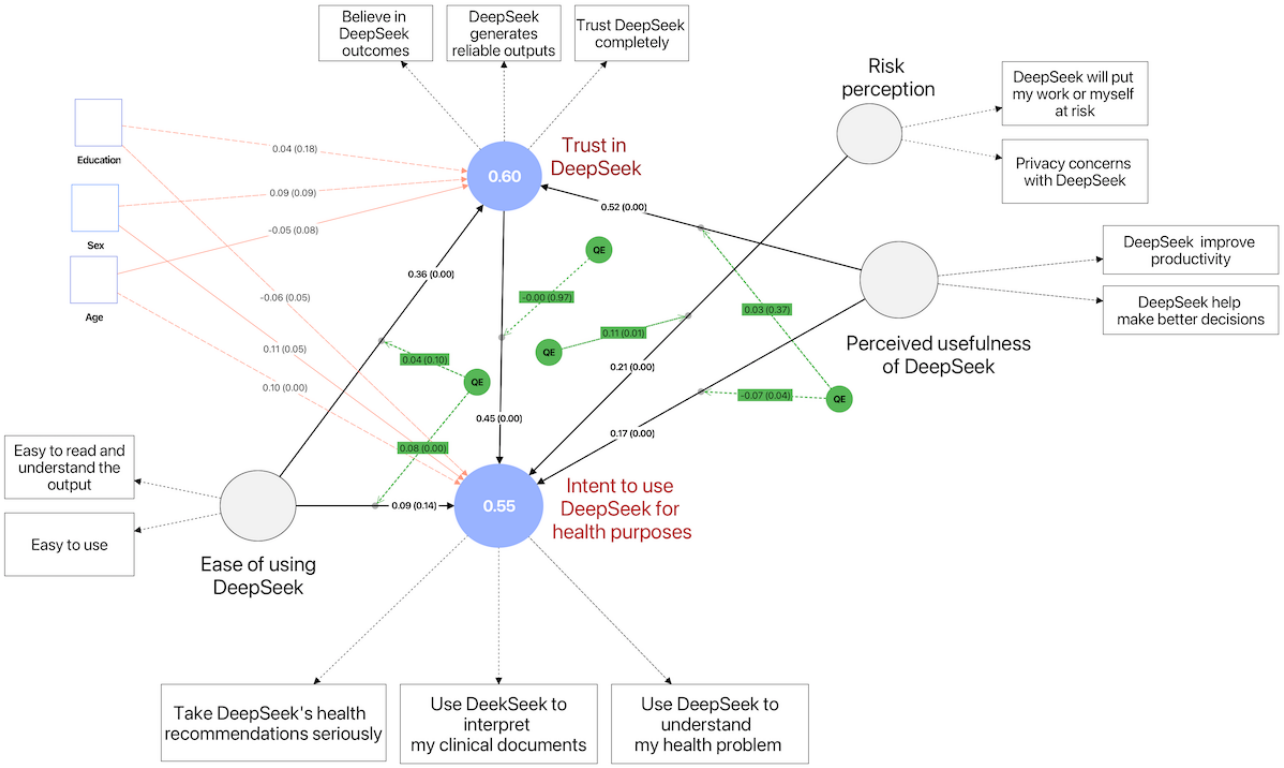
[a]β: standardized coefficient.

[b]Not applicable.

[c]$P<.001$.



[d]$P<.05$.

Perceived usefulness (*H5*) significantly increases *trust in DeepSeek*, indicating that when participants see value in DeepSeek's capabilities, their faith in the technology grows. *Perceived usefulness* also shows a robust direct effect on *intent to use DeepSeek* (*H6*), underscoring the salience of benefit-driven evaluations in motivating adoption. In addition, mediation analyses reveal that trust partially mediates the effect of perceived usefulness on intent: the direct path remains significant, while the indirect path further boosts intentions. Finally, *H7* and *H8* both concern mediation by trust. For *H7*

XSL•FO
RenderX

(*ease of use* → *trust* → *intent*), the indirect path is significant while the direct path is not, signifying a full mediation scenario in which ease of use shapes intentions solely through trust. For *H8* (*perceived usefulness* → *trust* → *intent*), there is evidence of partial mediation, as both the direct and indirect paths are significant. Figure 2 summarizes the overall findings.

Figure 2. The structural model. It illustrates the 5 latent constructs—ease of using DeepSeek, perceived usefulness of DeepSeek, risk perception, trust in DeepSeek, and intent to use DeepSeek for health-related purposes. Each circle represents a latent construct with adjusted R^2 values. The rectangles show specific survey items measuring those constructs. The numeric values on the arrows are standardized path coefficients with *P* values in parentheses. QE captures the possible quadratic effects. QE: quadratic effect.

SEM (Quadratic Effects)

The model explored potential QE nonlinear relationships among the key constructs. The results indicate that the quadratic effect of *ease of use* on *intent to use DeepSeek for health-related purposes* is significant (β=0.08; *P*=.01), suggesting that beyond a certain point, the influence of ease of use on user intentions may intensify or plateau rather than progress linearly. In contrast, the quadratic term of ease of use on trust in DeepSeek was not significant (β=o.04; *P*=.10), indicating that trust levels respond to ease of use in a linear fashion. The quadratic effect of *risk perception* on *intent to use DeepSeek for health-related purposes* emerged as significant (β=−o.11; *P*=.01), implying that moderate risk perceptions might not affect adoption the same way extremely low or very high-risk perceptions do—potentially reflecting a threshold.

Perceived usefulness exhibited a negative but significant quadratic relationship with intent to use (β=–o.07; *P*=.04), suggesting that at very high levels of perceived usefulness, additional increases might yield diminishing or even marginally negative returns on user intentions. By contrast, no significant quadratic effect of Perceived usefulness was detected on trust in DeepSeek (β=o.03; *P*=.37), indicating that trust is likely more directly related to usefulness without an apparent nonlinear inflection point. These results demonstrate that while ease of use, risk perception, and perceived usefulness can shape user intentions curvilinearly, not all model relationships exhibit nonlinear patterns. For constructs such as trust, effects appear to follow a more straightforward linear trajectory. These findings underscore the importance of accounting for potential threshold or plateau effects in user adoption research, particularly in health-oriented applications where attitudes and behaviors can shift dramatically once certain risks or perceived benefits are reached.

Discussion

Summary

This study is among the first to explore user perception of DeepSeek for health-related purposes. Our findings suggest that many users see substantial benefits in using DeepSeek for health-related purposes. The key finding of this research is that ease of use and risk perception can exhibit nonlinear dynamics—these can be interpreted as plateau or threshold points in user attitudes toward DeepSeek. In practical terms, a plateau in ease of use implies that once the interface is sufficiently user-friendly, further refinements may have diminishing effects on adoption. Developers and user-experience designers should therefore balance interface simplicity with the system's perceived depth and reliability; an overly simplistic interface may inadvertently erode trust by making the platform seem superficial or incapable of handling complex health inquiries. Conversely, moderate risk can sometimes spur

XSL•FO
RenderX

vigilance and more thoughtful usage, while extremely high-perceived or extremely low-perceived risk may hinder responsible engagement—by either deterring users outright or breeding complacency. Other notable contribution of this study lies in its comprehensive examination of how ease of use, perceived usefulness, trust, and risk perception influence users' intentions to adopt DeepSeek for health-related purposes.

Ease of Use and Its Impact on Trust in DeepSeek

Our findings confirm that ease of use exerts a significantly positive effect on trust in DeepSeek. From a practical standpoint, developers should focus on streamlined navigation, ensuring that even users with limited digital literacy feel comfortable engaging with DeepSeek. For example, providing step-by-step guidance or context-sensitive help can reinforce the impression that the system is both user-friendly and thoroughly vetted. In contrast to some ChatGPT-based studies, where the interface is perceived as a general question and answer platform, our evidence suggests that for health-specific applications, straightforward interfaces function as a gateway to trust—a critical factor when individuals are dealing with health decisions.

Ease of Use and Intent to Use (Trust Mediation)

The findings regarding the relationship between ease of use and trust in DeepSeek illuminate the complexities of user engagement with AI systems, particularly in health care. Specifically, while ease of use appears to have a significant indirect effect on users' intent to use DeepSeek through the mediator of trust, it resonates with discussions within the larger AI acceptance literature, which posits that usability or interface simplicity alone does not drive adoption without concurrent confidence in the technology's reliability and accuracy [32]. The dynamics uncovered in this exploration emphasize that a merely simplistic interface does not cultivate trust in health-oriented LLMs; users must be assured of the technology's accuracy to engage and rely on it effectively. For instance, users seeking medical advice—such as someone with recurring migraines—may appreciate the user interface of DeepSeek, but their intention to use it consistently will hinge on the platform's perceived medical credibility derived from initial interactions [33]. This perspective is supported by findings from studies on ChatGPT that indicate user trust as a crucial factor influencing sustained interaction, particularly under high-stakes conditions where accuracy is paramount. For example, prior research has shown that while user engagement may be generated through conversational style and interactive query handling, these features fall short in fostering enduring user reliance without a foundational trust in the response quality [34,35] or robust data governance. In comparison, ChatGPT-focused studies highlight that while user engagement may increase through social and conversational interactions, the lack of trust could hinder consistent usage, especially in domains that influence personal well-being [36]. The comparison indicates that while features aimed at ease of use and interactivity can capture initial interest, the health care domain demands a systematic approach that combines usability with robust trust mechanisms to encourage adoption.

The operationalization of trust in AI health systems will likely involve continuous user feedback mechanisms and accuracy assessments to enhance reliability perceptions. Practical applications may include tools that elucidate the rationale behind AI-generated recommendations, thereby fostering a cycle of trust and utility that is essential for successful technology adoption in health care settings.

Risk Perception as a Barrier to Adoption

The finding of risk perception negatively influences intent to use AI applications in health care, such as DeepSeek, is supported by various studies highlighting consumer concerns regarding data privacy and the accuracy of outcomes. This foundational anxiety stems from the sensitive nature of health data, which is subject to strict privacy regulations and potential consequences from AI errors. Studies indicate that perceived risks can deter individuals from using AI-driven health services, emphasizing the necessity for well-defined communication regarding security measures and validations [37]. Studies also acknowledge risk perception as a key predictor of preventive behavioral intentions among health care workers, labeling risk perceptions as a barrier to adoption [38]. For instance, users are often more reassured by clear notifications of compliance with regulations such as Health Insurance Portability and Accountability Act; such risk mitigation strategies can create an environment conducive to adoption. Therefore, developing transparency and clear data-handling policies is crucial for platforms aiming to foster trust amid user apprehensions.

Perceived Usefulness (Direct and Mediated Effects on Trust and Intent)

The assertion that perceived usefulness exerts direct and indirect effects on user behavior is supported by a growing body of literature surrounding AI applications in health care, particularly findings related to ChatGPT and other LLMs. Evidence suggests that tangible benefits, such as improved accuracy and efficiency in information retrieval, significantly motivate user adoption. For instance, studies indicate that the effective performance of ChatGPT in answering medical queries enhances its perceived usefulness, thereby influencing user intention to use the technology [39,40]. The ability to provide relevant and timely medical information underpins the motivation for user engagement with systems such as DeepSeek, signifying that showcasing the background and effectiveness of AI tools is critical for fostering continued usage. Moreover, the notion that perceived usefulness enhances trust aligns with findings in the health AI literature, asserting that when users perceive real value in platform insights, their confidence in the system increases.

In the context of ChatGPT, users often appreciate the quality of responses, which can spur trust; however, this evaluation must also contend with concerns regarding the accuracy and potential misinformation [41]. Reviews of ChatGPT's effectiveness have highlighted its capacity to address diverse questions, reflecting a correlation between perceived usefulness and trust among users [42]. Practical demonstrations of efficacy, such as case studies that illustrate successful outcomes through the application of DeepSeek, resonate with sentiments found in studies involving ChatGPT. For instance, showcasing scenarios where ChatGPT effectively addresses patient inquiries can materially impact users' perceptions of its utility. As users witness consistent performance and tangible benefits, their trust

XSL•FO
RenderX

in the technology deepens. Research indicates that users are more inclined to rely on AI tools when they exhibit high reliability paired with clear demonstrations of past successes [43].

Furthermore, the mediating role of trust in enhancing the relationship between perceived usefulness and the intent to use is underscored by findings that highlight the importance of transparent communication about system performance and limitations. Studies suggest that even when users recognize the immediate utility of a system such as ChatGPT, their commitment to regular use depends on assurances of accuracy and reliability [44]. This illustrates that trust is not merely an adjunct to perceived usefulness but rather a cornerstone of it.

In contrasting DeepSeek with ChatGPT, it becomes evident that while both systems may demonstrate utility, the health context often requires additional layers of demonstrated effectiveness, such as compliance with health care standards or third-party validations. Users making health decisions are more likely to be influenced by the accessibility and clarity of information than those seeking general knowledge, leading to a tighter coupling of perceived usefulness and trust in these sensitive applications. This suggests that developers of health care–oriented AI applications need to focus on operationalizing trust through effective communication strategies, data governance, and continuous assessment of user feedback.

Ease of Use and Perceived Usefulness (Trust Mediation)

Our model indicating full mediation for ease of use → intent and partial mediation for perceived usefulness → intent reveals an interesting relationship between user experience and the adoption of AI technologies, particularly in health-related contexts. This suggests that while perceived ease of use is a critical pathway to intention, perceived usefulness plays a role that not only correlates with intent but also enhances trust. The findings resonate with studies exploring user engagement with AI technologies, highlighting the nuanced nature of technology adoption [45]. In the context of health care AI applications, users often assess functionality and convenience before establishing trust with the technology [46,47]. Studies show that potential users may adopt a system based on perceived usefulness, such as efficiency and practical advantages, even when confidence in the technology's reliability is still developing [48]. Users may appreciate how quickly and accurately an AI system can respond to queries about health-related issues, thereby fulfilling their perceived need for swift information retrieval, which correlates directly with intention to use [49].

