Volume 12 (2025) ISSN 2292-9495 Editor in Chief: Andre Kushniruk, BA, MSc, PhD, FACMI

Contents

Original Papers

Patient-Centered Televisit for Chronic Obstructive Pulmonary Disease Discharge Transitions: User-Centered Design Study (e77953)
Joanna Abraham, Alicia Meng, Nicolas Caravelli, Leah Traeger, May Nguyen, Vineet Arora, Valerie Press. 23

A Messaging App Empowering Lifestyle Modification in Chronic Kidney Disease (LINE Official Account “Kidney Lifestyle”): Platform Development and Usability Study (e73935)
Chun-Yi Ho, Deborah Siregar, Miaofen Yen, Junne-Ming Sung, Ming-Cheng Wang, Wei-Hung Lin. 53

Impact of Digital Phenotypes and Question-Asking on Emotional Disorders in Adolescents: 4-Week Field Study (e66536)
Minseo Cho, Doeun Park, Myounglee Choo, Doug Han, Jinwoo Kim. 80

Applying Human-Centered Design to Develop Smartphone-Based Intervention Messages to Help Young Adults Quit Using E-Cigarettes and Cigarettes: A Remote User Testing Study (e76503)
Thi Tran, Christine Tran, Pamela Ling, Lucy Popova, Nhung Nguyen. 97

User Requirements and Conceptual Design for an Electronic Data Platform for Interhospital Transfer Between Acute Care Hospitals: User-Centered Design Study (e67884)
Pamela Garabedian, Jazzarae Kain, Srinivas Emani, Stephanie Singleton, Ronen Rozenblum, Lipika Samal, Stephanie Mueller. 109

Growth Mindset Intervention's Impact on Positive Response to eHealth for Older Adults With Chronic Disease: Randomized Controlled Trial (e65519)
Meijuan Cao, Xiaojuan Xu, Yaling Zeng, Binyu Zhao, Chunqi Xie, Hailu Wu, Jianlin Lou. 121

Digital Informed Consent/Assent in Clinical Trials Among Pregnant Women, Minors, and Adults: Multicountry Cross-Sectional Evaluation of Comprehension and Satisfaction (e65569)
Jaime Fons-Martinez, Carlos Murciano-Gamborino, Cristina Ferrer-Albero, Carlos Vergara-Hernandez, Javier Diez-Domingo. 135

Improving Access to and Delivery of Maternal Health Care Services to Prevent Postpartum Hemorrhage in Selected States in Nigeria: Human-Centered Design Study (e58577)
Bosun Tijani, Uchenna Igbokwe, Temi Filani, Adefemi Adewemimo, Lola Ameyan, Martins Iyekekpolor, Steven Karera, Olatunji Oluyide, Emmanuela Ezike, Temidayo Akinreni, Obruche Ogefere, Victor Adetimilehin, Valentine Amasiatu, Chukwunonso Nwaokorie, Naanma Kangkum, Olufunke Fasawe, Eric Aigbogun Jr. 151

A Just-in-Time Adaptive Intervention (Shift) to Manage Problem Anger After Trauma: Co-Design and Development Study (e62960)
Olivia Metcalf, David Forbes, Lauren Henry, Tianchen Qian, Tracey Varker, Melissa Brotman, Sean Cowlishaw, Karen Lamb, Meaghan O'Donnell. 163

XSL•FO
RenderX

A Health Professional Mentorship Platform to Improve Equitable Access to Abortion: Development, Usability, and Content Evaluation (e63364)
Abdul-Fatawu Abdulai, Cam Duong, Eleni Stroulia, Efrat Czerniak, Rachel Chiu, Aashay Mehta, Ken Koike, Wendy Norman. 175

Developing an App for Real-Time Daily Life Observations in a Nursing Home Setting: Qualitative User-Centered Co-Design Approach (e57911)
Coen Hacking, Bram de Boer, Hilde Verbeek, Jan Hamers, Sil Aarts. 188

Oncology Clinicians' Perspectives of a Remote Patient Monitoring Program: Multi-Modal Case Study Approach (e60585)
Ann Mazzella-Ebstein, Robert Daly, Jennie Huang, Camila Bernal, Clare Wilhelm, Katherine Panageas, Jessie Holland, Rori Salvaggio, Jill Ackerman, Jennifer Cracchiolo, Gilad Kuperman, Jun Mao, Aaron Begue, Margaret Barton-Burke. 197

Evaluating the Safety and Usability of an Over-the-Counter Medical Device for Adults With Mild to Moderate Hearing Loss: Formative and Summative Usability Testing (e65142)
Megan Salwei, Shilo Anders, Carrie Reale, Jason Slagle, Todd Ricketts, Matthew Weinger. 211

Predictive Factors and the Predictive Scoring System for Falls in Acute Care Inpatients: Retrospective Cohort Study (e58073)
Chihiro Saito, Eiji Nakatani, Hatoko Sasaki, Naoko E Katsuki, Masaki Tago, Kiyoshi Harada. 228

An Explainable AI Application (AF'fective) to Support Monitoring of Patients With Atrial Fibrillation After Catheter Ablation: Qualitative Focus Group, Design Session, and Interview Study (e65923)
Wan She, Panote Siriaraya, Hibiki Iwakoshi, Noriaki Kuwahara, Keitaro Senoo. 244

Preadolescent Children Using Real-Time Heart Rate During Moderate to Vigorous Physical Activity: A Feasibility Study (e58715)
Lincoln Lu, Danielle Jake-Schoffman, Hannah Lavoie, Maedeh Agharazidermani, Kristy Boyer. 260

User-Centered Design of an Electronic Dashboard for Monitoring Facility-Level Basic Emergency Obstetric Care Readiness in Amhara, Ethiopia: Mixed Methods Study (e64131)
Kylie Dougherty, Yihenew Tesfaye, Heran Biza, Mulusew Belew, Natalie Benda, Abebe Gebremariam Gobezayehu, John Cranmer, Suzanne Bakken. 276

Co-Designing a Web-Based and Tablet App to Evaluate Clinical Outcomes of Early Psychosis Service Users in a Learning Health Care Network: User-Centered Design Workshop and Pilot Study (e65889)
Kathleen Burch, Valerie Tryon, Katherine Pierce, Laura Tully, Sabrina Ereshefsky, Mark Savill, Leigh Smith, Adam Wilcox, Christopher Hakusui, Viviana Padilla, Amanda McNamara, Merissa Kado-Walton, Andrew Padovani, Chelyah Miller, Madison Miles, Nitasha Sharma, Khanh Nguyen, Yi Zhang, Tara Niendam. 291

Exploring Mental Health Content Moderation and Well-Being Tools on Social Media Platforms: Walkthrough Analysis (e69817)
Zoë Haime, Lucy Biddle. 313

Examining Patient Characteristics Associated With Digital Outpatient Care for Type 1 Diabetes (DigiDiaS): Cross-Sectional Study (e73708)
Ingeborg Spildo, Heidi Holmen, Annesofie Lunde Jensen, Milada Hagen, Tone Singstad, Jacob Winther, Eirik Årsand, Astrid Torbjørnsen. . .
3 3 0

Gamified Physical-Digital Smoking Cessation Intervention for Young Adults: Mixed Methods Development and Usability Study (e72749)
Natalia Bartłomiejczyk, Alessio De Santo, Adrian Holzer. 350

Expanding the Design Space for Fall Prevention in Acute Orthopedic Hospital Care: Human-Centered Design Study (e73110)
Maria Ehn, Åsa Revenäs, Helena Tobiasson. . . . 370

Redesigning Telemedicine for Traditional Chinese Medicine: Service Design Approach to Digital Transformation (e76752)
Arisara Jiamsanguanwong, Romanee Luo, Ratchapoom Kaingam, Oran Kittithreerapronchai, Waratta Authayarat. . . . 648

An AI-Based Clinical Decision Support System for Antibiotic Therapy in Sepsis (KINBIOTICS): Use Case Analysis (e66699)
Juliane Düvel, David Lampe, Maren Kirchner, Svenja Elkenkamp, Philipp Cimiano, Christoph Düsing, Hannah Marchi, Sophie Schmiegel, Christiane Fuchs, Simon Claßen, Kirsten-Laura Meier, Rainer Borgstedt, Sebastian Rehberg, Wolfgang Greiner. . . . 664

The Impact of Human-Robot Collaboration Levels on Postural Stability During Working Tasks Performed While Standing: Experimental Study (e64892)
Daniele Bibbo, Giovanni Corvini, Maurizio Schmid, Simone Ranaldi, Silvia Conforto. . . . 675

Feasibility of a 12-Week, Therapist-Independent, Smartphone-Based Biofeedback Treatment for Episodic Migraine in Adults: Single-Center, Open-Label, 1-Armed Trial (e59622)
Amalie Poole, Ingunn Winnberg, Melanie Simpson, Anker Stubberud, Kjersti Vetvik, Marte-Helene Bjørk, Lise Øie, Petter Holmboe, Alexander Olsen, Erling Tronvik, Tore Wergeland. . . . 689

Usability Evaluation of an Electrically Powered Orthopedic Exerciser: Focus Group Interview and Satisfaction Survey Study (e60607)
Seojin Hong, Hyun Choi, Hyosun Kweon. . . . 704

Factors Shaping Public Perceptions of a Range of Robotic Technologies in Surgery: Cross-Sectional Web-Based Survey (e64224)
Sarek Shen, Deborah Xie, Andy Ding, Lisa Zhang, Francis Creighton. . . . 714

Evaluating the Usability of an HIV Prevention Artificial Intelligence Chatbot in Malaysia: National Observational Study (e70034)
Zhao Ni, Sunyoung Oh, Rumana Saifi, Iskandar Azwa, Frederick Altice. . . . 724

User Experience of a Bespoke Videoconferencing System for Web-Based Family Visitation for Patients in an Intensive Care Unit: 1-Year Cross-Sectional Survey of Nursing Staff (e54560)
Aoife Murray, Irial Conroy, Frank Kirrane, Leonie Cullen, Hemendra Worlikar, Derek O'Keeffe. . . . 733

Feasibility of Long-Term Physical Activity Measurement With a Wearable Activity Tracker in Patients With Axial Spondyloarthritis: 1-Year Longitudinal Observational Study (e68645)
Emil Thomassen, Anne Tveter, Inger Berg, Eirik Kristianslund, Andrew Reiner, Sarah Hakim, Laure Gossec, Gary J Macfarlane, Annette de Thurah, Nina Østerås. . . . 744

Building and Beta-Testing Be Well Buddy Chatbot, a Secure, Credible and Trustworthy AI Chatbot That Will Not Misinform, Hallucinate or Stigmatize Substance Use Disorder: Development and Usability Study (e69144)
Adam Salyers, Sheana Bull, Joshva Silvasstar, Kevin Howell, Tara Wright, Farnoush Banaei-Kashani. . . . 755

The mChoice App, an mHealth Tool for the Monitoring of Preexposure Prophylaxis Adherence and Sexual Behaviors in Young Men Who Have Sex With Men: Usability Evaluation (e59780)
Fabiana Dos Santos, Maeve Brin, Mary Tanner, Carla Galindo, Rebecca Schnall. . . . 763

Use of Wearable Transdermal Alcohol Sensors for Monitoring Alcohol Consumption After Detoxification With Contingency Management: Pilot Randomized Feasibility Trial (e64664)
Eileen Brobbin, Colin Drummond, Stephen Parkin, Paolo Deluca. . . . 772

Requirement Analysis for Data-Driven Electroencephalography Seizure Monitoring Software to Enhance Quality and Decision Making in Digital Care Pathways for Epilepsy: A Feasibility Study from the Perspectives of Health Care Professionals (e59558)
Pantea Keikhosrokiani, Johanna Annunen, Jonna Komulainen-Ebrahim, Jukka Kortelainen, Mika Kallio, Päivi Vieira, Minna Isomursu, Johanna Uusimaa. . . . 792

Integrating a Large Language Model Into a Socially Assistive Robot in a Hospital Geriatric Unit: Two-Wave Comparative Study on Performance, Engagement, and User Perceptions (e81936)
Lauriane Blavette, Sébastien Dacunha, Xavier Alameda-Pineda, Jeanne Cattoni, Anne-Sophie Rigaud, Maribel Pino. . . . 817

Enhancing Safety in Clinical Practice: Cross-Sectional, Within-Subjects, Simulated-Use Compliance Study Using BD PosiFlush SafeScrub (e78967)
Kyle De Boer, John Simpson, Purnima Sharma, Trevor Steele. . . . 839

Optimizing SloMo, a Digitally Supported Therapy Targeting Paranoia, for Implementation: Inclusive, Human-Centered Design Study (e75377)
Thomas Gant, Kathryn Taylor, Thomas Ward, Philippa Garety, Amy Hardy. . . . 850

Patient-Derived Design Principles for Technology-Enabled Healing at Home Following Hospital Discharge: Mixed Methods Study (e72913)
Lindsey Philpot, Abhinav Singla, Sagar Dugani, Rachel Canning, Christina Smith, Meredith DeZutter, Priya Ramar, Jennifer Hovell, Jon Ebbert.
8 6 7

Patient Experiences With a Mobile Self-Care Solution for Low-Complex Orthopedic Injuries: Mixed Methods Study (e53074)
Jelle Spierings, Gijs Willinge, Marike Kokke, Sjoerd Repping, Wendela de Lange, Thijs Geerdink, Ruben van Veen, Detlef van der Velde, J Goslings, Bas Twigt, Collaboration Group. . . . 880

Effect of SMS Ward Round Notifications on Inpatient Experience in Acute Medical Settings: Retrospective Cohort Study (e57470)
Jongchan Lee, Soyeon Ahn, Jung Ohn, Eun Kim, Yejee Lim, Hye Kim, Hee-Sun Park, Jae Cho, Sun-wook Kim, Jiwon Ryu, Jihye Kim, Hak Jang, Nak-Hyun Kim. . . . 893

Empowering Community Health Workers With Scripted Medicine: Design Science Research Study (e57545)
Dario Staehelin, Damaris Schmid, Felix Gerber, Mateusz Dolata, Gerhard Schwabe. . . . 902

Knowledge Sharing Maturity Model for Medical Imaging Departments: Development Study (e54484)
Maryam Almashmoum, James Cunningham, John Ainsworth. . . . 922

Device Failures and Adverse Events Associated With Rhinolaryngoscopes: Analysis of the Manufacturer and User Facility Device Experience (MAUDE) Database (e67036)
Shao-Hsuan Chang, Daishi Chen, Chi-Sheng Chen, Dong Zhou, Lung-Kun Yeh. . . . 964

Completion Rates for Ecological Momentary Assessments of Food Intake During Pregnancy and Post Partum: Descriptive Study (e67081)
Sarah Sanders, Serwaa Omowale, Andrea Casas, Alexis Kiyanda, Abigail Kosbie, Yu-Hsuan Lai, Meredith Wallace, Stephen Rathbun, Tiffany Gary-Webb, Esa Davis, Lora Burke, Dara Méndez. . . . 973

Text Messaging Between Patients With Inflammatory Rheumatic Diseases and Pharmacists to Solve Drug-Related Problems: Prospective Feasibility Study (e66514)
Lex Haegens, Charlotte Bekker, Marcel Flendrie, Bart van den Bemt, Victor Huiskes. . . . 984

Intention to Use Automated Diagnosis and Clinical Risk Perceptions Among First Contact Clinicians in Resource-Poor Settings: Questionnaire-Based Study Focusing on Acute Burns (e56300)
Constance Boissin, Lisa Blom, Zara Taha, Lee Wallis, Nikki Allorto, Lucie Laflamme. . . . 998

Mobile-Based Cognitive Behavioral Therapy for Health Care Workers' Mental Health in Ecuador: Quasi-Experimental Study (e58943)
Sandra Muñoz-Ortega, Rubén Alvarado Muñoz, Daniela Santamaria Guayaquil, Jade Pluas-Borja, Marco Faytong-Haro. . . . 1010

Finnish Registry-Based Protocol for Screening and Management of Fatigue and Cognitive Problems in Multiple Sclerosis: Observational Study (e67990)
Päivi Hämäläinen, Elina Lämsä, Matias Viitala, Hanna Kuusisto, Marja Niiranen, Sari Avikainen, Juha Puustinen, Mervi Ryytty, Juhani Ruutiainen, Merja Soilu-Hänninen. . . . 1026

Health Care Providers' Experiences and Perceptions With Telehealth Tools in a Hospital-at-Home Program: Mixed Methods Study (e56860)
Shi Low, Stephanie Ko, Ian Ang. . . . 1036

Assessing the Impact on Electronic Health Record Burden After Five Years of Physician Engagement in a Canadian Mental Health Organization: Mixed-Methods Study (e65656)
Tania Tajirian, Brian Lo, Gillian Strudwick, Adam Tasca, Emily Kendell, Brittany Poynter, Sanjeev Kumar, Po-Yen Chang, Candice Kung, Debbie Schachter, Gwyneth Zai, Michael Kiang, Tamara Hoppe, Sara Ling, Uzma Haider, Kavini Rabel, Noelle Coombe, Damian Jankowicz, Sanjeev Sockalingam. . . . 1052

Swedish Version of the System Usability Scale: Translation, Adaption, and Psychometric Evaluation (e64210)
Helene Åvik Persson, Charlotte Castor, Nilla Andersson, Mia Hylén. . . . 1068

Evaluating the Development, Reliability, and Validation of the Tele-Primary Care Oral Health Clinical Information System Questionnaire: Cross-Sectional Questionnaire Study (e53630)
Rosnah Sutan, Shahida Ismail, Roszita Ibrahim. . . . 1078

Creation of Text Vignettes Based on Patient-Reported Data to Facilitate a Better Understanding of the Patient Perspective: Design Study (e58077)
Sofia Kelly, Emilie Wegener, Lars Kayser. . . . 1093

Development of a Web-Based Intervention for Middle Managers to Enhance Resilience at the Individual, Team, and Organizational Levels in Health Care Systems: Multiphase Study (e67263)
Eva Gil-Hernández, Irene Carrillo, Jimmy Martin-Delgado, Daniel García-Torres, José Mira. . . . 1109

A Web-Based Lifestyle-Related Course for People Living With Multiple Sclerosis: Quantitative Evaluation of Course Completion, Satisfaction, and Lifestyle Changes Among Participants Enrolled in a Randomized Controlled Trial (e59363)
Maggie Yu, Sandra Neate, Steve Simpson-Yap, Rebekah Davenport, William Bevens, George Jelinek, Jeanette Reece. . . . 1127

Patients' Perceptions of Using a Digital Previsit Tool in Outpatient Settings (Part 2): Qualitative Study (e73477)
Petra Pohl, Emma Kjörk. . . . 1149

Pursuit of Digital Innovation in Psychiatric Data Handling Practices in Ireland: Comprehensive Case Study (e64919)
Rana Zeeshan, John Bogue, Amna Gill, Mamoona Asghar. . . . 1164

Usability and Quality of the JoyPop App: Prospective Evaluation Study (e65472)
Ishaq Malik, Teagan Neufeld, Aislin Mushquash. . . . 1177

Usability and Usefulness of Occupational Health Care Patient Portals: Patient-Based Cross-Sectional Study (e73197)
Sari Nissinen, Pauliina Toivio, Erja Sormunen. 1192

A Comprehensive Profiling System Integrating Myers-Briggs Type Indicator (MBTI) and Dominance, Influence, Steadiness, and Conscientiousness (DISC) for Personalized Health Training: Correlational Analysis and Usability Evaluation (e73397)
Donghyun Kim, Dong Lee, Mi Hwang. 1207

Personalized Digital Care Pathways Enable Enhanced Patient Management as Perceived by Health Care Professionals: Mixed-Methods Study (e68581)
David Rodrigues, Clara Jasmins, Ricardo Ladeiras-Lopes, Luis Patrao, Eduardo Rodrigues. 1219

ChatGPT-Delivered Physical Activity Intervention for Children With Autism Spectrum Disorder: Pre-Post Feasibility Study (e71119)
U ur Aydemir. 1228

Using a Mobile Health App (ColonClean) to Enhance the Effectiveness of Bowel Preparation: Development and Usability Study (e58479)
Hui-Yu Chen, Ming-Hsiang Tu, Miao-Yen Chen. 1238

NutriDiary, a Smartphone-Based Dietary Record App: Description and Usability Evaluation (e62776)
Linda Klasen, Stefanie Koch, Maike Benz, Johanna Conrad, Ute Alexy, Konrad Blaszkiewicz, Ionut Andone, Ute Nöthlings. 1250

Think-Aloud Testing of a Companion App for Colonoscopy Examinations: Usability Study (e67043)
Christine Jacob, Roman Müller, Sonja Schüler, Alix Rey, Guillaume Rey, Berj Armenian, Alain Vonlaufen, Michael Drepper, Marius Zimmerli. .
1 2 6 2

Comparison of a Novel Machine Learning–Based Clinical Query Platform With Traditional Guideline Searches for Hospital Emergencies: Prospective Pilot Study of User Experience and Time Efficiency (e52358)
Hamza Ejaz, Hon Tsui, Mehul Patel, Luis Ulloa Paredes, Ellen Knights, Shah Aftab, Christian Subbe. 1278

Usability and User Experience Testing of a Co-Designed Electronic Patient-Reported Outcomes App (“MyPal for Adults”) for Palliative Cancer Care: Mixed Methods Study (e57342)
Panos Bonotis, Pantelis Angelidis, Pantelis Natsiavas. 1287

Satisfaction and Usability of a Commercially Available Medication Adherence App (Medisafe) Among Medically Underserved Patients With Chronic Illnesses: Survey Study (e63653)
Christa Hartch, Mary Dietrich, B Lancaster, Shelagh Mulvaney, Deonni Stolldorf. 1303

Evaluating the Usability, Acceptability, User Experience, and Design of an Interactive Responsive Platform to Improve Perinatal Nurses’ Stigmatizing Attitudes Toward Substance Use in Pregnancy: Mixed Methods Study (e67685)
Michael Rubyan, Yana Gouseinov, Mikayla Morgan, Deborah Rubyan, Divya Jahagirdar, David Choberka, Carol Boyd, Clayton Shuman. . . .

Understanding the Behavioral Determinants of First Responder App Adoption by Integrating Perspectives From the Unified Theory of Acceptance and Use of Technology and Health Belief Model: Cross-Sectional Survey (e69934)
Cas von Winckelmann, Robyn Vanherle, Lara Schreurs, Olivier Hoogmartens, Heidi Salaets, Jan De Spiegeleer, Marc Sabbe, Kathleen Beullens. . . . 1356

Participants' Perspectives on the iCareBreast Mobile-Based Perioperative Care Program for Women Undergoing Breast Cancer Surgery: Qualitative Process Evaluation (e71686)
Yan Pang, Honggu He, Minna Pikkarainen, Swee-Ho Lim. . . . 1375

Patient's Perceptions of a Centralized Virtual Ward for Remote Patient Monitoring in Primary Care: Qualitative Study (e78780)
Alex Jaranka, Gunnar Nilsson, Terese Stenfors, Maria Hägglund, Panagiotis Papachristou, Marina Taloyan. . . . 1387

Family Caregivers' Perspectives on the Potential of Drone-Based Medication Delivery in Palliative Home Care: Qualitative Focus Group Study (e80320)
Franziska Fink, Sabrina Otto, Martin Grünthal, Anne Lehmann, Patrick Jahn. . . . 1400

Capturing Movement Behaviors in Latinas: Feasibility, Validity, and Acceptability Study of an Ecological Momentary Assessment Protocol (e75855)
Jaclyn Maher, Peyton Greco, Eugenia Fernandez, Brynn Hudgins, Sandra Echeverria. . . . 1413

Perceptions of User-Generated Content as a Source of Health Messages in Smoking Cessation Mobile Interventions: Focus Group Study (e76804)
Michael Wakeman, Lydia Tesfaye, Tim Gregory, Erin Leahy, Gunnar Baskin, Greg Gruse, Brandon Kendrick, Sherine El-Toukhy. . . . 1427

Improving Mental Health Referral Systems in Rural Australia: Co-Design Study With Health Professionals and Consumers (e73460)
Kate Bartel, Asini Siriwardene, Paul Worley, Kim Pearce, Niranjan Bidargaddi, Bronwin Patrickson, Simon Moody, Sharon Wingard, Martin Jones, Brian McKenny, Darryl Cameron, Sharon Lawn, Amy Mendham. . . . 1439

Exploratory Research With a Health Consumer Group on Social Robot Use Among Older Adults: Qualitative Study (e70462)
James Sadler, Aila Khan, Omar Mubin, Michael Lwin. . . . 1452

Testing the Acceptability and Feasibility of a Gender-Informed Smoking Cessation mHealth App for Women: Mixed Methods Approach (e71683)
Osnat Melamed, Kamna Mehra, Allison Gayapersad, Roshni Panda, Nadia Minian, Laurie Zawertailo, Leslie Buckley, Marta Maslej, Lorraine Greaves, Andreea Brabete, Jonathan Rose, Matt Ratto, Peter Selby. . . . 1461

Design Guidelines for a Game-Based Physical Rehabilitation System: Focus Group Study (e67336)
Ahmad S Elaklouk, Ratna Ramli, Samah M Alakklouk, Norsafinar Rahim. . . . 1475

Clinician Needs and Requirements for a Decision Aid Navigator: Qualitative Study (e69756)
Brad Morse, Carrie Reale, An Nguyen, Erin Latella, Hannah Bauguess, Shilo Anders, Pamela Roberts, Spencer SooHoo, Robert El-Kareh, Andrey Soares, Lisa Schilling. . . . 1493

Symptom Management Preference and Persona Development for Mobile Health Design Targeting Chinese Older Adult Patients With Breast Cancer: Descriptive Qualitative Study (e71448)
Danyu Li, Yanlin Zhu, Changrong Yuan, Qingmei Huang, Yang Yang, Zhaohui Geng, Xiaotong Yuan, Fulei Wu. . . . 1504

Exploring Clinician Experiences With a Digital Platform Supporting Orthopedic Care That Integrates Patient-Generated Health Data: Qualitative Study of Early Users (e65216)
Dmitri Katz, Daniel Gooch, Linda Price, Irum Rauf, Oliver Pearce, Blaine Price. . . . 1515

Abstract

Background: Chronic obstructive pulmonary disease (COPD) affects approximately 16 million Americans and often results in avoidable readmissions due, in part, to medication errors and lack of education. Telehealth interventions can support medication reconciliation and inhaler education following hospital discharge for patients with COPD.

Objective: This study aimed to design and prototype TELE-TOC (Telehealth Education: Leveraging Electronic Transitions of Care), a post-discharge, in-home, televisit intervention, and to map its workflow to ensure integration into the routine discharge care transition process for patients with COPD.

Methods: A user-centered design approach across 3 phases was followed to develop and prototype TELE-TOC. Participants included adult patients hospitalized for COPD exacerbations, their caregivers, clinicians involved in COPD care, and organizational leaders. Data collection methods included semi-structured interviews, system usability scale surveys, and cognitive walkthroughs of the TELE-TOC prototype to assess participants' perceptions on usability and feasibility of TELE-TOC implementation as part of routine COPD discharge care transitions. Qualitative data were analyzed using inductive thematic analysis and an inductive-deductive approach guided by the Agency for Healthcare Research and Quality–endorsed Care Transitions Framework. Quantitative data were summarized using basic descriptive statistics.

Results: Participants included 18 patients, 18 clinicians, 8 organizational leaders, and 2 caregivers. Phase 1 identified 3 interdependent stages of COPD hospital-to-home discharge: inpatient pre-discharge, at-home post-discharge, and outpatient clinic visit post-discharge. Key facilitators of discharge care transitions included the hospital's "meds-to-beds" program and high patient health literacy, while barriers to discharge included poor timing of education and conflicting patient priorities. Phase 2 delineated the core televisit components (eg, dedicated clinician, medication reconciliation, inhaler use, and self-management education) and flexible components (eg, reminder system and session frequency). Potential implementation enablers included multiple techniques for clinicians to access and support patient education and backup communication strategies in the event of technical issues. Potential implementation barriers included insufficient patient technology access and limited technology and health literacy, as well as limited clinician bandwidth for thorough COPD education and medication reconciliation. Phase 3 TELE-TOC prototype walkthroughs demonstrated a positive patient experience (average system usability scale score of 97.5/100), attributed to the benefits of videoconferencing technology for hands-on teaching and the use of the virtual teach-back method. Identified barriers included varying levels of patient technology literacy, insufficient inhaler education, limited patient understanding of medication lists, and clinician uncertainty around TELE-TOC documentation. Suggestions for mitigating these barriers included patient training for TELE-TOC sessions, amendments to pharmacists' "visit note," and enhanced patient preparation for medication reconciliation.

Conclusions: Using a co-design approach, we integrated multiple perspectives to develop and optimize TELE-TOC, a patient-centered televisit intervention aimed at supporting discharge care transitions to improve continuity of care and outcomes for patients with COPD. Future research will evaluate the impact of TELE-TOC on readmissions from acute exacerbations.

Introduction

Chronic obstructive pulmonary disease (COPD) affects over 16 million Americans [1]. A leading cause of hospital readmissions [2] and mortality [3], COPD is projected to cost American health care systems over US $60 billion by 2029 [4]. To reduce costs related to preventable readmissions after an index admission for COPD [5], the Centers for Medicare and Medicaid Services included COPD as part of the Hospital Readmissions Reduction Program (HRRP) financial penalty to reduce hospital readmissions and their associated costs [6,7].

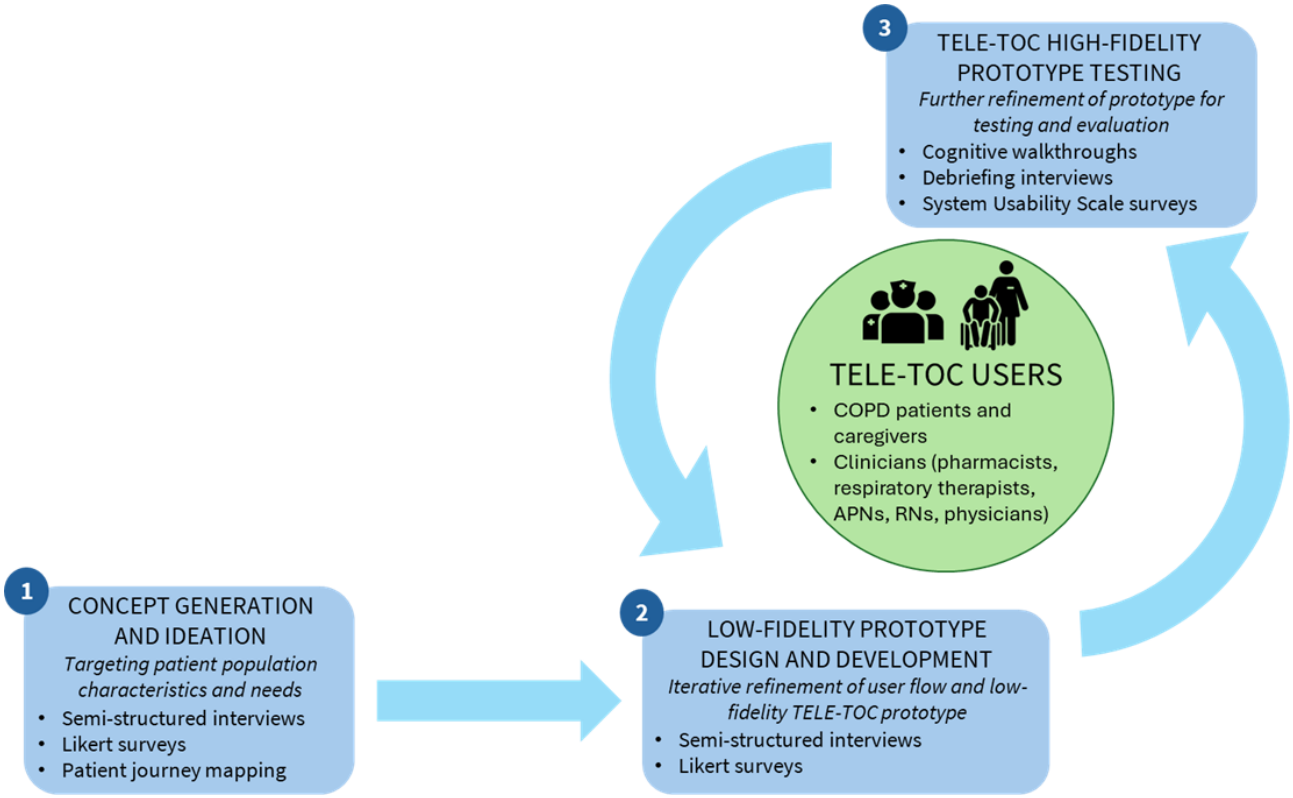
Several factors contribute to readmissions, including inadequate patient self-management of COPD and suboptimal care following a hospital discharge. These factors are often attributed to poor implementation of COPD care guidelines among clinicians during discharge [8], fragmented and inadequate discharge education on strategies to improve skills for COPD self-management at home [9,10], lack of follow-up with patients [11], and insufficient understanding about proper use of medications, including inhaler techniques [12-14]. To address these gaps in medication and symptom self-management, care transition interventions have been explored by many, including our team [15,16]. For instance, pharmacist-led medication reconciliation programs at discharge have been shown to reduce medication discrepancies and 30-day readmission rates for older patients with COPD [17]. Similarly, inhaler technique education using a "Teach-To-Goal" (TTG) approach, consisting of rounds of assessment and education prior to discharge, was shown to reduce all-cause readmissions after initial admissions for COPD compared to simply providing verbal instruction [13,16].

While promising, both medication reconciliation and TTG at discharge can be resource-intensive and challenging to implement at large scale within existing hospital workflows [16,17]. Moreover, although in-hospital pre-discharge interventions may improve patient self-management and potentially reduce readmissions, medication errors still occur in more than half of patients after hospital discharge [18]. Inpatient-only care is likely insufficient for many patients, and researchers recommend that interventions (eg, medication reconciliation and education) extend post-discharge for sustaining medication and COPD self-management skills [19].

To address sustainability and effectiveness concerns, our team helped to develop a pharmacist-led, at-home telehealth program, which has improved inhaler technique and quality of life among patients with COPD, while reducing symptoms [20,21]. Other research has also shown that post-discharge televisit medication reconciliation reduces medication errors across populations [22,23]. The virtual approach for medication review and reconciliation and teaching inhaler technique could enhance COPD education, medication management, and care quality without increasing costs. Informed by published evidence [20,21,24], we developed an end user–informed, comprehensive, post-discharge televisit service termed TELE-TOC (Telehealth Education: Leveraging Electronic Transitions of Care) to facilitate inhaler education and reinforcement of COPD self-management skills and provide opportunities for medication reconciliation and counseling by clinical pharmacists. Here we report on the development and prototyping of the TELE-TOC intervention and identify the components and implementation process necessary to fit TELE-TOC into our current COPD HRRP and DTOC (Discharge Transitions of Care) workflow.

Methods

Study Setting



The study was conducted at the University of Chicago Medicine (UCM). We are developing the TELE-TOC intervention for integration into our existing COPD HRRP [25].

Study Approach

We followed a user-centered design (UCD) approach to ensure TELE-TOC met the needs, preferences, and behaviors of end users (eg, patients, clinicians, and organizational leaders [OLs]) while considering usability and accessibility (eg, older age, limited health, and technology literacy) [26,27]. Multiple end users were actively engaged in the development of TELE-TOC across 3 iterative phases (Figure 1). Phase 1 mapped the current hospital-home-outpatient care transition workflow for patients with COPD, with emphasis on perceived workflow facilitators and barriers from multiple perspectives (ie, patient, caregiver, clinician, and OLs). Data-informed strategies were then developed to address care transition barriers and inform the TELE-TOC role within the current workflow. Phase 2 identified design ideas and implementation considerations using a low-fidelity TELE-TOC prototype with emphasis on potential facilitators and barriers to adoption and implementation. Phase 3 focused on evaluating the usability and feasibility of a high-fidelity TELE-TOC prototype.

XSL•FO
RenderX

Figure 1. User-centered design phases for Telehealth Education: Leveraging Electronic Transitions Of Care development. APN: advanced practice nurse; COPD: chronic obstructive pulmonary disease; RN: registered nurse; TELE-TOC: Telehealth Education: Leveraging Electronic Transitions of Care.

Participants

Phases 1 and 2: (1) adult patients admitted for COPD exacerbations enrolled in our COPD HRRP, (2) clinicians (pharmacists, advanced practice nurses [APNs], hospitalists, primary care physicians, pulmonologists, and respiratory therapists), and (3) OLs (patient safety and quality improvement hospital leaders). Phase 1 also included patient caregivers. Phase 3: TELE-TOC end users (adult patients and inpatient clinical pharmacists). While we planned to include caregivers in all phases, they were ultimately only included in Phase 1 due to challenges with further caregiver participation (eg, patient discomfort with caregiver involvement, lack of caregiver availability, passive caregiver, and lack of caregiver altogether).

Data Collection

We used semi-structured interviews to gather participant perspectives on current discharge care transitions. Interview guides were iteratively developed and refined with input from pilot interviews with 2 patients and caregivers from the COPD Foundation, a clinician involved in caring for patients with COPD, and an OL.

Phase 1 mapped current DTOC workflows, ascertained facilitators and barriers, and delineated potential for televisit interventions. Phase 2 assessed attitudes toward the proposed televisit intervention, a low-fidelity prototype of PowerPoint slides with process maps and instructions for inhaler education and identified potential facilitators and barriers to implementation. We asked participants to rate their experiences with medication reconciliation and COPD medication education using a Likert scale from 1 to 5, where 1 indicated “not prepared” or “not good” and 5 indicated “prepared” or “very good.” We requested patient feedback on preferred televisit format (phone, text, or video), comfort levels with video technology, experiences with technical difficulties, and confidence in internet usability. Phase 3 comprised televisit walkthrough usability sessions with 4 patients post-discharge from UCM and 2 clinical pharmacists using the TELE-TOC prototype, as previous research demonstrated that only 3 - 5 sessions were required to identify most usability issues [28]. High-fidelity TELE-TOC prototypes consisted of interactive web-based sessions integrated into MyChart (Epic Systems). Additionally, pharmacists piloted a TELE-TOC–specific templated “visit note” in the electronic health record (EHR) to document medication reconciliation and inhaler education (Figure 2). Participants verbalized their actions during the TELE-TOC process. After medication review and inhaler education, patients rated TELE-TOC usability on the system usability scale (SUS) [29] and completed debriefing interviews to assess user satisfaction and suggestions for improvement. Walkthroughs were conducted and recorded via a HIPAA (Health Insurance Portability and Accountability Act)–compliant Zoom platform (Zoom Video Communications Inc) (refer to guides in Multimedia Appendix 1).

Data Coding and Analysis

We followed an inductive (data-driven) thematic analysis approach for Phase 1 [30]. Two researchers (JA and EZ) independently read the data transcripts multiple times and openly coded the data with keywords representing the data, then identified relationships among codes, highlighting areas of similarity and overlap to form subthemes; repeated patterns among established subthemes identified overarching themes. Additionally, interview responses informed the development of a process map for care transitions of patients with COPD.

In Phase 2, we used an inductive-deductive thematic analysis approach to integrate insights on current discharge care transition processes with elements of an evidence-based AHRQ-endorsed care transition framework and implementation science guidelines, informing the design and implementation of our intervention [31]. This framework offers relevant guidelines for addressing challenges in discharge care transition processes and identifies contextual determinants that can inform intervention design and implementation (Figure 3). We used 5 of the 8 AHRQ-endorsed Care Transition Framework domains: intervention characteristics, organizational characteristics, characteristics and roles of clinicians, characteristics and roles of patients, and the process of implementation (Table 1).

Figure 3. Domains of the Agency for Healthcare Research and Quality–endorsed care transitions framework. APN: advanced practice nurse; COPD: chronic obstructive pulmonary disease; RN: registered nurse; TELE-TOC: Telehealth Education: Leveraging Electronic Transitions of Care; UCM: University of Chicago Medicine.

Table . Agency for Healthcare Research and Quality–endorsed care transitions framework for the Telehealth Education: Leveraging Electronic Transitions of Care context.

Domain	Definition	Domain contextualized for TELE-TOC[a]
Intervention characteristics	Characteristics and features of the intervention that impact implementation success	TELE-TOC characteristics (TELE-TOC visit scheduling, set-up of the reminders, TELE-TOC visit content, and TELE-TOC documentation)
Organizational characteristics	Characteristics of organizations involved in the intervention, including structural characteristics, networks and communications, culture, climate, and readiness that influence implementation	UCM[b] characteristics (insurance coverage, funding and sustainability, and ownership of TELE-TOC)
Characteristics and roles of clinicians	Attributes (eg, type of clinician, affiliations, and duties) of individuals who are engaged in the provision of care or treatment	Clinicians (medical assistant, patient service representative, pharmacist, APNs[c], RNs[d], etc) and their roles in TELE-TOC
Characteristics and roles of patients	Attributes (eg, type of patients) of individuals who are the recipients of care or treatment in the given intervention setting	Adult, low-acuity patients with COPD[e] enrolled in HRRP[f]
Process of implementation	Processes including planning, engaging, and reflecting to achieve the intended use of the intervention at both individual and organizational levels	Implementation strategies for TELE-TOC

[a]TELE-TOC: Telehealth Education: Leveraging Electronic Transitions of Care.

[b]UCM: University of Chicago Medicine.

[c]APN: advanced practice nurse.

[d]RN: registered nurse.

[e]COPD: chronic obstructive pulmonary disease.

[f]HRRP: Hospital Readmissions Reduction Program.

First, we (JA and LP) followed an inductive approach consistent with our Phase 1 analysis to generate open codes about the current discharge care transition process and contextual determinants for intervention design and implementation. We then applied the constructs underlying the AHRQ-endorsed Care Transitions Framework (CTF) [32] as a structured coding template to guide deductive thematic analysis. This step helped us to align and integrate our open codes with the constructs within each of the 5 domains in the CTF as outlined in Table 1 [33]. Following this, we then formed overarching themes, or patterns across the data that related to constructs within each care transition domain, highlighting the design and implementation needs for TELE-TOC.

In Phase 3, we (JA and AM) analyzed the cognitive walkthrough transcripts using an inductive thematic analysis approach. Usability, TELE-TOC ease-of-use, and televisit effectiveness were coded and categorized into themes and subthemes (eg, barriers and facilitators). In addition, debriefing interviews were thematically analyzed to identify TELE-TOC user experiences and suggestions for improvement.

Phases 1 and 2 surveys were summarized using basic descriptive statistics (mean). Phase 3 SUS surveys had 10 questions rated from 1 to 5. In accordance with recommendations and standard practice for analysis [29,34], we subtracted 1 from each value for odd-numbered questions sharing positive statements, and we subtracted each value from 5 for even-numbered questions sharing negative statements. After summing the new values across questions, we multiplied this final value by 2.5 and then found the average score across participants.

To ensure validity and reliability, we followed best methodological practices, including member checking and team debriefing [35]. Two researchers independently coded all data, and any inconsistencies were resolved through team discussions to reach a 100% consensus.

Ethical Considerations

This study was approved by the University of Chicago Institutional Review Board (IRB21-0947). All participants were informed of the study purpose, procedures, risks, and rights. Patients and caregivers provided written consent, and clinicians and OLs provided oral consent after reviewing the consent form with study staff. Trained personnel conducted all activities using standardized protocols, with strict confidentiality safeguards to protect participant privacy. Paper records were stored in a locked office, and electronic data were encrypted, password-protected, and housed on secure institutional servers. Hospital data were collected and stored in REDCap (Research Electronic Data Capture; Vanderbilt University), and interview data were maintained on a secure, HIPAA-compliant shared drive. Virtual sessions used the HIPAA-compliant Zoom platform with full security features enabled. Study identification numbers were used in place of personal identifiers for all analytic files. Any identifiable contact information used for scheduling or compensating participants was stored separately from study data and will be destroyed, along with audio recordings, at the conclusion of the study.

Participants in the semi-structured interviews were compensated for their time. Patients and caregivers received a US $50 gift card for each study phase they completed, and clinicians and

XSL•FO
RenderX

organizational leaders received a US $15 gift card for each phase in which they participated.

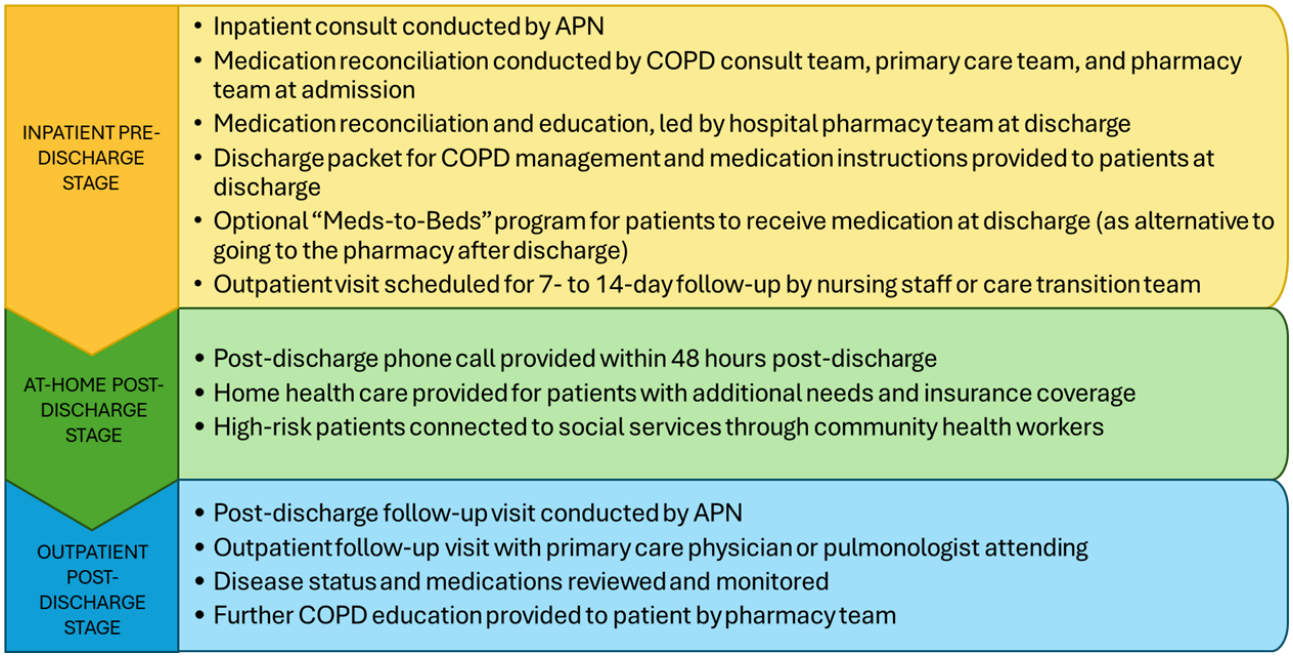
Results

Study Overview

Forty-five participants were enrolled across Phases 1, 2, and 3 (Table 2). Findings are presented across the following themes: Phase 1: current DTOC workflow for patients with COPD enrolled in HRRP; Phases 2 and 3: considerations for TELE-TOC design and implementation.

Table . Participant numbers and characteristics by phase.

Participants	Phase 1	Phase 2	Phase 3
Clinicians	12	4	2
Pharmacist	2	2	2
Respiratory therapist	3	2	0
Advanced practice nurse	3	0	0
Nurse	1	0	0
Physician	3	0	0
Organizational leaders	5	3	0
Caregivers	2	0	0
Patients	8	6	4
Age (years), mean (SD)	63.3 (9.7)	65 (11.3)	56.3 (11.0)
Race			
Black	8	6	4
White	0	0	0
Other	0	0	0
Non-Hispanic	8	5	4
Sex			
Female	4	2	3
Male	4	4	1
Other	0	0	0



The mean (SD) patient age across phases ranged from 56.3 (11.0) to 65 (11.3) years (Table 2). Most patients were identified as Black and non-Hispanic, with no representation from White or other racial groups. Sex distribution was evenly split, with 9 female and 9 male patients overall.

Phase 1: Current DTOC Workflow for Patients With COPD

The current inpatient-outpatient discharge transition of care workflow for acute exacerbations of COPD consists of 3 interdependent stages: (1) inpatient pre-discharge (hospital admission to discharge to home), (2) at-home post-discharge (home to outpatient follow-up), and (3) outpatient visit - (Figure 4).

XSL•FO
RenderX

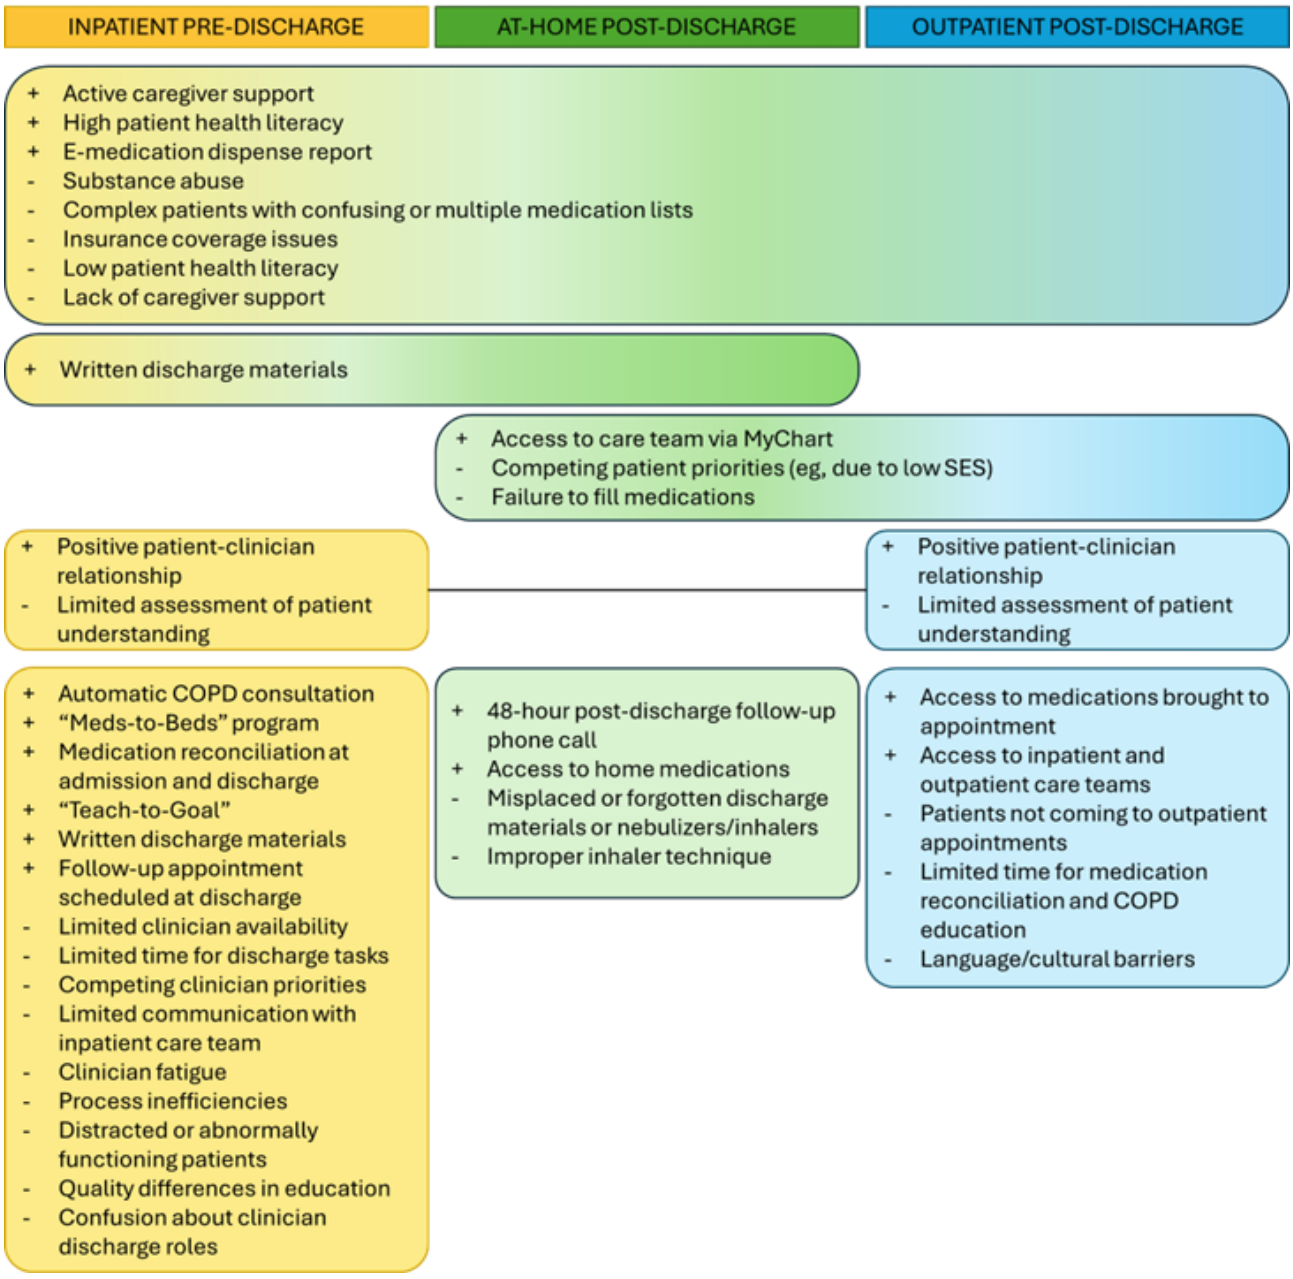


Figure 4. The interdependent stages of the Discharge Transitions of Care workflow. APN: advanced practice nurse; COPD: chronic obstructive pulmonary disease.

All participants emphasized that each stage relied on the successful execution of activities in the preceding stage, given the interdependence in the workflow. We identified additional key facilitators and barriers to the current DTOC workflow across these stages (Table 3)—with potential impacts on safety and care continuity outcomes (Figure 5).

XSL•FO
RenderX

Figure 5. Facilitators and barriers to standard inpatient to outpatient Discharge Transitions of Care workflow. COPD: chronic obstructive pulmonary disease; SES: socioeconomic status.

Table . Phase 1 topics with representative quotes. (+) Observed facilitators to current workflow; (–) observed barriers to current workflow.

Stage and topic	Quote
Inpatient pre-discharge	
(+) Medication reconciliation conducted with inpatient team	• Q1. "[The nurses] always keep contact. Because he doesn't have—he's not aware of a lot of things, and we always keep everything on my phone, his charts and everything. He always tells them, 'Ask my wife. I don't know anything.'" [CG1[a]] • Q2. "We try...talking to caregivers and involving caregivers on that discharge med reconciliation process." [C5[b]] • Q3. "I think that one of the tools that pharmacists sometimes use for medication reconciliation...It's a button called the dispense report in Epic, which can show you what patients have picked up at local pharmacies." [C11]
(+) Efficient meds-to-beds program	• Q4. "Meds-to-beds was the big thing, just because pharmacies are super short right now to make sure that they got their inhalers before they are able to go home, or a bronchodilator or steroids, anything really crucial for a COPDer." [C10]
(+) Teach-to-goal COPD[c] education	• Q5. "Our pharmacists will make sure everything's clinically relevant...[The prescription] goes over to a technician who enters it, fills it, gets it ready. Before we deliver it to the patient, my pharmacist will do a med education over the phone with the patient. So, they call the patient, do education. Once the patient confirms they understand what they're taking, what they're receiving, the technician will take it and deliver it to the room. And then the patient is discharged home." [OL3[d]]
(+) Teach-back of inhaler education	• Q6. "Really, the first step is just to have them try to explain it to me...what they're doing. And not only what they're doing, we try to get them to verbalize why they think they're doing it and connect those dots. So that's the primary mechanism." [C2]
(+) Building rapport with patients	• Q7. "Part of our needs assessment when they come in on admission is asking them about their history of smoking, how many packs, and for how many years. Sometimes they won't be as honest with you as others, that's why you try to establish rapport with them first so they kind of open up with you a little bit better." [C10]
(+) High patient health literacy	• Q8. "What I like a lot is when...the patient's...very well-educated, and they take care of their own health...I'll go over the medications. They're like, 'Yup, I know what this is for. I take it at this time.' And they verbally understand, and they can kind of repeat back to me, what's going on. And they already know that their scripts are ready at home as well." [C10]
(–) Discharge delays	• Q9."On the day that I'm supposed to be released, it was either you're waiting for the doctors to do the final paperwork, and the nurses having to bring it together to even the pharmacy gathering up the medicines that you'll be taking home with you to carry you until you get it going with your primary care and your pharmacist. So those were things that you just simply have to wait. And if one couldn't do something without—the pharmacist [can't] do their thing until the doctor does theirs. And the nurse can't do their thing until the doctor does their thing." [P4[e]]
(–) Insurance coverage issues	• Q10. "I would say 50% of drugs that we receive require prior authorization. If it's a prior authorization and we can't get it approved in time or we can't get it switched to a different therapy, we tell the patient to go home, and then we'll work on the prior authorization." [OL3]

XSL•FO

Stage and topic	Quote
(–) Absent or incomplete medication reconciliation	• Q11. “The information contained (in the expense report) is limited because sometimes people will pay cash rather than use insurance or may obtain their inhalers through different sample programs or free drug programs if they haven’t been affordable to them. So, I think the incompleteness of records that people are going into those scenarios with can be a barrier and inaccuracy in existing records, and that temptation to just confirm what’s already there can be a barrier.” [C11]
(–) Low patient health literacy	• Q12. “Unfortunately, the great majority of our patients don’t know their meds. And so, trying to speak to them about what is accurate and what might not be accurate on their medication list is a challenge.” [C2] • Q13. “I think it really depends on the patient’s health literacy and level of understanding and...we sometimes are able to get pharmacy teaching, but we don’t always get all of those patients. So, I think they’re not always as equipped as we would like them to be [for discharge].” [C5]
(–) Poor timing of COPD education	• Q14. “When a patient is getting discharged, all they think about is going home. So, we counsel them at bedside, and we give them their meds, and we teach them how to use an inhaler or whatever medication they’re receiving. But I think all they’re thinking about is going home.” [OL2]
(–) Loss of patient follow-up	• Q15. "But here, once a patient is discharged, the inpatient team is 100% done with that patient. There is no follow-up.” [C2]
(–) Varied quality of education	• Q16. “For patients that are started on biologic therapies that are hopefully helping them with their asthma/COPD, I think there’s sometimes confusion about whether or not they’re supposed to continue first-line therapy.” [C11]
(–) Limited knowledge of patient medications	• Q17. “I think a lot of it is done by pharmacy or nursing. The physician teams are not sitting and going through medications with patients for the most part.” [OL1] • Q18. “I’d say mostly just because it’s not often done by a pharmacist, and it’s done by another person who works in the institution...They don’t look to see what [the patient has] been taking, the dosage and frequencies are wrong. Routes are often wrong as well, so maybe due to lack of knowledge of some of the medications and how they’re supposed to be taken.” [C4]
(–) Time barriers and competing priorities	• Q19. “The other times when med reconciliations kind of fall apart are if they get admitted in very severe illness in the MICU, they’re focused on stabilizing the patient rather than on the med reconciliation, and so sometimes...it’s not prioritized as much as it could be...” [C5]
At-home post-discharge	

XSL•FO
RenderX

Stage and topic	Quote
(+) Active post-discharge communication	• Q20. "We do have a nurse that is part of the team that does make a 48-hour phone call. And so that's another mechanism where—if the patient actually answers the phone and is willing to engage in that conversation, that's another opportunity for the patient to voice like, 'Oh, I didn't get this inhaler.' I think she maybe reaches the patient 50 to 60 percent of the time." [C2] • Q21. "And then we also definitely found that there had to be an education component before the patient leaves the hospital, of course...I think because I think that one round of education might not be enough. And again, things might seem okay after you meet with a patient or a family, and they might feel okay about it, but then they have questions later or they forgot something." [OL4]
(+) Use of MyChart portal to facilitate communication	• Q22. "You see all them doctors I got? [sharing MyChart screen] I use [MyChart] for everything. Doctor, pharmacy, everything." [P3]
(+) Caregiver support	• Q23. "I'm thinking about one patient in particular with COPD that—and this is where the family caregivers come into play, when I need to talk to her, it's actually through her daughter." [C12]
(+) High patient health literacy	• Q24. "...the papers given explaining about different things concerning my treatment and the issues that I have, they were pretty thorough." [P4]
(–) Low patient health literacy	• Q25. "Someone who has a low literacy, you can explain it to them, but they still wouldn't get it." [C8] • Q26. "We do want our patients to be involved as much as they can be with their plan of care...But it is a lot for them at times...Sometimes we'll have charts of different inhalers, because they'll be trying to explain to us, 'Oh, I lost this one.'" [C4]
(–) Cost-related nonadherence to COPD management	• Q27. "Unfortunately, again, it's this demographic where there is such a high amount of poor health literacy, competing priorities with patients, housing instability, food insecurity, all of those things. So taking all [medications] of this in is just not on the top of their priority list." [C1] • Q28. "I think in terms of barriers...they may have different social situations or socioeconomic factors that kind of contribute to them being able to even take care of themselves when it comes to their health." [C5]
(–) Comorbidities impacting patient health	• Q29. "Quite a few of our [patients]...with COPD are still heavy smokers, and a lot of it's like, 'Yeah, I still smoke,' even though they're on oxygen. And so that's something else you also have to educate them on, and they're like, 'Well, I've been doing this for years. I'm okay.'" [C9]
Outpatient post-discharge	

XSL•FO
RenderX

Stage and topic	Quote
(+) Medication review in clinic	• Q30. “[In my] follow-up visit with primary care...[We go over] full medication review, how I’m feeling, [ask about] medicine I’m taking and everything.” [P7] • Q31. “But sometimes people aren’t really sure which medications they are taking. I mean, the names are different, and they get changed around from time to time. And so having someone actually at home verifying, ‘Oh, these are the inhalers that they actually have at home...’” I try to have them bring in their medications.” [C3]
(+) Caregiver support	• Q32. ”Also encourage them, if there is a family member or someone else that is sort of helping them with meds and kind of to keep things straight, to bring that patient—bring that person, rather, to the appointment“ [C2]
(–) Missed appointments due to travel barriers	• Q33. “...it’s often not super easy for them to leave the house. A lot of them require oxygen. They’re not extremely mobile. And so actually physically getting to the pharmacy or having someone pick their medications up can sometimes be difficult.” [C4]
(–) Missed appointments due to costs	• Q34. “They discuss[ed] price, like how would a medicine be obtained or any co-pays, any substitutions, or generic types. Because I was switched over to this Eliquis and more could have been explained about that.” [P4]
(–) Incomplete information/ communication with outpatient team	• Q35. “Patient comes for follow-up and generally, when you’re a primary care doctor or any doctor, I would imagine, you’re sort of triaging the most important to the least important. And education and med rec tend to fall further on the bottom than direct patient care and acuity of the patient.” [OL2] • Q36. “Every ambulatory clinic has a different system of how they reconcile or who reconciles or if they reconcile. So, for patients who see a lot of providers, they may or may not have a very up-to-date list.” [C2] • Q37. “I think the other thing, too, is, depending on the patient’s environment...there might be a language barrier as well.” [OL3]

[a]CG: caregiver.

[b]C: clinician.

[c]COPD: chronic obstructive pulmonary disease.

[d]OL: organizational leader.

[e]P: patient.

Inpatient Pre-Discharge Stage

Facilitators

Several facilitators enabled successful inpatient management and preparation for discharge. First, the COPD APN consultation was a mandatory step for enrolling in the COPD HRRP. In addition to clinical recommendations for the primary inpatient team, APNs provided written discharge materials to patients in the form of a COPD Action Plan. When possible, the pharmacy team provided medication reconciliation, which helped clinicians and patients to identify and address issues concerning missing or misused medications. At times, caregivers facilitated this process by playing an active role in medication reconciliation, aiding patients in recalling their home medications (Table 3, Q1 and Q2). Clinicians further noted that the Epic EHR medication dispense report aided in the medication reconciliation process (Table 3, Q3).

At discharge, eligible patients could receive additional medication reconciliation facilitated by the “meds-to-beds” program that delivered prescription medications directly to the bedside before discharge (Table 3, Q4). Finally, the pharmacy team provided inhaler instructions, using the TTG method to assess and encourage patient understanding (Table 3, Q5) [14]. Clinicians and OLs especially emphasized that using TTG at discharge significantly improved patients’ understanding of inhaler usage and follow-up care instructions (Table 3, Q6). Therefore, 67% of patients who responded in Phase 1 (4/6) felt prepared or extremely prepared to manage their COPD following inpatient discharge, with a mean (SD) survey score of 4.5 (1.03). Additionally, 83% of Phase 1 patients (5/6) agreed or strongly agreed that their inhaler education was helpful, with a mean (SD) survey score of 4.5 (0.84).

Clinicians and OLs further noted that an established positive clinician-patient relationship facilitated effective COPD education by creating rapport and improving patient comfort in speaking honestly about their needs (Table 3, Q7).

High patient health literacy also significantly aided the discharge process: both clinicians and patients felt that patients with a

XSL•FO
RenderX

clearer understanding of their health were better able to retain and use COPD self-management instructions. They also felt that patients' health literacy significantly improved medication reporting (Table 3, Q8). Finally, patients benefited from scheduling an outpatient follow-up appointment at discharge, which promoted care continuity and coordination of the next care steps with our program.

Barriers

Several barriers prevented a streamlined workflow and successful COPD education. Only 22% of clinicians in Phase 1 (2/9) felt satisfied with pre-discharge medication reconciliation, rating current practices a mean (SD) of 3 (0.83).

Frustrations were also reported around discharge delays due to inpatient processes that depended on multiple clinicians performing patient care tasks in a timely manner (Table 3, Q9). Another concern was inconsistent insurance coverage for "meds-to-beds." Clinicians reported other issues with insurance, stating that time-intensive processes (eg, prior authorization and communication with pharmacies) delayed medication delivery (Table 3, Q10). While medication reconciliation was highly recommended at admission and at discharge, limited pharmacy availability during some off-hour admissions resulted in missed consultations. In cases where pharmacists were available, other complications led to a lack of clear or accurate information on patient medication, hindering medication reconciliation (eg, complex medication lists, multiple patient records, undocumented and uninsured pharmacy purchases) (Table 3, Q11). Furthermore, clinicians and OLs observed that patients with poor health literacy struggled to correctly report their home medications, often relying on caregivers to understand their medication lists and provide accurate information (Table 3, Q12). Many clinicians noted that fast-paced education at discharge coupled with poor health literacy often resulted in patients failing to retain instructions (Table 3, Q13).

A few participants noted that educating patients immediately before discharge was not the optimal time, as patients with COPD were disoriented or eager to go home, failing to engage with the discharge COPD education and medication review, and returning home confused about self-management (Table 3, Q14). Furthermore, some patients were unable to contact their inpatient team following discharge when they had questions or were unsure about self-management (Table 3, Q15). Depending on the clinician's role (eg, respiratory therapist vs nurse vs pharmacist) and experience, the quality of patient education varied widely.

Additionally, with several inpatient team members visiting the patient and multiple lines of COPD therapy, confusion sometimes arose about instructions (Table 3, Q16). A few clinicians reported that with 6‐12 patients to manage simultaneously, challenges such as fatigue and limited understanding of roles and responsibilities in the discharge process prevented complete and successful education (Table 3, Q17 and Q18). Due to excessive clinician workloads, many stated that they frequently prioritized direct care over medication reconciliation and COPD education. As a result, only 17% of Phase 1 clinicians (2/12) felt that patients were prepared to manage their COPD following discharge (Table 3, Q19).

At-Home Post-Discharge Stage

Facilitators

Despite clinician dissatisfaction, 86% of Phase 1 patients (6/7) felt that they were prepared to take their medications following discharge from the hospital, with a mean (SD) score of 4.5 (0.76). Several aspects of the DTOC workflow enabled successful COPD self-management. Patients received a follow-up 48-hour phone call from a COPD registered nurse to check in on health and address any concerns or questions (eg, obtaining medications and post-discharge visit scheduling) (Table 3, Q20). Most patients appreciated the clarification on COPD self-management that the phone call offered (Table 3, Q21). Furthermore, patients enrolled in the MyChart patient portal had easy access to communication with both inpatient and outpatient teams during transitions (Table 3, Q22). Some patients received further support from caregivers who helped with medication compliance and proper inhaler use (Table 3, Q23). Patients with higher health literacy took a proactive role in their COPD self-management and remarked that the discharge materials given to them were useful and effective (Table 3, Q24).

Barriers

Conversely, patients with lower health literacy or patients of lower socioeconomic status are more likely to throw their discharge instructions away or neglect to read them, resulting in improper COPD self-management. In a few cases, patients lost their nebulizers or inhalers (Table 3, Q25 and Q26). Lower socioeconomic status patients also reported competing priorities (eg, housing and food insecurity) that prevented them from focusing on COPD self-management. In addition, some could not afford the cost of their medications and therefore did not fill their prescriptions (Table 3, Q27 and Q28). Finally, clinicians reported poor patient self-management due to individual factors, including substance abuse and mental health issues (Table 3, Q29).

Outpatient Post-Discharge Stage

Facilitators

At outpatient post-discharge follow-up, clinicians continued to monitor patient condition and COPD self-management. Patients were scheduled with COPD APNs for a post-discharge visit within 1‐2 weeks, where ongoing COPD care needs were evaluated and attended to; patients also received additional inhaler training from the pharmacy team. All Phase 2 patients (6/6) felt prepared or extremely prepared to manage their COPD following their outpatient follow-up, with a mean (SD) score of 4.5 (0.55). Like the inpatient setting, successful outpatient follow-ups were supported by an established relationship between the patient and the outpatient team.

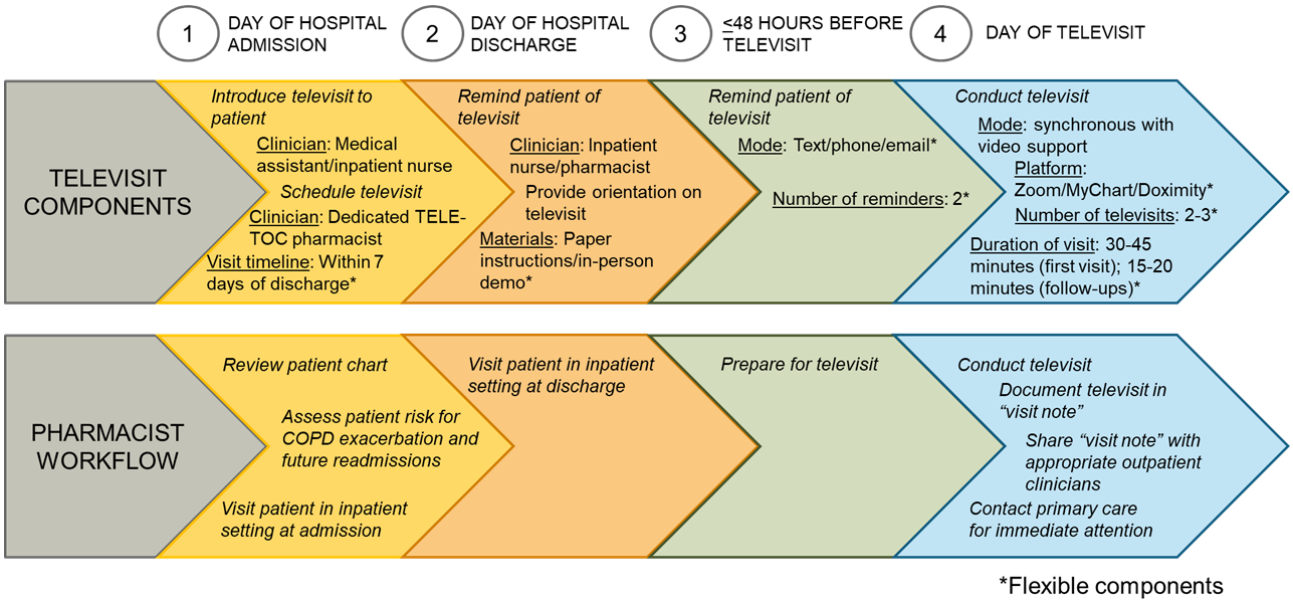
Some patients were able to discuss medications more clearly by physically bringing the medications to their appointment or having their caregivers attend. This, along with access to the medication dispense report, helped clinicians to clearly

XSL•FO
RenderX

understand the medications and dosages that patients were using (Table 3, Q30 and Q31).

Additional caregiver responsibilities included coordinating transportation to outpatient clinics and providing accurate descriptions of medication and inhaler use (Table 3, Q32).

Barriers



Clinicians reported that many patients missed their follow-up appointments for several reasons. Some could not physically travel to their outpatient follow-ups without assistance (Table 3, Q33). Furthermore, issues with insurance and medication costs continued into the outpatient stage, with patients sacrificing their follow-up appointments to pay for other necessities. Patients also reported going without medications due to expensive copays or if they were uninsured, leading to medication adherence discrepancies (Table 3, Q34).

Even though many patients spoke with their outpatient clinicians, the short appointment duration often resulted in incomplete medication reconciliation and limited assessment of patient literacy about medication use and COPD self-management. These issues, in addition to occasional cultural or language barriers, prevented clear communication and understanding between patient and clinician and sometimes resulted in misunderstandings about at-home care and medication use (Table 3, Q35-Q37).

Phase 2: Potential Role and Impact of Televisit Intervention on DTOC Workflow

Following our assessment of the DTOC workflow, we designed the televisit service with an initial, post-discharge, at-home televisit, followed by additional follow-up televisits before or after outpatient follow-up to maintain continuity of care. We developed a low-fidelity, televisit prototype for virtual pharmacist-led follow-up to provide inhaler training and medication reconciliation. Based on participant feedback, we categorized intervention design requirements as core (fundamental) or flexible (aspects tailored to patient preference) (Figure 6).

Figure 6. Telehealth Education: Leveraging Electronic Transitions of Care–integrated inpatient to outpatient Discharge Transitions of Care workflow. COPD: chronic obstructive pulmonary disease; TELE-TOC: Telehealth Education: Leveraging Electronic Transitions of Care.

Participant-proposed core components included a dedicated care transition clinician role, medication reconciliation, and coordination with outpatient care teams, and COPD education to reinforce inhaler techniques and skills with teach-back. Flexible components, adapted to patient needs and preferences, would include format, structure, reminders, and platform options. Participants felt that multiple options for these components would allow for flexibility and customization based on patients' preferences and needs. During the televisits, clinicians would use a checklist to ensure thorough inhaler education and teach-back. Additional patient COPD resources would be provided, including an inhaler use handout with visual aids and step-by-step instructions.

Most participants stated that televisits could address several barriers and augment the current DTOC workflow. They specifically mentioned potential improvements in patients' accessibility to virtual care, which could increase outpatient follow-up adherence. Participants' insights informed the iterative design of the televisit service, along with details on workflow and components according to patient and clinician preferences. We highlight the potential facilitators and barriers to televisit implementation (informed by the AHRQ-endorsed care transition framework) that may impact its buy-in and adoption (Table 4).

XSL•FO
RenderX

Table . Phase 2 topics with representative quotes. (+) Potential televisit facilitators; (–) potential televisit barriers.

CTF[a] domain and topic	Quote
Intervention characteristics	
(+) Use of televisit reminders	• Q1. "Maybe there's an initial text message that you're set for your appointment, this is your day, maybe 24 hours prior and then an hour maybe prior to their visit...Because I think that will remind a patient...like, 'Hey, it's time for you to get ready for your tele visit. Please sign on.' And maybe there's the link, and they go right to that link, and it takes them right to the visit." [OL6][b] • Q2. "A text would be best [to remind me]." [P9][c]
(+) Convenience of televisit	• Q3. "When it be cold and they don't have me coming out, that's when I do it on the phone with the doctors...Yeah. And raining. I ain't going out in the rain." [P11] • Q4. "We've actually seen an increase of [patients] attending visit(s) when it was telehealth because they didn't have to worry about getting a ride or commuting here." [OL3]
(+) Flexible televisit timing and frequency	• Q5. "[Wait to schedule the visit for] at least about a week...And that way, they...try to get familiarized with their house again because...coming home from the hospital is an experience." [P14] • Q6. "I think most of the time, patients are still overwhelmed when leaving the hospital...I think the sooner, the better to ensure that they start off on the right foot as far as utilizing their medications appropriately to prevent readmission." [C16][d] • Q7. "I think two to three visits would be reasonable..." [C15]
(+) Convenient documentation and education via televisit	• Q8. "One of the cool things about telehealth is you can actually have someone show you. So as long as they were doing it through a cell phone or a laptop or was mobile, I would say, 'Okay. Show me where you're storing your medications.' But through having patients show me their meds, I had a checklist of...is it being stored at the correct temperature, right? Is it in their fridge or not? Is it being stored mindfully with regard to if it's something that shouldn't be exposed to light?" [C11] • Q9. "I think the first visit is going to be primarily teaching, me showing them, 'This is how it's done, essentially.' And then second and third visit would be more assessing, 'Now that you've learned how to do this properly, how are you actually doing it?' And then additionally, outside of even inhaler technique, "Are you remembering to take it every day? How can we do those adherence sort of things, like setting reminders on your phones, engaging family members to help you, things like that?" [C13] • Q10. "In the first half, making sure there's no contraindications or medication, like disease and drug interactions. I always document that it's a virtual visit. And I also document if an interpreter or translator is needed. In the second half, I talk about medications: 'Are you still taking amlodipine? What are you taking for blood pressure...What medications are you taking?'" [C14]
(+) Dedicated role to support patients post-discharge	• Q11. "Just need the support (for a patient), either over the phone or in person to help navigate." [P9]
(–) Patient lack of access to technology	• Q12. "You want to make sure people have a camera, obviously, to use the video visits...So, getting a webcam. Making sure you either have headphones or a speaker or some way that you're going to physically communicate because a lot of the webcams may have speakers but may not necessarily have a microphone to pick up sound." [C15] • Q13. "I mean, there's plenty of barriers. Do they have phone service? Do they have cell service? Do they have internet access? Are they able to use Zoom or other video-conferencing software or MyChart software to access the visit?" [C5]
Characteristics of clinicians	

XSL•FO
RenderX

CTF[a] domain and topic	Quote
(+) Clear roles and responsibilities for clinicians	• Q14. “I think you also need a PSR to schedule them...It’s a big burden to worry about constantly scheduling the patients. What we do is we provide the schedulers with a template of the times where we are available, and then the schedulers place patients on that schedule.” [C14] • Q15. “I think the person that probably has the least time (to conduct a tele-visit) is probably the MD...It’s hard to say. My mind drifts towards RN maybe having more time.” [C13]
(–) Lack of clinician bandwidth	• Q16. “One big barrier for myself has kind of been a theme all along...doing the notes was a barrier for me. These notes...were relatively in-depth in that they were kind of like progress notes...But I think that was a major barrier for me in that if the average visit was 45 minutes and I had 60 minutes allotted to it, that meant I had to write my note in 15 minutes, which wasn’t always possible. And then sometimes staying late taking work home.” [C13]
(–) Inability to conduct in-person physical assessments	• Q17. “Some patients feel like it’s not a good visit, like it’s not a real visit because we didn’t touch them or really get to see them or do full vitals.” [C1]
Characteristics of patients	
(+) High patient health literacy	• Q18. “[I want to learn about] my health, medications, the do’s and the don’ts.” [P9] • Q19. “I do think you’re right. I think that there are some patients who you could probably do this in 10, 15 minutes, and it just goes by really quickly, and other patients that are going to take 45.” [C3]
(–) Low patient health literacy	• Q20. “Oftentimes, our patients have a gap in health literacy which impedes some things, which this would be a nice bridge to. But there would be also the concern that their technical literacy might also prevent them from doing a visit...” [OL4]
(–) Low patient technology literacy	• Q21. “What is their, I guess you can say, digital literacy? Do they know how to use it? Do they know how to get on to that?...When I think about the population that are most likely COPD, it’s usually an older population. I don’t know if they understand how to use that technology.” [OL3]
Process of implementation	

XSL•FO
RenderX

CTF[a] domain and topic	Quote
(+) Provision of training strategies for patients	• Q22. "So, I mean, if we're doing these visits through like a telehealth type visit...maybe it's techniques of how to be able to engage with a patient through a Zoom type of link and different techniques to make sure that you can assess the patient is able to do the proper techniques if they're using an inhaler or something." [OL6]
(+) Back-up strategies for implementation	• Q23. "Usually, we'll just ask the patient if we can call them on their cell phone. So that way, at least if there's anything major that we can still conduct most of the visit and still address anything that's immediate." [C16]
(+) Use of hands-on teaching strategies	• Q24. "I ask them to show me basically how do you do it, without actually doing it. And if they don't, then what I usually try and do is, if there's a video, I'll show them that, because I think that's really nice and typically, they can explain it better than I can. And then I'll supplement that with, "Okay. What questions do you have? And kind of show me what they showed you," and kind of do hands-on teaching from there." [C13]
(+) Incorporation of buy-in strategies	• Q25. "Yeah. And then you make sure that their inner (support) circle...knows [about COPD management]." [P14]
(–) Health care hierarchy clashes	• Q26. "I think doing the telemedicine at the skilled nursing facility is...really difficult. And the reason...is because they basically have somebody there giving them the medication...And theoretically, it's a trained professional who should be watching them do it. So I think that's difficult. Are you kind of stepping on someone's toes by doing it there? I don't know." [C13]
Organizational characteristics	
(–) Insufficient funding	• Q27. "I think that you're going to want to think about how...if the program is successful, how are you going to sustain it? A lot of these things that—it's great. They get grant funded. They get developed. And then once the grant funding runs out, then sustainability becomes an issue." [OL1]
(–) Lack of TELE-TOC[e] ownership	• Q28. "One of the things we had to figure out was who's going to own this process? Was it going to be nursing? Was it going to be my team? Was it going to be ambulatory? And so, coming up with that solution, I think, is one of the initial steps." [OL5]

[a]CTF: Care Transitions Framework.

[c]P: patient.

[d]C: clinician.

[e]TELE-TOC: Telehealth Education: Leveraging Electronic Transitions of Care.

Intervention Characteristics

Facilitators

All participants felt that televisits could be supported with 2 - 3 text or phone call reminders to increase attendance and effective usage. While most were flexible with reminder timing, some specifically requested a reminder the day before or on the day of the televisit. Patients who preferred text reminders also felt that helpful messages should include tele-visit details (eg, clinician information, timing, and connection instructions) (Table 4, Q1 and Q2). Several patients believed that clarification for questions and concerns was more easily addressed via televisit between discharge and outpatient follow-up, allowing easy access to a pharmacist in the comfort of their homes (Table 4, Q3 and Q4). All patients and most clinicians and OLs believed that 2 - 3 televisits would be optimal (Table 4, Q7). They also felt that patients needed to settle in at home, observe treatment effectiveness, and gather any questions or concerns they have regarding medication use or discharge instructions, so televisits should be scheduled at least a week past discharge (Table 4, Q5 and Q6).

A few clinicians highlighted that using video televisits allowed patients to more easily show pharmacists their medications and inhaler routines (Table 4, Q8 and Q9). Most clinicians and several OLs also felt that the televisit service could be facilitated with the Epic EHR visit note template to document patient information, medication regimen, adverse events, quality of life, and patient counseling. In the event of an emergency, this

XSL•FO
RenderX

template could be forwarded to other clinicians. Clinicians stated that documentation could reduce information omission and maintain consistency (Table 4, Q10). Additionally, clinicians suggested that visits should be led by a nurse or pharmacist, as they were knowledgeable about their patients and often had more availability. Some patients also believed that televisits could be more effective with technical support (Table 4, Q11).

Barriers

A few clinicians and OLs highlighted that a fraction of patients might not have internet access, limiting their ability to connect to the televisit. Furthermore, issues with internet connectivity or video quality could prevent clinicians from seeing patients and medications clearly (Table 4, Q12 and Q13).

Clinician Characteristics

Facilitators

To avoid confusion about responsibilities and promote successful televisit implementation, most clinicians felt that a medical assistant, patient service representative, or nurse should schedule televisits. Many also recommended that clear roles and responsibilities be outlined to ensure better coordination and improvement of patient outcomes (eg, medical assistant or patient service representative for scheduling, nurse or pharmacist for televisit) (Table 4, Q14 and Q15).

Barriers

Several clinicians mentioned that time and workload could significantly limit their ability to conduct and document televisits. They worried that extra time after the visit would be required to accurately document the session, increasing the workload and potentially affecting documentation quality (Table 4, Q16). Others also stated that they might struggle with assessing physical symptoms through virtual televisits, impacting patient satisfaction (Table 4, Q17).

Patient Characteristics

Facilitators

Several clinicians felt that patients with high health literacy would be the most proficient users of the televisit service, as they would be more likely to engage during COPD education (Table 4, Q18 and Q19).

Barriers

Some clinicians and OLs worried that poor patient health literacy or technology literacy could negatively impact patient engagement during the visit, limiting the effectiveness of televisit outcomes (Table 4, Q20 and Q21). A total of 50% of Phase 2 patients (3/6) stated they had never used video technology platforms or conducted televisits, and several were not comfortable with FaceTime (Apple, Inc), WhatsApp (WhatsApp LLC), or other video chat technologies, scoring their comfort a mean (SD) score of 2 (2.00). Furthermore, some clinicians predicted that patients might have difficulty using apps such as Zoom videoconferencing software or the MyChart patient portal. Only 1 patient respondent was 100% comfortable using the internet, and many stated that they would need help, with a mean (SD) score of 2.3 (1.63).

Process of Implementation

Facilitators

To successfully implement the televisit, participants all suggested training and education for both clinicians and patients on the visit procedure (Table 4, Q22). A few clinicians and OLs also suggested conducting televisits via phone call if technical issues occurred (Table 4, Q23). Several clinicians believed that using demonstrational videos or other visuals would help to engage patients during televisits, increasing their understanding of COPD management and improving patient outcomes (Table 4, Q24). To encourage buy-in, a few clinicians and patients suggested involving caregivers in the televisit. As caregivers played an active role in patients' lives, participants speculated that they could encourage treatment adherence and aid the medication reconciliation process (Table 4, Q25).

Barriers

Several clinicians mentioned that some patients might receive care at skilled nursing facilities, which could introduce patient management conflict between tele-visit clinicians and in-facility clinicians (Table 4, Q26).

Organizational Characteristics

Facilitators

Our participants did not report any organizational facilitators within our data.

Barriers

All clinicians and some OLs strongly felt that secured funding for and clear, defined ownership of the televisit service were essential for long-term sustainability and consistent clinician accountability (Table 4, Q27). A small number of clinicians also highlighted their lack of dedicated space to conduct televisits, potentially making both the clinician and patient uncomfortable and affecting the quality of communication (Table 4, Q28).

Phase 3: Participant Perceptions of TELE-TOC Prototype

Following 5 walkthroughs with our high-fidelity TELE-TOC prototype, patients and pharmacists discussed their perceptions of TELE-TOC and identified facilitators and barriers to TELE-TOC overall, medication reconciliation, and inhaler education. Furthermore, suggestions for improvement were made (Table 5).

XSL•FO

Table . Phase 3 topics with representative quotes. (+) Observed facilitators to Telehealth Education: Leveraging Electronic Transitions of Care; (–) observed barriers to Telehealth Education: Leveraging Electronic Transitions of Care.

Theme and topic	Quote
Participant perceptions of TELE-TOC[a]	
Appropriate content and duration of TELE-TOC sessions	• Q1. "I still have some questions too. And with the pharmacists too, we could sit down and we could talk a little bit more. I figured we didn't talk long enough." [P16][b] • Q2. "[The tele-visit] gave you all the—it gave me all the information I needed to help me, like I said, because I have to help me, not just let somebody else help. So that's what I like about this." [P17]
Preference for hands-on engagement	• Q3. "Just it was helpful to have someone actually really explain it rather than just hand you a piece of paper and your meds and say, 'Here you go.'" [P16] • Q4. "[The inhaler instruction] was easy because I can actually see the way he was showing me how to do it because I'm a visualist. I need to be able to see you do it so I know, 'Okay. This is how I need to do it.' And that helped me." [P17]
Improved confidence in COPD self-management	• Q5. [Upon being asked by the clinician whether the tele-visit made the patient more confident in COPD self-management] "Yes, because I know as long as I do what I'm supposed to do, my chances of going to the emergency room are decreased. I prefer to be able to—like you said, I'm in the comfort of my own home...I just want to have everything that I need right here with me and it'll be accessible to me so I can take care of me better." [P17] • Q6. "For me, it's just like a sparkle that somebody even cared enough to talk later...You came in there—you came in there and talked to me, and I feel like we've been knowing each other for—do you understand what I'm saying?" [P18]
Experiences with medication reconciliation component of TELE-TOC	
(+) Straightforward medication reconciliation with use of video technology	• Q7. [Upon patient confusion about two medications with the same cover but different names] "No, no, no, no, no. We got the Symbicort. I told you I had two of them. It was only one...Can you see that?" [P16]
(+) Easy access to patient health information via MyChart	• Q8. [Upon clinician asking if the patient was taking Lasix] "I was taking some Lasix. And I was just told to leave that alone too. So I'm not taking Lasix anymore...They cut that out." [P16] • Q9. [Upon clinician asking if the patient received azithromycin recently] "No, I don't even know what that is." [P16]
(+) Improved understanding of medication through in-depth patient education	• Q10. "When you give somebody or tell somebody to take stuff, tell them what it's for and make sure they understand what it's for. Just don't [say] like, 'Here, take this here three times a day and call me next week and let me know how you feel.'" [P16] • Q11. [Upon patient asking about what a spacer does in relationship to inhalers] "Oh, that's not for your inhalers. That helps strengthen your lungs. So that helps kind of control—so when you push this button, the medication comes out really quickly. This allows it to just kind of—allows us to take a much easier and deep breath with the medicine, and it allows it to get fully into our lungs." [C17][d]
(–) Lack of patient preparation for medication reconciliation	• Q12. "It would have been better if I had a copy of that [medication] list to go over it with you. [When asked if the patient could find their medications to show the clinician] I can't find them right now. That's what I was looking around for, but I was getting short of breath just looking for them." [P16]
Experiences with inhaler education component of TELE-TOC	

XSL•FO
RenderX

Theme and topic	Quote
(+) Enhanced inhaler education through visual cues from video technology	• Q13. “So what I’m going to have you do is you’re just going to act. As we go through this, you’re just going to act like you’re taking it. I’m not asking you to take an extra dose. But as we go through it, I want you to show me what you would normally do. So from the beginning, and don’t open the lid all the way, that’ll waste a dose, but we’ll act like the lid is open.” [C18]
(+) Improved understanding of inhaler education through teach-back method	• Q14. “I’m going to go ahead and show you really quickly. I’m just going to show you the steps and how I would use the inhaler and then have you show me one more time on how you go ahead and use it, okay?...[Upon explaining the steps and demonstrating inhaler use] That’s all I would do...Can you just go ahead and show me one more time how you would do it?” [C17]
(–) Lack of patient understanding despite education	• Q15. “[My confidence in my inhaler use is] still up in the air because I don’t know what triggers it. I don’t have a full understanding of my concentrators, of how they’re working and what to look for or when do I need to change the hoses on that and stuff. So there is still a lot more to be done with this topic.” [P16]
TELE-TOC use and implementation	

XSL•FO
RenderX

Theme and topic	Quote
(+) Smooth TELE-TOC process	• Q16. “Yeah. It was not something that I had to think hard about. It was easy for me to just go with the flow. I didn’t have to struggle trying to understand, “Okay. What are they going to ask?” I just went with it, and everything flowed right through naturally for me.” [P17] • Q17. “In terms of the last one, I think, honestly, overall, the flow was a little bit better. Obviously, this patient didn’t have their medications, but that is real world. But I think overall, say we were able to do the full visit top to bottom...” [C17]
(+) Convenient use of video technology	• Q18. [Interviewer asks whether the order of the tele-visit was easy to follow] “Yeah. Because I [inaudible] I see it.” [P15] • Q19. “[The tele-visit was] Great. I don’t have to come out. [laughter] I kind of struggle with [leaving the house]. And then I got anxiety. So, the fact is, when I can’t breathe, I panic, and it’s bad.” [P15] • Q20. “I felt good because I’m comfortable here. I didn’t have to come out into the cold or sitting in an office where I’d be uncomfortable. I’m comfortable sitting here. I’ve got my oxygen on too, so. But it felt good to be able to be at home and do something like this.” [P17]
(+) Helpful reminders for sessions	• Q21. “I appreciated [the reminder]. Yeah, it was very helpful because sometime I will forget some stuff. Then this morning they sent me one at 7:47 to say, ‘It’s time to log in.’ So I was able to log on in.” [P17]
(–) Patient desire for more in-depth education	• Q22. “I’m concerned about it all. And I need someone to be there to go over all of it. What should I do? If there’s something should happen, what should I do? I don’t want to be—I don’t want to be the one doctoring on myself.” [P16]
(–) Technical issues with Zoom	• Q23. “I can’t hear them. Can’t hear anybody.” [P16] • Q24. “My phone is not muted. My phone is not—hold on. Let me see. Microphone, iPhone microphone. We have your audio. I don’t know why you can’t hear me.” [C18]
(–) Low patient technology literacy	• Q25. [When asked about difficulty of logging into MyChart for tele-visit] “Usually, it’s really hard for me to get in, and I just give up. But it really wasn’t that bad. I guess I needed the hands-on to show me how to do it.” [P15]
(–) Confusing “visit note” for pharmacists	• Q26. “[It was confusing inputting information into the “visit note”]. Specifically under the section, quote, ‘script for pharmacist.‘ It just doesn’t feel like this necessarily belongs in a ‘visit note.‘ I’ve never seen an outpatient note say, ’This is your script that we want the doctor to say or the pharmacist to say, and then these are the responses.‘ So I just find it difficult to know what’s supposed to be included there. I’ll include his answers, but his answers are also included two or three other times in the note. For example, the question, ‘What medication do you take at home?‘ And then further down, it has a list of his medications. So I don’t really know. Do I type every medication there? It doesn’t make sense.” [C18]
Suggestions for improving content and implementation	

XSL•FO
RenderX

Theme and topic	Quote
Ask patients to prepare medications prior to sessions	• Q27. “Right. And then I would like to have— like to know to have all my medicines with me that I’m taking so that we can go over them. Don’t wait till I get on the meeting and say, ‘Dude, where’s your medicine? You got this. You got that.‘ You have all your medicines with you before we start this meeting. And that way, you got my undivided attention.” [P16]
Provide detailed education on COPD	• Q28. “[I’d like to know more about...] Maybe the causes of COPD. And how it could be treated. [Clinicians] usually just give you a paper and tell you to read aftercare, but I think if you talk about it more, people will understand it more.” [P15]
Provide clearer inhaler instructions at discharge	• Q29. “The [first day] I made it to a visit anywhere and somebody gave me an inhaler, we should have went over what we went over today. That should have been from day one...Anything that’s being used to help you breathe, it should be an in-depth— get a video of something that you should watch. All right? I mean, okay, a video is something. It’s a start.” [P16]
Provide a tutorial for TELE-TOC video chat	• Q30. “It probably would take maybe some training for them, or I would say if they were going to participate, don’t you know how you came in the room with me before we—you probably want to just ask them if you can see their phone and make sure the Zoom is set up on there.” [P18]
Amend “visit note” for streamlined sessions	• Q31. “Probably, just the template of the note I would reorganize a little bit because it kind of goes from med rec to COPD med rec and then—or COPD meds, and then it goes back to med rec again, which definitely threw me off. And there’s a lot of noise in the note, so it’s kind of hard to—while you’re trying to look at a patient, look at a note, but then also conduct something, it’s a lot to go back and forth. So I think probably rearranging the note a little more will be pretty beneficial by kind of just grouping med rec and then all the COPD stuff itself.” [C17]
Conduct TELE-TOC in a group setting	• Q32. “I would like to do it as a group. I’d like to have more than one, besides me, I want to have another patient there with me also. So we can compare our notes together. Me and that patient can talk. And that way, you’ll get a better understanding [of] how we feel...” [P16]
Target patients with medication needs	• Q33. “I think we were able to still go through the entire visit, identify some things that the patient can do better from their inhaler standpoint and then also how we can go ahead and assist the patient in terms of their medicines, not necessarily with adherence because we can’t dive too much into that, but in terms of medicines they need. Medicines that they’re out of and they need refills and stuff like that and also duplicate therapies.” [C17]

[a]TELE-TOC: Telehealth Education: Leveraging Electronic Transitions of Care.

[b]P: patient.

[c]COPD: chronic obstructive pulmonary disease.

[d]C: clinician.

Participant Perceptions of TELE-TOC

Patients and pharmacists described an overall positive experience with TELE-TOC. Patient SUS scores were reported as an average of 97.5/100, indicating that patients found TELE-TOC to be user-friendly and easy to use. Furthermore, when asked to rate the overall quality of TELE-TOC on a Likert scale from 1 (very poor) to 5 (very good), on average, patients rated TELE-TOC 5/5, while pharmacists rated TELE-TOC 3.8/5.

Most participants felt that TELE-TOC was not difficult to engage with and even suggested lengthening the sessions to create more time for questions and patient-specific concerns (Table 5, Q1 and Q2). When asked about TELE-TOC content, patients responded that they did not feel that any content needed to be removed; on the contrary, they requested the addition of more in-depth COPD information. Pharmacists and patients agreed that TELE-TOC was engaging and helpful, especially the inhaler education, which patients described as more hands-on than their discharge education and in-person follow-up visits

XSL•FO
RenderX

(Table 5, Q3 and Q4). Patients stressed that TELE-TOC's follow-up helped them to feel cared for and improved their confidence in medication management and inhaler use (Table 5, Q5 and Q6). They also felt that TELE-TOC motivated them to learn more and improve their COPD management.

Experiences With Medication Reconciliation Component of TELE-TOC

Facilitators

Regarding medication reconciliation, a pharmacist noted that it was easier to confirm which medications each patient was taking based on what they presented on video (Table 5, Q7). Furthermore, use of MyChart allowed pharmacists to easily access medication lists to double-check medication names, dosages, and frequency of use (Table 5, Q8 and Q9). Through TELE-TOC, pharmacists could identify prescription discrepancies while helping patients to better understand the purpose of each medication (Table 5, Q10 and Q11).

Barriers

Challenges with medication reconciliation included lack of patient preparation and low patient health literacy. Pharmacists noted that patients were not always adequately prepared to review their medication lists and may need reminders to have their medications ready for review in future sessions (Table 5, Q12). Some patients also simply read their medication labels but were unable to fully understand their medication management, even with help from the pharmacists.

Experiences With Inhaler Education Component of TELE-TOC

Facilitators

During inhaler education, video technology enabled pharmacists to see how patients used their inhalers and instruct them accordingly (Table 5, Q13). Most patients agreed that video technology made instructions easier to follow through visual feedback. They also enjoyed the teach-back method used by pharmacists, noting that it felt more engaging and helped them process and understand clinician instructions (Table 5, Q14).

Barriers

While most patients felt satisfied with their inhaler education from the TELE-TOC pharmacist, others reported that the lack of further in-depth education left them with an incomplete understanding of how to use an inhaler (Table 5, Q15). They felt that even with the education provided during the session, they were still not fully confident in their inhaler use.

TELE-TOC Use and Implementation

Facilitators

Overall, patients noted that TELE-TOC's flow was easy to follow and led to a more streamlined process of medication reconciliation and inhaler education (Table 5, Q16). Both pharmacist interventionists agreed that both components of TELE-TOC were easy to complete smoothly, and TELE-TOC did not require too much extra work to conduct (Table 5, Q17). Using video technology also allowed patients to speak to their pharmacists from the comfort of their home. Unanimously, patients agreed that the telemedicine nature of the intervention allowed for improved access to their clinicians and increased the likelihood of attending the virtual session, in comparison to a similar in-person follow-up (Table 5, Q18-Q20). Additional facilitators to TELE-TOC implementation included patient reminders via MyChart to ensure patient attendance (Table 5, Q21), as well as technology literacy among pharmacists to correctly set up visits. Both pharmacists noted that they did not have issues with navigating TELE-TOC or MyChart.

Barriers

Patients and pharmacists listed different barriers to TELE-TOC implementation. Several patients believed that TELE-TOC was helpful for those who were unfamiliar with their medications or inhalers, but others voiced the desire to learn more about their COPD and management beyond the general information provided alongside medication and inhaler education. For example, some patients wanted to better understand COPD epidemiology, along with signs and symptoms to watch out for at home; lack of further in-depth discussion about their condition and experiences left them feeling mildly dissatisfied (Table 5, Q22).

Technology literacy and technical issues were observed as impediments to conducting TELE-TOC. Over multiple sessions, technical issues within Epic EHR and over Zoom made TELE-TOC difficult to conduct (Table 5, Q23 and Q24). Further, while patients stated that they did not have too much difficulty or concern with navigating the technology required to conduct TELE-TOC, issues such as forgotten passwords, confusion about MyChart login information, and misunderstandings about Zoom settings were observed during walkthroughs. One patient even noted that without technology assistance from the clinician or a caregiver, they would likely have given up on TELE-TOC (Table 5, Q25). These issues were quickly resolved with the help of TELE-TOC pharmacists, who were trained to provide several solutions to technical barriers (eg, switching to telephone calls, moving from MyChart to Doximity, and providing clear instructions in the event of patient problems with log-in or calling).

Both pharmacists also provided feedback on the TELE-TOC workflow and tools, primarily voicing initial dissatisfaction with the "visit note." They initially felt that the "visit note" was not structured in a way that allowed for streamlined conversation and were unsure of the needed depth for the notes (Table 5, Q26). As both pharmacists conducted more walkthroughs, they verbalized that the structure and clarity of the "visit note" greatly improved over time.

Suggestions for Improving TELE-TOC Content, Function, and Implementation

Following the discussion of the barriers to their TELE-TOC experiences, participants provided a few suggestions to mitigate these challenges. To combat a lack of patient preparation for and to streamline medication reconciliation, it was suggested that pharmacists ask patients to preemptively prepare their medications prior to TELE-TOC (Table 5, Q27). Furthermore, more detailed education and anticipatory instructions on inhaler use and general COPD management were suggested as a method

XSL•FO
RenderX

to support patients who still felt unsure in how to care for their conditions (Table 5, Q28 and Q29).

Participants also felt that providing clear instructions and a tutorial on how to use Zoom and MyChart technology would be helpful in assisting patients with lower technology literacy (Table 5, Q30). Furthermore, amendments to the "visit note" were suggested: sequence the note in alignment with the structure of each session and provide clearer instructions for pharmacists to complete the document (Table 5, Q31). Other suggestions included establishing an additional group format of TELE-TOC to provide inhaler and COPD education for multiple patients at once (Table 5, Q28), as well as using TELE-TOC as an additional source of support for patients with medication needs, such as checking on refills or checking for duplicate therapies (Table 5, Q32).

Discussion

Principal Results

Our 3-phase, UCD approach tailored and optimized an evidence-based televisit medication management and education intervention for patients with COPD transitioning from hospital to home. We identified facilitators, barriers, and interdependencies across the current DTOC workflow for patients with COPD, seeking to amend the workflow and improve patient outcomes. Key facilitators across settings included the "meds-to-beds" program and caregiver support, while challenges to effective care included inopportune education timing, inaccurate medication records, and limited outpatient follow-ups. These findings suggested the need for more comprehensive post-discharge patient support, which indicates the utility of the TELE-TOC intervention.

While the study was open to patients of all races and ethnicities, all enrolled patients identified as Black and non-Hispanic. This aligns with trends observed in UCM's COPD HRRP, in which a large proportion of eligible patients are Black. As a result, our study sample reflects the demographic makeup of UCM's patient population. Several factors, including lower utility of health care services, health insurance coverage, and behavioral differences (eg, smoking habits), have increased COPD's impact on Black patients [36,37]. Hence, Black patients hospitalized with COPD exhibit greater symptom severity and have significantly higher odds of 30-day readmission in comparison to non-Hispanic White patients [38-40]. Despite this disproportionate effect, very few studies examining the implementation and effectiveness of COPD DTOC interventions have explicitly included Black populations [41].

Comparisons With Prior Work

Our study corroborates existing literature, which emphasizes clinician COPD training and positive patient-clinician relationships as key facilitators to successful post-discharge care, alongside key barriers such as resource constraints, limited patient understanding of the education provided, and inappropriate allocation of tasks among clinical staff [17,42,43]. However, we identified additional barriers not widely discussed in prior research, such as patients using cash online pharmacies, resulting in undocumented medication use. This underscores the importance of accurate medication reconciliation, which is often limited in hospital settings.

We then explored how to address these barriers using pharmacy-led, virtual, in-home televisits for medication reconciliation and inhaler education. Our data suggested that televisits would be well-received and engaging due to their convenience and the addition of a dedicated pharmacist during the critical care transition period. Prior literature also highlighted the significant advantages of telehealth in medication management and virtual health education. For example, a previous study found that patients benefited more from telehealth (vs usual care) medication reconciliation, showed higher engagement and buy-in, and maintained better adherence to prescribed medications [44]. Further, multiple reviews [24,45,46] noted that telehealth-based interventions have improved patients' post-discharge healthcare outcomes and quality of life.

Based on these insights, we refined the TELE-TOC components and workflow. Notably, TELE-TOC offers a customizable telehealth experience that tailors televisit format (eg, visit mode, dose, frequency, and structure) to meet patient preferences and clinical needs, enhancing engagement and ensuring more personalized care while retaining core patient discharge components. Both patients and clinicians found TELE-TOC effective and efficient for medication reconciliation and comprehensive inhaler education. Despite some patients suspecting they would struggle to log in and navigate to TELE-TOC on their own, SUS scores remained high due to support and clear instructions from clinicians. Furthermore, due to a 766% increase in telemedicine encounters following the COVID-19 pandemic [47,48], many patients and providers report improvements in their televisit competency, which could explain the high success rate of TELE-TOC among our participants. Apart from a few technical difficulties, both patients and providers noted positive experiences with TELE-TOC usability and effectiveness [49]; other studies have reported similar feasibility and usability of eHealth interventions for patients with chronic conditions [50]. Other key success factors included remote monitoring and feedback from clinicians, visual aids via videoconferencing tools, and access to medication lists at home. Use of previously successful implementation strategies, such as patient-personalized televisit format, inhaler education teach-back, and TTG methods, was crucial to the success of our TELE-TOC prototype [13,16,51]. Several implementation barriers were addressed, including clinician availability for COPD education and patient forgetfulness about medications [52-58]. However, structural barriers, such as patient financial burden related to payment structures, remain unaddressed [52,59-61].

To evaluate the clinical impact of TELE-TOC, we are currently conducting a randomized controlled trial evaluating the effectiveness and implementation potential of TELE-TOC compared to usual care at UCM (NCT06461403), which is expected to be completed in 2026 [62]. Our primary effectiveness outcome assesses inhaler technique at 30 days after discharge, based on a validated 12-step checklist. Secondary outcomes include acute care revisits, rehospitalizations, and mortality rates at 30, 90, and 180 days

XSL•FO
RenderX

post-discharge, in addition to medication errors, changes in COPD symptoms based on the COPD Assessment Test and the Modified Medical Research Council dyspnea scale, and inhaler technique. Our primary implementation outcome is intervention reach. If successful, TELE-TOC could serve as a scalable model for improving COPD discharge care transitions and reducing avoidable acute exacerbations of COPD readmissions.

Limitations

We acknowledge our study limitations. First, this is a single-site study at an urban academic medical center, which may limit generalizability. In particular, the racial homogeneity of our study sample may limit the generalizability of our findings to the broader US population. Nevertheless, this study attempts to address the research gap in developing COPD discharge care transition interventions to meet the needs of Black patients. Second, we acknowledge that within our small sample for Phase 3, some patients mentioned familiarity and experience with using phones and computers to perform tasks, including video calls. This experience with technology may strongly contribute to their usability ratings, and we acknowledge that our SUS findings may reflect limited sample diversity. However, as previously mentioned, televisit proficiency increased significantly during the COVID-19 pandemic, and we anticipate that within our current randomized controlled trial, with a larger, more diverse sample, we may see similar TELE-TOC proficiency among our target population. Third, the feasibility of televisit interventions may not be applicable across health care organizations, depending on institutional resources. To best address this, we will develop an evidence-based roadmap for pragmatic implementation and dissemination of TELE-TOC across diverse rural, urban, and suburban US hospitals.

Conclusions

We adopted a UCD approach to codevelop and optimize a pragmatic and patient-centered COPD televisit intervention to support hospital-to-home care transitions. The goals of the proposed TELE-TOC intervention were to reduce unnecessary readmissions and improve continuity of care, provide impactful medication management and education to improve outcomes such as COPD symptom control, and ascertain implementation outcomes, including reach, sustainability, and scalability of TELE-TOC.

Acknowledgments

The authors wish to thank all participants of the Telehealth Education: Leveraging Electronic Transitions of Care (TELE-TOC) study and our TELE-TOC pharmacist interventionists who participated in Phase 3 of the study. We would also like to thank Ms. Kelley Foyil for proofreading the article. The support for this work comes from the Agency for Healthcare Research and Quality (R01AS027804).

Funding

No external financial support or grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this article.

Abstract

Background: Regular lifestyle modification is crucial for chronic kidney disease (CKD) management; yet, older patients often struggle to sustain behavior change and rely on support from their significant others such as family caregivers or partners. In such cases, both members of the dyad require accessible, jointly usable tools to maintain healthier behaviors over time. Given the ubiquity of instant messaging platforms, a digital intervention delivered via such a platform offers strong potential to empower CKD dyads in active lifestyle modification.

Objective: Guided by the Digital Dyadic Empowerment Framework, this study aimed to develop, optimize, and test the usability of a digital platform named "Kidney Lifestyle," using the LINE Official Account (OA) and an integrated extended app to facilitate collaborative lifestyle modification among CKD dyads.

Methods: We adopted a three-phase Agile-based development cycle: (1) iterative development and trial use, (2) heuristic evaluation, and (3) usability testing. In phase 1, the platform prototype was codeveloped with health care professionals and trialed by CKD dyads who provided feedback on interface clarity, ease of use, acceptance, intention to continue usage, and overall satisfaction. In phase 2, multidisciplinary experts conducted heuristic evaluations, rating compliance with Nielsen's 10 usability principles and suggesting improvements. In phase 3, experienced CKD dyads from phase 1 performed 6 representative tasks using the platform. Task success rates, completion times, and operational errors were recorded, and usability perceptions were assessed using the After-Scenario Questionnaire (1 - 7) and the System Usability Scale (0 - 100).

Results: In phase 1, 10 CKD dyads (19 individuals) reported high acceptance (mean overall satisfaction 4.1/5), valuing real-time interaction, convenient health data monitoring, and educational resources. In phase 2, 5 experts found high usability compliance (89% - 93%) but noted navigation complexity and the need for more interactive feedback. In phase 3, usability testing with 5 dyads showed high task success (60% - 100%) and short completion times (1 - 5 minutes). Extended app tasks used for structured self-monitoring achieved higher satisfaction, reflecting simpler navigation than tasks within the LINE OA (mean After-Scenario Questionnaire 5.64 vs 3.87). Navigation difficulties within LINE OA were likely due to multilayered menus and limited customization. The average System Usability Scale was 67.5, indicating marginally acceptable usability.

Conclusions: The LINE-based digital dyadic empowerment platform "Kidney Lifestyle" demonstrated promising usability and engagement. It has clinical potential to improve CKD control by extending health education, enabling continuous self-monitoring, and allowing clinicians to track patients' daily living conditions. To enhance effectiveness, future work should include a larger-scale feasibility trial while pursuing ongoing platform optimization, specifically by simplifying navigation pathways, adding a return option, and improving interactive feedback. The platform is now publicly accessible via LINE ID search, as provided in phase 1 results.

Introduction

Background

Chronic kidney disease (CKD) poses a serious burden to global health, affecting approximately 9.1% of the population or around 700 million people worldwide [1]. In Taiwan, the increasing prevalence of end-stage kidney disease has escalated health care costs, imposing substantial strain on the National Health Insurance system [2]. Effective CKD management can delay disease progression to end-stage kidney disease, reduce the risk of complications, and enhance patients' quality of life [3,4]. However, significant barriers remain, including insufficient continuous monitoring, limited patient education, and restricted access to health care providers [5,6].

CKD primarily affects older adults, especially those older than 60 years with lower educational levels, underscoring the need for tailored interventions for this group [7-10]. Digital health interventions (DHIs) offer unique opportunities to maintain patient engagement and provide tailored health education, particularly for older adults to improve autonomy and overall well-being [11]. With the widespread use of digital and mobile technologies, DHIs have become a key part of chronic care, supporting various health needs effectively [12]. Previous studies have shown that DHIs can improve self-management among patients with CKD [13]. This potential has led to the ongoing development of diverse tools—ranging from smartphone apps to web-based platforms—designed to support CKD and dialysis self-care [14-17].

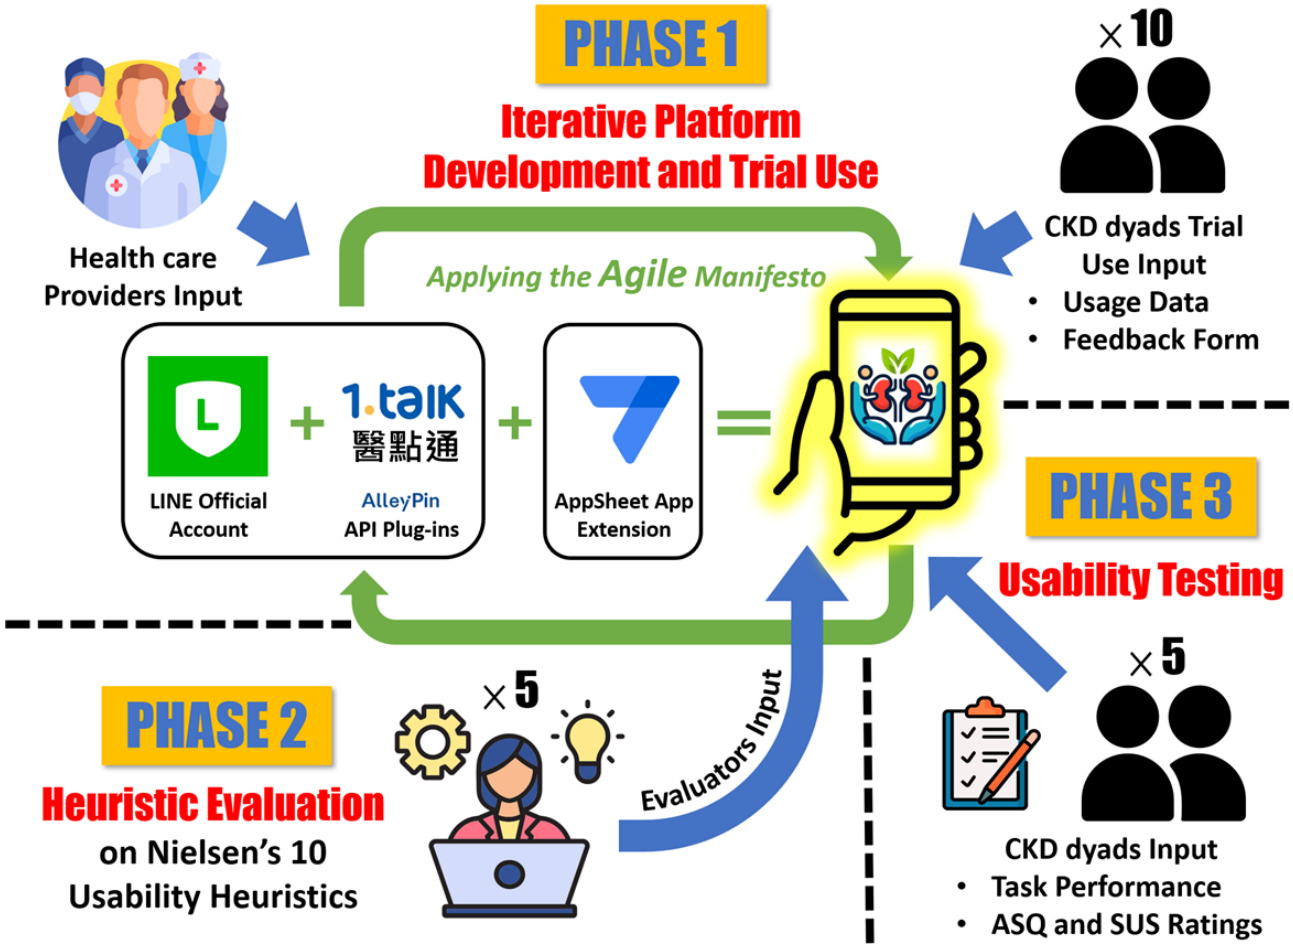
Building on these advances, instant messaging platforms have emerged as promising tools for ubiquitous CKD management support. LINE, in particular, has gained significant popularity in Asia due to its user-friendly interface and broad demographic reach, effectively engaging users of all ages [18]. In Taiwan, LINE dominates the instant messaging market with more than 90% market share, making it a highly suitable platform for health communication [19]. The LINE app has already demonstrated potential in facilitating health education and self-management among middle-aged patients with CKD [20,21]. However, a LINE-based platform promoting lifestyle modification for older (older than 60 years) patients with CKD and their caregivers remains scarce. The extensive user base of LINE presents a unique opportunity to deliver cost-effective DHIs supporting multifaceted CKD management for this older population through a LINE Official Account (LINE OA).

Previous Work

In our previous work, we developed the Digital Dyadic Empowerment Framework (DDEF) as a conceptual and practical guide for designing DHIs that empower both patients with CKD and their significant others (SOs) (eg, spouses and children) to sustain lifestyle modification. The framework identifies 5 core domains of dyadic empowerment, including *perceived control*, *understanding*, *adaptation*, *dyadic efficacy*, and *dyadic support*. It further proposes 5 digital strategies: *digital education*, *digital communication*, *digital monitoring*, *digital feedback*, and *digital analysis*, through which DHIs can be designed to strengthen these dyadic empowerment domains. Together, these domains and strategies specify *what* to empower in the dyad and *how* to operationalize dyadic empowerment through concrete digital features, providing a structured pathway for designing and evaluating DHIs that support collaborative CKD self-management.

Objectives

This study aimed to develop, evaluate, and optimize the usability of the LINE-based digital platform "Kidney Lifestyle" for CKD dyads. The platform was directly developed under the guidance of the DDEF, applying its 5 digital strategies to strengthen dyadic empowerment and promote sustainable lifestyle modification among CKD dyads. This research specifically investigates the platform's usability, user acceptance, and potential clinical application in CKD management.



Methods

Study Design

Following the guidelines outlined by Kushniruk and Patel [22], a 3-phase iterative system development cycle was used to develop and test our LINE-based digital dyadic empowerment platform. These phases included (1) iterative development and trial use, (2) heuristic evaluation, and (3) usability testing (Figure 1). An Agile project management methodology was applied throughout the development cycle to manage initial uncertainties and facilitate continuous stakeholder interaction [23]. During each phase, participants identified usability issues, which guided subsequent refinements of the digital platform. The details of each phase are described in the following sections.

XSL•FO
RenderX

Figure 1. A visualization of the 3-phase iterative system development cycle. Blue arrows denote the input provided by the participants from each phase. ASQ: After-Scenario Questionnaire; CKD: chronic kidney disease; SUS: System Usability Scale.

Phase 1: Iterative Development and Trial Use

Phase 1 focused on developing the platform, especially the functionalities and content. Summarizing retrospectively, the platform development process involved the following four iterative steps: (1) platform establishment, (2) technical partner collaboration, (3) extended platform development, and (4) all platform integration and intervention design.

Step 1: Platform Establishment

A regular LINE OA was first set up to explore its basic functionalities, applying two functions aligned with 3 DDEF digital strategies: (1) chat: "Digital Feedback" and "Digital Communication," and (2) multimedia and multipage messages: "Digital Education." For example, CKD-related information (eg, symptoms, staging, and risk factors) could be delivered through autoresponse messages triggered by specific keywords. However, such keyword-based use was inconvenient and insufficient for promoting lifestyle modification among CKD dyads, as prior medical applications of LINE OAs mainly focused on clinic operations (eg, appointment scheduling and reminders) rather than ongoing lifestyle support [24]. These limitations highlighted the need for integration with third-party application programming interface (API) plug-ins to enable more advanced functionalities.

Step 2: Technical Partner Collaboration

AlleyPin Interactive Ltd Co is a LINE-certified Gold-level technical partner in the health care industry, providing API technical resources to meet diverse needs. Their cloud-based doctor-patient interaction management system, "DoctorConnect 1.Talk," when integrated with the team's LINE OA, can provide more advanced and user-friendly functionalities, including (1) service menu setup: it allows up to 8 buttons with multilayered structures for resource integration, beyond the 6-button limit of LINE OA; (2) enhanced multimedia and multipage messages: multiple buttons can be set within a single message, enabling users to access tailored health information via menu clicks without manual text input; and (3) case tracking system: it supports member management, scheduled "Push" messages, and interaction through AlleyPin's independent backend.

The service menu content and layout were designed not only by following the DDEF but also in consultation with a health education nurse from a university-affiliated hospital and 2 nephrologists, ensuring the platform met clinical needs. Through the integration of LINE OA and AlleyPin Interactive's API plug-in, our platform now effectively adopted 3 digital strategies—"Digital Education," "Digital Feedback," and "Digital Communication"—to support CKD dyads. To further apply the other 2 digital strategies—"Digital Monitoring" and "Digital Analysis," an extended app was developed and integrated with the LINE OA in the next step.

XSL•FO
RenderX

Step 3: Extended App (AppSheet) Development

After exploring various options and evaluating alternative platforms, the team discovered that Google's AppSheet platform could effectively compensate for the current platform's shortcomings and integrate with LINE OA. AppSheet is a platform for developing mobile and web apps that do not require programming code and can integrate with cloud spreadsheets or databases such as Google Drive and Office 365 as data sources [25]. The team immediately began developing the app prototype and conducted iterative testing.

Step 4: Platform Integration and Intervention Design

As the digital platform was not selected during the development of DDEF, the team, after the platform selection and development process outlined in steps 1-3, reviewed the correspondence between the DDEF and the functions provided by this integrated digital platform. Based on this, interventions were designed to promote lifestyle modification for CKD dyads.

Platform Trial Use

After establishing our digital platform prototype, the team invited 10 early-stage CKD (stages 1-3) dyads receiving regular treatment at a university hospital to use the platform in their daily lives. Besides assisting dyads in installing the digital platform on their smartphones, a user manual (Multimedia Appendix 1) was provided for each dyad to learn the operations at home. At the time of enrollment, operational instructions for various functions were provided by a research assistant (CYH) according to the manual.

A user feedback form (Multimedia Appendix 2) was provided to be filled out by the dyads at least 1 month apart during their next clinic visit. For each of the 6 major functions, the form assessed the following five elements: (1) interface clarity, (2) ease of operation, (3) acceptability: like or not, (4) intention to continue usage, and (5) satisfaction rating from 1 to 5 (Table 1). A brief interview was conducted with each dyad to obtain further feedback. The platform was iteratively optimized based on both system usage data and user feedback.

XSL•FO
RenderX

Table . Content of user feedback form for phase 1 dyadic trial use[a].

Element (item number) and question		Type
Interface clarity (N-1)		
	Are there any unclear elements on the screen?	Yes/No
	If yes, please specify.	Short answer
Ease of operation (N-2)		
	Is this function easy to use?	Yes/No
	If not, please explain why.	Short answer
Acceptability (N-3)		
	Do you like this function?	Yes/No
	Tell us what you like about this function?	Short answer
	If you dislike this function, how can we improve?	Short answer
Intention to continue usage (N-4)		
	Will you keep using this function?	Yes/No
	Why or why not?	Short answer
Satisfaction (N-5)		
	Please rate your satisfaction with this function on a scale from 1 to 5.	5-Point Scale
Previous experience (7-1)		
	Have you ever used any other apps or websites for managing chronic kidney disease?	Yes/No
	If yes, what did you like or dislike about them?	Short answer
General platform satisfaction (7-2)		
	What is your overall satisfaction rating with our platform?	5-Point Scale
	Will you continue to use our platform for chronic kidney disease management?	Yes/No

[a]Items N-1 to N-5 are inquired repeatedly for each of the 6 functions of the platform, resulting in a total of 30 questions. Items 7 - 1 and 7 - 2 are general questions asked once, adding 2 more questions. Therefore, the total number of questions in this form is 32.

Phase 2: Heuristic Evaluation

To further examine whether our digital platform is user-friendly in its design, a heuristic evaluation involving 5 evaluators with backgrounds in health care or information engineering was conducted. Evaluators tried out the digital platform and assessed how well each of the 6 major functions in the interface design complies with Nielsen's 10 usability principles (10 usability heuristics) [26].

The team referred to Moran and Gordon's [27] suggested heuristic evaluation steps and designed an evaluation form based on their published *Heuristic Evaluation Handbook*. Considering that the digital platform's access is not limited by time or space and acknowledging the need for evaluators to independently conduct the evaluation, the team opted for evaluators to fill out Google Forms for remote participation.

The form begins by inviting evaluators to join our digital platform on LINE and set up the initial settings. Evaluators were then asked to use the platform for 3 days. Specifically, they explored the buttons' functionalities and information on the LINE OA service menu and the extended app, similar to the real-use scenarios in phase 1 dyadic trial use. Before starting the evaluation, evaluators are invited to visit relevant websites to familiarize themselves with the content of Nielsen's 10 usability heuristics [28]. The explanations and the assessment questions for each principle are shown in Table 2.

XSL•FO
RenderX

Table . Explanation of 10 usability heuristics and assessment questions[a].

Heuristic	Explanation	Assessment questions
Principle 1: Visibility of System Status	The design should always keep users informed about what is going on through appropriate feedback within a reasonable amount of time.	• Does the design clearly communicate its state? • Is feedback presented quickly after user actions?
Principle 2: Match Between System and the Real World	The design should speak the users' language. Use words, phrases, and concepts familiar to the user, rather than internal jargon. Follow real-world conventions, making information appear in a natural and logical order.	• Will the user be familiar with the terminology used in the design? • Do the design's controls follow real-world conventions?
Principle 3: User Control and Freedom	Users often perform actions by mistake. They need a clearly marked "emergency exit" to leave the unwanted action without having to go through an extended process.	• Does the design allow users to go back a step in the process? • Are exit links easily discoverable? • Can users easily cancel an action? • Is *Undo* and *Redo* supported?
Principle 4: Consistency and Standards	Users should not have to wonder whether different words, situations, or actions mean the same thing. Follow platform and industry conventions.	• Does the design follow industry conventions? • Are visual treatments used consistently throughout the design?
Principle 5: Error Prevention	Good error messages are important, but the best designs carefully prevent problems from occurring in the first place. Either eliminate error-prone conditions or check for them and present users with a confirmation option before they commit to the action.	• Does the design prevent slips by using helpful constraints? • Does the design warn users before they perform risky actions?
Principle 6: Recognition Rather Than Recall	Minimize the user's memory load by making elements, actions, and options visible. The user should not have to remember information from one part of the interface to another. Information required to use the design (eg, field labels[b] or menu items) should be visible or easily retrievable when needed.	• Does the design keep important information visible, so that users do not have to memorize it? • Does the design offer help in context?
Principle 7: Flexibility and Efficiency of Use	Shortcuts—hidden from novice users—may speed up the interaction for the expert user such that the design can cater to both inexperienced and experienced users. Allow users to tailor frequent actions.	• Does the design provide accelerators such as keyboard shortcuts and touch gestures? • Is content and functionality personalized or customized for individual users?
Principle 8: Esthetic and Minimalist Design	Interfaces should not contain information that is irrelevant or rarely needed. Every extra unit of information in an interface competes with the relevant units of information and diminishes their relative visibility.	• Is the visual design and content focused on the essentials? • Have all distracting, unnecessary elements been removed?
Principle 9: Help Users Recognize, Diagnose, and Recover From Errors	Error messages should be expressed in plain language (no error codes), precisely indicate the problem, and constructively suggest a solution.	• Does the design use traditional error message visuals, such as bold, red text? • Does the design offer a solution that solves the error immediately?
Principle 10: Help and Documentation	It is best if the system does not need any additional explanation. However, it may be necessary to provide documentation to help users understand how to complete their tasks.	• Is help documentation easy to search? • Is help provided in context right at the moment when the user requires it?

[a]Adapted from the "*Heuristic Evaluation Workbook*," by K. Moran & K. Gordon, 2023, Nielsen Norman Group.

[b]Field labels are commonly used in forms to provide context for information input.

Consistent with Donald et al [29], the evaluators assessed the degree to which each of the 6 major functions from our digital platform complies with the 10 usability principles. They gave ratings of "−1 (does not comply)," "0 (partially complies)," or "1 (complies)." If an item scores "does not comply" or "partially complies" with a principle, the evaluator will be asked to note specific issues in not adhering to that principle and provide suggestions for fixing these problems. If the evaluator finds that

XSL•FO
RenderX

the assessed principle does not apply to a specific function, they can select "N/A (not applicable)."

Phase 3: Usability Testing

Usability testing involves observing how users interact with the platform to fulfill their needs; understanding their behaviors, preferences, operational strategies, and paths; and collecting feedback to identify existing interface problems and possibilities for improvement.

We designed a task for each of the 6 major functions of our digital platform, which a realistic user would typically use in their daily lives. Five dyads who participated in phase 1, with at least 1 month of experience using the platform, were invited to perform the designed tasks. As the DDEF emphasizes helping relationships, tasks were performed jointly by the dyads, with each assisting the other throughout the process. Researchers provided instructions on task execution and responded to participant queries but refrained from providing guidance to avoid influencing their behavior. Task design and testing followed usability testing guidelines from Moran [30] and Nielsen [31]. Task success, time spent, and the number of operational errors during execution were recorded for each task.

Upon completion of each task, whether successful or not, participants filled out a postscenario questionnaire (After-Scenario Questionnaire [ASQ]) consisting of three questions to assess the perceived (1) ease of the task, (2) time required, and (3) support received during execution (help from the manual) on a scale from 1 to 7 [32]. A higher average ASQ score indicates greater user satisfaction and perceived usability. After completing all tasks, participants also filled out the System Usability Scale (SUS), a 10-item questionnaire designed to evaluate the overall usability and learnability of the digital platform [33]. A SUS score ranges from 0 to 100, with 68 indicating marginally acceptable perceived usability by the user and suggesting the existence of areas for improvement [34]. See Multimedia Appendix 3 for the full usability testing instrument. The task scenario and instruction for each of the 6 functions are shown in Table 3.

Table . Usability testing task scenarios and instructions for tested functions.

Task scenario	Instruction	Tested function
Task 1: Here are the values of your blood pressure and blood test results from today's visit: systolic blood pressure 125, diastolic blood pressure 78, heart rate 65, and creatinine (CREA) 1.4 mg/dL.	Please attempt to log the above values into our digital platform.	Record Values
Task 2: You want to know which stage of chronic kidney disease you are currently in. However, you found that your recent blood test report does not provide your "estimated glomerular filtration rate (eGFR)" value. You need to calculate your eGFR using "Creatinine (CREA)" (1.4 mg/dL), combined with your "gender" and "age."	Please try to explore our digital platform and calculate your eGFR.	Health Education Information
Task 3: Here is the date and time of your next appointment: December 28, 2023, afternoon clinic; suggested check-in time 14:10.	Please update the above information on our digital platform and notify the researchers through the platform.	Reminder Settings
Task 4: You want to learn about the symptoms of "hypoglycemia."	Please try to explore our digital platform and find the 7 possible symptoms of hypoglycemia.	Inquiry & Consultation
Task 5: Here is the content of your most recent meal: Half a bowl of white rice, 2 servings of bok choy, and 1 serving of chicken thigh.	Please record the above dietary information on our digital platform via photo or text note.	Kidney Health Mission
Task 6: Your partner (family member) has been trying hard to adjust their lifestyle recently. You want to know some ways to support their change.	Please try to explore our digital platform and write out support strategies corresponding to the following specific behaviors.	Kidney Support Teammate

Data Analysis

Data were compiled and analyzed using Google Sheets. Categorical variables (eg, user responses in feedback forms) were summarized as frequencies and percentages. Continuous variables, such as ASQ and SUS scores, were reported using means and ranges. Task success rates, completion times, and error frequencies were recorded and descriptively summarized for each usability task. No inferential statistical analyses were conducted, as the study primarily aimed to assess usability outcomes through descriptive measures.

Ethical Considerations

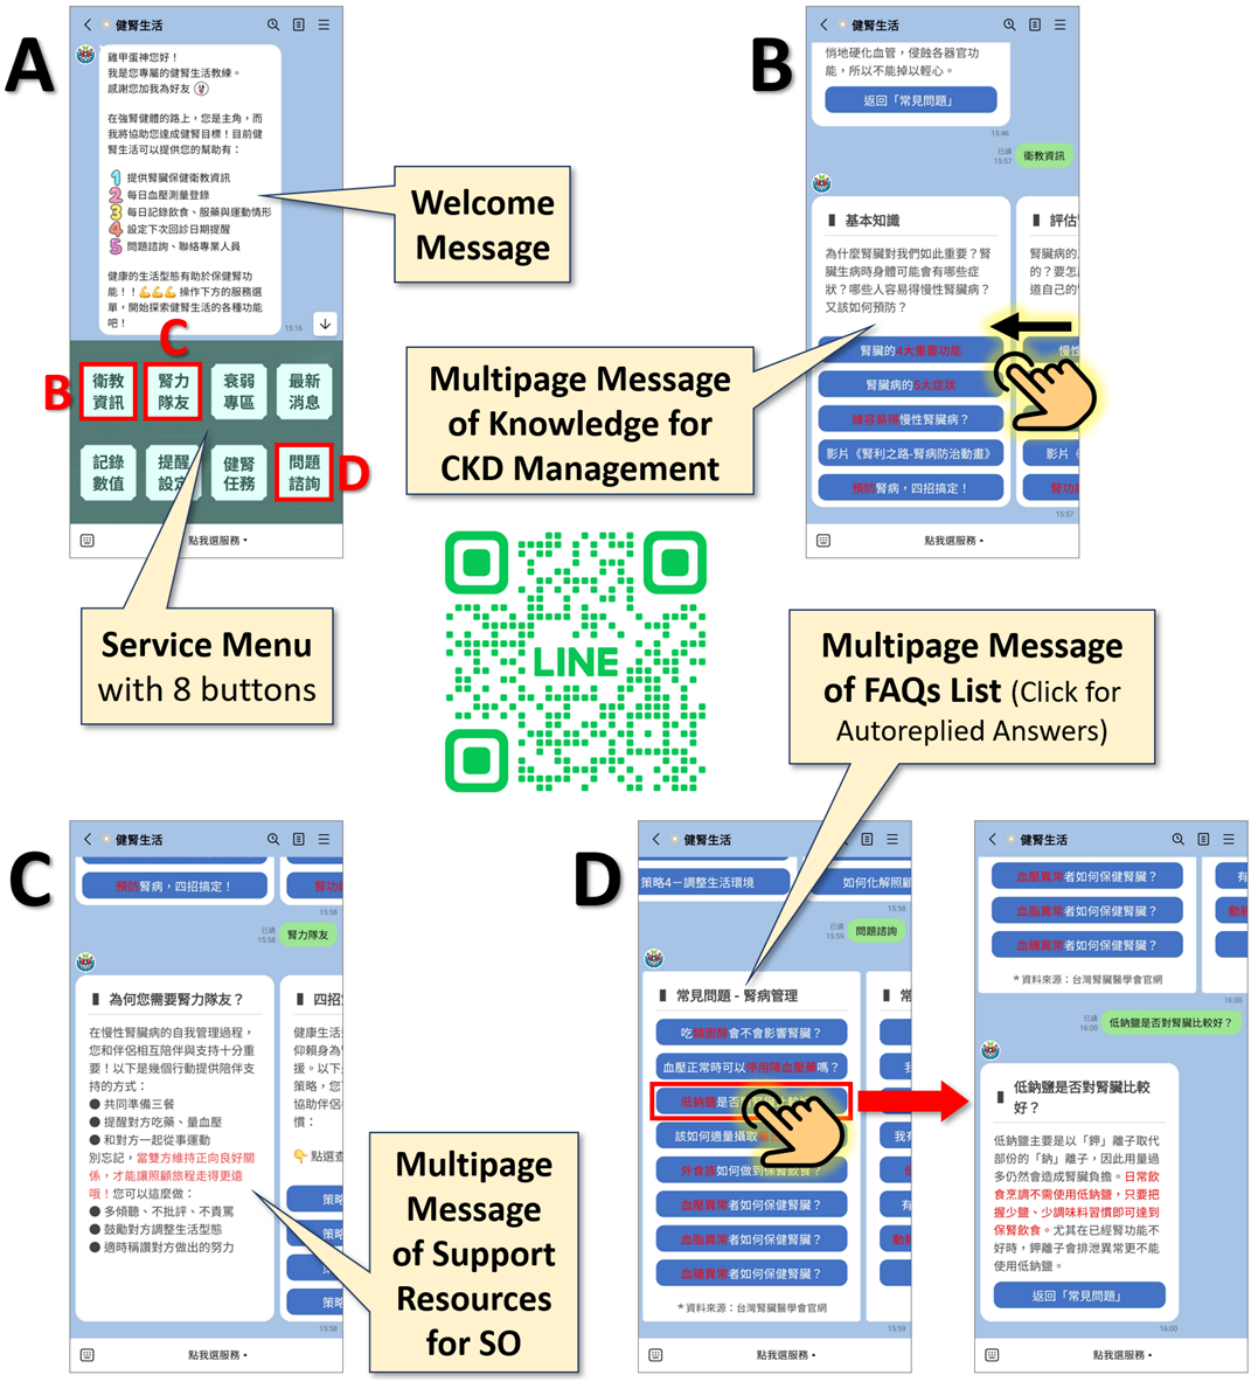
This study received approval from the institutional review board of National Cheng Kung University Hospital, Tainan, Taiwan (institutional review board no. B-ER-110-110). All participants were fully informed about the study's purpose, procedures, their rights, and data protection measures. Participation was voluntary, and participants could withdraw at any time without consequence. Paper source data were collected and stored in locked cabinets on site at the institution. Deidentified research data were stored on the institution's cloud servers and on password-protected personal computers, with access restricted to authorized study personnel only. All data will be retained

XSL•FO
RenderX

until 2029 and then securely destroyed. Each participant received a signed copy of the informed consent form. Participants received a gift voucher of NT $200 (approximately US $6) as compensation each time they completed a study task.

Results

Phase 1: Iterative Development and Trial Use



After collaborating with health care providers and technical partners for 3 months to develop our digital platform for intervention, we officially launched the prototype on July 25, 2023. Our LINE OA, named "Kidney Lifestyle," can be accessed by searching for LINE ID: @509kgajt. In addition, the extended app, named "Kidney Lifestyle App," is currently available through a dedicated link.

LINE OA "Kidney Lifestyle" With API Plug-Ins

Our LINE OA acts as the main hub for real-time interaction with users via text or voice chat. Moreover, by clicking buttons from the service menu (Figure 2A), users can access various resources for CKD management, retrieved or adapted from the official websites of *Taiwan Society of Nephrology* and *Taiwan Kidney Foundation*. The eight buttons featured on the service menu were introduced: (1) Health Education Information: providing basic kidney disease knowledge, evaluating kidney function, dietary and exercise guidelines, and so on (Figure 2B). (2) Kidney Support Teammate: multipage messages providing support resources for caregivers (SOs) (Figure 2C). (3) Frailty Section: providing health education information about frailty prevention and intervention. (4) Latest News: linking to the LINE OA's post area, forwarding information about relevant hospital events. (5) Record Values: users can log self-measured physiological values, and the system records and generates reports for feedback. (6) Reminder Settings: users can log their next appointment dates, and reminders are scheduled through the AlleyPin Interactive backend. (7) Kidney Health Mission: encouraging daily completion of "Record Values" and "Kidney Health Diary" (recording daily diet, medication, and physical activity). (8) Inquiry & Consultation: providing answers to frequently asked questions for CKD management; a consultation channel is provided for further queries (Figure 2D).

XSL•FO
RenderX

Figure 2. Interfaces of the LINE Official Account "Kidney Lifestyle" with a demonstration of user making inquiry about CKD management via automatic reply messages. The QR code provides access to "Kidney Lifestyle." (A) Basic Interface, (B) Health Education Information, (C) Kidney Support Teammate, and (D) Inquiry & Consultation. CKD: chronic kidney disease; FAQs: frequently asked questions; SO: significant other.

The Extended App "Kidney Lifestyle App" (AppSheet)

Our extended app mainly interconnects with the functions of "Record Values," "Reminder Settings," and "Kidney Health Mission" provided by our LINE OA with API plug-ins. Users can directly access the corresponding pages of the extended app by clicking on LINE OA service menu buttons, with the specific paths as follows: (1) Clicking "Record Values" on LINE OA service menu jumps to the "New Entry" page of the extended app, where users can log blood pressure, heart rate, and weight, and optionally enter blood sugar or blood test report data (Figure 3A). (2) Clicking "Reminder Settings" → "Go to Reminder Setting Page" on LINE OA service menu jumps to the extended app to view the next appointment date and time, which users can update manually (Figure 3B). (3) Clicking "Kidney Health Mission" on LINE OA service menu allows users to perform 2 "Daily Tasks," jump to the extended app to log physiological values or write a kidney health diary (recording daily diet, medication, and physical activity) (Figure 3C1). Alternatively, they can click "Challenge Missions" → "View Title Challenge Progress" on the extended app to confirm task execution status (Figure 3C2).

XSL•FO
RenderX

Figure 3. Interfaces of the extended app "Kidney Lifestyle App" and their connections with the LINE Official Account "Kidney Lifestyle" service menu. (A) The entry form of "Recording Values" and the chart viewing for self-measured physiological values, (B)"Reminder Settings" interface, and (C)"Kidney Health Mission," directing to (C1) Kidney Health Diary, records of daily diet, medication, and physical activity, and to (C2) Usage Report, presenting daily tasks execution status and progress.

In addition to the functionality accessible via LINE, the extended app interface also has a bottom-placed menu with five buttons (Figure 3), each briefly described as follows: (1) My Entries: viewing the "Usage Report" (the page redirected after clicking "View Title Challenge Progress" on LINE), "Physiological Value View," and "Blood Test Record" to check entered values. (2) Chart View: visualizing self-entered physiological values in graphical form. (3) New Entry: same as clicking "Record Values" on LINE OA. (4) Kidney Health Diary: adding, viewing, or editing written kidney health diaries. (5) Reminder Settings: same as clicking "Go to Reminder Setting Page" on LINE OA.

The data entered by users on various pages of the extended app were synchronized with their device IDs and sent back to the corresponding Google Sheets worksheets. Through these worksheets, the team can view all user-entered data and identify them based on the device ID and a custom user identification code. Subsequently, security filters were set up, distinguishing by device ID, enabling individual users on the front end (ie, extended app interfaces) to access only their entered data.

With the completion of the extended app's development and integration with the LINE OA, it can now fully use the "Digital Monitoring" strategy to allow both the research team and the users to track physiological values, daily diet, medication, and physical activity. For the application of the "Digital Analysis" strategy, we calculate user metrics such as accumulated entry counts, entry activity rates (EARs), and consecutive entry days. These serve as reference indicators for users' lifestyle modification progress, enabling personalized interventions through the LINE OA.

Interventions to Promote Platform Use

Referring to the DDEF, interventions delivered through our integrated digital platform were designed and finalized through the following three processes:

XSL•FO
RenderX

1. Defined 4 specific lifestyle modification behaviors: physiological values monitoring, healthy diet, adequate physical activity, and proper medication.
2. Designed 2 daily tasks on the digital platform to execute these four specific behaviors:
    - Record Physiological Values: measure physiological values and log them through "Record Values" (multiple times allowed).
    - Write Kidney Health Diary: record daily diet (photographs or textual notes); check whether medication was taken correctly and, if not, select a reason; and check whether physical activity for more than 30 minutes was done and record the number of steps taken.

After consulting health care providers and observing practical scenarios, we confirmed the benefits of regular execution of the 2 daily tasks for both patients and health care providers. Recording physiological values generates easily readable reports, facilitating quick understanding of trends in physiological value changes. Writing a kidney health diary allows health care providers to confirm whether the patient's meals align with the principles of a CKD diet, and it serves as a reminder for the patient to engage in physical activity and take medication correctly. Inappropriate medication check items reference the Chronic Kidney Disease Self-Care Scale [35] and the Elderly Medication Adherence Assessment [36], consolidated into 4 items: "missed medication," "not taking medication on time," "self-adjusted medication or dosage changes," and "using nonprescribed medication."

1. Designed strategies to promote the execution of daily tasks based on the principles of behavior change and processes of change listed in the DDEF, including:
    - Gamification Mode for Behavior Shaping: Different "Kidney Health Titles" are granted upon completing 2 daily tasks consecutively for 3 (*novice*), 7 (*intermediate*), 14 (*veteran*), 30 (*master*), and 60 (*grandmaster*) days. Users can view title challenge progress (in percentage) through the "Usage Report" page on the extended app.

To implement the gamification strategy, the team needed to calculate the number of consecutive days a user completed daily tasks from today backward. With the assistance of generative artificial intelligence, ChatGPT, for syntax writing, we used Google Apps Script to execute custom functions to solve this issue. Furthermore, the team further simulated data using RStudio (Posit Software, PBC) and attempted to interpret it using Item Response Theory to link the 2 indicators, "consecutive days" and "entry activity rate." The calculation method for the EAR is as follows:

$$\text{Entry activity rate} = \frac{\text{Days performing daily tasks}}{\text{Total observation days}} \times 100\%$$

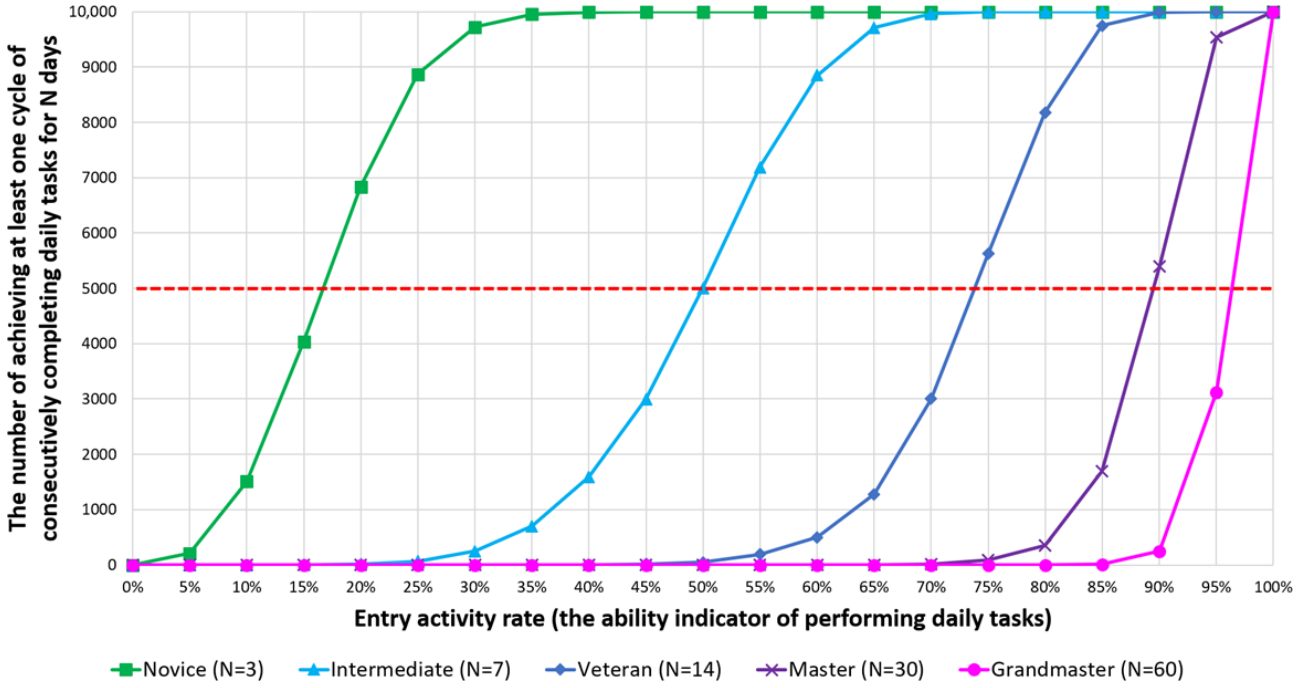
The EAR can be viewed as an "ability" indicator for users performing daily tasks. A higher EAR indicates a more regular execution of daily tasks. The team simulated different levels of EARs (from 0% to 100%, at intervals of 5%) for 180 observation days, with or without task execution, a total of 10,000 times. The frequency of achieving various Kidney Health Titles was calculated among these 10,000 simulations (Table 4).

XSL•FO
RenderX

Table . Occurrences of achieving different titles within 180 days based on various entry activity rates (simulation counts=10,000)[a,b].

EAR[c], %	Novice achieving counts	Intermediate achieving counts	Veteran achieving counts	Master achieving counts	Grandmaster achieving counts
0	0	0	0	0	0
5	211	0	0	0	0
10	1507	0	0	0	0
15	4040	1	0	0	0
20	6839	13	0	0	0
25	8873	64	0	0	0
30	9723	248	0	0	0
35	9954	698	0	0	0
40	9996	1590	2	0	0
45	10,000	2999	13	0	0
50	10,000	5003	48	0	0
55	10,000	7191	192	0	0
60	10,000	8852	502	0	0
65	10,000	9712	1275	0	0
70	10,000	9964	3001	17	0
75	10,000	9999	5629	82	0
80	10,000	10,000	8179	355	0
85	10,000	10,000	9746	1699	12
90	10,000	10,000	9994	5394	250
95	10,000	10,000	10,000	9541	3119
100	10,000	10,000	10,000	10,000	10,000

[a]EAR= (Number of days executing daily tasks/Total observation days) ×100%.



[b]Continuous execution days for each title: Kidney Health Novice—3 days; Kidney Health Intermediate—7 days; Kidney Health Veteran—14 days; Kidney Health Master—30 days; and Kidney Health Grandmaster—60 days.

[c]EAR: entry activity rate.

The simulation results provided item characteristic curve for each Kidney Health Title (Figure 4). These curves suggested that higher ability to perform daily tasks (indicated by a higher EAR) leads to a higher chance of achieving specific titles (indicated by more achievement instances). Using 5000 times of achievement as a baseline, its corresponding EAR on the item characteristic curve represents the difficulty level in achieving that specific Kidney Health Title. These results provide adequate rationality for the gamification strategy: assuming users in different stages of change have different EARs, this strategy sets appropriate challenges accordingly, aligning with our aim of providing corresponding interventions based on CKD dyads' different motivational states.

XSL•FO
RenderX

Figure 4. Item characteristic curves (ICCs) of achieving various kidney health titles within 180 days (simulation counts=10,000). According to Item Response Theory, with an achievement rate of 50% (ie, achieving 5000 times out of 10,000), the entry activity rate (EAR) corresponding to the ICC indicates the difficulty level to achieve that title. This simulation demonstrated the relationship between consecutively completing daily tasks for N days and its corresponding ability level, indicated by EAR. EAR = (Number of days executing daily tasks/Total observation days) × 100%. Continuous execution days for each title: Kidney Health Novice—3 days; Kidney Health Intermediate—7 days; Kidney Health Veteran—14 days; Kidney Health Master—30 days; and Kidney Health Grandmaster—60 days.

- Reinforcement management: Upon completing 2 daily tasks, users receive encouragement messages through the LINE OA; when obtaining a Kidney Health Title, the team sends encouragement messages and title certificates via LINE and informs their SOs. It also informs the patient's physician to provide face-to-face encouragement during the next visit (providing social reinforcement).
- Nudging through helping relationships: If a patient cannot complete tasks independently, the SO assists in recording. For patients in the early stages of change (eg, EAR below 50%) or those who have not performed tasks for more than 2 days, the system schedules LINE reminders via AlleyPin Interactive's case tracking system or notifies SOs to assist in reminders. References are drawn from the resources in "Kidney Support Teammate," providing assistance based on the patient's lifestyle context.

Platform Trial Use to Optimize the Platform

After the initial prototype of our digital platform went live, 10 CKD dyads visiting nephrology clinics regularly at a university hospital were invited to participate in the trial use from August to October 2023. One of the SOs (no. 003S) was invited by the patient but did not decide to participate in the end, resulting in a total of 19 participants. All dyads completed the user feedback form and returned it during the next visit. Table 5 shows the basic demographics of the participants. The following sections separately analyzed (1) the LINE message activity, (2) usage of the extended app, and (3) dyadic feedback content.

XSL•FO
RenderX

Table . Basic information of participants in phase 1 platform trial use (n=19).

ID[a]	Sex	Age (years)	Education	Relations	Stage of change	Primary user[b]

002P	Male	63	College			
002S	Female	62	Senior high			
003P and 003S				N/A	Preparation	P
003P	Male	64	College			
003S[c]	N/A[d]	N/A	N/A			
004P and 004S				Mother-son	Maintenance	S
004P	Female	81	Elementary			
004S	Male	53	College			
005P and 005S				Father-son	Maintenance	S
005P	Male	82	Illiterate			
005S	Male	56	Junior college			
006P and 006S				Mother-daughter	Preparation	P
006P	Female	37	College			
006S	Female	73	Junior college			
007P and 007S				Spouse	Maintenance	P
007P	Male	64	Junior high			
007S	Female	59	Elementary			
008P and 008S				Spouse	Contemplation	P
008P	Female	67	Junior college			
008S	Male	68	Junior high			
009P and 009S				Spouse	Action	P
009P	Male	52	College			
009S	Female	51	College			
010P and 010S				Mother-daughter	Maintenance	P
010P	Female	70	Senior high			
010S	Female	42	Junior college			

[a]ID marked with P denotes patients; S denotes significant others.

[b]Primary user refers to the one using the app for daily tasks, primarily patients.

[c]003S was invited by 003P to participate in the study but eventually chose not to.

[d]N/A: not applicable.

LINE Message Activity

Based on data from the LINE OA backend, a total of 849 messages were sent during the initial 28 days (October 30 to November 26, 2023) after participant recruitment completion (as shown in Table 6), averaging approximately 30 messages per day. This indicates continuous interaction and usage.

XSL•FO
RenderX

11/14	0	2	3	18	16	39
11/15	0	1	1	15	9	26
11/16	0	1	3	15	21	40
11/17	0	0	3	11	19	33
11/18	0	0	2	11	6	19
11/19	0	0	1	9	3	13
11/20	0	0	2	15	12	29
11/21	0	1	3	11	12	27
11/22	0	1	3	18	45	67
11/23	0	0	1	10	5	16
11/24	0	1	1	11	2	15
11/25	0	0	2	9	5	16
11/26	0	0	1	12	1	14
Total	1	20	53	342	433	849

[a]Data obtained from LINE Official Account Manager.

[b]API: application programming interface.

[c]Push messages sent to remind users of follow-up visits and daily tasks execution.

[d]Messages returned when clicking service menu layers or push message buttons.

Notably, the proportion of messages sent through API plug-in modules is extremely high: there were 342 Push messages, accounting for approximately 40% (342/849) of all messages, used for reminders on returning for checkups or daily task reminders and regular automatic care. There were also 433 Reply messages, constituting around 51% (433/849) of all messages, automatically sent by the system when users clicked buttons in the service menu or Push message prompts. In comparison, manually sent messages amounted to only 53, which is around 6% (53/849) of the total, primarily aimed at assisting users with operational issues or scheduling research-related appointments. These data demonstrate that our LINE OA with API plug-in modules shows a high degree of automation and convenience, allowing remote and real-time intervention, significantly reducing manpower costs, and reserving resources for handling more complex and specific user queries.

XSL•FO
RenderX

Usage of the Extended App

Upon observing the data on daily task execution by the primary users among the 10 dyads on the extended app (as shown in Table 7), since the start of enrollment on August 29, 2023, until 2:30 PM on April 29, 2024, a total of 2402 sets of physiological values have been logged, and 1079 kidney health diaries have been uploaded. Notably, it was found that the average EAR for logging physiological values (63.70%) was higher than that for writing kidney health diaries (50.74%). This difference might be due to the ease of recording physiological values and the immediate feedback obtained through trend chart viewing.

Table . Phase 1 primary users' usage of extended app for daily tasks (n=10)[a].

ID	Enrollment date (YY/M/D)	Days	Physiological values		Kidney health diary		Highest kidney health title[d]
			Counts	Activity rate, %[b]	Counts	Activity rate, %[c]	
001P	23/8/29	245	530	95.92	232	94.69	Master
002P	23/9/18	225	438	100.00	209	92.89	Master
003P	23/9/21	222	164	62.61	133	59.91	Intermediate
004S	23/10/2	211	2	0.95	0	0.00	None
005S	23/10/3	210	579	89.52	168	80.00	Master
006P	23/10/17	196	100	51.02	7	3.57	Novice
007P	23/10/19	194	125	63.92	25	12.89	Intermediate
008P	23/10/23	190	0	0.00	0	0.00	None
009P	23/10/23	190	307	90.53	161	84.74	Master
010P	23/10/30	183	157	82.51	144	78.69	Master
Total (Average)		206.6	2402	63.70	1079	50.74	N/A[e]

[a]This table is updated until April 29, 2024, at 2:30 PM.

[b]Activity rate for physiological values = (Days logged/Days enrolled) × 100%.

[c]Activity rate for kidney health diary = (Days written/Days enrolled) × 100%.

[d]Continuous execution days for each Kidney Health Title: novice—3 days; intermediate—7 days; veteran—14 days; and master—30 days.

[e]N/A: not applicable.

Eight users had an activity rate higher than 50% for logging physiological values, and among them, 6 also had an activity rate higher than 50% for writing kidney health diaries, indicating these users have a moderate to high level of acceptance and capability in performing daily tasks on the extended app. Regarding the challenges for Kidney Health Titles: 8 out of 10 users achieved consecutive logging of physiological values and writing kidney health diaries for at least 3 days (granted the "Kidney Novice" title) during the observation period; among the previously mentioned highly active 6 users, they achieved challenges of logging physiological values and writing kidney health diaries consecutively for 7 days (*intermediate*) or even 30 days (*master*). This demonstrates that higher activity levels correlate with a higher chance of long-term adoption of a healthy lifestyle, aligning well with the conclusions drawn from the simulation study.

Dyadic Feedback Content

Table 8 summarized the average ratings for each of the 6 major functions of our integrated platform, as provided by the 10 dyads in their user feedback forms. Generally, more than 80% of the dyads (more than 8) perceived each function to have a clear interface and to be easy to use. Similarly, most of the dyads (more than 80%) found each function acceptable and expressed their intention to continue usage. The average satisfaction rating for each function ranged from 3.5 to 4.3, with an overall rating of 4.1 for the platform as a whole.

XSL•FO
RenderX

Table . Phase 1 dyadic trial use feedback form rating summary (N=10)[a].

Functions of the digital platform	Assessed elements				
	#N-1: Interface clarity	#N-2: Ease of operation	#N-3: Acceptability	#N-4, 7‐2: Intention to continue usage	#N-5, 7‐2: Satisfaction rating (from 1 to 5)
Health Education Information	90%	90%	90%	90%	3.9
Kidney Support Teammate	90%	100%	90%	90%	3.5
Record Values	90%	80%	90%	80%	4.3
Reminder Settings	100%	90%	90%	90%	4.1
Kidney Health Mission	80%	90%	80%	80%	3.8
Inquiry & Consultation	100%	90%	80%	90%	3.7
Average	91.67%	90%	86.67%	86.67%	3.9
Overall platform evaluation	N/A[b]	N/A	N/A	90%	4.1

[a]The percentages in this table reflect the proportion of participant dyads who answered "Yes" to the corresponding Yes/No questions in the user feedback form.

[b]N/A: not applicable.

Qualitative feedback on each function, gathered through user feedback forms and brief interviews, is organized according to its positive and negative aspects:

1. Health Education Information (LINE): Dyads generally appreciated this function for its simplicity, clarity, and informative nature, noting that "it provided access to various, accurate CKD-related information at any time" (no. 005). However, one dyad (no. 010) suggested that "the font size should be enlarged, and the navigation of this function needs simplification to avoid getting lost."
2. Kidney Support Teammate (LINE): The majority of dyads found this function to be beneficial, appreciating its provision of "mutual support, encouragement, reminders, and detailed knowledge" (nos. 001 and 002). However, 2 dyads expressed concerns regarding its usage, with one noting "not using this function" (no. 005) and the other mentioning that "the colors are too vibrant, making it difficult to grasp key points, and navigating within the function could lead to getting lost" (no. 007).
3. Record Values (LINE+ App extension): Overall, dyads expressed satisfaction with this function, noting its advantages in "replacing traditional paper records, convenience, ease of use, and the ability to track data" (nos. 001, 002, and 009). Specifically, 1 dyad (no. 005) appreciated the support for chart view upon logging in data, facilitating easy tracking. However, 1 dyad (no. 010) mentioned dissatisfaction with the small font size and confusion regarding certain actions due to unclear wording.
4. Reminder Settings (LINE+ App extension): Dyads expressed overall satisfaction with this function, particularly highlighting its capability to provide advance notifications for upcoming clinical appointments. This function was deemed convenient and provided peace of mind by several dyads (no. 001, 005, and 009), eliminating the need to remember appointment dates. No negative feedback was received about this function.
5. Kidney Health Mission (LINE+ App extension): Overall, dyads who appreciated this function found its operation to be straightforward. Some dyads specifically noted its convenience for recording daily diet by uploading a photograph (no. 005) and its provision of daily data for tracking (no. 002). Conversely, 1 dyad found this function "troublesome, causing psychological pressure," and despite its good intent, felt "it lacked feedback from healthcare providers" (no. 001). Another dyad expressed inconvenience due to the small font size and difficulties logging in data (no. 010).
6. Inquiry & Consultation (LINE): Dyads provided positive feedback regarding the helpfulness of this function, particularly emphasizing its ability to provide answers to various relevant questions (nos. 002, 005, and 009). One dyad noted that "for new CKD patients, this function could serve as a substitute for in-person health education; however, for experienced patients, this function may seem unnecessary as they are already familiar with the answers" (no. 001). Another dyad commented on the potential for getting lost while navigating through the content of this function (no. 007).

