had missing demographic data (age or gender) or if they exceeded the authorized number of counseling sessions (eg, >5 sessions in the pre-DPS group). These exclusions were necessary to control for confounding variables, as participants requiring more intensive mental health support (beyond 5 sessions) may have

had significantly different needs compared with those who adhered to the 5-session model. This approach ensured that the study focused on participants whose engagement with EAP services reflected typical utilization patterns.

Peer Support Moderators

Peer support moderators (PSMs) are human moderators trained in digital safety monitoring who provide real-time, text-based support. PSMs receive up to 164 hours of training within the first 90 days of hire, focusing on engaging in digital conversations, facilitating synchronous group chats, and managing the psychological safety of chat users by monitoring for and removing trolls, as well as enacting safety protocols, such as referring users who may be in active crisis to appropriate services. Additionally, PSMs receive 36 hours of ongoing asynchronous and synchronous clinical supervision and consultation per quarter.

Procedures

Overview

This retrospective study evaluated the differences in the EAP's services before and after DPS to assess the programmatic impact and added social value.

Data Variables

The primary data sources for this study were aggregated engagement variables, such as chat time, number of chats, age, gender, user struggles or presenting concerns, and national-level cost-of-service value data.

Data Extraction and Management

The data extraction process involved retrieving DPS chat data, which included digital chat records, user interactions with the platform, and usage patterns. All collected data were deidentified and anonymized to ensure participant privacy and confidentiality. Data management procedures adhered to institutional and regulatory guidelines, ensuring data security and integrity, with access restricted to authorized personnel. Measures were in place to maintain data security, integrity, and confidentiality throughout the analysis process.

Statistical Analysis

Analysis and Group Comparability

Descriptive statistics were used to summarize participant characteristics and their engagement with DPS and EAP services. To assess differences in service utilization and sentiment scores between pre-DPS and post-DPS groups, paired *t* tests (2-tailed) were conducted for continuous data (eg, session frequency), and chi-square tests were used for categorical data (eg, gender, emotional concern). As DPS is anonymous, it was not possible to directly track which EAP participants used the service. Using volunteered age and gender data from DPS participants as a starting point, propensity score matching was applied to control for potential confounders such as age, gender, and emotional concern, ensuring group comparability before DPS integration.

Mood Categorization

Clinical counseling experts reviewed the emotional concerns reported by DPS participants, categorizing them into mood categories such as depression, anxiety, adjustment, and relational concerns to align DPS participants with the presenting emotional concerns of EAP participants. The counseling experts were 2 licensed psychologists with doctoral degrees in counseling psychology and a combined 50 years of experience in the field. The clinical interpretation process, guided by the Biopsychosocial Model [37], involved categorizing participants' emotional struggles into mood categories. This model integrates biological, psychological, and social dimensions to provide a comprehensive understanding of mental health. For example, participants' reports of feeling "trapped" or "isolated" were examined through a psychological lens to identify depressive thought patterns, while work-related stress (eg, "I hate my boss") was contextualized within the social environment to classify relational concerns [38]. By incorporating these factors, the model enabled clinical experts to holistically interpret participants' struggles, ensuring that the categorizations captured the complexity of their emotional experiences. The categorization process involved initially reviewing the raw data from participants' reported "struggles" and presenting concerns in therapy individually, followed by cross-validation between the 2 experts to ensure consistency. This collaborative step helped reconcile differences in categorization and address overlapping cases. It is important to note that neither the text-based struggle data from DPS nor the presenting concerns from EAP represented formal diagnoses; rather, they reflected participants' personal interpretations of their symptoms. Keywords such as *helpless* or *sadness* were flagged for depression-related presenting concerns, while terms related to *fear, excessive worry,* or *panic* were matched with anxiety-focused concerns. In cases where symptoms overlapped (eg, depression and anxiety), the experts aligned their categorizations based on the primary presenting concern reflected in the participant's statement. For example, if a participant's statement indicated feelings of hopelessness and despair alongside anxious thoughts, the struggle was categorized as depression. Alternatively, if worry or nervousness predominated, it was categorized as anxiety. In scenarios where a specific relationship was mentioned alongside anxious or depressive feelings, the struggle was categorized primarily as a relational concern. Symptom overlap was resolved by categorizing the statement according to the dominant theme present in the participant's experience. Table 1 provides examples of these interpretations.

Table 1. Clinical interpretation of comparable emotional concerns shared on digital peer support service with employee assistance program service.

Participant's struggle	Presenting concern[a]
"I am feeling pretty suicidal and trapped. I am new to my work from home job and I need help, resources, a plan something or this will only get worse. I am trapped with no transportation, no friends or any meaningful relationships in life. Just a work schedule and I'm isolated."	Depression
"I hate my job and my boss"	Relational concern
"I've been feeling a lot of anxiety around work and my personal life"	Anxiety/stress
"Alcohol addiction"	Substance use

[a]These are not diagnoses, they are layperson understandings.

Sentiment Analysis

Peer-to-peer conversations were analyzed to produce a quantitative measure of emotional change. Each participant's chat session, referred to as a "user-chat-session" or simply "user-chat," was treated as an independent unit of analysis, regardless of whether the same participant took part in multiple sessions. As the DPS service is anonymous, each user and their experience in a given chat session were considered separately, without combining data from different sessions for the same user. This approach ensures that each user's experience is analyzed in isolation, providing a more accurate, user-centric view of emotional changes.

Each user's message was analyzed in the context of preceding messages from other users to capture their emotional journey throughout the chat session. Context was defined as the concatenation of all preceding messages from other users in the same chat, starting from the latest message of the user of interest. A user's initial struggle and first message had no prior context and were evaluated with an empty context. For example, in the following conversation:

userA: message1

userB: message2

moderator: message3

userA: message4

userB: message5

This example assumes that message1 and message2 are the first messages of user A and user B, respectively, in the chat session. User A's emotional journey was quantified by evaluating message1 with an empty context and message4 in the context of message2 + message3. Similarly, for user B, message2 was evaluated without context, and message5 was evaluated in the context of message3 + message4.

Each user's message, along with its corresponding context, was evaluated for sentiments of sadness, loneliness, and stress using a scale of 1-10, where 1 indicates low intensity, 5 indicates moderate intensity, and 10 indicates high intensity of the sentiment. The analysis focused on chat sessions where participants exhibited at least moderate sentiment intensity (score≥5) from the beginning.

A third-party, public natural language processing model from OpenAI, called GPT-4, was used to assign sentiment scores to each user message and its preceding context [39]. A few-shot learning approach was applied, where the model was provided with 10 examples representing different sentiment intensities to calibrate its interpretations [40]. GPT-4 demonstrates an advanced capacity to interpret emotion, surpassing benchmarks from the general population and offering highly congruent performance in emotion interpretation [41]. See Table 2 for examples provided to GPT-4 to predict loneliness levels.

Sentiment analysis evaluated each user's chat messages in temporal order. The quantified emotions were then interpolated and extrapolated to generate a collective sentiment trend across peer-to-peer chats of varying lengths. A one-sided Mann-Whitney *U* test was used to compare emotion scores at the start and end of the conversations.

Table 2. Examples provided to GPT-4 to interpret loneliness intensities in a few-shot manner.

Intensities	Loneliness
1=low	"Take care everyone. Thanks for the great talk"
5=moderate	"I went on Monday and today. After today's class is when I felt worse as I chatted with a lady in class who told me that she got really depressed when she retired."
10=high	"I just always feel totally alone. Like no one understands what is going on in my head"

SROI Methodology

Historically, the SROI methodology has relied on qualitative methods to identify outcome themes most relevant to participants, followed by quantitative approaches to determine monetary proxies for the identified outcomes and related values [41].

With the advent of natural language processing models, significantly larger volumes of text-based data can now be analyzed, allowing qualitative data to be graphically represented. This study utilized text-based data from peer group participants—including open-ended questions, affirmations, reflective questions, and summaries—to examine changes in sentiments such as sadness, loneliness, and stress within

peer-support chats [42]. The SROI methodology was applied to assess the social value created by integrating DPS into the EAP. Qualitative data from peer-to-peer conversations, including open-ended questions, affirmations, and summaries, were analyzed to understand sentiment changes and emotional shifts within the peer group chats. Quantitative methods were used to calculate a monetary proxy for the emotional outcomes. The Sopact SROI calculator, available on the Sopact website [41], was utilized to determine the social value generated by the DPS service, incorporating factors such as enhanced emotional well-being and cost savings from reduced therapy usage. Given the novelty of DPS and its integration into the EAP, a small sample size was anticipated. This limitation was addressed through rigorous matching techniques and statistical analyses to ensure the findings remained valid and robust despite the smaller sample size. Moreover, it is acknowledged that some participants may have preferred individual counseling services over DPS, potentially introducing selection bias among those who opted for the DPS model.

Ethical Considerations

Informed consent was obtained from all participants before their involvement in the study. The consent process included clear explanations of the research's purpose, data collection methods, and the measures implemented to ensure participant privacy and confidentiality. All data collected were deidentified to safeguard participants' anonymity. The study complied with all institutional and regulatory guidelines related to data protection and participant privacy. To ensure participant safety within the DPS, real-time moderation was provided by trained human moderators specializing in digital safety monitoring. Furthermore, the Pearl Institutional Review Board reviewed and approved the study (approval ID 2024-0442).

Results

Total DPS Utilization

- Study hypothesis 1: The introduction of the 24/7 DPS service may be associated with utilization changes of EAP counseling services within a 5-session model, specifically among participants who engage with DPS.

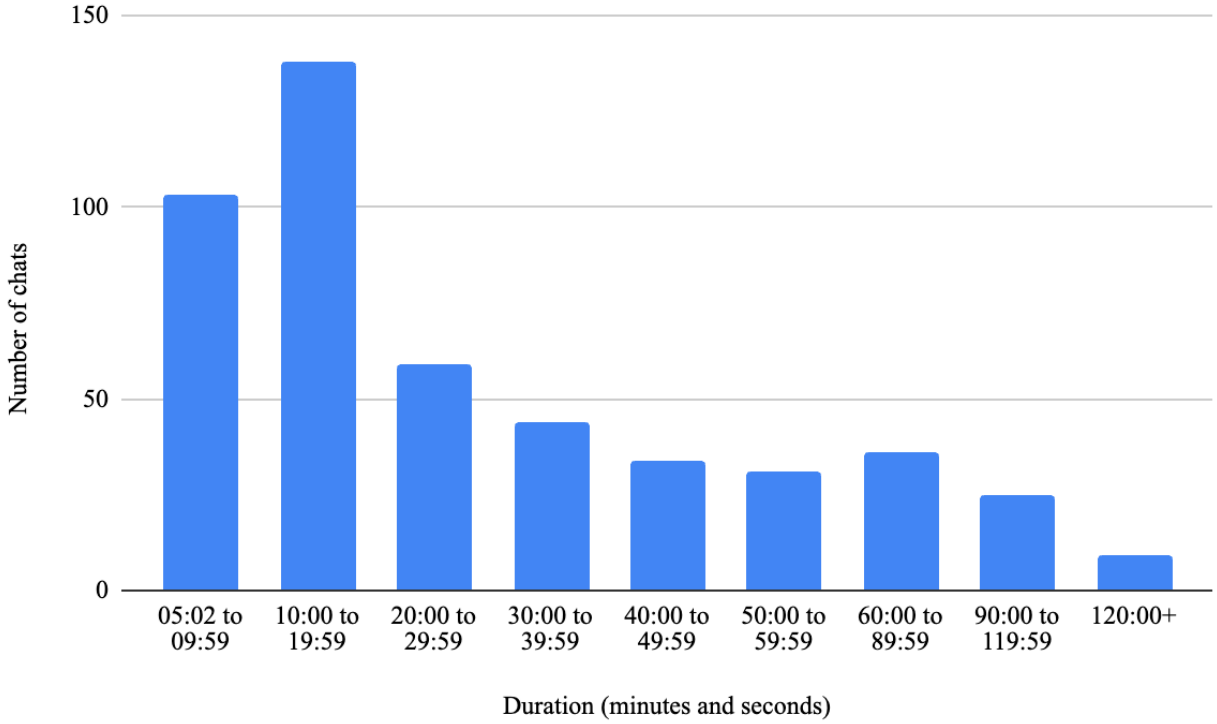
Out of 587 total chats, 432 took place between 5 PM and 8 AM, hours when most therapy offices are typically closed. Chats lasting less than 5 minutes were excluded from the analysis, as the initial 5 minutes are generally used for introductions and setting expectations [30]. Consequently, 107 chats were omitted. A summary of the data is provided in Table 3.

When categorized by duration, the data revealed that 103 chats lasted between 0 and 9 minutes 59 seconds, 138 chats between 10 and 19 minutes and 59 seconds, and 59 chats between 20 and 29 minutes and 59 seconds. Additionally, 44 chats lasted between 30 and 39 minutes and 59 seconds, 34 chats between 40 and 49 minutes and 59 seconds, and 31 chats between 50 and 59 minutes and 59 seconds. While longer chats were less common, they occurred consistently: 36 chats lasted between 60 and 89 minutes and 59 seconds, 25 chats between 90 and 119 minutes and 59 seconds, and 9 chats exceeded 120 minutes. Refer to Figure 1 for further details.

Table 3. Peer support program utilization data.

Metric	Value
Total chats, n	480
Total messages, n	7219
Total duration, hours:minutes:seconds	254:17:57
Average duration, hours:minutes:seconds	0:31:51
Shortest duration, hours:minutes:seconds	0:05:02
Longest duration, hours:minutes:seconds	3:19:11

Figure 1. Chat duration distribution.



Pre-Post Analysis

Matched Cohort Analysis

To evaluate the utilization impact of DPS on the EAP's 5-session model, semimatched cohorts were created for the periods before (June 2022 to May 2023) and after DPS implementation (June 2023 to May 2024). Because of the anonymous nature of the DPS service, only participants who voluntarily provided their age and gender were included in the matching process for analysis in the EAP's pre- and post-DPS cohorts. The matching variables comprised age, gender, and presenting emotional concerns.

Sample

Data on presenting emotional concerns were readily available based on participants' responses to the question, "What's your struggle?"—the sole query asked before matching them with the DPS service. A total of 45 unique users provided both their age and gender information voluntarily. These users ranged in age from 18 to 51 years, with a mean age of 34.97 (SD 9.71) years. Gender distribution was as follows: 18 (40%) males, 26 (58%) females, and 1 (2%) nonbinary individual.

The availability of participant age, gender, and emotional concern data from the DPS service enabled the creation of a matched pre-DPS EAP cohort. The frequency of emotional concerns in the peer support program sample is presented in Table 4.

Table 4. Emotional concern frequency in the digital peer support sample (n=45).

Emotional concern type	Value, *n* (%)
Adjustment	1 (2)
Depression	18 (40)
Anxiety	8 (18)
Posttraumatic stress disorder	2 (4)
Relational concern	14 (31)
Substance use	2 (4)

Statistical Analysis

Using age and gender data from the DPS service participant pool, a total sample of 72 EAP participants—36 pre-DPS and 36 post-DPS—was analyzed for differences. The ages of EAP participants ranged from 18 to 51 years, with a mean age of 33.86 (SD 8.18) years. Females comprised the majority of participants (n=68, 94%), while males accounted for a smaller proportion (n=4, 6%) in both the pre- and post-DPS cohorts.

To assess the impact of the DPS addition, a paired samples *t* test (2-tailed) was performed, comparing the number of therapy

sessions utilized by participants pre- and post-DPS within the matched cohort. The analysis revealed a mean difference of –2.07 (SD 1.77) sessions (t_{71}=9.92; P<.001), indicating a significant reduction in the number of therapy sessions used after the intervention. These findings suggest that the intervention may have been associated with a decrease in therapy session utilization among the sampled participants.

Effect Size

In addition to the *t* test, Cohen *d* was calculated to determine the effect size of the intervention. Based on Cohen guidelines, effect sizes are classified as small (0.2), medium (0.5), and large (0.8). The effect size in this study was 1.77, which is considered large. This suggests that the DPS service had a substantial impact on reducing the number of therapy sessions utilized by participants.

The CI for the mean difference in therapy session utilization was calculated to be between –1.47 and –0.87 at the 95% CI level. This range further supports the reliability of the observed reduction in session utilization, providing evidence that the DPS service may have effectively decreased the number of therapy sessions used by participants in the small sample group.

- Study hypothesis 2: Participants who utilize the DPS service will experience significant changes in sentiment (eg, reduced sadness, loneliness, and stress) throughout their engagement with the service.

Sentiment Change

From the DPS service's sampled cohort (n=45), sentiment changes for sadness, loneliness, and stress were investigated for each user chat. The results are presented in Figures 2-4, showing the changes in sentiment for these 3 emotions. All 3 emotions demonstrated statistically significant reductions (sadness, loneliness, and stress: P<.001) in sentiment intensity during the chat sessions. The sentiment intensity levels are categorized as follows: 1-4 as "low," 4-7 as "moderate," and 7-10 as "high."

Figure 2. Significant (P<.001) changes in sadness sentiment during chats.

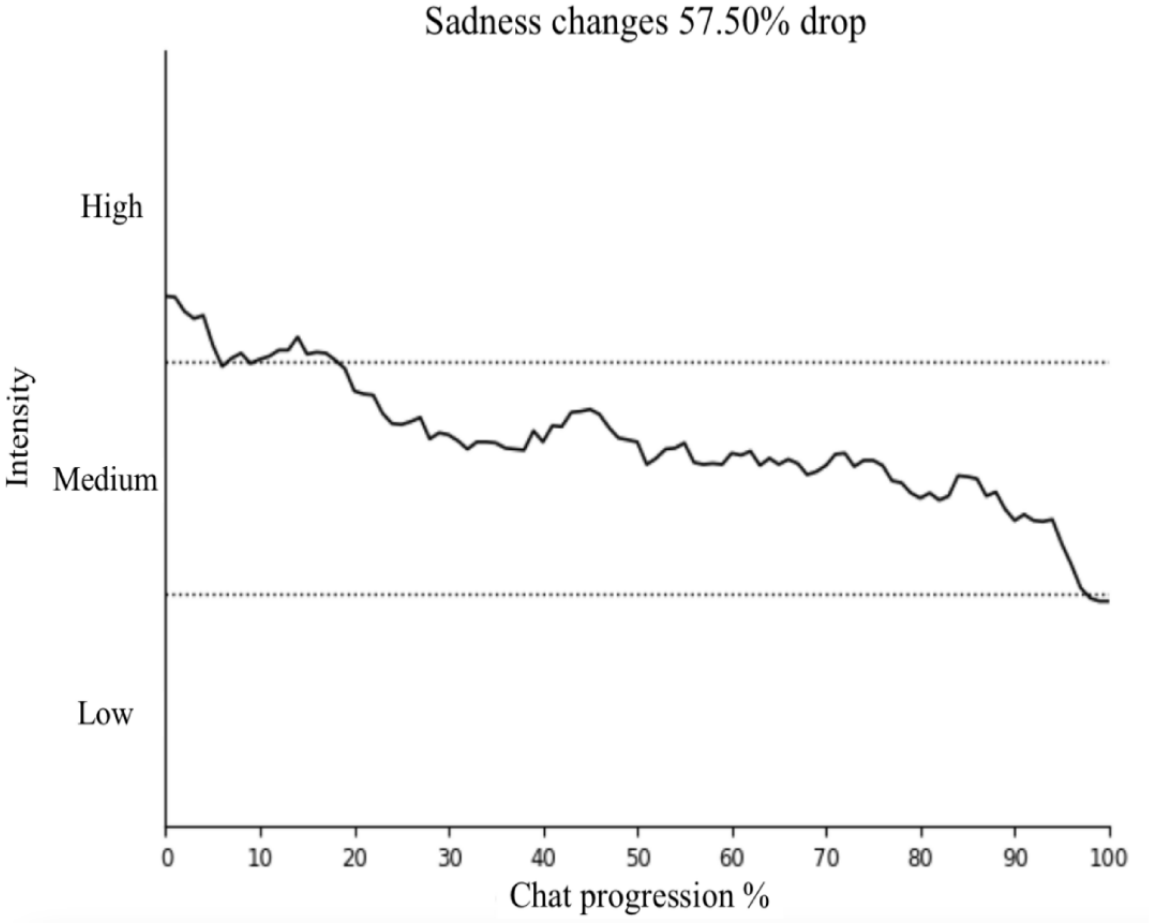


Figure 3. Significant (*P*<.001) changes in loneliness sentiment during chats.

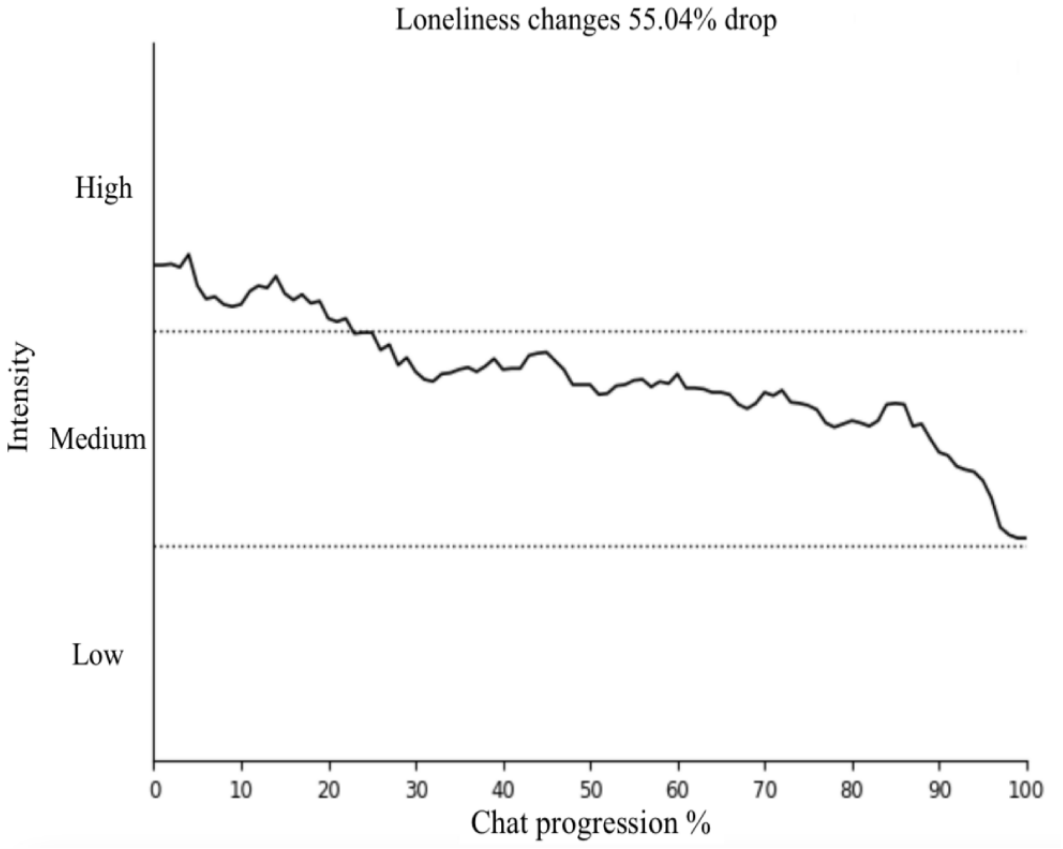

Figure 4. Significant (*P*<.001) changes in stress sentiment during chats.

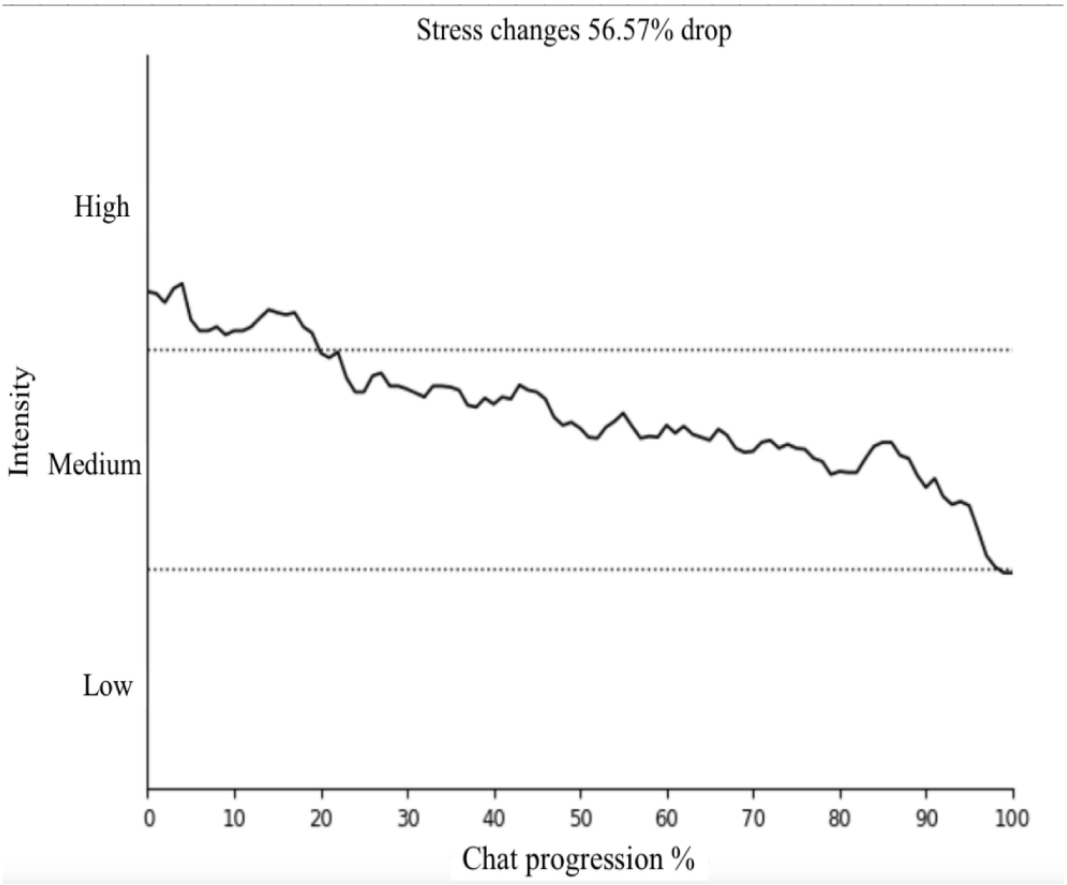

Social Return on Investment Analysis

SROI assigns financial proxies to quantify the value of each identified sentiment change, enabling the attribution of a market price when no direct market value exists [41]. The proxies were carefully selected based on their relevance and supported by cited research studies to ensure the credibility of the assigned market prices. Table 5 presents the financial proxies used for each sentiment.

- Study hypothesis 3: The integration of DPS into the EAP will generate a positive SROI, reflecting the added value of peer support services for EAP clientele.

Table 5. Financial proxies for each sentiment.

Factors in which digital peer support users experience a reduction	Financial proxy	Cost
Sadness	Average unit cost of treating someone with depression (National Institutes of Health)	• PPPY[a]: US $10,074 (SD $25,694) • PPPM[b,c]: US $839.50
Loneliness and isolation	Average unit cost of treating someone with objective isolation and loneliness (National Institutes of Health)	• PPPY: US $1643 in Medicare spending (objective isolation) • PPPM: US $136.92
Stress (eg, generalized anxiety)	Average unit cost of treating someone with stress	• PPPY: US $6475 • PPPM: US $539.58

[a]PPPY: per person per year.

[b]PPPM: per person per month.

[c]PPPM calculations were made by dividing the PPPY value by 12 months.

SROI Analysis

The primary objective of this SROI analysis is to calculate and present a ratio that compares the cost of investment (US $) in an intervention with the total social, environmental, and economic value (US $) it generates. To prevent overestimation, the SROI methodology recommends certain considerations (see Table 6) [41].

The SROI analysis demonstrated that the DPS program generates positive social value, complementing overall treatment. The SROI values ranged from US $1.66 (loneliness) to US $2.50 (stress) to US $2.58 (sadness) for every dollar invested. Detailed calculations for the impact ratio are available in Multimedia Appendix 1.

Table 6. Factors considered for calculating the social return on investment impact ratio.

Factor	Description
Deadweight	A measure to describe the amount of an outcome that would have happened anyway, even if the DPS[a] service had not been offered. For example, the participants experiencing reductions in momentary loneliness may have a deadweight value of 10% from simply joining the DPS chat, but without further intervention from the peer support moderator or other peers.
Displacement	An assessment of what activities or services are displaced by the presence of the digital peer group. There was no evidence of displacement as, before the digital support option was added, there were no after-hours DPS chat services for employee assistance program members to access.
Attribution	A measure to consider how much of an identified theme is a result of the group studied or is influenced by external factors, for example, if participants also attend another service, such as counseling, which reduces their sense of chronic sadness, a conservative estimate of 20% of the identified momentary sentiment change may be attributed to the group studied.
Dropoff	The percentage of the outcome that decreases after the intervention is complete. For example, a conservative percentage of 10% re-emergence of stress may be expected after the user ends their DPS chat due to a return to their stressful environment.