Conversely, the aspect of trust and its relationship with perceived usefulness and ease of use is well documented in literature surrounding AI adoption. A robust trust underpinning offers the necessary assurance for sustained engagement with an AI tool. The propensity for individuals to leverage technology relies significantly on their established trust in its reliability, as users frequently remain wary of potential harms associated with incorrect medical information. This caution echoes findings that highlight how user skepticism toward AI systems can hinder adoption, even when perceived usefulness is acknowledged [50].

The dual pathways of adoption in health-related AI involve balance between functionality and trust. Users seeking immediate solutions may prioritize perceived utility—understandably, hospitals and clinics are increasingly looking for AI tools that can aid in diagnosing or managing conditions effectively. However, for deeper and continued engagement, systems must also establish credibility through transparency and accuracy, showcasing validated performance metrics and explicit contextual understanding of the system's capabilities and limitations.

It is imperative for health care–related AI platforms to combine a user-friendly interface—highlighting ease of use—with rigorous communication about their value propositions, as a multitiered approach could cater to both segments of potential users: those motivated primarily by immediate functionality and those seeking strong reliability assurances.

Implications and Recommendations

The significant quadratic terms for ease of use, risk perception, and perceived usefulness underscore that users' intentions to adopt DeepSeek do not always progress linearly. When ease of use displays a positive quadratic relationship with adoption intent, it suggests an initial stage where incremental usability enhancements produce modest gains, followed by a threshold at which further improvements can yield disproportionately greater jumps in adoption. However, past a certain point (a potential plateau), refining the interface may no longer yield significant returns. In essence, once LLMs (DeepSeek) is intuitive enough for typical health inquiries, polishing it further provides only marginal benefit. Therefore, developers should identify the *must-have* design features that bring users up to a comfortable baseline. Past that usability threshold, design resources may be more effectively spent on reliability or improving specific functionalities rather than continuously tweaking the interface. Certain groups (eg, older adults or low digital literacy populations) might require more emphasis on fundamental interface clarity to reach the plateau, whereas advanced users might appreciate specialized features or customization only after basic needs are met.

When risk perception follows a negative quadratic, it indicates that moderate levels of perceived risk may actually promote adoption—perhaps by encouraging vigilance and serious engagement—whereas extremely low or extremely high levels deter usage. Therefore, overemphasizing safety or claiming near-zero risk can paradoxically cause users to discount the tool. They may believe that it is oversimplified or unrealistic for complex scenarios. Conversely, if the system warns of too many uncertainties or potential errors, individuals may deem it too risky. AI stakeholders should aim for transparency that conveys some caution while also stressing evidence of reliability. LLM developers should consider implementing context-based disclaimers that vary by query severity. For minor health checks, a lighter cautionary note may suffice; for serious conditions, stronger reminders encourage users to seek professional verification. Similarly, for perceived usefulness, a negative quadratic implies that while moderately high

XSL•FO
RenderX

usefulness strongly encourages adoption, users can become skeptical if the AI is portrayed as flawless. Exaggerated claims raise suspicion or frustration when real-world performance inevitably falls short. While highlighting success stories or quick turnarounds boosts perceived usefulness, providers must avoid overpromising. Instead, disclosing known limitations, success rates, and typical error margins can actually enhance credibility.

Ultimately, these nonlinear relationships highlight the complexity of user psychology in AI-driven contexts. Rather than presuming a simple the more, the better paradigm, developers and stakeholders should fine-tune system design, risk messaging, and utility claims to steer clear of undesirable plateaus or inversions. By identifying and respecting these inflection points, it becomes possible to sustain healthy, informed user adoption of LLM-based platforms such as DeepSeek.

Limitations

A few constraints must be acknowledged when interpreting these findings. First, this cross-sectional study cannot establish causal direction definitively, although the robust model fit and theoretical grounding strengthen causal inferences. Second, although the sample size was large and relatively balanced across 3 regions, the results may not generalize to other cultural or regulatory contexts where attitudes toward AI-driven health tools differ. Third, the study relied on self-reported measures, which may be subject to social desirability bias or inaccuracies in recalling frequency and manner of use. Our data being collected via web-based panels are inherently composed of volunteers who may differ systematically from the general population (eg, in terms of motivation or digital literacy), thus limiting broad representativeness. True coverage bias remains possible if some segments of the population are less likely to enroll or remain active in web-based panels. While the model covered central factors in technology acceptance (ease of use, usefulness, trust, and risk), other contextual variables—such as domain expertise, quality of health care infrastructure, or cultural norms—may also shape AI adoption in health contexts. Future studies could integrate longitudinal or experimental designs to verify these relationships and examine how usage behaviors evolve with extended AI exposure in real clinical or personal health settings.

Conclusions

The findings indicate that users are generally receptive to DeepSeek when it is perceived as easy to use, useful, and trustworthy. Ease of use significantly enhances trust, which drives the intent to use DeepSeek for health-related purposes.

not only directly boosts both trust and user intent but also has an indirect effect through trust. Conversely, higher risk perception detracts from the intent to use the system. Moreover, the presence of significant quadratic impact suggests that the influence of ease of use, risk perception, and perceived usefulness on user intentions may exhibit threshold or plateau effects. Overall, the validated model underscores the pivotal role of trust as a mediator and highlights the nuanced, nonlinear dynamics shaping user adoption of AI-driven health care tools such as DeepSeek. Future research should replicate this study across different health care settings and populations to validate the generalizability of these findings. Expanding the model to include additional mediators or moderators—such as privacy concerns, cultural differences, and prior experience with AI—might provide deeper insights into user adoption dynamics. Moreover, longitudinal or experimental designs could help establish causality and track changes in user attitudes over time. Finally, given the observed quadratic effects, further investigation into threshold and plateau phenomena could refine our understanding of how perceptions of ease of use, risk, and usefulness evolve as users become more familiar with AI-driven health care tools.

Abstract

Background: As artificial intelligence (AI) evolves, its roles have expanded from helping out with routine tasks to making complex decisions, once the exclusive domain of human experts. This shift is pronounced in health care, where AI aids in tasks ranging from image recognition in radiology to personalized treatment plans, demonstrating the potential to, at times, surpass human accuracy and efficiency. Despite AI's accuracy in some critical tasks, the adoption of AI in health care is a challenge, in part because of skepticism about being able to rely on AI decisions.

Objective: This study aimed to identify and delve into more effective and acceptable ways of integrating AI into a broader spectrum of health care tasks.

Methods: We included 2 qualitative phases to explore podiatrists' views on AI in health care. Initially, we interviewed 9 podiatrists (7 women and 2 men) with a mean age of 41 (SD 12) years and aimed to capture their sentiments regarding the use and role of AI in their work. Subsequently, a focus group with 5 podiatrists (4 women and 1 man) with a mean age of 54 (SD 10) years delved into AI's supportive and diagnostic roles on the basis of the interviews. All interviews were recorded, transcribed verbatim, and analyzed using Atlas.ti and QDA-Miner, using both thematic analysis for broad patterns and framework analysis for structured insights per established guidelines.

Results: Our research unveiled 9 themes and 3 subthemes, clarifying podiatrists' nuanced views on AI in health care. Key overlapping insights in the 2 phases included a preference for using AI in supportive roles, such as triage, because of its efficiency and process optimization capabilities. There is a discernible hesitancy toward leveraging AI for diagnostic purposes, driven by concerns regarding its accuracy and the essential nature of human expertise. The need for transparency and explainability in AI systems emerged as a critical factor for fostering trust in both phases.

Conclusions: The findings highlight a complex view from podiatrists on AI, showing openness to its application in supportive roles while exercising caution with diagnostic use. This result is consistent with a careful introduction of AI into health care in roles, such as triage, in which there is initial trust, as opposed to roles that ask the AI for a complete diagnosis. Such strategic adoption can mitigate initial resistance, gradually building the confidence to explore AI's capabilities in more nuanced tasks, including diagnostics, where skepticism is currently more pronounced. Adopting AI stepwise could thus enhance trust and acceptance across a broader range of health care tasks, aligning technology integration with professional comfort and patient care standards.

Introduction

Background

As artificial intelligence (AI) continues to advance, its potential to revolutionize health care is unquestionable. AI systems are increasingly capable of performing tasks that range from routine data analysis to complex decision-making processes that were once the sole domain of human experts. These technologies offer the promise of more accurate predictions [1], more precise patient condition explanations [2], autonomous diagnoses [3], and personalized treatment plans [4]. Despite these capabilities, there remains an evident hesitancy among health care professionals and patients alike to embrace AI-driven recommendations fully. This skepticism is partly rooted in worries about AI's capacity to grasp patients' nuanced, individual scenarios [5], to integrate the crucial human elements of empathy and understanding [6,7], and to deal with complex ethical considerations in health care [8].

The literature on trust in AI highlights concerted efforts to foster trust by exploring strategies to address trust issues between AI systems and users. For example, some studies suggest that redefining AI as a supportive adjunct to professionals rather than a standalone solution could promote acceptance [9,10]. In addition, showcasing instances where AI surpasses human experts in specific tasks may enhance humans' trust in AI [5,9,11]. Emphasizing transparency and providing understandable explanations of AI processes are crucial, with evidence showing users how AI works can greatly diminish skepticism [12-15]. For example, applying explainable AI (XAI) techniques to explain the basis of AI-generated predictions can, in certain contexts, enhance human trust and understanding [12]. Although XAI can potentially be valuable in increasing trust and understanding, the specific implementation of XAI (eg, the complexity and relevance of the explanation) is crucial in achieving those goals [16]. However, despite these positive developments, fully integrating AI into practice remains challenging, and professionals and laypersons often still prefer human judgment and intuition over AI recommendations [6,7,10,17].

AI's potential applications within health care are vast and multifaceted. Its well-established ability to detect diseases such as cancer and predict various health conditions highlights its substantial role in diagnostics. Not only does AI excel in recognizing patterns within medical images for early disease detection, offering a level of precision that can sometimes surpass traditional methods [3,18,19], but also its influence extends beyond diagnostics. AI assumes a crucial supportive role in health care operations, such as triaging in emergency departments where algorithms prioritize care based on urgency and outcomes, thereby optimizing resource allocation and ensuring timely patient attention [20]. Furthermore, AI's capacity for enhancing operational efficiency is evident across a spectrum of health care activities. It predicts bed availability and automates the conversion of patient consultations into concise summaries, thereby freeing health care professionals from administrative work. This enables more patient-centered care and marks AI as a transformative tool in health care [21].

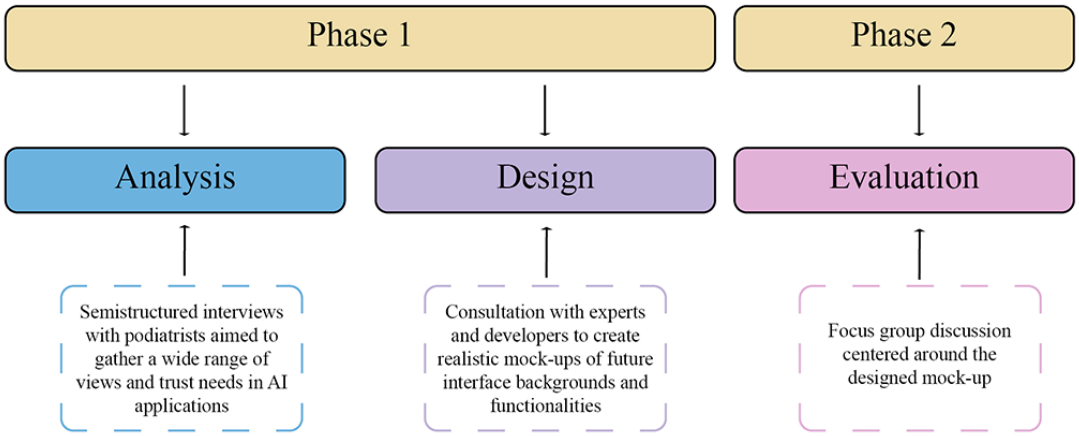
This study seeks to delve deeper into health care providers' perspectives on AI's current and potential role and value in their field. While previous studies often focus on assessing trust in already developed AI systems, this study takes a different approach by involving health care professionals from the outset in identifying potential applications of AI. Early engagement allows us to determine where AI is anticipated to be most valuable, fostering a more collaborative and user-centered integration that aligns with professionals' needs and expectations. By engaging directly with health care professionals who are the prospective users of these AI applications, the study seeks to pinpoint areas where AI integration would be most advantageous and eagerly anticipated by practitioners. Through this inquiry, we aspire to pave the way for more effective and user-endorsed integration of AI in health care, aligning technological advancements with health care professionals' real-world needs and preferences.

Objective

Our study explores health care providers' perceptions of AI's potential benefits in patient care and operational efficiency, with examples including risk assessments and diagnostics. The effectiveness of AI technologies depends on their advanced capabilities and, more crucially, on their acceptance by health care professionals. Without their acceptance, achieving a truly successful implementation becomes only partial, leading to the largely unrealized potential of AI. Thus, we aim to understand these professionals' perspectives on AI adoption, emphasizing the development of trust and integration strategies and identifying approaches that position AI as a valuable tool complementing human expertise, not replacing it [10]. Consequently, the central research question we propose is as follows: How can AI be effectively integrated into practice in a way that ensures health care professionals' acceptance and trust in its advice?

We adopt a qualitative approach to address our research question, focusing on the FootCheck (RondOm Podiatrists) app (in Dutch: Voetencheck app). This app, specifically designed for the daily monitoring of patients with diabetes in the Netherlands, sends daily push notifications to guide these patients through a foot screening process, featuring instructional videos and questions. This enables patients to submit photos to podiatrists to evaluate potential issues such as wounds or ulcers. During its successful pilot phase, which occurred amid the COVID-19 pandemic, the app was used by over 1700 individuals, leading to more than 43,000 screenings [22]. Recognizing the growing interest of stakeholders in leveraging

XSL•FO
RenderX



AI to enhance efficiency and health care quality, we believe the FootCheck app provides an ideal basis for exploring AI's potential. It is important to note that the app still lacks AI integration, highlighting the potential benefits of AI for future enhancements. Our study includes interviews with diverse podiatrists, encompassing current and potential future app users. These interviews aim to understand their experiences and perspectives regarding using the app as it is and the prospects for integrating AI into the screening process of future versions of the app.