Regarding the overall evaluation of the digital platform, neither dyad had previously used other apps or websites for managing CKD. Almost all of the dyads (90%) expressed willingness to continue using it to aid in managing their CKD. Upon further in-depth interviews with researchers about dyadic feedback, all agreed that the digital platform's functions were comprehensive, with no suggestions for additional functions. The first patient (no. 001P) mentioned that using the platform provided a "routine" after retirement. His SO (no. 001S) also mentioned the lack of diverse social activities after retirement for the patient

XSL•FO
RenderX

and expressed interest in participating in hospital support groups to share their experiences with other CKD dyads.

Phase 2: Heuristic Evaluation

By early November 2023, the team collected responses from 5 evaluators who participated in the heuristic evaluation. The evaluators' basic information is shown in Table 9.

Table . Basic information of phase 2 heuristic evaluation participants (N=5).

No.	Sex	Age (years)	Education	Background	Current occupation
1	Female	55	PhD	Nursing	Professor
2	Female	42	PhD	Health care science	Associate professor
3	Female	45	PhD	Nursing	Assistant professor
4	Female	54	PhD	Nursing	Assistant professor
5	Male	28	Master's degree	Electrical engineering	Engineer

General Compliance Rating

Their scores regarding the compliance of various functions with usability principles were tallied, averaged, and summarized in Table 10. On average, the compliance scores for each principle ranged between 0 (*partially complies*) and 1 (*complies*). The functions' average compliance with the 10 usability principles ranged from 89% to 93%. This suggests that the evaluators generally perceived that the digital platform's various functions mostly complied with the usability principles.

Table . Phase 2 heuristic evaluation compliance rating summary (N=5)[a].

Degree of compliance with each usability principle	Functions of the digital platform					
	Health Education Information, %	Kidney Support Teammate, %	Record Values, %	Reminder Settings, %	Kidney Health Mission, %	Inquiry & Consultation, %
Principle 1	60	80	100	80	80	100
Principle 2	100	100	100	100	80	100
Principle 3	100	80	80	60	100	75
Principle 4	100	100	100	100	100	100
Principle 5	100	100	100	100	100	100
Principle 6	80	80	100	100	100	75
Principle 7	80	80	100	60	100	80
Principle 8	100	100	100	100	100	100
Principle 9	100	100	33.33	100	33.33	100
Principle 10	100	100	100	100	100	100
Overall result	92	92	91.33	90	89.33	93

[a]Compliance percentages represent the sum of evaluator ratings (−1, 0, or 1) for each function's compliance with each usability principle, divided by the number of valid responses (ie, excluding "N/A [not applicable]" selections), and then multiplied by 100%.

Recommendations for Improvement

The breakdown of issues raised by evaluators about each function's incompliance with certain principles and their recommendations is as follows:

1. Health Education Information

- Principle 1 (60% compliance): Evaluator 1 found that "clicking into the five stages of CKD and lab test reports didn't lead to corresponding content." Evaluator 5 suggested "transforming health education information into daily articles and actively pushing them to users with thematic context."
- Principle 6 (80% compliance): Evaluator 2 felt that the design here might cause information loss or be easily forgotten after closing the linked web page and suggested implementing a memory function for highly clicked queries.
- Principle 7 (80% compliance): Evaluator 2 believed that this function lacked personal flexibility and suggested establishing personalized zones based on click rates to access or push commonly used information.

2. Kidney Support Teammate

- Principle 1 (80% compliance): Evaluator 5 felt that while the information was comprehensive, the incentive for users to actively read this information was slightly weak and suggested recommending correct concepts based on user records.
- Principle 3 (80% compliance): Evaluator 2 noticed that once clicked, the buttons for some information, returning to the previous message is not supported, requiring scrolling

XSL•FO
RenderX

or clicking on the service menu again, recommending immediate display of original options after dialogue box content appears.
- Principle 6 (80% compliance): Same as evaluator 2's feedback in (1) "principle 6 (80% compliance)."
- Principle 7 (80% compliance): Same as evaluator 2's feedback in (1) "principle 7 (80% compliance)."

3. Record Values

- Principle 3 (80% compliance): Evaluator 1 noted that after entering values, the entire app needed closing to return to the main screen and suggested adjusting this.
- Principle 9 (33% compliance): Evaluator 5 noticed that there were no notifications for abnormal physiological values and suggested providing automatic or manual messages based on professional or objective facts for abnormal values.

4. Reminder Settings

- Principle 1 (80% compliance): No specific issues or suggestions were mentioned by the evaluator.
- Principle 3 (60% compliance): Evaluator 5 discovered that alterations in the reminder function required notification to researchers and suggested allowing users to freely set daily or appointment reminders, similar to setting alarms on a phone.
- Principle 7 (60% compliance): Same as evaluator 5's feedback in (4) "principle 3 (60% compliance)."

5. Kidney Health Mission

- Principle 1 (80% compliance): Evaluator 5 felt that the current daily diet recording was based on self-assessment without professional guidance and suggested having professionals review information and provide guidance.
- Principle 2 (80% compliance): Same as evaluator 5's feedback in (5) "principle 1 (80% compliance)."
- Principle 9 (33% compliance): Same as evaluator 5's feedback in (3) "principle 9 (33% compliance)."

6. Inquiry & Consultation

- Principle 3 (75% compliance): Same as Evaluator 2's feedback in (2) "principle 3 (80% compliance)."
- Principle 6 (75% compliance): Same as evaluator 2's feedback in (1) "principle 6 (80% compliance)."
- Principle 7 (80% compliance): Same as evaluator 2's feedback in (1) "principle 7 (80% compliance)."

Overall, based on the evaluation scores and feedback from evaluators on each function of the digital platform concerning various principles, this phase successfully acquired specific recommendations for improving the platform's usability. These suggestions can generally be categorized into three aspects: (1) enhancing user operation convenience, such as adding a return option in Health Education Information, Kidney Support Teammate, and Inquiry & Consultation, reducing repetitive operation hassles; (2) pushing more relevant and engaging information, for instance, pushing corresponding educational content based on user records; and (3) enhancing interactivity and feedback of functions, such as providing personalized memory functions for highly clicked content, warning after inputting abnormal physiological values, or providing feedback from professionals. Results of the heuristic evaluation have guided the modification of the digital platform for the next iteration to enhance user experience.

Phase 3: Usability Testing

Following the design of tasks, the selection of participants for phase 3 involved convenience sampling by inviting 5 dyads who participated in phase 1 trial use during their next clinic visits. Eventually, dyad numbers 001, 002, 005, 007, and 009 agreed to take part in the testing. The results of their average performance on our designed tasks and their average ASQ ratings are summarized in Table 11.

Table . Phase 3 usability testing task performance and rating summary (N=5).

	Functions of the digital platform					
	Health Education Information	Kidney Support Teammate	Record Values	Reminder Settings	Kidney Health Mission	Inquiry & Consultation
Task success[a]	60%	80%	100%	100%	100%	80%
Task time (mm:ss)	04:23	05:16	01:06	01:52	01:04	02:55
Average error times (range)	1 (0 - 2)	1.4 (1-2)	0.2 (0 - 1)	0.8 (0 - 1)	0	1.2 (0 - 2)
ASQ: ease of use[b]	3.6	4	6.2	5.4	6	4.2
ASQ: time required	3.4	4.2	6.4	5.2	6.2	4.2
ASQ: help received	3.8	3.8	6	4.2	5.2	3.6
Average ASQ score	3.6	4	6.2	4.9	5.8	4

[a]Task success = (Number of dyads successfully completed the task/N) × 100%.

[b]ASQ: After-Scenario Questionnaire. The score of ASQ ranges from 1 to 7, with higher score indicating higher level of satisfaction.

XSL•FO
RenderX

Task Performance and ASQ

This section describes the designed task scenario for each function and summarizes participants' general task performance as well as their ASQ ratings:

1. Health Education Information: The task scenario reflected the need for patients with CKD to calculate their estimated glomerular filtration rate (eGFR) independently. To accomplish this task, users can navigate through the Health Education Information section in our LINE OA to find a link to a web page with an eGFR calculator. Results indicated that 3 out of 5 dyads completed this task successfully (success rate 60%), with an average completion time of approximately 4.5 minutes. Operational errors were observed with numbers 002, 005, and 009, who navigated to the wrong sections, causing them additional time to locate the eGFR calculator. Another error occurred when number 007 could not find the box to enter the value of creatinine (CREA), as the enlarged font size setting obscured a clear presentation of the calculator elements on the smartphone. The average ASQ score for this task is 3.6, which is the lowest score among all tasks, indicating that dyads were the least satisfied with the ease and the time required for this task. They also perceived minimal help from the user manual.

2. Kidney Support Teammate: The task scenario involved an SO finding effective ways to support a patient who is attempting lifestyle modification. The Kidney Support Teammate in our LINE OA provides such information for SOs to implement supportive strategies. The task success rate is 80%, with only 1 dyad failing to complete this task. The average completion time exceeded 5 minutes, which is the longest among all tasks. All dyads took time to navigate different sections before they located the target information for this task. Dyads numbers 005 and 009 experienced uncertainty as they browsed through the correct section but did not recognize the target information. The average ASQ score is 4, indicating a moderate but relatively low level of user satisfaction compared with the other tasks.

3. Record Values: The task scenario reflects the need for patients with CKD to monitor their own physiological data. Completing this task requires the user to click "Record Values" on the service menu of our LINE OA or click "New Entry" on the extended app and input the numbers. The task success rate is 100%, with an average completion time of only 1 minute. Dyad number 007 encountered initial difficulty when trying to input the CREA value. The average ASQ score is 6.2, which is the highest among all tasks. These results suggested that this function is user-friendly and intuitive, leading to high user satisfaction.

4. Reminder Settings: The task scenario arises when patients with CKD wish to set a reminder for their upcoming clinical appointment. Dyads will need to input the date and time of their next appointment using the extended app and notify the research team via LINE OA to set an automatic message reminder. The task success rate is 100%, with an average completion time of around 2 minutes. Dyads numbers 002 and 007 seemed unfamiliar with this function as they clicked "New Entry" on the extended app, which redirected them to the wrong page. The average ASQ score is 4.9, indicating a moderate satisfaction level with this function.

5. Kidney Health Mission: The task scenario revolves around the essential practice of tracking daily diet, a key aspect of managing CKD. Users can access this task by clicking "Kidney Health Mission" on the service menu of our LINE OA or selecting "Kidney Health Diary" on the extended app to upload a photograph or text note regarding their diet. The task success rate is 100%, with an average completion time of just 1 minute. All dyads completed the task without encountering any operational errors, indicating that the design of this function is sufficiently intuitive. The average ASQ score is 5.8, demonstrating a relatively high level of satisfaction compared with the other tasks.

6. Inquiry & Consultation: This task scenario arises when patients with CKD encounter health-related inquiries at home without access to a health care professional. Users can explore the frequently asked question section in our LINE OA to seek answers to their questions. For instance, this task involves users wanting to learn about the symptoms of hypoglycemia (low blood sugar) using our platform. The task success rate is 80%, with dyad number 002 failing to complete the task. On average, it takes around 3 minutes to complete the task, as all dyads navigate through different sections of our LINE OA to find the desired information. Errors occurred when all dyads, except number 001, attempted to locate the answer in the Health Education Information section. The average ASQ score is 4, indicating a moderate but relatively low level of user satisfaction, highlighting areas for usability improvement.

Overall Platform Usability

The SUS scores provided by the 5 dyads range from 57.5 to 87.5, with an average score of 67.5, just below the industry standard threshold of 68. This indicates that users found the platform to be marginally acceptable in terms of usability, indicating areas for improvement. In combination with the performance and ASQ ratings of the 6 tasks, it was observed that the 3 tasks involving operations on the extended app (ie, Record Values, Reminder Settings, and Kidney Health Mission) all achieved a 100% success rate, with shorter completion times, fewer operational errors, and higher satisfaction (mean average ASQ score: 5.64 vs 3.87 for the other 3 tasks). Conversely, tasks with lower performance and ASQ scores (ie, Health Education Information, Kidney Support Teammate, and Inquiry & Consultation) all involved finding information within LINE OA, suggesting that underlying significant usability issues in this area may have contributed to the low overall platform SUS score.

Discussion

Principal Results

In this study, we demonstrated that through an instant messaging app, our digital platform aimed at empowering lifestyle modification for CKD dyads holds promise for its cost-effectiveness, high user engagement, and potential clinical practicality. Key insights emerged from the 3-phase development cycle are as follows.

First, the application of Agile methods facilitated a flexible and efficient process in developing our digital platform. Notably,

XSL•FO
RenderX

the platform design and deployment were accomplished within a remarkably short time frame of 3 months, with the ability to accommodate modifications, typically within a week. Such adaptability of our platform ensured responsiveness to user needs throughout the development cycle.

Second, guided by the DDEF, this study introduced 2 quantifiable daily self-management tasks—logging physiological values and maintaining a kidney health diary—to address the multifaceted nature of CKD management. These tasks, coupled with behavior change techniques, aimed to promote sustained user engagement. The EAR of these tasks emerged as a simple, innovative, and promising indicator of users' lifestyle modification abilities, which could facilitate more precise tailored interventions based on different user activity levels.

Third, comprehensive evaluation across 3 phases revealed high user acceptance and satisfaction with our digital platform. However, usability challenges, particularly concerning information layout within the LINE OA, were identified. The absence of CKD dyad involvement during the initial prototype development hindered the alignment of the content of LINE OA service menu with varying user mental models, potentially causing users to struggle with navigation [37]. This finding underscores the importance of considering user expectations early in the development cycle to ensure optimal usability.

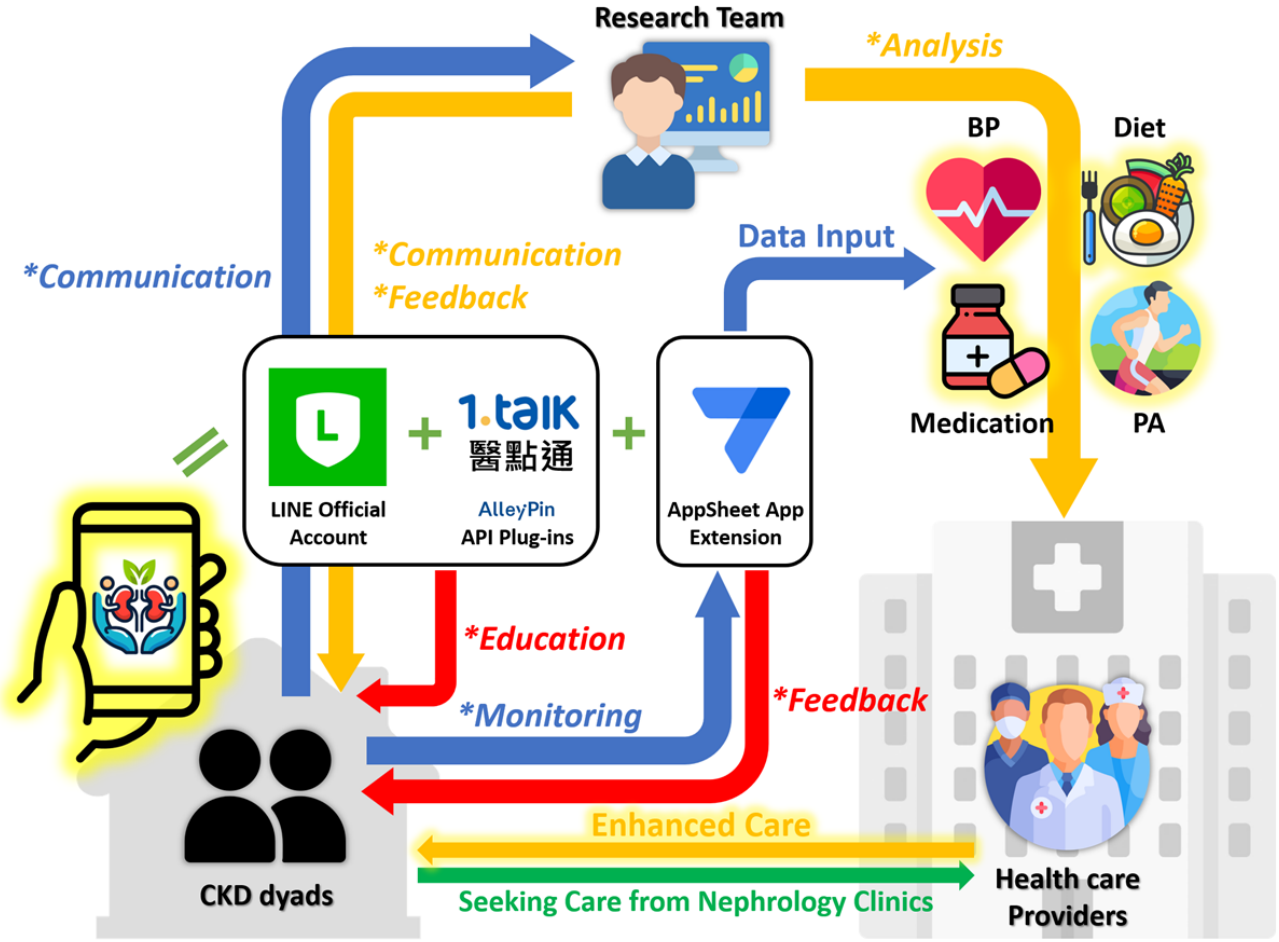
Comparison With Prior Work

Previous DHIs for CKD management have adopted various approaches, including a mobile app [15], a web-based platform [17], a chatbot [21], and the combination of a mobile app and wearable devices with instant messaging support [20]. These interventions have demonstrated potential in supporting CKD health education and self-management. However, challenges were faced such as limited evidence of sustained use—many reported low [15] or unclear usage rates [17,20,21]—and participant samples skewed toward younger, tech-savvy patients (mean age around 50 years), due to the necessity of internet access and smartphone proficiency. Moreover, prior systems typically focused on a single aspect of care (education or tracking) and rarely involved patients' family members, potentially excluding older patients who require caregiver support. In contrast, our LINE-based digital dyadic empowerment platform addresses these gaps through the following strengths mentioned in the subsections.

Diverse Participant Backgrounds

Our study encompassed participants with diverse backgrounds, ranging from health care providers (including nephrologists and nurses) within the institution involved in phase 1 system development, to patients with CKD and SOs engaged in both phase 1 platform trial use and phase 3 usability testing. Health care and electrical engineering experts from external institutions were involved in phase 2 heuristic evaluation. Of these participants, 41.7% (10/24) were male, spanning ages from 28 to 82 years, and educational attainment ranging from elementary school to doctoral degrees. Such diversity maximized the input from all potential stakeholders who could use or benefit from our digital platform. We ensured that various perspectives were considered throughout the development cycle, thereby optimizing platform usability while accommodating user differences.

Notably, the design of including SOs with patients with CKD in our study was pivotal. It not only enriched the diversity of perspectives but also prevented the exclusion of patients who might face challenges participating independently, such as those from older age groups or with lower educational levels, potentially constituting digitally disadvantaged groups. This inclusive approach, exemplified by dyads numbers 004 and 005 (Table 5), served to mitigate selection bias and promote health equity at the digital resource level.



A Scalable and Practical Digital Platform

In a 2023 internet survey conducted in Taiwan, it was found that 98.51% of internet users use instant messaging tools, with LINE holding a dominant market share of 91.61% [38]. Our digital platform operates within Taiwan's most prevalent instant messaging app, significantly improving its accessibility and ubiquity. This integration closely aligns CKD self-management with the most frequent daily use of digital technology. Data extracted from the backend of the LINE OA further revealed consistent user engagement with our digital platform, with more than 90% of interactions being automatic Push or Reply messages (Table 6). This underscores the high automation and low-cost model of our digital platform, demonstrating its potential for scalable application in medical settings.

Figure 5 further illustrates the interactive relationship between CKD dyads, the research team, and health care providers, elucidating how our digital platform can enhance CKD care in medical settings. The green arrow at the bottom represents patients with CKD and their SOs seeking routine care at the hospital. Blue arrows depict CKD dyads using LINE OA, either through encouragement or voluntary interaction, to stay connected with the research team (*communication* strategy); or using the extended app to log home-based health records, including blood pressure, diet, medication, and physical activity (*monitoring* strategy). Red arrows signify the fully automated services offered by our digital platform, such as providing health education information through LINE OA Push or Reply messages (*education* strategy); or accessing physiological trend charts and usage reports via the extended app (*feedback* strategy). Orange arrows indicate the interventions that the research team can deliver through the digital platform, such as maintaining contact with CKD dyads (*communication* strategy); or answering CKD dyads' queries and sending encouraging messages (*feedback* strategy) via LINE OA. Finally, the research team can further analyze and aggregate home-based self-monitoring records logged by CKD dyads through the extended app (*analysis* strategy) and provide reports to health care providers. This additional information will furnish health care providers with supplementary insights during CKD dyads' visits, aiding in treatment recommendations to enhance the quality of CKD care.

XSL•FO
RenderX

Figure 5. The schematic diagram of the LINE Official Account "Kidney Lifestyle" and the extended app in enhancing CKD care. The arrows marked with an asterisk (*) represent the practical application of the 5 digital strategies mentioned in the Digital Dyadic Empowerment Framework. Blue arrows represent the active engagement from CKD dyads. Orange arrows denote service flows involving human support, while red arrows denote service flows with full automation. BP: blood pressure; CKD: chronic kidney disease; PA: physical activity.

Empirical Evidence for Sustained User Engagement

This study provides empirical evidence of high user acceptance and satisfaction with our digital platform, as indicated by self-reported satisfaction ratings and intentions to continue usage during phase 1 trial use, as well as by the ASQ scores obtained from phase 3 usability testing. While self-reported ratings could potentially be inflated by demand characteristics [39,40], the robustness of these findings is further supported by users' consistent execution of the 2 daily self-management tasks. As depicted in Table 7, more than half of the 10 trial users maintained an EAR from 50% to 100% for the 2 daily tasks for more than 6 months. Notably, 5 users had a record of executing the 2 daily tasks consecutively for 30 days or more, demonstrating their ability to sustain regular usage. These findings imply their persistent commitment to using our digital platform for managing CKD, even after they completed the study. Such ongoing engagement serves as compelling evidence of our digital platform's potential as a highly acceptable digital health solution, empowering CKD dyads in the process of lifestyle modification.

Limitations

Potential Selection Bias Induced by Digital Divides

Despite the wide availability of our digital platform on LINE OA and the inclusive dyadic design, this study might still have suffered from selection bias due to digital divides between those with access to our platform and those without [41]. During phase 1 participant recruitment, we encountered instances where some CKD dyads, particularly spouses, reported lacking access to smartphones or the internet. Conversely, some dyads had smartphones with internet access but lacked diverse digital skills or did not have LINE installed on their phones. All these factors could impede the implementation of our study and raise concerns over health inequity. Although the extent of these digital divides was not thoroughly investigated within the scope of this study, their existence warrants careful consideration in our future work to prevent selection bias favoring participants with higher digital proficiency.

For participants facing difficulties in using our platform, personalized assistance will be provided through interactive learning sessions and the user manual, reducing the likelihood of their attrition from the study. Furthermore, future research could investigate the prevalence and characteristics of digitally disadvantaged groups within the CKD population. Assessing the severity and underlying causes of digital divides may help

XSL•FO
RenderX

mitigate their impact on the implementation of our DHI. Alternatively, programs empowering lifestyle modification tailored to CKD dyads who are not internet or smartphone users could be developed.

Usability Issues With LINE OA Navigation

Despite continuous optimization, the SUS scores obtained from phase 3 usability testing indicate that the usability of our digital platform remains marginally acceptable. Particularly, significant usability issues were identified within the information layout of the service menu on LINE OA. During phase 1 trial use, dyads reported difficulties navigating sections including Health Education Information, Kidney Support Teammate, and Inquiry & Consultation, often getting lost. Similarly, task performance and user satisfaction related to these sections were relatively low in phase 3 usability testing. However, tracking individual user interactions with specific sections in LINE OA is challenging due to its backend limitations, as only aggregate user activity data are available. This impedes the establishment of personalized sections, as suggested by the heuristic evaluators in phase 2.

Analysis of phase 3 error records further revealed 2 major sources of confusion (Multimedia Appendix 4). First, users were often unsure whether to seek answers in Health Education Information or Inquiry & Consultation, as both sections were perceived to serve a similar purpose of obtaining CKD-related knowledge. This mismatch between users' mental models and the platform's menu structure frequently led them to attempt tasks in the wrong section, causing navigation failures. Second, the design of LINE OA as an instant messaging interface posed inherent challenges: the service menu occupies nearly one-third of the small mobile screen, while new messages push earlier information upward, forcing users to scroll back or reselect menu buttons to revisit prior content. When combined with multilayered menu depth, these constraints increased cognitive load and disorientation, further compounding the likelihood of users getting lost.

To overcome these challenges, several measures have been introduced and others are planned. In response to phase 2 feedback, we incorporated a "return to previous level" option within the Kidney Support Teammate and Inquiry & Consultation sections (Figure 2D), providing a route back when disoriented. Future platform refinements could also consolidate Health Education Information and Inquiry & Consultation into a single section, for instance, by embedding Inquiry & Consultation under Health Education Information to reduce functional overlap and user confusion. Moreover, involving CKD dyads in early stages of prototype development remains essential. Interviews on information needs and common questions could align menu structures more closely with users' mental models. Finally, harnessing the instant messaging nature of LINE OA, the inclusion of a chatbot could provide more efficient and context-sensitive access to disease-related information through automated dialogue interactions, thereby enhancing overall usability [21].

Concerns for Low EARs

Despite our efforts to simplify the design of our digital platform, reducing hierarchies and operational paths, along with manual support and relevant skill teachings, some users, as shown in Table 7, have an activity rate below 50% for logging physiological values (2 users) or writing kidney diaries (4 users). We identified 3 potential reasons for these low EARs, indicating the need for more comprehensive interventions as mentioned in the following sections.

Dyads in the Preaction Stages of Change

Observations from Tables 5 and 7 revealed a positive relationship between dyads' self-reported readiness for lifestyle modification (ie, stages of change) and their execution of daily tasks. The 5 most active dyads, with EARs exceeding 75% for both tasks and having achieved the *Master* kidney health title, were all in the late stages of change (*action* or *maintenance*), while of the other 5 dyads, 3 were in the preaction stages (*contemplation* or *preparation*). Despite daily task reminders, there was no observed increase in activity rates among lower-activity users. Future interventions may focus on leveraging helping relationships with SOs and providing proactive caring phone calls to enhance their motivation for change.

Dyads Perceive No Need for Use

Among the previously mentioned 5 dyads with lower activity rates, 2 self-reported being in the late stage of change (*maintenance*). These dyads might have already engaged in regular lifestyle modifications but perceive minimal help from our digital platform and hence feel no necessity in using it. To address this, future implementation could focus on highlighting the platform's strengths and collaborating with health care providers to promote the platform's benefits to patients and their caregivers.

Dyads Face Usage Obstacles and Perceive High Execution Difficulty

Another possible cause of low EARs is shortcomings in the digital platform's design and user manual, leading dyads to perceive high cognitive load and execution difficulty. To address this, helping relationships from SOs and providing assistance are crucial. Regular caring and reminder messages, platform design optimization, and personalized teaching during return visits can help address usage obstacles and enhance usability.

Another promising future direction is to assess the feasibility of organizing support groups for CKD dyads, based on our dyadic feedback in phase 1. Support groups may facilitate the process of social liberation, exposing dyads to a supportive social environment for behavior change [42]. Dyads in the preaction stages might find positive support from the group, enhancing their motivation for change. Support groups can also promote community participation through connections and information exchange and allow their efforts to gain recognition and reinforcement from the group. For dyads perceiving minimal help from the digital platform or finding it too challenging to use, they can observe and learn from other dyads in the support groups, enhancing their confidence and skills in usage.

XSL•FO
RenderX

Lack of Feedback From Health Care Providers

In phase 1 dyad trial use and phase 2 heuristic evaluation, participants highlighted the need for health care provider feedback on user self-monitoring records. However, our digital platform currently lacks feedback mechanisms beyond system-generated physiological trend charts and platform usage reports from the extended app (Figures 3A and 3C). Specifically, feedback from health care providers on dietary, medication, and exercise content in the kidney health diary is absent. As observed in Figure 5, health care providers currently do not interact with CKD dyads through our digital platform and are thus unable to provide feedback on the content of the kidney health diary. This gap may contribute to lower activity rates for the kidney health diary compared with physiological values (Table 7). Workflow integration challenges are common in the development and application of new digital health tools, as they might potentially burden health care providers with additional tasks or even necessitate practice reorganization [15,43].

Recognizing the temporary difficulty in overcoming this challenge, an alternative approach involves compiling CKD dyads' self-monitoring records into paper-based reports for health care providers. These reports are provided to health care providers on CKD dyads' follow-up visit days for reference. During consultations, health care providers can then access the extended app with CKD dyads to review the kidney health diary content as needed. While conducting trials to assess the effect of our digital platform on CKD management is imperative, our future work should also tackle workflow integration issues through close collaboration with health care system personnel to promote platform adoption.

Conclusions

Guided by DDEF and using Agile methods, this study successfully developed, evaluated, and optimized an instant messaging–based digital platform tailored for CKD care across a 3-phase development cycle. The resulting product, the LINE OA "Kidney Lifestyle" and its associated extended app, aims to empower lifestyle modification for CKD dyads. Our investigation uncovered robustly high user acceptance and satisfaction with the platform, evidenced by both self-report ratings and ongoing engagement beyond the study period, lasting over 6 months. The platform's wide availability, high automation, and cost-effective operational model underscore its potential for scalable application in practical health care settings. While our digital solution shows considerable promise, a feasibility study is the logical next step to evaluate implementation factors and potential impacts on CKD management outcomes. Meanwhile, our future works should also bridge digital divides, enhance usability, foster support groups, and integrate our platform into current health care workflow to maximize its effectiveness and scalability. In sum, this study contributes significantly to the growing field of digital health for CKD management by showcasing the potential of an innovative platform integrated with the LINE instant messaging app.

Acknowledgments

The authors would like to thank all participants who took part in this study. The authors are especially grateful to the *Taiwan Kidney Foundation* for authorizing the use of their official educational resources within the platform developed in this study. The authors also extend their sincere thanks to Ms Yu-Chen Kuo, health education nurse at the Health Education Center of National Cheng Kung University Hospital, and to their technical development partner, AlleyPin Interactive Co, LTD, for their valuable suggestions and support throughout the platform development process. The authors additionally thank 2 research assistants, Jung-Jung Liang and Wei-Tung Kao, for their assistance in participant enrollment and data processing. During intervention development, OpenAI's ChatGPT was used to assist in the creation of Google Apps Script functions for backend automation, such as calculating daily task patterns and simulating gamification logic. It was also used to improve language clarity and structure in the manuscript. All outputs were reviewed and edited by the authors, who assume full responsibility for the final content.

Funding

This study was supported by the National Health Research Institutes, Taiwan, through the Integrated Research Grants in Health and Medical Sciences (Innovative Research Grant, grant no. NHRI-EX112-11106PI). The funding agency had no role in the design and conduct of the study; collection, management, analysis, and interpretation of data; or preparation, review, and approval of the manuscript.

Data Availability

The complete dataset generated during this study—including raw item-level feedback from phase 1 dyads, heuristic evaluation scores and qualitative comments from phase 2 experts, and individual-level task performance metrics and questionnaire responses from phase 3 usability testing—is available in Multimedia Appendix 4. Multimedia Appendix 4 also contains summary tables that correspond to the results reported in Tables 8, 10, and 11 of the manuscript.

Authors' Contributions

MY conceived the study idea, developed the initial study design, secured research funding, and supervised the overall implementation of the study. CYH optimized the study design based on practical considerations, led the development and integration of the digital platform, and was responsible for participant recruitment, data collection, analysis, interpretation, and

XSL•FO
RenderX

manuscript preparation. DS contributed to the initial drafting of the "Introduction" section. JMS, MCW, and WHL provided suggestions on platform design and assisted with participant referral. All authors critically reviewed and revised the manuscript for intellectual content and approved the final version for publication.

Abstract

Background: Adolescence is the period with the highest incidence of mental disorders, with approximately one-third, half, and two-thirds of cases emerging by ages 14, 18, and 25 years, respectively. Proactive interventions are essential, and digital phenotyping has emerged as a promising approach for timely detection and management. However, passive digital phenotyping is limited to sensor-detectable behaviors, while active phenotyping is often confined to clinical scales, missing the opportunity to capture users' subjective perspectives and emotional nuances. Furthermore, the potential therapeutic effect of the data collection process itself on emotional disorder management remains underexplored.

Objective: This study developed and tested a mobile app that collects passive and active digital phenotypes related to adolescents' emotions and daily behaviors. The study aimed to assess the app's impact on managing emotional disorders through self-monitoring and to identify daily lifestyle indicators that can predict and track the development of such disorders.

Methods: A 4-week parallel, nonequivalent control group design was employed. The intervention group installed a digital phenotype collection tool on their mobile devices for 28 days. Passive data (location, sleep, and screen time) were continuously recorded. Active data were collected through ecological momentary assessments delivered randomly up to 8 times daily, prompting participants to report their current mood and levels of depression, anxiety, and stress. The control group received no intervention. Both groups were assessed at time points on emotional disorders, self-efficacy, and time management. Postintervention interviews were conducted with the intervention group.

Results: Thirty-six Korean adolescents participated (19 control, 17 intervention). The intervention group showed significant reductions in depression (P=.04, d=0.42) and stress (P=.03, d=0.46) and improvements in self-efficacy (P=.002, d=0.50) and time management abilities (P<.001, d=0.39), with small to large effect sizes. No significant change was observed in anxiety levels (P=.11). Correlational analysis revealed weak but significant links between passive digital phenotypes and daily emotional states.

Conclusions: Integrating active and passive digital phenotypes through a mobile collection tool can help manage emotional disorders in adolescents. Use of the tool was associated with moderate reductions in depression and stress, as well as improvements in self-efficacy and time management, while anxiety levels remained unchanged, possibly due to adolescents' differing perceptions of anxiety. Passive digital phenotypes such as location variability and phone usage showed modest correlations with daily emotional states, supporting their potential as ecological markers. These findings suggest that digital phenotype collection not only aids in monitoring but may also have therapeutic benefits by promoting self-reflection on mood and behavior. High adherence rates further support the practicality and acceptability of this approach for long-term emotional disorder management in adolescents.

Introduction

Background

Alarming statistics reveal that nearly half of all mental illnesses begin before the age of 18 years, placing adolescents at the highest risk of developing emotional disorders [1,2]. Depression and anxiety are the most diagnosed conditions in adolescents, affecting nearly every aspect of their lives. These conditions can disrupt school, strain family relationships [3], and fuel risky behaviors such as smoking, drinking, and substance abuse. Most disturbingly, depression is a leading risk factor for suicide among adolescents [4]. Adolescence is a critical period of physiological, psychological, and social development; as such, mental health during this phase is intricately linked to well-being in adulthood [5]. This underscores the urgent need for early diagnosis and timely intervention in adolescent emotional disorders.

Digital phenotypes, the real-time collection of physiological and behavioral data through computer-based tools, have gained attention as a means to prevent and address mental disorders [4]. By capturing continuous, comprehensive data often unavailable through traditional methods, digital phenotypes offer new opportunities for the early detection and treatment of emotional disorders. These phenotypes can be categorized as active and passive. Active digital phenotypes require conscious user input, such as responses to self-reported surveys. Passive digital phenotypes collect data unobtrusively through smartphone sensors like accelerometers and Global Positioning System (GPS) as individuals go about their daily lives [6]. Research shows that digital phenotypes can effectively detect the severity of social anxiety, predict depression recurrence [6], identify suicidal ideation, and even prevent symptom deterioration with real-time monitoring [7].

However, opinions vary on whether passive digital phenotypes are sufficient to understand and explain emotional disorders. Context is crucial in shaping an individual's emotional perceptions and reactions, yet passive digital phenotypes often fail to capture this nuanced information. While behaviors such as movement or physical activity can be easily inferred from GPS and accelerometer data, more complex activities or emotional states that require inferences or are inaccessible to sensors remain unknown through passive sensing alone.

To gain a deeper understanding of emotional disorders, active digital phenotypes must be used to complement passive methods [8]. However, existing research primarily relies on clinical scales that may not fully account for the contextual factors relevant to emotional disorders [6,9-13]. Moreover, much of the literature treats digital phenotypes merely as data collection outcomes [14,15]. In contrast, active digital phenotyping functions as a form of self-monitoring, empowering individuals to gain insights into their emotional responses and develop targeted strategies to improve their mental health [16]. Therefore, the process of collecting active digital phenotypes may itself contribute to addressing emotional disorders.

In this context, our study is among the first to integrate both passive and active data collection in a single tool and to deploy it in the real world among adolescents. This dual-mode approach enables the collection of context-rich, ecologically valid data that neither passive nor active methods alone can provide. By analyzing the relationship between these digital phenotypes and daily assessed emotional disorder levels, we aim to determine how passive and active digital phenotypes function as complementary, parallel indicators of adolescent emotional health. Furthermore, this study investigates how the process of data collection can promote emotional disorder levels, self-efficacy, and time management skills.

Related Works

Digital Phenotypes and Emotional Disorders

Passive digital phenotypes are data collected about people's daily lives using digital devices [6]. This definition contains 4 further elements [9]. First, it involves continuous data collection and analysis rather than collecting data at specific time points. Second, the individual is the unit of analysis. Third, data are collected in natural, uncontrolled environments to capture real-world behavior. This point distinguishes passive from active digital phenotypes, such as ecological momentary assessments (EMAs), which will be discussed later. Fourth, passive digital phenotypes can be collected by devices that individuals already own, such as smartphones, without additional instruments [9].

A variety of physiological and behavioral passive digital phenotypes can be used to identify abnormal behavioral patterns associated with mental disorders [6,10]. People with mental disorders exhibit symptoms that affect mobility, life satisfaction, and social interactions, some of which can be quantified through digital phenotypes [11,12]. Symptoms of depression include negative affect, hopelessness, devaluation of life, and inertia, while anxiety is characterized by physiological arousal such as sweating, trembling, increased heartbeat, and avoidance tendencies [13]. Tracking these symptoms with passive digital phenotypes can allow for the early diagnosis and timely treatment of certain diseases, thereby more effectively managing health.

Adolescence is a particularly vulnerable developmental stage, often characterized by exposure to various stressors and their debilitating mental health effects [17]. Stress is accompanied by physical, psychological, or social complaints or dysfunctions resulting from individuals feeling unable to meet requirements or expectations placed on them. Stress during adolescence is associated with negative outcomes such as decreased well-being, impaired mental health, anxiety, and depression [17-20]. These challenges often co-occur, and symptoms of one disorder may predict the concurrent or future development of other mental health disorders. Therefore, addressing stress and emotional disorders is crucial for promoting long-term mental health.

Digital phenotyping could be particularly effective in addressing adolescent mental health challenges as adolescents often lack self-awareness or face communication barriers, particularly due to externalizing psychiatric disorders [21]. Given that approximately 95% of adolescents own or have access to smartphones, most by age 11 years, these technologies could be especially effective at tracking and intervening in mental health issues [22]. Mobile sensing and digital phenotypes can

XSL•FO
RenderX

support health behaviors by enhancing individuals' responsibility for their health and have been shown to increase health literacy [23]. These technologies also promote stronger relationships between health care providers and adolescents by facilitating meaningful conversations based on collected data, enabling timely treatment and encouraging help-seeking behaviors [24].

Ecological Momentary Assessment

An EMA [25] is used to build a comprehensive understanding of individuals [26,27]. It collects real-time self-reports of individuals' behaviors, thoughts, and emotions in their daily lives [28]. EMAs examine the present moment and so are conducted repeatedly over an extended period. With advancements in technology, EMAs are often implemented through digital platforms, such as smartphones and wearable devices [25].

Emotions are not fixed or stable; they are highly responsive to immediate circumstances and daily experiences [29]. Traditional data collection methods that rely on retrospective reports may struggle to capture these dynamics due to several biases, such as recency and novelty effects, which may compromise their validity [30]. EMAs overcome this limitation by gathering data at the moment when these experiences occur. This real-time approach allows for a detailed examination of how emotions evolve throughout the day [31].

To effectively manage emotional disorders, it is necessary to understand the conditions that trigger them [32]. Clinical scales and interviews with health care providers rarely address the context of the symptoms. In contrast, EMAs solicit a wide range of information from individuals, such as their location, time, and interpersonal influences, which can identify specific contexts in which emotional disorders are triggered [25,33]. Such detailed information can be used to better manage these conditions.

Unlike passive digital phenotypes, which rely on data collected by sensors, EMAs can directly ask individuals about their subjective experiences, which allows them to capture contextual data that sensors may not be able to [33]. Active and passive digital phenotypes complement each other, and neither is inherently superior. By integrating EMAs with passive digital phenotypes, researchers can achieve a more comprehensive understanding of emotional disorders [34]. This study collected active digital phenotypes through EMAs and passive digital phenotypes to develop detailed insights into the contextual factors influencing emotional disorders in adolescents.

Self-Monitoring and Self-Efficacy

Self-monitoring is the process in which individuals observe and record their own behaviors, emotions, and thoughts and adjust themselves accordingly [35]. Through this process of data collection and reflection, individuals can enhance their self-awareness and choose to engage in behaviors to achieve specific goals. Emotional self-monitoring helps identify factors that influence mood, both positively and negatively, allowing individuals to develop strategies to improve their mental health [36]. Self-efficacy is an individual's belief in their ability to plan and execute actions to achieve desired outcomes [37] and is closely linked to mental health. By boosting self-efficacy, self-monitoring can enhance mental health, increasing an individual's belief that they can autonomously manage and overcome emotional challenges [38,39].

Previous studies have identified several benefits of self-monitoring. Regularly measuring symptoms of emotional disorders can help predict their recurrence and evaluate the effectiveness of the ongoing treatments [40]. It provides opportunities to reflect on the context surrounding symptom occurrences, aiding in understanding the causes. Moreover, self-monitoring helps identify factors that either alleviate or worsen emotional disorders, providing insights into their patterns and impacts [41]. Finally, self-monitoring is done independently without external interventions, so it encourages individuals to actively participate in managing their mental health [36,42,43], which can enhance an individual's agency, positively influencing their self-efficacy.

Combined with these benefits, self-monitoring has been shown to improve mental health symptoms [44]. Studies on adolescents in the early stages of depression have demonstrated that self-monitoring gives them insights into their health, which is the first step in a stepped-care approach [33,45,46]. Furthermore, self-monitoring extends symptom-free periods in patients with depressive disorders [47] and helps them focus on behaviors that can help them control their emotional disorders [48]. Even for individuals not clinically diagnosed with emotional disorders, self-monitoring has been shown to have positive effects, such as motivating them to pursue health management [49].

To effectively define the role of digital phenotypes in managing emotional disorder, it is crucial to understand them as self-monitoring. However, the role of digital phenotypes as a tool for self-monitoring has not been investigated yet. This study explored whether digital phenotypes could help individuals engage in self-monitoring of emotional disorders. Accordingly, a service was developed for this study that integrates the collection of digital phenotypes, which have been validated for their use in the early diagnosis and treatment of adolescent mood disorders. The study evaluated the effects of this service on adolescents' depression, anxiety, stress, and self-efficacy levels and time management abilities.

Methods

Study Design

Participants were not randomly assigned due to constraints related to the study tool's operational environment as the app was only compatible with Android smartphones. Given the limited number of adolescents using Android devices who were available to participate, it was not feasible to recruit a sufficiently large sample for both groups exclusively from Android users. The study used a 4-week parallel, nonequivalent control group design.

The intervention group consisted of Android users who installed and used the app for 28 days. The control group, which was not required to use the app, had no restrictions on smartphone type. Both groups were assessed on key variables at baseline (day 0), midpoint (day 14), and postintervention (day 28). Following

XSL•FO
RenderX

the intervention, semistructured interviews were conducted with the intervention group to explore their experiences using the digital phenotype collection tool.

Interviews were conducted via the Zoom online conferencing tool within 1 week after the intervention period ended. With participants' consent, all interviews were audio-recorded, transcribed verbatim, and then deleted to maintain confidentiality. Topics covered the perceived impact of app usage on personal life and mood and suggestions for improvement. Data were analyzed using thematic analysis, with 2 researchers independently coding to identify recurring themes and patterns.

Recruitment

This study included individuals who: (1) were South Korean residents in the age group of 12 - 18 years, (2) were enrolled in middle or high school, (3) spoke Korean as their native language and had no difficulty communicating in it, and (4) understood the study purpose and voluntarily agreed to participate. Participants were recruited to the intervention group if they owned an Android smartphone and had no issues using it to ensure the efficient operation of research tools.

Participants were recruited through multiple channels, including digital flyers posted on social media platforms (eg, Instagram, KakaoTalk channels), online youth community forums, and outreach via collaborating clinicians. Recruitment materials briefly explained the study purpose and provided a link to an online preassessment survey. Those who completed the survey received the download link to the study tool via a text message.

This recruitment strategy may have introduced selection bias as participants were more likely to be adolescents who actively engage with digital platforms and possess higher digital literacy. Additionally, the requirement for Android smartphone ownership in the intervention group may have introduced systematic differences between groups, particularly in terms of socioeconomic status and smartphone usage patterns.

Sample Size Calculation

The sample size was calculated using a 2-sided significance level of .05, a statistical power of 80%, 2 groups, and 3 repeated measures. Based on these parameters, a sample size of 26 participants per group was estimated to be sufficient to detect an effect size of .33 in the reduction of depression levels. This effect size was selected based on findings from a systematic review of digital mental health interventions targeting young people, which reported small to moderate effect sizes for similar outcomes. To account for a potential 5% dropout rate, we increased the target sample size to 56 participants in total.

Intervention

The study tool was an app that collects digital phenotypes validated as predictive indicators for emotional disorders. The app was developed based on exploratory research into adolescents' intentions and behaviors in voluntarily recording emotions and daily activities [50]. To develop the tool, we first observed how adolescents recorded target active digital phenotypes regarding emotions and lifestyle behaviors within a digital environment and inquired about the tools they used, including their advantages and disadvantages.

These observations were then translated into system design goals, which included designing interfaces that resemble digital planners, streamlining data input processes with shortcut interactions, providing visual reports on collected data to reward users' efforts, and writing friendly EMA prompts. By aligning the system's features with users' natural behaviors, the app was designed to enhance the quality of collected active digital phenotypes.

Emotional recording followed an EMA methodology where users responded to notifications delivered randomly throughout the day (Figure 1). These notifications were sent upon waking, before school, during lunchtime, after school, before private tutoring, after private tutoring, before bedtime, and if the phone was used for more than 30 minutes after midnight. Users were restricted to recording their emotions only when prompted by these notifications.

The recording of lifestyle behaviors was facilitated through a screen displaying a table that divided the 24-hour day into 30-minute intervals, resulting in 48 cells (Figure 2). By clicking on each cell, users could access a pop-up screen with sleep, exercise, leisure, and study categories, each of which included specific activities, like napping or meeting friends. The recorded data were then processed into reports, allowing users to gain detailed insights into the structure of their daily lives and their levels of emotional disorders.

Measures

Demographic Information

Participants provided demographic information, namely gender, age, level of education, and address. The level of effort typically invested in mood and life management was assessed using a 5-point Likert scale, ranging from 1 (“very low”) to 5 (“very high”).

Korean Version of the Depression Anxiety Stress Scale

The Korean version of the Depression Anxiety Stress Scale, adapted by Lee (2002) from the version shortened by Henry of the original developed by Lovibond, was used to measure levels of depression, anxiety, and stress [51-53]. This shortened scale consists of 21 items, with 7 items assessing each symptom. Each item is rated on a 4-point Likert scale from 0 (“does not apply at all”) to 3 (“applies most of the time”), with higher scores indicating greater severity of symptoms.

Self-Efficacy Scale

Self-efficacy was measured using a scale developed by Sherer and translated by Kim [54,55]. The scale includes 22 items divided into 3 subfactors: confidence, self-regulatory efficacy, and preference for task difficulty. Each item is rated on a 5-point

XSL•FO
RenderX

Likert scale from 1 (“strongly disagree”) to 5 (“strongly agree”), with higher scores indicating higher self-efficacy. The internal consistency coefficient, Cronbach α, for this scale is 0.88.

Time Management Ability Scale

Time management ability was evaluated with a scale developed by Jeong and Jang, which includes 30 items categorized into 3 subfactors: planning ability, execution ability, and evaluation ability [56]. Participants rated each item on a 5-point Likert scale from 1 (“not at all”) to 5 (“always”), with higher scores indicating better management ability. The internal consistency coefficients, Cronbach α, for these subfactors are 0.91, 0.86, and 0.89, respectively.

mHealth App Usability Questionnaire

To evaluate the usability of the app developed for this study, we used a self-reported scale that assesses the usefulness and usability of mobile health apps [57]. The scale consists of 21 items rated on a 7-point scale from 1 (“strongly disagree”) to 7 (“strongly agree”). The questionnaire is divided into 3 subfactors: ease of use and satisfaction, assessed by 8 items, system information arrangement, assessed by 6 items, and usefulness, assessed by 7 items.

Passive Digital Phenotypes

The location digital phenotypes, collected using the devices’ GPS functions, included total distance traveled, total travel time, location variance, entropy, and normalized entropy. These data were preprocessed by estimating travel speed through time derivatives. Using a threshold of 1 km/h, the data were classified as either stationary or moving [57,58]. The stationary data were analyzed with the K-means clustering algorithm to identify the locations where participants spent most of their time.

The sleep digital phenotypes included total amount of sleep, total daytime sleep, and total nighttime sleep. Considering the daily routine and schedule of adolescents, daytime was defined as 7 AM to 11 PM and nighttime as from 11 PM to 7 AM. Sleep states were estimated using data collected from cameras, microphones, accelerometers, and smartphone log data, considering factors such as ambient light, noise, and smartphone screen time [59].

Digital phenotypes calculated from screentime data contained in device logs included total phone usage duration, total daytime phone usage, total nighttime phone usage, total phone lock duration, and the frequency of phone unlocks [60]. We handled outliers using the interquartile range method, where values outside 1.5 times the IQR were considered outliers and excluded. We did not attempt to impute missing values as the data were passive and imputation could introduce artifacts.

Active Digital Phenotypes

Mood records were collected using EMAs. System notifications were delivered randomly throughout the day, except during school, private tutoring, and sleep. Upon receiving a notification, participants recorded their current mood by selecting the mood-related adjectives (eg, happy, sad, relaxed) and rated their levels of depression, anxiety, and stress on a scale from 1 (“very low”) to 5 (“very high”).

Participants recorded their daily activities using predefined options. Key lifestyle areas include sleep, exercise, leisure, and study-related activities. Each 24-hour day was divided into 30-minute intervals and participants were asked to select the corresponding activity for each time slot (eg, studying, walking). The recorded lifestyle behaviors were organized by type, start time, and end time.

Statistical Analysis

Analyses were conducted using SPSS 26.0. Descriptive statistics were used to describe and compare participants’ baseline characteristics. Univariate analyses were performed to compare baseline values using the *t* test for independent samples. A 2-way ANOVA model followed by Scheffé post hoc tests was used to test the effect of app usage on each variable. Data were analyzed using 2×3 repeated measures ANOVAs with 1 between-subject factor (intervention group and control group) and 1 within-subject factor (preintervention, midintervention, and postintervention). The statistical significance level was defined as α=.05.

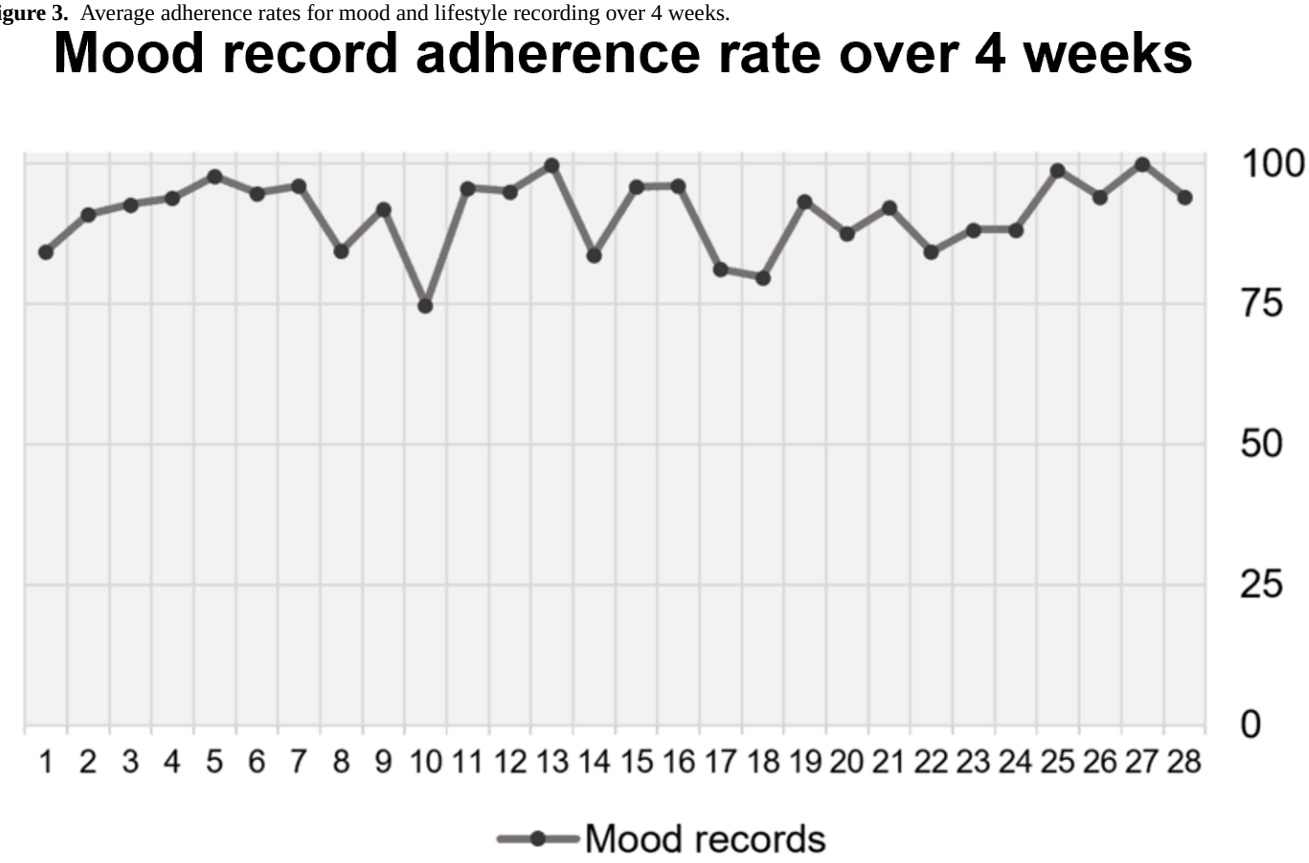
Ethical Considerations

This study was reviewed and approved by the Yonsei University Institutional Review Board (IRB no. 7001988-202406-HR-2045-05). All participants provided written informed consent after receiving a full explanation of the study purpose and procedures from the research team. Participant confidentiality was maintained throughout the study, with each individual assigned a numerical code according to their order of participation. Upon completion of the study, participants received compensation of 100,000 KRW (US $72.00).

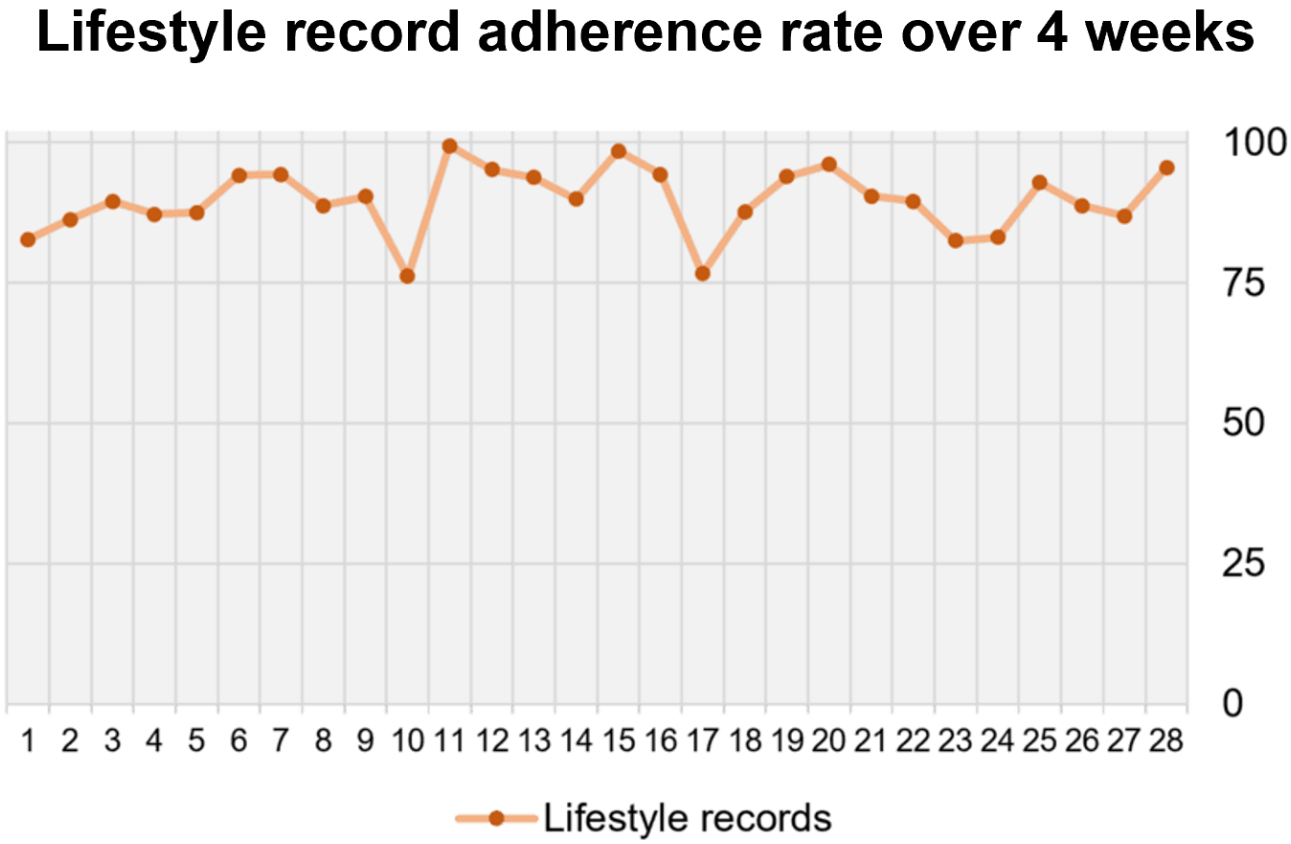
Results

Descriptive Statistics

Of the 21 participants in the intervention group, 17 completed the study, resulting in an 81% retention rate. Dropouts occurred due to technical issues (n=2), failure to complete the preintervention survey (n=1), and personal reasons (n=1). In the control group, all 19 participants completed the study, resulting in a 100% retention rate. The intervention group consisted of 3 male and 14 female participants, with a mean age of 16.70 (SD 0.98) years. The control group included 2 male and 17 female participants, with a mean age of 16.63 (SD 1.02) years. There were no statistically significant differences in gender distribution or age between the two groups.



At baseline, there were no statistically significant differences between the groups in anxiety, self-efficacy, or time management abilities. However, the intervention group showed significantly higher levels of depression and stress. For depression, the control group had a mean score of 10.21 (SD 2.20), while the intervention group had a mean score of 18.12 (SD 3.60); this difference was statistically significant (t_{34}=–2.25, P=.03). For stress, the control group’s mean score was 12.00 (SD 3.10) and the intervention group’s score was 19.76 (SD 3.80). A Mann–Whitney U test indicated a significant difference between the groups (U=234.5, P=.02).



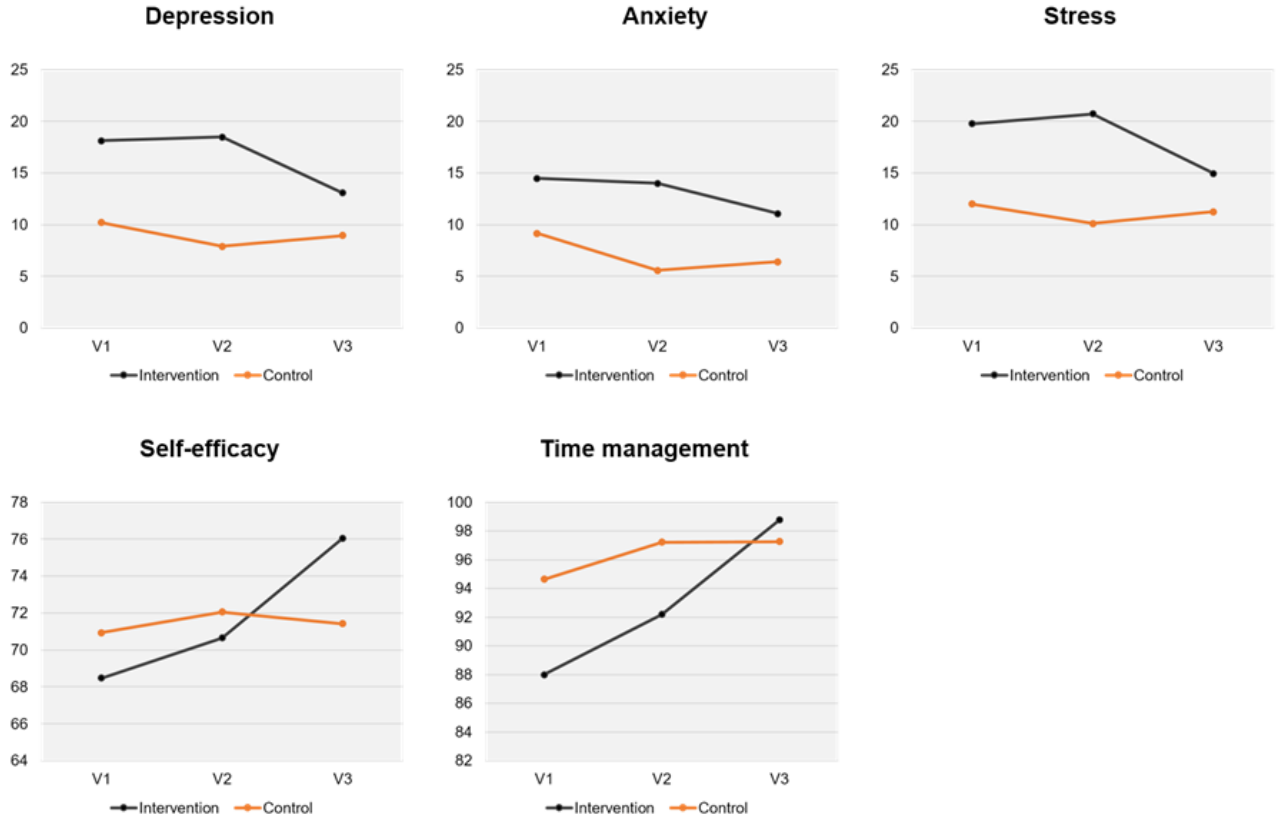
XSL•FO
RenderX

Adherence to lifestyle records was defined as the percentage of records made from the 48 requests. Adherence to mood records was defined as the percentage of responses to the 28 daily EMA alerts sent. Lifestyle record adherence had an average of 89.68% and a range of 71.5% - 99.6% (Multimedia Appendix 1). Mood record adherence had an average of 90.65% and a range of 79.3% - 99.6%. The average adherence rates per participant indicate that most participants complied with the system's requests for collecting digital phenotypes (Figure 3).

XSL•FO
RenderX

Figure 3. Average adherence rates for mood and lifestyle recording over 4 weeks.

XSL•FO
RenderX



Intervention group satisfaction was assessed using the mHealth App Usability Questionnaire at the end of the intervention. The survey consisted of 21 items rated on a 7-point scale, evaluating the tool's ease of use, user satisfaction, system information arrangement, and usefulness. Participants' responses showed a high level of satisfaction, with an average score of 6.31 of 7. The median score was 6.29, indicating that half of the participants rated the tool at or above this value.

Scores ranged from a minimum of 5.81 to a maximum of 6.86, demonstrating relatively low variability in user evaluations. The SD was 0.31, further confirming consistent positive feedback across the participant group. These findings suggest that the digital phenotype collection tool was generally well-received by adolescents, both in terms of usability and usefulness, which is also reflected in the high adherence rate throughout the intervention period [57].

Changes in Repeated Measures

A repeated measures ANOVA revealed a significant main effect of time ($F_{2, 68}$=3.62, P=.04), indicating that depression levels changed significantly across the 3 time points, regardless of group. A repeated measures ANOVA revealed a statistically significant interaction effect between time and group for depression levels ($F_{2, 68}$=3.65, P=.04), indicating that the intervention group experienced a different trajectory of change compared with the control group (Figure 4). For anxiety, although a significant main effect of time was observed ($F_{2, 68}$=5.64, P=.009), the interaction effect was not significant ($F_{2, 68}$=2.35, P=.11), suggesting similar changes across both groups.

Figure 4. Repeated measures ANOVA results comparing the intervention and control groups.

In contrast, stress levels showed no significant main effect of time ($F_{2, 68}$=2.56, P=.07), but there was a significant interaction between time and group ($F_{2, 68}$=3.55, P=.03). Time management ability significantly improved over time ($F_{2, 68}$=11.54, P<.001), with a significant interaction effect ($F_{2, 68}$=4.78, P=.01), indicating a greater improvement in the intervention group. Similarly, self-efficacy scores showed both a significant main effect of time ($F_{2, 68}$=6.99, P=.002) and a significant interaction effect ($F_{2, 68}$=5.27, P=.007). These results suggest that the intervention had a positive and differential effect on depression, stress, time management, and self-efficacy when compared with the control group.

Passive Digital Phenotypes and EMA

We analyzed the relationship between passive digital phenotypes and emotional disorder levels over time. While previous studies often clustered subjects based on their baseline emotional disorder scores, this study used ecologically assessed emotional disorder levels collected over a 4-week period [61,62]. This approach aimed at the same timeframe of the data in the analysis and to capture the dynamic nature of an individual's emotional disorders, which fluctuate within a day.

Collected passive digital phenotypes were categorized by participants and averaged daily, resulting in 28 sets of passive digital phenotypes per participant. Outliers and missing values were excluded from the analysis. The results of the analysis are

XSL•FO

XSL•FO
RenderX

For location digital phenotypes, there were no statistically significant correlations between total travel time and emotional disorders. Total travel distance was negatively correlated with depression (r=−0.0932, P=.04). Statistically significant positive correlations emerged between location variance and depression (r=0.1041, P=.02), anxiety (r=0.1376, P=.003), and stress (r=0.0955, P=.04). Location entropy was negatively correlated with depression (r=−0.1186, P=.01) and anxiety (r=−0.1234, P=.007), while normalized location entropy was statistically significantly negatively correlated with depression (r=−0.1186, P=.01) and anxiety (r=−0.1089, P=.02).

Regarding sleep digital phenotypes, there were no statistically significant correlations between total sleep duration, nighttime total sleep duration, and the level of emotional disorders. However, daytime total sleep duration showed statistically significant positive correlations with depression (r=0.0988, P=.03), anxiety (r=0.1342, P=.003), and stress (r=0.1262, P=.006). These results suggest that as daily levels of emotional disorders increase, daytime sleep duration or nap duration also tends to increase.

The relationships between digital phenotypes of phone use and daily depression, anxiety, and stress levels are presented in Tables 1-3. Statistically significant correlations were found between all variables except for daytime phone usage. Total phone usage exhibited a statistically significant negative correlation with depression (r=−0.1123, P=.01) and anxiety levels (r=−0.9078, P<.001). Phone screens unlock frequency showed statistically significant negative correlations with depression (r=−0.1151, P<.001), anxiety (r=−0.1159, P=.01), and stress levels (r=−0.1798, P<.001).

Total phone screen lock time showed a statistically significant positive correlation with depression (r=0.0980, P=.03) and negative correlation with anxiety (r=−0.1159, P=.01), whereas nighttime phone usage time exhibited statistically significant negative correlations with depression (r=−0.1421, P=.002), anxiety (r=−0.1329, P=.004), and stress levels (r=−0.1074, P=.02). These findings suggest that as daily levels of emotional disorders increase, nighttime phone usage decreases. Overall phone usage tends to decrease on days with higher depression and anxiety levels, while total phone screen lock time increases on days with higher anxiety levels.

Discussion

Main Results

Overview

This study developed and deployed a tool that captures both passive and active digital phenotypes in real-world settings to build a comprehensive dataset for understanding emotional disorders in adolescents. The tool collects behavioral data commonly used in prior studies of passive digital phenotypes, such as location, sleep patterns, and phone usage, and extends data collection into domains that are not easily captured by sensors, including study and rest routines, self-reported mood, and subjective emotional distress.

Unlike studies that focused solely on passive sensing or retrospective self-reports, this study positioned self-monitoring as both a data collection strategy and an intervention mechanism. As participants recorded their emotions, they became more aware of their levels of depression, anxiety, and stress and examined the underlying causes of these feelings. This process caused participants to integrate their reflections on both emotions and daily life, allowing them to construct causal relationships between daily experiences and emotional states based on the gathered digital phenotypes. This aligns with prior findings that self-monitoring can facilitate emotional awareness and behavior change, but this study extends that work by integrating real-time active digital phenotypes with passively collected context.

Furthermore, the correlation analysis between passive and active digital phenotypes revealed patterns consistent with earlier findings. For instance, higher late-night phone use and irregular sleep patterns were associated with elevated stress and depression levels. These observations suggest that integrated digital phenotype systems can surface meaningful, co-occurring patterns between lifestyle behaviors and emotional states among adolescents. The strength of this study is further supported by the high adherence rate across both active and passive data streams. Overall, the findings demonstrate how combining passive sensing with active self-reporting can generate a comprehensive understanding of emotional well-being and support light-touch interventions through self-reflection.

User-Centric Design for Digital Phenotypes

As demonstrated in this study, having individuals consistently record their mood and lifestyle behaviors can aid in managing emotional disorders by leveraging the benefits of self-monitoring. While developing our study tool, we applied exploratory research to enhance both the quantity and quality of active phenotype data. A pilot study with adolescents helped us understand how their daily routines and digital habits could inform a design aligned with their lived experiences.

Based on these insights, we implemented a timetable-based interface that reflected the structure of a typical adolescent day, allowing participants to intuitively locate and record emotions in the context of their daily schedules. We designed context-aware EMA nudges that prompted emotion recordings at relevant points in the day, increasing compliance without causing notification fatigue. The visualization of the collected data prioritized the types of insights adolescents reported to value most, making the reflection more meaningful.

The impact of these design features is reflected in the tool's high usability and strong adherence. Our findings suggest that in designing tools to collect active digital phenotypes from adolescents, it is essential to find an appropriate balance between the burden of self-reporting and the perceived value of data reflection. A well-designed interface that minimizes friction and maximizes personal relevance can significantly improve both engagement and the quality of self-reported data.

Digital Phenotypes and Personalized EMAs

The potential of digital phenotype collection as an intervention also emerged using EMA notifications. In follow-up interviews,

XSL•FO
RenderX

participants reported that when EMA alerts were tailored to their daily life context rather than generic reminders, they experienced a stronger sense of social support and were more motivated to engage with the tool. The effect was particularly notable when prompts included words of encouragement and comfort, such as cheering them on to attend school or private tutoring sessions. Additionally, the tool issued EMAs during extended periods of late-night device usage. Participants interpreted these messages as expressions of care, which encouraged them to reflect on their behavior and, in many cases, reduce nighttime screen time.

In this study, EMA notifications were primarily time-based and followed a fixed template designed by the researchers. However, by integrating both passive and active digital phenotypes, EMA prompts could be further personalized to match each user's real-time context. For example, if an adolescent logs study time that exceeds recommended limits, the tool could deliver a supportive message acknowledging their effort while gently encouraging balance. Likewise, if an increase in physical activity is detected, a message might inquire about their experience, reinforcing awareness and positive habits. Such personalization could be significantly enhanced by generative artificial intelligence, which would allow EMA content to evolve dynamically based on ongoing user interactions and behavioral patterns.

This personalized, context-aware approach can extend to facilitating more proactive interventions. By analyzing trends in digital phenotype data when heightened distress is reported, we can infer individual patterns related to emotional disorders. For instance, this study found a positive correlation between increased nap duration and elevated emotional disorder levels. If the system detects more frequent or longer naps, it could adjust EMA notification such as, "You've been napping more than usual; have you been feeling more down lately?" However, it is important that these prompts are framed with care. Messages should invite introspection rather than make assumptions and always be mindful of user privacy, especially when dealing with sensitive behavioral data.

Our findings extend the current discourse on digital phenotypes in 2 significant ways. First, EMA can be more than simply assessments by indirectly helping to alleviate emotional disorders. EMAs involve frequent interactions between the system and the user, with each session shaping the user experience. In this study, we particularly designed empathetic survey prompts, which helped build rapport with and provide emotional support to participants. Second, this study showed how passive digital phenotypes, which are commonly used to determine the timing of EMA prompts, could be used. Participants viewed the tool's apparent interest in them as a major benefit, which suggests that passive digital phenotypes could be used more broadly to optimize timing and personalize other aspects of EMAs based on users' behavioral and psychological characteristics.

Limitations

This study has several limitations. First, although it included both an intervention group that used a tool for 4 weeks and a control group that did not use it, participants were not randomly assigned to the groups and there was a gap in recruitment timing. The tool was exclusively designed for Android phones, which limited our ability to randomly assign participants to groups. While we attempted to ensure homogeneity by considering factors such as age, gender, residential area, and grade, there may have been unexamined characteristics that could have influenced the study results.

Second, active digital phenotypes were collected via self-reporting, which was only possible when participants were not otherwise engaged. To accurately assess participants' daily routines, the study needed to be conducted during school terms but not around major school events, such as national examinations, which could affect levels of depression, anxiety, and stress. Thus, there was a 1-month difference in the start times between the intervention and control groups, which might have affected the results. Third, there were statistically significant differences in depression and stress level baseline scores between the two groups. The intervention group reported higher levels of both depression and stress initially. This discrepancy indicates that the intervention group had greater potential for improvement, so the positive impact of the digital phenotype collection service should be interpreted with caution.

Fourth, there was an uneven distribution of gender and grade among participants. Female participants were more represented than male participants in both groups, and there were more high school students than middle school students. These imbalances may limit the generalizability of the findings to male and middle school students. However, emotional disorders are generally more frequent and severe among female adolescents, so this distribution may reflect real-life conditions. Additionally, as the study was conducted exclusively with Korean adolescents, cultural factors unique to Korea may have influenced participants' behaviors and responses. This cultural specificity could limit the applicability of the findings to adolescents in other cultural contexts. Future studies should aim for a more balanced representation by gender and grade and include more diverse cultural settings to improve the generalizability of the results.

Fifth, this study did not specifically target adolescents diagnosed with emotional disorders. Although some participants had high emotional disorder scores, these scores did not necessarily equate to clinical diagnoses. Furthermore, the EMAs assessed depression, anxiety, and stress levels using single items for ease of response, which may not fully represent the participants' clinical status. Future research should focus on participants with clinically diagnosed emotional disorders to enhance the generalizability and clinical relevance of the study findings.

Conclusions

This study explored how digital phenotypes can be used to manage emotional disorders among adolescents. To this end, we developed a digital phenotype collection tool that integrates active digital phenotypes into EMAs for mood disorders and related daily contexts. This study included a 4-week field test to investigate the potential diagnostic and therapeutic roles of active digital phenotypes to assess how participating in digital phenotype collection affects the emotional disorders of depression, anxiety, and stress; self-efficacy; and time

XSL•FO
RenderX

management abilities. We also examined the relationships between passive digital phenotypes and adolescents' daily emotional states.

The results showed that tool use was negatively correlated with depression and stress levels and positively correlated with self-efficacy and time management abilities. However, it was not correlated with anxiety levels and interviews with participants provided insights as to why. Adolescents understood depression in a way that matched clinical definitions, such as lethargy and sadness. However, adolescents tend to interpret anxiety in a more situational manner, associating it with specific stressors like upcoming examinations or incomplete homework, rather than recognizing it as a clinical condition. This discrepancy might explain why no significant improvement in anxiety levels was observed when assessed using clinical scales.

Furthermore, we analyzed the relationship between passive digital phenotypes and their relationships with adolescents' levels of depression, anxiety, and stress via EMAs. This correlation analysis revealed that location variance, location entropy, daytime sleep duration, phone usage time, and phone screens unlock frequency were weak but statistically significantly correlated with daily levels of depression, anxiety, and stress, which is like trends observed in other studies [4,63]. Unlike past research that typically compared baseline scores, our study used long-term, ecologically assessed data, showing that EMAs can be used to establish predictive correlations with passive digital phenotypes.

These findings suggest that digital phenotype collection services can be used to understand and manage adolescent emotional disorders. Despite the recognized potential of digital phenotypes for this purpose, few studies have collected active digital phenotypes in the context of emotional disorders, and none have focused on their effectiveness in managing these disorders. This study provides preliminary evidence that the use of a digital phenotype collection tool, particularly through the process of reflecting on both mood and lifestyle-related behaviors, may contribute to improvements in depression, self-efficacy, and time management among adolescents. These findings suggest that the integration of passive and active digital phenotypes could play a supportive role in better understanding and potentially addressing emotional challenges in this population. Additionally, the high level of adherence maintained throughout the study, despite the extensive user participation required, indicates that the methods used to collect digital phenotypes were successful.

Abstract

Background: Despite the popularity of concurrent use of electronic cigarettes (e-cigarettes) and cigarettes (dual tobacco use) among young adults, few interventions address the cessation of both tobacco products. The application of a human-centered design (HCD) approach in the development of such interventions remains limited.

Objective: This study used an HCD approach to develop smartphone-based intervention messages for dual tobacco cessation for young adults.

Methods: Intervention messages were developed based on theories, cessation guidelines, existing messages, and our previous formative study. Three rounds of message testing were conducted asynchronously via an online platform with 35 young adults (18 - 29 years old) who currently used both e-cigarettes and cigarettes and were motivated to quit either smoking or vaping in the next 6 months. In each round, a new sample of 10 - 12 participants evaluated the messages individually. For the quantitative assessment, participants viewed and rated each message on a scale from 1 ("very low degree") to 5 ("very high degree") across 4 components: Comprehension ("This message is easy to understand"), Usefulness ("This message is useful for encouraging tobacco cessation"), Tone ("The language is clear and non-judgmental"), and Design ("The design is appealing"). For the qualitative assessment, participants used a platform-enabled feature to place markers on specific parts of messages they liked, disliked, or found confusing and then provided brief explanations for their feedback. Initial messages were assessed during the first 2 rounds of testing, and those with low mean scores were revised based on participants' feedback and retested in the third round.

Results: We found significant improvements in message ratings after refinement. The overall mean score increased from 3.6 (SD 0.4) to 4.6 (SD 0.2) (P<.001), using paired t tests. Specifically, the mean score of "Comprehension" improved from 4.0 (SD 0.5) to 4.9 (SD 0.2) (P<.001), the mean score of "Usefulness" increased from 3.0 (SD 0.6) to 4.4 (SD 0.4) (P<.001), the mean score of "Tone" increased from 3.8 (SD 0.6) to 4.8 (SD 0.2) (P<.001), and the mean score of "Design" increased from 3.4 (SD 0.48) to 4.4 (SD 0.3) (P<.001). The qualitative assessments highlighted design elements related to message liking, such as clear layout, minimalistic imagery, italicized quotes, and highlighted keywords. Conversely, design features related to message dislike included color shades, lengthy text, and confusing wording.

Conclusions: This study demonstrated the use of HCD in developing smartphone-based intervention messages to support dual tobacco cessation among young adults. Integrating remote message testing improved the feasibility of rapid prototyping while enhancing the relevance and appeal of message content and design. Future interventions targeting emerging health behaviors among young adults may benefit from incorporating a remote testing method to efficiently gather user feedback and refine intervention messages in a timely manner.

Introduction

Concurrent use of electronic cigarettes (e-cigarettes) and cigarettes in the past 30 days (dual tobacco use) is prevalent among US young adults aged 18 to 29 years. In 2021, among young adults who smoked cigarettes, 15% - 30% also used e-cigarettes; among young adults who used e-cigarettes, 30% - 67% also smoked cigarettes [1,2]. This dual-use behavior is associated with a higher risk of various health conditions, such as stroke, metabolic dysfunction, asthma, chronic obstructive pulmonary disease, and oral disease [3], and has been linked to an increased risk of nicotine dependence, subsequent substance use [4], and more difficulty with cessation [5]. Most young adults who use tobacco express a strong desire to quit and want to stop using all tobacco and nicotine products [6,7]. Yet, cessation interventions addressing both e-cigarettes and cigarettes remain limited [8].

Smartphone-based apps could offer cost-effective access to evidence-based cessation support for young adults [9], as over 95% of them own smartphones [10]. Of several available smartphone-based cessation apps, almost all were either for smoking cessation or vaping cessation [11], offered limited features for vaping cessation [12], and lacked rigorous development and testing [13-15]. Furthermore, existing apps typically adopt a "one-size-fits-all" approach and often fail to incorporate meaningful input from end users early in the development process [16]. This limited evidence on effective strategies addressing dual tobacco use among young adults highlights the need for developing new intervention messages addressing the use of both e-cigarettes and cigarettes among young adults [8,17].

A human-centered design (HCD) approach can be used to develop a smartphone app intervention that meets a variety of individual cessation needs [18]. HCD is defined as "an approach to systems design and development that aims to make interactive systems more usable by focusing on the use of the system and applying human factors/ergonomics and usability knowledge and techniques" [19]. Its systematic approach engages with and prioritizes the needs and preferences of end users in the development of an intervention, ensuring that interventions are likely to be used effectively in a real-world context [18]. We used the IDEAS framework (including 4 stages: Integrate, DEsign, Assess, and Share, described in the next paragraph), which integrates behavioral theory, design thinking, and intervention evaluation and dissemination into systematic guidance for the development of effective interventions [20]. This framework has guided the development of previous substance use interventions, including tobacco smoking cessation [21-23]. There are 10 phases (Empathize, Specify, Ground, Ideate, Prototype, Gather, Build, Pilot, Evaluate, and Share) across the 4 stages. Although HCD is increasingly used in mobile health interventions, there is limited published research on how the HCD approach is applied to developing interventions for young adult dual tobacco cessation [24].

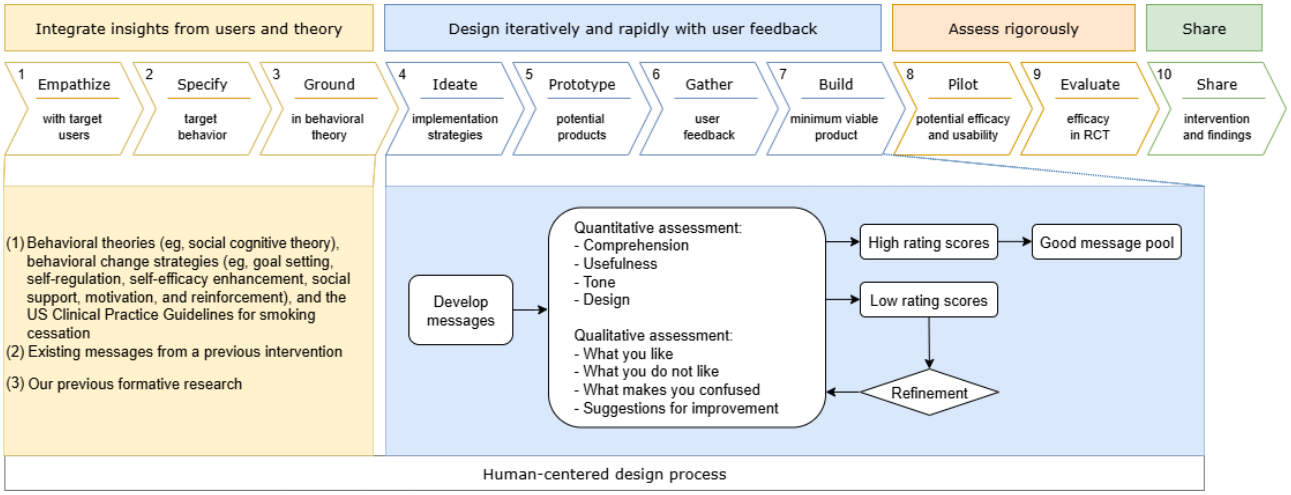
By applying the HCD approach, the first 3 phases in the "*Integrate*" stage (empathizing with the target users, specifying targets for future interventions, and grounding findings in behavioral theories) were conducted in our previous formative research using in-depth interviews with young adults to elicit needs and preferences for dual tobacco cessation interventions [6]. This formative work led to our "*Design*" stage, in which we aim to ideate intervention strategies, prototype intervention messages, gather user feedback, and build an intervention prototype that includes smartphone-based intervention messages for dual tobacco cessation among young adults. The developed intervention prototype will then be used in the next stage, "*Access*," where we plan to pilot and evaluate its efficacy in a randomized controlled trial (RCT). Focusing on the "*Design*" stage, this study aims to describe our process for ideating, prototyping, and refining intervention message mockups through iterative feedback from young adults. Our remote HCD approach may serve as a methodological model for message development and remote testing in future digital health interventions.

Methods

Design

This study is the second phase of a project aiming to develop a smartphone-based intervention targeting dual tobacco cessation among young adults. In the first phase, we conducted a needs assessment study to understand young adults' desires and preferences for cessation of both e-cigarette vaping and cigarette smoking [6]. In the second phase (ie, this study), we developed intervention messages for use in the smartphone-based intervention, which will be evaluated in an RCT in the next phase.

Participants



Participants were recruited through targeted advertisements on Instagram linking to the study website. Eligible participants were young adult men and women (aged 18 to 29 years) who: (1) speak English, (2) own a smartphone, (3) report use of both cigarettes and e-cigarettes at least weekly during the past month [6], and (4) intend to quit either smoking or vaping in the next 6 months. Overall, 35 participants were enrolled in message testing.

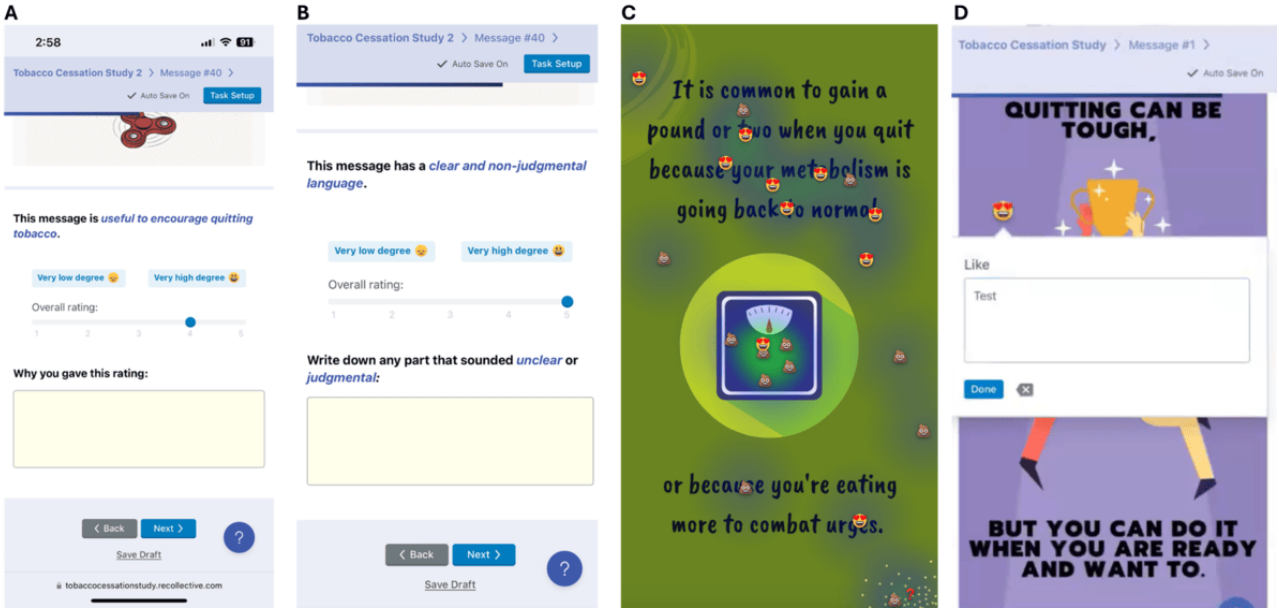
Message Development

The HCD approach in the development of tobacco cessation messages is displayed in Figure 1. The message development was guided by behavioral theories (eg, Social Cognitive Theory), behavioral change strategies (eg, goal setting, self-regulation, self-efficacy enhancement, social support, motivation, and reinforcement) [25], and the US Clinical Practice Guidelines for smoking cessation [26]. The message content was also based on existing messages in a previous intervention that effectively increased smoking abstinence among young adults [26]. We further refined message content to specifically target young adult dual tobacco users' needs and preferences determined previously in our formative research, including providing cessation support to quit one prioritized product while preventing switching between 2 products, and emphasizing unique facilitators and barriers to quitting each product (eg, unpleasant smell of cigarettes facilitating smoking cessation and accessibility of e-cigarettes hindering vaping cessation) [6].

XSL•FO
RenderX

Figure 1. Human-centered design approach in the development of tobacco cessation messages for young adults who use both electronic cigarettes and cigarettes. RCT: randomized controlled trial.

To fit with smartphone interfaces, we then designed 90 mockups of the messages. We added design elements (eg, color and style of text, graphics, and pictures) to the text messages to enhance visual aesthetics and user engagement.



Message Testing and Refinement

The testing was conducted remotely via Recollective (Recollective Inc), a platform for conducting user experience research. Each participant logged into the platform via phone or computer to complete the message rating tasks at a time convenient for them. This flexible and self-paced approach with asynchronous features could enhance accessibility to the testing process. We conducted 3 rounds of testing, with the first 2 rounds assessing the developed messages (prerefinement) and the third round retesting the refined messages (postrefinement). To enhance the representativeness of the target users and gather diverse insights, we included a new sample of 10 - 12 young adults in each round. This approach also minimized participant fatigue and disengagement through repeated rounds of testing. We provided participants with a video with detailed instructions to facilitate their message assessment. Participants evaluated the messages individually, with no access to others' assessments. Each message rating task took 3 - 5 minutes to complete. To avoid overburdening participants and allow sufficient time to complete all message ratings, we asked participants to evaluate 45 messages within 2 weeks in each round of testing (a total of 2 testing rounds). Our team monitored participants' progress daily and sent reminders to ensure the message evaluation was completed within the predefined timeframe.

Messages were evaluated using both quantitative and qualitative assessments. For the quantitative assessment, participants viewed and rated each message on a scale from 1="very low degree" to 5="very high degree" across 4 components, with 1 question for each component: Comprehension (ie, "This message is easy to understand"), Usefulness (ie, "This message is useful for encouraging tobacco cessation"), Tone (ie, "The language is clear and non-judgmental"), and Design (ie, "The design is appealing") [27,28], together with optional text box provided for participants to explain their ratings (Figure 2A and 2B). For the qualitative assessment, participants could place an unlimited number of markers on specific parts of the messages they liked, disliked, or found confusing, without seeing others' markers (Figure 2C). For each marker placed, participants were asked to type in a pop-up text box to briefly explain their specific reasons for liking, disliking, or confusion (Figure 2D).

XSL•FO
RenderX

Figure 2. Screenshots illustrating the testing process: (A and B) examples of component rating, (C) markers indicating whether participants liked, disliked, or found messages confusing, and (D) a text box for providing brief explanations of their specific reasons. The icons on the original message indicate the specific parts that participants liked ( ), disliked ( ), or found confusing ( ).

All 90 developed messages were revised based on participants' feedback. Due to time and resource constraints for rapid testing, we retested only 35 out of 90 messages with low rating mean scores (eg, a mean score of less than 4 out of the maximum score of 5) in the subsequent round, while the remaining messages with high rating scores were also revised but not retested [24].

We encountered a small number of open-ended comments that were ambiguous or lacked sufficient context for accurate interpretation. Our team carefully reviewed these comments and collaboratively discussed potential meanings. When a comment could not be reasonably interpreted through consensus discussion, it was excluded from the message revision to avoid potential misrepresentation. These exclusions were minimal and ensured that only responses with sufficient clarity informed the message refinement.

Data Analysis

For the qualitative analysis of participants' comments, we summarized their feedback on design features, confusing content, notes on usefulness and tone, and suggestions for message improvement.

To evaluate the overall improvement of the 35 retested messages, we compared the mean scores across the 4 components (Comprehension, Usefulness, Tone, and Design) and the overall score before and after refinement. Messages that initially had high scores and did not require refinement were excluded from the analysis. Paired *t* tests were conducted to examine whether the postrefinement mean scores were significantly higher than the prerefinement mean scores. The quantitative data analysis was performed using STATA software version 18 (StataCorp LLC).

Ethical Considerations

The study was approved by the Institutional Review Board at the University of California, San Francisco (no. 352216). All participants were provided with the study information and completed electronic informed consent on the study website. An identification number was assigned to each participant to maintain anonymity, and all data were deidentified. Participants received a US $100 e-gift card for their participation.

Results

Participants' Characteristics

The demographic characteristics of study participants are shown in Table 1. The study sample had a mean age of 22 years (SD 3). In total, 20 out of 35 participants (57%) were female and 26 participants (74%) were not Hispanic, Latino, or of Spanish origin. Regarding race, the largest group was White (n=20, 57%), followed by multiracial individuals (n=6, 17%), Asian (n=4, 11%), and Black or African American (n=3, 9%). In addition, 27 out of 35 participants (77%) were currently enrolled in college.

Multiracial	6 (17)
Education attainment, n (%)	
Currently in college	27 (77)
Currently in graduate school	2 (6)
Currently in professional or technical school	1 (3)
Not attending school	5 (14)

Results of Message Development

To address dual tobacco cessation, we developed messages that encourage quitting all tobacco and nicotine products by using terms “any tobacco” or “nicotine.” Another strategy was to develop messages that address shared barriers (eg, craving) and facilitators (eg, social support and rewarding) for quitting both e-cigarettes and cigarettes, as identified in our previous formative research. In addition, our previous study indicated that users usually did not attempt to quit both tobacco products simultaneously but instead prioritized quitting one before the other. Therefore, in addition to promoting dual tobacco cessation, we also developed single-product cessation messages. This tailored approach allows message delivery to align with an individual’s preferred quitting sequence, which can be implemented in the next phase. For instance, if a user prioritized quitting smoking, they would receive more messages focused on smoking cessation while still being exposed to messages encouraging the cessation of all tobacco and nicotine products in our future RCT. Moreover, we also developed messages to prevent switching between e-cigarettes and cigarettes. Multimedia Appendix 1 provides examples of these messages before refinement, including those promoting dual tobacco cessation, addressing shared barriers and facilitators to quitting both products (eg, craving management, social support, and rewarding), targeting single-product cessation, and discouraging switching between e-cigarettes and cigarettes.

Results of Message Testing and Refinement

Overview

After each round of testing, we revised the messages based on participants’ feedback. One key challenge in this refinement process was balancing the diverse needs and preferences of young adults. Participants often provided multiple, sometimes conflicting, suggestions for improving the messages, making it difficult to determine the best approach to fully address the diverse feedback. To address this issue, our team balanced their needs with practical feasibility and resource restraints. In some cases, we created multiple versions of messages tailored to different subgroups. Multimedia Appendix 2 shows an example of two revised versions of a message promoting exercise to manage nicotine cravings, tailored separately for males and females.

Quantitative Results

To meet the rapid timeline of iterative testing cycles, we prioritized refining the 35 messages with low ratings and retested them in the subsequent round. Multimedia Appendix 3 presents average scores for the 35 retested messages before and after refinement, covering 4 components. All 4 components showed significant improvement after refinement: Comprehension increased from 4.0 (SD 0.5) to 4.9 (SD 0.2), Usefulness rose from 3 (SD 0.6) to 4.4 (SD 0.4), Tone increased from 3.8 (SD 0.6) to 4.8 (SD 0.2), and Design increased from 3.4 (SD 0.48)

XSL•FO
RenderX

to 4.4 (SD 0.3). Overall, the mean score increased significantly after refinement, rising from 3.6 (SD 0.4) to 4.6 (SD 0.2). All paired *t* tests showed statistically significant results with $P<.001$.

Qualitative Results

Overall, based on the participants' comments during the message testing, the design features that participants liked the most included a clear layout, minimalistic imagery, italicized quotes, and highlighted keywords. The design features of message disliking included color shades, lengthy text, and confusing words. Given the large number of refined messages, below we provide 2 examples illustrating how specific messages were revised based on participants' feedback.

Figure 3A provides an example of a message encouraging self-reward after quitting. While many participants liked illustrations and colors, some found the original messages confusing, with one stating, "*a bit confused as to why the bottom half of the left tooth looks like cheese.*" To address this, we revised the graphic by removing the yellow streaks and replacing them with smiley teeth illustrations to maintain consistency across messages. In addition, we removed the word "*dentist,*" as many participants expressed their dislike of this word. Some participants also found the message somewhat unclear and "*seems kind of out of left field, not extremely relevant,*" and suggested "*change the text to make it more convincing.*" In response, we revised the bottom text to be more direct and affirmative, aligning with a common theme of the message.

XSL•FO
RenderX

Figure 3. Two examples of messages before and after refinement based on participants' feedback.

XSL•FO
RenderX

Figure 3B provides an example of a message promoting gratitude and emotional well-being as supportive strategies for tobacco cessation. Some participants expressed that the message seemed unrelated, stating that "*not see how this relates to vaping*," "*not specific to tobacco*," "*not sure if they are trying to convince people to give up tobacco*," and "*not sure what this message is trying to address*." To strengthen its relevance to tobacco cessation, we added an element acknowledging that "*quitting tobacco is hard*." In addition, given that messages telling people to be grateful can come off wrong to some people, we refined it as a coping strategy for quitting. The bottom part was refined to be more specific and actionable, encouraging participants to identify 3 things they are grateful for.

Discussion

Principal Results

This study showcases an HCD approach to develop messages for a smartphone-based intervention to support young adults' dual tobacco cessation. As an early stage of intervention development, we built a low-cost and low-fidelity prototype of the intervention (mockups of intervention messages) that could be developed rapidly to gather feedback from target users early and often, allowing exploration of alternative solutions before investing significant resources in any one particular or potentially suboptimal solution. We found that the HCD approach significantly improved the comprehension, usefulness, tone, and design of the intervention messages, which can ultimately increase the intervention's real-world impact and end-user engagement. As a methodological example of remote message testing, our study demonstrated the feasibility of engaging young adults in remote user experience testing without the need for face-to-face interactions, which can speed up the intervention development process while saving research costs. Another notable contribution of this study is to develop intervention messages specifically for dual tobacco cessation among young adults—a critical gap in the literature.

In this study, we applied the HCD principles to translate evidence-based tobacco cessation treatment into a real-world solution. Aligned with a traditional approach, we initially developed core message content based on a comprehensive evidence base, combining best practices for tobacco treatment, behavioral theories, behavior change techniques, previous interventions, and our formative needs assessment. Traditional message development methods are typically content-focused and expert-driven, which could overlook the lived experiences, preferences, and contextual needs of the end users. Rooted in empathy-driven focus, our HCD approach addresses these issues by prioritizing the preferences of end users and integrating design strategies that enhance the engagement and usability of the core content. Particularly, our participants' iterative feedback revealed that messages could be made more appealing by incorporating a clear layout, minimalistic imagery, italicized quotes, and highlighted keywords while avoiding lengthy text and confusing wording. This is especially important for smartphone apps, as well-designed message interfaces can significantly influence how young adults perceive messages' clarity, appeal, and the overall effectiveness in supporting tobacco cessation.

Comparison with Prior Work

Unlike previous smartphone app interventions that primarily focused on single-product smoking cessation (eg, cigarette use) and were often grounded in single behavioral change theory, our study used a more robust approach to intervention design. We integrated multiple behavioral theories or techniques and clinical guidance with users' needs and preferences. This user-centered design process ensured that the messages were not only scientifically evidence-based but also relevant and engaging in a real-world context. Previous studies used an HCD approach to design mHealth apps for smoking cessation among pregnant women [29], people with serious mental illness [30], and people with HIV [29-33]. Consistent with our findings, user-centered design and usability testing in these studies helped align the interventions with users' needs for smoking cessation. Moreover, this approach also enhances the ability to create multiple tailored message versions (eg, for males and females), enhancing the personalization of interventions, which is an important direction highlighted in previous mHealth research [34].

A key contribution of this study is the use of remote quantitative and qualitative assessments from target users, offering greater flexibility and accessibility than traditional in-person feedback collection. This approach enabled participants to provide detailed input not only on content but also on specific design elements, such as colors, symbols, and other visual features. The entire process of message testing was conducted remotely, with the self-guided video instruction provided beforehand, which allowed participants to complete the tasks independently. Unlike prior studies that relied heavily on researcher-facilitated interviews or focus groups, our method reduced the need for real-time involvement from the research team, minimizing the time and resource burden on both researchers and participants. This low-cost, asynchronous approach also enhances access to user testing and may facilitate more open and honest feedback as participants provide responses privately, potentially reducing social desirability bias often present in interviews and the "groupthink" effect commonly observed in focus groups [35]. Overall, our remote testing method presents a promising and scalable methodology for future message development efforts targeting emerging health behaviors among young adults.

Future Research

The final message set will be implemented in the next phase, "*Assess*," in which we will deliver the intervention via smartphone app and evaluate its efficacy and effectiveness on dual tobacco cessation among young adults. Past research highlighted the need to investigate important mediators of smartphone interventions' success, such as psychological empowerment (the intervention helping one find ways to think and behave differently), hedonic well-being (the intervention making one happier), and inspiration (the intervention motivating one to be a person they want to be) [36]. These perceptions are influenced by the content of the intervention and are, in turn, predictive of behavior, such that psychological empowerment and hedonic well-being are positively, but

XSL•FO
RenderX

inspiration is negatively, associated with quitting and reducing smoking [36]. Thus, in future studies, it would be worthwhile to not only assess the impact of the intervention on tobacco cessation, but also examine these and other potential mechanisms of impact.

Limitations

First, the participants in our study may not fully represent the broader young adult population, and recruiting through social media may have restricted our reach to more diverse groups. This may reflect the perspectives and experiences of White younger individuals who are more digitally connected, limiting the breadth of feedback for the intervention messages and the generalizability of our findings to the broader target population. Therefore, future studies could consider alternative recruitment strategies to ensure a more representative sample. Second, some open-ended comments from participants were unclear, which posed challenges for interpretation. Finally, since our repeated testing involved different participant samples, significant differences in quantitative assessments may reflect not only improvements to the messages but also variations in sample characteristics. While engaging different groups allowed us to capture feedback from more young adults, this approach may introduce the possibility of confounding due to between-sample differences. To mitigate this limitation, future studies may consider a longitudinal design in which the same participants assess messages over time, allowing for greater control over individual-level variability and clearer attribution of changes to message revisions.

Conclusions

In conclusion, this study offers valuable insights into using a remote HCD approach to develop smartphone-based intervention messages for young adults aiming to quit e-cigarettes and cigarettes. The use of self-instructional videos and asynchronous feedback collection enhanced the accessibility and feasibility of remote message testing. This approach improved message comprehension, usefulness, tone, and design. These findings can inform future message development and remote user testing efforts for tobacco cessation. Moreover, our HCD process is adaptable to other behavioral topics, populations, delivery formats (eg, video and audio), and platforms (eg, social media). Future research can build on this work to optimize engagement and effectiveness in digital health interventions targeting health behavior changes among young adults.

Acknowledgments

We are grateful to all study participants who helped to advance the science of tobacco cessation for young people. We would also like to thank Dr Johannes Thrul for inspiring us to conduct remote user experience research, Dr Kimberly Koester for guiding the use of the Recollective platform, and Sara Perez for helping with the initial study setup. Preliminary findings were presented as a poster at the Society of Behavioral Medicine Annual Meeting 2024. This research was supported by the National Institutes of Health (NIH)/National Institute on Drug Abuse (K01DA056693), the California Tobacco-Related Disease Research Program (T32KT5071), and the NIH/National Center for Advancing Translational Sciences through UCSF-CTSI (UL1 TR001872). Abstract

Background: The transfer of patients between hospitals, that is, interhospital transfer (IHT), introduces discontinuity of care, including gaps in health information transfer, which may worsen patient outcomes.

Objective: This is the first phase of a 5-year research study. Our goals are (1) to understand the gaps in health information exchange (HIE) and the clinician experience in accessing and using the electronic health record (EHR) during IHT and (2) to identify clinician user requirements for the development of an internal EHR solution for IHT.

Methods: We used prior work on HIE during IHT, coupled with a user-centered design (UCD) process to engage in discussions with clinical users and gather input on EHR workflow during IHT patient admission and planning. A total of 8 UCD sessions were held between February and July 2023, involving 18 clinicians who interact with the EHR during IHT, including 3 medicine residents, 10 advanced practice providers (APPs), and 5 direct care attendings—all responsible for caring for IHT patients at Brigham and Women's Hospital Cardiology, Medicine, Oncology, and intensive care unit services. Discussions highlighted facilitators and barriers and suggested improvements for data access and availability at the time of transfer. UCD sessions were recorded, analyzed, and coded by 2 independent reviewers to identify common themes driving suboptimal HIE. User requirements were derived from the sessions with users and iteratively refined throughout the process.

Results: Qualitative analysis revealed that a significant number of frontline clinicians experience suboptimal availability of clinical information in the EHR at the time of IHT, including gaps in communication, incomplete data, and inefficient access to clinical data. User requirements emerged from these themes and primarily focused on information prioritization, data accessibility, and workflow and efficiency.

Conclusions: Notable levels of missing information and inefficient access to clinical data were reported by end users caring for IHT patients at the time of transfer. Conducting user research to understand the current process of IHT, involving users in conceptual design and information architecture, and generating prototypes for feedback from users can aid in designing a solution that meets user needs. The results of these early UCD activities will be used to develop and implement a data platform to support clinicians during IHT.

Introduction

The transfer of patients between acute care hospitals (interhospital transfer [IHT]) occurs regularly, with one study of nationally representative Medicare data reporting over 100,000 patients undergoing IHT each year and a particularly high frequency of IHT among patients with multiple chronic conditions [1-5]. During IHT, health information exchange (HIE), which can be defined as "appropriate, timely sharing of vital patient information," is an essential part of the transfer process for appropriate care to be provided to the transferred patient [6]. Importantly, effective HIE encompasses both timely

XSL•FO
RenderX

access to data (ie, data exchange), as well as an organized presentation of clinical information (ie, data visualization) so that the receiving or accepting clinician can safely and efficiently provide care to transferred patients without unnecessary cognitive load [7].

Though the concept of HIE is easy to understand, achieving effective HIE has proven difficult due to several factors: (1) accepting clinicians who care for IHT patients after arrival are working within a busy hospital environment. Thus, any solution aimed at improving HIE during IHT must fit seamlessly into the workflow of these busy clinicians, while also not creating delays in patient transfer which could impact patient outcomes; (2) existing interoperability of different electronic health records (EHRs) between different hospital systems is often insufficient, resulting in lack of complete or adequate data exchange [8-13]. In some cases, this is due to active information blocking by developers of certified HIEs or others, but in many cases, it is due to insufficient adoption of interoperability standards [14,15]. Therefore, effective HIE must include adequate interoperability; and (3) even when HIE occurs effectively, there is often a lack of organized presentation of the data; up to 34% of clinicians report delays in their care of transferred patients due to disorganization of medical records requiring extra time to review [16,17]. Thus, improving HIE during IHT must also address the user interface.

There is a critical need for an integrated, interoperable HIE that addresses these 3 factors, along with other domains such as ease of use and usability of the information. At the same time, there is limited research on user requirements to support the development of such HIE.

This is the first phase of a 5-year study that aims to design, implement, and rigorously evaluate the implementation of an HIE platform to improve data access during IHT [18]. This paper reports on the utilization of user-centered design principles to better understand the clinician experience of HIE in the IHT process and identify key user requirements for the design of an effective HIE platform to support IHT. User requirements reflect the user needs of a system and can be used broadly to design solutions to address them.

Methods

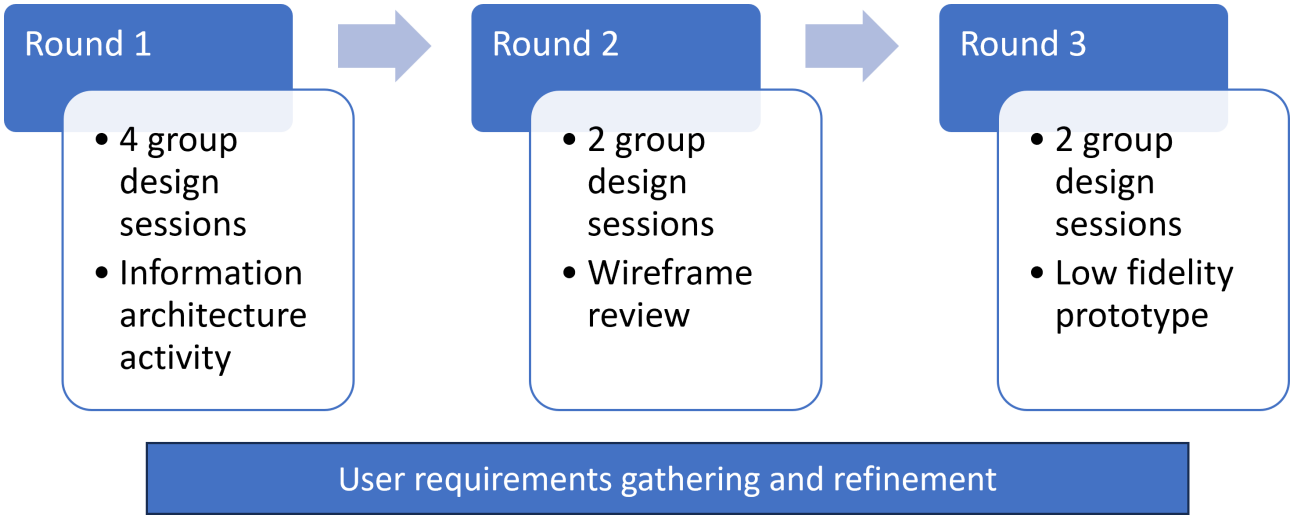
Design, Setting, Participants, and Recruitment

This study was conducted at Brigham and Women's Hospital (BWH), Boston, Massachusetts, an 826-bed quaternary care hospital that cares for a high volume of patients who are transferred from other acute care facilities for specialized care. BWH uses Epic (Epic, MyChart, Care Everywhere; Epic Systems Corporation) as their enterprise EHR, which allows the transfer of health information between institutions using Epic through an HIE feature called Care Everywhere [19].

We recruited APPs, direct care attendings, and residents who regularly care for patients who undergo IHT to the general medical, oncology, cardiology, and intensive care unit services at BWH to participate in the design sessions. A general recruitment letter with information describing the goals of the study, human research committee approval, and study team contact information was emailed to all eligible clinicians requesting volunteers to participate in design sessions, with recurring emails sent up to 3 times until target recruitment was reached, ensuring appropriate representation among each participant role. Interested participants could sign up via a link included in the email and were contacted by the study team to coordinate available timing for the design session.

Ethical Considerations

The study was approved by the Mass General Brigham Institutional Review Board for Human Research (2022P001284). Participants were informed that their participation was voluntary, would not affect their employment, and that all collected data would remain confidential, with results presented only in the aggregate. Participants gave verbal consent to participate in the design sessions. At the completion of the session, participants were given a US $50 gift card for their time.



Design Sessions

All sessions were conducted virtually over Teams (Microsoft Corp). Sessions were led by a user experience specialist (PG) and assisted by a research team member with content expertise (SM).

Following a user-centered design process (Figure 1), we conducted the first round of 4 group design sessions to understand existing processes around HIE during IHT, using a semistructured group discussion guide (Multimedia Appendix 1). The interview guide was developed by the user experience specialist (PG) and qualitative research expert (RR) with input from the content expert (SM) and additional research team members and piloted prior to participant sessions. The discussion guide covered topics including prompts for sharing the current state of workflow during IHT and interaction with the EHR, with a particular focus on accessing clinical data from hospitals in different systems and with different EHRs, as well as a discussion of barriers and facilitators with the current systems of data access during IHT. During this part of the discussion, we included current screenshots of Epic using redacted real-life patient transfer examples to understand their data-gathering activities more explicitly. Design sessions also gathered participant input on essential clinical data elements available during IHT and included an interactive information architecture activity using previously identified key data elements during IHT (Multimedia Appendix 2), where participants were prompted to group, add, and organize data elements according to their preferences for optimal data review when caring for a transferred patient [20].

XSL•FO
RenderX

Figure 1. User research process.

Following this first round of design sessions, we performed rapid analyses to generate a preliminary list of user requirements to be refined and discussed during later rounds of design sessions. We drafted an initial wireframe based on these user requirements to be used during our next round of design sessions. The second round of 2 design sessions focused on iteratively refining the draft wireframe and preliminary list of user requirements, with directed input from participants on what they liked and disliked, what was missing, and how they would use, reorganize, group, and manipulate the data. We again performed rapid analysis to develop the draft wireframes into low-fidelity prototypes of an IHT data platform within Epic, developed by Mass General Brigham Digital, which we then presented to end users in the third round of 2 design sessions. In this last stage, we gathered iterative end user feedback to optimize data elements and presentation prior to further development and testing of the IHT data platform within the EHR.

Analysis

We used a modified framework and rapid analysis approach to analyze the focus group data starting after the first round of design sessions and continuing with each additional session. Sessions were transcribed using the automated feature of Teams, reviewed for accuracy, and then reviewed independently by 2 study team members (JK and PG) to develop a preliminary set of codes. The codebook was refined during multiple meetings among the 2 coders and a third research team member to provide content expertise (SM) until a final codebook was developed. Data were input into MAXQDA qualitative analysis software (VERBI GmbH), and the final analytical framework was applied to participant comments. To further analyze the data, a matrix was created to identify larger themes and subthemes among the data. Data from the information architecture activity was organized using Excel (Microsoft Corp) to identify how often data elements were sorted into any given category.

User requirements emerged from the participant comments, including the information architecture activity. The user requirements reflect the user's needs, expectations for the system, and what is required to support the user's goals and tasks. Although we identified solutions to these requirements within our Epic environment, the user needs and expectations are applicable regardless of the platform or technology. The requirements were iterated on throughout the design sessions using a rapid analysis approach and summarized as refinements to the user requirements.

Results

Participant Characteristics

Of the 34 clinicians who expressed interest in participating in one of our design sessions during this period of the study, 18 clinicians were selected. We conducted 8 design sessions between February and November 2023, involving 3 medicine residents, 10 APPs, and 5 direct care attendings. Most participants were female (n=14, 78%), general internal medicine clinicians (n=13, 72%), and APPs (n=10, 63%; Table 1).

Design Sessions

Summary

The analytic process resulted in multiple codes which were categorized into three main themes and subthemes that reflect the essential aspects of effective HIE during IHT from the perspective of frontline clinicians: (1) communication, (2) data availability and completeness, and (3) efficiency of access to data.

Theme 1: Communication

Overview

Clinicians tended to frame their responses about data in a way that was often tied to a desire for complementary communication to accompany the discrete patient data available to them within the EHR. Participants expressed that, in current IHT processes, communication is often lacking, and felt as though adding information on the timing of patient arrival or a "warm handoff" (verbal communication to help synthesize the clinical information) would add valuable contextual information to improve their ability to care for IHT patients on arrival. Communication was categorized into 2 subthemes: written and verbal.

Written Communication

In addition to specific data elements (as described below), participants also identified a requirement for additional communication related to aspects of the transfer process that would be essential in guiding their workflow. These included transfer process characteristics such as status or timeline of the transfer (eg, final decision to accept and anticipated time of arrival), any other consultants or care team members that were involved in the transfer process (eg, transferring clinician contact information, accepting physician, and consultants involved prior to transfer), and clinical aspects of care that required follow up (eg, pending tests or reports).

Verbal Communication

One of the challenges mentioned by accepting clinicians was a lack of verbal communication or "warm handoff." Participants relayed that with select, complicated patient transfers, the opportunity to have a "warm handoff" was helpful to synthesize the clinical data available to them within the EHR, to help them optimize care for IHT patients. As such, participants identified that the availability of accurate contact information for the transferring physician, as well as the accepting physician, would be beneficial, such that they could then directly contact these individuals to help clarify information as needed. One participant shared, "Patient information can be lost or forgotten due to unclear communication ... if communication for pass off is not addressed, patients can be harmed."

Notably, there were some overlaps between these 2 subthemes. For example, in many circumstances, participants expressed a need for clearer communication without distinction as to whether they prefer that this occurs via written or verbal communication, particularly related to the contextual aspects of the transfer (eg, timing of arrival).

Theme 2: Data Availability and Completeness

Overview

Participants additionally shared their challenges in being able to access complete data about a patient from the transferring hospital. Data completeness was defined as access to essential clinical patient information to effectively care for the transferred patient on arrival, and was categorized into 6 subthemes: brief summary, imaging, laboratory data, notes, medications, and contact information.

Brief Summary

Commonly mentioned as one of the most important data elements that was commonly unavailable to frontline clinicians was a "brief summary" of the clinical scenario. Clinicians described the need for access to a "brief summary" or "snapshot" of the patient, including a "one-liner" on the patient's active medical issues and pertinent past medical history, the reason for transfer and the patient's immediate needs, and the patient's acuity level or illness severity. Participants relayed the need for this summary for all transferred patients and endorsed that this information was especially critical when patients were unable to provide history on their own. Importantly, participants also indicated the need for real-time updates to this summary if the clinical status of the patient were to evolve while awaiting transfer.

Radiology Imaging

In addition, one of the most challenging data completeness issues expressed by the participants was the availability of radiology images (eg, the computed tomography scan or chest x-ray images) rather than solely the interpretive reports of the imaging studies completed by the radiologist at the transferring hospital. Participants relayed that EHR system incompatibility, specifically the part of the EHR system that manages radiology images, contributes to the lack of access.

Laboratory Data

Participants requested access to specific laboratory data depending on the clinical condition of the patient (eg, cardiac enzymes for patients with cardiac symptoms), as well as information about laboratory tests that were pending at the time of transfer (eg, sent by the transferring hospital but not yet resulted), which was often unavailable at the time of transfer. One participant stated, "…we want to be able to have previous data for what's happening, is patient getting better or worse."

Clinical Notes

Participants also relayed that incomplete availability of clinical notes felt to be important in caring for transferred patients, including notes related to prior admissions (eg, discharge summaries), prior office visits, and notes related to the patient's current admission at the transferring hospital (eg, their initial history and physical, or "H & P"). One participant stated their need for "the most recent pertinent data from the hospitalization, if they do not get most of the care from our hospital, we want a bigger time frame of information ... is their health problem new? We need back data or a link out to prior data. That would be helpful."

XSL•FO
RenderX

Medications

Participants relayed challenges with the availability of an accurate medication list at the time of transfer. Importantly, they expressed the desire for access to several different aspects of the patient's medication list, including an accurate list of medications the patient was taking prior to admission to the transferring hospital to provide historical context, an accurate list of medications the patient was taking at the time of transfer, and particularly a desire for access to the medication administration record, which is a documentation of the timing of medication administration. This latter list was felt essential to be able to make efficient decisions about medication orders when the patient arrives at the hospital.

Contact Information

Participants expressed that they infrequently have available to them contact names and numbers they need throughout the transfer process, including the contact information for the transferring clinician (ie, to be able to contact with any questions), as well as the contact information for the patient's specialists, which in many cases can help provide significant insight into the case.

Theme 3: Efficiency of Access to Data

Overview

In addition to challenges with the availability of data from transferring hospitals, participants noted that, even when available, they experienced inefficient access to it. Efficiency of access to data was categorized into 5 subthemes: dependence on manual processes, EHR organization and presentation, clinical notes, laboratory data and vital signs, and awareness of existing EHR capabilities.

Dependence on Manual Processes

Participants explained that in cases when the patient is transferred from a hospital outside the health care system, many processes are manual, such as searching through paper or electronically faxed records that are often PDF scans of paper. They also relayed that occasionally, the clinical data for the patient is on a disc or USB that requires manual uploading and sorting. This dependence on manual processes is felt to be extremely cumbersome and an inefficient way to access patient data.

EHR Organization and Presentation

Participants explained that for patients transferring from a hospital within the health care system or from a hospital with the same EHR, the "Care Everywhere" feature of Epic provides access to data but processes of distilling that information and finding relevant data points to the current patient situation is challenging and inefficient. Participants described it as "disorganized, difficult to navigate" and requiring "lots of digging." In addition, participants describe organizational issues that impact their workflow. For example, one participant shared this about imaging and imaging reports: "Putting images and encounters together would be helpful. They are usually separate from the report."

Clinical Notes

In addition to the incomplete availability of select clinical notes (described above), relevant notes such as the discharge summary and history and physical from the transferring hospital are not always easy to find. In addition, participants shared that, when available, they use the filtering feature for notes and different specialty tabs, such as the cardiology tab, to find relevant notes more quickly.

Laboratory Data and Vital Signs

In addition to incomplete access to laboratory data (described above), participants also described frequent inefficiencies in the ability to view historical laboratory data and vital signs to be able to effectively evaluate for trends, particularly if the patient had data in disparate hospital settings or EHRs. Participants expressed a desire for direct access to the most recent laboratory data and vital signs, but with easily accessible historical data organized in a coherent chronological way, even when these data are coming from disparate sources. A participant shared, "I think it's great to have it [lab data] in one spot. I think not everybody knows how to grab things from Care Everywhere..."

Awareness of Existing EHR Capabilities

Most participants noted a lack of familiarity with or use of the "access center note"—a document reflecting a brief summary of the most recent transfer hospital information entered by access center nurses at the time the patient was accepted for transfer until the time of patient arrival. Additionally, most participants relayed not knowing how to locate the "transfer module," also used by the access center nurses during the acceptance process, which includes a call log and running timeline of transfer hospital information and communication. "Two reasons why people cannot see the transfer module is either because they do not have access to see it or they don't know what it is (that the information exists) and don't bother to look for the information in notes."

Information Architecture: Organization of Data Elements

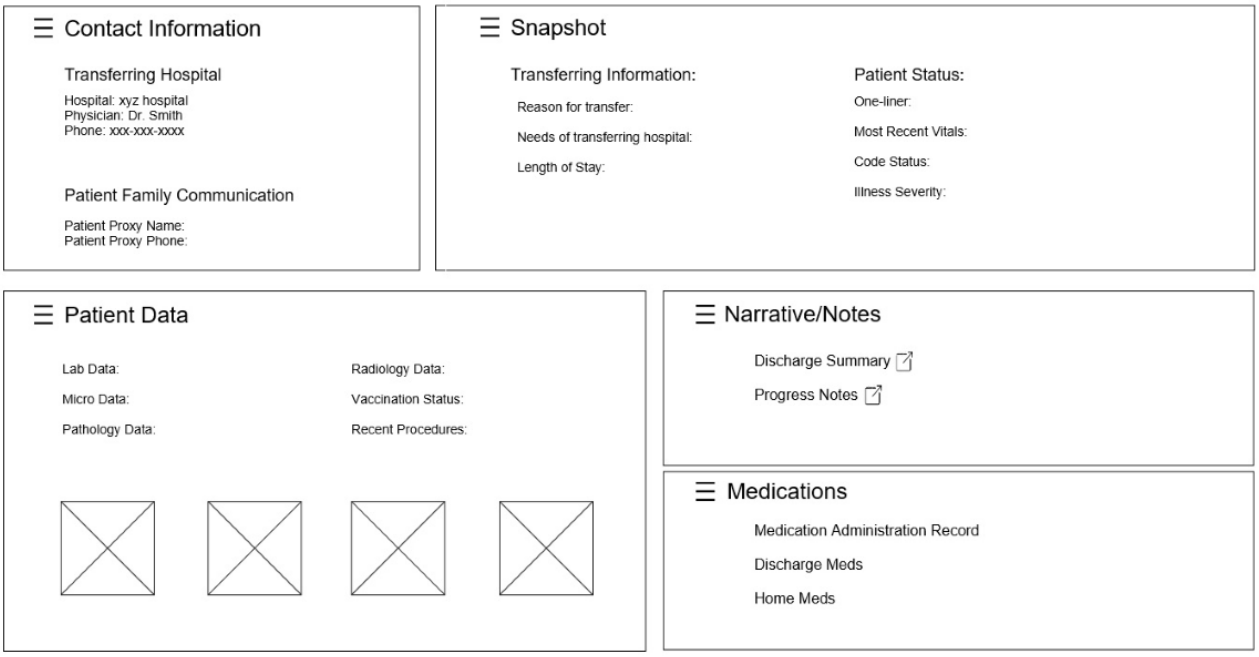
In parallel to the above analyses, we analyzed participant feedback from the information architecture activity conducted as part of the first 4 design sessions to identify the preferred organization of essential data elements, naming for the groupings, and additional data elements to include. Participants grouped patient demographic data and transferred hospital contact information together. Participants organized data elements such as the reason for transfer, needs of transferring hospital, and a patient "one-liner" into a "brief summary" or "snapshot" section. Most participants grouped clinical patient data together, including vital signs, laboratory data, microbiology data, radiology data, and other clinical data. Narrative data, like clinical notes and summaries, were grouped together, and medications often got placed in a category of their own.

User Requirements

Throughout the design sessions, we generated and refined a list of user requirements. The user requirements represent how the

XSL•FO
RenderX

system needs to support the work of the end user and were identified from the themes and subthemes outlined above, as well as the results of the information architecture activity. In total, we generated a list of 17 user requirements categorized into information prioritization, data accessibility, and workflow and efficiency:



Information prioritization includes requirements that reflect the user preferences for the order in which they view data (ie, user needs to see select patient data in line-of-sight vs via click-to-expand, eg, second or third priority).

Data accessibility requirements cover the users' needs for relevant data elements and additional clinical information that is not currently readily accessible to them. For example, users describe a desire to access the various data elements within "medications," including access to the patient's home medications (prior to hospitalization at the transferring hospital), medications at the time of transfer, and the medication administration record, which includes details of the timing of most recent medication administration.

Workflow and efficiency include requirements that address the user needs for solutions that work within their current workflow, minimize steps, and provide easier ways to accomplish their task. (ie, user wants flexible displays of data to be able to view the most critical and choose to access more detail).

For each identified user requirement within these 3 categories, we brainstormed potential solutions to address the requirement and iteratively refined each requirement and proposed solution via additional design sessions. Wireframes were developed based on these user requirements and used during subsequent group sessions to elicit feedback and validate requirements (Figure 2). The wireframes included sections for demographic data and transferring hospital contact information; a collated patient "snapshot" or "brief summary" including a "one-liner" and reason for transfer; and sections of clinical data grouped into classical categories including vital signs, laboratory data, microbiology data, radiology data, other clinical data, clinical notes, and medications. Participants from later design sessions shared more specific feedback on how they prefer to view and organize certain data based on refinement from earlier sessions. More details on our user requirements and proposed solutions can be found in Table 2.

Figure 2. Wireframe of the electronic interhospital data platform.

XSL•FO
RenderX

Table . User requirements and proposed design features.

User requirement	Proposed solutions
Information prioritization	
System places contact information as high priority	• Suggested data elements: number for transferring floor, name or contact of transferring physician, name of accepting hospital and other clinicians involved, contact information for health care proxy. • Contact information section in the top left corner of the summary page.
System places critical clinical information as high priority	• Suggested data elements: a brief summary of the patient's clinical status, reason for transfer, anticipated patient needs in the first 24 hours, length of stay at the transferring hospital, code status, and level of illness severity. • "Snapshot" section in the top right corner of the summary page.
System places clinical patient data as mixed high and low priority	• Suggested data elements: vitals data, laboratory data, radiology data, microbiology data, pathology data, vaccination status including COVID-19, and recent procedures. • Data section in the left center of the summary page. • Combination of preview and controls that expand or link out.
System places narrative of clinical course at transferring hospital as mixed higher and lower priority	• Suggested data elements: progress notes, discharge or transfer summery, prior discharge summaries, consult notes, history and physical note. • Notes section on the right side of the summary page, below the snapshot. • Combination of preview and controls that expand or link out.
Data accessibility	
System supports user in efficiently accessing contact information for the patients care team	• Provide contact information within line of sight.
System allows easy access to home medications, medications at time of transfer, and medication administration record	• Active medication list shown before home medication list. • Medications listed in alphabetical order. • Access to medication administration record via a link or collapsible content (to reduce overcrowding on the summary page).
System includes a way to view trends in vitals, laboratory data, and historical out of range lab data	• Display last 3 values or days. • Search function for specific laboratory data. • Present an option to view laboratory data in tabular format.
System supports access to current and prior admission notes, progress notes, recent PCP[a] notes, specialist consult notes, and discharge summary	• "Notes" displays patient clinical notes in reverse chronological order. • Links to admission notes, progress notes, recent PCP notes, specialist consult notes, and discharge summary.
System allows user to access all prior patient records	• Display links to all available outside hospital records.
System allows user to access pending data at time of transfer	• Links to pending data included within pertinent sections (eg, laboratory data and microbiology data).
Workflow and efficiency	
System supports user in accessing transferred patient data in one location and in one logical timeline to avoid searching through outside records and faxes	• Generate a Patient Summary Page with all outside records pulled into structured sections. • List data in reverse chronological order. • Provide links to specific data points or outside records for additional information.
System provides flexible displays of data so users can view most critical and choose to access more detail	• Provide progressive disclosure for lengthy content. • Combination of preview and controls that expand or link out
System provides user with access to the status of a transfer as it evolves during the transfer process	• Provide access to the patient timeline documentation as documented by the accepting hospital (generated at time of acceptance for transfer).

XSL•FO
RenderX

User requirement	Proposed solutions
System provides user with access to radiology images (not just reports)	• Provide access to the radiology image and report within same location. • Organize this within the "radiology data" section.
System allows user to choose their timeline for select data presentation	• Provide link out to additional historical data.
System allows user to view Patient Summary Page while viewing other windows with detailed information to reduce back and forth between tabs	• Design Patient Summary Page as an embedded tab within the electronic health record. • Option to open other parts of the patient chart on the side panel while viewing the Patient Summary Page. • Option to "pin" page to workbench for easier access.
System allows user to pull data from the Patient Summary Page into their current patient documentation	• Provide functionality to pull data from the Patient Summary Page to patient documentation.

[a]PCP: primary care provider.

Discussion

Principal Findings

We identified 3 major themes that are important to address in the design and development of an IHT summary: communication, data completeness, and efficiency of access to data. The user requirements generated from the design sessions were centered around these themes and focused on prioritizing critical information, easily accessing and viewing data from outside sources in one place, and organizing the data within the existing workflow to maximize efficiency. This study highlights the need for one location within the EHR where clinicians can access all the relevant and available data from a transferring hospital as it relates to the care of the transferred patient.

Most prior studies of HIE have focused on the technical requirements for the exchange of data, such as addressing the fragmentation caused by a lack of standards and the governance of EHR vendors [21,22]. Within this framework, several studies have targeted select aspects of HIE; for example, several studies targeted the transfer of medications between systems. One such study relied on qualitative semistructured interviews of key stakeholders to assess challenges and opportunities for more effective information exchange to achieve more accurate medication lists. This study identified similar challenges to our findings, including incomplete patient records and gaps in the availability of digital data, along with barriers related to lack of interoperability and poor IT and change management [23]. Another study reported the use of a design science research methodology, including assessing stakeholder requirements, to develop an interoperable open standards solution for the transfer of medication information between acute and postacute care facilities using 2 different EHRs [24]. Although the transfer of medication information is an essential component of HIE, it does not encompass the entirety of clinical information that should be included with effective HIE. A third study, which also used qualitative semistructured interviews of key stakeholders to address HIE more broadly, identified 3 themes related to user requirements for interoperability of HIE between systems: technological (eg, interoperability challenges), organizational (facilitators of interoperability), and environmental (policy domain) [21]. Other studies have identified similar themes, such as technological and organizational barriers to interoperability [22,25-27]. This study contributes to this body of literature, importantly by highlighting user needs beyond interoperability, particularly regarding the presentation and usability of the data once integrated into the EHR, and the ability to act upon the data within clinical workflow. Our rigorous methodology, using tools such as prototyping and participatory design, ensured that we adequately represented the clinician's perspective and defined the user requirements [28]. This distinction is essential to ensuring that HIE is effective in allowing data to be easily accessible and understandable by the end user.

While addressing the technical aspects of data availability is critical, our findings suggest that improving clinician experiences during IHT requires more than back-end technical solutions alone. This study found that access to critical data remains a challenge for providers, particularly when it comes to imaging, medication records, and laboratory values. In addition, this study highlights the burden on the clinician when the data is available but difficult to find or digest. Many providers are experiencing significant effort required to "click around" and find the data they need, which has been shown in other studies to contribute to clinician burnout [29]. Even within existing HIE tools that allow access to external data (eg, CareEverywhere within Epic), this study highlights that clinicians still struggle to navigate the information and quickly retrieve essential details needed to care for the patient in front of them. Although EHR vendors are continually improving and working to address these issues, our findings show that there are still significant challenges in distributing these solutions to end users [30]. This may lead to delays in patient care and increased effort for clinicians, negatively impacting the transfer process. This is supported by prior work that demonstrates a high frequency of suboptimal HIE, with up to 35% of patient transfers missing essential clinical data on transfer [16,17,31]. Suboptimal HIE during IHT has also been associated with patient harm, such as therapeutic errors and delays in care, and it may contribute to greater mortality observed among IHT patients with select diagnoses, in addition to other outcomes such as greater resource utilization [4,9,17,32-35].

One significant subtheme that we identified within the data availability and completeness themes was the mention of the "brief summary" or "snapshot" of the patient transfer. This data

XSL•FO
RenderX

request was unique in that it is an unstructured piece of information, often evolving and dynamic; therefore, unlike more discrete pieces of data such as lab values or medications, there are challenges in identifying the source and responsibility for this information and making it available to clinicians in an accurate and useful presentation. With advances in existing technologies such as artificial intelligence and natural language processing [36], our findings highlight the potential to leverage these newer modalities to assist in this identified need to synthesize clinical information and present a "brief summary" to the clinician. For example, natural language processing algorithms can be used to analyze unstructured text and parse the data to create a structured patient summary. In addition, artificial intelligence algorithms can pull data from disparate sources and consolidate it into a unified summary for a full picture of a patient's relevant history.

Limitations

Our study has several limitations. We gathered requirements from clinicians working at one health care institution using Epic, therefore, the results may not be generalizable to other settings and EHRs. While the user requirements can be applied broadly, the information exchange may vary depending on the health system, so the successful application of these findings may vary depending on the environment. Indeed, any solution that meets these identified user requirements must also comply with data privacy and security regulations, which may restrict the extent of successful information exchange. Future research will include additional sites and EHR systems to understand whether there are additional needs across different health care environments and geographical regions. Furthermore, we restricted the qualitative sessions to direct care attending physicians, residents, and APPs on the medicine, oncology, cardiology, and intensive care units. Thus, the providers who participated may not be representative of all providers. However, we wanted to focus on those who had been most relevant to this study in order to get more detailed feedback about our potential intervention. In exploring solutions to address the user requirements, constraints of the Epic system and compatibility issues surfaced as limitations in addressing the user needs fully. Additional iterative refinement and usability testing will be essential during the development of an HIE platform to ensure its usability and relevance in improving the IHT process, as technology advances and health care culture and workflows evolve.

Conclusions

Optimal HIE has the potential to improve the safety of IHT and to meet the workflow needs of the clinicians caring for transferred patients. Current EHR interoperability and disorganized, insufficient information make these conditions difficult and can cause delays in patient planning and treatment. We have identified key themes within existing HIE and end user requirements for effective HIE, incorporating both data needs and interface design of key data elements. The next steps include using these key findings to develop an organized IHT HIE platform within the EHR, capable of gathering the most pertinent transfer patient information quickly and securely, with the goal of both bettering patient outcomes and reducing provider burden.

Acknowledgments

We would like to acknowledge the Mass General Brigham Digital eCare Development Team for their contribution to the development of the prototypes. We would also like to acknowledge the clinicians at Brigham and Women's Hospital in the Cardiology, Medicine, Oncology, and Intensive Care services for their support and participation in our design process.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

RR reports holding equity in Hospitech Respiration, which makes Airway Management Solutions. RR also receives equity from TRI-O, which makes a medical device for diabetic foot ulcers; AEYE Health, which provides an automated artificial intelligence–based diagnostic screening solution for retinal imaging; RxE2, which integrates the practice of pharmacy into clinical trials; and OtheReality, which provides a virtual reality technology to boost empathy in health care, all of which is unrelated to this work. RR is also receiving research funding from Telem, Calosense Health, Breath of Health, and BriefCam, all of which are unrelated to this work.

Abstract

Background: Although eHealth has shown promise in managing chronic diseases, there remains a substantial digital divide among older adults. The concept of a growth mindset, based on psychological theory, offers a new direction and potential breakthrough for addressing this dilemma.

Objective: This study aims to develop and explore the feasibility and efficacy of a growth mindset intervention for older adults with chronic diseases and their positive response to eHealth.

Methods: A randomized controlled trial was conducted at the internal medicine departments of a hospital in Hangzhou, Zhejiang Province, China, from September 2021 to October 2022. A total of 77 older patients with chronic disease initially participated in the study. The mean age of the participants was 67.16 (SD 7.04) years, with 42.86% (33/77) being women and 57.14% (44/77) being men. The experimental group received an eHealth program intervention plus a growth mindset intervention over 12 weeks, with weekly sessions for the first 6 weeks and biweekly follow-up phone calls for the next 6 weeks. Each session lasted at least 25 - 45 minutes. Data were collected using a personal information form, the Implicit Theories of Intelligence Scale-6 (ITIS-6), and a questionnaire on knowledge, willingness, confidence, and practice of smart medicine (KWCP-SM). Measurements were taken at the beginning of the study (T0), immediately after the 6 weeks of training provided to the experimental group (T1), and after the 12 weeks of training for the intervention (T2). Data were analyzed using repeated-measures analysis of variance and analysis of covariance.

Results: The final sample comprised 74 participants, of which 36 were in the experimental group and 38 in the control group. After 12 weeks of intervention, the level of growth mindset was significantly higher in the intervention group (P<.05) and significant group × time interaction was observed (Wald=11.57; P<.05) between the two groups. KWCP-SM scores increased in both groups (P<.05), with more significant changes in the intervention group.

Conclusions: This study demonstrated the effectiveness of the intervention program in improving the growth mindset level of older adults with chronic diseases and bridging the “digital divide” among them. Future studies should refine this intervention, considering the characteristics and needs of this population, to create fault-tolerant and lifelong growth environments that enhance growth mindset in older adults.

Introduction

Chronic disease is one of the major causes of morbidity and mortality worldwide, which occurs predominantly among older adults [1]. According to the Chinese Bureau of Statistics, the population aged 60 years and older reached 260 million in 2020, while 75% were diagnosed with at least one chronic disease [2,3]. As a health-vulnerable group, older adults with chronic disease require long-term health care service and self-management to adapt to physiological changes, posing a tremendous burden on patients, caregivers, and the health care system [4-6], and this is where eHealth can contribute.

eHealth is characterized by information technology, automation, and intelligence, and enables patients, especially those with

XSL•FO
RenderX

chronic disease, to monitor their health parameters automatically, receive quality clinical care remotely, and achieve health management goals through interactions with eHealth systems, medical personnel, and health care institutions [7,8]. It is regarded as an efficient approach to solve the uneven distribution of limited medical resources and reduce the burden of health care expenses [7-9]. By 2020 , more than 5000 hospitals in China provided online medical services, and over 900 internet hospitals were established, covering national prefecture-level cities [10]. Studies have shown that eHealth such as eHealth apps, monitoring devices [11], wearable devices [12], and rehabilitation systems [13], can improve the outcomes of chronic disease significantly. However, patients with chronic diseases in old age, especially those with age-related stereotypes and fixed mindsets, possess a low degree of willingness and confidence in using eHealth services. Vailati Riboni and Pagnini [14] found that negative stereotypes can trigger stereotype threat, causing older adults to experience anxiety and inferiority when encountering new technologies, thereby impairing their operational abilities. They frequently struggle to comprehend overwhelming and boring information offered across eHealth services [15,16], and may be reluctant to try eHealth service due to previous unsuccessful experiences [17,18]. Consequently, the online health care resource use rate among older adults is merely 15.2% [19]. Previous studies have demonstrated that an increased growth mindset is a potential key strategy for improving positive responses to eHealth because older adults with a growth mindset can improve age-related stereotypes, increase their willingness to adopt healthy behaviors and resilience in the face of difficulties, and tend to use eHealth more [20-23].

The growth mindset theory, proposed by Dweck and Leggett [24], theorizes that individuals possess one of two types of mindsets—fixed mindset and growth mindset—regarding the malleability of abilities, intelligence, and other attributes. Individuals with fixed mindsets view the attributes as unchangeable and uncontrollable internal parameters, and often withdraw or abandon efforts when faced with difficulties. Conversely, growth mindset individuals believe the attributes are malleable and controllable, and they always view failure as an opportunity to learn and improve [25]. In addition, the literature suggests that a mindset intervention is particularly effective in changing behavior by improving participants' persistence in goal-oriented behavior [26]. Therefore, the eHealth mindset for an intervention program appeared to be a promising approach.

Many studies have shown that interventions fostering a growth mindset are beneficial to behavior change, such as improving performance in students [27-29]. mitigating weight gain resulting from dieting setbacks [30], controlling healthy eating and exercise in obese youth [31], and smoking cessation [23]. In the geriatric population, existing studies have shown that a growth mindset is significantly associated with intention to engage in health behavior [32], cognitive function [33], and successful aging [34]. Experimental studies have demonstrated its benefits in improving age-related stereotypes [35] and memory performance [36] as well. Dang and Liu [37] have provided evidence that individuals who believe human mental capacity is incremental report more positive feelings about robots and show higher willingness to interact with them.

In summary, previous studies have investigated the growth mindset in different populations and have demonstrated potential relationships between growth mindset and positive responses to eHealth. Studies have also been conducted on the growth mindset levels of older adults, the results have demonstrated that this aspect needs to be improved [20,38], and that growth mindset may be a key target in bridging the "digital divide" among older adults. However, most of these studies were cross-sectional and descriptive, making it difficult to provide direct guidance for practice. Therefore, this study was conducted to develop and investigate the effectiveness of a growth mindset intervention based on growth mindset theory. It aimed to improve the levels of growth mindset and knowledge, willingness, belief, and practice of smart medicine among older patients with chronic disease in the context of global trends in aging and chronic diseases.

Methods

Design

This study used a quasi-randomized controlled trial design conducted over 12 weeks. Before conducting the study, the researchers numbered the wards of internal medicine departments (excluding intensive care units) according to the order of bed number. The wards were then randomly divided into intervention wards and control wards using a random number generator. Patients were recruited to the control group (eHealth only) in the control ward and the intervention group (growth mindset intervention + eHealth) in the intervention unit. Participants in the control group could undergo the training after the study concluded. The study was registered on ClinicalTrials.gov (NCT06550817).

Setting and Participants

Participants (N=77) were enrolled from a hospital internal medicine department in Hangzhou, Zhejiang Province in China between September 2021 and October 2022. The inclusion criteria were: (1) participants aged 60 years and older, (2) diagnosed with ≥1 chronic disease, (3) owned at least one smartphone, (4) ability to communicate clearly in writing or orally, and (5) willingness to participate in this study. The exclusion criteria were: (1) inability to use WeChat (Tencent Holdings Limited) or phone to communicate, (2) diagnosed as having a mental illness or cognitive impairment, (3) acute severe disease or loss of self-care ability, and (4) concurrent participation in other similar training.

This study used a quasi-experimental design, and the sample size was calculated based on comparing the means of the two samples [39]. An a priori power analysis showed that 34 participants per group (total N=68), accounting for anticipated attrition, would achieve 90% power at a 5% significance level to detect the expected mean difference. Finally, 77 participants started the intervention, and 74 completed the 12-week intervention period, with an attendance rate of 96.10% (74/77).

XSL•FO
RenderX

Ethical Considerations

The ethics committee of the School of Nursing at Hangzhou Normal University has approved this study (2022015). Informed consent was obtained from all participants involved in this study. Participants were informed of the study's purpose, methods, and process, as well as their right to withdraw at any time. Only the relevant data of the participants were used for this study and all collected data were pseudonymized to protect participants' confidentiality. As compensation for study participation, participants received a ¥50 (US $6.95) supermarket voucher and a vegetable package upon study completion.

Blinding and Randomization

The single-blind principle was strictly applied in this study. Neither the study participants nor the data collectors had access to the grouping and the content of the intervention, thus mitigating subjective bias. Patients were recruited into the control group in the control ward and into the intervention group in the intervention ward. Random grouping by ward avoided cross-contamination when patients in the same ward were divided into different groups. Participants were debriefed at the end of the study regarding the full purpose and differences between groups in the study.

Intervention

The eHealth training program was delivered to participants by nursing students with a master's degree, who have received training in growth mindset knowledge, and training related to the construction and implementation of nursing training studies. Psychological counselors, professors in geriatric nursing, and clinical experts in geriatric nursing served as consultants. The purpose, duration, and main contents of the training were introduced to the patients by the faculty before the training. Patients were asked about their learning experience and whether they were confused about the content of the lectures after the training. The faculty used the video training platform to track patients' learning, and for those who did not complete the training in time, telephone communication was implemented to encourage them to improve their learning progress. This ensured that the patients mastered the content of the training and assistance was offered in solving problems.

Growth Mindset Intervention

Based on the previous literature review, this study found that previous intervention [27], deeply aligned with the growth mindset theory. The program is mature and verified by large samples in multiple regions, and hence, based on the framework of the intervention, the following 3 strategies were used for creating the intervention content: recognize growth mindset, explore growth mindset deeply, and apply growth mindset. The purpose of "recognize growth mindset" was to convince patients that they could still change their intelligence through learning, strengthening the belief that their brain can be exercised. The purpose of "explore growth mindset deeply" was to increase patients' understanding of growth mindset and promote their willingness to cultivate a growth mindset. The purpose of "apply growth mindset" was for patients to learn to apply a growth mindset and connect it to real life. In addition, some studies have noted that there are adaptation issues in the implementation of the growth mindset [40]. The physical and mental functions of older adults show an irreversible decline trend, thus the cultivation and adaptation of the growth mindset in older adults are more difficult. Therefore, this study takes the characteristics of older adults into account and adds the theme "growth mindset in life" under the guidance of ife span theory by Baltes et al [41], to further cultivate the habit of using growth mindset in practice in older patients with chronic diseases. In this manner, the above 4 strategies were identified for the study.

Research shows that the introduction of brain science, story rewriting, skill training, and other methods can enhance the subjects' identification and internalization of the growth mindset [42,43], so the research group formulated the intervention program based on this and the actual situation of older patients with chronic diseases. Table 1 shows the specific content. The intervention duration is 12 weeks. Themes 1 - 6: once a week, online intervention is implemented and it lasts about 20 minutes each time, while face-to-face intervention lasts about 30 minutes each time, and they are carried out for a total of six weeks; theme 7: face-to-face or telephone intervention is implemented once every two weeks for about 15 minutes each time, and it is carried out for a total of six weeks.

XSL•FO
RenderX

Table . Implementation form of the growth mindset intervention program.

Intervention strategy	Intervention theme	Intervention content	Intervention form
Recognize growth mindset	Is intelligence innate?	• Introduced the structure and function of the brain and neurons. • Explained the plasticity of the brain. • Emphasized the importance of learning and challenging new things. • Strengthened the belief of "exercising the brain" and "the more the brain is used, the more flexible it is."	Video lessons
	Can older adults become smart?	• Introduce the changes in brain structure and function in older adults. • List relevant scientific research to encourage patients to believe that the brain of older adults is still plastic. • Encourage patients to talk about the relationship between "the plasticity of older adults' brain" and their own intelligent medical.	Video lessons and face-to-face interaction
Explore growth mindset deeply	The 2 different mindsets	• Introduce the concept of growth mindset. • Share different mindsets in the process of learning eHealth, and guide patients to understand different behaviors, and results of the 2 mindsets. • Emphasize the benefits of the growth mindset for older adults. • Encourage patients to rewrite stories from the perspective of the growth mindset.	Video lessons, telelecture, and story rewriting
	Facing difficulties and challenges	• Encourage patients to share their experiences of overcoming difficulties and guide them to discover the importance of a growth mindset. • Make a case of the common difficulties and challenges of older adults with chronic diseases in the use of eHealth. • Ask patients to imagine how to solve the problem through efforts, strategies, seeking help, and other ways if they are the parties.	Experience sharing and case studies

XSL•FO
RenderX

Intervention strategy	Intervention theme	Intervention content	Intervention form
Apply growth mindset	The 4 steps of growth mindset	• Introduce Dweck's 4 step strategy to change the mindset: accept, observe, name, and educate. • Encourage patients to describe the experience of the emergence of a fixed mindset during eHealth use and discuss how to implement the 4 steps of the growth mindset.	Video lessons and telelecture
	Growing mindset habit cultivation plan	• Review the interventions that have been implemented. • Encourage patients to talk about the challenges related to eHealth, and guide them to think about how to use a growth mindset to face the challenges. • Complete the "growth mindset habit cue card."	Face-to-face interaction
Growth mindset in life	Growth mindset in life	• Encourage patients with good application of the growth mindset, and help patients with difficulties to solve problems.	Telephone follow-up

eHealth Program

The eHealth program intervention aimed to increase patients' knowledge of eHealth and help them master common operational skills. The intervention forms included face-to-face instruction, video teaching, training manual, and telephone follow-up. Video teaching included "Smart Phone Basics, Online Registration, Mobile Phone Payment and Report Query," "Introduction and Operation of Online Health Consultation," "Introduction and Operation of Online Prescriptions and Residents' Electronic Health Archives," "Introduction and Operation of Hospital Online Disease Management," "Methods to Obtain and Identify Reliable Health Knowledge," and "Introduction to Wearable Mobile Medical Devices." The training manual was a video supporting content, which was used with the videos. Finally, telephone follow-up was conducted to understand the learning situation and difficulties of the participants. The program lasted for 12 weeks. In the first 6 weeks, face-to-face eHealth teaching in the internal medicine department and telephone follow-up were conducted once a week, for about 10 minutes each time. In the last 6 weeks, only telephone follow-up was conducted.

Measures

Implicit Theories of Intelligence Scale-6 (ITIS-6)

The Implicit Theories of Intelligence Scale-6 (ITIS-6) [44] was used to assess participants' level of growth mindset. Participants completed the scale at baseline, 6, and 12 weeks of intervention. The scale contains 3 growth mindset items and 3 fixed mindset items. The Likert-6 scoring method was used, and a reverse scoring method was adopted for the fixed mindset dimension, with a higher score on the scale signifying a higher level of growth mindset. In this study, the Cronbach α coefficient for ITIS-6 was 0.95, indicating good internal consistency.

Questionnaire of Knowledge, Willingness, Confidence, and Practice of Smart Medicine (KWCP-SM)

According to the relevant policy documents on the promotion and implementation of eHealth, this study invited 5 experts with 10 years or more of work experience (including 2 clinical nurses, 1 community nurse, and 2 community doctors) to conduct face-to-face interviews, and developed the questionnaire of knowledge, willingness, confidence, and practice of smart medicine. The final questionnaire had the 4 dimensions of knowledge, willingness, confidence, practice, and 9 items including online registration, and mobile phone payment. There were 36 items in total. The questionnaire adopted the Likert-5 scoring method. The higher score indicated a higher level of knowledge, willingness, confidence, and practice of smart medicine. The Cronbach α coefficient for the scale was 0.97, indicating good internal consistency.

Statistical Analysis

Baseline demographic and medical characteristics within groups were compared with an independent-sample *t* test (for quantitative variables), $\chi 2$ test (qualitative variables), or nonparametric rank-sum test (qualitative variables following grade data). The Mann-Whitney *U* test was applied to assess the difference in growth mindset and KWCP-SM between the two groups because of their abnormal distributions. Within-group comparisons were performed by the Wilcoxon signed ranks test. To evaluate the between-group differences over time, a generalized estimation equation (GEE) was performed. Statistical analysis was carried out with SPSS 25.0 version (IBM). $P<.05$ was considered statistically significant.

Results

Participants

Out of the 77 participants who participated in the intervention, 74 completed the 12-week intervention period, resulting in an attendance rate of 96.10% (74/77), with 36 in the intervention group and 38 in the control group. Among the 3 participants in the two groups who withdrew from the study, 2 participants in the intervention group reported health issues and lost interest, respectively, and 1 participant in the control group lost interest. Figure 1 shows the CONSORT (Consolidated Standards of Reporting Trials) diagram of the participant flow and the EHEALTH checklist is provided (see Checklist 1). Table 2 shows the baseline characteristics of participants. No significant differences were observed between the intervention and control groups regarding demographic and medical characteristics, growth mindset, and KWCP-SM of participants.

Growth Mindset

In terms of growth mindset level, there was no significant difference between the two groups at baseline (*P*>.05), but there was a significant difference between the two groups after intervention (*P*<.05). The intervention group demonstrated a significant improvement in group changes in growth mindset at 12 weeks (9.89% change from baseline; *z* score=−5.13, *P*<.05), while no statistically significant change was observed in the control group (2.68% change from baseline; *z* score=−5.13, *P*>.05). The GEE analysis revealed the growth mindset changes over time in the intervention and the control groups. A significant group × time interaction was observed at 12 weeks of intervention (Wald=11.57; *P*<.05), indicating that there was a significant improvement in the intervention group than the control group.

KWCP-SM

Table 3 shows the mean, SE, percentage change of outcomes, and the results of the Wilcoxon signed ranks test. Table 4 shows the GEE results of outcome valuables over time between the two groups. Regarding knowledge of smart medicine, at 12 weeks both the intervention group (29.35% change from baseline; *z*=−5.20; *P*<.001) and control group (27.06% change from baseline; *z*=−4.85; *P*<.001) had statistically significant within-group changes, but the difference between groups (Wald=1.14; *P*=.57) was not significant.

For willingness to use smart medicine, at 12 weeks the intervention group (19.53% change from baseline; *z*

XSL•FO
RenderX

score=−3.25, *P*=.001) showed a marked improvement compared with baseline score, while the control group (1.12% change from baseline; *z* score=−0.67; *P*=.50) showed a slight decrease. The GEE analysis revealed a significant interactive effect between time and groups (Wald=10.63; *P*=.005).

For confidence in smart medicine, both groups experienced improvement during the 12-week intervention, while this improvement was larger in the intervention group (30.25% change from baseline; *z* score=−3.75; *P*<.001) than the control group (5.45% change from baseline; *z* score=−1.77; *P*=.08). In addition, a significant difference in group × time interactive effect was observed (Wald=25.09; *P*<.001).

For the practice of smart medicine, both the intervention group (6.61% change from baseline; *z* score=−1.69; *P*=.09) and control group (4.14% change from baseline; *z* score=−1.50; *P*=.13) showed a slight improvement at 12 weeks compared with baseline. However, no significant between-group difference was observed (Wald=1.51; *P*=.47).

Table . Comparison of pre- and postintervention mean of outcomes (growth mindset; knowledge, willingness, confidence, and practice of smart medicine [KWCP-SM]).

Discussion

Principal Findings

This study constructed a growth mindset intervention program for older patients with chronic diseases and evaluated its effects on their growth mindset and positive response to eHealth. After 12 weeks of intervention, the findings showed a significant improvement in the total ITIS-6 and KWCP-SM scores of patients in the intervention group compared with the control group, which suggests that the intervention was effective. We tailored our growth mindset program to address the mindset and micro-psychology of older adult patients with chronic diseases. This approach offers a new direction in bridging the digital divide targeting older adults.

XSL•FO
RenderX

Comparison With Previous Work

While the intervention program of this study effectively improves the growth mindset of older adults with chronic diseases,research on the effectiveness of growth mindset interventions in increasing the level of growth mindset in different populations is not entirely consistent. For example, Plaks and Chasteen [36] conducted a growth mindset psychological experiment with 88 older adults and found significant increases in the growth mindset in the experimental group. Orvidas et al [31] conducted an online growth mindset intervention with 48 obese children and adolescents and showed that the experimental group had better levels of growth mindset than the control group and significantly improved perceptions of health behaviors and self-efficacy. However, Sridharan et al [23] conducted an online growth mindset intervention with 398 smokers for 24 days and found that there was no significant difference in the level of growth mindset between the intervention group and the control group after the intervention, which may be due to the excessive amount of growth mindset intervention content provided to the participants. In this study, the intervention group showed better improvement in growth mindset than the control group, which could be attributed to the following reasons: First, we consulted previous growth mindset interventions that worked and adopted the framework of the intervention program previously published [27] as the main theme. At the same time, we combined the characteristics of psychological dependence of older adults to construct the themes, a total of 4 strategies along with the themes were included. The “Recognizing growth mindset” strategy used video lessons and face-to-face interaction to let the participants believe the plasticity of the brain of their own; the “Exploring growth mindset deeply” strategy used video lessons, telelecture, and story rewriting to promote deeply understanding and internalization of the growth mindset; the “Applying growth mindset” strategy used daily practice to promote the integration of growth mindset into the patient’s real life and learn to apply it; the “growth mindset in life” strategy used phone follow-up to help older adults with difficulties to solve problem and promote habit formation. Second, considering that effective training and dependence behavior are important measures for individual growth in old age [45], we helped patients identify the timing of a fixed mindset and adjust and cultivate a growth mindset through four steps: acceptance, observation, naming, and education. Furthermore, by teaching older adults about brain plasticity and the experience of growth mindset activities, this study, to a certain extent, broke the stereotype of “old age is frailty,” and instilled the hope of improvement in older adults. In addition, patients overcame difficulties through the growth mindset intervention and successfully mastered the experience of eHealth treatment, enabling them to realize that the growth of older adults is controllable, achievable, and recognized by society. This hopeful and emotional experience enhanced their belief that their ability can still be developed, improving their level of growth mindset.

After the 12-week eHealth program intervention, the total score of KWCP-SM, which measured the level of willingness and confidence in smart medicine, improved significantly in both the intervention and control groups compared to the pre-intervention period. This suggests that the traditional teaching model can improve the ability of older adults to use eHealth to some extent, and the result is consistent with the study by Zhao et al [46]. There are some possible explanations for this. First, existing studies have found that older adults experience major negative psychological emotions such as age-related stereotype, frustrated self-esteem, and dwindling motivation, which hinder the integration of eHealth in their lives [47,48]. Growth mindset intervention can effectively improve age-related stereotypes by instilling the belief in the plasticity of older adults’ intelligence and ability [49,50]. It also reduces patients’ excessive attention to learning outcomes, regards failure as a process of learning and improvement, protects their self-esteem and secondary fear of science and technology in the event of failure to a certain extent, and stimulates their internal motivation [51-53]. Second, the theory of growth mindset emphasizes that efforts, strategies, and timely help-seeking are important paths for learning and growth [27]. This study not only teaches patients to learn knowledge and skills, emphasizing that the key premise is hard work, but also empowers patients with eHealth learning strategies and help-seeking methods. Furthermore, our intervention met the practical needs of older adults who urgently need eHealth health care but are unable to take full advantage of it because they have not kept pace with technological developments. As a result, the willingness and interest of older people to learn are relatively high and the outcomes of this eHealth program are more positive.

Strengths and Limitations

The growth mindset intervention in this trial was developed in a theoretical and evidence-based manner and contains a tailored education program taking the characteristics of the older adults with chronic diseases into account. In addition, the training program organically integrates local slang into the training, increases the patients’ trust in the plasticity of older adults’ brains and their belief in lifelong learning, and sets up regular and multiple nurse-patient communication sessions, which facilitate real-time interaction and feedback, thus meeting the patients’ personalized needs.

Several limitations of this study should be noted here. First, the study was carried out at only one comprehensive hospital in Hangzhou. More multicenter and large sample studies should be carried out to further verify the scheme’s effectiveness. Second, the between-group difference in actual eHealth behavior change was not statistically significant. This may due to time constraints, only the effect of the growth mindset intervention for 12 weeks was confirmed. In the future, research should continue to track participants for 12 weeks or more to identify the effectiveness of the intervention program over the long term. Third, this study took the lead in building a growth mindset intervention program for older patients with chronic diseases and preliminarily verified the effectiveness. However, during the intervention, individual differences were found among older adults which may partly explain the nonsignificant finding, so future studies need to constantly adjust and improve the intervention plan according to the characteristics and needs of the participants.

XSL•FO
RenderX

Future studies should also implement the double-blind method and increase the objective evaluation indicators related to eHealth (such as frequency of visiting doctors, compliance, clinical nursing outcomes, etc.) to verify the efficacy of this program. Finally, future studies can build a platform for elderly growth mindset intervention with emerging technologies to achieve large-scale and accurate intervention, to improve the level of growth mindset in older adults to a greater extent.

Conclusions

The growth mindset intervention program for older adults with chronic diseases constructed in this study effectively improves the growth mindset of older adults with chronic diseases, enhances their mastery of eHealth knowledge, and boosts their confidence and willingness to use eHealth tools. It is expected to help patients meet their own diagnostic, treatment, disease control, and other practical needs through eHealth solutions. A growth mindset shows high potential in promoting eHealth use among older adults. This study is referable due to its creation of training content based on the growth mindset theory and investigation of the effect of the training on a range of variables. Further research is needed to improve the growth mindset intervention, in particular by considering older patients' needs and interests, improving its adoption, and developing fault-tolerant and lifelong growth environments that enhance growth mindset among older adults with chronic diseases. The growth mindset intervention program in this study could also be applied to enhance growth mindset and eHealth behaviors among older adults with chronic diseases in other countries by integrating localized case examples, community specific customs, and beliefs.

Abstract

Background: Informed consent (IC) is a cornerstone of ethical clinical research, yet comprehension gaps persist. The i-CONSENT guidelines aim to improve IC materials by enhancing clarity, accessibility, and tailoring them to the needs of diverse populations. This study evaluates the effectiveness of electronic IC (eIC) materials developed under these guidelines for 3 target populations—minors, pregnant women, and adults—across Spain, the United Kingdom, and Romania.