[a]DPS: digital peer support.

Discussion

Principal Findings

The study examined the impact of integrating a DPS service within an EAP on utilization rates, sentiment change, and therapy session use over 1 year. Additionally, it assessed the social, environmental, and economic impact of the DPS service by estimating an SROI value. Results indicated that DPS service utilization primarily occurred after hours. In the matched sample, participants used fewer therapy sessions post-DPS integration. The SROI ranged from US $1.66 to US $2.50 to US $2.58 for every dollar invested for loneliness, stress, and sadness sentiments, respectively. These findings suggest that combining DPS with traditional EAP services may provide noncrisis

emotional support after hours, potentially reducing EAP therapy session use for lower-acuity emotional concerns. This, in turn, could allow EAPs to allocate funds toward additional ancillary support services and enable employers to benefit from a positive SROI.

The study's findings—that participants experience significant improvements in sentiment, such as reduced sadness, loneliness, and stress—align with existing literature on patient activation [7,8]. Research indicates that when individuals are activated—meaning they gain confidence and skills in managing their health—they tend to experience improvements in emotional well-being [8]. By providing peer support that fosters autonomy and self-efficacy, participants can develop coping strategies that reduce distress and promote mental health [43]. This aligns with findings that patient activation leads to better emotional outcomes through the development of personal coping mechanisms and self-management [8]. The positive SROI from integrating DPS into EAP services is also consistent with the literature on patient activation. Activated patients, who feel more in control of their health, contribute to more efficient resource utilization and improved outcomes [44]. The integration of peer support services such as DPS has been shown to enhance engagement with formal mental health services, creating value not only for individuals but also for the broader service system [44]. This supports the idea that empowering individuals through peer support can yield both personal and systemic benefits, ultimately leading to a positive SROI.

The study may also contribute to the quality of life literature, which is commonly used in cost-effectiveness studies. Health-related quality of life (HRQoL) refers to a person's physical, emotional, and social well-being as influenced by a health intervention [45]. While this study did not include standardized HRQoL assessments (eg, 36-item Short Form [SF-36] or EQ-5D) due to real-world data collection constraints and the anonymous nature of the DPS service, sentiment changes and therapy utilization could serve as HRQoL proxies [46]. Significant reductions in sadness, loneliness, and stress during DPS chats suggest improvements in emotional well-being, a core component of HRQoL. The reduction in momentary negative sentiments may indicate that participants used DPS as a coping mechanism for emotional stability. Additionally, the suggested decrease in therapy sessions implies that participants may have achieved better emotional regulation or relief through DPS, ultimately impacting their overall quality of life. Relatedly, the high utilization of DPS after hours addresses a gap in traditional mental health services and may contribute to participants' perceived control over their emotional health. Such improvements in HRQoL proxies could translate into better job performance [47] and employee satisfaction [48], while also serving as a valuable complement to therapy. This approach allows mental health providers to focus on higher-acuity cases while DPS services address lower-acuity concerns—key objectives for most EAP organizations [48]. Finally, the calculated SROI highlights tangible benefits for emotional health (eg, sadness, loneliness, stress), further demonstrating the intervention's effectiveness in enhancing HRQoL's socioemotional components.

The study's findings further align with existing literature in several key areas. The use of AI for matching participants with peers who have shared lived experiences, as well as for sentiment analysis, supports growing evidence that AI can enhance the personalization and efficiency of life struggle and nonmental health services [49-52] This study offers several novel contributions to the literature on mental health interventions and EAPs. It is among the first to demonstrate that integrating a DPS service with EAPs may enhance after-hours support, reduce the utilization of EAP therapy sessions—allowing EAPs to allocate resources more effectively for higher-acuity emotional concerns—and provide supplementary SROI. DPS services are unique within the EAP environment and may be particularly valuable for EAP participants who are not yet ready to confront the stigma or commitment often associated with therapy [53] but still benefit from peer support. By leveraging AI-driven natural language processing to match users based on their struggles and conducting sentiment analysis on chat narratives, this study highlights an innovative use of technology to enhance support for stress and life challenges. Conducted in a naturalistic setting with a diverse sample, the study's design strengthens ecological validity, demonstrating the practical feasibility and effectiveness of DPS in real-world organizational environments.

Study Limitations

This study faced several potential threats to both internal and external validity and implemented strategies to mitigate these issues. One threat to internal validity was the influence of external events (history) during the study period (June 2023 to May 2024) [54,55]. To address this, a comparison group from the previous year (June 2022 to May 2023) was used, and quarterly data monitoring helped identify and adjust for significant external changes [55]. Matched samples based on additional demographics were not possible due to the anonymity of DPS users. Future research using alternative study designs with nonanonymized data may be necessary.

Maturation effects, referring to the natural changes in participants' mental health over time, were addressed using a cohort design with propensity score matching. This approach ensured that participants in both the intervention and control groups were similar in age, gender, and presenting concerns [56]. By balancing the groups, it minimized the impact of maturation on the results [56]. Additionally, selection bias was mitigated through propensity score matching, which created comparable groups by matching participants in the pre-DPS and post-DPS periods based on key demographics and presenting concerns [57].

Experimental mortality, or dropout, was another concern. To address this, the study included multiple participants matched on the same variables, ensuring that the analysis could proceed even if some participants dropped out [57]. A diverse sample across age and gender was included to reduce the impact of selection biases on generalizability. Additionally, conducting the study in a naturalistic setting, where participants used the DPS and EAP services as they would in real life, helped minimize the reactive effects of experimental arrangements, enhancing ecological validity [55]. Furthermore, the availability

and normalization of the EAP program may have influenced participant engagement. EAP programs are voluntary for companies in the United States, Australia, Canada, and England, whereas Nordic countries have legal mandates requiring mandatory EAPs [58]. This distinction is relevant from the perspective of patient activation. Voluntary EAPs may require high awareness and active promotion to engage participants and may primarily attract individuals with higher activation or those who are more self-directed. As a result, individuals with lower activation or those in the early stages of their mental health concerns may remain underserved [58]. Additionally, factors such as program promotion and mental health stigma could contribute to uneven access across the workforce. By contrast, mandatory EAPs may help normalize access to mental health support, encourage early and preventive engagement, and promote continuity of care by integrating with public health systems, unlike the segmentation often seen with voluntary EAPs [59]. Limitations of the SROI process include the complexity of assigning financial proxies to sentiment change and the availability of data required for robust calculations, such as displacement and attribution values. A key risk in SROI analysis is an overemphasis on the ratio itself, without considering the underlying content, which provides deeper insight into the value created by different groups [58]. By acknowledging and addressing these challenges through design and analysis strategies, the study generated meaningful insights into the impact of integrating DPS services within an EAP.

Future Research

The study opens several avenues for future research. Long-term impact assessments are needed to evaluate how integrating DPS with EAP services influences therapy utilization and outcomes over extended periods. A broader demographic analysis could provide insights into how factors such as age, socioeconomic status, and cultural background affect engagement with these services. Additionally, incorporating qualitative insights may help illuminate user experiences and satisfaction, offering a deeper understanding of which aspects of the service are most effective or subjectively valued by clients.

Future research could also compare DPS with other digital mental health interventions to identify which models offer the greatest benefits in different contexts. Investigating how DPS integrates with other mental health services, such as primary care or community programs, could provide a more comprehensive understanding of its role within the broader health care system. While comparisons of single- versus multilayered support ecosystems fall beyond the scope of this study, they represent a valuable avenue for future exploration (eg, digital mental health vs in-person services or EAP vs DPS). Additionally, examining DPS's impact on different mental health conditions and conducting a detailed economic analysis of cost savings could further strengthen the case for its adoption. Moreover, this study did not calculate quality-adjusted life years; however, the observed improvements and associated cost reductions provide strong support for the intervention's economic value. Future research could explore additional methods to further quantify these benefits. These efforts would deepen our understanding of DPS' effectiveness and its potential applications across diverse settings.

Conclusions

This study demonstrates that integrating DPS services within an EAP may influence therapy utilization, allowing EAPs to serve higher-acuity clients while lower-acuity clients access supplementary support, such as DPS, for everyday emotional needs. Additionally, the research highlights the potential social, environmental, and broader economic benefits of incorporating DPS services into the emotional support ecosystem, with positive estimated SROI outcomes. By leveraging AI-driven natural language processing for user matching and sentiment analysis, the study underscores the potential of technology to enhance stress management, address life challenges, support mental health, and optimize resource allocation. The findings emphasize the need for further research into DPS effectiveness, particularly regarding long-term impacts, demographic variations, and comparative effectiveness with other interventions. Overall, this study provides valuable insights into the evolving landscape of digital mental health services, reinforcing their role in enhancing organizational wellness programs and identifying key areas for future exploration to maximize their potential.

Conflicts of Interest

Abstract

Background: The social media platform YouTube is a recognized educational resource for health information, but few studies have explored its value for conveying the lived experience of individuals managing chronic health conditions and end users' interactions with medical device technology. Our study explores self-care strategies and end user needs of people living with a stoma because patient education and engagement in ostomy self-care are essential for avoiding ostomy-related complications. Ostomy surgery creates a stoma (an opening) in the abdomen to alter the route of excreta from digestive and urinary organs into a detachable external pouching system. After hospital discharge, people who have undergone ostomies perform critical self-care tasks including frequent ostomy appliance changes and stomal and peristomal skin maintenance.

Objective: The purpose of this study was to systematically assess YouTube videos narrated by people who have undergone ostomies about their ostomy self-care in home (nonhospital) settings with a focus on identifying end user needs and different strategies used by people who have undergone ostomies during critical self-care tasks.

Methods: Using predefined search terms and clear inclusion and exclusion criteria, we identified YouTube videos depicting narrators who have undergone ostomies and their ostomy self-care in home settings. Using a consensus coding approach among 3 independent reviewers, all videos were analyzed to collect metadata, data of narrators who have undergone ostomies, and specific content data.

Results: There were 65 user-generated YouTube videos that met the inclusion and exclusion criteria. These videos were posted by 28 unique content creators representing a broad range of ages who used a variety of supplies. The common challenges discussed were peristomal skin complications, inadequate appliance adhesion and subsequent leakage, and supplies-related challenges. Narrators who have undergone ostomies discussed various expert tricks and tips to successfully combat these challenges.

Conclusions: This study used a novel approach to gain insights about end user interactions with medical devices while performing ostomy self-care, which are difficult to gain using traditional behavioral techniques. The analysis revealed that people who have undergone ostomies are willing to share their personal experience with ostomy self-care on the web and that these videos are viewed by the public. User-generated videos demonstrated a variety of supplies used, end user needs, and different strategies for performing ostomy self-care. Future research should examine how these findings connect to YouTube ostomy self-care content generated by health care professionals and organizations and to guidelines for ostomy self-care.

(JMIR Hum Factors 2025;12:e66634) doi:10.2196/66634

Introduction

YouTube as Health Information Resource

Individuals are increasingly seeking health-related information on the web, and in some cases, patients rely on the internet as much or more than their physicians [1,2]. Patients have also reported using web-based resources to make health-related decisions and to manage chronic conditions [2,3].

YouTube, the largest on the web video-sharing platform worldwide for streaming a variety of user-generated content with 2.5 billion users worldwide [4] is a recognized educational resource for sharing and disseminating health-related information and influencing individuals' viewpoints related to health care topics such as disease prevention, treatment therapy, or immunizations [2,3]. Several studies highlight the informational flaws and biases in a wide variety of YouTube health information videos related to clinical decision-making, diagnosing, treatment recommendation, and health promotion. The analysis in these studies generally focuses on the health information provided rather than the individual user experience with the health issue [2,5-9].

Studies involving so-called "e-patients" who are motivated to share health-related personal experiences on the web reveal that sharing their lived experience and knowledge of their disease can empower and engage others while also providing (and gaining) social support [10,11]. While many health-related government organizations such as the World Health Organization, the National Institute of Health, the Center for Disease Control and Prevention, and the American Red Cross use YouTube to disseminate health information [1], user-generated videos are also used as an educational resource. This suggests that user-generated content decreases the gap between health information delivered by health care professionals and the lived experience of dealing with a disease.

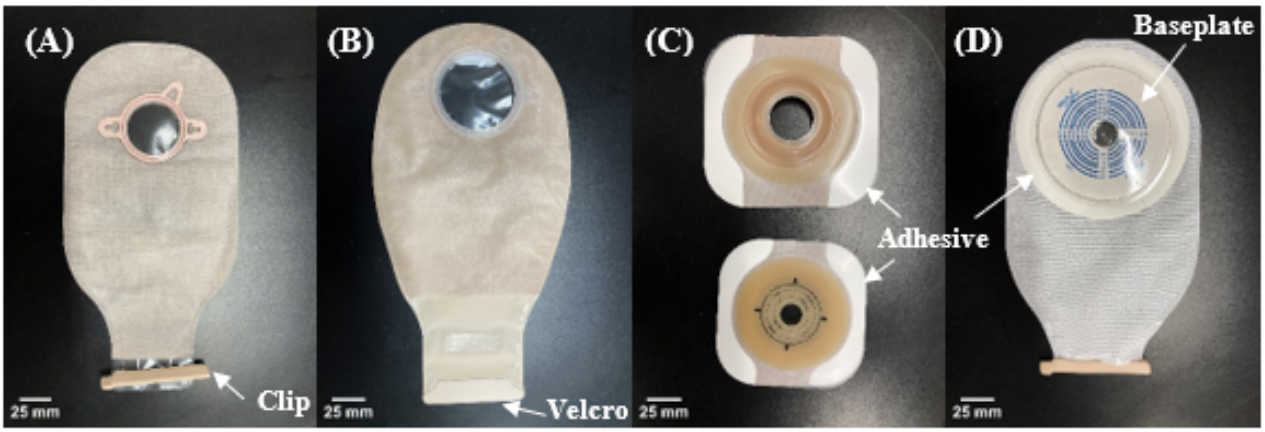
Medical Device Usability in the Home Setting

Usability studies examining the interaction between medical device technology and end users are essential for developing medical devices that are safe and effective [12]. These studies allow for actively including end users in the design process while considering end user competencies and environment, thus, continuously improving medical device design to fit user needs [13]. Capturing the real world, end user experience of people with chronic conditions and their interaction with complex medical device technology in home (nonhospital) settings is challenging [12], such as having a stoma and routinely using an ostomy appliance, and to our knowledge, these studies are limited [14].

Ostomy Surgery

There are about one million people living with ostomy in the United States and more than 150,000 Americans undergo ostomy surgery each year [15,16]. Ostomy surgery alters the route of excreta from internal digestive and urinary organs through a stoma in the abdomen and into a detachable external pouching system (Figure 1) that fits snugly around the stoma [16]. People who have undergone ostomies perform critical self-care tasks that include frequent changing of the pouching system (3-10 changes per week) and maintaining healthy stoma and peristomal skin [17]. Therefore, there is a need to understand the usability of medical device technology used by people who have undergone ostomies in ostomy appliance change procedures and self-care.

Figure 1. An ostomy appliance consists of an external pouching system that is attached to the abdomen of people who have undergone an ostomy using adhesive. There are various design features, including a (A) 2-piece pouch with clip closure, (B) 2-piece pouch with Velcro closure, (C) precut (top) and moldable (bottom) baseplate that is subsequently attached to the 2-piece pouch [in (A) or (B)] at the ring, and (D) 1-piece appliance with clip closure (pouch and baseplate being 1 part).



Ostomy Care Patient Education and Self-Management

It is widely recognized that patient education and engagement in ostomy self-care are essential for avoiding ostomy-related complications [18-20]. However, the education of new people who have undergone ostomies to gain the knowledge and skills needed for managing chronic conditions and performing self-care tasks is not well defined [18]. Ideally, according to the Wound, Ostomy, and Continence Nurses Society Clinical Guidelines and recommendations [21], new people who have undergone ostomies should obtain education from ostomy nurse specialists. Nevertheless, there is evidence of insufficient pre- and postoperative education provided to new people who have undergone ostomies related to stoma and peristomal skin care and complications [22-25]. Due to the short hospitalization trends and the limited availability of ostomy nurse specialists, there is limited teaching time and formal follow-up with the specialists [22-25]. Further, new people who have undergone ostomies may not be mentally and physically prepared for self-management of their ostomy, which requires gaining new knowledge, skills, and attitudes [26,27]. Most people who have undergone ostomies experience some long-term challenges concerning the management of daily self-care of their stoma that broadly impact their health-related quality of life and outcomes [28,29]. Peristomal skin complications are a common problem following ostomy surgery affecting over one-third of patients with ostomies within 90 days post surgery and up to 80% within 2 years [30-33]. While it is known that skin problems interfere with pouch adhesion, causing challenges with pouch leakage, and thus odor, and the necessity for frequent and unscheduled appliance changes [29], it is very difficult to study real-world responses to such challenges.

Study Objective

Given the complexity of ostomy appliance change procedure medical technology and self-care, there is a need to assess the usability of this technology and how self-management skills are developed by people who have undergone ostomies over time. We completed a systematic analysis of user-generated videos related to ostomy self-care published on YouTube and created by individuals with expertise in managing chronic conditions about ostomy self-care in home (eg, nonhospital) settings. Our objective was to identify end user experiences with ostomy medical device technology and the different strategies and procedures used by these experts to change their ostomy appliance and perform stomal and peristomal skin care.

Methods

Ethical Considerations

This study was excluded from an institutional ethics board review because it assessed only copyrighted, public source information and no individual user data was included in the manuscript.

Search Terms and Search Strategy

Search terms related to ostomy self-care were defined by the research team (Table 1) for identifying videos using the search tools within YouTube. During December 2023, YouTube was searched for relevant videos using search terms and Boolean operators under the search category “videos only” tab or “video” filter. All searches were conducted using an incognito or private browser that did not retain cookies to prevent suggested related videos from appearing on search results and to ensure that the search for each term could be replicated. The first 20 videos for each search term were reviewed and documented in a spreadsheet. No videos were included in the analysis if they appeared in the YouTube search result under the “people also watched,” “shorts,” or “sponsored websites” section as these videos may or may not have met the search term criteria. The initial search resulted in 960 videos.

Table 1. Search terms used to search for relevant user-generated videos published on YouTube.

Search term category	Search terms
Ostomy pouch change procedure	[a] + (pouch OR bag) + (care OR change OR procedure)
Ostomy tips and tricks	[a] + (pouch OR bag) + (pros and cons OR tips OR tips and tricks OR empty OR cleaning OR care OR leakage OR leakage prevention)
Ostomy self-care and home management	[a] + (pouch change OR bag change) + (home OR self-care OR care)
Ostomy skincare	[a] + (skin OR peristomal skin) + (care OR treatment OR irritation OR dermatitis)

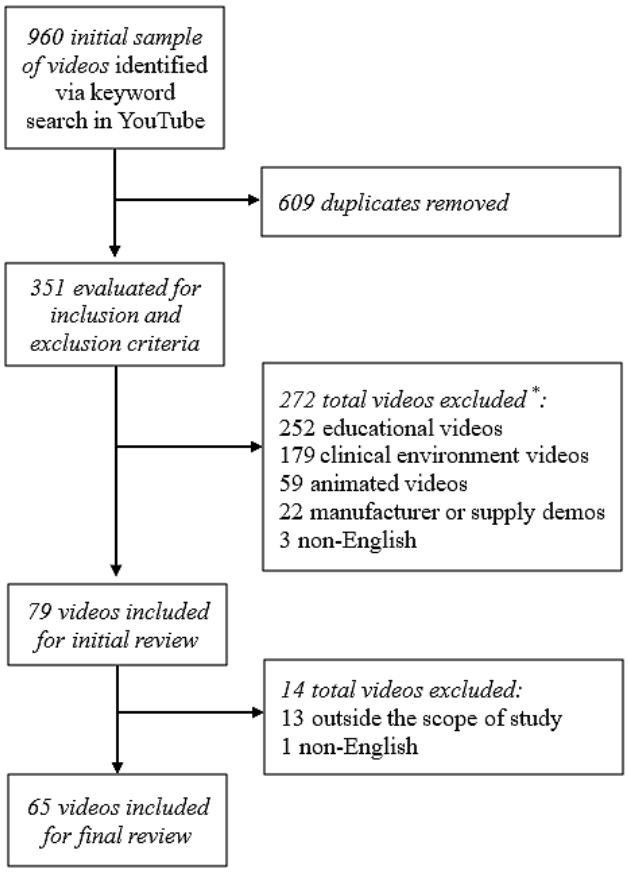
[a]Is ostomy OR urostomy OR colostomy OR ileostomy OR stoma OR colorectal cancer OR Crohn disease OR inflammatory bowel disease OR IBD OR diverticulitis OR bladder cancer OR cystectomy.

Inclusion and Exclusion Criteria

Overview

From the initial set of 960 videos, a final set of 65 videos (Figure 2) was identified for review after the removal of duplicates and the application of inclusion and exclusion criteria (Textbox 1). Duplicate videos (n=609) were identified and removed by channel grouping and comparing URLs and video titles. The inclusion and exclusion criteria were applied to eliminate educational videos (n=252), videos recorded in a clinical environment (n=179), animated videos (n=59), supply or manufacturer demonstration videos (n=22), videos in languages other than English (n=4) and those videos that were outside the scope of this study (n=13) such as broad discussions of clinical issues or ostomy support. Educational videos were defined as videos not discussing personal experiences related to ostomy self-care, for example, videos providing information related to ostomy belts.

Figure 2. Video search inclusion and exclusion process. *Some videos were excluded for multiple criteria.



Textbox 1. Specific inclusion and exclusion criteria.

Included videos

- Were found using search terms
- Included a user narrative
- Involved any channel, age, gender, race, ethnicity, year, or length
- Depicted ostomy appliance change procedures in a nonhospital setting
- Discussed ostomy self-care, tips, tricks, or challenges
- Involved a person living with a stoma as a narrator
- Were published in the English language

Excluded videos

- Were recorded in a clinical environment or were narrated by a medical professional (not having a stoma)
- Included experiences of users who have not undergone ostomies
- Were educational videos
- Were supply or manufacturer demonstration videos
- Were animated
- Duplicated videos from other search terms
- Were published in the non-English language
- Categorized as video “shorts”
- Were outside the scope of this study

Data Coding

In total, 3 categories of video-specific variables were recorded, including video metadata, narrator data, and specific content data (Table 2). The researchers used consensus coding of the included videos, which is a well-accepted method to enhance credibility and reliability in qualitative research [34]. Before video reviews, 3 general categories and 15 variables were named and defined (Table 2). Each video was then coded individually by 2 reviewers using the defined categories and any discrepancies between reviewers were discussed. If consensus was not reached, a third reviewer reviewed the video and data coding to address bias and reach consensus and to ensure accuracy in data coding. The category definitions were then revised as needed before a final consensus coding of all the included videos by 2 reviewers.

Table 2. Data coding for 3 categories of videos including specific variables, and their definition and type.

Category and variable	Definition
Video metadata	
Title	The title of the video by the content creator
URL	The web address of the video
Channel	The name of the page where videos are posted for viewing
Posted year	The year that video was publicly posted to the YouTube platform
Video length	The time duration of the video
View counts	The number of times the video was viewed as of January 4, 2024
Public ratings	The number of likes or dislikes as of January 4, 2024
Data of narrators who have undergone ostomies	
Presenting assumed gender	The assumed gender of the content creator based on gender markers such as physical build, voice, clothes, and hair
Presenting assumed age group	The assumed age group of the content creator mainly based on physical appearance and hair coloration
Specific video content data	
Supplies used	Any item, product, equipment, or accessory used or discussed as used by a narrator who has undergone an ostomy during the ostomy appliance change procedure
Appliance change frequency[a]	How frequently the narrator who has undergone an ostomy completed an appliance change process
Type of ostomy[a,b]	The type of ostomy disclosed by the narrator who has undergone an ostomy
Underlying condition for ostomy[a,b]	The medical condition experienced by the narrator who has undergone an ostomy and contributing to the ostomy surgery
Common challenges[a]	Description of the problems related to ostomy, ostomy appliance change procedures, and ostomy self-care
Expert tips and tricks	Advice or recommendation given by a narrator who has undergone an ostomy to the audience to address common challenges, aid in expediting or easing the appliance change process, or provide additional information to improve the overall user experience

[a]Variable was not communicated in every video.

[b]If not communicated in the video, the intro page and the about me page for the creator were reviewed.

Results

Video Metadata

After removing duplicate videos and applying the inclusion and exclusion criteria, there were 65 videos that explored different topics related to ostomy, ostomy appliance change procedures, and the self-care of people who have undergone ostomies. Included videos were posted between 2011 and 2023 and averaged about 9.5 minutes in length, over a quarter-million views, and more than 3000 likes (Table 3).

Table 3. The video metadata descriptive statistics for the videos included in the analysis.

Video metadata	Data
Posted year, n/N (%)	Between 2011 and 2023 (11/65, 17% and 12/65, 18% videos in 2020 and 2023, respectively)
Video length, mean (SD; range)	9:36 min (SD 6:30 s; 1:00-31:40 min)
View counts, mean (SD; range)	269,076 (SD 922,352; 1900-5,493,702) views
Public ratings, mean (SD; range)	3015 (SD 8761; 0-58,000) likes

Data of Narrators Who Have Undergone Ostomies

There were 28 unique content creators with several individual creators posting multiple videos. Further, 2 high volume narrators who have undergone ostomies uploaded almost half (31/65) of all the videos (24 and 7 videos from the 2 most frequent content creators). Most videos included a female narrator and a narrator in the 20-30 years age range followed by a middle-aged narrator, an older narrator, and a teenage narrator (Table 4). None of the narrators who have undergone ostomies communicated their gender or age in the videos. Therefore, the presenting assumed gender was determined by the reviewers based on the gender markers such as physical build, voice, clothes, and hair and the presenting assumed age based on the physical appearance and hair coloration.

Table 4. Data of narrators who have undergone ostomies for videos included in the final review.

Unique narrators who have undergone ostomies (n=28)	Data, n/N (%)
Presenting assumed gender	
Female	20/28 (71% narrators who have undergone ostomies)
Male	8/28 (29% narrators who have undergone ostomies)
Presenting assumed age group	
Infant[a]	1/65 (2% videos)
Teenager	4/65 (6% videos)
Aged 20-30 years	42/65 (65% videos)
Middle age	13/65 (20% videos)
Older	5/65 (8% videos)

[a]One video was presented about an infant with an ostomy that was narrated by the parent caregiver.

Specific Video Content Data

Ostomy Video Content

From the final set of 65 videos, 26/65 (40%) videos discussed ostomy self-care tips and tricks that focused most frequently on maintaining peristomal skin health, preventing leaks, pancaking, supply use, and general tips; 21/65 (32%) videos captured a full ostomy appliance change procedure and 14/65 (22%) videos included part of an ostomy appliance change procedure such as emptying, specific supply use, and skin preparation and appliance application, among others; and 4/65 (6%) videos were about the personal experience of a person living with a stoma (Table 5).

Table 5. Types of ostomy-related video content, its frequency, and topics discussed.

Supplies Used

The narrators who have undergone ostomies did not all use identical supplies and there was a variety of types, numbers, and frequencies of supplies used during the ostomy appliance change procedures (Table 6). Among the 35 videos that captured a full or partial ostomy appliance change procedure, 25/35 (71%) included a 2-piece pouching system, and 9/35 (26%) included a 1-piece pouching system (Table 6). In 1/35 (3%) videos, the type of ostomy appliance could not be determined. Furthermore, the baseplate was cut to fit or precut by the supplier in 25/35 (71%) videos and molded by hand in 3/35 (9%) videos. In 7/35 (20%) videos, the method for sizing the baseplate by cutting or molding could not be determined.

Further, supplies used to clean the peristomal skin and remove any remaining adhesive or output included paper towel or toilet paper in 19/35 (54%) videos, adhesive remover wipes in 17/35 (49%) videos, adhesive remover spray in 14/35 (40%) videos, dry wipes in 11/35 (31%) videos, towel or washcloth in 9/35 (26%) videos, water in 7/35 (20%) videos, and wet wipes in 4/35 (11%) videos. Supplies used to protect the skin included a barrier ring in 17/35 (49%) videos, skin barrier in the form of wipe, spray, or cream in 15/35 (43%) videos, and ostomy paste in 6/35 (17%) videos. Supplies used to treat peristomal skin disorders included stoma powder in 12/35 (34%) videos and skin treatments (eg, corticosteroids, and antifungal or other anti-inflammatory medications) in 8/35 (23%) videos. Supplies used to aid adhesion between the pouch and peristomal skin included extenders in 5/35 (14%) videos and belts in 4/35 (11%) videos. Supplies used to prevent or minimize odor issues were odor eliminators in 9/35 (26%) videos and lubricating deodorant in 5/35 (14%) videos. Other general ostomy supplies that were used included plastic bags in 19/35 (54%) to discard the ostomy appliance before disposal, scissors in 16/35 (46%) videos to cut a baseplate to match the size of the stoma, some kind of bag in 4/35 (11%) videos to carry ostomy supplies, and some type of container in 4/35 (11%) videos to rinse the pouch with water.