Methods

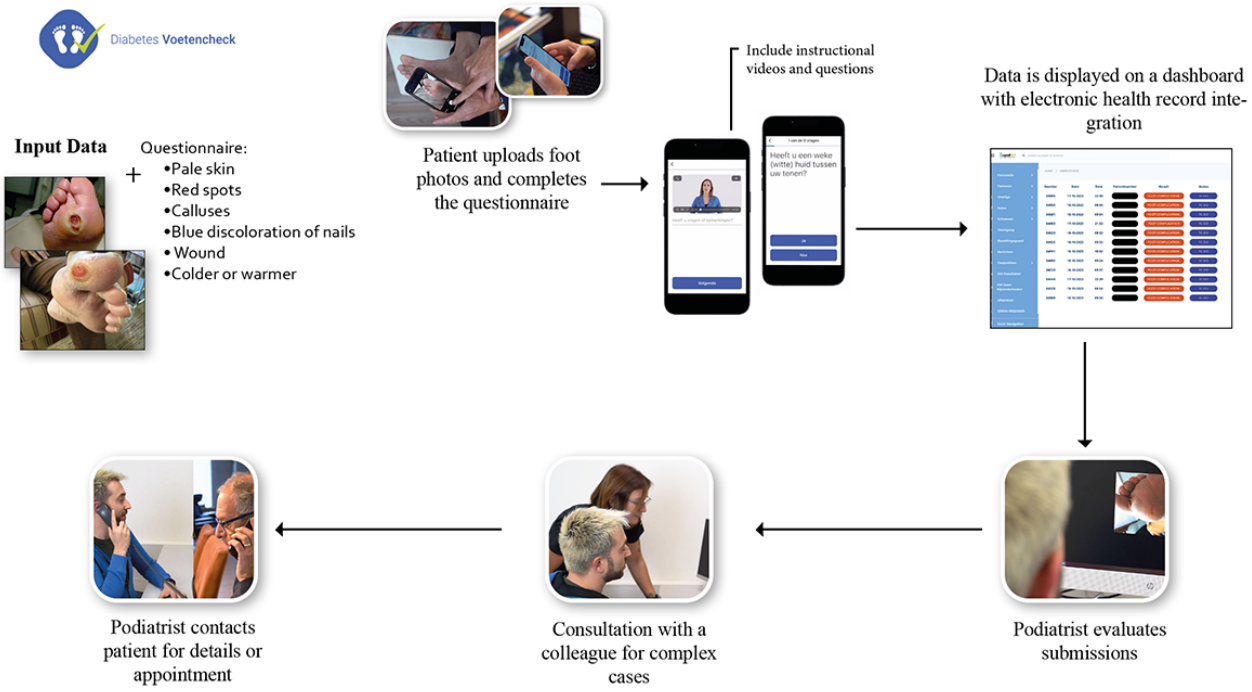
Design and Setting

We conducted a qualitative study structured in 2 phases to investigate trust and acceptance in AI. In phase 1, we sought to capture diverse perspectives and needs from podiatrists regarding their trust in and acceptance of AI technologies through semistructured interviews. The insights gathered from these interviews served as input to the mock-up design process. Phase 2 aimed to further explore specific AI applications through a focus group session. Figure 1 provides a visual representation of these phases.

Figure 1. A visual presentation of the 2 phases of the study. AI: artificial intelligence.

The FootCheck App and Decision-Making Process

The practical application of AI in health care settings we studied was the FootCheck app, developed for RondOm Podiatrists. As one of the largest podiatry chains in the Netherlands, RondOm Podiatrists introduced this app during the COVID-19 pandemic to ensure continuous care for their patients. The app has since been used to facilitate daily monitoring of foot health for patients with diabetes, allowing patients to submit photographs for screening. The workflow from patient submission to professional evaluation is illustrated in Figure 2.



RondOm Podiatrists are keenly interested in the potential of AI to enhance their app and streamline decision-making processes. The system does not use AI currently, but there are numerous potential areas where AI could provide substantial benefits. For example, AI could be instrumental in assessing the suitability of submitted photos for evaluation. This capability would significantly reduce the workload on professionals by automatically filtering out low-quality or irrelevant images, ensuring that only those suitable for review are presented. This efficiency gain is crucial as it allows podiatrists to focus their expertise where it is most needed rather than on preliminary sorting tasks.

Moreover, AI could assist in prioritizing cases on the basis of urgency. Currently, podiatrists must manually open and evaluate all submitted photos, which is time-consuming and potentially less effective in quickly identifying urgent cases. By implementing AI to perform a preselection of instances based on predetermined criteria of urgency, the system could ensure that patients requiring immediate attention are identified and prioritized, thereby optimizing patient care and resource allocation.

Another critical area in which AI could have a significant role is aiding in the diagnosis of foot conditions. The increasing number of patients with diabetes and a relative shortage of podiatrists present a growing challenge. AI can alleviate some of this burden by providing preliminary assessments based on the analysis of photos. While the professional community may have reservations about relying entirely on AI for diagnoses, its role in offering support and preliminary assessments could be invaluable. This assistance could help bridge the gap in service provision, ensuring that more patients receive timely and effective care.

XSL•FO
RenderX

Figure 2. Workflow from patient submission to professional evaluation.

Phase 1: Participants and Recruitment Process

In the first phase of our study, we engaged in interviews with 9 podiatrists from 4 distinct practices, aiming to gather diverse insights into the use and perception of the health care app in question. The actual use of the current app varied considerably among participants, encompassing some who used the app daily and others who, while not yet current users, were familiar with its functionalities. Furthermore, participants' professional expertise spanned different aspects of podiatric care, including both foot care for patients with diabetes and general foot health services.

The recruitment of participants was facilitated through a collaborative effort with the Fontys University of Applied Sciences, one of the leading institutions for podiatry education in the Netherlands. This collaboration was essential for 2 reasons. First, Fontys University maintains strong ties with its alumni, many of whom stay actively engaged with the university through professional networks, alumni events, and workshops. Second, Fontys University's Health Innovations & Technology research group maintains regular collaborations with health care institutions, ensuring strong connections within the field. Through these partnerships, we recruited a diverse group of motivated podiatrists who voluntarily participated in the study. By using Fontys University's network and its respected position within the field, we ensured the participation of podiatrists with varying levels of experience and expertise across different areas of podiatric care, contributing to a representative sample for our study. To accommodate our participants' varying schedules and preferences, the interviews were conducted using a hybrid approach; some were held in person, taking advantage of the natural setting of the participants' practice environments, while others were carried out through the Teams (Microsoft Corp) platform.

Data Collection

We started an extensive literature review on trust in AI, both generally and within the health care context, from which we identified key topics. These topics were categorized into 4 groups as follows: knowledge of AI, trust in humans and AI advice, AI's added value to daily tasks, and factors affecting trust in AI. On the basis of these categories and codes, we formulated initial interview questions. Next, we sought feedback on these initial questions from experts in human and machine interaction. We incorporated their feedback and refined the questions to ensure their relevance and comprehensiveness. To validate the clarity and comprehensiveness of these questions, we conducted a preliminary interview with an experienced podiatrist. This pilot interview served to ensure the questions were understandable and relevant for the prospective interviewees, and it also provided an opportunity to identify any missing questions from the practical perspective of podiatry. The resulting interview guide is detailed in Multimedia Appendix 1.

Participants were briefed on the study's objectives—namely, to explore their perceptions of AI, identify factors influencing trust in AI among podiatrists, examine the impact of trust on AI adoption, and assess their needs for trusting AI in patient care. They were requested to share demographic information via a link before the interview sessions. The specific interview questions were withheld in advance to preserve the authenticity of responses. The interviews were conducted from July to September 2023.

Consent for recording was obtained from all podiatrists, with the sessions captured either on a voice recorder or through the Teams platform, depending on the interview format. These recordings were transcribed verbatim, using Amberscript [23] for efficiency and accuracy. For interviews conducted on the

XSL•FO
RenderX

Teams platform, we leveraged the platform's transcription functionality. Each interview spanned approximately 30 to 45 minutes, with podiatrists having provided explicit consent, either written or digital, for participating and recording their responses. They were also assured of their right to withdraw from the study at any time.

Data Analysis of the Semistructured Interviews

We used a dual-coding strategy, where 2 researchers independently analyzed the interview transcripts to ensure a robust examination of the data. Researcher 1 (MAT), a PhD candidate with a solid background in qualitative research methodologies, and researcher 2 (Ruben Gloudemans) used distinct software tools for coding—Atlas.ti (version 11; Atlas.ti Scientific Software Development GmbH) and QDA-Miner (version 6.0; Provalis Research). This divergence in tool use stemmed from their prior experiences and the software licenses available.

Following the thematic analysis by Braun and Clarke [24], we initiated our analysis by thoroughly reading the transcripts to gain an initial understanding and verify their accuracy. First, we labeled the transcripts without predefined categories, using an inductive approach leading to an extensive list of initial codes directly derived from the data. For example, codes such as human interaction, urgency ranking, efficiency, risk detection, and false advice were formed. We then examined these initial codes to determine if they overlapped with the topics we had previously identified from the literature and combined them if needed. For example, urgency ranking and risk detection were put together since both are related to the topic added value of AI. In this step, we started a deductive approach, where we applied existing theoretical frameworks to refine our codes into coherent themes. We repeated this analytical process several times, refining our approach each time to ensure the emergence of concrete themes. This process yielded a preliminary set of themes.

Subsequently, our individually identified themes were compared in a meeting, discovering significant overlap. For some themes where our interpretations initially diverged, we reached consensus through discussion, using inductive and deductive reasoning. These discussions revealed that, despite using different terminologies, we were referring to the same thematic content. Our thematic analysis was refined further through this iterative process of inductive and deductive coding.

Mock-Up Design

Guided by our research question on how AI can effectively integrate into the FootCheck app's existing screening process with user acceptance, we sought the podiatrists' insights on how they would like to receive advice and in which forms to ensure their confidence in it. Various suggestions emerged, such as explaining the reasoning behind the advice, photos pinpointing potential complications on the feet, and color-coding systems for triage. However, the first phase did not conclusively determine which forms of applications and the level of transparency would foster greater trust.

To further explore these possibilities, we organized a focus group featuring mock-ups. Presenting a realistic representation was crucial, particularly considering that currently, the app and its screening process do not use AI.

1. The first mock-up was designed to assess the effectiveness of AI in a supportive role, specifically in scheduling and prioritizing patient consultations based on an array of time indicators.
2. The second mock-up aimed to explore the potential of AI in diagnosing conditions by analyzing photographs submitted by users and identifying common foot complications such as ulcers or calluses.

We aimed to delve deeper into assessing these AI roles by examining their functionality and acceptability among podiatrists. We crafted 3 distinct design variations for each mock-up to achieve this, guided by needs and concerns expressed in the first interviews with the podiatrists. Our primary reason for this approach was to facilitate a broad discussion by presenting transparency levels varying from low to medium to high. This method allowed us to not only compare the discussions across different AI applications but also delve into the discussions within each level of transparency. Thereby, we aimed to explore the range in podiatrists' perceptions and acceptance extensively.

In designing these mock-ups, we used the current interface environment to ensure familiarity for users. In addition, we consulted with experts during the design process to ensure the mock-ups were practical and reflective of current best practices in the field. For an illustration of mock-up 1 with a high transparency level, see Figure 3; for the diagnostic mock-up set in a medium transparency, refer to Figure 4. For a detailed overview of all variants, refer to Multimedia Appendix 2.

XSL•FO
RenderX

Figure 3. Mock-up 1: high-transparency variant.

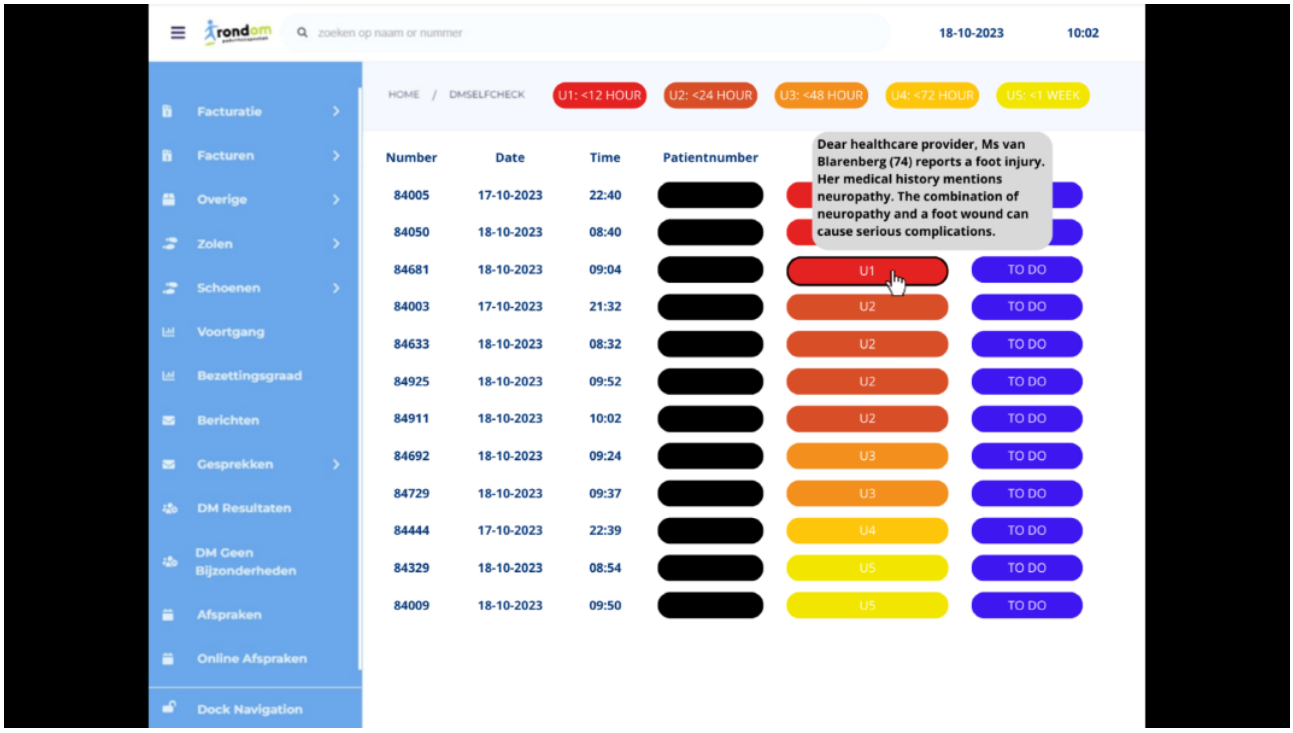


Figure 4. Mock-up 2: medium-transparency variant.