Objective: The primary aim of this study is to assess participants' comprehension of and satisfaction with eIC materials tailored to their specific needs. The secondary objectives are to identify demographic predictors of comprehension, evaluate the cross-cultural applicability of materials, and explore format preferences.

Methods: A cross-sectional study was conducted with 1757 participants (620 minors, 312 pregnant women, and 825 adults), who reviewed eIC materials through a digital platform offering layered web content, narrative videos, printable documents, and infographics. Materials were co-designed using participatory methods, including design thinking sessions with minors and pregnant women, and online surveys with adults. Comprehension was assessed using an adapted version of the Quality of the Informed Consent questionnaire. Objective comprehension (part A) was categorized as low (<70%), moderate (70% - 80%), adequate (80% - 90%), or high (≥90%). Subjective comprehension (part B) was measured using a 5-point Likert scale. Satisfaction was evaluated through Likert scales and usability questions, with scores ≥80% considered acceptable. Multivariable regression models were applied to identify predictors of comprehension.

Results: Objective comprehension exceeded 80% across all groups: minors (mean 83.3, SD 13.5), pregnant women (mean 82.2, SD 11.0), and adults (mean 84.8, SD 10.8). Women/girls outperformed men/boys (β=+.16 to +.36). Generation X adults scored higher than millennials (β=+.26, *P*<.001), while prior trial participation was associated with lower comprehension scores (β=−.47 to −1.77). Among minors, compared with participants from Spain with no previous clinical trial experience, comprehension was significantly lower in Spain (*P*=.03), Romania (*P*<.001), and the United Kingdom (*P*<.001). Format preferences varied: 382 out of 620 (61.6%) minors and 152 out of 312 (48.7%) pregnant women preferred videos, whereas 452 out of 825 (54.8%) adults favored text (*P*<.001). Satisfaction rates surpassed 90% in all groups (minors, 604/620, 97.4%; pregnant women, 303/312, 97.1%; and adults, 804/825, 97.5%), with 777 out of 825 (94.2%) adults also indicating that the materials facilitated understanding. While translated materials maintained high efficacy across countries, comprehension scores in Romania were lower among participants with lower educational levels (β=−1.05, *P*=.001). Materials cocreated in Spain were effective across countries but yielded higher comprehension within the original target population.

Conclusions: eIC materials developed following the i-CONSENT guidelines achieved high levels of comprehension and satisfaction across diverse populations, demonstrating scalability for multinational trials. Cocreation and multimodal design effectively addressed participant preferences; however, cultural adaptation remained crucial for optimizing outcomes. The negative impact of prior trial participation highlights the need for tailored engagement strategies for returning participants. Future research should explore regional disparities, evaluate interventions for overconfident returning participants, and validate these tools across broader cultural contexts.

Introduction

Background

Informed consent (IC) is a key element in ensuring the autonomy of potential participants when deciding whether to partake in a study. To be effective, IC must meet 5 key criteria: voluntariness, capacity, disclosure, understanding, and decision-making. However, numerous studies have highlighted persistent gaps in participants' comprehension of the information provided during the IC process [1].

The i-CONSENT project was initiated to address these challenges by improving IC materials to make them more comprehensible, accessible, and tailored to the specific needs of diverse populations. As part of this initiative, the project developed the "Guidelines for Tailoring the Informed Consent Process in Clinical Studies" [2] (i-CONSENT guidelines). Among the recommendations included in the guidelines, involving potential participants in the preparation of the IC and its associated materials has been identified as a key factor [3].

To evaluate the impact of these guidelines, 3 mock studies were conducted, each focusing on a distinct population: minors, pregnant women, and adults. The IC materials were presented in electronic formats (electronic IC [eIC]), incorporating innovative features such as layered web content, narrative videos, printable documents, and customized infographics. These formats allowed participants to engage with the information in ways that suited their preferences and cognitive styles.

This study aims to assess participants' comprehension of and satisfaction with eIC materials tailored to their specific needs. Additionally, it seeks to explore cross-cultural applicability by implementing these materials across 3 countries—Spain, the United Kingdom, and Romania—and examining demographic predictors of comprehension. The findings contribute to advancing inclusive and participant-centered IC processes in clinical research while promoting informed decision-making.

Objective

The main objective of this study is to estimate the proportion of potential participants who understand the 3 different eIC materials prepared following the i-CONSENT guidelines. Additional objectives are to (1) analyze differences in comprehension across countries (Spain, the United Kingdom, and Romania) and evaluate whether materials designed for one region apply to other regions or languages; (2) assess comprehension within specific domains of IC information; and (3) evaluate participant satisfaction with the eIC materials. Additional objectives for adults include exploring differences in comprehension by gender and age, while for minors, the objective is to explore differences in comprehension by gender.

Methods

Elaboration of e-Consent Materials

Overview

Electronic information materials have been prepared for 3 mock studies on vaccine clinical trials, each addressed to a different population group (see Table 1).

XSL•FO
RenderX

Table . Description of the 3 case studies.

Variable	Minors	Pregnant women	Adults
Target population			
Age (years)	12-13	≥18	Millennials: 18 - 38; Generation X: 39 - 53
Genders included	Both male and female	N/A[a]	Both male and female
Sample size, n	620	312	825
Case scenarios	Human papillomavirus vaccination in minors, considering gender differences.	Respiratory syncytial virus vaccination in pregnant women, considering both their needs and those of their babies.	Meningococcal vaccination in adults, considering gender and generational differences.
How was the target population involved?	One design thinking session with children and parents, 1 session with children alone, and piloting of the contents of the information sheet and the survey.	Two design thinking sessions with pregnant women and piloting of materials.	An online-based self-administered survey used for piloting.
Materials prepared	eConsent[b], including information in 3 formats: a website page (layered approach), a video (storytelling format), and a document (improved format).	eConsent included information in 3 formats: a website page (layered approach), 1 infographic (about the study procedures), a video (question-and-answer format), and a document (improved format).	eConsent included information in 3 formats: a website page (layered approach), 5 infographics (covering general information, procedures, benefits and risks, legal aspects, and data protection), and a document (improved format).

[a]N/A: not applicable.

[b]eConsent: electronic consent.

The materials have been prepared following the i-CONSENT guidelines, taking into account potential participants' preferences and needs [4]. Different formats were included, and participants could choose among these formats or combine them. Table 1 provides information about the materials prepared.

Development Process

The materials were originally prepared in Spanish through a cocreation process involving representatives from the target population. A multidisciplinary team comprising clinical trial physicians, epidemiologists, a sociologist, a journalist, and a nurse collaborated on the design. This approach ensured that the materials were scientifically accurate while addressing the cognitive and cultural needs of participants. The cocreation methodology included participatory sessions with minors and pregnant women in Spain to ensure that the materials were relevant and engaging for these groups. For adults, online surveys provided insights into preferences and usability. This iterative process allowed for refinement based on user feedback before finalizing the materials.

To facilitate cross-cultural implementation, the materials were professionally translated into English and Romanian by native speakers of the target languages. The translation process adhered to a rigorous rubric that prioritized fidelity to meaning, contextual appropriateness, and adaptation to local customs and linguistic conventions. Each translation was independently reviewed by another professional translator to ensure quality and consistency.

Formats Offered

Participants accessed the eIC materials via a dedicated website, where they could choose from multiple formats based on their preferences or combine them as needed. The formats offered (depending on the specific case study) included the following:

- Layered web content: A modular approach that allowed participants to access additional details or definitions by clicking on specific terms.
- Narrative videos: Tailored video formats for minors and pregnant women (a question-and-answer style for pregnant women and narrative storytelling for minors).
- Printable documents: Text-based materials with integrated images, designed for participants who prefer physical copies.
- Infographics: Simplified visual representations of complex topics such as legal aspects or participant rights.

The formats were not mutually exclusive, and participants could engage with any combination of formats according to their preferences.

Comprehension Assessment Tool

Adaptation of the Quality of the Informed Consent Questionnaire for Target Populations

To evaluate comprehension, 3 tailored adaptations of the Quality of the Informed Consent questionnaire (QuIC) [5] were used, 1 for each mock study. The adaptations were based on the original version of the QuiC developed by Joffe et al [5] and subsequent modifications by Paris et al [6,7]. The adjustments accounted for the nature of the study (vaccine clinical trials in healthy populations), the characteristics of the target groups (minors, pregnant women, and adults), and European regulations on data protection and clinical trials.

XSL•FO
RenderX

Development and Validation

Each adaptation process was conducted independently for the respective population. For minors and pregnant women, cocreation sessions were held with representatives from these groups to ensure that the questionnaires were appropriate and comprehensible. Feedback from these sessions informed iterative revisions, resulting in the final versions of the tools. The adapted questionnaires were originally developed in Spanish and subsequently translated into English and Romanian by professional translators. These translations followed a rigorous rubric that prioritized fidelity to meaning, cultural appropriateness, and linguistic clarity.

Structure of the Questionnaires

The surveys, as their predecessors, consist of 2 parts to assess understanding: part A measures objective understanding, and part B measures subjective understanding.

In the surveys for adults and pregnant women, part A includes 22 questions with 3 response options ("no," "don't know," and "yes"). The scoring system follows that of the original version of the QuIC [5]: 0 points for an incorrect answer, 50 points for a "don't know" response, 100 points for a correct answer. The questions in part A are grouped into 7 domains: "Nature/purposes of research," "Risks and benefits," "Alternative procedures," "Legal, participant protection," "Compensation," "Contacts, information," and "Participants' rights." Part B consists of 13 questions scored using a 5-point Likert scale. Scores are assigned as follows: 0 points for a rating of 1, 25 points for 2, 50 points for 3, 75 points for 4, and 100 points for 5.

The survey to measure children's understanding was designed in a cocreation session with children and resulted in the Assent Comprehension Questionnaire for vaccine studies (abbreviated *CCAsIn*, from its Spanish title *Cuestionario de Comprensión del Asentimiento Informado*) [4]. In this survey, part A includes 14 questions with 2 response options ("agree" and "disagree"); correct answers score 100 points, and incorrect answers score 0 points. Part B consists of 10 questions, scored using the same values as in the adult version. The minors' survey includes 3 domains: "Nature/purposes of research," "Risks and benefits," and "Participants' rights."

The global score of each part was calculated as the average score of all questions in that part. Domain-specific scores were also calculated for part A by averaging the scores within each domain.

Additionally, 2 sections were added: 1 with sociodemographic questions and 1 with questions addressing acceptance, preferences, and satisfaction with the eIC materials. A multiple-choice question was included to capture participants' preferences regarding information formats.

The final versions of the questionnaires underwent pilot testing with representatives from each target population to ensure validity and reliability. Feedback from participants informed minor adjustments before implementation in the main study.

Parts A and B of each survey are included in Multimedia Appendix 1, along with the frequency of responses for each question. Multimedia Appendix 1 also presents the questions grouped by domain.

Ethical Considerations

Ethics Review and Approvals

This study was conducted in accordance with the Declaration of Helsinki and received ethical approval from the Research Ethics Committee of the Foundation for the Promotion of Health and Biomedical Research of the Valencia Region (FISABIO; approval number 20200109/09).

Informed Consent

All participants provided IC before participation (see Multimedia Appendix 1). For minors, parental/guardian consent was obtained alongside assent from the children themselves. Online participants provided consent/assent electronically via a digital form integrated into the survey platform. Participants were explicitly informed that their involvement was voluntary and not related to any actual clinical trial.

Privacy and Confidentiality

All data collected were anonymized and securely stored on password-protected servers. Personal identifiers were removed before analysis, and participants were assured that their responses would remain confidential. Access to the raw data was restricted to the research team.

Compensation

Participants received compensation based on their recruitment group:

- Minors in Spain: Schools where the surveys were conducted received an Amazon voucher worth €200 (US $235) as an institutional incentive. For minors outside Spain, no direct compensation was provided due to logistical constraints; instead, recruitment was facilitated by the market research company (GfK) that visited schools to oversee participation.
- Adults and pregnant women: Participants recruited through the market research company's panel database received points equivalent to €4 to €5 (US $5 to US $6), which could be redeemed for gift cards or other rewards through the panel's system.

Recruitment

Rationale for Selecting Target Populations

The study targeted 3 distinct populations: minors, pregnant women, and adults. These groups were selected due to their specific ethical and regulatory considerations in vaccine clinical trials. Minors were included because their participation requires both assent and parental authorization, presenting ethical challenges due to their classification as a vulnerable population. Pregnant women were chosen to examine ethical safeguards and risk perceptions that may influence their willingness to participate, particularly in the context of vaccines administered during pregnancy to protect the unborn child. Adults were included as they represent the primary target population for vaccine trials, allowing for an assessment of IC comprehension and decision-making within a generally healthy population, as well as enabling intergenerational comparisons.

XSL•FO
RenderX

Surveys were conducted in 3 countries —Spain, the United Kingdom, and Romania—through the market research company with established household panel databases (30,000 panelists in Spain, 700,000 in Romania, and 2 million in the United Kingdom). The selection of these countries followed a cluster sampling approach based on their geographical distribution across Northern, Southern, and Eastern Europe. Factors such as cultural and linguistic diversity, country size, the number of registered clinical trials, and affiliation with the consortium were considered in the selection process.

Recruitment of Minors

For minors, recruitment was initially intended to be conducted face-to-face in schools. However, due to COVID-19 restrictions, this approach was adapted to online surveys in the United Kingdom and Romania. In Spain, surveys were partially conducted at state-subsidized schools under controlled conditions and complemented by online surveys completed at home. To ensure comparability across countries, recruitment targeted children aged 12 - 13 attending state-subsidized schools or equivalent educational settings.

A recruitment questionnaire was sent to randomly selected panelists with children aged 12 or 13 years. Parents were asked whether their children attended subsidized schools; if they responded affirmatively, they were invited to participate. Once parental IC was obtained, children were asked to provide their assent to participate. Parents also signed a certification confirming that survey responses were provided by their children rather than themselves. Materials and surveys were then sent online to participants who agreed to participate.

In Spain, 187 out of 312 students completed the survey in information technology classrooms under the supervision of study representatives, while the remainder participated from home. The data obtained across all 3 countries were fully comparable, as the sample profiles of children were matched across regions and the surveys that were conducted using similar procedures.

Recruitment of Adults and Pregnant Women

Adults and pregnant women were recruited using the market research company's household panel database for online studies. Invitations were sent to randomized samples of panelists who met the age and sex criteria. Sampling was controlled by area, age group, and socioeconomic level to ensure representativeness.

To identify pregnant women, the recruitment questionnaire included the question, "Are you currently pregnant?" All women who replied in the affirmative were included in the study group for pregnant women.

In Spain, due to the smaller panel size for pregnant women and the larger sample requirements, part of the recruitment was conducted face-to-face near health centers in Valencia and Madrid. This was carried out by professional recruiters using convenience sampling criteria. Pregnant women approached by recruiters were asked whether they wished to participate after being presented with the study details. Interested participants provided their email addresses via a dedicated form for follow-up communication. Subsequently, documentation and participation links were sent electronically in the same manner as for other panelists.

Instructions Provided to Participants

Participants received materials via email along with a standardized script explaining the study's purpose and procedures. This script included (1) an introduction to FISABIO's research within the framework of the European i-CONSENT project; (2) a statement clarifying that participation was voluntary and unrelated to any actual clinical trial; (3) an overview of the study structure (reviewing IC materials followed by a survey); and (4) estimated times for viewing the materials (35-40 minutes) and completing the survey (a minimum of 12 minutes).

Participants were instructed to review all materials before completing the survey. They accessed the materials via a private link sent to their email or provided during recruitment. The website allowed participants to open the materials in a browser tab while completing the survey in another, enabling them to refer back to the information as needed during data collection.

Fieldwork Period

All fieldwork for all study groups and countries was conducted between September and October 2020.

Survey Platform and Data Management

The surveys were administered using Confirmit Horizons v24, a multimodal platform employed by GfK for data collection via computer-assisted telephone interviewing, computer-assisted personal interviewing, or computer-assisted web interviewing methodologies. Data were securely transmitted from the platform to the research team, ensuring anonymization and compliance with data protection standards.

Adaptations Due to the COVID-19 Pandemic

A pilot test was conducted in Spain in July 2020 to evaluate the feasibility of face-to-face recruitment. The results (530 people approached, 467 uninterested, 5 completed surveys on-site, and 58 completed surveys from home via email) highlighted significant challenges with in-person recruitment and demonstrated the practicality of online data collection methods. Consequently, all surveys were conducted online, except for minors in Spain, where a hybrid approach was used (see the CHERRIES [Checklist for Reporting Results of Internet E-Surveys] checklist in Multimedia Appendix 1).

Statistical Analysis

Summary of Descriptive Statistics

Descriptive statistics were calculated for the study database, stratified by country, age, and gender (except for pregnant women, where gender was not applicable). Categorical variables were summarized using frequencies and percentages, while quantitative variables were described using means and SDs.

Comprehension Score

Comprehension of the study materials was assessed using the total score from part A of the adapted QuIC surveys, as well as by individual domains of IC. Scores were categorized as follows, based on the maximum score: below 70% indicated low

XSL•FO
RenderX

comprehension; between 70% and 79% indicated moderate comprehension; between 80% and 89% indicated adequate comprehension; and 90% or higher indicated high comprehension.

These cut-off points were established based on previous studies [8-10].

Regression Modeling

To evaluate differences in comprehension scores (part A) by country, age (adults), or gender (adults and minors), a linear regression model was constructed. Given the exploratory nature of the objectives, the model was adjusted for age (adults only), country, gender, previous participation in a clinical trial, and educational level (up to primary vs tertiary education, adults only), as these factors were anticipated to be strong predictors of comprehension. Interactions between variables were tested, and the Akaike information criterion (AIC) was used to select the optimal model by penalizing for model complexity. As the mean score did not follow a normal distribution, an ordered quantile normalizing transformation was applied to the data before regression analysis [11].

The analysis was carried out using the statistical software R, version 4.0.3 (R Foundation).

Data Exclusion Criteria

Participants whose response pattern indicated that more than 80% of items in the part A questionnaire were answered as "don't know" were excluded from the analyses (n=6).

Results

Study Sample and Participant Characteristics

After exclusions, a total of 1757 participants were included in the analysis: 825 adults, 312 pregnant women, and 620 minors. Key sociodemographic characteristics are summarized in Tables 2-4.

Table . Characteristics of the minors (n=620).

Characteristics	Spain (n=312), n (%)	Romania (n=125), n (%)	United Kingdom (n=183), n (%)	All (n=620), n (%)
Age				
12 years old	149 (47.8)	72 (57.6)	103 (56.3)	324 (52.3)

Objective Comprehension (Part A)

Comprehension Outcomes by Population Group

The mean objective comprehension scores (adapted QuIC part A) were high across all groups: minors, mean 83.3 (SD 13.5); pregnant women, mean 82.2 (SD 11.0); and adults, mean 84.8 (SD 10.8). All domains achieved mean scores above 70%, with no domains falling below 80% in any of the target populations (Table 5). The distribution of comprehension levels is presented in Table 6.

Table . Mean scores and SDs of each domain by study case (adapted QuIC[a] part A).

Domain	Minors, mean (SD)	Pregnant women, mean (SD)	Adults, mean (SD)
Nature/purpose of research	84.3 (16.2)	85.8 (17.3)	85.7 (15.3)
Risks and benefits	85.4 (13.2)	70.5 (21.4)	82.8 (19.3)
Alternative procedures	N/A[b]	90.2 (24.9)	77.0 (23.4)
Legal, participant protection	N/A	78.9 (19.9)	87.3 (15.6)
Compensation	N/A	84.0 (20.3)	82.7 (21.3)
Contacts, information	N/A	80.8 (16.4)	79.2 (20.7)
Participants' rights	88.8 (23.2)[c]	90.0 (14.7)	92.3 (13.0)
Final score for QuIC part A	83.3 (13.5)	82.2 (11.0)	84.8 (10.8)

[a]QuIC: Quality of the Informed Consent questionnaire.

[b]N/A: not applicable.

[c]In the minors' survey "Contacts, information" and "Participants' rights" were grouped into a single domain, as there was only 1 question on "Contacts, information" (A12), which made it very weak for analysis.

Table . Distribution of participants in each level of comprehension by case study (N=1757).

Degree of comprehension (part A)	Minors (n=620), n (%)	Pregnant (n=312), n (%)	Adults (n=825), n (%)
High (≥90%)	259 (41.8)	91 (29.2)	322 (39.0)
Adequate (≥80% and <90%)	109 (17.6)	100 (32.1)	287 (34.8)
Moderate (≥70% and <80%)	153 (24.7)	80 (25.6)	117 (14.2)
Low (<70%)	99 (16.0)	41 (13.1)	99 (12.0)

XSL•FO
RenderX

Factors That Have an Influence on the Understanding

Regression analyses identified several predictors of comprehension: (1) in minors, lower scores were associated with being male, aged 13, non-Spanish, and having prior clinical trial participation (Table 7); (2) among pregnant women, lower scores were linked to previous trial participation and lower education levels, particularly in Romania (Table 8); and (3) for adults, higher scores were observed among women, members of Generation X, Spanish participants, those with higher education, and those without prior trial participation (Table 9).

[b]N/A: not applicable.

Materials cocreated in Spain were effective across all countries, although comprehension was generally higher in the original target population. Lower educational levels in Romania were associated with reduced comprehension.

Subjective Comprehension (Part B)

Comprehension Outcomes by Population Group

This was measured using a 5-point Likert scale ranging from 1 (“I did not understand anything”) to 5 (“I understood everything”), and a final score was calculated. Subjective comprehension was high across all groups, with mean scores exceeding 85 out of 100 (Table 10).

Total score (QuIC part B)	85.2 (14.1)	87.9 (13.7)	88.9 (13.2)

[a]QuIC: Quality of the Informed Consent questionnaire.

[b]N/A: not applicable.

Preferences and Satisfaction

Minors and pregnant women preferred video, while adults favored text (Table 11). Satisfaction was high, with over 90% of participants in all groups (minors, 604/620, 97.4%; pregnant women, 303/312, 97.1%; and adults, 804/825, 97.5%) reporting that the materials were easy to understand and helpful (Table 12).

Table . Preferred information formats by target population.

How would you prefer to be given the information if you were to participate in a clinical trial? (You may choose various answers)	Minors (n=620), n (%)	Pregnant women (n=312), n (%)	Adults (n=825), n (%)

Discussion

Principal Findings

This exploratory, cross-sectional study provides preliminary evidence that eIC materials developed according to the i-CONSENT guidelines may be associated with high levels of comprehension and satisfaction among minors, pregnant women, and adults in 3 European countries. Objective comprehension scores (part A) exceeded 80% in all groups, and subjective comprehension (part B) was similarly high. However, a discrepancy was observed between subjective and objective understanding, consistent with previous research using QuIC-based tools [6,12-16]. This suggests that self-perceived understanding may not always reflect actual comprehension, underscoring the importance of ongoing assessment and targeted improvements in consent materials.

Minors exhibited greater variability in comprehension scores, with a higher proportion of both high (≥90%) and low (<70%) results compared with other groups. This finding highlights the challenges in tailoring materials for younger populations and suggests that additional support may be needed to facilitate their understanding. Certain domains, such as randomization and placebo concepts, remained difficult to understand for all groups, consistent with prior studies [1,14,17].

Notably, some survey questions yielded poor comprehension rates, particularly those requiring a "disagree" response or containing negative phrasing, consistent with findings from the original QuIC questionnaire [5]. Negatively worded items are known to increase cognitive load and reduce response accuracy [18]. Although these questions aimed to assess understanding of critical concepts such as randomization and placebo, their structure may have contributed to the observed difficulties. In the case of minors, the questionnaire was cocreated with children to ensure suitability [4], making it difficult to determine whether the phrasing of the questions or the complexity of the concepts was the primary factor influencing comprehension.

Formats designed using a layered approach allowed participants to engage with content according to their needs and preferences, which may have contributed to the overall high satisfaction and comprehension rates. Format preferences varied by population: minors and pregnant women tended to prefer video, while adults favored written text. These findings are consistent with previous research suggesting that offering multiple formats can accommodate diverse learning styles and improve engagement [19,20]. The separation of information delivery from discussion with the investigator was reinforced, aligning with literature indicating that combining both methods—especially when accompanied by extended discussion—can further enhance understanding [21].

Satisfaction with the materials was high across all groups, with 1604 out of 1757 (91.29%) participants rating the materials as easy or very easy to understand, and fewer than 3% (46/1757, 2.62%) expressing dissatisfaction. These results suggest that the cocreation process, which actively involved representatives from each target population, contributed to the development of user-friendly materials tailored to diverse needs [3,4,19]. The integration of multimedia tools, including layered content presentation and interactive features, likely supported engagement and comprehension [19], although the impact of

XSL•FO
RenderX

these features on actual decision-making remains to be further explored. It is also important to consider the potential limitations of digital resources, particularly for populations with limited access to technology or low digital literacy, as these factors could influence both comprehension and satisfaction outcomes [22,23].

Comparison With Previous Work

The results of this exploratory study are consistent with previous research indicating that structured, multimodal information materials can enhance participant comprehension and satisfaction in the IC process. Compared with the original QuIC study by Joffe et al [5], which reported a mean objective score of 77.8, our study achieved higher mean scores across all target populations (ranging from 82 to 84.8), while subjective comprehension scores remained similar (mean 85.2 - 88.9). This suggests that the application of the i-CONSENT guidelines, particularly the use of layered and cocreated materials, may contribute to improved understanding without inflating self-perceived comprehension.

The layered approach and the inclusion of multiple formats (text, video, infographics) align with recommendations from the i-CONSENT guidelines and recent systematic reviews, which highlight the importance of tailoring information to participant needs and preferences to address health literacy barriers and support informed decision-making [3,4,19]. Our findings reinforce the value of cocreation, as actively involving representatives from the target population in the development of materials has been shown to increase relevance, accessibility, and user satisfaction [4]. This is consistent with the i-CONSENT project's emphasis on participatory design and the RAND/UCLA (University of California, Los Angeles) expert consensus, which identified cocreation and a layered approach as key strategies for improving IC [3].

Demographic factors such as gender, age, and education were significant predictors of comprehension, consistent with previous literature. Women consistently achieved higher comprehension scores than men, a trend also observed by Raich et al [24] and Tam et al [1]. Age-related differences were apparent: older adults generally outperformed younger adults, in line with findings by Klima et al [25] and Tam et al [1]. By contrast, among minors, older participants scored lower than their younger peers, suggesting that factors such as motivation or engagement may influence comprehension in this subgroup and warrant further investigation [26].

A notable and unexpected finding was the negative association between prior clinical trial participation and comprehension. While some previous studies have suggested that experience in clinical trials enhances understanding [22,25], our results indicate that returning participants may overlook critical information due to perceived familiarity, potentially leading to overconfidence and knowledge gaps. Given the relatively small proportion of prior participants in our sample (adults, 60/825, 7.3%; pregnant women, 49/312, 15.7%; and minors, 33/620, 5.3%), this trend should be interpreted with caution. Future research should explore whether repeated exposure to trial materials influences learning patterns or whether targeted interventions can address overconfidence in returning participants.

Socioeconomic and cultural factors also played a role in comprehension outcomes. Higher education attainment was associated with better understanding, as reported in previous studies [1,16,22,27], yet participants with lower education still achieved reasonable scores, suggesting that the design of the materials may have mitigated some barriers related to health literacy. Comprehension remained high (>80%) in translated materials, consistent with Addissie et al [22], indicating that cocreated materials developed in one country can be effectively utilized in others. However, the observed differences in comprehension between Spain and other countries suggest that further adaptation to local linguistic and cultural contexts may be beneficial to optimize understanding across all populations.

Format preferences also influenced comprehension. The preference for video formats among minors and pregnant women aligns with Gesualdo et al [19], while adults' preference for text-based materials is consistent with health literacy principles described by Lorenzen et al [28]. These findings underscore the importance of offering multiple formats to accommodate diverse learning styles and ensure accessibility for all participants.

Strengths and Limitations

Overview

This section presents the main strengths that support the validity and applicability of the findings, as well as the limitations that should be taken into account to interpret the results and guide future research.

Strengths

One of the key strengths of this study is its multinational design, which evaluated eIC materials across 3 distinct cultural contexts—Spain, the United Kingdom, and Romania. This approach enhances the external validity of the findings and demonstrates the potential applicability of the i-CONSENT guidelines in diverse settings. The large sample size (1757 participants) and the inclusion of 3 target populations—minors, pregnant women, and adults—allowed for robust subgroup analyses and increased the generalizability of the results.

The cocreation process, which actively involved representatives from each target population, is another notable strength. This participatory methodology ensured that the materials were tailored to real-world needs and preferences, likely contributing to the high satisfaction and comprehension rates observed [3]. The use of multiple content formats (layered web content, videos, printable documents, and infographics) provided participants with flexibility in how they accessed information, accommodating different learning styles and potentially reducing barriers related to health literacy [19].

The study also benefited from the use of adapted versions of the QuIC questionnaire, which enabled a comprehensive assessment of both objective and subjective understanding. This dual assessment helped identify specific comprehension challenges, allowing for targeted recommendations for improvement [5]. For minors, the survey was codeveloped with

XSL•FO
RenderX

children, further enhancing its relevance and appropriateness for this group [4].

Limitations

Several limitations should be considered when interpreting these findings. First, the study used a cross-sectional design without a control group, which limits the ability to attribute observed outcomes directly to the i-CONSENT guidelines.

Second, the materials tested represent only 3 specific examples of eIC products developed according to the i-CONSENT guidelines. While these materials were tailored to the needs of minors, pregnant women, and adults, they do not encompass the full range of possible designs or clinical contexts. Additionally, participant engagement with specific formats was not monitored, so the impact of each format on comprehension could not be directly assessed.

Third, recruitment was conducted primarily online due to COVID-19 restrictions, which may have excluded individuals with limited digital access or lower digital literacy. Although printable documents were offered as an alternative format to mitigate this limitation, the sample may not fully represent populations with the greatest barriers to digital participation.

Fourth, while professional translators prepared the English and Romanian versions of the materials, end-user validation of translations was not performed. Although the translations were reviewed by native speakers within the consortium, the lack of direct feedback from target users may have affected comprehension, particularly in non-Spanish populations. Prior studies have highlighted that lower education levels can negatively impact comprehension of IC materials [22], and this effect has been particularly noted among Romanian participants [23].

Finally, the proportion of participants with prior clinical trial experience was relatively small, which may limit the interpretation of findings related to this subgroup. The exploratory nature of the study and the specific sample characteristics further limit the generalizability of the results.

Future Directions

Building on the exploratory findings of this study, several avenues for future research are warranted to further advance the development and implementation of IC materials tailored to diverse populations.

First, additional research should investigate the underlying causes of the polarized comprehension scores among minors and the negative association between prior clinical trial participation and understanding. Qualitative studies or mixed-method approaches could help elucidate whether factors such as motivation, engagement, or overconfidence contribute to these trends. Interventions designed to address these factors, such as interactive modules, adaptive content, or targeted reminders, should be evaluated for their effectiveness in improving comprehension, particularly among returning participants.

Second, the impact of multimedia formats on comprehension and satisfaction merits further exploration. While video content was preferred by minors and pregnant women, its overall effectiveness in improving comprehension remains unclear [19]. Future studies could apply experimental designs, user engagement analytics, or eye-tracking methodologies to assess how participants interact with various formats and which features most effectively support comprehension and retention. Additionally, the role of specific multimedia elements, such as animations or interactive elements, should be systematically evaluated.

Third, the generalizability of cocreated materials across broader cultural and linguistic contexts requires further validation. Although this study demonstrated that materials cocreated in one country can be applied in others, local adaptation and end-user validation may be necessary to optimize comprehension, especially in populations with lower educational attainment or limited health literacy. Comparative studies across additional countries and languages, as well as research on the impact of different translation and adaptation strategies, would provide valuable insights.

Finally, longitudinal research is needed to assess whether improved comprehension at the time of consent translates into better retention of information and more informed decision-making over the course of clinical trial participation. Such studies could also explore the long-term effects of digital consent tools on participant engagement, satisfaction, and trust in research.

Conclusions

This exploratory study provides preliminary evidence supporting the effectiveness of eIC materials developed according to the i-CONSENT guidelines in enhancing comprehension and satisfaction among diverse populations. Across 3 countries—Spain, the United Kingdom, and Romania—and 3 target groups—minors, pregnant women, and adults—objective comprehension scores consistently exceeded 80%, while subjective comprehension and satisfaction rates surpassed 90%. These findings highlight the potential of cocreated, multimodal consent materials to address diverse participant needs and preferences.

Demographic factors such as gender, age, and educational attainment significantly influenced comprehension outcomes. Women consistently outperformed men, and older adults achieved higher scores than younger ones. However, the negative association between prior clinical trial participation and comprehension underscores the need for targeted strategies to engage returning participants and address potential overconfidence or reduced attention to consent materials. These findings call for further investigation into how prior experience shapes participant behavior during the IC process.

The study also demonstrated that materials cocreated in one cultural context can be effectively applied in others, provided that cultural and linguistic adaptations are carefully implemented. However, differences in comprehension scores between countries suggest that additional localization efforts may further optimize outcomes. Format preferences varied across populations, reinforcing the importance of offering

XSL•FO
RenderX

multiple formats to accommodate different learning styles and align with cognitive needs.

While these results are promising, they should be interpreted with caution due to the study's cross-sectional design and exploratory nature. The absence of a control group limits causal inference, and the findings may not be generalizable beyond the specific populations and settings studied. Future research should employ longitudinal designs to assess comprehension retention over time and explore whether improved understanding translates into more informed decision-making throughout clinical trial participation.

These results highlight the potential of user-centered design principles, such as cocreation, multimodal delivery, and cultural adaptation, to improve IC processes in clinical research. The present findings provide a foundation for further development and validation of digital consent tools across broader populations and contexts. Continued efforts to refine these approaches will be essential to ensuring that IC processes remain inclusive, effective, and responsive to participant needs.

Acknowledgments

We thank the participants in the study, Gfk for conducting the fieldwork, and the entire i-CONSENT Consortium for their support and contribution throughout the project. This research was funded by Horizon 2020 SwafS-17-2016 GA n.741856 and conducted in the framework of the European project Improving the Guidelines for Informed Consent, including vulnerable populations, under a gender perspective (i-CONSENT).

Abstract

Background: A significant cause of postpartum hemorrhage (PPH) is access to and delivery of maternal health care services. Several multisectoral strategies have been deployed to address the challenges with little success, thereby necessitating the use of human-centered design (HCD) to enhance health care delivery, particularly in PPH management.

Objective: This study aims to develop facility-level solutions for optimizing uterotonic supply chain systems and health service delivery in PPH management through an HCD approach in selected Nigerian states.

Methods: The research used a four-phase HCD methodology: (1) co-research, (2) co-design, (3) co-refinement, and (4) implementation. However, this paper focused on the first 3 phases. In the co-research phase, 203 interviews were conducted, involving 80 pregnant women and nursing mothers, 97 health care workers, and 26 key stakeholders. Additionally, 33 sites were observed across a 3-level continuum of care. Interviews and focus group discussions revealed insights into the distribution of health workers and observed PPH cases, alongside knowledge and administration of uterotonics. Data analysis was carried out using three key steps: (1) identifying key themes from the collected data, (2) developing insight statements that encapsulate these themes, and (3) translating each insight statement into actionable design opportunities.

Results: About 150 ideas were produced and translated into 12 solution prototypes in the co-design phase. Progressive refinement following feedback from 140 stakeholders led to the selection of three final solutions: (1) implementing a referral linkage system to improve the transportation of pregnant women to nearby health facilities, (2) increasing demand for antenatal care services among pregnant women and their families, and (3) delivering a comprehensive uterotonic logistics management program for streamlined uterotonic storage and management.

Conclusions: This approach aligns with global health trends advocating for HCD integration in health care programming and aims to empower local champions to drive sustainable improvements in maternal health outcomes. Judicious implementation of the developed prototypes across the states can strengthen clinical care and potentially reduce maternal health service delivery gaps.

Introduction

Maternal mortality occurs due to complications that arise during and after pregnancy and childbirth. The major complications responsible for most maternal deaths include postpartum hemorrhage (PPH), postpartum infections, pre-eclampsia and eclampsia, complications during delivery, and unsafe abortion [1].

Globally, PPH is most pronounced in low-income countries [2], inflicting suffering on women and their families and also causing a strain on local and national health systems. Generally, PPH varies among regions, largely due to demographic and socioeconomic factors such as age, race, and social status, with low-income countries having a 12% higher occurrence [3]. One of the major drivers is limited access to timely, safe, and quality maternal care, which results in inequalities in maternal health services globally. Following a systematic review, 24.5% of maternal deaths in sub-Saharan Africa were attributed to PPH [4]. Over the past two decades, substantial efforts have been made to improve maternal care in sub-Saharan Africa, resulting in a 40% reduction in maternal mortality [5]. However, there are still significant challenges, such as substandard care, poor management skills, lack of knowledge, and delays in transferring women to the next level of care [6].

In Nigeria, PPH is the leading cause of maternal mortality, responsible for at least 21% of maternal deaths [7]. The country also bears a significant burden of maternal deaths, with 28.5% (82,000) of global maternal deaths occurring there annually [8]. Roughly 31% of female deaths in Nigeria are attributed to maternal causes, and in 2018, the country recorded a maternal mortality ratio of 512 maternal deaths per 100,000 live births [9]. Some factors contributing to this sad reality include poor access to essential medicines, including uterotonics for PPH management, and inadequate health care providers [10]. To address this threat, timely dissemination of information, primary preventive measures, comprehensive antenatal care (ANC), and strong political commitment are essential [3]. The key lies in proactive prevention, underscoring the need to analyze PPH comprehensively to develop effective mitigation and treatment strategies. Although several interventions have been carried out to prevent PPH, such as assessing coverage, acceptability, and feasibility of a comprehensive program [11-14], these interventions were health facility-centered and overlooked the broader ecosystem of care. Therefore, it was imperative to introduce the human-centered design (HCD), a collaborative method to enhance clinical care and bridge gaps in maternal health services delivery. This method involves not only health care providers but also other actors integral to providing and receiving care, including policy makers and patients [15,16].

The HCD approach has been applied successfully in global health programming, offering a human-centered approach to entrenched issues [15]. One example is the Support Sisters Intervention in the United States, a community-based peer-support intervention to help Medicaid-insured pregnant women access services and appointments [16]. In light of the global successes of using HCDs, its application to address service delivery complexities associated with maternal health care in Nigeria became imperative.

Hence, this study aimed to describe the use of HCD as an approach to develop facility-level solutions for optimizing uterotonic supply chain systems and health service delivery in managing PPH in selected Nigerian states.

Methods

Study Design and Setting

This study was designed as participatory research using the HCD through co-research, co-design, and co-refinement phases involving desk reviews, interviews, brainstorming, and rapid prototyping. The aim was to identify and develop facility-level solutions to strengthen the appropriate use of uterotonics for PPH prevention and treatment, reduce gaps in maternal health services, and drive improvements in uterotonic use for PPH prevention and treatment in Kano, Lagos, and Niger states in Nigeria through the development and integration of solutions to achieve a safe pre- and post-childbirth delivery experience for women in Nigeria.

This study was guided by the principle that the quality of PPH care spans the entire lifecycle of the uterotonic administration, beginning from production to proper usage within the hospital setting. It recognizes that people play a pivotal role at every stage of this process and emphasizes the importance of understanding the system to facilitate necessary improvements for better outcomes.

HCD Approach

The data collection and synthesis involved incorporating the principles of HCD. This is a user-inclusive approach that has been adopted to address and proffer customized solutions to complex challenges that impact the public health space, as well as suit the beneficiaries of the solutions [16]. It entails a mindset that starts with the people for whom the intervention is designed and ends with new solutions that are tailor-made to suit their needs. This approach disrupts traditional methods where researchers, health care providers, and administrators design new care models based solely on studies and expert opinions, instead integrating health care users' perspectives across all stages of the process [17-19].

The HCD process used in this study included co-research, co-design, and co-refinement phases (Table 1). Each of these phases enabled the discovery and an understanding of the problem and allowed us to co-create and test the developed solutions using iterative processes (Figure 1).

XSL•FO
RenderX

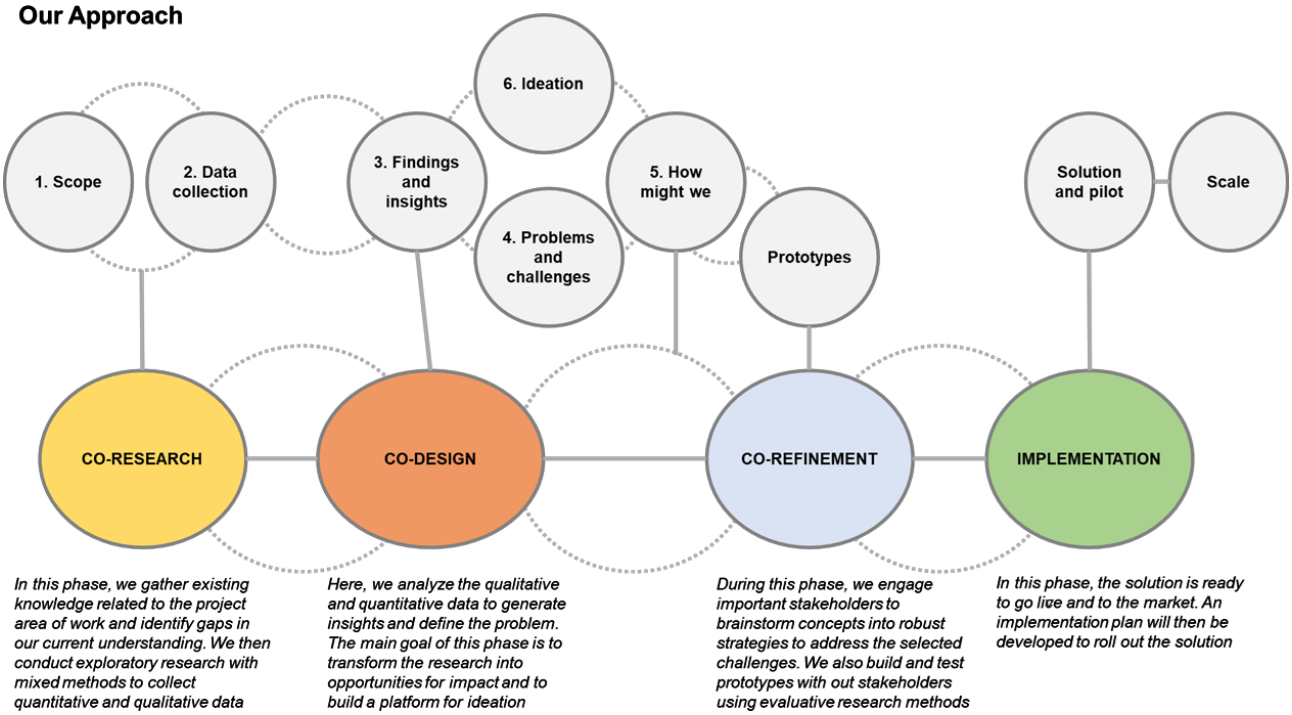

Table . The study's HCD[a] phases, approaches, and rationale.

HCD phases	Participatory approach	Rationale or comment
Co-research	Desk reviews, interviews, and site observations	Understand the PPH[b] landscape in the states, frame research questions, design the data collection tools, and collect data
Co-design	Brainstorming and alignment	Promote creativity, idea generation, and collaborative problem-solving
Co-refinement	Rapid prototyping and streamlining (redoing, discarding, and refining)	Generate tangible results iteratively through early feedback and revision of solutions
Co-implementation	Not part of the study	Recommendations were made to the states on the need to implement the developed prototypes

[a]HCD: human-centered design.

[b]PPH: postpartum hemorrhage.

Figure 1. The study's human-centered design framework.

Co-Research Phase: Understanding the User Needs, Goals and Contexts, and Tool Design (Phase 1)

The co-research phase was conducted across the 3 program states—Kano, Lagos, and Niger—from May 24 to October 24, 2022. It kick-started the HCD process and involved identifying the knowledge gaps around maternal mortality due to PPH through desk reviews to (1) understand the current status of PPH in Kano, Niger, and Lagos states; (2) frame research questions; and (3) design the data collection. The insights gleaned from this phase were subsequently translated into opportunities for impact.

Co-Design Phase: Designing, Piloting, and Testing (Phase 2)

The co-design phase was conducted across the 3 program states from November 7, 2022, to January 10, 2023. The co-design phase aimed at transforming insights that were identified during the co-research phase into new and more structured ideas via the brainstorming process, which encouraged the champions to think expansively.

Co-Refinement Phase: Refining the Prototypes (Phase 3)

The co-refinement phase took about 1 month to achieve between January 2 and February 23, 2023. During the co-refinement phase, each of the context-based solutions was validated through rapid prototyping.

Data Collection

In the co-research phase, 58 champions were trained in data collection across these 3 states. Training on proper interviewing techniques and mock sessions were held across the states. This enabled the government stakeholders from the program State Ministries of Health and the State Primary Health Care Boards, assigned as HCD champions, to review existing knowledge, identify gaps, and define the research methodology needed to deepen understanding of the problem.

XSL•FO
RenderX

The methodology for data collection was selected based on the timeframe, understanding of the local context, and resources available. The following exploratory methods were selected: (1) site visit observation (live-birth observation); (2) interviews with key informants (government officials); and (3) one-on-one interviews with pregnant women, health care providers (ie, nurses, midwives, doctors, and other health professionals), traditional birth attendants (TBAs), or health facility representatives (ie, facility in-charges and administrators).

The data collection tools were developed based on identified gaps from the landscape review and to answer the research question on these core areas: facility profile, knowledge and information on the use of uterotonics, the types and challenges regarding uterotonic use, facility equipment, and uterotonic availability.

Three unique tools were developed to solicit responses from the participants: (1) an observatory tool for the site visit (health facilities); (2) key informant interview guides; and (3) survey tools for health care providers, TBAs, and pregnant women. These tools differed for each group, ensuring the questions were tailored to their various contexts.

A 3-day workshop was organized in each of the 3 program states to gather the data collected from the field activities. This workshop focused on identifying the knowledge gaps gathered, having a clear and robust understanding of the challenges to be addressed, as well as generating insights to be translated into areas for opportunities.

Data Analysis: Synthesis and Intervention Development

The data collected (site visit observation, interviews with key government informants, and one-on-one interviews with pregnant women, health care providers, TBAs, or health facility representatives) were analyzed using a descriptive analysis method to constructively summarize data points.

Data analysis followed three steps in accordance with the HCD methodology: (1) identifying key themes from the collected data, (2) developing “insight statements” that encapsulate these themes, and (3) translating each insight statement into actionable “design opportunities” [16,20]. The synthesis and actionability of the findings from the co-research phase were carried out in the co-design and co-refinement phases.

The co-design phase featured a 2-day workshop in the program states where the HCD champions collectively brainstormed over 60 unique ideas from individual concepts and bundled them into 12 distinct robust prototypes of substance that were best suited to address the challenge. In the co-refinement phase, the solutions (prototypes) were tested with the intended users, and their feedback was integrated. This involved redoing, discarding, and refining the solutions based on a rich understanding of the context, and many potential points of failure that have been uncovered and resolved. Following the testing and feedback activity, the most viable solution was selected, one for each state, and a plan of action was created for implementation on a larger scale. These co-design and co-refinement processes were iterative to ensure the most appropriate models were achieved.

Ethical Considerations

The study was carried out between May 24, 2022, and February 23, 2023, and was conducted in strict compliance with the ethical standards outlined in the Helsinki Declaration, ensuring the well-being of the participants. These standards encompassed obtaining informed consent, guaranteeing confidentiality, and safeguarding participants’ rights. Prior to commencement, the research received its ethical approval from the National Health Research Ethics Committee of Nigeria (NHREC) under the approval number NHREC/01/01/2007-15/03/2022 on March 15, 2022.

Results

Participant Groups

In total, 203 interviews were conducted among 97 health care providers, TBAs, and CHIPS (Community Health Influencers, Promoters and Services) Programme agents; 80 pregnant women or nursing mothers; and 26 government officials, with observations conducted at 33 sites across a 3-level continuum of care. Table 2 presents the participant distribution across the states.

The findings were classified based on the 3 HCD phases used in this research. Following the analysis of the data collected in the field during the co-research phase, the strong findings were subsequently categorized under common themes according to the different participant groups as described in Table 2. The findings were further synthesized into insights that were translated into opportunity areas for impact in the co-research phase.

Table . Distribution of study participants interviewed during the co-research phase.

State	Site observation (n=33), n	Doctors, nurses or midwives, TBAs[a], and CHIPS[b] agents interviewed (n=97), n	Pregnant women or nursing mothers interviewed (n=80), n	Government officials interviewed (n=26), n
Kano State	12	33	28	8
Niger State	11	35	26	10
Lagos State	10	29	26	8

[a]TBAs: traditional birth attendants.

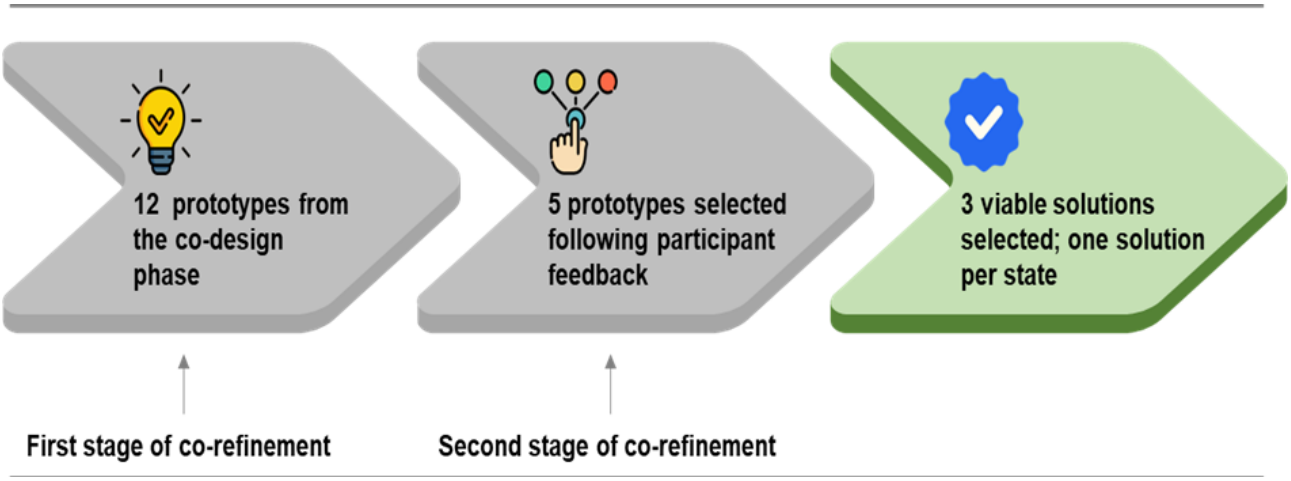
[b]CHIPS: Community Health Influencers, Promoters and Services Programme.

XSL•FO
RenderX

Co-Research: Understanding the User Needs, Goals and Contexts, and Tool Design

All of the activities in the co-research phase ensured a robust and clear understanding of the challenge to be addressed. The key insights from the co-creation phase across the 3 program states included the challenges faced by pregnant women in rural areas concerning affordability, accessibility, and awareness of health care services; health care workers' strong commitment to maternal health despite issues with service efficiency and working conditions; observations indicating inadequacies in equipment and space management within health care facilities; and key informants expressing concerns about the current health care system's ability to deliver adequate maternal care, emphasizing the need for ongoing improvements in service delivery and coordination.

Co-Design: Designing, Piloting, and Testing



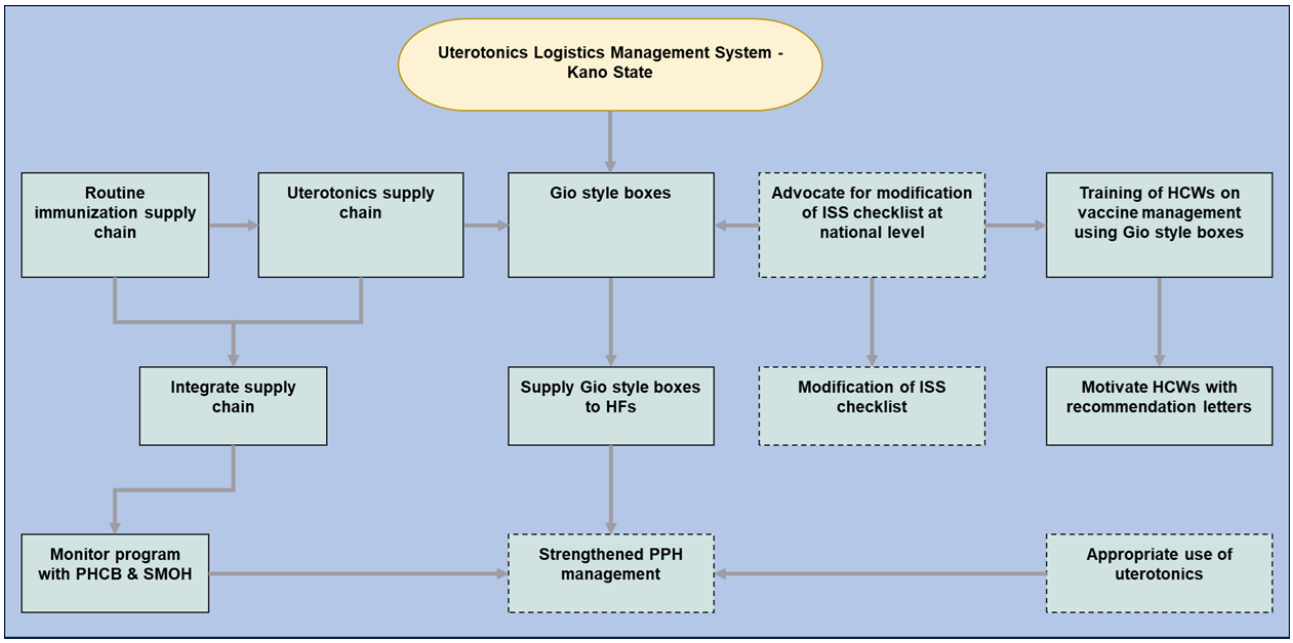
The workshop focused on finding solutions to the challenges from the findings from the co-research phase. These solutions aimed to provide improvements in clinical care and appropriate use of uterotonics for PPH management and treatment.

During the co-design session, ideas and concepts were synthesized, reviewed, and narrowed down to a set of concepts that could be developed for testing. The main components of this phase were framing the design challenge, generating "how might we" questions to proffer solutions to the identified challenge area, brainstorming ideas, creating appropriate storyboards for promising solutions, and conducting rapid prototyping sessions. In this phase, over 100 different ideas were submitted by champions across the various states to resolve the identified challenge statement.

Co-Refinement: Refining the Prototypes

The co-refinement phase comprised 2 stages to contextualize the prototypes developed from the co-creation phase (Figure 2). In the first stage, 12 initial prototypes were carefully evaluated for their suitability to address the state-specific issues and narrowed down to 5 prototypes with the most promising qualities. These 5 prototypes underwent further evaluation in the second co-refinement stage to produce 3 prototypes, one for each state, that best addressed the specific issues related to optimizing uterotonic supply chain systems and health service delivery in managing PPH.

Figure 2. Stages of the co-refinement phase.



Prototype Profile 1

Challenge Statement 1: How Might We Increase the Storage of Uterotonic Drugs in the Health Facilities in Kano State?

The Uterotonics Logistics Management Program is an integrative program that aims to include uterotonics in the general supply chain and storage for routine vaccinations within the state (Figure 3). This program aims to create an advocacy strategy by creating an alliance within the State Ministry of Health to include uterotonics into the integrative supply list for routine immunization.

XSL•FO
RenderX

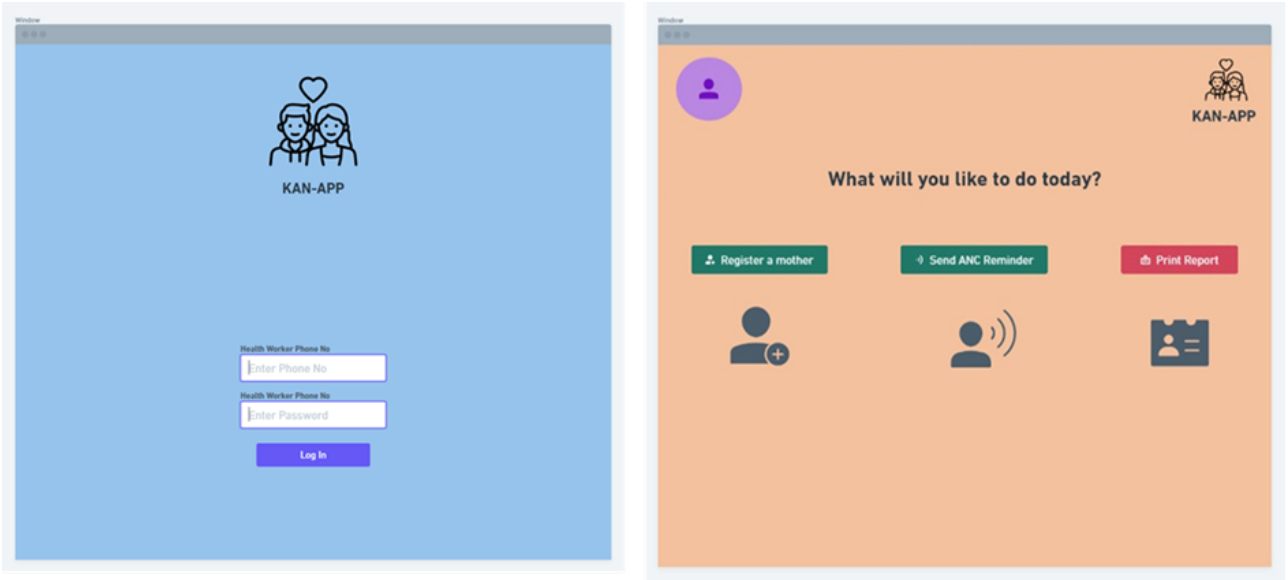


Figure 3. Flowchart of the Uterotonics Logistics Management System. HCW: health care worker; HF: health facility; ISS: integrated supportive supervision; PHCB: Primary Health Care Board; PPH: postpartum hemorrhage; SMOH: State Ministry of Health.

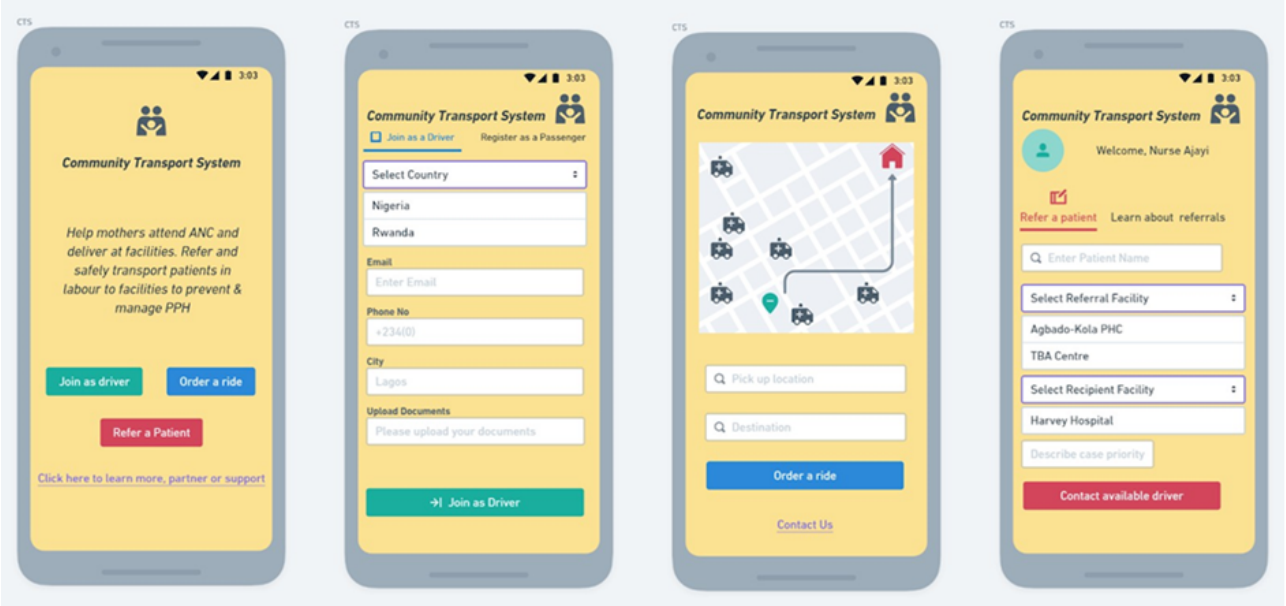
Challenge Statement 2: How Might We Improve Care-Seeking Behavior for Handling PPH Cases Among Women of Childbearing Age in Kano State?

The need to increase the level of awareness about PPH in Kano State is high, particularly due to women's preference for home delivery (Figure 4), a decision that is highly influenced by their spouses. Hence, women of childbearing age may tend to demand health services like ANC following reinforcement from their husbands. The Kan-App program has three core elements for improving care-seeking behavior among women of childbearing age in Kano: (1) health care workers will be able to send reminders to husbands about the ANC visit schedules of their wives; for unmarried women or single mothers, the app will send reminders to their close relatives; (2) distribution of maternity blankets designed with key information on PPH and why women should attend ANC sessions, highlighting the role of the community in identifying the danger signs of pregnancy and the safety of facility-based delivery; and (3) radio programs to educate women on the dangerous signs of pregnancy and delivery.

Figure 4. Kan-App for the increase in the demand for antenatal care services among pregnant women and their families, particularly their spouses.



XSL•FO
RenderX

Prototype Profile 2

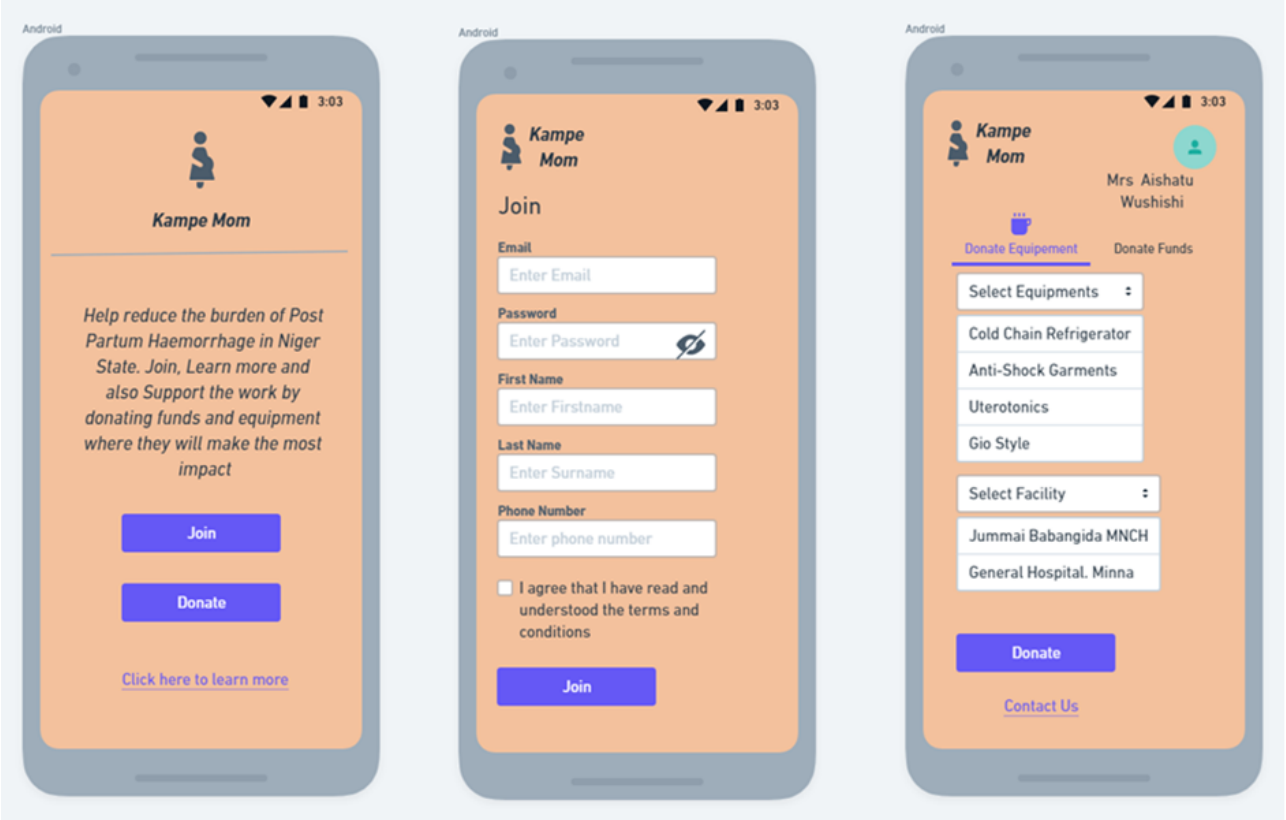
Challenge Statement 1: How Might We Improve the Transportation and Referral Linkage for the Primary Health Care Facilities?

The community-based transport system is a simplified intervention designed to leverage the already existing network of Keke Napep drivers, Yellow Cab drivers, or the National Union of Road Transport Workers (NURTW), as well as the local security agencies in Lagos State (Figure 5). The State Primary Health Care Board in conjunction with the State Ministry of Health will develop a memorandum of understanding with the NURTW, Keke Napep, and the security agencies. A database of drivers will be developed for the 20 local government areas in Lagos State, and drivers will be informed of the MoU (memorandum of understanding) and the program, allowing them to volunteer their services and provide their contact details. Each primary health care (PHC) facility would be furnished with a list of drivers and emergency contacts, which will be shared with pregnant women as well as TBAs nearby. TBAs can use the drivers to refer women to PHC facilities. The key elements of the program include (1) pre-established communication between the health facilities, drivers, and security agencies; (2) a database of the drivers and unique communication lines; (3) unique terrain and level of care specific to hard-to-reach areas and gridlock areas (Keke Napep and Yellow Cabs); and (4) selection (volunteer), remuneration, and recognition of the drivers.

Figure 5. Community transport system app for improving the transportation and referral linkage for the primary health care facilities.

Prototype Profile 3

Challenge Statement 1: How Might We Increase the Storage of Uterotonic Drugs in the Health Facilities in Niger State?



The Niger State Primary Health Care Development Agency (NSPHCDA) Mobile and Electronic Application Platform (Kampe Mom) is an open-source web-based application that visualizes the equipment needs of PHC facilities within the state. This platform will be open to government actors (ministries, departments, and agencies), philanthropists, and organizations who are willing to contribute toward purchasing equipment for PHC facilities based on identified needs (Figure 6). The equipment will be displayed based on the order of priority and needs of the PHC facility at the time. In addition, there would be key events such as charity walks and fundraising events to create awareness of PPH and safe motherhood and generate funds that will feed into the purchase of this equipment for the PHC facilities.

The elements of the solution include the following:

- Registration of 1400 PHC facilities in Niger State on the platform. These PHC facilities will be disaggregated by location, accessibility, patient in-flow, etc.
- Equipment needed in all 25 local government areas will be captured on the platform and open to philanthropists, key decision-makers, legislators, community-based organizations, civil society organizations, women groups, etc.
- Charity walk can be placed on the platform for fundraising.
- Create awareness once a year on May 22, which is the world's safe motherhood day. Progress updates will be provided on programs about maternal and child health.
- The target audience will be pregnant women, fathers, families, policy makers, community and religious leaders and gatekeepers, TBAs/CHIPS agents, other community volunteers, community-based organizations, civil society organizations, etc.

Discussion

HCD Process and Outcomes

While much of the global effort has focused on a health system–strengthening approach to reducing pregnancy-related deaths in low- and middle-income countries [21,22], less energy has been focused on solutions that take into consideration the major challenges mothers go through during pregnancy, so as to develop a client-centered solution that effectively addresses their needs. This research was aimed at proffering solutions to develop context-specific solutions to enhance service delivery for postpartum care in Lagos, Kano, and Niger states using HCD.

In the co-discovery phase, the study was able to uncover critical challenges faced by both pregnant women and health care workers in rural settings, with a focus on maternal health care access and service delivery. Pregnant women primarily struggle with affordability, accessibility, and awareness. Many of these women are housewives in rural areas, with limited financial resources and logistical difficulties in accessing health care facilities [23]. These findings are consistent with existing literature, which highlights that rural women often face significant socioeconomic barriers, including poverty, transportation challenges, and limited access to health care services [24-26].

Health care workers, on the other hand, are very committed to improving maternal health but face challenges resulting from gaps in care levels between primary and secondary facilities. The strain is particularly evident in facilities with high client volumes and limited human resources [27,28], underscoring the need for better support systems for health care providers in these settings. There were also issues of inadequate health care infrastructure, such as insufficient storage systems and overcrowded delivery wards, which could compromise the quality of care provided during critical moments like prolonged labor [28,29]. There is also the issue of the service delivery system, which requires continuous strengthening to meet the needs of these vulnerable populations. Addressing these issues will require a multifaceted approach, which should include a better system for managing the human resource problems, improved health communication strategy, demand generation, and enhanced coordination of care to ensure that both health care workers and pregnant women receive the support they need to achieve better health outcomes [11].

In this research, the co-design phase was aimed at synthesizing relevant questions to create potential solutions for the identified problems affecting the appropriate use of uterotonics and PPH care, particularly in resource-limited settings. This process highlighted the importance of involving the intended users in the HCD co-design process to ensure that the developed solutions are tailored to the specific contexts and challenges identified [30,31]. For instance, the HCD co-design phase was used to develop health solutions to enhance the comfort, health outcomes, and overall satisfaction and experience of patients [16,32].

More than 100 questions and ideas gathered from the initial co-research phase were ideated in brainstorming sessions to identify the 12 most feasible prototypes. These solutions were narrowed down by selecting the questions that most exhaustively discussed the challenges with service delivery for PPH care, suited the contexts in each state, and considered the most

XSL•FO
RenderX

frequently occurring challenges and issues. This was done to ensure the final prioritized questions would generate solutions that would incite the most impact in each state. The brainstorming approach to co-design was used to further foster creative thinking and ideation, as well as generate comprehensive, user-centric solutions [16,33]. The 12 prototypes were further refined to select the most fitting solutions for the 3 states.

The implementation of brainstorming sessions in the co-design phase aided the co-refinement of the 12 prototypes. The collaborative relationships built during this session fostered the iteration and feedback process, ensuring that the prototypes selected aligned with the needs of the users and were actionable and sustainable [33,34]. The 12 prototypes were narrowed down to 3 final solutions, which were selected based on their operationalizability (how well they worked), feasibility (how possible it is to implement), and specificity (how they matched each state's unique challenges).

Challenges Faced and Lessons Learned

Stakeholder Engagement

The project team had to put mechanisms in place to consistently check in and follow up with stakeholders on aligned timelines to ensure the timely execution of activities. Moreover, additional meeting time was allocated with stakeholders for the review of data and findings to generate insights for further validation.

Technical Execution

Priority and preference were given to hybrid engagements or blended delivery to ensure that the entire process was worthwhile and all planned activities were completed in record time. Due to the emergence of the COVID-19 pandemic, the development of an engagement protocol for physical sessions had to be developed in accordance with globally accepted guidelines.

Teamwork

It became apparent that the sharing of lessons learned was instrumental to team bonding and fostered synergy within the team. The project leveraged the expertise and strengths within the consortium in cases where such was necessary.

Program Management

During the course of the project, appropriate and real-time communication channels and structures had to be put in place for the effective passage of information across partners and stakeholders.

Schedule Conflict

Some of the champions were involved in other programs that were running simultaneously as the HCD co-research workshop. This necessitated the modification of the workshop agendas to suit the needs and time demands of the participants. Going forward, the scheduling process should be improved to enable more champions to attend the workshop.

Conclusion

The study has successfully applied HCD to develop unique solutions capable of strengthening clinical care, reducing gaps in the delivery of maternal health services, and driving improvements in the use of uterotonics for PPH prevention and treatment using statements generated from the co-research and co-design phases. The study objective of developing facility-level solutions for optimizing uterotonic supply chain systems and health service delivery in PPH management was achieved through the creation of solutions that were able to increase the demand for ANC services among pregnant women and their families, particularly their spouses, improve the storage and supply of uterotonics, and generate equitable distribution and improved capacity of health care workers to handle PPH. Although the designed solutions do not address all the issues raised, their implementation can strengthen an evidence-based approach to maternal and child health services and, in turn, improve PPH management. This implementation phase will involve deploying the uptake building of the solutions and documentation outcomes, building a comprehensive picture of the entire process, and identifying potential points for intervention.

Study Limitations

First, this study was conducted in only 3 states within Nigeria, indicating that the developed solutions may not be applicable in other regions with different cultural, socioeconomic, and health care contexts. Second, it focused on proffering solutions to improve uterotonic supply chain systems and health service delivery in PPH management, overlooking other critical aspects like cultural and religious beliefs, as well as the quality of care. Third, the short timeframe of the study and the lack of implementation mean that the long-term outcomes or effectiveness of the solutions were not captured.

Acknowledgments

The authors are grateful to all the respondents who participated in this study. We also wish to appreciate the Kano, Lagos, and Niger States' Ministries of Health, and their respective Primary Health Care Boards for their collaboration and assistance throughout the study lifecycle. This publication was supported by funding from MSD, through its MSD for Mothers initiative. MSD had no role in the design, collection, analysis, and interpretation of data, in the writing of the manuscript, or in the decision to submit the manuscript for publication. The content of this publication is solely the responsibility of the authors and does not represent the official views of MSD. MSD for Mothers is an initiative of Merck & Co, Inc, Rahway, NJ, USA.

Abstract

Background: Problem anger is common after experiencing trauma and is under-recognized relative to other posttraumatic mental health issues. Previous research has shown that digital mental health tools have significant potential to support individuals with problem anger after trauma.

Objective: The objective of this study was to describe the co-design and development of a just-in-time adaptive intervention (JITAI) targeting problem anger in individuals who have experienced trauma.

Methods: We used a participatory design process following the double-diamond framework. Phase 1 involved one-on-one qualitative interviews with trauma-exposed individuals with problem anger (n=10). Using an inductive approach (interpretative phenomenological analysis), we thematically coded interview data to create design principles for this population and generate potential content for the intervention. Phase 2 involved academic and clinical experts in trauma and experts in digital health reviewing the Phase 1 results and an evidence-based cognitive behavioral approach to treating anger. We then created intervention content and prototypes, which we then took to workshops with all participants for feedback, using group discussions and ratings of desirability and feasibility.

Results: From Phase 1, core considerations for a JITAI included look and feel preferences, self-led and personalized support and content, and different support needed for each anger stage. A JITAI was developed with the following components: (1) personalized schedules and content onboarding; (2) psychoeducation about problem anger; (3) crisis support; (4) mood monitoring via anger check-ins; (5) self-led and personalized circuit breakers; (6) cognitive-behavioral based skills; (7) and a digital Coach embedded in the app. Some suggested features, such as social networking and sharing data with loved ones, were not pursued due to feasibility reasons relating to participant safety or technical costs.

Conclusions: The resulting JITAI, termed “Shift,” is the first digital mental health tool designed with end users to manage anger after trauma.

Introduction

Problem anger, defined as anger occurring at an intensity, frequency, and duration that negatively impacts an individual and their relationships, is one of the most common posttraumatic mental health issues, and is highly prevalent in predominately male military and first responder populations [1,2], as well as women who have experienced trauma [3]. While cognitive behavioral therapy (CBT)-based treatments can be effective, there are difficulties engaging individuals with problem anger in treatment due to impacts of hostility, mistrust, and interpersonal conflicts on therapeutic relationships [4]. Mental

XSL•FO
RenderX

health practitioners commonly report feeling more drained, more therapeutic ruptures, and providing shorter treatments in response to antagonistic client presentations, resulting in worse outcomes [5].

Advancements in digital mental health tools may provide nontraditional treatment options for problem anger [6]. As an emotion, anger is unique because it manifests as primarily externally-focused, in that an external agent often activates anger, such as how other people have behaved in a hurtful, disrespectful, or otherwise anger-triggering way [7]. Accordingly, interventions that increase internal focus are likely to support greater self-awareness to offset focus on anger-provoking events. Early efforts in this area used digital technologies such as smartphones and wearables to record physiological data, monitor symptoms, and support practicing of CBT-based skills as an adjunct to traditional CBT, and while effective in reducing anger symptoms, did not have additive effects beyond standard psychological treatment [8]. Recent research using wearables and regular mood monitoring delivered via smartphone have shown promise [9]. Despite the potential, there are many challenges to the development of innovative digital mental health tools for anger. First, the overwhelming majority of research into digital mental health tools has focused on depression and anxiety, and the foundation for building anger-focused digital solutions is limited and nonspecific [10]. Second, digital mental health tools more broadly face significant challenges around uptake and usage [11]. Modest engagement with digital mental health apps is due to a variety of reasons including that may include a lack of user involvement in the design, as well as lack of tailoring to suit the times an individual most needs support [12]. As such, digital mental health tools that are designed alongside users and support real-world moments of high need may be beneficial.

JITAI are 1 type of new digital health approach that may overcome challenges associated with low engagement by providing the right information at the right time [13]. JITAIs deliver intervention content that are adapted to an individual's context, such as the level and type of support matched to an individual's current emotional state [14]. Efforts to develop such interventions in physical activity [15], depression [16], substance use [17], and adolescent mental health [18] have shown promise in improving affect, cognition, and behavior. A JITAI includes 6 key elements, namely a distal outcome, proximal outcomes, decision points, intervention options, tailoring variables, and decision rules. While research has established that digital mental health tools for problem anger are feasible, much remains unknown about how to design a JITAI for this population, and more empirical work including data-driven approaches to designing JITAI is needed [14,17]. The aim of this study was to understand the tailoring variables and co-design the intervention options of a JITAI with individuals who have experienced trauma and problem anger, alongside experts in digital and mental health, by understanding:

1. What is the preferred language, visual features, and content of a digital mental health tool to help individuals manage their problem anger?
2. When do individuals need support to manage their anger differently?
3. Taking the findings from above, and combining them with evidence-based CBT-approaches, what is acceptable and feasible content for a JITAI for problem anger?

Methods

Overview

This study had 2 phases, following the double diamond framework (ie, discover, define, develop, and deliver) [19] which is user-centered and well validated in digital health tool research [20]. Phase 1 involved qualitative interviews with individuals with problem anger after trauma (termed "experts by experience") to understand their experiences with digital mental health tools and treatment for anger, their "pain points" regarding day-to-day management of their anger, and views about essential content, features, and functionality components of smartphone-delivered interventions for problem anger. Phase 2 involved co-design workshops with a mixture of experts by experience, and experts by profession, which included digital health experts, trauma researchers, and clinical psychologists to converge on core components of a prototype JITAI, using CBT for anger after trauma principles [21]. Both phases were conducted in line with trauma-informed research principles outlined in the recent Trauma and Resilience Informed Research Principles and Practice (TRIRPP) Framework [22], which aims to improve participation in research by individuals who have experienced trauma and to avoid retraumatization of participants. Specifically, our study involved actively minimizing retraumatization by structuring interview guides so that participants do not have to discuss their trauma, framing the research process as relational, addressing power imbalances by having twice the number of experts by experience than experts by profession, and making available women-identifying groups only for the group sessions, recognizing many women experience trauma as a result of gendered violence. We also made available individual co-design workshops for participants who did not want to engage in group work for any reason.

Phase 1

Participants

A total of 10 experts by experience (5 out of 10 were women; aged 19 - 49 years old) with a history of trauma exposure and problem anger were invited to participate via the researchers' database, which contained a list of individuals who had participated in previous trauma and anger–related research at the University of Melbourne. Participants needed to meet the criteria for problem anger and have reported experiencing a traumatic event previously, be residing in Australia, have access to Zoom, be over the age of 18 years, and be fluent in English. All participants had sought help for their mental health previously, and 4 had received a diagnosis of posttraumatic stress disorder. One individual identified as living with a disability. In addition, 8 participants had previously tried apps to support their mental health. All participants verbally consented to participate in the qualitative interviews. Data were collected virtually via Zoom (Zoom Communications) using audio-video recordings across August-September 2023 by author OM using a semistructured interview guide and interviews lasted

XSL•FO
RenderX

approximately 45 minutes. Interview guides were developed by the research team after reviewing the literature around problem anger experiences, and digital mental health tools. Interview guides are in Multimedia Appendix 1.

Analyses

Qualitative interview data were transcribed verbatim from audio-video recordings. Data were analyzed using NVivo (Lumivero) and using an inductive approach (interpretive phenomenological analysis) by 2 independent coders who were part of the research team, to allow identification of themes about the experiences of problem anger treatments, and views and preferences about content, features, and functionality of the JITAI [23]. Each coder read the transcripts, coded the insights, and clustered the codes into themes. Coders discussed consensus at the insights and themes stage to reach convergence. No formal inter-rater reliability was conducted.

Phase 2

Participants

All participants from Phase 1 were invited to attend Phase 2 and agreed to participate. In addition, 6 experts by profession (ie, clinicians and researchers in problem anger and digital health) were invited to participate. This number was determined to balance the power dynamics between expert types and to ensure experts by experience were not outnumbered in workshops. Experts by profession were identified by the research team based on their expertise in the field of anger, trauma, or digital health and invited directly. Data were collected virtually across October 2023. Focus group sizes varied between 4 - 6 individuals per group and lasted approximately 90 minutes and were conducted via Zoom. Phase 2 were not audio-recorded.

Analyses

The themes from Phase 1 were reviewed by the research team alongside the content from an evidence-based CBT manual developed by one of the authors (DF) for managing anger after trauma [21] to distill into a range of possible content features that could help users manage their anger. These content features, as well as 3 different aesthetics styles developed by the digital health experts after reviewing the Phase 1 data, were then taken to Phase 2 workshops in the form of low fidelity prototypes for discussion about content to keep, alter, or remove [24], with the goal of converging on a final prototype. The app title, and the stages of anger was also the focus of the workshops, in terms of converging on a consensus for how to represent them. Finally, the workshop participants charted components of the possible prototype on a 2 by 2 feasibility (low to high) and desirability (low to high) matrix. Workshop discussions were captured as detailed written notes by the facilitator [OM] and another member of the research team who was observing, and comments typed into the Zoom chat function from participants within each of the workshops relating to suggestions to keep, alter, or remove aspects of content, and the charting results of feasibility and acceptability.

Ethical Considerations

This study was approved by the University of Melbourne Human Research Ethics Committee (Approval number: 2023-26108-39829-4). Written informed consent was obtained for the study. Experts by experience were reimbursed for their time in the form of a voucher ($96.06; AUD $1 = US $1.56) for Phase 1 and 2, while experts by profession were not.

Results

Phase 1

The results from the individual interviews revealed several themes, listed in Table 1, relating to preferences for a JITAI for anger. First, participants described wanting an app that was free, with no ads, and easy to use. Second, several themes relating to design principles were identified. These included the “Look & Feel,” which detailed specific preferences for the language and imagery used in the app. Experts by experience felt that many mental health apps overused the word “calm” and imagery with strong meditation and wellness themes, as well as being too directive, using terms such as “should” and “need” to direct users. As a result, they felt that many mental health apps were condescending and irritating, and worsened anger when used for self-management. The theme “Strengths-based” described preferences of experts by experience for an app that felt supportive and addressed the guilt and shame they felt about their anger. Experts by experience reflected wanting digital mental health tools that feel like a companion: “a trusted mate.” Under the theme of “Personalized,” there was divergence regarding the types of content individuals wanted, such as military and first-responder-specific information explaining the role of occupation in anger, the links between anger and substance use, as well as menstrual health. Strongly linked was the theme “Self-led” which encompassed accounts of who support should come from and how information should be delivered, particularly during heightened states of anger. While the voice of professional experts and lived experience was valued, overwhelmingly, experts by experience conveyed that the person they would listen to was themselves. Conversely, some experts by experience conveyed how complex trauma left them uncertain about trusting their own voice, and thus they would want information delivered to them by an avatar they could create.

XSL•FO
RenderX

Table . Design principles and desired intervention components from qualitative interviews with ten participants aged 19 - 49 years old with a history of trauma and problem anger.

Themes	Example quote
Design principles	
Free and no ads	__[a]
Easy to use	*The most annoying and triggering thing about using an app is when it doesn't do what you want it to do, or you're trying to do something, and then you['re] hit with roadblocks*. [Expert by Experience 1]
Look & Feel	*It would have to be written in a way that it comes from someone that isn't condescending; that doesn't make you angry reading it*. [Expert by Experience 1]
	It tells you to take three deep breaths when you log in on that [mental health app]. I'm like, I don't want to take three deep breaths. I can't. When I breathe, it makes me angry. [Expert by Experience 2]
Strengths-based	*I'm not going to use anything that is just focused on my anger. Like who would want that, just some negative app going [beep] 'you are mad again'. [laughs] praise me for stuff too*. [Expert by Experience 2]
Personalized	*One option could be you could tick in the app, 'these are the things that really affect me and are related to my anger.' And for you, that might be anxiety, it might not be pain or sleep. And then you could also perhaps get support specifically around that. So you have a really personalized kind of list*. [Expert by Experience 1]
Self-led	*Don't tell me what to do straight up*. [Expert by Experience 2]
	I don't want to listen to some expert, no offence. I don't read your textbooks, I don't like studies, theses. I didn't read them. [Expert by Experience 7]
Preferred features of an anger-focused app	
Anger is experienced in distinct stages with different support needed for each stage	*'1 to 10' for my anger- that doesn't mean anything to me. It's out of control, or it's not*. [Expert by Experience 3]
	I want [an app] that … would recognize over time –'okay, he needs an aid, so I sort of guess he's feeling these sorts of things'. And then it would give me something structured more for that for that level for me, rather than just a generic one. [Expert by Experience 4]
Targeting cognition and behavioral aspects of anger	*Rumination is something I've had to work really hard on, because it's caused me a lot of problems recently…I like to say to myself, 'it's done. It's finished, you're safe, it's past.' And I almost take it out of myself and then put it down and say I'm leaving it there. And it's not going any further. And then when I catch myself ruminating about it if I get home, I say no, that's outside of I haven't brought that in I'm not gonna let that come into my calm area of home*. [Expert by Experience 3]
Leveraging physiological data	*I've used a wearable and with the blood pressure and seeing the heartrate, that's very intriguing*. [Expert by Experience 6]
Complimenting current mental health treatments	*If I trusted [a psychologist] and felt like things were progressing, [an app] would be something that I would seek out her opinion on*. [Expert by Experience 7]
Regular check ins	*The process of a check-in and reflecting your anger [is] good, because I never really do that. Like, I don't think anyone does. I don't think anyone really sits there and reflects on how they're feeling or anything like that*. [Expert by Experience 5]
Add-ons	
Social features with other users	*An app that could connect us all, so we don't feel like we're all alone, that we still got an identity, something that although we're doing the app by ourselves, but gives us a feeling that we're not by ourselves*. [Expert by Experience 7]
Sharing data with loved ones	*I would like the app to send something to my husband saying I've had a shocking day, because then that way, he'll be prepared before he comes home*. [Expert by Experience 3]

RenderX

Themes	Example quote
Parenting support	*This is hard for me to admit, but my anger with my kids is such a huge trigger [pause interview due to distress]. Yeah, so anyway, things that help me be a better mum.* [Expert by Experience 8]

[a] —: not available.

In addition to these design features, several other themes emerged in relation to a JITAI for anger. In identifying opportunities to intervene, participants reported that their anger is experienced in distinct stages, highlighting that for them, anger is either increasing, or completely out of control, with different support needed for each stage. Participants also wanted support in the form of ”targeting cognition and behavioral aspects of anger” such as rumination and supporting interactions with others when angry, ”leveraging physiological data” to detect their mood, an app that was “complimenting current mental health treatments,” and “regular check ins” of their anger.

Phase 2

After reviewing Phase 1 results, the trauma experts selected content from an anger-focused CBT-based manual [21] that related to psychoeducation, managing rumination, circuit breakers, cognitive reframing, managing physiological arousal, and assertive communication. This potential content and low-fidelity prototype design options were taken to co-design workshops. The results from the co-design workshop included convergence on the way anger stages should be represented, convergence on the look and feel of the app, convergence on the CBT-based content, and discussions around the feasibility of add-ons. While experts by profession discussed anger in terms of Likert scales (ie, 1 to 10), the experts by experience spoke about how “anger was experienced in stages,” with some individuals likening this to a runaway train. The workshops converged on the following stages of anger, shown in Figure 1: (1) “no anger,” (2) “frustrated” (ie, anger is still within an individual’s control, and while heightened, the individual can engage in cognitive, behavioral, or physiological activities), (3) “out of control” (ie, the individual and/or others are not safe), and (iv) “after a crash” (ie, anger at others has dissipated, and feelings of shame, regret, guilt, anger at self, sadness, and loneliness are high). In terms of content, all the recommended CBT skills were considered feasible. While the add-ons such as social networking and sharing data with loved ones was highly desirable by experts by experience, they were rated low in feasibility by the experts by profession, due to technical challenges, cost, and the lack of information on how to protect users’ safety, so were not included. Parenting support was considered as out of scope for the first iteration of the app.

XSL•FO
RenderX

Figure 1. The tailoring variables of the “Shift” just-in-time adaptive intervention in the form of anger stages.

XSL•FO
RenderX

The results of both phases led to the development of a JITAI named "Shift" (Figure 2 and Textbox 1), combines mood monitoring (ie, 4 daily check-ins on anger stages, with ability to check-in outside of these 4) with tailored CBT-based support based on the stage of anger. When users check-in as "frustrated," 6 CBT and arousal management skills, under the categories of "Body, Mind, and Actions" in (Textbox 1) are made available. When users check-in as "out of control," a personalized circuit breaker preset by the user at the download of the app sends a safe, supportive message, video, photo, image, or song to circuit break the situation. And when users check-in as "after a crash," warm and emphatic audio messages from their "Shift" Coach are sent reassuring them that set-backs are normal in recovery and reminding them to do some self-care to get back on track. In addition to these JITAI components are psychoeducation content available on demand.

XSL•FO
RenderX

Figure 2. Home screen and psychoeducation section of “Shift.”

XSL•FO
RenderX

Textbox 1. Content structure of the just-in-time adaptive intervention "Shift."

Onboarding:

- Welcome and explanation that "Shift" was created by people with lived experience.
- Set up personalized circuit breakers for when anger is out of control.
- Set-up notification schedule for check-ins.
- Switch-off for unwanted information, such as alcohol-related information, menstrual health, and military and first responder.
- Select from one of the 2 coaches, who is a digital voiceover that provides the audio for the app, the welcome message, and the messages provided when an individual reports losing control of their anger.

Psychoeducation:

- Anger after trauma.
- Healthy versus unhealthy anger.
- Baseline arousal and how to reduce stress levels using progressive muscle relaxation.
- How anger is linked to military or first responder roles.
- How menstrual health and anger might be connected.
- How diet, exercise, sleep, connection, and substance use is connected to overall well-being.
- Rumination and how to stop it.
- Assertive communication versus unhealthy communication styles.

Mood monitoring:

- Four daily check-ins on anger stage (ie, no anger, escalating, out of control, and after a crash; Figure 1).

Intervention components:

- When users check-in as having no anger, they are prompted to either practice progressive muscle relaxation, or engage with the psychoeducation components of "Shift."
- When users check-in that their anger is escalating, they are prompted to practice a cognitive-behavioral-therapy–based skill that focuses on the physiological aspect of anger (termed, "body"), the cognitive aspect of anger (termed "mind"), or their behavior when angry (termed "action"). The "body" intervention components are isometric exercises, a targeted form of tension release designed specifically for discharging anger from the body, and cyclic sighing, recognized as the simplest and most effective way to increase relaxation. The "mind" intervention components target stopping anger rumination, and cognitive reframing for anger-provoking situations. The "action" intervention components provide assertive communication skills to use.
- When users check-in that their anger is out of control, they receive one of their circuit breakers established at the onboarding of the app.
- When users check-in that they have had an episode of anger, and behaved in a way they regret, (termed "after a crash"), a warm supportive message and suggestions for self-care are provided by the app coach.

Crisis:

- At any time, users can go into the app and receive tailored helpline information to support a crisis state.

Discussion

Principal Findings

The aim of this study was to co-design and develop a JITAI for individuals who have experienced trauma and problem anger. We engaged experts by experience and experts by profession to establish design principles and content, as well as opportunities to intervene, resulting in the JITAI "Shift." Building on previous work that has used mood monitoring for problem anger [2,9], "Shift" is a JITAI that leverages regular check-ins on anger state as the tailoring variables with bite-sized, digitally delivered CBT-based skills to manage lower levels of anger, and a personalized, self-led circuit breaker for when anger is out of control. "Shift" is now developed because of these findings and a micro-randomized trial is being conducted.

From a design perspective, using individual interviews before group workshops was valuable for managing trauma, sensitive personal issues, and the feelings of shame that can accompany problem anger in experts by experience, as it allowed individuals to generate information about the intervention privately, but then also benefit from sharing ideas in a group format. Other methods within the workshop to improve the participant experience include not using digital tools to collect data, which can be frustrating or challenging to learn to navigate, and not getting participants to actively criticize or provide feedback on each other's ideas. Although there is potential for more work in this area, these findings speak to the importance of research and development of digital mental health tools being

XSL•FO
RenderX

co-designed with potential end users. Emerging research is showing that co-design is an important step to ensuring that digital mental health tools are accessible, appropriate, and effective [24]. Without end-user involvement, interventions could miss the mark in terms of developing effective and acceptable digital health programs. Very little research has used co-design in problem anger, or in the design of JITAI. Our findings are consistent with a study that co-designed a JITAI for children to limit sun exposure, in that both opportune times to intervene, and the content and design of the intervention were uncovered as a result of co-design [25].

Several learnings from this study have significant implications for design of digital mental health tools for understudied populations and problem anger more broadly. First, our results showed that individuals with problem anger often try digital mental health tools focused on symptoms of anxiety and depression and can find these anger-provoking. Second, while previous research has established the value of lived experience stories in digital mental health tools for trauma-exposed populations [26], our study found that individuals with problem anger preferred a self-led approach rather than hearing others stories. Third, our results shows that individuals with problem anger have significant unmet needs in the aftermath of a high anger episode. Finally, our results showed that digital mental health tools must balance a focus on changing pathological thoughts, feelings, and behavior with providing warmth, empathy, validation, and support, all of which are typically provided via the therapeutic relationship in psychological treatment and are at risk of being lost in digital approaches. Important next steps are evaluating the components of "Shift" using methods such as a micro-randomized trial, followed by a randomized controlled trial to validate efficacy.

Limitations

While the study had diversity in terms of gender, some representation of disability, and a diversity of trauma experiences, this study is limited by a sample that contained English-speaking individuals only. In addition, the study only collected qualitative data and work is needed to pilot the intervention to determine acceptability and feasibility of the intervention to individuals who have experienced trauma and have problem anger. Finally, EMA-driven JITAIs can become burdensome for participants, and innovations in sensor-based detection of mood states will likely advance "Shift" [27]. As yet, preliminary work in detecting anger in this population from wearables has found promising results that remain technically challenging to deploy, and sensor-based JITAIs in this space warrant further investigation [28].

Acknowledgments

This study was funded by the Australian National Health and Medical Research Council. This research was supported in part by the Intramural Research Program of the NIMH (National Institute of Mental Health; No.: ZIA-MH002969). The funders were not involved in any aspect of this study.

Abstract

Background: Access to safe abortion care is a reproductive right for all individuals across Canada. Underserved populations are overrepresented among those with unintended pregnancies and particularly those seeking abortion. Yet, few resources exist to help health care and allied helping professionals provide culturally competent and gender-affirming abortion care to such a population group.

Objective: This project aimed to redesign and adapt an existing subscription-based medication abortion mentorship platform into a culturally appropriate and gender-affirming open-access website of curated health professional resources to promote equitable, accessible, high-quality abortion care, particularly for underserved populations.

Methods: We drew on a user-centered design framework to redesign the web platform in 5 iterative phases. Health care and allied helping professionals were engaged in each stage of the development process including the initial design of the platform, curation of the resources, review of the content, and evaluation of the wireframes and the end product.

Results: This project resulted in an open-access bilingual (English and French) web-based platform containing comprehensive information and resources on abortion care for health care providers (physicians, nurse practitioners, and pharmacists) and allied helping professionals (midwives, medical officers, community workers, and social workers). The website incorporated information on clinical, logistical, and administrative guidance, including culturally competent and gender-affirming toolkits that could equip health care professionals with the requisite knowledge to provide abortion care for underserved populations.

Conclusions: This platform contains resources that can increase the competencies of health care professionals to initiate and sustain culturally and contextually appropriate abortion care for underserved groups while clarifying myths and misconceptions that often militate against initiating abortion. Our resource also has the potential to support equitable access to high-quality abortion care, particularly for those among underserved populations who may have the greatest unmet need for abortion services yet face the greatest barriers to accessing care.

(JMIR Hum Factors 2025;12:e63364) doi:10.2196/63364

KEYWORDS

medication abortion; mifepristone; web-based platform; user-centered design; underserved populations; abortion; equitable; accessibility; open-access website; gender-affirming; user-centered; Canada; unwanted pregnancy; framework

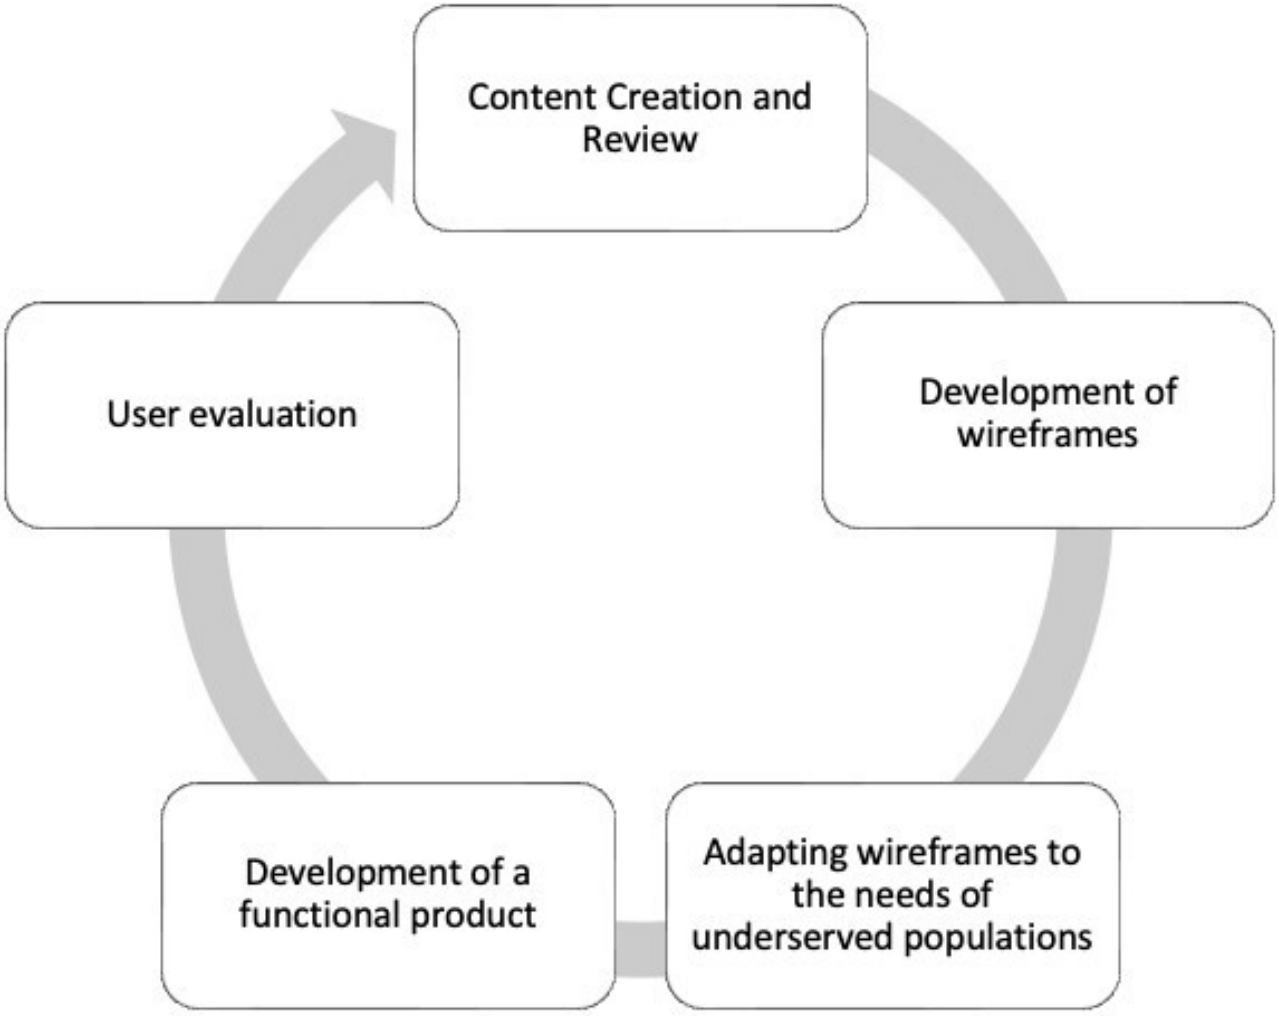
Introduction

Access to abortion is a fundamental human right and a critical component of sexual and reproductive health care [1]. Each year, approximately 56 million abortions occur across the globe—translating to 35 abortions per 1000 women. In Canada, nearly half (~40%) of pregnancies are unplanned, and one-third of women and pregnancy-capable people will have at least 1 abortion in their lifetime [2,3]. Medication abortion using mifepristone is the international gold standard for first-trimester medication abortions and currently accounts for over 50% of all abortions in most European countries and the United States. Canada's unique regulations allow nonphysician prescribers to prescribe and dispense the medication and allow people without

XSL•FO
RenderX

access to ultrasound to access medication abortion services. Despite the loosening of restrictions in Canada, timely access to safe abortion services can be difficult for historically, persistently, or systemically marginalized (HPSM) populations including racialized groups, migrants, Indigenous people, people with disabilities, homeless and underhoused people, sex workers, two-spirit, lesbian, gay, bisexual, transgender, queer, intersex, and gender-diverse (2SLGBTQI+) people, youths, and people living in rural and remote areas [4,5]. For instance, Indigenous people in Canada experience more abortion access barriers than non-Indigenous Canadian people [6]. In addition, approximately 18% of people in Canada traveled more than 100 km to access abortion services [7]. While most clinicians in Canada indicated providing abortion services to underserved populations, the majority of them did not have the appropriate cultural training to provide care to underserved populations. For instance, a recent study suggests that most clinicians in Canada who provide abortion services to underserved populations (91.2%) reported not receiving any form of training for providing care to such populations [8]. A lack of training or mentorship in culturally safe and gender-affirming care would further exacerbate barriers to accessing abortion services that already bedevil underserved populations including Indigenous people [9,10].

To provide culturally safe and gender-affirming abortion services, there is an urgent need to develop, evaluate, and implement training and mentorship resources that will equip health care professionals in providing equitable abortion services to underserved populations in Canada. In this paper, we reported on the processes we adopted in redesigning our already-established web-based community of practice platform into an open-access website. We also highlighted on the considerations for developing a gender-affirming, culturally appropriate, and inclusive web platform to support health professionals in providing abortion to equity-deserving populations. With the internet increasingly becoming a major source of information on abortion [11], an open-access web platform could not only help in disseminating evidence-based abortion resources to all health care professionals but also help in dispelling the myths and misconceptions that often fuel abortion-related stigmas. Furthermore, an open-access web platform could assist in countering abortion-related misinformation or disinformation that is often targeted at health professionals by antichoice groups.



Methods

Study Design

We used a mixed methods user-centered design approach in developing the content and structure of the website [12]. In compliance with the user-centered design process, we engaged with the relevant stakeholders in Canada (health professional associations and abortion advocacy organizations) in 5 iterative design phases. The five phases include (1) content creation and review, (2) development of wireframes, (3) adaptation of wireframes to end-user needs, (4) development of a functional product, and (5) user evaluation. We adopted a user-centered design process to emphasize the clinician-centeredness of the website while revealing the knowledge gaps that need to be addressed to create an inclusive web platform. Figure 1 shows a schematic presentation of the website's development process.

XSL•FO
RenderX

Figure 1. A schematic depiction of the website development process.

Ethical Considerations

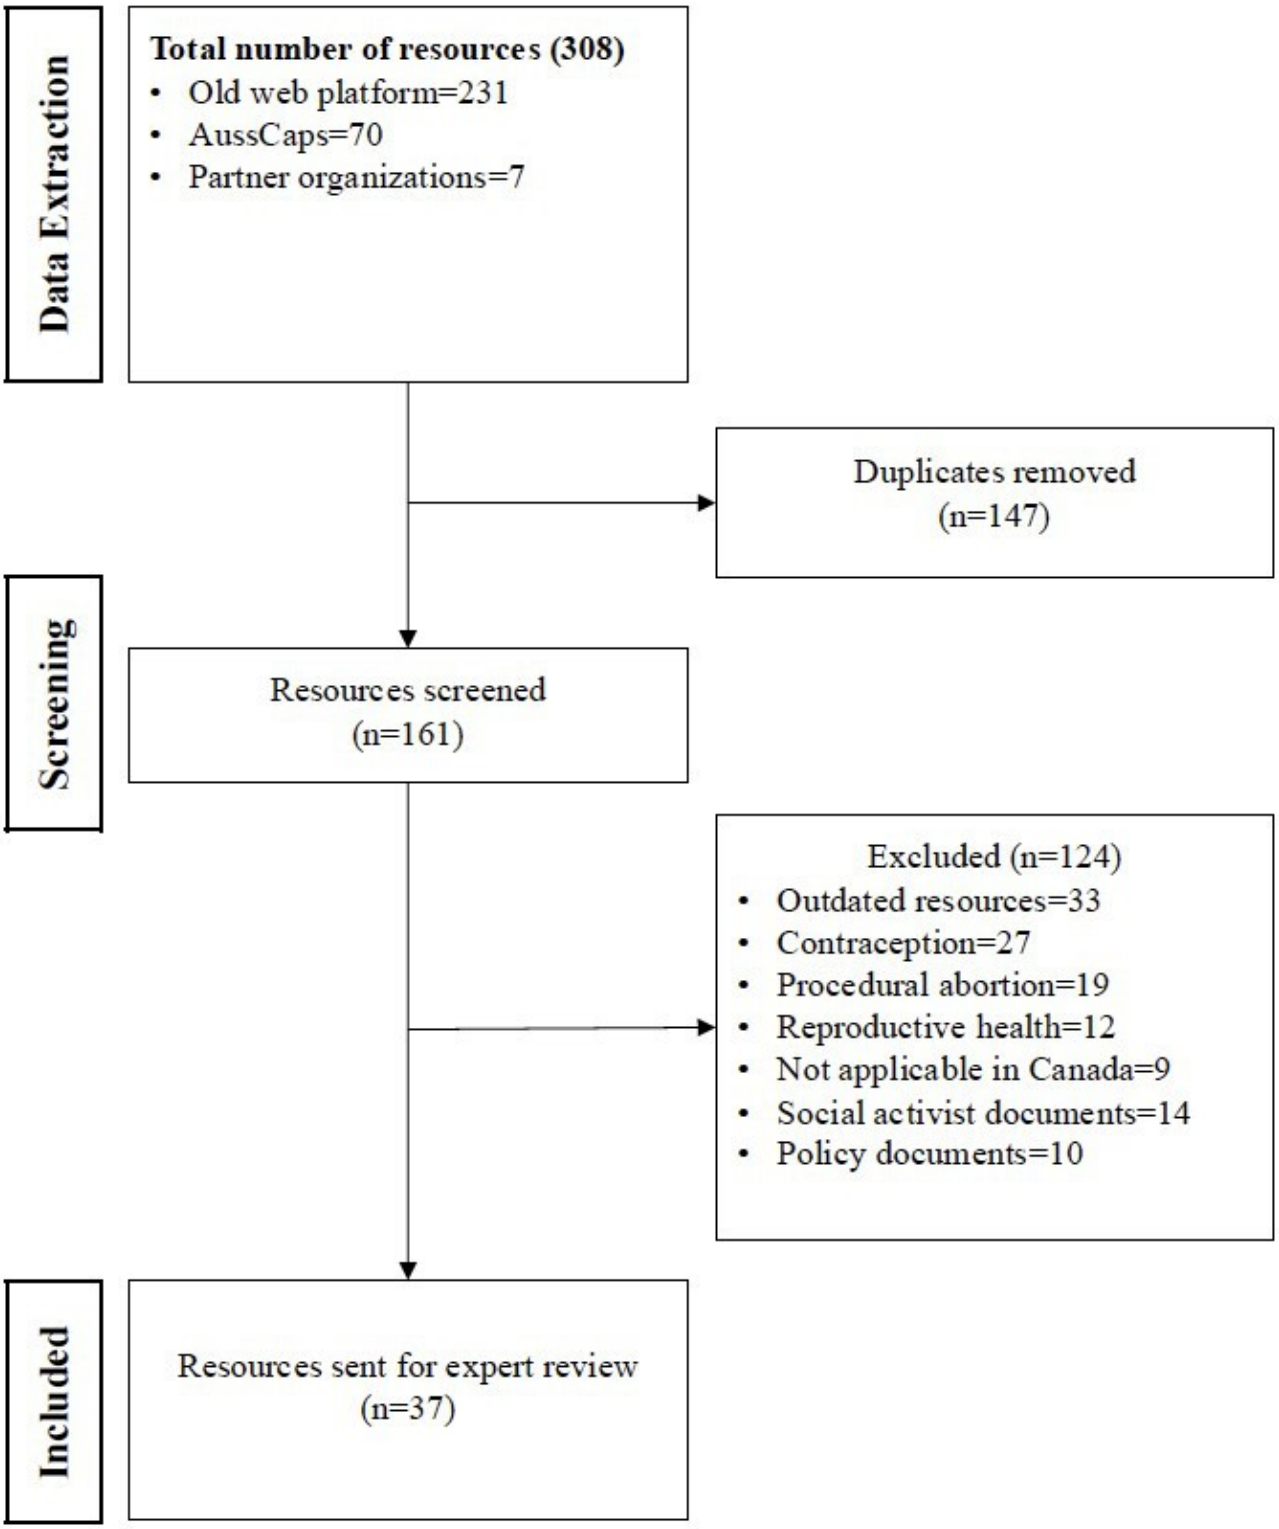
This project was approved by the University of British Columbia Behavioral Research Ethics Board (approval H22-03342). All participants who took part in the interviews were provided with CAD $150 (US $103.34) honoraria.

Phase 1: Content Creation and Review

Overview

The content creation phase comprised 2 steps to ensure that the content is up-to-date and reliable. These include (1) the content curation process, in which we searched for resources that are relevant to medication abortion, and (2) the content review process.

Content Curation



We actively engaged with health professional associations, health regulatory agencies, and sexual and reproductive health advocacy organizations across Canada to curate relevant content for the website. To ensure high-quality, appropriate, evidence-based materials specific to Canadian health care professionals, we focused our content curation efforts on sources within Canada as well as trusted and reliable international evidence on medication abortion. The main sources for curating our content include the national health professional organizations (Society of Obstetricians and Gynaecologists of Canada, Canadian Pharmacy Association, Canadian Association of Midwives, and Canadian Association of Schools of Nursing) and advocacy groups (Action Canada for Sexual Health and Rights and National Abortion Federation) as well as our already-established web-based community of practice platform [13]. We examined relevant resources from a partner website in Australia (the Australian Contraception and Abortion Primary Care Practitioner Support Network) [14]. We limited our focus to medication abortion to enhance relevance and usability for clinicians looking to adopt, improve, and sustain the practice of this newly available service in Canada. After identifying the data sources and establishing a working relationship with stakeholders, we undertook focused data extraction from May 2023 to November 2023. The data extraction process yielded a total of 308 documents detailing resources on medication abortion. These were compiled into a Microsoft Excel sheet, and 147 duplicates were removed. Following this, we conducted an initial screening of the resources by examining the titles, abstracts, headings, and subheadings to determine their relevance to medication abortion. To be eligible for inclusion, each resource must be focused on medication abortion services including clinical (guidelines, protocols, checklists, and factsheets) and nonclinical services (financial, legal, and social). Since our objective was to improve equitable access to abortion among underserved populations, medication abortion resources

XSL•FO
RenderX

focusing on Indigenous populations, racialized groups, and gender minorities were included. Resources were excluded if they were dated more than 20 years ago, not relevant to the Canadian context, beyond the scope of medication abortion, or not targeted to health care providers (ie, physicians, pharmacists, social workers, and midwives). Most papers were not relevant to the Canadian context because of the constant regulatory changes regarding the prescription, dispensing, and use of medication abortion in Canada since 2017 [15-17]. We also excluded resources that were exclusively focused on procedural abortion, contraception, or general reproductive health or illnesses. Procedural abortion resources were excluded because procedural abortion demands specialized training, and we considered a web platform as an inappropriate training source for those seeking to provide this skilled task. After screening the resources against the inclusion and exclusion criteria, 124 resources were excluded, leaving us with 37 resources for a detailed expert review. Figure 2 shows the data extraction and review process.

XSL•FO

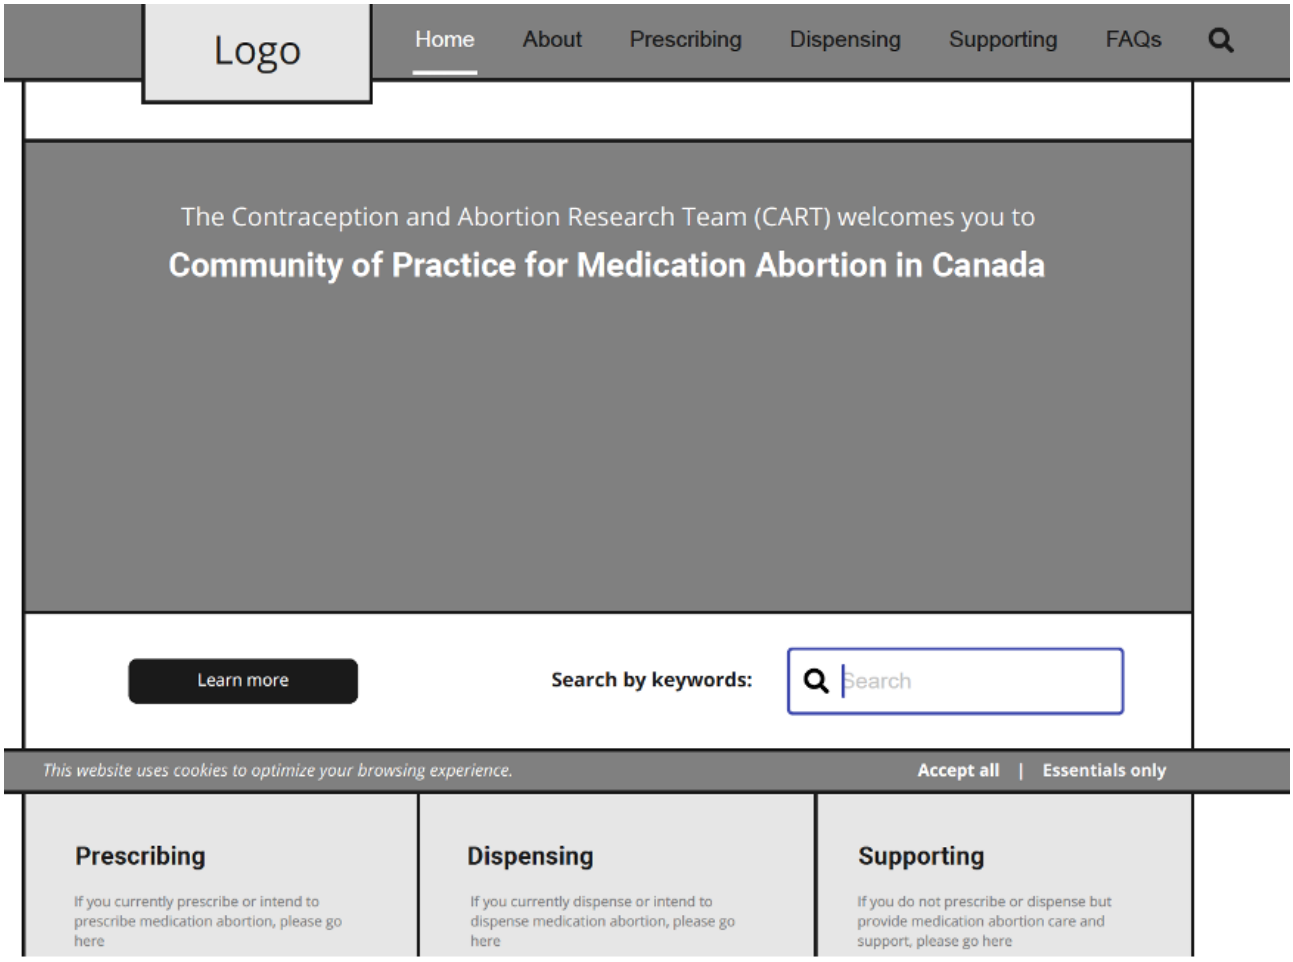
Figure 2. Resource extraction and screening process.

Content Review

Even though the resources were extracted from credible sources, medication abortion regulations and professional practice guidelines in Canada have evolved over time, and with these changes, some of the resources might have become outdated. To ensure our website contains up-to-date resources and is in line with current practices, we engaged 10 health care and allied helping professionals providing abortion services to review the 37 resources for accuracy, currency, and relevance for providing medication abortion, particularly for equity-deserving populations. These health care professionals include physicians, nurse practitioners, pharmacists, and midwives. We asked each health care professional to review each document and respond to the following questions: (1) How do you think this resource will be relevant or useful for you to initiate or strengthen your medication abortion services and why? (2) Please indicate specific parts that you feel are most useful for your practice. (3) Please indicate specific parts that you think are out of date, not useful, or contradict your current practice.



XSL•FO
RenderX

All reviewers provided their feedback within 1 month, and all feedback was compiled into a single document. Following the review, we then engaged 2 experts in abortion care (a family physician and an obstetrician and gynecologist) to discuss and reconcile any differences or contradictory comments by the reviewers. The 2 expert reviewers resolved any differences and wrote a master document containing up-to-date resources on current medication abortion practices. The master file was organized into three main sections including (1) prescriber resources (how medication abortion works, preabortion medication evaluation, postabortion assessment, web-based and hybrid care, physician billing information, regulations, and inclusivity toolkit), (2) dispenser resources (coverage information, patient communication guidelines, checklist for dispensing abortion, and pre- and postabortion assessment), and (3) supporting resources (patient counseling before and after abortion and social worker support resources). This master document was used to inform the content of the website.

Phase 2: Development of Wireframes

Using a web-based design tool known as Figma (Figma Inc), we created wireframes of the website. A wireframe is a visual guide that shows a skeletal framework of a web interface [18]. The wireframe was designed to follow the format of the resources on the master file. The framework depicted the page layout and arrangement of content on the website including interface elements, navigational features, the range of functions to include, and the relative prioritization of content. This wireframe was reviewed by 3 experts in abortion care, and revisions were made regarding space allocation and content prioritization for each of the resource sections outlined in the master file. Following this review, the skeletal framework was then populated with the content from the master file. Figure 3 shows the wireframe of the website.

Figure 3. A screenshot of the wireframe.

Phase 3: Adapting the Wireframes to the Needs of Underserved Populations

After populating the skeletal framework with the revised content, we then conducted a focus group discussion with 14 health care professionals who currently provide, or intend to provide, medication abortion in Canada. The essence of the focus group was to understand how the wireframe can be adapted to equip health care professionals to provide inclusive, gender-affirming, and culturally safe abortions to underserved populations in Canada. We also wanted to identify potential areas for improvement before moving on to developing a functioning website.

Before the start of each focus group, we distributed a visual layout of the website containing relevant content to all participants. The participants were asked to review the visual layouts ahead of the web-based meetings. During the focus group discussions, participants were asked about (1) how the

XSL•FO
RenderX

information on the wireframe could be adapted to support them in providing evidence-based, culturally safe, and accessible abortion services to HPSM populations and (2) any additional features, functionalities, and considerations for ensuring confidentiality, appropriateness, culturally affirmativeness, and supportive resources for improving access and quality of abortion seeking experience for HPSM populations.

The focus groups were led by author AFA, with assistance from RC. Each session lasted approximately 1 hour, and the data were transcribed verbatim. The data from this focus group were analyzed thematically, and the findings (reported under the Results section) were used to modify the Figma designs before moving on to developing a functional product. The findings from the focus groups helped to minimize the design flaws and reduce the possibilities for major changes once a product was eventually developed.

Phase 4: Development of a Functional Website

After making changes to the Figma design, we engaged our software engineers to translate the Figma design into a functioning website. To further explain the Figma design to the development team, we wrote a Systems Requirements Specification Document to further explain the Figma design to the development team. This document included a breakdown of the Figma designs into various components and specifying each design feature as contained in the guide [19]. Figure 4 shows the interface of the functional website. To make sure that the functional product reflects the Figma design and meets the knowledge needs of the end-user clinicians, the development team sought ongoing feedback from our team as well as from the health care professionals who reviewed the resources. We held biweekly consultation meetings with the software development team starting from August 2023 until we had a functional website in February 2024. In compliance with the user-centered design process, we evaluated the functional website with end-user clinicians.

Figure 4. The home page of the functional website.

Phase 5: User Evaluation

We conducted a user evaluation of the website using a think-aloud observation method with 26 health care professionals across Canada. A think-aloud observation is a user evaluation method, in which participants verbalize their thought processes as they interact with a system [20]. The purpose of the user evaluation was to determine the relevance and usefulness of the website in providing abortion services to equity-deserving and HSPM populations, understand the ease of use of the website, detect any design flaws, and make final changes before the website is launched. During the think-aloud observation, we provided participants with 5 tasks related to information retrieval on our website. As participants navigated the website, they verbalized their thought processes by commenting on aspects of the website that they found confusing, difficult to navigate, or irrelevant to their purpose. The think-aloud data were analyzed using simple content analysis. The findings (reported under the Results section) were used to revise the website.

XSL•FO
RenderX

Results

Overview

In this section, we focus on the findings from the focus group discussions of the wireframes as well as the user evaluation of the functional website. Overall, the health professionals who took part in the focus group discussions and the end-user evaluation acknowledged that our web platform was an important educational resource that would equip them with the necessary knowledge to provide abortion care. They also provided recommendations on how this web-based platform could be adapted to support them in providing inclusive abortion care to underserved populations.

Findings From the Focus Group Discussion

Overview

The participants expressed their satisfaction with the layout and the content displayed on the wireframes. They indicated that the various clinical guidelines, factsheets, and checklists on medication abortion would help demystify the myths and misconceptions associated with providing abortion. The usefulness of the resources in demystifying abortion provision was a very important feature considering participants' self-described limited understanding of medication abortion. While acknowledging the importance and potential usefulness of the wireframes, participants noted some limitations on the interfaces of the wireframes and suggested ways in which they could be adapted to improve the capacity of health care professionals to provide abortion services to equity-deserving and HPSM populations. These recommendations fell into 4 thematic areas.

Inclusive and Culturally Sensitive Content

Participants expressed the need for the website to contain inclusive and culturally sensitive language that has the least chance of causing harm to underserved populations including Indigenous, trans, and nonbinary people who seek abortion. To enable health professionals to provide inclusive abortion services to trans people, the participants suggested that the website should contain gender-neutral terms as well as handouts and factsheets on abortion and postabortion care in multiple languages. A physician who provides abortion stated:

> *A lot of my patients can speak English but there are instances [where] I get patients that cannot speak English properly. In such cases, it will be good to have some resources in their language that I can give out to them.*

Some of them also suggested having a print-out function to provide materials for patients who do not speak English. The participants also expressed the need for low bandwidth connectivity to enable health care providers in rural areas with poor internet access to access resources.

Indigenous and Gender-Diverse Resources

The participants also called for the inclusion of Indigenous and 2SLGBTQI+ resources on the website because they indicated that one of the groups facing the most barriers to accessing health services includes Indigenous groups and the 2SLGBTQI+ populations. This could be seen in one of the statements given by one of the participants:

> *it isn't just about understanding the clinical guidelines and factsheets. But we also need to understand the other aspects of Indigenous cultural safety when providing abortion to Indigenous patients like the relationship between abortion care and legacies of forced apprehension/the millennial scoop, information on the knowledge and risk of reproductive coercion (either for or against abortion) etc.*

These calls were particularly made by participants who provide services to Indigenous communities. Other participants indicated a need for a learning hub or short courses on Indigenous cultural safety, gender-affirming, and trauma-informed abortion care—arguing that these additional knowledge sources will help them to provide services to abortion seekers who experienced historical and intergenerational traumas.

Providing Resources for Noninsured Clients

The participants also indicated how the website could be a "one-stop shop" of information if they included information on how to support noninsured clients. This recommendation was made by a midwife who revealed the challenges of providing abortion services for noninsured clients such as undocumented migrants:

> *More than half of my clients were unhoused, or street-involved or living in extreme poverty, or they were refugees, recently landed immigrants, or people of color and trans communities. You know there is a significant intersection between such populations and those living in poverty so there needs to be some resources around how to make sure that these populations are also getting access to abortion services.*

Protecting the Privacy of Website Users and Abortion Seekers

The participants acknowledged the stigmatizing nature of abortion and the need to protect people's privacy. Thus, they suggested including a built-in exit button that would enable users to immediately exit the website, particularly in public places. They also indicated the need for the website to contain geolocation features that can map out nearby abortion providers and pharmacies outside of people's communities. One participant stated:

> *I provide services in a local community, and some don't feel comfortable seeking abortion services from me because I may probably know them. When this happens, it's difficult to refer because they won't even come to you. So, it will be good to have a feature on this platform where patients themselves can search for nearby abortion providers that they can approach with comfort.*

According to the participants, this will make visible nearby abortion providers that could serve as alternative sources for patients who may be reluctant to seek abortion services within

XSL•FO
RenderX

their (particularly very small) communities due to privacy concerns.

Findings From the User Evaluation

Overview

Iterative feedback from the focus group informed changes to the website, as participants serially identified gaps and problems to be addressed before it was launched. Some health care professionals indicated that the functional website felt too medical and was insufficiently focused on the social aspects of abortion. They perceived our banner image on the home page as overrepresenting physicians and not sufficiently acknowledging the role of midwives and supporting professionals. They also made recommendations on how the website could be adapted for navigability and to touch on the stories of underserved populations. The recommendations from the user evaluation fell into 3 thematic areas.

Portraying a Positive Image of Abortion via Visual Effects

Some health care professionals commented that the initial wireframes lacked a human touch and thus suggested adding more vibrant and bright colors that reflect the identities of diverse groups of health professionals and the diversity of patients. Participants felt that such adaptations could portray abortion as something that is considered normal for everyone to seek, normal for every health professional to provide or support, and to ensure the abortion-seeking experience is positive.

> *maybe some colors will be nice because I feel that when I am looking into abortion care, I just want to take this stigma away. So, having colors that are dark for me is like you are doing something bad, right? So maybe having some lighter colors and highlighting on socio-cultural aspects of abortion would be helpful. People need to feel that abortion is normal after going through this website.*

Connecting With Patients

Other health professionals explained that although the website targets health care professionals, it is ultimately about caring for people. They thus suggested that it would be great to have images of health care providers taking care of patients from diverse gender and racial backgrounds or better still include images of patients having children to remove the myth that people seeking abortion are irresponsible adults without children or families. One participant stated:

> *This website is about people getting care. So, we need to see how so many people who have pregnancy termination also have children already. So, it's not just like the unwed single woman who wants to terminate her pregnancy.*

The participants also expressed the need for the website to help health care professionals understand the patient populations most likely to seek abortion services from them. This way, the website would not only provide clinical information but also help providers to connect with the patients' stories.

Making Compromises Between Being Comprehensive and Practical

Many participants acknowledged the comprehensiveness of the website and were confident that they would be able to find relevant information should the need arise. They also acknowledged that being comprehensive might make the website a less suitable quick reference guide, particularly during clinician-patient encounters. This concern could be a challenge for high-volume providers and providers in rural and remote areas. One midwife stated:

> *the information that I'm seeing is actually really good. It's really good information, and I'm intrigued to read more about what's in here. But [it's] too much. It would be really good for like education and training, but not when you have a patient in front of you.*

While this theme was not specifically related to providing abortion to underserved populations, it highlighted the busy schedule of clinicians vis-à-vis looking for information in a dense and cluttered web platform.

Discussion

Principal Findings

In this study, we report on the cocreation of an open-access web-based abortion platform and highlight considerations for promoting access to abortion for underserved populations. This study followed an intersectionality study we conducted with end-user clinicians before embarking on the development of the website [21]. Our study incorporated rigorous engagement of end-user clinicians, and our user evaluation data demonstrated an accessible, acceptable website that could better equip health and allied helping professionals to provide equitable, culturally safe, and gender-affirming resources to equity-deserving and HSPM populations. It is important to note that many health professionals in Canada, including nurse practitioners and midwives, had not received any formal training on abortion as part of their education, leading to limited knowledge and general uncertainties in providing abortion [22]. The limited knowledge may lead to some hesitation in providing abortion, particularly for patients from underserved populations who present with complex health challenges. We believe that this mentorship platform will equip health professionals with the necessary knowledge to provide abortion to patients who face intersecting barriers to access services while also enhancing timely decision-making for health professionals in rural and remote areas. For a time-sensitive procedure such as abortion, expeditious decision-making is crucial to high-quality care for women and pregnancy-capable people who request abortion services.

In addition to information dissemination and helping with decision-making, an open-access abortion web platform may also serve to counter abortion-related misinformation and disinformation that are often targeted at health care professionals. This is important at a time when the proliferation of disinformation, together with the stigma and belief-based refusal to provide legal and appropriate abortion care, creates interpersonal tensions that make it difficult for some health

XSL•FO
RenderX

professionals to meet the reproductive needs of their patients [23,24]. Health professionals may further be disadvantaged when there are frequent changes in medication abortion guidelines and regulations [17]. These changes, together with the need for quality improvement, highlight the importance of such a web-based platform for updating the competencies of health care professionals who provide or intend to provide abortion. This is more relevant, as there is an increasing call for the timely integration of research evidence in routine clinical practice [25].

Our findings suggest that adopting a user-centered design in this project resulted in a platform that was largely considered by potential end-user clinicians as inclusive. While engaging stakeholders from diverse clinicians and organizations was quite challenging, we acknowledged that the process was essential to fulfill the principles of user-centered design. Our team believes that the active engagement of clinicians, health professional organizations, and abortion advocacy groups in cocreating this web-based platform enhanced the appropriateness of the content while facilitating clinician recruitment, dissemination, and subsequent uptake of the resource among end-user health care professionals.

It is also important to note that few digital health projects are designed from gender equity and Indigenous rights perspective [26]. In the context of abortion-related websites, intersectionality is particularly important, as it helps illuminate ways in which the website could be tailored to the needs of the population subgroups facing the most barriers in access to abortion (racialized groups, migrants, people with disabilities, homeless and underhoused people, sex workers, 2SLGBTQI+ people, Indigenous people, and youths) [21,27]. Indeed, available evidence suggests that such minority groups are overrepresented among those with unintended pregnancies and particularly among those seeking abortion [28-30]. Therefore, engaging with a group of health professionals who serve diverse populations in developing and evaluating our web platform made the website unique, as it cedes all decisions on the content and structure in the hands of the end-user clinicians who may have first-hand experience in providing services to underserved populations. This approach to developing our website supports the vision of “design justice” where the community owns the design artifacts [31]. By cocreating with health care professionals, we were able to generate website content that illuminates ways health care professionals can provide abortion services to underserved populations who present with complex, historical, and intersecting health challenges. This approach is more likely to lead to a seamless translation of the web platform into practice since the clinicians and partner organizations were more or less coowners of the end product.

Creating web platforms that are inclusive of equity-deserving and HSPM populations requires more than just technically sophisticated algorithms but a deep understanding of users’ needs and specific considerations that promote inequities in access to health care [32]. The inclusive design recommendations from the participants in this study were aimed at equipping health care professionals with the necessary tools to address inequities in access to abortion care. The integration of low-bandwidth connectivity for instance would improve accessibility of the resources to health professionals in rural and remote areas with low internet connectivity. Improved web access could help improve abortion access in rural and remote areas where medication abortion might be the only, or most accessible, option [33]. Furthermore, the recommendation for including geolocation services could help address abortion-related stigma and provide better privacy for abortion seekers in communities with conservative values around abortion. While the argument for geolocation features was seen as a way of helping patients easily locate abortion providers and pharmacists, some were concerned that geolocation services could be used by antichoice groups to target abortion providers. Additional security measures may be needed if geolocation features are to be implemented on abortion-related web platforms.

Limitations

Our study was not without limitations. Even though our objective was to design a web platform that supports health care professionals to provide equitable access to abortion for underserved populations, we did not rigorously engage abortion seekers the same way we engaged with clinicians. A future improvement would be to engage the patients’ voices in resource development to better reflect the peculiar needs of underserved populations. Our ultimate goal for this website is to empower health care professionals to provide equitable and inclusive abortion to underserved populations. However, we cannot ascertain if we have achieved that objective at the time of writing this paper. Future evaluation reports from users would tell us if the resources provided in this platform are indeed useful in providing abortion services to underserved populations. Furthermore, the participants made several recommendations in the focus group and the user evaluation that were not implemented mainly due to time and resource constraints. While we acknowledge this as a limitation, it is not uncommon to see such limitations in digital health projects, as it is practically impossible to implement all findings from user evaluation [34,35]. Finally, even though we planned to recruit health professionals who identify as or have expertise in providing abortion services to underserved populations (ie, racialized people, migrants, people with disabilities, homeless and underhoused people, sex workers, 2SLGBTQI+ people, and youths as well as those living in or providing abortion services in rural or remote areas), it was difficult to find health professionals who identify as or has expertise in all these diverse populations. Therefore, some phases were completed without adequate input from health professionals with expertise or experience in providing abortion services to underserved populations.

Conclusions

Drawing on a user-centered design approach, we cocreated a gender-affirming and culturally appropriate open-access mentorship platform with and for health care professionals to support the equitable provision of abortion in Canada. We believe that a platform of this nature would increase medication abortion awareness among health care professionals and destigmatize abortion care while clarifying the myths and misconceptions that often create tensions and foment general

XSL•FO
RenderX

uncertainties in initiating and sustaining abortion care. With underserved populations more likely to have unintended pregnancies than the general population [36,37], a website that specifically seeks to improve the competencies of health care professionals in providing abortion services to this population is important and timely. We believe that this platform has the potential to enhance the knowledge and expertise of health care professionals, particularly those in rural and remote areas on how to initiate and sustain abortion care for HPSM populations in Canada who face the most barriers in access to health services. This platform is also expected to provide the necessary resources needed to support health care professionals in providing evidence-based and culturally safe medication abortion for health care professionals in rural and remote areas.

Acknowledgments

The funding for this project was received from the Health Canada Sexual and Reproductive Health Fund under the Health Care Policy and Strategies Program. The authors would also like to acknowledge the Health Professional Association (ie, Society of Obstetricians and Gynaecologists of Canada, Canadian Pharmacy Association, Canadian Association of Midwives, and Canadian Association of Schools of Nursing), advocacy groups (Action Canada for Sexual Health and Rights and National Abortion Federation), and health care professional participants who provided diligent reviews of the resources.

Conflicts of Interest

Abstract

Background: Assessing the daily lives of older adults, including their activities, social interactions, and well-being is essential, particularly in nursing homes, as it gains insights into their quality of life. Methods such as the Microsoft Excel-based Maastricht Electronic Daily Life Observation (MEDLO) tool are time-consuming and require extensive manual input, making them difficult to use.

Objective: This study aimed to develop an app-based version of the MEDLO using a user-centered design (UCD) and co-design approach to enhance efficiency and usability. We looked to actively involve researchers and care professionals who have used the MEDLO before, throughout the development process.

Methods: Participants included a diverse group of researchers and care professionals experienced in using the MEDLO tool. The UCD approach involved multiple iterative phases including semistructured interviews, user research sessions, and application development. Data were analyzed using a qualitative (thematic) approach of UCD and user research sessions. The app, which was preferred to the traditional Excel-based MEDLO, underwent multiple iterations. This method primed the continuous iterative development of the app, aimed for a minimum viable product (MVP).

Results: This study included 14 participants, primarily female, from diverse professional backgrounds. Their feedback highlighted the need for efficiency improvements in tool preparation and data management. Key improvements included automated data handling, an intuitive tablet interface, and functionalities such as randomization and offline data syncing.

Conclusions: The iterative development process led to an app that aligns with end-user needs, indicating potential for improved usability. Early and continuous user involvement was key in enhancing the application's usability, demonstrating the importance of user feedback in the development process.

Introduction

Assessing the daily lives of older adults, particularly in the context of nursing homes, is essential for gaining insights into quality of life [1,2]. It allows health care providers to detect and address issues related to their physical health (eg, mobility limitations, pain), mental well-being (eg, mood disturbances, cognitive decline), and social interactions (eg, isolation, engagement in activities) in a timely manner [1,3,4]. This information can then be used to personalize care plans, thereby potentially improving health outcomes and enhancing the overall quality of life of older adults [5,6].

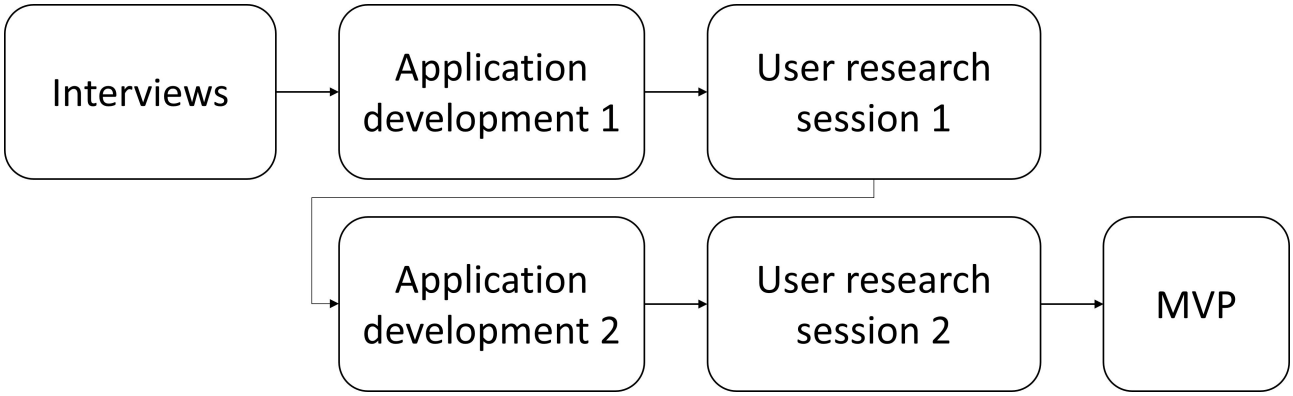
Ecological momentary assessments (EMAs) have been developed to facilitate this process by providing real-time, on-site evaluations of an individual's well-being [5,7,8]. EMA involves collecting data on individuals' behaviors and experiences in their natural environments, which can then be used to identify patterns and inform interventions [7]. However, existing EMA tools are mainly used in research settings, and their implementation in clinical practice has been challenging due to the time-consuming nature of data collection and the complexity of the tools [9,10]. The Maastricht Electronic Daily Life Observation tool (MEDLO-tool) is designed to assess the daily lives of nursing home residents using EMA methodologies [1,4]. The tool captures real-time information across several key dimensions of daily life, including activity levels (eg, participation in communal or solitary activities), agitation, mood states, and interactions with staff, fellow residents, and visitors [1,4,11]. By systematically observing and recording these

XSL•FO
RenderX

aspects, the MEDLO-tool provides a nuanced view of residents' experiences, which can inform personalized care strategies [4]. However, the MEDLO-tool relies on Excel templates that require significant manual input and are not user-friendly for care professionals [1,4]. The complexity of the Excel-based system poses significant challenges, including data entry errors, time inefficiency, and barriers to widespread adoption in clinical settings [12,13]. This complexity can be particularly problematic in nursing homes, where staff may have limited time and technological proficiency [13].

Developing a mobile application for the MEDLO-tool could address these challenges by automating data collection processes, reducing manual input, and providing an intuitive interface for users [14,15]. An app could streamline observations, enable real-time data analysis, and facilitate immediate feedback to care providers, thereby enhancing the tool's use in clinical practice. Furthermore, considering the unique needs of residents with dementia, it is important that such an app is designed to account for cognitive impairments and communication difficulties [16,17]. The development of such an app requires a thorough understanding of the needs and preferences of the end-users. A user-centered design (UCD) approach is vital for developing software that truly meets users' needs [14,18]. UCD emphasizes involving users throughout the design process to ensure that the product aligns with their requirements and preferences [19]. This involves iterative cycles of user need assessment, design, prototyping, and testing [20].

Co-design, a component of UCD, involves direct collaboration between users and designers, requiring the active participation of users in generating ideas, making decisions, and solving problems [21,22]. This not only ensures the software's functionality but also its usability [21].



Potential barriers to implementing such technology include technological literacy among staff, user engagement, and ensuring data privacy and security [13,23]. By actively involving care professionals and stakeholders in the design process, we aim to create a tool that is both functional and user-friendly, facilitating its adoption in clinical practice and ultimately improving the quality of care for residents with dementia. Therefore, this study is aimed at developing an app for measuring the daily life of residents with dementia living in nursing homes, using a user-centered and co-design approach.

Methods

Study Design

This methodological study aimed to develop a mobile application version of the MEDLO-tool for use in long-term care facilities, using a UCD approach [24-26]. The study unfolded in multiple iterative phases, including semistructured interviews, user research sessions, application development, and comprehensive data analysis, as illustrated in Figure 1. The project culminated in the achievement of a minimum viable product (MVP).

Figure 1. The iterative process of app development. MVP: minimum viable product.

Participants

Participants were selected through purposive sampling to include individuals with experience using the MEDLO-tool. The sample consisted of researchers and health care professionals affiliated with Maastricht University and local nursing homes. Inclusion criteria were previous use of the MEDLO-tool and willingness to participate in the study. A total of 14 participants were recruited, comprising research assistants, PhD candidates, postdoctoral researchers, senior researchers, occupational therapists, research coordinators, and associate professors.

Data Collection

Data collection involved semistructured interviews and user research sessions conducted between January and June 2023.

Interviews

Semistructured interviews were guided by a comprehensive list of topics derived from available literature and consultation with the researchers who developed the original MEDLO-tool [1,4]. The interview guide can be found in Multimedia Appendix 1. The interviews aimed to gather insights into participants' experiences with the Excel-based MEDLO-tool, usability issues, functionality requirements, data analysis techniques, and general impressions [27]. Each interview lasted approximately 45 to 60 minutes and was audio-recorded with participants' consent. The audio was transcribed verbatim for analysis. The interview guide is provided in the supplementary materials.

The interview transcriptions were subjected to a 6-phase thematic analysis process, aligning with the methodologies supported by previous research [28-30]. The inductive analysis was conducted by one researcher. A second researcher reviewed

XSL•FO
RenderX

the coding to enhance trustworthiness. This comprehensive process involved familiarization with the data, generating initial codes, identifying themes, reviewing themes, defining and naming themes, and ultimately, reporting the results. The resulting report summarized the key findings, interpretations, and implications, to provide valuable insights for the next stages of the development of the app.

User Research Sessions

A total of 2 user research sessions were conducted monthly to involve participants in the iterative development process. The session guide can be found in Multimedia Appendix 2. Each session lasted approximately 2 hours and was held at Maastricht University. Participants interacted with app prototypes using tablets and smartphones provided by the research team. The sessions included guided tasks (eg, completing an observation using the app), open-ended discussions, and interactive feedback activities facilitated by researchers using prototypes and interactive demos. The structure of these sessions was informed by previous co-design methodologies [1,3,31].

Data Analysis

Qualitative Analysis of Interviews

Interview recordings were transcribed verbatim and analyzed using thematic analysis following Braun and Clarke's 6-phase approach [28]. A total of 2 researchers independently coded the transcripts to enhance reliability. Initial codes were generated and organized into potential themes. Discrepancies in coding were discussed and resolved through consensus meetings. Themes were reviewed and refined to ensure they accurately represented the data. The final themes captured key insights into the usability and functionality of the MEDLO-tool, informing the app development. The overall process of thematic analysis was guided by earlier works in this field [29,30]. The session guide is provided in Multimedia Appendix 1.

User Research Sessions

Each user research session included guided tasks (eg, completing an observation using the app), open-ended discussions, and interactive feedback activities facilitated by researchers using mock-ups and interactive demos. Feedback from user research sessions was documented through field notes and audio recordings. An inductive content analysis was conducted by one researcher, who coded feedback and categorized issues into 4 themes: layout, functionality, errors, and appearance. A second researcher reviewed the coding to enhance trustworthiness. This categorization allowed the development team to prioritize user concerns based on frequency and severity, ensuring a user-centric approach to app refinement.

Application Development

The application was developed using ".NET MAUI" (ie, a framework designed by Microsoft) for cross-platform compatibility on iOS and Android devices. The server-side (ie, where the data are sent to) used "ASP.NET Core" (ie, a framework designed by Microsoft) for a maintainable and performant application. The development process was iterative, with weekly meetings between developers and researchers to integrate user feedback from the interviews and user research sessions.

Usability testing involved participants completing specific tasks using the app prototypes while researchers observed and noted any issues. Testing sessions were conducted in a controlled environment to simulate actual usage conditions. Feedback from these tests informed further refinements and addressed potential adoption or feasibility issues.

Ethical Considerations

This study did not require formal ethics approval under the Medical Research Involving Human Subjects Act (WMO). In the Netherlands, research that collects only anonymized or nonsensitive feedback—without requiring participants to undergo procedures that affect their physical or psychological integrity—is not considered WMO research and is therefore exempt from ethics review. The guidelines provided by the Central Committee on Research Involving Human Subjects clarify that retrospective or noninvasive studies using aggregated or anonymized data do not fall under the scope of the WMO [32]. The Maastricht University Medical Center+ Research Code also confirms that studies conducted with minimal risk, such as those analyzing collective feedback, do not require formal ethical review. All participant feedback was anonymized and is presented in aggregate form to ensure confidentiality [33].

Results

Sample

The study involved 14 participants with an average age of 36 (SD 10; median 39; range 24 - 57) years, and 93% (13/14) of them were female. The participants represented a diverse range of professions, including research assistants (n=3), PhD candidates (n=4), postdoctoral researchers (n=2), a senior researcher (n=1), an occupational therapist (n=1), a research coordinator (n=1), an associate professor (n=1), and an individual who was currently unemployed. Most participants (9/14, 64%) were affiliated with Maastricht University, while others worked at health care providers (4/14, 29%) or were unemployed (1/14, 7%). The average duration of employment at their respective institutions was 6 (SD 5; median 6; range 0.5 - 16) years.

All 14 participants had previous experience with the MEDLO-tool; 12 (86%) participants had used it directly in their research, while 2 (14%) participants had used it as inspiration for developing other tools different from MEDLO. All participants had also been in contact with the developers of the MEDLO-tool. Table 1 presents the demographic information of the participants in detail.

XSL•FO

Table . Demographic information of the participants.

Characteristic		Values
Age (years), mean (SD)		
	24 - 57	36 (7.7)
Gender, n (%)		
	Female	13 (93)
	Male	1 (7)
Time at institution, mean (SD)		
	6 months to 16 years	6 (3.3)
Use of the tool, n (%)		
	Used in research	12 (86)
	Inspiration for another tool	2 (14)
Contact with developers, n (%)		
	All participants	14 (100)
Participants' affiliations, n (%)		
	University	9 (64)
	Health care provider	4 (29)
	Unemployed	1 (7)

Interviews

The participants described the process of using the MEDLO-tool in research projects as comprising 7 distinct phases: (1) acquiring informed consent, (2) preparing the Excel sheets before the observation, (3) familiarizing themselves with the faces of the residents who would be observed, (4) conducting the observations, (5) fixing issues with the data (such as missing values or inconsistencies), (6) analyzing the data, and (7) communicating the data back to the care organizations.

Participants emphasized that the preparation of the tool and the subsequent data cleaning were particularly time-consuming and would significantly benefit from automation. One participant stated, "Every time before we do a new observation, we have to look at the participants, randomize them several times, and input all of this into the Excel sheet." Another participant highlighted the challenges faced after data collection, "After the observation is done, I have to go through the whole document to check all the fields that I didn't have time to fill out or that I didn't know how to rate." These comments reflect the manual and labor-intensive nature of the existing process, which participants found cumbersome.

Participants reported that during observations, they used separate pieces of paper to write down descriptions of each resident's appearance because the observation periods were too short to input this information into the Excel sheet in real time. They suggested that having an additional field to securely write this information directly on the tablet would make the process more accessible. One participant explained, "We usually arrive at least half an hour earlier, so we can ask the nurses which participant corresponds to which name, and write down what they look like. We do that to find them back more easily during the observation." Another participant elaborated on the logistical challenges, "The data entry process on the tablet is intuitive, but we also have to keep track of the patient names and descriptions on paper, we carry the manual, and we use a timer on our phone to ensure that we don't spend too long on any resident. This is a lot to carry around." Regarding data reporting, participants indicated that the data reported back to the nursing homes primarily consisted of quantitative measures, which could potentially be automated through a dashboard (eg, Microsoft PowerBI). Participants expressed that automating this process would reduce the time between data collection and reporting, which currently could be several months. One participant noted, "When we want to report back the numbers to the care organization, we make a PowerPoint presentation that includes aggregated numbers. This usually takes place several months after the observations." Another participant suggested: "I think some of the numbers could be reported back automatically."

Overall, participants preferred using a tablet compared to using pen and paper, citing the intuitive data entry process. However, they also mentioned that a tool compatible with smartphones would be beneficial, especially for care professionals who might find tablets less convenient. One participant remarked, "I think the tool works well, but I'm not sure if it would be usable like this for nurses."

Initial User Research Session

Based on the information gathered during the interviews and the suggested points for improvement, an initial version of the application was created and provided to the participants for the first user research session. This first draft of the application consisted of an dashboard web application and a mobile app, both of which included the core components but had limited functionality. Multimedia Appendix 3 shows the app and dashboard as they were presented to the participants. Multimedia

XSL•FO
RenderX

Appendix 4 provides a detailed overview the feedback received during the initial user research session.

During the initial user research session, participants expressed largely positive sentiments towards the concept of the application and appreciated the efforts made in its development. One participant commented, "I know we have a lot of complaints about the app, but we really appreciate the work [the development team] has done already." However, participants also identified several areas for improvement. They expressed concerns regarding certain features of the app, such as the timer functionality, which lacked a reset option. Participants noted that in their current practice, they used interval timers on their phones to manage observation times for each resident, and the app's timer did not adequately support this need. One participant suggested, "What could be nice is some kind of interval timer. That's what we currently use on our phones." In addition, participants missed the comprehensive overview provided by the Excel-based MEDLO-tool, as the prototype app had been designed primarily for phone screens and did not offer the same level of data visibility. One participant observed, "Normally, you could easily scroll back in the overview." Furthermore, there were some unclear aspects of the app, such as certain functionalities being available only through the dashboard and not within the app itself. Participants found labels on buttons to be unclear, which led to confusion during navigation. They recommended improving the screen layout for better usability and enabling easy switching between participants by a list.

Participants raised concerns about data storage and security, even though these aspects had been addressed in the app's design. They questioned how the data was stored and whether it was encrypted. It was explained to them that the data was stored on the device (ie, phone or tablet) in encrypted form and could be synced to a secure server. Regarding randomization, participants asked how it would be conducted within the app and where they could access this feature. It was clarified that randomization was performed automatically upon creating a new observation group. A participant inquired, "How do I randomize the participants in the app?" To which the response was, "That is done automatically when an observation group is added."

Participants inquired about features that had not yet been implemented but were planned for future updates. For example, they asked if the app would work offline, which was an important consideration for use in environments with limited internet connectivity. They also asked whether the data could be exported to Excel for further analysis. These features were already part of the application's development roadmap but were not yet available in the user interface at the time of the session. One participant expressed concern, "I don't know if it's an issue when I lose connection, or whether I lose my data." Another participant discussed data export capabilities, "These are the data you see when you download the Excel file. With Excel, it looks a bit different, but what you see here are all the column names."

Second User Research Session

Following the initial user research session, the app was updated to address the feedback received. Adjustments were made to the timer functionality, screen layout, language translation, and several other features as per the participants' suggestions. A second version of the application was then provided to the participants for the subsequent user research session. In Multimedia Appendix 5, the feedback received during the second user research session is detailed.

In the second session, participants expressed fewer concerns regarding the application, indicating that many of their initial issues had been resolved. However, they still provided valuable feedback on functionality and appearance. One of the main concerns was that the app was not yet fully translated into Dutch; while significant progress had been made, some parts remained in English. Participants emphasized the importance of complete translation before the app could be effectively used by nurses and other care professionals. One participant remarked, "Most of the app has been translated, but some of the texts are still only in English." Another participant added, "This all needs to be translated before we can hand this to nurses."

Participants also suggested that the criteria for showing and hiding fields during observations should be further refined based on relevance, to streamline the data entry process and reduce cognitive load. They discussed various small changes in the appearance of the app to enhance usability and visual appeal. For instance, they recommended that the "star" button used to mark important observations be made a different color to stand out more prominently. One participant suggested, "Could you make the star button orange to make it stand out a bit more?" In addition, participants found the criteria for marking an observation as "complete" to be somewhat confusing. They proposed that once an activity has been set for an observation, it should be automatically marked as complete to provide clearer feedback to the user. One participant explained, "I would prefer it if the observation could be marked as 'complete' when the activity has been set." Participants also recommended offering flexibility in the number of observation rounds that could be added, as different research protocols or care routines might require varying numbers of observations. They suggested making the process more efficient by creating a priority list or extending the default time block for certain observations that typically take longer. Furthermore, participants emphasized the importance of ensuring that the app's manual could be accessed from within the app itself. They stressed that the manual should be clear, comprehensive, and align with users' practical experiences to facilitate ease of use, especially for new users.

By the conclusion of the second user research session, participants expressed optimism about the app's potential to improve their workflow and reduce the time spent on manual data entry and processing. They acknowledged the responsiveness of the development team to their feedback and looked forward to future iterations of the app that would incorporate their latest suggestions.

Discussion

Principal Findings

This study successfully developed an app-based version of the MEDLO-tool aimed at assessing the daily life of residents with

XSL•FO
RenderX

dementia in nursing homes. By using a UCD approach, we incorporated feedback from participants throughout the development process, resulting in a minimum viable product that aligns with the needs and preferences of end-users.

The iterative development process revealed that larger issues, such as bugs and significant feature requests, were identified and addressed in the initial phases. Subsequent user research sessions showed a decrease in the number and severity of issues, indicating progressive refinement of the app. Participants expressed that the app improved upon the Excel-based MEDLO-tool by streamlining data collection and reducing manual input, thereby potentially enhancing usability.

Balancing end-user feedback with established best practices and user interface guidelines was crucial during development [34-37]. While participants provided valuable suggestions, not all could be implemented due to conflicting requests and constraints related to usability standards. For instance, some users desired a more complex timer feature, whereas others preferred simplicity. Decisions were made to benefit the majority and adhere to platform guidelines to ensure familiarity and ease of use [34,35].

The effectiveness of the UCD approach in this study aligns with previous research demonstrating its benefits in software development [38,39]. A key factor in our success was the development team's familiarity with the context of long-term care for older adults. This domain knowledge facilitated insightful conversations between developers and participants, reducing misunderstandings and accelerating the development process. Previous studies have highlighted that cognitive similarity and shared jargon can enhance team performance [40,41].

Limitations

Despite these strengths, the study has limitations that warrant consideration. The participant sample consisted primarily of researchers affiliated with the University, which may limit the generalizability of the findings to care professionals who are the intended end-users in clinical settings. While these researchers had extensive experience with the MEDLO-tool, involving a broader range of stakeholders, including nurses and other care staff, could provide additional insights into usability and practical implementation. Furthermore, the app was not tested in a real-life nursing home environment, which could have revealed context-specific challenges and opportunities.

Future Work

Future research should focus on conducting pilot studies to evaluate the feasibility and effectiveness of the MEDLO app in real-world nursing home settings. Involving care professionals in these studies would help assess the app's usability, accessibility, and impact on daily workflows. In addition, gathering feedback from residents and their families could provide a more comprehensive understanding of the app's influence on care quality.

Further development could explore integrating advanced technologies, such as artificial intelligence and machine learning, to enhance data analysis and provide predictive insights [42,43]. For example, natural language processing could be used to automate the interpretation of observational data, aiding care providers in identifying patterns and potential areas for intervention. However, implementing such technologies would require careful consideration of ethical implications, data privacy, and user acceptance.

Future research may also investigate the usability in practice, by letting nurses use the app in their daily work. This could provide valuable insights into the app's integration into existing workflows and its impact on the quality of care provided to residents. In addition, longitudinal studies could assess the long-term effects of using the app on care outcomes and staff satisfaction. This information could inform further refinements and improvements to the MEDLO app, ensuring its relevance in long-term care.

Conclusion

This study successfully demonstrates the viability and demand for an app-based MEDLO-tool for assessing residents with dementia in nursing homes. By using a UCD approach, this study addressed the limitations of the existing Excel-based system by offering a more efficient and user-friendly alternative. This study shows that involving users early on in the process and keeping them involved can have a positive effect on the usability of an application. The MEDLO app shows that a UCD approach can provide real benefits in the development of a digital tools in nursing homes.

Data Availability

Abstract

Background: Remote patient monitoring (RPM) aims to improve patient access to care and communication with clinical providers. Overall, understanding the usability of RPM applications and their influence on clinical care workflows is limited from the perspectives of clinician end users at a cancer center in the Northeastern United States.

Objective: This study aims to explore the usability and functionality of RPM and elicit the perceptions and experiences of oncology clinicians using RPM for oncology patients after hospital discharge.

Methods: The sample included 30 of 98 clinicians (31% response rate) managing at least 5 patients in the RPM program and responding to the mHealth usability between March 2021 and October 2021. Overall, clinicians responded positively to the survey. Item responses with the highest proportion of disagreement were explored further. A nested sample of 5 clinicians who responded to the study survey (30% response rate) participated in interview sessions conducted from November 2021 to February 2022, averaging 60 minutes each.

Results: Survey responses highlighted that RPM was easy to use and learn and verified symptom alerts during follow-up phone calls. Areas to improve identified practice changes from reporting RPM alerts through digital portals and its influence on clinicians' workload burden. Interview sessions revealed 3 main themes: clinician understanding and usability constraints, patient constraints, and suggestions for improving the program. Subthemes for each theme were explored, characterizing technical and functional limitations that could be addressed to enhance efficiency, workflow, and user experience.

Conclusions: Clinicians support the value of RPM for improving symptom management and engaging with providers. Improvements to address RPM challenges include functional changes to enhance the program's utility, such as input from patients about temporal changes in their symptoms and technical resources for home monitoring devices.

Introduction

Improving the patient's access to care and enhancing their quality of life by preventing readmission is the primary goal of posthospital care delivery, yet traditional oncology care models often lack communication and monitoring after discharge [1-5]. Consequently, re-admissions for oncology patients within 30 days of discharge for symptoms that could be mitigated with proactive, remote patient monitoring (RPM) is an opportunity for advancing oncology patient care [6-8]. Our prior research at Memorial Sloan Kettering Cancer Center (MSK) highlights the potential of RPM to facilitate transitions of care through optimized patient-provider communication and proactive engagement through digital technology [7,8]. The RPM program was designed to reduce unplanned care visits following discharge from the hospital by proactively monitoring patient status via daily questionnaires. Electronic patient-reported outcome (ePRO) assessments generated alerts for patients enrolled in the RPM that were sent to the patient's primary oncology care clinician team. Details regarding the early development and integration of the organizational RPM project, as well as the patients recruited have been previously published [3,9-11]. However, limited research exists describing the perspectives and experiences of the clinician end users regarding how digital interventions are integrated into clinical care and the influence of technological health care models on patient care workflows.

To address this gap, our team developed this study to gain a greater understanding of the influence of RPM on clinical workflows in daily practice as part of a larger institutional initiative supporting center-wide symptom management during the transition of care from the inpatient to the outpatient setting [3,9-11]. The purpose of this study is to explore the usability of the RPM program and the perceptions and experiences of oncology clinicians using RPM to care for patients in practice after hospital discharge. The broader aim was to identify the impact, perceived usefulness ease of use, user control of the RPM, and barriers and facilitators experienced during the initial RPM implementation. The Consolidated Framework for Implementation Research [12] guided this study to query oncology clinicians, the key contributors to this management strategy, about their experiences, satisfaction, usefulness, and value of RPM.

Methods

Overview

The study's design used a multi-modal case study approach, using quantitative (survey) and qualitative (interviews and focus groups) to characterize the phenomenon and context of integrating RPM into the practice setting [13-18]. This approach encourages multiple sources of evidence to understand the clinician's perspectives about the use and function of RPM in real-world clinical practice and its influence on patient care workflows.

Initially, survey methods assessed clinicians' responses to the overall usability, functionality, and value of RPM. Second, clinicians participated in semistructured interviews and focus group sessions to elicit feedback and explanations about items of concern found in the survey responses [13,14,17]. The interview sessions aimed to delve deeper into the survey concerns and examine the use of the RPM application from a clinical perspective.

Setting and Clinician Sample

This study focused on clinician end users, specifically nurses involved in clinical office practices that integrated the initial organization's RPM initiative [3,9-11] from October 15, 2018, to July 10, 2019, at MSK in the Northeastern United States. The clinicians in this study were the first group of end users involved in caring for oncology patients using RPM. The RPM program was rolled out sequentially, beginning with the oncology services that care for patients with the highest symptom burden (Table 1). Clinicians from physician office practice settings, who had experience in caring for at least 5 patients enrolled in RPM, were invited to participate in the usability survey. This criterion ensured that the clinicians had ample experience with using the RPM program. Additionally, a nested sample of clinicians who completed the survey were recruited to take part in semistructured interviews to provide further information about the challenges of the RPM identified from the survey [19-22].