Table 6. Supplies used or discussed in the 35 videos depicting full or partial ostomy appliance change procedures organized by supply category.

Supply category and supply	Videos[a], n (%)
Pouching system

Underlying Condition and Type of Ostomy

One-third of the narrators who have undergone ostomies (9/28, 32%) did not disclose their underlying condition. Crohn disease was the most frequently reported underlying condition for 10/28 (36%) narrators who have undergone ostomies followed by ulcerative colitis (3/28, 11%), cancer (3/28, 11%), and unspecified inflammatory bowel disease (1/28). Further, 2 (7%) narrators who have undergone ostomies reported other underlying conditions for their ostomy surgery. Per the type of ostomy, ileostomies accounted for 79% (22/28) and colostomies accounted for 14% (4/28). Furthermore, 2 narrators who have undergone ostomies did not report their type of ostomy and no urostomy videos met inclusion and exclusion criteria for final review.

Appliance Change Frequency

More than half of narrators who have undergone ostomies (16/28, 57%) did not discuss appliance change frequency. For the remaining narrators who have undergone ostomies (12/28, 43%), there was considerable variability in ostomy appliance change frequency. In general, a majority of narrators who have undergone ostomies (n=10) reported changing their appliance within a 2-5-day interval, 2 every 7 and 15 days, and 1 when the pouch is full. Further, 1 narrator reported various changing frequencies across 4 videos (2-3 days, 3-4 days, every 4 days, and 4-5 days). Additionally, 2 narrators who have undergone ostomies commented on changing the appliance more frequently when having peristomal skin issues (every day or every other day) and emptying the ostomy appliance 5 to 8 times a day.

Common Challenges

About one-third of the content creators noted specific issues with supplies or processes that required workarounds or techniques to be implemented. Major challenges included peristomal skin complications (21/65 videos, 32%), leaks around the adhesive area (20/65 videos, 31%), inadequate appliance adhesion (13/65 videos, 20%), and no control over stoma effluent discharge making it difficult to keep the stoma and peristomal skin clean while changing the ostomy appliance (13/65 videos, 20%). Within the videos, the narrators who have undergone ostomies reported peristomal skin complications related to skin irritation and redness due to the output leakage, peristomal skin disorders such as granulomas, or allergic reactions toward specific ostomy supplies and these complications subsequently compromised appliance adhesion, caused pain, and led to further leaks.

Narrators who have undergone ostomies also expressed difficulties related to supplies in 17/65 (26%) videos. For example, supplies leaving residues on the skin compromising appliance adhesion, supplies containing alcohol causing a burning sensation on the wounded skin, variability in supplies' names causing confusion, and supplies not delivered on time or not working properly for a given individual. Challenges with the design of the ostomy appliance were noted, including the clip of the pouch being uncomfortable, difficulty with cleaning the end of the pouch after emptying, moisture absorption by the barrier ring leading to inadequate adhesion, or a 2-piece appliance being more difficult to apply. Finally, pouch pancaking with the output being trapped at the top of the pouch, pouch ballooning due to the gas accumulating in the ostomy appliance, cutting the baseplate to fit the stoma size, emptying an ostomy appliance and its cleaning, lifestyle adjustments (clothing, diet, relationships, intimacy, travelling, etc), and odor were additional challenges discussed in the videos.

Expert Tips and Tricks

The narrators who have undergone ostomies identified various strategies to address the challenges encountered. To overcome peristomal skin complications, narrators who have undergone ostomies (1) emphasized the importance of cleaning peristomal skin (eg, shower without an appliance and using adhesive remover to remove any output residue which could further irritate the skin); (2) avoided supplies containing alcohol to minimize burning sensations on the skin; (3) used a crusting technique which involves the application of stoma powder over sore skin followed by moistening the powder with skin barrier (wipe or spray), letting the powder dry, and repeating the process multiple times [16]; (4) used ostomy paste, or barrier ring to protect and allow healing of the wounded skin by creating a protective barrier between the wounded skin and appliance, or implemented more aggressive skin treatment products such as steroids or silver nitrate based on the consultation with ostomy care nurse specialists; and (5) recommended balance between changing an appliance too frequently or too rarely.

The tips of narrators who have undergone ostomies to avoid leakage included (1) properly fitting the appliance baseplate with the sizing of the opening for the stoma not to be too tight or too big; (2) using a barrier ring or ostomy paste to fill any abdominal gaps and divots; (3) using an ostomy belt, extenders, or medical tape to support the weight of the pouch; (4) trying different supplies (eg, convex pouches for retracted stomas) and different suppliers to identify supplies working properly for a given individual, while also emphasizing not using too many supplies; and (5) emptying an appliance regularly.

Narrators who have undergone ostomies believed that appliance adhesion was improved by (1) cleaning the skin properly using an adhesive remover followed by cleaning with water or some type of wipe to avoid leaving any residues that could compromise adhesion, (2) ensuring the peristomal skin is dry before applying an appliance, (3) wearing an ostomy belt, (4)

using an equalizer ring that applies an equal pressure around the stoma or ostomy paste that fills any divots or gaps between appliance and abdomen, (5) applying an appliance on a flat abdominal surface (eg, leaning backward or standing), (6) massaging the baseplate and running a finger around the stoma, and (7) using heat to stimulate baseplate adhesion to the abdomen (eg, hairdryer on low setting, heating pad, or holding hand over pouch). Narrators who have undergone ostomies also acknowledged there is not only one proper way of performing ostomy self-care and that what works for them may not work for someone else. Thus, they recommended trying different supplies and self-care strategies and consulting with ostomy nursing care specialists about supplies selection and their use for skin care.

Concerning managing a frequent and uncontrollable stoma output, some narrators who have undergone ostomies found it effective to eat marshmallows or to fast before changing an appliance to slow down the output, covering the stoma with some type of wipe, paper towel, or gauze while changing the appliance to protect the skin and make it easier to clean, and organizing or preparing all supplies and emptying the pouch before starting to change the appliance.

Narrators who have undergone ostomies conveyed strategies to prevent "pancaking" such as using a lubricant or some type of oil inside the pouch, emptying and rinsing the pouch with water, disabling an appliance filter, and blowing air into the pouch. Further, they used deodorants and "burped" (let the air out of the pouch) their appliance to prevent ballooning. They used an ostomy cover and deodorizing drops along with eating naturally deodorizing food such as kefir, yoghurt, or parsley to deal with the odor. To overcome the challenge of cutting a baseplate to the proper size, narrators who have undergone ostomies traced the stoma size with a marker on the template and saved the template with a marking for repeated use, or ordered the appliance precut from suppliers once their stoma size remained constant. Strategies used to adjust to the postostomy lifestyle included (1) finding and joining a support group, (2) talking to people who "get it," (3) learning about their stomas (eg, diversity of supplies, proper diet and hydration, or clothing tips), (4) exercising to reduce anxiety, and (5) developing an ability to perform ostomy self-care while also having someone else who can change their appliance.

Discussion

Principal Findings

This study uses a novel approach for gaining insight into ostomy care end user (person who has undergone an ostomy) experience and usability with medical device (ostomy appliance change) technology through the identification of strategies and supplies used, and common challenges and needs experienced by people who have undergone ostomies while changing the ostomy appliance and performing self-care. The needs, supply choices, and self-care strategies that people who have undergone ostomies used and discussed reflected the need to address a common challenge of peristomal skin complications following an ostomy surgery [21-23] and demonstrated characteristics of an expert understanding [24-27].

YouTube as Ostomy Self-Care Resource

This study examined YouTube videos related to the interaction of people who have undergone ostomies with medical device technology and self-care that were provided by and for the public, and the need for additional information related to long-term ostomy self-care in home (nonhospital) settings. In our study, we initially identified 960 ostomy-related videos and analyzed 65 videos with a narrator who has undergone an ostomy that met our inclusion criteria. Each of these videos was viewed 269,000 times on average, liked 3000 times on average, and posted by 28 unique content creators representing a broad range of ages and both, female and male genders. Our study supports current research suggesting that individuals are increasingly seeking health-related information on the web and patients use web-based resources to make health-related decisions and to manage chronic conditions [1-3,35,36]. Patient education and engagement in ostomy self-care are essential for performing self-care tasks and successful management of their chronic condition [18-20,35]. Nevertheless, research evidence shows the pre- and postoperative education provided to people who have undergone ostomies is insufficient [22-25] and new people who have undergone ostomies may not be prepared to gain new knowledge, skills, and attitudes necessary for self-care management of their ostomy immediately post surgery [26,27]. Therefore, our study suggests patients are looking for additional support and resources for ostomy self-care.

The video metadata and data of narrators who have undergone ostomies show that people who have undergone ostomies of various ages and genders are willing to share their personal experiences with ostomy self-care and appliance change procedures on the web and that these videos are viewed by others. Through YouTube, people who have undergone ostomies can share their stories, empower and help other people who have undergone ostomies, and develop a sense of community with other people who have undergone ostomies [10,11], which goes beyond the ability of health care providers not living with a stoma. In our study, narrators who have undergone ostomies created videos depicting ostomy self-care not to substitute health care professional guidelines and recommended practices, but rather to share a lived experience with a chronic illness, and their challenges and wins. They also commented on being able to develop a sense of community, learn from the lived experiences of other people who have undergone ostomies, and adjust to postostomy surgery lifestyle changes such as by finding and joining a support group or talking to people who "get it." Many of the narrators who have undergone ostomies made disclosures that they were not giving medical advice and commented on positive experiences with and encouraged interaction with ostomy care nurse specialists. The ostomy self-care-related videos depicted what it is like living life with a stoma, and what self-care strategies were found to be effective and what were not. This type of data would be difficult to gain using traditional observational techniques and surveys.

End User Experience With Ostomy Medical Device Technology

The narrators who have undergone ostomies used a variety of supplies at different frequencies to change their ostomy

appliance and discussed challenges related to supplies, challenges with peristomal skin health, appliance adhesion, leakage, and not having control over the stoma output which reflects their user needs. For example, peristomal skin complications were identified by narrators who have undergone ostomies in approximately one-third of analyzed ostomy self-care YouTube videos, and stoma powder (used to treat skin complications) and skin treatments were included and discussed in 12 (34%) and 8 (23%) of the videos depicting an ostomy appliance change procedures, respectively. This finding aligns with extensive research on peristomal skin complications following an ostomy surgery representing a common challenge [30,37,38] and negatively impacting the quality of life of people who have undergone ostomies [39]. The use of peristomal skin protection supplies such as barrier rings, skin barriers, and ostomy paste in 17 (49%), 15 (43%), and 6 (17%) of videos, respectively, and adhesion supplies such as extenders, ostomy belts, and skin adhesives in 5 (14%), 4 (11%), and 3 (9%) of the videos, respectively, manifests the need for properly fitting and adhering external pouching system [17,40]. Thus, the selection of supplies may have been associated with attempts to address appliance adhesion and leakage issues and thus peristomal skin complications.

Narrators who have undergone ostomies reported usability issues with supplies, such as the difficulty with out-of-package baseplate not adhering to "warm" body temperature skin, supplies that are effective in cleaning but compromise peristomal skin health and ostomy appliance adhesion and cause pain (eg, alcohol-based ostomy paste), which call for design improvements of ostomy supplies or redesign related to their properties (eg, baseplate adhesion to peristomal skin, or alcohol-free supplies).

Moldable technology is believed to improve peristomal skin health, reduce the incidence of irritant dermatitis, and be well-perceived by people who have undergone ostomies for its ease of use, ease of learning, and comfort [41,42]. However, in our study, only 3 (9%) of videos depicting the full or part of the ostomy appliance change procedure included a moldable baseplate compared to 25 (71%) of videos where the baseplate was cut to fit or precut and people who have undergone ostomies reported challenges with cutting the baseplate to size. If the stoma hole is too small, the stoma can be damaged, if the stoma hole is too big, the output is more likely to leak on the peristomal skin which in turn will lead to peristomal skin complications. Generally, there are 3 designs of baseplate, precut (cut by supplier), cut-to-size (cut by a person who has undergone an ostomy), and moldable. Moldable baseplate technology does not require cutting the baseplate with scissors but rather using fingers to roll flexible material to size and around ("turtle necking") the stoma and allows for adjusting the stoma hole to fit snuggly around the stoma while also creating a protective barrier and preventing output from reaching peristomal skin [41]. The narrators who have undergone ostomies did not elaborate on the reason for cutting versus molding baseplate to size, except for 1 video where the narrator who has undergone an ostomy had her husband change the appliance and commented on the molding being "easier to use at first." Therefore, further studies should be conducted to explain this trend and to more specifically identify user needs. Additionally, future work should determine if people who have undergone ostomies are aware of and educated on the benefits of using moldable baseplate technology versus using cut-to-fit or precut appliances and if moldable appliances are widely available to people who have undergone ostomies.

Experts' User-Generated Ostomy Self-Care Strategies

The tips and tricks discussed by the narrators who have undergone ostomies in the videos we examined provide evidence of problem-solving strategies useful for decision-making and ostomy self-management. Ostomy self-care requires complex daily decision-making to solve ostomy-related challenges such as compromised appliance adhesion, leaks, or peristomal skin complications discussed above. People who have undergone ostomies have to monitor their daily output, diet, and stomal or peristomal skin health; perform ostomy appliance changes; and plan future self-management. In previous studies of professional expertise, experts stood out in their ability to identify problems [43], understand functional relationships [44], and use problem-solving strategies [45].

Lippa et al [46] suggest that in the self-management of chronic conditions, such as diabetes, professional expertise may be useful for aiding decision-making and supporting patient's strategies. Lippa et al [46] also found that diabetic patients who used functional knowledge and problem-solving strategies reported higher levels of adherence to treatment and glycemic control and that descriptive knowledge about diabetes may not necessarily correlate with effective self-management [46]. In our study, narrators who have undergone ostomies demonstrated their expert understanding while elaborating and showing their self-care strategies and adaptation to ostomy-related challenges. These strategies relate to supplies use and organization, ostomy appliance adhesion, baseplate sizing, maintenance of healthy peristomal skin, pouch pancaking and ballooning, and adjustments to lifestyle changes.

Finally, our study of ostomy self-care and end user experiences with ostomy appliance change technology complements the "Ostomy Life Study," [47] a global effort to gain knowledge about what is it like to live with a stoma and the user experience with ostomy-related supplies. Our study identifies an efficient alternative to traditional observational and survey methods for obtaining end user data that have implications for addressing patient safety and quality of care issues.

Limitations

Several limitations should be considered when interpreting the results of this study and guiding the direction of future research. In our sample of videos, there were more ileostomies than colostomies, and there were no urostomies, therefore, our findings did not compare different types of ostomies. Further, the narrators who have undergone ostomies were essentially "performing" and demonstrating for the video, therefore, these videos may not capture the routine procedures people who have undergone ostomies use for self-care. In our data analysis, half of the narrators who have undergone ostomies were within an assumed age of 20-30 years and approximately one-third of narrators who have undergone ostomies were in their middle

age. This is likely due to most YouTube users falling between the ages of 18 and 44 years [48].

There were also limitations related to demographics in this study. All videos analyzed were narrated in English, but the global representation is unknown. This may limit the global generalizability of this study. Additionally, we did not examine any race, gender, or ethnicity differences in the experiences of people who have undergone ostomies.

Future Work

Further, it should examine differences in ostomy appliance change procedure and self-care strategies across all the types of ostomies, more specifically, whether ileostomies are more prone to peristomal skin complications considering ileostomies' output is frequent, more liquid, and high in digestive enzymes [32]; and the prevalence and decision-making of using a moldable versus cut-to-fit appliance technology among people who have undergone ostomies. Future research should also specifically study younger and older people who have undergone ostomies and their experiences, complement this work in other languages and for individuals with experiences in other health care systems, and examine if there are differences among various populations of people who have undergone ostomies.

We identified 28 individual narrators who have undergone ostomies, and their videos were widely viewed. In addition to counting likes, future research should examine who is viewing these videos, what they are learning from them, and the content of viewer comments and discussions related to the video content. The comments analysis could provide a rich discussion around the strategies and ostomy self-care provided in the ostomy self-care videos.

In our study, we purposely did not include any video content from medical professionals or health care professional organizations because it can contain different information about ostomy self-care strategies than what is practiced by people who have undergone ostomies in home settings [35]. We intended to evaluate end user experiences with ostomy self-care rather than how people engage with YouTube videos created by health care professionals. However, we recognize there is value in comparing user-generated information to what clinicians and health-related government organizations may communicate about ostomy self-care as they use YouTube to disseminate health information [1] that is considered to be the most reliable and accurate information [6]. Future research should examine the content in the ostomy self-care videos created by health care professionals and professional organizations and evaluate how they compare to the user-generated ostomy self-care YouTube videos examined in this study.

Conclusions

This study used a novel approach for ostomy care (YouTube videos) to gain insights into ostomy self-care in home settings and end user interactions with medical devices while performing self-care, which are difficult to gather using traditional behavioral techniques. Using YouTube or other publicly available content created by individuals dealing with a chronic condition is a low-cost means to identify successful strategies, potential design problems, and potential workaround for issues that would be difficult to obtain in other study designs and approaches. The analysis of 65 videos showed that people who have undergone ostomies are willing to share their personal experience with ostomy self-care on the web and that these videos are viewed by the public. The findings also identify user needs related to medical device technology and indicate that narrators who have undergone ostomies were able to use problem-solving strategies for decision-making and successful ostomy self-management. This study demonstrates the potential value of these videos for filling the gap between health information delivered by health care professionals and the lived experience of individuals dealing with a chronic condition.

Additional information related to long-term ostomy self-care in a home (nonhospital) setting and the differences between what is clinically recommended and how the procedures and supplies are actually used by individuals living with ostomies needs to be more clearly understood for the design and testing of future ostomy supplies as well as for patient education from clinicians. Future research could use these approaches to address other types of clinical information that other clinical populations need to learn or be able to access when at home as well as strategies to design better medical devices for home health care in the future.

Abstract

Background: Effective symptom identification, a key responsibility for community pharmacists, requires patients to describe their symptoms accurately and comprehensively. However, current practices in pharmacies may be insufficient in capturing patient-reported symptoms comprehensively, potentially affecting the quality of pharmaceutical care and patient safety.

Objective: This study aimed to construct a new, hierarchical symptom list derived from the Patient-Friendly Term List of the Medical Dictionary for Regulatory Activities (MedDRA) and to develop and evaluate a mobile app incorporating this list for facilitating symptom reporting by patients in pharmacy settings. The study also aimed to assess the usability and acceptance of this app among potential users.

Methods: Subjective symptom-related terms were extracted from the Patient-Friendly Term List version 23.0 of the MedDRA. These terms were systematically consolidated and organized into a hierarchical, user-friendly symptom list. A mobile app incorporating this list was developed for pharmacy settings, featuring a symptom selection interface and a free-text input field for additional symptoms. The app included an instructional video explaining the importance of symptom reporting and guidance on navigation. Usability tests and semistructured interviews were conducted with participants aged >20 years. Interview transcripts were analyzed using the Unified Theory of Acceptance and Use of Technology (UTAUT) model to evaluate factors influencing the acceptance of technology.

Results: From the initial 1440 terms in the Patient-Friendly Term List, 795 relevant terms were selected and organized into 40 site-specific subcategories, which were then grouped into broader site categories (mental, head, trunk, upper limb, lower limb, physical condition, and others). These terms were further consolidated into 211 patient-friendly symptom terms, forming a hierarchical symptom list. The app's interface design limited options to 10 items per screen to assist with decision-making. A total of 5 adults participated in the usability test. Participants found the interface intuitive and easy to use, requiring minimal effort, and provided positive feedback regarding the potential utility of the app in pharmacy settings. The UTAUT analysis identified several facilitating factors, including ease of use and the potential for enhanced pharmacist-patient communication. However, concerns were raised about usability for older adults and the need for simplified technical terminology.

Conclusions: The user-friendly app with a hierarchically structured symptom list and complementary free-text entry has potential benefits for improving the accuracy and efficiency of symptom reporting in pharmacy settings. The positive user acceptance and identified areas for improvement provide a foundation for further development and implementation of this technology to enhance communication between patients and pharmacists. Future improvements should focus on addressing usability for older adults and simplifying technical terminology.

KEYWORDS

patient symptom monitoring; hierarchical symptom list; community pharmacy; interview survey; mobile application

Introduction

Patient-reported symptoms are critical indicators in health care, essential for maintaining patient safety and improving therapeutic outcomes in clinical settings [1,2]. In Japan, the Ministry of Health, Labour and Welfare launched "Pharmacy Visions for Patients" in 2015, clearly outlining the role of community pharmacies, including comprehensive monitoring of medications, as well as providing tailored drug management and guidance [3]. A key responsibility for community pharmacies in this context is to gather and monitor patient-reported symptoms, essential for identifying potential health issues and ensuring timely intervention.

For pharmacists, collecting patient-reported symptoms plays multiple critical roles in medication therapy management. First, it facilitates the early detection and monitoring of potential adverse drug reactions, enabling timely interventions to prevent serious complications. Second, comprehensive symptom information helps pharmacists assess therapeutic effectiveness and adjust medication regimens accordingly. Third, systematic symptom monitoring supports pharmacists in providing targeted patient education and improving medication adherence through a better understanding of patient experiences. These activities are fundamental to the pharmacist's role in ensuring medication safety and optimizing therapeutic outcomes.

While health care providers traditionally collect symptom information through direct questioning, a patient-centered approach that enables patients to report symptoms at their own pace using familiar terminology may improve the accuracy and comprehensiveness of symptom reporting. Such an approach acknowledges patients as active participants in their health care, potentially leading to better identification of health-related issues and more effective interventions. A cross-sectional study demonstrated that structured symptom reporting tools can help identify numerous patient-reported symptoms and their potential associations with medications, providing valuable information for medication reviews [4]. However, another previous study showed that patients often underreported symptoms to health care providers, either because they do not attribute symptoms to the medication or do not recognize the significance of the symptoms [5].

To facilitate patient reporting, various symptom questionnaires have been developed, enabling patients to describe their experiences [6]. However, many of these tools lack thorough validation. In Japan, Nojo et al [7] introduced the "Adverse Drug Reaction Signal Check Sheet," which lists subjective symptoms of side effects for patients taking high-risk drugs. Although limited to specific drugs, the sheet proved effective in prompting patients to communicate their symptoms during consultations with pharmacists. This approach suggests that selecting symptoms from a structured list can support patient reporting.

The Medical Dictionary for Regulatory Activities (MedDRA), a globally recognized dictionary of medical terminology, includes a Patient-Friendly Term List that reflects a wide range of symptoms reported by patients in safety databases [8]. MedDRA has a hierarchical structure with organ categories at the top, and its Patient-Friendly Term List is a supplementary list made up of the lowest-level terms of the MedDRA. This structured approach allows patients to progressively identify and report their symptoms. However, international research has indicated that patients do not fully use this list when reporting adverse drug reactions [9], suggesting challenges in the direct adoption of a symptom-reporting system.

This study aimed to construct a new hierarchical list of symptoms derived from the Patient-Friendly Term List of the MedDRA to simplify and facilitate incremental symptom selection by patients. Moreover, we aimed to develop an app incorporating this list to enhance communications between patients and pharmacists by facilitating more accurate symptom reporting.

Methods

Creation of the New Hierarchical, Patient-Friendly List of Symptoms

A hierarchical list of subjective symptoms was created using the Patient-Friendly Term List version 23.0 from the MedDRA. MedDRA, developed by the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, is a standardized medical terminology used in pharmaceutical regulation. The MedDRA Patient-Friendly Term List was selected for this study due to its standardized structure and global adoption in pharmacovigilance. This list consists of patient-friendly terms derived from MedDRA, ensuring that the terminology is both medically accurate and comprehensible to nonexpert users. The structured format of this list was expected to facilitate consistent symptom categorization while remaining accessible to patients, supporting pharmacists in identifying potential adverse drug reactions (ADRs) and optimizing medication therapy management.

Terms associated with subjective symptoms were extracted from the Patient-Friendly Term List and categorized by body part. Similar terms were consolidated into "symptoms," forming the lowest level of a 3-tier hierarchical structure, with "broader site categories" and "site-specific subcategories" as the upper levels. This new hierarchical list was reviewed and refined through multiple rounds of consensus by three researchers (WS, KH, and HS). WS was an undergraduate student in the Faculty of Pharmaceutical Sciences, and KH and HS were researchers in the Faculty of Pharmaceutical Sciences.

Development of a Patient Symptom-Reporting Application

An app was developed to incorporate the newly created hierarchical list of symptoms. The app featured a symptom selection interface, an instructional video explaining the importance of symptom reporting, and guidance on how to navigate the app. To assist with decision-making, no more than 10 options were displayed on the screen at a time. In addition to the structured symptom list, the app included a complementary free-text entry, allowing users to input symptoms that may not be represented on the list or when the listed symptoms did not fit their condition. The app is intended for use in a pharmacy setting and was designed to capture a

wide range of symptoms, beyond those related to side effects of specific drugs. Apache Cordova, an open-source mobile app development framework, was used for the development. The operating system used was Android, and the app was run on a HUAWEI MediaPad T3. The content of the app was written in Japanese.

Usability Study and Interviews

A usability study was conducted from September to October 2020 with adults aged >20 years, recruited through research flyers. Participants first completed a questionnaire on their demographics, medication use, history of ADRs, and familiarity with digital devices. They were then briefed on the purpose of the app in a pharmacy setting and the interview format. Participants tested the app on a HUAWEI MediaPad T3, entering personal and symptom data on 5 hypothetical patient scenarios (Table S1 in Multimedia Appendix 1). Following the app trial, a semistructured interview was conducted, based on the interview guide (Table S2 in Multimedia Appendix 1), to gather feedback on the app. Interviews were conducted in Japanese, focusing on impressions of the app from participants and their awareness of reporting side effects. All interviews were recorded with the consent of participants and conducted by a single researcher (WS).

Analysis of the Interview

Thematic analysis was applied to the recorded interview transcripts using a deductive and theoretical approach. The Unified Theory of Acceptance and Use of Technology (UTAUT) model was used for this analysis. Initially proposed by Venkatesh et al [10] in 2003, the UTAUT model has been widely adopted in the medical field in recent years [11]. This model is particularly useful for understanding factors influencing the adoption of new technologies. It posits that performance expectancy (expected benefits of using new technology), effort expectancy (expectations of the ease of use and understanding of new technology), and social influence (how much the user's decisions about technology are influenced by others) determine behavioral intention to adopt the technology. Behavioral intention, along with facilitating conditions, influence actual technology use. In addition, gender, age, experience with similar technologies, and spontaneity of use serve as general adjustment variables (moderators). The translation of these constructs was based on the work of Ono [12]. In total, 3 researchers conducted analyses to ensure objectivity.