Phase 2: Participants and Recruitment Process

Phase 2 was aimed at enriching our understanding and validating the outcomes of the first phase. Initially, we used the same approaches that had effectively recruited participants for phase 1, including relying on Fontys University's network and existing partnerships within the podiatry field. We also reached out to contacts from our previous interviews. However, these efforts alone were insufficient to meet our needs for new participants for phase 2. To broaden our reach, we engaged with potential candidates on social media platforms such as LinkedIn (LinkedIn Corp) and Facebook (Meta Platforms, Inc) and attended podiatrist conferences to connect with new professionals. Through these combined efforts, we recruited 4 new podiatrists who had not been involved in the first phase and reinvited one participant from phase 1. The focus group session was organized at the Fontys University of Applied Sciences' inspiration space in December 2023.

XSL•FO
RenderX

Procedure for Focus Group and Data Collection

To evaluate our mock-ups, we created an interview guide on essential topics derived from the findings of phase 1: trust in AI's role, transparency preferences, and AI's effect on decision-making, outlined in Multimedia Appendix 3. During the focus group session, participants were thoroughly briefed on the structure of the session that was divided into two 45-minute segments with a break in between. The first session explored mock-up 1, while the second delved into mock-up 2.

The roles of MAT and Ruben Gloudemans within the session were clearly defined for participants; MAT served as the observer, summarizing discussions and posing questions, whereas Ruben Gloudemans led the session and presented the materials. Participants provided written consent by signing a consent form.

After a brief introduction, participants were provided two A3-sized sheets, each showcasing 3 mock-up variants highlighting different transparency levels. Before initiating the group discussions, participants were asked to individually rank these variants from 1 to 3, with 1 being their top preference, and to write down comments next to each variant explaining their choices. This step was designed to minimize mutual influence and ensure that each participant's initial reactions and thoughts were captured independently. Following this individual reflection, detailed group discussions were held, focusing on participants' rationale regarding their preferences and trust in the AI advice shown in each variant.

Data Analysis Focus Group

All participants attended in person for the data collection of phase 2. Initially planned as two 45-minute segments with a 15-minute break in between, the session ultimately lasted 70 minutes in a single stretch. This was shorter than anticipated, primarily because the first segment was concluded earlier than expected, and participants opted to proceed without taking the scheduled break.

We adopted a more structured coding method as we progressed to the second phase, building on the codes and themes identified in the first phase. This shift was enabled by implementing a thematic framework approach, a systematic strategy that helped us to systematically organize and interpret the data [25].

After verifying transcription accuracy and familiarizing ourselves with the transcript, we developed an analytical framework. This framework included predefined themes from phase 1: AI's roles, transparency levels, data reliability, trust development, and the significance of human interaction. This step laid the groundwork for indexing, where we systematically tagged the data with our framework's themes. Next, through charting, we distilled participants' responses into structured summaries, aligning them with the thematic framework. In the indexing and charting phase, we organized the data into themes linked to our research goals, creating visual charts. This approach helped us spot patterns and differences, uncovering insights that enhanced our understanding.

Ethical Considerations

No medical devices were used in the studies, and no physical interventions were performed on participants. The image used in mock-up 2 originated from publicly available internet sources and was appropriately licensed. Consequently, under regulations stipulated by the Dutch Medical Research Involving Human Subjects Act (WMO), the necessity for ethics approval from a national ethics committee was circumvented. However, ethical clearance was proactively obtained from the internal ethics committee of Fontys University of Applied Sciences, documented under project numbers 050324 and 080324. There were no conflicts of interest between the participants and the FootCheck app. None of the participants had any financial, developmental, or other professional ties to the app.

Results

Phase 1: Semistructured Interviews

Participants

Participant demographics for phase 1 are listed in Table 1. In total, 9 individuals, all with backgrounds in podiatry, participated in the first phase of our study. A distinguishing characteristic of this cohort is their active engagement in clinical practice, that is, their extensive practical experience.

Themes From the Interviews

The interviews with podiatrists revealed 3 critical themes regarding podiatrists' perspectives and requirements for AI integration in the FootCheck app and related decision-making process: trust in human experts versus in AI, the added value of AI, and the factors influencing trust in AI. Each theme is further divided into 3 subthemes. A detailed overview of these key themes can be found in Figure 5.

XSL•FO
RenderX

Figure 5. Generated themes and subthemes from phase 1: perspectives of experienced podiatrists on the FootCheck app and decision-making process. AI: artificial intelligence.

Theme 1: Trust in Experts Versus AI

In the initial phase of the interview, we began by asking participants about their understanding of AI and their trust in it compared with their colleagues (ie, experts). We aimed to uncover how AI impacts their trust levels and the underlying reasons for these views.

Theme 1.1: Trust in Experts and Skepticism Toward AI

Podiatrists expressed trust in the advice from expert colleagues, on the basis of their extensive knowledge and experience. They recognized that making mistakes is part of being human and considered it normal for colleagues to err every now and then. Conversely, when receiving advice from AI, direct trust is not immediately established for most podiatrists. They maintained a critical stance, emphasizing the need to verify the accuracy of AI-generated advice:

> *I trust a colleague, sometimes blindly, because they have much experience.* [Participant 7, female, age group 61-70 years]
>
> *I see the added value of AI advice. But I still want to check it or have something alongside it.* [Participant 2, female, age group 51-60 years]
>
> *I do have trust in advice from colleagues. I've considered practical situations, and nine times out of ten, I agree with them just fine. And there are always nuanced differences because you see things slightly differently with your experience, perspective, and view. But let me put it this way: I firmly trust it.* [Participant 8, male, age group 41-50 years]

XSL•FO
RenderX

Theme 1.2: Long-Term Trust Development

Participants indicated that AI may initially struggle to provide accurate advice due to the limited data available and the learning phase required for the model. They also mentioned their initial lack of experience with using AI, which leads to uncertainty about its performance. However, participants felt their trust can increase as they gain more experience with the AI model:

> *In the beginning, I was sceptical, but as it sees and evaluates more photos, my trust grows.* [Participant 9, female, age group 20-30 years]
>
> *Yes, AI needs to prove itself first, and then it can add value.* [Participant 7, female, age group 61-70 years]
>
> *Indeed, my trust in AI would significantly increase if, over time, the technology evolves to a stage where the AI system is fully operational and applicable.* [Participant 6, female, age group 41-50 years]

Theme 1.3: Skepticism Regarding AI

Participants expressed significant concerns about the potential errors an AI system might make and the severe consequences that could arise from such mistakes. In addition, they highlighted a notable limitation of AI: its inability to conduct physical examinations on patients. Such examinations are often essential for a thorough understanding of a patient's foot health, indicating a gap in AI's capabilities in health care settings:

> *Yes, if a patient says: "I have pain in my foot, for example, in the ankles." Well, AI can't see that or physically feel or move it.* [Participant 9, female, age group 20-30 years]
>
> *We're not talking about a patient getting advice to buy Shoe A, and then they say it's too big and buy another shoe.... We're talking about serious outcomes, like the loss of a foot, a leg, or even a life, and that's a significant responsibility.* [Participant 4, female, age group 31-40 years]
>
> *The consequences are quite significant if you miss something there.* [Participant 7, female, age group 61-70 years]

Theme 2: Added Value of AI

Overview

In exploring AI's potential impact on podiatry, we engaged participants in discussions about integrating AI into their everyday practice. This dialogue revealed 3 insightful subthemes, each shedding light on AI's role in enhancing podiatric care. The following sections delve into these emergent themes.

Theme 2.1: Distinction Between Supportive Tasks and Diagnosis

Nearly all participants agreed that AI should be used for support tasks such as triage. They highlighted that significant time is spent retrieving missing information not provided by patients and addressing issues with incorrect photo submissions that impede accurate assessment. They were of the opinion that these tasks could be efficiently managed by AI, thereby streamlining the process and improving overall efficiency. However, opinions varied on whether AI can diagnose foot conditions in patients with diabetes. Most participants were of the opinion that AI is incapable to do so, emphasizing the need for physical examinations by human experts to come up with an accurate diagnosis. They pointed out that photos fail to reveal crucial details, such as hidden wounds beneath calluses, which are not directly visible in pictures. Furthermore, participants noted the importance of physically assessing the feet for swelling and temperature variations (ie, warmth or coldness) that cannot be discerned from photos alone:

> *If it can highlight specific areas of concern, suggesting "pay attention here, this is alarming," then I do place my trust in it.* [Participant 3, female, age group 41-50 years]
>
> *AI can't make complete diagnoses; you need to hold the foot in your hands.* [Participant 2, female, age group 41-50 years]
>
> *I'm considering integrating a feature for predicting situations where an immediate consultation is crucial and distinguishing those from cases where it might not be as urgent.* [Participant 1, male, age group 41-50 years]
>
> *If it integrates well with practical needs, like photos can be easily uploaded directly into the file, making follow-up simpler. Yes, so it actually assists in your work.* [Participant 6, female, age group 41-50 years]

Theme 2.2: AI as a Learning Tool

Participants acknowledged the potential of AI as a valuable learning tool, particularly for identifying unfamiliar diseases and suggesting innovative treatment strategies. They expressed optimism about AI's ability to broaden their diagnostic and therapeutic horizons:

> *Maybe the AI will uncover a disease pattern I haven't encountered before, offering me an opportunity to expand my knowledge.* [Participant 1, male, age group 41-50 years]
>
> *Hey, AI sees things differently, and that's something I can learn from. I do see the added value in that.* [Participant 5, female, age group 20-30 years]
>
> *In this light, I believe that when an AI indicates, "this is the optimal treatment," it becomes incredibly fascinating. It prompts a collective inquiry: "Why hadn't this occurred to us before? Is this indeed the correct approach? Or is there already a hospital implementing this method?"* [Participant 4, female, age group 31-40 years]

Theme 2.3: Reducing Workload Through AI

Participants highlighted the health care sector's challenge of increasing workloads, worsened by a decreasing number of podiatrists and a growing number of patients with diabetes. There was widespread agreement on AI's ability to alleviate this load. By automating processes such as triage, AI can significantly reduce the workload, freeing podiatrists to focus on the more crucial parts of patient care:

XSL•FO
RenderX

> *As the pressure continues to increase, I see AI as a great tool to indeed perform a kind of triage to ensure that the workload doesn't become overwhelming.* [Participant 3, female, age group 41-50 years]
>
> *But yes, to be completely honest, looking towards the future, we definitely need to reduce the workload; otherwise, we'll end up with even fewer people having to help more individuals.* [Participant 4, female, age group 31-40 years]

Theme 3: Factors Influencing Trust

Overview

Finally, we delved into the pivotal elements that shape trust in AI-provided advice. We also probed when participants might be inclined to defer to AI's judgment over their own. This investigation unveiled 3 subthemes, each shedding light on the interaction between humans and AI systems.

Theme 3.1: Transparency and Explainability of AI

All participants agreed that clear explanations and transparency are essential, considering them as fundamental to trusting AI. They wished to comprehend the methodology AI uses to arrive at its recommendations. They proposed several methods to enhance transparency, such as providing concise explanations of the criteria AI uses for its evaluations, statistical performance data, or visual aids such as photos with overlaying layers or color coding:

> *I believe factors like the colour of the callus, the size of the area, its location, and history also play a role. Has there been a wound in that spot before? Yes, things like that.* [Participant 8, male, age group 41-50 years]
>
> *For example, I want to see a number of photos of the foot along with some explanation about them. I want to understand how the evaluation system is designed and the data it uses.* [Participant 2, female, age group 51-60 years]
>
> *It increases my confidence in knowing the sources from which AI retrieves its information or the ones I've provided to it.* [Participant 1, male, age group 41-50 years]

Theme 3.2: Ensuring Reliability and Adequate Training

Participants were of the opinion that AI should be advanced enough from the beginning, emphasizing that a more extensive database of photos would increase their trust in the system. They would like AI to provide consistent advice, ideally on par with a fellow podiatrist. Training was highlighted as a crucial element for enhancing AI's performance. In addition, understanding who the designers are and the data used for training is considered necessary. If participants know the designers are experts in their field, they feel more confident in the AI tool's reliability:

> *Well, if you've only input three things into it, I won't trust it. But if you've input 300,000 things, then at some point, you really know better.* [Participant 2, male, age group 41-50 years]
>
> *Well, I'm not quite sure how that works, but if that's the case, then the people involved in setting it up need to have the right background knowledge, the right experience with the subject; they need to be specialists, so to speak.* [Participant 2, female, age group 51-60 years]

Theme 3.3: The Value of Human Interaction

Participants emphasized that future AI applications must not compromise their interaction with patients, highlighting each patient's uniqueness and background. They cautioned that AI may not always account for these personal nuances, underlining the importance of maintaining the human touch in health care:

> *I still believe that personal human contact will never disappear.* [Participant 3, female, age group 41-50 years]
>
> *All those kinds of things. Yes, they're slightly different for everyone.* [Participant 1, male, age group 41-50 years]
>
> *But you still maintain human contact between the client and yourself, allowing them to easily ask additional questions, for instance, to you.* [Participant 5, female, age group 61-70 years]

Moving From Phase 1 to Phase 2

The findings from phase 1 revealed that AI can significantly improve various practical aspects of podiatry, particularly by alleviating workloads and serving as a learning tool. A clear preference was observed for using AI in supportive tasks rather than diagnostic roles. This reflects a cautious attitude of podiatrists toward AI-generated advice and raised the question: Will AI support be more readily accepted in supportive than in diagnostic tasks, and what factors influence this difference in acceptance?