[a]Percentage of the sample.

Data Collection

Survey

Eligible clinicians in this study who met the study criteria were identified using the RPMs dashboard. Clinicians were recruited using the organization's email with a link to a web-based consent and m-Adapted Health Usability Questionnaire from March 2021 to October 2021. To maintain the anonymity of the clinicians, broad demographic data were collected to quantify clinicians' years of experience in their current organizational roles and use RPMs within electronic health record systems.

The m-Adapted Health Usability Questionnaire [23,24], is a 29-item self-report survey, that assessed an overall understanding of the functionality of the RPM from the perspectives of the clinician end users including the quality of work life, perceived usefulness, and ease of use, and user control of RPM in a 7-point Likert Scale (1 [strongly disagree] to 7 [strongly agree]). The questionnaire takes about 13 minutes to complete in REDCap (research electronic data capture; Vanderbilt University) [25]. The Cronbach α for all scale values was >0.7 with scores ranging from 0.85 to 0.92. Permission to use the questionnaire was not required [24].

Interview Sessions and Guide

Clinicians who completed the study's survey were also recruited through the organization's email to take part in 60-minute interviews or focus group sessions. The interview guide was developed by the research team based on understanding areas where the usability of RPM was challenging for the clinicians. Items from the usability survey where the percentage of responders who disagree, disagree, and strongly disagree exceeded 44%, informed the interview and focus group guide. Topics in the guide were broad enough to elicit narrative data describing the background and contextual characteristics related to the clinician's experience with RPM [26,27]. The interview guide was organized into four topics: (1) General understanding and information about the RPM; (2) Experiences, barriers, and challenges with using the RPM; (3) The Influence of the RPM on the current workflow; and (4) Suggestions for improvement (Table 2). Interviews and focus groups were conducted via the web by the PI (AMME) and the qualitative methods specialist (MBB) from November 2021 to February 2022. Verbal consent was obtained from clinicians to record sessions.

RenderX

Table . Interview guide.

Topic	Main statements	Probe questions	Aligns survey
Topic 1: provide general information about the topic of study and ask questions related to the specific service and the specific patient needs.	• Where do you work? • Can you tell me about your work with RPM[a]? • What can you tell us/each other about RPM?	• Can you briefly describe the patient group in your office practices (patient symptom burden, any factors in this group that need to be addressed through RPM)? • Can you describe your workflow and the technology systems used in your daily work activities? • Can you describe the workflow, and the systems used when providing care? • How does the RPM fit into the care workflow?	Q[b] 3,4
Topic 2: issues and barriers that are specific to using the RPM.	• What are the strengths/barriers to using RPM from the nursing perspective? • What are the strengths/barriers to using RPM from the patient's perspective? • Do you think RPM is valuable: to nurses the patients?	• What functionality is found in the current systems and applications used during patient care activities to make caring for patients easy? • What functionality in the RPM is not working? Describe? • Do you think the patients like using the RPM? • Does the RPM provide value for the patients? Care? • Do you think patient education about the RPM helps?	Q 7,9,10,13
Topic 3: practice workflow; getting to the issue about the RPM, frequency of using the toolkit, and the influence of workflow.	• How does the RPM toolkit work with your workflow? • How do you use the RPM apps to provide care? • How do you use the RPM toolkit using the digital apps?	• Describe how you use the RPM (and patients with remote monitoring devised, ie, pulse oximetry) • How do you use the information in caring for your patients? • Can you describe the communication among practitioners using the RPM?	Q 18 - 20
Topic 4: functionality, if modified, would be meaningful and helpful for the RPM, improved workflow, user satisfaction, and improved patient outcomes.	• What are your thoughts about how RPM functions? • How could it be improved?	• If you could fix anything about the RPM, what would it be? • To what extent do you think the modifications described could influence patient outcomes that patient care? • What current functionality has the greatest influence on workflow?	Q 23 - 25

[a]RPM: remote patient monitoring.

[b]Q: question.

Data Analysis

Survey

Survey response data were extracted from REDCap [25] to a deidentified Excel spreadsheet before analysis. To ensure anonymity, demographic information was only provided for clinicians who were sent the surveys and not collected for clinicians who responded. Data responses were initially scored in REDCap [25] for the frequency and proportion of agreement or disagreement with survey items consistent with the 7-point response scale. The scale responses were then collapsed into 3 groups, disagreement (strongly disagree, disagree), neutral (neither agree nor disagree), and agreement (agree and strongly agree). The Strengthening the Reporting of Observational Studies in Epidemiology guidelines were used to report the study's quantitative findings [28].

Interviews Sessions

Data from the interviews and focus groups followed the Consolidated Criteria for Reporting Qualitative Research

XSL•FO
RenderX

guidelines and were used to report the study's findings [29]. The rigor and validity of the data were supported by clarifying participants' statements during interview sessions. The transcripts were audio recorded, transcribed verbatim, and independently reviewed by 2 reviewers using thematic content analysis [30]. Themes and subthemes were constructed based on the verbal responses from the clinicians. Team consensus was determined by agreeing upon the best representation of the data [24,26,27,30].

Ethical Considerations

This research is part of an ongoing organizational program of RPM initiatives. This research obtained ethical approval from the MSK Institutional Review Board (X20-086) as exempt research and follows the ethical principles and guidelines of the Belmont Report. All responders to surveys completed web-based informed consent to participate. Participants in focus groups and interviews provided informed verbal consent.

Results

Overview

A total of 35 clinicians participated in this study from both survey and interview sessions. Of the 98 clinicians who had experiences with at least 5 patients enrolled in RPM and received the study's survey, 30 responded (31% response rate). A nested sample of 5 clinicians (17% response rate) from this original group of 30 clinicians who completed the survey, also agreed to take part in 4 sessions (3 interviews; 1 focus group of 2 clinicians). Demographic data were not collected with the survey to maintain the anonymity of the clinician responders. However, the majority of clinicians who responded to the survey and interview sessions represented the Gastrointestinal, Thoracic, and Breast oncology services known to have the highest symptom burden. Of the clinicians who took part in the interview sessions, 3 clinicians had 5 or more years of organizational work experience, while 2 clinicians had 2 years or less of experience.

Survey Responses

Overall, the clinicians reported that the RPM was easy to use and learn and that symptoms communicated through the RPM program were confirmed during follow-up phone calls. Suggested areas for improvement included communication and practice changes related to symptom management and the clinicians' workload burden. Findings highlighting survey items with the highest frequency and proportion of survey responses are presented (Table 3).

[a]Number of participants who answered the survey.

[b]Percentage of the group responses.

Usability

The RPM was easy for clinicians to use but was influenced by a shift in basic assumptions with patients now instructed to report symptoms through portal messages rather than calling the medical offices (14/26, 54%).

Integrated Workflows

The proportion of responses was fairly divided between agreement and disagreement. While 14 (52%) clinicians agreed that the RPM had usable functions and capabilities, 14 (52%) clinicians disagreed that the RPM was suitable for their patient care needs.

Acceptability in Practice

A total of 16 (59%) clinicians reported a disagreement with the notion that RPM improved their ability to care for their patients and, 12 (46%) clinicians reported that the RPM was useful in their practice.

Convenience in Patient Care

Despite similar proportions of agreement and disagreement overall, a higher proportion of clinicians (13/26, 50%) disagreed with feeling comfortable communicating with patients about symptoms through portal messages.

Symptom Management

Clinicians reported that devices were appropriately used for 12 (44%) patients and that high-risk symptoms were confirmed during follow-up phone calls to 20 (74%) patients. The responses were fairly split between agreement (10/27, 37%) and disagreement (12/27, 44%) on how well the devices provided severity levels. Additionally, 10 (38%) patients agreed that RPM helped them manage their patients.

Satisfaction and Value

A total of 21 (81%) clinicians reported that the RPM did not decrease their workload and 15 (56%) clinicians reported it did not improve job satisfaction. In addition, 14 (52%) of the clinicians were not satisfied with RPM, and 13 (50%) clinicians would not recommend the RPM to colleagues. The proportion of clinicians who neither agreed nor disagreed was similar to those who reported disagreement and was further explored in the interview sessions.

Interview Sessions

The interviews and focus group sessions consistently provided similar information about the RPM thus achieving thematic saturation [30]. All clinicians reported a limited understanding of the RPM during its implementation and suggested that ongoing educational modules and supporting technical support would enhance the RPM program for the clinician end users. Three major themes emerged from the interviews: clinician understanding and usability constraints, patient constraints, and suggestions for improvement. Subthemes were further explored (Table 4).

Table . Themes and subthemes.

Theme	Subthemes
Theme 1: Clinician understanding and usability constraints	• Clinician uncertainty • Repetitive alerts • Alignment with clinician workflows • Program value
Theme 2: Patient constraints	• Appropriate patient enrollment • Timing of enrollment • Communication during and after enrollment
Theme 3: Suggestions for improvement	• Clinical champions needed • Program modifications • Information technology support for end users

XSL•FO
RenderX

Theme 1: Clinician Understanding and Usability Constraints

Overview

Theme 1 encompasses the information given to the clinicians during their RPM orientation and how they applied the application to their current workflow. Three subthemes included clinician uncertainty, repetitive alerts, alignment with clinician workflows, and program value.

Subtheme: Clinician Uncertainty

The RPM was rolled out in stages starting with oncology services known to have patients with high symptom burdens. The clinicians involved in the initial rollout reported more knowledge and understanding about the RPM compared with clinicians who were involved later in the rollout. Clinicians joining later in the rollout reported having little training about the RPM. However, they reported that the increased frequency of using the RPM helped them navigate the program for addressing symptom management alerts and functionality.

> *I have only worked with it (RPM) for a couple of patients in the outpatient setting, but I get a notification (through) the portal … to notify us that the patient has enrolled in the RPM program…During this timeframe patients (complete) a survey every day about their symptoms and how they feel.* [R32]

Subtheme: Repetitive Alerts

All clinicians reported concerns about repetitive alerts from daily patient surveys. Each day that a patient reported a symptom and generated an alert [1,3,10], clinicians called the patient to verify it and confirm if the symptom was worse, better, or the same as the previous survey. Although they could see past patient response trends in the system, this required substantial effort and did improve the patient's care for symptoms. When alerts were consistently reported, the clinicians used their judgment to decide when to call patients for verification.

> *There are a couple of categories that we feel were a little monotonous. ie, was (the pain/symptom) worse? If they are at stage four lung cancer, (the patient) is on treatment and they have fatigue, every day… (the patient cannot modify) their answers, (for example) moderate fatigue; I am having trouble doing my activities of daily living, so they are clicking that every day.* [R11]

Subtheme: Aligning With Clinician Workflow

Clinicians reported that before implementing the RPM, patients were instructed to call the physician's medical offices to report symptoms. Although none of the clinicians reported significant changes to their clinical workflows, they all raised concerns about the shift from patients calling the medical oncology office for unrelieved symptoms through a digital portal. This change made clinicians apprehensive about potentially missing symptoms reported in patient portals.

> *Before RPM, patients were not supposed to report symptoms through the portal, but a lot of patients, ended up just doing that because they were home.* [R11]

Subtheme: Program Value

Clinicians reported that the RPM was of immense value to them and their patients and supported its inclusion in the organization's future care delivery. Patients liked that their office practice clinician proactively contacted and interacted with them after they were discharged from the hospital.

> *I do not think they (the patients) mind and love to be followed up closely, I mean my patients would love for me, a call them every day. I think patients prefer (clinicians) calling them over calling the office.* [R41]

Theme 2: Patient Constraints

Overview

The patient constraint themes involved the transition of care from the inpatient setting to RPM following discharge. Three subthemes emerged: the appropriate patient enrollment, the timing of enrollment, and communication during and after enrollment.

Subtheme: Appropriate Patient Enrollment

Nurses from the discharging inpatient unit were responsible for educating patients about using RPM and program enrollment. However, office practice clinicians stated that not all patients enrolled by the discharge team were appropriate due to a lack of technical proficiency, ability, and understanding of the purpose of the RPM. Clinicians consistently reported that they should be included in RPM enrollment decisions for their patients.

> *There is a disconnect, (between enrolling the patient and educating them about the program) and sending symptoms via the portal messaging using the patient portal. The policy is that we are given two business days to answer portal messages…clearly, we cannot do that when it is a separate message. We need to speak to that person (By phone).* [R21]

Subtheme: Timing of Enrollment

Office practice clinicians reported that the time of discharge is overwhelming for patients and inpatient unit teams have limited time to prepare the patients to leave the hospital. During this study, pandemic-related social distancing restrictions prevented caregivers and family members from taking part in the discharge process, further complicated RPM enrollment.

> *The second thing that I wanted to suggest for patients wanting to quickly leave the hospital and be discharged and suddenly just get bombarded with all this information, is to discuss the RPM program the day (before) discharge.* [R32]

Subtheme: Communication During and After Enrollment

Clinicians reported that a patient's age was not a factor in RPM enrollment, as older adults familiar with technology could engage digitally with providers. However, patients with language barriers or limited access to electronic devices needed assistance from caregivers or family members similar to findings in a prior

XSL•FO
RenderX

study [8]. The RPM assessments were intended to be completed during weekday work hours, from 9 AM to 5 PM Monday through Friday. Clinicians described receiving the surveys late in the day, or after hours added stress for the nursing team to address alerts.

> *We have a lot of foreign-speaking patients ---, you know it is not them who are filling out the survey ... and it may be one of their relatives or their daughter. But the daughter may not live with them ... so how do you know what is going on?* [R11]

Theme 3: Suggestions for Improvement

Overview

The Clinicians supported using RPM to sustain patient care posthospital discharge. From their perspective, 3 subthemes emerged, the need for clinical champions, technology support for end users (clinicians and patients), and specific RPM modifications.

Subtheme: Clinical Champions Needed

Clinicians expressed the need for continuing education and updates on RPM improvements, infrequent use required relearning the system for each new patient. While there were few Clinical Champions during the initial rollout, additional experts would have helped them navigate the program and supported novice clinicians. They also suggested developing informative slides or videos addressing specific program issues.

> *I think nursing (clinician end-user) … needs more education on the portal because it (the portal) is such a big part of our job. More training is needed for using (connecting) pulse ox to an iPhone (or other devices ie, Android).* [R11]

Subtheme: Program Modifications

Clinicians reported that patient enrollment before hospitalization or early in their hospital admission would improve the transition from inpatient to outpatient care. They also requested allowing patients to change or clarify their symptom responses within the assessment. Frequent patient alerts were seen as potentially problematic [31] and suggested that enabling patients the option to modify their assessment responses would provide more accurate symptom information to the clinical team.

> *There should be a way for them (patients) to say (respond in the survey) no changes or something… so that we don't get the same exact thing (response) that we spoke to the patient yesterday---about because it's not realistic, that I call the patient every day to talk to them about the same time (symptom).* [R42]

Subtheme: Information Technology Support for End Users

Clinicians raised concerns about the lack of integrated IT systems they use for delivering patient care. Additionally, clinicians expressed the need for greater IT support for both patients and staff. Clinicians conveyed concern about the difficulty in resolving connectivity issues and requested dedicated assistance from IT teams.

> *The patients are calling in a panic and you are trying to walk them through over the phone how to set up the device (RPM on patient's device ie, phone, tablet). If it was not set up correctly on discharge, or the device is just not working. (These issues) add more stress to the patient, but it also adds stress to you (the clinician) This becomes the added work.* [R11]

Discussion

Principal Results

This study presented the perceptions and experiences of oncology clinicians when caring for their patients using RPM after hospital discharge. Initially, clinician survey responses highlighted concerns about their understanding, perceptions, and challenges when using RPM as well as its influence on their clinical workflows. These topics were further explored in interview sessions and revealed 3 themes: clinician understanding and usability constraints, patient constraints, and suggestions for improvement. Most clinicians found the RPM easy to use and learn, allowing them to confirm the patient's reported symptoms during follow-up phone calls. They supported RPM's value for both clinicians and patients as a care delivery method in oncology practice, aligning with findings from other organizational studies using ePROs [11,31-36], as well as the challenges and limitations of addressing symptom alerts after the patient transitions from an inpatient to the home setting [7,35,36].

Challenges and Opportunities From the Clinical Setting

This research further emphasized multiple challenges faced by clinicians during the initial RPM roll-out. A major concern was the practice change in clinical workflows whereby patients reported symptoms through electronic portals rather than contacting the medical offices by phone. Despite this change, clinicians felt their comfort level would improve with more experience, and as RPMs aligned with their workflows [7]. An opportunity to improve clinician confidence includes continuing educational tutorials from the initial RPM orientation and more technical and clinical support for both patients and clinicians. These efforts would facilitate aligning clinician workflows with clinical practice, thus leading to reduced stress and improved job satisfaction when caring for oncology patients using RPM [7].

Another challenge was patient constraints and their lack of understanding of RPM, which clinicians suggested might contribute to their uncertainty in digital symptom management reporting. Some patients completed surveys late in the clinic hours making it difficult to address symptoms. In many instances, clinicians reported that family members completed the surveys instead of the patients which raised concerns about the integrity of the symptom alerts. Further research could enhance the understanding of logistical limitations involving patients and caregivers with completing postdischarge symptom assessments at home. A similar study recommended that concerns revealed by patients and caregivers postdischarge could be included in future clinical outcomes [37]. Additionally, the timeframe for enrolling patients in RPM was another

XSL•FO
RenderX

constraint identified by clinicians. Although older patients were comfortable using the RPM [38,39], enrollment at discharge was considered suboptimal. They suggested educating patients in a relaxed environment or office practices before hospitalizations would benefit patients and improve the enrollment process.

A major opportunity for RPM improvement involves addressing repetitive alerts from the daily ePRO assessments, also identified in other ePRO studies [23]. Clinicians verify all patient-reported symptom alerts. When prior symptoms are stable, these alerts could be averted to reduce their workflow burden [40,41]. To enhance effective communication with the patients, clinicians recommended adding context about symptom changes relative to the prior day's ePRO assessment to improve the integrity of alerts.

The perspectives of all clinicians involved in this study expressed a need for additional resources to improve the effectiveness of RPM and their ability to clinically support it. The RPM was initially implemented using a core team of designated clinicians for addressing patient alerts. Studies of RPM cited the inclusion of core teams for this purpose which may be a preferred approach for clinicians in other studies [42]. However, clinicians in this research preferred a hybrid RPM program with primary care clinicians in the clinical practices addressing alerts on weekdays and centralized after-hours and on weekends. Clinicians proposed that leaders provide consistent status updates and education about RPM functionality through tutorial videos in an accessible location. Additional technological support could improve data collection and relieve clinicians of the burden of providing technical support for patients at home [41,42], which is not the best use of their skills [43].

Strengths and Limitations

The consistent reports from survey responses and interviewed clinicians strengthen the study's findings and provide pragmatic recommendations for workflow redesign and enhancing access to care for oncology patients postdischarge [1,2,7,31], As a result of this study, selected modifications were implemented into practice to improve the program's experience for both clinicians and patients. These results provide important foundational work for future pragmatic trials and implementation science to enhance the usability and value of RPM in oncology practice.

The sample was limited to only clinicians who had experiences with at least 5 patients enrolled in the RPM, but typical for case studies [13-18]. They expressed strong positive or negative experiences with the RPM which may have created a selection bias. The study's design was multi-modal which could have included both interviewer and report biases. Clinicians were also employees of the organization and therefore specific demographics were not collected to ensure their anonymity. This study was conducted at one comprehensive cancer center, limiting the generalizability of results. However, the perspectives of clinician end users from oncology services with known symptom burdens can apply to similar RPM implementation initiatives in other organizations worldwide.

Conclusion

The National Cancer Institute calls for studies about cancer-related interventions, which also include program effectiveness from the perspectives of both patients and clinician end users [44]. This study contributes to the National Cancer Institute's initiatives, demonstrating that RPM is a valuable method for communicating with clinical providers and managing patient symptoms during transitions of care from inpatient to the home setting.

Acknowledgments

The authors want to thank the clinicians who participated in this study for their insight and dedication to oncology practice.

Authors' Contributions

AMME drafted the nursing perspective aspect of the proposal and conducted the interviews, transcribed and analyzed the interview data, and drafted the original manuscript. MBB conducted interviews with AMME, reviewed the transcript data, and edited the manuscript. RD is the principal investigator of the organizational protocol involving remote patient monitoring and reviewed and edited the manuscript. J Huang, CB, and JA are involved in providing protocol support for the daily activities of this study. CW was involved with drafting the manuscript and editing the study proposal. KSP, GK, and JM were involved with the organizational protocol and its development, and manuscript review. J Holland, RS, JC, and AB are involved with the organizational project development and review of the manuscript.

Conflicts of Interest

RD reports grant support from the National Institutes of Health and the Emerson Collective, participation on a data safety monitoring board or advisory board with Varian Medical Systems, and stock or stock options in Roche. The remaining authors do not have conflicts of interest to declare.

Abstract

Background: Only 15% of the nearly 30 million Americans with hearing loss use hearing aids, partly due to high cost, stigma, and limited access to professional hearing care. Hearing impairment in adults can lead to social isolation and depression and is associated with an increased risk of falls. Given the persistent barriers to hearing aid use, the Food and Drug Administration issued a final rule to allow over-the-counter hearing aids to be sold directly to adult consumers with perceived mild to moderate hearing loss at pharmacies, stores, and online retailers without seeing a physician or licensed hearing health care professional.

Objective: We evaluated the safety and usability of an over-the-counter hearing aid prior to Food and Drug Administration approval and market release.

Methods: We first conducted a formative usability test of the device and associated app with 5 intended users to identify outstanding safety and usability issues (testing round 1). Following design modifications, we performed a summative usability test with 15 intended users of the device (testing round 2). We concurrently conducted a test with 21 nonintended users (ie, users with contraindications to use) to ascertain if consumers could determine when they should not use the device, based on the packaging, instructions, and labeling (testing round 3). Participants were asked to complete 2 - 5 tasks, as if they were using the hearing aid in real life. After each task, participants rated the task difficulty. At the end of each session, participants completed a 10-question knowledge assessment and the System Usability Scale and then participated in debriefing interviews to gather qualitative feedback. All sessions were video recorded and analyzed to identify use errors and design improvement opportunities.

Results: Usability issues were identified in all 3 usability testing rounds. There were minimal safety-related issues with the device. Round 1 testing led to several design modifications which then increased task success in round 2 testing. Participants had the most difficulty with the task of pairing the hearing aids to the cell phone. Participants also had difficulty distinguishing the right and left earbuds. Nonintended users did not always understand device contraindications (eg, tinnitus and severe hearing loss). Overall, test findings informed 9 actionable design modifications (eg, clarifying pairing steps and increasing font size) that improved device usability and safety.

Conclusions: This study evaluated the usability and safety of an over-the-counter hearing aid for adults with mild to moderate hearing loss. Human factors engineering methods identified opportunities to improve the safety and usability of this direct-to-consumer medical device for individuals with perceived mild-moderate hearing loss.

KEYWORDS

usability; human factors; patient safety; over-the-counter hearing aids; direct-to-consumer hearing aids; medical device; hearing loss; adult; hearing impairment; hearing aid use; hearing care; formative usability test; safety; mobile phone

Introduction

Approximately 1 in 4 people older than 12 years of age in the United States have hearing loss in 1 or both ears [1], and 30 million American adults could benefit from hearing aid use [2]. Hearing loss is associated with an increased risk for falls [3] and may lead to cognitive decline [4] and dementia [5]. Yet, only 1 in 3 older adults [6] and 15% of all adults with hearing loss use hearing aids [7]. Some barriers preventing adoption

XSL•FO
RenderX

include lack of access, stigma, and financial challenges with traditional hearing aids costing between US $1000 and US $6000 per ear [8]. Aiming to mitigate these barriers, the Food and Drug Administration (FDA) issued a final rule in 2022 [9] permitting the sale of hearing aid devices without a prescription or medical exam. Yet, there are few studies of the usability and safety design challenges of over-the-counter medical devices intended to be sold widely in consumer markets.

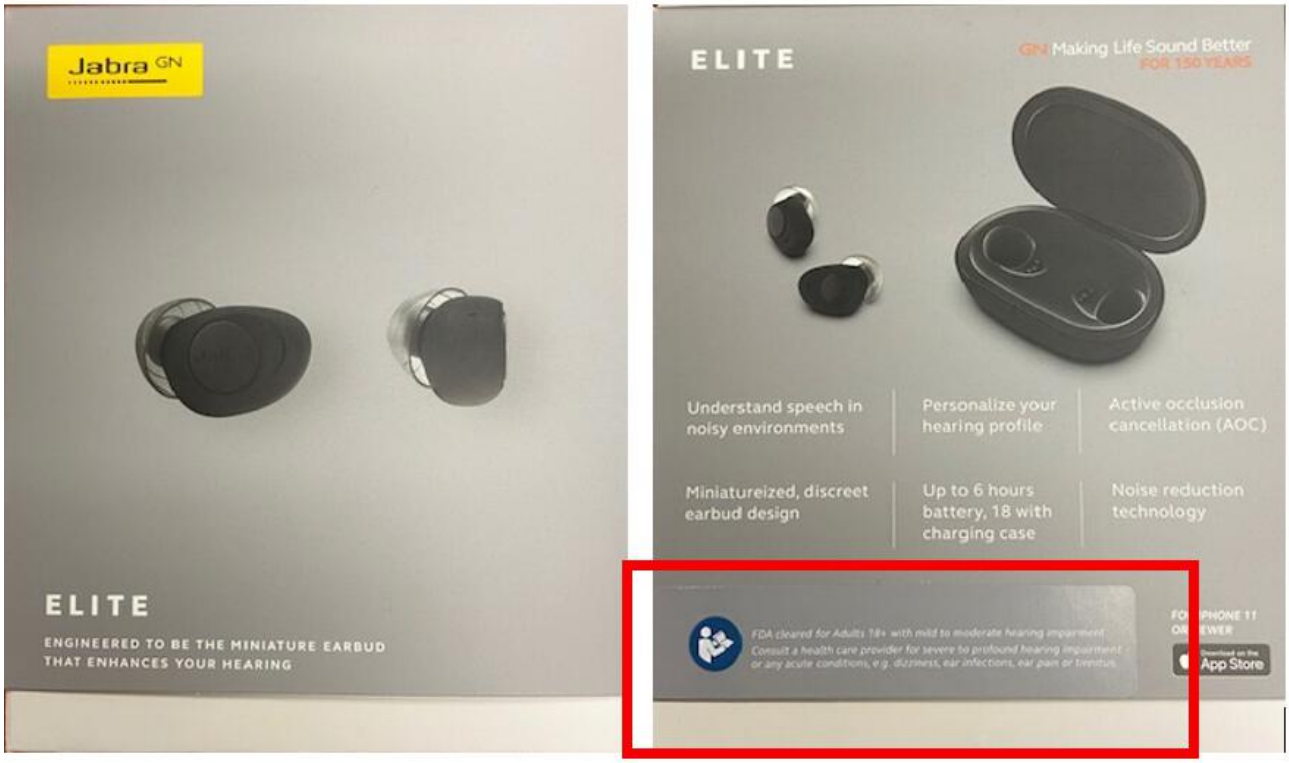
Over-the-counter or direct-to-consumer medical devices do not require a prescription and can be sold at retail outlets including pharmacies, big-box stores, and online. Examples include self-monitoring blood glucose test systems and at-home pregnancy tests. Typically used outside of health care settings, these devices must have (1) low potential for misuse; (2) benefits that outweigh their safety risks; and (3) sufficient labeling so that lay-users can self-diagnose their condition, self-determine that the device is appropriate for their condition, and understand how to use the device without clinician assistance or instruction [10]. To minimize use errors and their associated risks, the FDA requires premarket review of the safety and effectiveness for most direct-to-consumer medical devices. This review process includes rigorous human factors usability testing with representative users to validate that the warnings, cautions, and contraindications are transparent, assess if users can complete critical tasks of the device, and identify areas of foreseeable misuse (including use of the device by unintended users) [11].

Numerous studies have evaluated the safety and usability of clinician-facing medical devices (eg, smart intravenous infusion pumps) [12-15], as well as patient-facing medical devices (eg, glucometers, ventilators, and epinephrine injectors) [16]. Typically, clinicians still mediate the use of these patient-facing medical devices either by providing a prescription to use the device or instructions on how to use the device appropriately [17]. There remains limited research on the safety and usability of direct-to-consumer medical devices, especially those used by underserved populations (eg, people with hearing impairment) [18-20].

Compared to clinician-facing medical devices, patient-facing devices present a challenge to designers as the potential environment of use and characteristics of end users is much more diverse [16]. The usability of direct-to-consumer devices is especially important given the lack of clinical supervision to support appropriate use. For instance, over-the-counter hearing aids will be on the shelf at consumer electronics stores next to other, nonmedical devices (eg, wireless headphones) and consumers may come across the device without previously identifying a need for a hearing aid. While the risk is minimal, use of hearing aids by those with normal hearing could result in noise-induced hearing loss. In this context, the packaging of the device and communication of its intended use (and contraindications to use such as an ear infection, tinnitus, or severe hearing loss) is especially important. In this study, we evaluated the safety and usability of an over-the-counter hearing aid among adults in the United States.

Methods

Ethical Considerations



We conducted usability testing of an over-the-counter hearing aid to evaluate the safety and usability of the device prior to market release. This study was approved by the Vanderbilt University Medical Center's institutional review board (201894). At the start of each session, we reviewed the consent document with participants and answered any questions they had. All participants provided written consent to be in the study. Data have been deidentified.

Hearing Aid

We evaluated the Jabra Enhance Plus (formerly called the "Jabra Elite" during the study), an over-the-counter hearing aid that is intended to enhance hearing but can also be used for phone calls and listening to music. Users can purchase these hearing aids at a suggested retail price of US $799 per pair. The hearing aids are physically similar to wireless earbuds with adjustable ear gels. Users can pair them to a smartphone and personalize their own hearing aid profile using a free smartphone app (ie, Jabra Enhance app). The miniaturized in-the-ear style earbuds (see Figure 1) come in a small charging case and can be used up to 12 hours on a single charge.

XSL•FO
RenderX

Figure 1. Front and back of the device box.

Participants and Setting

We conducted usability testing with production equivalent prototype devices (ie, packaging, hearing aids, charging case, and user manual) including an iPhone with the Jabra Enhance app installed. We only used iPhones in the usability testing since the Jabra Enhance app was only available for iPhones at the time of testing. We recruited two participant populations for the study, (1) intended users of the device and (2) nonintended users (Textbox 1). We identified potential participants meeting our study criteria through medical record chart review, university newsletters, and word of mouth. Eligible participants conducted a prescreening questionnaire, via phone call or email, to verify they met the inclusion criteria for the study before scheduling. The testing occurred from December 2020 to August 2021.

Textbox 1. Eligibility criteria for intended and nonintended users.

Intended users (adults aged 18+) with:

- Mild to moderate hearing impairment

Nonintended users (adults aged 18+) with:

- Normal hearing,
- Severe to profound hearing impairment, and/or
- Acute conditions including tinnitus, dizziness, ear infections, and ear pain

Intended Users

To start, we conducted usability testing with 5 intended users of the device. Based on the safety and usability issues identified in the testing round (round 1), we made recommendations for modifications to the device packaging and app screens. We then conducted round 2 of usability testing of the revised product with 15 intended users. In each usability testing session, participants were asked to complete 5 tasks (see Textbox 2) within 90 minutes. Participants received a US $50 gift card at the end of the session.

XSL•FO
RenderX

Textbox 2. Task descriptions.

Tasks for intended users (rounds 1 and 2)

- Read outer label and indicate if use is appropriate
- Set up the hearing aids and app including
- Find and open hearing aid app
- Register product and accept terms and conditions
- Pair the hearing aids
- Finalize the set up of the hearing aids
- Fit the hearing aids into ear
- Recharge the hearing aids
- Clean the hearing aids

Tasks for nonintended users (round 3)

- Read outer label and indicate if use is appropriate
- Read the inner box contents (note that the inner box contents were available to the participants, but they did not receive explicit instructions on how to read them) and indicate if use is appropriate

Nonintended Users

We conducted a third round of usability testing with 21 nonintended users of the devices to evaluate if consumers could ascertain that they should not use the device based on the external and internal labeling, user manual, and app screens. We recruited participants who were contraindicated to use the device including adults with normal hearing, adults with severe to profound hearing loss, and adults with tinnitus or severe dizziness. Round 3 participants were scheduled for a 30-minute test session, in which they were asked to complete 2 tasks (see Textbox 2). Participants received a US $20 gift card at the end of the session.

Data Collection

We conducted functional simulated use studies with end users completing real-world tasks. One human factors engineer facilitated the sessions. In line with real-world use of the device, participants received no training prior to testing. We read task instructions out loud while displaying the same instructions on a computer monitor with closed captioning. Participants were directed to complete 5 (rounds 1 and 2) or 2 tasks (round 3, see Textbox 2). After each task, participants rated how easy or difficult the task was to complete on a scale from 1 (very difficult) to 5 (very easy). After all tasks were completed, we asked intended and nonintended users 10 questions to assess their knowledge of the device and its contraindications for use (see Multimedia Appendix 1). Participants then completed the System Usability Scale (SUS), a 10-item validated survey for assessing the usability of interactive systems [21] (see Multimedia Appendix 2). To conclude the session, we conducted debrief interviews to gather additional qualitative feedback about the safety and usability of the device. The interview guide can be found in Multimedia Appendix 3. All sessions were video recorded and uploaded to Morae (TechSmith), a software suite for usability testing that supports video annotation (eg, of use errors) and logging of tasks.

Data Analysis

One researcher coded the videos in Morae, annotating areas of difficulty, confusion, safety-related issues, and errors. We analyzed the participant's path (ie, steps) through the attempted completion of each task. Any deviation that occurred in the attempt to complete the task (eg, participant clicks on an incorrect menu item or participant struggled to get the user manual out of the box) was coded as a "use error." For task 2, we specifically noted any instances where participants' workflow deviated from the expected workflow (see steps in Textbox 2). We analyzed the time spent on each task and if the tasks were (1) completed, (2) completed with difficulty, or (3) not completed (task failure). We then calculated the task success rate. A task was only scored as a success if the user was able to complete the task requirements on their own without facilitator assistance. We calculated participants' rating of difficulty for each task and the SUS scores. One researcher listened to the audio recording of each debrief interview and created a comprehensive list of feedback (eg, longer battery life) organized into two categories (1) what participants liked about the device and (2) areas for improvement. A team of human factors researchers reviewed all identified errors and participant difficulties completing tasks to develop design recommendations to improve the device, app, and packaging prior to market release. We mapped each design recommendation to specific human factors design principles, using the list of design heuristics described in Barton et al [22], which combined the commonly used heuristics for medical device design [23], interactive systems [24], and medical documents [25].

Results

Overview

Table 1 shows the participant demographics for each round of usability testing. Table 2 depicts the task success rates, number

XSL•FO
RenderX

of use errors, task durations, and difficulty ratings for each task and round of usability testing.

While we identified minimal safety concerns with the device, we identified numerous usability issues, which led to several design modifications. We outline the key issues identified from the usability testing in the following sections.

Table . Participant demographics for each usability testing round.

	Round 1 (intended users, n=5)	Round 2 (intended users, n=15)	Round 3 (nonintended users, n=21)
Hearing loss, n (%)			
None or normal hearing	0 (0)	0 (0)	18 (86)
Mild	2 (40)	7 (47)	0 (0)
Mild to moderate	1 (20)	2 (13)	0 (0)
Moderate	2 (40)	6 (40)	0 (0)
Severe	0 (0)	0 (0)	3 (14)
Tinnitus (ringing in ears), n (%)	0 (0)	0 (0)	5 (24)
Average age (years), n (range)	65 (57 - 73)	66 (56 - 79)	65 (52 - 77)
Women, n (%)	2 (40)	8 (53)	13 (62)
Education, n (%)			
High school or General Educational Development	0 (0)	5 (33)	5 (24)
Associate's or trade school	1 (20)	2 (13)	4 (19)
4-year college	2 (40)	3 (20)	7 (33)
Graduate or professional school	2 (40)	5 (33)	5 (24)

Table . Usability testing performance.

Measure and round	Task 1	Task 2	Task 3	Task 4	Task 5
Task success rate, n (%)					
Round 1	3 (60)	2 (40)	2 (40)	5 (100)	3 (60)
Round 2	12 (80)	10 (67)	7 (47)	15 (100)	10 (67)
Round 3	10 (48)	10 (48)	—[a]	—	—
Average task duration (minutes), mean (SD) [b]					
Round 1	0.72 (0.3)	9.33 (0.5)	1.37 (0.6)	0.50 (0.2)	1.08 (1.1)
Round 2	0.83 (0.5)	11.24 (4.0)	2.21 (0.9)	0.67 (0.6)	0.95 (0.8)
Round 3	—	—	—	—	—
Average difficulty rating, mean (SD) [c]					
Round 1	4.6 (0.5)	3.4 (1.2)	4.2 (0.8)	5 (0)	5 (0)
Round 2	4.87 (0.4)	3.27 (1.4)	3.73 (1.2)	4.53 (0.8)	4.67 (0.6)
Round 3	4.71 (0.6)	4.43 (0.9)	—	—	—
Number of use errors per participant, n					
Round 1	0	4	0	0	0
Round 2	0	4.9	0.5	0.6	0
Round 3	0	0.7	—	—	—

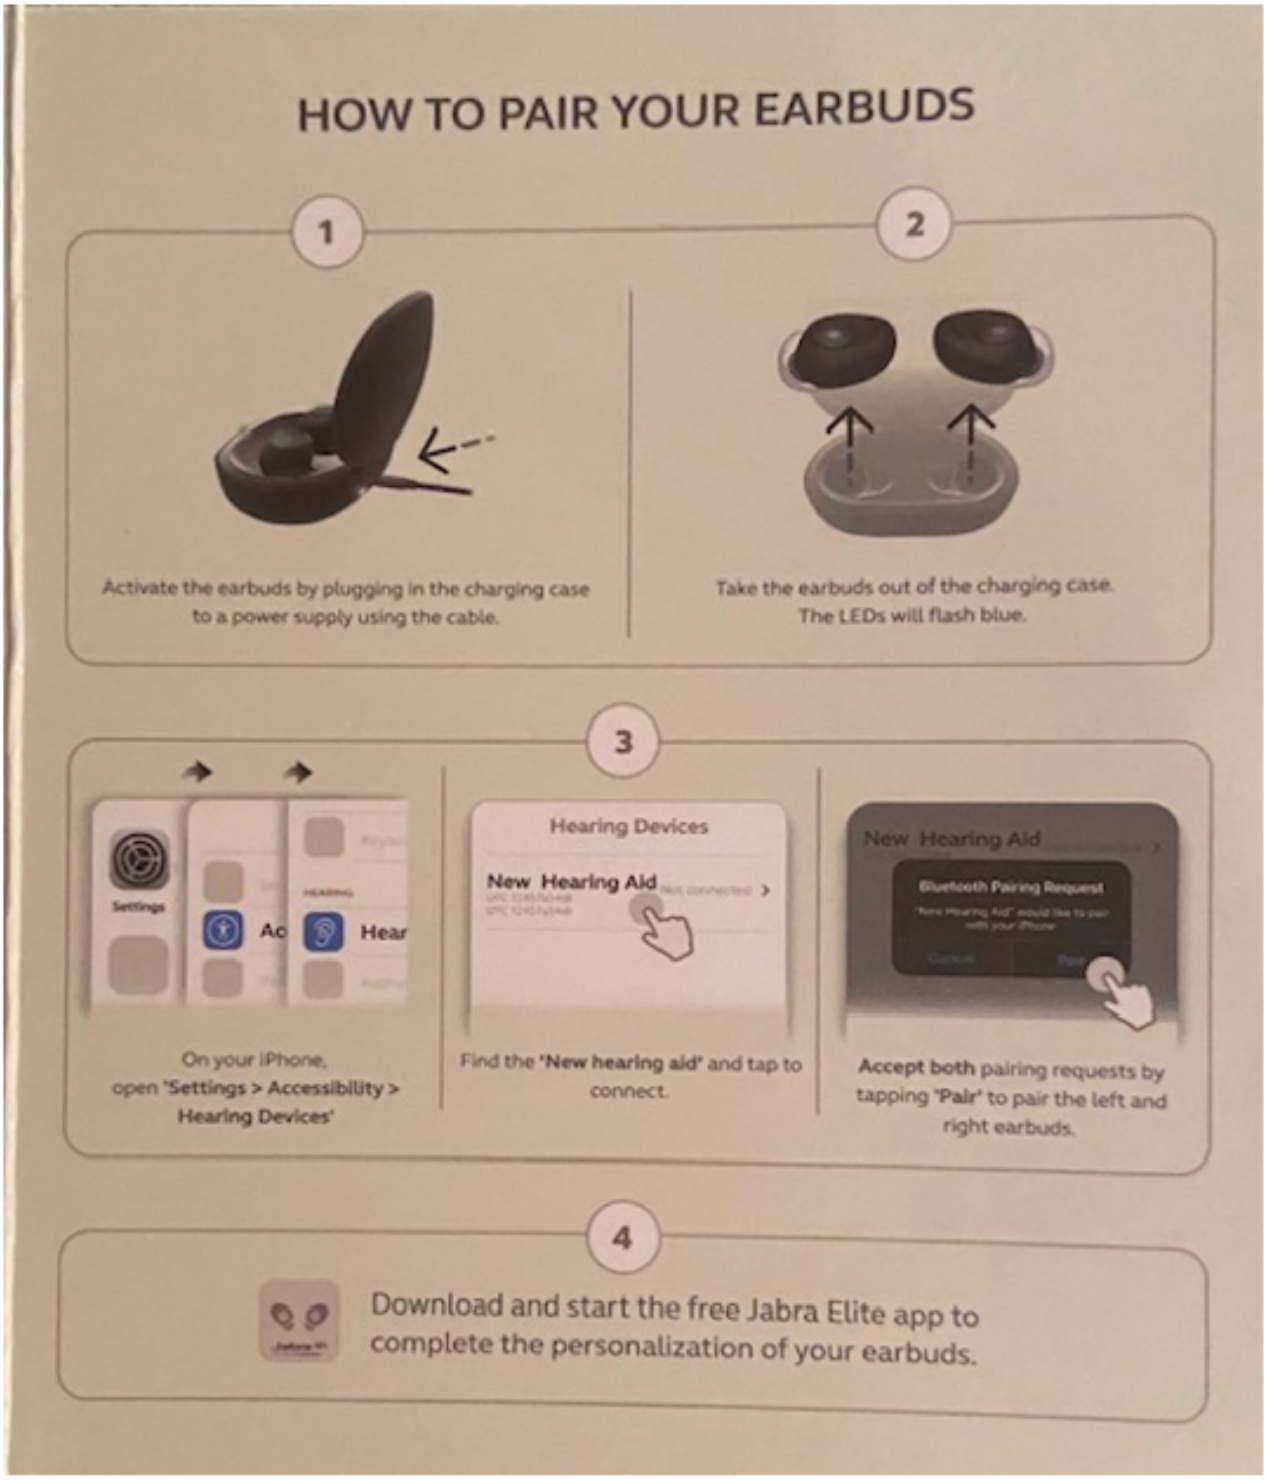
Package Labeling

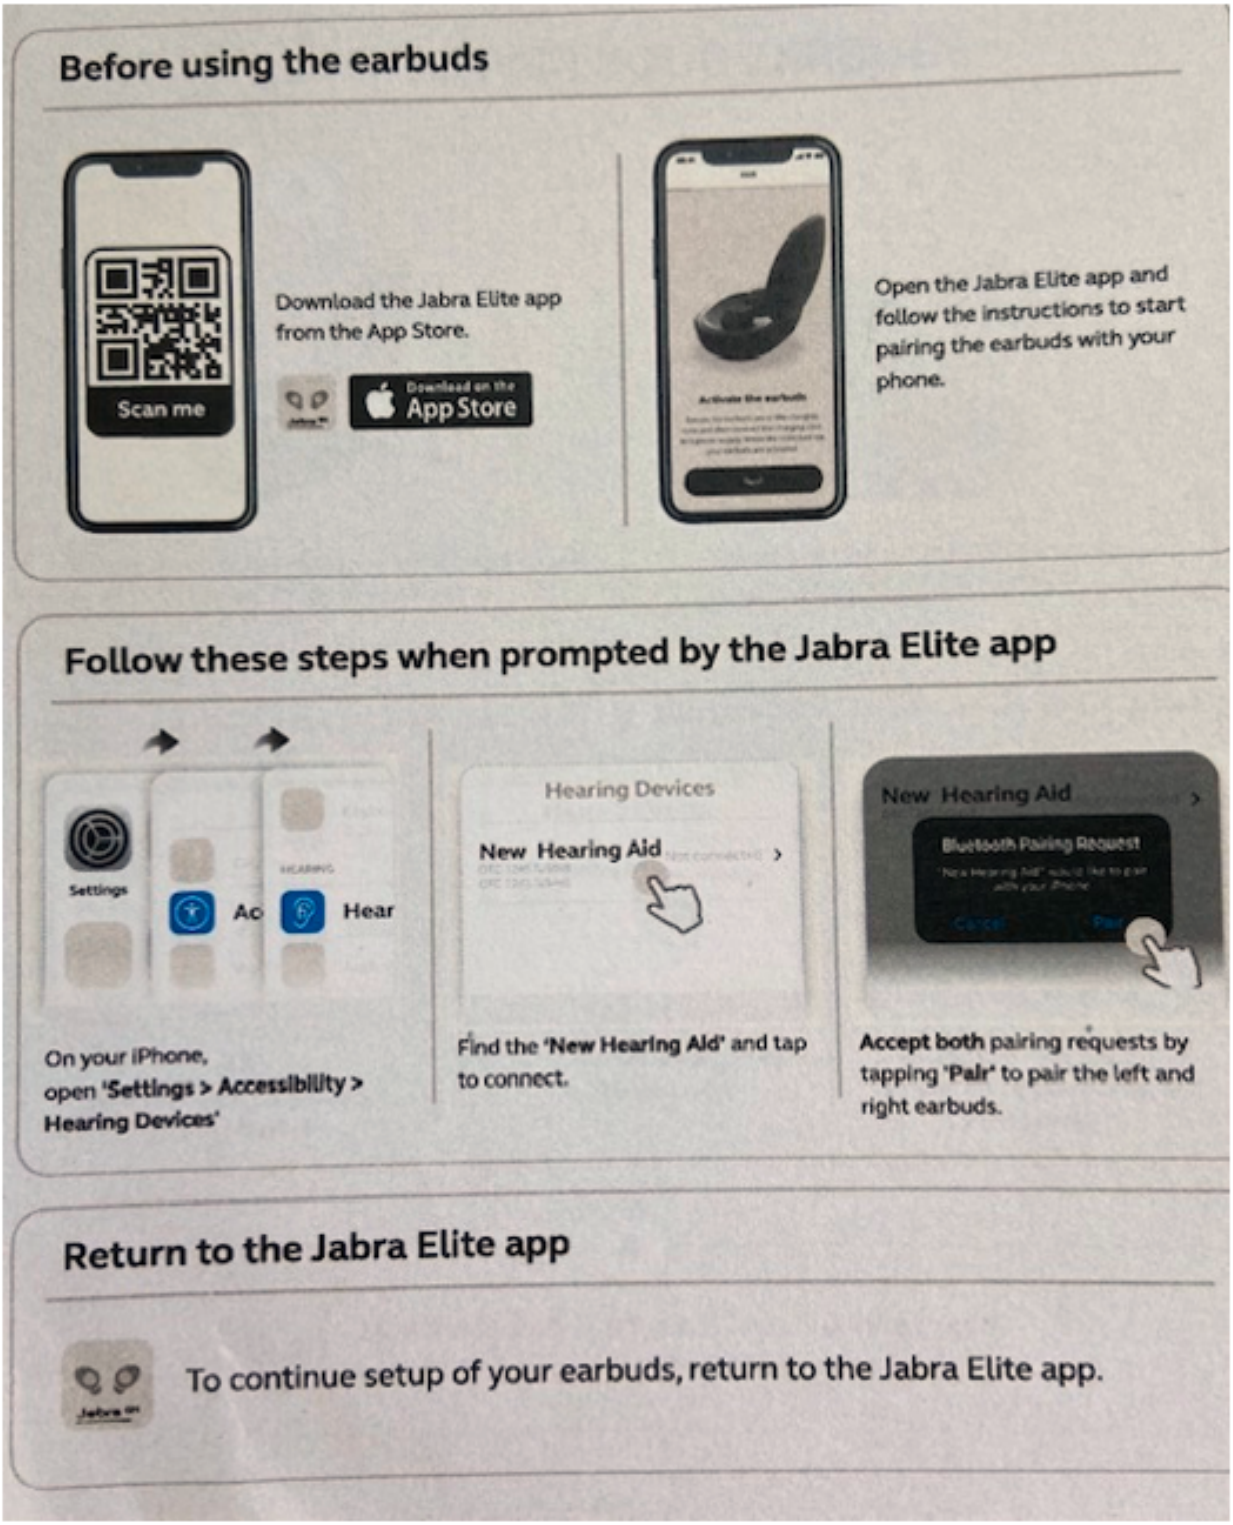
Overall, we found minimal safety issues with the set up and use of the device across all 3 rounds of testing. The one issue that presented potential, albeit minimal, concerns to safety was related to the accessibility of intended use and contraindications to use of the device. We found that the font size and color on the outside of the box made the intended use of the device hard to see and read (right side of Figure 1). Few participants saw or read this information on the box, and several participants indicated that they would not know the device was a hearing aid based on the outside of the box, stating "to know they are hearing aids, off the bat, I would have walked right by them."



A total of 3 participants in usability testing rounds 1 and 2 failed task 1 (read outer label) since they could not determine if it was appropriate for them to use the product based on the outside of the box. We identified the same problem with nonintended users of the device, with over half of the participants in round 3 stating that they did not know that the device was a hearing aid from the labeling on the outside of the box. All 3 of the participants with severe hearing loss and 3/4 of participants with tinnitus said (incorrectly) that the device would be appropriate for them to use based on the labeling on the outside of the box.

Device Pairing

The primary usability challenge with the device was setting up and pairing the hearing aids to the iPhone (task 2). In round 1, a total of 3 of 5 participants failed this task, and a fourth participant had difficulty completing it. A common challenge was that participants did not know that they needed to return to the app to complete the hearing aid set up after pairing the hearing aids to the iPhone. Rather, participants thought they were done setting up the device once they followed the Quick Guide pairing instructions (see Figure 2). The only participant to complete the task easily followed the workflow: open the Jabra Enhance app → pair the hearing aids using the iPhone → return to the app to complete the set up. As a result, we recommended design changes to the Quick Guide prior to round 2. As shown in Figure 3, the Quick Guide was revised to inform users to first go to the Jabra Enhance app before pairing the hearing aids to the phone. We further emphasized that users should return to the Jabra Enhance app after pairing to finish set up.



XSL•FO
RenderX

Figure 2. Quick guide instructions (December 2020 version—round 1 testing).

XSL•FO
RenderX

Figure 3. Quick guide (February 2021 version—round 2 testing).

Following these design changes, task 2 success rate increased from 40% (2 out of 5 in round 1) to 67% (10 out of 15 in round 2). Yet, there were still several use errors during pairing and setting up the earbuds in round 2. For instance, 2 (13%) participants did not understand that they needed to go to an app to set up the earbuds. Several participants had trouble reading the Quick Guide instructions as the text was too small (see Figure 3). A total of 3 participants did not know what to do after pairing the earbuds to the phone. Finally, it was unclear to participants which section of the iPhone settings to use to pair the hearing aids. Some participants had difficulty finding the "Accessibility" section in the iPhone's system settings, and some participants then went to the "Bluetooth" rather than the "Hearing Devices" section to pair the hearing aids.

Distinguishing the Right and Left Earbud

Participants had difficulty determining which earbud was for the right versus the left ear. Several participants stated that they

XSL•FO
RenderX

saw a "R" and "L" on the charging case, but not on the earbuds themselves. For instance, one participant stated, "so, there's not a right and a left?" while another participant said, "I don't see a left and right, they don't indicate that right?" Some participants were eventually able to identify the "R" and "L" markings on the earbuds stating,

> *Ah, there's an R on the end, that's really hard to see. I'd make that bigger...yeah that's really hard to see.*

The inability to distinguish the right from the left earbud resulted in several use errors, including difficulty placing the earbuds in the ears and difficulty placing the earbuds back in the charging case.

User Manual

The user manual contained information about the intended use and about most of the hazards of device use. The location of the user manual at the bottom of the box led to several use errors. Several participants were not able to find the manual. Finding the user manual was challenging since the text "User manual" was partially covered by the cardboard insert (see Figure 4). One participant said,

> *it's kind of hidden though...that's a little deceiving maybe, because I would have looked at this first.*

Another participant asked, "Where are the directions?" In total, 5 (33%) participants, all of whom identified the user manual, struggled to get it out of the box. Several more participants never took the manual out of the box; it is possible that these participants could not find the manual but did not verbalize this. Additionally, in round 1 testing, we found that there was not an entry in the table of contents to indicate on which page the "intended use" and "health and safety information" was within the user manual. This was corrected prior to round 2.

XSL•FO
RenderX

Figure 4. User manual cutout in box.

Product Design

Overall, participants were very positive about the device. They liked the size and design of the charging case (eg, small and easy to put in a pocket or purse), and they liked that the device was rechargeable, and thus did not require batteries. Participants liked the sleek and modern looking design stating, "it feels high-end" and said that the hearing aids were easy to place in their ears. They appreciated the different sized ear gels and the magnets that assured that the earbuds clicked into the correct charging position in the case. Participants were excited that they could purchase the device "off-the-shelf" and stated it would be helpful to use when they were in crowded rooms. Despite observed difficulties with setting up and pairing the hearing aids to the iPhone (task 2), participants reported that the app was easy to use. Finally, participants liked that they could adjust the hearing aids' settings on their phone.

XSL•FO
RenderX

Participants recommended several areas for improvement. Most participants desired a longer battery life (which was 6 h at the time of testing) so that they could wear the hearing aids all day without needing to recharge them. They also recommended that technical terms be better explained in the manual and on the box. One participant recommended that the hearing aids come in more discreet colors (ie, skin colored) instead of black. Participants recommended some modifications to the front of the box saying,

> *it should have more on the front about like if it's better for a noisier environment or something, because I'd be more likely to use it if it said, "will improve your hearing in a crowded environment" because I have a very hard time hearing when there is background noise.*

Some participants also found the contrast of white and red text on a gray background hard to read.

Knowledge Assessment

Table 3 details the scores for each of the 10 knowledge assessment questions across all 3 rounds of testing. Participants who used the user manual performed better overall compared to those who did not access or refer to the user manual. The user manual appeared to help the most on question 9—whether someone who had a recent episode of dizziness should use the earbuds.

Table . Knowledge assessment (percent correct answers).

#	Question topic	Round 1 (n=5), n (%)[a]	Round 2 (n=15), n (%)[b]	Round 3 (n=21), n (%)[c]
1	Tinnitus	1 (20)	13 (87)	13 (62)
2	Sinus infection	0 (0)	15 (100)	15 (71)
3	Severe hearing loss	4 (80)	8 (53)	5 (24)
4	Rapid hearing loss	1 (20)	11 (73)	11 (52)
5	Preference for earbuds	1 (20)	12 (80)	15 (71)
6	Laryngitis	3 (60)	4 (27)	7 (33)
7	Sore in ear	5 (100)	13 (87)	17 (81)
8	Ear wax	3 (60)	12 (80)	11 (52)
9	Dizziness	4 (80)	9 (60)	11 (52)
10	Ear infection	5 (100)	15 (100)	21 (100)

[a]Average percent correct: 50%.

[b]Average percent correct: 75%.

[c]Average percent correct: 60%.

Design Recommendations

Based on the identified usability issues, we recommended 9 design changes to the earbud system and its packaging (Table 4). We rated these recommendations as "high,""medium," or "low" priority. A total of 4 of the proposed changes (items 1, 2, 3, and 7 in Table 4) were implemented prior to subsequent testing rounds and all but 2 (items 4 and 5) were implemented prior to initial product release. Each design recommendation corresponds to a human factor's design principle (descriptions of the design principles can be found in Barton et al [22]).

XSL•FO
RenderX

Table . Design recommendations derived from the results of 3 rounds of usability testing.

#	Priority	Addressed before round 2 testing?	Addressed before product release?	Design recommendation	Corresponding human factors principle
1	High	Yes	Yes	• Increase the font size of the text in the Quick Guide	Readability (font and capitalization)
2	High	Yes	Yes	• Revise the Quick Set-up Guide and user manual to clearly show the following steps: • Download Jabra Enhance app from app store • Open the Jabra Enhance app (show a picture of the app) • Register and set up the hearing aids following the steps on the app • Pair the hearing aids with the iPhone (show pictures to show the steps of going to settings > accessibility > hearing devices), select "New Hearing Aid" device, accept both pairing requests • Return to the Jabra Enhance app (show picture of returning to app)	Organization (order)
3	High	Yes	Yes	• Add a section in the user manual's table of contents for "Intended use and warnings"	Organization (navigation tools)
4	High	No	No	• Add a screen in the app that lists the contraindications of use (eg, severe hearing loss, tinnitus, and dizziness). This could be a screen after the registration in the app that participants acknowledge they understand reasons they should not use the device.	Content (emphasis)

XSL•FO
RenderX

#	Priority	Addressed before round 2 testing?	Addressed before product release?	Design recommendation	Corresponding human factors principle
5	Medium	No	No	• Increase the font size of text about contraindications and intended use on the outside of the box.	Readability (font and capitalization)
6	Medium	No	Yes	• More clearly indicate on the box that the device is to support those with hearing loss. It may be helpful to add the below text from the user manual, page 1, somewhere onto the outside of the box: "This product may help you, if you: • Strain to follow conversations in both quiet and noisier environments • Miss important information during conversations • Have trouble hearing at a distance • Have trouble understanding the television or telephone calls"	Content (clarity of content)
7	Low	Yes	Yes	• Revise the app name and other aspects in the app and user materials to have a consistent term for the Jabra earbuds, for example, "Jabra Elite," "Jabra earbuds," and "Jabra hearing aid."	Comprehensibility (terminology)
8	Low	No	Yes	• Make the cut-out in the white box bigger so that the entire "User Manual" text can be seen (Figure 4), and add text directing users that the user manual is under the white box. Could say "User Manual" with an arrow pointing below the box.	Readability (layout and position)
9	Low	No	Yes		

XSL•FO
RenderX

#	Priority	Addressed before round 2 testing?	Addressed before product release?	Design recommendation	Corresponding human factors principle
				• Add a note on the "manual pairing" page of the user manual that participants should refer to the "first time use" section if it is their first time setting up the device: "if this is the first-time use, please refer to page X."	Organization (navigational tools)

Device Packaging

We recommended that the warnings and intended use information on the outside of the box be better emphasized (eg, larger font size and more color contrast) to ensure appropriate use. Due to participants' difficulty finding the user manual and getting it out of the bottom of the box, we recommended placing the user manual on the top so the user sees and touches it before accessing the product. This could improve safety as the user manual contains most of the warnings and intended use information about the device.

Pairing the Device

To better support the pairing of the device to the smartphone, we recommended that the Quick Guide be revised. Despite modifications after round 1 testing, participants still could not read or follow the Quick Guide instructions due to the small text size. We recommended that the font size in the Quick Guide be significantly increased given the older population intended to use this device. We also recommended modifying the Quick Guide to clearly outline the pairing steps (eg, go to "Settings" then "Accessibility" then "Hearing devices"). As participants did not know to return to the app to complete set up after pairing the earbuds to the iPhone, we recommended that the steps in the Quick Guide be more clearly sequentially marked (eg, 1, 2, 3,... or a, b, c,...).

Discussion

Principal Findings

In this study, we evaluated the safety and usability of an over-the-counter hearing aid for people with mild to moderate hearing loss. We conducted usability testing with 20 intended and 21 nonintended users of the device. We identified numerous usability issues hindering the optimal use of the hearing aid, and generated design recommendations to mitigate use errors and improve the overall design of the device.

This work expands our understanding of the safety and usability of novel, over-the-counter hearing devices [18,26]. Overall, we found minimal safety-related issues with the device. The primary safety risk is that the diagnosis and treatment of a serious condition, such as sudden deafness due to infection, may be delayed due to the lack of medical screening prior to the device use [27]. Consistent with this, the main challenge we found was related to the lack of understanding by nonintended users, including those with tinnitus and severe hearing loss, that they should not use the device. This issue underscores the importance of ensuring that device contraindications and safety warnings are clearly displayed and legible, preferably on the outside packaging. Further, redundant messaging should be incorporated; we recommended a verification dialog in the phone app during device set up to ensure that users understood device use contraindications.

Usability testing identified numerous usability issues with the device, which largely related to violations of human factors design principles. Some examples of violations of the principle, readability (font and capitalization), were the small font size of the contraindications on the outside of the box, the Quick Guide, and the markings of "L" and "R" on the hearing aids. We also identified issues with comprehensibility (terminology), as the device was referred to by different terms (eg, "Elite" and "Rogue") throughout the packaging and app. Based on our design recommendations, there were significant improvements in the usability of the device between the testing rounds. Human factors design principles [23,24], including those developed specifically for patient-facing medical documents [22,25], should be incorporated into the design of patient-facing medical devices. In hearing care, specific design guidelines for older adults (eg, use 12-14 pt font sizes, write in third-sixth grade level) [28] should be followed to maximize the ease of use of these devices given the substantial diversity in patients' physical and cognitive attributes and abilities, experience, and background.

We observed appreciable tension between the goals of designing for safety and designing for ease of use, aesthetics, and marketability. For instance, from a safety perspective, the device's contraindications for use (eg, tinnitus) should have been displayed in a large font such that they covered much of the back of the box. However, this would not be aesthetically appealing and there were concerns that it would deter customers from purchasing the device. Similarly, from a safety perspective, we recommended adding a hard stop in the app setup to ensure that the user understood the intended use of the device. However, this would have decreased the ease of pairing the earbuds to the phone. With over-the-counter medical devices, both product safety and aesthetic appeal are important [16] and

XSL•FO
RenderX

it can be challenging to achieve both concurrently resulting in trade-off decisions. For devices with greater safety risks, safety should be prioritized.

We found that participants were excited about an over-the-counter hearing aid and appreciated this product's design attributes. Similar to prior studies [18,26], participants liked the earbuds' discreet size and form factor, which made hearing aid use less obvious, especially given the growing general use of earbuds for listening to music or talking on the phone. Participants also liked that the device did not require batteries and that it had a small carrying case that could easily fit in a pocket or purse. Our study identified excitement about the device from the intended user population, which may result in increased access to and use of hearing aids.

We uncovered challenges in conducting usability testing with nonintended users of the device. One goal of the FDA device approval process is to identify areas of foreseeable misuse including use of the device by unintended users [11]. This is a unique issue with over-the-counter devices, as there is no clinical mediation to ensure appropriate use. During testing, we found that only 50% of nonintended users were able to determine that they should not use the hearing device. While the design of the device and packaging likely contributed to this, another challenge is that participants may have assumed they should use the device since they were recruited to participate in the study. In essence, participants may have been "tricked" into thinking they should use the device due to the nature of usability testing. Future research should explore additional methods or approaches for eliciting information from nonintended users of over-the-counter medical devices.

Another limitation of this study is that the findings are based on users' interaction with the device over only a short period of time; it is possible that as users learn to use the device, ease of use would increase or alternatively, new usability issues may emerge over prolonged use that we did not observe. We only used iPhones for testing and some of the participants were Android users. Despite diversity in participants' age, hearing ability, comfort with technology, and education level, our sample may not have included the full range of end user cognitive abilities, experiences, and backgrounds. In the real environment of use, older adults may rely on adult children or other family members to assist with device pairing and set up; our study highlights the usability issues encountered by older adults setting up the device on their own, without assistance. We also did not test actual use of the hearing aid to enhance participant hearing so we cannot draw conclusions on the function of the hearing aid technology. Future studies should evaluate the use of the hearing aid in the real environment over time to determine if it supports users' needs. There is increasing evidence, however, demonstrating efficacy of over-the-counter hearing aids in comparison to prescriptive devices [29,30].

Conclusions

This study describes the safety and usability of an over-the-counter hearing aid for adults with mild to moderate hearing loss. Based on the usability testing, we proposed human factors design recommendations to enhance the usability and safety of the device. For instance, the intended user group and contraindications for use (eg, tinnitus) should be clearly displayed on the outside of the box, as well as throughout the set up materials. Clear step-by-step guidelines should be available to support user set up and pairing of the device. We identified challenges to the design and testing of direct-to-consumer devices. As the population ages and technologies continue to pervade every aspect of our lives, the direct use of medical devices by laypersons will continue to expand. This study lays the foundation for future studies on best practices for the user interface design of direct-to-consumer medical devices.

Abstract

Background: Falls in hospitalized patients are a serious problem, resulting in physical injury, secondary complications, impaired activities of daily living, prolonged hospital stays, and increased medical costs. Establishing a fall prediction scoring system to identify patients most likely to fall can help prevent falls among hospitalized patients.

Objectives: This study aimed to identify predictive factors of falls in acute care hospital patients, develop a scoring system, and evaluate its validity.

Methods: This single-center, retrospective cohort study involved patients aged 20 years or older admitted to Shizuoka General Hospital between April 2019 and September 2020. Demographic data, candidate predictors at admission, and fall occurrence reports were collected from medical records. The outcome was the time from admission to a fall requiring medical resources. Two-thirds of cases were randomly selected as the training set for analysis, and univariable and multivariable Cox regression analyses were used to identify factors affecting fall risk. We scored the fall risk based on the estimated hazard ratios (HRs) and constructed a fall prediction scoring system. The remaining one-third of cases was used as the test set to evaluate the predictive performance of the new scoring system.

Results: A total of 13,725 individuals were included. During the study period, 2.4% (326/13,725) of patients experienced a fall. In the training dataset (n=9150), Cox regression analysis identified sex (male: HR 1.60, 95% CI 1.21 - 2.13), age (65 to <80 years: HR 2.26, 95% CI 1.48 - 3.44; ≥80 years: HR 2.50, 95% CI 1.60 - 3.92 vs 20-<65 years), BMI (18.5 to <25 kg/m²: HR 1.36, 95% CI 0.94 - 1.97; <18.5 kg/m²: HR 1.57, 95% CI 1.01 - 2.44 vs ≥25 kg/m²), independence degree of daily living for older adults with disabilities (bedriddenness rank A: HR 1.81, 95% CI 1.26 - 2.60; rank B: HR 2.03, 95% CI 1.31 - 3.14; rank C: HR 1.23, 95% CI 0.83 - 1.83 vs rank J), department (internal medicine: HR 1.23, 95% CI 0.92 - 1.64; emergency department: HR 1.81, 95% CI 1.26 - 2.60 vs department of surgery), and history of falls within 1 year (yes: HR 1.66, 95% CI 1.21 - 2.27) as predictors of falls. Using these factors, we developed a fall prediction scoring system categorizing patients into 3 risk groups: low risk (0-4 points), intermediate risk (5-9 points), and high risk (10-15 points). The c-index indicating predictive performance in the test set (n=4575) was 0.733 (95% CI 0.684 - 0.782).

Conclusions: We developed a new fall prediction scoring system for patients admitted to acute care hospitals by identifying predictors of falls in Japan. This system may be useful for preventive interventions in patient populations with a high likelihood of falling in acute care settings.

(JMIR Hum Factors 2025;12:e58073) doi:10.2196/58073

KEYWORDS

falls; inpatient falls; acute care hospital; predictive factor; risk factors

Introduction

In 2022, the proportion of the population aged 65 years or older in Japan reached a record high of 29% [1]. A 2017 survey by the Ministry of Health, Labour and Welfare of Japan revealed that patients aged 75 years or older accounted for 41.5% of all patients admitted to acute care hospitals [2]. Given the trend in population aging, it is projected that the number of older adult

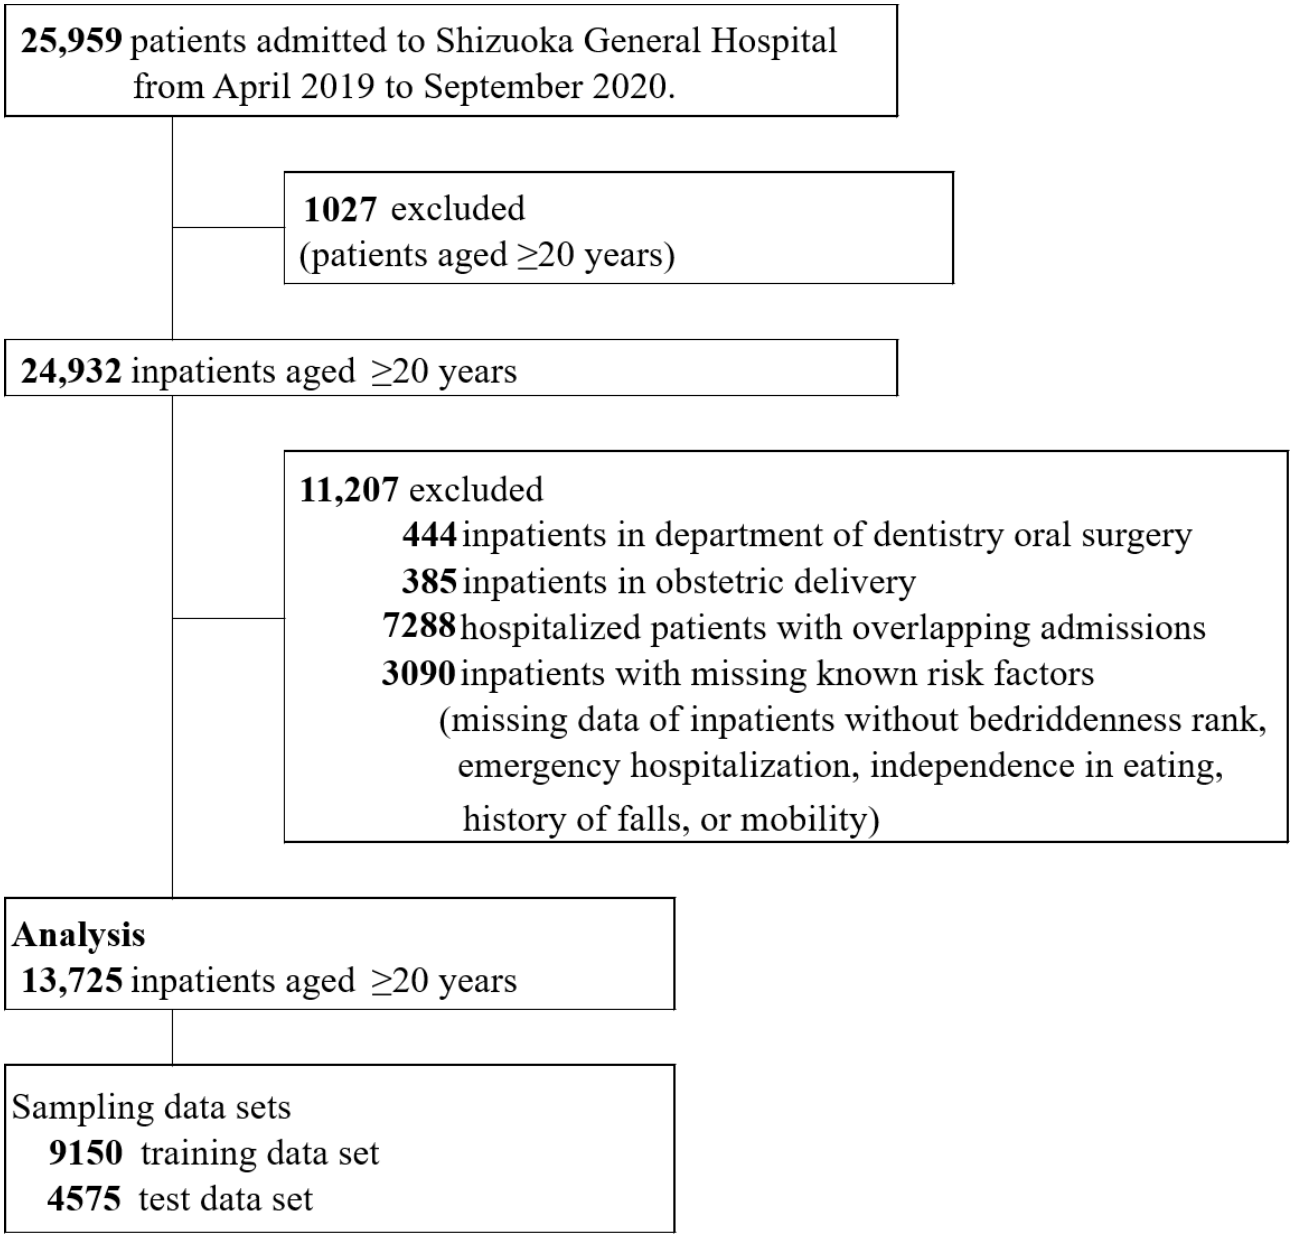
XSL•FO
RenderX

patients with a high risk of falling will further escalate in the future. Falls are not limited to older adults, and falls in hospitalized patients can lead to severe physical injuries, secondary complications, a marked decline in activities of daily living (ADL), and even death in extreme cases [3,4]. Therefore, fall prevention has become an important issue to protect patients' lives and quality of life [5].

Interventions for fall prevention must be strategically targeted to populations with a high risk of falling during hospitalization. Furthermore, previous studies have emphasized the importance of patient exercise therapy [6,7] and education for both patients and health care providers in fall prevention [8-12]. Educating patients about the risks of falls and strategies to mitigate these risks is crucial in reducing the incidence of falls in hospitalized patients. To effectively conduct patient education, it is imperative to construct a fall prediction model for the accurate identification of these high-risk patients. Currently, fall prevention measures in hospitals include fall prediction models using information from electronic health record (EHR) systems [13-22], as well as predictive models that analyze patient information from EHRs and nursing records using artificial intelligence [15,23]. Here, we present several fall prediction models that can be used with EHRs [17-20]. The STRATIFY scale [17] uses a history of falls, visual impairment, mental status, frequency of elimination, and ability to transfer and move as factors in a prediction model. The Morse Fall Scale [18] includes 6 items related to a history of falls, comorbidities, use of walking aids, intravenous fluids, ability to walk and move, and mental status. The Medication Fall Risk Score and Evaluation Tool [19] assesses the medication-related fall risk. This tool considers a patient's use of medications as predictors, classified according to the associated risk levels. Tago et al [20] reported 8 predictors of falls in people with disabilities in Japan: age, sex, emergency hospitalization, admission to neurosurgery, use of sleeping pills, history of falls, independence in eating, and level of independence in daily living.

Although fall prediction tools are widely used in Japanese hospitals, existing models vary in predictors and are often difficult to apply due to differences in facility and patient characteristics. Many hospitals also rely on tools that lack a strong evidence base [24,25] and are not well integrated with EHR systems. In our clinical environment, we found it challenging to implement existing models due to their reliance on numerous variables that are either difficult to extract from the EHR or unavailable. Therefore, we aimed to develop a streamlined fall risk assessment tool that considers facility-specific factors and can be seamlessly integrated with EHR systems, enabling real-time insights and more efficient fall prevention strategies.

The purpose of this study was to identify predictive factors for falls in patients admitted to an acute care hospital as well as to develop a scoring system using these factors and evaluate its validity.



Methods

Participants and Study Design

We conducted a retrospective cohort study of patients aged ≥20 years admitted to Shizuoka General Hospital between April 2019 and September 2020. Inpatients excluded from the study included those not covered by the Diagnosis Procedure Combination system, such as dental and oral surgery patients and obstetrics and gynecology inpatients during pregnancy, childbirth, and postpartum. In addition, inpatients lacking data on known risk factors such as the degree of independence in daily living for the older adults with disabilities, bedriddenness rank (BR), emergency admission, dietary independence, mobility, and history of falls in the past year were also excluded, as illustrated in Figure 1.

XSL•FO
RenderX

Figure 1. Flowchart illustrating the study population.

Variables at Hospitalization as Candidate Predictive Factors

All data used in this study were extracted from patients' medical records as of February 3, 2022. Preadmission medical history variables included dementia [5,6], Parkinson disease [7,26], stroke [6], visual impairment (with or with no diagnosis of glaucoma or cataracts) [4,5], history of falls [5,16,20,27], and use of sleep medications [20,28-30]. The following variables at admission were also collected: age [6,16,20,27], sex [20,27,28], BMI [31-35], date of admission [20], disease name at admission, department [20], mode of admission, ambulance transport, consciousness disorders [16,23,28], requirement for nursing care, good sleep condition, use of sleeping medication [20,28,30], status of medication management, BR [20,36], Cognitive Function Scores [5,6], ADL at admission (eating, transferring, dressing, toilet transfer or use, bathing, level walking, stair use, changing clothes, defecation management, and urinary management) [17,18,20], fall assessment end points at admission (history of falls or falls within 1 year, inability to stand without holding on [28], impaired judgment and comprehension, toilet assistance, and use of portable toilet), and presence of physical restraint screening at admission.

The BR [20,36] is an official assessment tool in Japan's long-term care insurance system [37]. The BR is an assessment of the degree to which a person's daily life is restricted; this degree is mainly assessed in terms of mobility in daily life, such as whether the person is independent, in a wheelchair, or bed bound. The Ministry of Health, Labour and Welfare ranks the degree of BR based on evaluations by nurses and other health care professionals according to the daily care they provide during hospitalization, as well as on reports from family members. The procedure for assessing BR and its reliability have been reported [20,36].

Falls During Hospitalization as an Outcome

The primary end point was the time from the date of admission to a fall at incident level [38] 2 or higher (hereafter referred to

XSL•FO
RenderX

as “fall”), which requires medical resources. For patients who died during hospitalization and those who did not have a fall, the date of death or date of discharge, respectively, was used as the censoring date. The classification of incident levels is shown in Table S1 in Multimedia Appendix 1.

Statistical Analysis

Demographic data and potential predictors at the time of hospital admission were summarized as follows. Continuous variables are described using mean (SD) or median (range), considering the distribution type. Categorical variables are summarized as frequency (%). For comparisons between the groups with and with no fall occurrence, *t* tests were used for continuous variables and chi-squared tests for categorical variables. The Kaplan-Meier method was applied to estimate the fall rate.

We explored predictors of falls and constructed a predictive model using two-thirds of the total cases, randomly selected as the training group, with the remaining one-third serving as the validation group for the scoring system. In the training group, predictive factors were identified using the Cox proportional hazards model, and we calculated hazard ratios (HRs), 95% confidence intervals (CIs), and *P* values. Predictive candidates that were significant ($P<.05$) in the comparison of backgrounds among patients with and with no falls, along with known predictors, were included in a multivariable model. Factors with *P* value of <.2 in this model were identified as predictors of inhospital falls. Independence between explanatory variables was confirmed using an absolute value of Spearman rank correlation coefficient of >0.4. Among 2 correlated variables, 1 was chosen based on ease of collection or clinical significance; this variable was then included in the multivariable model. According to the identified predictive factors, a score was created for each HR, and these scores were summed. We used a method called “conditional inference tree analysis” to categorize patients into 3 groups based on their risk of falling. This approach works by first dividing the data into 2 groups based on their overall scores. Then, a statistical test is performed to see whether these 2 groups are significantly different, and the variable that shows the strongest difference (the one with the lowest *P* value) is used to split the groups. This process is repeated within each subgroup until no further meaningful divisions can be made or the smallest group size allowed is reached. The predictive performance of this score and the fall risk groups in the validation group were evaluated using the c-index.

The significance level of the 2-tailed test was set at .05. Missing values were not imputed in the analyses. All analyses were performed using R (version 4.1.1; The R Foundation for Statistical Computing), EZR (version 1.54; Saitama Medical Center, Jichi Medical University) [39], and IBM SPSS (version 28; IBM Corp).

Ethical Considerations

This study conformed to the Ethical Principles for Medical Research Involving Human Subjects issued by the Ministry of Health, Labour and Welfare and the Ministry of Education, Culture, Sports, Science and Technology of Japan. Following these guidelines, the Shizuoka General Hospital research ethical committee determined that individual patient informed consent was not required because we analyzed existing information in this study, and patients were given the right to refuse participation via disclosure. After obtaining committee approval (SGHIRB #2020075; January 15, 2022) and publishing the disclosure document on Shizuoka General Hospital’s website, the information for each individual was anonymized, and the analysis was conducted.

Results

Patient Background and Falls at Incident Level 2 or Higher on Admission

From April 1, 2019, to September 30, 2020, a total of 24,932 inpatients aged 20 years or older were admitted to Shizuoka General Hospital. We excluded 3.3% (829/24,932) of patients not covered by the Diagnosis Procedure Combination, 29.2% (7288/24,932) with duplicate admissions, and 12.4% (3090/24,932) with missing known risk factors of falls. Consequently, 55% (13,725/24,932) of patients were included in the analysis (Figure 1).

During the observation period, defined as the length of hospital stay (median [range]: 13 [1-271] days), 3.6% (489/13,725) of patients experienced falls across all incident levels, of which 2.4% (326/13,725) falls were classified as incident level 2 or higher. For this study, we used fall data meticulously managed by the hospital’s medical safety department, ensuring accuracy and reliability. The details are shown in Table S2 in Multimedia Appendix 1. The median age (range) of the patients included in the analysis was 66 (20-103) years, with 52.1% (7150/13,725) male patients, and the median BMI (range) was 22.8 (9.6 - 58.1) kg/m^2. Table S3 in Multimedia Appendix 1 shows the results of the comparison between the backgrounds of patients in the training and test datasets. In a univariable analysis of the training dataset (n=9150; two-thirds of the study population), we compared patient backgrounds according to the presence of falls (Table 1).

Predictors of Falls

In the training dataset, univariable Cox regression analysis compared patient backgrounds based on the presence or absence of falls and identified factors affecting the time from admission to the date of fall (Table 2, left side). Correlations between explanatory variables were checked using Spearman correlation coefficients, and independent explanatory variables were entered into a multivariable regression model. The variables were narrowed down by applying a high absolute value of the Spearman correlation coefficient (>0.4) (Table S4 in Multimedia Appendix 1). Among the 21 variables that were significant in the univariable analysis, 5 variables (age, sex, BMI, department, and history of falls within 1 year) were not correlated with each other. Sixteen variables (including 12 ADL-related variables, emergency admission, and consciousness disorders) had a correlation coefficient of 0.4 or higher. From the correlated variables, BR was ultimately chosen. This decision was influenced by the fact that 12 other ADL variables showed correlation, and BR could potentially explain physical severity, including factors such as emergency transport and impaired consciousness. The variables were chosen based on ease of collection or clinical significance.

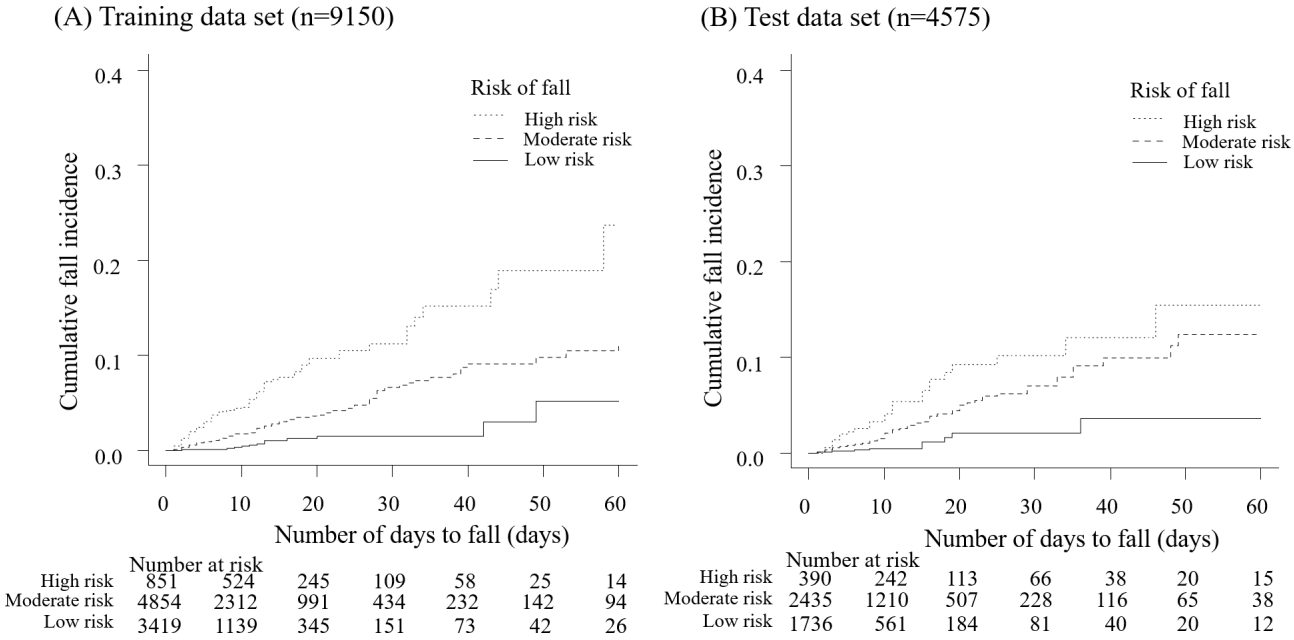
[c]Not applicable.

In multivariable analysis, age (65 to <80 years: HR 2.26, 95% CI 1.48 - 3.44; ≥80 years: HR 2.50, 95% CI 1.60 - 3.92 vs 20 to <65 years), sex (male: HR 1.60, 95% CI 1.21 - 2.13), BMI (18.5 to <25 kg/m²: HR 1.36, 95% CI 0.94 - 1.97; <18.5 kg/m²: HR 1.57, 95% CI 1.01 - 2.44 vs ≥25 kg/m²), BR (rank A: HR 1.81, 95% CI 1.26 - 2.60; rank B: HR 2.03, 95% CI 1.31 - 3.14; rank C: HR 1.23, 95% CI 0.83 - 1.83 vs rank J), emergency department (internal medicine: HR 1.23, 95% CI 0.92 - 1.64; emergency department: HR 1.81, 95% CI 1.26 - 2.60 vs department of surgery), and history of falls within 1 year (yes: HR 1.66, 95% CI 1.21 - 2.27) are shown as predictors of inhospital falls (Table 2, right side).

Construction of a Fall Scoring System

Based on the results of multivariable analysis using the training set, we weighted the scores based on each HR (Table 2, right side) and formed 3 fall-risk groups (low risk: 0-4 points, moderate risk: 5-9 points, and high risk: 10-15 points) using conditional inference tree analysis (Figure S1 in Multimedia Appendix 1). The new fall prediction scoring system built on this basis is shown in Figure 2. As a predictor of the performance of these 3 classifications of fall prediction, the c-index in the validation set (n=4561) was 0.733 (95% CI 0.684 - 0.782). The cumulative fall incidences in training and test datasets are

XSL•FO
RenderX



shown, with Kaplan-Meier curves presented for the training dataset (Figure 3A) and the test dataset (Figure 3B).

Discussion

Principal Results

This study was a retrospective cohort investigation conducted at an institution specialized in acute inpatient care, aimed at identifying the risk factors for falls using the time from admission to fall as the outcome variable. Fall risk factors included age, sex, BMI, BR, emergency department, and history of falls within 1 year. Specifically, the study found that older patients (aged 80 years and older) had a higher risk of falls, with men being more at risk than women. Patients with a BMI of <18.5 and those admitted through the emergency department had an increased risk. In addition, those with a history of falls within the past year were particularly vulnerable. We constructed a new predictive scoring system for falls by weighting scores based on each HR according to the results of multivariable analysis and using statistical methods to classify fall risk groups into 3 categories (low risk: 0-4 points, moderate risk: 5-9 points, and high risk: 10-15 points). The present fall prediction scoring system could facilitate preventive interventions for high-risk patients, potentially reducing the likelihood of falls among the most susceptible patient populations and improving patient safety and care in the hospital environment.

Comparison With Prior Work

In terms of age-specific fall incidence, it was evident that a higher proportion of falls occurred among people aged 65 years and older. This result is in alignment with previous reports [6,16,20,22,27,40] identifying advanced age as a predictive factor for falls. Consistent with past studies [5,16,20,22,40], a history of falls was determined to be a predictive factor.

Previous reports on predictors of falls have shown that sex can be a predictor for both men and women. In this study, being male was identified as a risk factor. In addition, men have been found to experience multiple falls more frequently [27]. Past reports indicating that being male increases the risk of falls [20,28] have focused on hospitalized patients whereas those suggesting an increased risk for women [41,42] have focused on community-dwelling individuals. These differences may be owing to the different characteristics of the study populations, that is, relatively healthy community residents and patients in health care facilities. This may be related to the fact that hospitalized patients tend to have reduced physical activity, which increases the risk of falls. However, the relationship between sex differences and fall risk factors in the hospitalized population remains unclear, and further research is needed to elucidate these aspects.

A systematic review targeting community-dwelling older adults showed that a low BMI (<17 kg/m^2) is associated with a greater risk of falls, when using 23.5 kg/m^2 as the baseline [34]. In addition, some reports indicate that both high (25 - 35 kg/m^2 or above) and low (below 18.5 kg/m^2) BMI values are associated with increased fall risks [31-33,35]. These findings suggest that extreme BMI values influence the risk of falling. However, in our study, we identified low BMI (below 18.5 kg/m^2) and normal BMI (18.5 - 25 kg/m^2) as risk factors for falls, using high BMI (25 kg/m^2 or above) as the reference category. This divergence in results might be attributed to the fact that in our Japanese study population, few patients met the international high BMI criterion (>30 kg/m^2). In the study, because only 5.7% (6/741) of people in this training category fell, BMI >30 kg/m^2 was not able to be included as the category for a categorical variable BMI.

The BR degree, which is strongly correlated with ADL, was identified as a risk factor for inhospital falls. This finding aligns with several fall prediction models [17,18,20], demonstrating the significant role of a decline in ADL, as it is known that exercise therapy is effective in fall prevention [6,7]. This underscores that impaired ADL is a crucial factor in determining the outcomes of patients who experience falls. In addition,

XSL•FO
RenderX

because the overall assessment of ADL is predominantly based on mobility, a substantial correlation [43] between ADL and BR has been observed. In our study, of the 15 variables that showed a correlation with BR, 12 were related to components of ADL.

Being admitted to the emergency department (as an inpatient department) was identified as a risk factor for inhospital falls. The emergency department inpatient population comprises patients who have been transported to the emergency department or who otherwise came voluntarily to the emergency department. This population typically has more severe illness, which may explain why emergency department admission is a risk factor for inhospital falls. Moreover, a history of falls within the past 1 year was identified as a risk factor for inhospital falls. This result was similar to previous reports that identified a fall history as a risk factor for subsequent falls [17,18,20].

Falls are internationally recognized as a serious health issue [3,30], and various efforts to prevent falls are undertaken worldwide. Particularly in Japan, where rapid aging is prevalent, fall prevention has become an increasingly critical issue. Education for patients and staff is considered a fundamental approach to addressing this problem [8,10-12,44], and the introduction and enhancement of educational programs in Japanese hospitals are desirable [10]. To achieve this, it is essential to identify high-priority patients among inpatients and implement fall prevention measures as a high-risk approach. Multifactorial interventions to comprehensively assess and address multiple fall risk factors have proven effective [10]. However, some tools for evaluating fall risk have been criticized for their time-consuming nature and limited effectiveness [45-47], necessitating judicious selection and effective use. Recent research supports these multifactorial interventions and highlights the importance of tailored educational programs and effective risk assessment tools. Guidelines from the United Kingdom's National Institute for Health and Care Excellence offer specific approaches for fall prevention [48], which could serve as valuable references for fall prevention strategies in Japan. In the approach to fall prevention in Japanese hospitals, international insights and guidelines should be considered while also tailoring unique approaches according to facility characteristics, health care delivery systems, and patient backgrounds.

Statistical Validation and Clinical Application of Risk Categorization

In our research, we used the conditional inference tree method for statistical analysis to categorize patients into low-, middle-, and high-risk groups, as detailed in Table S4 in Multimedia Appendix 1. This methodological choice ensured that our risk stratifications were based on solid data analysis, avoiding arbitrary determinations. In addition, this scoring approach permits adjustment of cutoff values based on each health care facility's resources and circumstances, enhancing its applicability in diverse clinical settings. Our aim is not to change the patient's fall risk level based on resources but to adjust the intensity of preventive interventions according to available resources. The fall risk classification is based solely on clinical characteristics, while resource availability guides the prioritization and distribution of these interventions.

For patients identified as high risk for falls according to our predictive model, it is important to recognize that identifying these individuals is only the first step; providing effective interventions is a separate and critical challenge. Based on prior research demonstrating their effectiveness, we recommend several interventions tailored to implement fall prevention measures as a high priority. Here, we outline interventions such as increased monitoring, personalized environmental adjustments, nonslip footwear, assistive devices such as walkers or canes, one-on-one support, and immediate assistance. In addition, patient education and rehabilitation are crucial components. Educating both patients and health care providers about fall risks and preventive strategies, combined with physical therapy to enhance strength and balance, can significantly reduce the risk of falls [6-12]. However, it may be necessary to adjust these cutoffs based on sensitivity and specificity considerations to enhance the accuracy of patient risk identification, aligning more closely with practical prediction practices in health care.

The fall prediction tool we developed integrates seamlessly with a hospital's EHR system. Upon a patient's admission, it automatically retrieves EHR data and calculates a fall risk score based on various predictors. This integration allows all health care providers, including emergency and trauma physicians, to easily access the patient's fall risk assessment. Emergency or trauma physicians can use this tool to quickly identify patients at high risk for falls and implement appropriate interventions. This proactive approach can significantly reduce the incidence of falls and enhance patient safety in fast-paced and high-stress environments such as emergency departments and trauma centers.

Limitations

This study has several limitations. First, owing to the identification of inhospital fall predictors based on the characteristics of the facility and patient population in an acute care hospital, generalizing the findings to other all hospitals may be challenging. While the generalizability of our model is not fully guaranteed due to the lack of external validation, hospitals with similar facilities and patient characteristics might find the identified predictors and scoring system developed in this study applicable to their setting. Second, our study did not examine psychiatric symptoms, including delirium, as a potential predictive factor [49,50]. Because previous studies have shown that psychiatric symptoms can be a risk factor for falls [17,18,28], it can be necessary to reconstruct the prediction model by including additional predictors of falls, including psychiatric symptoms such as delirium, in future studies. Third, we did not examine the association between medications and falls. Previous studies have shown that taking sleeping pills [19,20,28-30,51] and the number of medications [42,52-54] are risk factors for falls. At the time of our study, limitations in our EHR system made it difficult to collect accurate medication data. This prevented us from including medication type and number as predictors. Since then, our EHR system has been upgraded, and we can now reliably obtain medication data. We

plan to incorporate these variables in future studies to enhance the accuracy of our fall prediction model. Fourth, we could not compare the results of our model with those of existing fall prediction models. However, we believe that our newly developed fall prediction model is highly useful in that it is easy to apply in many Japanese hospitals with acute care settings, similar to that in this study.

To further enhance the practical application of our fall prediction scoring system, we plan to integrate it into our hospital's EHRs to gather real-world evidence. This will allow us to evaluate its usability, accuracy, and impact on reducing inhospital falls. Future research will include multisite longitudinal studies to validate the tool's effectiveness across different health care settings.

Conclusions

We successfully identified predictors of falls within a patient population admitted to an acute care hospital and developed a novel prediction model in Japan. This model could serve as an effective tool to guide preventive interventions for both individual hospitalized patients and high-risk populations in many hospitals with acute care settings.

Acknowledgments

We thank Motoe Yumioka, Satomi Unno, Kazuyo Okushio, Sumiko Sano, Hideko Mochizuki, and Kazue Sano for their guidance in conducting this study. We thank Ms Etsuko Nagahashi and Mr Hiroki Ueda of the Information Support Office of Shizuoka General Hospital for assistance with data acquisition. We thank Katherine Thieltges and Analisa Avila, MPH, ELS, from Edanz for editing a draft of the manuscript. This study was supported by a grant-in-aid for Medical Research Promotion from the Shizuoka Prefectural Hospital Organization and a research instruction budget from the Shizuoka Graduate University of Public Health.

Data Availability

The datasets generated and analyzed during this study are not publicly available since the authors failed to obtain informed consent regarding the disclosure of raw patient data at the start of the study, which means the data in the manuscript, supporting information files, or public repositories cannot be freely accessed. However, the datasets are available from the Clinical Trial Management Office at Shizuoka General Hospital, located at 4-27-1 Kita-ando, Aoi-ku, Shizuoka, Japan 420-8527 (chiken-sougou@shizuoka-pho.jp), on reasonable request.

Authors' Contributions

CS and EN contributed to study concept and design and data analysis; CS and KH contributed to data acquisition; CS, EN, HS, NEK, MT, and KH did data interpretation; and CS contributed to first draft of the manuscript. All authors read drafts of the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: The opaque nature of artificial intelligence (AI) algorithms has led to distrust in medical contexts, particularly in the treatment and monitoring of atrial fibrillation. Although previous studies in explainable AI have demonstrated potential to address this issue, they often focus solely on electrocardiography graphs and lack real-world field insights.

Objective: We addressed this gap by incorporating standardized clinical interpretation of electrocardiography graphs into the system and collaborating with cardiologists to co-design and evaluate this approach using real-world patient cases and data.

Methods: We conducted a 3-stage iterative design process with 23 cardiologists to co-design, evaluate, and pilot an explainable AI application. In the first stage, we identified 4 physician personas and 7 explainability strategies, which were reviewed in the second stage. A total of 4 strategies were deemed highly effective and feasible for pilot deployment. On the basis of these strategies, we developed a progressive web application and tested it with cardiologists in the third stage.

Results: The final progressive web application prototype received above-average user experience evaluations and effectively motivated physicians to adopt it owing to its ease of use, reliable information, and explainable functionality. In addition, we gathered in-depth field insights from cardiologists who used the system in clinical contexts.

Conclusions: Our study identified effective explainability strategies, emphasized the importance of curating actionable features and setting accurate expectations, and suggested that many of these insights could apply to other disease care contexts, paving the way for future real-world clinical evaluations.

Introduction

Background

While the role of artificial intelligence (AI) in health care is growing, concerns about its reliability and transparency remain largely unaddressed [1]. The opaque nature of AI algorithms challenges trust, particularly in cardiology, where the lack of interpretability in deep learning models limits their adoption and utility [2,3]. This has led to increased interest in developing explainable AI models that offer accurate predictions along with clear explanations of the rationale behind the predictive results [4].

Our study explored the advantages and challenges of using AI models in cardiovascular treatment, focusing on designing an explainable AI system to aid posttreatment care for patients with atrial fibrillation (AF) after catheter ablation. There were >3 million new cases of AF, a common arrhythmic disorder [5], in 2017, with numbers expected to rise due to aging [6]. Although often undetected, AF is a significant risk factor for severe conditions such as stroke or heart failure [7] and can greatly impact patients' quality of life [5,8]. While catheter ablation is effective, AF can recur after ablation, requiring careful monitoring of risk factors [9].

Several machine learning models, from screening algorithms [10,11] to those predicting AF recurrence after ablation [12], have been developed, but integrating them into health care remains challenging. Physicians often require detailed justifications due to prediction uncertainties. While explainable AI algorithms [5,13] could assist, a more holistic approach is needed in posttreatment scenarios to effectively integrate additional information, which remains poorly understood in real-world care contexts (discussed in the next section).

To better integrate a machine learning model into the ongoing decision-making ecosystem and identify unmet clinical needs beyond performance optimization, we used a user-centered, iterative design approach to develop AF'fective, an explainable AI system for posttreatment monitoring of patients with AF. By conducting semistructured interviews, design sessions, and focus groups with 23 cardiologists, we aimed to identify key principles for the effective design and use of explainable AI in real-life cardiac treatment and management. In this section, we first review the development of explainable AI in relevant fields in the second subsection and summarize our first 2 study stages in the third subsection. We then detail and discuss our final-stage findings and conclude with reflections on the study's implications and the generalizability of our insights.

High Accuracy but (Still) Rejected: Machine Learning Models in Cardiology

Cardiology is one field of medicine that has seen extensive use of AI to aid in medical practice. Various machine learning models have been developed and used to assist in a wide range of tasks, from helping predict the prognosis or readmission after heart failure [14,15] to detecting various cardiovascular diseases from medical images [16]. In the area of arrhythmia, previous studies have focused particularly on two key areas: (1) prevention, which involves assisting in the early detection of various arrhythmic conditions; and (2) monitoring, which involves supporting the management of such conditions after treatment [17]. In the preventive area, researchers have shown how machine learning models could be developed and used to detect irregular conditions using electrocardiography (ECG) signals [18] or even through photoplethysmography sensors from commercially available smartwatches [19,20]. In most cases, such models were able to diagnose these irregular conditions with a high degree of accuracy (97%) [20]. However, the potential for a high rate of false positives when implemented through commercial smartwatches has triggered concerns among researchers, and as a result, they have cautioned against using such systems for population-wide screening and emphasized maintaining the 12-lead ECG as the gold standard [21]. Given the prevalence of AF, several of the developed models in this domain have chosen to focus specifically on this condition, with various deep learning ECG models being developed to help screen people for AF, stratify patients based on their risk level, and even predict the chances of the condition occurring in the future (see the study by Sehrawat et al [21] for a comprehensive review).

In the monitoring area, to support posttreatment care, previous studies have developed models capable of predicting patient mortality or echocardiographic response after procedures such as cardiac resynchronization therapy [22]. Other studies have even shown how the risk of recurrence for conditions such as AF could be predicted using patient demographics and 3D computed tomography images of the left atrium [23]. Similarly, several studies have demonstrated how the recurrence of AF or 30-day hospital readmission after catheter ablation can be predicted using various deep learning and non–deep learning strategies (eg, convolutional neural network [CNN] and Extreme Gradient Boosting) [12,13,24]. In other cases, deep learning algorithms have also been developed to detect an AF episode 4.5 minutes before onset, thus enabling prompt interventions to prevent their occurrence [25].

Overall, while the findings of these studies all appear to demonstrate significant potential for implementing predictive models to support AF treatment, we have encountered substantial pushback from clinical partners when attempting to implement such a model in clinical practice. Despite the promising performance of the model in the study by Nishimura et al [26] (area under the curve of 0.72 with 83% sensitivity and 58% specificity), there was still strong resistance from physicians regarding trusting the predicted outcomes. Such hesitation and resistance to adopting machine learning models among clinical staff have also been frequently identified in previous studies [1,27]. Given the delicate and often critical nature of treatment in this field, it is not surprising that the lack of interpretability undermines trust in these models, preventing clinicians from using them in medical treatment (see the study by Petch et al [2]). Moreover, the opaque process raises concerns regarding how mistakes could be rectified, not to mention that it may cause potentially disruptive emotions when discussing such results with patients. Therefore, at present, the high accuracy, accessibility, and (possibly) low cost of machine learning models often do not lead to their adoption in medical practice.

Explainable AI in AF

Recently, explainable AI has gained attention as a potential approach to address these issues of transparency and interpretability [28-30]. In the context of AF treatment, ECG data are generally used as a main data source for screening irregular rhythm and predicting the risk of AF recurrence, and as such, explainable AI techniques such as Shapley Additive Explanations (SHAP) have been used with the ECG data to identify features contributing to the predictive outcomes [31]. In previous studies, researchers have proposed an explainable deep learning model that not only detects AF but also describes the reasons behind their decisions and visualizes key regions within the ECG signal identified as important predictors using techniques such as Gradient-Weighted Class Activation Mapping (Grad-CAM) or a deep visual attention [29,32,33]. Building upon earlier models, researchers such as Raza et al [34] incorporated federated learning techniques alongside explainable AI to preserve patient ECG data privacy. In more recent studies, explainable models have even been created that are capable of identifying patients at high risk after catheter ablation and highlighting the features (eg, type of AF, age, and left atrial diameter) that the model used to decide on the risk level for each patient [30]. The use of "explainable" models in this manner has been argued to have the added benefit of allowing clinicians to better understand the relationship between each contributing factor and the predicted outcome of an individual case, helping clinicians justify their decisions and treatments more effectively [35].

While explainable AI techniques are believed to enhance the interpretability of algorithms, incorporating them to truly improve patient outcomes in real-life medical contexts remains challenging [36]. Understanding of the strengths and limitations of these approaches in different use cases and how human and AI-based diagnoses can complement each other is still lacking [36]. Deploying these models effectively requires a thorough examination of the patient journey and adapting the explainable strategy accordingly. Recent studies [37,38] have begun to address these issues by examining the use of explainable AI in more realistic settings with various stakeholders to ensure safe adoption in clinical practice.

Overall, although the integration of explainable AI into medical contexts holds great promise, it requires a concerted effort to address technical, ethical, and practical challenges. Insights from near-live and real-life case studies can help develop best practices and trustworthy methods for implementing such systems in clinical settings, thereby enabling users and professionals to fully benefit from AI technology.

Early Study Stages and Findings in a Nutshell

In this section, we summarize and report the in-depth insights from the 2 early stages of interviews (partially reported as a poster in the study by She et al [39]) and group design sessions to conceptualize and pilot-test our design strategies and prototype. We chose to include some key findings from these early stages to enhance readers' understanding of our design decisions in developing the final prototype for evaluation.

Stage 1

Overview

In the first stage, we conducted semistructured interviews with physicians to gain insights into their experiences and best practices for posttreatment care of patients with AF. Physicians were asked to share their positive and negative experiences, communication strategies, and effective procedures for monitoring posttreatment patients with AF. To sensitize and prepare participants, we provided a 1-week workbook with reflection exercises sent 1 to 2 weeks before the interview. Each interview lasted approximately 45 minutes and was fully recorded with the consent of the physicians.

Participants

We invited 8 physicians from different specialties, such as emergency medicine, internal medicine, and cardiology, to join us for interviews at Kyoto Prefectural University of Medicine in Japan. We made sure to include a mix of experience levels and backgrounds in cardiology to obtain insights that could be more broadly generalized to other medical contexts.

Measurements and Study Apparatus

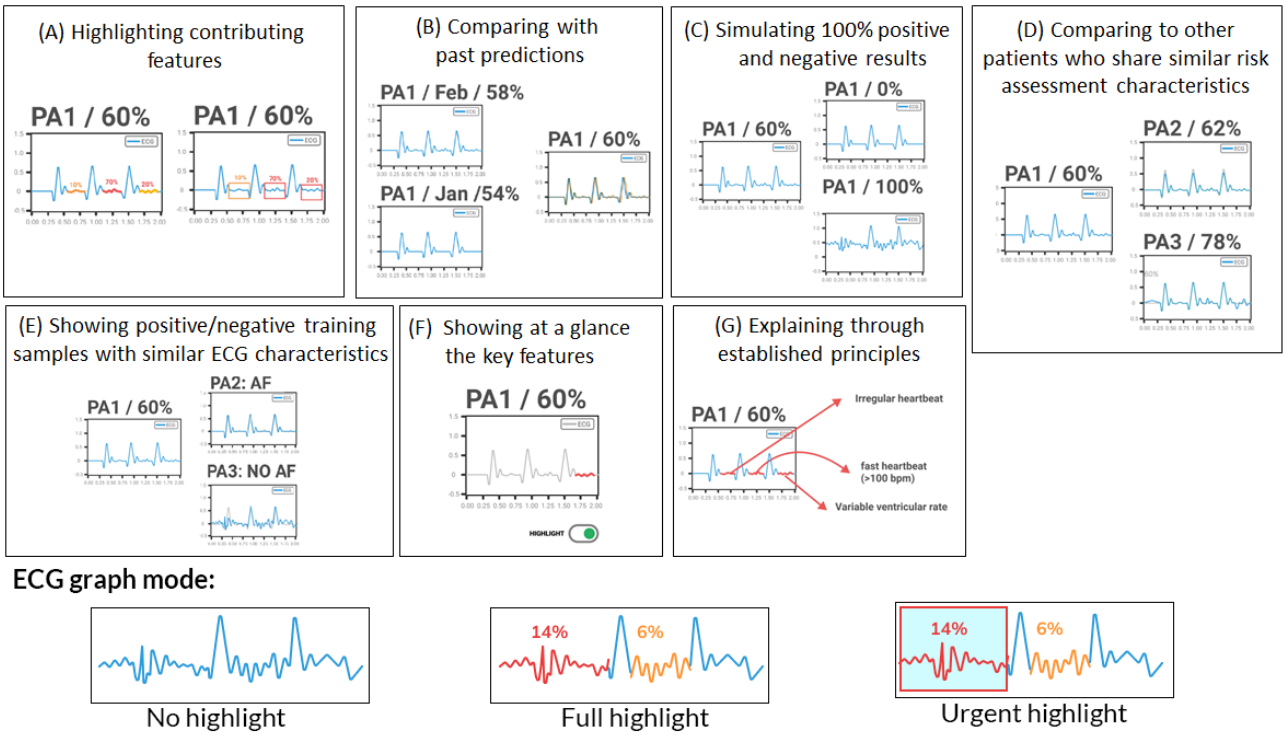
A week before the interview, each physician received a toolkit to reflect on their clinical practice. The toolkit included a workbook with 7 daily assignments on their experiences and patient interactions as well as stickers featuring emotional words and contextual images to help express their thoughts and feelings.

Study Process

We asked physicians to reflect on their process for diagnosing patients and explaining treatment plans, especially in difficult situations such as delivering bad news. They were also asked to share strategies for handling uncooperative patients or those who rejected treatment. Physicians were encouraged to use the 2 sticker sets to respond to workbook questions or use them as interview resources. During the interview, physicians were guided through the workbook to discuss their specific approaches, experiences, motivations, stressors, and methods for negotiating treatment plans.

Analysis

In total, 2 researchers from the human-computer interaction (HCI) field and a cardiologist analyzed the interview data, with all recordings fully transcribed. The HCI researchers developed design strategies through thematic analysis, whereas the cardiologist reviewed and selected strategies for further evaluation in stage 2.



Results

Our initial interviews with 8 physicians produced 2 key outputs: 4 physician personas (*teamworker*, *minimum effort professional*, *the veteran*, and *self-actualizer*) and 7 design strategies for explainable prediction. Each persona included pseudodemographics and progress bars depicting their personalities across 4 parameters: *passionate/realistic*, *rookie/veteran*, *work-oriented/life-oriented*, and *individualism/collectivism*.

XSL•FO
RenderX

The research team discovered that participants had common concerns about self-efficacy in patient treatment, feeling validated when treatments succeeded but disempowered when seen as incompetent. This insight led to the development of 7 design strategies for explainable prediction. Participants emphasized the need to justify decisions by clearly explaining issues such as ECG results to patients. We reviewed and adapted explainable AI strategies from previous studies [40] for cardiology. The seven strategies were (1) highlighting key ECG features (strategy A), (2) comparing with historical predictions (strategy B), (3) simulating extreme ECG outcomes (strategy C), (4) comparing with similar patients (strategy D), (5) showing similar training examples (strategy E), (6) providing an at-a-glance mode (strategy F), and (7) explaining through established ECG principles (strategy G; Figure 1 [39]).

Figure 1. The 7 explainable artificial intelligence strategies (A-G) that were examined in the initial 2 stages of the study, expanded from the previous publication [39]. AF: atrial fibrillation; bpm: beats per minute; ECG: electrocardiography; PA1: patient 1; PA2: patient 2; PA3: patient 3.

Stage 2

Overview

In the second stage, we evaluated the feasibility of the 7 design strategies from the first stage, focusing on those that could be implemented using explainable AI. Physicians first described their usual process for assessing recurrence risk and discussed the potential role of predictive models and explainable AI. We then introduced the explainable AI strategies and gathered detailed feedback on which would most effectively clarify predicted outcomes for other physicians and patients.

Study Process and Findings to Guide the Prototype Development

We conducted 2 group design sessions with 8 cardiologists to critically review and assess our design strategies. Initially, 5 cardiologists were asked to evaluate the advantages and disadvantages of each strategy, describe scenarios in which they would be useful, and reflect on their concerns regarding implementing such explainable features.

From the 7 proposed strategies, we selected 4 (strategies A, B, D, and G) for further development into a web-based prototype using a high-fidelity explainable CNN model with real patient data. In total, 3 cardiologists reviewed the prototype using the concurrent think-aloud approach [41] and provided feedback. They also discussed concerns about using AI during posttreatment care, specifically on whether the explainable features enhanced their trust in the AI system and how the system might add or reduce value in their practice.

Participants

A total of 5 cardiologists with experience treating AF were recruited from Kyoto Prefectural University of Medicine to assess the explainable AI strategies. In addition, 3 cardiologists from the same institution were brought on to evaluate a web-based prototype.

Results and Study Apparatus Development

The 4 effective design strategies identified were highlighting contributing features (strategy A), comparing with past predictors (strategy B), comparing with other patients (strategy D), and explaining through established principles (strategy G). Participants' choices were guided by 3 principles: discernibility (highlighting relevant noteworthy parts), comparability (intra- and interpersonal comparisons), and evidence-based approaches (derived from diagnostic examples or clinical literature).

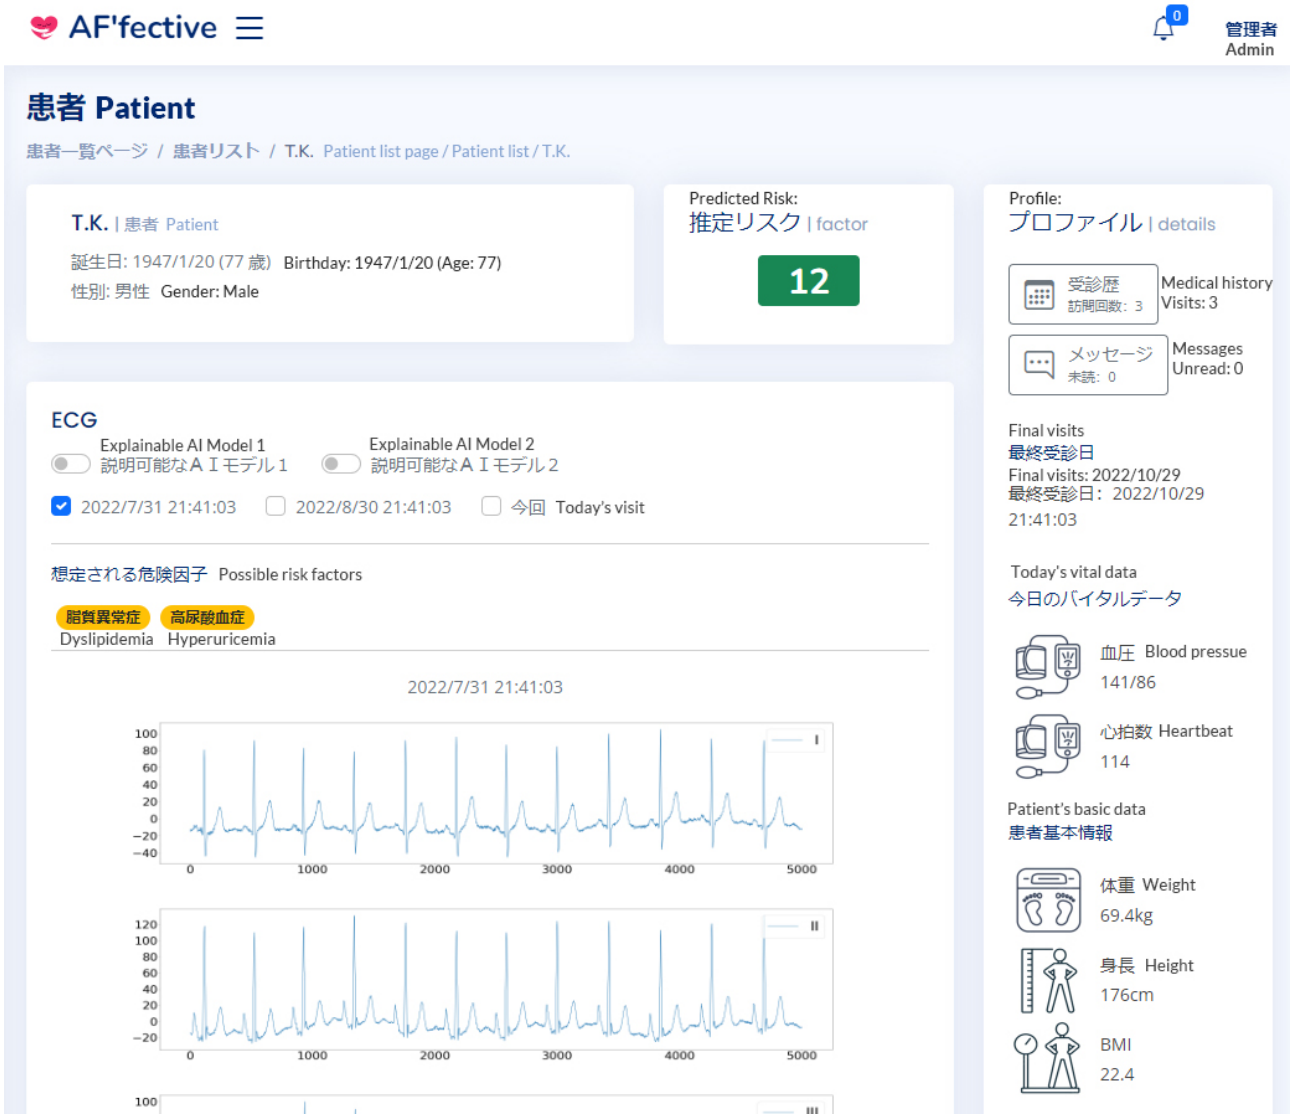
XSL•FO
RenderX

Strategies to avoid included non–evidence-based methods and those showing only partial graphs.

In general, physicians were highly receptive to the AF'fective prototype, particularly its explainable features, which they found useful for evaluating treatment effectiveness in posttreatment monitoring. On the basis of their feedback, we advanced to web-based prototyping.

The web-based prototype was developed using Figma (Figma, Inc), a popular tool among user experience (UX) designers for creating high-fidelity and web-based prototypes at minimal cost during the development process. Our prototype comprised 2 main screens: a patient overview screen and an individual health record dashboard (to avoid repetition of similar images, we share the screenshots from the final system in this paper instead; Figures 2 and 3).

The overview screen displays patients' demographic details and predicted recurrence risks, allowing cardiologists to sort by various demographic and risk factors. The health record dashboard displays (comparable and evidence-based) health information gathered from a patient's previous visits. Our predictive model will automatically extract and highlight keywords or risk factors based on the patient's visits and health data. In addition, the model differentiates the importance of the risk factors and offers 3 tiers of ECG result presentation based on the level of urgency for physicians: no highlight, full highlight, and critical highlight only.



In critical highlight mode, only urgent health information is shown, whereas the full highlight mode displays all details, including less urgent AI highlights. Validated risk factors are listed as diagnostic keywords in the right panel, helping physicians quickly identify the main contributors to the predictive outcome.

Methods

Overview

Our research followed a 3-phase approach collaborating with stakeholders familiar with AF management. In the first phase, we conducted semistructured interviews with 8 cardiologists to explore potential explainable AI strategies for postablation care. From these insights, we developed 7 design concepts, which were then critically assessed and refined by another 8 cardiologists in the second phase. This process led to the selection of 4 explainable strategies. In this section (the final phase of the study), we built a functional prototype incorporating real patient data and invited a third group of 7 cardiologists to evaluate its effectiveness and feasibility in clinical settings.

Ethical Considerations

This study received ethics approval from the relevant institutional review boards (IRBs) in Japan, including the Kyoto Institute of Technology IRB (2021-08) and the Kyoto Prefectural University of Medicine IRB (ERB-C-2014). Informed consent was obtained from all participating physicians, who volunteered to take part in the study without receiving any compensation. To ensure the privacy and confidentiality of patient health data, all personally identifiable information, including patients' names, was removed and replaced with unique codes. This anonymization process ensured that no data could be traced back to individual patients.

Stage 3

The web-based prototype from the previous stage was developed into a fully functional progressive web application (PWA) prototype, which was then tested and evaluated by cardiologists.

Patient Data

A total of 11 postablation patients consented to provide data for the prototype. Protected health information, such as names and birthdays, was masked or replaced due to IRB requests, but other health data (eg, ECG, body measurements, blood pressure, and visit history) were used to closely resemble the original patient health data for a realistic prototype.

Participants

In total, 7 cardiologists involved in the treatment of AF were recruited from the Kyoto Prefectural University of Medicine in

XSL•FO
RenderX

Japan. All of them had experience diagnosing patients with AF and performing catheter ablation.

Measurements and Study Apparatus

In total, 3 widely adapted UX-related questionnaires were implemented in our study: the User Experience Questionnaire (UEQ), technology acceptance model (TAM), and Mobile App Rating Scale (MARS). The rationales for including these questionnaires are explained in the following sections.

UEQ Inclusion Rationale

The UEQ, developed by Laugwitz et al [42] in 2008, consists of 26 items across 6 dimensions: attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty. The scale ranges from −3 (*most negative*) to +3 (*most positive*). Scores closer to 0 are considered "neutral." A data analysis tool is provided for interpreting the results, with benchmarks in 5 tiers: excellent, good, above average, below average, and bad [43]. Our goal during prototyping was to achieve above-average ratings. The English version was translated into Japanese.

TAM Inclusion Rationale

Previous research suggests that a user's intention to use is the primary predictor of actual system use [44]. To ensure that our PWA was both useful and usable in a medical context, we implemented the TAM to assess user acceptance and intention to use our explainable AI system. Originally developed by Davis et al [45], the TAM is a key model in new technology development. We adapted it for our PWA evaluation focusing on 3 dimensions: efficiency (perceived usefulness), ease of use (perceived ease of use), and intention to use (behavioral intention to use). For the TAM, a 7-point Likert scale is used, ranging from 1 (*strongly disagree*) to 7 (*strongly agree*). A score of 4 represents neutrality.

MARS Inclusion Rationale

Despite its name, the MARS is widely used to assess the quality of health applications across various types of digital platforms. It evaluates 4 dimensions: engagement, functionality, esthetics, and information quality [46,47]. We selected the MARS to assess the information quality of our PWA using the Japanese translation by Yamamoto et al [48]. The MARS uses a 5-point Likert scale ranging from 1 (*inadequate*) to 5 (*excellent*). Scores of >3 are considered above average.

AF'fective: The Web-Based PWA

A fully web-based PWA was developed using the Ionic framework (Drifty) for the front end and Python (Python Software Foundation) for the back end. Access was strictly controlled through an authentication system to ensure data security. The PWA included 2 main pages that were developed based on our explainable strategies: a patient overview screen (corresponding to strategy D) and an individual health record dashboard (corresponding to strategies A, B, and G). One noteworthy change was made to our predictive model, which also influenced our explainable features. On the basis of physicians' feedback, we omitted direct highlights on the raw ECG graph in stage 2 (using Grad-CAM; see the demonstration in Figure 1 [39]) and, instead, used the 7-item features derived from the standardized clinical interpretation of ECG graphs (corresponding to strategies A and G in particular; see the demonstration in Figures 4 and 5). In particular, we replaced the explainable AI model used in previous stages with a SHAP model [49], which was constructed to highlight the extent to which different key clinical features—commonly used as established interpretation principles in AF prediction for ECG data (eg, maximum P wave duration and augmented vector right [aVR]/first precordial lead [V1])—contributed to the decision-making process for strategy G. Therefore, the predictive model was updated from a CNN model (image based) used in the previous 2 stages to a Cox regression model (feature based) [26] to accommodate the introduction of 7 standard features for prediction (and, later on, SHAP for explaining). While physicians were not shown the Cox regression model's performance to avoid biasing them, it achieved strong evaluations, with an area under the curve of 0.72, sensitivity of 83%, and specificity of 58%. The model was trained on data from 502 patients, with an average follow-up of 6.2 (SD 3.5) years. A total of 13.1% (66/502) of the patients developed new-onset AF [26].

These standardized clinical explainable features are included in the following list. These features were derived from the interpretation standards that cardiologists commonly apply when reading an ECG graph and assessing a patient's risk level. As indicated in our previous studies, while directly highlighting sections of the ECG graph that contributed to the predictive model's output can explain the model's prediction, it does not aid physicians in interpreting the graph. To enhance the interpretability and physician-friendly explanation, we asked cardiologists to standardize their interpretation of the ECG graph into higher-level features that are more straightforward and easier to understand for their fellow cardiologists. Our previous work [26] provides details on training a predictive model based on these new features:

1. Max P wave duration >125 ms: whether the maximum P wave duration is >125 ms
2. aVR/V1<1: whether the amplitude ratio of the P wave is <1
3. Amplitude V1≥10: whether the P wave amplitude in V1 is >0.1 mV
4. Amplitude aVR<4=0: whether the P wave amplitude in the lead aVR is <0.04 mV
5. PAC on ECG=1.0: whether there was one or more supraventricular ectopies during recording (removed in the latest model for simplicity from the work by Nishimura et al [26])
6. RV5SV1≥2.2=0: whether the amplitude (height) of the R wave in the fifth precordial lead plus the amplitude (depth) of the S wave in V1 is >2.2 mV
7. PR≥185=0: whether the interval between the P and R waves is >185 ms

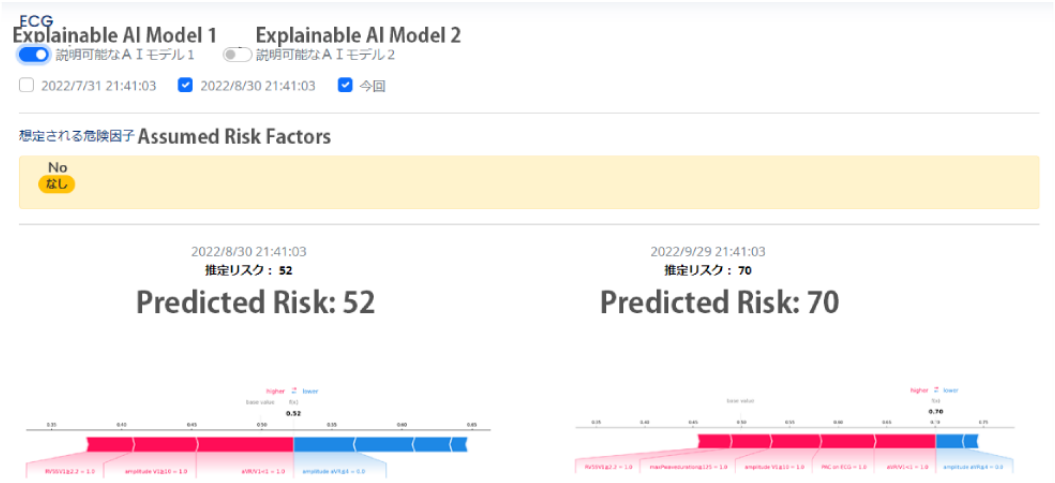
The individual health record dashboard (as shown in Figure 3) also allowed physicians to check past visit ECG graphs and explainable features (corresponding to strategy B). The physicians can obtain an overview of the basic patient data in the top left corner and then proceed to the raw ECG graph. In the main graph section, they can choose between 2 types of explainable models (see Figures 4 and 5 for the corresponding

XSL•FO
RenderX

graphs) and add data from the patient's history for comparison. The right panel provides additional patient correspondence data and physical measurements such as weight and blood pressure. The standardized features made it easier to compare patients when physicians navigated the patient overview board (corresponding to strategy G).

We also developed 2 interfaces to summarize the explainable features. The first interface (Figure 4) was developed using SHAP, a popular tool for explaining the outcomes of machine learning models [49]. It features a single bar chart that shows the combined influence of risk and protective factors. The second interface uses a pie chart to show the relative importance of the 7 items and their risk or protective contributions to the predictive outcome (Figure 5). Cardiologists were advised to access it using a computer, although the site is also available on mobile devices, to simulate their normal use context.

Figure 4. Screenshot of the explainable items and how they were displayed in the system—explainable model 1. ECG: electrocardiography.



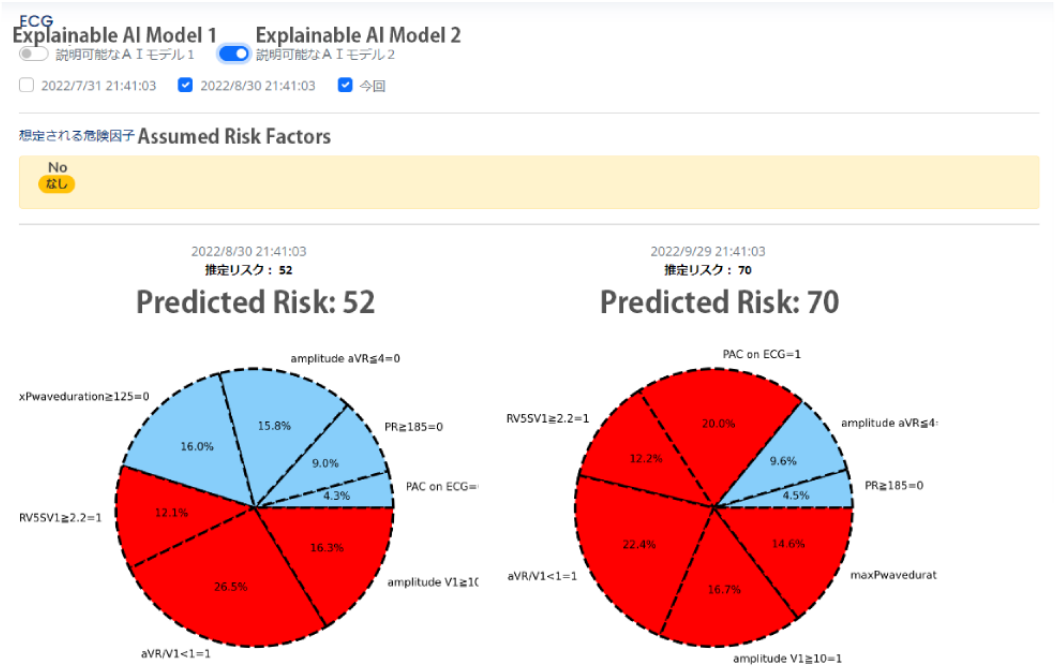


Figure 5. Screenshot of the explainable items and how they were displayed in the system—explainable model 2. aVR: Augmented Vector Right; ECG: electrocardiography. PAC: Premature Atrial Contraction; PR: PR Interval (the onset of the P wave to the start of the QRS complex).

Study Process

Each cardiologist participated in a 1-on-2 interview with an HCI researcher and a cardiologist. Before the interview began, the HCI researcher set the scene for the cardiologist using the following statement: "You have 11 patients that you are currently caring for. You can see a list of them in the AF'fective system, which indicates their risks levels for recurrence." Participants were first briefed on the system and then asked to test it by imagining the following four scenarios: (1) viewing a patient's status, (2) checking a patient's ECG graph, (3) viewing explainable model 1, and (4) viewing explainable model 2. We then asked the cardiologists to complete the study measurements (UEQ, TAM, and MARS, as described in a previous section)

XSL•FO
RenderX

and began the semistructured interviews. Each interview lasted 45 minutes to an hour. All the interviews were conducted in Japanese and fully recorded, including screen recordings of the participants testing the AF'fective PWA.

Analysis

For the survey data, we calculated the mean and SD for each item in all surveys except for the UEQ, which has its own analysis tool in Microsoft Excel (Microsoft Corp) format. We compared our mean scores for the TAM and MARS against the theoretical average scores to determine whether physicians experienced any usability issues related to the interface design, functionality, information quality, or accessibility.

For the interview data, we reviewed and analyzed the transcripts following the thematic analysis framework proposed by Clarke et al [50]. The analysis was carried out by 3 researchers, 2 from the HCI field and 1 with a cardiology background. As the 2 HCI researchers were more familiar with the analysis method selected and had a long history of conducting thematic analysis, the initial formation of the themes was first conducted by them. The HCI researchers first read through all the transcripts to familiarize themselves with the content and highlighted interesting quotes. The quotes were then summarized and independently interpreted as "topics of interest" by the HCI researchers. The researchers then grouped the topics into several potential "themes" and involved the cardiologist to approve and edit the themes. The cardiologist researcher then joined the evaluation to come up with the final findings that were deemed meaningful in both the HCI and medical fields.

Results

Overview

In the final stage, we recruited 7 male cardiologists (aged 31 to 55 years) with 8 to 30 years of cardiology experience. After the interviews, they completed the surveys, and we calculated the mean scores to identify potential usability or design issues. The results suggested no significant usability problems, and the prototype showed strong potential to motivate physicians' intention to use it due to its ease of use, reliable information, and explainable functionality. The detailed survey results are reported in the following sections.

UEQ Results: Positive Perspicuity

The results from the UEQ showed that perspicuity received a positive evaluation (mean 1.21, SD 0.96), whereas attractiveness (mean 0.56, SD 0.71), efficiency (mean 0.625, SD 0.27), dependability (mean 0.33, SD 0.27), stimulation (mean 0.5, SD 0.3), and novelty (mean 0.58, SD 0.27) received neutral evaluations. Perspicuity stood out as the most positively perceived aspect of the UX, suggesting that ease of use and clarity are strong points of the AF'fective system. The neutral evaluations for the other aspects (attractiveness, efficiency, dependability, stimulation, and novelty) indicated that physicians had average or mixed perceptions of these factors.

TAM Results: Above-Average Technical Acceptance

In addition, the TAM measures showed that perceived usefulness (mean 4.22, SD 0.31), perceived ease of use (mean 5.13, SD 0.77), and behavioral intention to use (mean 4.77, SD 0.68) scores were all above the average (mean 3.5). The behavioral intention to use score indicated a strong intention to use the AF'fective system. These results suggest that the identified factors motivated users to engage with the system.

MARS Results: Perceived High Functionality and Information Reliability

Finally, the results of the MARS showed above-average scores for functionality (mean 4.25, SD 0.42), esthetics (mean 3.61, SD 0.68), information reliability (mean 3.38, SD 0.54), and perceived impact on practice (mean 3.33, SD 0.76). These results indicated that users perceived high functionality and reliable information from the AF'fective system, whereas they rated its esthetics and perceived impact on practice as somewhat mediocre. We were particularly interested in the physicians' high ratings for information reliability as these suggested that they felt confident in understanding and agreeing with the predictive model's decisions. Notably, this rating was achieved without physicians knowing the predictive model's performance. This serves as a strong indicator that insights derived from explainable models play a crucial role in physicians' adaptation to our technology. This was deemed acceptable for a system in its prototype phase.

Discussion

Principal Findings

Overview

Aligned with our positive survey results, cardiologists expressed strong acceptance of the explainable features and willingness to use the system during the in-depth interviews. They also praised the system's enhanced efficiency, comprehensibility, comparability, consistency, and trustworthiness:

> *I think it is useful to be able to express in a general, universal, numerical way what we used to say in the past, like, "This person is likely to have a recurrence," by using a risk score. I think it is useful.* [P04; male]

> *In clinical practice, we honestly don't have that much time to look at ECGs and scores in detail, so I think AI is a way to make it easier for us to get the numbers out.* [P07; male]

> *I think it is easy to pick up if you can tell from a quick glance at the list that a person in red is at higher risk of recurrence, or that a person in green has a low probability of recurrence.* [P06; male]

While most cardiologists in our study viewed the real data–backed explainable AI system positively, we identified potential concerns and (possibly) false expectations for its real-life implementation. During the interviews, cardiologists were asked to envision using the system in their daily routines, leading to a realistic discussion after 2 rounds of iterative design. This probing step was crucial for understanding the feasibility and challenges of implementing the system in clinical settings. Our findings are discussed in the following sections through 4 key themes.

XSL•FO
RenderX

Explaining the Symptoms Does Not Equal to Identifying the Causes

Perhaps due to our intentional mimicry of cardiologists' methods for identifying irregularities in ECG graphs, participants showed high acceptance of the predicted results after viewing our 7-item AF clinical explainable features. In fact, P04 gave a very positive endorsement of why the explainable items were necessary:

> *I am of course curious as to why the risk was higher, so the AI [predictive] model would be rather meaningless without a graph [with explainable AI items] that can explain it, or perhaps it would make me wonder why the model [makes such a decision].* [P04; male]

According to P04, the predictive model's results may fail to convince them without an explanation of why the model makes a particular decision. P04's reaction suggests that physicians find explanations based on the new clinical explainable features both agreeable and trustworthy. However, a concern emerged regarding the limitations of these features. A key request was, "Then what should I do?"—cardiologists wanted to understand the features influencing the risk score and actionable strategies to address them. This aligns with previous insights showing a preference for clear indicators and actionable steps. In one case, P05 even suggested using the system to nudge patients toward behavior change:

> *We are at a stage where only these numbers [of explainable items] are available. 40 or something like this is the only thing that comes out, so what should I do [with each of the items]?* [P04; male]
>
> *I feel that the numbers alone don't mean much, or don't seem to lead to a change in [patient's] behavior.* [P05; male]

It should be noted that physicians treated each explainable feature as a "treatable item," which was not possible with an ECG graph–based explainable model. This improvement suggests that converting graphical highlights into standardized feature explanations can foster the expectation that addressing each item will reduce the risk score. In our current phase, it is still too early to determine how to further link our features with treatment approaches; however, this does indicate an interesting and operationalizable future implementation for explainable models.

Hence, in our current system, while these features influence the predictive outcome, clinical causal insights should be interpreted with caution. Our 7-item explainable features are based on standard ECG wave interpretation, identifying AF symptoms but not directly indicating underlying causes such as excessive drinking or sleep apnea. As noted in the document by Shapley [51], estimating causal effects from explainable items can be misleading. Cardiologists should be cautioned about this limitation and guided to set appropriate expectations for decision-making.

A key lesson from our interviews was the need for better curation of explainable features in the model, especially in clinical contexts. While various approaches provide transparency in AI decision-making [31,39,52,53], it is crucial that the chosen features are relevant, operationalizable, and actionable for medical professionals. This focus ensures that AI predictions are both understandable and practically applicable, enhancing postablation patient care.

Window for Interpretation: When 0% and 100% Recurrence Risk Does Not Exist

While a predictive model can theoretically provide risk scores from 0% to 100%, in real life, extreme scores such as 0% or 100% are unattainable. Participants noted that the possibility of such extreme scores diminishes the perceived realism and reliability of the model's predictions:

> *Theoretically speaking, it has to be 0, so even if it's low, it's still bad. You can't say 30 is a good thing. There is still a chance for a recurrence...So there are cases where it comes out as 0? (Cardiologist interviewer: That would be considered extreme score. Well, some might be zero, but I think the smallest is probably 3 or 4 [in the natural clinical contexts].)* [P03; male]
>
> *I'm not quite sure what [the risk score] means. There are a lot of questions about what 12 means and what we should think about it. It's not 0 [even for a normal person], So are you saying that AF can happen to anyone? (Interviewer: I don't think we can lower that number any further.)* [P05; male]

In a similar manner, participants also questioned whether a predictive score of 100% was at all meaningful in clinical practice:

> *Are you saying that even if all of [the items] were full, it would not be 100?(Interviewer: Even if [all of the items were] full, I think it will probably be around 80-92, which is the highest risk score [in the natural clinical contexts].)* [P01; male]

It should be noted that it is uncommon for a predictive model to yield a full 100% score in clinical contexts, particularly in postsurgery contexts. The contributing factors would generally contain complex interactions and dependencies.

Cardiologists emphasized that recurrence risk scores should be viewed as reference points, not absolute indicators. Establishing a threshold, such as 50, is essential for guiding actions, but borderline scores (eg, 49 or 51) still warrant patient warnings or follow-ups. Similar "borderline windows" were noted in a grief-related study [52] where psychologists suggested taking the score as a reference for concerning cases. Although the width of the borderline window can also be highly subjective for each individual cardiologist and possibly for patients, this approach is common in clinical practice. Future studies should develop nuanced protocols for borderline cases to prevent misdiagnoses and patient stress, potentially standardizing risk level interpretation, as suggested by P05:

> *I think it would be better to indicate the risk of developing the disease on a 5-point scale, such as low, medium, and high, because I don't think there is such a difference between 40 and 41.* [P05; male]

XSL•FO
RenderX

In treatment decision-making, another notable implication from our findings was the patient's presumptive belief that the risk score should be 0%, particularly after undergoing ablation. It was apparently conflicting with what the predictive model would reveal:

> *However, if you think about it, after AF ablation, the number of people who think that AF recurrence is quite small. For example, more than 70% to 80% of the patients think it is zero.* [P03; male]

Even cardiologists familiar with the postablation risk might expect that addressing the explainable items (see the Methods section for more discussion on these items) could eliminate the recurrence risk:

> *Considering the importance of risk scoring...I am very interested in the explanatory factors or items involved, and which of them are [positively correlated to the risk score]. If the purpose of this system is to follow up the patient, it would be even better if we could get such risk factors and know what kind of intervention is being done here.* [P01; male]

It struck the research team that popular explainable AI approaches could lead to misinterpretations and unrealistic expectations, such as believing that a 0% recurrence risk is easily attainable. Our study highlights the need to set accurate expectations about what predictive results and explainable features truly imply in a clinical context and how much they can be influenced through intervention.

Offer a Holistic Risk Overview by Integrating Other Risk Factors and Temporal Data

In our study, we adopted the flow of cardiologists' diagnostic process by reviewing ECG graphs and assessing the presence of known risk factors one by one. Therefore, other known risk factors, such as high blood pressure, smoking, and drinking, were included as additional "risk factors" alongside the predicted risk score derived from the patient's ECG data. While we believed that this approach resembled a cardiologist's normal decision-making procedure and would increase their acceptance of the model's predicted results, our interviewees expressed concerns about the potential for the predictive model to yield biased risk estimates:

> *There are many known risks that are commonly associated with AF, such as high blood pressure, obesity, lack of exercise, etc... Inputting it would further make this risk [score], or perhaps, the evaluation, more correct.* [P03; male]

> *So we are predicting the risk score purely based on ECG...If you are going to make progress, I think it would be good to include obesity information, bmi, waist circumference, and so on.* [P06; male]

Furthermore, some of our participants also indicated that they would prefer a clear display and association with the medications or ongoing treatments that the patients are receiving. For instance, P02 requested us to explore whether the explainable model could reflect the effects of the patient's medications, and P01 indicated that it would be better to see which interventions were done to lead to the risk score:

> *If there was information on arrhythmia medications, it would be more useful. I think the doctor might be able to think about it more holistically, such as, "This ECG variation [highlighted by the explainable model] is caused by the medicine the patient is taking."* [P02; male]

> *If the purpose of this system is to follow up the patient, it would be even better if we could get such risk scores and know what kind of intervention is being done here.* [P01; male]

As the cardiologists pointed out, although our model provided an overview of the other risk factors, it would only be meaningful if they could establish a connection between the variation in risk scores and the specific risk factors. Our findings indicated that, for explainable elements to be truly useful in real-life practice, they need to relate to more holistic and treatment-related risk factors or medications. Otherwise, the contribution of such a predictive, even explainable, model to preventing disease recurrence would be quite limited.

In the end, perhaps the most important takeaway from the interviews was the need to provide a holistic overview and explanation of intrapatient temporal data and risk scores. Echoing the insights from previous interviews, the design strategy of comparing interpersonal ECGs (strategy G) was heavily criticized by the physicians as individual risk factors can vary significantly. However, comparing a patient's current and historical risk factors could provide valuable insights into the evolution of these factors and potential trends in recurrence risk. For instance, participants P04 and P06 described how they would like to plan their interventions by tracking variations in risk scores and identifying the underlying causal factors over different time points:

> *For a patient with a high estimated risk this time, but lower estimated risk in the previous times, why did it become so high? What factors contributed to it? [I would expect] this AI model to estimate and explain.* [P04; male]

> *I think it would be better to look at it...from a longitudinal point of view...to see what kind of intervention I should use, what's going wrong, and what the reason is for the increase [of the risk score].* [P06; male]

We were intrigued by the design opportunities revealed in our findings. As cardiologists reminded us, a significant and crucial aspect of their profession involves deciding on appropriate interventions. Although explainable AI models have shown promise in diagnosing and identifying patients at risk, they have yet to offer actionable insights for intervention planning. We believe that explainable AI tools should integrate comprehensive patient data, including temporal variations in risk factors, medications, and treatments, to enhance the model's relevance and utility in real-world settings. In addition, the insights generated should be clearly linked to potential intervention strategies that could influence risk scores. Without such integration, the potential of explainable AI tools to contribute meaningfully to patient care, particularly in preventing disease recurrence, may remain limited.

A Sense of Control and Learning From the Model

The findings of our interviews revealed that cardiologists valued the sense of control and the learning opportunities provided by these models, aligned with the findings in the previous rounds that suggested a self-actualizing and constant learning side of cardiologists.

One of the key insights that emerged from our study is the potential of explainable AI models to help cardiologists prioritize patients at higher risk. As P04 addressed, there was a potential for these models to become an integral part of daily practice:

> *If it becomes a habit, I will probably look at people with high estimated risk and wonder why they were at higher risk.* [P04; male]

Moreover, P02 also offered a similar thought regarding triaging patients based on the risk scores:

> *So the follow-up should be more thorough, and those who are more likely to be affected [by the recurrence risk] should be followed up in a shorter period of time.* [P02; male]

By discriminating the patients that need urgent attention, physicians gain a sense of control over who to allocate more time and treatment resources to. Cardiologists indicated that such a potential new routine would enhance their work efficiency and allow them to spare cognitive capacity for more critical treatment planning. Interestingly, our interview findings suggest that cardiologists may appreciate useful "hints" or "interpretations" from explainable models to help them narrow down potential problems:

> *I understand that the ECG is used as the reference, but I think it would be easier to understand if there was an explanation of what is of interest in this ECG, even though those who understand may [already] understand it.* [P01; male]

The power dynamic between cardiologists and the AI model is worth exploring. To what extent should an AI model's interpretations be considered, and to what extent should cardiologists accept its suggestions? These boundaries are critical to explore to ensure that the final AI models can be effectively integrated into the patient care routines.

Further enhancement of control over the prevention procedure might also occur as cardiologists begin to learn more from AI-augmented interpretation and actionability. Interestingly, the explainability of AI models appears to increase cardiologists' desire to validate their treatment approaches:

> *So, at the time of the ablation, if I burn the tricuspid valve, you know [the score will go down], or if I burn the superior vena cava, you know [the score will go down]...you can learn more and more from time to time.* [P03; male]
>
> *I would take another ECG before prescribing too much medication, and see if [the risk score] goes up or down on the next ECG...For those in yellow...I will adjust my [treatment plan] according to the risk level of the next ECG.* [P06; male]

P06 went further and emphasized that, while AI models are valuable for providing quantitative assessments, their true worth lies in delivering actionable insights that can guide clinical decision-making. This sentiment reflects a broader interest among cardiologists in understanding how AI models arrive at their conclusions, particularly in relation to identifying intervention points:

> *I wonder if you are highlighting these risk factors to tell us these are the areas for intervention. I wonder if there is a reason for this risk factor, such as if we treat these factors, it could lower the risk.* [P06; male]

In general, our findings indicate that cardiologists, particularly self-actualizers, are not only open to integrating AI suggestions into their decision-making processes but also eager to enhance their knowledge through interaction with the AI model provided that these suggestions are accompanied by clear rationales and practical recommendations.

Implications of Creating a Software as a Medical Device

In the development of AI algorithms for clinical applications, it is crucial to not only meet the user interface requirements but also ensure compliance with regulatory standards. Software as a medical device must adhere to international standards such as International Organization for Standardization (ISO) 13485 (medical device quality management systems), ISO 14971 (medical device risk management), and ISO 62304 (software life cycle processes). In addition, compliance with Food and Drug Administration approval and the European Medical Device Regulation is essential from the perspectives of patient safety, effectiveness, and legal requirements.

While the AF'fective study provides valuable foundational knowledge on user interface, it is still considered in the early stages of technology readiness level (1-3). However, with advancements in AI technology, the insights from this research could contribute to the revision of existing standards, such as the International Electrotechnical Commission 62366-1:2015 (usability engineering for medical devices). Specifically, the consideration of explainability in the AI result display methods proposed in this research—such as visually clarifying the rationale behind suggestions and intuitively conveying risk and uncertainty in interface design—will play a crucial role in helping health care professionals accurately understand AI-generated proposals and integrate them into clinical decision-making. Moreover, our study highlighted that health care professionals do not need to fully comprehend the technical background or mechanisms of AI. Instead, it is crucial to create a state in which users can reasonably understand "why this result was reached," which is effective in building trust in AI. Such efforts extend beyond display design and have the potential to be incorporated into new standards that facilitate smooth communication between AI and health care professionals.

Conclusions

This paper reports a 3-stage study involving 23 physicians to co-design, assess, and pilot an explainable AI system for AF postablation monitoring called AF'fective. Our co-design approach effectively identified 4 feasible explainable strategies.

XSL•FO
RenderX

Furthermore, while we actively used explainable AI to identify the features contributing to the predictive results, our explainable strategies enabled the design of a more holistic patient monitoring system that incorporates contextual factors such as patient history and established principles to support physicians' decision-making rather than merely explaining the features indicated by ECG graphs. In the third stage, the system prompted cardiologists to envision its use in their routines, leading to highly contextualized feedback. This study highlighted the need to curate actionable explainable features and set correct expectations for interpreting predictive scores. In addition, cardiologists were interested in understanding the AI's reasoning and identifying strategies to address recurrence risk factors.

Interestingly, although our focus was on AF recurrence prevention, many insights appear generalizable to other disease care contexts, such as temporal risk score monitoring and setting realistic expectations for scoring, particularly as extreme scores (0% and 100%) are practically unattainable. Further investigation is needed to determine whether these insights can be universally applied to enhance the feasibility of implementing explainable AI in clinical settings.

A future study will build on these findings and further evaluate the potential challenges and advantages when implementing the AF'fective system in near-live or live clinical care routines. We believe that AI possesses the potential to revolutionize medical practices and we can only realize it through putting the technology in actual use case scenarios.

Abstract

Background: Given the global burden of insufficient physical activity (PA) in children, effective behavioral interventions are needed to increase PA levels. Novel technologies can help expand the reach and accessibility of these programs. Despite the potential to use heart rate (HR) to target moderate- to vigorous-intensity PA (MVPA), most HR research to date has focused on the accuracy of HR devices or used HR for PA surveillance rather than as an intervention tool. Furthermore, most commercial HR sensors are designed for adults, and their suitability for children is unknown. Further research about the feasibility and usability of commercial HR devices is required to understand how children may use HR during PA.

Objective: This study aimed to explore the use of a chest-worn HR sensor paired with a real-time HR display as an intervention tool among preadolescent children and the usability of a custom-designed app (Connexx) for viewing real-time HR.

Methods: We developed Connexx, an HR information display app with an HR analytics portal to view HR tracking. Children were recruited via flyers distributed at local public schools, word of mouth, and social media posts. Eligible participants were children aged 9 to 12 years who did not have any medical contraindications to MVPA. Participants took part in a single in-person study session where they monitored their own HR using a commercial HR sensor, learned about HR, and engaged in a series of PAs while using the Connexx app to view their real-time HR. We took field note observations about participant interactions with the HR devices. Participants engaged in a semistructured interview about their experience using Connexx and HR during PA and completed the System Usability Scale (SUS) about the Connexx app. Study sessions were audio and video recorded and transcribed verbatim.

Results: A total of 11 participants (n=6, 55% male; n=9, 82%, non-Hispanic White) with an average age of 10.4 (SD 1.0) years were recruited for the study. Data from observations, interviews, and SUS indicated that preadolescent children can use real-time HR information during MVPA. Observational and interview data indicated that the participants were able to understand their HR after a basic lesson and demonstrated the ability to make use of their HR information during PA. Interview and SUS responses demonstrated that the Connexx app was highly usable, despite some accessibility challenges (eg, small display font). Feedback about usability issues has been incorporated into a redesign of the Connexx app, including larger, color-coded fonts for HR information.

Conclusions: The results of this study indicate that preadolescent children understood their HR data and were able to use it in real time during PA. The findings suggest that future interventions targeting MVPA in this population should test strategies to use HR and HR monitoring as direct program targets.

Introduction

Background

Physical activity (PA) levels are insufficient across most of the world's population [1], constituting a persistent problem in global health. PA engagement in the United States is reflective of global trends: only 25% of US children meet the minimum daily recommended amount of moderate- to vigorous- PA (MVPA) [2]. PA behaviors and insufficient PA developed during childhood often worsen during adolescence if not addressed through intervention [3]. Insufficient PA is also a risk factor for obesity, a condition related to various comorbidities [4] that can persist into adulthood [5,6]. Alarmingly, children who develop obesity at a young age are more likely to have obesity into adulthood [7]. Therefore, addressing obesogenic factors (eg, PA) during childhood has the potential to positively impact long-term overall health [8,9].

Effective behavioral interventions are essential to address insufficient PA, particularly before the significant decline that often occurs during adolescence, around the age of 13 years [10]. Novel technologies can help expand the reach and accessibility of PA promotion efforts. To date, most research leveraging commercial PA devices has focused on adult populations [11], although some studies focusing on children have examined step counts as a PA outcome [12]. Step count measures basic movement, but this metric insufficiently captures the intensity of movement and, therefore, may be inadequate for measuring or promoting MVPA.

In contrast to step count, heart rate (HR) holds great promise for measuring MVPA. Moreover, it is possible that novel technologies allowing children to view their HR in real time could foster PA awareness and engagement. However, this great potential is understudied; a recent systematic review found only two studies that examined the use of existing commercial sports-style HR sensors for use in preadolescent children [13]. The studies identified by the systematic review focused on whether children would wear an HR sensor on their chest paired with a wrist-worn HR display over a long time period [14] and the accuracy of commercial HR sensors on a preadolescent child's wrist against a medical-grade control [15]. Another recent study involved the use of chest-worn HR sensors paired with a wrist-worn HR display to monitor PA in adolescents and young adults. However, the study did not provide participants with education on HR or guidance on effectively using HR to achieve MVPA goals [16].

These studies demonstrate the accuracy of commercial HR sensors and displays for preadolescent children. The adoption of devices capable of displaying real-time HR information is growing in this age group, matching trends across the demographic spectrum. Recent statistics indicate wide adoption of smartphones: 97% of Americans own a smartphone [17], and ownership is equitable across racial and socioeconomic groups [18]. Statistics from a survey conducted in July 2019 reported that approximately 21% of the US population owned a smartwatch [19]. Smart device adoption is growing among preadolescent children in the United States; by their teenage years, 95% of children either have their own smartphone or have access to one through their family [20]. Despite the growing ubiquity of these devices, research has only focused on the technical ability of smart devices to surveille user HR [16]. Research should now be conducted to explore the use of real-time HR as an intervention tool to target specific MVPA goals.

Objectives

Pairing chest-worn HR sensors with existing smart devices in the form of smartphones and smartwatches is a novel opportunity that has not been sufficiently explored. However, providing real-time HR information without exploring preadolescent children's ability to understand and use HR in real time to effectively target MVPA would only replicate existing studies with new hardware [16]. Therefore, we provided participants with information about HR and how to target different HR zones during PA. This study primarily aimed to explore whether preadolescent children can use real-time HR information to target specific MVPA goals. A chest-worn HR sensor was paired to a smart device (eg, smartphone or smartwatch) that displayed real-time HR information. As the HR sensors used in this study were originally designed for adult use, a secondary objective of this study was to explore whether preadolescent children could feasibly use a chest-worn HR sensor paired with a smart device.

Another secondary objective of this study was to explore the usability of a custom app (Connexx) developed by the research team. As part of a broader program of research, the team is exploring the impact of collaboration on PA, and one facet of this research explores collaborative pairs in a family dyad consisting of a parent or guardian and child. Dyads collaborate by viewing each other's real-time HR information during PA. There are currently no commercial apps capable of transmitting and displaying real-time HR information between two users. We developed the Connexx app with this functionality. However, a key aim of this study was to explore the usability of Connexx for preadolescent children, who represent half of the intended pair in parent or guardian and child collaborative dyads. Thus, this study explored the usability of the Connexx app in solo mode to establish its feasibility in use with preadolescent children.

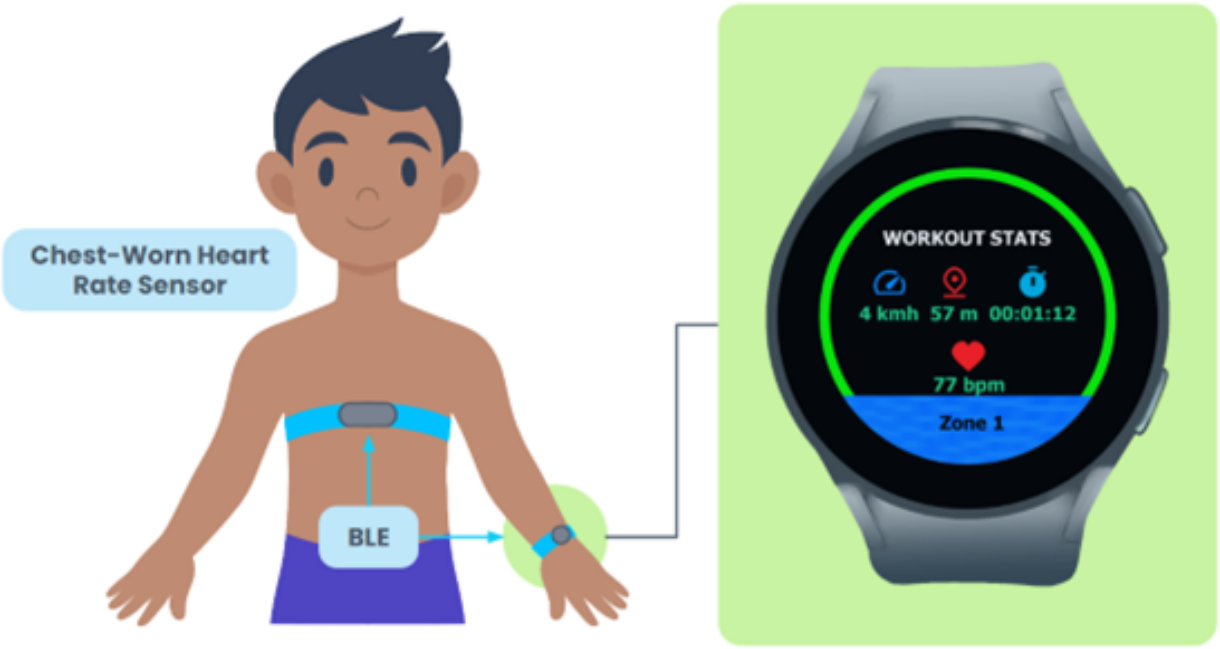
Methods

Study Setting

This feasibility study was conducted at the University of Florida, Gainesville, Florida. Data collection occurred between October 2023 and February 2024.

Ethical Considerations

The study was approved by the University of Florida Institutional Review Board (IRB202301463) and complies with the ethical guidelines mandated therein. Informed consent was



XSL•FO
RenderX

obtained from a parent or guardian electronically, and written assent was obtained from the participants themselves at the start of each study session. Audio and video recordings from study sessions were stored on secured servers mandated as part of the University of Florida Institutional Review Board parameters. A US $25 Amazon e-gift card was provided to the participant's parent or guardian at the conclusion of the study session.

Study Equipment

Several pieces of commercial technology were used to measure and display HR information (Figure 1). HR was measured using a sport-style chest-worn HR sensor (Garmin HRM-Pro Plus), and HR information was transmitted via Bluetooth Low Energy and displayed on either a smartphone or smartwatch. The smartphone used was a Google Pixel 4A, selected due to its low cost and the ability of Android phones to sideload apps, allowing us to install the Connexx app on the smartphone. The smartwatch used was a Samsung Galaxy Watch 4, selected for its Android-based operating system, which allows the Connexx app to be modified from the smartphone version to be compatible with the Galaxy Watch 4.

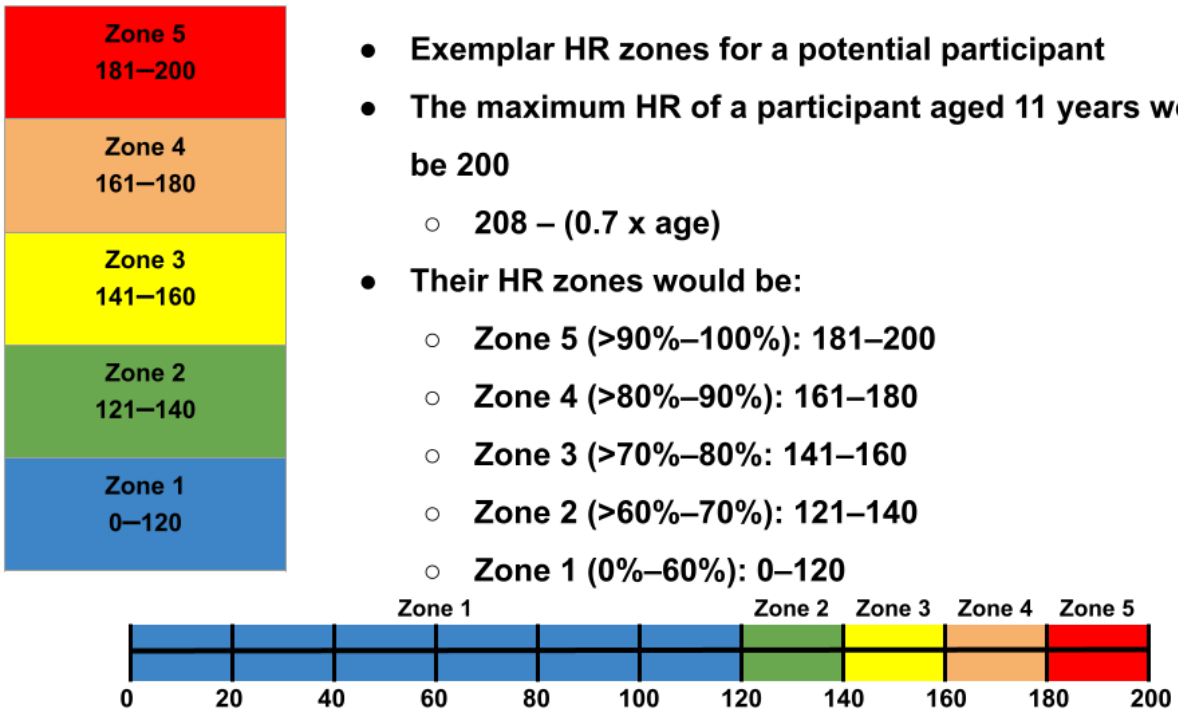


Figure 1. Smartwatch with solo workout screen connected to Bluetooth heart rate sensor. bpm: beats per minute; BLE: Bluetooth Low Energy.