Ethical Considerations

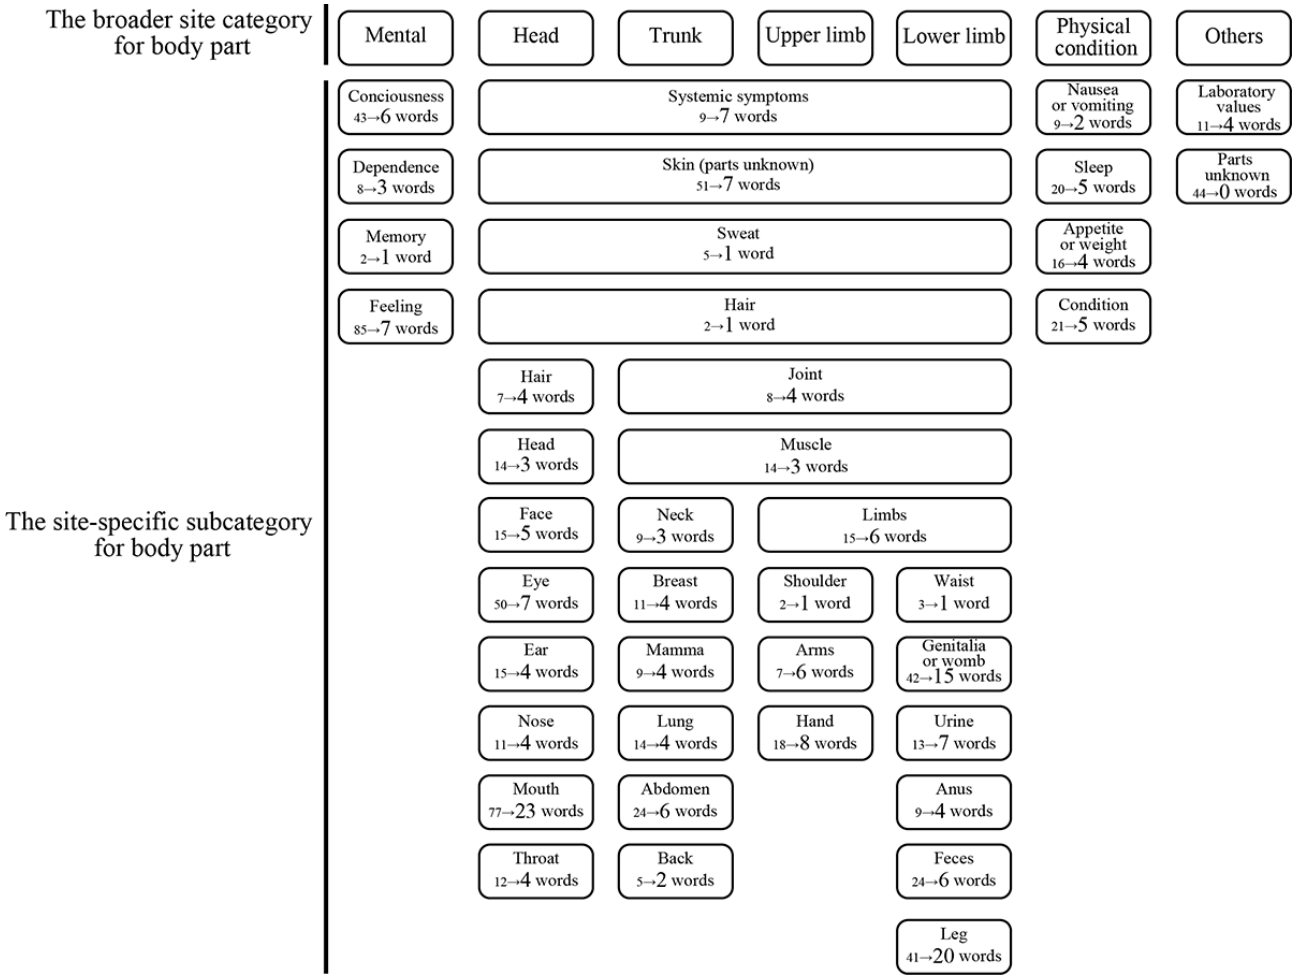
On the day of the usability study and interview, the survey content, privacy protection, and plans for publishing the research results were comprehensively explained to the participants, and written informed consent to participate in the survey was obtained. The preinterview questionnaire was self-administered anonymously. Participants received compensation in the form of a gift card (Quo Card) valued at 1000 JPY for their participation in the study. This survey was conducted after being approved by the Ethics Committee for Research Involving Human Subjects, Keio University Faculty of pharmacy, following the Ethical Guidelines for Medical Research Involving Human Subjects (200213-3).

Results

Creation of the New Patient-Friendly Symptom List

From the 1440 terms in the Patient-Friendly Term List version 23.0, duplicates with the same Japanese translations were removed, resulting in 1288 terms. Subsequently, 12 product-related terms such as "suspected counterfeit products" were excluded. In addition, 450 terms that were difficult for patients to self-identify, including those requiring a medical diagnosis or those specific to certain conditions, were removed. Another 31 terms unrelated to medications were deleted, leaving a total of 795 terms. The 795 terms were systematically sorted into 40 site-specific subcategories based on information related to the locus of impact of each word. These site-specific subcategories were grouped into 7 broad site categories: mental, head, trunk, upper limb, lower limb, physical condition, and others (Figure 1). Within each site-specific subcategory, similar terms were consolidated by grouping related symptoms (eg, various types of arm discomfort such as "arm paralysis" and "arm discomfort") and creating standardized descriptive names (eg, "tingling and discomfort in the arm") that accurately represent the consolidated symptoms. This consolidation process aimed to simplify symptom selection while maintaining clinical relevance, yielding 211 subjective symptoms (Figure 1). Finally, a hierarchical list of patient-friendly symptoms was created using the hierarchical structure of site categories, subcategories, and symptoms.

Figure 1. The broader site categories and site-specific categories for body parts, as well as the word counts before and after consolidation. The 795 terms were systematically sorted into 40 site-specific subcategories based on information related to the locus of impact of each word. These site-specific subcategories were grouped into 7 broad site categories: mental, head, trunk, upper limb, lower limb, physical condition, and others. Within each site-specific subcategory, similar terms were consolidated by grouping related symptoms (eg, various types of arm discomfort such as "arm paralysis" and "arm discomfort") and creating standardized descriptive names (eg, "tingling and discomfort in the arm") that accurately represent the consolidated symptoms. This consolidation process aimed to simplify symptom selection while maintaining clinical relevance. In this figure, the number on the left side of each arrow represents the count of terms before consolidation and the number on the right indicates the count following this unification process.



To integrate this list into the app, we designed a question flow that allowed for easy symptom selection. Broader and site-specific subcategories were modified and recombined into major site categories and site subcategories for an intuitive question flow (Figure S1 in Multimedia Appendix 1). As an example, the hierarchy under the major site category "upper limbs" and its subcategories is detailed in Table 1. The app included a free-text entry field labeled as "other" at each categorical level to capture symptoms that users could not find in the structured list. This feature was implemented to ensure comprehensive symptom reporting and to collect data for future improvements of the symptom list.

Table 1. Details of selection items (excerpt for upper limbs only). The major site categories, site subcategories, lower-level terms, and symptoms after consolidation were described in Japanese. The table presented here has been translated into English for this publication.

Major site categories and subcategories of body parts (LLT[a])	LLT code	Symptoms after consolidation
Upper limb		
Shoulder		
Scapular pain	10040610	Shoulder pain
Shoulder pain	10040617	Shoulder pain
Arm		
Upper limb pain	10033421	Arm pain
Elbow pain	10033424	Elbow pain
Arm rash	10037875	Arm rash
Arm paralysis	10003098	Tingling and discomfort in the arm
Arm discomfort	10049877	Tingling and discomfort in the arm
Arm swelling	10042680	Arm swelling and edema

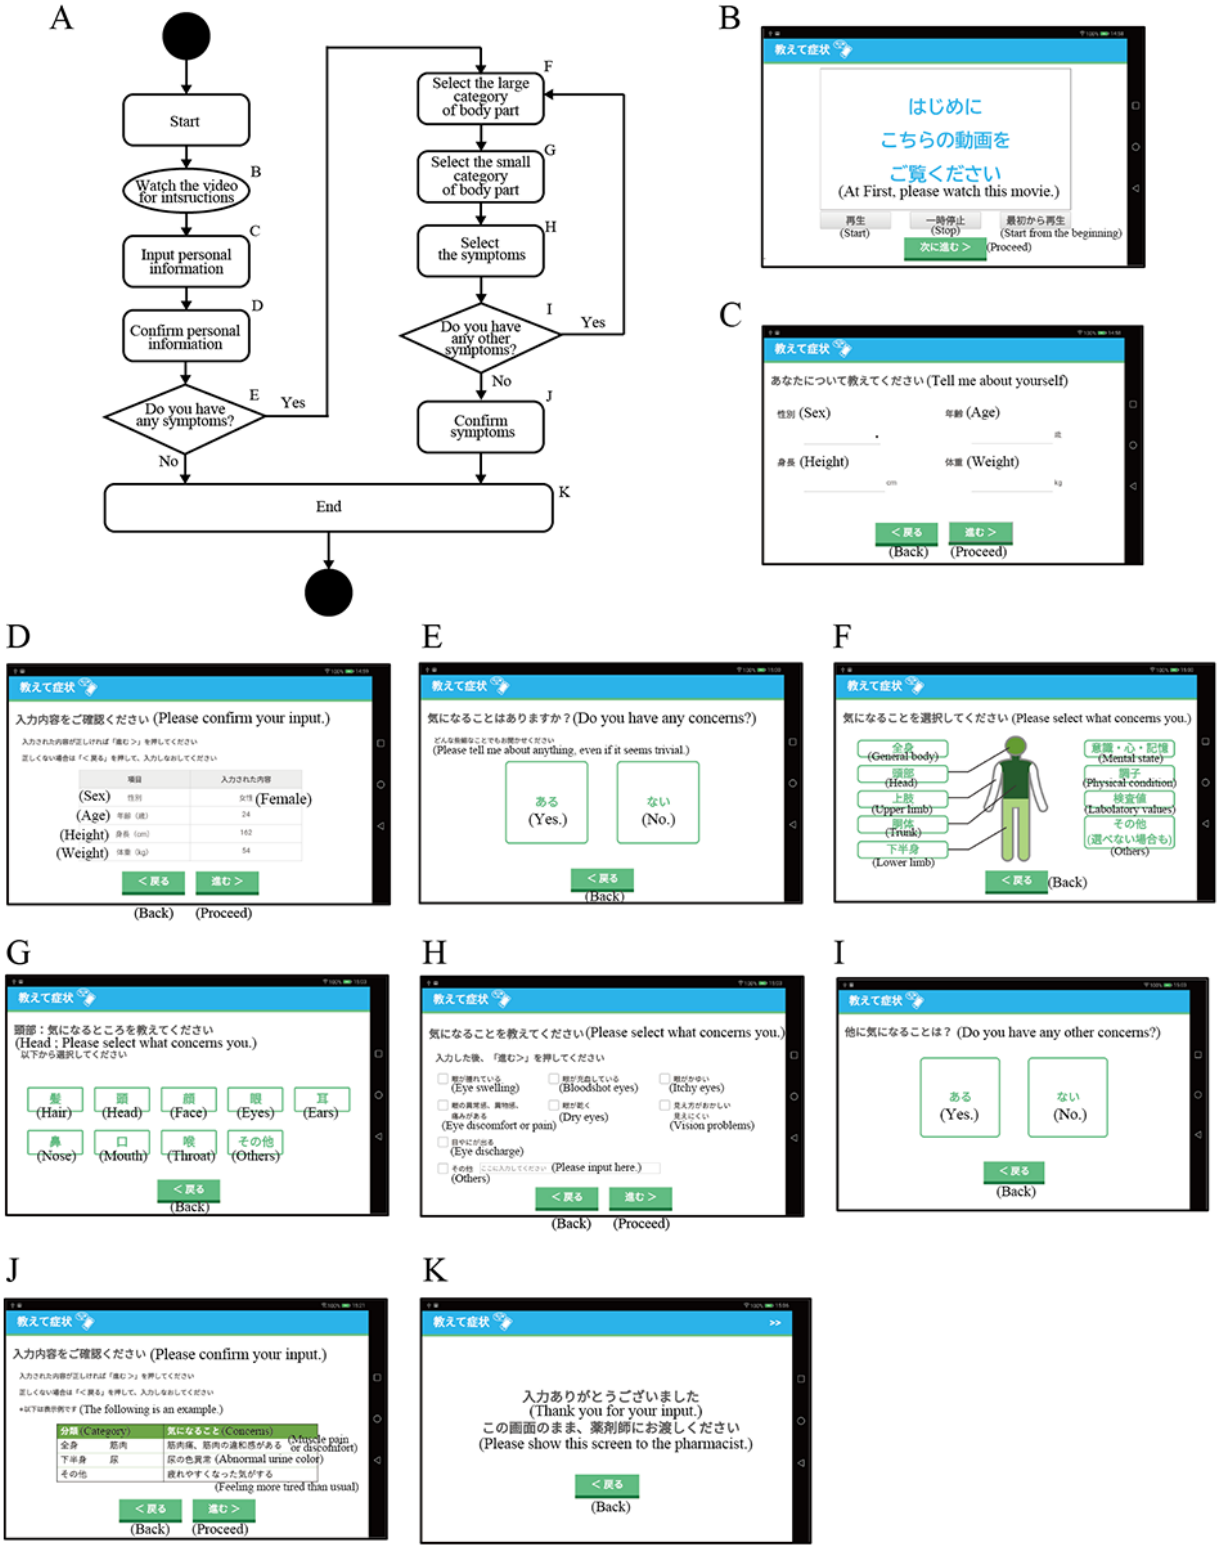
[a]LLT: lowest-level term.

Development of a Symptom-Reporting App

The screen transition diagram and display screens for the app are shown in Figure 2. Figure 2A shows the screen transition diagram of the app. The starting screen featured an instructional video explaining the purpose of the app and the importance of comprehensive symptom reporting (Figure 2B), followed by a series of intuitive selections for symptom identification (Figure 2E-J). The closed screen signaled the end of the session, prompting the user to pass the device on to the pharmacist (Figure 2K). To minimize cognitive overload, no more than 10 options were displayed per screen, making symptom selection easier and more manageable. An instructional video was included to explain the importance of symptom reporting, providing users with essential background knowledge before using the app. In addition, a free-text entry field was implemented to allow patients to describe symptoms not covered by the structured list, ensuring flexibility while maintaining structured reporting as the primary method. These features were designed to enhance the accuracy and completeness of symptom reporting, thereby improving communication between patients and pharmacists.

Figure 2. Screen transition diagram and display screen of the app. (A) Screen transition. (B) Start and video viewing section. (C) Input of personal information, (D) Confirmation of personal information. (E) Selection of the presence or absence of symptoms. (F) The large category of body parts. (G) The small category of body parts. (H) The selection of symptoms. (I) Selection of presence of other symptoms. (J) Confirmation of the selected symptoms. (K) End. The app screen in Japanese is shown since the actual app is in Japanese. English translations of the screen elements are provided in parentheses within the figure.



Usability of the Symptom-Reporting App

In total, 5 adults participated in the usability study and interviews. Table 2 presents the demographic characteristics of the interviewees. Overall, 4 of the 5 interviewees regularly used smartphones, and 4 of the 5 interviewees had previously experienced side effects. The interviews elicited valuable opinions on the usability of the app, as summarized in Table 3, with an analysis aligned with the UTAUT model presented in Figure S2 in Multimedia Appendix 1.

Table 2. Basic information of interviewees.

No.	Age (years)	Sex	Occupation	Types of medicines taken, n	Experience of side effects	Smartphone or tablet	
						Possession	Frequency
1	79	Female	Unemployed	9	Yes	No	Do not use
2	24	Male	Student	3	Yes	Yes	Frequently
3	23	Male	Office worker	None	No	Yes	Frequently
4	50	Male	Sole proprietorship	3	Yes	Yes	Frequently
5	54	Female	Medical office worker	1	Yes	Yes	Frequently

Table 3. Opinions on app usability based on the Unified Theory of Acceptance and Use of Technology (UTAUT) model.

UTAUT category	Details
Performance expectancy	
Ease of consultation	• Easier to answer than to be asked • Easier to tell something than in person • Gives a chance to talk • Unclear what the app is used for
Contribution for medication	• May contribute to the treatment of others
Feedback from health care professionals	• Good to have an opinion from a pharmacist • Good to have continuous monitoring • Good to have topics related to daily life • Good to have a comfortable relationship with the pharmacist
Other functions	• Good to provide information about medication • Good to enter one's medication status • Good to be able to discuss other issues besides symptoms • Good to be linked to other systems • Good to be used outside the pharmacy • Concerns about adding too many functions
Effort expectancy	
Ease of use	• Usable without problems • Easy to use selective forms • Easy to be guided by selective forms • Negative feelings though none of the options apply to me • Difficult to enter free-text fields • Difficult to check, change, or add information • Difficult to use for older people who are not used to using smartphones or tablets
Expression of question items	• Usable without problems • Very detailed items • Many specialized words and phrases • Difficult to understand the words of the site classification • Difficult to understand the way the questions are asked
Social influence	
Influence from health care professionals	• Easy to answer if a health care provider asks about symptoms • App that can be used by pharmacists in medication instruction
Information collection and management	• Resistance to data being stored
Facilitating conditions	
Appearance	• Easy-to-read layout • Easy-to-read colors • Easy-to-read font size • Difficult reading text for older people
Device	• Difficult to use keyboard • No problems with the size of device • Easy to use the device with horizontal screen display • Probably being too small for older people
Behavioral intention	
Use of app	• Want to use the app • Should be used also outside of pharmacies • Probably not being able to be used for older people alone • Sometimes difficult to tell something even with app

In terms of "performance expectancy," participants expressed a preference for using the app to consult with pharmacists because "it is easier to answer than when being asked by a person," "it is easier to communicate than doing it face-to-face,"

and “it gives me a chance to talk to someone.” Some participants suggested that “it would be beneficial to receive expert opinions as feedback from a pharmacist.” In terms of “effort expectancy” (expectations about the ease of use and understanding of new technology), usability and expressions were both deemed “usable without problems,” while issues such as “too many technical terms” and “I feel bad when there are no applicable choices” were identified. Regarding “social influence” (the extent to which the user’s technology decisions are influenced by others), opinions included “it is easy to answer when a medical professional asks about symptoms” and “pharmacists can use it in medication guidance,” indicating that the influence of medical professionals contributes to the behavioral intention to use the technology. Regarding the “facilitating conditions,” it was suggested that there should be no problems with the design and terminal. Based on the above, all participants were positive about their behavioral intention to use the app, and some suggested that the app should be used outside pharmacies. Concerns were raised regarding the use of the app by older adults.

Several factors that did not align with the UTAUT model but significantly affected how ADRs reported to health care providers were identified. These factors included “I recognize pharmacist as a person to consult, but do not want to consult,” “I will not consult if not sure of side effect,” “I will not consult if the side effect is minor or not necessary to discuss by myself,” and “I will not consult if I think it is a side effect.” In addition, factors specifically affecting the reporting of ADRs to health care providers comprised “I recognize that it is an ADR but do not want to discuss it with a pharmacist,” “I do not discuss it unless I am sure it is an adverse drug reaction,” “I do not discuss it unless I am sure it is an adverse drug reaction,” and “I feel uncomfortable reporting an adverse drug reaction.”

Discussion

Principal Findings

In this study, we developed a hierarchical list of symptoms based on the MedDRA Patient-Friendly Term List and created an app that enables patients to easily select symptoms. The potential use of the app in pharmacies was well received, indicating that it could significantly aid patients in communicating their symptoms more effectively.

Our newly created list comprised 211 symptoms, and to improve user-friendliness, we implemented a “questionnaire flow” within the app, based on the hierarchical structure. This approach allows users to systematically select symptoms by navigating through major site categories, site subcategories, and detailed symptoms. Participants using the app in 5 hypothetical patient scenarios praised its ease of use, confirming the feasibility of using the hierarchical list of symptoms and the app for effective symptom selection. Previous research revealed that approximately 20% of reports on side effects used patient-friendly terms, with the majority opting for free-text entries [5]. By limiting displayed options to 10 or fewer, while providing a free-text input field for unlisted symptoms, our app may improve the ease of symptom identification. This design feature was further supported by the overall positive feedback from the participants. Future updates to the symptom list, informed by the analysis of real-world, free-text entries, could further streamline symptom reporting.

Participants in our study expressed their opinions about reporting usual self-aware symptoms such as “I do not discuss subjective symptoms unless I am sure they are side effects” and “I do not mention side effects if they seem minor or unnecessary to report,” which aligns with reasons reported in previous research for underreporting symptoms to health care providers [5]. These responses highlight common barriers to symptom reporting in health care settings, including patients’ uncertainty about whether symptoms are drug-related and their hesitation to mention symptoms they perceive as minor. To address these universal challenges, our app was designed with a structured interface and a hierarchical organization of symptoms, guiding patients through a systematic symptom-reporting process. The hierarchical structure of the app enables patients to progressively identify and select symptoms, potentially increasing the comprehensiveness of reported symptoms while reducing psychological barriers to reporting even minor or uncertain symptoms. Positive feedback from participants, such as “easier to answer than being asked by someone,” “easier to communicate than doing it face-to-face,” and “becomes a trigger to talk,” suggests that this structured approach could effectively address these reporting barriers. In addition, participants’ feedback indicating the app’s effortlessness (“can use without a problem”) and willingness to use (“I want to use it”) suggests its potential for successful implementation in pharmacy practice.

From the perspective of health care providers, pharmacists can review these structured patient reports before medicine consultation, enabling more focused and efficient discussions. These features, combined with the ability of the app to document patient-reported outcomes systematically, provide a foundation for continuous monitoring of therapy effectiveness and early detection of drug-related problems.

While our usability study received positive feedback regarding the potential of the app, we also identified several usability issues, particularly among older users. A participant aged 79 years expressed concerns, stating “I might not be able to use it on my own,” and other feedback pointed to specific issues such as “The size may be too small for elderly users” and “The text might be difficult to read.” Given that many customers of pharmacies are older adults, future usability assessments should focus on this population.

Implementing our app in pharmacy settings strategically aligns with the evolving health care landscape in Japan, particularly in aging societies where pharmacies are expanding beyond traditional medication dispensing [3,13]. Pharmacies offer several unique advantages as ideal implementation sites, including their high accessibility, regular patient visits, and prescription preparation waiting time, which offers a natural opportunity for symptom reporting without disrupting workflow. While the app could be valuable in various health care settings, including clinics and hospitals, pharmacies offer unique advantages. Pharmacists’ expertise in medication, combined with their frequent patient interactions, makes them ideal providers for continuous symptom monitoring and self-care

support. Their role has evolved from traditional medication dispensing and adverse effect monitoring to more comprehensive patient care support. Integrating the app into pharmacy practice could particularly support patient engagement in their own health care by enabling systematic symptom reporting in a familiar, low-pressure environment. This approach not only supports pharmacists' evolving role in comprehensive patient care but also promotes active patient participation in medication management.

Future research should systematically evaluate the effectiveness of the app in achieving its intended outcomes. Key areas of investigation include the impact of the app on the number and types of symptoms reported. Quantitative measurements will be valuable in assessing the impact on pharmaceutical interventions, including the identification of drug-related problems and subsequent care recommendations. Further research opportunities lie in evaluating improvements in the quality of patient-pharmacist communication and the effect of the app on the efficiency of pharmacy workflow. These investigations would benefit from including a larger, more diverse patient population in real-world pharmacy settings, with particular attention to older adults who represent a significant portion of pharmacy patients.

Although our sample size of 5 participants is consistent with recommendations for initial usability testing suggesting that 5 users can identify approximately 80% of major usability issues [14], this small sample size limits the generalizability of our findings. This limitation highlights the need for additional testing with a larger and more diverse user group to ensure the app meets the needs of all potential users in pharmacy settings.

Conclusions

We successfully developed a new hierarchical list of symptoms and an accompanying app. The app, designed to enable users to select symptoms from a structured list, was positively accepted and showed strong potential for improving patient behavior in symptom reporting. Future improvements to the design of the app design, particularly for older users, will further enhance its utility in both pharmacy settings and broader health care environments.

Abstract

Background: Chronic kidney disease (CKD) is a common condition worldwide and home dialysis (HD) provides economic, quality of life, and clinical advantages compared to other dialysis modalities. Human-centered design aims to support the development of eHealth solutions with high usability and user experience. However, research on the eHealth needs of patients using HD is scarce.

Objective: This study aimed to support the design of eHealth for patients with CKD, particularly for patients using HD, by developing a kidney disease experience map that illustrates user needs, concerns, and barriers. The research questions were (1) what experiences do patients, particularly older adults, have in their everyday lives with CKD? (2) what user needs do patients with CKD have for HD eHealth? (3) how can these needs be illustrated using the experience map technique? The study focused on patients aged >60 years, as they are at a higher risk of chronic conditions. The study was conducted as part of the eHealth in HD project, coordinated by Hospital District of Helsinki and Uusimaa, Finland.

Methods: In total, 18 patients in different care modalities participated in retrospective interviews conducted between October 2020 and April 2021. The interviews included a preliminary task with patient journey illustrations and questions about their experiences and everyday lives with CKD. The data analysis was conducted using a thematic analysis approach and the process included several phases.

Results: On the basis of the thematic analysis, 5 categories were identified: healthy habits, concerns about and barriers to eHealth use, digital communication, patients' emotions, and everyday life with CKD. These were illustrated in the first version of the kidney disease experience map. The patients had different healthy habits regarding social life, sports, and other activities. They had challenges with poorly functioning eHealth software and experienced other factors, such as a lack of interest and lack of skills for eHealth use. Technical devices do not always meet the emotional or physical needs of their users. This caused feelings of frustration, worry, and fear in patients, yet also fostered situational awareness and hope.

Conclusions: The experience map is a promising method for illustrating user needs and communicating the patient's voice for eHealth development. eHealth offers possibilities to support patient's everyday life with chronic disease. The patient's situation and capacity to use eHealth solutions vary with their everyday challenges, opportunities, and their current stage of treatment. The kidney disease experience map will be used and further developed in the ongoing research project "Better Health at Home—Optimized Human-Centered Care of Predialysis and Home Dialysis Patients" (2022 to 2026).

KEYWORDS

user need; chronic illness; kidney disease; older adult; eHealth; experience map; human-centered design; home dialysis

Introduction

Background

Chronic kidney disease (CKD) is a common condition worldwide. It has been estimated that 11% to 13% of the population in high-income countries have CKD. The number of patients with advanced kidney disease is growing 5% to 7% per year [1,2]. The prevalence of CKD is highest among older adults, ranging from 38% to 44% in patients aged >65 years [3,4]. In total 2.05 million people were treated with dialysis worldwide in 2010 [2]. In 2017, 1.2 million people died globally because of CKD [5].

Patients with end-stage CKD need kidney transplants or dialysis to survive. Dialysis can be performed in a dialysis unit in a hospital (ie, in-center dialysis), in a satellite dialysis unit, or at home using peritoneal dialysis or hemodialysis. The dialysis modality may vary depending on the patient's current health and life situation. Both in-center and satellite dialysis can be laborious for patients [6] and impose a heavy financial burden on medical care [7]. Therefore, home dialysis (HD) provides better quality of life and clinical advantages and empowers patients by providing them with more flexibility in their everyday lives [6,8].

Even though bringing dialysis treatment to a patient's home might be burdensome and complicated for both the patient and the health care unit [8,9], there is a common understanding that HD prevalence needs to increase [1]. HD creates opportunities to improve the patient's safety and quality of life, as well as to support self-management of health [6,10]. HD has also proven to be feasible for older adults, even though challenges such as fear of needles or doubts about handling them, or other physical limitations have been recognized [8,11,12].

Research advises a holistic eHealth design that integrates technologies, end users, and use contexts [13-15]. Using human-centered design (HCD) approach [16], our study aimed to support the design of eHealth for patients with CKD, especially those on HD care, by investigating user needs, concerns, and digital service barriers, and illustrating those in the format of a kidney disease experience map. Due to the high prevalence of CKD among older adults [8], both in Finland and worldwide [17], the focus of the study was set on the perspective of older adults. The research questions were as follows:

1. What experiences do patients, particularly older adults, have in their everyday lives with CKD?
2. What user needs do patients with CKD have for HD eHealth?
3. How can these needs be illustrated using the experience map technique?

The study was part of the eHealth in HD project ("device research") [18] coordinated by the Hospital District of Helsinki and Uusimaa in Finland from 2020 to 2022. The project aimed to create a novel eHealth solution for patients with CKD undergoing HD (named "Home dialysis eHealth solution") and research devices that support patients both before and throughout dialysis therapy by gathering monitoring data, managing HD supply orders, and facilitating communication between the patient and the health care team (Figure 1).

HCD of eHealth Solutions

HCD is an approach to interactive system development that aims to develop solutions with high usability and user experience [16]. The principles of HCD highlight the importance of involving end users in an iterative design process [16,19] and understanding their needs at the beginning of the development process [16,19].

When exploring user needs, researchers collect information, for example, about what features digital services should contain and how they should function from the perspectives of end users. The user needs exploration is important as it helps service designers to understand the role and meaning of the solutions for end users, in our case, patients using HD. eHealth is used to refer to digital health services, and health information offered through the internet or other technology solutions improving health care [20,21]. By designing in a human-centric way and involving end users in the development, eHealth can offer more value and new ways to provide health care and well-being services for patients and all citizens [13,21]. For patients with chronic illnesses, eHealth solutions can offer new communication possibilities between the patient and the health care team, as well as support empowerment and improve quality of life [21,22].

Patient Journey Maps and Experience Maps as Illustrations of User Needs

A patient journey map and an experience map are tools for 2 different purposes. In this study, patient journey maps were used as a part of patient interviews [23], and an experience map was used to communicate the results of the study holistically.