Therefore, phase 2 of our study sought to explore the specific applications of AI in supportive versus diagnostic roles within podiatry in detail. Given the ongoing reluctance toward its role in diagnostics, this study aimed to understand the elements that can foster trust in AI for supportive tasks. By introducing a new group of podiatrists, phase 2 of our study aimed to gather fresh insights and assess whether the findings observed in phase 1 align with new professional perspectives.

Phase 2: Focus Group

Participants

Table 2 outlines an overview of the demographics of the focus group participants. The group consisted of 5 participants, 4 of whom were new podiatrists who engaged in the discussion. This group consisted of specialists in foot care for patients with diabetes, who primarily provide daily consultations to these patients.

XSL•FO
RenderX

Table 2. Participants' characteristics from focus groups in phase 2 (n=5).

Characteristics	Participants, n (%)
Sex	
Female	4 (80)
Male	1 (20)
Age group (y)	
41-50	2 (40)
51-60	2 (40)
61-70	1 (20)
Education level	
Bachelor's	2 (40)
Master's	3 (60)
Specialized in foot care for patients with diabetes	
Yes	5 (100)
No	0 (0)
Experience (y)	
20-30	4 (80)
31-40	1 (20)
Experience with the app	
Yes	2 (40)
No	3 (60)

In phase 1 of our study, we opted for a flexible approach, allowing themes to emerge directly from the transcribed data. This exploratory phase enabled us to capture many insights directly from participants' experiences and perspectives. Moving into phase 2, we shifted toward a more structured approach, using themes, which were relevant for phase 2 and predefined in phase 1. This transition allowed us to refine our analysis, focusing on the detailed examination of specific, predetermined themes to gain deeper insights and understanding of the topics at hand.

For a clear overview, we first present the key findings from the participants about various transparency levels for the 2 mock-ups in Table 3. Subsequently, in Table 4, we display the other themes carried forward from phase 1 for further analysis in phase 2, ensuring a comprehensive and structured exploration of the data.

XSL•FO
RenderX

Table 3. Thematic framework analysis for key findings and preferences of transparency levels in AI[a] applications.

Theme: transparency and explainability of AI	Mock-up 1: AI support (triage and scheduling)	Mock-up 2: AI diagnosis (photo analysis)
Low (variant A)	Podiatrists perceive this variant as a "black box," with unclear determination of urgency and relevance of the presented information	Feedback indicates general dissatisfaction and a lack of clarity on how AI reaches its conclusions
First preference	—[b]	P4 and P5 (n=2)
Second preference	—	—
Third preference	P1-P5 (n=5)	P1-P3 (n=3)
Medium (variant B)	Podiatrists express concerns over the reliability of patient feedback as input for AI, pointing out a lack of crucial information such as wound location	While the text is deemed acceptable, this variant raises questions about the necessity of repeating information
First preference	—	—
Second preference	P1-P5 (n=5)	P1-P5 (n=5)
Third preference	—	—
High (variant C)	Preference is given to detailed information, including specific medical details and clear patient identification	Podiatrists appreciate the clarity and added layer of understanding this variant provides but question the necessity of certain statistics, such as a reliability percentage
First preference	P1-P5 (n=5)	P1-P3 (n=3)
Second preference	—	—
Third preference	—	P4 and P5 (n=2)

[a]AI: artificial intelligence.

[b]Not applicable.

Table 4. Thematic framework analysis for AI[a] applications and predefined themes.

Themes	Participant 1 (female; age group 51-60 y)	Participant 2 (female; age group 41-50 y)	Participant 3 (male; age group 41-50 y)	Participant 4 (female; age group 51-60 y)	Participant 5 (female; age group 61-70 y)
Distinction between supportive tasks and diagnosis	Prefers AI for triage due to speed and accuracy. Skeptical about diagnostic capability without physical examination	—[b]	Values AI's ability to prioritize photos based on urgency, enhancing patient care efficiency	Believes AI is incapable of handling complex diagnostic tasks, such as differentiating between types of wounds	Asserts that computers cannot replace human nuanced observation in diagnostics, emphasizing AI's use in triage
Ensuring reliability and adequate training	Values the volume of feedback, similar to how reviews inform vacation choices	Trust is reinforced by a large volume of photos, indicating data reliability	Importance of data diversity, including training AI on poor-quality photos	Questions the repetitive mention of the photo database size suggest it is only necessary in training	Trust depends on knowing the AI's advice is based on an extensive and diverse photo database
Long-term trust development	—	Trust in the algorithm grows over time with proven accuracy	Initial skepticism evolves into trust after multiple positive experiences	—	Anticipates a future shift in acceptance of AI's advice, especially without a photo, within a decade
The value of human interaction	—	—	—	Asserts that physical tools and examination are indispensable for accurate diagnostics	Stresses the irreplaceable role of human involvement in making accurate diagnoses

[a]AI: artificial intelligence.

[b]Not applicable.

For the frameworks (Tables 3 and 4), instead of using quotes from focus group participants, we chose to provide summaries of the key findings, following the common practice in thematic framework analysis. By creating summaries, we were able to handle the complex discussion, which involved a record with 7 speakers, more easily.

XSL•FO
RenderX

Interpretations of Thematic Framework Analysis

On the basis of the thematic framework analysis of podiatrists' preferences for AI integration in clinical settings, a clear pattern emerges regarding the desired application and form of transparency in AI systems for triage. Podiatrists prefer using AI in triage, emphasizing the importance of transparency that goes beyond just being open. They are looking for a kind of transparency that involves clinically relevant and detailed information—such as patient history, specific conditions such as the presence of vascular diseases, and exact wound locations—that significantly augment the decision-making process:

> *The added value for me is that the ranking is done by the AI, so photos are prioritised based on urgency.* [Participant 3, male, age group 41-50 years]

> *My preference is for triage; an AI can perform it much faster than a human. Well, I believe that AI is capable of making a risk assessment.* [Participant 1, female, age group 41-50 years]

> *Key abnormalities must be quickly recognised and addressed, achievable through triage.* [Participant 5, female, age group 61-70 years]

In the domain of triage, skepticism toward patient-reported data as the sole basis for AI-generated advice is evident (eg, medium transparency mock-up 1). The concern centers on the reliability of such data, highlighting a preference for AI systems that incorporate a comprehensive training dataset to inform their assessments. This reflects a broader apprehension regarding the accuracy of AI recommendations based on potentially incomplete or inaccurate patient self-assessments:

> *I'm not entirely convinced by the patients' responses. If they say they have a wound on their feet, then yes, I might believe it, but if they don't have a wound, I'm sceptical.* [Participant 1, female, age group 41-50 years]

> *Patients often do not have a clear understanding of complications.* [Participant 3, male, age group 41-50 years]

Podiatrists recognize the potential benefits but are cautious regarding the use of AI for diagnostic applications, particularly those involving the analysis of photographic evidence of foot conditions. This caution is based on the understanding that certain conditions cannot be fully diagnosed through images alone, emphasizing the need for AI systems to supplement rather than replace traditional diagnostic methods:

> *Computers can't replace humans in diagnostics, especially not for tasks requiring nuanced observation, like identifying underlying issues beneath a callus that AI might miss.* [Participant 5, female, age group 61-70 years]

> *AI is incapable of making diagnoses. AI cannot handle complex conditions like distinguishing between warm and cold wounds.* [Participant 4, female, age group 51-60 years]

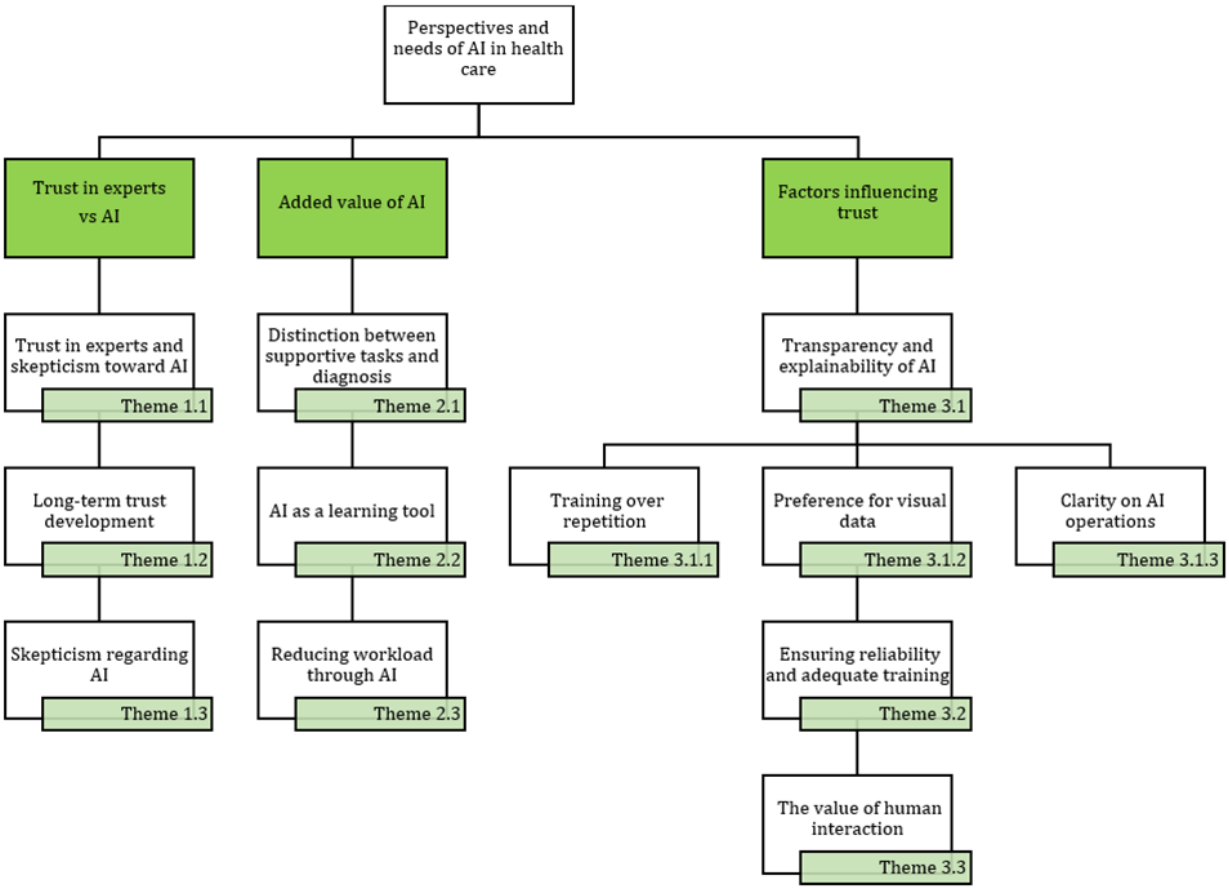
> *Even a human can't make a diagnosis just from an image. The foot needs to be examined in person and potentially opened up for an accurate assessment.* [Participant 1, female, age group 41-50 years]

The desired level of transparency in diagnostic AI varies among podiatrists. While some value additional explanatory features, such as annotated images or textual diagnostics, others caution against the potential for such features to overly focus attention on a specific area, possibly leading to the overlooking of important symptoms in other areas. This division highlights the need for a careful balance in using AI; while it is beneficial to receive detailed, actionable insights, it is crucial to ensure that these insights do not overshadow the importance of using one's own professional knowledge and experience in decision-making:

> *Works well for me; the layer aids in understanding the basis of the text.* [Participant 3, male, age group 41-50 years]

> *Also, here, the text is okay. I also like the layer, so now I know what the text is referring to.* [Participant 1, female, age group 41-50 years]

> *The explanatory text doesn't interest me much; I'll take it on faith what it's based on.* [Participant 4, female, age group 51-60 years]



> *And that layer, I can see that for myself, too. Adding a layer can also be risky; I see even more things, and now AI dictates where I should look. A less experienced podiatrist might then focus solely on that.* [Participant 5, female, age group 61-70 years]

In addition to emphasizing transparency in integrating AI into clinical podiatry practice, our analysis has other predefined themes within the framework (Table 4). These themes enrich our understanding of how AI can be effectively applied in triage and diagnostics, emphasizing the need for clear, actionable insights and the importance of trust and data reliability as foundational elements. Reflecting on the preferences expressed by podiatrists, it becomes apparent that alongside transparency and explainability, considerations around data reliability, human interaction, trust development, and trust establishment align with sentiments from the first phase of our study.

However, we have defined 3 additional themes that resonated strongly with the initial input for transparency and explainability. Figure 6 presents a comprehensive overview of all the themes, including the 3 subthemes (ie, 3.1.1: Training Versus Repetition; 3.1.2: Preference for Visual Data; and 3.1.3: Clarity on AI Operations) and their implications for integrating AI into podiatry. The following sections detail these additional subthemes further.

XSL•FO
RenderX

Figure 6. Generated themes and subthemes from phases 1 and 2: perspectives of experienced podiatrists on the FootCheck app and decision-making process. AI: artificial intelligence.