This study used HR rather than accelerometry readings to measure MVPA. HR was chosen because it can be used to display effort in real time across various types of activities, which can contribute to a more accurate measure of the amount of time spent in MVPA [16]. We developed the Connexx app to display real-time HR information between two users. The Connexx app transmits real-time HR information between two devices via a traditional Bluetooth connection. However, Connexx is also capable of operating in solo mode, displaying the real-time HR of a single user, as we did in this study (Figure 1). Information on the user's current speed, distance covered during the workout, and workout duration was displayed along the top row of the Connexx solo workout screen. Speed and distance fields can be toggled between metric and imperial units by tapping on the display. The middle row of the workout screen displays the user's real-time HR. Connexx is able to display real-time HR information as either beats per minute (BPM) or as a percentage of maximum HR; users can toggle between these two display options by tapping on the HR display. A color-coded HR zone indicator is displayed below the HR field. This color coding matched the colors on HR exemplar cards used to explain HR information to participants (Figure 2). In this study, maximum HR was calculated using an established formula that is accurate for preadolescent children: 208 – (0.7 × age) [21]. The Connexx app automatically calculates HR zones using a straightforward 5-zone division based on the percentage of maximum HR, selected because there was no clear consensus or definitive definition of specific HR zones for preadolescent children [22-24] (zone 1: 0%-60%, zone 2: >60%-70%, zone 3: >70%-80%, zone 4: >80%-90%, and zone 5: >90%-100%). Furthermore, the Connexx app has an analytics portal; after the app records a workout, the information is sent to this portal, capable of displaying data from the workout on a graph.

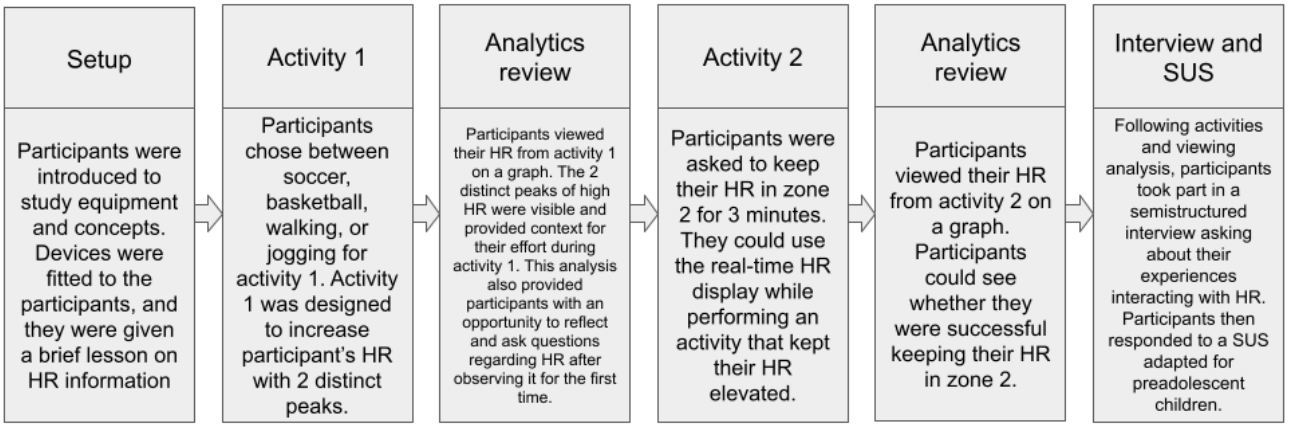
Participants, Eligibility, Recruitment, and Screening



This study aimed to enroll a sample of 12 diverse preadolescent children to complete the full protocol. This sample size was chosen based on best practices in usability testing, showing that a sample of 10 to 12 participants is able to identify most major user issues [25]. Children were eligible to participate if they were aged 9 to 12 years and in good health with no physical conditions, injuries, or other conditions precluding them from engaging in MVPA for up to 30 minutes (assessed via a modified Physical Activity Readiness questionnaire for everyone [26]). We sought an equal number of male and female participants and equal distribution between Black, Hispanic, and non-Hispanic White participants (the three largest racial or ethnic groups in the local area).

Recruitment targeted parents of potentially eligible children using an electronic flyer distributed via local public elementary and middle schools, social media posts, and word of mouth. The flyer provided basic information regarding the study, eligibility criteria, compensation (US $25 Amazon e-gift card), and a link or QR code to a Qualtrics screening questionnaire. Parents or guardians completed the eligibility questionnaire, which included demographic information about their child. If the child was eligible, the parent or guardian was contacted via email to sign an electronic consent form through REDCap (Research Electronic Data Capture; Vanderbilt University). Once consent was obtained, a study team member (LL) scheduled the child for a study session.

Study Session

Study sessions were conducted at an indoor multiuse facility at the University of Florida. The space measures approximately 1021 square meters (27.7 meters by 36.9 meters) and can be used for a variety of uses, including basketball and volleyball; it has a maximum capacity of 1140 people. The study session began with obtaining assent for participation from the preadolescent child and followed the format outlined in Figure 3.

Figure 3. Study session activities flowchart. HR: heart rate; SUS: System Usability Scale.

XSL•FO
RenderX

Device Setup

Following assent, participants were fitted with Rode wireless lapel microphones. A researcher (LL) explained the study equipment and demonstrated the functionality of the chest-worn HR sensor. Parents aided participants in putting on the HR sensor. The session was recorded with a video camera. Next, participants chose between a smartphone and a smartwatch to view their real-time HR information. The Connexx app was available to all participants on either a smartphone or a smartwatch. However, all participants chose to use the smartwatch. The participants were guided through the process of entering their study information, such as their research identification number, age, and maximum HR, into the Connexx app. A workout was then initiated on the app, allowing participants to view their HR in real time, with more HR information provided to them.

HR Information

HR and HR zones were explained to the participants using a real-time HR display in Connexx (Figure 1) and an exemplar HR information card (Figure 2) based on their age (Table 1). Additional language used to explain HR and HR zones is provided in Multimedia Appendix 1. The goal of the brief explanation was to frame the upcoming activities in a way that participants could understand in relation to their HR zones. The researcher encouraged the participants to ask questions during the HR explanation.

Table 1. Example of the 5-zone heart rate (HR) categorization and description for participants aged 11 years.

HR zones	BPM[a]	Zone effort category	Example activities associated with the zone	Description of the zone
Zone 5	181 to 200	Maximum	Very high effort activities, which are often repeated (eg, sprinting in games such as tag multiple times in a row)	Extremely difficult to hold a conversation and most people must wait until after this effort to speak
Zone 4	161 to 180	Vigorous	Vigorous activities, such as playing a sport (eg, soccer or basketball), strenuous hiking, running, or climbing flights of stairs continually at a brisk pace	Difficult to hold conversation and often can only squeeze in short 1- or 2-word responses around breathing
Zone 3	141 to 160	Endurance	Shorter vigorous activities or long endurance activities (eg, climbing 2 to 3 flights of stairs or walking or hiking for an hour)	Slight difficulty to hold a normal conversation and speech is negotiated around breathing
Zone 2	121 to 140	Low endurance	Watching an exciting program and slow walk for short distances (eg, walking to the kitchen and walking around the block at a slow pace)	Can hold normal conversations without thinking about breathing
Zone 1	≤120	Rest	Sleeping, sitting and reading a book, or watching television	Can hold normal conversations without thinking about breathing

[a]BPM: beats per minute.

Activities

Next, we outlined the structure of the study to participants (Figure 3). The study consisted of 2 activity intervals; activity 1 lasted for 10 minutes and activity 2 lasted for 3 minutes, each followed by a brief rest period during which participants could view their HR information via an analytics portal on a laptop.

Activity 1

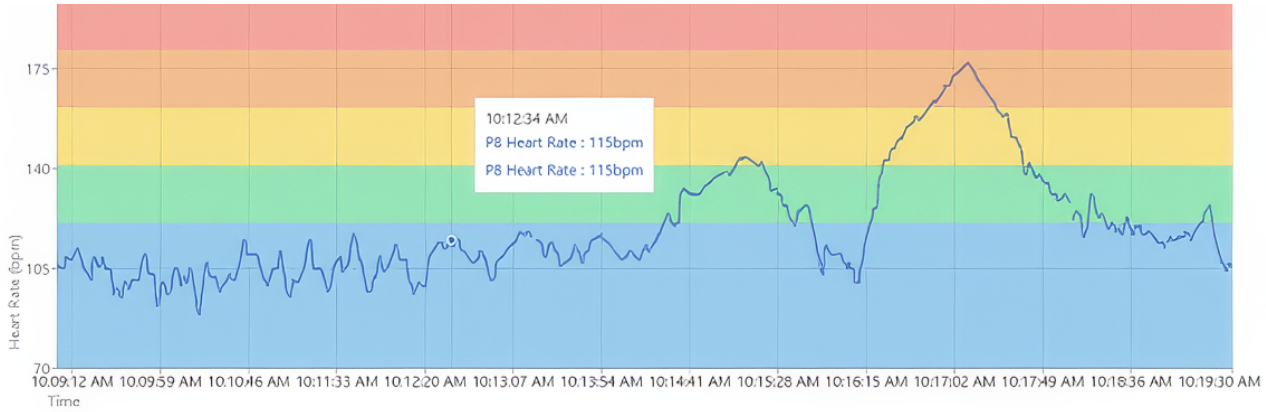
This study primarily aimed to explore whether preadolescent children can use real-time HR information to target specific MVPA goals. Activity 1 was designed to provide participants with an opportunity to observe their HR as it elevated through several different zones aligning with MVPA, providing practical, experiential use of HR information for participants. For activity 1, participants chose from playing basketball or soccer, or walking or jogging around the gym space. A researcher moderated participant effort during activity 1 by speeding up or slowing down the activity to take participants through a range of HR values. During this activity, the researcher asked participants to report their real-time HR at regular intervals. Querying for HR regularly was intended to help participants notice how their HR responded to various activity levels. Activity 1 was designed to increase participants' HR through multiple HR zones twice. Participants viewed their HR through the Connexx app while engaged in PA. After completing activity 1, the researcher guided participants through ending the workout on the Connexx app, and then, participants viewed a graphical representation of their HR in a Connexx analytics portal. We guided participants through the HR observation process, drawing attention to how HR can vary at rest, how HR responds to effort levels during PA, and how the body feels at various HRs.

Analytics Reflection

Once a workout ended on the Connexx app, workout data were uploaded to the analytics portal. The analytics portal displayed the participant's color-coded HR zones in the background of the graph, with HR in BPM on the vertical axis and duration on the horizontal axis (Figure 4). The researcher pointed to the connection between the HR graph and PA level: the more intense the PA level, the steeper the HR graph line became. Furthermore, the researcher pointed to how variable HR was: when at rest, HR did not stay at a consistent BPM; rather, it varied up and down slightly. In addition to the HR timeline graph, the analytics portal also presents an HR zone breakdown, which is a bar graph showing the total cumulative time the participants' HR spent in each zone (Figure 5). Participants were encouraged to ask questions throughout the process of viewing their HR graph.

XSL•FO
RenderX

Figure 4. Sample heart rate graph following activity 1. bpm: beats per minute.



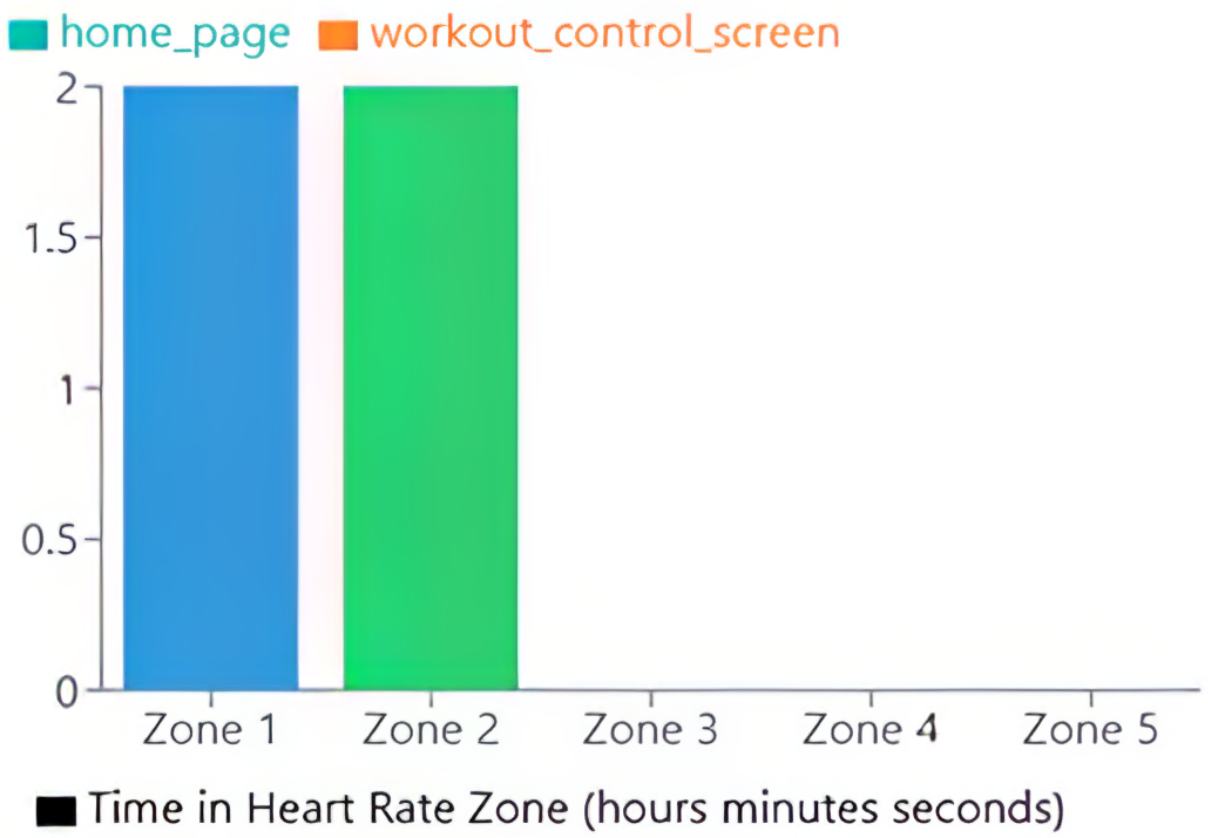


Figure 5. Sample heart rate zone cumulative time.

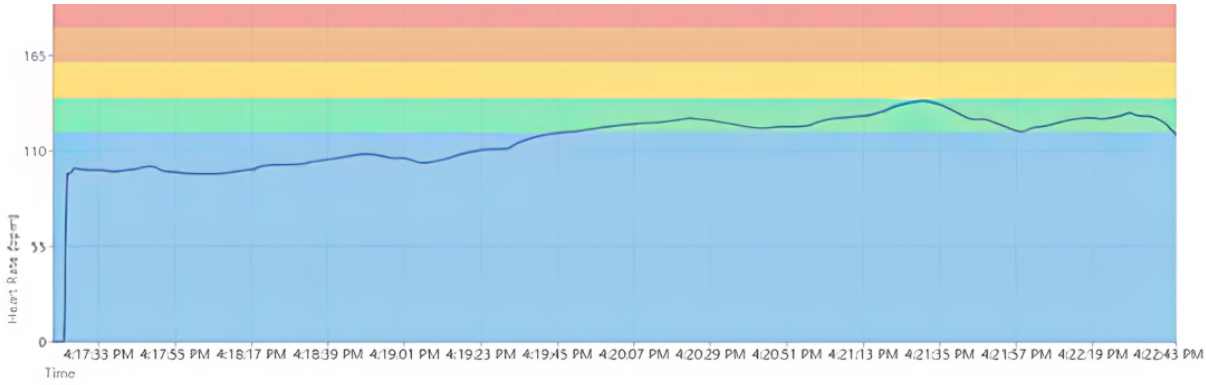
Activity 2



Activity 2 was designed to determine whether participants could make use of the tools provided to them so far (such as the information they have learned about HR, the HR sensor they were wearing, and the Connexx display, which provided a real-time display of their HR in BPM and HR zones) to maintain their HR in a targeted zone. Participants were asked to maintain their HR in zone 2 while engaged in the PA of their choice (basketball, soccer, walking, or jogging). Zone 2 was chosen because it was accessible to all participants, regardless of their fitness level, and they had to use the tools provided to maintain zone 2 HR, as they could easily exceed zone 2 HR by exercising too intensely. Participants could use the Connexx display to monitor their own HR and HR zone in real time to maintain zone 2 HR. The only prompts we provided were for timing (eg, when each minute elapsed). After 3 minutes, the participant was invited to save and end their workout on the Connexx app and view their HR graph for the second interval.

Analytics Review

The analytics portal displayed whether participants were successful in maintaining their HR in zone 2 (Figure 6). The HR zone breakdown also indicated the total time participants spent in each HR zone.

XSL•FO
RenderX

Figure 6. Sample heart rate graphical displays following activity 2. bpm: beats per minute.

Interview and System Usability Scale

After completing the 2 activities, participants engaged in a semistructured interview about their experiences. The interview explored participants' preference for smartwatch or smartphone, the comfort of commercial chest-worn HR sensors and smart devices, the participant's real-time actions to adjust their HR to meet a target goal, what HR zones mean to them, their preference for HR zones, whether they had previous experience with HR, and their enjoyment and potential future use of the Connexx app (refer to Multimedia Appendix 2 for the full interview script). During the interview, relevant objects and visual aids were presented to the participants as needed (eg, smartwatches and HR zone cards).

Finally, after the interview, participants filled out a modified version of the System Usability Scale (SUS) specifically modified and validated for use with preadolescent children [27]. This 10-item scale is used to calculate a usability score between 0 and 100. The commonly accepted threshold for a usable technology is a score of 68 [28].

Observational Data Collection Measures

We conducted observational data collection during each study session. In the event of recording capture device failure, a physical copy of the start and end times of each activity and a log of the participant's HR report and its corresponding value during the study session provide an overview of the participant's HR. Fortunately, this backup was not necessary during analysis.

The researcher who primarily interacted with the participants recorded field notes after each session. Notes focused on participant interaction with the instruments that might not be captured through the interview or SUS questionnaire, such as whether additional adjustments to the chest-worn HR sensor were required and how quickly participants adapted to the input methods for the Connexx app.

Analysis

Demographic data were summarized with descriptive statistics. Observational data were collated with the session transcripts to provide more depth and nuance to the thematic analysis. Additional observations that were not captured in the transcripts or SUS results are included as separate findings in the Observational Findings section.

Interviews were recorded and automatically transcribed via Microsoft OneDrive; we reviewed and revised autogenerated transcripts. Three researchers (LL, MA, and HAL) with qualitative research experience performed an inductive thematic analysis [29]. They followed the 6 steps of thematic analysis: data familiarization, initial code generation, searching for themes, theme review, defining and naming themes, and reporting [30,31]. While this study was designed with several objectives, we remained open to accepting any informative findings in the data. LL, MA, and HAL collaborated to familiarize themselves with the data and generate codes using a sample of the first 2 participant transcripts. The researchers worked together to search and identify themes, creating a codebook. The team then coded transcripts independently, meeting after completing the third and fourth participant transcripts to refine the codebook. Then, they coded the rest of the participant transcripts independently. Intercoder reliability was calculated using Krippendorff α [32] on a sample of 4 independently coded transcripts across 3 coders using the SPSS software (IBM Corp) extension developed by Hayes and Krippendorff [33]. Krippendorff α reliability estimate for the 3 coders was 0.907 (95% CI 0.8348-0.9621), corresponding to a high degree of agreement among them.

Results

Participant Demographics

A total of 11 preadolescent children with an average age of 10.5 (SD 1.0) years participated in this study, of whom 6 (55%) were male and 9 (82%) were non-Hispanic White. While the team sought to recruit a sample with equal numbers of male and female children and an even distribution of races and ethnicities, this diversity was not achieved in the final sample.

Observational Findings

Several observations demonstrated that preadolescent children can use real-time HR information to target specific MVPA goals. Participants shared a strong interest in their real-time HR information; some participants were quick to explore how their HR would respond to changes in PA. Participants looked at their HR information multiple times after initially starting a workout in the Connexx app and observed how controlling their breathing or fidgeting in their chairs may impact their HR. Their ability to use real-time HR information was further demonstrated by the actions of participants in activity 2. For activity 2,

XSL•FO
RenderX

participants were asked to maintain their HR in zone 2 for 3 minutes of PA. A total of 7 participants successfully used the Connexx display to hold their HR in zone 2. Of the remaining 4 participants, 1 (25%) initially ran at a high intensity that raised her HR above zone 2; however, throughout the rest of the 3-minute activity, she ran progressively slower to bring her HR back into zone 2. The 3 (75%) other participants took the opportunity to exert themselves as hard as possible in an attempt to achieve the highest HR reading instead of holding their HR in zone 2. These participants knew how to use the Connexx display to observe their HR in real time, as they looked at their smartwatch throughout activity 2. However, these 3 participants had a strong desire to see how high their HR could go. The parent of 1 of these 3 participants noted that she was highly competitive and always wanted to outcompete her older brother (who was also a participant in this study). One of the participants who successfully held his HR in zone 2 during the second activity demonstrated a similar desire to achieve a high HR value when he asked to be allowed to run around the gym space after completing the study so that he could see how fast his HR could read in the Connexx app.

Regarding hardware suitability for the children, all 11 participants chose to use a smartwatch to observe their HR in real time, and the watch straps successfully fit across a range of wrist sizes. However, there were some challenges with the chest-strap HR sensor. Two (18%) of the 11 participants needed the strap on the HR sensor to be shortened beyond its normal range to fit securely around their bodies. In both cases, the strap was shortened by <5 cm (by folding the excess fabric over and securing it with a safety pin) from the lower limit of the original strap range.

Furthermore, participants were able to quickly learn how to use the Connexx app. All participants were able to report their real-time HR and HR zone when prompted. Several participants (7/11, 64%) were also able to navigate the Connexx app themselves after the initial setup. They could swipe through the different screens in the app and start and end workouts themselves, and 2 (18%) out of 11 participants were able to navigate the text input interface with minimal guidance from the researcher. However, participants identified a substantial issue with the Connexx app in its current state. During the activities, participants noted that the font size of their HR display was too small. This was of particular concern during activity 1, as participants were moving vigorously at points to raise their HR through multiple HR zones. Participants had to adopt several different strategies to be able to see their HR values, including bringing the watch close to their face or slowing down their movement. The small font size of the Connexx app contributed to interruptions in the MVPA participants were engaged in.

Interview Findings

The interview provided rich data that generated themes related to using commercial devices to observe real-time HR to target specific MVPA goals. Three major themes emerged: one focused on real-time use of HR, one related to HR knowledge, and another on device and app use. Specific subthemes ranged from reports of real-time HR to preferences for the construction of HR zones. Themes, subthemes, definitions, and sample quotes are provided in Table 2. Major subthemes are described in the following sections in detail.

XSL•FO
RenderX

Table 2. Interview themes and sample quotes.

Theme and subtheme	Subtheme definition	Sample quotes
Real-time sensemaking of HR[a]		
Reporting HR and HR zones	Declarations of participant's real-time HR and HR zone	"Oh, I'm at Zone 4!... (which is) 160 (BPM)." [Participant 2]
Real-time HR use	How participants make use of real-time HR during activities	"I just looked at the watch a couple of times throughout the exercise and I saw Zone 2 and I'm like, OK, I'm, I was and I, you know, thought that I was doing good. So, I just kept it at that pace." [Participant 9]
HR and correlation to body sensations	How participant's body feels at different HR and HR zones	"I feel like I have to breathe more, but it mostly feels similar." [Participant 1]
HR-related knowledge		
Confusion regarding HR	Confusion about HR or HR zones	"I was just walking up and going over there to play soccer and it (HR) was (already) at 117." [Participant 4]
HR as an achievement	Desire for a high HR or HR zone displayed	"... with five, it's, I just like feel kind of accomplished." [Participant 8]
Previous knowledge of HR	Previous experience learning about HR	"In elementary school in PE class... count... how many beats we have in six seconds? And then he would tell us to, like, multiply it by 10 and that's beats per minute" [Participant 4]
HR zone preferences	Preference for HR zones, 3 larger or 5 smaller zones	"I personally like breaking stuff down to like smaller pieces and understanding it better." [Participant 9]
Device and app		
Device user experience	Comments on function and design of the device	"The smartwatch, you could just turn it over to look..." [Participant 7]
Device comfort or discomfort	How the devices felt for participants	"Wasn't too tight, too heavy... it feels comfortable." [Participant 3]
App usability	Like or dislike the app and willingness to use (or not use) the app in the future	"Probably just for like for fun, just to see (my HR)." [Participant 7]

[a]HR: heart rate.

Using Real-Time HR Information

During the interview, participants were asked about their strategies for adjusting their efforts to meet specific MVPA goals, including holding their HR in zone 2 for 3 minutes in activity 2. Participants who successfully held their HR in zone 2 discussed how they adjusted their effort based on the HR display (coded as "Real-time HR use" in Table 2):

> *I tried to keep the same speed when it was in Zone 2, because if I got faster, it [referring to his HR] will go higher, and if I went slower, it will go to Zone 1.* [Participant 3]

Often, this involved reducing their effort to not exceed the upper limit of zone 2 (coded as "HR and correlation to body sensations" in Table 2):

> *I tried using less power for [basketball] shots and like, try and walk or running across slower to conserve [energy].* [Participant 1]

The participants who were successful in keeping their HR steady in zone 2 used their smartwatch to adjust their effort much more often:

> *I just kept looking at the watch.* [Participant 2]

Some participants (2/11, 18%) noticed that their HR would change even when they did not think their actions should correspond to the change (coded as "Confusion regarding HR" in Table 2):

> *I was just walking up and going over there to play soccer and it [HR] was [already] at 117.* [Participant 4]

However, noting this unexpected result demonstrated that the participant was actively making connections between their PA and the displayed HR.

Not all participants were able to successfully keep their HR in zone 2 during activity 2. These participants acknowledged that they knew the goal was to maintain their HR in zone 2, but they wanted to achieve the highest HR possible. When asked what their HR was, participant 1 stated that "it just hit Zone 4, it is 161... I can go way faster than that!" (coded as "HR as achievement" in Table 2), and participant 8 expressed interest in his HR throughout the course of the study session. After finishing activity 1, he told the researcher that he "would like to see what it (his HR) looks like on a graph." Furthermore, after activity 2, where he was not successful in keeping his HR in zone 2, he told the researcher that he did "want to see how long I was in [zone] 5 for."

XSL•FO
RenderX

HR-Related Knowledge

In addition to findings on the specific research objectives, several themes emerged during the inductive thematic analysis process.

Previous Experience With HR

Four (36%) of the 11 participants had learned about HR in school before taking part in the study (coded as "Prior knowledge of HR" in Table 2); however, none of the participants had a complete understanding of HR. Learning about HR in school was summed up by a participant as follows:

> *[We would] do jumping jacks or jog in place for like 30 seconds, 20 seconds, and then... count our heart, how many beats we have in six seconds, and then he would tell us to, like multiply it by 10, and that's beats per minute.* [Participant 4]

None of the participants had used a chest-worn HR sensor before the study.

HR Zones

Participants were asked to describe what HR zones meant in their own words, and overall, they were able to provide a basic description of each zone. A participant explained the zones in a manner similar to how we had explained them before activity 1, as follows:

> *Zone 1, just calm, sitting down and not doing anything. Zone 2 I might be walking around, and I don't know. Zone 3 I would start to feel really hard to breathe and a little faster [breathing]. Zone 4, I might be breathing kind of heavier and having to slow down a little bit.* [Participant 4]

Other participants described the zones in relation to their own experiences during the study:

> *[Zone] 4 was like, I got to 4 when I was like shooting the ball and running.* [Participant 7]

Participants were asked whether they had a preference for the 5 HR zones used in this study or a more simplified 3 HR zones (coded as "HR zone preferences" in Table 2). Three (27%) of the 11 participants preferred the simplicity of having fewer zones:

> *It would be easier to look at if there was just easy, medium, hard. It would be easier to keep it in the easy-medium zone [referring to Zone 2].* [Participant 4]

The other participants (8/11, 73%) preferred 5 HR zones. Reasons for preferring 5 zones differed between participants; some preferred the greater granularity offered by more zones, and others preferred more HR zones as it provided a sense of achievement. A participant explained the meaning of having more HR zones as follows:

> *It would narrow it down and be easier just to keep it at that zone.* [Participant 6]

Another participant explained his preference for more HR zones as follows:

> *Oh, it's just like an achievement. It kind of feels like an achievement.* [Participant 7]
>
> *I just want to know if I'm in Zone 5, because, like, it's exciting.* [Participant 7]

Feasibility of Chest-Worn HR Sensors Paired to Smart Devices

Device Preference

To explore device preferences, participants were asked why they chose to use a smartwatch over a smartphone to observe their HR during PA (which all participants did). While only 2 (18%) of the 11 participants had consistently used a smartwatch before the study (one had their own, and another used their father's), all participants commented on the greater convenience they could foresee with a smartwatch, particularly while engaging in PA (coded as "Device user experience" in Table 2):

> *The smartwatch, you could just turn it over to look. But for a smartphone, you have to grab it, then you have to [mimes the action of pulling a phone out of their pocket to look at it]. If you're like working out, and you want to know [your HR] you could just look.* [Participant 7]

Device Comfort

When asked about the comfort or discomfort of the devices, all participants stated that the smartwatch felt comfortable (coded as "Device comfort or discomfort" in Table 2):

> *I'm used to wearing watches, so it's pretty normal for me to put one [smartwatch] on.* [Participant 1]

While there was some initial discomfort with the chest-worn HR sensor, it soon became unnoticeable:

> *When I first put it on, it kind of feels weird. But I got used to it when I used it for quite a while.* [Participant 3]

Only one participant reported continued discomfort and a desire to take off the HR sensor before the conclusion of the interview:

> *It was hot and kind of squeezing, so you get uncomfortable feeling.* [Participant 7]

Furthermore, one participant noted that using a softer fabric for the strap would increase the comfort of the instrument:

> *If like the material is different, so you didn't feel it as much. Like if it's like a smoother material or something maybe not as thick.* [Participant 6]

Usability of the Connexx App

Overall, participants were enthusiastic about the Connexx app and the ability to observe their own HR data (coded as "App usability" in Table 2). Participant 7 represented most participants when he declared that using Connexx "was kind of fun!" However, the small font size on the Connexx display made it challenging to view real-time HR while engaged in PA. For instance, participant 1 stated that what he "found frustrating was when we were running that when I wanted to check my HR, I couldn't see it straight because of it shaking." Many

XSL•FO
RenderX

participants (9/11, 82%) expressed interest in using the Connexx app in the future. The final response of participant 11 to a series of questions regarding the Connexx app and the ability to view her own HR was that she could "use it for playing games" with her friends. Similarly, participant 7 noted that he would like to use the Connexx app again in the future, "probably just for like for fun."

SUS Findings

The Connexx app can be considered highly usable in its current iteration; participants rated the Connexx app with an average score of 77.1 (SD 13.7), well above the threshold score of 68 [28]. However, feedback from this study will contribute to its future refinement to further increase usability.

Discussion

Principal Findings

While significant research has demonstrated the accuracy of commercially available HR devices for children [15], there has been insufficient research on how real-time HR information can be used to target MVPA goals. In this study, preadolescent children were provided with a basic lesson about their HR and HR zones, and then, they engaged in 2 PA sessions. Participants demonstrated an understanding of the HR display during PA by effectively using it to regulate their efforts. Therefore, real-time HR information can be used by children as a tool to meet PA guidelines more effectively; children can monitor their own HR information to ensure that they are engaged in MVPA. In addition, this study provides insight into the feasibility of HR sensors and smart devices, smart device preferences, the usability of a custom HR app, preadolescent children's previous HR experiences, and HR zone preferences.

Preadolescent Children Using Real-Time HR Information to Target Specific MVPA Goals

The findings of this study are unique in research on HR device use. Previous research often focused exclusively on accuracy [34], overlooked how users interact with commercial fitness trackers [35], or did not include HR information [36] in the design. In fact, preadolescent children in one study complained that the only real-time information they could see were step count and distance [36]. Participants in a study that paired chest-worn HR sensors with a wrist-worn display regulated their effort based on running speed; these participants did not use their available real-time HR information to adjust their effort [16]. Participants in this study demonstrated their ability to use real-time HR and HR zone information during PA by successfully keeping their HR in zone 2. We observed participants adjusting their effort while exercising (during activity 2) to keep their HR in zone 2. Participants confirmed in the interview that they adjusted their movement speed based on their real-time HR display, demonstrating an ability to use their real-time HR information to target specific MVPA goals during the study session.

Feasibility of Chest-Worn HR Sensors Paired to Smart Devices

Results of this study suggest that chest-worn HR sensors are feasible for use by preadolescent children. While some participants (2/11, 18%) mentioned slight discomfort when first putting on the chest-worn HR sensor, this did not seem to be an ongoing issue and was not brought up during activity 1 or 2. This study provides a more comprehensive investigation into the comfort and usability of these devices compared to previous research. One study that examined the use of a chest-strap HR sensor in conjunction with a wrist-worn device for preadolescent children focused on the accuracy of measurement rather than how preadolescent children felt about using these devices [14]. Another study focused on the accuracy of commercial devices for HR measurements, in this case, wrist-worn devices, without consideration for the comfort of the device [15]. Participants in this study were undergoing surgery, which may not be an appropriate situation to consider the comfort of an HR monitoring device. Furthermore, previous research that focused on the comfort of devices [16] examined an older population, whose more developed bodies may be better suited for devices typically designed for adults. However, the findings of this study indicate that chest-worn HR sensors and smartwatches were generally comfortable for preadolescent children.

Preference for Smartwatch

An interesting finding of this study on the feasibility of smart devices is the appeal of a smartwatch over a smartphone. Researchers did not anticipate all participants to choose a smartwatch over a smartphone for observing their HR information during the study. This is an issue that was not discussed in previous literature [37,38]. Upon reflection, this preference aligns with current commercial trends. Most preadolescent children (9/11, 82%) who participated in this study did not have previous experience with smartwatches or wristwatches in general, which may have contributed to a novelty effect. However, during the interview, they identified the convenience of using a wrist-worn device to view their HR in real time. Several participants (6/11, 54%) commented on perceived ease of use, where they would only have to move their wrists up to be able to view their HR rather than pulling a phone out of a pocket. Other participants (5/11, 45%) favored the security of a worn device, noting that they do not have to worry about dropping a watch compared to a phone. Furthermore, some participants (2/11, 18%) noted that watches may be more comfortable during PA, as a phone in their pocket would move undesirably.

Usability

Research on the design of mobile apps and the use of commercial wearable sensors has focused on the design process; technical limitations, such as loading speed; and efforts to ensure hardware capabilities and accuracy [39,40]. We developed the Connexx app following best practices based on industry standards and previous research [40,41]. Participants rated the Connexx app with a SUS score of 77, which is above the threshold score of 68 [28], indicating that the app has above-average usability. In addition, the Connexx app received a higher score than other digital health apps, more in line with

XSL•FO
RenderX

other PA apps [42]. The usability of the Connexx app was demonstrated by participants throughout the study.

For most participants (9/11, 82%), this was their first time using a smartwatch, and for all participants, this was their first time observing their real-time HR. We helped participants with the initial setup, such as inputting their age and other information in the Connexx app. However, many participants (7/11, 64%) quickly figured out how to operate the Connexx app themselves, and they could input text, navigate the menus, and begin and end workouts on their own without our intervention. This ability not only demonstrated the Connexx app's usability but also this population's familiarity with modern technology and its use, which was a concern for developing health-related apps for preadolescent children [43].

Despite the high SUS score, there were issues with the Connexx app. The Connexx app was initially developed for smartphones and then adapted to smartwatches, creating unanticipated usability challenges. The main PA screen for Connexx featured live tracking of several data fields, including HR, activity time, and speed. While this was easy to read on a smartphone display, on a smaller smartwatch display, the presence of multiple data fields resulted in each field being too small to be easily legible during PA. Thus, participants used multiple strategies to stabilize the smartwatch to be able to read what their HR was. The inclusion of a large color-coded portion at the bottom of the smartwatch display was helpful in informing participants of their HR zone at a glance. Despite difficulty reading portions of the app display, participants found it easy and fun to use. Furthermore, some participants (2/11, 18%) indicated that they not only wanted to use the app again in the future but also would like to share it with their friends.

Other HR Findings

Additional findings from this study indicated that an introductory lesson on HR helped provide participants with a basic understanding of their HR and demonstrated the feasibility of using HR during MVPA. Some participants (2/11, 18%) viewed high HR as an achievement, and the preferences for HR zones are linked to HR achievements for some participants.

Many participants (7/11, 64%) did not have previous experience with HR. An introductory lesson on HR and HR zones was provided for participants at the beginning of the study session, using a simple description of HR zones, including color-coded visual aids (Figure 2) and multiple descriptors that demonstrated how the participants' bodies might respond to various HR zones (Table 1). Participants subsequently demonstrated an understanding of their HR information while engaged in PA, responding to our queries about their HR with reports of both their HR and the corresponding HR zones. Furthermore, participants recalled the introductory lesson on HR well enough after engaging in PA to describe HR zones during the interview; some repeated the descriptors from the lesson, while others applied the descriptors to their own experiences. These findings suggest that participants were able to quickly grasp the HR concepts taught during the session and that using HR to target MVPA with preadolescent children is feasible.

This understanding of HR is even demonstrated by participants who were unable to keep their HR in zone 2 during activity 2. Participants who did not keep their HR in zone 2 demonstrated their understanding of HR by fully exerting themselves in an attempt to achieve a high HR reading. These participants were more interested in hitting the highest HR and HR zone possible; they viewed higher HR and HR zone as an accomplishment. While participants used the technology in a way not originally intended by the study's design, it still showed their understanding of HR and its application during PA.

Finally, many participants (8/11, 73%) preferred having a more granular HR zone division, favoring the 5-zone model over the 3-zone option. Some participants (2/11, 18%) equated zone 5 with a higher sense of accomplishment, mirroring the drive to achieve the highest HR possible. The drive for higher values is reflected in commercially available products for PA tracking. Platforms such as Strava [44] reward users by keeping track of their personal records. Furthermore, when a user's best performance is faster than any other user for a particular segment, the fastest user is rewarded with a crown icon and the title "King of the Mountain" or "Queen of the Mountain." The desire for high achievement of these participants is likely a reason why gamification and leaderboards are more effective in PA promotion than health benefits [45].

Limitations

Despite these findings, this study is not without its limitations. First, the participants had never encountered an app such as Connexx before; therefore, the novelty factor of a new measurement offered by the Connexx app may have offset potential shortcomings arising from font size or other use limitations [46]. As participants continue to use the Connexx app, the SUS score may decrease, as the novelty of displaying real-time HR information wears off. However, as participants indicated having little previous experience or education with HR, this highlights an educational opportunity missing from school curricula, as the participants were interested in learning about their HR.

In addition, the small sample size of this feasibility study limits the generalizability of the findings. While there were almost equal numbers of male and female participants, there was little racial or ethnic diversity (9/11, 82% non-Hispanic White). However, the sample size was still sufficient to demonstrate the usability of these HR monitoring technologies with preadolescent children [25]. Future research is needed to explore the technologies with a larger, more diverse sample.

Because this was a feasibility study to explore whether adolescent children could understand and use their HR information in real time as opposed to measuring HR change in response to PA, we did not control for other confounding variables (eg, the child's fitness level, diet, and resting HR). Rather, as a first step, this study simply examined whether HR use was possible. Moreover, due to the study design, this study did not take advantage of the full scope of capabilities developed as part of the Connexx app, including displaying a paired partner's HR information in real time. Future studies will further explore these capabilities of the Connexx app.

XSL•FO
RenderX

Conclusions

This study aimed to investigate the feasibility and usability of multiple technologies to measure and display HR information for preadolescent children. It examined whether preadolescent children could effectively use these devices to view their HR and make practical use of the information. The results indicate that preadolescent children understood and used their HR to regulate their MVPA and enjoyed using Connexx for real-time HR observation. Participant responses demonstrate the ability to use and the desire for access to real-time HR information during PA. Future research should build on these findings regarding the use of real-time HR as an intervention tool to target specific MVPA goals. This could involve testing strategies that use HR and real-time monitoring as direct targets in program designs. Preadolescent children's interest in using real-time HR should be leveraged by researchers, health professionals, and educators to promote MVPA in an engaging way for this population.

Acknowledgments

The authors would like to thank Sunny Dhama for assisting with software and investigation, Lidong Lin for assisting with the investigation, and Wesly Menard and Mollie Brewer for assisting with the conceptualization and methodology of the study. Abstract

Background: Maternal mortality remains a persistent public health concern in sub-Saharan African countries such as Ethiopia. Health information technology solutions are a flexible and low-cost method for improving health outcomes with proven benefits in low- to middle-income countries' health systems.

Objective: This study aimed to develop and assess the usability of an electronic dashboard to monitor facility-level readiness to manage basic emergency obstetric care (BEmOC) in Amhara, Ethiopia.

Methods: The study used three methods to iteratively refine the dashboard: (1) user-centered design sessions with individuals who interact with the BEmOC supply chain, (2) review and feedback from domain and information visualization subject matter experts (SMEs) to refine the dashboard, and (3) usability heuristic evaluation with human-computer interaction (HCI) SMEs.

Results: User-centered design sessions resulted in a preliminary version of the dashboard informed by end-user preferences and perceptions, with recommendations focusing on aesthetic design, filtering and sorting, and matching with the real world. An example of an end-user recommendation included increasing font sizes on the dashboard and using a red, yellow, and green color-coding scheme. Next, domain and visualization SMEs continued the dashboard's iterative refinement, focusing on aesthetic design and navigation, by confirming design choices incorporated from the user-centered design sessions and recommending changes to enhance user experience moving through the dashboard, such as adding more filtering options. HCI SMEs rated the dashboard as highly usable (0.82 on a scale of 0-4, with 0 being no usability concern and 4 being a catastrophic usability concern). The principle with the highest usability severity scores was a match between the system and the real world with a score of 1.4. The HCI SMEs also rated the information visualization aspects of the dashboard favorably with 2 usability principles, spatial organization and information coding, scoring 0.

Conclusions: Dashboards are a novel method for promoting and tracking facility capacity to manage BEmOC. By including targeted end users and SMEs in the design process, the team was able to tailor the dashboard to meet user needs, fit it into the existing government health systems, and ensure that the dashboard follows design best practices. Collectively, the novel, customized

XSL•FO

Introduction

Maternal mortality is a critical public health issue, particularly in low-resource settings like sub-Saharan Africa, which accounts for over three-fourths of global maternal deaths [1]. Despite progress in reducing adverse maternal outcomes in countries like Ethiopia, high maternal mortality ratios persist, largely due to gaps and stockouts of essential supplies for managing obstetric emergencies [2,3]. Inadequate supplies for basic emergency obstetric care (BEmOC) can lead to delayed or suboptimal care. A study on facility-level readiness to manage BEmOC in Amhara, Ethiopia, using the Clinical Cascades reported a 63.3% mean overall BEmOC readiness for managing the 6 most common emergencies, which underscores the need for improving facility-level BEmOC readiness in this region [4].

A promising approach to improve facility-level BEmOC readiness is the development and implementation of health information technology (HIT) to monitor critical supply availability. HIT involves the processing, storage, and exchange of health information in an electronic environment, and has been shown to improve health outcomes and strengthen health systems in low-resource settings [5,6]. Electronic dashboards are a form of HIT that can be used to track critical information, provide alerts, assess performance indicators, develop reports, and customize data views, which makes them a useful tool for monitoring inventory data and facility-level readiness [7,8]. For example, dashboards were used in Ethiopia to monitor the supply inventory of malaria medications and prevent stockouts from occurring, and a simple dashboard was merged into the existing Integrated Pharmaceutical Logistics System (IPLS) in the Amhara and Oromia regions of Ethiopia, resulting in improved facility-level readiness to treat tuberculosis by ensuring health care facilities had adequate supplies [7,8]. Beyond Ethiopia, HIT has been used to anticipate medical stockouts and improve maternal health outcomes in low-resource settings [9,10]. This evidence highlights the potential for HIT to improve facility-level BEmOC readiness in Amhara, ultimately contributing to improved maternal care quality and reduced maternal mortality ratios.

Previous studies, including those conducted in low-resource settings and Ethiopia, have demonstrated the benefits of HIT and dashboards in improving facility-level readiness [5-8]. Furthermore, the growing utilization of technology and cellular services across Africa further supports the feasibility of implementing successful electronic solutions, driven by the increasing adoption of HIT [11,12]. Finally, Ethiopia has recognized the value of HIT in strengthening health care systems and has been implementing electronic medical records in its health care facilities since 2013 [13].

However, while dashboards can be a powerful tool for improving health outcomes, their success depends on ensuring high usability, enabling end users to effectively accomplish their tasks. Usability is defined as “the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use” [14]. Despite the potential of HIT, many implementations have failed due to insufficient consideration of end users’ needs and the environment in which the technology is applied [15,16]. Similarly, while dashboards show promise for improving facility-level BEmOC readiness, their success relies on development that incorporates input from targeted end users, accounts for the context of use, and adheres to usability principles. This study aims to develop and assess the usability of an electronic dashboard for monitoring facility-level BEmOC readiness.

Methods

Overview

To create the initial version of the dashboard, the team incorporated findings from previous qualitative interviews with individuals who worked in Ethiopia’s obstetric emergency supply chain, used information and designs from the preexisting dashboards in Ethiopia’s IPLS, and followed best practices found in the current literature for dashboard development [17-20]. The initial dashboard and its components were developed in Microsoft PowerPoint (refer to Multimedia Appendix 1).

To ensure adequate fit between the dashboard, the required tasks, the current system, the environment, and intended users, the research team conducted participatory user-centered design sessions, performed informal evaluations with domain and information visualization subject matter experts (SMEs), and completed a heuristic usability evaluation with human-computer interaction (HCI) SMEs.

Ethics Considerations

The research team obtained ethics approval from Columbia University’s institutional review board (IRB) (IRB-AAAU2006), Emory University’s IRB (MOD005-STUDY00005335), and the Amhara Public Health Institute (NoH/RfftTlDlo7l44). Before collecting data, the research team provided participants with an information sheet and gave them time to ask questions about the study. Once all questions had been answered, the team obtained verbal informed consent from all participants before

XSL•FO
RenderX

collecting data. All ethics review boards waived the requirement for written documentation of informed consent because the study procedures met the criteria for minimal risk to participants. All data was de-identified and participants data was linked to a random identification number. Only KD had access to the list of participant names linked to the ID numbers. None of the targeted end-users, domain experts, or subject matter experts received compensation for their participation in the study. Human-computer interaction experts participating in the heuristic evaluation received a $50 amazon gift card for their participation.

Sample Selection

User-Centered Participatory Design Sample Selection

Consistent with existing literature in the field of participatory design, the team estimated that a sample size of 15 would be sufficient to reach design saturation, a state where the design sessions reveal no major revisions to the designs reviewed [21,22]. The research team purposively recruited individuals with firsthand experience working within the BEmOC supply chain in Amhara, Ethiopia, at both the regional and local or facility levels. Participants were required to be at least 18 years old. Study participants were Ethiopian citizens and full-time employees in one aspect of Amhara's BEmOC supply chain, such as hospital supply managers, regional hub employees, and pharmacists.

Informal Expert Review Sample Selection

The domain SME was a research team member with over 6 years of experience conducting research in Amhara, Ethiopia; evaluating the supply chain; and measuring facility-level readiness to manage BEmOC. The information visualization SMEs were individuals from Columbia University School of Nursing's Visualization Design Studio, where individuals with varying levels of expertise can learn and gain advice on their current projects. The discussions at this studio were led by 2 PhD-level faculty, a nurse scientist with expertise in visualization design and evaluation, and a human-factors engineer. Key contributions also came from other faculty members at the university who have training in the areas of nursing research and biomedical informatics. All information visualization SMEs have published in the areas of information visualization, HCI, and user experience.

Heuristic Evaluation Sample Selection

The study sample included 5 HCI SMEs who were recruited through the team's professional networks. Previous research has found that 5-8 SMEs can identify over 80% of HIT usability violations [23,24]. HCI SMEs were eligible for inclusion if they had conducted research or published in the field of user interfaces or information visualizations and had not previously evaluated the dashboard.

Procedures

User-Centered Design Procedures

Staff from Emory-Ethiopia Partnership and Amhara Regional Health Bureau identified BEmOC supply chain stakeholders and reached out to determine if they were interested in participating in this study. A member of the research team contacted interested individuals via phone call, email, and WhatsApp (Meta) messaging to explain the study in detail, answer any questions, and set a time to meet in person with the participant to obtain verbal consent and perform the research activities. We used multiple communication channels to reach potential participants; in particular, WhatsApp has been found to be a useful tool for recruiting participants, specifically in global settings [25,26]. Design sessions were conducted in English and Amharic, and data collection tools were available in both languages since Amharic is the national language and Ethiopia's health care professionals receive clinical training in English [27,28].

Design sessions lasted approximately 60 minutes and occurred in small groups of 2-4 people within the health care facility or health bureau offices. Participants were given printed copies of the initial dashboard and asked to verbalize their thought processes as they explored the visualizations and information in the preliminary dashboard [29-32]. Design sessions were audio recorded and transcribed into English for analysis by a team member who is bilingual in Amharic and English. The individual conducting the analysis is a native Amharic speaker with over a decade of experience translating Amharic to English for health care research. Given their extensive expertise and the time constraints of the study, the team opted not to perform back translations. The dashboard development followed an iterative process, consisting of 4 design sessions. After each session, the research team incorporated recommended changes into the dashboard, which were then presented in the subsequent sessions [30].

Informal Expert Review Procedures

The team presented the Microsoft PowerPoint dashboard to a domain expert and a group of information visualization SMEs. Team member (KD) used Zoom (Zoom Video Communications) screen-sharing capabilities to walk the domain expert through the dashboard and their various features. The domain expert then reviewed the dashboard and provided recommendations for improvement.

KD presented the same dashboard to information visualization SMEs at 2 sessions of the Visualization Design Studio [33]. KD walked the SMEs through the dashboard, answered questions about their intended use, and elicited feedback and recommendations. Collectively, both rounds of feedback were used to optimize and further develop a medium-fidelity version of the dashboard for use in the heuristic usability evaluation.

Heuristic Evaluation Procedures

The team used Figma to develop a medium-fidelity prototype, which allowed the simulation of the dashboard's workflow [34]. Using Zoom Pro, a Health and Insurance Portability Accountability Act (HIPAA)–compliant videoconference platform, and its screen-sharing technology, KD asked the HCI SMEs to complete several tasks using the dashboard and encouraged them to explore other components of the dashboard (Multimedia Appendix 2). During their exploration, participants completed a heuristic evaluation checklist to identify and rank the severity of the usability violations and had the opportunity

XSL•FO
RenderX

to explain the violations they encountered [23,24,32]. They were also asked to describe what they were thinking, feeling, and seeing while completing the various tasks. The sessions were video recorded, and KD took field notes. At the end of the sessions, the HCI SMEs and KD discussed potential solutions for the identified usability violations. Participants were asked to complete tasks during the heuristic usability evaluation mentioned in Textbox 1.

Textbox 1. List of tasks participants were asked to complete during the heuristic usability evaluation.

Heuristic usability evaluation tasks

- Filter the main screen to only view primary hospitals.
- Determine which health care facilities are not ready to manage retained placenta.
- Determine if [hospital name] is ready to manage hypertensive emergencies. If not, identify which items are missing.
- Determine if [hospital name] is ready to manage maternal sepsis or infection. If not, identify which items are missing.
- Determine what emergencies [hospital name] is ready to manage.
- For prolonged labor at [hospital name] filter the supplies table to see the items that are at the emergency order point.
- For prolonged labor at [hospital name] filter the supplies to see the items that are overstocked.
- Determine how many health care facilities are at risk for not being able to manage retained placentas.

The Heuristic Evaluation Checklist used in this study was guided by Nielsen's 10 usability heuristics (ie, best practices; Table 1) [24,35] and includes a 5-item scale where experts rate each usability heuristic on a scale of 0 (not a problem) to 4 (catastrophic violation; Table 2) [23,32,36]. The research team modified the original checklist to fit the needs of a medium-fidelity dashboard (Multimedia Appendix 2). For example, questions for heuristics related to error prevention, help users with errors, and help and documentation were excluded since those tasks could not be simulated with the medium-fidelity prototype. In addition, 3 usability heuristics specific to information visualizations in the dashboards were included: spatial organization, information coding, and orientation [19].

Table 1. Usability heuristics and their definitions used in the heuristic usability evaluation.

Usability heuristic	Type	Definition
Visibility of system status	HIT[a]	The system should always keep users informed about what is going on through appropriate feedback in a reasonable time.
System and real-world match	HIT	The system should speak the user's language, with words, phrases, and concepts familiar to the user. The system should follow real-world conventions and ensure the dashboard fits within the existing workflow and technology system.
User control and freedom	HIT	Users should be free to select and sequence tasks and make their own decisions regarding the cost of exiting current work. Users should have clearly marked "emergency exit" to leave the unwanted state.
Consistency and standards	HIT	Users should not have to wonder whether different words, situations, or actions mean the same thing. Systems should maintain interface design choices in similar contexts and differ in different contexts.
Recognition rather than recall	HIT	The user should not have to remember information from one part of the dialogue to another. Objects, actions, and options should be easily visible, and instructions should be visible or easily retrievable whenever appropriate.
Flexibility and efficiency of use	HIT	The system should offer users several options for finding content. Users should be able to customize their interface and achieve their goals in an efficient manner and have the capacity to adapt to users' needs.
Aesthetic and minimalist design	HIT	The main dashboard should not contain information that is irrelevant or rarely needed. The system should present the largest amount of data with the least amount of ink.
Spatial organization	Information visualization	The overall layout of a visual representation should make it easy for the user to locate an information element in the display.
Information coding	Information visualization	The symbols and numbers used in the visualization should aid perception. The numeracy and graph literacy of the visualization should match the intended users' ability.
Orientation and help	Information visualization	The system should provide support for the user and help to orient them in their visualization.

[a]HIT: health information technology.

XSL•FO
RenderX

Table 2. Severity ratings for usability violations in the heuristic evaluation.

Score	Usability problem	Explanation
0	Not a usability problem at all	No problem identified
1	Cosmetic problem	Need not be fixed unless extra time is available on the project
2	Minor problem	Fixing this should be a low priority
3	Major usability	Important to fix, so should be given high priority
4	Usability catastrophe	Imperative to fix this before the product can be released

Data Analysis

User-Centered Design Analysis

Analysis was concurrent with data collection with modifications of the dashboard occurring after the initial 2 design sessions and following the third and fourth sessions. Using the translated transcripts of audio-recorded sessions and field notes, KD extracted key preferences, identified poorly performing graphics and dashboard components, and improved the design based on participant feedback. The team maintained detailed notes on design decisions and the rationale for those decisions alongside the notes and transcripts, which functioned as an audit trail.

Heuristic Usability Evaluation Analysis

The responses on the Heuristic Evaluation Checklist were transferred into Microsoft Excel for analysis [19,20]. The research team used unique participant numbers to link the responses to a confidential participant list. The data were analyzed with descriptive statistics (frequencies and means) [37]. Both session field notes and qualitative responses reported in the free response comments section of the checklist were used to understand usability and enhance the dashboard's design. During the evaluations, KD documented key areas of concern that HCI SMEs verbalized during the sessions. Combing those notes with the free-response comments, KD used the frequency that those concerns were mentioned to understand their importance. The usability concerns and potential solutions reported from the free-response comments were also compiled into a single list of action items, with duplicates removed, and KD used this list to guide the refinement of the next version of the dashboard.

Results

User-Centered Design Sessions

Sample Characteristics

In total, 6 individuals, who work at the regional health bureau or regional hubs for supply distribution, participated in the first 2 design sessions and reviewed the initial version of the dashboard. Following the refinement of the dashboard by KD, 5 individuals who work at health care facilities in the region participated in the third and fourth design sessions and reviewed the updated version of the dashboard. Recruitment and data collection ended prematurely at 11 participants due to civil unrest and safety concerns in the region [38].

Evolution of the Dashboard Design

During design sessions 1 and 2, participants reviewed the initial version of the prototype, and during design sessions 3 and 4, they reviewed a revised version that incorporated feedback from study participants in design sessions 1 and 2. During design sessions 1 and 2, participants viewed the initial design of the dashboard and were able to easily grasp the idea the dashboard was trying to portray related to facility readiness to manage BEmOC. The users felt the dashboard, specifically, the regional view, helped them to understand which facilities would be ready to handle the emergencies. One regional respondent stated,

> *This image [dashboard] demonstrates how they [individual health care facilities] would be able to handle each health issue considering the level of the supplies that each hospital has for these health problems. In general, we can conclude from this image [regional dashboard] that some hospitals are in good condition for these health issues and others are not in good condition for these health issues.*

Generally, participants in the first two sessions focused on (1) individual graphical component preferences such as which type of charts they preferred to see the data presented and (2) how they would want the data to be filtered and sorted. The third and fourth sessions with the refined dashboard focused on (1) confirming the terminology in the dashboard, and that it matched terms used in the supply chain, and (2) affirming design changes that were incorporated from the earlier sessions. Respondents in the third and fourth sessions also provided feedback on which job roles should have access to the dashboard. A participant during the fourth design session stated,

> *This dashboard [emergency-specific view] is essential for the dispensary unit as well. The store and supply officer bears most of the workload or duty in this workplace, but if the pharmacists and hospital managers have access to the data, it would be very good.*

The changes that were incorporated during the design sessions, as well as the session number, iterations of the dashboard, and job level that provided the recommendations, can be found in Multimedia Appendix 3. In the following paragraphs, more details are provided on aesthetic design, filtering and sorting, and matching with real-world preferences.

Aesthetic Design

For colors used throughout the dashboard, participants wanted to use multiple colors that were consistent with those currently used in the existing dashboard. Furthermore, participants in the

XSL•FO
RenderX

first 2 design sessions identified pieces of information that they thought should be removed from the dashboard because they did not assist the end users with making decisions related to supply ordering or maintaining facility-level readiness. However, to ensure users could find information that was not included in the dashboard, the research team added a button that would allow users to view the comprehensive drug list, which is already embedded in the electronic components of the existing IPLS. Facility-level participants, during design sessions 3 and 4, explained that not all health posts will manage certain obstetric emergencies, such as sepsis, so they should not receive readiness classifications for those emergencies. In response to this, the research team grayed out the classifications for those facilities and their corresponding emergencies.

Another aesthetic preference in the early design sessions included requests to include keys in the dashboard that define the colors and terms. Participants in design sessions 3 and 4 agreed that the keys assisted in their comprehension of the dashboard. Participants in design sessions 3 and 4 affirmed the design choices of the previous sessions and provided only small recommendations for the overall look of the dashboard, such as increasing the font size. Related to aesthetic decisions, design saturation was met with the smaller sample size.

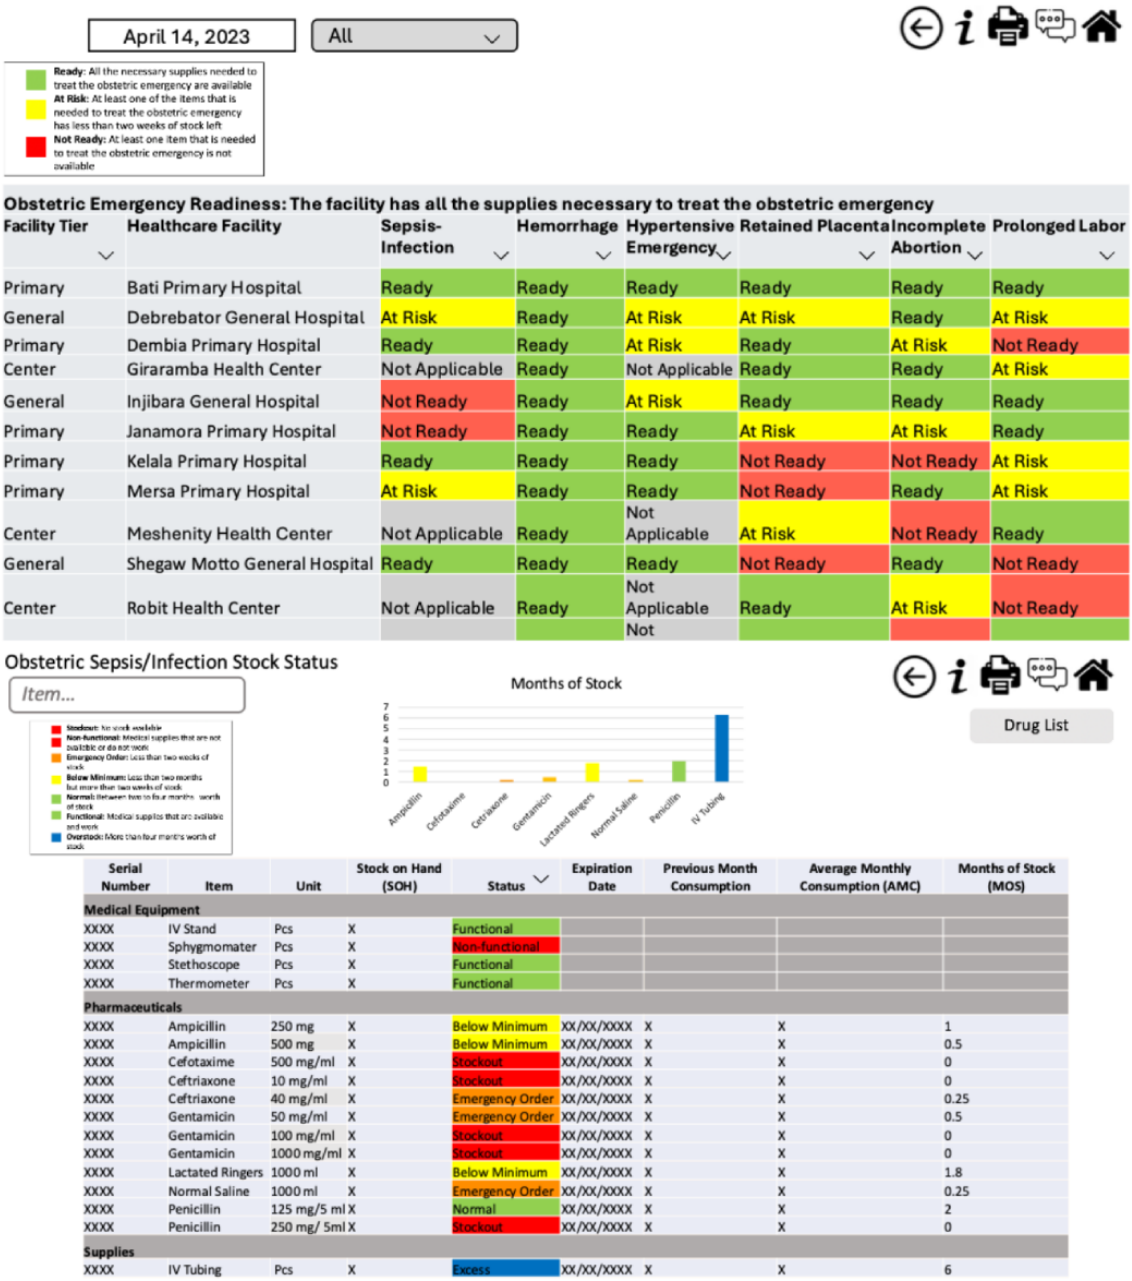
Filtering and Sorting

Participants in the early sessions wanted to ensure there were multiple ways to filter the data so they could view pieces of information that were most important to them. Preferred filtering and sorting options included viewing inventory alphabetically within preestablished categories from the Ethiopian Pharmaceutical Supply System (eg, medical equipment, pharmaceuticals, and supplies), filtering supplies based on quantity available at the facility, and filtering facility by health care facility tier (eg, primary, general, referral, and center) [17]. Participants during the third and fourth design sessions endorsed the filtering options identified in the earlier sessions.

The participants from design sessions 3 and 4 also wanted employees at individual facilities to be able to view inventory data at other facilities besides their own. They felt having access to these data could support transferring excess supplies from one facility to another when neighboring facilities faced stockouts or were at an emergency order point. Thus, the research team added the ability for facility-level users to select different facility readiness data, similar to the regional-level users. Since there was very little new information identified during the second 2 design sessions, the research team determined that the study achieved design saturation for filtering preferences even with the smaller respondent sample.

Match With the Real-World Preferences

A feature that was a very important point of discussion in all the design sessions was using appropriate terminology that aligned with the participants' current workflow and job expectations. Participants wanted to ensure that all the terms used within the dashboard aligned with terms from the IPLS. For example, supply names and categories as well as terms for quantities available were updated (eg, overstock changed to excess, and normal changed to functional for the category medical supplies).



One important change to note is that during the third design session, participants recommended changing the terminology for BEmOC readiness from ready, at risk, and not ready to normal, emergency order, and stockout so they would be the same as the terms used with the emergency-specific dashboard view. Based on this recommendation, the research team created 3 different readiness terminology keys. The 3 options included the original terms; the newly recommended terms; and a third option of yes, no, and emergency order. Since the team could not confirm their preferred choice for readiness terminology due to the civil conflict in the region, the domain expert selected the final terms—yes, at risk, and no. Since the team was unable to obtain user preferences related to this final change, the study did not achieve design saturation in the "match with the real-world" domain.

Final Design

The final design comprised 2 different dashboard views for monitoring BEmOC readiness—one for the regional level and another for the facility level. The regional-level dashboard view provides a summary of readiness for the 6 obstetric emergencies for all health care facilities in the region. The facility-level dashboard view focuses on one facility and one obstetric emergency at a time. Overall study participants viewed the dashboard positively, with one respondent from design session 4 reporting "The hard copies [of the dashboard] you showed us today are beautiful and wonderful." Figure 1 shows the design of the dashboard following the integration of the findings from the third and fourth user-centered design sessions, and Multimedia Appendix 3 lists all the changes that were incorporated into the dashboard following the user-centered design sessions.

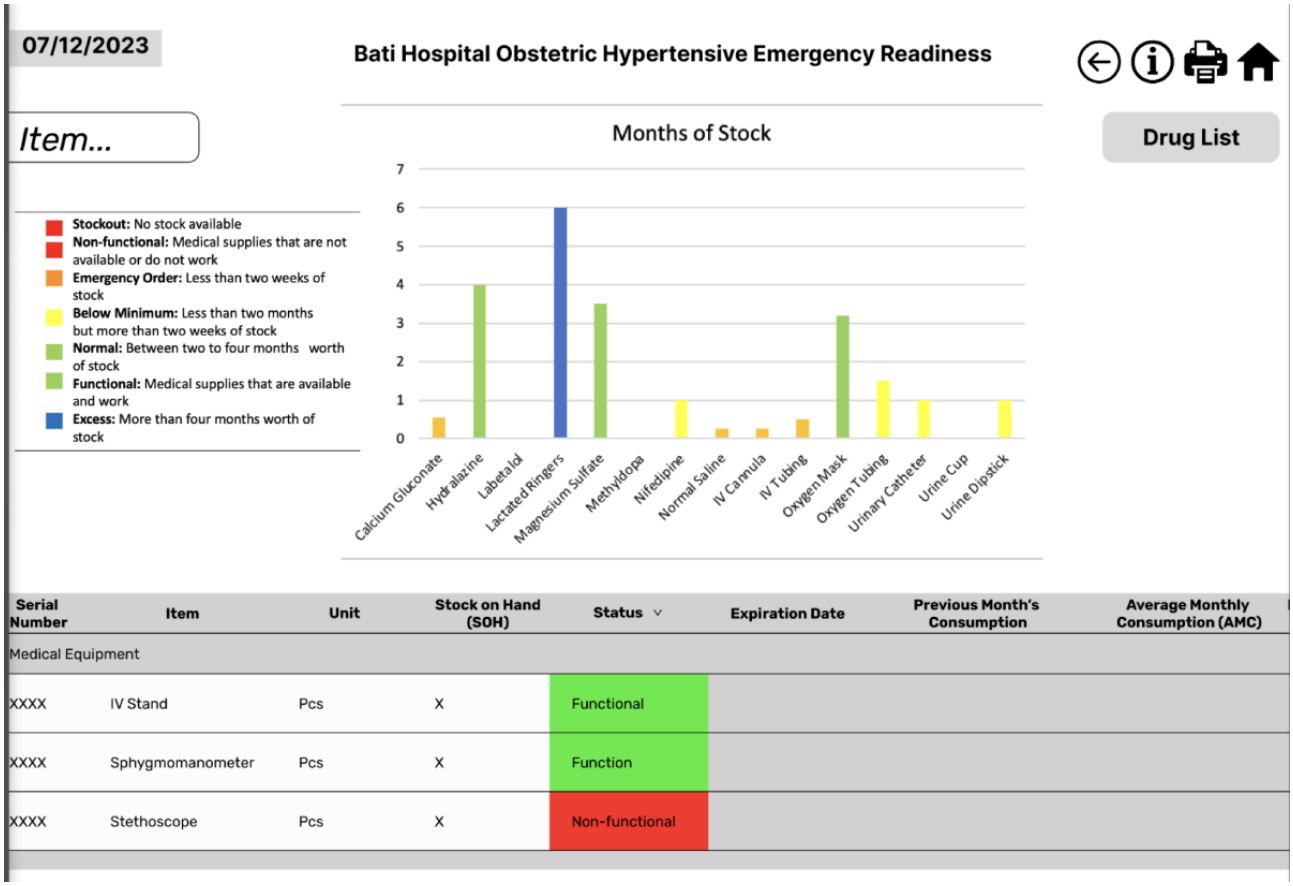
RenderX

Figure 1. Regional basic emergency obstetric care (BEmOC) readiness dashboard and emergency-specific, facility-level dashboard following user-centered design sessions. Hospital names are real, but all readiness data are fictitious.

Informal Expert Review



The domain expert's largest contribution to the refinement of the dashboard was his input on which terms to use to define BEmOC readiness, specifically for the regional view dashboard. To make the final decision on readiness classification terms that were discussed in the final user-centered design session, KD presented the domain expert with 3 different options created following the fourth design session. After reviewing the options, the domain expert recommended KD use yes, emergency order, and no. The rationale for this decision was the yes and no choice was the simplest option, and he believed the end users would be able to readily act based on these classification terms. The domain expert also affirmed KD's decisions to group data at the regional and facility levels and felt that no critical information was missing from the dashboard.

During the review by information visualization SMEs, most recommendations aesthetics related to aesthetics and navigation. In terms of aesthetic design, the recommendations mainly focused on where to place different pieces of information or graphics to best grab the users' attention or prevent overcrowding on a screen, for example, moving several columns of data to the right in the emergency-specific dashboard view. This would allow users to scroll horizontally to see that information, but it would not be visible without scrolling so there would be less information crowding the page. To improve navigation between the various dashboard views, the SMEs during the design studio recommended adding additional filtering options, such as for emergency readiness categories. They also recommended adding an affordance feature to the dashboard so that users would be able to see which items on the screen are clickable or not. In addition, the experts

XSL•FO
RenderX

recommended adding several additional titles to different dashboard views to enhance clarity. These changes were incorporated when the dashboard was updated from PowerPoint to Figma (Figure 2).

Figure 2. Regional view dashboard following informal expert review. All inventory data in this dashboard are fictitious.

Heuristic Usability Evaluation With Human-Computer Interaction Experts

The heuristic evaluation took approximately 30 minutes per session. The years of experience for HCI SMEs ranged from 4 to 14 years, with a mean of 9. All HCI SMEs were female.

Overall, severity scores for heuristic evaluation ranged from 0 to 3 for the 10 usability principles. The mean usability score for all ten heuristics combined was 0.82 (SD 0.98), with a mode of zero. The principle with the highest severity rating was a match between the system and the real world, with a score of 1.4, which falls between a minor and cosmetic usability concern. For this principle, 4 HCI SMEs identified inappropriate color choices for both potential users with color blindness and using colors not congruent with common color-coding expectations as a common issue. Additional problems included the dashboard using concepts and phrases that were unfamiliar to the evaluators, and 3 evaluators felt the section headings were not ordered in the most logical fashion. HCI SMEs identified issues with usability principles visibility of system status, user control and freedom, consistency and standards, and recognition rather than recall (mean 1.2 for each, SD 0.84, 1.3, 0.84, and 1.3, respectively), which also falls between a cosmetic and minor usability concern. Concerns related to these principles included 2 of the HCI SMEs identifying the lack of clear exits for every dashboard and feeling that the current design hindered their ability to efficiently navigate the system. Table 3 shows the mean value, range, and mode for the 10 heuristic principles.

XSL•FO
RenderX

Table 3. Identified heuristic usability problems and their severity scores.

Heuristic category	Problems	Score, mean (SD)	Score, range	Score, mode
Visibility of system status	• Title font is too small • Color choices may be inappropriate for color-blind users • Vertical bar charts make reading supply labels more difficult • Need hyperlinks to improve navigation • Menu-naming terminology is not consistent with the user's task domain	1.2 (0.84)	2	1 and 2
Match between system and real-world	• Color choices may be inappropriate for color-blind users • Section headings and subheadings are not ordered in the most logical way • Not all words, concepts, and phrases were familiar to the human-computer interaction subject matter experts • Some of the colors used in the dashboard do not correspond to common expectations about color codes	1.4 (0.89)	2	1
User control and freedom	• Need hyperlinks to improve navigation • Not a clear exit on each dashboard screen • Not all screens are accessible across the system • Users could not easily move forward and backward between fields	1.2 (1.3)	3	0
Consistency and standards	• Titles on the regional view dashboard do not update when the user filters the data • Abbreviations not clearly explained • Some colors are too similar to distinguish from other categories • Not enough or inconsistent visual cues to identify active screens	1.2 (0.84)	2	1 and 2
Recognition rather than recall	• White space is not optimized within the emergency-specific dashboard view • Prompts, cues, and messages are not placed where the eye is likely to be looking on the screen	1.2 (1.3)	3	0
Flexibility and efficiency of use	• Need hyperlinks to improve navigation	0.6 (0.89)	2	0
Aesthetic and minimalist design	• Not all field labels are brief, familiar, or descriptive • Large objects, bold fonts, and simple areas have not been used to distinguish sections • There is not enough white space between color representation • Too much text is present in the keys which makes the screens look busy	0.8 (0.84)	2	0 and 1
Spatial organization	• Font size is too small throughout the dashboard • Information does not follow a logical flow	0 (0.0)	0	0
Information coding	• No problems identified	0 (0.0)	0	0
Orientation	• Measurement units are not displayed clearly • Users cannot control the level of detail they see in a representation	0.6 (1.3)	3	0

The experts provided several recommendations for how to remedy the problems identified during the heuristic evaluation. They believed adding hyperlink functions would improve users' ability to navigate between the dashboard views, thus increasing usability scores for visibility of system status, user control and freedom, and flexibility and efficiency of use. Aesthetically, the experts believed increasing the font size of titles and data within the dashboard, as well as moving different components of the dashboard around to maximize white space would improve scores for spatial organization, aesthetic and minimalist design, recognition rather than recall, and visibility of system status.

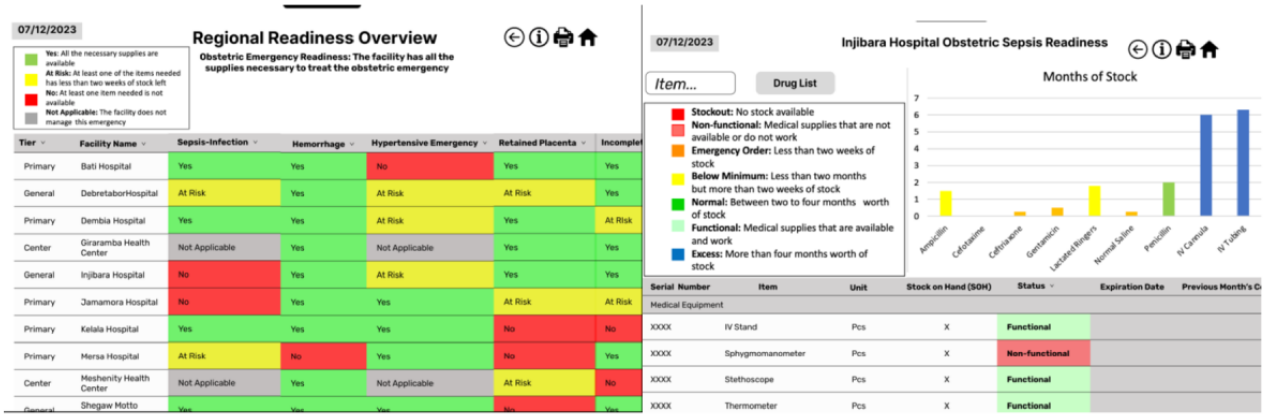
HCI SMEs also made recommendations that disagreed with user preferences identified during the design sessions. These differences included the experts preferring horizontal bar charts compared to vertical bar charts. An expert explained the rationale for this preference stating a horizontal bar chart allows for the labels in the table to be read horizontally, which can be easier for users. However, during the user-centered design sessions, the participants had a resounding preference for the vertical bar charts because they were more familiar with that format since some of their preexisting dashboards included vertical bar charts in the IPLS. Given the importance of the new dashboard to mimic the look of the existing ones, as well as the

XSL•FO
RenderX

fact that the users explicitly preferred the vertical presentation, KD chose to retain the vertical bar charts. The color of the tables and graphs was also a point of disagreement between experts and users. The experts did not think the red, yellow, and green color choices were appropriate because these colors can be difficult to distinguish if individuals are color blind [39]. However, the targeted end users of the dashboard preferred those colors because the colors reminded them of traffic lights, and the users could make assumptions related to the significance of the colors based on what those colors mean by a traffic light. The research team chose to keep the traffic light color scheme.

Beyond these recommendations, the reviewers cited several positive features of the dashboard. This includes things such as the belief that the icons used throughout the dashboard were clear and easy to associate with their function. In addition, the experts found the labels and keys to be clear and assisted with comprehension of the data. One respondent reported, "Your labels are quite clear. It's [the dashboard] very accessible and you have nice keys right here." The heuristic violation severity scores for information visualization-specific heuristics were low with scores of zero for spatial organization and information coding, and 0.6 for orientation. Table 4 summarizes the changes incorporated into the dashboard following the completion of the heuristic usability evaluation. The final dashboard is displayed in Figure 3.

Table 4. Summary of changes incorporated into the dashboard following the heuristic evaluation



Heuristic category	Changes following heuristic evaluation
Visibility of system status	• Increased font size throughout the dashboard • Added hyperlinks to the dashboard
Match between system and real-world	• Updated section headings to reflect filtering capabilities • Updated the terminology defining BEmOCa readiness on the regional-level dashboard
User control and freedom	• Added hyperlinks to the dashboard • Ensured exit buttons on every screen are activated • Activated more functions within the dashboard to make it a higher-fidelity prototype
Consistency and standards	• Updated section headings to reflect filtering capabilities • Defined all abbreviations used in the dashboard • Changed the colors for functional and nonfunctional on the emergency-specific screen so that they are more easily distinguishable from the other colors used on the screen • Added additional visual cues to identify active screens
Recognition rather than recall	• Moved graphics at the top of the dashboard to optimize white space • Added additional visual cues to identify active screens
Flexibility and efficiency of use	• Added hyperlinks to the dashboard
Aesthetic and minimalist design	• Shortened information in the keys to make them one line of text • Shortened data within the tables to make it one line of text • Used bold fonts for all titles • Moved graphics at the top of the dashboard to optimize white space
Spatial organization	• Increased font size throughout the dashboard • Improved the navigation between dashboard views to make them a higher-fidelity prototype
Information coding	• N/Ab
Orientation	• Increased font size for measurement units • Activated more functions within the dashboard to make it a higher-fidelity prototype

Figure 3. Final regional view and emergency-specific view of the dashboard following the heuristic usability evaluation. Hospital names are real, but all readiness data are fictitious.

Discussion

Principal Findings

The dashboard underwent iterative refinement based on user input, domain expert feedback, information visualization evaluations, and heuristic usability assessments. Regional participants emphasized preferences for vertical bar charts, traffic-light color coding, and keys to define readiness levels, while facility-level users focused on aligning terminology with existing workflows and tailoring readiness classifications. The information domain expert provided critical input on readiness terminology, and information visualization experts suggested improvements in layout, navigation, and aesthetics, such as optimizing white space and increasing font sizes. Collectively, the central tendency of heuristic severity scores, combined with a mode of zero, indicated high overall usability of the dashboard. However, the HCI experts did highlight minor usability concerns, including navigation and accessibility improvements, which were addressed in the final design. While some expert recommendations, such as horizontal bar charts and alternative color schemes, differed from user preferences, the team prioritized end-user input to ensure practical usability. The final dashboard is intuitive, visually clear, and aligned with real-world needs, achieving high usability and user satisfaction.

This study highlights the importance of including participants from all targeted end-user groups. By including employees from both regional and facility levels, the team gathered diverse, relevant perspectives, ensuring the dashboard met the real-world needs of users across different supply chain roles and experiences. Feedback from both end users and experts enhanced the overall usability and functionality of the dashboard. This aligns with existing usability literature, which emphasizes the value of involving both end users and experts to identify distinct concerns and improve HIT design [40]. Participants' spontaneous interpretations of the dashboard underscore their understanding of the content, and obtaining these perceptions and insights can assist in preventing usability errors from occurring later in the piloting or implementation phase of HIT development. These refinements will likely maximize the ease of implementation and promote consistent uptake and utilization by future users [41,42].

There were 2 areas of disagreement between HCI SMEs' recommendations and end-user preferences: bar chart orientation and color schemes. The research team chose to keep the vertical bar charts for their familiarity with the end users and alignment with existing dashboards. In addition, lower color blindness prevalence among Black African and African American populations (4.2% compared to 6.6% and 1.4% compared to 5.6% respectively) compared to White populations (6.6% and 5.6%) [43,44] supported the decision to maintain the preferred color scheme, as most targeted end users were unlikely to face difficulties distinguishing the colors.

This study reinforces the notion that obtaining expert opinions and performing usability testing can be a low-cost, efficient method for exploring technology needs [45]. Performing the evaluations with the domain expert and the information visualization SMEs took less than an hour for both groups and provided critical information on how to improve upon the design of the dashboard. Performing usability evaluations can identify problems and usability concerns that may not have been noticed before HIT implementation, avoiding costly and time-consuming corrections [24].

Finally, this study contributes to the growing body of literature on the use of dashboards to support BEmOC in sub-Saharan Africa. Similar to findings by Banke-Thomas et al [46] and Wang et al [47], stakeholders expressed enthusiasm for dashboards and prioritized features like reporting facility characteristics on the dashboards. However, there remains a gap in the literature regarding the specific design preferences of end users. This study addresses that gap by highlighting key preferences, such as the use of stoplight color coding and IPLS-specific terminology, which enhance usability and are tailored specifically for dashboards intended for Ethiopia and BEmOC contexts.

Limitations

During data collection, there was unanticipated civil unrest in the Amhara region, which prevented the research team from recruiting participants outside of the regional capital of Bahir Dar and from completing participant recruitment from multiple facilities outside the regional capital. Despite this unforeseen barrier, design saturation was reached for 2 out of the 3 categories during the design sessions. There was also a lack of

XSL•FO
RenderX

gender diversity among our participants. Only one user-centered design participant from Ethiopia was female. However, this gender imbalance mirrored the existing gender imbalance in the existing health system for these roles. However, future research related to this dashboard and facility-level BEmOC readiness would benefit from an emphasis on opinions and participation from female participants with relevant expertise. Conversely, all HCI SMEs were female. While the incorporation of a female perspective is critical since the sample for user-centered design sessions was predominately male, the effect of having completely female HCI SMEs is unknown. Future research should incorporate technical and gender-balanced perspectives during both user and HCI SMEs' review of this dashboard.

Furthermore, the dashboard design was informed by responses from participants in qualitative interviews. However, due to time constraints, the initial prototype was developed by the research team rather than being cocreated with participants. While this approach allowed the team to efficiently move forward with development, it may have limited the incorporation of deeper, iterative feedback from participants during the initial design phase. This limitation could have influenced the alignment of the prototype with user needs and preferences, which may require further refinement in future iterations.

To prospectively limit social desirability bias, the research team created a low-stress, comfortable environment for data collection and emphasized our desire to obtain personal responses to the dashboard while reiterating that all opinions would be blinded so no one could identify specific feedback from specific participants. The team chose to have an Amharic-speaking Ethiopian team member conduct the user-centered design sessions rather than the principal investigator, who is from the United States and does not speak Amharic. The team took steps to ensure confidentiality and used indirect questioning techniques in an attempt to garner the participants' true opinions [48]. Furthermore, the dashboard reviewed in the heuristic usability evaluation was medium fidelity. This means the dashboard was not able to complete all required tasks and certain usability heuristics, such as *help and documentation* and *error prevention*, were excluded from this evaluation, since their tasks were not applicable at this stage in the design process. Future research will need to explore all usability heuristics before implementation to ensure no new concerns arise once the dashboard transitions from a medium- to high-fidelity model.

Conclusion

In conclusion, this study demonstrates the value of user-centered design and usability evaluations in developing HIT for low-resource settings. By integrating diverse perspectives from regional and facility-level participants, as well as domain and usability experts, the dashboard was refined to meet real-world needs and achieve high usability. This iterative approach not only addressed usability concerns but also incorporated end-user preferences, ensuring alignment with existing workflows. The study fills a gap in the literature by identifying design preferences tailored to Ethiopia's health care context, offering a model for future HIT development aimed at improving BEmOC readiness and maternal health outcomes. These findings emphasize the importance of engaging end users and experts early in the design process to create functional, user-friendly systems that support effective implementation and long-term adoption.

Acknowledgments

We would like to thank Emory-Ethiopia Partnership's Addis Ababa and Bahir Dar offices for their support and guidance in this research.

This work was supported by the National Institute of Nursing Research (F31NR020569), a Fulbright US Student research award to Ethiopia, and a research grant from Sigma Theta Tau Alpha Zeta chapter.

Authors' Contributions

YA performed data collection with support from MB and LA. HB supported the project administration and maintained ethics approvals throughout the study. KD analyzed the data and created the dashboard with assistance from SB and JNC. KD drafted the manuscript, and all other authors assisted in editing and refining the final manuscript. JNC conceptualized the nested study design and obtained parent funding for the Saving Little Lives study which this research was nested within. AG provided contextual expertise on Amhara and Ethiopian clinical care.

Abstract

Background: The Early Psychosis Intervention Network of California project, a learning health care network of California early psychosis intervention (EPI) programs, prioritized incorporation of community partner feedback while designing its eHealth app, Beehive. Though eHealth apps can support learning health care network data collection aims, low user acceptance or adoption can pose barriers to successful implementation. Adopting user-centered design (UCD) approaches, such as incorporation of user feedback, prototyping, iterative design, and continuous evaluation, can mitigate these potential barriers.

Objective: We aimed to use UCD during development of a data collection and data visualization web-based and tablet app, Beehive, to promote engagement with Beehive as part of standard EPI care across a diverse user-base.

Methods: Our UCD approach included incorporation of user feedback, prototyping, iterative design, and continuous evaluation. This started with user journey mapping to create storyboards, which were then presented in UCD workshops with service users, their support persons, and EPI providers. We incorporated feedback from these workshops into the alpha version of Beehive, which was also presented in a UCD workshop. Feedback was again incorporated into the beta version of Beehive. We provided Beehive training to 4 EPI programs who then piloted Beehive's beta version. During piloting, service users, their support persons, and EPI program providers completed Beehive surveys at enrollment and every 6 months after treatment initiation. To examine preliminary user acceptance and adoption during the piloting phase, we assessed rates of participant enrollment and survey completion, with a particular focus on completion of a prioritized survey: the Modified Colorado Symptom Index.

Results: UCD workshop feedback resulted in the creation of new workflows and interface changes in Beehive to improve the user experience. During piloting, 48 service users, 42 support persons, and 72 EPI program providers enrolled in Beehive. Data were available for 88% (n=42) of service users, including self-reported data for 79% (n=38), collateral-reported data for 42% (n=20), and clinician-entered data for 17% (n=8). The Modified Colorado Symptom Index was completed by 54% (n=26) of

XSL•FO
RenderX

service users (total score: mean 24.16, SD 16.81). In addition, 35 service users had a support person who could complete the Modified Colorado Symptom Index, and 56% (n=19) of support persons completed it (mean 26.71, SD 14.43).

Conclusions: Implementing UCD principles while developing the Beehive app resulted in early workflow changes and produced an app that was acceptable and feasible for collection of self-reported clinical outcomes data from service users. Additional support is needed to increase collateral-reported and clinician-entered data.

Introduction

Background

Research estimates that the lifetime prevalence of psychotic disorder diagnoses is approximately 1.5%, and the prevalence of psychotic symptoms is between 4.2% and 17.5% [1]. California, the most populous and second most diverse state in the United States [2], had a population of 39.11 million in 2023, according to the California Census Bureau. This indicates that 586,650 to 6.8 million Californians may experience psychosis symptoms in their lifetime. In response to this, many California counties have developed specialty early psychosis intervention (EPI) services, which vary widely in their implementation approach [3]. The Early Psychosis Intervention Network of California (EPI-CAL) [4] was developed to support the provision of quality EPI services and to create an infrastructure to conduct standardized measurement of the impact of early psychosis care delivery. To support this goal, the EPI-CAL team, in collaboration with several California counties, developed a learning health care network (LHCN) consisting of EPI programs across the state. The EPI-CAL LHCN later joined the national Early Psychosis Intervention Network [5], which allowed additional California EPI programs to participate. Members of the LHCN agreed to gather standardized information and outcomes from their clinics as part of measurement-based care (MBC). Collecting this information is critical to support quality early psychosis care provision within clinical programs as well as enhance statewide learning and development. For example, a narrative review of an MBC approach in behavioral health clinics found such benefits as significantly improving clinical outcomes, improving symptoms more quickly, and decreasing treatment costs [6].

To this end, the EPI-CAL team chose to design and implement a web-based and tablet app called Beehive. We chose the name Beehive to reflect the envisioned purpose for the app: to help LHCN programs learn and grow together for the betterment of the collective, just as bees work together to build a hive for the benefit of the colony. Beehive is a robust, stand-alone eHealth app for use by service users, their support persons, and EPI program providers. In this text, we use the term *service user* to refer to the individual with a psychosis diagnosis who is receiving mental health care from an early psychosis program. We use the term *support person* to refer to any person that the service user has chosen to involve in their care. This is typically the individual's parent but might be another family member, a friend, a partner, or some other close relative. Beehive's purpose is to promote MBC in EPI programs by standardizing data collection across a network of programs focusing on community partner priorities; supporting key components of care such as assessment, safety monitoring, and ongoing care delivery; supporting program-level management of care; and aggregating data across a large network to support evaluation and research at state and even national levels [4].

We chose an eHealth approach to implementing MBC due to its appropriateness for the EPI setting and its potential benefits. Despite the perceived challenges related to experiences of suspicion or paranoia, individuals experiencing mental health difficulties, such as schizophrenia and bipolar disorder, have widely found use of eHealth both feasible and acceptable [7-10]. Furthermore, the use of eHealth can support the advancement of MBC. For example, eHealth apps have been previously demonstrated to promote symptom and outcomes monitoring in both early psychosis care [11,12] and LHCNs [13]. Conducting MBC with eHealth enhances its benefits as it allows for data collection to be standardized across programs and instantly available. For example, MBC may promote collaboration across a care team [14-16], which is relevant for EPI programs for which the evidence-based treatment, coordinated specialty care, is inherently team based [17]. Use of eHealth to collect data in this setting allows data collected by one team member or entered by a service user to be instantly available for all team members. eHealth also enhances the benefits of MBC through data aggregation, which enables evaluation of program performance [16,18,19] or promotion of evidence-based treatments [16,20].

Though there are many potential benefits, there are also numerous barriers to implementation of both new eHealth technology and MBC. According to a systematic literature analysis, the top factors posing a barrier to eHealth app implementation include lack of digital health literacy, lack of devices, financing issues, service-user cognition, and security [21]. These barriers contribute to low adoption and user acceptance, which limit the success of implementation [22,23]. Barriers to implementation of MBC include training burden, concern that negative feedback causes harm to service users, and the time required for survey completion [24-26].

To pursue the benefits of using eHealth to implement MBC and mitigate the potential barriers, we developed Beehive with user-centered design (UCD) principles. UCD prioritizes the needs and expectations of the end user [27,28]. UCD approaches include dedicated design activities, active involvement of users

XSL•FO
RenderX

in the design process, incorporation of their feedback, prototyping, and continuous evaluation [29], which can address low user acceptance and low adoption [30]. Beehive's iterative development began with a collaborative process with service users, support persons, and EPI program providers to identify and prioritize which outcome measures should be collected in the app [31]. We also explored how service users, support persons, and EPI program providers wanted to be informed about data-sharing options in Beehive and built Beehive's end user license agreement (EULA) workflow to incorporate user perspectives [32]. With the survey content and EULA workflow finalized, we moved onto the development of the user-facing parts of Beehive.

Objectives

In this study, we aimed to (1) use UCD principles to create a co-designed web-based and tablet app, called Beehive, to support MBC in EPI programs, and (2) assess Beehive's initial feasibility in clinical settings by piloting it in 4 EPI programs.

Methods

Design

To promote Beehive engagement across multiple types of users and across multiple domains of engagement, we integrated UCD principles of incorporation of user feedback, prototyping, iterative design, and continuous evaluation. Service users, support persons, and EPI program providers had multiple opportunities to provide feedback, which was incorporated throughout Beehive development. Figure 1 shows the study design from conceptualization through data collection.

Figure 1. Study design for Beehive development.

The development process began with conceptualization of user journeys. User journey mapping envisions how specific types of users, such as a service user or a service provider, will interact with an app from access point through all required activities [33]. User journey mapping allowed us to identify which storyboards we should develop to present in UCD workshops and which user-types we needed to recruit for those workshops. Storyboards are a tool to visualize app workflows and the user interface [34]. We developed storyboards to present as prototypes in UCD workshops so that feedback could modify the app design before time was invested in coding the alpha version of the app. The alpha version of the app included core workflows and was both evaluated internally and presented in another UCD workshop to gather more feedback before coding the beta version of the app. The beta version of the app incorporated remaining feedback from storyboard workshops, new feedback from the alpha stage, and added the remaining core functionality that was not in-scope for the alpha version (eg, reports). The beta version of Beehive was piloted by 3 EPI programs over 6 months to further refine the app before launching it across all EPI-CAL programs. We used pilot data to assess initial use and uptake of Beehive's beta version.

This UCD approach allowed the EPI-CAL team to receive and incorporate feedback during conception, design, and testing phases of eHealth app development, and include multiple perspectives to facilitate user engagement in eHealth. Notably, UCD has also been demonstrated to increase eHealth adoption and user acceptance in research and clinical settings [30,35].

Participant Recruitment

UCD Workshops

For UCD workshops of the Beehive storyboard, we recruited participants from the following three EPI community partner

XSL•FO
RenderX

groups: (1) EPI service users, (2) their support persons, and (3) EPI providers. Eligible participants were (1) actively or formerly affiliated with an EPI-CAL EPI program, (2) English speaking, and (3) able to provide written informed consent and assent (minors or conserved adults). EPI program providers were recruited through contact with the team lead of the 12 active EPI-CAL EPI programs. Service users and support person participants were invited either through EPI program provider referral or by the research team directly contacting individuals who had previously consented to be contacted for future research opportunities.

One EPI-CAL clinic agreed to participate in a workshop for the alpha version of the app to support the refinement of Beehive before piloting.

Piloting

In total, 4 EPI-CAL clinics agreed to participate in 6 months of Beehive beta testing before Beehive's full launch across the entire EPI-CAL LHCN. During this period, programs integrated the Beehive app into standard clinical care. Pilot sites registered service users who were active in their program at the time of launching Beehive and new service users who started after the launch. Each participating program has different acceptance criteria for service users, and this has been described in a separate protocol paper for the EPI-CAL study (NCT04007510) [4]. Service users and support persons were excluded from piloting if they did not speak English because Beehive beta version was only available in English. At their first point of contact with Beehive, service users and primary support persons completed the Beehive EULA and were asked if they gave permission for their clinical data collected in Beehive to be used for research purposes [32]. We trained clinics to involve the legal guardians of service users aged <18 during EULA completion, and these service users were required to have a primary support person registered in Beehive. Individuals could update their data-sharing permissions at any time.

Methods

User Journey Mapping

The EPI-CAL research team worked collaboratively with the contracted app developer in the user journey mapping and storyboard design phases for the Beehive tablet and web apps. Three primary user groups with distinct roles were identified: (1) service users or support persons, (2) direct-service providers, and (3) program administrators. Beehive user journeys were developed for each group.

For all user groups, user journeys were designed to guide individuals smoothly through Beehive onboarding and account creation to the EULA explainer video detailing the types of information Beehive collects, who can access their data, and how to select their preferred permissions for who can view their data [32]. Users then choose their data-sharing permissions.

Beehive then presents service users and support persons with a series of one-time and longitudinal surveys to measure clinical outcomes at 6-month intervals. Specific survey items associated with risk, such as suicidal or homicidal ideation, send real-time alerts to EPI program providers if they are endorsed by service users. Beehive creates visualizations of this survey data. While service users and support persons cannot independently access survey visualizations, we considered this is as part of their user journey because it should be shown to them by EPI program staff as part of regular care.

EPI program provider user journeys were designed to facilitate easy management of service user records and smooth navigation to service user data. A dashboard presents the most important information to users, such as outstanding survey alerts or other action items. A client list presents all registered service user records in list format with the most relevant information displayed. EPI program provider users can click into service user records to view survey results, survey visualizations, and complete provider-entered surveys. Providers can display survey results and survey visualizations as part of ongoing care with service users and their support persons to facilitate understanding and coordinate treatment priorities.

Administrator user journeys were designed to promote clinic-level management tasks, such as Beehive implementation and quality assurance. Administrator dashboards present aggregate-level information of survey data and allow for the ability to compare clinic averages to the average of the EPI-CAL LHCN. Administrator dashboards also present summaries of Beehive activity across the clinic. Administrator users can also download reports, including survey data reports, to use their clinic data for quality assurance or reporting requirements.

UCD Workshops

Next, the development team created dynamic storyboards of the above user journeys. These storyboards were presented to community partners from early psychosis clinics in 90-minute UCD workshops. Figures 2 and 3 are images from the storyboards presented to community partners.

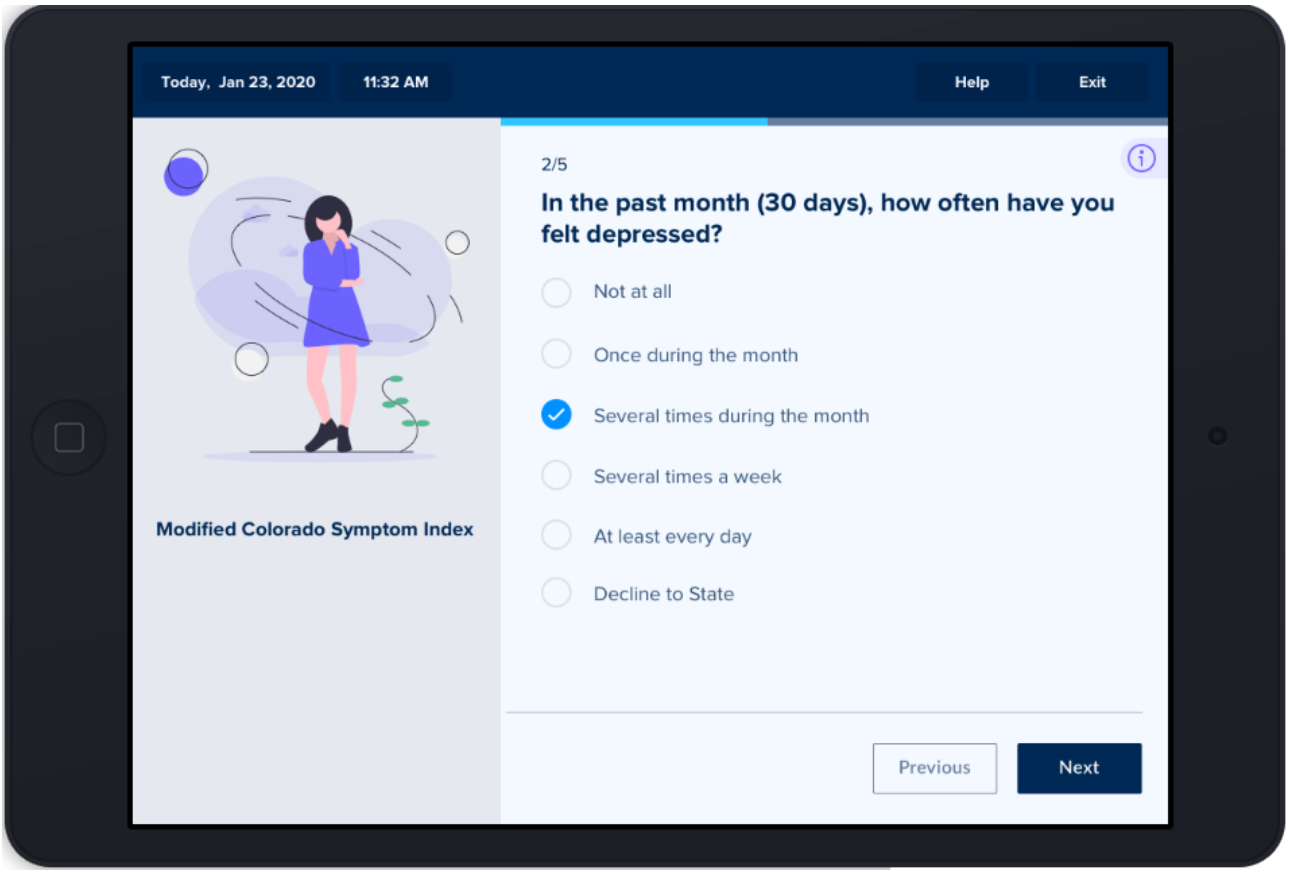
In the storyboard workshops, we presented major features of the app and asked for feedback on the app's look and feel, as well as functionality as it related to existing clinical workflow, and ease of use and acceptability for service users, their support persons, and EPI program providers. Because we determined 3 user-types during user journey mapping, we held 3 different types of storyboard workshops tailored to the journeys of these users: service users or support persons, direct-service providers, and program administrators. If EPI providers had roles in both direct-service provision and program administration, they could attend both groups. UCD workshops were conducted through videoconferencing to comply with the COVID-19 social distancing restrictions. Each session was audio recorded and included 2 facilitators (KEB, LMT, TAN, or SE) and a notetaker (VLT). There were no other individuals present other than researchers and participants. The notetaker took detailed notes, as close to verbatim as possible. Audio recordings were used as a reference to fix any portions of the notes which were not clear.

After storyboard workshops, we integrated feedback to make design changes to the alpha version of the app. During a 90-minute alpha testing workshop, we solicited feedback on the alpha app, with a special emphasis on how compatible it was with the existing clinical workflows. We created test

XSL•FO
RenderX

accounts for each participant and had them complete various core workflows in the app, such as registering a service user, completing surveys, and reviewing data visualizations. This workshop included one facilitator (KEB) and one notetaker (LS). After the conclusion of all workshops, we continued to integrate feedback to make design changes in the beta version of the app.

Figure 2. Survey item in storyboard.



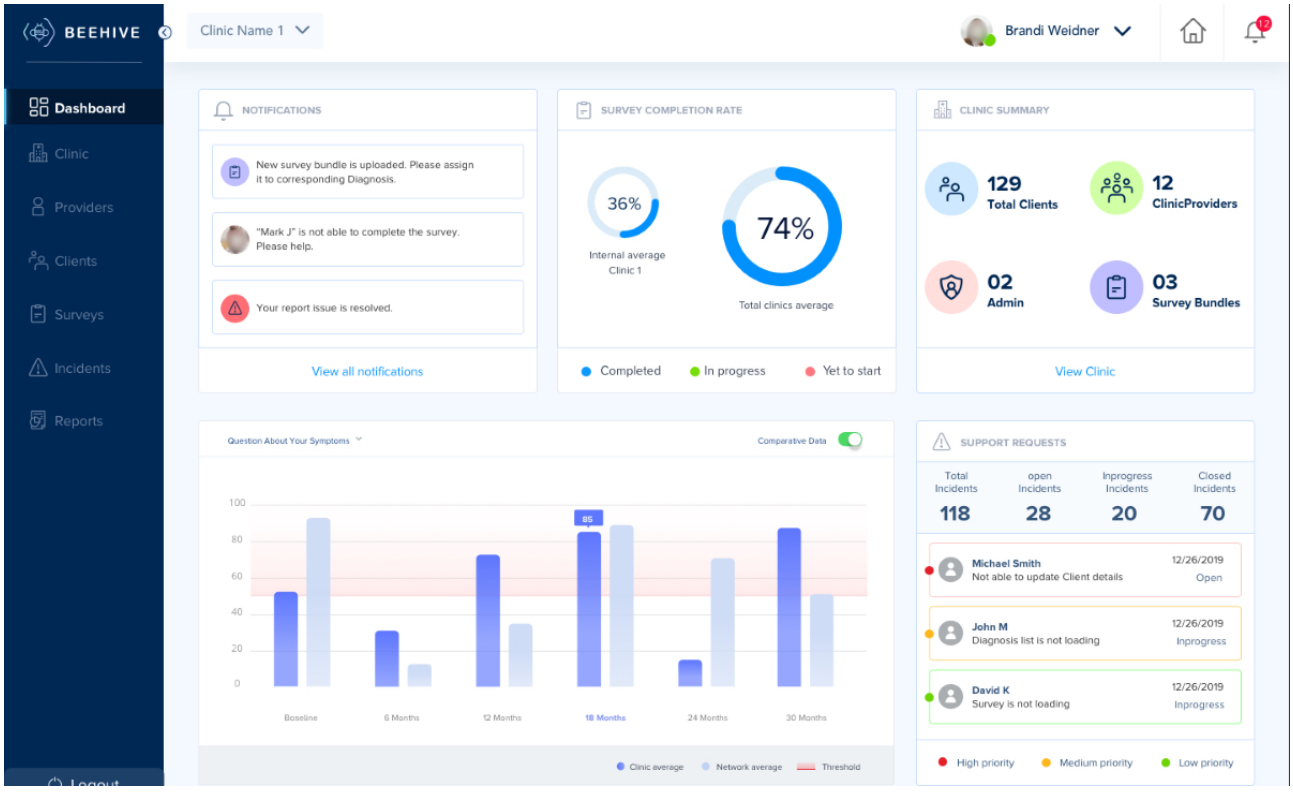


Figure 3. Clinical administrator dashboard in storyboard.

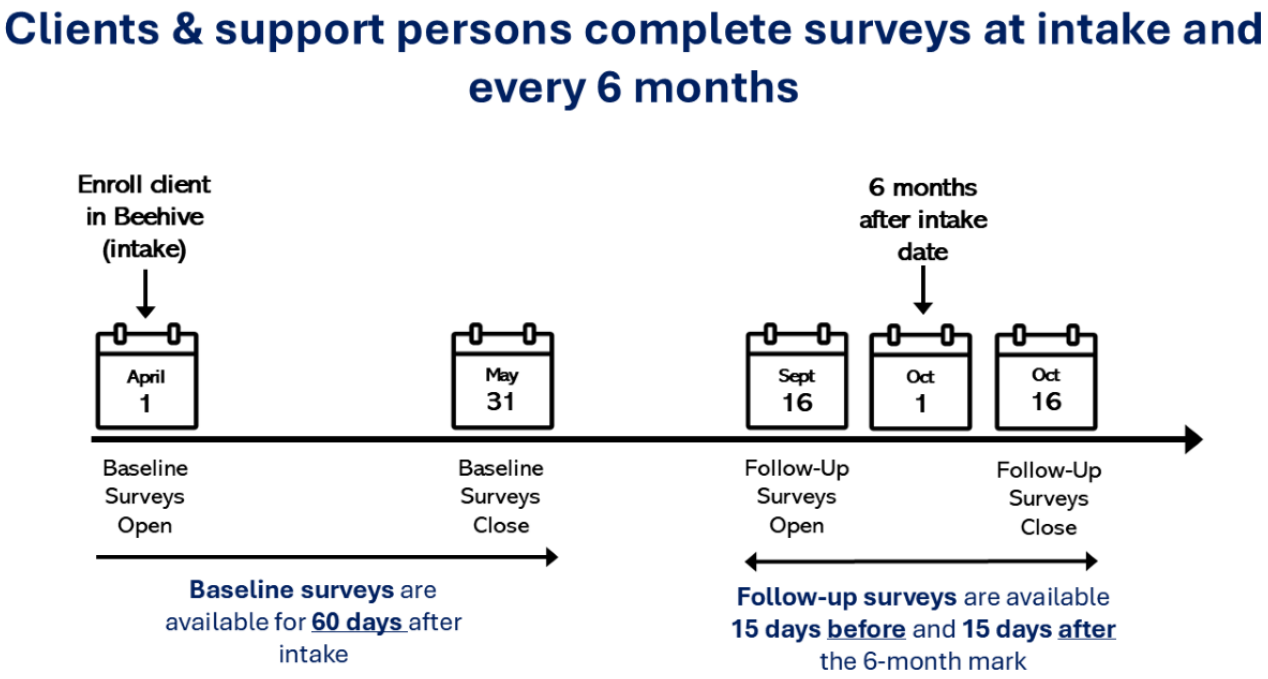

XSL•FO
RenderX

Piloting

Finally, piloting of the beta version of Beehive was conducted over a 6-month period with EPI-CAL LHCN programs that were identified as pilot sites. We provided training to each pilot site and assigned them a point person from our research team to provide regular support, troubleshoot implementation challenges, and escalate app bugs and implementation barriers. We trained all program staff, regardless of clinical role. The training series showed users how to complete key Beehive workflows, introduced the EPI-CAL core assessment battery, and included activities on how to interpret data visualizations. We also met with key staff at each program to support them to devise a plan to integrate Beehive into their existing clinical workflows, such as how to integrate service user registration during the clinical intake process. The full description of this training and support is described in a separate paper [4]. During this training and support process, we received informal feedback from program staff about implementation successes and challenges.

During piloting, programs integrated the Beehive app into standard clinical care for all service users. Service users and their support persons were registered in Beehive web app by staff at their EPI program. Program staff entered the service users' treatment start date which was considered the start of the service users' baseline window in Beehive. At enrollment, baseline, and every 6 months thereafter, surveys were assigned to service users, their support person, and their provider. One-time surveys assessing lifetime experiences were available for all respondents at enrollment. Service users had 3 enrollment surveys, support persons had 1, and clinicians had 1. Longitudinal surveys were assessed at treatment baseline and every 6 months thereafter. Service users had 17 longitudinal surveys, support persons had 6 surveys, and clinicians had 9 surveys. The duration of baseline survey window was 60 days; the duration of follow-up survey windows was 30 days (15 days before and after the target completion date). Figure 4 shows a Beehive training slide with a visualization of survey windows.

Figure 4. Beehive training slide showing survey windows during piloting.

Programs were instructed to enroll all service users, regardless of how long they had been affiliated with the EPI program. Therefore, some individuals may have been enrolled in Beehive after their baseline window had closed, and their first time point during piloting may have been a 6-month time point or a 12-month time point. Service users and support persons could access and complete surveys in-person at the clinic on the tablet app or they could complete them remotely via "web link." The "web link" was a unique link that was texted or emailed to them weekly during survey windows if surveys were not fully completed. Surveys accessed via web link could be completed on any personal device that had access to the internet and a web browser. Service providers completed surveys and could review data on the web app. Baseline surveys were intended to support the clinical intake process, including initial assessment and collaborative treatment planning. Follow-up surveys were intended to support ongoing assessment, adjustments to treatment planning, and monitoring of treatment goals.

The EPI-CAL core assessment battery, including how it was created and all included measures, is described in a separate paper [4]. Briefly, Beehive survey content includes both the Early Psychosis Intervention Network core assessment battery [36] and additional measures based on EPI community partner feedback determined in earlier qualitative work for the EPI-CAL study [4,31]. A table of measures is included in the Multimedia Appendix 1 [4]. One survey of particular interest is the Modified Colorado Symptom Index (MCSI) [37], a measure central to the aims of the broader EPI-CAL study and which we asked sites to prioritize [4]. The MCSI is a 14-item, self-report scale

XSL•FO
RenderX

which measures the frequency of psychiatric symptoms, including symptoms of mood, psychosis, cognition, forgetfulness, and risk to self and others. Respondents indicate frequency of symptoms over the past 30 days on a 0 to 4 scale of "not at all" to "at least every day." Total scores range between 0 and 56, with higher scores indicating higher frequency and number of psychiatric symptoms.

Data Analysis

In UCD workshops, we asked highly structured questions to solicit feedback on the storyboard and alpha version of Beehive. Subsequently, we organized our data categories relevant to the workflows and features we were evaluating. We then organized comments by whether they were supportive of the existing features or critical and asked for change so that we could focus on what features to move forward and what features to change as we created the alpha and beta versions of Beehive.

To investigate the initial feasibility of Beehive in EPI-CAL clinics, we reviewed descriptive statistics of pilot participants, including registration, enrollment, participant characteristics, and survey completion. Engagement with surveys and survey completion were examined in three ways as follows: (1) determine the proportion of service users for whom any data were entered, regardless of respondent type, (2) determine the rate of survey completion across all available surveys, and (3) evaluate whether participants completed all, partial, or no surveys across survey time points during piloting phase. Partial survey completion indicates that the respondent completed at least 1 survey, but did not complete all of their surveys in the specified time point. We also evaluated completion of MCSI because it is a measure that we asked programs to prioritize.

Ethical Considerations

The institutional review board of the University of California, Davis, approved the study (1403828-21, California Collaborative Network to Promote Data-Driven Care and Improve Outcomes in Early Psychosis). In addition, several of the counties and universities with a program participating in EPI-CAL required a separate review and approval of the project by their institutional review board. All study participants provided written informed consent and assent (as appropriate). Participants received US $30 compensation for each workshop they participated in. Participants in the piloting phase were not compensated because integration of Beehive was part of routine care in the EPI program. Audio recordings UCD workshops include voice print identifiers and are stored in compliance with University of California, Davis HIPAA (Health Insurance Portability and Accountability Act) policies and procedures. Data collected during piloting for research includes limited identifiers including zip code, dates of service, and month and year of birth. Only trained research staff with a need-to-access have access to identifiable data.

Results

UCD Workshops

We conducted 14 storyboard workshops with 77 total participants between April 3, 2020, and August 28, 2020. In total, 4 workshops were with service users (n=8, 10%) and their support persons (n=9, 12%). In addition, 10 workshops were with EPI program providers (n=60, 78%), including 6 for service providers, 3 for administrators, and 1 for both service providers and administrators. Demographics for workshop participants are provided in Table 1.

We completed an interim analysis of storyboard workshop data in May 2020. We completed the final analysis of workshop data in August 2020, after all groups were completed. After each analysis, we discussed and synthesized the feedback for the developers to support app development. We attempted to balance the needs of all types of participants. However, if there were needs or feedback in direct contrast with one another, we prioritized service-user feedback due to our value of centering service-user feedback in this app. This feedback and the action taken to address it are summarized in Table 2.

We conducted 1 alpha workshop in October 2020 with 4 EPI program provider participants. Feedback from this workshop was analyzed in October 2020. During this workshop, participants identified a few bugs in the app, but their feedback primarily focused on ideas for integrating Beehive into clinical workflows. For example, they suggested that Beehive training should include best practices for how providers can review the data, engage with the data, and make the most out of Beehive. They also shared concerns about using technology in telehealth settings. For example, switching to telehealth in response to the COVID-19 pandemic had been very difficult for some families, and they predicted those same families would find using Beehive challenging if the clinic could not meet with them in-person to teach them how to use it. They were less concerned about service users and support people using Beehive on a tablet in the clinic where they could provide in-person support. Finally, participants brought up the importance of shifting the culture of clinics to view data collection as an important part of treatment, not just an extra task where information is being extracted from service users. For example, surveys should be directly related to service-user recovery goals. Participants discussed how visualizations could be used to demonstrate the clinical utility of gathering these data. For example, 1 clinician said they would want to use the graphs to point out the way a service user is improving or doing better and that they would want to highlight their strengths. Another participant cautioned that some service users may not want to look at data visualizations and that this should be an optional part of their care. Figures 5 and 6 illustrate design changes present in the beta version of app after the conclusion of all workshops.

Table 2. Implementation of feedback from user-centered design workshops.

Problem or need identified in workshop	Solution implemented in alpha version
The color scheme and layout seemed "overly clinical"	Brought in more color into the palette and added icons for visual information
Some important aspects of the user-interface were too subtle, such as the survey progress bar or the urgent clinical issues widget	Changed color and design to make it more prominent
Service-user and support person registration were only available as self-registration and could not be completed by EPI program providers	Added this workflow to the web app so that EPI program providers may complete it in advance of service users engaging with surveys
Clinic-level data for service-user demographics was not visualized	Added clinic-level visualizations for race, ethnicity, sex, gender identity, and other demographic metrics
Not all service users or support persons wanted to see score thresholds or comparative data on clinical measures, but some did	Added a toggle to individual-level visualizations so that users can turn on the threshold information or comparative data if they want to see it, or turn it off if they do not want to see it
Service users might have differed on which individual-level survey visualization they wanted to see by default on their data view page	Added feature that allows users to set which measure displays by default for each service user
Some language used in the app needed to be clarified for users to understand what data was being collected or how certain features worked	Changed "homeless" to "without a permanent address" when assessing housing status; changed "help" to "Ask for help" to make it clearer that selecting button will alert the EPI program provider; changed "Diagnosis" to "Primary diagnosis"
Different programs used different words to refer to service users, and individuals might have varied on their preference for what word to use regardless of what their program tended to use	Wherever possible, implemented dynamic text so the service user's preferred name shows throughout the app, rather than any specific word to denote "service user"
Program staff wanted to see overall progress on completion of all surveys at any given time point	Added in visual indicator to show survey completion across multiple surveys (not just while completing one individual survey)
When visualizing a survey, they wanted to have more than just the global score visualized. Also, they wanted a visualization that showed responses to individual items	Added in a visualization that shows individual items as well as the global score
Service users and support persons might not have preferred the official names for measures and might have preferred a more simplified title	Added the ability to enter a display name for surveys (eg, "Family Impact" instead of "Burden Assessment Scale")
Early psychosis intervention program providers needed a way to see both the official measure name as well as the display name	Added a hover modal on survey titles to show the display name for the survey
The provision of clinic services might have been fully remote for the foreseeable future, and the current design of Beehive only allowed service users and support persons to complete surveys on a tablet in-person at the clinic	Design a web link solution which allows service users and support persons to answer surveys remotely. A link to complete their surveys can be emailed or texted to them

Piloting

We conducted piloting of Beehive beta app between March 2021 and September 2021. Our training and ongoing support of pilot sites allowed us to gather informal feedback about both the training and the Beehive app. We used this feedback to make adjustments in real time, when possible, or to plan for future changes to Beehive.

We made real-time changes to the training approach in response to program needs based on our observations and their feedback. At the time of training pilot sites in early 2021, these EPI programs were navigating constant uncertainty related to the COVID-19 pandemic, including influx of service users, uncertainty about work location, reduced workforce, etc. In response to this environment, we found it necessary to ask sites to focus on small implementation steps even though we trained them on all available workflows. For example, we asked pilot sites to initially focus on engaging service users and their support persons to complete enrollment and complete surveys. When that was mastered, we asked them to focus on engaging new service users and support persons with Beehive during their clinical intake process. Finally, toward the end of the piloting period, we encouraged them to focus on entering EPI program provider-entered data. Even if pilot sites registered existing service users, they were asked to set the service user's survey baseline date to align with their start in the EPI program. Therefore, some service users may have never been assigned surveys during their baseline survey window.

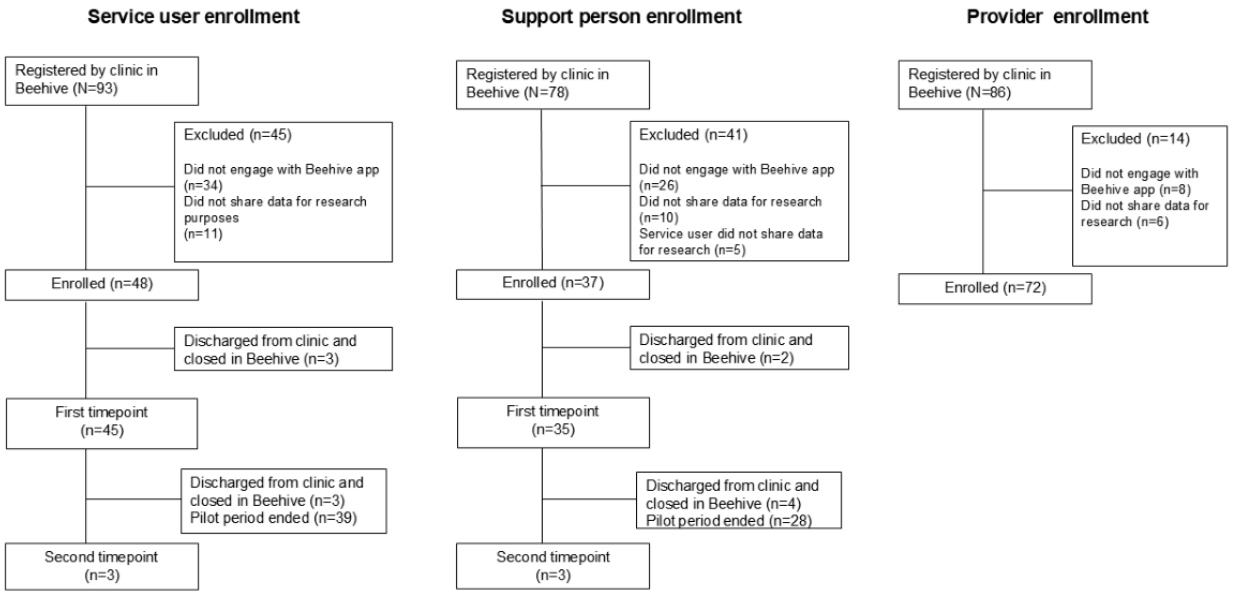
During the piloting phase, 93 service users, 78 support persons, and 86 service providers were registered across 4 clinics. Of the 93 service users who were registered into Beehive by their program, 59 (63%) completed the Beehive EULA during piloting, including 48 (51%) individuals who gave permission to use their data for research. Of the 78 support persons registered to a service user in Beehive, 52 (66%) completed the Beehive EULA, including 42 (54%) individuals who gave permission to use their data for research. Of these 42 support persons, 5 were excluded from analysis because the service user they were registered with did not give permission to use data in research, and we prioritize the data-sharing decision of the service user regarding use of collateral data for research purposes.

While most users entered at least one survey window during the piloting phase, 3 were discharged from their program before longitudinal surveys were available. Of the 86 service providers registered, 78 (91%) completed the Beehive EULA, including 72 (84%) individuals who gave permission to use their data for research. This information is presented in Figure 7.

Participant demographics and EPI program provider professional background are provided for individuals who agreed to share their data for research purposes in Tables 3 and 4. Of note, age is missing for some EPI program providers and support persons. This data was collected during registration, and this field was not included in the first release of the beta version of the app. Therefore, some users were not able to complete this field during registration and did not return later to update it, yielding missing data for 15 (36%) support persons and 37 (51%) EPI program providers.

First, to examine engagement during piloting, we assessed the number of service users that had entered any data that could be used in care. During piloting, respondents entered survey data for 85% (n=41) of service users. This includes self-reported data for 75% (n=36), collateral-reported data for 42% (n=20), and EPI program provider–entered data for 17% (n=8).

Second, we evaluated survey completion across the total amount of available surveys. A total of 1517 surveys were assigned across all respondent types during piloting and 35.4% (n=537) of those surveys were completed across all time points. We also evaluated survey completion by respondent type. Across all time points, service users completed 396 (49.4%) of 802 assigned surveys. Support persons completed 113 (47.5%) of 238 assigned surveys. EPI program providers completed 28 (5.9%) of 477 assigned surveys.



Finally, we evaluated how many respondents completed all, partial, or no surveys at each time point. Because participants could be enrolled at any point in treatment, the first time point for a service user may not have been their "baseline" appointment. These data are presented in Table 5.

The MCSI was completed by 54% (26) of service users, and 7 were excluded for responses of "prefer not to say" (Total Score: mean 19.58, SD 16.81). Additionally, 35 service users had a support person who could complete the Modified Colorado Symptom Index, and 56% (n=19) of support persons completed it. From these 19, 5 were excluded for responses of "prefer not to say" (mean 26.71, SD 14.43).

Through piloting, we also gathered informal feedback about workflows that could be improved in Beehive and that we would address with future change orders to the app after the testing of the beta version of Beehive. For example, we received feedback that the survey windows, initially chosen to mirror the data collection windows of clinical trials, were far too narrow and restrictive for data collection in community mental health programs. Program staff users also indicated that they wanted a better way of seeing a summary of what surveys service users and support persons completed. Service user and support person feedback was relayed to our team via program staff. For example, service users and support persons wanted to customize the day and time they received the web link via SMS text messaging and email.

Discussion

Principal Findings

This study describes the EPI-CAL program's design and acceptability testing approach for a custom web-based and tablet app, Beehive, to support systematic data collection, care delivery, program evaluation, and research across a statewide network of EPI programs. Our goal was to develop an app that was clinically useful for, usable by, and acceptable to diverse EPI programs across the state of California.

To ensure the app best matched the needs of the EPI participants, we adopted a UCD approach to develop Beehive. Previous research in the mental health digital space supports that active involvement from the app's intended users during the development phase can improve the appropriateness of the end product for the users of interest [38]. Initial feedback across the 3 development phases was primarily collected in workshops (storyboard and alpha version) and during pilot implementation (beta version). In storyboard and alpha workshops, we presented prototypes to demonstrate major features of the app and asked for feedback on the app's "look and feel," compatibility with existing clinical workflow, and ease of use and acceptability for service users, their support persons, and EPI program providers. Consistent with other studies who have included end users during the design phase of their eHealth apps [38-41],

XSL•FO
RenderX

feedback from these workshops resulted in immediate changes to the alpha and beta apps that would not have otherwise been made.

During piloting, we continued to collect user feedback around Beehive features, as well as assess acceptability of the app by examining preliminary enrollment and survey completion. Our enrollment and survey completion rates are consistent with the acceptability of other mental health apps developed using a UCD approach [42,43], although there is wide variability depending on the implementation approach.

During the design and testing phase, we observed that different types of community partners expressed different, and at times conflicting, needs. For example, we asked participants about their preferences for seeing score thresholds or comparative data as part of the visualization for their clinical measures. Some service users said that, in times of relapse or increasing intensity of symptoms, additional information on the visualization would be demoralizing. In contrast, many participants could imagine scenarios where that information would be useful as a form of psychoeducation to normalize service-user experiences or understand the relative severity of symptoms. To address these diverse needs and promote engagement with Beehive we added a toggle to individual-level visualizations so that users can turn the threshold information or comparative data on or off. A flexible design approach that is tailored to an individual's needs has been shown to be more efficacious in a mobile health app setting [43,44]. Therefore, design changes incorporated flexibility where possible to enable our team to meet the various needs of individuals while maintaining consistent implementation to meet evaluation and research goals.

Similarly, user feedback informed our training approach. For example, some EPI program provider users expressed that they would use the graphs in the app in clinical care with service users to highlight strengths and progress. In contrast, another EPI program provider participant cautioned that some service users may not want to look at data visualizations and that this should be an optional part of their care. Thus, our training approach highlights how visualizations may be used in direct care but are not prescriptive. Feedback from workshop participants also highlighted the importance of shifting clinic culture to view data collection as a key part of care provision. Our team considers EPI program providers to be integral in promoting engagement for service users and their support persons as it is the EPI program providers who communicate why Beehive is being used in care. To begin addressing potential barriers of buy-in and engagement for all users, we designed our trainings to include the context of why Beehive and MBC were being implemented in their programs, including a presentation on the potential value of Beehive (designed and delivered by author LS) [45].

During piloting, we observed barriers to integration. For example, despite our designing the first training such that the programs could start registering service users immediately afterward, the programs failed to do so. When asked, programs informed us that they were nervous to receive questions about Beehive that they did not know how to answer. This resulted in our team creating materials to provide more structure for programs as they introduced Beehive to service users, such as an introduction script, Beehive infographics, and other handouts. Once programs started enrolling existing service users, many found it difficult to transition enrolling new service users, given that they already had numerous documentation requirements during their clinical intake process. In response, we added a "workflow meeting" to our training series where we asked program leadership and key staff involved in intakes to walk us through their existing procedures so that we could help brainstorm where the required Beehive workflow steps could be implemented and who from their program would be responsible for each step. We additionally observed that clinician-entered data were hard for sites to prioritize. For example, there was a lack of clarity within teams about who was responsible for entering these data and what training was required. Therefore, we chose to add another "workflow meeting" between key program staff and our team to help programs identify who was responsible for which surveys, who needed training, and how programs could monitor survey completion. We added these workflow meetings to our formal training protocol and made the support materials available to all sites who joined after the piloting phase.

Furthermore, our team worked with programs beyond the piloting phase to ensure that we continued to incorporate individual feedback and offer continuous support, which is key to successful adoption and can improve engagement [46]. After the piloting of the beta version of Beehive concluded, we continued to make development changes to meet users' needs, such as further design changes to the admin dashboard, widening survey completion windows, adjusting and eventually allowing customization of the frequency and timing of web link notifications, allowing the EULA to be completed before survey baseline date, simplifying registration fields, adding a survey status page, adding additional survey visualizations, adding a workflow for providers to enter data collected outside of Beehive, and prioritizing the order of additional languages in the app based on active need in the participating clinics. This iterative approach in response to user feedback is consistent with the development process of other eHealth apps [47].

This study highlights how critical it is for programs using a continuous improvement approach, such as UCD, to budget appropriately for ongoing development needs and staff time for ongoing support. As long as an app is in use and collecting data from real users, there should be a plan for ongoing project management and app development to address feedback from users, improve engagement and useability, and respond to changing needs. Implementing UCD from the outset allowed our team to be aware of and address user concerns before investing valuable time and resources in initial development and implementation. Focusing on workflow during the storyboard and alpha phases of app and continuing this collaborative relationship throughout the implementation phase resulted in an app that represents the interests and needs of users.

During the piloting, we observed that survey completion rates varied among different types of users. This variance may be partially explained by our training approach during piloting (see the Results section). As we continue to collect data after the piloting phase, we can evaluate if this trend continues beyond

XSL•FO
RenderX

the initial onboarding period throughout multiple years of data collection. These varied results may also reflect the challenges of implementing MBC, with or without an eHealth app, such as the training burden and limited time to conduct new duties associated with eHealth implementation [24-26,31]. When implementing outcomes data collection in these settings, it may be critical to gather only the minimum required data from EPI program providers (eg, diagnosis) and rely on service-user self-report measures whenever possible. Future analyses will examine the relationship between characteristics of EPI program providers (eg, degree and years licensed) and completion rates of clinician-entered data. Future work, including barriers and facilitators interviews with users after they gain more experience using Beehive, will be used to prioritize the needs and perspectives of our users in the ongoing development of Beehive and to better understand the reasons why users do or do not engage with the app [48].

Limitations

The COVID-19 pandemic introduced multiple challenges for our study, which may have reduced the breadth and diversity of participation in various phases of the project. We offered workshops over remote teleconferencing instead of in-person, which may have excluded individuals who are less comfortable with using technology. This may have disproportionately impacted on the recruitment of service users and support persons for participation in workgroups, as our participant numbers were lower than previous studies where we were conducting in-person research [31]. To reduce bias that may have resulted from this imbalance, we chose to prioritize the feedback of service users and support persons if there was conflicting feedback between these participants and EPI program provider participants. In addition, the beta and full versions of Beehive have been introduced to all service users in participating programs, regardless of their comfort with technology, and this has allowed us to incorporate informal feedback from these individuals as we have continued to make improvements to Beehive.

Much of our data in UCD workshops were gathered at the start of the COVID-19 pandemic, before anyone had experienced the long-term shift in daily practices brought on by the increased use of telehealth and remote working. We sought feedback on an app that was intended for in-person use and received feedback based on participants' experience of using in-person services. This highlights the importance of planning multiple opportunities for soliciting and incorporating feedback from sites so that apps can be responsive to changing environments.

Our workshops and piloting were only conducted in English. To serve the diverse population of California, Beehive needs to be both translated and adapted, a process known as localization [49], into at least 15 languages. Since Beehive's launch, we have localized into 7 additional languages. We continue to solicit feedback from users, including those whose primary language is not English, to inform the ongoing development of Beehive, and we will continue localize this app into additional languages.

While we used our prior knowledge of mental health development in the development of Beehive [11,12], we did not use a structured analysis approach for the feedback obtained during workshops due to time constraints imposed by project deliverables. To reduce the impact of subjective biases, the researchers who conducted each group debriefed afterward to review the notes, and recordings were referenced if notes were unclear or vague. In addition, all decisions about how to incorporate feedback from these notes into app development were made collaboratively by authors KEB, LMT, TAN, and VLT. Future work in this area will benefit from organized approaches to data collection and formal qualitative analysis [50,51].

Conclusions

Working with community partners to co-design an eHealth app for use in community EPI programs helped us to anticipate and resolve barriers earlier in the app development and implementation pipeline. On the basis of our observation and the data, there appeared to be high levels of engagement with Beehive. This resulted in feedback and continued design improvements which allowed our team to be better poised to launch Beehive across the EPI-CAL LHCN. Variance in survey completion rates among respondent types suggests that support persons and EPI program providers especially may need additional support.

Acknowledgments

The authors would like to thank all service users, support persons, and EPI program providers who participated in this study, Binda Mangat of Quorum Technologies, and its team of professionals for supporting the development of Beehive, and the Early Psychosis Intervention Network of California learning health care network.

This research made was supported by One Mind, the National Institute of Mental Health under award R01MH120555-01, and the following California counties: Los Angeles, Napa, Orange, San Diego, Solano, Stanislaus, Lake, Nevada, Mono, Colusa, and Sonoma. Authors' Contributions

KEB conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, recruited participants, collected data, trained pilot sites, audited and cleaned data, analyzed data, drafted the manuscript, and reviewed and revised the manuscript for important intellectual content. VLT conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, collected data, trained pilot sites, drafted the manuscript, and reviewed and revised the manuscript for important intellectual content. KMP audited and cleaned data, drafted the manuscript, and reviewed and revised the manuscript for important intellectual content. LMT conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, collected data, trained pilot sites, and reviewed and revised the manuscript for important intellectual content. SE conceptualized and designed the study, created the focus group guides, collected data, trained pilot sites, and reviewed and revised the manuscript for important intellectual content. MS, ABW, and AJP conceptualized and designed the study and reviewed the manuscript for important intellectual content. LS collected data, trained pilot sites, and reviewed and revised the manuscript for important intellectual content. CKH trained pilot sites, audited and cleaned data, and reviewed and revised the manuscript for important intellectual content. VEP, APM, and MK-W trained pilot sites and reviewed and revised the manuscript for important intellectual content. CM, MJM, NS, KLHN, and YZ cleaned data and reviewed and revised the manuscript for important intellectual content. TAN obtained funding, conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, collected data, reviewed and revised the manuscript for important intellectual content.

Conflicts of Interest

KEB consulted with ChatOwl Inc after data collection and before submission. LMT was employed by ChatOwl Inc, a digital mental health company after data collection and before submission. LMT was a founder and owner of shares in Safari Health, Inc. during project implementation, data collection, and write up (no longer true at time of writing) and is an employee and shareholder at Kooth LLC at time of publication. TAN is a cofounder and shareholder in Safari Health, Inc.

Abstract

Background: Social networking site (SNS) users may experience mental health difficulties themselves or engage with mental health–related content on these platforms. While SNSs use moderation systems and user tools to limit harmful content availability, concerns persist regarding the implementation and effectiveness of these methods.

Objective: This study aimed to use an ethnographic walkthrough method to critically evaluate 4 SNSs—Instagram, TikTok, Tumblr, and Tellmi.

Methods: Walkthrough methods were used to identify and analyze mental health content moderation and safety and well-being resources of SNS platforms. We completed systematic checklists for each of the SNS platforms and then used thematic analysis to interpret the data.

Results: Findings highlighted both successes and challenges in balancing user safety and content moderation across platforms. While varied mental health resources were available on platforms, several issues emerged, including redundancy of information, broken links, and a lack of non–US-centric resources. In addition, despite the presence of several self-moderation tool options, there was insufficient evidence of user education and testing around these features, potentially limiting their effectiveness. Platforms also faced difficulties addressing harmful mental health content due to unclear language around what was allowed or disallowed. This was especially evident in the management of mental health–related terminology, where the emergence of "algospeak," where users adopt alternative codewords or phrases to avoid having content removed or banned by moderation systems, highlighted how users easily bypass platform censorship. Furthermore, platforms did not detail support for reporters or reportees of mental health–related content, leaving users susceptible.

Conclusions: Our study resulted in the production of preliminary recommendations for platforms regarding potential mental health content moderation and well-being procedures and tools. We also emphasized the need for more inclusive user-centered design, feedback, and research to improve SNS safety and moderation features.

Introduction

Background

Social networking sites (SNSs) can serve multiple purposes for individuals with mental health difficulties [1]. These include facilitating self-disclosure of mental health disorders, acting as discursive spaces, and offering exposure to both harmful and helpful mental health–related content [2,3]. However, several research studies have identified relationships between SNS use and development or exacerbation of mental health symptoms, including depression, anxiety, psychosis, eating disorder, self-harm, and suicide behaviors [4,5].

With approximately 1 in 8 people globally living with a mental health condition [6] and considering the multifaceted role SNSs can have in shaping mental health experiences, platforms have a significant responsibility to support and guide users in managing their well-being. SNSs currently use a variety of moderation and safety techniques to regulate their online communities, including blocking and removing content, banning users, outlining community guidelines, and providing mental health resources, through automatic and manual processes [7].

Despite this, concerns remain about the effectiveness of SNS safety practices [8]. For instance, users engaging with self-harm and suicide material online have reported actively avoiding online help during crises, including dismissing pop-ups and support links [9]. Furthermore, SNS users engaging with self-harm and suicide content online have criticized platform inconsistencies regarding content removal and the communication of decisions around this, reporting that these moderation actions can lead to feelings of stigmatization and harm [8,10]. In addition, studies have found that due to strict censorship of mental health–related terms, platform users may turn to "algospeak," where they adopt alternative codewords or phrases to avoid having content removed or banned by moderation systems [11], or to circumnavigate search filters [12,13]. Another study, which explored how people use platforms and technology to support their mental health [14] found that users wanted the provision of mental health support on SNSs to be more nuanced and trustworthy, with clear, evidence-based guidance. Concerns have also been raised more generally about users' ability to read and understand SNS policies and guidance. One study identified significant variation between community guidelines across platforms, highlighting how this can negatively impact user safety and trust [15]. Another study stated that users' contract requirements with SNSs whereby they state they have read and agreed to the terms of service (ToS) is "the biggest lie on the internet" [16].

These findings highlight possible inefficiencies in current moderation and safety mechanisms used by SNSs and significant potential risks, particularly for vulnerable users, including exposure to harmful content, inadequate crisis responses, and possible disengagement from regulated spaces in favor of less-moderated ones. The full extent of such moderation and safety challenges across SNSs remains unclear, highlighting the need for more in-depth explorations of user experiences. The introduction of the Online Safety Act (OSA) [17] in the United Kingdom, which aims to tighten safety regulations and standards for digital platforms, further emphasizes this need for comprehensive data on current SNS practices and their effectiveness, to fully assess and address issues.

The walkthrough method is a valuable tool for understanding user experiences on these online platforms [18,19]. It is a structured ethnographic approach examining application and platform features, settings, and interactions by "touring" the platform interactively. The method focuses on understanding how platform design and resources potentially encourage and impact user behavior. For instance, in their paper on a walkthrough of the dating platform Tinder, Gillett [20] identified several user safety issues, including the problematic placement and design of the reporting icon. The author proposed that these design choices could significantly influence user behavior, leading to potential unintended interactions with harmful content and adverse effects on user well-being. This study demonstrated how the walkthrough method can be used to reveal critical aspects of user experience that might otherwise be overlooked.

This Study

Using the walkthrough method, this study aimed to systematically identify how SNSs manage mental health content and user well-being through moderation, safety features, resources, and policies and to explore the potential impact of these platform attributes on users. By identifying platform successes and areas for improvement, the study aimed to contribute to the creation of safer and more supportive digital environments.

Methods

Research Design

This study used an ethnographic walkthrough method to systematically and critically assess the approaches of various SNSs in moderating mental health content and promoting user well-being. Researchers actively participated in the platforms as observers to evaluate their features, guidance, and resources.

Ethical Considerations

This study adhered to ethical guidelines for internet-mediated research [21]. Researchers ensured that their participation did not interfere with the functioning of the platforms, mislead other users, or go against platform regulations. Confidentiality was maintained by avoiding the recording of personally identifiable information, such as user-generated names or specific images. No interventions were made in response to harmful content observed, ensuring that the user experience and platform responses remained unaltered. No financial compensation was provided to researchers as they undertook the research as part of their routine professional role. There were well-being procedures in place for researchers, and they were able to withdraw from conducting the walkthrough checklists if they wished.

Ethics approval was received from the Faculty of Health Sciences Research Ethics Committee at the University of Bristol (approval number 17972).

Positionality Statement

As researchers in the field of mental health and digital technology, we acknowledge that our personal and professional experiences shape our perspectives and approach to this study. Researchers ZH and LB are both White women from the United Kingdom. ZH identifies as a digital native, reflecting a comfort with digital technology and early adoption of various online platforms throughout her life. In contrast, LB is a digital immigrant.

Data Collection

We selected 4 SNS platforms for evaluation. TikTok and Instagram were selected due to their status as two of the most widely used social media platforms in the United Kingdom, particularly among adolescents [22,23]. Tumblr was chosen for its established reputation as a significant SNS platform, offering a contrasting perspective to the newer platforms. In addition, although Tumblr has less representation in the current research literature and discussion around online safety [23], media reports indicate a recent shift in their user base toward the Gen Z population [24,25]. Tellmi was chosen as a smaller platform specializing in mental health support and discussion among young people, which offered an opportunity to evaluate a platform specifically designed with the mental health of users in mind, providing a useful comparison to SNSs that prioritize broader aspects of social interaction. For this study, Facebook was excluded from our SNS evaluation despite it being the most accessed platform in the United Kingdom. This was because of its lower popularity among younger UK users [23] and its likely similarities with Instagram, given their shared ownership by Meta.

To conduct our walkthroughs, we used 2 checklists (Multimedia Appendices 1 and 2) to systematically evaluate each platform's approach to moderating mental health content and supporting user well-being. Checklists were developed from previous research findings [8,26] and industry guidelines for suicide and self-harm content [27]. To conduct the walkthrough checklist, ZH used a new iOS device and LB used a web browser. Table 1 depicts the platform areas that the checklist focused on, and Table 2 shows the stages of use that were observed and documented through field notes and screenshots.

Table 1. Checklist focus areas.

Checklist focus areas	Description
Design, language, and features	Assessment of the design, language, and features of platform content related to mental health, safety, and well-being.
Policies and processes	Evaluation of the accessibility, availability, and relevance of information and policies concerning age limits, mental health rules, and safety guidelines.
Resources	Analysis of the accessibility, availability, and relevance of mental health resources, including those tailored for specific populations such as young people and parents or guardians.
Moderation processes	Examination of moderation processes, including self-moderation tools.

Table 2. Documented platform stages of use.

Stages of use	Details
Sign-up	For sign-up purposes, researchers entered a date of birth, making the account user <13 years, 15 years, and 19 years old, respectively. No account was created to comply with platform policies. New accounts were created by the researcher using their own date of birth for checklist completion. Tellmi also required users to enter a UK postcode. Researchers entered their own UK postcode. No other demographic data (eg, gender, ethnicity, and sexual orientation) was provided by researchers.
Standard platform use	Observations during typical use of the platform environment. Researchers only observed content and did not engage (eg, like, share, or comment) with content during this phase. However, in the case of Tumblr, some interactions (eg, following hashtags) were required during the sign-up process to proceed, as detailed in the Results section.
Searching for mental health terms	Searches were conducted for mental health–related terms, including algospeak terms related to eating disorders, self-harm, and suicide. Algospeak terms were informed by the Digital Dialogues Young Person's Group [28]. Algospeak terms are not listed to avoid unintentionally increasing their visibility. The full list is available to researchers on request to the authors.
Reporting mental health content	Reporting processes were observed, but no content or user reports were submitted to the platform.
Exploration of moderation, safety, and well-being information	Information provided by platforms about moderation, safety, and well-being was observed.
Exploration of self-moderation tools	Self-moderation tools available on platforms were observed and used.

Data Analysis

Data were analyzed using a thematic analysis approach [29,30]. Initially, ZH reviewed the field notes, observations, and screenshots, applying a deductive approach to generating codes based on the checklist format. These codes were then further refined through an iterative process. The codes were then organized into groups, based on similarities in the issues, ideas, or patterns they addressed. These grouped codes were then

XSL•FO
RenderX

defined as themes that represented meaningful constructs of the coded data. Data for each theme can be viewed in a comparative table, by platform (Multimedia Appendix 3).

Results

Overview

Data were analyzed to understand the current provisions by platforms regarding mental health–related content moderation and user well-being. The themes we defined are summarized in Table 3.

Table 3. Theme and theme descriptions.

Theme	Theme description
Observations of safety features	Includes how users are introduced to safety on the platform, particularly through explicit safety instructions during the user journey, and moderation interventions, such as during searches for mental health–related terms
Platform moderation and safety guidance and systems	Examines how platforms describe the mechanisms for content moderation, including automatic filters, content warnings, and moderation policies that impact what users see and how content is managed
User "self-moderation" tools and reporting	Explores functionality, accessibility, and availability of self-moderation tools for users
Platform support and resources	Explores the information and resources provided by platforms related to mental health and well-being
Platform interface and communication	Explores the style, format, and presentation of mental health–related information and tools to users via the platform

Observation of Safety Features

Sign-Up Processes

Across platforms, sign-up procedures generally lacked emphasis on key safety information. Instagram, TikTok, and Tumblr gave subtle displays of their ToS and privacy policies, without proactively engaging users with them. In addition, at sign-up, no platform provided direct links to their community guidelines (Moderation Guidelines on Tellmi), which detail important mental health content moderation information. Tellmi provided more safety-related prompts during the sign-up process, ensuring users agreed to data-sharing practices and were aware of the platform's limitations in handling mental health crises. In addition, they directed users to the ToS, making it clear that this was a key part of their agreement with the platform.

Age requirements varied, Instagram and TikTok set the minimum at 13 years, Tellmi set the minimum at 11 years, and Tumblr set the minimum at 16 years. During sign-up, TikTok and Instagram restricted users from changing their birthdate if they had originally attempted to sign up below the minimum age, while Tumblr and Tellmi allowed users to enter a different date and continue, exposing a lack of age verification procedures. Notably, during sign-up, TikTok offered additional videos to users aged 13 to 17 years on data protection and default settings, reflecting an attempt to mitigate risks for younger users.

As part of the sign-up process, Tumblr required users to follow other accounts before accessing content, by selecting from the platform's recommendation system for popular hashtags and accounts. We selected recommended hashtags that we believed could be problematic, which exposed us to potentially harmful disordered eating content early on. This highlighted insufficient moderation within Tumblr's algorithm-driven suggestions. In contrast, Instagram also directed users to engage with popular content, but all suggestions were verified, and we did not identify any potentially problematic accounts. Users also had the option to skip this step. TikTok and Tellmi did not prompt users to follow any specific content tags or accounts during sign-up.

Content Exposure

Initial platform use provided varying experiences in terms of content exposure. Tellmi, Instagram, and TikTok took deliberate steps to provide users with safe, moderated content. Tellmi presented users with a wide range of nonharmful posts on mental health–related topics, while Instagram and TikTok's algorithms effectively prioritized popular content such as humor, sports, and celebrities, avoiding explicitly harmful material. In contrast, due to Tumblr's requirements to follow accounts and the potentially problematic ones we chose, we were immediately exposed to harmful mental health–related content in our feed including images of graphic self-harm and severely underweight female-presenting figures, as well as further recommendations to follow other seemingly harmful accounts. In addition, other than during the sign-up of users aged 13 to 17 years on TikTok, where some self-moderation tools were mentioned in videos, none of the platforms offered explicit guidance on how to find or implement self-moderation or safety tools during initial use.

Mental Health–Related Content Searches

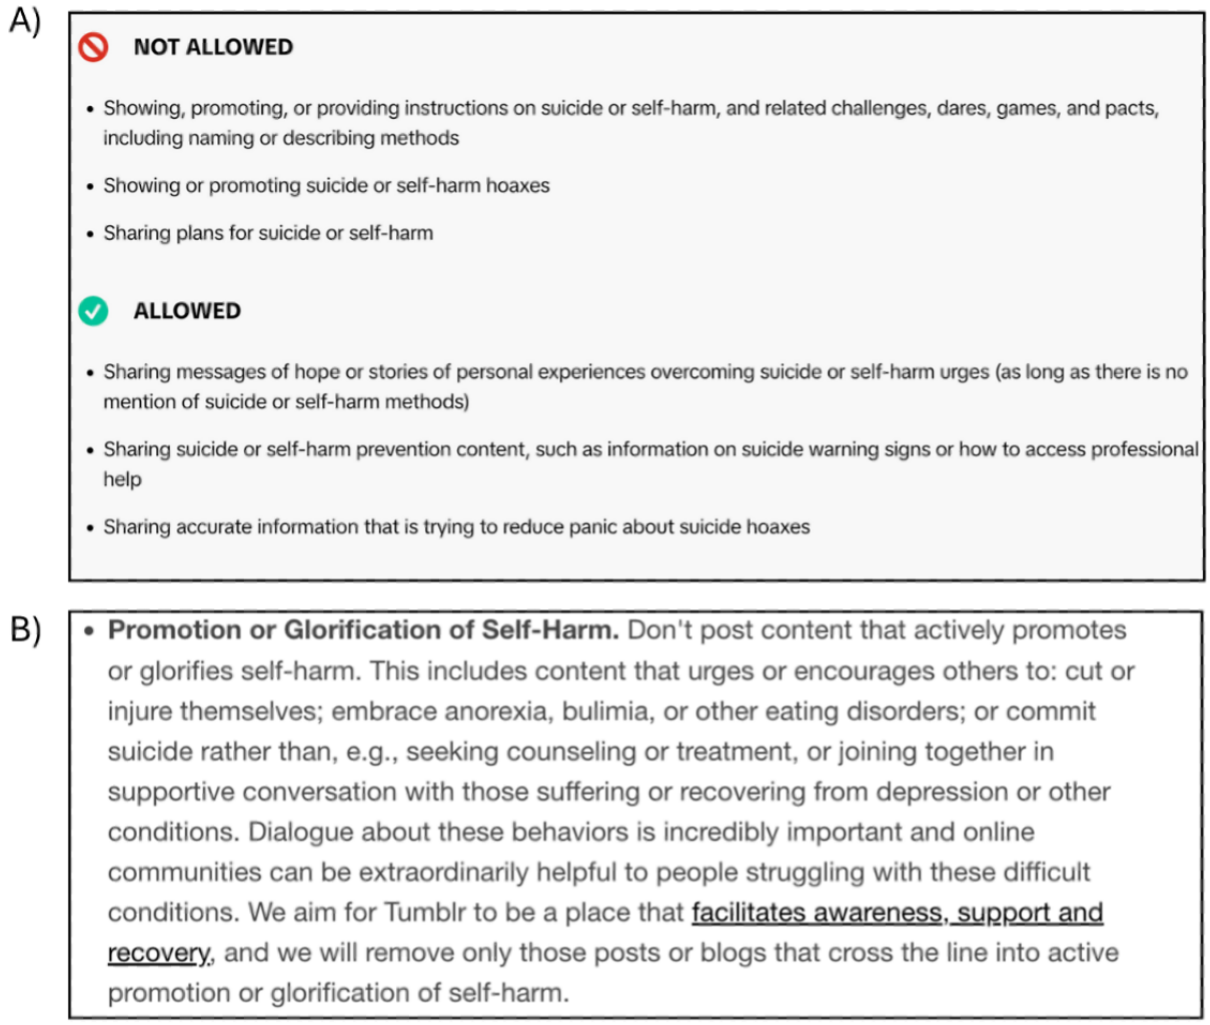
When searching for mental health–related terms, using default sensitive or mature content levels, the platforms differed in their handling of material. Tellmi allowed search results for discussions on topics such as suicide, self-harm, and eating disorders, but the content was moderated and nonharmful, focusing on recovery and support. In comparison, the same suicide and self-harm term searches returned no results on Instagram, TikTok, or Tumblr, although all 3 offered relevant support. Instagram provided details for multiple external support organizations, and their own general support resource on self-care tips. TikTok gave details for Samaritans, as well as their own support resource on self-harm and suicide, and Tumblr

XSL•FO
RenderX

provided details for mainly US-based organizations, as well as their internal "counseling and prevention" page. Neither Instagram nor TikTok is linked to their more developed internal self-harm and suicide help pages, available in their platform safety centers. For searches on the terms "eating disorders," "anorexia," and "bulimia," Tumblr showed a similar help message with details for several more US organizations and no results. TikTok showed no results but directed users to its internal "eating disorders" resource and contact details for Beat An Instagram search for "eating disorders" gave the same resource page as for "suicide" and "self-harm" searches on the platform. For the terms "anorexia" and "bulimia," Instagram gave these resources again but also provided the option for users to continue their search. Results included recovery and support posts, images of self-harm scars, content promoting disordered eating, related potentially harmful hashtags, access to user biographies that stated goal weights (below healthy adult weights), and the phrase "block don't report" (also found in Tumblr results). On Instagram, sensitive content warnings also appeared on some posts but were inconsistently applied.

In searches for algospeak, all platforms returned results for at least 1 algospeak term related to self-harm, suicide, or eating disorders. On Instagram, TikTok, and Tumblr, algospeak terms led to more graphic and harmful content, including identification of further algospeak hashtags. Tellmi again returned moderated content, meaning the discussions presented were not harmful.

Platform Moderation and Safety Guidance and Systems



Moderation Transparency

All platforms provided information on the moderation of mental health content, primarily through their community guidelines or equivalent. The level of detail and transparency varied, with Instagram and TikTok offering extensive information on mental health content moderation and user well-being across various internally dedicated "centers," "guides," and "resources." However, this spread of information often led to repetition, required users to navigate multiple links, and sometimes failed to provide essential resources for help and support such as details of emergency or external support services. Tumblr and Tellmi provided limited internal spaces for users to access detailed information when encountering specific mental health–related content or seeking support for their own mental health needs. Users on Tellmi could access relevant areas of the directory, and on Tumblr, their "counselling and prevention resources" page. However, in both cases, resources were external to the platform.

TikTok and Instagram provided the most concise and specific information about what mental health–related content was and was not allowed on their platform, including clear examples. Instagram further outlined content they may label as sensitive, such as "older instances of self-harm such as healed cuts" or "content that depicts ribs, collar bones, thigh gaps, hips, concave stomach or protruding spine or scapula in a recovery context." In contrast, Tumblr and Tellmi guidance offered less clarity regarding disallowed content, often merging eating disorder, self-harm, or suicide content into a single category and using more abstract language, such as Tumblr prohibiting content that "embrace[s] anorexia" (Figure 1).

XSL•FO
RenderX

Figure 1. (A) Screenshot of TikTok community guidelines for allowed and disallowed suicide and self-harm content. (B) Screenshot of Tumblr user guidelines for promotion or glorification of self-harm.

Content Moderation Systems and Enforcement

TikTok, Tumblr, and Instagram described the use of automated moderation systems alongside human moderators, although roles were sometimes unclear. TikTok and Instagram further provided quarterly updates through their transparency centers, offering insights into the volume of mental health–related content removed both automatically and through user reporting. Tellmi detailed their unique approach of using entirely human moderation, emphasizing how this allowed for more nuanced decision-making and a personal approach to safety. However, we noted Tellmi moderators went offline from 11 PM to 8:30 AM (UK time), meaning no posting, and we also noted that during periods of heavy user engagement, posting would also be restricted to manage moderation load.

All platforms indicated that they could ban users or remove their content if it did not meet their required standards. However, the mechanisms and systems for enforcing these rules varied significantly. For instance, TikTok used a “strike” system to manage violations, but the details were somewhat vague, as the specifics of how strikes were issued and accumulated were not clearly communicated. Instagram stated that users “may” receive warnings before content was removed; however, the language used was noncommittal, leading to ambiguity about the enforcement process. TikTok and Instagram did allow users to track their account status, which indicated violations to the user and allowed for efficient use of the appeals process. Alternatively, Tumblr stated that they would inform users only after removing content or terminating accounts, except in the case of sexually explicit content, where users were given an opportunity to review, amend, or remove content. Tellmi’s approach was more explicit, stating that posts or replies that did not meet their moderation standards would be rejected and users would receive a brief explanation for the rejection to which they could directly respond to a human moderator.

Age-Based Protections

TikTok and, more recently, Instagram have implemented age-related defaults aimed at protecting young users, particularly those aged between 13 and 17 years. These focus on limiting potentially sensitive content exposure, managing screen time, and restricting interactions with unknown users. Both platforms enforce age-related settings with distinct approaches. On TikTok, younger teenagers (aged 13-15 years) face restrictions that cannot be altered. These include preventing others from downloading their videos, blocking all direct messaging, keeping

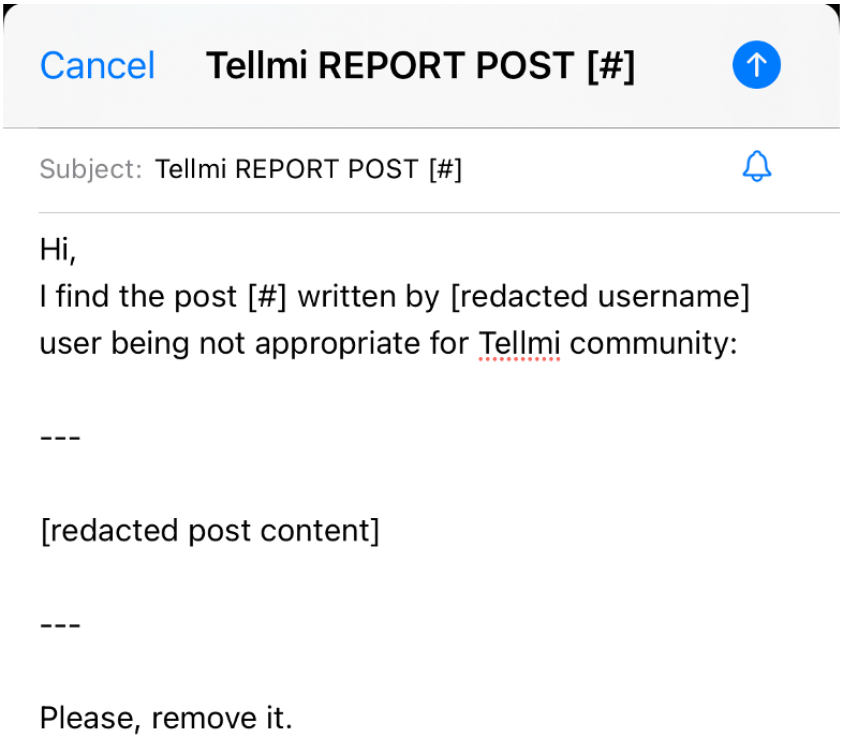
XSL•FO
RenderX

accounts private, and disabling features such as video stitching, duetting, and comments (stitching refers to combining an existing video with one you are creating; duetting refers to you posting your video side-by-side with an existing video on TikTok). Instagram similarly defaults those aged 13 to 15 years to private accounts and enforces restrictions including time limits, sleep mode, and disabling interaction features. Unlike TikTok, Instagram allows teenagers to request changes to these settings, but parental approval is required for modifications. Teenagers aged 16 to 17 years on both platforms have slightly more flexibility, such as enabling public accounts, but on Instagram, parental supervision is still necessary for approving changes. Alternatively, Tellmi adopted an age-banding approach to ensure users <20 years primarily interact with peers within 2 years of their age. Despite this, Tellmi informs users that responses to discussions may introduce wider age gaps, potentially affecting their intended interactions. In addition, Tumblr limits potentially mature content to audiences aged >18 years but does not implement any other age-based functions.

User "Self-Moderation" Tools and Reporting

User Control and Access to Tools

Self-moderation tools across platforms were often presented as options in user profile menus but with limited context regarding their potential effects. Even where their functionality was described in detail on platform help or safety pages, it was rare that well-being benefits were reflected to the user. Instagram and TikTok provided 21 and 23 self-moderation tools, respectively, offering time management, filtering, and privacy controls. Generally, these tools were in similar places on the platforms, making them intuitive to locate for those familiar with these types of online environments, but occasionally, they were in unexpected spaces or were less straightforward to implement. Some tools seemed to have overlapping functions, which may inhibit users' understanding of their functionality. Time management tools offered by Instagram and TikTok included prompts to take screen breaks, have quiet time, or go to sleep. These were easily accessible in time management controls of the respective platforms, where users could also view a visual tracker of their engagement. Both platforms offered preset time options for these tools, with TikTok's settings being slightly more customizable than Instagram's. However, the imposed limits on these presets suggested that neither platform was actively promoting extended or frequent disengagement. Self-moderation tools on the other platforms were much more limited. Tumblr offered 12 tools, primarily focused on privacy with some options for content filtering, and while Tellmi's role as a mental health support platform may make disengagement tools less intuitive, they provided 3 relevant self-moderation tools, with only 1 for hiding content related to certain mental health categories, limiting user control over their experiences.



All platforms also implemented some form of sensitivity content rating, mostly to prevent access to what they termed mature content. TikTok, Tumblr, and Instagram automatically restricted such content for users aged <18 years, although definitions of mature or sensitive content for TikTok and Tumblr were vague. Tellmi offered greater transparency by clearly indicating that higher sensitivity would limit access to potentially triggering content. However, the specific content covered by each sensitivity level remained unclear. On Instagram and Tellmi, where sensitivity ratings could be adjusted by users, more restrictive settings limited search results for mental health and algospeak terms, suggesting that mental health content was included in these sensitivity categories for both platforms.