Patient journey maps as tools for visualizing patient journeys can be used to support the design of eHealth in several ways. The maps can help researchers and designers to identify how health care processes can be improved, for example, identify gaps and improve the processes by integrating eHealth solutions as part of those processes [24]. The patient journey maps sum up patients' experiences and care activities in a single, chronological, timeline-type visualization [24]. As the maps can help to explain what patients go through with their disease [23,24], they can help designers promote empathy, which is important in HCD [25-27]. Furthermore, they can help the sharing of knowledge between stakeholders as well as activate creative thinking [28].

Patient journey maps can be applied in various specialties regardless of the medical condition. For example, patient journey maps have been used to illustrate home isolation experiences of people with mild COVID-19 [29], hypertensive disorders in pregnancy [30], cancer [24], cervical dystonia [31], and kidney diseases [32]. In literature, the focus of patient journey maps varies from communicating patients' emotions and identifying process gaps to the importance of shared decision-making [33].

Experience maps are tools to combine situations, functions, emotions, and contacts in the same visualization [34]. Experience maps are valuable in the development of various eHealth, mobile health, and other apps, helping to communicate, for example, how cancer affects a patient's life and capturing patients' voices [35]. However, similar to patient journey maps, there is no standardized way to visualize and use them in an eHealth development context [33]. To our knowledge, no experience maps have been produced to represent the everyday life of patients with CKD using HD. Even though working with experience maps helps to identify users' needs [34], based on our literature review, few patient journey maps or experience maps focus on illustrating and communicating the needs as a basis for eHealth design and requirements specification.

Older Adults as eHealth Users

The European population is aging [36]. In Finland, >2 million citizens (ie, 36% of the population) are ≥55 years old [37]. Finnish older adults have good self-confidence in using digital services. In the 55 to 64 age group, >80% of Finns felt that their digital skills were at least on par with those of other Finns, and in the 65 to 74 age group, >60% of Finns felt the same [38]. At the same time, the number of patients in Finland who undergo dialysis, is expected to increase by >36% before 2040 [39]. Therefore, Finnish older adults seem to have both a need for and self-confidence in using CKD eHealth.

Older adults, due to an increase in diseases and complex health issues, could benefit substantially from eHealth [40]. Still, they experience several barriers to using eHealth, such as privacy concerns, lack of motivation to use digital solutions [41,42], and challenges to finding, accessing and understanding health-related information [40,43]. In addition, they have concerns about eHealth reducing the time with the physicians during appointments [42]. Although they can benefit from eHealth, they still face several challenges that could be solved with careful design.

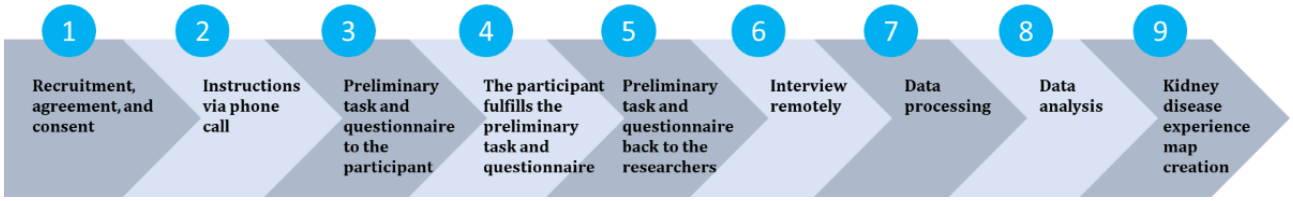
The health situation also affects the use of the eHealth and user needs. Many eHealth tools are intended for the treatment of a specific disease. One or more chronic health conditions can lead to several regular self-management tasks [40], which can potentially affect a patient's everyday life and the use context of eHealth. Therefore, eHealth should be adapted to each user's special situation [44].

Methods

Overview

Combining different context-specific strategies is important when developing services in a complex environment, such as health care [15]. Our study on user needs of patients with CKD for eHealth used a qualitative research approach and semistructured interviews [23,45] as the primary method for data gathering. The interviews were supported with preliminary tasks, which included visualizing patient's journey in the form of a timeline drawing [23]. The procedure of the study included several phases starting from the recruitment and ending with the creation of the kidney disease experience map illustration (Figure 2).

Figure 2. Procedure of the study.



Ethical Considerations

The empirical study was conducted as part of the eHealth in HD project, which received permission from the ethical committee of the Hospital District of Helsinki and Uusimaa (HUS/1649/2020, Jarkko Ihalainen). All participants gave their voluntary, informed, and written consent. The patients' capabilities to participate in the study were ensured. While analyzing the data, the information of the patients participating in the study was pseudonymized and coded with the identification numbers. Only the researchers assigned to the study had access to the data. No compensation was paid to the participants for their participation.

Participants

In total, 18 patients aged ≥60 years participated in the study: 5 patients in predialysis phase, 4 patients in satellite dialysis, 5 patients in home peritoneal dialysis care, and 4 patients in home hemodialysis care (Table 1). Most of the participants were retired. The sample excluded in-center patients with dialysis, but included patients with dialysis in satellite units. The participants were recruited from the group of patients who were participating in the larger research project of HD eHealth solution development.

Table 1. Demographics of study participants (N=18).

Demographics	Frequency, n (%)
Dialysis	
Predialysis	5 (28)
Satellite dialysis	4 (22)
Home peritoneal dialysis	5 (28)
Home hemodialysis	4 (22)
Gender	
Woman	4 (22)
Man	14 (78)
Education	
Basic education	4 (22)
Upper secondary level	4 (22)
Bachelor's degree	5 (28)
Master's degree	3 (17)
Other	2 (11)
Technology skills (self-assessed)	
Good	6 (33)
Basic	11 (61)
Weak	1 (6)

The health care team recruited the patients by distributing materials about the study and asking about their interest in participation. Participation was voluntary and they did not get any compensation. The study participants were already familiar with the novel HD eHealth solution under development and had tested the first version of the solution. The research nurse contacted the potential participants first and informed them about the study. If the participants wanted to participate in the study, they signed the consent form, and the research nurse provided their contact information to the researchers. Then, the research material package, prepared by the researchers, consisting of a cover letter, a preliminary interview task, background information forms, and the responsible researcher's contact details were sent to the participants. After sending the package to the participants, the researcher called them to provide more detailed instructions, answer any questions, and schedule a time for the remote interview.

Preliminary Tasks and Retrospective Interviews

Interviews are useful in the phases of any development process related to eHealth [15]. In our study, retrospective interviews included questions about the patient's journey, treatments experiences, cooperation with the health care team, technology experiences, and visions for the future. The themes broadly covered patients' everyday experiences with the illness, practical questions, and the comprehensive timeline with CKD.

The idea of the visual timeline drawing as the preliminary task for the interview was to (1) help the interviewee to process and structure their multistage patient path even before the interview, and (2) help with communication between the interviewee and researcher during the remote interview [23]. The preliminary task was sent to the interviewees 2 weeks before each interview. In this task, patients were asked to identify and illustrate significant milestones, events, and experiences with their illness to a timeline. The patients returned the task to the researchers before the remote interview.

The interviews were conducted between October 2020 and April 2021 when the second wave of COVID-19 was underway in Finland. For safety reasons, the interviews were arranged remotely via Microsoft Teams. Two researchers were present in the interview session with the participating patient: one researcher being the interviewer and the other note-taker. Interviews were audio-recorded using recording functionality of Microsoft Teams. Data gathering was conducted in collaboration with 5 researchers (SL, NK, JV, SH, and PV): 2 doctoral researchers, 2 students, and a professor from the human-computer interaction field.

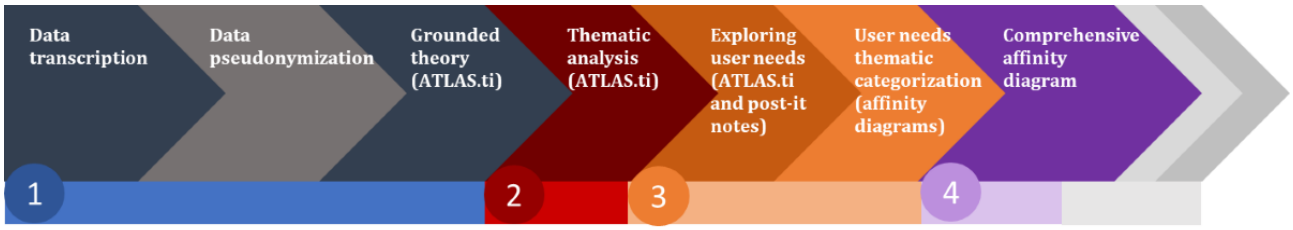
Data and Analysis

Overview

The data included recordings and notes from the interviews, as well as illustrations of patient journeys. The interview notes were finalized according to audio recordings and the transcriptions were pseudonymized. In total, the data consisted of 155 pages (ie, 58,429 words) of written notes and 18 paper-based patient journey visualizations (ie, visual timeline drawings). A total of 5 researchers (SL, NK, JV, SH, and PV) participated in the data analysis.

The data were analyzed in 4 phases (Figure 3): (1) grounded theory analysis, (2) thematic analysis, (3) user needs exploration and thematic categorization, and (4) comprehensive affinity diagram creation. The data included many different perspectives to understand the different nuances and ensure reliability, and the analysis was done in collaboration with several researchers in many phases.

Figure 3. Four phases of data analysis.



Phase 1: Grounded Theory Analysis

In the first phase [46], the pseudonymized interview transcripts were analyzed following the main structure of grounded theory [47,48] using ATLAS.ti software version 9.1.5.0 (ATLAS.ti Scientific Software Development GmbH, "ATLAS.ti") [46]. During the analysis, the interview data was coded using researcher-denoted concepts and open coding influenced by the grounded theory [46,47]. The first round of interview data analysis following grounded theory was conducted by SL.

Phase 2: Thematic Analysis

In the second phase, the principles of the thematic analysis method [48,49] were followed to analyze the interview data from 18 participants from an existentialist perspective, including references to death, well-being, and atmosphere in life (eg, emotions) [50-52]. In addition, the analysis used the holistic framework [13-15] of exploring the context of use, technology, and people.

On the basis of the analysis, 3 thematic categories were identified: healthy habits, concerns and barriers for eHealth use, and everyday life with CKD. Observations based on interview transcripts were written on post-it notes and thematically categorized following the phases of the affinity diagram method [48,49]. The data gathered using preliminary task of patient journeys were mapped in line with the interview transcripts. In addition to the initial 3 themes, 2 categories were formed based on thematic analysis: digital communication and patients' emotions. Concerns and use barriers for eHealth were investigated from the data by two researchers (PV and SH). The digital communication affinity diagram was done by three researchers (PV, SH, and JV).

The thematic analysis categories include several aspects as presented in Textbox 1.

Textbox 1. Categories of thematic analysis.

- Healthy habits: health-promoting activities and hobbies that were mentioned by interviewees, including the whole scale of activities from sports to eating habits.
- Concerns and use barriers for eHealth: observations related to everyday life challenges with the disease, use challenges and barriers of digital services, negative emotions, such as worries or dissatisfactions, and patient path challenges.
- Digital communication: observations concerning health care-related digital communication habits, channels, and experiences.
- Patients' emotions: observations of emotions and experiences interviewees mentioned in the interviews and patient journey visualizations. The emotions included the whole scale of emotions, from fear and confusion to happiness.
- Everyday life with chronic kidney disease: observations related to interviewees' thoughts, stories, and experiences of their everyday lives, including references to death. Death made the participants reflect from different perspectives: their own (forthcoming) death was compared to other deaths, the actions to avoid death were listed, and the inevitable nature of death was considered.

Finally, the frequency of observations per theme was calculated (Multimedia Appendix 1). Most of the observations were related to concerns and barriers to technology use. Emotions and healthy habits were also common topics in all the interviews.

Phase 3: The User Needs Exploration and Thematic Categorization

The third phase focused on analyzing user needs. All the gathered data were explored from the viewpoint of user needs from 2 perspectives: exploring digital communication needs and exploring overall user needs for interactive solution development. In the analysis, 2 researchers (PV and SH) explored the data labeled "digital communication," "user needs," and "to eHealth solution concept" in ATLAS.ti and formulated the observations as user needs. The second round resulted in 165 needs.

After this, the digital communication affinity diagram was created in collaboration with 3 researchers (SH, JV, and PV). The user needs were written on post-it-notes by PV, and analyzed, and regrouped to the affinity diagram in collaboration with SH, JV, and PV. In the affinity diagram, the identified needs (n=165, 100%) were thematically grouped under 5 categories: overall interaction and communication (n=77, 47% of all identified needs), patients' digital activities (n=28, 17%), instruments (n=27, 16%), inventory and ordering dialysis supplies (n=19, 12%), and digital communication with the health care team (n=14, 8%). While creating the affinity diagram of digital communication needs, doubles were removed.

When exploring overall user needs, the data transcriptions of 18 interviews were analyzed using ATLAS.ti. During this analysis, the data labeled with the following codes—"user needs," "healthy habits and hobbies," "suggestion," "communication," "digital services," "tasks," "care team," "communication," "social relationships," "equipment," "challenges," "positive experiences," and "device research"—were explored and formulated as user needs. In total, 287 user needs were identified and written on post-it notes as preparation for the comprehensive affinity diagram work.

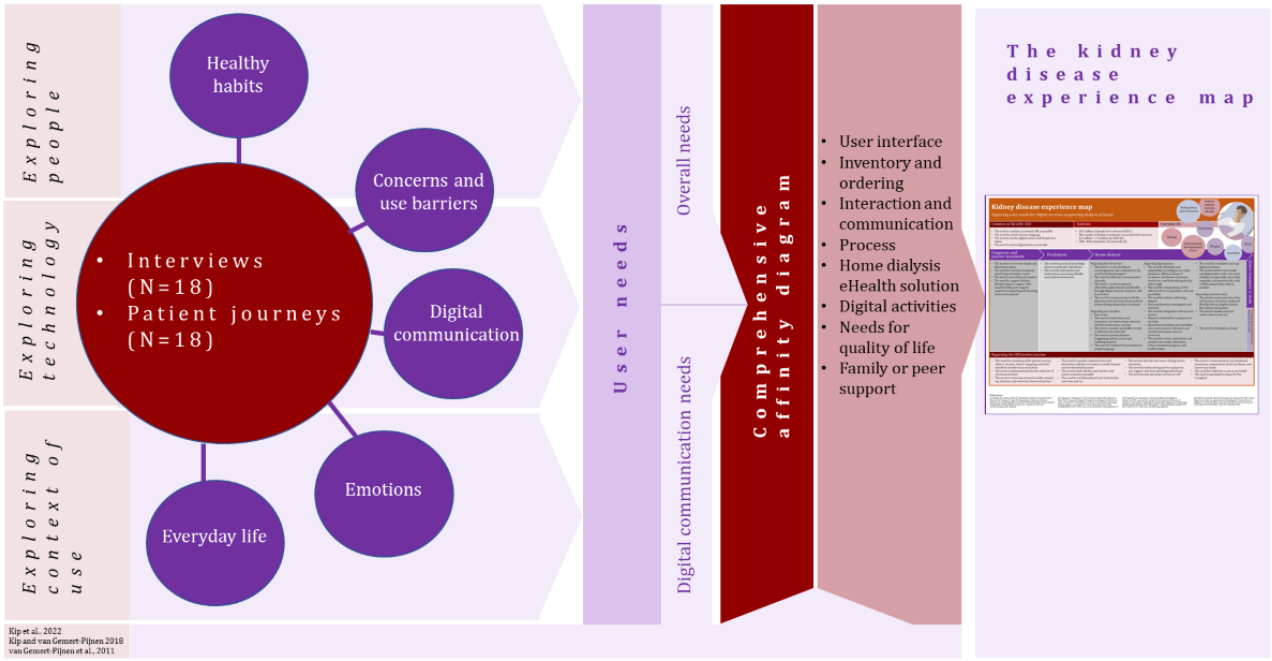
Phase 4: Comprehensive Affinity Diagram

In the fourth phase, the affinity diagrams created in the previous analysis phase were merged to form a comprehensive affinity diagram. Three researchers recategorized the post-it notes to create a comprehensive affinity diagram of user needs. The main themes of the diagram were "eHealth user interfaces," "Inventory and ordering dialysis supplies," "Overall interaction and communication," "Process," "HD eHealth solution," "Family/peer-support," "Patients' digital activities," and "Needs for improving the quality of life" (Multimedia Appendix 2). These 5 were used as the leading themes to guide the design of the first version of the kidney disease experience map. Data analysis results were discussed between PV, SH, VR, and JV.

Creation of the First Version of the Kidney Disease Experience Map

An experience map is a tool that strings the perspectives of the context of use, people, and technology, together in a holistic manner [13-15]. The maps can be used to support the communication between stakeholders and to capture a patient's voice in eHealth design [35]. The first version of the kidney disease patient experience map (Figure 4) was made by combining remarks from existing example models particularly the cancer experience map [35]. In the first paper-based template of our map, the preliminary phases from the preliminary tasks (ie, patient journey maps) were illustrated: "before diagnosis," "diagnosis and passive treatment," "treatment method selection," "beginning of treatment/training," and "home dialysis." Post-it notes from the comprehensive affinity diagram were added under those phases. The first draft of the patient experience map was created in collaboration with 3 researchers.

Figure 4. Overview of the data analysis process leading to the creation of the first version of the kidney disease experience map.



Next, the structure of the experience map was refined based on the number of post-it notes in each phase. The duplicate post-it notes were removed and the content of the map was reorganized (PV, SH, and JV). To validate the contents of the draft map further, 2 researchers (PV and SH) reexamined the post-it notes after which 4 other researchers (JV, NK, SL, and VR) gave feedback on the next version of the map. After all, in total of 6 researchers (PV, SH, JV, NK, SL, and VR) participated at least somehow in the experience map visualization process. The published version of the first version of the kidney disease experience map was finalized by PV. An overview of the multiphase analysis process which led to the creation of this first version of the kidney disease experience map is illustrated in Figure 4.

Results

Overview

As the outcome of the study, the first version of the kidney disease experience map, which illustrates the user needs, concerns, and barriers of patients with CKD for eHealth, was created. This section explores the patients (ie, people), technology, and context of use perspectives [13-15]. First, patients' healthy habits are investigated and their concerns and barriers to technology are addressed. Then, the technology is examined, concentrating on digital communication. Finally, the context of use from the perspective of patients' everyday lives is explored. Due to sensitive personal issues, research results and citations are presented without identification information to ensure complete anonymity of the participants.

Exploring the People: Healthy Habits

The patients had different needs for healthy habits regarding social life, sports, and other activities (Multimedia Appendix 3). Patients mentioned that social life and taking care of close relatives, such as grandchildren, were important to them. Incidental exercises, including gardening or shoveling snow, were popular. Being in nature, picking mushrooms or berries, fishing, and hiking, along with other everyday life activities, such as club and society activities or studying, brought well-being to the participants. Animals, for example, dogs, cats, and summer chickens, also supported the participants' well-being. Handcrafting, art, and culture were also seen as important, but COVID-19 restricted those activities. The importance of many remote social contacts was mentioned in the data, and patients had to learn new eating habits, such as losing weight or cutting down on alcohol consumption.

Exploring the People: Concerns and Barriers for eHealth Use

Patients were challenged with poorly functioning available eHealth solutions and also experienced other negative factors, such as lack of interest or lack of skills (Multimedia Appendix 4). Technical devices did not always meet the emotional or physical needs of their users. This caused emotions like frustration, worry, and fear from patients. The patients' responses covered their available eHealth solutions, not focusing especially on the HD eHealth solution.

The solution or software used by patients for their CKD care was found to function poorly in many ways. For example, the devices as a part of the HD eHealth solution did not work as expected, or they worked differently than they expected:

> *I have no control over the information. If I measure my blood pressure, I press the BT button and then it should be delivered, but I don't know if it did. The same goes for the scale, *beep*, and maybe it synchronized.* [P18]

Alongside poorly functioning devices, in some cases, the HD eHealth app also did not work well. The software content (eg, one's results or visualizations of one's health situations) was challenging to understand or find. The HD eHealth app was challenging to use with small mobile phone screens and its user interface terminology caused problems for patients:

> *There have been a few problems with the phone. There will be updates and then it will freeze somehow. I don't understand much; the basic things are in Finnish, but then they are English words so... This was at least the third time that the nurse had visited us.* [P17]

> *Others have also worked well. Even the mobile phone. You can monitor your health from it, even though it has those [health status] curves that you don't understand much about.* [P13]

The participants doubted the functionality of the HD eHealth solution, both devices and the app. With the dialysis monitor, they were worried that something would go wrong:

> *I haven't used (ie, the devices and instruments) much, I've just tried. I'm a bit lazy. I doubt whether the instrument is still in good condition. There was an error message about a month ago. There was a notification that there was still something wrong. I thought I'd let it be and fix the instrument before I started.* [P24]

> *When the first treatments started, it was so exciting. But after a month had passed, it had become routine and was no longer exciting. Then, when I moved home from hospital, I started to get excited again.* [P22]

Exploring the Technology: Digital Communication

Overview

Patients commented on digital devices and the app from many different aspects in terms of the technical functionality and the emotion they cause. The contents of the solution's user interface (Figure 1), as well as other user interfaces, were also commented on. Patients linked and communicated with the health care team through digital channels and used technology independently as a part of their HD treatment during the research.

Many Groups Communicate With the Patient

Communication within the health care team is important, but also nurses, physicians, and patients share information (Multimedia Appendix 2). To get the supplies and instruments needed for HD care, the patient also needs to be in regular contact with the pharmacy or the health care team. Relatives must not be forgotten either, as patients may want to share information with them:

> *To be able to get in touch with the on-call nephrologist or the other way around, perhaps you could organize a little more frequent meeting. I think that many patients could have questions for the doctor that the nurses cannot or are not allowed to answer. Nephrologist on-call from the computer.* [P24]

Examples of Current Communication Channels

Depending on the patients' devices and patients' capabilities to use them, HD patients use different communication channels for following their health records and CKD-specific operations. They order HD supplies once per month. Some patients have created their digital tools (eg, Excel sheets), which calculate the number of needed supplies automatically. After that, the order will be sent via email to the nurse. Still, Excel sheets or other tools for ordering dialysis supplies are not an option for everybody. Therefore, an easy-to-use solution for ordering supplies and managing inventory is needed for HD patients:

> *Orders must be sent once a month. I have an Excel sheet that automatically keeps the balances. Then, there is a page where you can automatically see what needs to be ordered. I have made Excel sheets myself. It's quite a job when there are more than 30 different supplies. Syringes... you must know their numbers. Sometimes, I also check some information. If one item is true, then so are all the others. It's automatic. I then make a .pdf list from the Excel sheet, one A4, and then it goes [by e-mail to the nurse].* [P30]

In Finland, patients follow their health records via national or local patient portals (eg, "My Kanta Pages" [53] or "MyChart" [54]). Patients with chronic illness have many laboratory tests taken. They appreciate that all their health records are found in one place, but each record is shown in detail separately, too. Therefore, easy-to-read visualizations of test results and current health situations are needed:

> *MyChart is as hopeless as My Kanta, both of which break down the lab results separately, even if they want to see them as a whole. Applying for your results is difficult.* [P37]

> *I look at the results on 'My Kanta,' all diagnoses come there, as well as laboratory test results. From there, I can see them all. The information is readable and remains stored. I think 'My Kanta' is really good. There you can also see laboratory visits from a certain period if you want to follow a limited period.* [P21]

Positive Attitude Toward Digital Communication

All patients participating in the study seemed to have a positive attitude toward digital communication tools. For example, paper-based dialysis supply orderings may be forgotten and instead, digital tools can step in and help patients with their everyday lives. Patients felt that digital solutions enabled information-seeking and offered more flexibility in meetings with the health care team and other contacts:

> *Their version is that they hand out an A4 paper. You should fill it in; it's difficult manually. The risk is that you forget.* [P30]

> *We have internet and e-mail. My wife uses them more; I just read. The wife handles banking and other things remotely. I kind of stopped using the computer when I don't need to. You could probably handle things digitally. I haven't come across anything like that. I have had to deal with a lot of paper. I have not been approached digitally. Yes, it would be even easier. You could reach the staff at any time.* [P24]

Exploring the Context of Use: Everyday Life and Emotions

Overview

The main themes related to everyday life were thinking of death, the importance of care, changes in well-being after treatment started, and emotions (Multimedia Appendix 5).

The Presence of Death

With kidney disease, death is present in life. It is known that without dialysis or receiving a transplant, one dies. The logic of the disease is unequivocal: when dialysis no longer helps, the person knows they are going to die:

> *I think that the disease is deadly and must be treated.* [P21]
>
> *Everyone knows that life ends eventually, but I'm not afraid of it in any way.* [P1]

The General Well-Being of the Participants Varied

The patients understood the essentiality of treatment and often felt better after the treatment started. They wished to be able to continue life as normally as possible. One patient (P9) described experiencing leg cramps at night, which had caused them to sleep poorly. After the dialysis treatment started, the cramps stopped. They managed better than before and could even go for walks:

> *I hope I don't end up on dialysis. Of course, it is ahead, but hopefully as far as possible. It is a wish.* [P20]
>
> *It's just that now I feel like I'm getting older. I recently turned 70, so all kinds of unnecessary aches and pains will increase.* [P25]

Everyday Life Is Characterized by Waiting

The health situation of a patient can be improved either with dialysis or a transplant. Having to wait for transplant can have major setbacks; one patient (P24) had to be removed from the transplantation waiting list due to amputation and sepsis, which is why they now focus on keeping themselves in the best possible physical condition through physical activities. Patients were waiting to travel.

A Wide Range of Emotions in Everyday Life

A wide range of emotions appeared in the interview data about the patient's everyday life. Despite the challenges of the disease, most of the patients described their lives with the disease in somewhat positive terms. Everyday life with the disease seemed to go somewhat smoothly.

In addition to positive feelings, patients also expressed negative emotions, such as confusion, fear, irritation, anger, and frustration. Feelings of confusion were caused by changes in health status and events in the patient's journey, uncertainty of the future steps in the journey, or technology that worked unexpectedly. After receiving the diagnosis, one patient was confused because they did not fully understand what kind of disease the diagnosis was about. Several patients brought up fear in the interviews. Things related to the treatments were especially scary. Most of the patients also described irritation or anger at least sometimes during the patient journey. In addition, half of the patients reported frustration. Health challenges, the difficulty or even failure of a treatment, and the commitment to dialysis treatment were irritating. The most frustrating thing was when HD treatment did not go as well as planned. Another source of frustration was digital systems, equipment, and devices:

> *And a little fear. I am quite hopeful that I will get there on the transplantation waiting list and that it will be successful at some point. I hope that I can make it there (ie, from a health perspective), and if this continues, then there is nothing to worry about.* [P11]
>
> *Actigraphy, a part of HD eHealth solution, is inconvenient, but there is nothing wrong with the other devices, everything is fine. I have a strong belief that information will go forward. It's enough for me to see on the scale and blood pressure monitor that my weight and blood pressure are okay.* [P18]
>
> *This home dialysis takes up a lot of space. Do you see these boxes? A huge package comes once a month. The dialysis monitor also takes up quite a lot of space. And then the cabinets, where you put all the treatment consumables. And there is a bottle like this: hand sanitizer comes once a month. Quite a lot of supplies come from the hospital once a month. This room is completely reserved for dialysis.* [P30]

HD taking up too much space or other resources was both irritating and frustrating. HD requires much space at home, so some patients had to renovate their homes. However, almost half of the patients felt that their living conditions did not require changes due to HD. The patients felt it was important that the dialysis treatment could also be done at the summer cottage.

Positive emotions included joy, optimism, hope, and satisfaction. A third of the patients mentioned joy in the interviews and most patients expressed hope and optimism. They were satisfied with the professional staff and the stability of the current situation. The supportive and successful dialysis made them happy. Keeping their health situation stable was their biggest wish. Patients also mentioned their willingness to continue their hobbies.

The patients were satisfied with both their health condition and the information related to it. Half of them were satisfied with the treatment. The patients were pleased with the eHealth solution in use during the study and the HD treatment was experienced as proceeding smoothly. The nursing staff was considered friendly and knowledgeable:

> *I have been very satisfied. They, the care team, have guided me, and when I have challenged them, they have accepted challenges and promised to sort things out.* [P37]
>
> *Home dialysis has gone surprisingly well—no major problems.* [P34]
>
> *At least now, this present moment looks bright.* [P13]

The First Version of the Kidney Disease Experience Map

The first version of the kidney disease experience map (Figure 5 [1-3,35]) was developed from the perspective of user needs of eHealth. It includes their needs for everyday life with CKD (ie, "Common needs"), needs relating to 4 phases of the journey of patients with CKD, and needs in all journey phases of patient with CKD from diagnosis to kidney transplant or death. The patient journey phases, which are inspired by the experience timeline of cancer experience map [35], are "Diagnosis and passive treatment," "Predialysis," "HD," and "Preparing for kidney transplant or death." In the top corner of our map kidney disease statistics and patients' everyday life experiences with CKD are illustrated.