Subtheme 3.1.1: Training Versus Repetition

While participants in phase 1 primarily highlighted concerns among podiatrists regarding data reliability, phase 2 revealed a nuanced understanding of how and when this information should be introduced. This is particularly relevant during the initial training sessions where podiatrists are first taught how to use the AI system. Feedback on mock-up 2 indicated that emphasizing data reliability in every AI recommendation is not always seen as necessary. Some participants supported this viewpoint, while others preferred having this information included. In addition, there was consensus that explanations should offer insights beyond basic knowledge, aiming to augment understanding rather than merely repeat well-known information:

> *In the introduction (training), mention somewhere that the data is based on 5000 photos, but that doesn't need to be in every piece of advice.* [Participant 4, female, age group 51-60 years]
>
> *I expect an AI to be backed by a vast photo database, so it's unnecessary to reiterate that point for me.* [Participant 5, female, age group 61-70 years]
>
> *The text is helpful; it lets me know what the AI is based on.* [Participant 3, male, age group 41-50 years]

Subtheme 3.1.2: Preference for Visual Data

There is a significant inclination toward incorporating visual data alongside algorithmic risk assessments. Participants consider combining photos with textual advice crucial, enhancing their ability to make knowledgeable decisions. The need for visual confirmation to solidify trust in AI-generated advice is highlighted, with participants expressing reservations about relying entirely on text-based recommendations. Although color-coded elements are appreciated for their clarity, the facility to view photos directly via pop-ups is deemed essential for building confidence in the advice provided:

> *The colour coding in mock-up 1 is helpful, but I'd prefer to see the photos appear as pop-ups.* [Participant 4, male, age group 41-50 years]
>
> *Just text, without a photo, doesn't inspire my trust.* [Participant 3, female, age group 51-60 years]
>
> *It seems like a small ask to quickly review the photo for a better trust in the advice.* [Participant 4, female, age group 51-60 years]

Subtheme 3.1.3: Clarity on AI Operations

Podiatrists highlight the necessity for transparency regarding the process behind AI-generated advice, which is essential for building trust and enabling users to understand when and how to rely on these recommendations. Opinions vary on the best way to present this information, with some finding objective data in photos and layered visuals helpful for understanding the advice's basis, as seen in mock-up 2. Others question the interpretability of numerical data, such as "73%," without seeing the patient in person:

XSL•FO
RenderX

> *Now, with a photo and layer, the information is more objective; you know what the text is about.* [Participant 3, male, age group 41-50 years]
>
> *I appreciate it, as then I know what it's based on, mock-up 2.* [Participant 1, female, age group 51-60 years]

Discussion

AI in Supportive Roles Versus Diagnostic Tasks

Our study aimed to discern the multifaceted roles AI could assume in health care, specifically focusing on how AI can be effectively integrated into practice in a way that ensures health care professionals' acceptance and trust in its advice. The findings from our studies suggest a preference for deploying AI in supportive roles. For instance, AI's use in triaging processes is evident; by evaluating submitted photos for urgency, AI can advise health care providers in prioritizing patient consultations. This enables a more efficient allocation of resources, ensuring that patients requiring urgent care receive it promptly, while less-critical cases are appropriately prioritized. Such applications align with and enrich suggestions from the literature, including studies by Verma et al [10] and Longoni et al [5], suggesting the supportive use of AI to foster trust within health care settings. However, a contrasting perspective is presented in another experiment by Longoni et al [5], where preference leans toward human expertise over automated systems for triage tasks. This discrepancy from our findings may stem from differing viewpoints, with the study results of Longoni et al [5] being based on patient perspectives, whereas our study was performed among health care providers.

Another critical insight from our study highlights health care professionals' hesitancy to embrace AI for diagnostic purposes, a sentiment that aligns with previous research findings [5,7,9,10,18]. While there is acknowledgment of AI's proficiency in critical functions, such as making diagnoses, with results that match or even surpass human expertise, there remains skepticism among participants about AI's current proficiency in performing these tasks accurately. The observed reluctance may stem from unfamiliarity with the full scope of AI's capabilities, as evidenced by the fact that particularly participants without prior AI experience expressed reservations. Moreover, the conversations uncovered that identifying conditions such as diabetic foot complications poses distinct obstacles for AI. The participants pointed out that superficial evaluations, such as analyzing diabetic wounds via photographs, could be inadequate without the physical removal of calluses to reveal the actual problem, an action AI is incapable of without a physical examination. This underlines the importance of direct human interaction in specific diagnostic processes, highlighting limitations in the potential application of AI.

Algorithm Aversion Among Podiatrists

The observed phenomenon of algorithm aversion among podiatrists, particularly their preference for human expertise over AI-generated recommendations, reflects a trend noted across various fields where AI competes with human judgment [26-29]. For example, Önkal et al [30] demonstrated a similar inclination among forecasters to favor expert opinions in forecasting decisions. A notable factor contributing to this aversion is the concern over mistakes made by AI systems [26], with our podiatrists voicing worries about the grave repercussions of such errors, including the risk of limb amputation. Although the significance of decisions ranges from health care to forecasting tasks in logistics, the underlying dread of AI-induced errors remains pervasive.

However, in our studies, this aversion was primarily directed at diagnostic tasks rather than supportive functions. Participants expressed confidence in the expertise and experience of their colleagues but also showed openness to considering AI-generated advice for tasks such as triage. This nuanced view suggests a complex relationship between podiatrists and AI, where trust may be contingent on the specific task at hand and the perceived reliability of AI in enhancing rather than replacing human judgment.

Transparency and Explainability

The discussions surrounding transparency and explainability in our studies mirrored the diversity of perspectives found in the broader literature on these subjects [12,14,19]. The need for explanation and transparency depends significantly on podiatrists' individual preferences. Our study provides 3 key insights regarding the implementation of explainability and transparency in AI systems.

First, precise and valuable explanations that avoid redundancy are essential for enhancing user understanding and trust in AI. Second, visual aids alongside textual advice can boost confidence in AI recommendations more than text alone, by making the motivation behind complex decisions more accessible. Finally, it is important to remind users to balance AI advice with their professional judgment, highlighting the crucial role of human oversight in AI decision-making.

However, these discussions were particularly animated regarding the scenario involving AI-generated diagnoses, where participants displayed heightened criticality toward the information received from AI. This suggests that individuals are particularly cautious about relying on AI for diagnostic tasks, scrutinizing the transparency and explainability of such systems with greater intensity. Interestingly, these issues were less extensively debated in contexts involving AI for supportive tasks. This observation highlights an area for future research.

Development of Trust Over Time

Most participants indicated a higher level of trust in their colleagues than in AI systems, suggesting that trust in AI might evolve positively with increased exposure and evidence of AI's efficacy. However, this remains speculative, as our participants have not extensively experimented with AI in their professional practice. The notion that repeated interactions with AI could enhance trust aligns with existing literature [31,32]. This area, highlighting the dynamic interplay between growing familiarity with AI and the shifting landscape of trust and reliance, remains underexplored in our studies and represents a fruitful avenue for further research.

XSL•FO
RenderX

Strengths and Limitations

Our research is strengthened by several methodological approaches that enhance the credibility of our findings. The employment of 2 independent researchers for parallel data coding in both studies significantly contributed to the reliability of our results, as evidenced by the substantial agreement in their coding outcomes [33].

The relatively small sample sizes of 9 podiatrists in the first phase and 5 in the second phase may seem to be a limitation for generating general conclusions. However, qualitative research often reaches a point of data saturation, where small samples are already sufficient to uncover dependable themes. In our study, we observed that no new codes or themes emerged after 7 interviews in the first phase, indicating that data saturation had been reached. This aligns with the findings of Guest et al [34], who noted that most codes are identified within the first 6 interviews. Guest et al [35] also supported this by providing a systematic method for assessing saturation, further validating our sample size.

The significant expertise of the podiatrists involved, that is, all specialists in the area considered, adds depth to our insights and strengthens the credibility of our findings. In addition, the second phase, with mostly new participants, confirmed the results of phase 1. By focusing on how AI might be more accepted in supportive tasks compared with diagnostic tasks, we were able to further validate the earlier findings and ensure that no new themes emerged, indicating that saturation had been reached.

Conclusions

In conclusion, the findings reveal podiatrists' complex attitudes toward AI in health care, demonstrating openness to AI assistance for supportive tasks while being cautionary regarding its application for diagnostics. This underscores the necessity for developers and policy makers to prioritize trust-building strategies, starting with opportunities that allow podiatrists to experience firsthand how AI can support their role. Such initial experiences could clarify AI's benefits and capabilities to users, reduce perceived threats, and facilitate a smoother transition toward acceptance. With a foundation of trust established through the application of AI for supportive tasks, podiatrists may become more receptive to exploring AI's potential for diagnostic tasks. Gradually expanding AI's role from foundational tasks, including decision support, to areas requiring deeper trust, such as diagnostics, could enhance acceptance and integration of AI technologies in podiatric practice.

Acknowledgments

The authors extend their heartfelt gratitude to all individuals who generously shared their insights and experiences, making this research possible. Special thanks are extended to Ruben Gloudemans for his invaluable assistance with conducting interviews, engaging in thorough analyses and participating in wide-ranging discussions that significantly enriched this work. The authors appreciate RondOm Podiatrists for providing access to the FootCheck app, an essential resource for our study. This work is part of the project Vertrouwen in Algoritmes (project number 023.017.109), under the auspices of the Promotiebeurs voor Leraren program, generously funded by the Dutch Research Council (NWO). Additionally, this study was part of the Technology Support for Diabetes project, which is subsidized by SIA RAAK EXZ.EXZ.01.004. The research efforts of the authors were greatly supported by these contributions, for which they are profoundly grateful.

Data Availability

The corresponding author will make the datasets supporting these studies available upon reasonable request.

Abstract

Background: The prevalence of anxiety and depression is increasing globally, outpacing the capacity of traditional mental health services. Digital mental health interventions (DMHIs) provide a cost-effective alternative, but user engagement remains limited. Integrating artificial intelligence (AI)–powered conversational agents may enhance engagement and improve the user experience; however, with AI technology rapidly evolving, the acceptability of these solutions remains uncertain.

Objective: This study aims to examine the acceptability, engagement, and usability of a conversational agent–led DMHI with human support for generalized anxiety by exploring patient expectations and experiences through a mixed methods approach.

Methods: Participants (N=299) were offered a DMHI for up to 9 weeks and completed postintervention self-report measures of engagement (User Engagement Scale [UES]; n=190), usability (System Usability Scale [SUS]; n=203), and acceptability (Service User Technology Acceptability Questionnaire [SUTAQ]; n=203). To explore expectations and experiences with the program, a subsample of participants completed qualitative semistructured interviews before the intervention (n=21) and after the intervention (n=16), which were analyzed using inductive thematic analysis.

Results: Participants rated the digital program as engaging (mean UES total score 3.7; 95% CI 3.5-3.8), rewarding (mean UES rewarding subscale 4.1; 95% CI 4.0-4.2), and easy to use (mean SUS total score 78.6; 95% CI 76.5-80.7). They were satisfied with the program and reported that it increased access to and enhanced their care (mean SUTAQ subscales 4.3-4.9; 95% CI 4.1-5.1). Insights from pre- and postintervention qualitative interviews highlighted 5 themes representing user needs important for acceptability: (1) accessible mental health support, in terms of availability and emotional approachability (Accessible Care); (2) practical and effective solutions leading to tangible improvements (Effective Solutions); (3) a personalized and tailored experience (Personal Experience); (4) guidance within a clear structure, while retaining control (Guided but in Control); and (5) a sense of support facilitated by human involvement (Feeling Supported). Overall, the DMHI met participant expectations, except for theme 3, as participants desired greater personalization and reported frustration when the conversational agent misunderstood them.

Conclusions: Incorporating factors critical to patient acceptability into DMHIs is essential to maximize their global impact on mental health care. This study provides both quantitative and qualitative evidence for the acceptability of a structured, conversational agent–driven digital program with human support for adults experiencing generalized anxiety. The findings highlight the importance of design, clinical, and implementation factors in enhancing engagement and reveal opportunities for ongoing optimization and innovation. Scalable models with stratified human support and the safe integration of generative AI have the potential to transform patient experience and increase the real-world impact of conversational agent–led DMHIs.

Introduction

Demand for mental health care is increasing, with 1 in 8 individuals globally living with a mental health condition [1]. Despite this growing need, there are only 4 psychiatrists per 100,000 people worldwide [2], leading to long waiting lists and a lack of care [3-5]. The traditional 1:1 mental health care model is proving insufficient to meet the rising demand.

Digital mental health interventions (DMHIs) provide a cost-effective way to increase access to care worldwide [6], but face challenges with user engagement and adherence [7-9]. Engagement is often operationalized through objective behavioral metrics (frequency and duration of use), but users' cognitive and emotional investment (subjective engagement), such as focused attention and psychological investment, is equally critical to understanding how users meaningfully engage with DMHIs to drive clinical impact [10,11]. Key factors impacting engagement include available guidance, perceived fit, and personalization [12]. Artificial intelligence (AI)–powered conversational agents, typically using tree-based dialogue systems, have shown potential to enhance DMHI engagement by offering more interactive and personalized experiences compared with self-guided activities [13]. Meta-analytic evidence suggests that these agents reduce attrition rates [14] and show promising efficacy [15-18]. However, the agent's misunderstanding of user input can be frustrating [19]. Advances in generative AI, such as OpenAI's ChatGPT (released November 2022), are rapidly evolving and enable more fluid and naturalistic interactions that have the potential to transform DMHIs. However, currently, most DMHIs rely on tree-based dialogue systems with templated responses to ensure a patient's experience is safe, evidence-based, and deterministic. It is unclear how user familiarity with generative AI applications will impact perceived effectiveness and engagement with conversational-agent DMHIs reliant on tree-based dialogue systems.

Acceptability is central to developing and evaluating DMHIs as it is linked to engagement, effectiveness, and adoption [20]. Acceptability is a multidimensional construct that reflects how people think and feel about an intervention and whether they view it as appropriate, either before, during, or after using it [21]. Qualitative studies suggest that conversational agent–led DMHIs are perceived positively by users [22,23], in part by providing easily accessible and judgment-free environments [24]. However, uptake of such interventions is impacted by mixed expectations on their effectiveness [25,26]. Presence or absence of empathy, personalization, and the ability of the agent to understand user messages also impact the user experience [19,27]. Our current understanding of conversational agent–led DMHI acceptability relies on limited qualitative data (eg, app store reviews and answers to in-app free-text questions about positive and negative experiences) [15,28-31]. A deeper understanding of the many factors contributing to user perception and experience with conversational agent–led DMHIs is important to maximize their impact.