Reporting Systems

All platforms also shared similarities in encouraging users to report harmful content throughout their health, safety, and policy pages, often referring to user responsibility to report others' content that violates platform terms. Instagram and TikTok allowed users to report specific categories of mental health content such as suicide, self-harm, and disordered eating. Tumblr only provided a mental health content option for reporting suicide and self-harm, potentially hindering users aiming to report disordered eating content. However, Tumblr's reporting process was more detailed, requiring users to indicate if the person posting content was actively threatening suicide and to explain their concerns. In contrast, TikTok included reminders of platform rules regarding mental health–related content before users submitted their report, reinforcing guidelines and giving users a clear understanding of the platform's expectations. Tellmi offered a more manual process, where users reported any content by sending an email to the platform's support team via an automated template that could be personalized before submission (Figure 2). This method contrasted with the more automated systems of the other platforms.

XSL•FO
RenderX

Figure 2. Screenshot of an automated Tellmi template report email.

The platforms also differed in how they handled report follow-ups. Instagram and TikTok allowed users to check the status of their reports and appeal any decisions made, creating a straightforward process for feedback. Notably, Instagram also indicated that user reports may influence the content algorithm for their feed:

> *We may use your report to make content similar to what you reported appear lower in your Feed or in the recommendations we make for you, such as Suggested posts and Explore.* [Instagram's "Staying Safe" section in the Help Centre]

The other platforms lacked tracking features for their reporting systems, although Tellmi did offer email correspondence regarding decisions made on reports, allowing users to engage directly with a human moderator. None of the platforms provided information about whether they offered follow-up with support or resources for users who reported mental health–related content or for those whose content was reported, and as we did not report mental health content within this study, we cannot confirm their processes.

Platform Support and Resources

Platform resources for mental health support varied significantly. Instagram and TikTok provided a range of internal resources on self-harm, suicide, and disordered eating, including pages with practical advice, educational content, and emergency procedures that were written in consultation with credible external organizations. Uniquely, TikTok also published a page focused on creator burnout, and Tellmi allowed users to complete and track scores in mental health quizzes. In addition, Instagram hosted a variety of resources around mental health that had been developed and published by external services and charities, which users were able to download. Similarly, Tellmi directed users to a wealth of resources hosted externally. Both Instagram and TikTok provided a somewhat overwhelmingly wide range of guidance and policy pages directed at young people and their parents or guardians, again providing information on well-being support and practical online advice. Tumblr only provided 1 brief page for users that aimed to help with mental health needs, giving specific advice on what to do in response to immediate harm. On this page, Tumblr also gave contact details for a couple of UK-based mental health organizations. Tellmi and Instagram offered a broader range of relevant organizations, including those focused on mental health, online harms, and intersectional factors such as sexuality and religion. Notably, TikTok, Instagram, and Tumblr often featured US-centric resources across help and safety pages, which sometimes excluded other countries.

Platform Interface and Communication

Platforms generally communicated with their users using clear and professional language, suitable for their audiences. However, Tumblr's casual style veered into potentially patronizing territory:

> *You have to be the Minimum Age to use Tumblr. We're serious: it's a hard rule. "But I'm, like, almost old enough!" you plead. Nope, sorry. If you're not old enough, don't use Tumblr. Ask your parents for a PlayStation 4, or try books.* [Tumblr's ToS]

All platforms occasionally relied on nondefinite language regarding processes, which could potentially confuse users and create opportunities for inconsistent practices. When conveying information, Instagram and TikTok were reasonably text heavy, although attempts were made to use more mixed media in youth-centered areas of the platform. Tellmi used images and short descriptions, likely in an attempt to keep younger users

XSL•FO
RenderX

engaged. Tumblr was more effective at using a mix of media—such as illustrations, GIFs, and videos—throughout their information and guidance pages aimed at all audiences.

Tellmi organized its resources and help pages in a single directory, and Tumblr, across a few pages, resulting in a concise and user-friendly experience. In contrast, Instagram and TikTok disseminated information about mental health policies, guidance, and resources across various centers, with Instagram often redirecting users to additional Meta sites as well. Although this approach offered multiple valuable resources and ways to discover them, it complicated user navigation and increased information burden and repetition.

Within the app interface, Tumblr, TikTok, and Instagram provided a trigram "hamburger"  icon for access to most tools, pages, and policies, whereas Tellmi did not use familiar icons along a navigation bar. On the browser, access to all relevant documentation was available in the footer of the platform home page. In addition, several platforms functioned differently depending on device, occasionally restricting direct access to self-moderation options on browsers. Finally, Instagram's use of hidden links—accessible only through specific paths—and TikTok and Instagram's occasional reliance on blog posts for self-moderation tool descriptions limited accessibility for users.

Discussion

Principal Findings

This study extended our understanding of how a selection of SNSs manage user safety and well-being. Using walkthrough analysis, we observed both accomplishments by platforms and challenges they face in balancing content management, moderation, and user empowerment, leading to the development of preliminary recommendations for the industry (Textbox 1). Findings raised some critical concerns regarding the effectiveness of existing practices and the need for further research.

XSL•FO
RenderX

Textbox 1. Preliminary recommendations for the industry.

User onboarding and education

- Use the first-time new user's engagement with the platform to guide them to self-moderation tools and inform them of default settings (including those related to age restrictions) and moderation procedures.
- During sign-up, consider introducing prompts to encourage users to read the terms of service, privacy policies, and community guidelines. Alternatively, give users access to brief explanations of relevant key information from policies.
- Consider giving users the option to not follow accounts during their initial interactions on the platform.
- Consider implementing transition periods when users move into the 16- to 17-year and then >18-year age bands on age-restricted platforms. During this period, provide tailored education information on self-moderation tools and the benefits of using them.

Reporting content or users

- Offer clear guidance on reporting any potentially harmful mental health–related content, ensuring the process is simple and user-friendly, with any information about outreach and resources sent to reported users. Consider adding a system for users to track reports.
- Offer immediate follow-up resources to users who report mental health–related content.
- Consider a warning system for users whose content or accounts are reported for harmful mental health–related content, giving them the opportunity to review and amend their post. When content is removed or accounts are banned, ensure transparency around decisions and consider sending mental health support resources.
- Consider allowing users access to information about the effectiveness of platform moderation systems through reports on content removal and user bans for posting mental health–related content.
- Consider shifting away from language that expects users to report content and instead highlight the platform's commitment to proactive moderation and safety measures.

Support and resources

- Provide evidence-based internal support resources around mental health so users can access information in a familiar and trusted space. Consolidate and streamline these resources to avoid overwhelming vulnerable users.
- Ensure that resources and support are regionally and culturally relevant across platform pages. Platforms should strive to include organizations that address intersectional factors, promoting inclusivity and better serving diverse user needs.
- Consider specifying the evidence base for default safety mechanisms (including age restrictions).

Self-moderation tools

- Ensure users have access to a variety of self-moderation tools, offering them flexibility in managing and controlling their platform use. Clearly explain the purpose and functionality of each tool, ensuring they are distinct, practical, and easy to use.
- Ensure that users have access to clear explanations about the benefits of self-moderation tools for their well-being.
- Consider adding clear step-by-step written instructions and visual aids (eg, GIFs, screenshots, and short videos) when instructing users on the implementation of self-moderation and well-being tools.
- Consider the introduction of more default user options, such as automatically clearing search history or readjusting content level settings after a session to reduce the burden on users, giving them opt-out options.

Platform algorithms and content allowance

- Be explicit about what mental health–related content is allowed and restricted, using examples and unambiguous language.
- Where platforms use recommendation systems to influence content users engage with, prioritize giving users the ability to "refresh" their platform algorithm.
- Strive to enhance the robustness of automatic moderation systems, aiming for improved detection of potentially harmful mental health content (including severe, graphic, competitive, and instructive content). Recognize the complexity of this task and consider an approach that integrates human oversight.
- Consider alternatives to censoring common mental health terms, such as increasing the number of steps needed for users to access content, using overlays, and "pushing" recovery or positive mental health related content via platform algorithms.
- Consider implementing rate limits on accounts for repeated searches of potentially harmful content or algospeak terms. This could involve introducing novel help messaging or alerts after engagement attempts, which change depending on the frequency or severity of search terms.

Early Intervention

Previous studies have shown that application onboarding periods are critical in various contexts, including assisting new users' engagement with features [31,32], and helping patients with mental health disorders manage expectations and build confidence and proficiency with technology [33,34]. However, findings from this study showed that platforms were limited in

XSL•FO
RenderX

their education of users during initial engagements, particularly lacking clear direction to "community guidelines" and "self-moderation" tools. Such a passive approach may contribute to users feeling less informed about platform features and potentially susceptible [35].

Despite this, there was some evidence of platforms using nudges—subtle prompts designed to positively influence user behavior [36]—during this period. This included TikTok's data protection and safety videos for younger teenagers, Instagram and Tumblr's prompts for users to follow accounts, personalizing recommendations, and Tellmi's information regarding its limitations in terms of crisis support. These nudges served as proactive ways of engaging users with platform mechanisms, leveraging early interactions to educate or apply settings that could benefit users in the future [36], though there were some limitations, TikTok's instructional videos could be overwhelming, especially given that online users perceive learning about privacy settings as burdensome [37]. In addition, targeting younger teenagers excluded other users who may need the guidance. Furthermore, TikTok and Instagram allowed users to skip their processes, which, although encouraging autonomy, could result in users being less informed [36]. Tumblr did not offer the same skipping option, but findings indicated that the recommendation system offered options to engage with potentially harmful content, exposing broader moderation issues [38]. This suggests that while platforms have some capacity to engage users through nudges, they may be missing a valuable opportunity for early intervention around safety features and content moderation for their respective user bases. In addition, recommendation system inadequacies need to be considered significant in the safety of new or susceptible users.

Navigating the Platform

Instagram and TikTok offered comprehensive internal mental health–related support, including resources on suicide, self-harm, and disordered eating, as well as areas for younger or parent and guardian audiences. Integrating evidence-based resources internally and matching platform branding may be an effective approach for capturing users' attention through familiarity and perceived reliability [39,40]. However, the volume of mental health–related resources often led to repetition, resulting in the redundancy of information and potentially user fatigue [41]. Given evidence that individuals with severe mental illness struggle to understand complex content or navigation, platforms should aim to avoid overwhelming users with excessive psychoeducation, safety, and well-being content [42,43]. Furthermore, the presence of broken links and spelling mistakes in some of these sections emphasized poor maintenance, highlighting potential concerns around the platforms' commitment to providing high-quality, up-to-date resources [44].

Instagram also gave access to several mental health–related resources produced by other organizations, and Tellmi provided similar links to external content in various media forms. This approach allowed platforms to offer a wider range of resources, including those addressing intersectional factors in mental health, without needing to produce the content themselves, thereby improving efficiency. However, directing users away from internal platform resources may have drawbacks, including the need for monitoring external updates and possible inconsistencies in resource branding that could confuse users [44].

Following searches for harmful content, all platforms provided contact information for mental health organizations and emergency services. However, these details were often absent in other mental health–related platform spaces, missing opportunities for preventive intervention [45]. In addition, except for Tellmi, which is for young people in the United Kingdom, platforms overrepresented US resources. This reflects a broader issue of US-centric content bias on global platforms that may marginalize non–US users by limiting accessibility to relevant information [46].

Design decisions on platforms, particularly those impacting usability and accessibility to features, were also considered. Tumblr, TikTok, and Instagram used the "hamburger" icon for access to settings, policies, and resources, although some features were directly accessible during platform use. While the hamburger icon is widely recognized by experienced users, it may appear hidden or unclear to those without prior online knowledge [47]. Tellmi used a ring-bound notepad symbol for their "directory" resources page, which may be less recognizable. Research shows that users with mental health disorders often find abstract icons challenging, highlighting potential usability barriers associated with these icon designs [48].

Encouraging User Agency

Study findings indicated that while major platforms have implemented some "self-moderation" strategies to comply with guidelines in the OSA [17], significant gaps remain in how they promote user empowerment, particularly for those engaging with mental health–related content or experiencing mental health difficulties. For instance, TikTok and Instagram introduced screen break tools to encourage user control, but these tools allowed users to return after short periods or to be easily overridden, potentially undermining their effectiveness in favor of user retention. This reinforces criticisms that commercial interests may outweigh ethical considerations in social networking design [49].

In contrast, Tumblr's limited self-moderation tools and weak content moderation increased users' potential exposure to harmful content, while Tellmi, although also offering fewer self-moderation tools, compensated with robust content moderation offering better avoidance from unsafe material. However, the supportive nature of interactions on Tellmi could create a sense of responsibility among users, potentially resulting in excessive engagement that current "self-moderation" tools do not address [50]. In addition, the absence of Tellmi moderators overnight could result in user migration to other platforms, leading to riskier engagements elsewhere [51]. Alternatively, TikTok's "refresh your for you feed" feature was a novel self-moderation tool that empowered users and allowed for continual platform engagement, highlighting benefits for both users and SNSs. However, as with other self-moderation tools, its effectiveness relied on users recognizing the need for online behavior change and having the capacity to act, which

XSL•FO
RenderX

may be challenging for individuals experiencing poorer mental health or with lower metacognition skills [26].

This highlights a critical limitation found across platforms—the lack of proactive intervention to raise awareness about "self-moderation" tools. These findings align with the survey by Ofcom video-sharing platform [52], which found that only 42% of UK-based video-sharing platform users were aware of platform safety mechanisms. Along with minimal prompts directing users to tools, our findings revealed insufficient education on their functionality and usefulness. There was also a significant lack of information on tool adoption or any evidence that they underwent user testing, raising questions about their efficacy. This is especially relevant considering a recent research by Bright et al [35] indicating users' dissatisfaction with online safety technology. These findings suggest platforms may be superficially complying with OSA requirements rather than genuinely committing to empowering users. They also indicate a broader failure across the industry to address the importance of digital literacy surrounding "self-moderation" tools.

Platforms in this study also attempted to improve user safety by implementing default feature restrictions. However, default sensitivity or mature content controls often lacked clarity on whether they addressed mental health–related content or the types of content covered under each level, potentially confusing users [8]. On TikTok and Tumblr, the strictest restrictions were largely applied until users reached the age of 18 years, suggesting platforms may assume age as a qualifier of user efficacy. This overlooks the risks of removing protective measures for users who have not developed the skills or awareness needed to manage their safety independently [53]. Alternatively, Instagram, via its "teen accounts" approach allowed teenaged users to modify defaults with parental approval, encouraging a more open dialogue between users and their families. However, this approach shifts responsibility from platforms to parents. These measures also fail to address prevalent issues of age falsification among young users [54] and parents permitting their children to use social media before reaching the minimum age [52,55]. In contrast, Tellmi stood out by allowing all users to adjust their sensitivity content controls, prioritizing user agency over imposed controls [53].

Despite a lack of proactive user empowerment strategies, the changes made by platforms to improve user safety have likely been driven by the introduction of recent regulations such as the Digital Services Act in Europe [56] and the OSA in the United Kingdom [17]. These frameworks have specifically prompted platforms to implement changes that focus on the safety of young users and the moderation of dangerous or harmful content. However, the effectiveness of regulation implementation remains unclear [57,58]. For instance, an initial case study of Instagram's "teen accounts" revealed that young people using the feature remain exposed to inappropriate content [59].

In addition, while platforms adapt to meet the technical requirements of regulations, they likely remain unable to overcome long-standing limitations in moderating harmful content without further support or guidance from legislators. Current regulations also overlook variability between types of SNS platforms, including differences in resource availability and community make-up. This lack of insight risks the introduction of regulation that may inadvertently suppress or disempower online users. Country-specific regulations further fail to account for workarounds by users, such as the use of virtual private networks, allowing them to bypass geographical restrictions and access platforms from countries where regulations do not exist. This suggests that although platforms may implement changes in response to legislation, ongoing challenges in user safety and content moderation could remain unaddressed due to gaps in regulatory focus and scope.

Our findings also showed that platforms often implied it was the user's responsibility to identify and report harmful content, which may be problematic for susceptible users [8] and those unaware of reporting mechanisms [60]. In addition, Instagram's claim that reported content would feature less for the reporter could discourage the behavior, as users who engage with mental health–related content may fear limiting their own access to resources or information [26]. Observations also revealed that transparency reports on harmful content removal, when available, were difficult for users to locate and interpret. Improving their visibility could alleviate user pressure by showing that much disallowed mental health–related content is automatically flagged, but the continued reliance on user reporting for content that evades moderation systems may undermine confidence.

Platforms did make efforts to streamline reporting, with Instagram and TikTok offering feedback mechanisms and Tellmi providing direct communication with human moderators. However, it remains unclear whether the reporter or reportee receives any support after harmful content is reported, and the absence of feedback or mental health resources for reporters may discourage action [8]. Furthermore, if reported users are not offered appropriate resources, platforms may inadvertently punish individuals for sharing mental health struggles, reinforcing stigma [61]. This highlights the need for greater transparency around platform reporting procedures and clearer communication about the resources and support available to those whose content is reported.

Posting Harmful Mental Health–Related Content

All platforms gave some indication of the types of mental health content that were prohibited. However, while TikTok and Instagram included in-depth examples of allowed and disallowed content, other platforms lacked similar specificity. Furthermore, guidelines often overlooked mental health–related terminology, and there was minimal mention of rules around mental health topics unrelated to suicide, self-harm, or disordered eating. This lack of clarity could lead to subjective interpretations, resulting in self-censorship or unintentional posting of harmful material. Furthermore, only Instagram addressed the allowance of content depicting self-harm scars, a significant oversight by other platforms given that users have previously criticized moderation practices regarding this issue [26]. In addition, consequences for posting harmful content were frequently vague, with platforms using ambiguous language to describe repercussions. While this may allow for nuanced moderation, it risks confusing

XSL•FO
RenderX

users and deterring them from posting around their mental health, potentially perpetuating feelings of isolation and stigma [62].

Availability of Harmful Mental Health–Related Content

Harmful mental health content was not immediately visible on TikTok, Instagram, or Tellmi. However, on Tumblr, it was available following recommendation choices, posing higher risks to susceptible users [63]. After searching common mental health–related terms, all platforms other than Tellmi provided help resources, as expected for Tellmi as a platform focused on mental health discussion. In some instances, sensitive content overlays were used on harmful images on Instagram, which may empower users by giving them the opportunity to make informed decisions about engagement, encouraging metacognitive skills [64]. Although, if similar messages are presented repeatedly, it may result in desensitization [65] and could increase curiosity among susceptible users [26]. Furthermore, we found the application of overlays on Instagram was inconsistent, which may reduce their effectiveness.

Notably, one algospeak term resulted in content on Tellmi. Although this content was not harmful, its inclusion by human moderators indicated an acceptance of the language. This presents a broader issue in mental health content moderation where censoring common mental health terms can normalize algospeak terms as substitutes, effectively reverting platforms to their original state concerning mental health language moderation [11]. Similarly, mental health–related algospeak terms bypassed moderation on TikTok, Tumblr, and Instagram and resulted in harmful content. This highlights the danger that algospeak terms can more readily expose users to risky content, and their use instead of common mental health terms may exclude users from finding and sharing genuine information and support [12,13].

On Instagram and Tumblr, some user biographies featured the phrase “block don’t report.” This showed an online culture where users actively attempted to circumnavigate content moderation [66]. This direction to others may indicate that those engaging with mental health content believe users are responsible for their own safety through “self-moderation,” rather than relying on the platform to provide protection. It may also reflect a community norm, which could result in newer members feeling pressured to conform and avoid reporting. At the same time, the statement highlights the existence of a space where users feel empowered to express themselves by sharing content. This highlights an ongoing tension for platforms between allowing users to feel empowered through self-expression and ensuring their safety.

Future Research

Our work found no evidence that platforms evaluated the effectiveness of their self-moderation tools and guidance relevant to user mental health and well-being. This included assessing the usability, accessibility, and function of mental health–related resources and tools as well as the acceptability and practicality of moderation procedures. Notably, there was a lack of evidence of user input and testing, potentially raising concerns about the current efficacy and value of existing measures among users. If such evaluations are being conducted internally, platforms should be encouraged to share these insights publicly to enhance transparency, adding to user confidence and supporting learning across the industry. Future research evaluating these features remains essential to ensure that platforms meet users’ needs and do not promote ineffective or even risky features or guidance.

While this study did expose gaps in the current availability and accessibility of mental health and well-being resources and functions across a selection of SNS platforms, there remains a spectrum of platforms further research should aim to investigate. This includes safety and well-being resources, features, and guidance available on social media, dating, communication, e-commerce, pornography, mental health, and gaming platforms. In addition, research is needed into newly developed SNSs such as those including artificial intelligence chatbot integration plus smaller online communities that are less likely to undergo media or governmental attention.

This study resulted in a set of preliminary recommendations for industry, which give potential ways for platforms to address mental health–related content and moderation concerns. However, these recommendations need further validation and refinement, with stakeholder input, to ensure their applicability and effectiveness.

Limitations

Due to the rapidly evolving nature of online platforms, we acknowledge that the data collected may become outdated. This research aims to capture a moment in time, and it is possible and hopeful that platforms have since updated their practices to address some of the issues highlighted and align with our recommendations. Nevertheless, we believe these observations remain valuable in understanding user experiences. In addition, the recommendations provided are likely to be relevant for similar emerging or popular platforms.

We also understand the limitations of using the walkthrough method in this study. This approach relies on subjective interpretations of researchers’ observations, which may have led to biases. Although the checklist approach allowed the researchers to be systematic in their investigation of the platforms, it did not represent the real-world experience of a user, limiting the ecological validity. To mitigate these limitations, we included both a digital native and a digital immigrant researcher in an attempt to understand different interpretations and perspectives of platforms. However, as a next step, research should engage directly with users to reflect on their experiences of online mental health–related content moderation and safety.

Tellmi was included in this study as a smaller UK-based SNS, characterized by its user-generated content and social interaction around mental health. We recognize that Tellmi is not equivalent to Instagram, TikTok, or Tumblr in terms of target user populations, content diversity, and platform functionalities. However, given its direct focus on mental health and younger users, we considered Tellmi valuable as a comparator to platforms not specifically related to mental health in evaluating

XSL•FO
RenderX

their management of user features, guidance, and resources. Through our analysis, we identified notable practice differences and approaches across all platforms that helped to refine our recommendations.

Conclusions

These findings indicate that while platforms use some successful strategies, they are not effectively addressing the mental health moderation and well-being needs of all users. While larger platforms that undergo governmental scrutiny may introduce changes, these can seem superficial, appearing to prioritize user retention and engagement over meaningful safety intervention. Smaller platforms which face less scrutiny could also present risks due to weaker automated moderation systems resulting in access to harmful content or challenges in managing high user traffic, causing potential engagements with alternative less-moderated platforms. Using human moderation before material is posted may be the most effective approach to avoiding harmful content availability but is likely unfeasible for larger, global platforms due to scalability issues. It also raises concerns about limiting online freedoms, which could have negative consequences for users, particularly for those intentionally sharing harmful content. Platforms should focus on empowering users by educating them about safety mechanisms early, giving them agency over their decisions, and providing clear information regarding content moderation. In addition, while platforms have a responsibility toward the safety of young users, they should also consider other susceptible users, such as those with mental health disorders, during their moderation policy decisions. This study also highlights the need for improvements in the scope and global relevance of government regulations to better address user needs on platforms. Further research is essential to understand the effectiveness of existing interventions used by platforms, including self-moderation tools. User involvement is also necessary for meaningful improvement.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

LB has previously collaborated with Tellmi on research to evaluate and enhance their platform.

Abstract

Background: People with type 1 diabetes require ongoing self-management and frequent follow-up care. Digital care models might offer flexible solutions and increased sustainability, and while the clinical opportunities of these care models have been explored, the characteristics of patients inclined to opt for digital care remain unclear.

Objective: This study aimed to investigate which selected sociodemographic and disease-related patient characteristics are associated with opting for digital outpatient care among patients with type 1 diabetes.

Methods: This cross-sectional study was conducted at the endocrinology department of Akershus University Hospital in Norway, as part of a larger longitudinal study. Adult patients with type 1 diabetes were eligible to participate and were recruited consecutively. Patients could choose either a novel, mobile health–based, digital, tailored, outpatient care model (DigiDiaS care) or continuation of usual care. DigiDiaS care is delivered via an app comprising a message service; preconsultation questionnaires; options for physical, video, or telephone consultations; an information page; and an e-learning course. Sociodemographic and clinical data were collected from the participants' medical records and the national diabetes registry. Self-reported data comprised self-management measured using the Patient Activation Measure 13 (PAM-13), diabetes distress (20-item Problem Areas in Diabetes; PAID-20), well-being (World Health Organization-Five Well-Being Index; WHO-5), and health literacy (12-item short version of the European Health Literacy Survey Questionnaire; HLS-19 Q12) questionnaires. We explored group differences and conducted logistic regression to identify factors associated with opting for DigiDiaS care versus usual care.

Results: A total of 237 patients consented to participate in the study, with 185 (78.1%) opting for DigiDiaS care and 52 (21.9%) opting for usual care. The DigiDiaS care group had a statistically significantly shorter duration of diabetes (median 19, range 0-51 years) compared with the usual care group (median 29, range 3-58 years; P<.001); higher proportions of users of insulin pumps than insulin pens for insulin delivery (DigiDiaS care: 74/185, 40%; usual care: 12/185, 23.1%; P=.007), and a lower median well-being care score (DigiDiaS care: median score 60, range 4-96; usual care: median score 68, range 16-100; P=.04). The DigiDiaS care and usual care groups did not differ in sociodemographic variables, presence of late complications from diabetes or comorbidities, self-management, diabetes distress, or health literacy.

Conclusions: This study reveals that most patients with type 1 diabetes choose digital outpatient care when it is offered. Our study suggests that those opting for DigiDiaS care are already familiar with using diabetes-related technology, have a shorter diabetes duration, and have lower well-being. It is essential to understand the characteristics of patients who opt for usual care

XSL•FO
RenderX

to ensure high-quality health care services. Further studies should also focus on how the implementation of digital solutions in outpatient care can affect how and if patients use them.

Introduction

Background

Living with type 1 diabetes can be challenging and is associated with health complications such as poor mental well-being and poor quality of life, and it requires lifelong self-management and support to prevent these complications [1-3]. A life with type 1 diabetes can affect patients' ability to self-manage, increasing their risk of diabetes complications [4,5]. Often, diabetes care and self-management education and support are provided through multidisciplinary teams [6-8]. However, the traditional calendar-based approach in outpatient care is often rigid, giving patients little opportunity to influence their care. Consequently, the calendar-based approach threatens health care service resource sustainability and presents several challenges; it is not given that outpatient care is appropriate or necessary at the time of the consultation [7,9,10]. Conversely, a patient-centered approach in outpatient care, where patients themselves influence the timing and nature of treatment based on patients preferences and needs, has been suggested as a solution to these problems [11]. Furthermore, individualization through patient-centered care can strengthen the patient's autonomy and participation in their own treatment.

The increasing focus on individualizing care aligns with an increased recognition of how digital solutions in outpatient care can provide closer interaction with health care services [8]. Such digital outpatient care may include various forms of synchronous and asynchronous remote patient monitoring; telephone and video consultations; messaging services; connection to wireless tools, such as glucose sensors and insulin pumps; or other forms of telecommunication tools [12]. Allowing and facilitating a more active patient role, patient-reported outcomes (PROs) can be integrated into digital tools for follow-up care [8]. PROs offer direct feedback from patients themselves about their health, which, among other things, provides a broader perspective on clinical goals and serves as a conversational tool [13,14]. While PROs in clinical care have gained increasing attention in recent years, a scoping review found the use of PRO as part of routine treatment in diabetes outpatient settings to be scarce [15].

Although interest in and recognition of the opportunities for digital outpatient care have been acknowledged by international panels of health care professionals in recent years [8], few studies have investigated PROs in digital outpatient care [15]. A pioneering study from Denmark used the PRO measure DiabetesFlex before scheduled consultations delivered in a digital solution to allow patients to voice their need for consultations or cancel if not deemed necessary [16]. This resulted in reduced face-to-face visits and improved well-being and diabetes distress while providing safe diabetes management. In addition, DiabetesFlex altered the interactions between clinicians and patients as it shifted toward the patients' perspectives on living with diabetes [17]. It increased patient involvement, strengthened their sense of responsibility, and tailored diabetes care to meet individual needs [16,17].

Despite previous research emphasizing the positive contribution of digital outpatient care solutions in diabetes outpatient care, there remains a lack of research to establish an evidence base. For instance, not everyone wanted to continue with DiabetesFlex after the end of the study period, despite their positive experiences [17]. Furthermore, there is a lack of knowledge on the characteristics of patients choosing digital or flexible diabetes follow-ups. Characteristics such as sociodemographics, clinical measures, and disease-specific measures can reveal whether users and nonusers of digital outpatient care differ and whether they possess specific traits or factors. Exploring such characteristics can provide insights into the actions and choices of patients with type 1 diabetes in their outpatient care [18-20].

Objective

This study aims to investigate which selected sociodemographic and disease-related patient characteristics are associated with opting for digital outpatient care among patients with type 1 diabetes.

Methods

Study Design

This study used a cross-sectional design to investigate characteristics of patients with type 1 diabetes opting for digital outpatient care compared with those opting for usual care. The data used in this study is collected as part of a larger multimethod prospective observational study assessing the integration of digital outpatient care procedures for patients with type 1 diabetes and their clinicians [21]. In this paper, we explored the baseline characteristics of these participants, and the recruitment of participants and data collection took place from October 2022 to October 2023. This study is reported according to the Strengthening the Reporting of Observational studies in Epidemiology (STROBE) reporting guideline [22].

Setting

The study was carried out at the Endocrinological Outpatient Clinic at Akershus University Hospital. In November 2021, the clinic developed and introduced a voluntary digital mobile health (mHealth) supplement outpatient care program specifically tailored to patients with type 1 diabetes called DigiDiaS.

XSL•FO
RenderX

Participants

Eligibility Criteria

The inclusion and exclusion criteria for participants are listed in Textbox 1. Both users and nonusers of DigiDiaS care were eligible for participation.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Aged ≥18 years
- Having type 1 diabetes and receiving treatment and care at the endocrinological outpatient clinic at Akershus University Hospital
- Ability to read and understand Norwegian

Exclusion criteria

- Having type 2 diabetes or gestational diabetes
- Individuals with impaired cognitive abilities who are unable to complete the self-reported data independently or understand the nature of the study

Recruitment

Participants were recruited through consecutive sampling. There was no randomization, and the participants could choose whether they opted for DigiDiaS care or to continue with usual care. Participants were introduced to the study and invited to participate during a routine consultation with a diabetes specialist nurse or an endocrinologist. If they were not already using the digital outpatient care DigiDiaS, they were provided with details on both the study and the digital outpatient care solution. For patients interested in DigiDiaS care and new to this digital outpatient care solution, their diabetes specialist nurse provided a brief introduction to the app and offered support to download it, if needed. The patients received brief written and oral information about the study and were asked if a researcher (IS) could contact them. Those consenting to further information received a phone call before they received a link to a digital consent form. If a patient expressed a desire to participate in the study over the phone but did not consent, a reminder was sent via text message. The written informed consent form was also made available in paper format, if needed.

Diabetes Outpatient Care

Usual Care

At the endocrinology outpatient clinic in which this study was conducted, usual care for type 1 diabetes follows a routine, calendar-based system in accordance with Norwegian national diabetes guidelines [6]. In Norway, all patients with type 1 diabetes are offered follow-up care in specialist outpatient care, provided by interdisciplinary health care teams, including endocrinologists, diabetes-specific nurses, and dieticians. This care includes an extended annual check-up and a routine midyear check-up. Patients with recent diagnoses of diabetes, comorbidities, late complications, or poorly controlled diabetes may receive more frequent consultations. Under this system, appointments are approximately prescheduled, giving patients limited flexibility to influence the timing and nature of their own outpatient care. The usual care group in this study continued with this routine—calendar-based system of receiving a prescheduled time for consultation with limited flexibility to influence their follow-up care.

DigiDiaS Care

DigiDiaS care serves as a flexible digital supplement designed to support the patients' interactions with clinicians during outpatient care, allowing the individual patient's needs to guide contact with clinicians [21]. DigiDiaS care is delivered through a free app that patients can download onto their private smartphones from the App Store or Google Play, following an invitation from a health care professional. The main components in DigiDiaS care provided by Dignio Connected Care are simple and intuitive to use, comprising the patient app MyDignio and the clinician's software DignioPrevent delivered through a web browser via a direct link from the medical record system. Dignio Connected Care meets the necessary safety requirements, including CE certification [23].

The digital outpatient care solution includes several features in the MyDignio app for patients. First, a messaging service enables patients to contact the health care service outside of planned outpatient care, if necessary, with asynchronous messages. Second, before scheduled follow-up consultations, patients receive a PRO-based questionnaire, which includes questions about well-being, diabetes-specific outcomes, and the need for a consultation and questions for patients to prepare topics they want to address in the scheduled outpatient care. The PRO-based questionnaire is based on the Danish DiabetesFlex [16]. It was adapted to Norwegian and further refined in collaboration with user representatives, clinicians, and managers to suit the digital platform used at the clinic [13]. The third feature of DigiDiaS care is that patients can choose between remote video consultation, telephone consultation, or in-person attendance for routine outpatient care consultations. Finally, clinicians can provide patients with e-learning courses and create a tailored information page for each patient, if needed. Patients receive notifications about new activities from the app through push notifications or text messages.

For clinicians, digital outpatient care is conducted through software accessible from web app DignioPrevent, providing clinicians with features for flexible patient care [21]. Through this system, clinicians manage the asynchronous chat, send out the PRO-based questionnaire before consultations, and edit the information page. The answers on the PRO-based questionnaires

XSL•FO
RenderX

have defined thresholds dependent on the patients' responses, using a traffic light model, with green, yellow, and red alerts and an additional orange alert if the questionnaire has not been completed. Green questionnaires indicate no issues and are not visible in DignioPrevent; however, all yellow and red questionnaires from the past are available for comparison. Clinicians also provide patients with information and e-learning courses, both through premade templates and an open-text field. It is also possible to contact the patient directly through video consultation with DignioPrevent. However, for scheduled appointments, a separate system called Whereby is used for video consultations as it communicates with the calendar within the medical record system that DignioPrevent does not.

Data Collection

Data were collected through 3 primary sources: self-reported questionnaires, electronic medical records, and the national quality registry for diabetes, the Norwegian Organization for Quality Improvement of Laboratory Examinations (NOKLUS). Self-reported data and the digital consent form were collected using Nettskjema [24], a secure platform that stores data in the Services for Sensitive Data (TSD) platform for confidential handling. To deliver the digital consent form and self-reported data, the patients received a secure link via SMS text message or email, requiring them to log in with their national ID for secure access. Patients who preferred the consent form and self-reported data on paper received this and submitted these papers back to the clinic which was stored in a locked safety box. Data from medical records and the national diabetes quality registry (NOKLUS) were manually extracted into Microsoft Excel files, stored, and managed in TSD. To ensure the accuracy of the data extraction, a coresearcher cross-checked all extracted data against the original medical records and NOKLUS registry, as described in the protocol [15].

In addition, to compare our sample with the overall hospital sample comprising all patients with type 1 diabetes and the national population of people with type 1 diabetes, we received aggregated data directly from NOKLUS on the variables age, gender, education, years since diabetes duration, insulin delivery method, and glycated hemoglobin (HbA_{1c}), all provided in median and range. Comparing our sample with the national population is essential to identify and assess biases, ensuring that our findings are representative and applicable to the broader hospital sample and national population.

To explore the role of patients' travel time from home to the outpatient clinic, an estimate of travel time was calculated based on the patients' postal code. Google Maps was used to determine the travel time by car to the main premises of the hospital. Akershus University Hospital is a local hospital with a defined coverage area. Participants living outside this area were typically students or recent movers who had not switched to their local hospital or individuals who, for other reasons, did not receive outpatient care at their local hospital. Public transport is only available for parts of the coverage area and was therefore not used in the calculation.

Measures

Sociodemographic and Clinical Variables

Sociodemographic variables, gathered from the medical records, included age, gender, education, employment, ethnicity, comorbidities, cohabitation, single resident status, travel time to the hospital, and use of other health-related applications (Table 1). Clinical variables comprised diabetes duration, HbA_{1c}, insulin delivery method, blood glucose monitoring method, time-in-range, diabetic ketoacidosis, hypoglycemia, late complications from diabetes, BMI, cholesterol, blood pressure, and comorbidities (Table 2). While time-in-range can be provided in various ranges when aiming to present the ambulatory glucose profiles of the patients, in this study, we present time-in-range for the last 14 days as this is most frequently used in this study's clinical setting. All clinical variables are from the last measurement before consent to participate in the study, except for HbA_{1c}, which is the last measurement inclusion in the digital solution for the DigiDiaS care group, and the last measurement before consent to the study for the usual care group. Self-reported data encompassed self-management, diabetes distress, well-being, and health literacy (Table 3).

Table 1. Sociodemographic variables.

Variables	Categories or data type	Merged into categories for analysis	Data source
Age	Years	__[a]	Medical records
Gender	Woman or man	—	Medical records
Education	Not completed primary school (10 y), primary upper secondary school (13 y), vocational school (13 y), college or university (≤4 y), college or university (>4 y), unknown	“13 years or less” and “over 14 years”	Medical records
Employment status	Full- or part-time employment, being a student, job seeking, receiving disability benefits, and retirement (based on the Norwegian retirement age of 67 y)	—	Self-reported
Ethnicity	European, Asian, African, or unknown	European, Asian, or African, with a separate category for missing data	Medical records
Cohabitation	Living in a partnership or not living in a partnership	Yes or no	Medical records
Single resident	Living alone or not living alone	Yes or no	Medical records
Travel time to hospital	Estimate based on postal code using Google Maps to identify travel time by car, in min	>30 min travel time, <30 min, or living outside of coverage area	Medical records and Google Maps
Use of other health-related apps	One question with the response alternatives “daily” “weekly,” “monthly,” “not using this now but having used it before.” or “not using other health-related apps”	Daily or weekly use, monthly use or used before, never or previous use	Self-reported

[a]Not applicable.

Table 2. Clinical variables.

Variables	Categories or data type	Merged into categories for analysis	Data source
Diabetes duration	• The year from onset to when participants consented to participate in this study	—[a]	NOKLUS[b] registry
HbA_{1c}[c]<75 mmol/mol	• HbA1c (mmol/mol) on a continuous scale • The proportion of participants with HbA1c above 75 mmol/L	—	NOKLUS registry
Insulin delivery	• Pump or pen	—	NOKLUS registry
Blood glucose monitoring	• CGMd or glucometer	—	NOKLUS registry
Time-in-range, for those using CGM	• Percentage of time-in-range (3.9-10 mmol/L) last 14 d	—	NOKLUS registry
Diabetic ketoacidosis	• Never • Once • Several times or unknown	Recoded into none, 1≥, missing	NOKLUS registry
Hypoglycemia	• Never • Once • Several times or unknown	Recoded into none, ≥1, missing	NOKLUS registry
Late complications from diabetes	• Albuminuria • Dialysis treatment • Kidney transplantation • Retinopathy • Neuropathy • Stroke • Arterial vascular surgery • Amputation • Diabetic foot ulcers	Recoded into none, 1, ≥2, and missing	NOKLUS registry
BMI (kg/m^2)	• Weight and height	BMI=weight (kg)/[height (m)]^2	NOKLUS registry
Cholesterol	• Low-density lipoprotein	—	NOKLUS registry
Blood pressure	• Systolic blood pressure and • Diastolic blood pressure in mm Hg	—	NOKLUS registry
Comorbidities	• Charlson Comorbidity Index, which includes a range of conditions such as myocardial infarction, congestive heart failure, peripheral vascular disease, and others	None, 1, ≥2, and missing	Self-reported

Table 3. Measures for self-management, diabetes distress, well-being, and health literacy.

Measures	Items, scale, and domains	Interpretation

Self-management (PAM-13[a])	• 13 items, rated from 1 “disagree strongly,” to 4, “strongly agree,” with an additional “not applicable”
	• 4 domains: knowledge, beliefs, confidence, and skills for managing one’s health.
		• The total PAM-13 score is calculated using a formula that weighs the various questions and that forms a scale from 0-100. Higher scores indicate higher activation [25]. A 3.2 change on a 1-100 scale is considered small but clinically relevant [26]
		• There are 4 levels:
		  • Level 1 (score ≤47), disengaged and overwhelmed
		  • Level 2 (score 47.1-55.1), becoming aware but still struggling
		  • Level 3 (score 55.2-67), taking action
		  • Level 4 (score≥67.1), maintaining behavior and pushing further
		• Levels 1 and 2, 3 and 4 were merged into categories for analysis

Diabetes distress (PAID[b])	• 20 items, ranked on a 5-point Likert scale from 0, “not a problem” to 4, “serious problem”	• Sum of all 20 items and multiplied by 1.25, giving a total score ranging from 0-100 [26] • A higher score reflects greater emotional distress. A score of ≥40 indicates severe emotional distress.
Well-being (WHO-5[c])	• The 5 items are measured in a 6-point Likert scale from 5 "all the time" to 0 "at no time".	• Sum of 5 items multiplied by 4 to create a scale from 0-100 [27] • A higher score indicates higher well-being • Score <50 may be an identification of mild to severe depressive affect [28]

Health literacy (HLS19-Q12[d])	• The 12 items are measured in a 4-point Likert scale from 1, “very hard” to 4, “very easy” with added “I don’t know”	• Sum of the 12 items is calculated. Higher scores reflect higher health literacy [29]
		• The scale is divided into 4 levels with expected characteristics:
		  • Below level 1; lack key knowledge and skills about health and may have challenges in understanding and applying health information
		  • Level 1; where you are expected to be able to access, understand, and apply health information relevant to staying healthy
		  • Level 2; access, appraise, understand, and apply health information and advice relevant to enhancing physical and mental health
		  • Level 3; access, appraise, understand, and apply health information and advice relevant to making informed health care choices by critically evaluating health claims and judiciously comparing treatments
		  • The items can also be distributed into the 3 different domains they measure—health care, disease prevention, and health promotion, and the individual domain can be scored with a minimum of points 0 maximum of 16 points per domain

[a]PAM-13: Patient Activation Measure 13.

[b]PAID: Problem Areas in Diabetes.

[c]WHO-5: World Health Organization-Five Well-Being Index.

[d]HLS19-Q12: 12-item short version of the European Health Literacy Survey Questionnaire.

Self-Management

Self-management and the ability to manage one’s health was assessed with the “Patient activation measure” short version (Patient Activation Measure 13 [PAM-13]) [30] (Table 3). Hibbard et al [30,31] developed and validated the PAM-13 questionnaire as a generic questionnaire for people with and without chronic conditions. The PAM-13 questionnaire has been validated in Norwegian and has previously been used to evaluate patient education in various diagnoses, including type 2 diabetes [25,32,33]. It has been used in multiple contexts across several countries, with findings suggesting that Norwegians generally exhibit higher activation than other populations [33]. Furthermore, the PAM is also suitable for the evaluation of digital interventions [34]. The reliability of the PAM-13 scale in this study was confirmed with a Cronbach α of 0.894, indicating high internal consistency among the items.

Diabetes Distress

Diabetes distress was assessed using the disease-specific questionnaire 20-item Problem Area in Diabetes (PAID-20) [26] (Table 3). PAID-20 has been previously translated and validated in Norwegian by Graue et al [35] and has been used as a tool to prepare for consultations for patients with type 1 diabetes in a previous study [36]. The reliability of the PAID-20 scale in this study was confirmed with a Cronbach α of 0.939, indicating excellent internal consistency among the items.

Well-Being

Psychological well-being and quality of life were measured with the generic tool World Health Organization–Five Well-Being Index (WHO-5) [37] (Table 3). WHO-5 has been translated to Norwegian and is validated for the type 1 diabetes population [27,38,39]. A score <50 may indicate that the patient is feeling unwell and should be examined further to investigate mild to moderate depression [40]. The reliability of the WHO-5

XSL•FO
RenderX

in this study was confirmed with a Cronbach α of 0.826, indicating high internal consistency among the items.

Health Literacy

Health literacy and the ability to make informed health choices were measured using the 12-item short version of the European Health Literacy Survey Questionnaire (HLS19-Q12) [41]. HLS_{19}-Q12 is translated into many languages and has been used in 19 European countries, including Norway [42] (Table 3). The HSL_{19}-Q12 has been validated and used in both a large general population and in patients with type 2 diabetes in Norway [41,43,44]. The reliability of the HLS_{19}-Q12 scale in this study was confirmed with a Cronbach α of 0.871, indicating high internal consistency among the items.

Ethical Considerations

As this research project involves human subjects, the project has been reported to the Norwegian Agency for Shared Services in Education and Research (SIKT; reference number: 456954) and approved by the local data protection officer at Akershus University Hospital (reference: 2022_125). The project was presented to the Regional Committees for Medical and Health Research Ethics (REK; reference number: 407539), and they deemed it to be outside their scope and defined as a quality improvement project.

All participants received oral and written information before providing informed consent to participate in this study and filling out the self-reported data. Digital consent forms, medical records data, and self-reported data were stored and managed in TSD. Participants provided their social security numbers for in the consent form but were assigned ID numbers for deidentification. The code key was stored in a separate file within TSD. Data received from NOKLUS for comparison with the overall hospital sample and the national population were aggregated and thus anonymous. The study participants were not compensated for participating in this study.

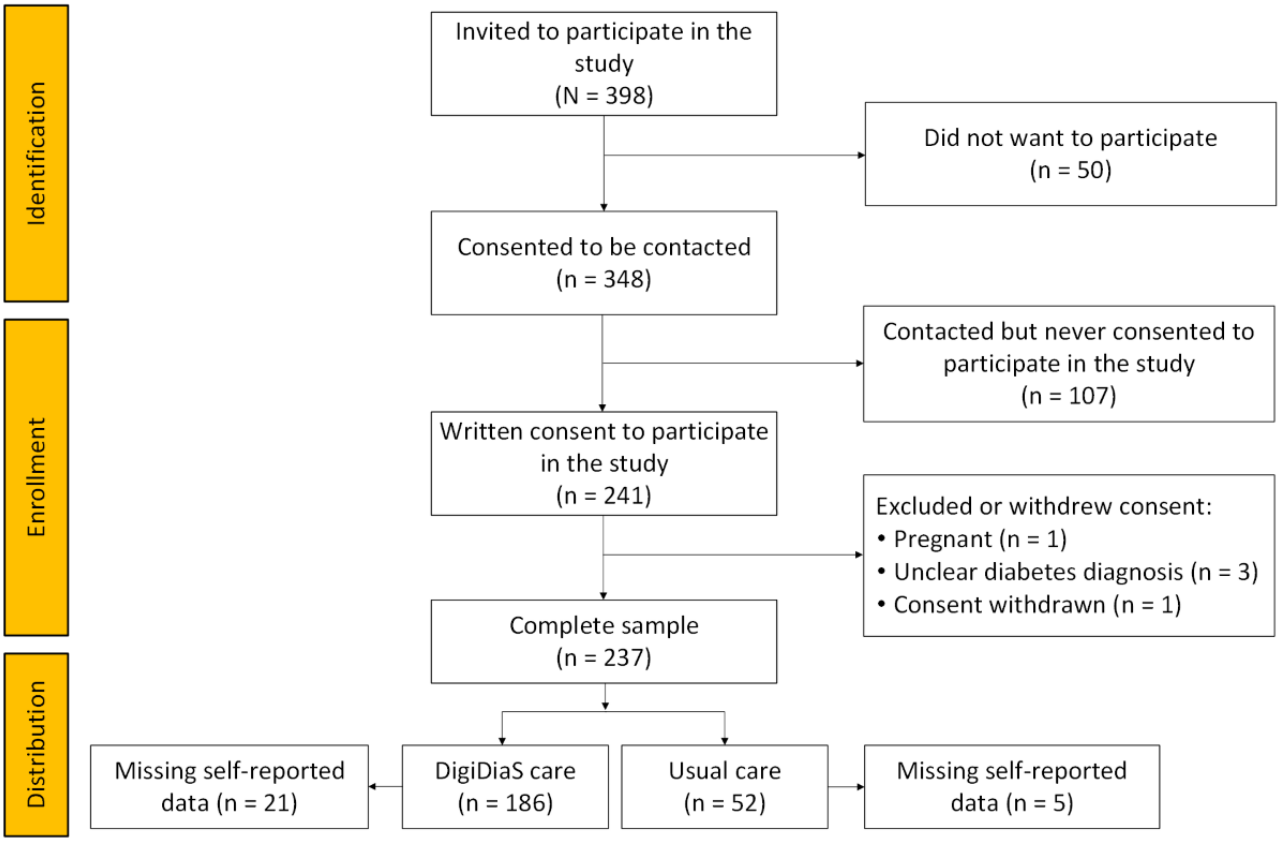
Statistical Analysis

Categorical variables are described with counts and percentages; continuous variables are presented with median values and ranges. To compare DigiDiaS care and usual care, we used nonparametric chi-square tests for pairs of categorical variables and Mann-Whitney *U* tests for pairs of continuous data. Missing data were not imputed, and the counts and proportions of missing values for each variable are presented in tables. Responses such as “don’t know” or “not applicable” in self-reported questionnaires were treated as missing values. To assess internal consistency of the scales used in the study, Cronbach α was calculated for the validated questionnaires [45].

To assess the strength of the possible association between the selected patient- and disease-related variables and the outcome, univariate logistic regression was conducted. Variables that were statistically significant in univariate analyses were entered into a multiple regression model, and the final model was fitted using the backward conditional selection process. The results are expressed as odds ratios (ORs) with 95% CIs. All tests were 2-sided, and *P* values <.05 were considered statistically significant.

In addition, to compare our sample with the overall hospital sample comprising all patients with type 1 diabetes and the national population of people with type 1 diabetes, we calculated CIs for the median values in our study sample to compare with the median and min-max values of the hospital sample and national population.

All data were processed using Excel (Microsoft Office Professional Plus 2016) and SPSS (version 29.0.0.0).



Results

Overview

Of the 398 patients invited to participate in the study, 241 consented to participate (Figure 1). Of the 237 patients included, 185 patients opted for DigiDiaS care, and 52 patients opted to continue with usual care. In the DigiDiaS care groups, 21 self-reported data were missing and 5 from the usual care group.

XSL•FO
RenderX

Figure 1. Flowchart of the participants using DigiDiaS care and usual care.

Demographics

In the complete sample, the included participants ranged in age from 19 to 81 years, with a median age of 49 years (Table 4). The median duration of diabetes was 21 (range 0-58; Table 5) years. Overall, one-third of the participants had university or college education at the bachelor level or higher (81/237, 34%), and the majority were either currently employed or students (139/237, 58.6%; Table 4). Just under half of the participants had an estimated travel time to the hospital of >30 minutes (98/237, 41.2%). Over half of all participants used other health-related apps daily (137/237, 57.8%).

Clinical Variables

The median HbA_{1c} for the complete sample was 58 mmol/mol (range 35-117 mmol/mol; Table 5). Furthermore, 15.5% (36/237) had an HbA_{1c} >75 mmol/mol, considered poorly regulated. Over one-third of the participants used an insulin pump (87/237, 36.7%), while the remaining participants used an insulin pen (150/237, 63.2%) for insulin delivery. Over half of the participants had no late complications of diabetes (136/237, 57.4%), and nearly half reported no comorbidities (97/237, 40.8%).

Self-Management, Diabetes Distress, Well-Being, and Health Literacy

The median self-management score of 72.5 (range 9-100) corresponds with a high self-management level (Table 6). This high median score corresponds with the highest PAM level: "Maintaining behaviors and pushing forward." Regarding the distribution across the 4 levels, half of the participants were at level 4 (116/237, 54.9%), and one-third were at level 3 for "taking action" (68/237, 32.2%).

Table 6. Self-reported outcomes for self-management, problem areas in diabetes, well-being, and health literacy.

	Total (n=211)	DigiDiaS care (n=164)	Usual care (n=47)	*P* value
Self-management (PAM-13[a]) score, median (range)	72.5 (9-100)	72.5 (9-100)	75 (27-100)	.33
Level 1: disengaged and overwhelmed, n (%)	14 (5.9)	11 (5.9)	3 (5.8)	
Level 2: becoming aware, but still struggling, n (%)	13 (5.5)	8 (4.3)	5 (9.6)	
Level 3: taking action, n (%)	68 (28.6)	59 (31.7)	9 (17.3)	
Level 4: maintaining behaviors and pushing forward, n (%)	116 (48.7)	86 (46.2)	30 (57.7)	.33[e]
Diabetes distress (PAID [b]) score, median (range)	23.75 (0-71.25)	23.75 (0-71.25)	21.25 (0-50)	.25
>40, n (%)	42 (17.6)	35 (18.8)	7 (13.5)	.33
Well-being (WHO-5[c]) score, median (range)	60 (4-100)	60 (4-96)	68 (16-100)	.01
<50, n (%)	46 (21.8)	40 (21.5)	6 (11.5)	.09
Health literacy (HLS19-Q12[d]) score, median (range)	35 (13-48)	35 (13-48)	34 (19-45)	.85
Below level 1, n (%)	27 (12.8)	23 (14)	4 (8.5)	
Level 1: access, understand, and apply, n (%)	52 (24.6)	38 (23.2)	14 (29.8)	
Level 2: appraise, understand, and apply, n (%)	79 (37.4)	62 (37.8)	17 (36.2)	
Level 3: making informed choices by critically evaluating, n (%)	53 (25.1)	41 (25)	12 (25.5)	.67[e]
Health literacy (HLS19-Q12) domains, median (range)				.63
Health care	12 (2-16)	12 (2-16)	12 (5-15)	
Disease prevention	11 (3-16)	11 (3-16)	11 (4-15)	
Health promotion	12 (4-16)	12 (4-16)	12 (5-16)	

[a]PAM-13: Patient Activation Measure; the score ranges from 0 to 100, with higher scores representing higher activation. Level 1: ≤47; level 2: 47.1 to 55.1; level 3: 55.2 to 67; level 4: ≥67.1.

[b]PAID: 20-item Problem Area in Diabetes; the score ranges from 0 to 100, with a higher score reflecting greater emotional distress. A score of ≥40 indicates severe emotional distress.

[c]WHO-5: World Health Organization-Five Well-Being Index; the score ranges from 0 to 100 with a higher score indicating higher well-being. A score <50 may be an identification of mild to severe depressive affects.

[d]HLS19-Q12: 12-item short version of the European Health Literacy Survey Questionnaire. Higher scores reflect higher health literacy. Below level 1: <27; level 1: ≥27; level 2: ≥33; and level 3: ≥39 (with associated characteristics). Domains can have a minimum score of 0 and a maximum score of 16.

[e]The *P* value represents the differences across all levels combined, not between individual levels. The level of diabetes distress was low, with a median score of 23 (range 0-71.25) of a possible maximum score of 100. However, almost 1 in 5 (42/237, 17.6%) of the participants reported scores >40, indicating diabetes distress.

Regarding well-being, the participants had a median score of 60 (range 4-100). However, 21.8% (46/237) of the participants had a WHO-5 score <50, indicating symptoms of mild to severe depression.

Overall, the participants had a fairly good health literacy score with a median health literacy score of 35 (range 13-48), characterized by the ability to appraise, understand, and apply health information (level 2).

Study Sample, Hospital Sample, and National Population

When comparing the study participants with the hospital sample of patients with type 1 diabetes at Akershus University Hospital, which includes all individuals with type 1 diabetes followed up

XSL•FO
RenderX

at Akershus University Hospital, and the national population of patients with type 1 diabetes, which includes all individuals with type 1 diabetes in Norway, the 3 samples were comparable regarding gender, education, insulin administration, HbA_{1c}, age, and diabetes duration (Table 7). However, regarding HbA_{1c} ≥75 mmol/mol, the proportion of such individuals was significantly lower in the national population compared with the study sample, indicating that our sample comprised individuals with less well-regulated diabetes.

Table 7. Comparison of study sample, hospital sample, and national population on sociodemographic and clinical variables.

Variables	Study sample (N=237)	Hospital sample (n=1643)	National population in Norway (n=22,408)

Comparing Patient Characteristics in DigiDias Care Versus Usual Care

Demographic Variables

Most participants opted for DigiDiaS care (185/237, 78.1%), while the remaining participants (52/237, 21.9%) opted to continue with usual care. Among those choosing DigiDiaS care, half had been included in DigiDiaS care more than 90 days before consenting to participate in the study (92/185, 49.7%), thereby having had access to the digital outpatient care solution from before.

The participants in the DigiDiaS care group were significantly younger, with a median age of 47 (range 19-79) years, compared with those choosing usual care (median age 59, range 23-81 years; *P*<.001; Table 4). DigiDiaS care patients have had diabetes for a median of 10 years shorter than the usual care group (*P*<.001; Table 5). A statistically significant linear relationship was found between age and duration of diabetes in the complete sample (*P*<.001).

There was no statistically significant difference in the education level between DigiDiaS care and usual care (*P*=.42). However, there was a statistically significant higher proportion of individuals in the usual care group (16/52, 31%) who were outside the labor market or received disability benefits of working age than with DigiDiaS care (28/185, 15.1%; *P*=.01). A higher proportion lived alone and were single residents in usual care (13/52, 25%) than in DigiDiaS care (29/185, 15.7%). However, the difference was not statistically significant (*P*=.12). Further demographic variables are summarized in Table 4.

Concerning the use of other health-related mobile apps, there were more individuals in the usual care group who had never or only previously used other health-related apps (10/52, 21%)

XSL•FO
RenderX

compared with the participants in the DigiDiaS care group (14/185, 8.5%); however, the difference was not statistically significant (*P*=.27; Table 4).

Clinical Variables

In the DigiDiaS care group, the participants had a median HbA_{1c} significantly higher at 59 (range 35-117) mmol/mol compared with 52 (range 41-90) mmol/mol in the usual care group (*P*=.004; Table 5). In terms of insulin delivery, there was a significantly higher use of an insulin pump in the DigiDiaS care group (74/185, 40%) than in the usual care group (23/52, 23%; *P*=.02).

There were no statistically significant differences in late complications from diabetes (*P*=.76). Concerning comorbidities, there were no differences between the DigiDiaS care group and usual care (*P*=.63). Further details on between-group differences in diabetes clinical variables are presented in Table 5.

Self-Management, Diabetes Distress, Well-Being, and Health Literacy Across the Two Groups

There were no differences between the DigiDiaS participants compared with usual care in self-management (*P*=.33), diabetes distress (*P*=.25), or the health literacy scale (*P*=.85; Table 6).

Well-Being

The usual care group (median 68, range 16-100) had a statistically significant higher well-being score than the DigiDiaS care group (*P*=.01) indicating better well-being, with the usual care group having a higher well-being score than DigiDiaS care (median 60, range 4-96; Table 6).

Furthermore, we assessed the correlation between well-being scores and HbA_{1c} levels using Spearman correlation, finding no statistically significant relationship in the study sample, within the DigiDiaS care group (*P*=.37), or the usual care group (*P*=.33).

If the median value or percentage for the hospital selection and national population falls within the CI of the study sample, there is no significant difference. However, if the median value or percentage falls outside the CI, the groups may be significantly different.

Group Comparison

Univariate Analyses

In the univariate logistic regression analyses, we identified statistically significant differences between those who chose DigiDiaS care and usual care regarding the following variables: gender, employment, diabetes duration, HbA_{1c}, insulin delivery method, and well-being, as seen in Table 8. However, age was not associated with the choice of DigiDiaS or usual care.

Table 8. Logistic regression univariate and multivariate of the significant outcomes from Tables 2-4.

Variables	Unadjusted odds ratio (95% CI)	*P* value	Adjusted odds ratio (95% CI)	*P* value
Age (y)	0.99 (0.98-1.01)	.94	—[a]	—
Gender: man or woman (ref)	1.93 (1.01-3.70)	.04	1.10 (0.52-2.36)	.97
Employment: yes (ref) and no	2.60 (1.22-5.52)	.01	2.1 (0.94-5.07)	.68
Diabetes duration (y)	0.96 (0.93-0.98)	<.001	0.95 (0.93-0.97)	<.001
HbA_{1c}	1.03 (1.00-1.06)	.01	1.02 (0.99-1.05)	.07
Insulin delivery: pen and pump (ref)	0.32 (1.09-4.52)	.02	3.16 (1.37-7.32)	.007
Well-being (WHO-5[b] score)	0.97 (0.95-0.99)	.01	0.97 (0.95-0.99)	.03

[a]Not included in the multivariate analysis because it was not statistically significant in the univariate analysis.

[b]WHO-5: World Health Organization-Five Well-Being Index.

Multivariate Analysis

In multiple analyses with variables that were statistically significant in univariate analyses (Table 8), we found that a longer duration of diabetes was associated with statistically significant lower odds of opting for DigiDiaS care (OR 0.95, 95% CI 0.93-0.97). Similarly, a higher well-being score was associated with lower odds of choosing DigiDiaS care (OR 0.97, 95% CI 0.95-099). Participants using an insulin pump for insulin delivery were found to have 3 times higher odds of choosing DigiDiaS care (OR 3.16, 95% CI 1.37-7.32) in comparison to insulin pump users. Furthermore, the insulin delivery method was the variable with the strongest association with choosing DigiDiaS care versus usual care.

The multivariate logistic regression is divided into 2 rounds to avoid overfitting of the model, marked with the hard line in between—round 1 consists gender, employment in working age, and diabetes duration and round 2 consists HbA_{1c}, insulin delivery, and well-being.

Discussion

Principal Findings

This cross-sectional study was designed to explore the characteristics of patients with type 1 diabetes who were given a choice between a novel, flexible digital mHealth supplement for outpatient care, referred to as DigiDiaS care, or continuing with their usual care.

XSL•FO
RenderX

Our main findings reveal, as expected, that the vast majority of the 238 participants included in the study opted for DigiDiaS care rather than usual care. When comparing the two groups, the DigiDiaS care group had a shorter duration of diabetes, more use of insulin pumps than insulin pens for insulin delivery, and a lower well-being score compared with the usual care group. Those who opted for DigiDiaS care did not differ from those who continued with their usual care in terms of sociodemographic variables, presence of late complications or comorbidities from diabetes, self-management, diabetes distress, or health literacy. Furthermore, our study sample did not differ from the outpatient sample or the national population on relevant variables.

Comparison With Prior Evidence

Not surprisingly, most participants opted for DigiDiaS care, aligning well with their profile of being both younger and already users of technology for insulin administration. Using an insulin pump requires certain technical skills, which are also necessary to use the DigiDiaS care app. Using an insulin pump instead of an insulin pen was the strongest characteristic associated with the choice of DigiDiaS care over usual care. This aligns well with previous research findings on how familiarity with diabetes-related technology might drive the adoption of other digital health tools [46,47]. These findings indicate that patients already accustomed to using advanced diabetes management technologies are more likely to embrace new digital health solutions, such as DigiDiaS care. In general, patients in the usual care group had longer diabetes duration compared with those in the DigiDiaS care group, and they may have established a routine for their outpatient care, making them less inclined to try out something new. Thus, when introducing digital care solutions in diabetes management, those already using diabetes technology equipment may be more prone to exploring the possibilities within new ways of receiving outpatient care.

In our sample, those opting for DigiDiaS care had lower well-being scores than those in the usual care group. Living with a chronic condition requiring ongoing self-management, such as type 1 diabetes, can affect well-being, even though well-being can vary throughout life and with age [4]. This variation in well-being is also observed in the Norwegian general population, where well-being appears to increase with age from the early 40s to the mid-70s [48]. This might correspond with how our participants opting for DigiDiaS care had a median age of 48 years—that is, 11 years younger than those opting for usual care and reporting a higher well-being score. Compared with the Norwegian population of adults with type 1 diabetes, both groups in our sample had a median well-being score higher than the national average [49]. Thus, despite our DigiDiaS group presenting a lower well-being score compared with those continuing with usual care, all participants had a fair level of well-being without symptoms of depression interfering with their abilities to self-manage.

Although most of the recruited participants opted for DigiDiaS care, a small proportion of the participants chose to continue with usual care, thus declining the opportunity to explore digital follow-up. In our study, we did not investigate actual use but rather the willingness to use DigiDiaS care. To the best of our knowledge, DigiDiaS care is the first outpatient care model comprising specific components, such as a message service, PRO-based questionnaires, an information page, and video consultations for diabetes care [15]. The closest alternative to our knowledge is DiabetesFlex, and our study is a response to the call by Jensen et al [17] after interviewing patients with type 1 diabetes who received flexible PRO-based telehealth as part of their diabetes follow-up in Denmark, questioning whether this type of solution is acceptable for all patients. Our findings show that not all patients opt for digital outpatient care. A previous scoping review on reasons for nonuse of digital PRO identified factors, such as ability to use the PRO, engagement, emotional distress, and technical barriers [50]. Our identified differences in the use of insulin delivery equipment may represent differences in the technical skills required to use an insulin pump. Furthermore, the scoping review highlighted how participants with few symptoms or those in good health stopped using digital PRO solutions more frequently [50]. This aligns well with the differences in well-being among our groups, where those with higher well-being chose usual care.

In contrast to previous research highlighting the importance of socioeconomic background when offering digital health services, differences in such characteristics were not observed in our sample. Previous research highlights that health literacy and socioeconomically disadvantaged backgrounds may be less likely to be considered for digital PRO-based outpatient care [51]. Our findings show that there are no statistical differences in health literacy or socioeconomic status between the DigiDiaS care and usual care groups, suggesting that there is no reason not to consider such patients to use these solutions. However, this may be contextual, as the Norwegian population in general has a high socioeconomic status. Yet, further research can provide a deeper understanding of the specific characteristics that influence patients' decisions to choose digital outpatient care.

Although we examined various characteristics from medical records and self-reported questionnaires, we did not investigate all potential influencing factors. For instance, while we assessed general health literacy to understand the ability to find, understand, evaluate, and apply health information, digital health literacy could provide deeper insights into patients' ability to effectively use such solutions [52]. In addition, efforts should be made to explore whether the use of digital outpatient care solutions such as DigiDiaS care varies with factors, such as geography, travel time, and the availability of health care services. The introduction of new technology in health care services is a complex process [53], and patient acceptance of new solutions is influenced by how health care professionals adopt and support these technologies [54]. Further understanding and investigation of these dynamics may reveal factors for successful implementation in practice.

Strengths and Limitations

This study presents strengths and limitations that are important to consider when interpreting the findings. First, this study explores a fully implemented digital outpatient care service [21], hindering the use of established gold standard research

XSL•FO
RenderX

designs. However, our nonrandomized study design was essential in capturing the participants' preferences, allowing them to choose either DigiDiaS care or continuing with usual care. This approach enabled us to investigate characteristics based on the participants' choice of follow-up, which would not have been possible with other study designs, such as randomization or a stepped wedge design. The resulting skewed distribution was, therefore, expected and reflects these treatment choices. To compensate for the skewed distribution, nonparametric tests were used; nevertheless, the results should be interpreted with caution due to the uneven distribution.

While a none-randomized design with consecutive sampling may introduce some bias, it provides valuable insights into real-world decision-making and patient preferences that are crucial for understanding the adoption and effectiveness of the DigiDiaS care model [21], especially considering the needs and choices of the minority group who continued with usual care. Acknowledging that some participants do not wish to use this type of outpatient care is important, and the reasons for this should be further investigated. Qualitative interviews may reveal factors that we may not have detected in this study.

Second, this study does not examine the usability of individual components in the patient app or the specific solution of the app, but rather its clinical implications. Our investigation does not exhaustively cover all factors that may influence the choice of digital outpatient care given the complexity of such decisions. However, by collecting a broad range of data from medical records and self-reported data from the PRO questionnaire, we have gathered a comprehensive dataset. Our cross-sectional study, incorporating both generic and disease-specific well-validated measures, allowed us to add depth to the medical records data [55]. The richness of PRO data lies in the patient perspective it provides, reflecting their experiences, symptoms, and the impact of the disease on their daily lives [56].

Third, the digital outpatient care solution was introduced to half of the participants in the DigiDiaS care group before they were included in this study. The extent to which this was used is unknown, as its use is mainly related to the patients' need to contact the clinic outside of fixed appointments, preparation for consultation or information, and e-learning courses received in connection with consultations. The time before we started recruiting for this study was also an introductory period in the use of DigiDiaS care for the clinic. We do not see it as a limitation that participants had access to the app before the start of the study, as we investigated opting for use of DigiDiaS care or not in this paper. However, as previously addressed, experiences from the Danish DiabetesFlex indicated that not everyone wanted to continue with DiabetesFlex after the study period [17], and even though our participants were opting for DigiDiaS care, actual use should be further investigated.

Conclusions

This study reveals that patients with type 1 diabetes are opting to use a digital outpatient care solution when it is offered. Most of participants opted for DigiDiaS care, the novel mHealth solution, while a smaller proportion opted to continue with usual care. Those opting for DigiDiaS care are characterized by being already familiar with using diabetes-related technology, having a shorter diabetes duration and lower well-being than the usual care group.

Importantly, our findings indicate that factors such as demographic and clinical variables, as well as self-management, health literacy, and diabetes distress did not differ significantly between DigiDiaS care and usual care. Even though only a small proportion continued with usual care, the characteristics of this group should be further explored to understand how these individuals can also be included in digital outpatient care solutions. Further studies should also focus on how the implementation of digital solutions in outpatient care can affect how and if patients use them.

Acknowledgments

The authors would like to express their heartfelt thanks to all the participants in the study, the diabetes nurses, and endocrinologists at Akershus University Hospital for their assistance in recruitment. They are also grateful to the NOKLUS Diabetes Registry for its contribution to the data. Finally, they would like to thank their colleague Maria Aadland Mollestad for patience in controlling the data.

The paper does not contain text generated by artificial intelligence (AI). However, AI was used to assist with proofreading, alongside a professional proofreader.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

IS and AT conceptualized the research questions. TS and JAW facilitated recruitment of participants. IS recruited participants and collected data. IS, AT, and MH managed the data analysis. IS drafted the manuscript with support from HH and AT. ALJ, MH, TS, JAW, and EÅ revised the manuscript. All authors contributed to the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: Smoking remains a leading cause of death worldwide, with young adults particularly at risk due to the lack of targeted cessation initiatives. While mobile apps show promise in supporting smoking cessation, they primarily target smokers already motivated enough to install them, highlighting the need for interventions that reach those who are not yet ready to take that step.

Objective: This paper focuses on designing and evaluating Smokwit, a digital smoking cessation intervention aimed at young adults during the act of smoking. Smokwit seeks to investigate the early stages of smoking cessation (precontemplation and contemplation) that are important yet rarely investigated.

Methods: The paper is based on the design science research methodology where a digital intervention—Smokwit—was designed and evaluated in the wild using a mixed method approach combining quantitative results of a quasi-experiment with qualitative insights from users and experts. More specifically, Smokwit is a novel gamified ambient intervention that integrates a connected ashtray with a mobile app. The ashtray aims to trigger processes of change, in particular consciousness raising and social liberation (as part of the transtheoretical model of change) by provoking curiosity, self-reflection, and ad-hoc peer discussions among smokers. The linked mobile app is designed to reinforce this goal by providing smoking cessation self-help material and coaching possibilities. We evaluated the effectiveness of this intervention through a 3-month field study designed as a quasi-experiment with a treatment and control group (n=46). A qualitative analysis with users (n=10) and smoking cessation experts (n=7) provides insights into the type of interactions that happened within and outside the system as well as practical implications for smoking cessation organizations.

Results: The qualitative findings revealed that the intervention promoted smokers' self-reflection, peer discussions, and mobile app interactions. Furthermore, the quantitative analysis uncovered a possible trend toward increased readiness to quit among smokers in the treatment group compared to the control group; however, this did not reach conventional levels of statistical significance (b=1.33; z=1.91; P=.06).

Conclusions: Smokwit provides encouraging insights into how to design a bottom-up digital intervention that targets young adults at an opportune moment to support them on their smoking cessation journey.

Introduction

Background

Despite many years of prevention, tobacco addiction is still the cause of approximately 8 million deaths annually, making it the foremost preventable cause of death globally [1]. Efforts to pass comprehensive laws and regulations can be hindered in countries where the tobacco industry provides economic benefits and thus wields significant lobbying power. For example, in Switzerland, where the industry has some of its major headquarters, this lobbying power is particularly strong [2]. Specifically, the tobacco industry in Switzerland contributes approximately US $7 billion in annual revenue, representing about 1% of the country's gross domestic product, and provides employment for around 11,500 people (0.2% of the labor force) [3]. However, it can be argued that these economic benefits are offset by the health-related expenses of US $11 billion yearly [4], including the 10,000 smoking-related deaths annually [5]; thus, passing top-down regulation remains highly challenging. As a result, in such countries, it is crucial to devise effective bottom-up prevention measures to support smoking cessation.

There are effective evidence-based interventions that could be helpful for young smokers; these include brief advice, behavioral support, pharmacotherapy, and abstinence evaluation [6]. Furthermore, digital technologies, such as mobile apps, have been identified as a potentially effective, lightweight, and scalable complementary support for smoking cessation [7-9]. These technologies could represent a particular interest, potentially lowering current funding, time, and human resource barriers for health promotion [10]. For instance, there is a wide range of specialized mobile apps that could act as catalysts to provide this support [9,11]. However, despite their potential benefits, there remains a challenge with user engagement, especially when the apps are not well-designed or integrated into clinical or daily workflows [12]. Indeed, even minor frictions prevent smokers from engaging in effective behavior change interventions [13]. For instance, it is challenging to get a smoker to seek digital self-help information, sign up for peer support, or even register for face-to-face counseling [14]. As such, one of the main challenges in smoking cessation interventions is effectively getting smokers on board [15,16]. Most existing digital solutions require individuals to first be aware of the app's existence, and then take the additional steps of downloading and installing it; there are barriers that can deter engagement, especially for those not actively seeking help. Conversely, our approach initiates onboarding directly at smoking hotspots through physical devices, offering immediate and contextual engagement. This paper aims to address this gap by exploring an alternative, low-threshold entry point into cessation support.

A particularly important demographic to target prevention measures are young adults (ages 18 to 35 years). Most smokers start early, with 87% beginning before the age of 21 years [17], and young adults often represent the largest smoking demographic [17]. This is particularly problematic because the earlier one starts smoking regularly, the faster addiction sets in [18], thus making it harder to quit. Despite approximately half of young people wishing to quit [19], only an estimated 5% manage to do so during their youth [20]. Furthermore, smoking cessation initiatives that are specifically aimed at young adults are lacking [21]. As such, we seek to address the following research question: How can a digital intervention be designed to increase young adult engagement with evidence-based smoking cessation interventions?

Contributions

This research makes 3 main contributions to the literature on digital interventions for smoking cessation. First, it introduces Smokwit—a novel digital system specifically designed to reach smokers at physical smoking hotspots—immediately before, during, or after the act of smoking. Unlike conventional tools that rely on user motivation or active digital engagement, Smokwit reduces entry barriers by engaging users in situ and at opportune moments [22,23]. It leverages connected ashtrays as ambient objects [24], facilitating a seamless transition from the physical environment to digital smoking cessation resources. Furthermore, Smokwit is conceptualized as a motivational affordance [25], a system intentionally designed to trigger behavioral outcomes by incorporating gamification mechanisms such as competition and rewards [26], with the goal of increasing engagement with evidence-based interventions. Second, this paper presents a real-world validation of the Smokwit system through a 3-month quasi-experimental field study (n=46) conducted across 2 university campuses. This study combines quantitative data (surveys and system logs) with qualitative insights from interviews with participants (n=10) and experts (n=7), thus providing a comprehensive understanding of system engagement and user experience in a natural context. Third, the paper contributes empirical insights into the early stages of smoking cessation, specifically the precontemplation and contemplation stages as defined by the transtheoretical model (TTM) of health behavior change [27]. These stages are critical yet underexplored in digital health research [28]; our findings shed light on how low-friction, context-aware interventions can effectively engage smokers who are not yet actively seeking help.

Smoking Cessation Process

Giving up smoking is more of a process rather than a single decision or action [29]. A useful theoretical lens for analyzing this process is the TTM [27], which conceptualizes behavior change as a progression through discrete stages. Unlike continuum models, which assume interventions can be applied at any point, stage models such as the TTM emphasize that different strategies are appropriate at different stages in the change process [29-31]. In this context, the stages toward smoking cessation can be seen as a smoker's readiness to quit (RTQ). TTM hypothesizes that this change occurs in 6 distinct steps, also called stages of change:

- Stage 1 – precontemplation: no intention of taking action within the next 6 months.
- Stage 2 – contemplation: intention of taking action within the next 6 months.
- Stage 3 – preparation: intention of taking action within the next 30 days; thus, some behavioral steps have already been taken.

XSL•FO
RenderX

- Stage 4 – action: changed overt behavior for less than 6 months.
- Stage 5 – maintenance: changed overt behavior for more than 6 months.
- Stage 6 – termination: no temptation to relapse and 100% confidence.

In this paper, we focus on the early stages—precontemplation and contemplation—that are especially underaddressed in digital health interventions. These are stages where smokers are not yet ready to take direct action; however, they may be more receptive to change through targeted support. According to TTM, progress between these stages is mediated by cognitive and affective processes such as raising consciousness, meaning increasing awareness through information and feedback, and social liberation, thus reinforcing social norms that support healthy behavior [31].

Our intervention, Smokwit, is deliberately designed to activate these processes in contextually appropriate ways. By placing connected ashtrays at smoking hotspots, Smokwit raises awareness of quitting resources (consciousness raising) and introduces quitting as a socially supported behavior (social liberation). The use of ambient technology lowers friction for engagement, helping reach users who are not yet actively seeking help. Moreover, Smokwit incorporates gamification elements, such as rewards and peer comparison, to further reinforce social motivation and self-reflection [25,26]. In line with TTM, these mechanisms aim to help users move from passive awareness (stage 1) to the contemplation of change (stage 2).

In addition to these motivational design elements, Smokwit supports 2 evidence-based engagement strategies. First, peer interaction is integrated into the system to support social comparison and group influence, which have been shown to strengthen motivation and behavior change in stopping smoking [6,32,33]. This leads to our first premise:

- Premise 1: Engagement with peer groups helps smokers increase their RTQ.

Second, Smokwit offers access to curated self-help material, which can also support users in the early stages of change. Prior studies on smoking cessation apps show that such content can improve RTQ, especially among less motivated users [9,34-37]. This confirms our second premise:

- Premise 2: Engagement with self-help material helps smokers increase their RTQ.

By aligning Smokwit's design with key TTM processes and stages, we aim to offer a context-sensitive intervention that addresses a critical gap in digital smoking cessation efforts.

Gamifying Smoking Cessation Interventions

There is a growing number of technological solutions, such as forums and mobile apps, that give smokers access to self-help material and leverage peer support by facilitating multilateral interactions between smokers on dedicated social media channels [6,9,38,39]. However, it is unclear how many smokers actually engage with such resources [9]. A particular challenge is to capture smokers who are still in the precontemplation phase and, as such, are not interested in quitting at present and to engage for the first time.

One approach to increase engagement with digital or mobile content is to conceptualize interventions as motivational affordances, such as gamification or digital nudging [40]. These are artifacts designed to foster specific behaviors [25]. An immediate behavioral outcome in our case would be increased engagement with digital self-help resources or peer group reflection. A distal outcome would be to move smokers from the precontemplation to the contemplation stage by increasing their RTQ.

The gamification approach [26], where game elements such as points, leaderboards, or badges are integrated into nongame systems, has already been extensively used in mobile apps targeting smoking cessation [9]. Typically, around 65% of the top 100 smoking cessation apps include some kind of reward system, such as points or digital badges and trophies awarded when milestones are reached (eg, number of days without smoking) [9]. However, these systems primarily use these mechanisms to encourage existing users to stay on the platform and are not designed to engage new users. In this paper, we want to address this gap by focusing on bringing new users to the system.

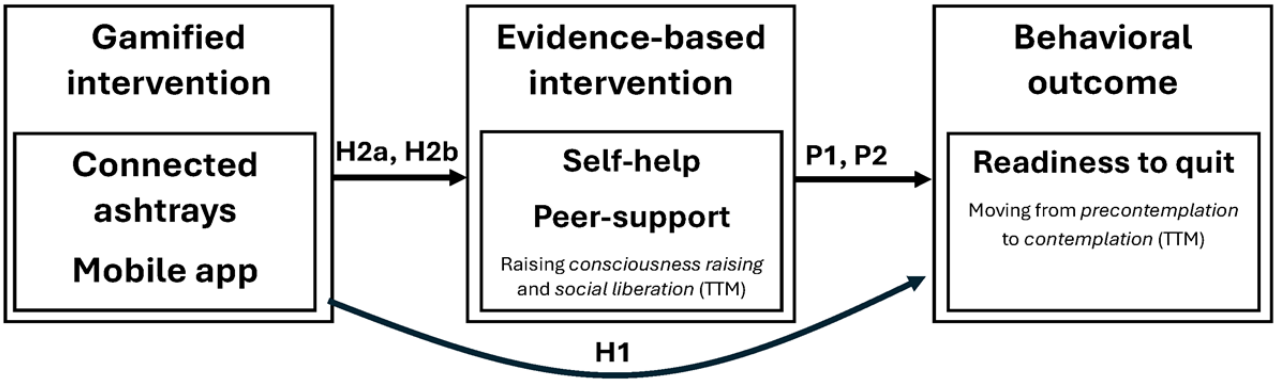
Opportune Moment Prompting

One approach to bringing users to the system can be inspired by digital nudging—a motivational affordance approach that modifies a user's choice to make certain behaviors more attractive [41]. The idea with certain types of digital nudges is to prompt users at opportune times to transition from one context to another [23,42]. An example of such prompting is simply to display push notifications on the phone, which indicate to users that something is happening, for example, a message has been received, a location reached, or a time limit exceeded. The opportune timing of prompting is an important aspect [22]. These moments can be life events, where stopping smoking could be linked to a health-related event such as a doctor's visit, pregnancy, or hospitalization [43]. However, there could also be moments close to more mundane behavior. For instance, road safety, reminding drivers to use their seat belts shortly before they drive away, significantly increases seat belt compliance in comparison to reminding drivers 5 minutes before they drive away [44]. In the smoking context, a recent study found promising results for face-to-face interventions in areas where smokers gather to smoke (smoking hotspots) [45]. In this paper, we build on these insights to investigate how a digital artifact could prompt users at smoking hotspots without the need for in-person interventions.

Ambient Transition Device

A promising approach to transition from a physical context, smoking, to a digital context, accessing digital content, is the use of ambient devices. An ambient device is a regular object from physical space augmented through a digital artifact, which can enhance awareness of digital activities [46]. In a knowledge-sharing system, a connected aquarium was designed to visualize digital contributions to motivate users to log in and make their own contributions [24]. Similarly, in the

XSL•FO
RenderX



energy-saving context, artistic screens connected to smart meter data have been shown to increase awareness of energy consumption and encourage energy-saving behaviors [47]. In the medical domain, researchers provided patients with asthma with an "Asthma Buddy" teddy bear [48]. In this system, simple feedback is provided through the teddy bear, and more elaborate data are displayed on a mobile app. We build on these previous findings to hypothesize that a gamified ambient device at a hotspot could help reduce the friction for smokers to engage more with digital self-help and peer support. This increased engagement will lead to progress in the process of stopping smoking such as RTQ. Figure 1 illustrates our conceptual model. The gamified intervention, implemented through connected ashtrays in public smoking areas, acts as a playful and tangible nudge toward 2 core evidence-based strategies, self-help and peer support. We state our main hypothesis as follows:

- Hypothesis 1: Gamifying an ambient device at smoking hotspots increases RTQ.

We argue that this increase can happen by increasing engagement with self-help material and reflection among peers. Formally stated:

- Hypothesis 2a: Gamifying an ambient device at smoking hotspots increases engagement with self-help material.
- Hypothesis 2b: Gamifying an ambient device at smoking hotspots increases engagement with peers.

Figure 1. Overview of the full conceptual model illustrating our hypotheses (H1, H2a, and H2b) and premises (P1 and P2). TTM: transtheoretical model.

Methods

Overview

This research uses a user-centered design approach [49], which incorporates elements of design thinking [50] and design science research methodology [51,52]. The artifact's design was guided by practice and theory, with psychological and behavioral outcomes used to measure its effectiveness. This project involved an 18-month collaborative effort with a multidisciplinary team of human-computer interaction and information systems researchers, embedded systems engineers, and partners from smoking cessation organizations. Co-design workshops were conducted with these partners to understand the issue and explore the design space before creating initial prototypes. Then the design was evaluated in the wild in a field study. The study takes a mixed method approach [53], combining elements from a quantitative quasi-experimental design setup with qualitative interview analyses. We adopted a multimodal data collection approach [54], with survey data, system logs, and interview transcripts.

Ethical Considerations

The regional ethics committee of the Canton of Vaud, Switzerland (CER-VD) reviewed the study and determined that it fell outside the scope of the Swiss Human Research Act (Req-2022-01567); thus, no formal ethics approval was required. At the beginning of the survey, participants were informed about the purpose of the study, the voluntary nature of participation, and their right to withdraw at any time without consequences. Informed consent was implied by clicking "Next" to begin the survey. Data were pseudonymized, stored securely on access-restricted servers, and reported only in aggregate. No direct financial compensation was provided; participants completing both surveys were entered into a prize draw, while interviewees received no compensation.

Smokwit System Design

Overview

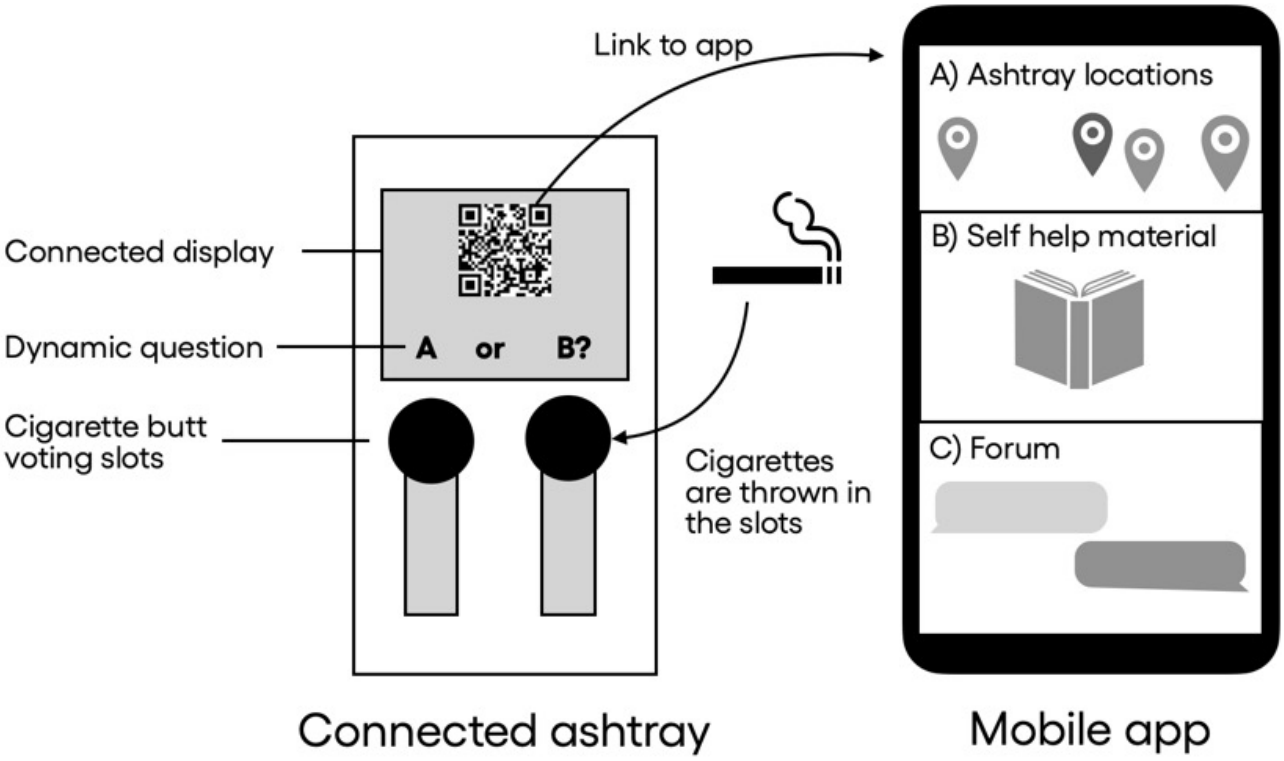
To help young smokers in the precontemplation phase to increase their RTQ, Smokwit leverages two evidence-based behavioral support approaches directly at the smoking hotspot: (1) self-help material and (2) peer group support. The first approach, self-help material such as digital videos, can aid smokers without needing outside assistance, and it is deemed useful if it is tailored to individual smokers [55]. In the second approach, which may be more effective [56,57], peers provide mutual support and encouragement, either through a digital forum [11] or during in-person group sessions.

At the center of the Smokwit system are connected voting ashtrays, which act as ambient transition devices, providing a link between the physical smoking hotspot and a mobile app, which provides digital support (Figure 2). The interaction with the Smokwit system can be described through 6 phases, representing a typical user flow (Figure 3). The journey begins when a smoker arrives at a hotspot and notices the connected ashtray during the "smoking break starts" phase. In the "connected ashtray engagement" phase, the smoker interacts with the ashtray by reading reflective questions and scanning a QR code to access additional digital resources, linking the

XSL•FO
RenderX

physical and digital components of the system. The ashtray presents a question (Table 1) along with 2 answer options, each corresponding to a separate ashtray compartment. Smokers cast their vote by placing their cigarette butt in the slot, which reflects their answer. The questions were divided into 2 sets. The first set aimed to capture individual smokers' perceptions, while the second set presented aggregated feedback from the broader smoking community on each campus. At the hotspot, smokers could also engage in peer discussions fostered by the ashtray's presence, creating opportunities for shared reflection and mutual support. Scanning the QR code transitions the smoker to the "mobile app engagement" phase, where they can access self-help materials, coaching resources, maps, and forums. The journey may continue into the "postsmoking engagement" phase, where smokers further interact with the mobile app. They can create an account to participate in forums, analyze personal statistics, or contact support organizations.

Figure 2. The Smokwit system design concept includes the connected voting ashtray with a link redirecting users to a mobile app with digital support materials.



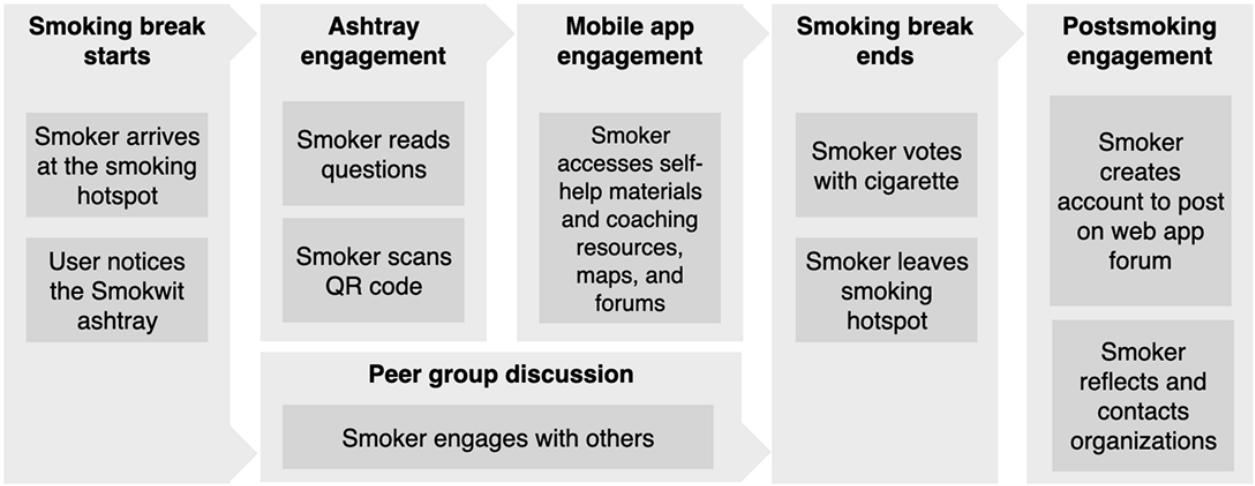


Figure 3. Smokwit smoker journey represented by 6 phases: smoking break starts, ashtray engagement, mobile app engagement, peer group discussion, smoking break ends, and postsmoking engagement.

RenderX

Table 1. Poll questions displayed on Smokwit ashtrays and the number of cigarette butts collected for each response from 1 hotspot.

Poll question examples	Set	Option 1	Butts for option 1, n	Option 2	Butts for option 2, n
I smoked this cigarette to give myself a boost	1	Yes	51	No	82
I found this cigarette ...	1	Great	67	Not great	30
This cigarette will help me focus	1	I think so	32	No need!	22
On Campus 1, what % of cigarettes are smoked to get a boost?	2	<50%	20	≥50%	41
What % of Campus 1 smokers actually enjoy cigarettes?	2	<50%	5	≥50%	16
On Campus 1, what % of cigarettes are smoked to help focus?	2	<50%	10	≥50%	18

One of the main system design priorities for the user experience was lowering friction. We focused on the solution's simplicity to ensure that anyone, regardless of prior experience or technical proficiency, can become a potential user. To engage users with self-help materials and group discussions, the system was designed following Zhang's [25] 5 key principles for creating motivational affordances, which are design elements intended to promote specific user behaviors. These design principles (DPs) are (DP1) allowing autonomy and self-control, (DP2) supporting competence and achievement, (DP3) fostering social connections, (DP4) facilitating leadership and followership, and (DP5) triggering emotions. Moreover, the system design incorporates the Fogg Behavior Model [58], ensuring that all 3 essential elements as in motivation, ability, and behavior triggers are present to support behavior change in cigarette addiction effectively.

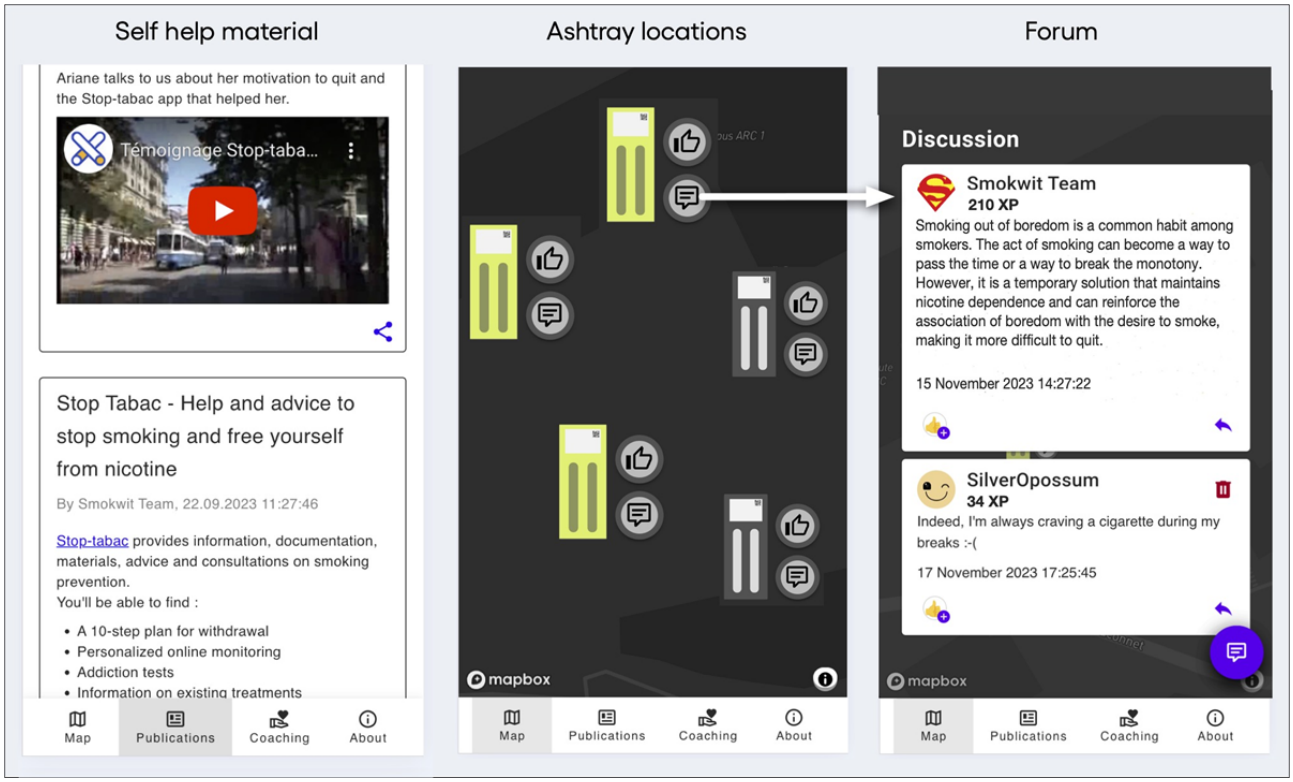
The Smokwit ashtray's simple design eliminates the need for advanced abilities or complex instructions, ensuring that the system is intuitive and accessible to all users. Smokers can cast their "vote" by placing their cigarette butt in the compartment, which corresponds to their answer (DP1). This low physical effort supports the ability component [58] by minimizing barriers to engagement while simultaneously strengthening motivation by fostering a sense of autonomy and ease of use. Users are free to choose whether to participate and which ashtray they want to interact with. The system is designed to support competency and achievement (DP2) through a check-in mechanism where scanning a new ashtray's QR code unlocks it in the mobile app and grants access to its statistics and forum. The app displays both discovered and locked ashtrays on a campus map and presents poll results, giving users a clear sense of progress. This feature is designed to motivate users to go to different places and engage in reflection both in person and within the app's forum (DP3). This incorporates facilitator triggers, which reduce friction with spark triggers such as gamified rewards and visible progress to prompt participation in discussions [58]. When joining discussions, users create a username and can upload an avatar; however, their true identity is not required. Conversations are anchored in the ashtray's shared question and poll results, offering opportunities for asynchronous peer reflection and social connections. The system also provides experience points (XPs) to users who participate in forum discussions to support the leadership or followership, social comparison, aspect (DP4). These points are displayed under the usernames in the forum, making active users more visible to others and potentially encouraging further engagement through subtle social referencing. This feature incorporates motivational elements such as social acceptance [58]. Finally, the system supports curiosity (DP5) with a bright yellow ashtray that draws attention, a rotating set of reflective questions on its display, and prompts to discover other ashtrays on campus. These features initiate a pleasure motivator, a spark trigger, which both arouse interest and motivate users to engage further [58].

Connected Ashtrays

The Smokwit connected ashtrays (Figure 4) are based on modified commercial voting ashtrays. A voting ashtray consists of 2 compartments, each labeled with a distinct choice in the form of a printed question or poll. In the Smokwit version of the ashtrays, the paper has been replaced with a connected e-paper screen, and sensors were installed on the inside of the ashtray to allow the counting of cigarette butts in both ashtray compartments. An ESP32 microcontroller unit is used to pilot the e-paper screen, sensors, and Wi-Fi connectivity to (1) update questions remotely and (2) send counted votes to the mobile app. To make the ashtrays energy autonomous, they include a 10,000 mAh battery and a 6 W solar panel.

XSL•FO
RenderX

Figure 4. Smokwit connected ashtray at the smoking hotspot.



Mobile App

The Smokwit mobile app (Figure 5) was developed as a responsive web app. The mobile app provides self-help material with tobacco prevention content as well as a coaching section, where users can contact regional smoking cessation experts. The main screen of the mobile app is the campus 1 map, on which the Smokwit ashtrays have been geolocated. Each ashtray has a scannable QR code. By scanning the QR code, the user unlocks the ashtray on the mobile app and earns XPs. The physical ashtray can be used independently; however, the app enhances the experience by providing additional insights. When scanning an ashtray, it unlocks it on the map by becoming yellow. By unlocking the ashtray on the platform, the user directly arrives at the ashtray page and has access to the digital discussion forum associated with the ashtray's current poll question. Indeed, users can access this information without registration. Open access promotes inclusivity and user engagement, making it easier for individuals to join in forum discussions and explore resources at their own pace. The user is invited to comment on the poll question by leaving a message or using emojis in the dedicated community section. Each action is rewarded with XPs. Posting and reacting to messages require an account, which can be created on the go by creating only a username and password. A username is automatically generated and suggested to the user to minimize friction and maintain anonymity. When the ashtray is unlocked, the user can also consult information regarding current and past polls as well as additional statistics such as the daily and hourly inflow of cigarette butts. There is an ashtray page for each Smokwit ashtray.

Field Study

A field study was designed in the wild on 2 university campuses to assess the impact of the Smokwit intervention on enhancing smokers' progress in their quitting process through their RTQ (hypothesis 1) by fostering self-reflection (hypothesis 2a) and peer support (hypothesis 2b).

Measures

To better understand the participants, in addition to age and sex, we also inquire about the age the smokers started, if they were smoking daily, and their number of previous attempts to stop smoking as a preliminary measure of their desire to stop [59,60].

To assess the user experience and understand self-reflection and peer support processes, we log activity on the mobile app as well as the number of votes from the ashtrays. Furthermore, to obtain more in-depth insights, we conducted semistructured interviews with smokers exposed to Smokwit and experts from smoking cessation organizations.

The selected metric to measure progress on the quitting smoking process is the RTQ ladder [59] (Table 2). This provides a graphic representation of the continuum of change, ranking smokers' RTQ smoking from 1 to 10. Level 1 for smokers having no interest in quitting at all to level 10 for smokers who have become permanent nonsmokers and who have little concern that they will relapse. Levels 2 to 5 are precontemplators, according to the TTM. Level 6 is equivalent to the contemplation stage. Levels 7 and 8 indicate that the smoker is, respectively, in the preparation and action stages, whereas level 9 indicates maintenance.

XSL•FO
RenderX

Table 2. Readiness to quit ladder with stages of change, their level equivalents, and descriptions.

Stage of change	Level	Description
Termination	10	I have quit smoking, and I will never smoke again.
Maintenance	9	I have quit smoking, but I still worry about slipping back, so I need to keep working on living smoke-free.
Action	8	I still smoke, but I have begun to change, for example, cutting back the number of cigarettes I smoke. I am ready to set a quit date.
Preparation	7	I definitely plan to quit smoking in the next 30 days.
Contemplation	6	I definitely plan to quit smoking in the next 6 months.
Precontemplation	5	I often think about quitting smoking, but I have no plans to quit.
Precontemplation	4	I sometimes think about quitting smoking, but I have no plans to quit.
Precontemplation	3	I rarely think about quitting smoking, and I have no plans to quit.
Precontemplation	2	I never think about quitting smoking, and I have no plans to quit.
None	1	I enjoy smoking and have decided not to quit smoking for my lifetime. I have no interest in quitting.

Evaluation Setup

Overview

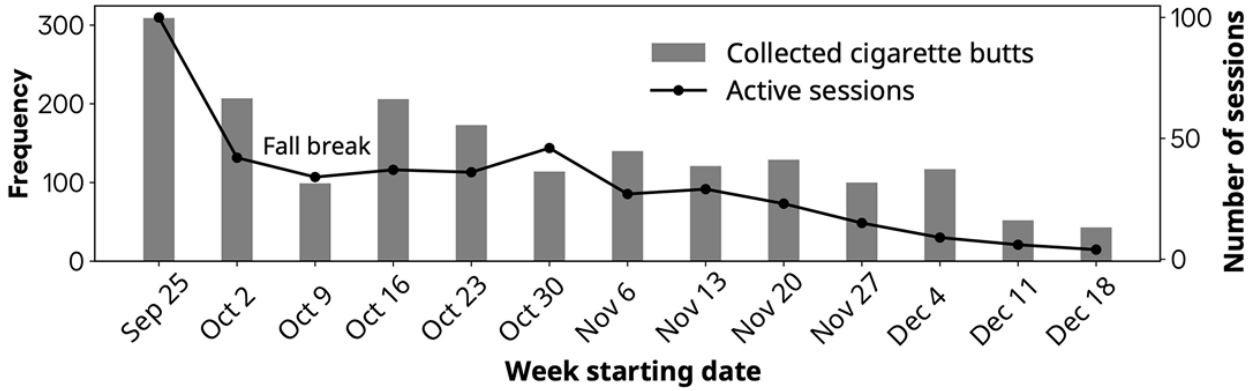
We conducted the field study on 2 university campuses following a quasi-experimental design with a treatment (campus 1) and a control (campus 2) condition. We performed the study in a campus setting because the student population would, by design, consist of young adults, who are our target demographic. Furthermore, in such contexts, students tend to smoke at the same time, meaning during lecture breaks, which is prone to group discussion. It is a quasi-experiment, as the participants were the natural members of each geographically distant campus of the same university and thus were not randomly assigned. Table 3 gives an overview of the field study.

Table 3. Experimental phases with study groups and participant amount.

	Phase 1 (June to September 2023): presurvey, n (%)	Phase 2 (September to December 2023): intervention	Phase 3 (January to March 2024): postsurvey, n (attrition %)	Phase 4 (June to November 2024): postinterviews, n (%)
Treatment	47 (65)	Prevention day + 4 Smokwit ashtrays	27 (43)	10 (21)
Control	25 (35)	Prevention day	19 (24)	—[a]
Experts	—	—	—	7 (—)
Total	72 (100)	—	46 (36)	10 (—)

[a]Not applicable.

Phase 1: Recruitment Pretest



Before the experiment began, we recruited participants by asking smokers in various smoking locations on the 2 campuses for their email addresses. A total of 119 participants registered for the study, and 72 fully completed the presurveys (47 for the treatment and 25 for the control conditions). Two researchers developed the survey and pretested it in collaboration with regional smoking cessation experts (Cipret Neuchâtel). It included 9 items on demographics, smoking habits, and the literature-validated RTQ scale, which participants completed in approximately 6.50 (SD 7.08) minutes.

Phase 2: Intervention

The intervention phase lasted 3 months. It began with a smoking prevention day on both campuses, led by 2 experts from a local smoking prevention organization (Cipret Neuchâtel). The event featured a free information stand aimed at encouraging participants in both conditions to consider quitting and providing contact information. This setup was designed to reduce the risk of social desirability bias by giving participants on both campuses a sense of being part of an experiment. During the entire intervention phase, 4 Smokwit ashtrays were deployed only on campus 1 (the treatment condition). Each Smokwit ashtray showed a different poll question, and the polls were updated every 3 days. In total, 70 poll items were created. The first set of 35 poll questions (ie, set 1 in Table 1) aimed to gather community data (eg, “I smoked this cigarette to give myself a boost,” yes or no). The second set of 35 poll questions (ie, set 2 in Table 1) aimed to raise awareness about consumption and encourage contemplation on quitting smoking (eg, “On Campus 1, what % of cigarettes are smoked to get a boost?,” <50% or ≥50%). Every butt tossed into a Smokwit ashtray was detected by sensors and considered for the poll question statistics. Figure 6 illustrates the number of cigarette butts tossed weekly alongside the number of sessions on the mobile app. These data indicate that smokers were more active in the early weeks of September. Reduced smoking activity happened when the weather gets colder, and this has been observed previously [61].

XSL•FO
RenderX

Figure 6. Number of cigarette butts collected by ashtrays and number of active sessions on the mobile app.

Phase 3: Postsurvey

The postsurvey included the same questions on smoking habits and RTQ as presurvey. A survey was sent to all participants after the experiment in mid-January 2024, with a follow-up email in late February. The postsurvey was fully completed by 46 valid participants who also completed the presurvey (27 in the treatment condition and 19 in the control condition). This took on average 5.30 (SD 2.06) minutes to complete.

Phase 4: Postinterviews

We conducted 2 rounds of follow-up interviews with participants to understand user experience and long-term impressions. The first round was conducted in June 2024 with 5 participants, and the second one in November 2024 with 5 additional participants. We invited participants who had completed both pre- and postsurvey and expressed interest in a follow-up interview. Through these interviews, we sought to understand motivations, barriers, and decision-making processes, providing deeper insight into their behavior and perceptions of the system. Furthermore, in November 2024, we interviewed 7 smoking cessation experts to gather their professional feedback.

Results

Overview

Hereafter, we present the quantitative results of the quasi-experiment. We conducted all analyses using Python scripts, which are available alongside the datasets in Multimedia Appendix 1. The demographics and smoking habits are presented in Figure 7 and summarized in Tables 4 and 5. They show that the participants belong to the demographic that we planned to address, namely, mainly young adults in their 20s, who are in their precontemplation phase when it comes to stopping smoking.

Figure 7. Presurvey results for demographics, smoking habits, and readiness to quit (treatment group: n=46 and control group: n=27).

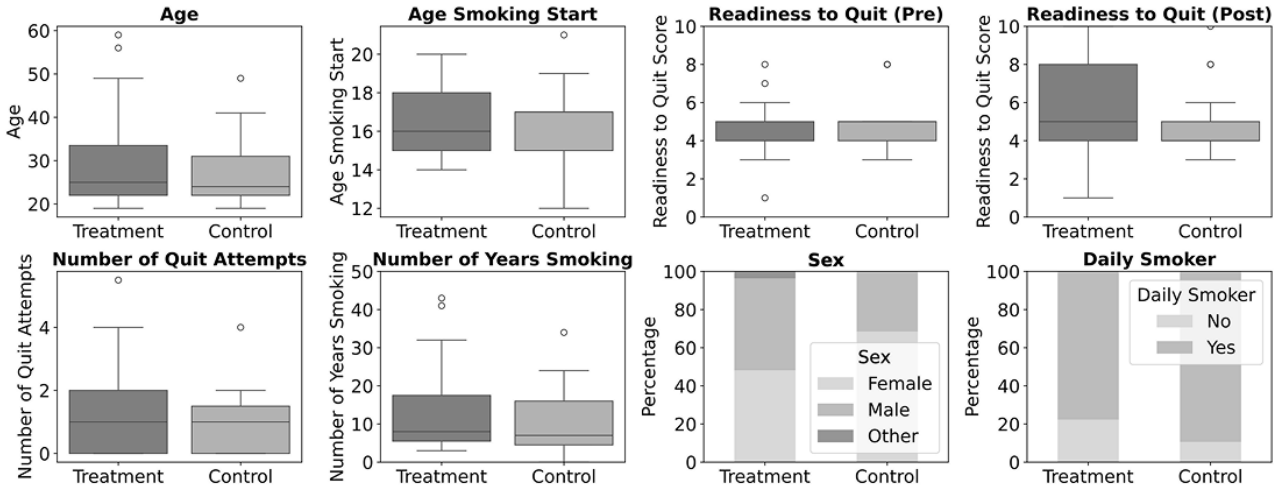


Table 4. Summary statistics for treatment and control groups (n=46) collected in presurvey from participants who completed both pre- and poststudy surveys.

Variable	Treatment (n=27), n (%)	Control (n=19), n (%)
Female	13 (48)	13 (68)
Other	1 (4)	0 (0)
Daily smoker	21 (78)	17 (89)

XSL•FO
RenderX

Table 5. Descriptive statistics for age, age smoking start, number of quit attempts, readiness to quit (RTQ) in presurvey, and RTQ in postsurvey for treatment and control groups.

Variable	Treatment group			Control group		
	Mean (SD)	Range	25%, 50%, 75%	Mean (SD)	Range	25%, 50%, 75%
Age (years)	30.00 (11.73)	19-59	22, 25, 33	27.37 (8.72)	19-49	22, 24, 31
Age smoking start (years)	16.59 (1.74)	14-20	15, 16, 18	16.42 (2.06)	12-21	15, 17, 17
Number of quit attempts	1.52 (1.47)	0-5.5	0, 1, 2	0.89 (1.10)	0-4	0, 1, 1.5
RTQ (pre)	4.37 (1.36)	1-8	4, 4, 5	4.95 (1.51)	3-8	4, 5, 5
RTQ (post)	5.67 (2.62)	1-10	4, 5, 8	5.00 (1.83)	3-10	4, 4, 5

In terms of interaction with the Smokwit system, the QR codes on the ashtrays were scanned 245 times. Based on session IDs, we could account for 74 people with an average interaction duration of 2 minutes and 11 seconds (SD 70 seconds). The ashtrays' webpages were viewed 2409 times, with a mean of 50.9 (SD 35.0) views per user and an average length of engagement of 59 (SD 36.1) seconds. The page containing self-help material was viewed 44 times, with a mean of 3.67 (SD 1.57) views per user and an average length of engagement of 20 (SD 7.54) seconds. This use is in line with what could be expected with the number of participants in the treatment group (77 people in the beginning and 46 at the end).

Attrition Rate

The overall attrition rate of the study was 36% (n=46), with 24% (n=19) in the control group and 43% (n=27) in the treatment group. This attrition rate is rather high and common in smoking cessation studies over several months, where attrition rates have been found to be as high as 77% [62] and even 90% [37]. Nevertheless, it is important to understand that this attrition might have created an imbalance in the sample and potentially introduced bias. We assessed if there was a statistical difference between participants who provided full answers to both surveys (n=46) and those who only answered the presurvey (n=72) across all measures taken in the presurvey (sex, age, age smoking start, group, number of quit attempts, and RTQ). The sample was balanced, although 2 motivation-related variables showed marginally significant outcomes. Smokers with more quitting attempts (t_{25}=1.81; *P*=.08) and higher RTQ scores (t_{25}=1.79; *P*=.08) may have left the study more often than those with lower RTQ scores and fewer attempts to quit. The results suggest that, even if such imbalances exist, the primary target population of this study, namely, individuals in the early stages of their smoking cessation process, has been retained in the sample. Nevertheless, future studies with larger samples should replicate our findings to ensure that attrition bias did not modify the results.

Ambient Gamification and RTQ (Hypothesis 1)

To test hypothesis 1, we analyzed whether the Smokwit intervention increased participants' RTQ compared to a control group. A linear mixed effects model was used with restricted maximum likelihood estimation [63]. The model included time (pre or post), treatment (Smokwit vs control), and their interaction, along with relevant covariates: sex, age, number of quit attempts, age smoking start, and smokes daily. A random intercept was included for each participant to account for individual differences in baseline RTQ.

The results (Table 6) show a possible interaction effect (Figure 8) between time and treatment: when controlling for all other variables, participants in the treatment group showed a potential greater increase in RTQ scores compared to the control group after the 3-month experiment (b=1.33; *z*=1.91; *P*=.06). Even though the result is close to statistical significance, it does not reach it. This finding hints at possible support for hypothesis 1. The effect size for this interaction, measured using Cohen f^2, was 0.04, representing a small effect size according to conventional benchmarks [64]. While modest, such effects are typical and meaningful in behavioral science and digital health research [65]. To evaluate model fit, we computed the marginal and conditional R^2 values. The marginal R^2 (variance explained by fixed effects) was 0.27, and the conditional R^2 (fixed + random effects) was 0.38, indicating that both predictors and individual variability contributed meaningfully to the variance in RTQ. The results indicate no significant association between RTQ and sex or the age of smoking start.

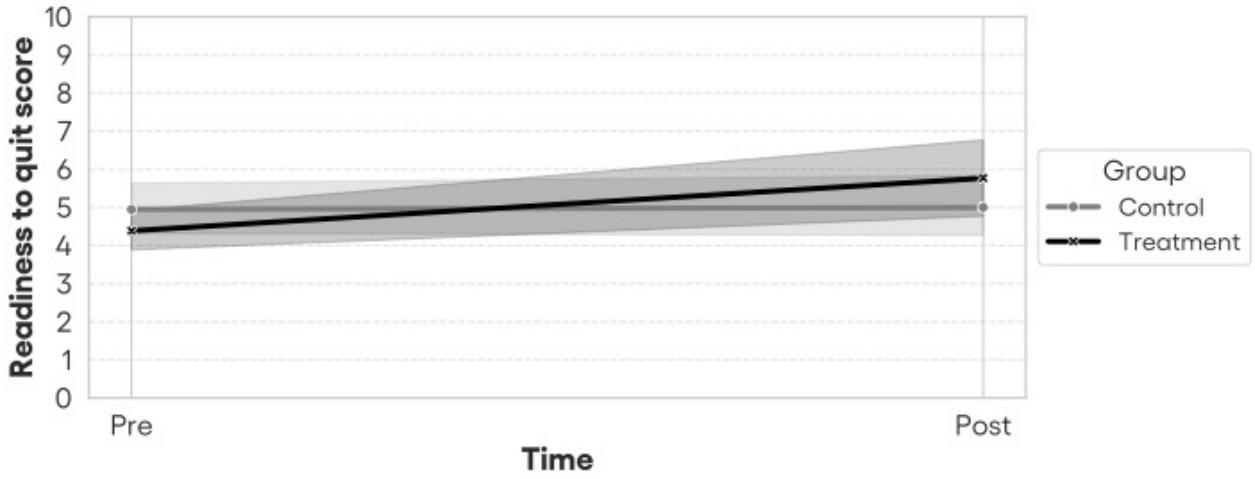
Additionally, the results show that the number of past quit attempts is positively associated with RTQ (b=0.60; *z*=3.81; *P*<.001), and daily smokers reported lower RTQ scores than nondaily smokers (b=–1.07; *z*=–1.99; *P*=.047), meaning that the higher the number of previous quit attempts, the higher the smoker's RTQ, and the more a smoker smokes, the lower their RTQ. Furthermore, the results also show a negative marginally significant trend (b=–0.04; *z*=–1.83; *P*=.07), indicating that younger smokers may have a higher RTQ than the older ones.

Note that the results also indicated a potential imbalance in the baseline sample when controlling for the other variables, because the main effect of treatment was significant (b=–1.09; *z*=–1.97; *P*=.049) when pooling pre- and postresults together. This means that the treatment group may have had a lower baseline RTQ than the control group. Figure 8 visualizes these results.

To further investigate the difference between pre- and postlevels of RTQ in both conditions, we conducted a complementary paired sample for each group. In the treatment group, RTQ scores increased significantly from pre- to postintervention (pre: mean 4.37, SD 1.36; post: mean 5.67, SD 2.62; t_{26}=2.72; *P*=.01), with a medium effect size (Cohen *d*=0.52). Conversely, the control group showed no significant change (pre: mean 4.95, SD 1.51; post: mean 5.00, SD 1.83; t_{18}=0.11; *P*=.91; *d*=0.03).

XSL•FO
RenderX

A post hoc power analysis based on the observed effect size (d=0.52) and sample size (n=27) indicated a power of 0.74 to detect the change in RTQ, which is close to the conventional threshold of 0.80 [64]. This suggests that while the study may be slightly underpowered, the observed effect is meaningful and warrants further investigation with larger samples.



Taken together, these results cautiously support hypothesis 1: ambient gamification through the Smokwit device may help increase RTQ among young adults; however, future studies with larger samples are needed to confirm the robustness of this effect.

Table 6. Results of the mixed linear model regression on readiness to quit scores.

Effect	Coefficient b (SE)	*z* score	*P* value	95% CI
Intercept	7.69 (2.03)	3.78	<.001	3.71 to 11.66
Time (post)	0.05 (0.53)	0.10	.92	–0.99 to 1.09
Treatment	–1.09 (0.55)	–1.97	.049	–2.16 to –0.01
Treatment over time (interaction)	1.33 (0.70)	1.91	.06	–0.03 to 2.70
Number of quit attempts	0.60 (0.16)	3.81	<.001	0.29 to 0.91
Age of smoking start	–0.09 (0.11)	–0.81	.42	–0.30 to 0.13
Smokes daily	–1.07 (0.54)	–1.99	.047	–2.12 to –0.02
Sex (male)	0.68 (0.42)	1.63	.10	–0.14 to 1.49
Age	–0.04 (0.02)	–1.83	.07	–0.08 to 0.00
Group variance	0.45 (0.34)	—[a]	—	—

Qualitative Analysis (Hypothesis 2a and Hypothesis 2b)

Overview

To gain additional insights into the user experience with Smokwit, we conducted interviews with 10 participants and 7 smoking cessation experts. We conducted semistructured interviews with 10 participants (Participant 1-Participant 10) from the treatment group between 6 and 9 months after the end of the study. These interviews focused on four key themes: (1) interactions with the ashtrays, (2) self-reflection, (3) peer support, and (4) user feedback. The discussions explored participants' memories of the study, including their interactions with the ashtrays, the system, and other smokers, as well as their smoking habits and suggestions for improving the intervention. Additionally, we presented our project at the Swiss Association for Tobacco Control (AT Switzerland) Conference 2024, where we collected feedback from 7 smoking cessation experts (Expert 1-Expert 7) on our system.

We followed a qualitative data analysis via a general inductive approach [66]. Interviews were audio-recorded, transcribed uniformly, and reviewed multiple times to identify recurring patterns and derive significant themes.

Ashtrays Interactions

The interviews revealed that participants found the Smokwit ashtrays' questions engaging, particularly at the beginning of the intervention. Participant 1 remarked, "I liked these questions, not all of them, but often, they were funny. They made me laugh," highlighting the positive reception to the reflective prompts. Participant 3 also described the questions as highly

XSL•FO
RenderX

engaging and innovative, noting how they encouraged smokers to reflect on their habit. Similarly, Participant 4 appreciated the weekly changing questions, which sparked curiosity and led to meaningful reflections on smoking habits. The gamified and humorous design of the questions was central to sustaining participants' interest and stimulating self-reflection. Participant 5 highlighted the ashtrays' visibility, noting their "super visible yellow" color, which made them accessible and noticeable on campus. Participant 9 and Participant 8 also remarked on the ashtrays' appealing design, describing it as "hard to miss" and "innovative and engaging, especially during the initial weeks of use." The ashtrays managed to attract attention beyond smokers, as Participant 3 observed, "We were all going to see the question, even non-smokers were going to see." However, this broad appeal diminished over time as the novelty wore off, as Participant 3 noted, "At first, it was attractive, but afterward, I think they didn't change the questions every day." Practical challenges, such as crowding during peak hours, also reduced engagement, as Participant 10 explained, "The voting process sometimes felt crowded, which could have discouraged participation." Experts empathized with the nonintrusive nature of the ashtrays, noting their passive presence in smokers' environments. Expert 2 remarked, "I like the passive side of the object. It is present in the smoker environment, but it is not intrusive," which allowed participants to engage without feeling pressured. Expert 1 highlighted the ashtrays' potential for workplace deployment, suggesting that companies could use them to gather data and justify targeted interventions. Expert 6 further noted, "Smoking prevention centers would be able to use these ashtrays as an extra tool prior to traditional in-person meetings and hold discussions on various subjects depending on the information gathered." Expert 7 recommended testing the ashtrays in public spaces such as bus stops to evaluate their effectiveness in diverse contexts, "It could be interesting to test it on bus stops also." These suggestions highlight the flexibility of intervention design for alternative environments. Despite challenges such as diminished novelty and logistical issues, the intervention successfully sparked curiosity and reflection among participants. The ashtrays' design and passive approach made them a versatile tool, with potential apps extending beyond individual behavior changes to organizational and community contexts.

Self-Reflection

The interviews revealed that the Smokwit system fostered self-reflection, disrupting habitual smoking behavior. The questions posed by the ashtrays prompted smokers to think more critically about their habits. As Participant 1 remarked, "it (ashtray) makes you think, yes, think about what you're doing," while Participant 2 emphasized, "It makes smoking more conscious." These prompts heightened awareness and occasionally sparked discussions about the broader implications of smoking, as observed by Participant 10. Participant 4 highlighted the intervention's dual impact, stating, "It's true that these are not necessarily reflections that we usually ask ourselves." By encouraging such reflections, the ashtray helped participants reconsider their behaviors and the broader implications of their smoking habits. Participant 3 acknowledged, "It (ashtray) told me even more that I should quit smoking," suggesting that while the ashtrays did not directly reduce smoking, they reinforced the motivation to stop. This indicates that the intervention planted seeds of change, providing a foundation for future behavior modification. The gamified aspect of the ashtrays, such as combining playful and thought-provoking questions, further stimulated self-reflection. As Participant 10 remarked, "I liked the fact that it was a bit playful. And then, it made us think, so they were surely good questions." However, Participant 6 noted that without frequent updates, the questions became less relevant over time. Participant 2, who initially felt uncomfortable with the ashtrays' focus on her smoking habit, engaged indirectly through discussions with colleagues who had interacted directly with the system. Even by indirect engagement, her smoking became more conscious, demonstrating the ashtrays' broader impact on mindfulness. Although participants reported limited immediate changes in their smoking behavior, the intervention reinforced awareness and the desire to quit. Experts emphasized the ashtrays' ability to disrupt smoking rituals, prompting deeper reflection. Expert 3 explained, "Smoking is seen by smokers as a ritual. Intervening during the ritual is absolutely fantastic and has, in my opinion, great potential. It also breaks the routine." External stressors, such as life challenges and academic pressure, influenced participants' engagement with reflective prompts. Participant 3 mentioned going through a particularly difficult period, which may have impacted both smoking habits and engagement with the ashtrays: "We've always got excuses, so you had put them (ashtrays) in July, you had put them in whenever. It would all be the same. I had a lot of problems at that time, it would not change anything," highlighting the impact of personal difficulties on the intervention's effectiveness. Participant 7 similarly emphasized, "Quitting is harder than reflecting, it's the execution that counts." Additionally, Participant 5 pointed out that academic stress often led students who did not normally smoke to resume during high-pressure periods, such as examinations. These insights suggest that while immediate behavior change was limited, the intervention laid the foundation for future efforts by increasing awareness and prompting critical self-reflection. By encouraging smokers to think more critically about their habits, even amid external stressors, the Smokwit system shows promise as a long-term catalyst for change. These findings provide some qualified support for hypothesis 2a.

Colocated Peer Support on Smoking Hotspots

Our results show that the Smokwit system fostered peer support and facilitated meaningful discussions among smokers. The intervention encouraged conversations about smoking cessation, helping smokers build a support network. Participant 1 shared, "We talked a little about our experiences. Of our attempts to quit," illustrating how the ashtrays encouraged smokers to share their personal experiences and reflections. The gamified elements of the ashtrays, such as the changing questions and the visible, playful design, served as conversation starters, breaking down barriers and making it easier for smokers to engage with one another. According to Participant 10, the ashtrays "sparked meaningful debates among colleagues about smoking," while Participant 9 noted, "The ashtrays encouraged casual debates among smokers, sometimes involving

XSL•FO
RenderX

non-smokers too." These interactions fostered a sense of community, as observed by Participant 4: "And then the interactions we can have with the smokers around." Experts emphasized the strength of leveraging smoker communities for behavior change. Expert 3 explained, "A smoker community is felt by the smokers as an entity. Acting in the community itself is a real strength of the project. Smokers in the community will talk with each other and are influenced by each other." Expert 6 suggested that the ashtrays could be deployed in workplace settings to facilitate discussions before formal interventions, stating, "Smoking prevention center could use these ashtrays to promote dialogue around smoking behaviors and cessation efforts prior to in-person meetings." Expert 7 proposed that using ashtrays over an extended period before interventions would help target those most willing to engage in cessation programs. The ashtrays promoted social connections and collective reflection, creating a supportive environment, which encouraged participants to reconsider their smoking habits. Participant 4 mentioned that the ashtrays often led to small debates, reinforcing the collective effort to rethink smoking behaviors. Similarly, Participant 3 observed that both smokers and nonsmokers were drawn to the ashtrays, leading to some level of interaction and conversation, although this later declined as the novelty wore off.

By facilitating conversations and fostering social connections, the Smokwit system showed potential in influencing attitudes concerning smoking within the campus community. These findings suggest that the intervention not only supported individuals but also laid the groundwork for a more collaborative approach to addressing smoking habits, providing some qualified support for hypothesis 2b.

User Feedback

Participants offered valuable suggestions for improving the Smokwit intervention. Participant 1 and Participant 10 proposed extending the playful voting system using cigarette butts, which Participant 10 described as "a simple yet engaging mechanism." Participant 9 and Participant 5 proposed expanding the forum functionalities by creating a dedicated space for smokers to log their reflections digitally, emphasizing that "a platform for shared experiences could boost long-term involvement." Participant 9 suggested enhancing engagement by offering rewards following interactions with the ashtray, such as displaying live statistics not only within the mobile app but also directly on the ashtray screen. To keep the content relevant, Participant 3 highlighted the importance of updating questions more frequently and incorporating humor. Technological challenges with the app were sometimes a concern. Participant 6 and Participant 1 experienced difficulties scanning QR codes due to outdated smartphones, while Participant 7 and Participant 8 preferred direct interactions with the ashtray over using a QR code. Participant 7 noted, "Taking out the phone and scanning the QR code, even if it's only two minutes, can be a hindrance," and Participant 8 added, "Interacting directly with the physical object would be more immediate and engaging." Experts recommended tailoring ashtray questions to different stages of behavioral change and integrating self-management tools. Expert 1 remarked, "It could be a good idea to have a similar kind of artifact for sugar and alcohol but also other forms of tobacco/nicotine consumption." Expert 5 highlighted the value of deploying ashtrays in diverse settings, such as universities, to compare results across demographic groups, noting, "I would like to have this ashtray at the university where I work to compare the results between different types of cultural backgrounds." Both participants and experts offered constructive feedback for improvement, offering a clear path for refining the Smokwit intervention. By addressing these technological opportunities and incorporating feedback, future iterations of the Smokwit intervention can become more engaging and impactful.

Discussion

Principal Findings

The results provide tentative support for the fact that including a gamified ambient object—a connected voting ashtray—at a smoking hotspot visited by young adults can complement existing evidence-based interventions and lead to increased RTQ among this demographic. Our findings align with previous research, which shows that simple interventions can potentially yield positive results [6,34]. Our controlled quasi-experiment results indicate a potential tendency for participants in the treatment condition to progress from the precontemplation to the contemplation stage, which could potentially lead to an increase in RTQ compared to the control condition (hypothesis 1). This tentative result may represent an early indication of the intervention's potential to motivate change in young smokers, though its significance needs investigation in larger samples. While previous research has shown promise for in-person interventions at the smoking hotspots to leverage the act of smoking as an opportune moment to incentivize change [45], our research extends these findings by showing that ambient objects could be used as transitional devices. Although this study extended over 3 months and included follow-up interviews at 6 and 9 months, future research should aim to replicate and extend these findings in studies with longer durations and larger sample sizes. This would help clarify the role of novelty effects, the influence of community dynamics, and participants' ongoing progress in the smoking cessation journey. Building on our work, future studies could also use path analysis to test the underlying conceptual model and examine both direct and indirect effects of the intervention components.

Characteristics of the Target Population

The Smokwit intervention focused on young adults, aged 18 to 35 years, an important and understudied demographic. Indeed, smoking initiation often occurs before 21 years [17], and young adults tend to remain in the precontemplation stage longer due to lower perceived risks [45]. By embedding gamified ashtrays in habitual smoking environments, the intervention facilitated reflection and dialogue without requiring formal participation. The gamified intervention was tailored to young adults with gamification and fun poll questions, which were appreciated by participants. Although the study targeted young adults, participants older than 35 years of age were not excluded, reflecting the diversity of real-world smoking environments.

In our qualitative analysis, stress emerged as a key influence on smoking behaviors, with participants citing academic

XSL•FO
RenderX

pressure and personal challenges as triggers. This is aligned with previous findings, which list smoking urges and stress as smoking triggers [67,68]. Participants often indicated that life challenges, such as academic or personal stress, played a role in their smoking patterns and their engagement with the intervention. Future work could aim to better understand the role of stress in the outcome of such interventions and how they could be designed to better cater to this characteristic.

Ambient Interaction

Interaction analyses and interviews shed light on the mechanisms, which led to this outcome. First, the connected ashtrays, with their thought-provoking questions and gamified features, led participants to engage with the digital material by scanning the QR codes. The qualitative data suggest that the engagement with the ambient object played a critical role in raising awareness about smoking behaviors and encouraging self-reflection (hypothesis 2a). This aligns with previous research in other contexts, which showed the use of an ambient object to transition from physical to digital environments [24]. This also aligns with literature suggesting that behavior change apps should be designed to give users maximum control over their level of engagement and disengagement [69]. In this study, the Smokwit ashtray acted as a passive entry point into the digital intervention. Participants did not need to sign up or commit to a program to begin reflecting on their behavior. Instead, smokers encountered provocative, low-effort prompts in a familiar space, which encouraged casual interaction. This dynamic encouraged ongoing self-assessment, even among those not actively seeking to quit, and appeared to contribute to increased RTQ over time. This approach differs from typical behavior change apps, which rely on continuous digital engagement [70]. In Smokwit, a minimal physical interaction, voting with a cigarette butt, initiated a reflective process and offered a seamless path into digital support. Future research could investigate how to deepen these interactions directly at the smoking hotspot. For instance, integrating chatbots into the ashtray's interface could increase playfulness and interaction while reducing friction to access self-help material [59]. Moreover, they could contribute to increasing emotional attachment to the system and potentially motivation to change behavior [71]. One participant mentioned that even though she felt the intervention was positive in the end, it could come across as moralizing. This could be problematic, as it might create reactance and backfire [72]. Future work should clarify how widespread this feeling is and how design strategies can mitigate unintended negative effects.

Sense of Community

Our findings align with previous literature, supporting that engagement in digital smoking cessation communities is positively associated with the process of change [8]. While face-to-face peer groups have long been recognized as effective for fostering behavior change [32], this study extends that understanding by demonstrating the unique value of spontaneously formed, physically colocated peer groups. These groups emerge naturally at smoking hotspots, therefore eliminating the need for individuals to actively register or join formal programs. By delivering the intervention directly to smokers in their habitual environments, this approach reduces many of the typical barriers associated with participating in structured peer-support programs and leverages a gamified, spontaneous design to encourage engagement. Smokers may find it easier to make changes in their own lives if they are encouraged to share their experiences in digital communities dedicated to quitting smoking [8], but also in real-life, directly at the smoking hotspot. The ashtrays not only facilitated individual self-reflection but also promoted social interactions among smokers (hypothesis 2b). The gamified questions functioned as conversation starters, enabling smokers to discuss their experiences and challenges in real time, directly at the smoking hotspot. This sense of community fostered through the intervention may have reinforced participants' RTQ by providing social support, an essential component in the process of behavior change [6]. Initiatives such as Weight Watchers have shown that "the magic of the meeting" has long been seen as an effective means of enhancing behavior [32]. Future work should explore how these spontaneous peer groups could be sustained over longer periods and investigate the mechanisms underlying their formation and effectiveness. Additionally, future research could examine the interplay between the various components of this intervention, including the app, forum, information, and ambient devices, as well as the influence of the implementation context. The context in which the intervention is deployed may mediate the sense of community it fosters, which is critical for its success [73].

Implications for Practice

Smokwit facilitated discussions among campus smokers about the intervention and, to some extent, quitting smoking. The physical-digital integration, combining ashtrays at smoking hotspots with a mobile app, engages young smokers in both physical and digital environments. This approach increases accessibility and encourages spontaneous peer support by enabling interactions at familiar locations while providing digital resources and community forums without time and space limits. Moreover, it also improved the RTQ.

The findings from this study, informed by participants' experiences and smoking cessation experts' feedback, suggest several practical strategies for designing and implementing smoking cessation interventions. First, embedding interventions in habitual environments, such as smoking hotspots, fosters spontaneous peer groups. This approach encourages immediate social support and organic discussions about smoking behaviors. Second, tailoring intervention content to align with different stages of behavioral change enhances relevance and effectiveness, particularly when paired with gamified elements, which sustain engagement. To address varying user preferences, digital tools such as web platforms for sharing reflections can complement physical interventions and encourage long-term involvement. Experts highlighted the ashtrays' passive and accessible design, which reduces barriers to participation and makes them suitable for diverse settings, including workplaces, bus stops, and public spaces. The ashtrays' ability to collect data while engaging participants underscores their potential for broader applications in other contexts. These insights emphasize the importance of integrating interventions into users' daily routines and combining physical and digital elements to

XSL•FO
RenderX

maximize accessibility and impact. Future research could further explore how such an intervention could leverage context particularities to increase engagement. For instance, research could investigate if social mechanisms such as competition between groups or reciprocity could be used to foster higher peer support or a sense of community around a digital intervention. Such refinements could improve RTQ and deepen the intervention's long-term impact.

Limitations

This research is not without limitations. First, as with other experiments performed in the wild over several months, sample decline and potential differences between conditions (campus 1 and campus 2) might be beyond the researchers' control. To address these sample differences, we controlled demographic characteristics such as age and sex in the analysis. However, other factors may still have influenced the outcome. Second, the intervention included several aspects of gamification, such as initial prompts (the poll questions), a treasure hunt feature (finding other ashtrays), and status (the XPs), making it challenging to isolate the effects of individual components. Third, while the ashtrays initially attracted significant attention, engagement declined over time. The reason for this cannot be clearly identified because it could be due to the waning of the novelty effect or lower smoking activity during cooler months to name 2 potential reasons. Future studies could aim to better understand optimal timing and durations for such interventions. Finally, external factors such as personal challenges and academic stress further moderate the intervention's effectiveness on smoking behavior. The postintervention interviews demonstrated that the Smokwit ashtrays positively affect smokers' awareness and social interactions regarding smoking. Although the immediate impact on smoking behavior was limited, the intervention raised consciousness concerning smoking habits and sparked discussions about quitting, providing a foundation for future enhancements, which could further amplify the intervention's effectiveness and reach. It is important to note that the higher education context of the study may limit generalizability, because participants were more likely to adopt technology than the general population. Finally, the RTQ scale relied on self-reported data, which may be subject to social desirability bias. Additionally, the postsurvey timing at the beginning of the year, from January 17 to March 5, 2024, coincided with the "New Year's Resolution" effect, which may have inflated RTQ scores. While these overestimations likely affected both conditions similarly, it cannot be excluded that one condition was more susceptible to these biases than the other.

Conclusions

In this study, we investigated how a gamified ambient intervention called Smokwit deployed directly at a smoking hotspot could help smokers progress at the early stage of their smoking cessation process. This is a crucial public health issue, as this demographic represents the largest tobacco consumer base. Our approach was designed to complement existing evidence-based interventions and act as an entry point toward self-help material and peer support. We designed gamified voting ashtrays, which would engage smokers at the smoking hotspot and lead them to discuss with each other and access digital material, leading them to increase their RTQ. The qualitative results of our field experiment showed that the intervention did indeed foster digital interaction and discussions among peers. Furthermore, our quantitative analysis provided preliminary evidence that smokers in the intervention condition may have experienced a greater increase in RTQ, more than those in the control group, although the statistical strength of this observation remains limited. Overall, these findings are encouraging and indicate that well-designed digital interventions can potentially act as important complements to existing interventions, driving significant behavior change and promoting healthier lifestyles within the campus community. Despite encouraging trends, the study's limited power necessitates cautious interpretation of the results. These preliminary findings should be confirmed in future trials with larger and more balanced samples.

Abstract

Background: In-hospital fall prevention is a complex phenomenon most efficiently addressed via a wide range of multifactorial interventions. Technology may contribute, but research in this field has so far mainly focused on detecting falls. As a result, new knowledge from a system perspective is needed regarding when and how new technologies may support fall prevention among patients who have been hospitalized.

Objective: This study aimed to explore and describe clinical practices in an acute orthopedic hospital ward for fall prevention from a system perspective; determine the needs and possibilities related to support for clinical practices for fall prevention; and test whether a framework for studying interactions between people, activities, contexts, and technologies can be used to support observations of complex phenomena such as clinical fall prevention.

Methods: This qualitative study followed the principles of human-centered design while combining focused ethnography with a workshop. Eight health care professionals representing different staff categories in an acute hospital ward of an orthopedic clinic participated in on-site interviews or were observed in their clinical practice. Data from these events were subjected to qualitative content analysis to describe the clinical practices for fall prevention observed in terms of people, activities, context, and tools. In a workshop, a larger group of clinic personnel provided their views on fall prevention, described the activities and tools they observed to prevent falls, and discussed needs for further support.

Results: This study determined that health personnel considered fall prevention in all their interactions with patients, which included a wide range of activities for fall prevention wherein staff categories played complementary roles. These staff-patient meetings were goal oriented, responsive, and patient centered. The staff often served as key “tools” in assessment, communication, and coaching, while digital tools (mainly computer-based software programs) were used for information retrieval, documentation, and communication. The personnel worked to prevent patient falls both during hospitalization and after discharge. They believed that the long-term perspective was much more difficult to address in their clinical practice, and they expressed a need for more homelike environments in the hospital.

Conclusions: The view on technology-based in-hospital fall prevention can be broadened not only to mainly include monitoring and alarm systems, information systems in general, or computer-based information in particular systems but also to support activities performed by health personnel that engage patients in fall prevention. For example, tools such as these can be implemented in training involving daily activities and mobility within safe yet more homelike clinical contexts.

falls; prevention; hospital; technology; interaction

Introduction

Background

Falls are the most common adverse event reported in hospitals [1,2]. In-hospital falls may be effectively prevented by multifactorial interventions, but this may apply mostly to a subacute setting [3], and the interventions' content can vary widely [4]. Home hazard minimization has been proven to reduce the number of falls among older patients recently discharged from hospitals, particularly if they had a history of recent falls [5]. However, interventions effective in preventing falls among older adults in general are not automatically transferable to this group [5]. So far, research on technology-based fall prevention [6] has mainly focused on systems for older adults living in the community [7] and resulted in few implementations in real-world situations. A systematic review of health technologies, which are defined as "...the application of organised knowledge and skills in the form of devices, medicines, vaccines, procedures and systems developed to solve a health problem and improve the quality of lives" [8], identified that highly heterogenous multicomponent or multifactorial interventions were most common in hospital settings, followed by technical devices to detect falls [9]. A few examples of fall detection technologies have been tested with patients [10-13], but most of them were emerging technologies that had not yet been tested on patients beforehand [9]. Nevertheless, an artificial intelligence–based motion alarm that notifies health personnel of fall risk situations has recently proved promising for in-hospital fall prevention [14]. To enable new complementary fall prevention technologies to evolve, a system perspective on fall prevention is needed.

Prior Work

Previous studies on in-hospital fall prevention from a system perspective include the literature review by Taylor and Hignett [15], which analyzed risk factors and interventions to prevent in-hospital falls based on human factors and ergonomics. This review also presented a model describing the complex interplay between organizations, people, and environments related to in-hospital fall prevention [15]. The importance of human factors and ergonomics in the design of health care environments to support well-being and high performance has also been advocated by Hignett [16] and Hignett and Masud [17]. Through ethnographic observations and interviews of older persons on the subject of orthopedics in hospital wards, Mcvey et al [18] studied interactions between hospital staff and patients who have been hospitalized with cognitive impairments to engage patients in fall prevention. Mcvey et al [18] determined that patients who engaged with staff regarding fall prevention were able to express their needs and, to a certain extent, collaborate with the staff on fall prevention. The positive impact of patient and care team partnerships regarding fall prevention was also observed by Dykes et al [19] in their evaluation of the tailored prevention of inpatient falls tool. This tool, whose usability and patient centeredness have been improved in an iterative user-centered design process [20], clearly illustrates the importance of human factors in fall prevention. Similarly, Bianco et al [21] determined that insufficient dialogue with older adults about their personal goals results in the development of stigmatizing solutions for fall prevention that will not be accepted and implemented by the older users. Older adults' experiences and perceptions of digital technologies for home-based fall prevention have also been investigated in a field study by Ogonowski et al [22]. This study concluded that the self-monitoring of results and self-assessment of fall risks made the system valuable and motivating for the users and that the successful integration of the system into daily life could increase the users' quality of life, technical confidence, and awareness of measures for fall prevention [22].

The system perspective is also essential in human-centered design (HCD), which supports systems design based on human needs and functions from a holistic point of view [23]. HCD has been widely used in health research and innovations [24], such as in systems designed to prevent falls by assessing a person's balance [25] and fall risk [26]. An essential part of HCD is developing activities to understand and specify the context of use, defined as "the combination of users, goals and tasks, resources and environment" [23]. Therefore, holistic studies of humans in their natural settings based on ethnographic principles are common in HCD [27]. Because ethnography is useful for producing detailed descriptions of phenomena, the method has also been suggested as suitable for health care research [28,29] and health care improvements [30]. Focused ethnography is a type of ethnography that studies specific aspects of field work such as interactions and activities; compared to classical ethnography, it typically involves shorter field visits, more extensive data and analysis work, and a greater focus on communicative activities [31]. This approach has been used to study older adults' and their children's perceptions of fall risks [32]. Workshops are another method commonly used in HCD for creating a common arena, enabling participants to discuss issues from different perspectives and areas of competence to develop a common experience within a complex phenomenon [33]. Workshops are widely used in health care innovation [34] and have been used by McKenzie et al [35] to support interprofessional learning to reduce the number of falls experienced by older adults. McKenzie et al [35] reported that their workshop participants believed the workshops provided them with the confidence to implement the fall-preventive practices presented and discussed in the workshops.

Purpose of This Study

The three objectives of this study were as follows: (1) to explore and describe the clinical practices for fall prevention in an acute orthopedic hospital ward from a system perspective; (2) to determine the needs of patients and the possibilities of further supporting clinical practices for fall prevention; and (3) to test whether a framework for studying interactions between people, activities, contexts, and technologies (PACT) can be used to support observations of complex phenomena such as clinical fall prevention.

XSL•FO
RenderX

Methods

The methods used in this study have been reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Studies) guidelines [36].

Study Design

Because this study aimed to provide a detailed description of clinical practices for fall prevention, it had a qualitative research design based on HCD principles [23], signifying that it combined holistic studies of humans in their natural settings via focused ethnography [31] and a workshop [34].

Theoretical Frameworks

PACT Framework

The PACT framework supports the analysis of people who use innovative technologies or tools, the activities that these people are willing to undertake, the contexts in which these activities take place, and the key features of meaningful innovative technologies [37]. PACT analyses have been used to transfer design knowledge from non–health care domains to health care to increase the usefulness of health care information systems [38].

Activities to Prevent Falls

Due to the well-documented need for effective strategies to prevent falls among inpatients during their high-risk hospital-to-home transition [39-41], this study included activities to prevent falls during the patients' hospital stay and the hospitals' efforts to prepare inpatients to take an active role in fall prevention after their discharge. On the basis of the clinical practices and guidelines recommended for Swedish caregivers and health care personnel [42,43], evidence-based methods to prevent in-hospital falls [44], and activities aiming to increase the patients' possibilities to implement fall prevention actions at home [45] after their hospital discharge, this study has defined "activities to prevent falls" as the following:

- Fall risk assessments (related to fall histories, hospital personnel's overall assessment, clinical instruments, and aspects related to the fall prevention activities mentioned subsequently)
- Fall prevention activities (related to medication, cognitive impairment, nutrition, care environment, physical exercise and mobilization, mobility aids, bathroom visits, and personal hygiene)
- Documentation regarding fall risks and fall prevention activities (from previous care providers regarding patients considered to be at risk, risk activities, risk moments, and any fall risk mentioned in a patient's health record)
- Informational activities (regarding the fall risk of patients considered to be at risk as well as handover)
- Activities supporting patients' physical activity and home modifications to prevent falls after hospital discharge

Ethical Considerations

On the basis of the Swedish Act Concerning the Ethical Review of Research Involving Humans, the research in this study (ethnography and workshop) did not require ethical vetting. An application for the ethical review of the ethnographic work was submitted to the Swedish Ethical Review Authority. The written decision from the authority (Dnr 2022-05412-01) confirmed that this research did not require ethical vetting, and the authority stated that it did not see any ethical difficulties related to the research. All the research performed in this study was conducted in accordance with good research practices. The persons interested in participating in the clinical observations and on-site interviews received oral and written information about the study, and informed written consent was collected from all participants before their participation. The workshop participants received oral and written information through a Microsoft PowerPoint presentation before completing the questionnaire and provided written consent on the questionnaire to participate in the research.

Research Setting

This study was performed in an orthopedic clinic at a hospital located in a medium-sized Swedish city with approximately 150,000 inhabitants. The clinic performed pre and postoperative rehabilitation and outpatient and inpatient care, including elective and acute surgical operations. The ethnography was conducted at the clinic's acute hospital ward, and the user workshop was held during a seminar open to staff from the entire clinic. The study was performed by ME, a researcher in medical and health technology with expertise in user-centered development. ÅR, a researcher in physiotherapy also working at the orthopedic clinic, and HT, a human-computer interaction researcher, participated in peer debriefing. Both had clinical experience as physiotherapists. All 3 researchers are female.

Participants and Recruitment

Participants in Clinical Observations and On-Site Interviews

The 8 participants came from the approximately 100 health care workers in the acute ward (Table 1). They had been recruited according to principles of purposive sampling, combining criterion-based (personnel active in fall prevention within a specific clinical setting) and stratified purposeful (personnel representing a variety of staff categories) sampling strategies [46]. The participants represented the following staff categories: assistant nurse, clinical pharmacist, nurse, occupational therapist, physician, and physiotherapist. One of the nurses was a discharge coordinator. The study aimed to recruit at least 1 person per staff category and cover both morning and afternoon shifts.

XSL•FO
RenderX

Table 1. Data collection events and participants.

Events specified by consecutive number	Participants	Time
Clinical observations		
1	Physiotherapist and occupational therapist	Morning
2	Assistant nurse	Afternoon
3	Nurse	Afternoon
4	Nurse	Morning
5	Physician	Morning
On-site interviews		
6	Clinical pharmacist	Morning
7	Discharge coordinator	Morning
Workshop		
8	Representatives of several health care occupations (refer to the Workshop Participants subsection)	Lunch

To recruit participants, ME presented the study at staff meetings and on the clinic's intranet. Thereafter, she booked appointments with 5 interested staff members by email and found 3 interested staff members while visiting the ward to see if any health personnel would volunteer to be observed.

Workshop Participants

The participants were clinical staff members who attended a research seminar at the orthopedic clinic and filled in a questionnaire. The participants represented the following health occupations: assistant nurse, health counselor, medical secretary, nurse, occupational therapist, physician, and physical therapist.

Data Collection and Curation

Overview

An overview of the data collection events and their respective participants is presented in Table 1. The methods used in each event are thoroughly described subsequently. The clinical observations and on-site interviews were performed from February to May 2023, and the workshop was held in November 2023.

On-Site Observations and Interviews

On-site observations of health personnel were performed on 5 different occasions (Table 1). Each time, a researcher followed 1 or 2 participants for 2 to 4 hours to observe them during routine patient care. Apart from the participants' health care occupation, no personal information was collected from any of the persons observed. Instead, general types of attributes relevant to the persons' involvement in fall prevention activities were observed along with any attributes the health care personnel discussed and considered in their work with patients. The observations were documented via written notes in a structured protocol that recorded the activities observed to prevent falls, any other persons involved, and the context in which the activities took place (Multimedia Appendix 1). At the end of each observation, the researcher asked the participant a few questions regarding whether something unusual had happened or the person had done anything more or less than usual during the shift; whether the person had used any specific templates or forms to provide or receive a report before, during, or after the shift; and whether the person would like to correct or add something to the researchers' observational notes by following a brief interview guide (Multimedia Appendix 1). Of the 8 health care personnel, 2 (25 %) who worked in an office participated in unstructured on-site interviews for 60 to 90 minutes instead of the observations (Table 1). These interviews focused on the same aspects as the observations. All the interviews were documented through written notes. Audio recordings were avoided to help participants feel more at ease. Before the first observation, the researcher examined an empty patient room and used the observation protocol to document what they saw via photos and written notes. After each observation (the same or following day), the researcher wrote down their reflections, ideas, and questions in notes, which were later transferred to the observation protocol. Thereafter, the researcher prepared a text integrating the observational data and their own reflections (based on the protocol), the interview data, and any additional information that they recalled during the writing process.

Workshop

Data were collected during a research seminar for the entire orthopedic clinic's staff. The seminar included presentations of 3 projects, of which 1 was the ethnographic work from this study The presentation of our ethnographic work provided a brief background on in-hospital fall prevention and current research regarding supporting technologies; the study's approach, aim, expected results, and methodology; how the researcher defined the "activities used to prevent falls" in the study; the potential benefits of staff participating in the study; and the clinical observations. Next, the researcher presented the preliminary results regarding the observed activities that the respective health professions implemented to prevent falls, as well as the tools used during these activities. Finally, the researcher introduced the workshop approach, which included group discussions on the 3 questions related to the staff's views on the definition of "activities to prevent falls" and how these activities contribute to preventing falls both in the short and

XSL•FO
RenderX

long term; whether adjustments were needed in the presentation of in-hospital activities to prevent falls as well as the tools supporting the activities; and what may be needed to further develop any aspect of the activities, context, or tools to further improve the work to prevent falls (Multimedia Appendix 2). Participants were also invited to contribute their own responses to the research by providing written consent and submitting the completed forms to the researcher.

Data Analysis

On-Site Observations and Interviews

A qualitative content analysis was performed based on principles described by Elo and Kyngas [47] using Microsoft Excel as the software tool for the categorizations. All descriptive texts integrating the observational and interview data, as well as the researcher's own reflections for each individual observation and on-site interview, were first analyzed separately in an unconstrained categorization matrix based on PACT [37]. In this adaptation, the category "tools" was used in place of "technology," as originally defined in the PACT model. ME, who was familiar with the material from data collection and curation, read the running text and coded phrases based on their content as people, activities, contexts, or tools. Data categorized as people and context were further categorized into health personnel; patients; external people; and organizational, social, and physical environment, respectively. Data from the people and context subcategories, as well as the tools and activities categories, were analyzed following principles of inductive content analysis [47]. Thereafter, the main and subcharacteristics of the matrix elements related to people, contexts, and tools from all observations and interviews, as well as from the activities of all health care occupations, were reviewed and integrated by ME, who subsequently wrote new descriptive texts for all characteristics in the individual matrix elements. ÅR and HT, who had not been involved in data collection or curation, participated in peer debriefing, during which they gave their views on the descriptive texts, coding, and categorizations, as well as the overall analysis process [32,48]. The activities from each health care personnel category were visualized, and information on the type of tool used in specific activities was added to the visualizations. In some cases, the titles and structures of the categorization's main and subgroups were modified during the writing process.

Workshop

Free-text answers from the groups on the open-ended questionnaire were summarized in a table. The answers were read and discussed by all the authors.

Strategies Used in the Study to Achieve Trustworthiness

Overview

The strategies this study applied to achieve trustworthiness are described subsequently and based on the parallel criteria for trustworthiness in qualitative research developed by Lincoln and Guba [49], who recommend applying strategies to qualitative research that better achieve their 4 criteria for trustworthiness (credibility, transferability, dependability, and confirmability). Application of the 4 criteria by Lincoln and Guba [49] in qualitative research has been reported by other researchers, for example, by Enworo [50] and Forero et al [51].

Credibility

This study applied the following strategies to achieve credibility: *prolonged and varied engagement with the setting*, by ME visiting the clinical environment on several occasions over several months during different activities; *in-method triangulation*, by integrating observations, interviews, and the workshop; *data source triangulation*, by involving personnel representing different staff categories within different settings at the orthopedic clinic; *peer review*, with ÅR and HT reviewing data, analysis process, and the result; and *member check*, which was performed through the brief interviews at the end of the observations and the workshop, during which the study findings were presented and discussed with a broader group of health personnel.

Dependability

To achieve dependability, this study applied the following 2 strategies: *rich description of study methods*, as reflected in the methods description guided by the COREQ checklist [36], and *member check* (refer to the description mentioned earlier under the Credibility subsection).

Confirmability

To achieve confirmability, this study applied 2 strategies: *reflexivity*, via ME's self-reflections after each observation and on-site interview, the researchers' common reflections in the peer review meetings, and the workshop participants' reflections on the study results presented; and *triangulation* (refer to the description mentioned earlier under the Credibility subsection).

Transferability

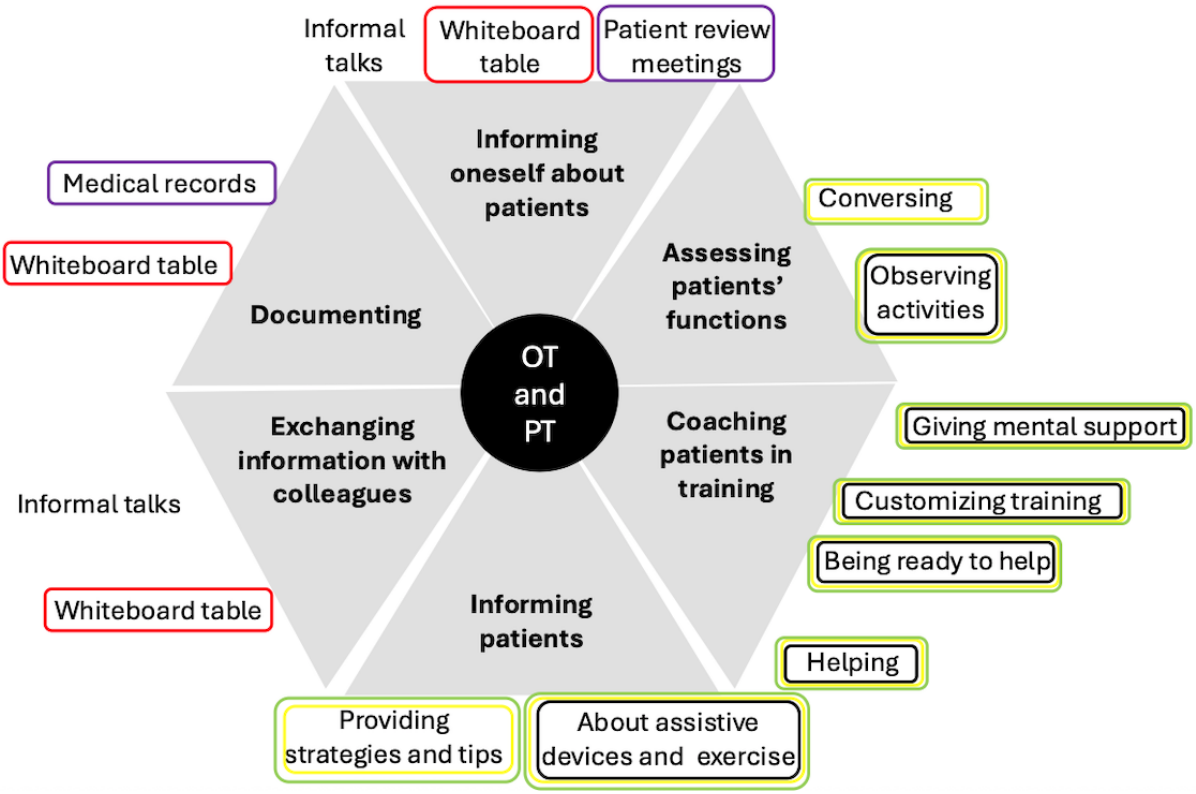
To achieve transferability, this study applied the 2 strategies: *purposeful sampling*, by combining criterion-based (personal active in fall prevention in a specific clinical setting) and stratified purposeful (personal representing a variety of staff categories) sampling strategies, and *thick description*, in which the integration of data collected from several sources (observations, interviews, reflections, and the workshop) on several different occasions contributed to a rich and detailed description of in-hospital fall prevention.

Results

Clinical Observations and On-Site Interviews

People

The people involved in activities to prevent falls were health personnel, patients, and external persons. Main and subcategories are presented in Multimedia Appendix 3. The clinical practices implemented by individual members of the *health personnel* depended on which health occupation they were licensed in, their amount of clinical experience, whether they held specific positions in management or coordination, and their individual competencies. Moreover, the health personnel customized fall prevention activities for the individual *patients*, who were all adults of varied age. The individualization



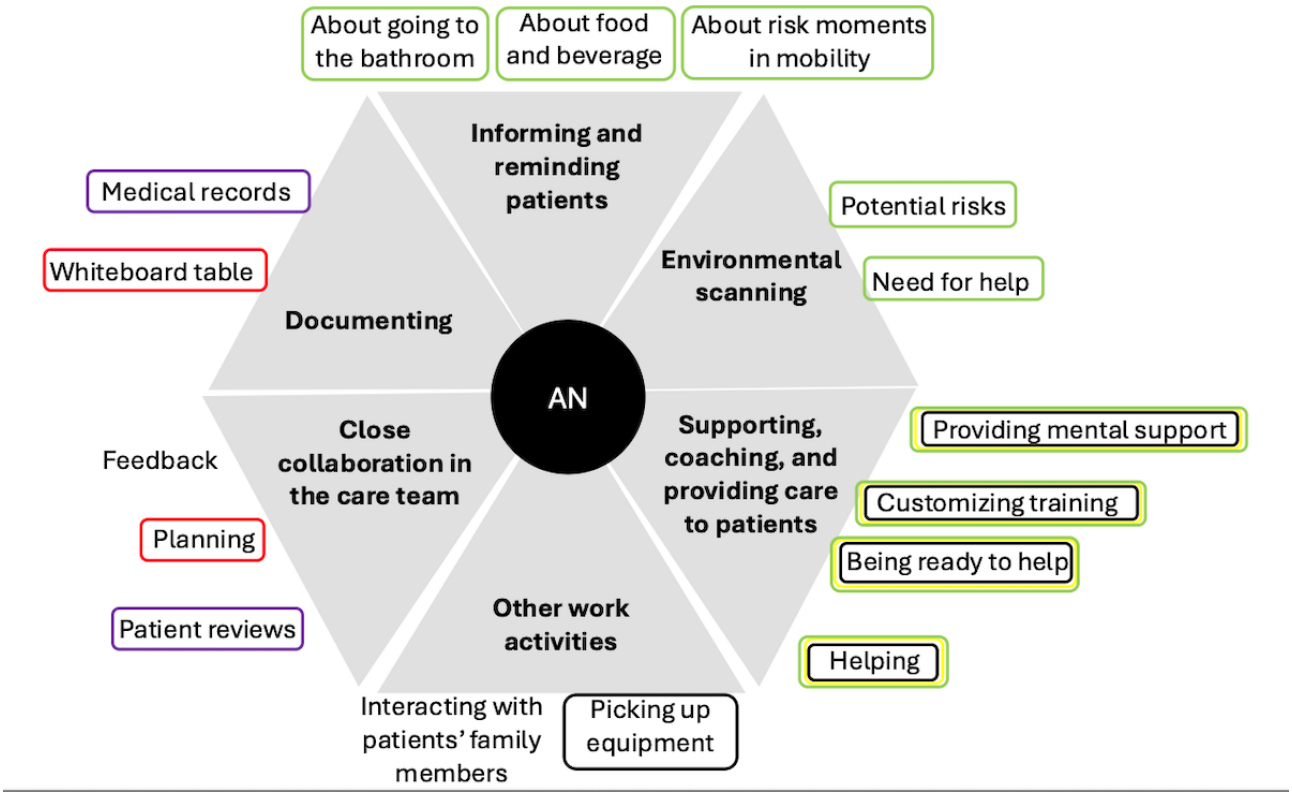
XSL•FO
RenderX

was based on the patient's overall health status, which could include both the reason that the patient had sought acute orthopedic care and any other potential additional health problems. The patient's personal factors, such as communication, life situation, self-awareness, and preferences, also needed to be taken into account. In some cases, the patients and health personnel also interacted with *external persons* in fall prevention. This could include health personnel from other clinical units in patient transportation, medical consultations, and referrals to primary care, as well as municipal staff in planning continued care along with the patients' family members.