Figure 5. The first version of the kidney disease experience map from a user needs perspective. A higher resolution image is available in Multimedia Appendix 6. CKD: chronic kidney disease. KD: kidney disease.

The first version of the kidney disease experience map (Figure 5) includes aspects from all three perspectives [13-15]:

1. Context of use: the context of use perspective can be found especially in the patient journey phases and the "everyday life with CKD" part of the map.
2. People: information about people is available in the "statistics and everyday life with CKD" parts of the map.
3. Technology: technology aspects are mainly covered in the form of user needs.

Discussion

Principal Findings

On the basis of our study, eHealth as a part of the daily lives of the patients with CKD was perceived as being useful, but the patients also had challenges with devices and apps. Acknowledging that CKD is a long-lasting journey, it is essential to consider long-term user experiences. Finally, several user needs in different phases of the journey of patients with CKD were identified and illustrated with the first version of the kidney disease experience map.

Answers to Research Questions

Overview

This study had three research questions: (1) what experiences do patients, particularly older adults, have in their everyday lives with CKD; (2) what user needs do patients with CKD have for HD eHealth; and (3) how can these needs be illustrated using the experience map technique?

What Experiences Do Patients, Particularly Older Adults, Have in Their Lives With CKD?

Three key experiences related to daily life of patients with CKD were identified as depicted in Textbox 2

Textbox 2. Key experiences related to daily life of patients with chronic kidney disease (CKD).

- Patients' healthy habits: patients with CKD must adapt to the changes in their everyday lives resulting from dialysis care. For example, patients must learn new routines for their treatment at home. Patients felt that CKD limited their lives, but they dealt with it in different ways: some were frustrated and others continued to live as normally as possible. However, they understood the necessity of the treatment and continued the treatment as usual. Similar findings were reported from a study involving cancer patients [35], who expressed concerns with unknown, life-threatening, and life-changing experiences.
- Patients' concerns and barriers to use for eHealth: patients had challenges with user interface and technical devices, including dialysis monitors and research devices of HD eHealth solution (Figure 1), that did not always meet the users' needs.
- Digital communication: digital communication opportunities via the eHealth solution play an important role for patients. Digital solutions made information-seeking possible and offered more flexibility when meeting the health care team and other contacts. Information gaps did not accumulate as easily as for cancer [24].

What User Needs Do Patients With CKD Have for HD eHealth?

In our study, both general needs and needs related to different patient journey phases were identified and illustrated in the first version of the kidney disease experience map (Figure 5). We found that CKD was different from day to day, and thus the use context of eHealth varied. Poor usability burdens the everyday life of a person with disease even more. Similar observations were reported in the case of digital independent living supporting systems of older adults [34]: designers were important to understand the treatment stage, the transition from health to illness, and statuses between them. Furthermore, the needs and experiences of patients with cancer were found to vary during the care process [35].

The HD eHealth solution is targeted to all patients with CKD, as well as individuals with disabilities, such as low vision or even amputated limbs. The solution is to be used during the entire patient journey, which may last for years. Considering this, the HD eHealth solution is observed to play a remarkable role in the patient's life and highlights the need for research on long-term user experience.

How Can the User Needs Be Illustrated Using the Experience Map Technique?

Typically, user needs are illustrated with use cases or user needs tables, and they can be processed further to requirements format [55]. Findings from user research can also be presented as user profile illustrations, such as personas [15,34], stakeholder maps [15], experience maps [34], and visualizations of stakeholders [34].

In our study, we used the experience map method to illustrate user needs. As with the cancer experience map [35], we identified the phases of care and relevant themes for grouping the findings. We considered the experience map technique applicable for illustrating not only the phases but also the eHealth related needs of the patients. We found a group of general needs, which are common for all phases of care, but also needs that arise from specific phases of care. Understanding the care process and how user needs evolve is important for the designers and also for the health care team, who are responsible for introducing the services to patients and training them. Experience maps help to ensure the care continuum in service development [34].

In this study, the created experience map represents a common higher-level experience map, which can illustrate a specific persona, or the timeline could be narrower (ie, 1 month or 1 day). In the first version of the kidney disease experience map, the HD eHealth solution covers different wearable solutions and the software (ie, including the wearable solutions and software connected to the dialysis monitors); however, different physical dimensions (ie, dialysis monitors, packing materials of supplies ordered) are not covered.

Experience mapping can be seen as a promising but laborious method for illustrating user needs and communicating a patient's voice holistically to eHealth development, especially in a case where the experience map is based on extensive qualitative data. Following the example of cancer experience map [35], we captured patient's voices with their quotes. Similarly, we also focused on reporting patient quotes in the paper instead of the experience map. Therefore, the first version of the kidney disease experience map can be used both separately and with the paper. Our interpretation is that similar to the integrated patient journey map for hypertensive disorders in pregnancy [30] and the cancer experience map [35], the kidney disease experience map can help developers build effective eHealth solutions and promote empathy and shared understanding between the developing team members. It can also help empower patients and help with shared decision-making [33]. Like the patient journey map [24], the first version of the kidney disease experience map has the potential to help simplify and optimize processes for better health outcomes. In addition to that, similar to the cervical dystonia patient journey map [31], it can help to communicate the different phases of the care to the patients and help them to understand their needs at each phase.

Relevance of the Research

In the study, the experience map describing the patient's experience was formed based on the qualitative data from retrospective interviews and preliminary tasks. This first version of the kidney disease experience map can be used as a basis for other experience maps related to kidney diseases in the future. In addition, it can also bring perspective to the experience maps of other chronic diseases.

The presented results can be used to support the further development of HD eHealth. The results have already been used in HD eHealth solution development project in Finland (eg, to inform the redesign of the solution user interfaces).

Experience maps, such as the map created in the study, can help researchers, designers, and developers to empathize with the patients with chronic illnesses, and to understand their needs and use contexts for future eHealth innovations. We see our kidney disease experience map and other similar maps having the potential to help design the solutions from a more holistic perspective compared to currently prevailing practices [13,21], as well as to create a base for the new ecosystems and new ways to offer health care in the future [21]. We continue the work in the ongoing research project "Better Health at Home—Optimized Human-Centered Care of Predialysis and Home Dialysis Patients" (2022 to 2026).

Evaluation of the Study

Our study had some limitations. First, exploring the context of use was not allowed at patients' homes due to COVID-19 restrictions. Therefore, we needed to collect data remotely. This was partly problematic because the patient's home is the main context of using HD eHealth. In contrast, due to the patient journey preliminary task and participants' open-minded attitude during the interviews, we were able to gather rich data about user needs and the context of eHealth use. In our study, the possible impact of the COVID-19 period was considered.

Our sample size is quite small, however, typical for a qualitative interview study. The representativeness of our sample can be questioned as it is divided from a larger patient group based on age and treatment methods. To find as comprehensive a sample as possible, while ensuring the safety of the participants with their ongoing treatment, the health care team helped researchers in recruiting participants for the research study.

Due to the personal nature of health information and privacy, we could not release the participants' background information, such as specific ages or treatments in this paper. In addition, the indirect identifiers have been removed from the paper. The relative satisfaction of the patients in their lives despite CKD could have been influenced by various factors, besides the HD eHealth solution. First, the target group in this study included only active patients with relatively good physical conditions for research ethics reasons. Second, many of them were waiting for a kidney transplant, which brought them hope with the disease. Overall, there was a lot of variation in emotions, but deep gloom appeared in the data only rarely.

The first version of the kidney disease experience map was created based on a reasonable amount of qualitative data of the everyday lives on patients aged ≥60 years in Finland. Before participating in this study, the patients already knew that the study covered new eHealth solution testing. Therefore, perspectives from patients whose condition is very weak and those whose attitude is not open to new technology are missing in this study. In contrast, research shows that HD is optimal for those who live in areas with long distances to travel to an in-center dialysis unit [6,7]. In part, this can also be seen in the first version of the kidney disease experience map: the study did not include patient experiences during the kidney transplant phase—meaning that the user needs related to this essential phase of the patient journey are missing from our map. In future, the introduced version of the kidney disease experience map can be updated by including motivational issues for HD.

The study was conducted as an integrated part of the patient's normal CKD treatment, so the research setup was organized in line with the patients' typical daily conditions and treatments. The study included participants who started using the HD eHealth solution shortly before the interviews but also those who had already been using the solution for several months. Thus, the study covered both novice users and more experienced users. Patients' reported technology skills varied from weak to good.

Further Research

This study provided initial experiences of creating an experience map to illustrate patients' needs for eHealth. In addition, the patients' experiences from the HD eHealth solution development can offer important perspectives to other development projects regarding patients with CKD. Further research is needed to gather more experience about the applicability of the method. We aim to continue the research with patients with CKD and HD eHealth designs. We will use the illustrated first version of the kidney disease experience map and the listed user needs in further analysis, which will aim to describe design principles and guidelines for HCD of eHealth for patients using HD and other patients with chronic illnesses.

The outcome of the first version of the kidney disease experience map offers insights to the different phases of the patient journey for patients with kidney disease at the HD care. Due to the diverse experiences of patients in different phases of the care process, different types of kidney diseases could also be studied and visualized with experience maps. In addition, the next versions of the kidney disease experience maps could focus on specific days and months. The next versions of the kidney disease experience maps could also be created from the health care team's perspective.

The content of the first version of the kidney disease experience map was collected with qualitative research methods, which made the consideration of the many different nuances possible. Due to the qualitative nature of the data collection for the first version of the kidney disease experience map, we did not prioritize the available content, for example, based on the amount of the post-it notes. However, without careful prioritization, there is always a risk that the map is too challenging to use as a part of the practical software development work. Therefore, we will involve the patients, as well as the health care team, designers, and software developers, in prioritizing the content of the map in the future.

The perspectives of patients using in-center dialysis are missing from that data, which was the base of the first version of the kidney disease experience map. However, we believe the creation of experience maps for the eHealth needs of patients using in-center dialysis is important for the future as the dialysis modalities might change depending on the patient's health and life situation.

Our study pointed out the need for further research on the existentialism perspectives of the patients with chronic illnesses using eHealth. Deeper understanding is required on user needs and the role of eHealth as a part of patients' everyday lives, even when life is nearing its end [50-52].

Conclusions

eHealth offers possibilities to support the key needs of patients with chronic diseases, such as CKD; however, digital services need to adapt to a wide variety of situations and user needs because kidney diseases are unique to each patient. Patient experiences vary both between and within the stages of treatment. In addition, the patient's situation, needs, and capacity to use eHealth vary with everyday challenges and opportunities. Furthermore, with older adult patients, the problems that come with age increase the spectrum of barriers to use eHealth and associated challenges.

eHealth should enable proactive communication between the patient and the health care team. Furthermore, awareness of the status should be formed for both parties in real time, as much as possible. In this way, the patients feel safe, are more motivated in their treatment, and take responsibility for themselves.

The experience map is a promising method for illustrating user needs for eHealth, communicating a patient's voice and describing the longitudinal patient journey to support eHealth development. Our first version of the kidney disease experience map combines people, context of use, and technology perspectives holistically and illustrates the eHealth needs of patients with CKD for the future.

Acknowledgments

The project eHealth in Home Dialysis was part of the CleverHealth Network ecosystem and the project (eCare for Me Homedialysis) was funded by participating companies, the Hospital District of Helsinki and Uusimaa, and Business Finland. We thank our project partners Tiina Puurtinen and Pirgit Silvast-Äikäs from Helsinki University Hospital and Malin Ekholm from Helsinki University, and the patients who participated in this study.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the ethical reasons as stated in the research permit application.

Authors' Contributions

The study was conceptualized by PV, SL, SH, NK, VR, and JV. Data were collected by five researchers (PV, SH, SL, NK, and JV). PV, SL, and SH were involved in the methodology, investigation, project administration, data curation, visualizations, and formal analysis of the study. PV finalized the experience map. JV contributed to the resources, validation, supervision, project administration, and funding acquisition of the study. VR contributed to funding acquisition, project administration, resource collection, supervision, and results' validation. All authors were involved in writing, reviewing, and editing the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Telehealth has grown, especially during the COVID-19 pandemic, improving access for those in remote or underserved areas. However, its implementation faces technological, practical, and interpersonal barriers.

Objective: The aim of this study was to identify and consolidate best practices for telehealth delivery, specifically for video call sessions, by synthesizing the insights of health care professionals across various disciplines.

Methods: We first identified 15 common telehealth barriers from a preceding scoping review. Subsequently, a modified Delphi method was used, involving 9 health care professionals (physiotherapists, speech and language therapists, dietitians, and midwife) with telehealth experience in qualitative interviews and 2 iterative rounds of web-based surveys to form consensus.

Results: This study addressed 15 telehealth barriers and identified 105 best practices. Among these, 20 are technology-related and 85 concern health care practices. Emphasis was placed on setting up telehealth environments, ensuring safety, building relationships and trust, using nonmanual methods, and enhancing observation and assessment skills. Best practice recommendations for dealing with patients or caregiver skepticism or lack of telehealth-specific knowledge were developed. Further, approaches for unstable networks and privacy and IT security issues were identified. Areas with fewer best practices were the lack of technology skills or technology access, unreliability of hardware and software, increased workload, and a lack of caregiver support.

Conclusions: This guide of best practices serves as an actionable resource for health care providers to navigate the complexities of telehealth. Despite a small participant sample and the potential for profession-specific biases, the findings provide a foundation for improving telehealth services and inform future research for its application and education.

telehealth; best practices; video call; Delphi study; health communication; barriers; health care professionals; qualitative interviews; web-based survey; physiotherapists; speech therapists; language therapists; dietitians; midwife

Introduction

Video call–based telehealth refers to the use of information and communication technologies to deliver health care services remotely and synchronously, bridging the gap between patients and health care providers [1]. Over the past few years, telehealth has seen an increase in adoption due to its potential to improve access to health care services, particularly for individuals living in rural or remote areas [2]. The COVID-19 pandemic has further accelerated this trend, as the need for remote health care solutions to reduce the risk of infection transmission has become more urgent [3]. As a result, telehealth has emerged as an essential part of modern health care delivery, offering new opportunities and challenges for both patients and health care providers.

Telehealth has the potential to offer numerous advantages and benefits for patients, health care providers, and the overall health care system. Benefits summarized in previous reviews include, for example, increased access and convenience, cost savings, improved family involvement, and better management [4]. Increased access refers particularly to individuals living in remote or underserved areas [2], as well as to those with mobility limitations or chronic conditions that require frequent monitoring [5]. Furthermore, telehealth enables patients to receive care from the comfort of their own homes, reducing the need for travel and waiting times associated with in-person appointments and providing a more convenient way of service provision [6]. By reducing travel costs, decreasing hospital readmissions, and minimizing the need for in-person consultations, telehealth might also have the potential to reduce health care costs for both patients and providers [7,8].

Despite its numerous advantages, telehealth also faces several challenges and barriers that can hinder its successful implementation. Recent studies and reviews have highlighted various obstacles to delivering care via real-time video consultations. These include technical issues such as unstable internet connectivity [4,9,10], lack of technology skills among both patients and providers [4,9,11], and concerns over privacy and data security [9,12]. Moreover, health care professionals have reported challenges in establishing rapport and trust with patients via video call [9,11], and there exists skepticism about the effectiveness of remote care compared to in-person sessions [9]. Addressing these barriers is especially critical when considering the rapid shift to telehealth prompted by the COVID-19 pandemic, which has underscored the potential benefits of video consultations but also exposed the need for clearer guidelines to ensure quality of care [9,13]. Despite growing evidence on these challenges, the literature lacks a comprehensive set of actionable best practices to mitigate barriers associated with video consultations. This study therefore aims to fill that gap by drawing on multiple health care disciplines and using a modified Delphi process to achieve expert consensus on best practices to maximize the potential benefits of video call–based telehealth for patients, health care providers, and the overall health care system [14].

Methods

Overview

In this study, we used a modified Delphi method [15] to identify best practices to overcome common barriers in video call–based telehealth. The reporting follows the proposed Delphi reporting guideline by Spranger et al [16].

Research Paradigm

The epistemological positioning of this study is based on a pragmatic paradigm that recognizes the value of diverse viewpoints and the importance of practical solutions to real-world problems. Pragmatism has been identified as relevant and useful for qualitative research on organizational processes [17], as well as in patient-oriented research [18]. This approach also aligns with the goals of the modified Delphi method, which aims to synthesize expert knowledge into actionable best practices. It acknowledges the dynamic and iterative nature of knowledge creation and embraces subjective experiences to address the complex challenges of telehealth implementation.

Study Design

Our modified Delphi method was characterized by 2 main adaptations to the traditional Delphi process. First, we used preliminary expert interviews to gather an initial pool of best practices. These interviews guided the development of a list of 131 practice statements and 15 barriers, which were then presented to the expert panel for rating. Second, our survey structure diverged from a classic Delphi by using (1) a 4-point Likert scale and (2) an additional response option “This practice is not relevant for my profession.” This allowed professionals from various health care disciplines to opt out of rating statements they found inapplicable. We also set specific thresholds for acceptance (≥80% agreement after round 1; ≥75% agreement after round 2) to ensure each item reached a robust consensus without necessitating a third round. These modifications provided a more streamlined approach and helped account for the diverse professional backgrounds of the participants and time and resource limitations.

Recruitment

We recruited participants via a combination of email invitations, professional social media groups, and a snowball sampling strategy. Known telehealth practitioners were first contacted directly by the research team and then invited to share the invitation within their professional networks. To ensure broad representation across allied health professions, we distributed the study invitation to professional associations and specialized digital communities. To be eligible, participants had to (1) have at least 2 years of professional experience in a non-physician health care field (eg, nursing, dietetics, occupational therapy, speech-language therapy, physiotherapy, orthoptics, or

midwifery), (2) have delivered a minimum of 10 video call–based telehealth sessions in the preceding quarter, and (3) have excellent German language proficiency. All participants were given detailed information about the study objectives, procedures, and time commitments.

Participants

A total of 9 health care professionals (4 physiotherapists (PTs), 3 speech and language therapists (SLTs), 1 dietitian, and 1 midwife) were purposively recruited based on their experience with telehealth. All participants were licensed and currently practicing health care professionals with at least 2 years of experience in their field. They each had conducted a minimum of 10 video-based telehealth sessions in the preceding quarter and practiced in an area where telehealth is applicable. Their professional experience ranged from 2 to 32 years, and encompassed diverse health care settings such as neurorehabilitation, musculoskeletal care, adults, and pediatric care, bariatric medicine, mixed practice settings, respiratory therapy, independent midwifery, and pelvic health. In total, 4 panelists were female and 5 were male.

Interviews

The expert interviews were conducted using Zoom videoconferencing software (Zoom Video Communications) in September 2022. Specifically, 4 interview sessions took place: 3 small-group focus groups and 1 individual interview. Focus group 1 included 2 PTs and lasted 1 hour 34 minutes; focus group 2 included 2 SLTs and lasted 1 hour 3 minutes; and focus group 3 included 2 PTs, 1 SLT, and 1 dietitian, lasting 1 hour and 32 minutes. The one-on-one interview was conducted with a midwife and lasted 29 minutes. We used a semistructured interview guide to help focus the discussions, which was based on commonly reported barriers with video call–based telehealth, found in the existing research for these health care fields (Multimedia Appendix 1). All interviews were conducted by the lead author (LR), who is experienced in qualitative research methods and trained in facilitating interviews and focus groups.

The barriers discussed during the expert interviews were identified through a preceding scoping review [9]: Lack of technology access, unstable internet connections, lack of privacy & IT security, lack of technology skills, unreliability of hardware and software, reluctance of patients or caregivers to use telehealth, decreased establishment of relationships and trust, decreased validity of observations and assessments, lack of hands-on methods, decreased quality and effectiveness, lack of telehealth training, increased workload, lack of support for patients from caregivers, increased safety risks for patients, and unsuitability of setting for telehealth. Experts were asked to provide insights and best practices for addressing these barriers, based on their experience.

Each interview was transcribed verbatim by the lead author (LR) with support from an automated transcription software. After automated transcription, LR reviewed the transcripts to ensure accuracy and fidelity to the original recordings. The final transcripts were analyzed using qualitative content analysis, following the framework proposed by Kuckartz and Rädiker [19]. The first author (LR) conducted the initial deductive coding by extracting passages that contained strategies for overcoming telehealth barriers. These excerpts were then assigned to the corresponding barriers. For each identified strategy, the main characteristics and essential elements were extracted to form a clear and actionable statement. To enhance the reliability of the coding, the research team engaged in multiple team rounds to discuss the initial findings. During these sessions, the team identified similarities across different strategies, combined overlapping or related strategies to reduce redundancy, and formulated precise statements that accurately captured the essence of each strategy. Through iterative discussions, codes were refined and adjusted to better represent the data, thereby enhancing the credibility of the findings.

Ethical Considerations

Prior to participation, all individuals provided informed consent, thereby ensuring ethical compliance and voluntary engagement in the study. The ethics committee confirmed the adherence to ethical principles, and an ethical approval was not required as the study involved only expert consultations without collecting or processing sensitive patient data. All participants gave informed consent, and data collection did not involve patient data. The Ethics Committee for Research Activities of FH Campus Wien, University of Applied Sciences, confirmed that no formal approval was needed for this study (EK 243/2025). The participants did not receive any financial compensation.

Delphi Rounds

Following the qualitative interviews, we conducted Delphi rounds to achieve expert consensus on best practices for video call–based telehealth. The Delphi process was carried out in 2 rounds. Round 1 was initiated at the beginning of November 2022 and remained open for 2 weeks. During this round, panelists received a web-based survey containing a demographic data section, including name and profession, and 15 sections on barriers and corresponding strategies. Round 2 was conducted at the end of November and beginning of December 2022, also open for 2 weeks. In this round, panelists were presented with a survey of 11 sections with the remaining best practices that were lacking consensus.

Barriers

Barriers were rated for their perceived magnitude (1=very small barrier, 2=rather small barrier, 3=rather big barrier, 4=very big barrier) in round 1. Frequency distributions were calculated to determine the perceived magnitude of each barrier among panelists. These results serve to contextualize the forthcoming best practice recommendations.

Analysis of Best Practices

Best practices, on the other hand, were rated for their perceived helpfulness (1=not helpful, 2=rather not helpful, 3=rather helpful, 4=very helpful). In recognition of the diverse professional backgrounds of the panelists, the survey items included an additional response option: “This practice is not relevant for my profession.” Additionally, the survey invited the panelists to contribute further comments and propose new best practices not previously covered, thereby contributing to a more comprehensive dataset.

Response percentages were calculated, and the perceived helpfulness of each practice was quantified using frequency distributions for each response category. Following the first survey round, any practice that received a "helpful" or "very helpful" rating from ≥80% of participants and elicited no comments was automatically included in the final guide. Practices with ratings between 50% and 79% or those that received substantive comments moved on to the second round for reevaluation. Regarding practices rated "helpful" or "very helpful" by <50% of participants, we weighed the risk of prematurely discarding potentially relevant items against the need to maintain focus on practices demonstrating at least a minimal level of acceptance by the panel. After careful consideration, the study team decided to exclude these practices immediately following round 1, rather than carrying them forward. However, participants were given opportunities to propose modifications or new practices at the end of each round, ensuring that any critical practice could be reintroduced or reframed if panelists believed it had merit. The research team discussed all received comments and considered if any rephrasing based on the comments should be made. In case the comments led to a rephrasing of a best practice, both the original and revised versions were presented in the second round for further evaluation. During this round, panelists were provided with the remaining best practices along with the percentage of previous agreement and anonymized comments for each best practice in December 2022. Participants were offered 2 response options: "This practice should be included in the best practice guide" or "This practice should not be included in the best practice guide." When 2 variations of a practice were presented, panelists could select their preferred version or "none of both." Practices that carried over from round 1 required at least 75% agreement among participants to be included in the final best practice guide [20]. This slightly lower threshold accounted for the fact that these practices already showed moderate support or warranted further discussion due to comments. In case 2 versions of a best practice existed, the version receiving the higher preference was selected.

Results

Barriers and Best Practices

The qualitative content analysis on the expert interviews yielded a total of 422 coded text segments. From this process, an initial set of 131 practices was developed. The association of the practices with the discussed barriers can be found in Table 1, and the perceived importance of the 15 presented barriers is shown in Figure 1.

In the first Delphi round, 108 practices exceeded the 80% approval threshold for perceived helpfulness; 83 of these practices had no comments and were therefore included directly. In total, 48 practices met the criteria to proceed to the second round: 23 practices rated as "very helpful" or "helpful" by 50%-79% of the experts; 18 without changes but with comments from the first round; and 7 practices with alternative revision based on comments. One entirely new strategy was introduced (Figure 2). Upon completion of the second round, the final best practice guide emerged with 105 practices, covering practices addressing 5 technology barriers and 10 practical barriers (Table 2 and Textbox 1).

In total, we identified 105 best practices addressing 15 telehealth barriers, with 20 aimed at technology challenges and 85 focused on practice issues.

Table 1. Demographic characteristics of the panelists.

Panelist number	Gender	Profession	Years of professional experience	Professional experience
1	Male	Physiotherapist	15	Orthopedics, traumatology, neurolrehabilitation
2	Male	Physiotherapist	3	Orthopedics, musculoskeletal, training
3	Female	Speech and language therapist	20	Swallowing disorders, functional voice disorders
4	Female	Speech and language therapist	2	Childhood speech development disorders
5	Male	Physiotherapist	32	Orthopedics, respiratory therapy
6	Female	Dietitian	4	Bariatrics
7	Male	Speech therapist	2.5	General speech therapy, respiratory therapy
8	Female	Physiotherapist	20	Pelvic floor therapy
9	Female	Midwife	28	Birth preparation, support, and aftercare

Figure 1. Panelists' (n=9) perceived magnitude of the 15 barriers presented (bars represent absolute frequencies).

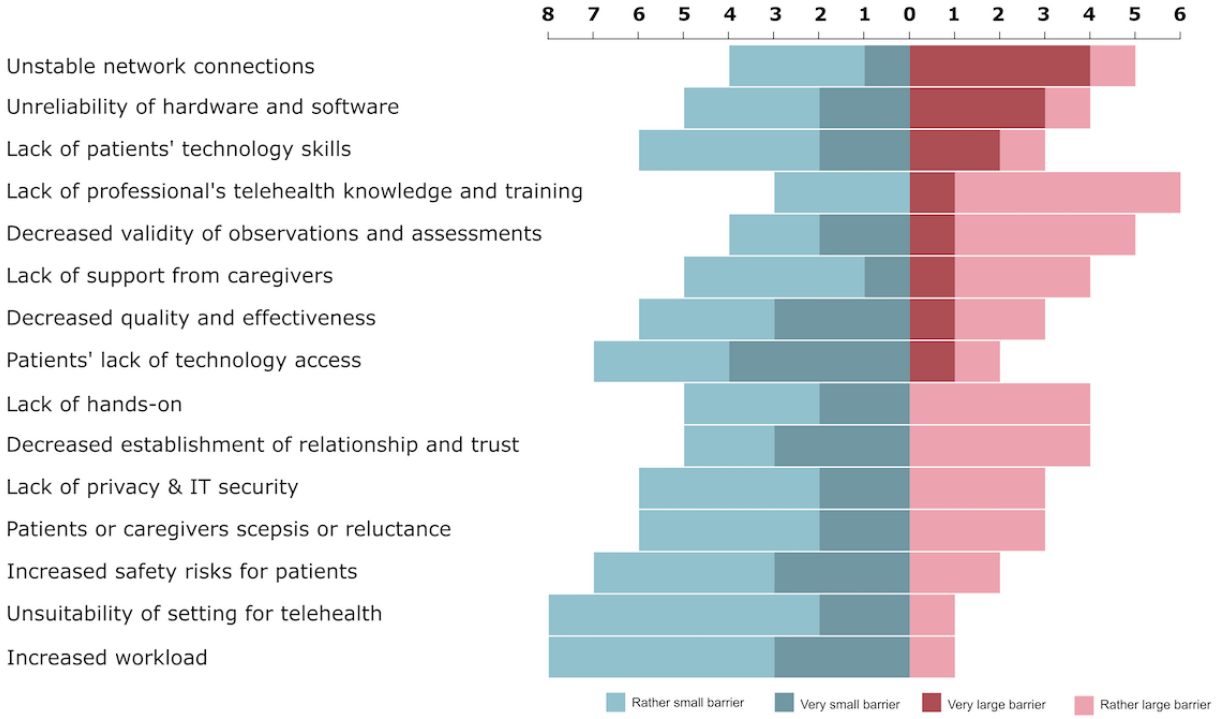

Figure 2. Flowchart of the Delphi process.