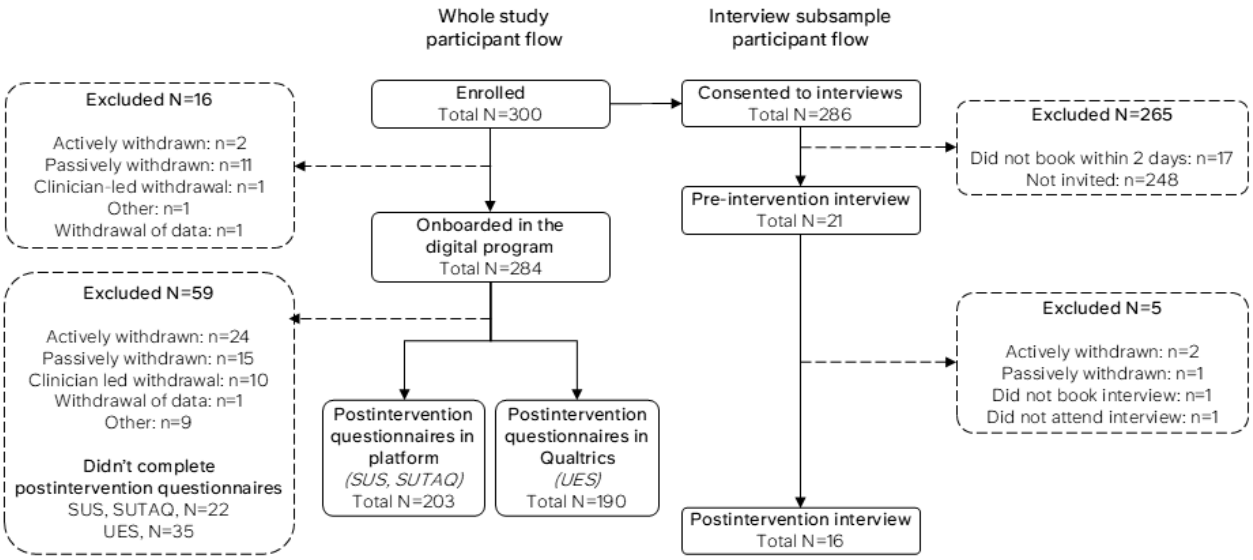
Using mixed methods is recommended when iteratively developing and evaluating complex interventions such as DMHIs [32,33]. Validated questionnaires offer standardized quantitative benchmarks for comparison with other interventions and evaluation of iterative improvements [34]. By contrast, qualitative methods, such as semistructured interviews, enable richer insights into context-specific user needs and intervention-specific experiences, and allow for the discovery of emergent topics [35]. Through open-ended questions and in-depth explorations of user perspectives and experiences, multidimensional concepts such as acceptability and subjective engagement can be assessed [32,35]. Combining these methods provides complementary insights, where quantitative data describe behavior across the sample, and qualitative findings clarify the underlying reasons and nuances of user experiences.

This study reports additional patient-reported end points from a propensity-matched study evaluating the effectiveness, acceptability, engagement, and safety of a digital program for adults with mild to severe symptoms of generalized anxiety [18]. Participants engaged with the program for up to 9 weeks via a smartphone app. The intervention consisted of a structured program using traditional and third-wave cognitive behavioral therapy (CBT) approaches delivered through multimedia content and text-based interactions with an AI-powered conversational agent. The conversational agent followed a tree-based dialogue system, using natural language processing to deliver appropriate clinician prewritten responses. The program was combined with human support, aimed to enhance user experience and adherence with the program, addressing documented barriers to engagement [12]. The digital program showed a mean reduction in anxiety symptoms comparable to traditional human-delivered therapy [18]. This substudy aimed to understand the acceptability, engagement, and usability of the digital program by combining quantitative and qualitative methods to explore patient expectations and experiences with the intervention and examine the extent to which the program met their needs. Self-report measures for subjective engagement, usability, and acceptability were collected postintervention to quantify the user experience, and qualitative semistructured interviews were conducted with a subsample of participants both before and after the intervention to provide deeper insights into user needs and experiences.

Methods

Study Design

This mixed methods substudy explored the perspectives and experiences of individuals with mild, moderate, and severe symptoms of generalized anxiety before and after engaging with a DMHI. It was conducted within a wider pragmatic, single-intervention arm study with a sample of 299 participants from the United Kingdom [18].



XSL•FO
RenderX

Potentially eligible individuals completed a clinical assessment with a qualified clinician to determine eligibility. At the point of consent, participants were asked if they wanted to participate in qualitative interviews. A subsample of participants (n=21) attended a semistructured interview preintervention. All participants were asked to download the software on their smartphone and engage with the 6-module program in their own time, over a 9-week period. Participants from the interviewed subsample were invited to attend a second semistructured interview after using the program. All outcomes collected at different time points are reported in Palmer et al [18]. For this study, engagement, usability, and acceptability measures, collected with validated questionnaires postintervention, were analyzed, as well as qualitative analysis of the pre- and postintervention semistructured interviews.

Ethics Considerations

The study was preregistered (ISRCTN ID 52546704) and obtained ethical approval before recruitment (IRAS ID: 327897, National Health Service [NHS] Research Ethics Committee: West of Scotland REC 4). The participant CONSORT (Consolidated Standards of Reporting Trials) flowchart for the whole sample and the interviewed subsample is summarized in Figure 1. For more details on participant flow before enrollment, please refer to Palmer et al [18]. In line with the Declaration of Helsinki, informed consent was obtained from all participants before enrollment, including optional consent for participation in semistructured interviews. Participants were debriefed at the conclusion of the study.

Figure 1. Participant flow for the study sample and interviewed subsample. Recruitment sources and preenrollment flow are described in Palmer et al [18]. Participants were withdrawn actively (requested withdrawal), passively (dropped out or disengaged), clinician-led (withdrawn on clinician recommendation), or for other reasons (eg, technical issues). Interview participation was offered on a first-come, first-served basis, with a 2-day response window, and invitations ceased once a sufficient number of preintervention interviews had been completed. Postintervention questionnaires were administered through ieso's validated clinical delivery platform (System Usability Scale [SUS] and Service User Technology Acceptability Questionnaire [SUTAQ]) and through Qualtrics (User Engagement Scale [UES]).

Description of Digital Intervention

The intervention consisted of a 6-module digital program delivered via a smartphone app (ieso Digital Program; software name IDH-DP2-001), developed by ieso Digital Health [36], a mental health technology company and provider within NHS Talking Therapies delivering 1:1 human-delivered CBT via a typed modality to treat patients with common mental health disorders. The ieso Digital Program used a conversational agent to guide users through activities, with clinical oversight and user support provided by nonclinical research coordinators. The program was designed for people primarily presenting with symptoms of generalized anxiety and was based on principles from traditional CBT and third-wave approaches such as acceptance and commitment therapy. The 6 modules consisted of an introduction module, 3 core modules, and 2 consolidation modules. All modules began with a symptom "check-in" consisting of the 7-item Generalized Anxiety Disorder (GAD-7) scale and 9-item Patient Health Questionnaire (PHQ-9) scale. The minimum meaningful program dose was defined a priori by accredited CBT therapists as completion of modules 1-3 and the module 4 check-in. There were 16 sessions total, released on a timed schedule, subject to completing the prior session, allowing space for practice and reflection between sessions. Each session included videos, educational content, conversations, and worksheets written by accredited clinicians. The clinical team had an average of 14 years' experience delivering therapy to patients with complex needs and diverse backgrounds in the United Kingdom. To ensure safety and clinical quality of the messages delivered to the user, the conversational agent used in this version of the program followed a tree-based dialogue system, using natural language processing to understand user input and deliver appropriate prewritten responses. The program complied with ISO 13485

XSL•FO
RenderX

[37] and was registered as a UKCA (UK Conformity Assessed) marked Class 1 medical device. For additional details, including screenshots of the interface and schematics of the program, see Palmer et al [18].

Participants

Adults with mild to severe anxiety symptoms were recruited between October 10, 2023, and February 2, 2024, through 3 streams: (1) referrals to ieso's typed therapy service (self-referral or via their NHS Provider) [38]; (2) responses to online advertisements; and (3) responses to email invitations through the NIHR BioResource [39].

Participants had to meet the following eligibility criteria: (1) be over the age of 18 years at point of recruitment; (2) GAD-7 total score >7; (3) PHQ-9 total score <16; (4) have a primary presenting problem of generalized anxiety disorder, as established through a clinician assessment (based on the International Classification of Diseases, 10th Revision [ICD-10] code in line with the NHS Talking Therapies manual [40]); (5) have access to a smartphone and internet connection; and (6) be registered with a general practitioner in the United Kingdom. To be suitable for the CBT protocol used in the intervention, individuals were excluded if presenting with (1) complex comorbid presentations (diagnosis of multiple disorders, psychotic or personality disorder, autism spectrum condition, or intellectual disability); (2) untreated mental health conditions (including substance misuse), except generalized anxiety disorder or major depressive disorder; or diagnoses of (3) posttraumatic stress disorder, obsessive-compulsive disorder or panic disorder. Additionally, individuals were excluded if they (1) were currently receiving psychological therapy, (2) had changes in psychiatric medication in the past 1 month; or (3) displayed a significant risk of harm to self, to others, or from others (established with the clinical assessment). Any individual who had previously participated in user research for the digital program was also excluded.

Considering the study's aims and design, participant specificity, and experienced user researchers collecting data, a moderate sample size between 15 and 30 participants was estimated to provide sufficient informational power [41]. We aimed to enroll up to 30 participants to account for an estimated 50% attrition rate with the goal of having at least 15 postintervention interviews. Those who consented to interviews self-selected into the interviewed subsample by signing up for a preintervention interview slot on a first-come, first-served basis. If they did not sign up within 2 days of receiving the invitation, they were sent the information to continue with the app download to avoid delays. Interview invitations were sent out from December 2023, 2 months into the enrollment period. Interview invitations were stopped once a sufficient sample had attended a preintervention interview.

Vouchers up to a total of £60 (US $81.1) were provided for participating in the study based on study assessments and completion of modules. An additional £15 (US $20.2) voucher per interview was provided to those who attended an interview.

Patient and Public Involvement

Experts by lived experience were involved as members of a patient and public involvement (PPI) panel. PPI members took part in study conceptualization and supported recruitment through co-designing marketing campaigns and participant-facing documents. PPI members were also involved at the end of the thematic analysis process through a workshop aimed to discuss the coherence of thematic groupings and theme names, and limitations and implications of these results. Before the workshop, PPI members were introduced to thematic analysis and qualitative methods. More details are provided in Multimedia Appendix 1.

Data Collection and Analysis

Self-Report Measures of User Experience

Overview

Validated self-report measures of user experience were collected at postintervention between January and April 2024 (after completion or after 9 weeks), via either ieso's validated clinical delivery platform (System Usability Scale [SUS] and Service User Technology Acceptability Questionnaire [SUTAQ]) or Qualtrics (User Engagement Scale [UES]). Demographic data were collected at enrollment and are summarized in Table 1.

Table 1. Sample characteristics of all study samples.

Demographic and category	Questionnaire sample (N=203)	Interview subsample (n=21)	
		Preintervention sample (n=21)	Postintervention sample (n=16)
Baseline GAD-7 score, mean (SD)[a]	12.4 (3.4)	11.8 (3.2)	11.6 (3.6)
Baseline PHQ-9 score, mean (SD)[b]	7.9 (3.8)	7.7 (2.4)	7.7 (2.5)
Age, mean (SD)	41.0 (12.0)	46.0 (13.4)	44.0 (13.3)
Gender, n (%)			
Female	163 (80.3)	17 (81.0)	13 (81.3)
Male	34 (16.7)	3 (14.3)	2 (12.5)
Other	2 (1.0)	1 (4.8)	1 (6.3)
Not known	4 (2.0)	0 (0)	0 (0)
Ethnicity, n (%)			
White	185 (91.1)	19 (90.5)	15 (93.8)
Mixed	3 (1.5)	0 (0)	0 (0)
Asian	9 (4.4)	2 (9.5)	1 (6.3)
Black/African/Caribbean/Black British	1 (0.5)	0 (0)	0 (0)
Other	1 (0.5)	0 (0)	0 (0)
Prefer not to say	4 (2.0)	0 (0)	0 (0)
Long-term condition, n (%)			
Yes	83 (40.9)	9 (42.9)	6 (37.5)
No	112 (55.2)	10 (47.6)	9 (56.3)
Not known	8 (3.9)	2 (9.5)	1 (6.3)

[a]7-item Generalized Anxiety Disorder categories: mild (scores 5-9), moderate (scores 10-14), and severe (scores ≥15).

[b]9-item Patient Health Questionnaire categories: mild (scores 5-9), moderate (scores 10-14), moderately severe (scores 15-19), and severe (scores ≥20).

Engagement

Engagement was evaluated with the UES short form [42], a validated scale to measure user engagement with digital systems. This scale consisted of 12 items across 4 subscales: (1) *Focused Attention* (ie, how absorbed the individual was in the intervention); (2) *Perceived Usability* (ie, whether the intervention was taxing or frustrating to use); (3) *Aesthetic Appeal* (ie, how visually appealing the intervention was; and (4) *Rewarding* (ie, whether using the intervention was worthwhile). The 12 items were rated on a 5-point scale (1=strongly disagree to 5=strongly agree). A high score can be interpreted as positive perceived engagement. Items were presented in a random order for each participant. Three items on the *Perceived Usability* subscale were reverse scored, such that a lower value on each item was associated with greater perceived engagement. Individual items are reported as the number and percentage of participants who selected each Likert rating. These were averaged across items within each subscale to estimate the distribution of participants who on average agreed or disagreed with the items within each subscale. Average percentage agreement or disagreement to subscales across participants was also reported, calculated by regrouping all levels of agreement (agree/strongly agree) or disagreement (disagree/strongly disagree).