Activities and Tools

Fall prevention activities and supporting tools are presented by staff category in Figures 1-6 and in the descriptive texts subsequently.

Figure 1. The clinical practices for fall prevention performed by physical and occupational therapists, with the type of activity (main categories) presented in bold text in gray fields. Specific activities (associated subcategories) are presented in normal font text outside their respective gray field. The supporting tools are represented by circles around the activities. The color of the circle indicates the type of tool used: purple represents computer-based systems, red represents physical tools and systems, green represents the staff, black represents mechanical aids and assistive devices, and yellow represents physical barriers and mechanical tools. OT: occupational therapist; PT: physical therapist.



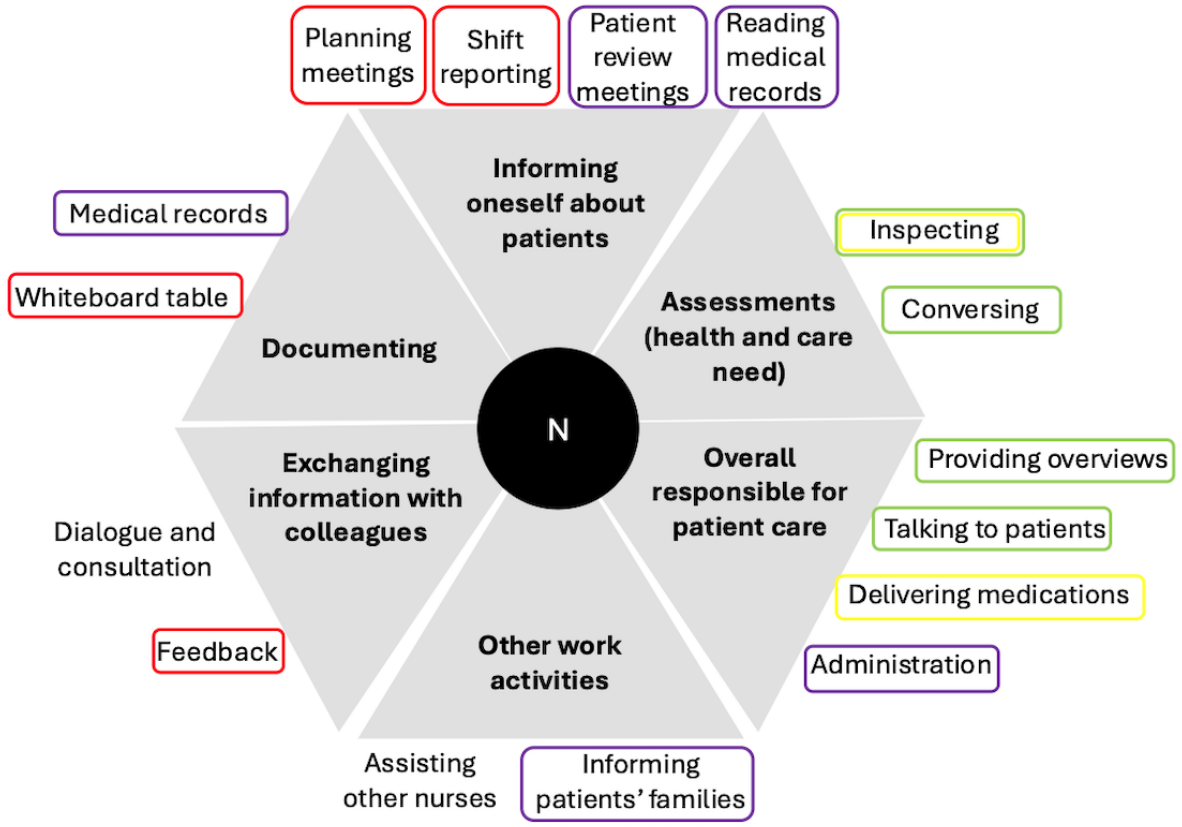
The physical and occupational therapists mainly supported patients in fall prevention during mobility training and activities in daily life (ADLs; Figure 1).

The therapists prioritized meeting patients who were new or close to being discharged. Their meetings focused on evaluating and supporting the patients as they underwent training in tasks essential for ADL. To initiate this, the therapists asked the patient to perform basic tasks, such as sitting up in bed. As the patient accomplished tasks, the therapists gradually introduced the patient to more challenging tasks, such as rising, standing, walking with mobility aids, and performing ADLs. Although the therapists encouraged the patients to try these tasks independently, they were constantly ready to support them immediately if needed. The therapists assessed the patient's functions and well-being by observing how the patient seemed to feel (eg, if they were affected by pain) and by listening to what the patient said (eg, regarding well-being, pain, mobility, their living situation, and assistive devices). They provided the patient with coaching and mental support, calming and encouraging them, based on the patient's individual needs. As they customized the training to the patient's current abilities, they prevented the patient from experiencing "failures." Tasks that seemed too challenging in training on 1 occasion could be postponed until an up-coming meeting or be supported by assistant nurses later the same day. The therapists gave advice related to safe mobility habits, ADL, and body positioning; provided practical help to patients; and eliminated safety risks in the physical environment near the patient.

Assistant nurses provided close care and support to patients, such as when they got dressed, visited the bathroom, and engaged in mobility training (Figure 2).

XSL•FO
RenderX

Figure 2. The clinical practices for fall prevention performed by assistant nurses, with the type of activity (main categories) presented by bold text in gray fields. Specific activities (associated subcategories) are presented in normal font text outside the respective gray field. The supporting tools are represented by circles around the activities. The color of the circle indicates the type of tool used: purple represents computer-based systems, red represents physical tools and systems, green represents the staff, black represents mechanical aids and assistive devices, and yellow represents physical barriers and mechanical tools. AN: assistant nurse.

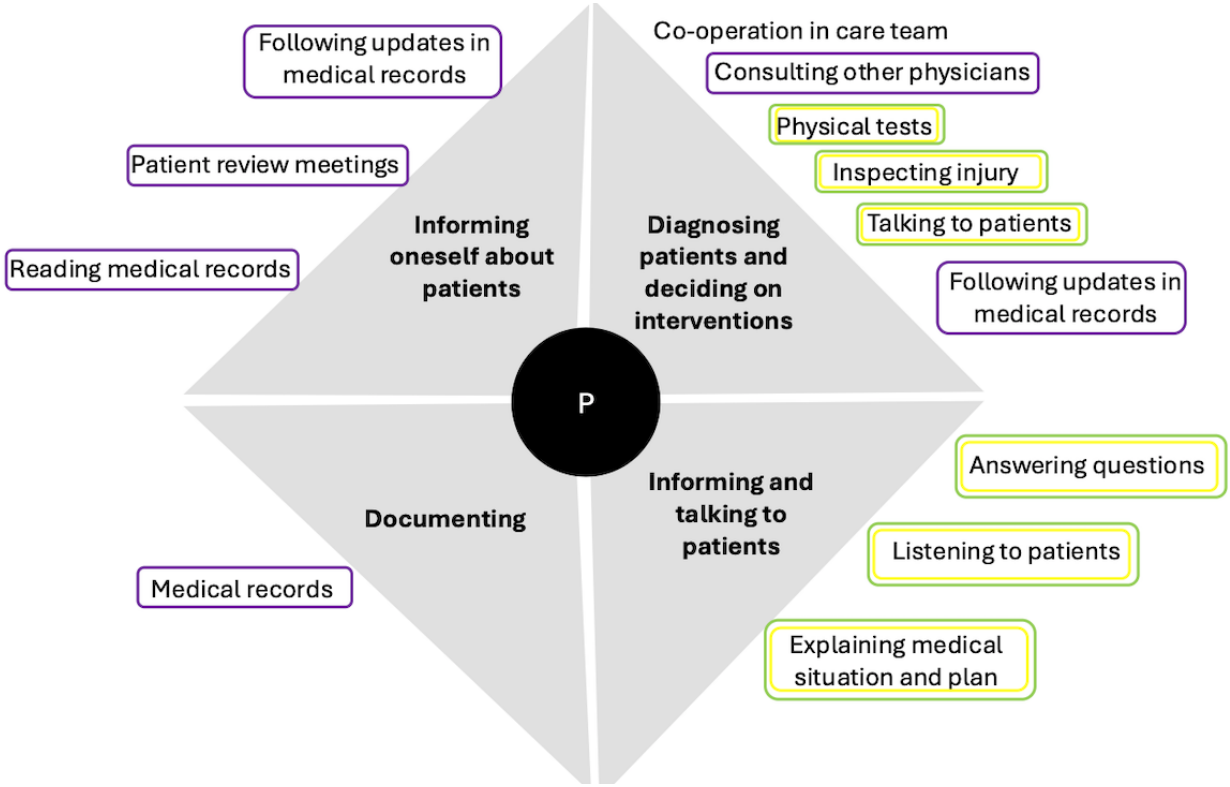


The assistant nurses moved along the corridor, scanning for patients in need of support, such as helping them go to the bathroom, and performing scheduled visits to see patients and to take food orders. They assisted patients with food orders by conversing, checking their documentation, and ensuring access to beverages. They also scanned for potential safety risks in the patient rooms and modified their physical environment by removing tripping hazards; helping patients to vary body position when needed; and reminding the patients about food, beverages, and bathroom visits, etc. They also supported patients in mobility training by reminding them, for example, of how to safely position their feet or lock their walker's wheels. While interacting with the patients, the assistant nurses were attentive, responsive, encouraging, calm, and clear and always one step ahead of the patient while focusing on safety. The assistant nurses collaborated closely with nurses, assisted colleagues, and interacted with the patients' family members at the ward.

Nurses were responsible for the care of a small group of patients, and there were approximately 4 to 6 patients per nurse. Their work included planning follow-up care, which in many cases involved prevention (Figure 3).

XSL•FO
RenderX

Figure 3. The clinical practices for fall prevention performed by nurses, with type of activity (main categories) presented by bold text in gray fields. Specific activities (associated subcategories) are presented in normal font text outside the respective gray field. The supporting tools are represented by circles around the activities. The color of the circle indicates the type of tool used: purple represents computer-based systems, red represents physical tools and systems, green represents the staff, black represents mechanical aids and assistive devices, and yellow represents physical barriers and mechanical tools. N: nurse.

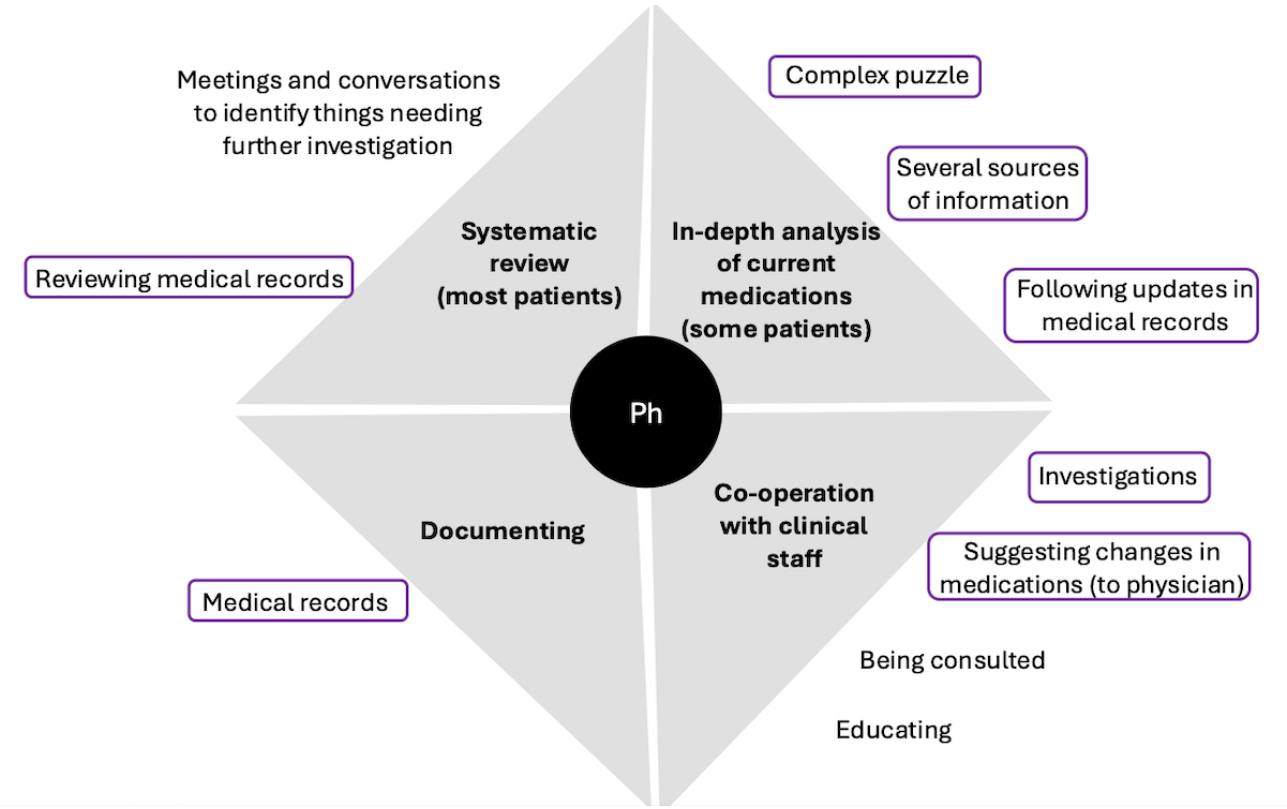


The nurses consistently kept themselves well informed of their patients' history and status through the patients' medical records, their own written notes from previous shifts, conversations with staff members from the outgoing and current shifts, and talking to patients during care activities and patient review meetings. Moreover, they continuously informed the care team's staff and interacted with the care team, physicians, and care coordinators through discussions, consultations, and information exchange. Together with the care team, they planned their activities and documented them on a whiteboard table and in their own written notes. Their interactions with assistant nurses, who carried out most of the point-of-care activities, were crucial and included continuous 2-way reporting performed orally and on the whiteboard table. The nurses documented all care activities provided in the patients' medical records, including notes from patient review meetings when necessary. They performed structured patient rounds to introduce themselves, check the patients' health status, and deliver medications and blood transfusions to patients. They also administered and followed up on medical and care activities, assisted colleagues, and talked to the patients' family members.

Physicians were responsible for the patients' medical care, including providing medication that could be closely related to fall prevention (Figure 4).

XSL•FO
RenderX

Figure 4. The clinical practices for fall prevention performed by physicians, with the type of activity (main categories) presented by bold text in gray fields. Specific activities (associated subcategories) are presented in normal font text outside the respective gray field. The supporting tools are represented by circles around the activities. The color of the circle indicates the type of tool used: purple represents computer-based systems, red represents physical tools and systems, green represents the staff, black represents mechanical aids and assistive devices, and yellow represents physical barriers and mechanical tools. P: physician.

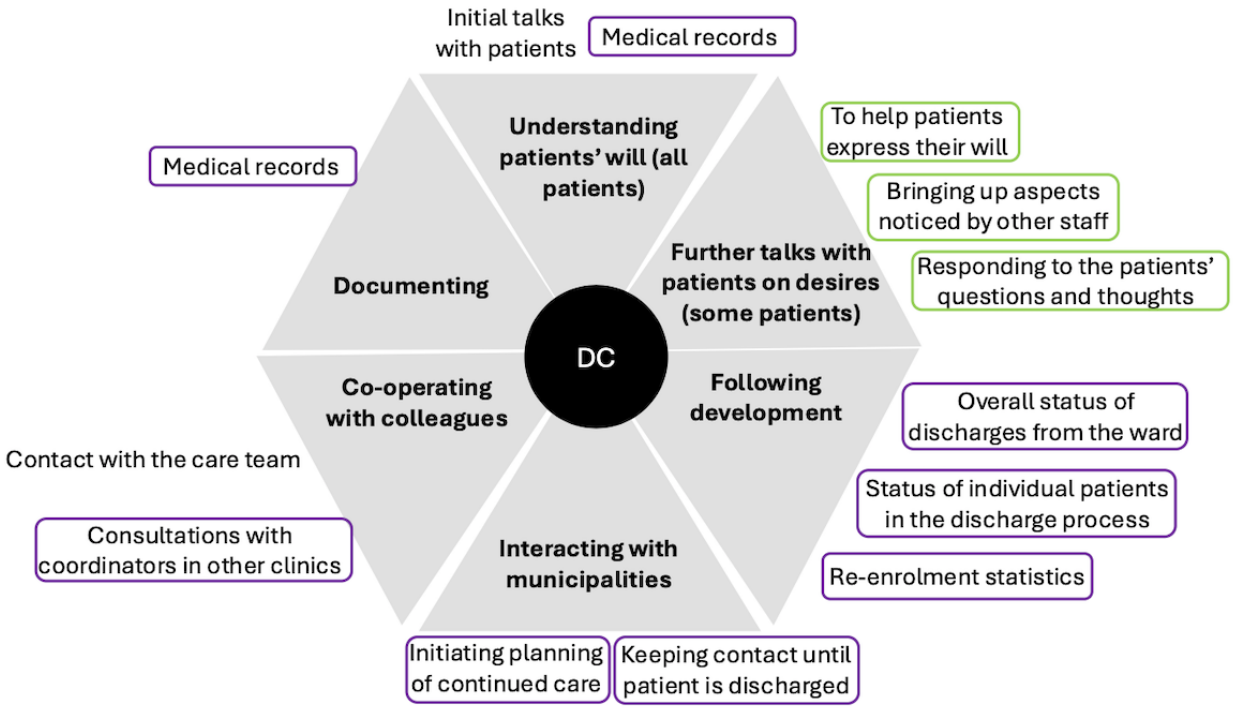


The ward physician was available in the ward during the daytime. They had support from a more senior colleague who, after having attended patient review meetings with patient care teams and participated in the clinical rounds at the ward, was accessible over phone. The ward physician consistently stayed well informed by reading medical records, leading the patient review meetings, and interacting with all the patients during their clinical rounds. In the patient review meetings, the care team informed the physicians about events from the past shift. In some cases, the ward physician reported on consultations with specialists in related domains. On the basis of reports, discussions, and consultations, the senior physician decided on the medical interventions, which the ward physician documented in the medical records. Thereafter, the physicians met all the patients in their rooms during their daily clinical rounds. Here, they assessed the patients' state of well-being and cognition based on conversations with them and their muscular and neural functions based on physical examinations, which included observations of the patients' responses to specific stimuli, visual inspections of any bandages, and subcutaneous bleeding. The specialist physician informed the patients of the results of their examinations, their medications, and any plans for ongoing evaluations and interventions. The physicians demonstrated where injuries were located by pointing at their own body. Before their discharge, patients received a written summary of the examinations and interventions they underwent, the results, and the plan for continued care. The physicians listened to the patients' experiences, answered questions, and asked them if they felt comfortable with the plans. In their conversations with patients, the physicians appeared clear and calm, and the patients showed them confidence and respect.

The clinical pharmacist supported the physicians and other health personnel by answering questions related to pharmacology, including those related to fall risks (Figure 5).

XSL•FO
RenderX

Figure 5. The clinical practices for fall prevention performed by the clinical pharmacist, with type of activities (main categories) presented by bold text in gray fields. Specific activities (associated subcategories) are presented in normal font text outside the respective gray field. The supporting tools are represented by circles around the activities. The color of the circle indicates the type of tool used: purple represents computer-based systems. Ph: clinical pharmacist.



The pharmacist systematically reviewed the drugs prescribed for most patients to identify any need to change them based on the information from the medical records, a national system for prescribed medications, patient review meetings with physicians and the patient care team, and consultations with the discharge coordinators. They screened for potential drug-related medical issues by checking the patients' medication lists and physiological parameters in the medical records. They also made thorough reviews of drug prescriptions for patients at risk of having drug-related health problems, such as patients with polypharmacy issues. These reviews were complex puzzles balancing combinations of risks and benefits. They focused on medications with documented issues affecting fall risks, either by themselves or in combination with other drugs, particularly among older patients. This may include prescribed combinations of medications that may cause drowsiness and fatigue, drug prescriptions deviating from general recommendations or those lacking evaluation, prescribed doses of antihypertensive drugs high enough to cause dizziness, and diuretics prescribed to be taken at certain times that could increase the risk of nocturnal bathroom visits. The analysis was done by manually comparing complex information from separate systems on the computer screen. The pharmacist documented suggested changes in drug prescriptions in the patients' medical records for the physicians to consider. The physicians then decided whether and at what point a change should be implemented. Changes more suitable to implement after the patients' hospital discharge were referred to physicians in primary care.

The discharge coordinators supported the patients in their discharge and safe transition home by addressing fall risks and considering the patients' desires (Figure 6).

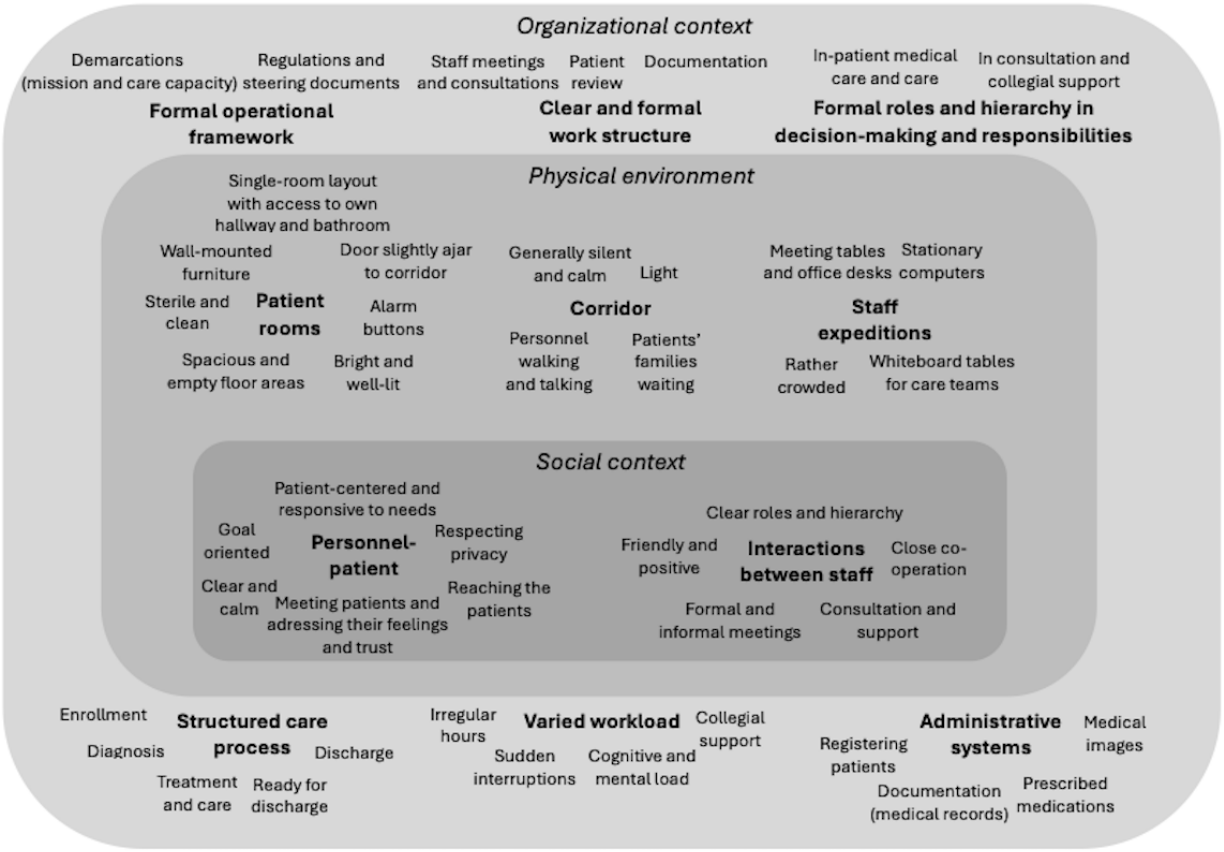
XSL•FO
RenderX

Figure 6. The clinical practices for fall prevention performed by discharge coordinators, with type of activities (main categories) presented by bold text in gray fields. Specific activities (associated subcategories) are presented in normal font text outside the respective gray field. The supporting tools are represented by circles around the activities. The color of the circle indicates the type of tool used: purple represents computer-based systems and green represents the staff. DC: discharge coordinator.

The discharge coordinators gathered information on the patients' desires by reading their medical records and talking to them. Some patients were able to clearly describe their living and occupational situations and express their requirements for discharge in a single conversation. Others needed more time to process what type of help they wanted or needed after their discharge. Therefore, the coordinator talked to them again to guide them in their decision-making process by asking them concrete questions about their daily life (eg, home environment, ADL capacity, etc) and by describing the possibilities of home-based help for patients interested in such support. Because the coordinators had a professional role different from that of the care team, they could spend more time talking to the patients about things they brought up or about needs that other staff members had noticed. The coordinators cooperated closely with the care team staff, listened to their assessments, and reminded them to carefully document the patients' state of well-being and activities in their health records. They also cooperated with municipal staff to plan for the continued care of patients who had given their consent and patients who needed such care but were unable to give their consent. The coordinators conveyed the patients' desires via telephone and a computerized system to the municipal care administrators, who decided on which activities the patient were entitled to. The coordinators also communicated with the patients' family members, who sometimes contacted the clinic to emphasize their relative's needs and were then reminded to talk to their relative about his or her desires. Although the coordinators tracked 30-day readmission statistics, their involvement ended once the patient was discharged.

The tools used in the wide range of activities described earlier to prevent falls (Figures 1-6) can be categorized into the 5 main categories:

- Computer-based systems, for example, medical records software (purple in figures)
- Physical tools and systems, for example, the care teams' whiteboard table (red)
- The staff, for example, their sight and hearing while assessing patients (green)
- Mechanical aids and assistive devices, for example, walkers for mobility (black)
- Physical barriers and mechanical tools, for example, sliding mats when lifting (yellow)



These are all summarized in Multimedia Appendix 4.

Context

Within the PACT framework, fall prevention is described in terms of the physical environment as well as the social and organizational contexts. The main and subcategories are presented in Multimedia Appendix 5 and Figure 7.

XSL•FO
RenderX

Figure 7. A description of the context, in which the main categories (in bold) and associated subcategories (nonbold) are summarized for the organizational context (outer circle area), physical environment (middle circle area), and social context (inner circle area).

The organizational context of fall prevention was highly structured in the work itself and the patient care process, and it was formal in the operational framework and the health personnel's roles and responsibilities. Other essential elements within the organizational context included a varied workload, which could be increased by mental and cognitive loads, sudden interruptions, and irregular work hours. The workload could also be reduced through collegial support and several administrative computer-based systems that the personnel used regularly.

The physical environment for fall prevention included the location where the health personnel met patients, which was primarily the patients' rooms; the location where the patient care teams met, which was primarily the office where the physicians did administrative work and held teaching meetings with the care team staff; and the office where nurses, licensed practical nurses, as well as physiotherapists and occupational therapists did administrative work, planning, and reporting. Both offices had meeting tables and office desks with desktop computers, but the physicians' office had a wall-mounted screen to project the physician's computer display during the teaching meetings. The care team's office had a large whiteboard on which the status and planned activities for all patients were documented. The location dedicated to the care teams (which included the patient rooms, day room, and health personnel team offices) was connected to long corridors, which were brightly lit, mostly silent, and calm. In the corridor, the health personnel could be seen walking on their way to see a patient or a colleague, occasionally pausing to have a quick word with a colleague. Occasionally, a patient walked along the corridor, and sometimes, the patients' families waited in the corridor outside a patient's room. Patient rooms were on 1 side of the corridor, with most of the doors opened slightly. Most patient rooms were single rooms with a small hallway leading into a spacious and bright bedroom with double windows and large open spaces. The walls and ceiling were painted white. The floor was light gray and free from raised sills and thresholds. The patients' rooms were well lit by several light sources on the ceiling and on the wall over a height-adjustable bed, which could be raised or lowered via a panel on 1 side. The bed also had height-adjustable safety rails on the sides. A wired patient alarm control unit was placed beside the bed, mostly near the patient on a mobile bedside table whose tabletop could be placed over the bed. The bedrooms also contained a basin along with disinfectants, a chair, and a large television, all of which were wall mounted. All the patient rooms had their own spacious bathrooms with a shower area, and they were equipped with several supportive grips placed at strategic places for safely sitting down and rising from the toilet seat and moving to and standing in the shower. Alarm buttons were placed near the toilet seat, door entrance, etc. A movable laundry basket was the only item set on the floor.

The social context for fall prevention included settings for the health personnel's interactions with patients, colleagues, and outside persons. The health personnel interacted with patients in different constellations, mostly when 1 or 2 members of the

XSL•FO
RenderX

health personnel visited the patient's room. The patient-staff interactions were patient centered, goal oriented, and empathetic. In sensitive situations, the personnel closed the door to the corridor to protect the patient's privacy. To reach out to the patients, the personnel needed to be perceptive, flexible, and prepared to handle difficult topics brought up by patients in a professional way. The personnel also had to act in a calm, clear, direct, and pedagogic manner to enable the patients to understand and assimilate information, as well as to instill trust and confidence. The patients listened to the personnel and occasionally expressed their feelings toward them, including trust and confidence. Interactions between health personnel took place between colleagues in the patient care team or between the patient care team and staff in specific positions. Here, their roles and responsibilities were noticeably clear. The health personnel consulted each other in both formal and informal meetings within a friendly and positive atmosphere. On the basis of their distinct roles, the health personnel could also complement each other when in contact with a patient. The personnel's interactions with external persons were also patient centered. The personnel stated that they sometimes needed to remind the patients' family members that care planning must be based on the patient's own preferences. Moreover, they stated that they had to respect and confide in the division of responsibilities between the clinic and municipality.

The Staff's View on Fall Prevention, Descriptions of Observed Activities and Tools, and the Need to Further Support Fall Prevention

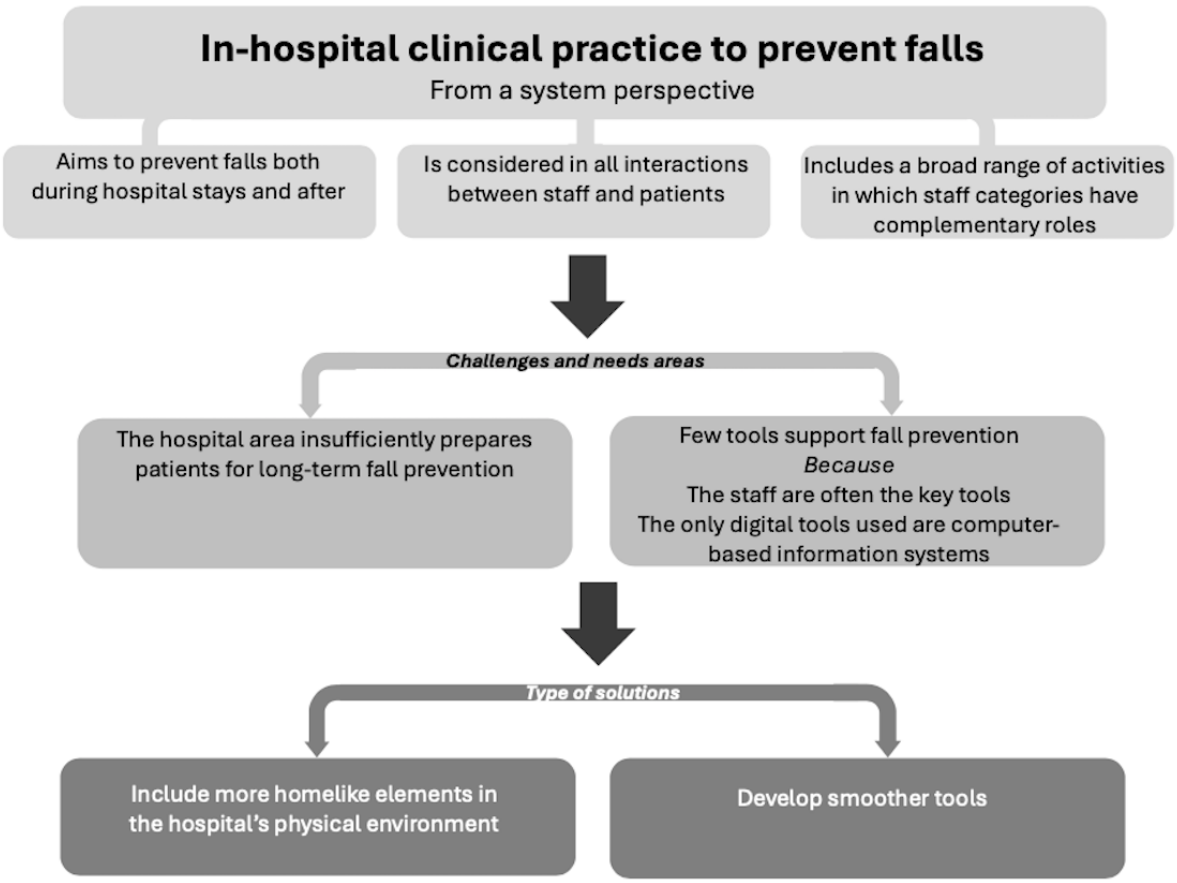
A larger number of staff members from the orthopedic clinic provided their views on the analysis of observed activities to prevent falls and the tools used to support these activities, which were presented in the Activities and Tools subsection earlier. The staff provided feedback in groups representing specific health staff categories, which included assistant nurse, health counselor, medical secretary, nurse, occupational therapist, physician, and physical therapist (Table 2). As can be seen in Table 2, the staff supported the broad definition of activities to prevent falls and said that they considered fall prevention in all interactions with patients. They also stated that long-term fall prevention was more difficult due to short hospital visits and their lack of influence over the home environment. They agreed on the presentation of activities to prevent falls and the tools used. The staff described the need to further support fall prevention, such as by using more practical "real-life tools" and "making the ward's physical environment more similar to the home environment."

Table 2. Health personnel's views on fall prevention, descriptions of observed activities and tools used to prevent falls, and identified needs for further support.

Group	View on the definition of "activities to prevent falls" as activities contributing to preventing falls both in the short and long term	View on whether adjustments are needed in the presentation of in-hospital activities to prevent falls and the tools supporting these activities	View on the need to further develop any part of the activities, context, or tools to further improve the work to prevent falls
Group 1 (occupational therapist, physiotherapist, and physician)	"It is possible to prevent falls in the short term at the hospital but more difficult to prevent falls in the long term because hospital stays are short and we cannot control the home environment."	"No."	"Make the hospital environment more like the home environment by incorporating features such as doorsteps, carpets, narrow spaces, and doors without automatic opening mechanisms."
Group 2 (assistant nurse and nurse)	"We agree."	"No."	"No."
Group 3 (medical secretary and nurse)	"Good, important work"	"Feels like you got it all."	Continue to develop more practical, real-life tools and access to the latest news
Group 4 (health counselor, physiotherapist, and occupational therapist)	"We consider fall prevention in all interactions with patients at the ward and automatically assess fall risks in everything we do together with the patients."	"No."	—[a]

[a]Not available.

Discussion



Principal Findings

The principal findings of this study (summarized in Figure 8) showed that the health staff had a holistic view of fall prevention, which was recognized in the clinical observations of the people, activities, context, and tools in a clinical ward. This view was also expressed verbally by the personnel in a workshop. As a result, the study determined that the PACT framework can be useful to support the observation of complex phenomena such as clinical fall prevention. The health personnel stated that they automatically assessed fall risks and considered fall prevention in all their interactions and activities with patients to prevent falls both in the hospital setting and after hospital discharge. It was clearly seen in the observations that the health personnel strived to make the hospital stay safe for the patients and to prepare the patients for a safe transition home (or to a care home). This was observed in the wide range of activities in which the respective health staff categories had complementary roles. For example, physiotherapists and occupational therapists focused on mobility training and ADLs

XSL•FO
RenderX

in their assessments and training with patients, while assistant nurses screened the patient environments for risk factors, supported patients in mobility training, and cooperated with nurses to provide all the patients with effective and safe care. The pharmacist and the physicians reviewed medications prescribed to each patient with the aim of minimizing fall risks, while the discharge coordinators interacted with patients to plan a safe home transition. In the workshop, the health personnel mentioned that the short hospital stays and their own lack of control over the patient's home environment made it more difficult for them to address long-term fall prevention in their clinical practice; therefore, they saw a need for making the hospital environment more homelike by incorporating elements such as doorsteps, carpets, narrow spaces, and manually operated doors. Observations in the wards confirmed that the physical environment was clean, spacious, and free from homelike physical elements that could both increase fall risk as well as enable ADL and mobility training in situations representative of the home setting. The responsive, goal-oriented, and patient-centered interactions between the patients and personnel, which seemed very important for engaging the patients in fall prevention, were also observed in the ward. The observations revealed that although the personnel used different tools in their work and possessed a broad range of skills and functions, they often served as key "tools" themselves in many of their fall prevention interactions by assessing and communicating with and coaching the patients, all while using digital tools (mainly computer-based software) for information retrieval, documentation, and communication. The personnel expressed that they were interested in more practical, real-life tools for fall prevention.

Figure 8. A summary of the main findings of the study, including key aspects of the in-hospital clinical practice to prevent falls studied from a system perspective based on the people, activities, contexts, and technologies framework, along with areas identified for further support and the types of solutions required by staff.

Limitations

This study has several limitations. The method used (ie, collecting clinical practice data relative to fall prevention via observations, interviews, and the workshop without collecting any personal data from the participants except for the health personnel's staff category) limited the results because they encompassed only observable actions, verbal expressions, and contexts related to the people, activities, and tools involved in fall prevention. Consequently, no conclusions were drawn in this study regarding the staff's personal experiences; feelings; mental models; or the psychological, social, and attitudinal attributes related to fall prevention. Moreover, the study explored the health staff's perspectives on fall prevention, and no data were collected regarding the patients' perspective other than what the patients expressed and did in their interactions with the staff.

XSL•FO
RenderX

Although the study applied several strategies (described in the Methods section) to achieve trustworthiness, the study also had methodological limitations. For example, the sampling, performed via criterion-based (personnel involved in fall prevention within a specific clinical setting) and stratified purposeful (personnel representing a variety of staff categories) sampling strategies [46], may have introduced biases into the study and thereby limited the generalizability of the result. It is possible that subgroups within staff categories (other than those described in the Results section) were not represented in the sample due to the researcher's unawareness. For example, it cannot be ruled out that a health staff member's interest in participating in a research study on fall prevention practices may have been affected by their interest in fall prevention. The relatively low number of participants in the study may have contributed further to this risk of sampling bias.

The competence and background of the observing researcher may also have limited the context-specific in-depth understanding of the observations. Although this researcher was knowledgeable in fall prevention due to participating in multidisciplinary research projects, they had no previous training or experience in health care work. Finally, because this study was performed in 1 specific clinical setting, these results may not be generalized to any other in-hospital setting.

Comparison With Prior Work

The holistic view on in-hospital fall prevention practices expressed by the health staff and observed in the clinical context of this study opens up new possibilities for using fall prevention technologies in hospital settings, such as to support staff activities that prepare patients for long-term fall prevention. This view is well in line with previous research confirming the positive impact of patient and care team partnerships to prevent falls and fall injuries and how this can be supported by human-centered tools [19,20]. The level of importance of contextual support to create more realistic "homelike" conditions during mobility and ADL training, which was pointed out by the staff in this study, is different and thus complements the previously studied technology-based in-hospital fall prevention tools and approaches, which aimed to detect early signs of acutely elevated fall risks and falls, such as those described by Cooper et al [9]. This includes chair sensor alarms [10], video- and image-based monitoring [11,12], wearable devices [13], and artificial intelligence–based motion alarms, such as those mentioned by Pagels [14]. The staff's request to make the clinical environment more "homelike" can be seen to reflect more holistic models of fall prevention that involve complex interplays between people, activities, processes, organization, environment, and technology, as seen in the models proposed by Choi et al [52] and Taylor and Hignett [15]. Although the review by Hignett and Masud [17] on the associations between inpatient falls and environmental modifications identified a lack of supporting scientific evidence for most recommendations on how to manage environmental hazards in hospital wards, which included flooring, lighting, and bed alarms, it is likely that making the ward's physical context more "homelike" could introduce new environmental hazards related to falls. As a result, environmental modifications in care settings must be implemented with precaution. Keeping patient rooms intact and introducing homelike elements in other locations outside the rooms is one strategy. Temporarily anchoring mobile, homelike modules in patient rooms offers a more flexible approach, allowing the hospital environment to be tailored to each patient's training needs. These modules could also incorporate embedded digital systems to support and enhance training. One idea would be to develop modules that could be used both in clinical settings and in-home settings, thus allowing patients to continue the training that they were introduced to in the hospital during their rehabilitation. This would allow them to gradually achieve a more active life after their hospital discharge. Information gained from previous research on how to create meaningful and feasible interactions between older adults and home-based digital systems for fall prevention training, such as that from Ogonowski et al [22], for example, can be of value in the design of these modules. It is also essential to build on the knowledge of how to engage in a creative dialogue with patients regarding their personal goals because incorporating these goals into nonstigmatizing designs of solutions to prevent falls is essential, as described by Bianco et al [21]. The dialogue between staff and patients is also essential when the patients are preparing themselves for the challenges posed by their home settings after hospital discharge [53]. For example, opportunities to experience homelike situations under the supervision of the clinical staff can contribute to strengthening the patients' experience with their postinjury bodies and thereby contribute to building self-confidence and self-efficacy in gross motor skills.

Conclusions

The following conclusions can be drawn from this study:

- Expanding the current view of technology-based in-hospital fall prevention to both include computer-based information- and communication systems and digital fall-protection tools aligns well with clinical practice. These technologies will provide support to the health personnel's activities to engage patients in fall prevention.
- Health professionals see a need for further support in their activities so that they can prepare patients who have been hospitalized for the challenges they will face after their hospital discharge. They also suggested that the clinical environment should contain more home-based elements. These could provide the patients with opportunities to experience homelike situations under the supervision of clinical staff and may contribute to strengthening the patients' experience with their postinjury bodies.
- The PACT model can serve as a useful framework for supporting observations, and workshops can be fruitful for enabling health personnel to discuss clinical practices for fall prevention and express their need for further support.

Acknowledgments

The authors would like to thank all study participants and all other personnel at the orthopedic clinic who contributed to the execution of this study. This study was funded by Vinnova (grant number: 2022-01193). Finalization of the manuscript and language review were funded by the multidisciplinary research initiative on human-centered technology at Mälardalen University.

Authors' Contributions

ME (the main researcher) designed the study, collected and analyzed the data, and was one of the main authors of the manuscript. ÅR and HT participated in peer debriefing (including reviewing) during the data analysis, critical review, and revision stages of the study. All the authors read and approved the final manuscript.

Abstract

Background: Older adults in rural communities face unique challenges, including geographic isolation, a shortage of health care providers, and limited access to specialized services. Artificial intelligence (AI) has emerged as a promising solution for improving health care access and delivery. However, concerns persist about equitable access and representation in these innovations, especially for marginalized populations where technological literacy and infrastructure may present additional barriers to effective use.

Objective: This systematic literature review aims to: (1) identify existing literature on AI for health research focused on rural older adults, and (2) critically evaluate the identified literature to highlight gaps and inform the development of inclusive AI for health research and design practices.

Methods: Between January 2024 and March 2025, we followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 Protocol to conduct a systematic search of health and computer science literature. We searched 7 databases (PubMed, CINAHL Plus with Full Text, PsycINFO, Web of Science, IEEE Explore, ACM Digital Library, and Scopus) to identify relevant research papers published between January 2013 and December 2023. We used predetermined search terms and built-in result limiters, including English language, human subjects, full text, and aged 65+. Publications were excluded if they were not empirical or did not include a focus on older adults, rural populations, or AI. The resulting data were reviewed, coded, and analyzed using thematic analysis.

Results: A total of 23 papers comprised the final sample. The results showed that the representation of rural older adults in AI for health literature is limited. We identified three salient themes: (1) Numbers over Narratives: The Quantitative Focus in AI for Health Research on Older Adults, (2) Efficacy over Impact: Prevalence Clinical Outcomes in AI for Health Research, and (3) Deepening Disparities: Representation of Rurality Missing in AI for Health Research. These themes underscore the need for a more nuanced understanding of how AI for health research can be tailored to the specific needs of rural older populations.

Conclusions: Our systematic analysis identified a robust body of research on AI for older adults. However, a critical gap emerged with a dearth of studies explicitly focusing on older adults in rural communities. This lack of representation raises concerns about the generalizability of findings and the potential for exacerbating existing health care disparities in rural areas. Future research should: (1) prioritize targeted recruitment strategies for rural older adult participants to ensure better representation in AI for health research; (2) develop community-based AI policies, practices, and products that reflect the specific needs and contexts of rural populations; and (3) explore solutions that address the limited representation of rural communities, ensuring that AI interventions are equitable, accessible, and beneficial for all.

Introduction

Background

The global aging population presents significant opportunities to expand and extend health care, and artificial intelligence (AI) offers promising avenues to address these issues. As the population gets older, successful AI integration into health care systems necessitates a deeper understanding of the specific needs and perspectives of older adults. The increasing prevalence of chronic health conditions among older adults intensifies the demand for health care services while also offering new opportunities for engagement through digital health tools [1]. AI holds promise for meeting these needs, from early disease detection [2] to personalized care management [3] and even robotic assistance for independent living [4]. However,

XSL•FO
RenderX

the integration of AI into health care is not without significant challenges. To be effective, AI-powered health care tools must be user-friendly, accessible to individuals with varying levels of technological literacy, and free from algorithmic biases that could disproportionately affect older populations [5].

Rurality and Older Adults' Health

The demographic shift toward an aging population is particularly pronounced in rural areas, where access to health care is often limited. Over the past decade, 106 rural hospitals in the United States have closed [6,7], and another 600 are at risk of following suit [8], leaving rural communities increasingly vulnerable to limited access to essential health care services. These hospitals have traditionally provided vital care to large populations of older adults, but as closures continue, there presents a need to rethink traditional in-person health care models. Approximately 20% of the US population, or 60 million people, live in rural areas, and they face disproportionately worse health outcomes compared to urban populations [9]. Rural older adults, in particular, experience higher rates of comorbidities, such as obesity, cardiovascular disease, and stroke, as well as a growing number of emergency department visits [9,10]. This has contributed to widening life expectancy gaps between rural and urban populations [11]. In addition, rural communities face unique barriers that make it harder for older adults to access the specialized care required to address these complex health challenges [10]. Although online care models and other AI for health solutions are beginning to demonstrate promise in improving access to specialized health care, many rural areas still lack the necessary infrastructure to implement these solutions [12]. Ensuring AI health care solutions address these challenges will be crucial in providing equitable care for rural older adults.

AI for Health Research

We use the phrase "AI for health research" to refer to the investigation and development of AI technologies to improve various aspects of health care. By leveraging machine learning, natural language processing, and other AI techniques, researchers aim to create systems that can process vast amounts of health data to enhance clinical decision-making as well as to deliver highly personalized and sometimes remote care. However, despite its potential, AI for health research faces several significant challenges [13]. One of the most pressing issues is the quality and representativeness of the data used to train AI systems [14]. Large datasets are essential for AI models; however, many of these datasets may be incomplete, biased, or not sufficiently diverse, raising concerns about the accuracy and fairness of AI-generated decisions [2]. Furthermore, the sensitive nature of health data raises ethical concerns, particularly around privacy, security, and the risk of misuse. Ensuring robust data protection mechanisms is crucial to maintaining public trust in AI-driven health care solutions [15].

Another major challenge lies in the "black box" nature of many AI algorithms, which makes it difficult for health care providers and patients to understand how decisions are made [16]. This lack of transparency undermines accountability and raises the potential for unrecognized biases and amplified health care disparities [17,18]. Research continues to show that top-down or prescriptive design processes in the development of technology, including AI, often fail to include the perspectives of older adults, overlooking their unique experiences within their communities [19]. However, when leveraging the knowledge of this group through community-based research practices, technology design can be more effectively tailored to address issues, such as usability, literacy, privacy, and data management [19]. In addition, there is a significant gap in understanding the perspectives of older adults and other marginalized populations, such as those in rural areas. Without incorporating their diverse experiences and needs, AI tools risk failing to address the specific challenges faced by these groups, potentially exacerbating existing health inequities [20]. Addressing these challenges is essential to ensuring that AI for health research leads to equitable, effective, and ethically sound health care solutions.

Study Aims

Building on the insights from the existing literature, it is clear that gaps remain in understanding how AI for health research can effectively address and incorporate the health care needs of rural older adults. This systematic literature review aims to: (1) identify existing literature on AI for health research specifically focused on older adults residing in rural communities, (2) critically evaluate the identified literature to highlight gaps, and (3) inform the development of inclusive AI for health research and design practices.

Methods

Study Design

We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 protocol for systematic literature reviews [21]. The PRISMA 2020 checklist is provided as Checklist 1. A protocol was not registered for this systematic literature review. A systematic review methodology was selected to enable a focused, critical appraisal of how rural older adults are represented in empirical AI for health research. Given the equity implications of AI in health care, a systematic review was appropriate to assess not only the presence but also the depth and nature of rural older adult representation using predefined inclusion criteria, structured data extraction, and formal critical appraisal tools (eg, Joanna Briggs Institute [JBI]).

We performed 4 rounds of systematic selection and review for the 7 selected databases (PubMed, CINAHL Plus with Full Text, PsycINFO, Web of Science, IEEE Explore, ACM Digital Library, and Scopus). In Round 1, we searched the databases using predetermined keywords. In Round 2, we screened titles and abstracts using predetermined inclusion and exclusion criteria. In Round 3, we further screened the full text of the selected papers using the same predetermined inclusion and exclusion criteria. Finally, in Round 4 we reviewed and coded each study in the final sample. A detailed description of our search strategies can be found in Multimedia Appendix 1. Once the articles were coded, the researchers met to analyze the data using thematic analysis [22]. The main themes identified centered on the representation of older adults in AI for health research.

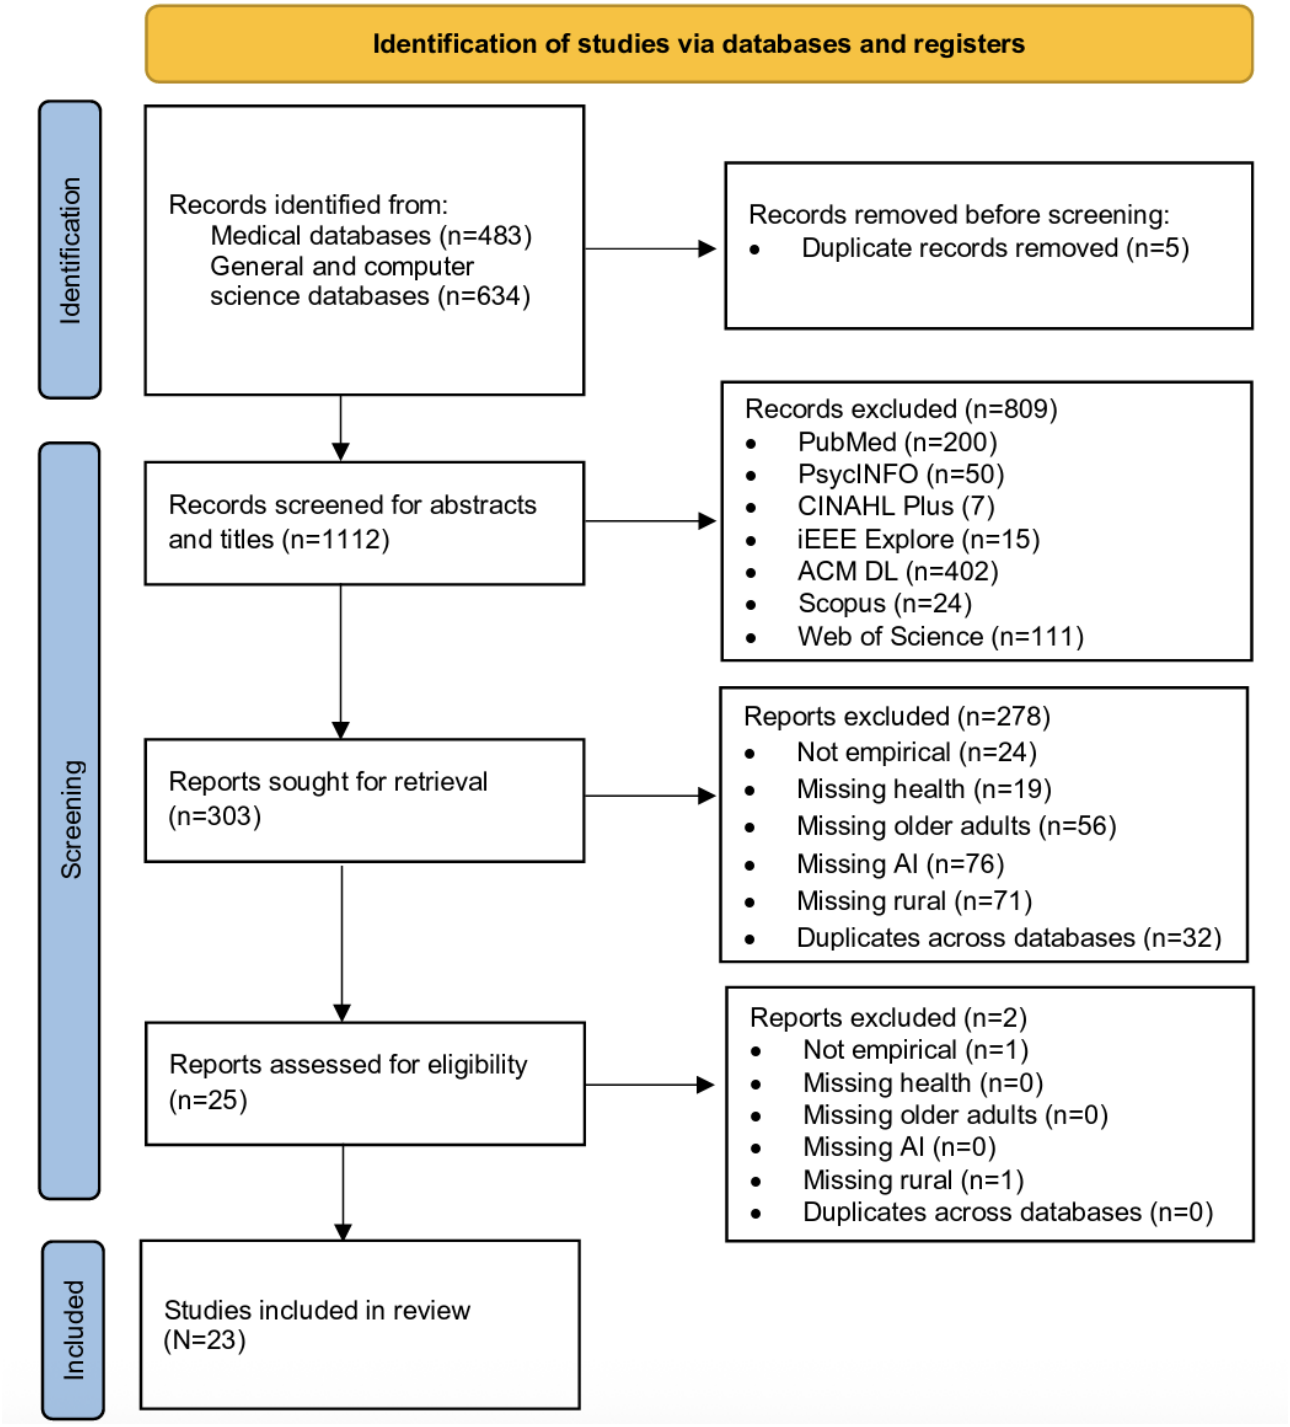
XSL•FO
RenderX

In addition, we assessed the levels of evidence reported in the 23 papers [23-45] using the appraisal tools developed by the JBI to evaluate study quality [46]. To calculate assessment scores, 1 point was assigned to each question answered as "Yes," while responses of "No" or "Unclear" received 0 points. The total score was then divided by the number of questions and multiplied by 100 to yield a percentage. Based on the resulting score, studies were categorized as very poor (0% - 30%), poor (31% - 50%), fair (51% - 70%), good (71% - 90%), or excellent (>90%). Both authors reviewed and independently completed the checklist for each study; disagreements were resolved through discussion.

Ethical Considerations

This systematic literature review was deemed exempt by the Louisiana State University Institutional Review Board.

Results



Search and Screening Outcomes

Round 1, keyword search, yielded 1112 publications across all databases, with 479 publications from medical databases and 633 from general and computing databases. After initial screening for the predetermined exclusion criteria, 303 remained for title and abstract screening in Round 2. During Round 2, a total of 278 publications were removed based on the predetermined exclusion criteria, leaving 25 publications for screening in Round 3. During Round 3, full-text screening, 2 publications were excluded.

This round resulted in a final sample comprised of 23 publications [23-45]. Among these, 8 publications [23-30] selected from the medical databases (PubMed, CINAHL Plus with Full Text, and PsycINFO) and 15 publications [31-45] selected from the general and computer science databases (Web of Science, Scopus, ACM DL, and IEEE Explore). The final PRISMA search strategy with results is illustrated in Figure 1 below.

Quality Assessment Outcomes

To evaluate the methodological quality of the included studies, we used the JBI Critical Appraisal Checklists. Each study was independently reviewed by 2 researchers, with discrepancies resolved through discussion to ensure consistency and minimize potential bias. Studies that met the majority of JBI criteria were retained for inclusion in the final synthesis, ensuring a high-quality evidence base. Results of the quality appraisal are provided in Multimedia Appendix 2. Of the included studies, 10/23 (43%) [23,25-27,36-39,43,45] were rated as excellent, 10/23 (43%) [24,28,29,31-34,40,41,44] as good, and 3/23 (13%) [30,35,42] as fair in overall methodological quality.

Descriptive Statistics

A summary of the characteristics of all 23 studies [23-45] is presented in Multimedia Appendices 3 and 4. Of the 23 [23-45] publications, the years of publication ranged from 2014 to 2023; the majority of the research has been published since 2021 (16, 70%) [23-27,29,33-38,42-45]. Studies were conducted in Asia (13, 57%) [23-27,29,33-35,39-41,45], Europe (2, 9%) [30,43], North America (7, 30%) [28,31,32,36,38,42,44], and Africa (1, 4%) [37]. Fields of study represented in this sample included health sciences (15, 65%) [23,26,30,32,33,35-40,42-45], psychology (3, 13%) [24,25,31], neuroscience (2, 9%) [29,34], gerontology (2, 9%) [27,41], and rehabilitation (1, 4%) [28].

XSL•FO
RenderX

Quantitative methods were almost exclusively used (19, 83%) [23-27,29,30,34-45]. The quantitative studies focused on aspects of AI in health research, such as prediction [24-26,42], screening [23,37], investigating [27,43], estimating [29], evaluating [30,38-41,44], and design and development [34-36,45]. The qualitative studies (4, 17%) [28,31-33] focused on patient experiences of robotic stroke therapy [28], the demand for smart health care services for older adults [33], and participatory design of socially assistive robots for mental health [31,32].

Sample sizes across the included studies ranged from as few as 10 to over 1.85 million older adult participants. Definitions of what constituted an "older adult" varied considerably. Participant ages spanned from 50 to 105 years, reflecting a lack of consensus on age-based eligibility criteria. Two studies did not specify age-based criteria but noted that participants were recruited from older care facilities, implying an assumed classification based on setting rather than age. It is important to note that there is no universally accepted standard for defining "older adult." The World Health Organization generally defines older adults as individuals aged 60 years and older, particularly in global and low- to middle-income contexts [47]. In contrast, the United States Census Bureau designates age 65 years as the threshold for older adulthood [48]. These variations highlight how classifications of "older adult" may differ by region, cultural context, or institutional policy.

The representation of rurality similarly varied across the studies. Only 7/23 (30%) [23,26,28,30,35,41,44] of the publications included in this review focused entirely on a rural population. The context of rurality in these studies included rural villages in Yangxi County, China [23]; villages and towns in rural districts of Beijing [35]; home-based care in rural China [41]; rural areas in the state of Georgia, United States [28]; small rural hospitals in the United States [44]; rural regions of South Korea [26]; and a rural health care center in Sweden [30]. However, rurality was often (14/23, 57%) [24,25,29,31-34,36-38,40,42,43,45] treated as a background variable used for comparison against urban settings rather than as a distinct sociocultural or structural context worthy of focused analysis. Furthermore, nearly half of the studies (11/23, 49%) [23-25,27,33-35,39-41,45] examining AI for health in rural areas were conducted in China, suggesting a potential geographic bias or overrepresentation that may limit the broader applicability of findings and obscure rural-specific insights from other regions.

The types of AI used across the included studies were primarily described as machine learning (n=7, 30%), which supported a range of predictive tasks, including identifying depression risk [24], forecasting cognitive decline [25], modeling active aging [27], predicting suicidal ideation in rural older adults [26], and developing risk scores for stroke and coronary heart disease [34,36,45]. Deep learning (n=1, 4%) was used for image-based screening, specifically for detecting retinal lesions in rural older adult populations [23]. Robotics (n=2, 9%) was applied in studies involving telerehabilitation for rural veterans [28] and remote consultation through robot-assisted echocardiography [30]. One additional study [31] described the ongoing participatory design of socially assistive robots with older adults, though it had not yet reported implementation outcomes. Notably, no studies examined the use of generative AI (eg, large language models). Moreover, few studies included qualitative data capturing older adults' own perceptions, experiences, or understanding of AI in their health care, limiting insight into how this population interprets, evaluates, or engages with AI technologies in practice.

AI was primarily examined as a strategy to extend health care services to remote and underserved areas. The largest proportion of studies (10/23, 43%) [23-26,31,34,36,37,42,45] focused on AI as a screening and predictive tool in rural health care settings, supporting early identification of retinal lesions [23], depression [24,31], cognitive decline [25], suicidal ideation [26], stroke risk [34], early hospitalizations due to ambulatory-care sensitive conditions [36], diabetes [37], novel disease association [42], and cardiovascular disease [45]. Fewer studies explored other applications of AI, including its use in robotic telerehabilitation, particularly for rural veterans with limited access to in-person care [28]; its role in supporting long-term public planning and social support through epidemiological modeling in aging populations [29]; and its utility in facilitating remote specialist consultation, such as through robot-assisted echocardiography that reduced time to care [30]. These findings highlight a dominant focus on AI's predictive capabilities in rural contexts, while pointing to emerging but underexplored applications in rehabilitation, planning, and remote access.

Discussion

Principal Findings

Across the literature, we identified three salient themes: (1) Numbers over Narrative: The Quantitative Focus in AI for Health Research on Older Adults, (2) Efficacy over Impact: Prevalence of Clinical Outcomes in AI for Health Research, and (3) Deepening Disparities: Rural Older Adults Missing in AI for Health Research. We examine these themes in the following sections.

Theme 1: Numbers Over Narratives: The Quantitative Focus in AI for Health Research on Older Adults

Across this systematic literature review, we identified that AI for health research predominantly emphasizes quantitative findings, focusing on measurable results, such as diagnostic accuracy, predictive modeling, and algorithmic efficacy. This trend reflects broader scientific priorities placed on numerical data and technical performance, often at the expense of deeper, qualitative insights into the lived experiences of older adults.

The studies reviewed generally included older adults as subjects of analysis, rather than as active participants in the research process. This suggests, and in many cases perpetuates, a research approach that focuses on older adults, rather than with them. By emphasizing AI's reach and capabilities in health research, such as screening [23,37], prediction [24-26,40,42], identification [27,38,43], and feasibility [30], the literature largely overlooks the personal narratives and lived experiences that are crucial for designing patient-centered, effective AI solutions. For example, Cui et al [23] designed their quantitative study to test the efficacy of AI as a screening tool for rural older adults who are particularly more susceptible to retinal lesions.

XSL•FO
RenderX

This application of AI, like most of the studies in this review, is provider-focused, as older adults were not asked to contribute their perspectives on the use of AI within their health care.

This focus on quantitative findings, while valuable in establishing initial data and baseline efficacy, remains a limitation in fully understanding the potential and impact of AI for health technologies [5]. The minimal presence of qualitative research undermines the broader relevance and applicability of AI solutions for marginalized populations, particularly rural older adults. Among the few studies that incorporated qualitative components, many offered limited depth or treated qualitative insights as secondary. For example, Lee et al [33] conducted a qualitative study with older adults in China and found that 81.6% of participants had never independently purchased or leased smart health care products, highlighting low levels of engagement and understanding of these tools, despite their increasing availability. Studies focused on clinical outcomes and algorithmic performance often fail to address the real-world implications of these technologies, such as usability, trust, and accessibility, which present critical factors in adoption and long-term success, especially in rural communities.

Most qualitative studies explore the experiences, preferences, and barriers faced by older adults [19]. This approach not only enriches the findings of quantitative studies but also ensures that AI for health tools is designed in ways that truly meet the needs of older adults, especially those in underrepresented communities. Without this qualitative dimension, the development of AI technologies will likely continue to miss crucial elements that could optimize their utility in everyday health care settings, particularly in rural and underserved populations. The current literature gap underscores the need for a more balanced research approach that integrates both quantitative and qualitative methods, ensuring that emerging technologies are both scientifically rigorous and human-centered.

Theme 2: Efficacy Over Impact: Prevalence of Clinical Outcomes in AI for Health Research

Our systematic literature review highlighted the prevalence of clinical outcomes in AI for health research within the context of rural older adult populations. A majority of studies in this sample concentrated on the efficacy of AI interventions designed to evaluate existing models or outcomes (6/23, 26%) [28,30,37-39,44], predicting health outcomes (4/23, 17%) [24-26,42], investigating determinants of health (3/23, 13%) [27,33,38], screening medical data (2/23, 9%) [23,45], estimating disease prevalence (1/23, 4%) [29], and analyzing associated factors (1/23, 4%) [41]. While the investigations of these outcomes are pivotal and promising, our review suggests that a more inclusive, participatory approach may ensure that AI tools are better aligned with the challenges and needs of rural older adults. In contrast to the clinical-centric focus, other technology sectors have increasingly adopted community-based participatory research models to engage users in the design and development process [20]. However, such approaches have yet to be widely applied in AI for health research, as seen in this systematic literature review.

Our findings suggest that while AI-driven tools demonstrate potential in improving diagnostic precision and personalizing care for older adults [2-4], the understanding of their real-world application in rural areas remains underexplored. Rural health care systems are complex, with challenges, such as limited broadband access, shortages of health care professionals, and transportation barriers, all of which may impede the successful implementation and sustainability of AI solutions [6-8]. In addition to those challenges, AI solutions also present unique challenges, including black box algorithms [16], privacy issues [19], and limited AI literacy [19,20]. None of the studies focused on any of these user-centered issues. This gap offers rich research opportunities for technology-driven, health-related fields, such as information science and computer science, to address these issues and contribute to a user-centered approach in understanding the development and implementation of AI for health research.

Furthermore, without a qualitative, community-centered approach to AI for health research, which includes understanding the barriers and experiences of rural older adults, the focus may likely remain on clinical outcomes rather than the broader community health outcomes that truly affect these populations [49].

Our literature review revealed a notable absence of initiatives aimed at improving digital and health literacy for rural older adults, highlighting a significant gap in current research. Beyond clinical outcomes, there are valuable opportunities to support the health of rural older adults through efforts focused on enhancing digital literacy as well as education on AI's impact on health care [19,20]. However, none of the studies within this review investigated older adults' digital literacy or AI literacy specifically focused on health care tools.

Theme 3: Deepening Disparities: Representation of Rurality Missing in AI for Health Research

The findings from this systematic review of the literature highlight a glaring gap in the representation in AI for health research of the perspectives of older adults from rural areas. During the initial screening, we found that using the term "rural" in combination with other key terms frequently yielded no results. As a result, we manually identified references to rural populations within the titles and abstracts. This process underscored not only the lack of focus on rural communities but also the challenges of finding research that includes rural older adults in a meaningful way. AI tools for health care and health decision support are developed using large datasets that, if not inclusive, will continue to marginalize communities like rural older adults [2].

Our review also reveals a geographic imbalance in the literature, with a substantial proportion of studies (11/23, 49%) [23-25,27,33-35,39-41,45] conducted in China. This concentration may suggest a geographic bias in the global development of AI for health research, raising concerns about the applicability and generalizability of findings to rural populations in other countries with different health care systems, cultural contexts, and infrastructure. Moreover, most of the studies we reviewed were heavily urban-centric, emphasizing data from metropolitan populations while overlooking the

XSL•FO
RenderX

distinct challenges and health contexts of rural communities. As a result, AI models developed in these contexts may fail to reflect the lived experiences or health care needs of rural older adults, further widening existing disparities [9-11].

Rurality was rarely a central focus in the studies reviewed. In most cases, it was treated as a background demographic variable rather than an analytical lens. Even in studies that addressed rural-related issues, such as health care access or social isolation, the quantitative data often lacked input from rural older adults themselves. This absence of direct perspectives limits the field's ability to design AI applications that are contextually relevant and responsive to diverse rural settings [13]. Beyond merely including rural populations as a demographic factor, it is essential to deeply understand the lived experiences of rural older adults within AI for health research. In many of the studies reviewed, rurality was treated as a simple comparative statistic, with little exploration of how rural-specific factors might impact research findings or health care outcomes. For example, in many of the studies (15/23, 65%) [24,25,27,29,31-34,36-38,40,42,43,45], rural populations were only mentioned in descriptive statistics, without any further analysis of how rurality influenced the research outcomes. This limited approach prevents a comprehensive understanding of the needs and challenges of rural older adults, ultimately undermining the development of AI solutions and algorithms that are equitable and effective for all populations [17].

Limitations and Future Directions

Like all systematic literature reviews, this study has limitations. Our search was constrained by the language spoken by the research team, limiting inclusion to studies published in English and potentially omitting relevant research in other languages. In addition, the set of keywords used in the search was not exhaustive, and future reviews using alternative or broader search terms may yield different findings. Despite these limitations, this review serves as an initial step in advancing a research agenda focused on the inclusion of older adults, particularly those from underrepresented, rural populations, in AI for health research. Our primary aim was to identify opportunities where AI can help address unmet health needs and enhance health care delivery for these communities. The findings from this review provide a foundation for the development and implementation of responsible, inclusive AI-driven health care solutions.

Conclusions

These findings suggest that AI for health care research is currently focused on (1) Numbers over Narrative and (2) Efficacy Over Impact, while (3) Deepening Disparities. While older adults are often described as lagging or in triple jeopardy when it comes to technology in health care, this literature review suggests that it is AI for health research that is actually lagging when it comes to understanding the specific community health care needs of this population. In addition, our findings identify a growing need for increased attention to qualitative research to investigate rural older adults' perspectives on the role of AI in the development of emerging health care solutions. In addition, there is a need for concerted efforts to examine the impacts of AI for health care research. This includes investigating the transparency of AI tools as well as older adults' access to education on the implications of AI within their health care.

Acknowledgments

We would like to acknowledge that preliminary findings of this systematic literature review were originally presented as a conference presentation at the 2024 Annual Scientific Meeting of the Gerontological Society of America. The authors attest that there was no use of generative artificial intelligence (AI) technology in the generation of text, figures, or other informational content of this manuscript.

Abstract

Background: Chatbots, as dialog-based platforms, have the potential to transform health education and behavior-change interventions. Despite the growing use of chatbots, qualitative insights into user and provider experiences remain underexplored, particularly with respect to experiences and perceptions, adoption factors, and the role of theoretical frameworks in design.

Objective: This systematic review of qualitative evidence aims to address three key research questions (RQs): (RQ1) user and provider experiences; (RQ2) facilitators and barriers to adoption; and (RQ3) role of theoretical frameworks.

Methods: We systematically searched PubMed, the Cochrane Library, and ScienceDirect from January 1, 2018, to October 1, 2023, for English- or German-language, peer-reviewed qualitative or mixed methods studies. Studies were included if they examined users' or providers' experiences with chatbots in health education or behavior-change contexts. Two reviewers independently screened titles, abstracts, and full texts (Cohen κ=0.82). We used the Joanna Briggs Institute Critical Appraisal Checklist for quality assessment and conducted a reflexive thematic analysis following Braun and Clarke's framework.

Results: Among the 1754 records identified, 27 studies from 10 countries met the inclusion criteria, encompassing 241 qualitative-only participants and 10,802 mixed method participants (657 contributing qualitative data). For RQ1, users emphasized empathy and emotional connection. For RQ2, accessibility and ease of use emerged as facilitators, whereas trust deficits, technical glitches, and cultural misalignment were key barriers. For RQ3, the integration of behavior-change theories emerged as underutilized despite their potential to increase motivation.

Conclusions: Chatbots demonstrate strong potential for health education and behavior-change interventions but must address privacy and trust issues, embed robust theoretical underpinnings, and overcome adoption barriers to fully realize their impact. Future directions should include evaluations of cultural adaptability and rigorous ethical considerations in chatbot design.

KEYWORDS

chatbot; health education; behavior change; user experience; privacy concerns; personalization; qualitative research.

Introduction

Chatbots are software applications designed for 2-way dialogue that simulate human conversation through text or speech and are increasingly integrated into health care systems to deliver health education and behavior-change interventions [1,2]. These applications provide tailored guidance and real-time support by leveraging the widespread availability of smartphones and internet connectivity, thereby delivering standalone health interventions [3]. Users receive timely information, reminders, and motivational messages that may improve health outcomes [4,5].

Despite their growing use, previous systematic reviews and meta-analyses have focused predominantly on quantitative outcomes, such as symptom reduction and behavioral compliance [1-3,6], leaving significant gaps in our understanding of the qualitative dimensions of chatbot interactions [7]. These gaps, namely, the limited qualitative insights into user experiences, the underutilization of theoretical frameworks in chatbot design, and an insufficient understanding of adoption

XSL•FO
RenderX

factors, form the foundation of this study and directly inform our 3 research questions (RQs).

Established theoretical frameworks, such as the health belief model (HBM), the technology acceptance model (TAM), and social cognitive theory, offer valuable constructs for understanding and motivating behavior change [8-11]; however, these models are rarely integrated into current chatbot designs. This underutilization may limit chatbots' capacity to enhance user engagement and sustain behavior change.

This review aims to synthesize qualitative insights into the following:

1. What are the experiences and perceptions of users and providers regarding chatbots in health education and behavior change?
2. What are the key facilitators and barriers affecting the adoption of healthcare chatbots?
3. How do theoretical frameworks guide the design and implementation of these chatbots?

Methods

Overview

This systematic review aligns with the meta-aggregation principles outlined by Lockwood et al [12] (adapted for qualitative evidence synthesis), which we have applied to the domain of health education and behavior change interventions delivered via conversation-based digital tools, including chatbots. This approach was chosen to explore in-depth user and provider experiences through a specific focus on qualitative data, directly addressing the RQs on perceptions, theoretical frameworks, and adoption facilitators and barriers. We adhered to the guidelines of the Joanna Briggs Institute (JBI) [13] for critical appraisal and reported our methods in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart and standard systematic review protocols. The review was registered with the Open Science Framework to ensure methodological transparency.

Search Strategy

We searched PubMed, the Cochrane Library, and ScienceDirect from January 1, 2018, to October 1, 2023, for English- or German-language, peer-reviewed qualitative or mixed methods studies. A medical librarian assisted in developing the search strategy to ensure comprehensive coverage. Our search syntax included terms such as "chatbot," "conversational agent," "digital health interventions," "qualitative," and "mixed methods." These terms were applied to titles, abstracts, and keywords to identify relevant studies examining conversation-based digital tools for health education or behavior change. The detailed search syntax is presented in Multimedia Appendix 1.

Study Selection

Two reviewers (SF and KEC) independently screened all titles and abstracts (Cohen κ=0.82), retrieving full texts when either deemed an article potentially relevant. Discrepancies were resolved by discussion, obviating the need for a third reviewer. Mixed methods studies were included if they provided relevant qualitative data, which were prioritized over quantitative findings during synthesis to ensure a comprehensive understanding of user and provider experiences. The final inclusion criteria limited articles to those presenting qualitative data on conversation-based digital tools in health education or behavior change, with participants or providers offering experiential insights. References were tracked and managed via EndNote (Clarivate) and manual cross-checking. An overview of the complete selection process is shown in Multimedia Appendix 2, along with the PRISMA flow diagram.

Inclusion and Exclusion Criteria

Studies were selected on the basis of the detailed inclusion and exclusion criteria outlined in Table 1. In brief, we included qualitative or mixed methods studies published in English or German between 2018 and 2023 that investigated user or provider experiences with conversation-based digital tools designed for health education or behavior change. These tools encompass various designations, including "chatbots," "conversational agents," and "digital health assistants," all of which rely fundamentally on dialog-based engagement. This inclusive approach enables a comprehensive examination of automated conversational systems within health intervention contexts. The time frame (2018 - 2023) was selected to capture recent developments in chatbot technology, while the language restriction was based on the research team's proficiency. Studies were excluded if they lacked conversational functionality, did not provide qualitative data, or focused on domains unrelated to health education and behavior change. These criteria were systematically applied to ensure consistent study selection and reduce potential bias.

XSL•FO
RenderX

Table . Inclusion and exclusion criteria.

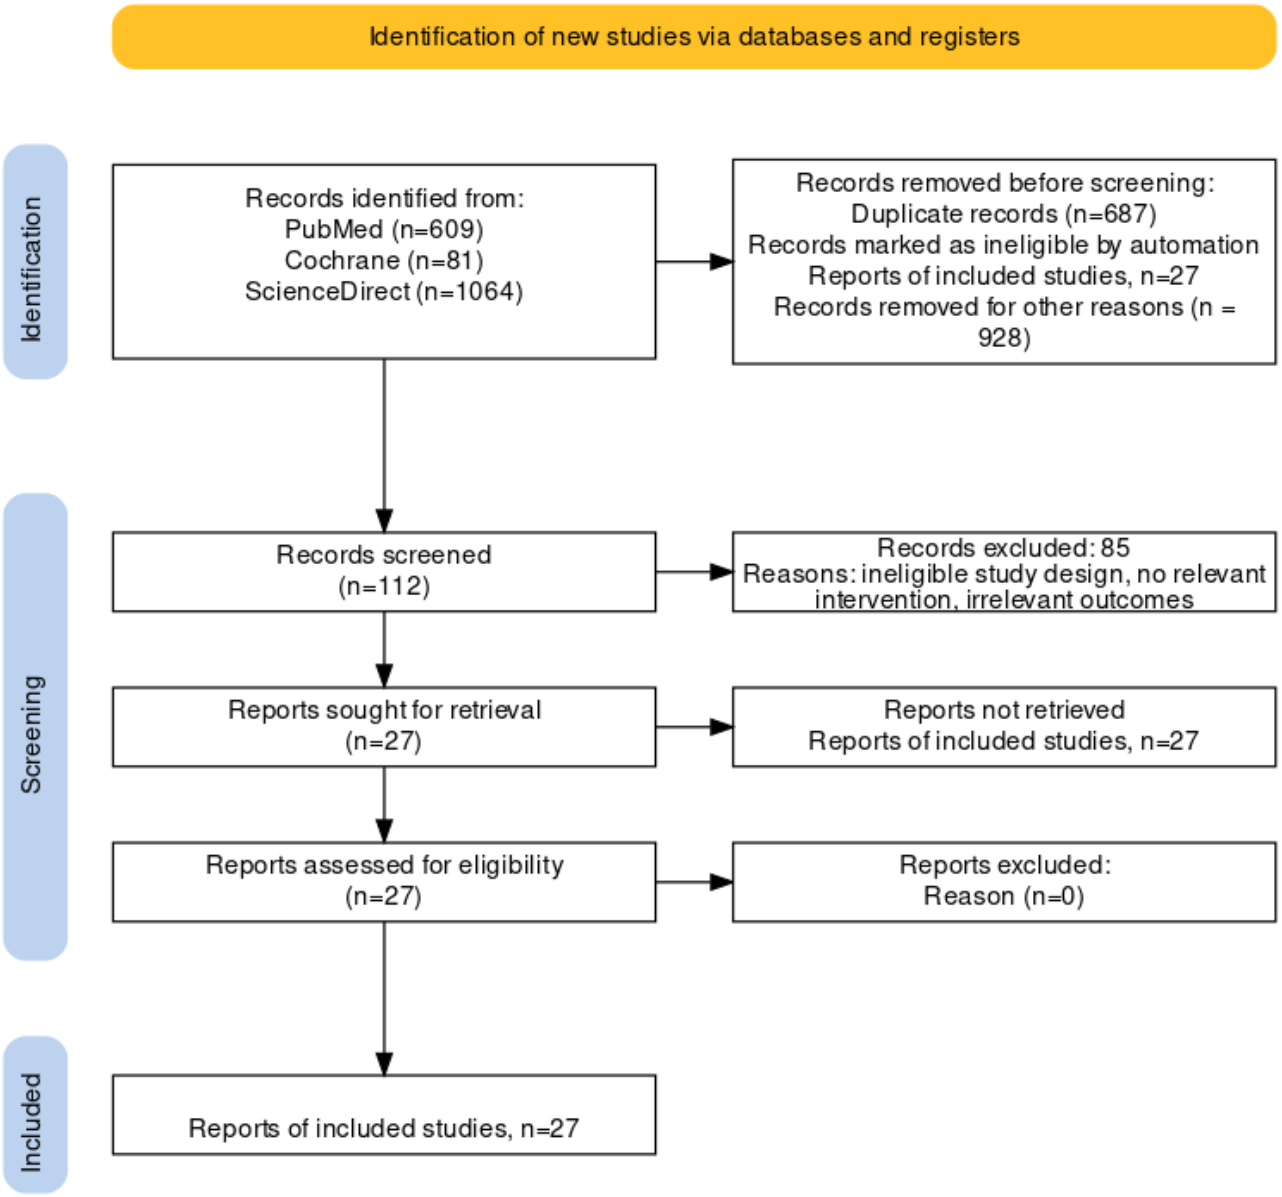
Criterion	Inclusion	Exclusion
Study type	Primary qualitative studies, mixed methods studies with qualitative components, and peer-reviewed articles	Purely quantitative studies, reviews, editorials, opinion pieces, conference abstracts, and non–peer-reviewed articles
Population	Patients and health consumers, health care professionals, adults (aged 18 years and older), adolescents (aged 12 - 19 years) with specific health conditions	Studies focused exclusively on children and studies without direct user and provider perspectives
Intervention	Chatbots and conversational agents for health education, chatbots for behavior change, artificial intelligence–driven health dialog systems	Mobile apps without conversational features, static health information systems, and noninteractive digital tools
Outcomes	User experiences, provider experiences, perceptions of chatbot use, qualitative feedback on usability, and implementation insights	Only quantitative outcomes, technical performance metrics, and cost-effectiveness analyses
Language	English and German	All other languages
Publication period	Published between 2018 and 2023	Studies published before 2018 and after 2023
Context	Health care settings, health education contexts, and behavior change interventions	Non–health care settings, commercial customer service, and general technology evaluation
Study design quality	Clear methodological description, appropriate data collection methods, and rigorous analysis procedures	Poor methodological quality, insufficient description of methods, and lack of ethical considerations

Data Extraction and Quality Appraisal

A standardized form was used to extract data on study design, participant demographics, chatbot features, outcomes, and key qualitative findings, ensuring consistency across studies. Two reviewers initially extracted data from 5 articles to establish a consistent approach before dividing the remaining articles; ongoing discussions resolved any ambiguities. The JBI Critical Appraisal Checklist for Qualitative Research was used to assess the methodological rigor and risk of bias (Multimedia Appendix 3). Rather than excluding studies failing to meet certain criteria, our appraisal informed the weighting of findings during synthesis.

Data Analysis

We conducted reflexive thematic analysis [14], beginning with immersive reading and coding of text fragments and progressing through 6 phases: (1) familiarization, (2) initial coding, (3) theme development, (4) review, (5) definition and naming, and (6) reporting. Subsequent iterative rounds of coding and discussion refined the analysis, and the themes were validated against the context of each article. To ensure rigor, investigator triangulation was used, with both reviewers achieving high interrater reliability (Cohen κ=0.82 for the screening process), along with regular analytic meetings and reflective journaling to mitigate researcher bias. The identified themes were organized in alignment with our 3 RQs, and representative participant quotes were integrated to illustrate key findings and enhance the credibility of the analysis.



Results

Overview of Included Studies

From the 1754 records identified, 27 articles from 10 countries satisfied our criteria, encompassing 169 participants in exclusively qualitative studies and 10,802 in mixed methods studies, of whom 657 contributed qualitative data (Figure 1). The studies varied in focus, encompassing chatbot design, technological innovations, behavior change, mental health, and user experience research. Participant ages ranged from adolescents to older adults, highlighting the broad adaptability of chatbots across diverse health contexts. The participants included patients, health care providers, and general users, with studies primarily using qualitative interviews or mixed methods designs. For a detailed summary of the study characteristics, see Table 2.

Table . Summary of study characteristics.

First author	Title	Year	Country	Aim of the study	Study design	Participants
Baptista et al [15]	Acceptability of an embodied conversational agent for type 2 diabetes self-management education and support	2020	Australia and New Zealand	To evaluate the acceptability of an embodied conversational agent, named Laura, used to deliver diabetes self-management education and support in the My Diabetes Coach (MDC) app.	Randomized controlled trial and mixed methods	93 participants in the intervention arm
Barnett et al [16]	Enacting "more-than-human" care: clients' and counsellors' views on the multiple affordances of chatbots in alcohol and other drug counseling	2021	Australia	The paper explores the experiences and perceptions of clients and counsellors of chatbots used in web-based alcohol and other drug counseling. It focuses on how these technologies afford (provide) or constrain online care and client interactions.	Mixed	20 clients (10 men and 10 women) and 8 counsellors (5 men and 3 women)
Beaudry et al [17]	Getting ready for adult healthcare: designing a chatbot to coach adolescents with special health needs through the transitions of care	2019	United States	To engage adolescents with chronic medical conditions using a chatbot and text messaging platform to promote skill attainment in self-care and ease the transition from pediatric to adult-focused care	Pilot study	13 adolescents with chronic conditions
Biro et al [18]	The effects of a health care chatbot's complexity and persona on user trust, perceived usability, and effectiveness: mixed methods study	2023	Clemson University, Clemson, United States	To examine how various design elements impact the efficacy of a health care chatbot intended for educational purposes.	Mixed methods	71 university students aged 18 - 26 years (28 males, 43 females; 69% Caucasian, 11.3% African American, 19.7% Asian)
Boggiss et al [19]	Improving the well-being of adolescents with type 1 diabetes during the COVID-19 pandemic: qualitative study exploring acceptability and clinical usability of a self-compassion chatbot	2023	Aotearoa, New Zealand	To assess the effectiveness and acceptance of a self-compassion chatbot (COMPASS) designed for adolescents with type 1 diabetes.	Qualitative	19 adolescents with type 1 diabetes and 11 diabetes health care professionals
Chang et al [20]	Why would you use medical chatbots? Interview and survey	2022	Taiwan	To understand the factors influencing individuals' attitudes and intentions to use medical chatbots.	Two-stage mixed-method approach	20 interview participants and 205 survey respondents

XSL•FO
RenderX

First author	Title	Year	Country	Aim of the study	Study design	Participants
Chen et al [5]	Developing a heart transplantation self-management support mobile health app in Taiwan: qualitative study	2020	Taiwan	To investigate the information needs of post–heart transplantation patients and develop a preliminary framework for a mobile health app to support their self-management.	Qualitative	17 post–heart transplantation patients and 4 health professionals
Galvão Gomes da Silva et al [21]	Experiences of a motivational interview delivered by a robot: qualitative study	2018	United Kingdom	To explore the experiences of individuals who have engaged in a motivational interview delivered by a social robot.	Qualitative	20 participants from the School of Psychology's pool of research volunteers
Griffin et al [22]	A chatbot for hypertension self-management support: user-centered design, development, and usability testing	2023	United States	To incorporate users' feedback into Medicagent through usability testing, leveraging the Information-Motivation-Behavioral skills model and the model of medication self-management	Mixed	10 adults with hypertension
Griffin et al [23]	Information needs and perceptions of chatbots for hypertension medication self-management: a mixed methods study	2021	Chapel Hill, North Carolina, United States	To understand information needs and perceptions toward using a chatbot to support hypertension medication self-management	Convergent mixed methods design	15 adults with hypertension
Han et al [24]	Preliminary evaluation of a conversational agent to support self-management of individuals living with posttraumatic stress disorder: interview study with clinical experts	2023	United States	To conduct a preliminary evaluation of the PTSDialogue, focusing on its usability and acceptance from the viewpoint of clinical experts.	Qualitative	10 clinical experts with experience in posttraumatic stress disorder care
Hurmuz et al [25]	Evaluation of a digital coaching system eHealth intervention: a mixed methods observational cohort study in the Netherlands	2022	The Netherlands	To assess the use, user experience, and potential health effects of a conversational agent-based eHealth platform among older adults.	Observational cohort study	51 older adults, 70.6% female, and average age of 65 years
Kornfield et al [26]	A text messaging intervention to support the mental health of young adults: user engagement and feedback from a field trial of an intervention prototype	2023	United States	To investigate young adults' engagement and experiences with a prototype of an interactive text messaging program for managing mental health concerns.	User-centered design	48 individuals (66.7% female and 33.3% male)

RQ1: User and Provider Experiences

RQ1 explores the general experiences and perceptions of users and providers regarding chatbots in health education and behavior change, which is distinct from the specific adoption factors addressed in RQ2.

XSL•FO
RenderX

Empathy and Emotional Connection

The participants valued human-like interactions in chatbots, particularly for emotional support. Ly et al [28] noted that participants perceived chatbots as living characters capable of forming relationships, emphasizing their potential to mimic human guidance and empathy. However, providers expressed skepticism about chatbots' empathetic capabilities. Nadarzynski et al [30] raised significant concerns, stating that chatbots are not capable of empathy, notably in recognizing users' emotional states and tailoring responses accordingly, potentially compromising user engagement.

Trust and Privacy Concerns

Privacy and data security are significant concerns affecting trust in chatbots. A participant in the study by Nadarzynski et al [30] stated, "Some things are confidential and you wouldn't just type it on the internet. You would want the confidentiality of [a doctor]," highlighting concerns over the chatbot's ability to maintain the confidentiality expected in traditional medical interactions. These concerns highlight the tension between accessibility and data protection.

RQ2: Facilitators and Barriers to Adoption

RQ2 investigates specific factors influencing the adoption of healthcare chatbots, distinguishing them from the broader experiences covered in RQ1.

Accessibility and Ease of Use

Round-the-clock availability and intuitive design were key facilitators. Boggiss et al [19] explicitly stated that chatbots offer unique advantages, including "24-hour availability, accessibility, remote delivery, scalability, and real-time personalized responses."

Personalization

Personalization enhanced adoption. Chang et al [20] highlighted user desire for personalized health information, rather than generic content, to enhance relevance and usefulness. Boggiss et al [19] further supported this, noting that nearly all users wanted to customize chatbot interactions.

Trust Deficits

Trust issues, particularly those related to privacy, hinder adoption. Barnett et al [16] expressed concerns about confidentiality, noting uncertainty regarding who has access to chatbot interactions and thus preferring traditional doctor–patient confidentiality.

Technical Glitches

Technical issues such as app freezes and connectivity problems were barriers. Mash et al [29] explicitly described technical problems such as repeated messages and system overloads affecting message dissemination to users, significantly disrupting user experiences. Svendsen et al [35] reported that faulty synchronization and login issues impact chatbot use.

Cultural Misalignment

Chatbots' inability to interpret cultural nuances posed obstacles. Papadopoulos et al [7] highlighted the chatbot's difficulty in understanding cultural contexts, stating, "It may interfere with the patient, the patient may not be able to explain the problem to the robot because the robot does not know how people grow in cultures in places."

RQ3: Role of Theoretical Frameworks

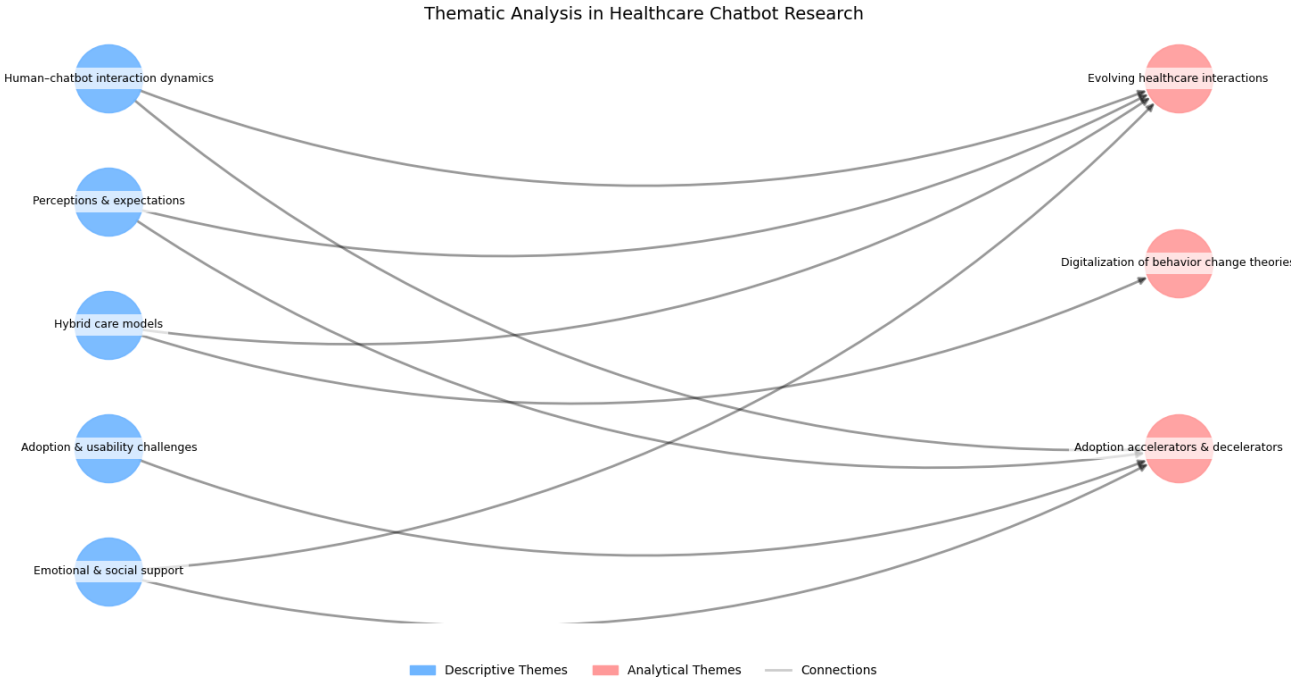
RQ3 examines how theoretical frameworks of health behavior change and how technology acceptance guides chatbot design and implementation.

Underutilization of Behavior Change Models

While some studies have integrated frameworks such as the HBM, TAM, or social cognitive theory, many have not, missing opportunities to increase user motivation. Griffin et al [22] explicitly used the IDEAS (Integrate, Design, Assess, and Share) framework and information-motivation-behavioral skills model to inform chatbot design for hypertension management, demonstrating the positive impact of theory-driven approaches. Conversely, Nadarzynski et al [30] identified the absence of a clear theoretical foundation as problematic, noting risks such as incorrect self-diagnosis and inadequate care from theoretically ungrounded chatbots.

Integration With Theoretical Constructs

Studies incorporating theoretical constructs reported improved engagement. Griffin et al [22] positively illustrated the integration of behavioral theories, notably the IDEAS framework and the information-motivation-behavioral skills model, effectively informing users and motivating behavior change.



Additional Analytical Themes

This section synthesizes insights from RQ1-RQ3 to illustrate how themes of empathy, trust, and theoretical grounding converge in the experiences of users and providers. Chatbots were seen as evolving interfaces capable of triaging minor questions before escalation, as highlighted by participants in Nadarzynski et al [30], who described chatbots effectively directing users either to immediate care or reassurance. They were also viewed as expansions of social networks, offering psychosocial support for isolated populations. Barnett et al [16] emphasized that chatbots might attract users needing extreme privacy and confidentiality, potentially engaging more individuals in treatment. By transparently integrating artificial intelligence (AI)–driven personalization with behavior-change theories, these digital tools not only strengthened emotional connections but also addressed key adoption barriers, creating a unified and trustworthy health-education experience.

Figure 2 provides a visual representation of the descriptive and analytical themes identified in our review, illustrating how user experiences (eg, empathy, trust) intersect with theoretical frameworks and adoption factors.

XSL•FO
RenderX

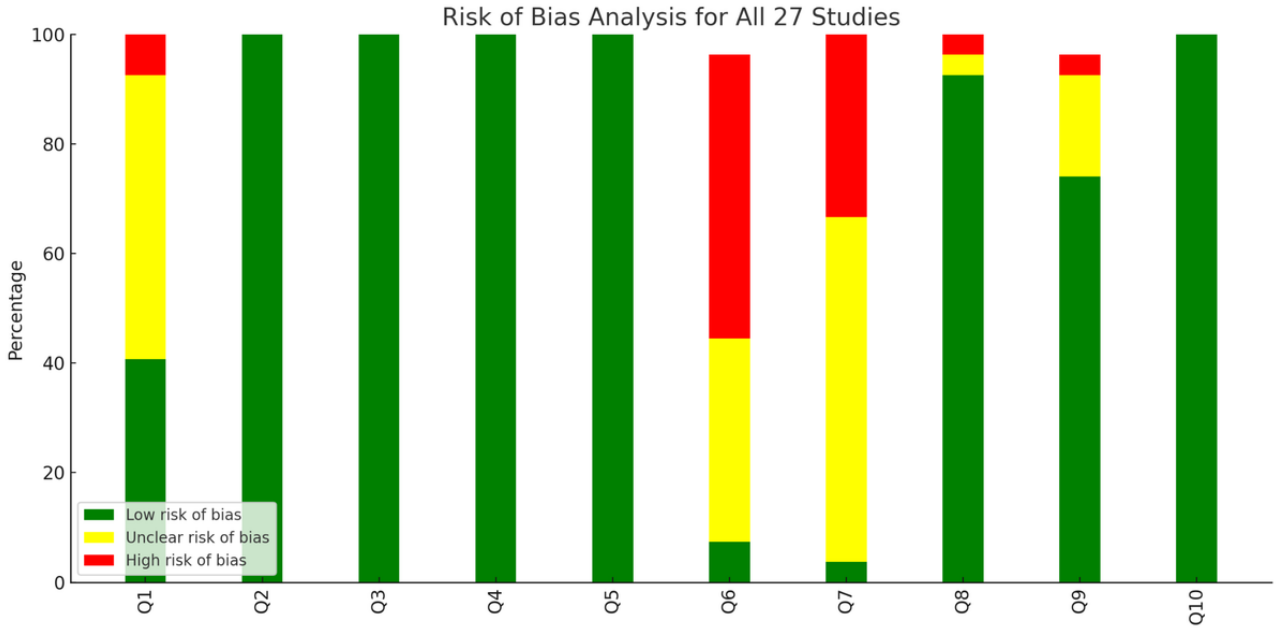


Figure 2. Thematic interconnections in health care chatbot research.

Methodological Quality and Risk of Bias

The methodological rigor of the 27 studies varied. Many aligned studies aim with qualitative methods, but some lack transparency in reporting researcher biases or ethical considerations. Using the JBI Critical Appraisal Checklist, 13 studies were at low risk of bias, 12 were at unclear risk, and 2 were at high risk, primarily due to limited ethical reporting or reflexivity. Figure 3 provides a summary of the risk of bias assessment for the included studies.

Figure 3. Summary of the risk of bias assessment for the 27 included studies.

Discussion

Principal Findings

Our synthesis reveals robust enthusiasm for chatbots as tools for health education and behavior change. In addressing RQ1 (User and Provider Experiences), we found that users value empathy and emotional support, yet they express concerns about trust and privacy. For RQ2 (Facilitators and Barriers to Adoption), 24/7 accessibility, ease of use, and personalization emerged as key facilitators, whereas trust deficits, technical glitches, and cultural misalignment were identified as major barriers. With respect to RQ3 (Role of Theoretical Frameworks), the underutilization of models such as the HBM or TAM in chatbot design has emerged as a critical gap, limiting the potential for enhanced motivational and behavioral outcomes.

Earlier meta-analyses, such as those by Laranjo et al [2], reported that chatbots can improve health outcomes, but our

XSL•FO
RenderX

qualitative review complements this by emphasizing user-centered dimensions such as trust, empathy, and cultural fit—factors often overlooked in quantitative studies. For example, Nadarzynski et al [30] identified privacy as a barrier to adoption, a concern supported by our findings and detailed in the results section. Our review also identified specific barriers, such as technical errors [19], privacy gaps [16,30], and cultural mismatches [7], which previous studies have not extensively addressed. This qualitative depth highlights that chatbot success depends not only on technical functionality but also on resonating with users personally and culturally—an insight crucial for developers and policymakers aiming to foster trust and adoption across diverse populations.

Our findings offer guidance for developers to embed behavior change theories and culturally adaptive content into chatbot design. Developers should prioritize incorporating prompts that address perceived barriers (eg, tailored reminders to overcome reluctance) and foster personalized feedback loops on the basis of theoretical constructs such as the HBM or information-motivation-behavioral skills model [22]. Developers should also embed culturally relevant content and empathetic responses to build trust and engagement. This systematic integration of theories is essential for optimizing chatbot effectiveness, addressing a gap in current designs.

Healthcare providers can integrate chatbots as triage tools to complement face-to-face care and reduce routine workloads. Providers should advocate for chatbots that support, rather than replace, human interaction. Training healthcare staff in how to use chatbot systems effectively can improve both patient outcomes and provider acceptance. Our qualitative insights suggest that providers are more likely to support chatbot integration when they perceive these tools as enhancing, not threatening, their professional roles.

Policymakers should promote transparent privacy standards and fund theory-based chatbot initiatives. Regulating data security and ensuring transparent privacy policies are essential to fostering user trust. Policymakers should support the integration of theoretical frameworks into digital health tools to ensure that they are evidence-based and effective. Funding initiatives promoting culturally sensitive chatbot designs could further support adoption. The emphasis on cultural relevance and ethical considerations in our findings points to a broader need for policies that prioritize user trust and inclusivity in digital health innovations.

Strengths and Limitations

A primary strength is the focus on qualitative evidence, offering granular insights into the emotional, cultural, and trust-based dimensions of chatbot use. The broad timescale (2018 - 2023) captures recent innovations, including AI-based chatbots. However, the 2018 - 2023 window may exclude older studies or those in languages beyond English/German, limiting the diversity of perspectives. Additionally, the rapid evolution of AI-driven chatbots, particularly large language models (LLMs), means that our results may not fully capture their latest affordances. The inclusion of broader conversational technologies [e.g., Biro et al [18], ; Chang et al [20], ; Svendsen et al [35],] to offer holistic insights may reduce the specificity of findings for strictly defined chatbots. Selection bias may have influenced the findings, as many studies recruited tech-savvy participants, potentially overrepresenting positive experiences. The heterogeneity of study designs and limited focus on specific populations (eg, older adults) also constrain generalizability.

Future Directions

Future research should examine how user perceptions (trust, empathy) evolve over time (RQ1), assess cultural influences on adoption barriers/facilitators (RQ2), and pilot systematic integration of theories into chatbot workflows (RQ3). For example, longitudinal studies should explore adherence and user engagement across time, whereas cross-cultural research could illuminate how regional dialects and health beliefs affect adoption. Methodologically, future work should strengthen transparency through preregistration and the use of qualitative reporting frameworks (eg, Consolidated Criteria for Reporting Qualitative Research), enhance ethical safeguards, adopt inclusive recruitment strategies, ensure human support during chatbot interactions, and establish clear data usage and privacy protocols. Collaborative efforts among developers, clinicians, behavioral scientists, and ethicists are essential for refining chatbot designs, ensuring data security, and embedding effective behavior

Conclusion

This systematic review highlights robust interest in chatbots for health education and behavior change while revealing significant challenges related to privacy, cultural alignment, and theoretical underpinnings. By addressing RQ1, RQ2, and RQ3, we identified key facilitators of and barriers to chatbot adoption and underscored the importance of embedding behavior change theories into chatbot design. Although chatbots extend the reach of healthcare by providing empathetic, accessible support, their full potential remains constrained without systematic integration of behavior change models and rigorous data safeguards. Developers should prioritize user trust, cultural relevance, and theoretical grounding to enhance chatbot adoption and effectiveness. Addressing these challenges through interprofessional collaboration, ethical oversight, and ongoing research will be crucial for realizing chatbots' transformative potential in global health systems. This review's qualitative insights provide a foundation for designing innovative, user-centered chatbots that address diverse populations' complex needs in digital health.

Abstract

Background: Aging is associated with various challenges, especially concerning mobility. Transportation planning e-tools are currently available to provide older adults with real-time travel information and help them choose trip options. However, many older adults find them challenging to use, as they are not tailored to their specific needs, such as lack of accessibility to the different means of transportation. It is necessary to identify knowledge gaps about design based on older adults' experience using transportation planning e-tools.

Objective: This study aims to identify knowledge gaps regarding the user experience design and its evaluation for older adults using transportation planning e-tools.

Methods: A scoping review of the scientific literature was conducted, based on Arksey and O'Malley's guidelines. The search covers sources published in English from January 2002 to October 2022 through 7 scientific databases, including MEDLINE, AgeLine, CINAHL, SCOPUS, ProQuest, IEEE Explore, and TRID (Transportation Research International Documentation), and was updated in October 2023. Data selection and extraction were performed by the first author and were co-validated by 2 co-authors. The identified sources were analyzed based on source characteristics (authors, year of publication, title of the article, source of article, country, and context of the studies), the purpose of the studies (objectives and study orientation), and the mapping of the methodology and evaluation of user experience (design approach, setting, type of data collection and analysis, type of usability evaluation, and sample size). Both descriptive-analytical methods and thematic analysis were used to analyze the categorized data.

Results: Overall, 1905 sources were identified through databases, and 40 sources were selected for full-text analysis. Data analysis revealed in recent years that there has been significant growth in e-tools designed for older adults, but only 2 studies were related to the field of transportation. In total, 12 studies aimed to evaluate user experience, and 22 studies focused on a user-centered design approach. Most of these studies (n=31) were carried out in a laboratory setting, using summative usability evaluation (user-based testing). The System Usability Scale (SUS) was the most prevalent tool (15 studies) to measure user efficiency and satisfaction. However, no studies have been found that specifically aim to improve the mobility experience of older adults using an age-friendly transportation planning e-tool in a real-life context.

Conclusions: There is a lack of studies assessing older adults' experience when using transportation planning e-tools in real-life situations. To bridge this gap, a participatory approach is necessary to better consider the needs of older adults in a real-life context and create age-friendly design guidelines for the development of transportation planning e-tools. This will not only enhance their user experience in trip planning but also promote their social engagement by improving their mobility.

Introduction

Background

The population of individuals aged 65 years and above is projected to increase from 900 million in 2015 to 2 billion by 2050 [1]. Recent data reported that 37.8% of Canadians over the age of 65 years live with a disability, which increases mobility issues in their daily travel [2]. Indeed, some age-related changes may impede the use of transportation for many older adults to participate in meaningful activities. Decreased vision [3-5] and hearing loss [6,7] make it difficult to see other road users (especially at night), recognize traffic signs (reading text and distinguishing colors) while driving, and hear high-frequency sounds when crossing the street. In addition, decreased flexibility, range of motion, and grip strength can limit driving control and impair driving safety [7], which makes it difficult for them to get around. Therefore, it is necessary to support the ability of older adults to know and use transportation options that are tailored to their needs so that they continue to be able to leave their homes, which is an essential characteristic of social participation [8].

Transportation-planning e-tools are currently available to provide older adults with information about transportation and trip options. These tools can take the form of websites or applications designed to assist users in planning, personalizing, and managing their travel. However, many older adults find them challenging to use. With increased aging, reduced dexterity and lower vision make it difficult to locate the necessary information on the screen or click on the appropriate button, which can impede their experience when planning travels in the community [9]. Specifically, visual decline also impacts the contrast sensitivity in using travel planning e-tools (eg, recognizing the elements in maps or e-tools). The decline of fine motor skills [4] may interfere with the use of electronic devices that allow movement planning. Moreover, lower executive abilities can lead to difficulty in planning travel and understanding public transportation options [10]. Besides, some older adults experience difficulty in travel planning due to their lack of digital literacy [11], which may raise challenges, such as access to the up-to-date flow of information for travel planning [12]. The interface of the developed tool should thus consider these age-related changes and the variability in numerical literacy [13] in planning trips. When it comes to designing an interface, user experience is essential [14].

User experience is defined as an "iterative set of decisions leading to a successful outcome with an interactive tool, as well as a productive and satisfying process while arriving at this outcome" [15]. According to Hassenzahl and Tractinsky [16], it is created by the interaction of the user's internal state, the characteristics of the designed system, and context. It should be noted that 2 other concepts should be introduced in relation to user experience: user interface and usability. User interface is "the part of technology that people interact with. The interaction between a computer and a user is a two-way interaction" [17]. Therefore, user interface design refers to "the iterative set of decisions leading to a successful implementation of an interactive tool" [15]. Usability refers to the fact that "when a product or service is truly usable, the user can do what she or he wants to do, the way she or he expects to be able to do it, without hindrance, hesitation or questions" [18]. Hassan and Galal-Edeen [19] argue that usability is a subset of user experience, and none alone can determine the degree of conformity of a product or service to the expectations and needs of its users. The usability criteria include usefulness, efficiency, effectiveness, satisfaction, learnability, accessibility, memorability, and error tolerance. Considering these definitions in the framework of this study, the user experience refers to the interaction of older adults with the aesthetic and functional aspects of the transportation planning e-tool to plan a trip that satisfactorily meets their needs and preferences.

A co-design design is a participatory approach that can be relevant to older adults to address their challenges in planning a trip and improve the user experience when using e-tools. Participatory design refers to "a process of investigating, understanding, reflecting upon, establishing, developing, and supporting mutual learning between multiple participants in collective reflection-in-action" [20]. Understanding the interactions and collaboration of older adults in co-design approaches such as participatory design [20] is an important aspect of user experience design [21] as older adults' needs and physical condition can affect their participation in the design process. Participatory design could help evaluate user experience. As there is a lack of research on user experience design for older adults [22], it is essential to support older adults' mobility through travel options that are tailored to their needs and preferences by identifying knowledge gaps regarding the user experience design of older adults when using a transportation planning e-tool.

Context and Objective

The aim of this scoping review is to identify knowledge gaps regarding the user experience design and its evaluation for older adults using transportation planning e-tools.

Methods

Study Design

This scoping review was based on Arksey and O'Malley's [23] framework with the following stages: (1) identifying the research question; (2) identifying the relevant sources; (3) selecting the studies; (4) charting the data; and (5) collecting, summarizing, and reporting results.

Identifying the Research Question

The question was formulated using a broad approach to ensure sufficient breadth during the literature search. The question is: What is known about the user experience design, co-design, and its evaluation for older adults using transportation-planning e-tools to move around in the community? This scoping review followed the PCC framework: (P) older adults, (C) user experience design, co-design, and usability evaluation, and (C) transportation-planning e-tools.

Identifying the Relevant Sources

This stage consisted of searching scientific literature published in English from January 2002 to October 2022, with an updated

XSL•FO
RenderX

search conducted on October 3, 2023. The search was performed across 7 databases: MEDLINE (PubMed, NCBI), AgeLine (EBSCOhost), CINAHL Plus with Full Text (EBSCOhost), SCOPUS (Elsevier), ProQuest Dissertations and Theses (ProQuest), IEEE Xplore (IEEE Xplore Digital Library), and TRID (Transportation Research Board).

Databases and keywords were selected and confirmed during a multi-step process. First, the keywords and databases were selected by two of the authors (SBG and VP). Then, an experienced librarian (FL) reviewed and refined them, ensuring that the selected terms and databases were relevant to the research question. As part of the search strategy confirmation, FL provided feedback aligned with the PRESS 2015 Guidelines [24], offering expert guidance on refining keywords, optimizing Boolean operators, and using controlled vocabulary where available. These adjustments helped ensure both the accuracy and comprehensiveness of the search. Some decisions were made to retrieve the largest number of relevant sources. During the pretesting of the research strategy, incorporating transportation-related keywords alongside other search terms significantly reduced the number of relevant studies. To address this issue, the librarian recommended removing these keywords and adding the TRID (Transportation Research International Documentation) and IEEE Xplore databases. This adjustment ensured a more comprehensive search and improved the scope of the review. Finally, the keywords and databases were confirmed by a senior researcher (HP), an experienced professor in the field of user experience. The full search strategies, including controlled vocabulary and keywords, are detailed in Table 1. To ensure comprehensive coverage, we first identified controlled vocabulary terms from each database's thesaurus (eg, MeSH in PubMed, CINAHL Headings, and IEEE Xplore's indexing terms). Based on these terms, we then created a structured list of keywords for each concept to capture both indexed and natural variations of relevant terms.

Table . Concepts and keywords.

Concept	Controlled Vocabulary (by Database)	Keywords
User experience	User-computer interface (MeSH—MEDLINE, PubMed) Usability testing (CINAHL headings) Human-computer interaction (IEEE Thesaurus)	"User Interface" OR "User interface design" OR "UI" OR "UI design" OR "User experience" OR "User experience design" OR "UX" OR "UX design" OR "Usability"
Aging	Aged (MeSH—MEDLINE, PubMed) Older adults (CINAHL headings) Older adults (TRB thesaurus)	"Older adult" OR "Old people" OR "Elderly" OR "Senior" OR "Aging" OR "Normal aging" OR "Frailty"
E-tool	Mobile applications (MeSH—MEDLINE, PubMed) Software applications (IEEE thesaurus) Web applications (CINAHL headings)	"Website" OR "Application" OR "E-tool" OR "Web application" OR "App" OR "Web"
Co-design	User-centered design (MeSH—MEDLINE, PubMed, CINAHL, SCOPUS) Participatory design (IEEE thesaurus)	"Co-design" OR "Participatory Design" OR "Co-operative Design" OR "User-Centered Design" OR "Co-creation"

The search results were exported into Zotero (Corporation for Digital Scholarship) for reference management. Duplicate records were initially removed using Zotero's automated deduplication feature, followed by a manual review by the first author (SBG) to identify and eliminate any remaining duplicates.

Selecting the Studies

The inclusion and exclusion criteria were established before the study commenced and applied during the screening process (SBG, VP, and HP). Sources were included if they were (1) focused on developing or evaluating e-tools, and (2) discussed e-tool usability or user experience. Sources were excluded if they did not apply to the target population (older adults). To evaluate a larger range of studies, articles whose target group was 50 years or older were considered. Some studies define 'older adults' as individuals aged 65 years and above, while others include individuals aged 50 years and older, especially in the context of research related to aging and technology use [25]. Considering individuals aged 50 years and older as "older adults" helped to retrieve a broader set of articles, particularly those focusing on promoting the use of e-tools for the aging population. This approach ensured that relevant studies addressing the needs of both younger and older segments of the aging population were included, capturing a more comprehensive view of user experience with transportation-planning e-tools. The first author (SBG) screened all identified sources by title and abstract, followed by a full-text review to assess their eligibility. To mitigate the risk of bias, 20% of the study selection process was independently reviewed and confirmed by co-authors (VP and HP).

Charting the Data

A data charting form was developed by SBG and validated by VP, using a Microsoft Excel software grid that included source characteristics (authors, year of publication, title of the article, source of article, country, and context of the studies), the purpose of the studies (objectives and study orientation), and mapping of the methodology and evaluation of user experience (design approach, setting, type of data collection and analysis, type of usability evaluation, and sample size).

Collecting, Summarizing, and Reporting Results

Both descriptive-analytical method and thematic analysis [26] were used to analyze all categories of data (characteristics of

XSL•FO
RenderX

sources, purpose of the studies, and the reflection of the methodology and evaluation). Results were discussed, analyzed, and combined to identify the knowledge gap. Table 2 shows the list of selected articles.

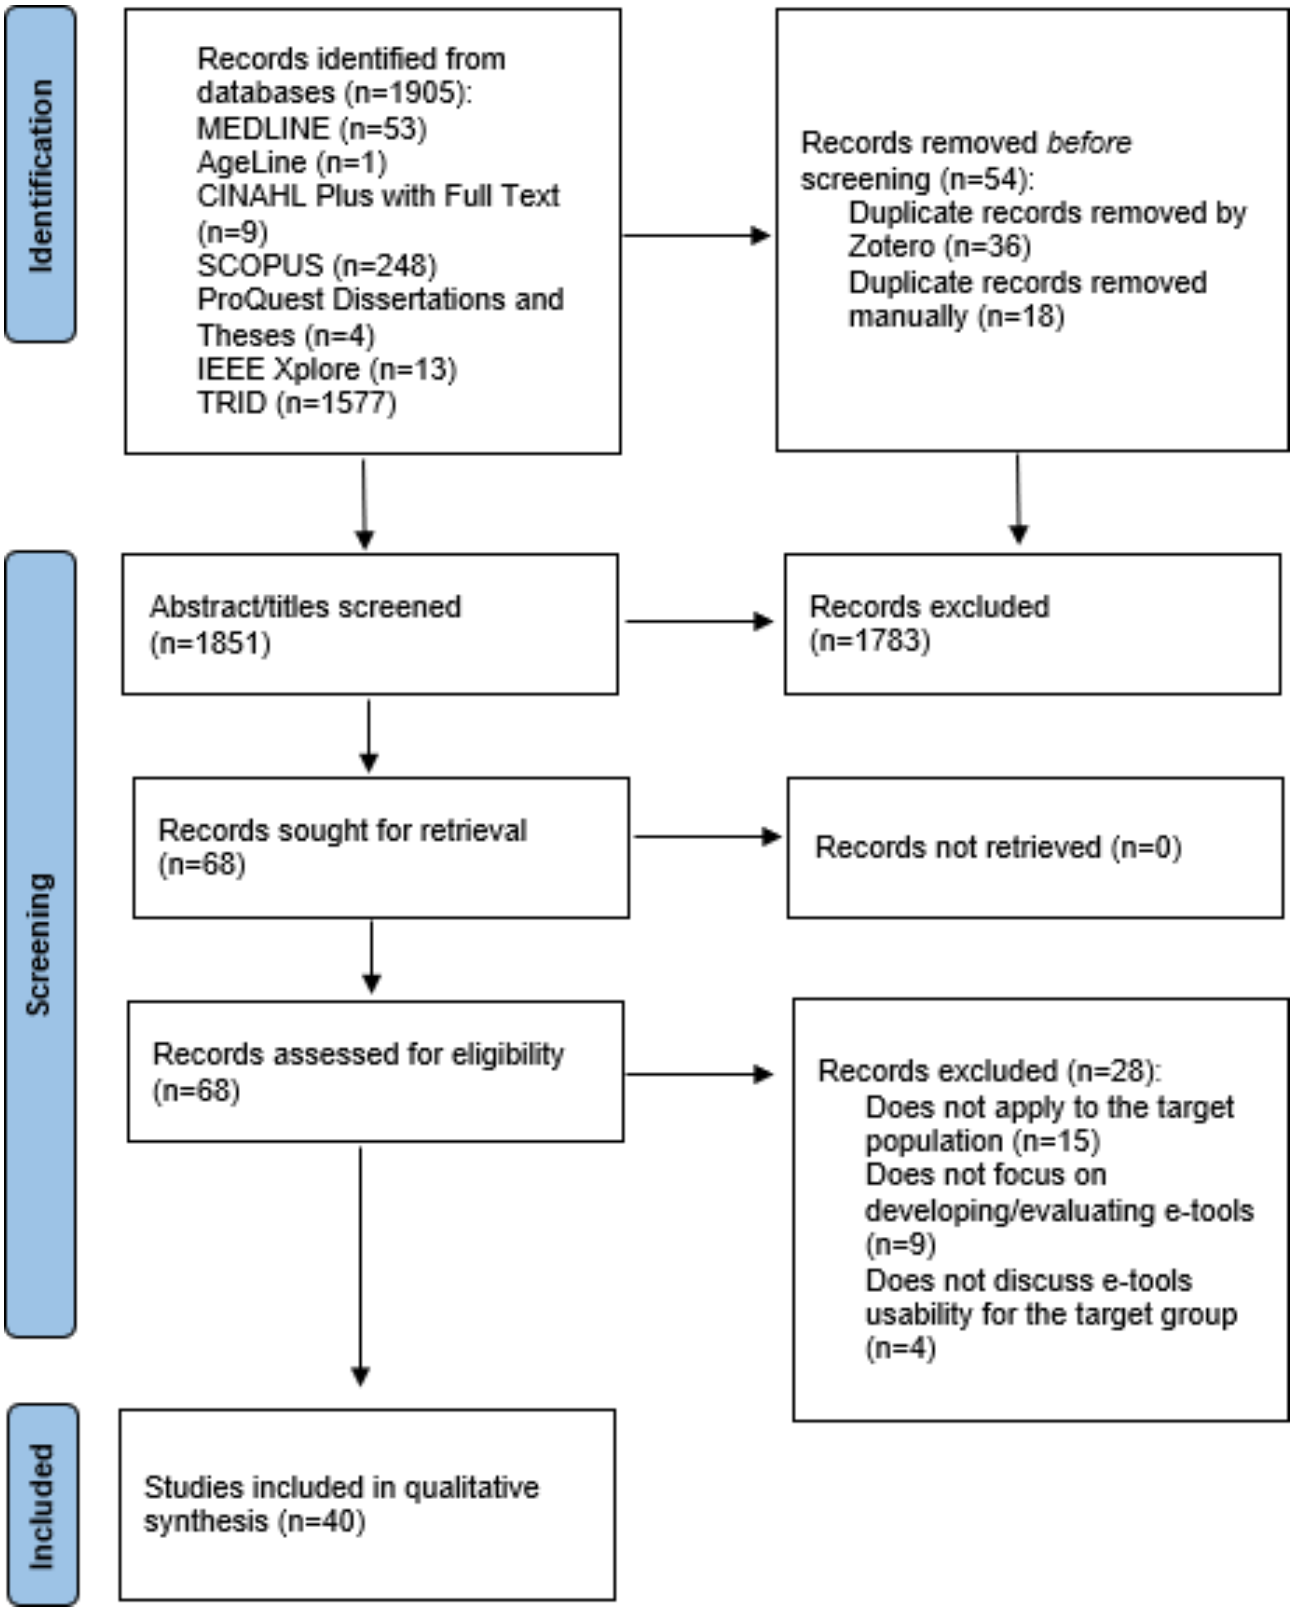
[a]not available.



Results

Screening Results

Overall, 1905 studies were identified through the databases. The record after duplicate elimination was 1854. In total, 68 sources were retained after screening for title and abstract. Finally, since 28 records did not meet the mentioned inclusion and exclusion criteria, 40 sources were included in this review (Figure 1; Checklist 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram detailing the process of literature search, screening, and selection.

Characteristics of Sources

Out of a total of 40 studies, 4 studies [27,52,57,58] were published during the first decade of the scope (2002 - 2012) (10%), while 36 studies [14,25,28-51,53-56,59-64] were published after 2012 (90%). These studies were conducted across different continents, with 14 (35%) in Europe [14,27-29,32,36,37,39,42,45,53,55,57,62], 10 (25%) in Asia [31,33,38,40,44,46,47,52,56,60], 12 (30%) in North America [25,30,35,43,49-51,54,58,59,63,64], and 4 (10%) in South America [34,41,48,61]. The majority of the sources (29 studies) were peer-reviewed articles, representing 72.5% of the total [14,25,30,32,33,35-45,48-51,54,55,57,58,60-64], while the

XSL•FO
RenderX

remaining 11 studies were conference articles (27.5%) [27-29,31,34,46,47,52,53,56,59].

Most contexts of the identified studies were related to health [14,28,32,34,35,37-39,41-44,49-51,54,60,62,64]. The other identified study contexts included tourism [27,57], shopping [31], daily planning [25], learning [45], social and physical well-being [47], physical activity [48], service provider [29], communication [30,40,61], nutrition [33,36], social network [53], entertainment [55], and weather [63]. In total, 3 articles did not specify the context of the study [46,58,59]. In total, 2 studies aimed to develop an e-tool and evaluate user experience in transportation [52,56].

The Purpose of the Selected Studies

The purpose of the selected articles was categorized into three groups: (1) documenting or extracting usability design principles specified to older adults, (2) evaluating user experience, and (3) developing or redesigning an e-tool for older adults. Out of the 40 articles, only 1 (2.5%) followed all 3 objectives [57]. In total, 12 (30%) articles [25,27,29-31,33,46,51,55,56,58,59] focused on evaluating user experience, while 19 (47.5%) articles [28,34,35,37,39,40,42,43,45,47,49,50,53,54,60-64] concentrated on both evaluating user experience and developing or redesigning an e-tool. The remaining 8 (20%) articles [14,32,36,38,41,44,48,52] only focused on developing or redesigning an e-tool. Evaluating user experience had the highest rate among all the studies, representing 80% of the total (32 studies) [25,27-31,33-35,37,39,40,42,43,45-47,49-51,53-64].

Empirical Methods of Usability Evaluation

Design Approach

Out of the total 40 articles, 22 (55%) of them were based on user-centered design [28,29,31-34,36,38-40,42,43,45-47,49-54,63], while 5 (12.5%) articles followed a co-design or participatory design approach [14,30,44,48,64]. In total, 3 (7.5%) articles used both user-centered design and co-design approaches [35,37,62], and 1 (2.5%) article followed an inclusive design approach [41]. There were 9 (22.5%) articles that did not specify any design approach [25,27,55-61].

Settings

Regarding experimental setting, 31 (77.5%) articles [14,25,27-29,31,33-40,43-48,50-52,55,57-61,63,64] were conducted in a laboratory setting, while the remaining 9 (22.5%) articles [30,32,41,42,49,53,54,56,62] took place in a real-world environment.

Type of Data Collection and Analysis

Most of the articles (31 studies) used both qualitative and quantitative methods for data collection and analysis [14,25,27-30,33,35-42,45,46,49-51,53,55-64], which represented 77.5% of studies. In total, 7 (17.5%) articles used the qualitative method [32,43,44,47,48,52,54], and just 2 (5%) articles [28,34] used only the quantitative method.

Usability Evaluation

Usability evaluation is usually divided into 2 general categories: (1) formative usability (usability inspection and expert-based): evaluating systems by experienced professionals using predetermined principles to identify usability issues [65], such as heuristic evaluation [66] and cognitive walkthrough [67]; and (2) summative usability (usability testing and user-based): evaluating the system by observing and recording the objective performance and subjective opinion of target users while interacting with a product to identify usability issues [68]. In usability tests, data are collected through diverse methods of objective performance and subjective opinions. A great number of studies (36/40) used summative usability evaluation (user-based), representing 90% of the studies [14,25,27-47,49-51,53,56-64]. Among the 40 articles, 10 articles (25%) used both summative and formative usability evaluation [29,39,44-46,50,57,58,61,62]. Only 1 (2.5%) article used formative usability evaluation [54], and 3 (7.5%) articles did not specify that they evaluated usability [48,52,55].

Data were collected through various methods during usability testing among older adults. Objective performance information was gathered from 19 articles, with task performance metrics being the most commonly used method [14,25,29,33,37,39,45,46,51,56-58,63], followed by observation 7 [14,30,40,42,43,47,64] and screen recording 3 [14,45,64] as less frequent methods. Subjective opinions (older adults' experiences and their design preferences) were predominantly collected via questionnaires [14,25,27,29-31,33-39,41,42,45,50,51,53,57-60,62-64], with additional methods including think-aloud protocol [14,35,37,38,40,44,45,50,51,54], interviews [30,32,35,36,38,40,42,47,49-51,53,56,57], focus groups [27,28,59,60], and open-ended questions [33,36,37,43,58,64]. A subset of studies also used formative usability evaluation, some including heuristic evaluations [29,39,44-46,50,57,58,61], and cognitive walkthrough a few articles [54,62].

The questionnaire was the most frequently used data collection method. Among them, the System Usability Scale (SUS), measuring efficacy and satisfaction with usability when users perform specific tasks [69], was the most prevalent one. Table 3 demonstrates a structured summary of the usability evaluation methods and their frequency.

XSL•FO
RenderX

Table . Usability testing data collection methods.

Usability evaluation type	Data collection method	n (%)
Objective performance	Task performance metrics	13 (32.5)
	Observation	7 (17.5)
	Screen recording	3 (7.5)
Subjective opinions	Questionnaire • System Usability Scale (SUS) (15 articles) • After-Scenario Questionnaire (ASQ) (2 articles) • Technology Acceptance Model (TAM) (3 articles) • Post-Study System Usability Questionnaire (PSSUQ) (1 article) • User Interface Satisfaction (QUIS) (2 articles) • NASA Task Load Index (NASA-TLX) (2 articles) • Health Information Technology Usability Evaluation Scale (Health-ITUES) (1 article) • Self-Assessment Manikin (SAM) (1 article) • Self-designed questionnaires (7 articles) • Usability Metric for User Experience (UMUX) (1 article) • Single Ease Question (SEQ) (1 article) • User Experience Questionnaire (UEQ) (1 article)	26 (65)
	Think-aloud	10 (25)
	Interview Semi-structured (5 articles)	14 (35)
	Focus group	4 (10)
	Open-ended questions	6 (15)

Sample Size

The number of participants varied, based on the purpose of the evaluation (ranging from 3 to 168). In the studies with a participatory or co-design approach (8 studies), the average sample size was 10, ranging from 3 to 22.

Synthesis of Results

Most of the studies focused on developing eHealth, and only 2 articles [52,56] were related to transportation. The first one [52] was about the usability evaluation of an existing travel planning website via a user-centered design approach and did not concentrate on developing the website, while the other one [56] concentrated on evaluating the user experience of existing rail terminal interfaces for older people without using any design approach. The first one was conducted in a laboratory setting with 3 older adults via various qualitative methods, while the second one was conducted in a real-life setting with 5 older adults and 5 adults via a combination of both qualitative and quantitative methods. Although 1 of these 2 articles was performed in a real-life setting, this study aimed to evaluate older adults' experience using existing services and did not concentrate on developing a transportation planning age-friendly e-tool.

Discussion

Principal Findings and Comparison With Previous Works

This scoping review aimed to identify knowledge gaps regarding the user experience design of older adults in using transportation planning e-tools. Our study reveals that e-tools designed for older adults have grown dramatically in recent years in health-related fields, while only 2 studies were related to transportation. Despite the large number of e-tools that have been developed to support transportation planning [70], documenting the user experience is rarely considered. This lack of focus may explain why it remains challenging for many older adults to use these e-tools effectively while planning their travels and finding their way from one place to another. For example, real-time travel information, as a crucial aspect of travel planning [71], is expected to significantly impact the user experience of older adults, by reducing the anxiety of getting lost [72], protect them from the weather traffic congestion [73,74] and enhance the use of modes of transportation that are tailored to their needs and preferences [75]. Statistics Canada [76] reported that only 54% of older adults have a smartphone for personal use, many of whom rarely use its various functions, which creates a gap between the intended goal of transportation planning e-tools and their current use. The lack of studies aiming

XSL•FO
RenderX

to document older adults' experience in using transportation planning e-tools might thus affect their accessibility in terms of content and functionality. In this context, Subasi et al [77] argue that developing a system that is not only universally accessible but that also meets the specific expectations of older adults will optimize their usage of the digital system.

This review also revealed the lack of studies concentrating on developing transportation planning e-tools using participatory design. This result might be explained by the challenges related to this design approach, such as substantial time, resources, and institutional commitment [78]. In participatory design, designers try to learn the realities of users' situations while the users strive to articulate their desired aims and learn the appropriate technological means to acquire them [20]. Although it seems that participatory design is an approach to the user-centered design [79], it is actually a shift in attitude from designing "for" users (user-centered design) to designing "by" users (participatory design) [80]. To address the challenges of participatory design, it would be good to understand the optimal methods and timing for involving users in the study process. Providing concrete deliverables and regular updates [81] could motivate participants by demonstrating the tangible results of their contributions to the development of transportation planning e-tools. Additionally, establishing a welcoming and enjoyable atmosphere at the beginning of co-designed sessions, such as icebreaking [9], can help participants feel comfortable and build trust with the researchers. Simplifying some consultation sessions into questionnaires or virtual sessions could lessen the burden of in-person meetings for both older adults and the research team, particularly during winter. This strategy would also facilitate frequent and balanced engagement with older adults while reducing expenses [82].

Although the aim of a considerable number of studies was to evaluate the experience of older adults using existing or newly developed e-tools, only 1 [57] considered not only evaluating user experience and redesigning an e-tool but also documenting usability design principles. It should be noted that developing usability design principles and guidelines for age-friendly e-tools is crucial due to variations in older adults' design characteristics [83]. Some user-centered methods, such as persona [84], might help to consider the needs and preferences of a wide range of older adults in developing age-friendly e-tools. More specifically, persona is used to identify user expectations through the definition of personality characteristics and specific personal details [84]. According to Cooper [85], the aim of persona is to have a comprehensive and global view of the target population to know for whom the product is not intended, and its approach is concentrating on "specific or canonical users" [84]. As none of the reviewed studies mentioned the use of persona, it would be interesting for future studies to explore how this method could help classify older adults with, for example, varying levels of digital literacy, diverse mobility profiles, and different travel planning habits. This could help identify variations in older adults' design characteristics and aid in the development of usability design principles.

Based on our results, combining formative (expert-based) and summative (user-based) usability evaluation using a mixed-method and providing the intersectoral participation of different disciplines might help to perform a comprehensive evaluation of the transportation planning e-tools for older adults. Indeed, most of the sources reviewed (77.5%) used both qualitative and quantitative methods for data collection and analysis, which helps to gain a detailed understanding of the needs and preferences of older adults. As argued by Creswell and Plano Clark [86], using a mixed method could provide a deeper understanding of older adults' expectations in travel planning via transportation planning e-tools that would help to further improve knowledge in the production of guidelines and—accordingly—develop useful e-tools. Furthermore, most of the articles conducted in standardized situations used summative usability evaluation (user-based testing), highlighting the urgent need to capture the experience of older adults, more specifically in real-life settings, to help design products as close to actual usage as possible [87]. However, conducting a summative usability evaluation in a real-life context is challenging, due to its resource-intensive and time-consuming nature, which makes it costly. To address these challenges effectively, it would be good to adopt a participatory design approach involving a minimum of 5 participants. These participants should encompass diverse mobility profiles, digital knowledge, and travel planning habits, representing the targeted end-users to address 80% of usability problems, as proposed by Nielsen [65].

Limitations

This study identified knowledge gaps regarding the design user experience of older adults when using transportation planning e-tools. However, it has certain limitations. Although the data selection and extraction processes were confirmed by co-authors, study screening was performed by the first author. It is possible that some articles were not retrieved due to the selected keywords and lack of consideration for gray literature. Moreover, we did not use the methodology suggested by Levac et al [88], that includes a consultation step. This step would be practical in transferring development knowledge for e-tools for a broad spectrum of older adults through different disciplines such as gerontology, web developing, and design. Finally, although we did not systematically account for all plural forms, alternative spellings, or flexible word order, the use of controlled vocabulary (eg, MeSH terms) and keyword variations helped maximize the retrieval of relevant literature, while the librarian's review ensured the rigor of the search strategy and adherence to best practices in systematic reviews.

Conclusions

Supporting the mobility of older adults should be a priority in developing a transportation-related e-tool. According to this review, there are no studies aimed at specifically improving the mobility experience of older adults using an age-friendly transportation planning e-tool in a real-life context. Therefore, it is necessary to fill this gap by using a participatory approach (co-design) to better understand the needs of older adults in a real context to create age-friendly design principles and guidelines in the development of a transportation planning e-tool. This will not only improve their usability experience when planning a trip using a transportation planning e-tool but also strengthen their social participation.

Abstract

Background: Nurses face a higher risk of developing work-related musculoskeletal disorders (WMSDs) due to their primary roles in patient care. Participatory ergonomics (PE), an approach that integrates large-scale interventions performed at organizational and systems levels with small-scale interventions, is widely considered a promising approach to mitigate health problems at the workplace. However, its effectiveness in addressing WMSDs and secondary outcomes such as sickness absence and work performance among nurses is not fully understood.

Objective: This systematic review assessed the effectiveness of PE interventions in preventing WMSDs and mitigating two related outcomes, sickness absence and work performance, among nurses.

Methods: A literature search was performed in four electronic databases, PubMed, ScienceDirect, Scopus, and PsycNet, guided by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines to retrieve relevant papers published between 2017 and 2023. Papers fulfilling the eligibility criteria were analyzed and subjected to quality appraisal.

Results: Overall, 19 papers were included in the final analysis. Various categories of ergonomic interventions were identified, with the predominant being exercise and physical activities, health promotional activities and training, educational programs, and patient handling devices. Multicomponent interventions, especially those involving physical activities and exercise, demonstrated stronger effects in reducing the risk of WMSDs at 6 months (OR 1.64, 95% CI 1.12 - 4.54) and 12 months postintervention (OR 2.70, 95% CI 1.52 - 4.51) compared with single interventions. However, most ergonomic interventions had no statistically significant effect (P>.05) on sickness absence and work performance. More than half (n=13) of the studies demonstrated moderate to high risk of bias, reflecting the need for better quality interventions.

Conclusions: Multicomponent interventions, particularly those involving physical activities and exercise, are more effective in reducing the risk of WMSDs among nurses compared with individual interventions. However, their long-term effects in addressing WMSDs, sick absenteeism, and work performance are still unclear. These gaps could be addressed by integrating organizational factors and prevention policies into existing ergonomic interventions, thereby offering opportunities to improve psychological health, job satisfaction, and work dynamics.

Introduction

Background

Nurses are highly exposed to risks of work-related disorders and injuries, culminating in burnout and low quality of care [1]. Such injuries may involve all body organs, especially the musculoskeletal system [2]. Musculoskeletal disorders (MSDs) refer to health problems affecting the locomotor apparatus, such as the skeleton, muscles, tendons, cartilage, ligaments, and nerves [3]. MSDs comprise several degenerative and inflammatory conditions affecting the joints, tendons, ligaments, muscles, peripheral nerves, and supporting blood vessels, leading to soreness and physical discomfort [3].

Among health care workers, nurses have a higher risk of developing work-related musculoskeletal disorders (WMSDs) [4]. Nurses play pivotal roles within the health care system, which can be physically challenging as they frequently help patients to mobilize, transfer between positions, and execute other daily life activities [5]. Multiple factors have been found to increase the risk of WMSDs among nurses, including physical load and work posture [6], psychosocial factors such as the presence of psychosomatic symptoms and personality, work tasks, and work organizational factors [5]. Thus, it is not surprising that nursing staff stationed in the operating room recorded a higher prevalence of occupational injuries compared with intensive care nurses, nonspecialized nurses, and radiologic technicians [7]. Events including static body posture, prolonged standing, using tools such as retractors during surgery, and manual tasks such as pushing, pulling, and lifting patients and surgery sets could elicit discomfort and WMSDs, particularly among nurses working in operating units [8]. Recent studies have also highlighted factors such as low educational level, increasing age, high BMI, and lifestyle as predictors of WMSDs among nurses [4].

Given the aforementioned points, several authors have advocated and explored effective workplace interventions to address the risk of WMSDs among nurses. Occupation-specific interventions and rehabilitation options have the potential to reduce functional disabilities among nursing staff that may result from these injuries [8,9]. Ergonomic interventions, particularly participatory ergonomics (PE), are a promising approach to reducing WMSDs. PE integrates large-scale interventions that are performed at organizational and systems levels with small-scale interventions where workers are opportune to use their knowledge in addressing work-related ergonomic issues [8]. It entails the active involvement of workers in controlling and planning a significant amount of their tasks or work activities while introducing ergonomic knowledge, changes, and procedures in order to enhance working conditions, productivity, safety, quality, and comfort [9].

Positive outcomes such as lower musculoskeletal symptoms and occupational injuries, improved psychological health, as well as a decrease in workers' compensation claims, productivity loss, and work absenteeism, were reported following PE interventions among various high-risk groups [9,10]. Despite ergonomic interventions being considered essential to reduce the increasing trend of WMSDs, there is no agreement or consensus on the most appropriate intervention, as the component and approach may vary with the workplace setting [[11]].

Importance of Ergonomics in Nursing

The risk of WMSDs can be predicted based on ergonomic, individual, and psychosocial factors [8]. Ergonomics scientifically discusses how a job can be aligned with a person's physical and psychological characteristics without causing any harm to the person's well-being and efficiency [11]. The onset and development of WMSDs can be prevented by acquiring more knowledge and applying ergonomics [12]. Nurses are motivated to become more efficient, experience higher job satisfaction, and reduce job-related stress, occupational-related diseases, accidents, and absenteeism when they work in appropriate ergonomic conditions [13].

An earlier study revealed several advantages and enhanced occupational health among community nurses following the implementation of a multifaceted ergonomic program [14]. Moazzami et al [15] reported that alterations in nurses' body movements were facilitated by ergonomic educational intervention, particularly from the contemplation and preparation phases to the action phase for adopting correct body postures in the operating room. Likewise, a significant reduction in musculoskeletal pain in the shoulder, neck, and knee regions was recorded among nurses in general wards after implementing an ergonomic educational intervention [16]. The use of ergonomic posture training among nursing assistants also led to a significant reduction in work-related low back pain 6 months after the intervention but did not affect disability scores [15]. However, some studies depicted limited success of ergonomic interventions on measured outcomes such as WMSDs [16,17], work productivity, and absenteeism [18], which may be linked to differences in the design of interventions, samples, data collection tools, settings, and research design. Thus, there is still limited information on the appropriate and effective ergonomic interventions for preventing and addressing WMSDs and their related consequences among nurses.

Rationale for Conducting This Review

Although more research is required to develop conclusive evidence on the effectiveness of ergonomics interventions in reducing WMSDs among nurses, pertinent information is yet to be gleaned from the several available studies in the literature. In the last decade, numerous studies have demonstrated the importance of diverse programs such as participatory, educational, single, and multidisciplinary ergonomics interventions among nursing professionals [12,19,20]. Nevertheless, findings from these studies are yet to be systematically reviewed. Most of the systematic reviews focused on office workers or workplace settings [21] and dental and health care professionals [22]. However, Sun et al [23] in a recent systematic review and meta-analyses, compared the efficacy of nondrug interventions on nonspecific low back pain among nurses and found that the most effective intervention was a combination of low back exercises and health education, followed by single low back exercises and yoga.

XSL•FO
RenderX

Previous literature reviews have investigated the effectiveness of interventions among nurses and in nurses' homes [14], including nursing assistants' risk of handling obese and overweight patients and interventions to reduce low back pain [24]. However, none of the past reviews looked into how ergonomic interventions ameliorate WMSDs and their consequences, particularly among nurses. The present review differs from prior attempts by systematically analyzing the various ergonomic interventions adopted in preventing WMSDs and other closely related outcomes, including sickness absenteeism and work performance or productivity in nurses. It seeks to provide evidence-based data and scientific support for developing an ergonomic intervention to prevent WMSDs among nursing professionals.

The objective of this systematic review is to assess the effectiveness of ergonomic interventions in preventing WMSDs and mitigating two related outcomes, sickness absence and work performance, among nurses.

Methods

Overview

This systematic review was conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. The PRISMA statement was developed to assist researchers in preparing a complete, accurate, and transparent review that is beneficial to users [25]. The PRISMA 2020 statement includes new reporting guidelines, particularly for systematic reviews of studies that appraise the effects of health interventions. The PRISMA statement was considered suitable for the present systematic review, given its provision for a clear definition of research questions, identification of the exclusion and inclusion criteria, and assessment of relevant and accessible scientific papers within a specific timeframe. In addition, this review has been registered in International Prospective Register of Systematic Reviews (PROSPERO) with the registration number CRD42023403981.

Formulation of Research Questions

Formulation of a concise and clear research question is an important phase to guide the authors in many aspects of the systematic review. PICO, a research question development tool (RQDT), was used in the formulation of the research question for this review. PICO is an acronym in which P is population, I is intervention, C is comparison, and Ois outcome, and the 3 main concepts of PICO are population or problem, interest, and context. The authors of this review made an effort to incorporate all the aspects in synthesizing the main research question. Considering the population of interest as nurses, ergonomic intervention as the intervention, other nonergonomic interventions as the comparison group, and WMSDs, work performance, and sickness absenteeism as the outcomes, the research questions for this systematic review are as follows:

1. What are the commonly implemented participatory ergonomic interventions to prevent WMSDs among nurses?
2. Are ergonomic interventions effective in preventing WMSDs, sickness absenteeism and enhancing work performance among nurses?

Systematic Literature Search

Identification

The identification process entailed the determination of suitable keywords to search for sufficient information. Aligning with the research question, a few main keywords were recognized, namely MSDs, WMSDs, musculoskeletal pain, and musculoskeletal symptoms. In terms of the study population, the selected keywords encompass nurse, nursing, nurse assistants, and health care professionalsor workers. While the former is more specific for the present study context, the term "health care workers" was considered since such studies may include diverse professionals including those from the nursing field. Moreover, by taking the term "health care" into account in the identified keywords, health care professions that entail heavy-lifting jobs (ie, important risk factors for WMSDs) can be covered in the literature search.

Search Strategy

Search functions, including truncation and Boolean operators (OR and AND), were used in combining the selected keywords, leading to the formation of search strings. Search strings relating to study participants or study population, intervention, and study outcomes were synthesized as follows:

1. Study participants: "Nurse" OR "Nursing" OR "Nurse assistant" OR "Healthcare professionals" OR "Healthcare workers."
2. Intervention: "Ergonomic" OR "Ergonomic Intervention" OR "Intervention" OR "Participatory Ergonomics"
3. Outcomes: "Work-related musculoskeletal disorders" OR "Musculoskeletal disorder" OR "Musculoskeletal Pain" OR "Musculoskeletal symptom" OR "Sick Absence" OR "Sick leave" OR "Sick Absenteeism" OR "Work Performance" OR "Work Productivity."

All the search strings outlined above were combined using the Boolean operator "AND," leading to the final search string used for each database. However, since each database is unique and programmed to operate differently, the search strings were modified accordingly to suit each database and to maximize the number of hits. For instance, ScienceDirect only accepts a maximum of 8 search terms, while PubMed requires all keywords to be placed in parentheses.

A detailed literature search was then carried out independently by the researcher and a research collaborator in four electronic databases: PubMed, ScienceDirect, Scopus, and PsycNet. These databases were selected as they offer an extensive collection of relevant journals, provisions for customizing an advanced search, and storage of retrieved papers. The literature search was first conducted in March 2023 and updated in March 2024 to gather original research papers written in English and published between 2017 and 2023. The search string used in all 4 databases, the number of papers retrieved, and the date of acquisition are presented in Table 1.

RenderX

Eligibility Criteria and Screening

Upon completing the literature search, the retrieved papers were screened according to the eligibility criteria. The first screening process was performed by using the filter feature provided in all 4 search engines. In terms of type of publication, only original papers were selected for further review, whereas chapters in books, books, and conference proceedings were removed. As for review papers, only those relevant to our review objective were assessed for vital information and to identify research papers that might have been missed during the literature search.

In terms of study duration, only papers in the last 7 years were considered for full-text reading. Based on preliminary analysis, the proposed timeline is sufficient to yield papers to facilitate a representative and comprehensive review of the research topic. Finally, only papers written and published in English were included in this study. This decision was taken to prevent any challenges during the data extraction since the researcher is only proficient in English. Issues arising during the process were resolved by consensus between all the review authors.

Data Extraction and Analysis

All the final papers were subjected to qualitative analysis. An Excel (Microsoft) spreadsheet form was generated before reviewing the papers to document basic data from the studies, such as the authors' names, titles, journals, and publication years. Data were extracted from each paper by scanning through the abstracts, methods, and results before proceeding to the full text. These processes assisted the researcher in recording the year of publication, study location, study design, specific ergonomic intervention used, instrument used, and main results or emerging themes.

First, available data were analyzed thematically to generate themes and subthemes. The potential themes considered were as follows: (1) study characteristics, (2) quality assessment, (3) common types of participatory ergonomic interventions, (4) multicomponents versus single components, and (5) effects of participatory ergonomic interventions on WMSDs, sickness absence, and work performance. Contrast analyses, specifically pairwise comparisons, were performed to ascertain the effect size report in each study involving intervention and control groups. For studies reporting WMSDs as categorical outcomes, the odds ratio (OR, 95% CI) was computed to measure the strength and direction of the association. Meanwhile, the mean difference (95% CI) was computed for studies reporting the outcome variables as continuous outcomes.

Quality Appraisal

Quality appraisal of each paper was performed using the widely accepted quality assessment tools for intervention studies, the *Cochrane Handbook for Systematic Reviews of Interventions* and the Risk of Bias in Non-randomized Studies-of Interventions (ROBINS-I) tool [26,27]. The Cochrane tool was used for experimental studies reporting randomized interventions.

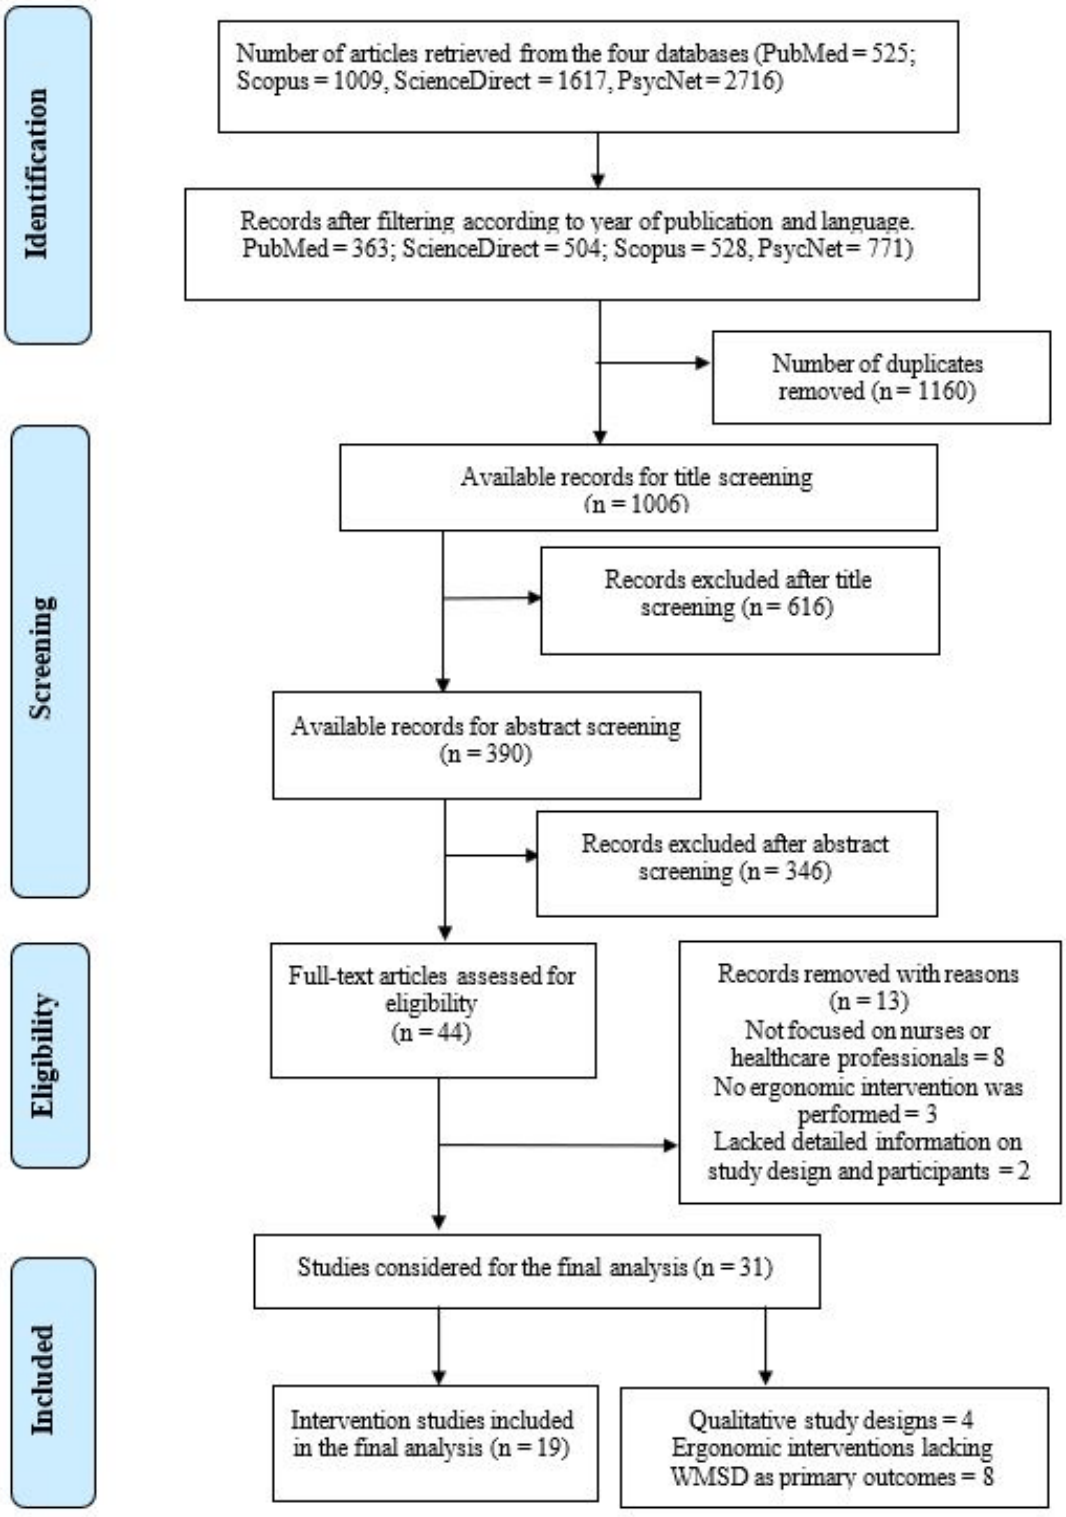
A total of 5 domains were considered for explicit reporting, comprising the sequence generation, allocation concealment, blinding, and completeness of data. For the first domain, the use of a randomized sampling method was assessed either by a random number table, tossing a coin, or computerized-generated numbers. Regarding the blinding of recruited patients, studies were considered adequate if both the intervention providers and outcome assessors were blinded (ie, minimal risk of compromised blinding) and inadequate if no blinding or partial blinding was performed. For outcome measures, trials were recorded as adequate if there were no missing data or if they stated the reasons for missing data that were unlikely to be associated with the true outcome. In addition, the studies were evaluated for selective reporting. Studies without sufficient information regarding the outcome reporting process were considered unclear. For all the aforementioned criteria, studies with insufficient information about each criterion were considered unclear. Other potential sources of bias were assessed, such as demographic characteristics between the treatment groups, by considering the baseline information of the participants.

Using the ROBINS-I tool, similar procedures described above were applied for the nonrandomized studies. The quality assessment tool focused on the randomization method, blinding of drug administration and assessment of treatment outcomes, data analysis techniques, sample size, and steps taken in addressing missing data and loss to follow-up. Studies reporting at least 70% (8/12) of the items in the quality assessment tool were considered of higher methodological quality or low risk of bias [27].

Ethical Considerations

Systematic review is part of a module development.Module development has obtained study ethics approval from the Medical Research Ethical Committee of Universiti Malaya Medical Centre (MREC ID No:20221019-11632) and National Medical Research Register (NMRR ID-23-01804-F44).

Results



Search Results

The initial search process before filtering and screening resulted in a total of 5867 papers, comprising 525 from PubMed, 1009 from Scopus, 1617 from ScienceDirect, and 2716 from PsycNet (Figure 1). Upon considering the years of publication (2017 - 2023) and language (ie, English), the remaining papers were reduced to 2166 (ie, PubMed=363, ScienceDirect=504, Scopus=528, and PsycNet=771).

Thereafter, 1160 papers were identified as duplicates and removed accordingly. To further reduce the number of records, the remaining results from each database were sorted and subjected to title screening. Out of the remaining papers (n=1006), those with irrelevant titles (n=616) and abstracts (n=346) were removed, leading to a total of 44 papers for full-text reading. Around 25 studies were excluded after reading the full texts because of irrelevant study populations (ie, not involving nurses or health care professionals, n=8), not reporting any ergonomic intervention (n=3), unclear study design (n=2), qualitative study designs (n=4), and ergonomic interventions with WMSDs as primary outcomes (n=8).

XSL•FO
RenderX

Figure 1. Literature search process using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. WMSD: work-related musculoskeletal disorder.

Descriptive Findings

Overall, 19 papers were experimental studies involving ergonomic interventions among nurses and other related health care professionals. These papers reported at least one of the following outcomes: WMSDs symptoms or pain, sickness absence, and work performance. Hence, all 19 papers were included in the final analysis and systematically reviewed. Table S1 in Multimedia Appendix 1 depicts the studies and participants' characteristics of types of ergonomic interventions and a summary of the main findings.

Ergonomic Interventions Reported in the Papers

As shown in Table 2, 7 categories of ergonomic interventions were identified in the 19 studies as follows: (1) exercise and physical activities, (2) educational programs, (3) health

XSL•FO
RenderX

promotional activities and training, (4) patient handling devices or equipment (acquired ergonomics equipment), (5 programmes) workstation and administrative interventions (organizational management), (6) counseling, and (7) others (case management and transcutaneous electrical nerve stimulation). The predominant ergonomic intervention was exercise and physical activities (11/19, 58%), followed by health promotional activities and training (8/19, 42%), educational programs (7/19, 36%), patient handling devices (4/19, 21%), workstation and administrative interventions (n=3), counseling (n=3), and case management (n=2). Furthermore, 3 studies reported specific exercises for back pain, 2 for neuromuscular pain, and 1 for neck pain. Around 10 studies (53%) each entailed either only multicomponent or single intervention, whereas 1 study compared both types of interventions.

Table . Types of participatory ergonomic interventions applied in the 19 studies.

Work-Related Musculoskeletal Disorders and Pain

Single Interventions

Among the 10 papers involving a single ergonomic intervention, significant reductions in either the prevalence, frequency, or pain intensity of WMSDs were reported in 6 studies [8,31,34,36,40,41]. The educational programs delivered by experts on ergonomic principles and risk factors of WMSDs led to a significant decrease (P<.05) in the risk of WMSDs, particularly in the ankle, wrist, lower back, and neck, pain intensity and Rapid Upper Limb Assessment ergonomic risk scores among nursing personnel with similar low effect sizes in both studies (0.30 vs 0.40) [8,36]. Likewise, ergonomic exercise (ie, neuromuscular and back exercise) performed in 3 studies was associated with significantly lower scores for low back pain (P=.05, effect size=0.45) [40] and overall pain scores (effect size=0.30 - 0.52) compared with either a control group or other nonergonomic single intervention such as transcutaneous electrical nerve stimulation [16,31].

In addition, 2 studies involving single ergonomic interventions, particularly online applications, were identified in this review [8,33]. Both studies recorded significantly lower low back pain scores in the intervention group compared to the control, with moderate to low effect size (ie, 0.30 - 0.50). Higuchi et al [33] focused on individual online therapy for low back pain, whereas Hosseini et al [41] used a Nursing Stretch Break app and reflected a significant reduction in WMSDs symptoms and pain intensity in nurses' body parts except the elbows and knees.

In contrast, 3 of the remaining studies found no significant effects of single ergonomic interventions such as educational programs [34], individual-based interventions [17], and patient handling devices [37] in preventing or managing WMSDs among nursing personnel. In Jakobsen et al [34] and Risør et al [37], despite improvement in the usage of patient-assisted devices posteducational program, no significant change was observed in the risk of low back pain and other WMSDs at 12-month follow-up. Similarly, individual-based ergonomic programs, including training, engineering, and administrative interventions, did not affect WMSDs scores at 18 months follow-up [17].

Multicomponent Interventions

Among the studies involving multicomponent ergonomic interventions, despite several combinations of interventions being reported, the results were analyzed based on whether they included exercise or physical activities or health promotional activities.

Around, 3 studies entailed a combination of health promotion activities and case management [19], workstation adjustment, and training without performing any exercise or physical activities [18,28]. Results from the studies revealed a significant reduction in the risk of WMSDs with an OR ranging from 1.64 (95% CI 1.12 - 4.54) at 6 months postintervention to 2.70 (95% CI 1.52 - 4.51) at 12 months postintervention [19,28]. In contrast, Rasmussen et al [10] found no significant effect of an intervention comprising three training workshops centred on focusing on workstation adjustment and health promotion in addressing WMSDs.

As for the 3 multicomponent interventional studies involving physical exercise, the pain intensity arising from WMSDs such as the lower back and shoulder or upper arm, neck, and hand or wrists body regions reduced significantly either 6 months or 12 months postintervention [28,32,38]. The effect size reported in these studies ranged from moderate to high (0.54 - 0.80), reflecting the greater efficacy of multicomponent PE comprising general or specific body exercise, for the management of WMSDs in nurses. Notably, the strongest effect size was observed in studies whereby exercise or physical activities were combined with either health promotion activities or educational or counseling programs such as pain neuroscience education and back care counseling [32,38]. Finally, the study by Marshall et al [39] found a significantly moderate reduction (OR=0.40) in subsequent acute cases of WMSD following multifactorial interventions comprising equipment intervention, educational ergonomics, and no-lift policies (administrative interventions).