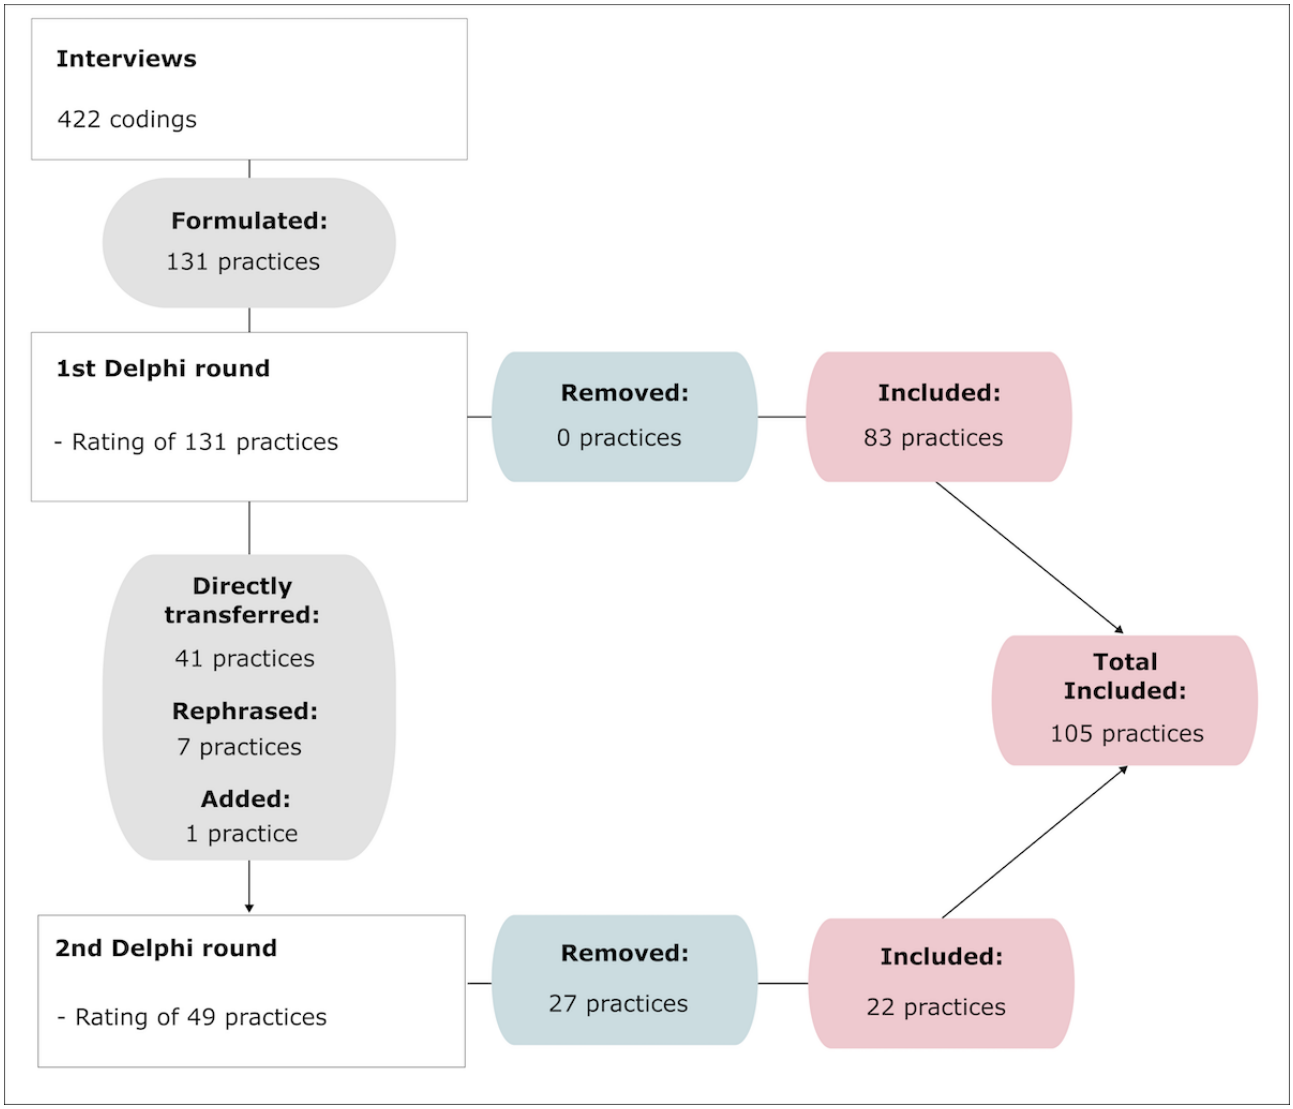

Table 2. Number of best practices for each presented barrier.

Barrier	Number of practices after expert interviews	Number of practices, included after round 1	Number of practices included after round 2	Final number of practices
Technology barriers				
Unstable network connections	9	3	3	6
Unreliability of hardware and software	4	1	1	2
Lack of technology skills	6	2	2	4
Lack of privacy and IT security	7	2	3	5
Lack of technology access	3	0	3	3
Health care practice barriers				
Lack of professional's telehealth knowledge and training	8	6	0	6
Decreased validity of observations and assessments	13	8	2	10
Lack of support from caregivers	3	1	0	1
Lack of hands-on	11	7	3	10
Reluctance of patients or caregivers to use telehealth	8	5	2	7
Decreased establishment of relationship and trust	11	9	1	10
Decreased quality and effectiveness	10	9	1	10
Increased safety risks for patients	13	10	1	11
Unsuitability of setting for telehealth	21	18	0	18
Increased workload	4	2	0	2
Sum total	131	83	22	105

Textbox 1. Best practice guide for barriers to telehealth via video call.

Best practices to address technology barriers

A. Unstable network connections

1. Every participant should choose a location with a stable network connection for video call sessions. This should be communicated to the clients in advance.
2. Other devices, persons, or activities should not use the same network connection during the video call session.
3. In case of an unstable network connection, the device may be exchanged.
4. In case of an unstable network connection, switching off the camera for a short time could help.
5. In case of network disconnection, the client should be informed about further steps by telephone (full agreement from all participants).
6. In case of audio transmission problems, an additional phone connection can be used.

B. Unreliability of hardware and software

1. The video call software used should be installed and tested in a timely manner by all participants before the start of the session.
2. If clients experience technical issues, possible solutions can be discussed and solved directly during the video call session or via telephone (full agreement from all participants).

C. Lack of technology skills

1. Health care professionals should gain digital literacy skills in using different devices and video call software, as this can help in solving common technical problems encountered by patients (full agreement from all participants).
2. For technically non-proficient individuals, user-friendly video call software should be selected. Getting started via a direct link without prior installation should be favored (full agreement from all participants).
3. Telephone support can help inexperienced individuals get started with video call software (full agreement from all participants).
4. As required, the operation of the video call software can be supported at the beginning or ongoing by relatives or other persons on site.

D. Lack of privacy & IT security

1. Software used should ensure encrypted data transmission (full agreement from all participants).
2. One's own decisions regarding the handling of client data should be made and communicated in accordance with current data protection laws.
3. Written consent from clients should be obtained in advance.
4. When using video call software, access should only be possible for invited individuals (full agreement from all participants).
5. If software has not been recommended by a certification body for use in health care, it should be reviewed concerning its data processing.

E. Lack of technology access

1. Providing a checklist of minimum technical requirements for video call sessions can optimize conditions in advance.
2. Availability of equipment should be confirmed prior to the beginning of the session.
3. For sessions that focus on visual demonstration or perception, it is recommended to use a device with a large, high image quality screen.

F. Lack of telehealth knowledge and training

1. Watching video call software tutorials can provide information on available functions and give confidence in handling.
2. Learning by doing can help to gain confidence in conducting video call sessions.
3. A test run with individuals from the private environment can provide confidence in using the technology (full agreement from all participants).
4. Materials for use in video call sessions can be researched on the internet (full agreement from all participants).
5. Reading current articles on the topic of telehealth can increase knowledge (full agreement from all participants).
6. Exchanging experiences with colleagues about the use of video units can expand one's own repertoire (full agreement from all participants).

G. Decreased validity of observations and assessments

1. Important assessments should be conducted in a supplementary face-to-face unit if specific information cannot be gathered via a video call session.
2. Clients should be informed that their clothing of choice should allow detailed observations of the body (full agreement from all participants).
3. Cameras should be positioned in a way that enables a stable image (full agreement from all participants).

4. Detailed and guided instructions on how to position the body or involved body parts in front of the camera should be given to ensure high-quality observations (full agreement from all participants).
5. The background should provide visual reference points for guiding and observing movements.
6. The observation quality of details can be improved by moving the corresponding body section closer to the camera (full agreement from all participants).
7. The observation quality of details can be improved with targeted lighting (full agreement from all participants).
8. Assessments can be adapted with the help of using objects in the client´s room during video call sessions (full agreement from all participants).
9. Increased attention should be given to small nonverbal signals of the clients.
10. Involving self-observation and self-perception of clients can supplement limited on-screen observation possibilities (full agreement from all participants).

H. Lack of support from caregivers

1. Ensuring that a support person is within reach can help to run a video call session smoothly (full agreement from all participants).

I. Lack of hands-on

1. Education about functional deficits and how to deal with them in everyday life should be emphasized in video call sessions.
2. Training self-awareness and empowering clients in their self-efficacy can be part of video call sessions to achieve lasting effects (full agreement from all participants).
3. Proven effectiveness of therapy interventions aiming at lifestyle modifications should be explained to clients (full agreement from all participants).
4. Exercises that can be performed by the clients independently should be selected (full agreement from all participants).
5. Exercises should be guided verbally in such a manner that they can be understood even if visual guidance is limited (full agreement from all participants).
6. In advance, material needed for the video call session should be communicated to the clients or relatives, and it should be prepared in a timely manner (full agreement from all participants).
7. Selected self-treatments can be taught to clients during the video call session (full agreement from all participants).
8. Clients should be given specific advice for performing self-control of guided exercises (full agreement from all participants).
9. Clients' self-awareness can be promoted by feeling movements or structures with their own hands, wherein possible misinterpretations should be considered.
10. Material required for a video call session should be communicated in advance with clear information, for example, on size, quantity, and weight.

J. Patients or caregivers scepsis or reluctance

1. Clients can be offered a combination of presence and video call sessions (full agreement from all participants).
2. It can be explained to skeptical clients that some therapy content is suitable for video call sessions, others not (full agreement from all participants).
3. Demonstrating video call software and discussing a possible video call session can reduce insecurities and help with decision-making.
4. A single video call session for familiarization can be offered to skeptical clients, followed by a discussion about the experience and further procedure.
5. After a few face-to-face sessions, video call sessions can be suggested again.
6. Involving relatives or the social environment can be facilitated with video call sessions.
7. The reduction of travel and increase in time flexibility can be used as an argument for using video call sessions.

K. Decreased establishment of relationship and trust

1. Authenticity and professionalism can be conveyed through conscious design choices and insight into the premises in the background (full agreement from all participants).
2. Optimally adjusted lighting of one's face can create a friendly atmosphere and convey mimic information well (full agreement from all participants).
3. A well-adjusted camera angle and optimal positioning in front of the screen support communication on an equal footing (full agreement from all participants).
4. Facial expressions and gestures during a video call session should be used consciously (full agreement from all participants).
5. Since real eye contact is not possible via the screen, this can be imitated by consciously looking into the camera.
6. Maintaining one's own appearance can promote authenticity in front of the camera (full agreement from all participants).
7. Conscious choice of clothing supports the professional appearance.

8. Seeing one's own camera image can be used as feedback about one’s own appearance (full agreement from all participants).
9. Framing a video call session with introductory words and a deliberate end can provide orientation (full agreement from all participants).
10. Spontaneous playful elements and humor can loosen up video call sessions and promote the relationship (full agreement from all participants).

L. Decreased quality and effectiveness

1. Clients who can benefit from video call sessions should be selected purposefully (full agreement from all participants).
2. The limitations of video call sessions for certain medical conditions should be clearly communicated to clients (full agreement from all participants).
3. The use of video call sessions should be evaluated regularly and adjusted if necessary.
4. Strategies to ensure whether elements learned in the session can be implemented independently should be used.
5. Video call sessions can be used to maintain a regular appointment frequency (full agreement from all participants).
6. By collecting relevant health parameters at the beginning and the end of the session, the effectiveness of treatment interventions can be evaluated.
7. At the beginning of a video call session, expectations should be gathered. At the end they should be compared with the session's content and success.
8. The role of relatives in the treatment process can be strengthened through targeted counseling during video call sessions.
9. By setting a clear focus and sequence for the video call session and individualizing the duration, one’s ability to focus can be considered (full agreement from all participants).
10. The video call session should take place during a time of the day when clients have a good ability to focus (full agreement from all participants).

M. Increased safety risks for patients

1. Clear exclusion and termination criteria for video call sessions for clients with safety-critical characteristics should be established and adhered to (full agreement from all participants).
2. Competent relatives can increase clients’ safety.
3. For video call sessions with children, a legal guardian should be present at the child's side (full agreement from all participants).
4. Clients or family members should be educated about making the environment as safe as possible to reduce potential hazards such as tripping, falling, or slipping (full agreement from all participants).
5. Client’s pets that may interfere with free movement in the room should be kept out of the client's room during video call sessions.
6. Exercises instructed via video call sessions should be chosen according to clients' abilities (full agreement from all participants).
7. Video call sessions should not include unfamiliar exercises that may jeopardize client safety.
8. Exercise difficulty should be increased only step by step, adapted to the client (full agreement from all participants).
9. In case of uncertainties regarding perceived health parameters, referral to specialists should be made (full agreement from all participants).
10. In psychologically tense situations, one’s own voice can serve as an instrument for calming down (full agreement from all participants).
11. The daytime of the video call session, and therefore a potentially limited suitability of certain measures, should be taken into consideration.

N. Unsuitability of setting for telehealth

1. A quiet room without distractions should be chosen for video call sessions (full agreement from all participants).
2. Background noise from people, pets, or household equipment should be reduced (full agreement from all participants).
3. For video call sessions, a room with good sound quality and reduced hall should be chosen (full agreement from all participants).
4. The speaker used should be tuned sufficiently loud (full agreement from all participants).
5. Balanced lighting conditions allowing good contrasts should be selected (full agreement from all participants).
6. Devices should be positioned stable to not produce blurry images (full agreement from all participants).
7. If a tablet or smartphone is used, it should be positioned at a 90-degree angle to the surface with a suitable mount (full agreement from all participants).
8. Clients should be guided in the optimal camera setup and positioning in front of it (full agreement from all participants).
9. The camera section should be chosen so that only things that one is willing to share are visible in the background (full agreement from all participants).
10. Other people in the household or work premises should be informed that a video call session is taking place to ensure privacy (full agreement from all participants).
11.

It should be discussed with the clients in which area of their premises the video session will take place in order to avoid the concern of giving insight into things they want to keep private (full agreement from all participants).

12. Windows and doors should be closed.
13. High-quality microphones and headphones can improve acoustic transmission.
14. Advice should be given on how to use built-in or external microphones to ensure good transmission and avoid noise interference.
15. Doors in the camera's field of view should be avoided to prevent unwanted privacy intrusion.
16. A dedicated therapy location—for example, at a table—can promote attention and concentration.
17. Marking one or more places where the camera is well positioned facilitates a sustainably working set-up.
18. If the video call session involves movement across the room, a flexible camera setup for rapid changes should be facilitated.

O. Increased workload

1. Using quick-to-use treatment or exercise methods that require little pre-planning and explanation can reduce preparation time.
2. By combining preparation time for several video units, one's own working time can be used efficiently.

Best Practices to Address Technology Barriers

In total, 20 best practices were selected by the participants to address the barriers of unstable network connections, unreliability of hardware and software, lack of technology skills, lack of privacy and IT security, and lack of technology access (A-E in Textbox 1). For optimal video call sessions, each participant should ensure a stable network connection, free from other devices and activities that might compete for bandwidth. When issues such as an unstable connection arise, switching devices, temporarily turning off the camera, or making a phone call can provide continuity and effective communication. Participants should install and test the video call software well before the session, with technical issues being addressed directly during the call or via telephone if necessary. Health care professionals should develop digital literacy for various devices and software to assist patients with technical issues. For less tech-savvy individuals, user-friendly software with direct links, telephone support, as well as on-site help from relatives, can facilitate the use of video call applications. To ensure data privacy and security, video call software must encrypt data transmission and comply with data protection laws. Informed consent should be obtained from users, and access should be restricted to invited participants. If software has not been recommended by a certification body for use in health care, it should be reviewed concerning its data processing. To optimize video call sessions, a checklist of technical requirements should be provided, and equipment availability should be confirmed beforehand. For visually intensive sessions, a high-quality large screen is recommended.

Best Practices to Address Health Care Practice Barriers

Overall, 85 best practices addressed practice issues such as lack of telehealth knowledge and training, decreased validity of observations and assessments, lack of support from caregivers, lack of hands-on, patients or caregivers scepsis or reluctance, decreased establishment of relationship and trust, decreased quality and effectiveness, increased safety risks for patients, unsuitability of setting for telehealth, and increased workload (F-O in Textbox 1).

Reviewing current telehealth publications and internet resources to search for material to use in telehealth sessions, as well as watching software tutorials, can enhance proficiency and confidence in conducting video call sessions, complemented by practical experience and sharing knowledge with colleagues.

For comprehensive assessments in telehealth, certain procedures may need to be supplemented with in-person visits. Clients should be guided on how to prepare for video sessions with appropriate clothing, camera positioning, lighting, and background setup to enhance the quality of observations. Additionally, using objects for adapted assessments, paying attention to subtle nonverbal cues, and involving clients in self-observation can maximize the efficacy of remote evaluations. Having a support person readily available can facilitate a smooth video call session.

In video call sessions, educating clients on functional deficits and self-management in daily life is crucial, with a focus on training self-awareness and self-efficacy for sustainable outcomes. For effective video call sessions, exercises that clients can perform independently should be chosen, and clear verbal guidance for exercises with limited visual cues should be given. This can be added with the training of self-treatments, advice for self-control during exercises, and the promotion of clients' self-awareness through tactile experiences while addressing potential misinterpretations. Clear communication and preparation of materials is necessary.

To address skepticism, clients can be offered a blend of in-person and video call sessions, emphasizing the suitability of certain therapy contents for remote delivery, with demonstrations and trial sessions helping to alleviate skepticism and showcasing the convenience and flexibility that video calls offer. To convey professionalism and authenticity in video calls, one should make deliberate design and setting choices, ensure optimal lighting for a friendly atmosphere, and use a camera angle that supports equitable communication. Conscious use of facial expressions, gestures, and clothing, along with looking into the camera to simulate eye contact, enhances authenticity. Additionally, framing the session with a clear beginning and end, along with the use of humor, can improve the interaction.

Purposeful selection of clients for video call sessions is essential, with transparent communication regarding their limitations for certain conditions. Regular evaluations should be conducted to assess effectiveness and determine if expectations are being met. Strategies to ensure whether elements learned in the session can be implemented independently should be used. Sessions should be structured in a way that they have a clear focus and sequence, an appropriate duration, and are scheduled for when the client's focus can optimize the session. Incorporating relatives into the treatment process via video call sessions can provide targeted counseling. Establishing clear criteria for excluding or terminating video call sessions is vital for clients with safety-critical concerns. Competent relatives can enhance safety. Guardian presence for children, safety education, and gradual exercise progression can ensure the clients' well-being during remote sessions.

For effective video call sessions, it is essential to choose a quiet room with as little background noise as possible, ensuring good sound quality and balanced lighting. Proper camera setup, privacy considerations, and guidance on microphone use enhance the session quality. Additionally, creating a dedicated therapy location and facilitating flexible camera setups can improve the overall experience and engagement during sessions. Efficient use of time in video sessions can be achieved by opting for quick and easy treatment methods and combining preparations for multiple video units.

Discussion

Principal Findings

The findings from this study, which encompassed expert interviews and a modified Delphi process, provide a best practice guideline for telehealth in health care. The key results underscore the importance of addressing the challenges of technology accessibility, enhancing observations and assessments, creating a professional setup, building relationships and trust, and ensuring privacy and IT security. Although the majority of the panelists were PTs and SLTs, their combined professional experiences—spanning areas such as neurorehabilitation and pediatric care—have facilitated a comprehensive exploration of these practices across various health care settings, thereby complementing the aims and findings of previous studies and guidelines [21-25].

The best practice guideline offers a starting point towards a unified guide to improve telehealth across various health care settings. Prior publications have established telehealth frameworks in disciplines such as occupational therapy, physiotherapy, and speech and language therapy [21-24], which partially align with our findings. A high level of agreement is seen in these existing frameworks, particularly regarding fundamental principles of telehealth delivery. However, there remain clear gaps in the current literature on how to manage these barriers through concise best practice statements [24]. Grogan-Johnson [25] discusses the challenges of maintaining engagement in virtual settings but provides limited guidance on how to address this. Our best practice guide suggests trust-building strategies, such as non-verbal communication enhancements, environmental adjustments, and interactive session structuring. Davies et al [13] outline the importance of technological proficiency for PTs but do not provide detailed practices for managing unstable networks or unreliable hardware, where our study adds explicit recommendations for overcoming technological challenges, including strategies for low-bandwidth settings, selecting robust hardware, and providing patient education on basic troubleshooting. Other studies limit their focus to specific populations or pathologies [22,25]. Cottrell and Russell [22], for instance, provide an in-depth analysis of pre-implementation considerations and practical steps specifically within the domain of musculoskeletal physiotherapy. Their work examines technological and operational challenges, offering targeted strategies to enhance the successful deployment of telehealth services. Other guidelines have delineated key technical principles health care professionals are expected to follow to ensure a smooth and secure telehealth experience [26,27], focusing on adherence to laws and regulations and the implementation of privacy and security measures. Our study extends these principles by proposing practical, applicable strategies and emphasizes dual-focused education, targeting both health care providers and patients. It includes specific methods to address skepticism and enhance digital literacy, particularly for populations unfamiliar with telehealth.

Notably, our research revealed a strong consensus on the effectiveness of specific strategies across health care settings, such as providing detailed technical guidelines, enhancing visual and audio components of telehealth sessions, and incorporating elements that foster a sense of connection and trust between health care providers and clients. These findings offer new insights into the practical implementation and adaptation of telehealth services in diverse health care contexts.

In examining the distribution of best practices identified to address various barriers, we found notable differences. "Unsuitability of setting for telehealth" yielded the largest set of best practices despite being rated as a relatively small barrier. This contrast likely arose because many aspects of the setting (eg, lighting, device positioning, noise reduction) are easily modified by health care professionals. These direct, practitioner-driven solutions help frame the barrier as "small," in that it can be quickly addressed through practical steps. In other words, the perception of a barrier's magnitude may reflect how empowered providers feel to remedy it: settings are simpler to adjust, whereas more systemic issues (eg, workload, limited technology access) require external interventions and may thus seem more significant.

Additionally, a significant collection of best practices has been identified to address practical implementation barriers such as "increased safety risks for patients," "decreased validity of observations and assessments," "lack of hands-on," "decreased establishment of relationship and trust," and "decreased quality and effectiveness." These best practices provide pragmatic strategies to navigate the range of challenges presented by telehealth, ensuring a higher standard of patient care and treatment integrity. On the other side, there were barriers that received fewer best practices to address them, such as "lack of support from caregivers" and "increased workload," both at the lower end, with 1 and 2 identified best practices. These issues

likely require organizational or systemic changes that are beyond the immediate control of the individual practitioner. Similarly, "lack of technology access" and "unreliability of hardware and software" are countered by only 3 best practices each, possibly indicating a gap between the technological requirements of telehealth and the ability of health professionals to influence these parameters.

Reflections on the Delphi Method

Our modified Delphi approach relied on 2 rounds, underpinned by preliminary interviews that generated a well-defined set of barriers and best practices. This groundwork contributed to a high level of initial consensus—83 of 108 items achieved ≥80% agreement in round 1. While we acknowledge that time constraints and difficulty finding sufficient participants limited the scope of our panel (n=9), each participant brought substantial experience: all met strict inclusion criteria (eg, minimum 2 years' professional practice, at least 10 video-based telehealth sessions in the previous quarter), ensuring specialized and recent expertise.

We employed a 2-threshold system: items achieving ≥80% agreement in round 1 were immediately included, while items carried forward required ≥75% agreement in round 2. This tiered approach balanced efficiency and adaptability by refining practices with moderate support without burdening participants with repeated rounds. Items garnering <50% agreement were excluded after round 1, given their limited traction; however, participants could introduce revisions or propose new items if they felt critical information was overlooked. Although this may appear stringent, it enabled us to produce a focused, consensus-driven guide for reducing barriers to video call–based telehealth within the time and resource constraints of our project.

While our study does not claim to capture every possible facet of telehealth across all health care contexts, the methodology employed aligned with recommended standards.

Limitations

This study still has several limitations that need to be acknowledged. First, the sample size was small, consisting of only 9 eligible experts in specific health professions. Our participant sample was relatively small, yet it was purposefully recruited to encompass diverse professional backgrounds and extensive telehealth experience. This approach generated a robust consensus on best practices for video call–based telehealth. Future studies with larger or more varied panels could further enhance and validate the findings, but our current methods provide a strong foundation for ongoing research and practical implementation. Second, the heterogeneity of the participants' professions may be both an advantage and a disadvantage. On the one hand, it allowed for a broader range of perspectives and strategies to be considered than if we would have focused on only one profession. On the other hand, it could also have resulted in the exclusion of profession-specific strategies that may be essential for a successful telehealth implementation, which could be studied in the future. Each profession uses telehealth differently based on their specific clinical needs and methods. For instance, PTs may focus more on movement assessments and exercise guidance, whereas SLTs might emphasize communication techniques and auditory assessments. This variation means that certain best practices identified may be more applicable to some professions than others, potentially limiting the universal applicability of the recommendations. The small number of distinct professions included in the study may have resulted in the exclusion of specialized best practices pertinent to each field. Essential strategies unique to specific clinical scenarios or patient interactions within each profession might not have been fully captured or emphasized, thereby affecting the comprehensiveness of the best practice guide for individual disciplines.

Moreover, the findings reflect the current state and must be interpreted as such. They likely are subject to change due to the continuous evolution of professional expertise in health care and ongoing technological advancements that are likely to shape the future landscape of telehealth. Furthermore, this study relied on self-reported data from the experts. While this method is commonly used in qualitative research, it is important to acknowledge that the data collected may be subject to bias or limitations in recall. Another important consideration is the length of the final best practice list. Although it represents a comprehensive set of potential solutions, its sheer number may pose challenges for day-to-day clinical application.

Implication of Findings

The study's findings offer valuable insights for various stakeholders within the telehealth ecosystem, promoting enhanced effectiveness, accessibility, and sustainability of video call–based telehealth services. The best practices serve as a practical guide for clinicians to optimize telehealth delivery. Implementing these strategies can improve care quality, strengthen patient-provider relationships, and increase patient satisfaction while reducing operational burdens through streamlined session management and technical troubleshooting. Using enhanced privacy measures and user-friendly technologies ensures a secure and confident telehealth experience for patients, particularly those in remote or underserved areas. Insights from this study can also inform the development of regulations and standards that promote equitable telehealth access. By addressing practical barriers and supporting measures such as technology funding and training programs, policy makers can facilitate the broader adoption and integration of telehealth into standard health care practices. Finally, incorporating these best practices into health care curricula ensures that future practitioners are equipped with the necessary digital literacy and remote communication skills. Training programs can emphasize technical competencies and patient engagement strategies specific to telehealth, preparing health care workers for modern care delivery.

Further Research

While this Delphi study provided insights into potential solutions, it would be beneficial to evaluate the impact of these strategies on the successful implementation of telehealth in different real-world settings by exploratory and confirmatory studies. For example, while this study focused on barriers and solutions in the selected health care professions, other health care specialties and settings may face different challenges and

would come up with different best practices when implementing telehealth. Evaluating these barriers and solutions in different contexts would provide a more comprehensive understanding of telehealth implementation. Moving forward, further research could investigate strategies to streamline or prioritize these recommendations, identifying which are most beneficial for specific professional groups or patient populations. Further, it would be interesting to create educational programs to see how teaching these strategies to students would increase their telehealth proficiency.

Conclusions

This publication presents a modified Delphi study that compiles best practices for overcoming barriers in video call–based telehealth. It includes insights from various health care professionals and focuses on enhancing telehealth's quality and effectiveness. The study emphasizes technology accessibility, professional setups, and patient-centered care. Limitations include a small sample size and self-reported data, suggesting future research should assess these strategies' real-world effectiveness, explore barriers in different health care specialties, and develop educational programs to increase telehealth proficiency.

Abstract

Background: The rapid advancement of telehealth has led to the emergence of avatar-based psychotherapy (ABP), which combines the benefits of anonymity with nonverbal communication. With the adoption of remote mental health services, understanding the efficacy and user experience of ABP has become increasingly important.

Objective: This study aimed to explore the user experience and therapeutic relationship formation in short-term ABP environments, focusing on psychological effects, user satisfaction, and critical factors for implementation.

Methods: This qualitative study involved 18 adult participants (8 women and 10 men). Participants engaged in two short-term ABP sessions (approximately 50 minutes per session) over 2 weeks, using an ABP metaverse system prototype. Semistructured in-depth interviews were conducted with both the participants and therapists before and after the ABP sessions. The interviews were conducted via an online platform, with each interview lasting approximately 30 minutes. The key topics included the sense of intimacy, communication effectiveness of avatar expressions, emotions toward one's avatar, concentration during sessions, and perceived important aspects of the ABP. Data were analyzed using thematic analysis.

Results: The analysis revealed 3 main themes with 8 subthemes: (1) reduction of psychological barriers through avatar use (subthemes: anonymity, ease of access, self-objectification, and potential for self-disclosure); (2) importance of the avatar–self-connection in therapeutic relationship formation (subthemes: avatar self-relevance and avatar–self-connection fostering intimacy and trust); and (3) importance of nonverbal communication (subthemes: significance of nonverbal expressions and formation of empathy and trust through nonverbal expressions). Participants reported enhanced comfort and self-disclosure owing to the anonymity provided by avatars, while emphasizing the importance of avatar customization and the role of nonverbal cues in facilitating communication and building rapport.

Conclusions: This pilot study provides valuable insights into the short-term ABP user experience and therapeutic relationship formation. Our findings suggest that ABP has the potential to reduce barriers to therapy through anonymity, ease of access, and potential for self-disclosure, while allowing for meaningful nonverbal communication. The avatar–self-connection emerged as a crucial factor in the effectiveness of ABP, highlighting the importance of avatar customization in enhancing user engagement and therapeutic outcomes. Future research and development in ABP should focus on improving avatar customization options, enhancing the fidelity of nonverbal cues, and investigating the long-term effectiveness of ABP compared with traditional face-to-face therapy.

KEYWORDS

avatar-based psychotherapy; telehealth; therapeutic relationship; user experience; anonymity; nonverbal communication; mental health; mobile phone

Introduction

Rapid advancements in information technology have led to significant developments in telehealth, particularly in addressing mental health issues, such as anxiety, depression, and stress-related disorders [1]. The COVID-19 pandemic has accelerated the transition from traditional face-to-face clinical services to telehealth solutions [2]. This shift has created new opportunities for individuals with difficulty accessing in-person psychotherapy owing to geographical constraints or personal reservations [3]. Avatar-based psychotherapy (ABP) has gained attention because of its unique ability to combine the benefits of anonymity and nonverbal communication. Recent research has demonstrated the potential effectiveness of metaverse-based counseling approaches compared to traditional in-person settings [4].

The therapeutic relationship between the client and psychotherapist is crucial for successful therapeutic outcomes. However, the dynamics of this relationship in ABP environments require further investigation [5]. Self-disclosure, a key element in relationship building, may be facilitated differently in ABP settings than in traditional face-to-face or video-based online therapy [6]. The concept of avatar–self-connection, which refers to the psychological link between users and their digital representations, may play a significant role in the effectiveness of ABP [7].

This study aimed to explore the user experience and therapeutic relationship formation in short-term ABP environments. Specifically, we sought to understand the psychological effects and satisfaction levels of users engaging in ABP and to identify critical factors to consider when implementing ABP systems.

Methods

Ethical Considerations

This study was conducted in accordance with the principles of the Declaration of Helsinki and approved by the Institutional Review Board of Korea University Anam Hospital (IRB No: 2023AN0504). All participants provided written informed consent before participation. Participants were informed that their participation was voluntary and that they could withdraw at any time without consequences. All interviews were audio-recorded with prior consent and subsequently transcribed for analysis. The data collected in this study were anonymized to ensure the privacy and confidentiality of all participants. This manuscript and its supplementary materials do not include any images or identifiable features of research participants.

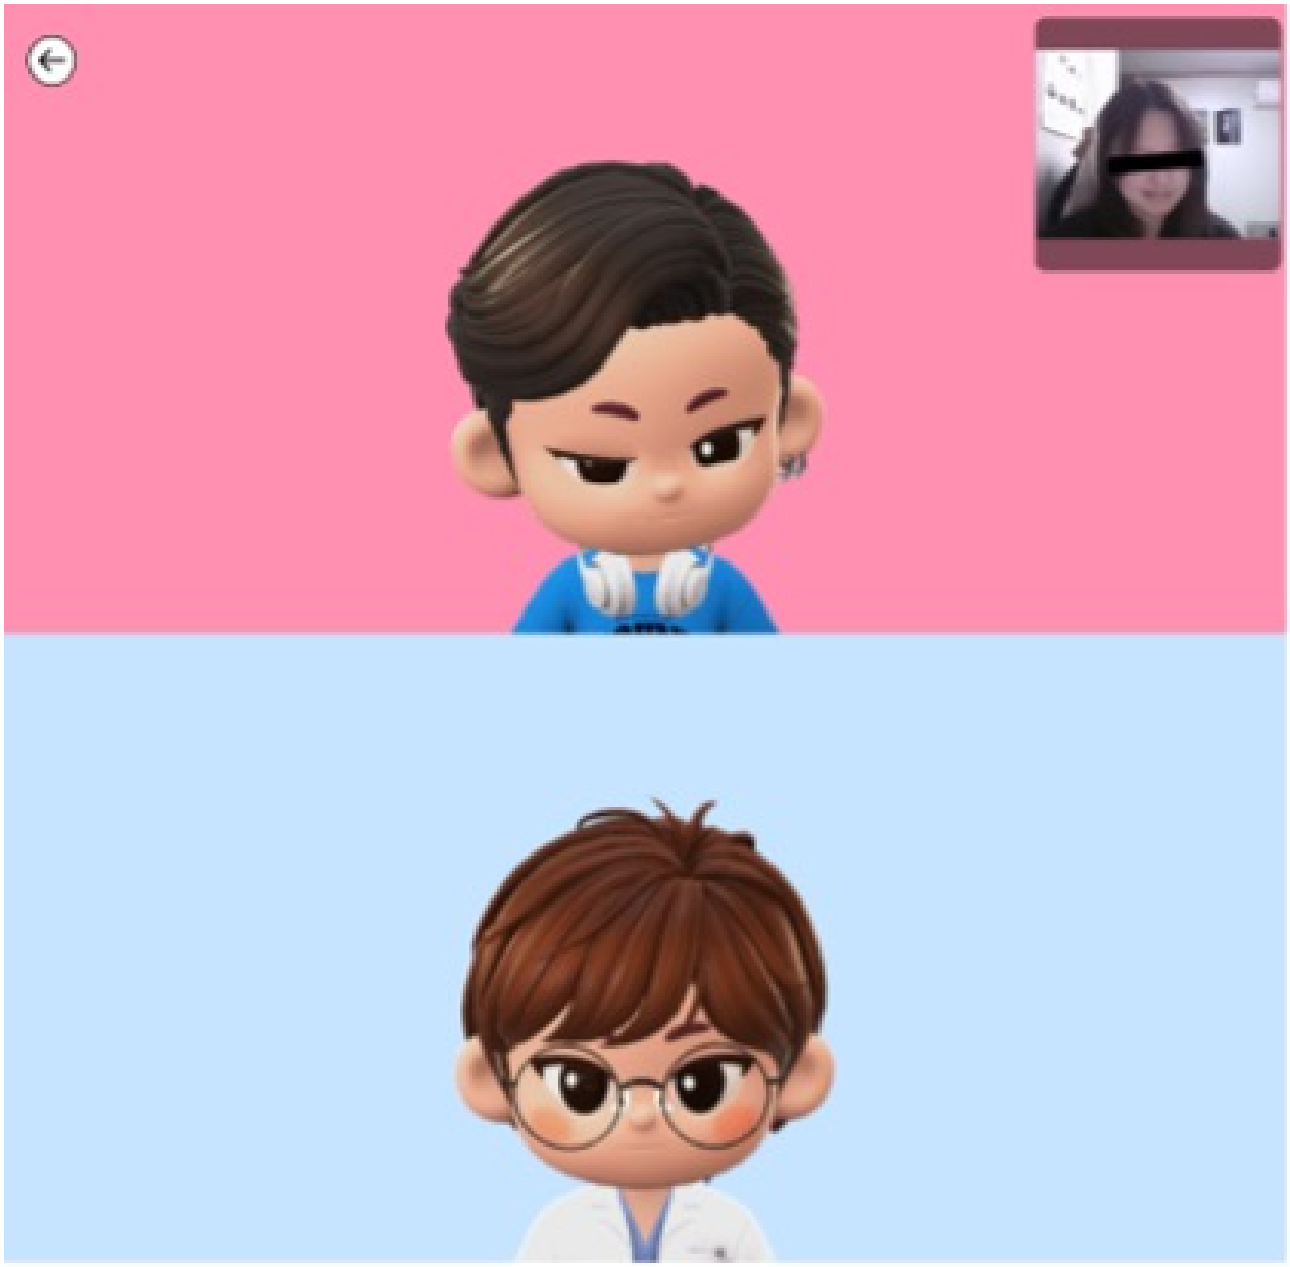
Study Design and Data Collection

This study was designed as a short-term intervention pilot study to explore initial user experiences with ABP. The two-session format was chosen to capture immediate reactions and early therapeutic relationship formation in the ABP environment. We conducted a qualitative study to gain an in-depth understanding of user experiences in ABP sessions. Eligible participants were adults aged 19 - 70 years who self-reported their need for psychological health management and had no previous experience with avatar-based counseling. We excluded individuals with intellectual disabilities, organic brain damage, or those currently receiving psychiatric treatment for major mental disorders (including major mood disorders, anxiety disorders, and schizophrenia spectrum disorders). Additionally, participants were required to have access to and the ability to use smartphones or computers.

An avatar that reflected facial movements in real time was established using a metaverse system prototype (Figure 1). This system allowed participants to engage in psychotherapy sessions through avatars, enabling verbal and nonverbal communication. Eighteen adult participants (8 women) were initially recruited in Seoul, South Korea. The participants engaged in two ABP sessions (approximately 50 minutes per session) over 2 weeks.

Semistructured in-depth interviews were conducted with both the participants and psychotherapists before and after the ABP sessions. These interviews, each lasting 30 minutes, were conducted using the Zoom platform (Zoom Video Communications, Inc.). The key topics included the sense of intimacy and communication effectiveness of avatar expressions, emotions and feelings toward one's avatar, concentration during the session, and perceived important aspects of the ABP sessions.

Figure 1. The avatar-based psychotherapy metaverse system prototype. Top avatar: participant; bottom avatar: psychotherapist. The real face box at the top can be turned off; in a real psychotherapy session, the real face is turned off and is conducted with only the avatar.



Data Analysis

We employed thematic analysis to analyze the data, using ATLAS.ti software (Version 23; ATLAS.ti Scientific Software Development GmbH, Berlin, Germany) [8]. The analysis was conducted in 6 phases: familiarization with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing reports. Four researchers (JB, HL, JH, and CHC) participated in the initial familiarization phase and carefully reviewed the transcripts before individual coding. The 174 initial codes were systematically categorized through iterative analysis. Through team discussions, these codes were refined and consolidated into 3 main themes of psychological barriers (41 codes), avatar–self-connection (29 codes), and nonverbal communication (38 codes). The remaining codes were excluded as they did not directly address the research questions.

Results

The thematic analysis revealed 3 main themes with 8 subthemes, as shown in Table 1. The 174 initial codes were systematically categorized through iterative analysis. Through team discussions, these codes were refined and consolidated into 3 main themes of psychological barriers (41 codes), avatar–self-connection (29 codes), and nonverbal communication (38 codes). The remaining codes were excluded as they did not directly address the research questions.

Table . Thematic framework of user experiences and therapeutic relationship formation in avatar-based psychotherapy: main themes, subthemes, code counts, and representative codes.

Main themes	Subthemes	Code counts	Representative codes
Reduction of psychological barriers through avatar use	1.1 Anonymity	12	• Anonymity reduces social anxiety. • Sense of security through anonymity. • Honest communication enabled. • Anonymity prevents judgment. • Reduced fear of personal recognition.
	1.2 Ease of access	10	• Flexible scheduling. • No travel required. • Accessible from anywhere. • Easier therapy initiation. • Reduced logistical challenges.
	1.3 Self-objectification	8	• Detached view encourages self-reflection. • Avatar mirrors emotional state. • Enhances self-awareness. • Observing oneself via the avatar. • Identifies overlooked emotions.
	1.4 Potential for self-disclosure	11	• Easier to discuss sensitive topics. • Safe space for expression. • Encourages honest sharing. • Enables communication without barriers. • Reduces hesitation in disclosure.
Importance of avatar–self-connection	2.1 Avatar self-relevance	15	• Personalized avatars foster comfort. • Realism enhances connection. • Reflects personal identity. • Improves immersion. • Mirrors user's traits effectively.
	2.2 Fostering intimacy and trust	14	• Facilitates faster rapport. • Acts as a conversational bridge. • Builds therapeutic trust. • Supports meaningful dialogue. • Encourages emotional openness.

Main themes	Subthemes	Code counts	Representative codes
Importance of nonverbal communication	3.1 Significance of nonverbal expressions	20	• Gestures enhance communication. • Nonverbal cues reduce misunderstandings. • Expressive avatars improve immersion. • Adds emotional depth. • Reinforces communication effectiveness.
	3.2 Empathy and trust formation	18	• Mirrors emotions effectively. • Conveys empathy through gestures. • Builds trust via nonverbal cues. • Enhances emotional understanding. • Reduces virtual communication gaps.

Theme 1: Reduction of Psychological Barriers Through Avatar Use

Theme 1, the reduction of psychological barriers through avatar use, emerged as the most prominent theme with 41 codes. These codes were distributed across 4 subthemes: anonymity (12 codes), ease of access (10 codes), self-objectification (8 codes), and potential for self-disclosure (11 codes). Participants reported that the use of avatars in psychotherapy sessions helped lower psychological barriers primarily through 3 mechanisms.

Subtheme 1.1: Anonymity

The anonymity provided by avatars was frequently mentioned as a key factor in facilitating open and honest communication. One participant noted, “Knowing that the therapist does not know my real face gives me a sense of security. Even if we met in real life, they would not recognize me, which is reassuring in a way.”

Subtheme 1.2: Ease of Access

The convenience of accessing ABP services through a metaverse platform was highlighted as a significant advantage. One participant stated, “The fact that psychotherapy sessions can be done from anywhere makes it more accessible and easier to form a rapport. I think anonymous ABP is more effective in this regard.”

Subtheme 1.3: Self-Objectification

Avatars facilitated self-objectification, allowing participants to view themselves from a detached perspective. One participant observed, “When I occasionally looked at my avatar, I noticed that I was not smiling much. It made me think, ‘I look a bit pitiful.’ This showed me how I appeared.”

Subtheme 1.4: Potential for Self-Disclosure

Avatars facilitated self-disclosure. One participant noted, “For people who want psychotherapy without revealing themselves too much, expressing themselves through an avatar in the metaverse can make it easier to talk honestly with the therapist.”

Theme 2: Importance of Avatar–Self-Connection in Therapeutic Relationship Formation

The importance of avatar–self-connection in therapeutic relationship formation emerged as the second major theme, comprising 29 codes. These were distributed between 2 key subthemes: avatar self-relevance (15 codes) and avatar–self-connection fostering intimacy and trust (14 codes). The results showed that the degree of connection between users and their avatar played a crucial role in the therapeutic relationship formation within the ABP environment.

Subtheme 2.1: Avatar Self-Relevance

Participants expressed a desire for their avatars to reflect aspects of their real selves. One participant noted, “If I could customize the avatar more to my liking and feel that it truly represents me, I think I would feel more completely connected to it.”

Subtheme 2.2: Avatar–Self-Connection Fostering Intimacy and Trust

A strong avatar–self-connection enhanced the sense of intimacy and trust in the therapeutic relationship. One participant shared, “When I felt that this avatar was really me, I could immerse myself more deeply in the session and form a stronger therapeutic relationship with the therapist.”

Theme 3: Importance of Nonverbal Communication

The importance of nonverbal communication emerged as a significant theme with 38 codes, distributed across 2 subthemes: significance of nonverbal expressions (20 codes) and formation of empathy and trust through nonverbal expressions (18 codes). The thematic analysis highlighted the significant role of nonverbal communication in ABP, emphasizing its impact on self-expression, empathy, and trust-building.

Subtheme 3.1: Significance of Nonverbal Expressions

The participants emphasized the importance of nonverbal cues in enhancing communication. One participant stated, “If the avatar could show hand gestures or body language, I think it would be even better. These physical movements can have psychological significance.”

Subtheme 3.2: Formation of Empathy and Trust Through Nonverbal Expressions

Nonverbal communication through avatars enhanced empathy and trust in the therapeutic relationship. One participant shared, "I think the avatar helped by expressing my gestures and expressions to some extent. This somewhat overcomes communication errors that can occur when we are not face-to-face."

Discussion

Study Findings and Comparison With Previous Findings

This study provides critical insights into ABP, highlighting 3 interconnected dimensions: psychological barrier reduction, avatar–self-connection, and the role of nonverbal communication in metaverse therapeutic systems.

The anonymity, accessibility, and potential for self-disclosure provided by avatars create a unique therapeutic environment that lowers the resistance to mental health engagement, consistent with previous research on online self-disclosure [5]. A novel finding of this study was the self-objectification through avatar use, suggesting a potential mechanism for enhanced self-awareness that resonates with self-distancing theories in psychology [9]. This indicates that ABP may offer a natural pathway for adaptive self-reflection, a key component in many therapeutic approaches.

The self-objectification observed in this study demonstrates an interesting contrast with findings from video conferencing research, which found that viewing one's actual image during video conferences can lead to greater cognitive burden and negative psychological effects, particularly for individuals with high public self-consciousness [10]. However, our findings suggest that avatar-mediated self-observation may offer distinct advantages. Unlike video conferencing where users see their actual image, avatar representation creates a beneficial psychological distance that facilitates more objective self-reflection while maintaining emotional engagement. This unique characteristic of avatar-mediated interaction may explain why participants in our study reported enhanced self-awareness without the negative psychological impacts often associated with direct self-viewing in video conferences. The avatar-mediated environment provides a unique balance between self-awareness and psychological comfort, potentially making it particularly suitable for therapeutic contexts where self-reflection is crucial but emotional safety needs to be maintained.

Furthermore, the avatar–self-connection played a crucial role in the therapeutic relationship formation, extending previous work on avatar realism [7]. Our findings directly linked this connection to the quality of the therapeutic relationship, underscoring the potential significance of avatar customization in fostering engagement and improving outcomes. The avatar may serve as a bridge between the client's inner world and the therapeutic space, facilitating deeper exploration of personal narratives.

Our observations of nonverbal communication in ABP expand on previous research, highlighting how even limited nonverbal cues can significantly impact the therapeutic process [11]. This adaptability suggests that ABP taps into fundamental aspects of human communication, offering a rich alternative to traditional face-to-face therapy.

The interplay among these elements in ABP creates a unique therapeutic ecosystem that balances self-disclosure and self-protection. As we continue to explore the potential of ABP, it is crucial to consider its place within the broader context of mental health care. ABP can be viewed as a complementary tool that can lead to more comprehensive and accessible care, potentially reaching individuals who might otherwise not receive treatment [12,13].

Strengths and Limitations

The findings of this study have several implications for clinical practice. First, ABP may be particularly beneficial for clients hesitant to engage in traditional face-to-face therapy because of social anxiety, stigma, or geographical limitations [14]. The anonymity and ease of access provided by ABP could serve as a stepping stone for these individuals to transition to other forms of therapy, if needed. Second, clinicians using ABP should be aware of the importance of the avatar–self-connection and consider ways to enhance this connection during therapy sessions. This might involve discussing the client's choice of avatar and exploring how it relates to their self-perception or therapeutic goals. However, although ABP offers many advantages, clinicians must be aware of its limitations. The reduced nonverbal cues in ABP compared with face-to-face therapy require clinicians to develop new skills in reading and interpreting client expressions and emotions through avatars.

Conclusion

These findings not only contribute to the growing body of knowledge on telehealth interventions, but also prompt us to reconsider the nature of the therapeutic relationship in the digital age. As technology continues to reshape our modes of interaction, ABP stands at the forefront of a new paradigm in mental health care that harnesses the power of the virtual world to foster real-world healing and growth.

Abstract

Background: Digital health innovations provide an opportunity to improve access to care, information, and quality of care during the perinatal period, a critical period of health for mothers and infants. However, research to develop perinatal digital health solutions needs to be informed by actual patient and health system needs in order to optimize implementation, adoption, and sustainability.

Objective: Our aim was to co-design a research agenda with defined research priorities that reflected health system realities and patient needs.

Methods: Co-design of the research agenda involved a series of activities: (1) review of the provincial Digital Health Strategy and Maternity Services Strategy to identify relevant health system priorities, (2) anonymous survey targeting perinatal care providers to ascertain their current use and perceived need for digital tools, (3) engagement meetings using human-centered design methods with multilingual patients who are currently or recently pregnant to understand their health experiences and needs, and (4) a workshop that brought together patients and other project partners to prioritize identified challenges and opportunities for perinatal digital health in a set of research questions. These questions were grouped into themes using a deductive analysis approach starting with current BC Digital Health Strategy guiding principles.

Results: Between September 15, 2022, and August 31, 2023, we engaged with more than 150 perinatal health care providers, researchers, and health system stakeholders and a patient advisory group of women who were recently pregnant to understand the perceived needs and priorities for digital innovation in perinatal care in British Columbia, Canada. As a combined group, partners were able to define 12 priority research questions in 3 themes. The themes prioritized are digital innovation for (1) patient

autonomy and support, (2) standardized educational resources for patients and providers, and (3) improved access to health information.

Conclusions: Our research agenda highlights the needs for perinatal digital health research to support improvements in the quality of care in British Columbia. By using a human-centered design approach, we were able to co-design research priorities that are meaningful to patients and health system stakeholders. The identified priority research questions are merely a stepping stone in the research process and now need to be actioned by research teams and health systems partners.

Introduction

The digital health sector continues to expand after being an integral part of health care delivery during the COVID-19 pandemic, resulting in a growing interest in digital health research and innovation. Digital health provides an opportunity to reduce health disparities by addressing barriers and facilitators to health care access and improving the health and lifestyle of those who use it [1]. Digital innovation is also essential to offering value-based health care, which involves changes in health systems that are measured by improvement in patient outcomes per unit health care expenditure [2]. Core to achieving improvements in value-based care is establishing an understanding of what value is based on identifying outcomes that matter to patients themselves.

Human-centered design (HCD) is an approach to problem-solving that can be used to increase value in health care by focusing on problems and outcomes of interest to patients. HCD also has a role in improving health equity [3,4]. Core characteristics of an HCD approach include an iterative process of empathy and discovery to identify the core problem and then systematic brainstorming of solutions where the human experiencing the problem plays a central role [5]. The HCD approach goes beyond simply working with the end user to focus on their interaction with the technology and considers the broader social context in which the technology is used and other partners who may indirectly be impacted by the use of the technology [4,5]. The result of working in partnership with people under these assumptions using the HCD approach is meant to be a product or service that meets real human needs and reflects their values. This approach has been used to solve complex health care challenges, such as improving pediatric patient experience in acute care [6] and increasing adherence to self-care practices for chronic conditions [7,8]. In a perinatal health setting, these methods have been used to develop digital interventions for gestational diabetes [9].

The perinatal period encompasses a person's experiences from conception to the first year after delivery including pregnancies that end in miscarriage or stillbirths. The majority of patients receiving perinatal care in British Columbia has access to a mobile device and the internet and are increasingly looking to digital technologies to inform and support their care [10,11]. Using digital technology in health care can improve the quality of care and health outcomes for patients and infants during this early stage of life. The use of digital health tools in perinatal care has already been shown to result in lower and healthier gestational weight, lower smoking rates, increased physical activity, and lower rates of maternal and infant morbidity (eg, fewer preterm births, gestational diabetes, and pre-eclampsia), leading to fewer planned and unplanned visits to health care facilities [1,12-14]. Digital health has also been demonstrated to reduce the practitioners' workload as well as relieve some of the resource strains on an overburdened system [15]. Due to the vast potentiality of digital health and opportunities for further innovation, it is important to engage with patients who have received perinatal care and care providers as end users to identify emerging priorities for future innovations and research that are informed by actual needs [16]. By identifying and responding to real patient and care provider needs, we can optimize the implementation, adoption, and sustainability of perinatal digital health solutions, create value, and ensure existing health inequities are not exacerbated [16,17].

In this paper, we report on the Research Agenda for Perinatal Innovation and Digital Health (RAPID) project [18], which was led by the BC Children's Hospital Research Institute and Women's Health Research Institute in partnership with the Provincial Health Services Authority (PHSA) and Perinatal Services BC (PSBC) with the aim of codeveloping research priorities with patients and care providers.

Methods

Ethical Considerations

This project was run as a knowledge translation initiative, and no research ethics board approval was required. The engagement activities conducted with partners were classified as quality improvement activities rather than systematic investigations to advance knowledge. Based on these distinctions, our institutional research ethics board determined that the project falls outside of the scope of research subject to ethics review, and a waiver was granted. All workshop and survey participants consented to the anonymous collection of their opinions. Members of our patient advisory committee were compensated hourly according to local standards to reflect their equal standing to research team members within the project.

Project Design and Setting

The patient and health system partners with whom we worked were partners in the research priority setting through co-design and were compensated for their time. All final workshop

participants provided consent to the collection of their opinions and views during the workshop and through the follow-up survey.

The objectives of the RAPID project were to facilitate activities that bring key partners and existing knowledge together to (1) identify gaps in the perinatal continuum of care that can be addressed with digital innovation to improve patient and family health and (2) define current barriers to optimal adoption of digital health interventions for perinatal health care from the patient and health system perspectives. This knowledge was then used to define research priorities and codevelop research questions to motivate digital innovation informed by care needs and addressing barriers.

Recruitment of Partners and Governance

Following guidance outlined by Concannon et al [19], we developed an engagement plan for our activities that describes an analysis of which partner groups should be involved, their roles and modes of participation, and sampling strategies (ie, snowball sampling). Partners to include in engagement activities were grouped as (1) people with lived experience of perinatal care who were pregnant or recently delivered a baby; (2) perinatal health care providers including nurses, midwives, physicians, and other allied health; and (3) health care decision makers who are involved with the design or delivery of perinatal health care in British Columbia.

This project was governed by two primary groups: (1) a steering committee and (2) a patient advisory committee (PAC). Using snowball sampling, starting with a core group of experts at BC Children Hospital Research Institute and Women's Health Research Institute, we identified key partners with expertise in research, innovation, and implementation processes related to perinatal, maternal, or digital health services to form the steering committee. The core group was involved from the initiation of the project including during the development of the funding proposal. This core group included 4 health system decision makers as research users and 4 researchers. Additional partners identified for the steering committee included 2 clinical care providers and 2 additional researchers. The final steering committee included 5 researchers, 3 health care providers, and 4 health system decision makers. The purpose of the steering committee was to oversee project objectives and align efforts to each of their organizations' known digital health priorities and ongoing work.

Patient partners for the advisory committee were recruited through social media and the local hospital patient engagement office. The criteria for participation were (1) multilingual and (2) pregnant or a caregiver of a child younger than 2 years of age. There were 15 respondents to the recruitment advertisements, 9 of whom responded to our invitation to complete a 15-minute informal interview so we could learn more about their background, and they could also learn more about our project. After the interviews, the steering committee was able to select 4 participants who were willing and able to commit the time required by the project and who had diverse perinatal experiences (based on type of care provider and mode of delivery), geographic location in British Columbia, and backgrounds (language spoken and profession). The PAC met separately with only 4 members of the study team and steering committee during the initial activities of the project. This was done to create a safe space that would limit the impact of known health system hierarchies and preserve the authentic patient voice in the identification of perinatal health system pain points and the development of initial insights related to these pain points [20]. Once initial insights were defined with the patient advisors, all partners were brought together in a final workshop to collaborate and build consensus on research priorities as described in more detail below.

Engagement Activities