Work Performance and Related Outcomes

Only 4 of the 19 papers considered work performance or presenteeism as musculoskeletal-related work performance, with 3 comprising multicomponent [19,30,38] and 1 including only a single intervention [40]. Both Imai et al [38] and Pereira et al [30] performed a dual-component intervention (ie, exercise and Pain Neuroscience Education (PNE) and workstation ergonomics and neck-specific exercise), leading to significant improvements in presenteeism (moderate to strong effect size=0.52 - 0.78) at 12 months follow-up. Meanwhile, using the same follow-up period, Soler-Font et al [19] found no significant difference in work functioning and performance in nurses exposed to a combination of PE, health promotion activities, and case management relative to the control group.

For the single-component studies, Taulaniemi et al [40] revealed a significant reduction in work-interfering pain (effect size=0.40; P=.046) in heavy nursing duties. Suni et al [32] also depicted that operating room nurses subjected to only back care counseling or neuromuscular exercise had a higher risk (OR 0.46) of work-related fear of pain compared with those administered a combination of both ergonomic interventions.

Sick Absenteeism

Sick absenteeism was reported in 6 studies included in this review, with 3 reporting multicomponent [10,19,30], 2 involving only single ergonomic interventions [17,32,37], and 1 study comparing both types [32].

For the multicomponent interventions, 2 studies found a significant reduction in musculoskeletal-related sickness absence in the intervention relative to comparison groups at 20 weeks [10] and 12 months postintervention [30]. Specifically, Rasmussen et al [10] entailed 20 weeks of PE comprising training workshops and health promotion activities, whereas Pereira et al [30] compared nurses subjected to workstation ergonomics and neck-specific exercises to those exposed to health promotion activities or information. Both studies found a moderate to strong effect size (−0.48 days per month, 95% CI −0.8 to −0.10 vs −0.72 days per month, 95% CI −0.52 to −0.94). In contrast, no significant difference was detected in sickness absence between nurses who administered PE, health

XSL•FO
RenderX

promotion activities, and case management compared with the control at 12 months postintervention [19].

The 2 studies involving single interventions, such as individual-based training, stretching exercises, motivation meetings, and patient handling devices or equipment, found no significant effect on sickness absence among nurses at 12 months [37] and 18 months of foled a singlelow-up [17]. These studies acknowledged the low likelihood of single-component ergonomic interventions in addressing musculoskeletal-related sickness absence, thus advocating for multicomponent programs, particularly administrative measures. This was further evidenced in the study comparing 4 different intervention arms, whereby only the combined arm (ie, neuromuscular exercise and back care counseling) demonstrated a significantly lower mean number of sickness absence days (effect size=0.55, *P*=.025) relative to the exercise-only groups at 12-month follow-up.

Quality Assessment Results

Out of the 11 RCTs evaluated using the Cochrane tool, 6 studies demonstrated a low risk of bias [10,19,28,30,32,34], 3 recorded a moderate risk of bias [16,33,40], and 2 papers had a high risk of bias [39,42], as shown in Table 3. All 6 studies with a low risk of bias showed high methodological quality in terms of randomization methods, concealment of treatment allocation, no significant difference between treatment groups at baseline, intervention delivery and adherence, as well as accounting for missing data and adjustment for possible confounders. Only one of the 6 studies performed a single-blinding procedure for the outcome assessment [32]. Meanwhile, the main issues observed in studies with moderate to high risk of bias were unclear or lack of information on the participants' baseline characteristics (n=4), a strong potential for confounding of the intervention's effect (n=4), lack of appropriate analysis method for confounder adjustment (n=5), no information on how missing data were addressed (n=3), incoherent onset of intervention and follow-up in most participants (n=3), unclear definition of intervention groups (n=2), poor adherence to the intervention regimen (n=2), and indications of selective reporting (n=2).

Table 4 depicts the quality appraisal for the nonrandomized or quasi-experimental studies (n=8), with 6 [8,17,31,35-37], and 2 papers identified as having high risk and moderate risk of bias, respectively [17,29]. The main methodological weaknesses observed in these studies were unclear or lack of information on the participants' baseline characteristics (n=3), the potential for confounding of the intervention's effect (n=3), limited information on missing data analysis (n=5), unclear definition of intervention groups (n=4), poor adherence to the intervention regimen (n=3), low sample size for acceptable statistical power (n=3), lack of appropriate analysis method for confounder adjustment (n=6), and disparity in the onset of intervention, and follow-up in most participants (n=4). In addition, 4 of the studies did not report the measures taken to ensure consistency in intervention delivery, and only 2 reported measures of intervention adherence. None of these studies performed a blinding procedure, as the active treatment group was usually recognisable.

Discussion

Principal Findings

Despite the heterogeneity of the 19 studies in this review in terms of study design, interventions used, sample size, measured outcomes, and research instruments, we were able to identify the participatory ergonomic interventions designed specifically for nursing professionals. In addition, the research designs and results revealed the methodological quality of the studies and evidence of the interventions in ameliorating WMSDs among this high-risk group of health care workers.

Descriptive findings from the systematic review revealed that the predominant PE interventions, specifically for preventing and managing WMSDs among nurses, were physical activities or exercise, health promotional activities, educational programs, and patient handling devices. These findings are consistent with previous systematic and integrative reviews focusing on interventions to address WMSDs and their secondary outcomes among health care professionals [43,44]. Physical activities and specific exercises are frequently considered in PE interventions either as individual or multifaceted approaches, given their efficacy in reducing musculoskeletal pain and associated symptoms [44]. Educational programs and health promotional activities are also integrated with most multicomponent

XSL•FO
RenderX

interventions to enhance nurses' knowledge, attitude, and self-efficacy toward lifestyle changes and behaviors to mitigate risk factors of WMSDs [43,45].

Single or individual interventions were applied in 10 studies ranging from physical activity to educational programs and the use of patient handling devices. Nevertheless, contradictory findings were gleaned from the studies, with few reflecting a low to moderate reduction in WMSD risk and ergonomic risk scores following educational programs [8,36]. Ergonomic exercise (ie, neuromuscular and back exercise) conducted in 3 studies also led to significantly lower scores for low back pain [40] and overall body pain scores [16,31]. These findings corroborate reports of individual exercise and physical activity proposed by Jakobsen et al [34] for the generality of health care professionals. Several prior studies have equally emphasized the positive effect of physical exercise on MSDs [20,29]. Moreover, physical exercise helps in preventing recurring and new episodes of WMSD pain [46], improving endurance, strength, and neuromuscular control in rehabilitation patients [47]. In contrast, 3 studies found no significant preventive effects of single interventions such as educational programs, individual-based interventions, and patient handling devices in ameliorating WMSDs among nurses and health care professionals [17,34,37]. These studies reflect the need for a multifaceted approach to addressing musculoskeletal pain, especially when designing interventions that include educational ergonomics. In other words, rather than using educational programs in isolation, they should be combined with other interventional approaches such as exercise.

As observed in this review, several studies entailed multifactorial interventions—a combination of procedures considering numerous factors and events acting on multiple levels [48]. This approach aligns with the multifaceted causes of WMSDs [19], which require integrated and comprehensive management strategieseducational program rather than isolated approches [42]. Comparisons between multicomponent and single interventions depicted that the former was more effective in reducing the risk of WMSDs among nurses relative to single type of ergonomic interventions. These results were evidenced in several studies involving a combination of health promotion activities and case management [19], workstation adjustment and training [10,28], educational ergonomics and patient handling equipment [39], as well as those involving physical activities and exercise [29,32,38]. In addition, moderate to high effect sizes were reported in studies where multicomponent interventions included at least one or more physical activities and exercise, whereas effects in those without exercise were generally low to moderate. These findings are consistent with a recent review conducted among health care professionals, in which the strongest reduction in WMSD injuries and pain stemmed from combined manual or mechanical patient lifting and handling training [44]. This could be explained by the fact that exercise, patient handling devices, and ergonomic training offer opportunities to mitigate physical risk factors and insufficient handling knowledge, which are the main contributing events to injuries among nurses and health care professionals [49,50]. More importantly, these studies highlight the significance of multifaceted PE aimed at comprehending the appropriate handling of patients or using the principles of biomechanics in executing such activities [30] and guidelines implementation [18]. These findings align with the Occupational Safety and Health Administration recommendations for increased availability of assistive facilities and devices, including both sophisticated and basic devices, that are crucial for safe patient handling [40].

Only a few reviewed studies investigated work performance and sickness absence, which may be because these events are secondary outcomes of WMSDs. This finding is not surprising, given that a systematic review of RCTs aimed at reducing sickness absence among health care workers identified only 7 relevant papers [45]. Results from the present review highlight the need to further explore how nurses' work performance and sickness absence can be improved by ergonomic interventions. Most studies found no significant effects of multicomponent and individual interventions on these secondary outcomes at different follow-up points [19,28,32]. For instance, complaints of low back pain and its associated cost persisted among nurses for several weeks and months after performing neuromuscular exercise and back care counseling [32].

These studies raise the question of whether some multifaceted PE interventions, such as ergonomic education, health promotion activities and case management, neuromuscular exercise, and back care counseling, are either productive or counterproductive in improving secondary outcomes primarily linked to WMSDs among nurses. On the contrary, reduced work-day absences and increased safe patient handling were observed in health care professionals subjected to task-specific and multifactorial interventions such as mechanical and practical in-ward activities [50]. These promising results from studies conducted among health care workers emphasized changing the work dynamics, increasing job satisfaction, productivity, and the complicity between workers [32]. Moreover, psychological stress constitutes approximately 28% and 84% of upper back injuries in health care professionals [51].

Although qualitative studies were not included in this review, results from the studies highlighted the importance of considering psychological health problems, ergonomic knowledge, and preventive behaviors that could shape the risk of WMSDs, sickness absence, and work performance [11,18]. Organizational, physical, psychosocial, and personal factors were found to play pivotal roles in the development of musculoskeletal problems and their related consequences, thereby supporting the use of multifaceted interventions. Hence, as recommended by Carneiro et al [52], the organizational aspects of the working environment have to be considered in order to address WMSDs and their direct consequences on nurses' health and productivity.

Multiple approaches are required to effect changes in practices and encourage a safety culture, such as ongoing training, skills, workflow processes, supervision, and communication between health care professionals about the risks [43,44]. This diverse and multifaceted approach is also crucial considering that long-term adherence to interventions is necessary for sustainable positive impacts on WMSDs, especially their secondary outcomes. For instance, although nurses enduring from WMSDs

XSL•FO
RenderX

can experience significant relief following a short-term ergonomic intervention, a prolonged duration is required for the effects on sick leaves and performance [45]. Hence, the long-term beneficial effects of adhering to these multicomponent interventions need to be analyzed and relentless efforts to effect the necessary changes are equally important [41].

Quality assessment results underscored various areas to be considered when interpreting the systematic review findings. For instance, moderate and high risk of bias was observed in 5 and 8 studies, respectively. Thus, only 6 papers were of high quality. Methodological issues identified in the studies mainly entailed limited information on participants' baseline characteristics, potential confounders that may affect the intervention's effect, not addressing missing data, incoherent onset of intervention and follow-up, and poor adherence to the intervention regimen. These findings highlight the need for well-designed and high-quality RCTs.

The strength of the systematic review stems from being among the first attempts to gather current evidence on ergonomic interventions for nursing professionals and their effects on WMSDs, sickness absence, and work performance. In addition, a comprehensive and systematic approach was used, thereby assisting the researcher in retrieving relevant papers from selected databases. Quality appraisal was also performed to identify the methodological gaps that need to be bridged in future research. Nevertheless, the limitations are well acknowledged. Given that only papers published between 2015 and 2023 were considered in the review, papers published before these dates might contain important findings that are relevant to the research topic. The literature search and screening processes were performed only by the principal investigator, reflecting the possibility of bias and unknown intraobserver reliability. Moreover, only papers written in English in 4 databases were considered, thus limiting relevant studies written in other languages that might have assisted in answering the review questions.

Conclusions

This systematic review synthesized evidence published between 2017 and 2024 on ergonomic interventions to reduce WMSDs and sickness absence and improve work performance among nurses. The most common interventions entailed physical activities or exercise, educational programs, health promotional activities, and training on the usage of patient handling devices or equipment, which were usually applied either as a single or multicomponent approach. Overall, the findings suggest that multifaceted interventions are more effective in reducing the risk of WMSDs and the associated pain in nursing professionals compared with individual interventions. The strongest effect size was observed in multicomponent interventions comprising at least one or more physical activities and exercise. Although these positive results are expected to lead to improved work functioning, work performance, and reduced sick leaves, available results are convincing to support the use of either single or combined ergonomic programs in achieving these secondary outcomes.

Apart from conducting high-quality RCTs, addressing the identified research gaps requires the integration of organizational factors and prevention policies to enhance psychological health, job satisfaction, and work dynamics into multicomponent ergonomic interventions. Since most interventions are designed for short-term periods, efforts to ensure their long-term effects are crucial for sustainable positive impacts on WMSDs, sickness absence, and work performance. For instance, introducing curricula content on the management of WMSDs and improving work performance, sickness absence and psychological health in nursing education may assist nurses in adopting the measures discussed in this review in clinical practice. This review may guide health care institutions on the most appropriate ergonomic interventions to prevent or reduce WMSDs among nurses, given their significance for well-being and economic implications in terms of absenteeism, work performance, and care for clients enduring mobility problems.

Abstract

Background: Personalized Interactive Music Systems (PIMSs) are emerging as promising devices for enhancing physical activity and exercise outcomes. By leveraging real-time data and adaptive technologies, PIMSs align musical features, such as tempo and genre, with users' physical activity patterns, including frequency and intensity, enhancing their overall experience.

Objective: This exploratory systematic review and meta-analysis evaluates the effectiveness of PIMSs across physical, psychophysical, and affective domains.

Methods: Searches across 9 databases identified 18 eligible studies, of which 6 (comprising 17 intervention arms) contained sufficient data for meta-analysis. Random-effects meta-analyses and meta-regression were performed to assess outcomes for physical activity levels, physical exertion, ratings of perceived exertion, and affective valence.

Results: Results showed significant improvements in physical activity levels (g=0.49, CI 0.07 to 0.91, P=.02, k=4) and affective valence (g=1.65, CI 0.35 to 2.96, P=.01, k=4), with faster music tempo identified as a significant moderator (P=.03). No significant effects were observed for ratings of perceived exertion (g=0.72, CI −0.13 to 1.58, P=.10, k=3) or physical exertion (g=0.78, CI −0.55 to 2.11, P=.25, k=5).

Conclusions: Substantial heterogeneity and limited study quality indicate the need for more robust, randomized controlled trials to establish the efficacy of PIMSs in diverse populations.

Introduction

Background

Regular physical activity and exercise are fundamental to maintaining and enhancing overall health and well-being. Despite their recognized role in preventing and managing noncommunicable diseases such as cardiovascular diseases, cancer, and diabetes, engagement in regular physical activity and exercise remains below the suboptimal level [1]. This deficiency undermines the potential for mental health benefits of physical exercise and its contributions to quality of life [2]. The World Health Organization defines physical activity broadly, encompassing all forms of bodily movement generated by skeletal muscles that require energy expenditure, including activities such as walking, sports, and dance [1]. In contrast, exercise has been defined as "physical activity that is planned, structured, repetitive, and purposive, aiming to improve or maintain one or more components of physical fitness" [3]. However, the broad spectrum of activities categorized as physical activity and exercise often presents challenges in promoting consistent engagement and uptake, including individual-level barriers such as motivation and time constraints [4]. Efforts to increase engagement in physical activity and exercise have faced significant challenges, frequently yielding inconsistent outcomes, as exemplified by interventions such as pedometer-based programs, which demonstrate variable effectiveness depending on factors including participant motivation and engagement [4,5].

Role of Music in Enhancing Physical Activity and Exercise

Music's rhythmic properties have been shown to influence perceptions, ergonomics, and physiological markers associated with physical activity and exercise [6-10]. Available evidence suggests that auditory-motor coupling facilitates predictive synchronization in physical activity and exercise settings, which can reduce perceived exertion and enhance endurance [11,12]. Additionally, when music aligns with individual preferences, such as through self-selection, it may further increase motivation, improve affective states, induce distraction, and lower perceived effort during physical activities and exercise [7,11].

The integration of music into exercise contexts can be further understood through theoretical frameworks such as the Affective-Reflective Theory (ART) and Dual-Mode Theory. ART emphasizes the importance of momentary affective responses—such as pleasure or displeasure—in shaping future exercise behaviors [13,14]. These responses, encapsulated in the construct of "affective valence," reflect the intrinsic pleasantness or unpleasantness of emotional states that fluctuate in response to internal and external stimuli. Conversely, Dual-Mode Theory posits that music's impact on affective responses is most pronounced at moderate exercise intensities, within a zone of response variability. This zone refers to the range of exercise intensity where affective responses—such as feelings of pleasure or displeasure—are particularly sensitive to individual differences (eg, fitness level and psychological state) and contextual factors (eg, music, environment, and social setting). In this range, attentional focus and physiological cues mediate affective experiences [15]. While both theories acknowledge the importance of affective responses in exercise, Dual-Mode Theory provides a more nuanced perspective by emphasizing intensity-dependent variability and its interaction with individual and contextual factors.

Extending the principles of ART and Dual-Mode Theory [16], the framework highlights how music's intrinsic properties—such as tempo, rhythm, and harmony—interact with personal and situational moderators, including exercise intensity and individual preferences, to influence affective and behavioral outcomes in exercise. Music operates through 3 primary mechanisms: regulating affective states, dissociating attention from exertional discomfort, and facilitating temporal prediction and rhythmic synchronization. These mechanisms are most effective within the zone of response variability, where affective valence dynamically influences exercise engagement [15,17]. Empirical studies consistently demonstrate that personalized music enhances energy efficiency, reduces perceived exertion, and improves adherence by fostering positive affect [17]. Such evidence positions personalized music systems as a key tool for optimizing both the immediate and long-term benefits of exercise.

Personalized Interactive Music Systems in Physical Activity and Exercise

Recently, advances in personalized music technologies have led to the development of Personalized Interactive Music Systems (PIMSs), which leverage software, sensors, and computer algorithms to deliver a dynamic, tailored music experience during physical activity and exercise [18,19]. These systems integrate with smartphones and wearable devices to monitor user movements and adjust musical features, such as tempo, style, and timbre, in real time to align with exercise routines, enhancing engagement and adherence to activity [20,21].

PIMSs have been designed for diverse contexts, targeting both intrinsic factors (eg, motivation and attentional focus) and extrinsic factors (eg, training guidance). For example, a PIMS, the moBeat system, used real-time interactive music and biophysical feedback to enhance cycling performance by increasing intrinsic motivation and maintaining pace and intensity [12]. Similarly, PIMS interventions for older adults have demonstrated benefits for physical endurance and engagement relative to conventional exercise conditions [22]. As mobile interventions incorporating personalization have been shown to be more effective at enhancing physical activity than nonpersonalized approaches [23], PIMSs hold promise for

XSL•FO
RenderX

improving physical activity adherence, reducing the ratings of perceived exertion (RPE), and fostering positive affective states during exercise by dynamically tailoring music to individual physiological, affective, and contextual needs [7,12,22].

Due to the relatively recent advancements of PIMSs, there is yet limited empirical evidence on their effectiveness across physical activity and exercise-related domains. Such information is essential for informing implementation, replication, and comparative evaluation of interventions aimed at promoting adherence to physical activity and exercise [24]. While systematic reviews and meta-analyses have explored the general effects of music on physical activity and exercise-related outcomes [6,7,25], these reviews predominantly focused on traditional music listening interventions and did not systematically evaluate the impact of personalized and interactive music systems. By specifically examining PIMSs, this review and meta-analysis contribute to understanding how tailored, interactive music interventions influence physical, psychophysical, and affective dimensions of physical activity and exercise engagement, thereby addressing a critical gap in the existing literature.

Therefore, this study combines a systematic review and exploratory meta-analysis to evaluate the effectiveness of PIMSs on physical activity and exercise-related outcomes. Specifically, this study synthesizes findings on physical activity levels, psychophysical measures (eg, RPE and physical exertion), and affective outcomes (eg, affective valence and mood states).

Our main research question is: How effective are PIMSs across physical, psychophysical, and affective outcomes during physical activity and exercise? This analysis intends to provide early insights into the specificity of PIMSs' effects and identify gaps in the literature that warrant further investigation.

Methods

Study Design

This systematic review and meta-analysis were designed based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol [26]. The full search strategy can be found in the review registration document (CRD42023465941).

Eligibility Criteria

We included (1) studies investigating the effect of PIMSs on physical activity or exercise, including their effects on motivation, exercise intensity, adherence, or related outcomes, (2) studies including participants from diverse populations (eg, sufficiently active and not sufficiently active individuals), and (3) papers in the English language, published from January 2010 to May 2024 in peer-reviewed journals or as published proceedings (conference papers were considered due to the limited number of peer-reviewed studies).

We excluded (1) studies from nonpeer-reviewed sources, books, dissertations, and theses; (2) papers written in languages other than English; and (3) studies that were not directly related to the effect of PIMSs on physical exercise or physical activity.

Information Sources

We searched the following databases: (1) Web of Science, (2) SPORTDiscus, (3) Medline, (4) Embase, (5) ACM Digital Library databases, (6) Springer, (7) Google Scholar, (8) IEEE Xplore, and (9) Scopus. The database search was supplemented by a backward snowball search, whereby the reference list of all papers was scanned for potential sources. The snowball search continued until no new sources could be identified. The initial interrater agreement for the identification of relevant sources was k=0.83, indicating a strong level of agreement among the 2 individuals performing 2 independent snowball searches (AD and TK). Full search strings for all databases used in this review are provided in Section S3 in Multimedia Appendix 1.

Search Strategy

A literature search was performed using terminology related to the effects of PIMSs on physical activity and exercise, ("Personali*ed Interactive Music System*" OR "Music Recommendation Algorithm" OR "Music Recommendation System*" OR "Streaming" OR "MP3" OR "Digital Music") AND ("Physical Activity" OR "Exercise" OR "Recovery" OR "Recuperation" OR "Sedentary Behav*" OR "Physical Inactivity").

Selection Process and Data Collection Process

The citations of all retrieved papers were imported into Zotero (Digital Scholar), where duplicates were systematically identified and removed. Subsequently, 2 authors (AD and TK) independently screened the titles and abstracts of the studies using ASReview (Utrecht University) [27] and Rayyan [28]. Papers that could not be definitively excluded based on the title or abstract underwent full-text retrieval for further evaluation. The full-text papers were then independently assessed for inclusion by the same 2 authors (AD and TK). Disagreements at any stage were resolved through discussion, with a third author consulted to achieve consensus when necessary.

Data Extraction

The studies' information was extracted to a spreadsheet, including study characteristics, such as the type of PIMS, the study design, PIMS measurement, and the target behavior of the PIMS (Target Physical Activity or Exercise; Table 1).

[p]The methodology involved recording footfalls and various music alignment strategies to synchronize music with participants' walking or running movements.

[q]Includes elements of a proof of concept design and an experimental design.

[r]Exact numbers are not specified, but a mention of a group size of 3 to 6 participants.

Preregistration Deviations

Where available, quantitative data suitable for meta-analysis were extracted. This was done for the preregistered outcome of physical activity level, as well as for affective valence, RPE, and physical exertion, which were not preregistered as outcomes. The decision to extract data on these additional outcomes was taken because of the close relationships between these variables and physical activity and exercise participation, their prevalence as outcomes in the included studies, and the limited number of studies reporting data on physical activity and exercise behavior. In cases where effect sizes could not be readily calculated based on the published papers, their authors (n=2) were contacted at least twice for additional data, resulting in the provision of calculations for 5 additional effect sizes.

Operationalization of Terms

This review operationalizes 4 key terms central to physical activity and exercise research. Physical activity level is defined by the quantified volume (eg, daily activity counts and weekly minutes), intensity (eg, metabolic equivalent of task [MET] and percent oxygen uptake reserve), and compliance (eg, adherence to heart rate zones or regimens) [45,46] of physical activity. Affective valence refers to the pleasure-displeasure dimension of emotional responses during or after physical activity, assessed using self-report scales such as the Feeling Scale (FS) [47] and the "good versus bad mood" subscale of the Multidimensional Mood Questionnaire (MDMQ) [48]. These measures capture subjective ratings of positivity or negativity without incorporating arousal [14,35,49]. Physical exertion encompasses physiological (eg, heart rate), biomechanical (eg, stride length), and perceptual demands, providing a comprehensive assessment of effort [50]. These constructs serve as the primary outcomes of interest in this review. The constructs are summarized in Table 2 and described further in Section S1 in Multimedia Appendix 1.

XSL•FO
RenderX

Table . Operationalization of terms.

Term	Definition	Operational metrics	References
Physical activity level	Encompasses the volume, intensity, and compliance with physical activity recommendations or exercise regimens.	• Volume: total activity counts per day via accelerometer, mean weekly minutes. Intensity: absolute intensity using metabolic equivalent of tasks, relative intensity as oxygen consumption reserve percentage. • Compliance: adherence to recommendations or regimens via changes in volume, device usage, or adherence to heart rate zones.	[45,46]
Physical exertion	Effort exerted to perform physical activity, involving physiological, biomechanical, and perceptual demands.	• Physiological: heart rate as an indicator of cardiovascular response. • Biomechanical: stride length and pace for activities such as running and walking. • Perceptual: integration of physiological and biomechanical cues to assess overall effort.	[50]
RPE[a]	Subjective numerical value reflecting perceived effort during physical activity, integrating sensory cues, and physiological sensations.	• Scale: Borg RPE scale for aerobic activities (cycling and running). • Category-Ratio Scale: Borg Category-Ratio 10 Scale to measure perceived exertion or other sensations. • Responses: local sensations (muscles, skin, and joints) and central factors (cardiopulmonary system).	[7,51,52]

Affective valence	The subjective feeling of pleasure or displeasure experienced during or after physical activity. It is independent of perceived exertion and reflects emotional responses to exercise, influenced by individual, contextual, and social factors.	Affective valence is measured using self-report scales, such as:
		• Scale:
		  • Feeling Scale: bipolar scale from +5 (very good) to −5 (very bad).
		  • Positive and negative affect schedule: assesses positive and negative emotions.
		  • Multidimensional Mood Questionnaire (MDMQ): evaluates mood during exercise using subscales for “good versus bad mood,” “calmness versus agitation,” and “alertness versus tiredness.” Only the “good versus bad mood” subscale aligns with the pleasure-displeasure dimension of affect.
		• Context: Measurement occurs before, during or immediately after exercise.
			[14,47-49]

[a]RPE: ratings of perceived exertion.

Study Risk of Bias Assessment

The quality of the studies was assessed by 2 authors (AD and TK) using the JBI's (Joanna Briggs Institute) critical appraisal checklist, including tools for quasi-experimental appraisal, qualitative research appraisal, and the revised checklist for randomized controlled trials [53].

Data Synthesis and Analysis Methods

We conducted a narrative synthesis, categorizing studies into two groups based on design: (1) experimental studies, including randomized, quasi-experimental, pilot, and within-subject designs, and (2) proof-of-concept and user-testing studies. This classification enabled the identification of trends within and across these categories.

For experimental studies, we examined outcomes related to physical activity levels, physical exertion, RPE, and affective valence. Proof-of-concept and user-testing studies were analyzed for their focus on PIMS design features and effectiveness, including synchronization, user engagement, and personalization.

Our synthesis followed the methodological framework of [54], facilitating systematic comparisons across study groups. Trends and variations in PIMSs' outcomes were interpreted through subgroup analyses, accounting for methodological rigor and study design. We also considered sample characteristics, including demographic variability (eg, age, fitness level, and population type) and sample size heterogeneity (ranging from n=10 to n=150). Limitations arising from study heterogeneity were explicitly addressed to provide transparency regarding factors affecting generalizability.

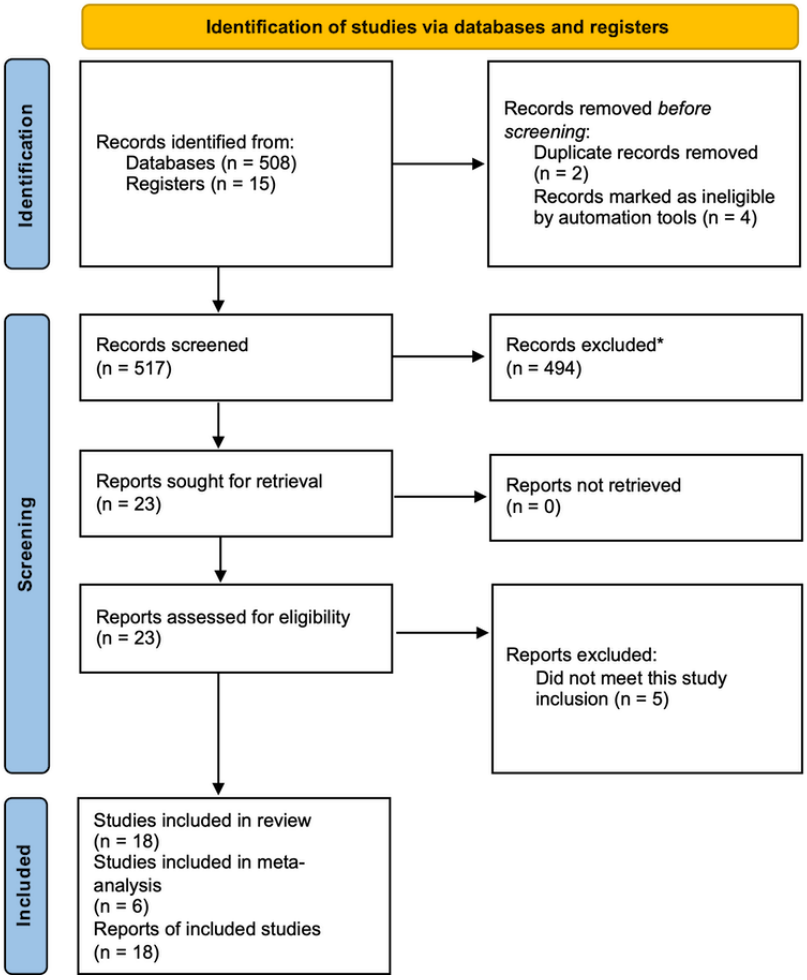
Hedges *g* effect sizes and SEs were calculated using the tool by Wilson [55]. Meta-analytic models were conducted in *R* (version 4.5.1) using the *metafor* package [56], applying a random-effects model with the DerSimonian-Laird estimator for physical activity level, physical exertion, RPE, and affective valence. These outcomes were selected based on the preregistration criterion: "meta-analyses will be performed when at least three studies provide data sufficient for effect size calculation." For inclusion in the meta-analysis, physical activity outcomes analyzed included behaviors such as walking, running, weight training, cycling, housework, and gardening, while studies focusing on nonphysical activity outcomes (eg, subjective feasibility of PIMSs) were excluded. Six studies (comprising 17 intervention arms) met this criterion, while outcomes with insufficient data were excluded.

Heterogeneity was assessed using the I^2 statistic (relative proportion of variability attributable to heterogeneity), τ^2 statistic (absolute variance), and Cochran *Q* statistic (a formal test of homogeneity). To address the dispersion of effects across studies, the prediction interval was calculated, as it provides insights into the range of effects expected in future comparable studies, beyond the mean effect size [57]. A sensitivity analysis was conducted to evaluate publication bias by examining the relationship between SEs and effect size estimates. Following the studies by Sterne and Egger [58] and Sterne and Harbord [59], funnel plots were produced to assess asymmetry, while forest plots were used to summarize the data. Data and syntax files for these analyses are available in Multimedia Appendix 2.

An exploratory meta-regression analysis was conducted to investigate potential moderators contributing to variability in the effectiveness of PIMSs on physical activity level, affect, RPE, and physical exertion. Candidate moderators were selected based on their theoretical relevance to physical activity and exercise research: study size, participant age, exercise intensity, and music tempo. Music tempo was categorized into tempo ranges to standardize data across studies with differing methodologies, reflecting its established influence on motivational and psychophysical responses [60]. Exercise intensity was classified using MET guidelines to enhance comparability [61]. Participant age and study size were included to address population-level and methodological variability, respectively. Due to the small number of studies included in the meta-analyses, the meta-regression encompassed all outcomes of interest, with a focus on generating hypotheses for future research.

Specifically, within the meta-regression analysis, music tempo was categorized into 3 distinct groups based on beats per minute (BPM): slow (60 - 90 BPM), coded as 1; medium (91 - 130 BPM), coded as 2; and fast (131+ BPM), coded as 3. When studies reported variable tempos, the average BPM or the dominant tempo range was used for classification. Exercise intensity was categorized using a 3-level scale aligned with MET guidelines [61]: low (<3 METs), coded as 1; moderate (3 - 6.9 METs), coded as 2; and high (≥7 METs), coded as 3. For studies that did not explicitly report METs, intensity was inferred from descriptions of the exercise type or target heart rate zones. Participant age was handled as follows: for studies reporting mean age directly, the provided value was used. In studies reporting age ranges, the midpoint of the range was used as an estimate. If group-specific mean ages were available, a weighted average was calculated based on group sizes to derive an overall mean age for the study.

Results



Study Selection

All records were excluded by ASReview [27,28].

A total of 523 papers were identified through the initial strategic search using the specified keywords. During the screening process, 3 papers were excluded as duplicates, while 4 additional papers were identified as ineligible based on the inclusion criteria. After screening titles and abstracts, 494 papers were excluded for not meeting the inclusion criteria. Subsequently, 23 full-text papers were assessed for eligibility. Of these, 5 papers were excluded [21,62-65] because they did not evaluate the desired effect or outcome. In total, 18 papers were eligible to be included in this review study (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA information flow describing the screening process. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Study Characteristics

The study characteristics (Table 1) encompass a diverse range of studies conducted across various countries, including Canada, Spain, Germany, Taiwan, Singapore, Denmark, Finland, Belgium, Switzerland, the Czech Republic, the Netherlands, Norway, and locations not specified. These studies, conducted between 2010 and 2024, provide a broad age range among participants, with some studies focusing on specific groups such as older adults, patients with cardiovascular disease, students, nonathletes, and office workers. The PIMSs used in these studies vary in their design and objectives, ranging from personalized music audio playlists [30,34,42] to interactive music systems linked to fitness devices [22,35]. These systems are used in different settings and for various purposes, ranging from synchronizing movement during physical activity and exercise to enhancing the experience of physical activity and exercise.

Reported Outcome Measures

A variety of outcome measures were reported across studies to explore the effects of PIMSs on physical activity and exercise-related behaviors. The outcome measures included assessments of physical activity levels, such as accelerometer-based metrics and adherence to specific heart rate zones, as well as psychological and perceptual outcomes such as mood (measured through tools such as the MDMQ and FS) and intrinsic motivation (measured via the Intrinsic Motivation Inventory, IMI). The RPE was frequently captured using the Borg Category-Ratio 10 Scale [51,52]. Table 3 presents this information. Further information on these outcome measurements can be found in Section S2 in Multimedia Appendix 1.

Studies used diverse technologies and protocols to assess PIMSs' effects on physical activity and exercise behaviors. Reported technologies included accelerometers, heart rate monitors, and systems such as JYMMiN, which integrate real-time musical feedback with gym equipment. Analytical methods, such as ANOVA and multivariate analysis of variance, were used to evaluate outcomes, with specific systems adapting music based on cadence, heart rate, and intensity. Table 4 presents a detailed overview of these technologies and protocols.

Risk of Bias in Studies

Following the assessment of the study quality using the JBI critical appraisal checklist tools, the nine criteria were adapted to the 5 risk-of-bias domains found in the R package for risk-of-bias assessments (robvis) in the study by McGuinness and Higgins [68]. This assessment tool tests the risk of bias resulting from the randomization process (domain [D1]), deviations from intended intervention (D2), missing outcome data (D3), measurement of the outcome (D4), and selection of the reported result (D5). Each domain is assessed with a judgment scale indicating a high risk of bias (red cross), some concerns (yellow circle), low risk of bias (green plus), and no information (blue question mark; cf Figure 2).

We included all 18 studies in the review regardless of their overall risk of bias rating (see Figure 2, column "overall"). The overall risk of bias rating for each study was assigned conservatively, reflecting the highest risk level present across any of the 5 domains (D1-D5). For example, if 1 domain was judged to have a high risk of bias, the overall rating for that study was classified as high risk. Of the 18 studies, 1 randomized experimental design study [29] was rated for low risk of bias. Seven studies received a moderate (some concerns) rating of risk of bias, and 10 were rated for a high risk of bias.

XSL•FO
RenderX

Figure 2. Evaluation of risk of bias in the included studies, categorized across 5 domains from D1 to D5 (cf [68]). An overall bias risk assessment for each study is also provided, conservatively summarizing the findings across all 5 domains [12,22,29-44]. D: domain.

PIMSs Used in Experimental Studies

PIMSs were explored in experimental studies for their influence on physical, psychophysical, and affective exercise–related outcomes. Several studies focused on synchronization and auditory-motor coupling. Moens et al [41] examined beat synchronization using the D-Jogger adaptive music player. They found that initiating music in phase synchrony significantly enhanced consistent sensorimotor patterns, while strategies relying on tempo adjustments alone were less effective. Maes et al [38] provided detailed analyses of synchronization strength using SoundBike (Ghent University), where musical sonification significantly increased pedal cadence synchronization with external music. Similarly, Jun et al [36] found significant increases in step frequency (swings per minute) when music tempo aligned with user pace, enhancing consistency and efficiency of the activity.

Rehfeld et al [22] and Fritz et al [35] reported on the JYMMiN system's role in improving mood and exercise duration. Notably, Fritz et al [35] observed mood enhancements in younger adults, while [22] noted prolonged exercise durations in older adult participants despite no significant mood changes. This may be potentially due to age-related differences in energy pacing. Rosseland [44] explored a tempo-responsive system for Alzheimer patients, observing improved synchronization and engagement. Additionally, van der Vlist et al [12] reported the moBeat system maintained exercise compliance while enhancing intrinsic motivation and attentional dissociation from discomfort. Sample sizes varied (N=10 to N=150), with participants aged 18 - 79 years across diverse demographics. Detailed descriptions of PIMSs used in these studies can be found in Table S1 in Multimedia Appendix 3.

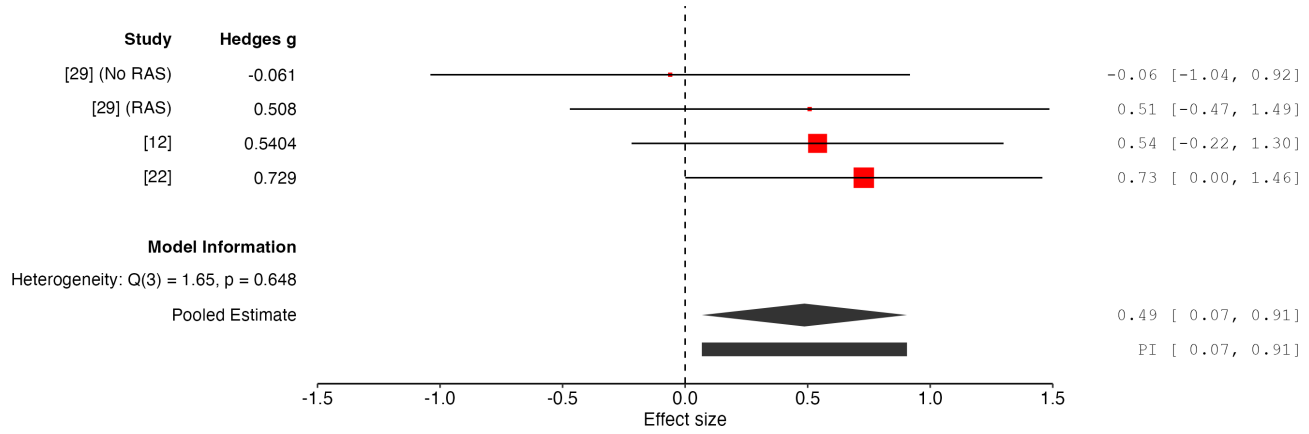
PIMSs Used in Proof of Concept and User Testing Studies

Proof-of-concept and user-testing studies used PIMSs to adapt music or audio feedback based on real-time physical activity and exercise-related data (eg, heart rate, oxygen saturation, and galvanic skin response), with a focus on music recommendation systems and synchronization features. Álvarez et al [30] tested DJ-Running (University of Zaragoza), which integrates environmental (GPS) and galvanic skin response data to provide personalized music recommendations using algorithms such as artificial neural networks. Ospina-Bohórquez et al [42] developed a context-aware recommender system using smartphone sensors to adjust music based on exercise intensity, providing evidence for preliminary efficacy in low-concentration activities (eg, low-to-moderate intensity activities that require minimal concentration, such as walking).

Two synchronization-based systems were included: [33] music-assisted run trainer, which adjusts music tempo to heart rate or step frequency; and [31] music feedback exercise system, which synchronizes music with movement intensity through advanced audio processing. For example, as exercise intensity increases, additional layers of musical elements such as rhythm guitar, bass, or drums are progressively added to the audio track. Mendoza et al [39] introduced musical sonification, converting movement data into music for users to identify different physical activity patterns. Maculewicz and Serafin [37] examined ecological soundscapes to influence cycling behavior. Soundscapes were, for example, dynamically altered based on users' cycling speed and heart rate.

Moens et al [40] reported optimal movement entrainment at ~120 BPM using D-Jogger but noted disruptions during song transitions. The reinforcement learning–based system by Fang et al [34] found improved user satisfaction and fewer track rejections, while Rosseland [44] found tempo-responsive music systems beneficial for older adults with Alzheimer disease. Details on these systems can be found in Table S2 in Multimedia Appendix 3.

Meta-Analyses



A single overall meta-analysis of the studies was not achievable due to heterogeneity across datasets and outcomes [69]. Instead, the outcomes were reported separately based on their focus. The reported outcomes distinguished between (1) physical activity levels, (2) physical exertion, (3) RPE, and (4) affective valence.

Results for Physical Activity Level

The overall effect size is 0.49 with a 95% CI of 0.07 to 0.91, and a *P* value of .02 (k=4, n=76). This indicates that the results are statistically significant, supporting the effectiveness of PIMSs in improving outcomes relating to physical activity level (Figure 3). The random-effects model indicates low heterogeneity (Q=1.65, P=.65, I^2=0%, τ^2=0.00) between the studies, suggesting it to be negligible. The calculated 95% prediction interval for the true effect size is 0.07 to 0.91, indicating that while the average effect is positive, the range of potential true effects across future studies could include larger positive outcomes.

XSL•FO
RenderX

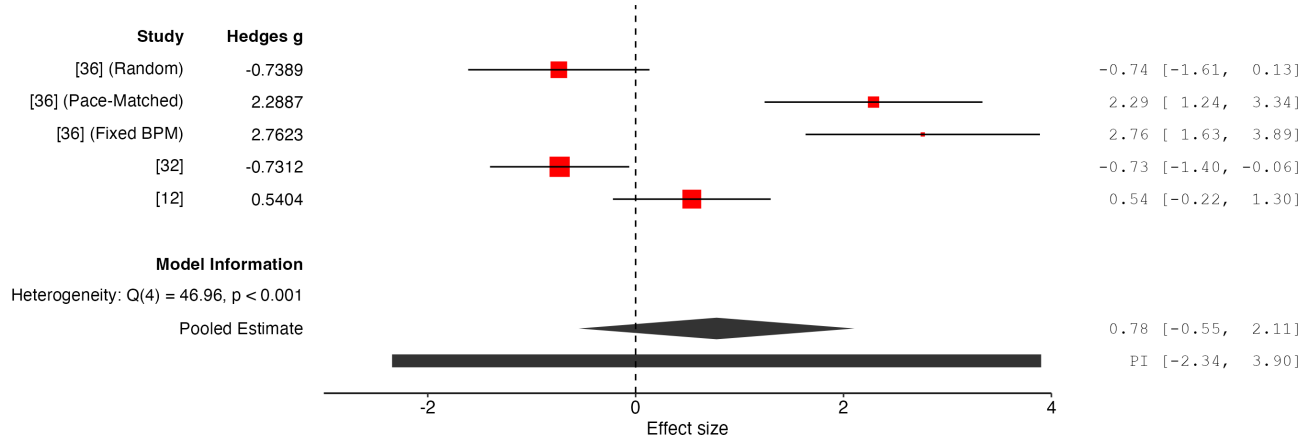


Figure 3. Forest plot of effect sizes for physical activity level outcomes associated with PIMSs [12,22,29]. PIMS: Personalized Interactive Music System; RAS: rhythmic auditory stimulation.

Results for Physical Exertion

The overall effect size is 0.78 with a 95% CI of −0.55 to 2.11, and a *P* value of .25 (*k*=5, n=142), indicating that the results are not statistically significant and do not support the effectiveness of PIMSs in improving physical exertion outcomes (Figure 4). The random-effects model indicates high heterogeneity (Q=46.96, P≤.001, I^2=91%, τ^2=2.08) between the studies. The calculated 95% prediction interval for the true effect size is −2.34 to 3.90, indicating the potential for considerable variation in the effects of PIMSs on physical exertion across future studies.

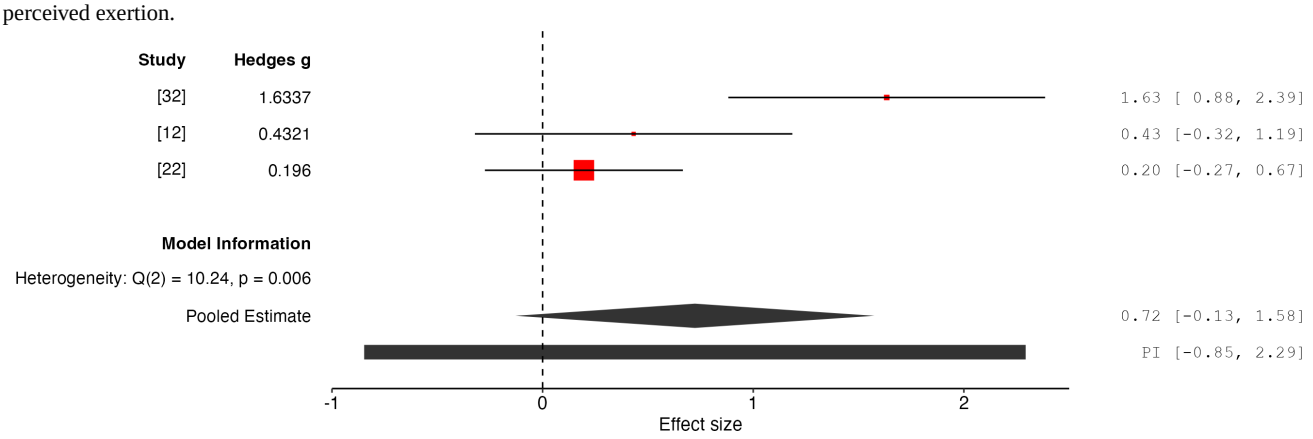

Figure 4. Forest plot of effect sizes for physical exertion outcomes associated with PIMSs [12,32,36]. BPM: beats per minute; PIMS: Personalized Interactive Music System.

Results for RPE

The overall effect size is 0.72 with a 95% CI of −0.13 to 1.58, and a *P* value of .10 (*k*=3, n=77), indicating that the results are not statistically significant and do not conclusively support the effectiveness of PIMSs in improving RPE outcomes (Figure 5). The random-effects model indicates substantial heterogeneity (Q=10.24, P=.01, I^2=80%, τ^2=0.45) between the studies. The calculated 95% prediction interval for the true effect size is −0.85 to 2.29, reflecting the significant variability in potential outcomes across future studies.

Figure 5. Forest plot of effect sizes for RPE outcomes associated with PIMSs [12,22,32]. PIMS: Personalized Interactive Music System; RPE: ratings of perceived exertion.

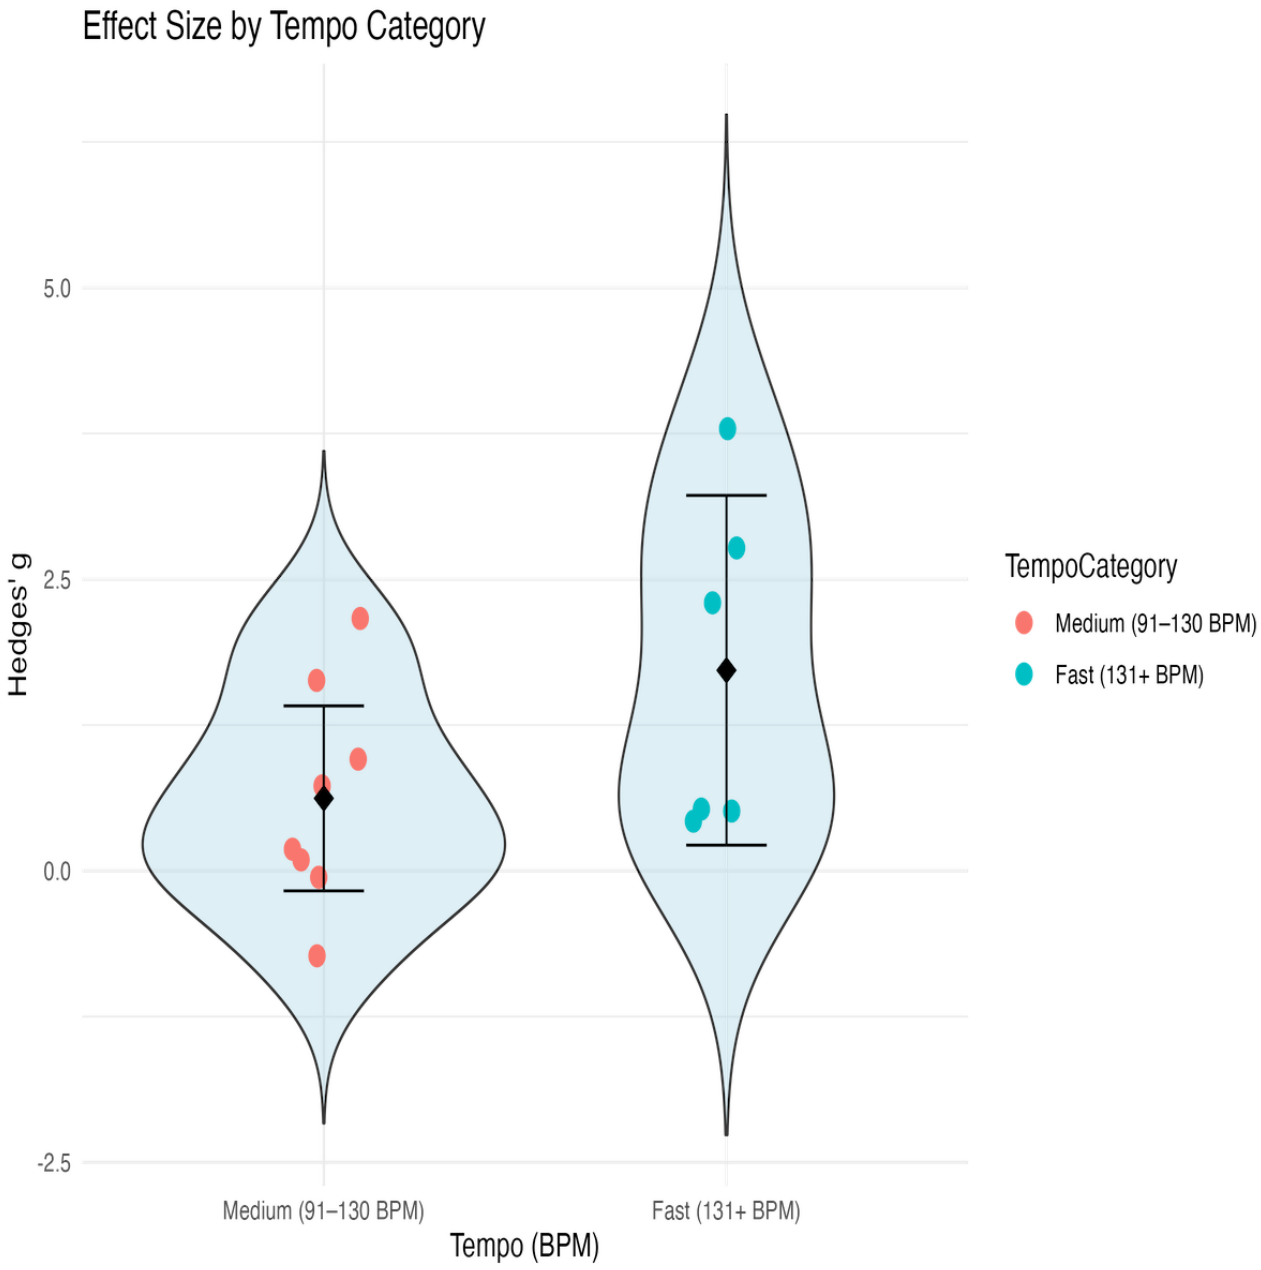
Results for Affective Valence

The overall effect size is 1.65 with a 95% CI of 0.35 to 2.96, and a *P* value of .01 (*k*=4, n=122), indicating that the results are statistically significant and thus consistent with the effectiveness of PIMSs in improving affective valence outcomes (Figure 6). The random-effects model indicates substantial heterogeneity (Q=36.69, P<.001, I^2=92%, τ^2=1.59) between the studies. The calculated 95% prediction interval for the true effect size is −1.14 to 4.44, highlighting significant variability in potential outcomes across future studies.

Figure 6. Forest plot of effect sizes for affective valence outcomes associated with PIMSs [12,22,32,35]. PIMS: Personalized Interactive Music System.

Meta-Regression Analysis



Heterogeneity was identified in the meta-analyses, prompting the use of meta-regression analysis to explore potential moderators of effect sizes. Music tempi showed a statistically significant positive association with effect sizes (β=.62, SE=0.29, *P*=.031), suggesting that faster tempi may have a significant effect across the outcomes of interest. None of the other predictors, including participant age, exercise intensity, or sample size, demonstrated a significant effect on effect sizes (Table 5 and Figure 7). The overall meta-regression model was not statistically significant, $Q_M(4)$=7.03, P=.135, and a substantial portion of heterogeneity remained unexplained, $Q_E(11)$=76.78, P<.001, I^2=85.67%, τ^2=0.92. This indicates that other, unexplored factors likely contribute to the variability in outcomes. Given the inclusion of all outcomes of interest in this analysis, the potential for residual variability and unaccounted-for heterogeneity is high.

Table . A summary of the meta-regression analysis.

Predictor	Estimate	SE	z	*P* value	95% CI
Intercept	1.194	2.965	0.402	.69	−4.619 to 7.006
Age	−0.035	0.040	−0.878	.38	−0.114 to 0.043
Music tempo	0.617	0.286	2.155	.031	0.056 to 1.178
Exercise intensity	0.212	1.262	0.168	.87	−2.262 to 2.686
Sample size	−0.025	0.062	−0.402	.69	−0.147 to 0.097

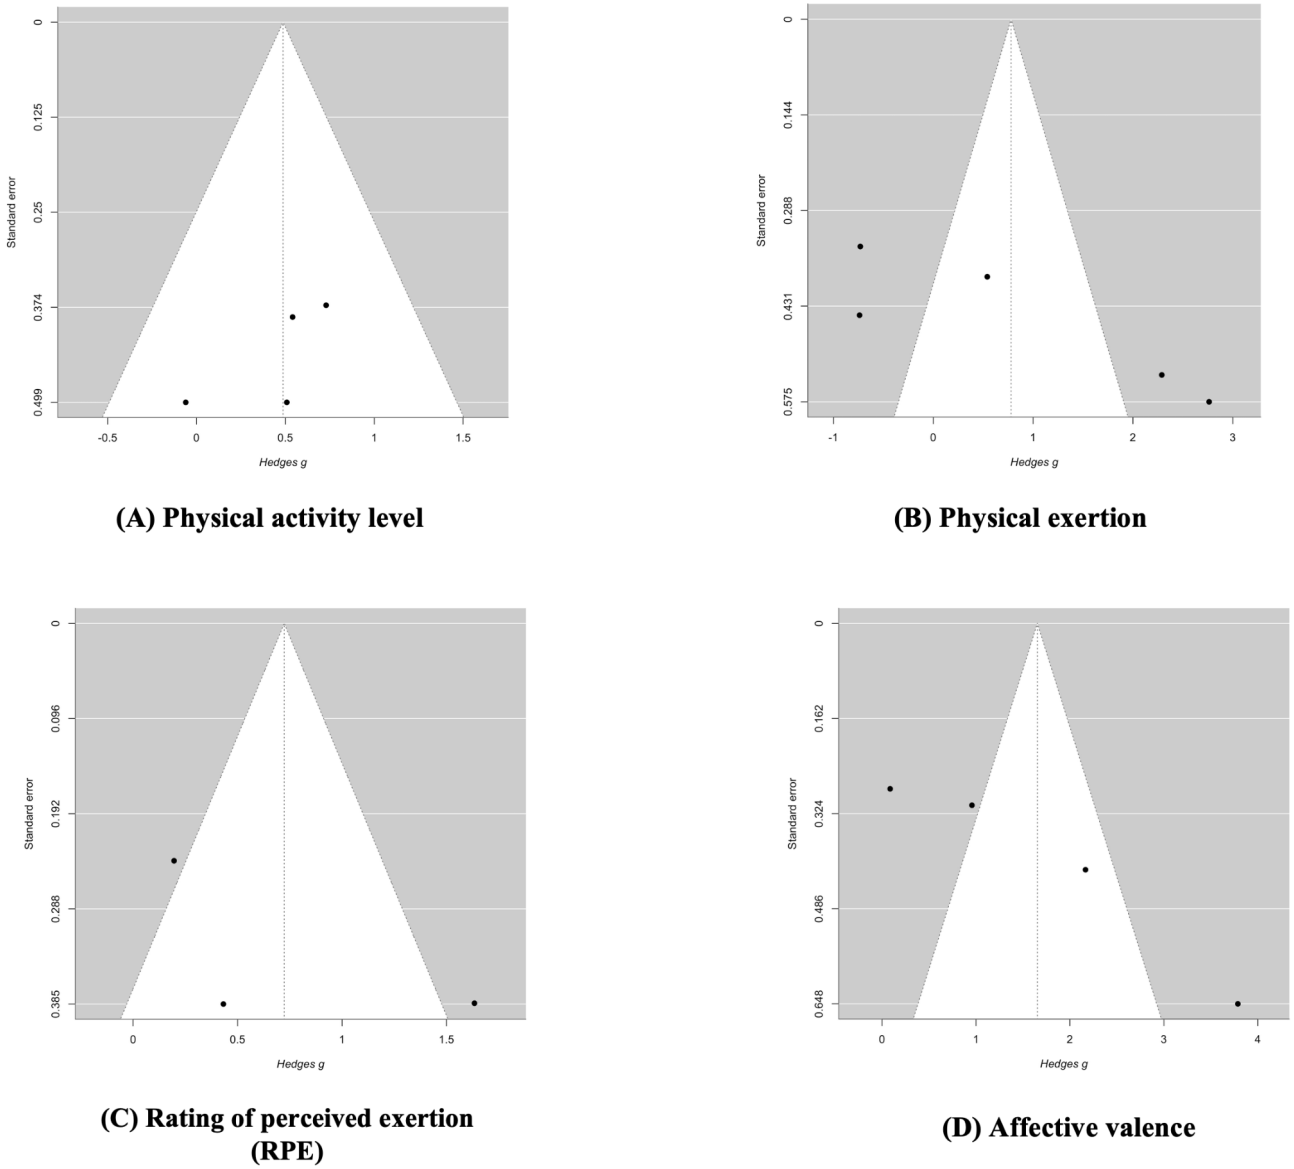
RenderX

Figure 7. Distribution of study-level effect sizes across music tempo categories. Violin plots illustrate the density and spread of Hedges *g* values for medium (91 - 130 BPM) and fast (131+ BPM) tempo groups. Dots represent individual study estimates; diamonds and error bars indicate group means and 95% CIs, respectively. BPM: beats per minute.



Publication Bias Analysis (Egger Test)

Egger test [70] indicated nonsignificant asymmetry for physical activity level (z=−0.968, P=.333), significant asymmetry for physical exertion (z=2.927, P=.003), nonsignificant asymmetry for RPE (z=0.832, P=.405), and significant asymmetry for affective valence (z=4.961, P<.001; Figure 8). Due to potential publication bias, the summary effect sizes for physical exertion and affective valence outcomes may thus be slightly inflated.

RenderX

Figure 8. Funnel plots for (A) physical activity level, (B) physical exertion, (C) RPE, and (D) affective valence. RPE: ratings of perceived exertion.

Discussion

Principal Findings

This review aimed to systematically evaluate the effectiveness of PIMSs across physical activity levels, physiological outcomes (eg, heart rate and step frequency), psychophysical outcomes (eg, the RPE), and affective valence in relation to physical activity and exercise behaviors. A central focus was an exploratory meta-analysis of PIMSs across these outcome domains.

The exploratory meta-analysis revealed that PIMSs demonstrate favorable effects on physical activity levels and affective valence, with effect size estimates surpassing those of general music listening [6]. However, the certainty of evidence is limited by methodological inconsistencies, a moderate to high risk of bias, and the limited number of published studies eligible for meta-analyses. Importantly, no significant effects were observed for RPE or measured physical exertion. This reflects variability in the psychophysical outcomes associated with interventions using PIMSs.

When examining the findings of individual studies separately, they offer preliminary evidence that PIMSs may improve physical, psychophysical, and affective outcomes related to physical activity and exercise. For example [22], observed longer exercise durations during sessions using JYMMiN compared to routines with passive music listening, without significant increases in perceived exertion. Similarly, Alter et al [29] reported increased weekly physical activity volumes among cardiovascular disease patients using personalized rhythmic auditory stimulation–enhanced playlists. Additionally, Ren et al [43] provided qualitative evidence suggesting that PIMSs may prompt physical activity, such as reducing sitting time in office settings.

However, interpreting these findings is challenging due to methodological limitations and variability in population characteristics. Some studies focus on clinical populations, such as cardiovascular disease patients [29], while others target healthy younger adults [33] or older adult participants [22]. Several studies lack demographic details entirely, further complicating the assessment of population-specific efficacy.

XSL•FO
RenderX

Sample sizes also vary widely, from single participants [31] to larger groups (N=36) [42].

Heterogeneity in PIMSs' Outcomes: Methodological Influences

The wide prediction intervals observed across outcome domains reflect the substantial heterogeneity in PIMSs' effects. For example, prediction intervals for physical activity levels and affective valence highlight significant variability in potential effect sizes. This suggests that while PIMSs may provide positive average effects, individual study outcomes could range from substantial benefits to negligible or even negative impacts. Similarly, the prediction intervals for RPE and physical exertion emphasize uncertainty surrounding these psychophysical outcomes, pointing to inconsistencies in measurement and intervention design.

Specifically, variations in study methodologies and control group conditions contribute significantly to this heterogeneity. Some studies used passive music or other auditory stimuli as controls, while others used no-music conditions. This negatively affects comparability. Well-powered randomized designs, such as that by Alter et al [29] produced robust findings, whereas smaller studies, such as that by Rehfeld et al [22] yielded nonsignificant results, pointing to the influence of study design and statistical power. Additionally, short intervention durations and small sample sizes [37,39] constrain the generalizability of findings. The absence of standardized metrics and protocols across studies further hinders the ability to synthesize outcomes and develop systematic guidelines for PIMS interventions. To alleviate this, future research should adopt standardized protocols and outcome measures. This could be achieved via a music selection and delivery protocol, ensuring uniformity through a predefined library of music tracks categorized by tempo and intensity, delivered via standardized systems (eg, wireless headphones at consistent volumes). Validated tools such as the Borg RPE and the FS for measuring affective valence, administered at fixed intervals, may enhance comparability.

Feasibility of PIMSs on Physical Activity Levels and Affective Outcomes

Despite methodological inconsistencies, our findings suggest that PIMSs may have a positive influence on physical activity levels. Studies in this cluster were rated as having low [29] to moderate [12,22] risk of bias, with both the studies by Alter et al [29] and Rehfeld et al [22] focusing on older adult populations. Positive effects include increased exercise duration (~66 seconds) [22] and overall weekly physical activity (~105.4 additional minutes per week on average) [29]. However, van der Vlist et al [12] found no significant impact of PIMSs on physical activity levels. The low heterogeneity in this cluster indicates consistent findings despite variations in study design and participant populations. This is promising and calls for further investigation.

Our results align with that of Clark et al [6], who noted that music listening, when combined with physical activity, enhances exercise outcomes in older adults. Both Alter et al [29] and van der Vlist et al [12] used synchronization strategies—rhythmic auditory stimulation and auditory-motor coupling, respectively—consistent with frameworks by Bood et al [8] and Clark et al [71] that link synchronized music to improved physical activity and exercise performance. However, the exploratory nature of the meta-analysis and the small number of studies limit the potential generalizability of these findings. Further research with diverse populations and robust methodologies is required to confirm whether PIMSs are effective adjuncts for increasing physical activity levels.

For affective valence, the large effect size estimate suggests PIMSs contribute to elevated affective experiences during physical activity and exercise [12,22,32,35]. However, this finding is strongly influenced by van der Vlist et al [12], whose notably high effect size estimate substantially raised the overall meta-analytic effect size estimate. In contrast, smaller effects observed in other studies [22,35] reduced the precision and generalizability of the overall meta-analytic finding. The differences in these outcomes likely reflect variations in music selection methods: researcher-selected music in the study by van der Vlist et al [12] prompted synchronization and enjoyment ("fun and enjoyment" ratings via IMI), while self-selected music [32] and device-generated feedback [22,35] influenced affective outcomes in distinct ways. In the study by van der Vlist [12], researcher-selected music facilitated synchronization, while Chen et al [32] used self-selected music based on participants' individual preferences. Rehfeld et al [22] and Fritz et al [35] used device-generated musical feedback, where participants' movements influenced the music. These differences suggest that PIMSs may enhance affective valence outcomes during physical activity and exercise through both self-selected and researcher-selected music, with evidence of positive effects for music tailored to individual preferences (aligning with prior research by Terry et al [7] and Khalfa et al [11]) as well as for standardized, researcher-selected stimuli.

Curiously, van der Vlist et al [12] reported no significant benefits for RPE, despite using auditory-motor coupling strategies. This discrepancy may find alignment with the Dual-Mode Theory, as even though music can enhance automatic synchronization and facilitate improved physical performance, it does not always mitigate RPE if reflective processes (eg, cognitive appraisal of effort) are less engaged [13]. The substantial heterogeneity within the affective valence cluster, driven by variability in musical strategies, participant demographics, and inconsistent measurement tools (eg, MDMQ, IMI, and FS), further supports ART's assertion that individual and contextual factors critically shape affective outcomes during exercise.

All studies in the affective valence cluster were deemed to have a moderate risk of bias. Furthermore, the reliance on measurement scales without strong theoretical grounding, as noted in the study by van der Vlist et al [12], suggests the need for alignment with validated frameworks such as ART. For instance, the FS used by Chen et al [32] directly measures the pleasure-displeasure dimensions central to ART, aligning with validated frameworks in physical activity and exercise contexts [72]. The FS provides a theoretically robust and context-specific assessment of affective responses, capturing the transient emotional states during exercise that ART posits are critical for

XSL•FO
RenderX

shaping future behavioral intentions. These findings tentatively indicate that these PIMSs leverage momentary affective responses to improve exercise experiences [6,7,17]. In sum, findings across the physical activity and affective valence meta-analytic clusters suggest PIMSs may support affect augmentation during physical activity, highlighting their potential to enhance both physical activity levels and affective outcomes [5,17].

PIMSs' Tempo Adjustments and Synchronization in Physical Activity and Exercise Outcomes

The identification of faster music tempi as a statistically significant moderator in the meta-regression aligns with evidence supporting the role of synchronization strength and auditory-motor coupling in enhancing exercise outcomes [8,60]. For instance, faster tempi provide consistent rhythmic cues that facilitate the alignment of motor actions with auditory stimuli. This can optimize auditory-motor coupling [8-10], which, in turn, enables predictive synchronization to reduce RPE [7]. For example, Chen et al [32] reported that real-time tempo adjustments based on heart rate significantly reduced RPE and improved affective responses. This indicates that synchronized music facilitated participants' dissociation from internal sensory signals and promoted enjoyment during exercise [7].

Limitations and Future Directions

This review presents the first systematic exploration of PIMSs exclusively within physical, psychophysical, and affective domains of physical activity and exercise. While it provides valuable insights, several limitations must be acknowledged. A significant proportion of the included studies (14 of 18) primarily assessed the feasibility of PIMSs, with few investigating direct outcomes related to physical activity or exercise. Many experimental studies were limited by short durations, small sample sizes, and insufficiently rigorous methodologies. Similarly, proof-of-concept and user-testing studies largely focused on system feasibility rather than assessing objective psychophysiological outcomes. Consequently, the high risk of bias in 10 studies underscores the overall low quality of evidence. Additionally, the small number of eligible studies precluded sensitivity analyses, which further emphasizes the preliminary nature of this review's findings.

Few studies identified physical activity as a primary outcome, often relegating it to secondary importance. Objective assessments of physical activity—such as measures of frequency, intensity, and duration—were notably absent, making it difficult to draw robust conclusions or compare results across studies. Standardizing methods for quantifying physical activity would enhance future research by enabling more meaningful cross-study comparisons.

Furthermore, the methodology used in this study was limited by substantial heterogeneity across studies. This prevents a unified meta-analysis and necessitates the reporting of separate outcomes. Variability in study designs, participant demographics, and measurement tools contributed to unexplained heterogeneity, while the small number of studies precluded sensitivity analyses. These factors, combined with the exploratory nature of the meta-analysis, point to the need for standardized methodologies and rigorous reporting in future research. Additional limitations include the possibility of publication and retrieval bias, as only English-language studies from selected databases were included. Furthermore, although screening and data extraction were independently conducted by 2 reviewers, the use of automated tools and subjective judgment may have introduced bias.

To address these limitations, future research should prioritize larger, randomized controlled trials with diverse populations and longer intervention periods. Longitudinal studies are particularly needed to evaluate the sustained impact of PIMSs on physical activity and exercise. Additionally, investigating the mechanisms underlying individual variability in PIMSs' responses could optimize these systems for different populations and exercise contexts. This highlights the need for more rigorous research to validate these effects and refine PIMSs' interventions, particularly through the development of dynamic systems that can adapt tempo in real time to suit diverse user needs and exercise contexts [41,71].

Emerging trends in PIMSs, such as music recommender systems examined by Álvarez et al [30], Fang et al [34], and Ospina-Bohórquez et al [42], highlight the potential for integration with streaming services such as Spotify (Spotify AB). These systems demonstrated promising user feedback [34] and feasibility, suggesting they could serve as a foundation for future hypothesis-driven studies. Incorporating feedback from wearable and smartphone devices offers another avenue for development, allowing PIMSs to adapt based on physical activity and exercise metrics as well as music preferences. Finally, many PIMSs are relatively low-cost interventions (eg, the devices in the study by Alter et al [29] cost approximately US $75 per patient) and could have significant cost-effectiveness implications as part of broader health policy strategies to enhance physical activity and exercise participation at the population level [5].

Conclusions

This systematic review provides exploratory evidence that PIMSs may positively impact physical activity levels and affective valence in physical activity and exercise contexts. The meta-analysis revealed moderate effect sizes for physical activity levels and significant but heterogeneously distributed effects for affective valence. However, outcomes for RPE and physical exertion were inconclusive due to high heterogeneity and limited study quality.

The findings are constrained by methodological limitations, including high risk of bias, small sample sizes, short study durations, and inconsistent measures across studies. Furthermore, the lack of theoretical frameworks for informing PIMSs' designs and the absence of standardization in quantifying physical activity outcomes limit the generalizability of these findings. PIMSs remain considerably underexplored, and further research is essential.

Overall, PIMSs provide promising potential for enhancing physical activity levels and elevated affective valence, offering engaging physical activity and exercise opportunities for the

XSL•FO
RenderX

public at large. With advancements in adaptive systems capable of real-time tempo adjustments, PIMSs may emerge as effective adjuncts for physical activity and exercise, pending rigorous validation in diverse populations.

Abstract

Background: Public sector organizations increasingly adopt information systems (ISs) to improve economic efficiency, service quality and overall adaptability. These projects represent substantial financial investments, making their success critical for organizational performance and societal impact.

Objective: This scoping review aimed to identify the driving and restraining forces influencing IS implementation in public sector organizations and to explore strategies that support successful change processes.

Methods: A total of 25 peer-reviewed articles were analyzed using Lewin's change theory to categorize and interpret driving and restraining forces. In addition, the narrative emerging from previous research on IS implementation was examined to explore how previous research portrays the success of IS implementation processes.

Results: The findings highlight that IS implementation is influenced by 6 domains: organizational practices and challenges, technological factors and barriers, management practices and issues, change project factors and challenges, end user factors and concerns, as well as institutional factors and barriers. Key driving forces include leadership support, stakeholder involvement and system usability, while restraining forces encompass user resistance, technical challenges, and organizational silos.

Conclusions: Despite the challenges, IS implementation offers significant opportunities for improving public sector operations and societal outcomes. Addressing restraining forces and leveraging driving forces is essential for achieving sustainable digital transformation. This study provides actionable insights for future IS implementation in the public sector.

(JMIR Hum Factors 2025;12:e71575) doi:10.2196/71575

KEYWORDS

information systems; implementation; public sector; digital transformation

Introduction

The implementation of information systems (ISs) is one of the greatest transformation challenges that organizations face. Digitalization of services and operations is fundamentally transforming public sector organizations. It is seen as a key component of administrative reforms, and as a solution to high public expenditure, inefficiency, increased user involvement, and the need for greater transparency in public administration [1,2]. In addition, the digital transformation observed in other sectors has led citizens to expect real time, high-value services from the public sector [3]. In this study, public sector organizations are defined as government-funded and operated entities, such as health and social care institutions.

In health care, ISs play a critical role in operational processes, directly influencing health service outcomes. The term IS refer to a set of digital technologies and processes designed to collect, process, store, and disseminate information within organizations, including tools like electronic health records (EHRs) and other information technology (IT) solutions to support organizational operations. The digitalization of health care has potential to enhance care effectiveness, improve cost efficiency, and enable new service delivery methods [4,5].

Despite the advanced quality of health ISs, they also represent significant financial investments [6]. Furthermore, IS development is filled with challenges [7-10]. There are numerous ways to cause large information technology projects to fall short of expectations [11-13]. The failure rates have been persistently high [14] with estimates suggesting that up to

XSL•FO
RenderX

60% - 70% of system projects in health care fail [15,16]. Despite the best intentions in software development, delays, failures, and complete abandonment remain possible outcomes [8,17]. The success of IS implementation refers to their ability to meet organizational needs, achieve user acceptance, and deliver intended outcomes, such as operational efficiency and financial sustainability.

Successful adoption of new technology is supported by considering factors related to the organization, people, work, and technology [18,19]. IS-related changes require effective leadership [20-22] and capability to modify practices both at the individual and organizational levels to achieve success [18,23,24]. However, the importance of context and process is often overlooked [25,26]. Implementation in this context refers to the process of planning, deploying, and integrating ISs into organizational workflows, encompassing technical aspects as well as organizational factors such as stakeholder engagement and change management.

Given the clear necessity for the IS development and increasing financial constraints faced by public sector organizations, successful implementation is essential. The complexity of these projects highlights the need for deeper understanding of the forces that influence their success. Previous research has approached IS implementations from multiple perspectives, including their impact on organizations, services and operations [15,27], individual responses to technology adoption and resistance [16,28-30], and project management and governance [11,31]. However, these studies have often remained fragmented, addressing isolated aspects rather than forming a cohesive understanding of IS implementation processes in public sector organizations. A comprehensive examination from the public sector's viewpoint provides a novel contribution to the existing literature. The purpose of the study is to improve the understanding of the factors influencing IS implementation in public sector organizations and to provide insights into preparing for a successful change process.

The analysis was conducted using Lewin's change model and its force fields [32], which categorizes factors as either driving or restraining forces [33-35]. According to model, change is influenced by driving forces which push toward change and support it, and restraining forces which seek to maintain the status quo and resist change [36]. With Lewin's model, it is possible to analyze and identify forces that either propel the change forward or create obstacles that can halt the desired change altogether [34]. Using Lewin's model, this study reveals new insights into the forces influencing IS implementations, building on previous research. Both the driving and restraining forces are identified and analyzed, offering a deeper understanding of the dynamics during a system adoption in public sector organizations.

Research questions are: (1) What are the driving and restraining forces in the implementation of ISs within public sector organizations? (2) What kind of narrative emerges about the success of the change process?

Methods

Research questions were addressed through a scoping review. This method allows to summarize the breadth and depth of the research field on the topic [37]. It helps to identify relevant literature, clarify concepts, and map research activity within the subject area [38]. Through a scoping review, existing knowledge can be identified, evaluated, interpreted, and combined [39,40].

Population, concept, context method [41] was used for topic definition and search strategy formulation. The databases selected were Scopus, Web of Science, and PubMed due to the relevance of the topic and the coverage.

The search queries and results are detailed in Table 1. The database searches were subject to general inclusion criteria described in Textbox 1.

Results

Overview

The data handling process is illustrated in the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) flow diagram (Figure 1) [42] and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist is present as Checklist 1. The final study included 25 primary research articles, and the data are summarized in Multimedia Appendix 1. Narratives about IS implementations presented in research articles are summarized in Multimedia Appendix 2. The data analysis was conducted by using force fields of the Lewin’s change model as it provides a framework to assess the success of IS reform in relation to planning, implementation, and user acceptance [34,35].

XSL•FO
RenderX

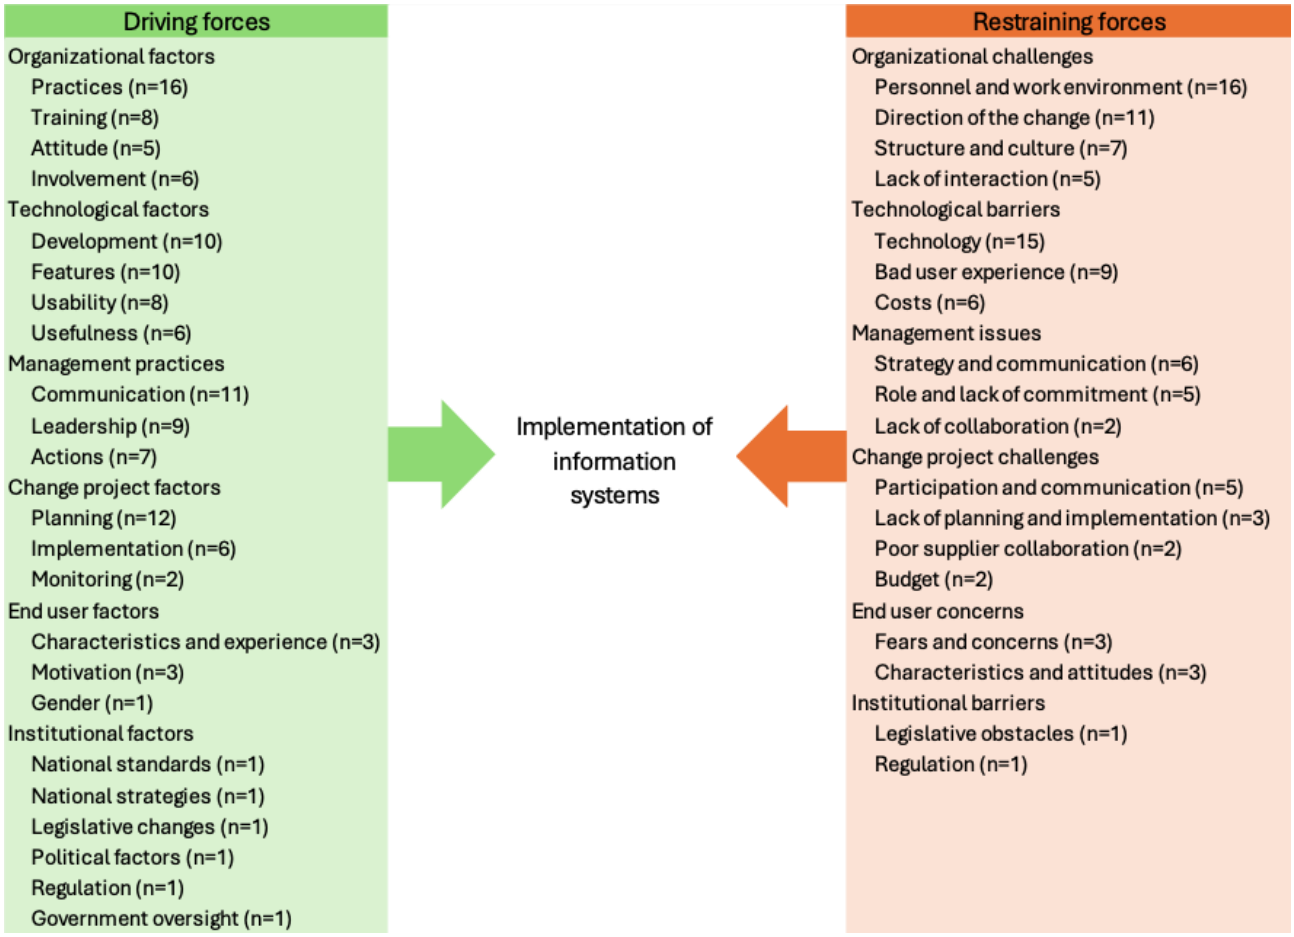

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [42].

The articles were published between 2018 and 2024. The publications originated from a total of 15 different countries and 5 different continents. Most of the studies were qualitative (n=18). In addition, there was 1 mixed methods study, 3 quantitative studies, and 3 literature reviews. Public sector domains were health care (n=18), government agencies (n=3), taxation (n=2), and social welfare (n=2). Forces that drive and restrain the implementation of ISs in public sector organizations were grouped into broader categories (Figure 2). Subgroups were created under the categories, highlighting the most frequently mentioned factors identified from the data (Figure 2). While numerous studies addressed avoidable restraining factors, the emphasis in the data was on the driving factors.

XSL•FO

Figure 2. Driving and restraining forces affecting on implementation of information systems.

Driving Forces

The implementation of ISs in public sector organizations is influenced by a range of driving forces. However, the majority individual forces fall under the categories of organizational and technological factors.

Organizational Factors

Existing practices within the organization can significantly promote the adoption of new systems. Key factors that enhance the personnel's readiness for change include openness [43], encouragement [44], providing safe space for expressing concerns [44], and proactively addressing issues [45]. If the organization learns through negotiation and interaction [465], it is more capable of implementing changes. Centralized coordination and standardization functions [46], implementation practices [47], and decision-making capability [48] within the organization are also important. Change is facilitated if the organization is built around integrated processes that evolve with changes [49] and if these processes are monitored and adjusted when necessary [50]. IT governance reform [48] should be considered as market-driven solution development [46] emerging as a driving factor. The use of a same brand [51] can promote the implementation of ISs in large entities. In extreme cases, personnel can be mandated to use the system [52].

Training of the personnel and end users was highlighted in 8 studies [44,51-57]. Training should occur before the implementation of the ISs, but postimplementation training and guidance should also be emphasized. In addition to training, participation was noted in 6 studies in the dataset [43,52,55,58-60]. All stakeholders, including frontline professionals [58], should be involved from the very beginning.

Attitudinal factors can manifest within the organization as a whole and among its members. In health care, there is a noticeable sense of moral and ethical obligation among professionals to promote change [59], particularly among those in leadership roles. A positive attitude toward innovation [43] and determined efforts [51] supports the change. The organization's ability to create space for creativity [43], agility, and communication along with confidence in the success of the change [59] eases the process.

Technological Factors

Key aspects of development include good software designing [61] and its feasibility [46], implementation strategy [61], testing and validation practices [55,61], and the sensitivity of software developers to the client's need [61]. Innovative solutions are more likely to emerge through local development [46], but it is crucial that solutions also pass pre-established quality gates [53].

ISs possess various features that either drive or restrain their implementation. The most significant driving factor is solution that support workflows [50,55,57,62]. Other factors include the system's observability [54], interoperability [55], and compatibility [54]. The more the system is used, the more likely

XSL•FO
RenderX

the usage will increase [56]. The IS must also fit within the organizational culture [53]. When the IS is perceived to provide more relative benefits, it further drives its adoption [54].

Ease of use was identified as a driving factor in 4 studies [50,56,58,62]. Usability of the IS was discussed in 2 studies [47,55]. It is essential that needed information must be accessible [62] and the system is available for user testing [54]. Perceived usefulness [55,56,58] and even forecasts of positive impacts [56] are considered driving factors. It is crucial that the IS has the potential to enhance aspects such as the quality of care [45] and it supports professionals in performing their tasks [63].

Management Practices

In the context of implementing ISs in public sector organization, management involves leadership activities, communication skills, continuous assessment, and collaboration. In terms of communication, the involvement of individuals in leadership positions emerged as significant factor [43,59]. At a more detailed level, it is essential for management to convey expectations [50] and objectives [60] related to the change. Ensuring that the organization's vision is clearly understood in the context of the change is important [64]. Expectations are placed on leaders' communication, as listening to concerns and doubts [55,60], thereby fostering greater understanding [59]. Managers must be able to address questions regarding changes [59] and be capable of negotiating potential tensions [65]. They should also possess the capability to motivate users [58].

Overall, leadership and change management were highlighted in 3 studies [44,52,55]. Those in leadership positions must ensure the success of the change process [60] and have confidence in the success of the change [65]. The alignment of differing perspectives [64] and the involvement of leaders [48] are also seen as driving factors. Notably, Fennelly et al [55] observed that successful implementation is more likely when the change is not managed directly by top leadership as otherwise the data emphasized the importance of active leadership engagement.

When leading the change, management should focus on preventing the consolidation of the conflicting views [64] and addressing any ambiguities or issues [60] to promote the acceptance of innovations. Managing the change process [58] and monitoring potential performance deficiencies [49] are key factors in implementation process. Management must be able to develop and communicate context-specific goals [58] for the change. Although it was previously noted that change should not be directly led by top management, a collaborative IT group led by management can promote the IS change [49].

Change Project Factors

At the beginning, it is essential to secure resources [55] and ensure clear roles and responsibilities [48,55]. A project team must be established [52] and the supporting structures for the change processes addressed [66]. Further driving factors include stakeholder involvement from the perspective of the change project [66] and the early engagement of various stakeholders [45]. Maintaining strong and trustworthy relationships with software vendors and consulting firms is critical [55]. In early stages of the change project, attention should be paid to the implementation strategy [55], as well as to the practices for adoption that will arise in later phases of the process [43].

During the implementation phase, the importance of the project management team and governance [55] becomes important. A well-planned implementation process [55] supports the change management of the project [50]. Establishing a command center for the adoption phase [48], involving operational-level leadership roles [55], facilitates the actual system rollout. The change project must have clear and measurable goals from a monitoring perspective [55]. Strong communication practices are essential to promoting the desired practical implementation [46].

End User Factors

Regarding user characteristics, a high level of education [56], technological proficiency [62], and overall competence [53] are identified as factors that drives the adoption of the IS. In addition, the motivation [44], commitment [44], and efforts [65] of end users are critical. In 1 study, being female was also identified as a driving factor [56].

Institutional Factors

Institutional factors refer to government guidance and external elements that influence the organizational environment. They are essential factors from the perspective of public sector organizations. National strategies [51] and standards [55] guide the development of the social and health care sectors. Legislative changes [51] and regulations [67] can support or accelerate system reforms within organizations. Government oversight [52] and political factors [67] are also driving forces.

Restraining Forces

Most individual factors restraining the implementation of ISs fell under the categories of organizational challenges and technological barriers. In total, 4 studies [43,47,51,62] did not address restraining factors.

Organizational Challenges

Concerns related to personnel and the work environment include various issues as the loss of professional identity, patient safety, reduced visibility of work and workforce retention, which negatively impact change processes related to ISs [44]. There are concerns about the possibility of professional expertise being replaced by technology or technology being designed for management rather than professionals [63]. There may be difficulties in harmonizing different interpretations of the technology within the organization [64]. Professionals are worried about potentially having less time with patients [44], compromising core values [63] and experiencing general fear [60]. The reluctance of personnel to adopt new systems [52] and resistance to change [54] are barriers that may be related to a lack of incentive systems [49]. Poor job satisfaction [44] and experienced stress among personnel [60] can restrain the change process and may trigger a wave of resignations due to the reform or stress it brings [66].

Factors restraining change also include phenomena related to the direction of the organization concerning the transformation. There may be active resistance to change within the organization, with a lack of belief in improvements as well as

XSL•FO
RenderX

concerns about successful implementation [59]. In addition, there may be covert resistance [67] to change. If there is a sense of being an outsider in the organization concerning the development and planning of ISs [44], the reform is likely to face opposition. The organization's inadequate learning capacity [49], especially the lack of administrative learning [46], restrain the change process. Factors restraining the direction of the reform within the organization may involve viewing technology as a limiting factor [63] or simply a lack of information [57]. External factors include a heavy reliance on partners or their lack of commitment to common changes, both of which can be obstructive factors [54].

As its worst, organizational culture can inherently restrain change [47]. Passive resistance and indifference embedded in its structures may surface during cycles of change [59]. The lack of a shared vision [49] and collaboration [53] are factors that inhibit change as well as a lack of trust between organizations [49]. Insufficient communication and tensions within the organization negatively impact not only the organization itself but also the implementation of change and ISs [64]. Hidden power dynamics [67], inappropriate behavior [60], and problems in social interactions [48] are restraining factors.

Technological Barriers

The complexity of the technology being implemented was identified as a restraining factor in 4 studies [46,50,53,54]. Another technological barrier may arise when software developers do not operate in the same environment where the software and tools are used [61]. If ISs are developed with a tool-centric rather than a user-centric approach [55], issues such as system underutilization [52], may occur. Technical problems [57], system downtime [44], and slow performance [44] can delay the stabilization of change. Technology can impose limitations [54] and cause workflow issues [48], which may lead to the adoption of undesirable practices [63]. Delays in transferring data from the old system to the new one [52] and the complete absence of data [44] do not support the wanted change.

In terms of user experience, the inflexibility of the system was highlighted in 2 studies [50,53]. Concerns related to the reform of ISs include issues regarding data protection, information security, and the doctor-patient relationship [55]. The potential narrowing of professional discretion [63] may be a concern for professionals. The lack of clinical efficiency and safety [65] affects the user experience. Negative previous experiences of professionals [54] influence their attitudes toward changes.

Cost factors related to ISs were identified in 2 studies [48,53]. In an ever-changing operational environment, costs can easily escalate [53]. The extensive need for customization [53] and the requirement for unique system adjustments [48] increase costs when using so called off-the-self-software. If the IS demands the use of specialized resources [53], this raises associated costs. High maintenance costs and inadequate support from the system provider to the organization are restraining factors [53].

Management Issues

Leadership must not leave strategic objectives vaguely defined [53]. A lack of communication regarding the vision [66], insufficient communication of the purpose [66], and inadequate presentation of goals [58] create significant obstacles to change. The lack of information [66] is one of the greatest challenges in transformations. Change initiatives may be deemed unsuccessful due to their scale [53]. If the upcoming implementation project is not adequately communicated to the personnel [59], the consequences may restrain the change.

The leader's role is to be visible and committed to the change [66], as lack of responsibility [52] is unfavorable from the perspective of reform. It is also common for personnel to not be informed at all due to uncertainty [59], leading to feelings of abandonment among employees [66]. Challenges arise especially when management's expectations for change conflict the values of the employees [66], such as with productivity expectations. In terms of collaboration, failure can occur in estimating the size of the project [53], often resulting in the project being larger than initially anticipated. Another identified barrier is the lack of close cooperation between clinical leadership and IT professionals [65].

Change Project Challenges

Inadequate communication about the project's tasks [48] provides an undesirable start to a change project. If the participation efforts of various stakeholders are not considered [59], this can increase resistance to change. Involving end users appropriately in the selection of the system [53] drives the implementation. Regarding the implementation process, the lack of transparency and improper execution [59] were identified as barriers. Poor planning [53], delays [53], and the inability to manage a centralized timeline [48] are challenges related to project planning and execution. Budget constraints and overruns [53] are restraining factors. As for supplier collaboration, inadequate screening of suppliers [53] and a nontransparent and nonopen relationship with the supplier can hinder the process.

End User Concerns

End users experience concerns and fears about the impact of artificial intelligence, data privacy, and the replacement of humans by technology [45]. Among user characteristics, advanced age was identified as a restraining factor [56]. In terms of attitudes, user frustration [44] and general resistance to acceptance [57] are also barriers.

Institutional Barriers

As with driving factors, institutional barriers have been identified in only few studies, but they are included due to their significance. Legislative obstacles refer to factors such as data protection and security laws [46]. Regulatory factors [58] can restrain or delay IS reforms, especially in the public sector.

A Narrative of the Change Process in IS Implementations

Based on the data, the procurement of ISs is one of the largest decisions a public sector organization can make [48]. These projects are complex [57] and often fail to meet their objectives [58,62,64]. The IS project represents a significant financial

XSL•FO
RenderX

investment [48,53]. If the system proves impractical and offers limited value, it is considered a poor investment [63]. Although health care has seen rapid technological growth over the past 50 years, it has lagged behind other industries in its use of technology [54,58] and integrating technology into health care remains challenging [50].

Large health care organizations frequently face difficulties in adopting high-quality, modern technological solutions [43]. Although the benefits of systems such as EHRs are widely recognized, their potential is not always fully realized, often due to the implementation process [55]. Furthermore, the introduction of new technology has been shown to increase stress among professionals, potentially worsen existing issues such as personnel shortages and heavy workloads [44].

Changes often lead to uncertainty [66] and anxiety about how they will affect employees' work [59]. The implementation of an IS requires time and resources from organization's perspective [53], and it can disrupt routines [45]. In public sector, digital projects can easily become stalled, resulting delays of several years [46]. Leaders should have necessary expertise to carry out these projects [49].

It appears that the implementation of ISs remains an unresolved challenge for organizations [43,58], but innovations also offer an opportunity to transform organizational practices [67]. Over the years, technological advancements have facilitated the organization and provision of services [62], and they can radically transform how business is conducted [44,52]. For instance, the new generation of EHR systems can offer various forms of support related to patient care and operational planning [62].

ISs play a crucial role in meeting the demands for reform in public sector organizations and the use of technology has increased within public services [63]. Technology offers significant advantages in reducing errors, improving communication and enhancing patient and customer satisfaction [56]. The use of health technology in hospital setting has resulted in several benefits, such as improved services and reduced medication errors, thus promoting patient safety [61]. However, new customer and patient safety errors caused by technology continue to be a significant issue [61]. Nonetheless, electronic health care has a clear and growing impact on health care delivery worldwide and contributes to the efficiency of health care systems [51]. Digitally operated public services can make citizens' lives easier, more satisfying, and safer [49].

Discussion

Principal Findings

The purpose of the study was to enhance the understanding of factors influencing the implementation of ISs in public sector organizations and how to prepare for such change. The main findings indicate that the implementation of ISs in public sector organizations is influenced by a range of driving and restraining forces. These forces can be categorized into six domains, which vary depending on whether the force is driving or restraining: (1) organizational practices and challenges, (2) technological factors and barriers, (3) management practices and issues, (4) change project factors and challenges, (5) end user factors and concerns as well as (6) institutional factors and barriers. The results align with previous research underscoring the persistent challenges in IS implementation within public sector, such as high failure rates, significant financial losses, and diminished trust in technology [6,11-16,43,64]. However, they also highlight the transformative potential of digital technologies, including improved efficiency, reduced errors, and enhanced user satisfaction [4,5,51,56,62].

Key driving forces (leadership, stakeholder involvement, and usability) and restraining forces (user resistance, lack of managerial expertise, and technical challenges) were identified as major factors influencing IS implementation public sector. These findings align with Lewin's change theory, which emphasizes that successful IS implementation depends on overcoming restraining forces and reinforcing driving forces to facilitate a sustainable transformation [34]. The Lewin's change model provides framework for understanding and managing the dynamics of the change as it helps to identify and analyze both driving and restraining forces to enable targeted actions to support the wanted outcome. Force field analysis helps organizations to plan their transformation journey [34,35].

Leadership support was identified as a critical driver, reducing resistance, and aligning organizational goals [43,44,49]. Leadership activities, such as addressing concerns [55,60] and fostering a shared vision for change [59] were pivotal in building trust and guiding the implementation process [64]. These findings align with earlier research highlighting the central role of active and engaged leadership in complex organizational transformations [11,18,20-22,31].

Training and stakeholder involvement were equally important, with 8 studies emphasizing pre- and postimplementation training as critical for building user competence and confidence [44,51-57]. Stakeholder participation, particularly from frontline professionals, facilitated a sense of ownership and reduced resistance, as noted in 6 studies [43,52,55,58-60].

On the other hand, user resistance [16,28-30], end users' key restraining force, was often rooted in fears of increased administrative burdens and reduced professional autonomy [44,60]. Technical challenges, such as bad user experience [50,53,54,65], system downtime [44] and slow performance [50] further interfered with the process. Organizational silos and a lack of a shared vision were also highlighted as significant barriers to successful implementation [49,64].

Previous research emphasizes the need to understand that even the best IS alone cannot meet the expectations placed on it and it is crucial to change practices at individual and organizational level [18,21,23]. Results of this study indicates that the most significant feature of an IS is its alignment with organizational workflows [50,55,57,62], which means that the objectives set for the IS project must consider the processes and the context of the operating environment [25,26].

A narrative analysis of the introduction sections of the studies included in this scoping review revealed how previous research has described IS implementations in public sector organizations. The findings indicate that IS implementation remains a complex

XSL•FO
RenderX

and unresolved challenge [43,57,58]. These projects require significant financial investment [48,53], yet they often fail to meet their objectives [58,62,64]. One major barrier is the disruption IS implementation causes to organizational routines, increasing stress among personnel and worsening workforce shortages [44,45]. Uncertainty about changes and a lack of leadership further hinder the progress [49]. Despite these challenges, the positive narrative from analyzed data emphasizes the benefits of the technology advancement and digitalization such as improved service organization [44,52,62] and increased efficiency [51] as well as reduced errors and enhanced satisfaction [49,55,61]. To conclude, studies acknowledge the significant challenges and risks involved in IS implementation, but they also emphasize the transformative potential in improving operations and service quality. This approach suggests that IS implementation is not inherently problematic, but rather that its success depends on how effectively the implementation process is managed and aligned with organizational needs.

Limitations

This scoping review aimed to provide a broad overview and summarize the breadth and depth of the known forces influencing IS implementation in public sector organizations and to examine the narrative presented in previous search. Existing knowledge was identified, evaluated, interpreted, and synthesized. The objective of this study was not to assess the quality of the evidence, although only peer-reviewed scientific papers were included in the review. While specific search queries and inclusion criteria were applied, it is possible that some relevant studies were not captured in the process.

Conclusions

The decision to implement an IS is a significant and complex process, often encountering challenges in achieving its objectives. These challenges relate to high costs, technical difficulties and the complexity of implementation. However, the adoption of technology also brings positive impacts. Successfully implemented ISs improve services, reduce errors, and increase customer and patient satisfaction. Despite the challenges, a well-managed implementation process can bring significant benefits for customers, organizations, and society.

This study contributes to a growing body of knowledge of public sector technology implementation, offering valuable insights for future projects, which should be examined and planned comprehensively from various identified perspectives. Previous research has primarily focused on the failure of IS implementations, highlighting the need for further studies on the factors influencing successful implementation in the public sector organizations.

Abstract

Background: Tailoring is an important strategy to improve uptake and efficacy of medical information and guidance provided through eHealth interventions. Given the rapid expansion of eHealth, understanding the design rationale of such tailored interventions is vital for further development of and research into eHealth interventions aimed at improving health and healthy behavior.

Objective: This systematic review examines the use of health literacy concepts through tailoring strategies in digital health interventions (eHealth) aimed at improving health and how these elements inform the overall design rationale.

Methods: A systematic search of PubMed, PsycINFO, Web of Science, and ACM databases yielded 31 eligible randomized trials that focused on adult health improvement through eHealth interventions. Eligible studies compared tailored versus nontailored eHealth interventions for adults, excluding non-English papers and those addressing solely readability or targeting populations with accessibility barriers. Data extraction focused on study characteristics, health literacy components, tailoring methods, and design rationales, with study quality evaluated using Quality Assessment for Diverse Studies (QuADS) by independent reviewers.

Results: Most interventions applied both cognitive and social health literacy concepts and predominantly used content matching as a tailoring strategy. Of all studies using content matching, most used one or more supporting theories as well as end-user data to inform the content matching. While choices for individual intervention components were mostly explicated, detailed descriptions of the design process were scarce, with only a few studies articulating an underlying narrative that integrated the most important chosen components.

Conclusions: While tailored eHealth interventions demonstrate promise in enhancing health literacy and the trial design of the interventions overall was of good quality, inconsistent documentation of design rationales impedes replicability and broader application of the used eHealth concepts. This calls for more detailed reporting on the design choices of the intervention in efficacy studies, so that reported outcomes can be easier connected to choices made in the design of the eHealth intervention.

Introduction

In recent years, the design, development, and implementation of digital health interventions, or eHealth interventions, has transformed the landscape of health care and health care delivery [1]. Through these interventions, a wide range of technologies, including mobile apps, portal websites, serious games, and wearables, have been conceived, tested, and implemented in various health care settings. These technologies have shown great promise to enhance accessibility [2] and usability of various health care concepts and services [3]. However, despite the potential benefits of eHealth interventions in improving health outcomes, their impact is not equally distributed. Many end users encounter difficulties in comprehending and using the information provided by these interventions, leading to

XSL•FO
RenderX

underperformance compared with their anticipated potential [4].

One of the most important mechanisms associated with health outcomes is health literacy [5]. Health literacy has been defined as people's knowledge, motivation, and competencies to access, understand, appraise, and apply health information in order to make judgments and take decisions in everyday life concerning health care, disease prevention, and health promotion [6]. Initially, health literacy was defined as a mainly cognitive skill focused on information processing, including understanding, reading, and knowledge of health information. Recent perspectives have adopted a more comprehensive approach to the concept by including the significance of social skills and executive capacities, such as goal-setting, taking action, confidence, motivation, beliefs, and role expectations [7,8]. Most likely, health literacy in its broadest sense impacts the use and effectiveness of eHealth interventions.

One strategy to increase the impact of eHealth interventions is to tailor these interventions toward the specific needs and capacity of the end-user, ensuring that desired knowledge and behavior cues are transferred in the most suitable manner. Tailoring refers to the optimization of communication and functionality based on assessable characteristics unique to that individual. Choosing tailoring tactics, guided by theoretical and empirical evidence, can lead to better understanding and uptake of information and subsequently increased efficacy of the intervention [9].

Regarding health literacy, especially the strategy of content matching, seems important. Named "the crux" of tailoring [10], content matching attempts to direct messages to individuals' status on key theoretical determinants (such as knowledge, outcome expectations, normative beliefs, efficacy, or skills) of the behavior of interest [9]. Ideally, these assessable determinants are established by an evaluative framework, supported by the use of specific supporting theories such as the Transtheoretical Model or the Social Cognitive Theory [10].

Indeed, tailoring for health literacy could follow 2 main conceptual approaches. The first one involves optimizing communication and functionality, focusing on the cognitive capacity of an end-user: in short, an end-user needs to understand and become susceptible to the provided health-related information to act accordingly [9]. The second involves focusing on the social capacity of an end-user. The end-user is advised or encouraged to show certain health-related behaviors [11]. Of course, these 2 approaches are not mutually exclusive and may both be present in an eHealth intervention at the same time, ideally both supporting the same targeted behavior.

The question is how these tailoring strategies, especially content matching, can help to translate the cognitive and social health literacy concepts into a usable and assessable eHealth intervention that meets the desired outcomes. This can be done by establishing the design rationale of the intervention: a representation of the reasoning behind the design of that intervention [12]. It explains choices such as type of technology, content, and usability from an underlying story of the concept that ties together the different elements of the solution into one coherent argument for the solution as a whole [13].

Unfortunately, there is a lack of an overview of how health literacy concepts and how tailoring strategies are used in eHealth interventions, including how health literacy and tailoring are combined. Several reviews have shown that tailored interventions are important for increasing health literacy itself [4,14,15]. However, they did not clarify how social and cognitive health literacy specifically contributed to the tailoring process. Moreover, they did not describe in what way the forthcoming tailoring strategies added to the design rationale of the intervention [4].

Therefore, in this study, we aim:

1. To provide a structured overview of the use of cognitive and social health literacy concepts in tailored eHealth interventions that aim to improve health.
2. To provide a structured overview of tailoring strategies used in eHealth interventions that aim to improve health.
3. To explore how these cognitive and social health literacy concepts and tailoring strategies contributed to the design rationale of eHealth interventions.

Methods

Overview

This systematic review was executed and reported according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) criteria for systematic reviews [16]. The review was registered with PROSPERO (International Prospective Register of Systematic Reviews; 225731). The review has been slightly altered after registration in PROSPERO in terms of focus and scope. While the original goal also included studying eHealth intervention efficacy and health literacy-related outcomes, the selected studies varied too much in terms of setup, execution, dosage, and population to draw useful overarching conclusions. Instead, we decided to focus on the design rationales of the eHealth interventions.

Search Strategy

Studies were identified by searching PubMed (MEDLINE), PsycINFO, Web of Science, and Association for Computing Machinery (ACM) for publications before June 2021. The search strategy was based on previous health literacy reviews [4,17]. For all databases, search strings were compiled using 3 main concepts: eHealth, Health Literacy, and Tailoring. For the string "eHealth", variations of the term eHealth as well as alternative descriptions for digital health interventions (ie, mobile health [mHealth], internet intervention, and online intervention) were used. For the search string "Health Literacy", both cognitive (knowledge, competence, and health literacy) and social (patient activation and motivation) health-related terms were used, based on the search strategy from the European Health Literacy Survey (HLS-EU) consortium [4]. For the string "Tailoring", the search strategy of an earlier review was adapted [17], which included terms such as "tailoring", "personalization." The 3 resulting search strings were combined using the Boolean operator "AND". The queries were then adjusted and optimized for any

XSL•FO
RenderX

of the databases. The complete strategy per database can be found in Table S1 in Multimedia Appendix 1.

Eligibility Criteria

When selecting relevant literature, we included (1) trials with at least one control group; (2) eHealth studies aimed at improving health, such as studies on patient education, decision support, risk assessment, health behavior change, treatment, or self-management of physical and psychological illnesses; (3) studies focused on adults; (4) studies that measured health literacy (cognitive, social); (5) studies that compared a tailored eHealth intervention with a nontailored intervention. We excluded all studies that (1) were not written in English; (2) targeted populations lacking basic accessibility requirements (functionally illiterate, deaf, or blind); (3) focused on cultural tailoring; (4) were only focusing on wording and readability of written content; (5) had active human involvement in the intervention, other than the patient himself; (6) only compared differences in medium type (eg. printed media compared with online media).

Study Selection

After extraction from the databases, all identified studies were uploaded to Covidence Systematic Review software (Veritas Health Innovation Ltd) for screening and removal of duplicates. First, titles and abstracts of uploaded studies were independently screened by 2 reviewers for the eligibility criteria (JH and CE). Any disagreements on the title and abstract screening were negotiated by accessing the full text to determine its appropriateness. In the second stage, full-text papers were further screened for the eligibility criteria. Any disagreements in all previous steps were extensively discussed and resolved by the reviewers (JH, CE) or, when they were unable to agree, by a third reviewer (JR, DK).

Data Extraction

All data were extracted independently by 2 reviewers (JH, CE for tailoring questions; JH, DK for design rationale questions, Quality Assessment for Diverse Studies [QuADS] by JH and CE).

General Characteristics

We extracted the first author, year of publication, country of origin, titles, and targeted illness or targeted behavior.

Health Literacy Concepts

When extracting information on health literacy, we focused on descriptions of both cognitive as well as social approaches to health literacy concepts in the intervention and extracted the reported details on these concepts.

Tailoring Strategies

Tailoring strategy types were categorized into Personalization, Feedback, and Content Matching, plus their corresponding subsets [10]. We also extracted information on the theoretical framework for content matching in the form of reported supporting theories and whether personal data of end-users was used for content matching.

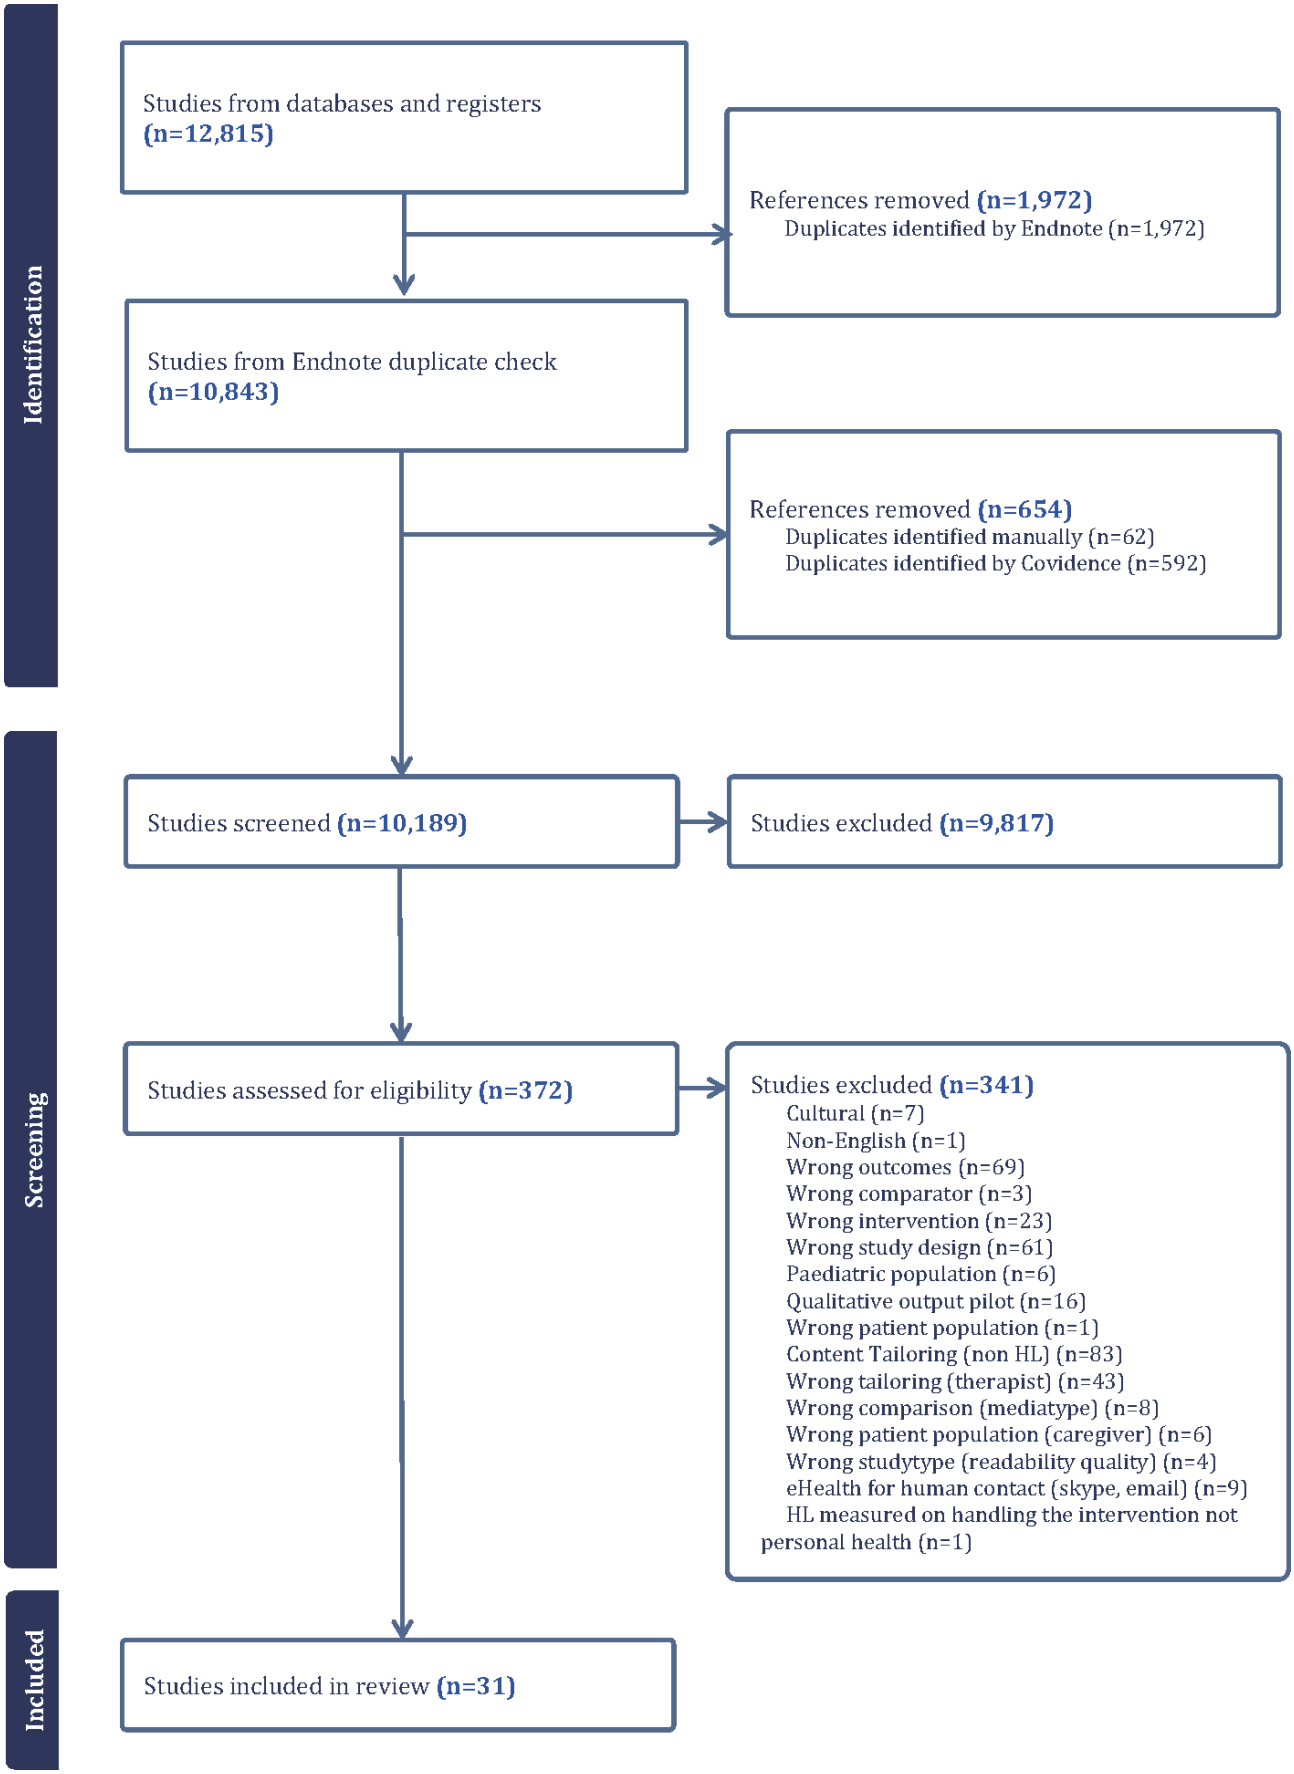
Design Rationale

To establish the design rationale of the intervention, we looked at the intervention itself, its intended goals, its components, the design process, and the reasoning behind the choices made in that process.

We therefore categorized (1) the medium (website, app, email, or message service), (2) the hardware (desktop, mobile app, wearable, or tablet), (3) the components (eLearning, Game or Game mechanics, Diary logging, or Questionnaires). We further extracted (4) hypotheses concerning envisioned or desired workings of the intervention connected to its intended goals; (5) information on the design process (if any such process was reported and whether a design method was used); and (6) the reasoning related to the choices for the health literacy, tailoring, and design characteristics of the intervention. We used a classification of 3 types of reasoning: pragmatic (based on ease of accessibility or availability), theoretical (based on relevant scientific evidence in other contexts) and contextual (based on evidence from the end user's context) and (7) whether an underlying story was provided which ties together the different elements of the solution.

Quality and Bias Assessment

We only included randomized controlled trials, and while this strategy was initially intended to study efficacy, we did choose to include the study quality review. Quality and bias assessment was based on the criteria of QuADS [18] by 2 independent reviewers using Covidence. Any disagreements were resolved by discussion between the reviewers (JH and CE) or, when they were unable to agree, by a third reviewer (JR).



Results

Search Results

The search yielded 12,815 results (Pubmed: 3308; Psychinfo 1916; Web of Science 3188, ACM 4403). EndNote was used to discard duplicates for all databases, after which 10,843 references were imported into Covidence. Using Covidence, a further 592 duplicates were removed before screening. Eventually, the screening resulted in 31 studies that were eligible for data extraction and analysis (Figure 1).

RenderX

General Characteristics

Of the 31 selected papers [19-49], 16 studies were from the United States [20,22,23,26-30,33,36,37,41-45], 4 from the Netherlands [25,31,39,40], 3 from Canada [21,24,32], 3 from Australia [19,47,49], and 1 each from New Zealand [38], Germany [34], Switzerland [34], and Hong Kong [48]; 1 study used an international sample [35].

Only 2 papers were published before 2010 [23,37]. Between 2010 and 2015, 11 papers were published [19,26,28,30,36,38,39,41,45-47], with 4 papers in 2015 alone [36,38,46,47]. Between 2016 and 2020, 17 papers were published [20-22,24,25,27,29,31-35,40,42-44,49], with 9 in 2020 alone [22,24,27,29,31,32,40,42,43]. For 2021, 1 paper was included [48], but this may be partly due to the extraction date.

Most of the interventions addressed a single clinical or behavioral topic, 1 addressed 2 topics [46], and 1 addressed 4 topics simultaneously [44].

Of the screened interventions, 52% (16) were targeted at specific illnesses, complaints, or symptoms, such as cancer (5) [19,27,33,45,47], diabetes (4) [22,34,43,46], cardiovascular diseases (4) [29,31,37,38], back pain (3) [28,36,46], menopausal symptoms (1) [23], and migraine (1) [26].

The remaining interventions (15) were focused on behavioral, preventative, or informative health-related activities such as food intake (3) [20,24,44], smoking (3) [25,44,49], physical activity (2) [40,44], STIs and prevention (2) [39,48], weight management (1) [44], or other preventative care (4) [30,35,41,48]. Two interventions informed end users on specific medical procedures, such as medicine adherence (1) [21], breast reconstruction (1) [42], and one intervention focused on coping strategies for domestic violence [32] (Table S1 in Multimedia Appendix 2).

Health Literacy Concepts

A total of 18 studies [19,23-33,36,39,42,43,45,48] described interventions that used both cognitive and social aspects of Health Literacy concepts. 6 studies [20,35,41,44,46,47] only contain interventions that take a cognitive approach to Health Literacy, while 7 studies [21,22,34,37,38,40,49] only aim to convey one or more social components of health literacy. Some of the health literacy concepts are used to explicitly convey knowledge or awareness on a certain health-related topic with very little or no behavioral cues [19,20], while others use a more practical approach and focus on the social component of health literacy by helping end users develop new behavioral patterns [21,22]. Interestingly, while all included interventions make use of health literacy related concepts, only a very few studies explicitly mention health literacy or a derivative such as food literacy [50], as a concept used to inform the design of the intervention (Table 1).

Tailoring Strategies

Content Matching (29 studies, [19-37,39-41,43-49]) was found in almost all studies, followed by Feedback (24 studies, [20-26,28,31-40,42-45,48,49]) and Personalization (21 studies, [19,21,22,24-33,36,38-40,43-46]); this includes 15 studies using all 3 tailoring strategies [21,22,24-26,28,31-33,36,39,40,43-45]. In one study, we also could discern all subsets [24]. 13 studies used 2 strategies [19,20,23,27,29,30,34,35,37,38,46,48,49] and 3 used only one [41,42,47]. Content Matching was often guided by personal data (25 studies, [23-37,39-41,44-48]) and by theoretical frameworks (28 studies [19-22,24-28,30-32,34-37,39-41,43-49]); only 2 studies [20,48] explicitly mention Health Literacy as a guiding principle for tailoring, while 2 name Food Literacy as a supporting theory [20,24]. Of all interventions, 13 used one supporting theory, 7 used 2 theories, 5 used 3 theories, and one intervention used 4 supporting theories. 5 interventions did not report any use of supporting theories. Of the interventions that did not use any supporting theories, 3 relied on personal data from end users for content matching. Apart from 7 theories that were reported twice, the most prevalent supporting theories were Social Cognitive Theory (5) and the Transtheoretical Model (3) (Table 2).

[a]HL: health literacy

[b]"Our gameful app, Pirate Bri's Grocery Adventure (PBGA), incorporates gameful design elements, such as challenges, personalization, and meaningful choices to motivate young adults to develop food literacy, increase awareness, and improve choices at the grocery store."

[c]United States Preventive Services Task Force

[d]"Taken together, these theoretical foundations point to the potential for casual observational learning to occur when people are intrinsically motivated to participate in learning activities to improve nutrition literacy on a social computing platform."

[e]"This program taught participants to identify which emotions were triggers for their smoking, and how music can be used as a substitute for the emotion regulating effect of smoking"

[f]"The game uses the self-determination theory as the theoretical framework. The self-determination theory is a widely researched theory of motivation that addresses both intrinsic and extrinsic motives for acting and has shown its utility in explaining processes that underpin exercise behavior as well as motivation to play video games. The goal of the game is to restore a decayed garden by planting trees and flowers. In doing so, the player attracts animals that used to live in the garden to come back and help with the restoration process. At the same time, the Schweinehund, the game's adversary, is kept in check. In German, "innerer Schweinehund" (inner swine hound) refers to the weak or lazy part of one's nature, often regarding PA, that has to be overcome to get one's self going. The garden setting was deliberately chosen, as its restoration stands metaphorically for the restoration of the player's body through regular PA. In addition, it has been shown that gardening is among the target group's preferred forms of PA and that gardening-themed games are quite popular and comprehensible to a wide range of players because of their straightforward mechanics."

Design Rationale

Most interventions used a website (24, [19-21,23,24,27,28,30-33,35-39,41,42,44-49]), while 7 interventions were described as an app or native application [22,24,25,29,34,40,43], 28 studies describe interventions using eLearning [19-21,23-34,36-39,41-49], 25 used a form of automated feedback [19-25,27,28,30-35,37-40,42-46,48] while 24 incorporated one or more questionnaires [19,20,23,25-37,39,41-46,48]. 11 interventions used diaries or logging [22,24,26,29,31,34,36,38,40,43,49], 5 interventions made use of a virtual agent [21,25,36,39,44], and 4 interventions used serious games or game mechanics [24,34,40,43] (Table S1 in Multimedia Appendix 3).

A clear trend in all studies is the use of eLearning. 28 studies report the use of this component to convey health-related information [19-21,23-34,36-39,41-49]. Out of the 3 studies that did not use eLearning [22,35,40], 2 did not use cognitive health literacy concepts either [22,40]. These studies relied heavily on providing automated feedback on end-user reporting and behavioral data, thus aiming to reinforce desired health-related behavior [22,40].

All studies (31) explicitly described envisioned or intended workings of the intervention by connecting the functional description of the intervention to its intended goals. Only 4 studies provided specifics concerning the design process of the intervention in the publication [22,42,43,46] while 10 studies referred to other publications for details on the design process [21,24,27-29,31,33,34,37,40]. The majority, however, did not report any details on the design process of the intervention (17). 12 studies mentioned a design method [22,25-27,29,31,38,40,42,43,45], of which 4 [25,31,39,45] referred to Intervention Mapping [51] and 2 pointed towards the International Patient Decision Aids Standards [52] as a framework for designing the intervention. Other examples of methods named were the mHealth Development and Evaluation Framework [53] and "User-Centered Design."

XSL•FO
RenderX

In 4 studies, we could pinpoint an "underlying story" that explicitly tied the elements of the solution together [20,21,24,34]. These "stories," however, varied significantly in detail and clarity. For example, Höchsmann et al [34] extensively explain how and why the choice of medium and components contribute to the transfer of health literacy concepts to the target group by using the metaphor used in the intervention as the underlying story—in this case the maintenance of a garden as a metaphor for living healthy—that ties the elements of the intervention together. Burgermaster et al [19-37,39-41,43-49], on the other hand, is much more succinct: the authors tie the intervention's goal, the medium, and the health literacy content together in one sentence from a theoretical starting point.

When it comes to reasoning, a clear trend is noticeable. The vast majority of reasoning types that were used was theoretical: reasoning based on earlier research in other contexts than the research or intervention's end user context. All but one intervention used theoretical reasoning for one or more components of the interventions. 16 of the 31 interventions use contextual reasoning to support choices for one or more of the components of the intervention [22-25,27-31,34,36,39,42-44,48] (Table 2).

Quality and Bias Assessment

The results of the QuADS assessments can be found in Table S1 in Multimedia Appendix 4. Of the included studies in this systematic review, 26 studies (79%) were of high quality (scoring above 66%), and 7 (21%) were of moderate quality (scoring between 33% and 66%). No low-quality studies were found. The lowest score was 51%. Main areas for quality improvements were: (1) strengths and limitations critically discussed; and (2) appropriate sampling to address the research aim.

Discussion

Principal Findings

The goal of this review was threefold: to provide an overview of the health literacy concepts and tailoring strategies used in eHealth interventions that aim to improve health and to determine how these elements contributed to the design choices of the interventions. In all selected studies, health literacy concepts are used to inform the design of the interventions. The types of concepts and their application vary significantly, as does the choice of tailoring strategies in these interventions. Content matching is present in almost all studies, but a clear trend in applied design strategies or patterns for tailoring strategies to inform the design of the interventions cannot be distinguished.

Concerning the overview of the health literacy concepts, in all extracted papers, we can identify the use of health literacy concepts as guiding principles to aid the development of the inner workings and content of the interventions. Most eHealth interventions used both cognitive and social health literacy concepts. However, there is a broad variety in how these concepts are described, used, and translated into design choices for the intervention and how these concepts are tailored towards the end users. Considering the differences in contexts and targeted illnesses and behaviors, this is not entirely surprising, but there are no clear patterns to be found in approaching health literacy on the whole.

As for the tailoring strategies, content matching can be found in all but 2 studies [19-37,39-41,43-48] while personalization and feedback are used significantly less. Personalization and feedback have been described as mechanisms aimed at "message processing" and "self-referencing," hinting at "creating preconditions for message processing" [9], while content tailoring is described as "the crux" of tailoring. This may explain why personalization and feedback are less common and why only 15 studies show the use of all tailoring strategies [21,22,24-26,28,31-33,36,39,40,43-45].

Only 2 studies [19,44] explicitly refer to the reporting recommendations for tailored interventions [10], in which these strategies are proposed. The way in which content matching is applied varies.

A minority of the studies reported a design process and even fewer reported a methodology for the design process of the intervention. Only 4 studies described a design process in the paper itself [22,42,43,46], although in most studies, rationales for choices for the main components of the interventions were provided. Interestingly, 2 of these interventions involved serious games [24,34]. This may be partly explained by the fact that serious games in the context of health literacy are a relatively novel approach to eHealth interventions, provoking more extensive reporting on how the product was conceived. Also, it is quite common that serious games are designed around a metaphor, which increases the chances of an overarching story that ties together the elements of the solution [54].

The main type of rationale provided for the choice of health literacy concepts, tailoring strategy, and technology was theoretical. Although a qualitative assessment on the rationales is difficult to make, choices for technology and modules would require some contextual reasoning: reasoning based on needs, affordances, and preferences of an end user's context [55]. In half of the studied interventions in this review, such reasoning was not reported.

As all extracted studies aimed to determine the intervention efficacy, the outcomes and conclusions of these studies are focused on answering the question whether the intervention works as intended and expected. However, for insights into why these interventions work and how the combined workings of their components contribute to efficacy, it is important to know what specific reasoning lies behind the choices for concepts, tailoring strategy, and choice of technology. Reporting on these aspects is thus important for the development and improvement of new and existing interventions.

However, we did not find any indication of formal methods such as Toulmin [56] or IBIS (Issue-Based Information Systems) [57], or use of the guidelines for reporting on tailored interventions [10]. While some of the studies were conducted before the latter guidelines were made, more recent papers also did not completely adhere to the provided recommendations. Moreover, some of these recommendations can be interpreted

XSL•FO
RenderX

as a call for a summarized design rationale of the intervention, rather than just a description of the study design. On the other hand, the recommendations do not move beyond describing how supporting theories translate into tailored messages. From an eHealth perspective, a reasoned choice of technology and technological components would certainly add to these recommendations.

eHealth interventions bring together both evidence-based health practices and human-computer interaction, and thus 2 highly different paradigms for design, development, and evaluation. For example, in 4 studies, intervention mapping was named as a design process. While this method does offer a well-documented evidence-based approach, it was not specifically developed for creating digital interventions and may not offer the most suitable procedural approach when designing digital interventions.

Literature calls for a deeper understanding of and appreciation for the differences in development methods to make more effective eHealth interventions and provide more useful documentation on its research [58]. Health intervention development focuses on choosing proven "mechanisms of action" or "active ingredients" [59]. Human-computer interaction, on the other hand, has a deeply rooted tradition in ethnological research and iterative design cycles where anticipated end-users are actively participating in the complete design process [55]. We have found little evidence of these types of design practices in the reporting.

Strengths and Limitations of This Review

This review is the first review on this topic. A strength of our approach is that it was multidisciplinary, involving researchers and databases from the fields of health and technology. Incorporating ACM as an extra source of data widened the scope of this review significantly. It also revealed that multiarmed randomized trials are far less common in this database, and eHealth evaluations tend to be more qualitative and iterative in smaller samples. In addition, we followed the PRISMA guidelines for systematic studies.

When interpreting the results of the review, the following limitations need to be considered. Because we initially planned to report on study health outcomes in relation to tailoring, we only included interventions that were used in a randomized trial. This sometimes resulted in the exclusion of interesting studies, such as research protocols, (speculative) design studies, and single-armed efficacy tests or pilot studies. However, limiting the included studies to multiarmed trials also entailed a certain level of product maturity, compared with more speculative or single-arm pilot studies. This is probably one reason why the quality of the included studies was moderate to high.

In addition, we initially aimed to study the comparative effectiveness of different tailoring strategies to optimize intervention outcomes; however, the degree of variation among the selected studies made this infeasible. A comparative effectiveness study is recommended for future research.

Another limitation is that we were dependent on the quality and focus of reporting. If a design rationale is not described, this does not necessarily mean that it was not present or part of the development process. The constraints of this review limited us from studying other publications linked to the intervention, for instance, study protocols or design studies where more information on the intervention's design rationale could have been present. In any case, our study suggests that design rationales for digital interventions are often not reported or even summarized in efficacy studies, implying that there are limited possibilities to be informed or inspired by approaches and choices of other researchers published in the scientific literature.

The quality of included studies in this review was moderate to high. For future studies, quality can be improved by improved samples selection and by a more critical discussion of strengths and limitations. Of course, QuADS focuses on the study design in general and whether useful conclusions can be drawn from the outcomes, not so much on whether the intervention itself was well designed or if the choices made in the design process are justifiable. As discussed, there may be opportunities to explicate standards on reporting that include (summaries of) design rationales for eHealth interventions.

Conclusion

In conclusion, we can see a broad variety of approaches to the use of health literacy concepts and tailoring strategies in tailored eHealth interventions. We identified rationales for choices of components in all studies, and in a small minority, we could discern overarching design rationales. Although we have been able to discern health literacy concepts, tailoring strategies, and design rationales in the interventions, only a few studies provide sufficient insight into the inner workings and overarching rationale behind the intervention. A significant number of studies refers to other sources for details on the design and design process of the intervention, and while this strategy of reporting on the origins of an intervention certainly is preferable over no reporting at all, it does provide an extra barrier in linking intervention design choices to observed outcomes. Indeed, existing frameworks already provide opportunities to consistently report on the design of tailored health interventions and could be used to report on the use of cognitive and social health literacy concepts as well.

In the field of human-computer interaction, extensive reporting on the design process, as well as describing an overarching rationale for a product, is far more common. Literature has already called for a stricter reporting standard on tailored interventions [10], and since these recommendations are not specifically aimed at digital interventions, there is room to iterate on these recommendations with digital health in mind. Indeed, there are clear opportunities to explore novel reporting frameworks that incorporate the key design rationales of eHealth interventions, in addition to their efficacy. If such frameworks are used regularly, it will be feasible to study comparative effectiveness of eHealth interventions with design rationales informed by specific tailoring strategies. Future studies should therefore prioritize comprehensive documentation on the design of the intervention to facilitate replicability and understanding of intervention efficacy.

Abstract

Background: With the rapid expansion of artificial intelligence (AI) applications, researchers have begun focusing on the concept of human-centered artificial intelligence (HCAI). This field is dedicated to designing AI systems that augment and improve human abilities, rather than substituting them.

Objective: The objective of the paper was to review the information on design principles, techniques, applications, methods, and outcomes adopted in the field of HCAI, in order to provide some insights on the discipline, in relation with the broader concepts of human-centered and user-centered design.

Methods: Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) checklist guidelines, we conducted a scoping review in PubMed, ScienceDirect, and IEEE Xplore, including all study types, excluding narrative reviews and editorials.

Results: Out of the 1035 studies retrieved, 14 studies conducted between 2018 and 2023 met the inclusion criteria. The main fields of application were the health sector and AI applications. Human-centered design methodologies were adopted in 3 studies, personas in 2 studies, while the remaining methodologies were adopted in individual studies.

Conclusions: HCAI emphasizes designing AI systems that prioritize human needs, satisfaction, and trustworthiness, but current principles and guidelines are often vague and difficult to implement. The review highlights the importance of involving users early in the development process to enhance trust, especially in fields like health care, but notes that there is a lack of standardized HCAI methodologies and limited practical applications adhering to these principles.

(JMIR Hum Factors 2025;12:e67350) doi:10.2196/67350

Introduction

User-centered design (UCD) is an iterative methodology that places the user at the center of the design of innovative solutions, allowing the information gathered since its early stages to define the product features and end user experience. This approach is typically enabled by interdisciplinary teams and different methodologies that work together synergistically to optimize the user experience of systems, products, and processes.

The interaction of users with innovation prototypes not only accelerates the identification of usability issues, highlighting improvement opportunities, but also strengthens the capacity

XSL•FO
RenderX

of researchers to define cost and benefits evaluation methods that are propaedeutic to identify the return of investments also in terms of economic benefit. The requirements and recommendations for human-centered design principles have been formalized in ISO 9241‐210, which details the role of UCD and its benefits for human-centered design applied to interactive technologies.

The use of appropriate UCD methods, especially when tailored to specific stakeholders' contexts, can reduce the risk of a given product not meeting stakeholder requirements or being rejected by users.

Similar to UCD, human-centered design (HCD) is an approach that prioritizes human needs, capabilities, and behavior. Therefore, HCD aims to address problems by putting people with their human perspective at the center of the processes, involving them in all stages of problem solving, from observation to brainstorming, conceptualizing, solution development, and final implementation [1]. It is believed that such an approach can improve the usability of an innovation, increasing product acceptance and user satisfaction, proving effective in all situations where solutions are needed that are not only useful, but also involve the emotional sphere of users in some way [2-4].

Recently, due to the increasing growth of artificial intelligence (AI) applications, researchers have shifted their attention to the construct called human-centered artificial intelligence (HCAI), a discipline aimed at creating AI systems to amplify and enhance human capabilities, rather than replace them [5]. As HCD, HCAI places people at the center by seeking to improve, experience after experience, their lives [6]. On the basis of the design phase of any technological product, there are a number of useful techniques that can be adopted to obtain quick feedback from the end users, even in the absence of a fully functioning solution, to provide creative design alternatives to fit the users' preferences and needs. If properly trained, HCAI could offer useful solutions tailored to the peculiar characteristics of the final users, for example, considering new approaches coming from the original combination of many variables.

Despite the undeniable richness of HCAI, there is the need to map the main concepts and constructs behind it, as well as to understand the methods and design principles that underpin it, in order to ensure that these metrics are adequately included in the experimental methodology and understand their role in supporting the UCD and HCD approach. The objective of this paper is to review the information on design principles, techniques, applications, methods, and outcomes adopted in the field of HCAI, in order to provide some insights on the discipline, in relation to the broader concepts of HCD and UCD.

Methods

The scoping review was carried out according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR; see Checklist 1) [7]. Before the start of the project, a protocol was developed to guide the review process, shared among the authors and registered on the Open Science Framework (OSF) platform. The topic of interest for the review was any application of HCAI for UCD, in any population of adults. The outcomes of interest were descriptions of the HCAI approach, description of the HCAI design, outcomes of the application of HCAI, user involvement in HCAI, description of use cases, methods for understanding and the user's mental model, description of user needs, and new working practices. Any other design methodology could serve as a comparator. All English-language studies, with the exception of narrative and editorial reviews, could be included. Clinical questions, exploring the applications of HCAI for design, were translated into epidemiological terms using the Patient, Intervention, Comparator, Outcome, and Study Type (PICOS) methodology (see Textbox 1).

Based on the identified PICOS, search strategies were created and applied to the electronic PubMed, ScienceDirect and IEEE Xplore databases from January 1, 2018, to October 27, 2023. Searches were performed by a single reviewer. The complete search strategies are presented in Multimedia Appendix 1.

The records retrieved from the search were imported into the review management platform Rayyan, where duplicate entries were removed. A total of 4 investigators (RB, EM, TB, and ML) working in pairs performed screening, selection, and data extraction. Specifically, 2 blinded reviewers assessed the title and abstracts to define eligibility for full-text assessment, and, at the subsequent step, assessed full-texts for inclusion. Disagreement was resolved by consensus. Data extraction from the included studies was performed by using a standardized extraction form, including general information on the paper, the field of application, design methods, the adopted model, design principles and properties, technology, and type of AI; extraction was performed by a reviewer and checked by a second one. Results were summarized in summary of findings tables. The methodological quality of the included studies was assessed by a single author (GS) with the SANRA (Scale for the Assessment of Narrative Review Articles) or the Critical Appraisal Skills Programme (CASP) checklist for qualitative studies, depending on the study design.

Textbox 1. PICOS (Patient, Intervention, Comparator, Outcome, Study Type) driving the search strategies and the inclusion criteria.

Patient:

- Any type of patient.

Intervention:

- Human-centered artificial intelligence (HCAI) for design.

Comparator:

- Any other technique adopted for design.

Outcome:

- Description of HCAI approaches.
- Description of HCAI design.
- Outcome of HCAI application.
- User involvement in HCAI.
- Description of study cases.
- Description of methods for understanding.
- Description of user's mental model.
- User's needs and new working practices.

Study type:

- All study types excluding narrative reviews and editorials.

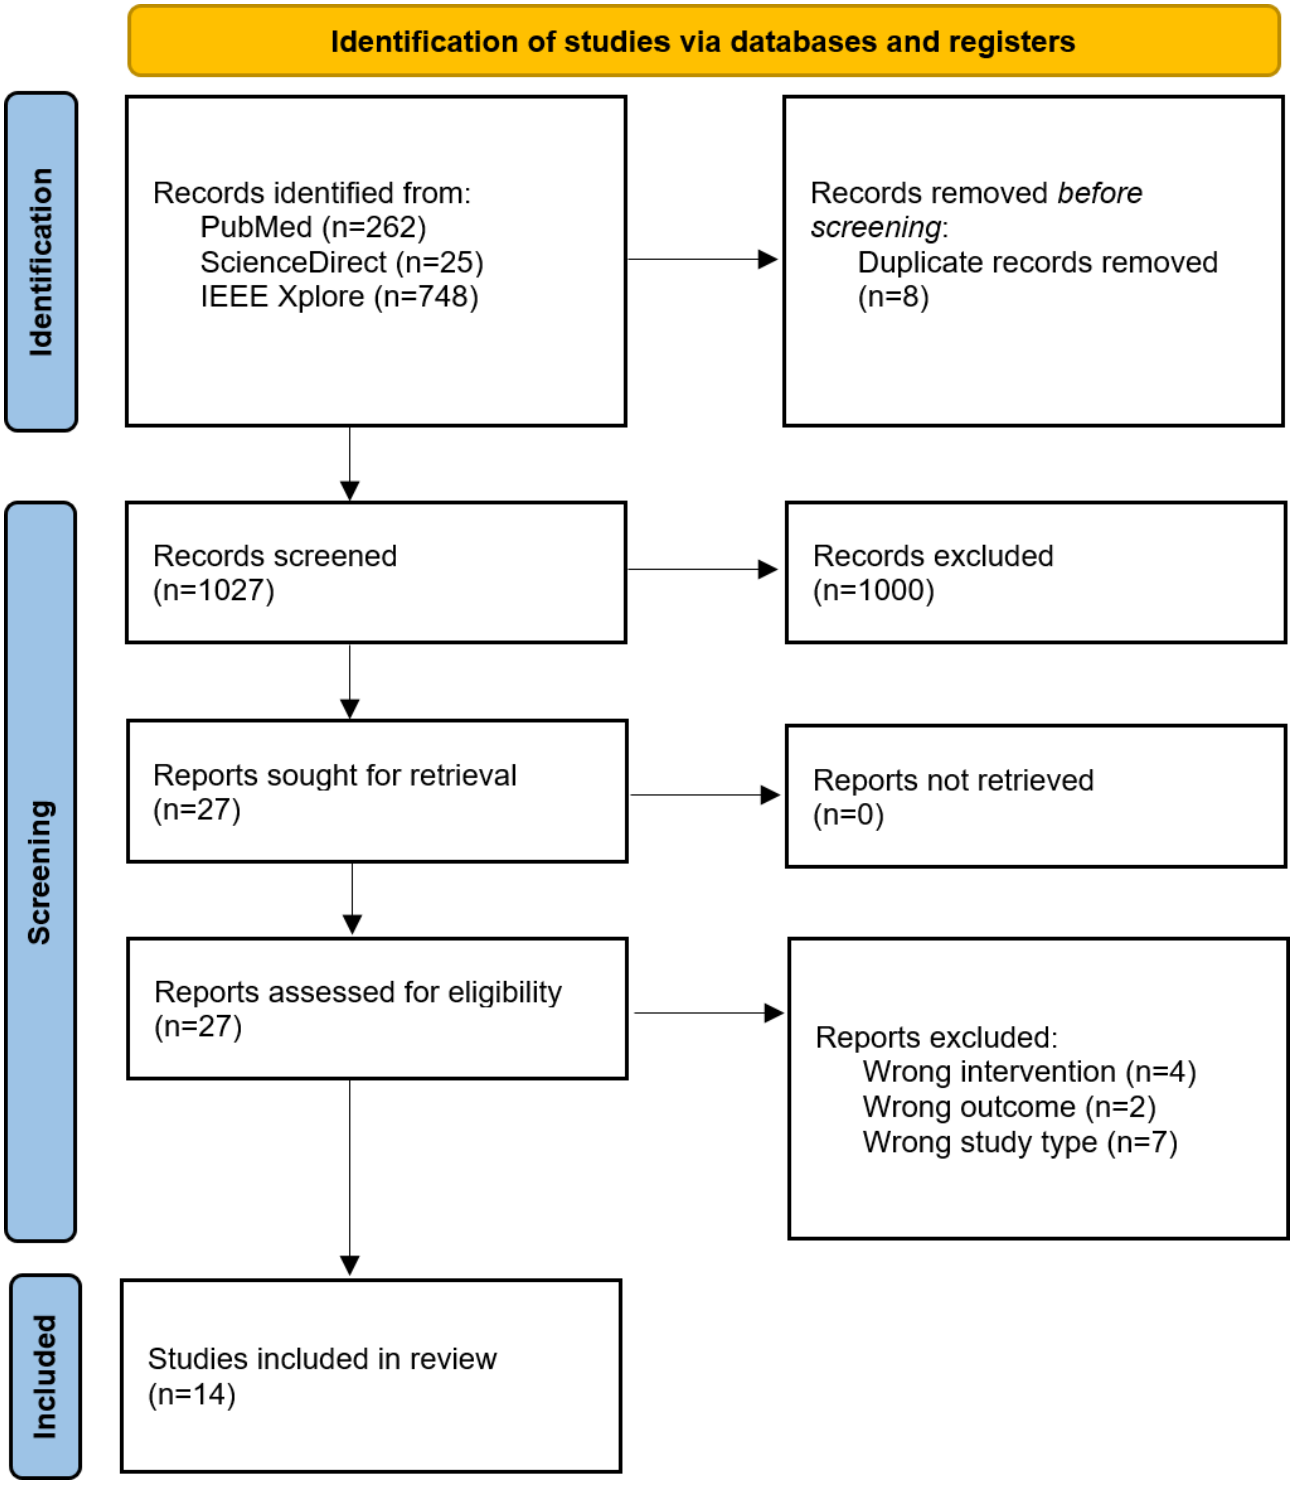
Results

The search in the electronic databases retrieved a total of 1035 articles, of which 8 were duplicates. Finally, the titles and abstracts of 1027 studies were screened. Based on the inclusion criteria, 27 studies were eligible for full-text review; of these, 14 studies fulfilled the criteria and were included in the scoping review. Studies excluded during the full-text analysis are listed in Multimedia Appendix 2, where the title of the paper and the reason for exclusion are indicated. Figure 1 shows the flowchart of the selection process.

Conference abstracts represented a relevant proportion of the retrieved evidence (7/15 studies), no study allowed comparison between techniques. The main fields of application were the health sector and AI applications (see Table 1).

The method adopted for design was described in 8/14 studies. In particular, HCD methodologies were adopted in 3 studies, personas in 2 studies, while the remaining methodologies were adopted in individual studies.

In 10/14 studies, a model was adopted, while in 3 studies this was not applied. Information was not available for a single study.



Design principles and properties were not described in 2 studies, in the remaining studies trustworthiness and explainability were the most frequently adopted principles (see Table 2).

The technology and type of AI were not described in 3 studies, while the remaining studies adopted very heterogeneous technologies.

Table 3 shows the characteristics of each study in terms of scope, presence of a model, design principles used, and technology.

[h]HAII: human–artificial intelligence interaction.

[i]HCD: human-centered design.

[j]UTAUT: Unified Theory of Acceptance and Use of Technology.

[k]TAM: technology acceptance model.

[l]MAIA: multifunctional adaptive and interactive artificial intelligent system.

The study by He et al [8] explores the critical role of trustworthiness in the acceptance of AI systems within the domains of safety, security, and health. By employing the Trustworthiness and Reliability Assessment System (TRAS) model, the research demonstrates that user acceptance is significantly influenced by the perceived trustworthiness and reliability. Socially assistive robots are used as a case study, illustrating how trust can be enhanced in AI systems within these critical fields.

Tyagi et al [9] investigates the application of AI in education through value-sensitive design methods. The study presents an enhanced HCAI framework and explores various AI applications such as intelligent tutoring systems and dialogue-based tutoring systems. The findings underscore the importance of aligning AI systems with educational values and addressing user needs to improve acceptance.

Kim et al [20], Chen et al [19], Soliman et al [18], Ventura et al [17], and Holzinger et al [10] focus on health care applications with distinct approaches. Kim et al [20] examines home care for older adults, highlighting human-AI collaboration and user satisfaction as critical design principles. Chen et al [19] address biases in the AI lifecycle within health care, emphasizing ethical principles, privacy protection, fairness, and transparency. Soliman et al [18] investigates clinical decision support systems for predicting heart failure patient readmission risks, emphasizing model performance, explainability, and trustworthiness. Ventura et al [17] explores health applications, emphasizing user needs and technology acceptance, particularly the perceived trustworthiness of AI systems. Holzinger et al [10] uses personas in the health sector to enhance AI explainability, integrating emotional and ethical considerations to improve user understanding and trust in AI technologies. These studies collectively contribute to advancing AI applications in health care by addressing various challenges and enhancing user confidence and acceptance.

Usmani et al [11] addresses general AI applications with an emphasis on user empowerment and ethical considerations. The research highlights the importance of human-AI collaboration and identifies design principles such as fairness, transparency, accountability, and privacy protection. These principles are crucial for developing trustworthy and ethical AI systems.

Fagbola and Thakur [12] and Ahmad et al [16] discuss the development of AI systems from complementary perspectives. Fagbola's study emphasizes interpretability, explainability, fairness, transparency, and safety as crucial design principles, introducing tools like FairML and IBM AIFairness 360. Ahmad's research focuses on human-centered methods, presenting RE4HCAI, a software that addresses user needs,

XSL•FO
RenderX

model requirements, data considerations, explainability, and trust. These approaches collectively aim to foster the development of fair, transparent, and user-centric AI systems, enhancing both usability and trust in AI applications, including virtual reality environments.

Beltrão et al [13] explores the use of human-centered design methods such as personas, scenarios, and journey maps in developing AI-based decision-support systems for clinical settings. The study highlights the importance of aligning AI systems with clinical user needs to improve decision-making processes.

Correia et al [14] delves into human-AI integration, focusing on acceptance models and technology use. The study uses models like Unified Theory of Acceptance and Use of Technology (UTAUT) and technology acceptance model to evaluate user acceptance, emphasizing trustworthiness and acceptability. These insights are vital for designing AI systems that users are more likely to adopt.

Elahi et al [15] examines privacy and health applications, using human-centered design methods. The study introduces a shared responsibility privacy model, underscoring privacy protection as a key design principle. This research highlights the importance of safeguarding user privacy in health-related AI systems.

Bingley et al [6] conducts a qualitative survey on HCAI. The study emphasizes the needs of AI developers and users, addressing aspects such as functionality, social impact, understandability, ethics, privacy, and security. These insights are crucial for developing AI systems that meet diverse stakeholder requirements.

The methodological quality of the included studies was overall adequate, with an unclear quality of the reporting of the relationship between the researcher and participants and ethical aspects in qualitative research, while the aspect of the literature research was not explicitly addressed in most studies with a narrative design (see Figures 2 and 3).

Figure 2. Methodological quality of the included studies presenting qualitative research, assessed with the Critical Appraisal Skill Programme (CASP) checklist for qualitative studies. Correspondence between the color and the items in the checklist: green=yes; red=no; yellow=can't tell [6,10,13-18,20].

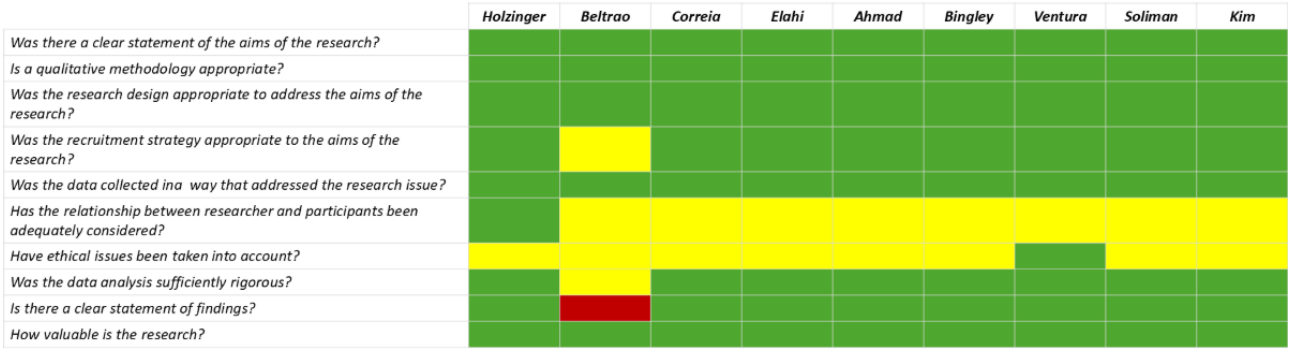

Figure 3. Methodological quality of the included studies presenting narrative results, assessed with the Scale for the Assessment of Narrative Review Articles (SANRA) checklist. Correspondence between the color and the items in the checklist: green=2 points; red=0 points; yellow=1 point [8,9,11,12,19].

Discussion

HCAI and Its Challenges in Practice

HCAI focuses on human experiences, satisfaction, and the needs, with the goal of "amplifying, enhancing, and improving human performance in ways that make systems reliable, safe, and trustworthy." This is pivotal to "support human self-efficacy, encourage creativity, clarify responsibility, and facilitate social participation" [21].

The HCAI seeks to shift the focus in AI development, from technologies to people. However, it is unclear whether existing HCAI principles and practices adequately achieve this goal.

The results of our review indicate that although many studies address the issue of trust and acceptability in HCAI systems, few adopt systematic strategies to mitigate demographic biases and biases in health data. However, in the absence of a standardized methodology to control bias, there is a need to develop more structured guidelines to ensure trustworthiness in AI systems applied to health. In order to formalize these developments, several guidelines have been proposed by governments, organizations, and researchers to translate the ideals of HCAI into practice [22]. For example, the European Union lists 7 key requirements that AI systems should meet to be trustworthy, including transparency, accountability, and promotion of social and environmental well-being [23].

XSL•FO
RenderX

Unfortunately, despite this proliferation of guidelines, IAE ideals have proven difficult to implement [21,24,25]. At this point, Shneiderman [26] argued that although ethical guidelines are a step in the right direction, they are often too vague to be useful to software engineers. Similarly, Mittelstadt [27] criticized AI ethics for having vague principles and lofty value statements that lack the detail and precision needed to make specific recommendations for improving practice.

In line with the literature in the field, our review highlighted the need for a deeper analysis of the design principles promoted by HCAI to understand how they can be put into practice from the outset and how they differ from those proposed by HCD in terms of their impact on end consumers.

In general, it can be said that there is a need to raise the awareness of researchers and developers on the special issues offered by HCAI: the review showed that there is still a limited number of applications for AI design and solutions already available developed in accordance with HCAI principles, mainly in the field of social assistive robotics. This can partly be explained by the innovative nature of the proposed concept, but also by the partial overlap with the more general definition of human-centered design and user-centered design, highlighting the need for a clear definition and standardization of the framework.

From the analysis of recent literature [28], the explainability represents one feature deeply investigated by developers and researchers in the field of AI applications. In the health care sector, in particular, it is possible to notice a relevant focus of attention given to this principle especially from the stakeholders' point of view. In fact, they are in charge of suggesting the use of AI systems to the final users and/or rely on AI decision support systems for complex diagnosis, for example. This evidence highlights the crucial need for transparency and understandability as the basis of explainability of AI, in particular in sensitive contexts as the healthcare sectors, in which erroneous or correct decisions have a significant impact on the well-being of older patients. At the same time, the concept of explainability overcame the mere role of technical prerequisite and became the essential driver to favor the systems' trustworthiness.

On the end users side, in fact, it seems that the value that mostly drives and supports the uptake of AI solutions is represented by the trustworthiness, as also supported by our findings.

Our review, in fact, showed that there is the need to focus more on the concept of trustworthiness when designing a system. Even if all the articles reviewed are in accordance with observing that a user needs to trust an AI-based system in order to use it, however, they differ in the approaches to reach this outcome.

This concept is in fact multifaceted and not easily defined or achieved, as dependent from intrinsic and extrinsic characteristics of the users and of the AI technology. Several theories on technology acceptance have underlined the role of trust especially in the field of social robotics, giving AI applications a primary role in the study of the topic of trust [29,30].

Embodiment, social presence, capacity to interact following social norms and proximity, and advanced dialog features are in fact key ingredients of social assistive robots, which stimulate reciprocity and trust in the relationship between human and robot [29,30].

In addition to explainability and trustworthiness, the main concepts that are taken into consideration in the papers reviewed are transparency, privacy, and safety, which contribute to making the system more trustworthy and acceptable for the user.

The way to better achieve these aspects is still an open challenge, but this review demonstrates the importance of involving real users and stakeholders from the early conceptualization and development stage, through the entire lifecycle and testing phases of a system. This becomes a crucial aspect, especially in the development of applications to support the decision-making by health professionals in clinical fields.

Furthermore, by incorporating user feedback into the design process, users can have a sense of ownership and control over AI systems, potentially promoting trust, acceptance and better adherence, even if in most cases they have had no previous experience with AI solutions.

In addition to the need for specific HCAI methods and techniques for the design and development of new AI systems, the articles examined either did not describe the methodologies used in the design process or used the same methods as those proposed by the user-centered design approach, such as focus groups, personification, scenarios, interviews, and others, as they are independent of the type of technology while maintaining the focus on users as a pillar.

Role of AI in Health Care

AI holds significant potential across various health care domains. AI-driven tools, particularly those based on machine learning algorithms, enhance early disease detection through advanced medical imaging analysis, such as radiography, CT, and MRI. Soliman et al [18] demonstrated the efficacy of AI in clinical decision support systems for predicting hospital readmission risk in heart failure patients, emphasizing model performance and explainability. Similarly, Chen et al [19] highlighted the use of AI to mitigate biases in healthcare applications, with a focus on ethical principles, privacy protection, and transparency. In addition, AI contributes to personalized medicine by analyzing large datasets to predict treatment responses and optimize drug dosages. Beltrão et al [13] explored AI-based clinical decision support systems, emphasizing human-centered methodologies, such as personas and journey maps [13]. Soliman et al [18] further demonstrated AI's role in improving clinical prediction models for readmission risk.

AI also enhances patient care through virtual agents and remote monitoring systems. Kim et al [20] investigated the use of assistive robots (DORI) for home care in older adults, highlighting human–AI collaboration and patient satisfaction. Elahi et al [15] introduced a shared-privacy model for ambient assisted living applications, emphasizing privacy protection as a key design principle. Furthermore, AI-powered medical imaging applications automate routine tasks and reduce

XSL•FO
RenderX

radiologists' cognitive load. Chen et al [19] underscored AI's role in reducing biases in image analysis. Holzinger et al [10] applied the concept of personas to improve explainability in AI systems for health care, integrating emotional and ethical dimensions to foster user trust. Despite these advancements, several challenges remain overlooked. A critical issue is the "black box" problem, referring to the opacity of AI decision-making processes, which prevents users from understanding how outcomes are generated. Although explainability and transparency have been discussed [10-12], the specific concept of the "black box"—which highlights the difficulty in interpreting model behavior—has not been directly addressed. Usmani et al [11] stressed the importance of fairness, transparency, accountability, and privacy protection in developing ethical and reliable AI systems. Fagbola et al [12] discussed tools such as FairML and IBM AI Fairness 360 to ensure algorithm interpretability and transparency. In addition, integrating AI into clinical workflows poses a challenge. Ventura et al [17] explored co-design processes with poststroke patients and caregivers, demonstrating that user involvement enhances AI solution acceptance and facilitates integration into care pathways. Correia et al [14] emphasized the importance of technological acceptance, using models like the UTAUT and technology acceptance model to assess AI's reliability and acceptability in health care environments.

Ethical Concerns in AI for Health Care

In addition to the technical and practical challenges, the integration of AI in health care also raises critical ethical concerns, particularly in sensitive contexts. AI decision-making in health care can have significant implications for vulnerable populations, such as those with serious or chronic conditions, the elderly, or minors. These decisions need to be made with the utmost care to avoid potential biases and discrimination. To address these concerns, AI systems must be designed with ethical safeguards that ensure fairness, transparency, and accountability, especially in critical decision-making processes.

Furthermore, AI's role in processing sensitive patient data underscores the importance of safeguarding privacy and ensuring data security. As AI systems handle increasingly personal and confidential information, adherence to privacy laws, such as the General Data Protection Regulation, becomes essential. Health care providers must ensure that AI technologies respect patient confidentiality while maintaining trust in the system.

Another ethical challenge involves the issue of informed consent. As AI becomes more integrated into clinical decision-making, patients must be fully informed about how AI systems are used in their care. This includes understanding the role of AI in diagnostics, treatment planning, and decision support, as well as the extent to which AI influences clinical outcomes. Clear and transparent consent protocols should be developed to ensure that patients have a clear understanding of their rights and the implications of AI technologies on their care.

Limitations and Future Directions for HCAI

Although this review provides important insights into HCAI, several limitations must be recognized. First, the number of studies focusing on HCAI remains limited and many of these overlap with human-computer interaction. This overlap hinders the differentiation between the two fields and underlines the need for further research to establish the differences between the two fields. A review of this work will be necessary in the coming years to follow the evolution of HCAI and assess the progress that will be made in establishing unique methodologies and contributions.

Another limitation is the need for a more systematic approach to define the design principles underlying HCAI. While co-design and participatory design are widely used, there is no clear guidance on how to integrate the specific principles of HCAI within these processes. Future studies should aim to develop frameworks that not only focus on technical aspects, but also address ethical, social, and contextual considerations.

Trustworthiness, explainability, and reliability remain the most critical issues for the adoption of AI-driven systems, particularly in health care. The ability to provide clear and complete explanations of AI-generated results is crucial to promote user trust. Future research should analyze practitioners' perceptions of explainability, exploring what factors enhance or hinder trust in AI systems.

Furthermore, these emerging tools represent an opportunity to improve the participatory design process by capturing both user needs and expectations. Research is needed to understand how these tools can complement traditional HCD methods and contribute to a more user-centered AI development.

Conclusions

HCAI emphasizes designing AI systems that prioritize human needs, satisfaction, and trustworthiness, but current principles and guidelines are often vague and difficult to implement. The review highlights the importance of involving users early in the development process to enhance trust, especially in fields like health care, but notes that there is a lack of standardized HCAI methodologies and limited practical applications adhering to these principles.

From our perspective, the future of HCAI will depend on its ability to establish itself as a structured and distinct research field. To achieve this, the development of standardized methodologies and principles tailored specifically to HCAI is essential. Rather than relying solely on existing human-centered approaches, the field should work toward codifying new design principles that account for the unique challenges posed by AI systems.

We anticipate that interdisciplinary collaboration will play a crucial role in advancing HCAI. Insights from psychology, cognitive science, and human factors engineering should be incorporated to refine HCAI methodologies, ensuring that AI systems align with human values and cognitive capabilities. Furthermore, integrating AI-based tools for user need assessment could significantly enhance the participatory design process, providing more precise and scalable insights into user expectations.

While AI in health care holds significant potential, there are critical gaps that require further investigation. Our review

XSL•FO
RenderX

highlights the need for a deeper understanding of how biases in training datasets could impact equitable health care outcomes, and how improving transparency in AI decision-making is crucial for building trust. Privacy and data security concerns also need ongoing attention, particularly as AI systems increasingly handle sensitive patient information.

To bridge these gaps, future research should prioritize the integration of AI into clinical workflows, addressing potential challenges to adoption and ensuring that AI solutions are practical, ethical, and aligned with the needs of both health care providers and patients. Moving forward, interdisciplinary approaches that combine technical advancements with human-centered design will be essential for creating AI systems that are not only efficient but also ethically sound and trustworthy