Usability

Usability was evaluated with the SUS [43]. The SUS consisted of 10 items relating to the overall usability of the intervention. Items were rated on a 5-point scale (1=strongly disagree to 5=strongly agree). An overall SUS score was calculated as a sum across all items after reverse coding certain items and scaling to produce a score from 0 to 100 [43]. A high score can be interpreted as positive perceived usability. Individual items are reported as the number and percentage of participants that selected each Likert rating. These were averaged across all items to estimate the proportion of participants that on average agreed or disagreed with items across the questionnaire. Average percentage agreement or disagreement per item and for the whole questionnaire across participants was also reported, calculated by regrouping all levels of agreement (agree/strongly agree) or disagreement (disagree/strongly disagree).

Acceptability

Acceptability was quantitatively evaluated with the SUTAQ [44]. It consisted of 22 items across 6 subscales: (1) *Care Personnel Concerns* (ie, concerns about the skills and continuity of the personnel looking after them); (2) *Enhanced Care* (ie, beliefs that the intervention can improve care); (3) *Increased Accessibility* (ie, beliefs that the intervention enhanced access to care); (4) *Kit as Substitution* (ie, beliefs that the intervention may be an alternative to regular care); (5) *Privacy and*

XSL•FO
RenderX

Discomfort (ie, concerns privacy and the intervention interfering with their daily life or making them feel uncomfortable); and (6) *Satisfaction* (ie, beliefs indicating acceptance and satisfaction with the kit and service provided). Participants rated their level of agreement with each item on a 6-point Likert scale (1=strongly disagree to 6=strongly agree). High scores can be interpreted as positive user perception, except for subscales *Care Personnel Concerns* and *Privacy and Discomfort* that are inverted; therefore, a low score is interpreted as a positive user perception. The intermediate value 3.5 is interpreted as a point of neutrality. Reverse coding was carried out on 1 item in the *Kit as Substitution* subscale [44] (item 18; see Table S3 in Multimedia Appendix 2). Individual items are reported as the number and percentage of participants that selected each Likert rating. These were averaged across items within each subscale to estimate the distribution of participants agreeing or disagreeing with the items within each subscale. Average percentage agreement or disagreement to subscales across participants was also reported in text, calculated by regrouping all levels of agreement (mildly, moderately, and strongly agree) or disagreement (mildly, moderately, and strongly disagree).

Qualitative Data

Semistructured interviews pre- and postintervention provided qualitative data about user expectations and experiences with the program, to assess the acceptability of the ieso Digital Program in meeting the needs of participants. Preintervention interviews, conducted by 2 user researchers between December 2023 and February 2024 (SD and MZ), lasted 16-38 minutes (mean 23 minutes). Postintervention interviews, conducted by 1 user researcher between February and April 2024 (MZ), lasted 30-47 minutes (mean 39 minutes). Interview topic guides were developed by user researchers, based on learnings from literature and from extensive internal user research and PPI workshops during the development phase of the program. Topic guides were reviewed by internal stakeholders with clinical and product expertise. Preintervention interviews explored participants' motivations to take part, their experience and views of using technology for mental health, and their expectations for the intervention. Postintervention interviews explored participants' overall experience with the intervention, engagement barriers and facilitators, perceived usefulness and effectiveness, and perceived safety and support. Refer to Multimedia Appendix 1 for detailed interview schedules. Interviews were conducted on Microsoft Teams and were automatically transcribed on Dovetail [45] and reviewed and anonymized by researchers.

Pre- and postintervention interviews were analyzed using reflexive thematic analysis [46,47], led by a researcher trained in qualitative research methods (PP) who familiarized with the data by reading interview transcripts multiple times and completed line-by-line inductive coding at both the semantic and latent levels in Dovetail. Codes were then grouped into candidate themes, which were then reviewed by returning to the underlying data. Final themes were defined by clarifying thematic boundaries and writing synopses. To ensure reflexivity and rigor in interpretations, analysis was regularly discussed between researchers (PP, CEP, MB, and MZ). A workshop with individuals with lived experience of mental health was held to review and discuss the thematic analysis findings. Final themes grouped both pre- and postinterview data linked by the common underlying concept of the theme. Results describe expectations and experiences in each theme. A detailed description of the thematic analysis process and workshop is available in Multimedia Appendix 1.

The framework method [48,49] was used to explore patterns between preintervention expectations and postintervention experiences. Inductive themes from the thematic analysis were used to create an analytical framework, and coded extracts were categorized within it. A framework matrix summarized data for each participant and theme by interview time (pre and post), with illustrative quotes. The framework matrix was interpreted by exploring patterns within and between participants, before and after the intervention, and relevant nuances and insights were added to our description of themes developed through thematic analysis.

Results

Self-Report Measures of User Experience

Overview

The final sample for analysis included 203 participants who completed the SUS and the SUTAQ, and 190 participants who completed the UES. Table 1 provides an overview of the demographic and clinical characteristics of participants enrolled in the intervention who completed the questionnaires (N=203). Of these, 163 (80.3%) were female, with a mean age of 41 (SD 12.0; range 19-75) years, and 168 (82.8%) completed the minimum meaningful clinical dose [18]. UES and SUTAQ subscale scores are reported in Figure 2, and average agreement or disagreement across scale items are reported in Tables 2 (UES and SUS) and 3 (SUTAQ). Item-level data for each scale can be found in Tables S1-S3 in Multimedia Appendix 2.

[a]SUTAQ: Service User Technology Acceptability Questionnaire.

Engagement

Overall, the mean total score for the UES was 3.7 (95% CI 3.5-3.8), indicating agreement that the program was engaging. On average, across the intervention sample who completed the UES (n=190), 159 (83.7%) agreed that the program was rewarding and worthwhile (*Rewarding*: mean 4.1; 95% CI 4.0-4.2), 129 (67.9%) perceived the app not to be frustrating or taxing (*Perceived Usability*: mean 3.7; 95% CI 3.6-3.9) and 133 (70%) found the app aesthetically pleasing (*Aesthetic Appeal*: mean 3.8; 95% CI 3.7-3.9). There were mixed views on whether participants were fully focused on the experience (*Focused Attention*: mean 3.1; 95% CI 2.9-3.2). Item-level scores indicated participants generally disagreed that they were "getting lost" in the experience, and there were mixed views on whether participants were fully absorbed in the app (see Table S1 in Multimedia Appendix 2).

Usability

Self-reported usability scores were high with a mean total score for the SUS of 78.6 (n=203; 95% CI 76.5-80.7). Item-level data (Table S3 in Multimedia Appendix 2) show that across the intervention sample (n=203), most participants agreed that the system was quick to learn to use (n=185, 91.1%), without the support of a technical person (n=188, 92.6%); 180 (88.7%) felt confident using the app and 179 (88.2%) found it easy to use. The item participants agreed the least strongly with was whether they would like to use the system frequently (n=135, 66.5% agreement).

Acceptability

Across the intervention sample (n=203), 180 (88.7%) participants were satisfied with the intervention (*Satisfaction*: mean 4.9; 95% CI 4.8-5.1). On average, 164 (80.8%) participants found that the app could improve care (*Enhanced Care*: mean 4.5; 95% CI 4.4-4.7) and 152 (74.9%) found that it increased access to care (*Increased Accessibility*: mean 4.3; 95% CI 4.1-4.4), without interfering with their daily life or making them feel uncomfortable (*Privacy and Discomfort*: mean[reverse scored] 2.1; 95% CI 2.0-2.2), and without concern about the skills and continuity of the personnel looking after them (*Care Personnel Concerns*: mean[reverse scored] 2.3; 95% CI 2.1-2.4). There were mixed responses about whether the program could be used as a substitution for their regular mental health care (*Kit as Substitution*: mean 3.3; 95% CI 3.2-3.5).

Qualitative Findings

Overview

Table 1 provides an overview of the demographic and clinical characteristics of participants enrolled in the interview subsample (n=21). Participants in the interview subsample were mostly White (n=19, 90%) and women (n=17, 81%), with a mean age of 46 (SD 13.1; range 19-72) years. Half of the sample had moderate anxiety (n=10, 48%), followed by mild (n=7, 33%) and severe (n=4, 19%) anxiety. Five participants did not do postintervention interviews: 3 were withdrawn from the study, and 2 did not book or attend their postintervention interview. Participants were highly engaged, with 14 out of 21 (67%) of the pre-intervention and 12 out of 16 (75%) of the postintervention interview subsamples completing a minimum meaningful clinical dose of the program.

Figure 3 shows a map of the themes developed through thematic analysis of the pre- and postintervention interviews. Five themes represent patient needs for conversational agent–led DMHIs and describe to what extent they were met, based on their expectations and experiences with the ieso Digital Program: (1) Accessible Care, (2) Effective Solutions, (3) Personal Experience, (4) Guided but in Control, and (5) Feeling Supported. Quotes are provided with interview type (pre, post), participant gender, age, and baseline anxiety severity.

XSL•FO
RenderX

Figure 3. Thematic map. Five qualitative themes illustrate user needs that influence the acceptability of conversational agent–led digital mental health interventions (DMHIs). Each theme summarizes user expectations and experiences drawn from pre- and postintervention interviews.

Theme 1: Accessible Care

This theme describes how participants sought mental health support that was accessible in terms of both availability and emotional approachability. The digital format was perceived as offering this kind of access and reached users who would not have accessed support otherwise.

Many participants were motivated to access mental health support that they felt was difficult to obtain through the NHS. Participants appreciated that the program was a faster, easier, and more affordable way to access support.

> *It's always easy to get an appointment but then from there the support is pretty much nonexistent....Basically, the advice is you could probably do with some more talking therapy, you can go on the waiting list and that will be up to a year, otherwise you can pay. So that's why the program is such a positive thing, because otherwise there's nothing.* [post, P14, female, 53, severe anxiety]

Some participants avoided seeking support due to guilt over using NHS resources. For some, the digital program was perceived as a good "first point of call" to address mental health concerns, and other options could be available after if needed.

> *I see it like, if I lined up Domino's, this is like Domino number one.* [pre, P16, female, 44, severe anxiety]

For many participants, a digital modality was an advantage. Participants wanted to reflect on their experiences and understand their triggers, thoughts, and feelings, and some believed that a digital program was better suited for them to do this work. Indeed, several participants expected and found it

XSL•FO
RenderX

easier to express their feelings to an app compared with a human therapist, especially if they had prior negative experiences with therapy. Participants felt less judged or embarrassed to open-up, and therefore self-censored less. Some participants also felt that the program may be less biased than a human therapist.

> *I liked it because I felt there wasn't any sense of judgment there. I've had a bad experience with therapy before where I didn't really get along with the therapist and there was quite a lot of judgment passed...And just knowing that that wasn't even something that could happen was really reassuring.* [post, P4, female, 19, mild anxiety]

Several participants preferred the privacy DMHIs would provide, compared with online therapy calls that could be overheard, and valued having more time to understand information and reflect before answering.

> *Text based certainly for me, I'm able to be much more thoughtful, much more introspective, much more precise is my answer when they're written rather than spoken. I think it gives me time to think deeper about things.* [pre, P12, female, 48, moderate anxiety]

Participants also valued being able to revisit and reflect on past content and discussions saved and centralized on an app. Many wanted continued app access poststudy to further review content.

> *If I could go back into the app to see how I wrote down what I was feeling, that would be, that would really reinforce it all.* [post, P9, female, 57, mild anxiety]

Theme 2: Effective Solutions

This theme describes participants' motivation to access effective solutions for anxiety. They sought practical tools to manage anxiety and would continue engaging if they perceived the program as effective.

A key motivation expressed in pre- and postintervention interviews was to access a solution-focused intervention to effectively manage or reduce anxiety. Participants differentiated the need to "offload," from their current need to "change behavior" and receive "tools" and "solutions." Most wanted to learn techniques to manage their anxiety long-term, while some sought momentary support or both. Participants practiced and applied techniques in everyday life, particularly when anxious or when facing a stressful situation.

> *[When I'm in a triggering situation], I would go either directly back to the app or I would go back to my book and I would look at what I've learned and I would go, ok, how can I approach this situation differently?* [post, P16, female, 44, severe anxiety]

Accessing helpful content and learning new information and techniques was crucial to participants and was for many a key motivator, even for participants who experienced frustration when the conversational agent misunderstood them. Nearly all participants interviewed found the program useful and effective. Seeing improvements and perceiving the program as beneficial was an important motivator for continued engagement with the program and continued application of techniques learned.

> *I was motivated to continue because each module had something which helped me. I felt that it was helping me reduce my anxiety right from the beginning. So, you wanted to do the next module.* [post, P5, female, 68, mild anxiety]

Participants noted the program's time and effort demands but emphasized the importance of engaging to see benefits. For many, this was acceptable as they began the program highly motivated and ready to engage; however, 1 participant was surprised by the program's workload and another shared that they could not have engaged similarly at another time in their mental health journey.

> *If you can stick with it and really commit to trying the things it suggests you try, you'll definitely find it helpful....But you have got to be willing to kind of commit to it and put in the time and do what it's asking you to do. So, you've got to be in the right headspace.* [post, P14, female, 53, severe anxiety]

Theme 3: Personal Experience

The third theme describes how participants wanted the program to be tailored and feel personal, but sometimes found the conversational agent to be generic or unnatural, and often felt misunderstood by it.

Preintervention, several participants expected personalized strategies for anxiety, tailored advice, and pathways or exercises based on their input or assessments. Half of the participants viewed technology and an AI guide as an opportunity for tailored and accurate support.

> *I would assume that based on my answer to questions or how I'm responding to things, that machine learning will tell the digital guide move things to get onto the right journey.* [pre, P7, female, 53, moderate anxiety]

Postintervention, some found the conversational agent impersonal or generic, and desired more context-specific advice, historical knowledge use, and the ability to ask questions.

> *I didn't quite enjoy that I was talking to a robot that didn't tell me things tailored to my needs, only generic things. So many times it didn't really matter what I said, the robot only repeated what I said.* [post, P2, male, 33, moderate anxiety]

Feeling heard and understood was crucial to participants. In preintervention interviews, interacting with a conversational agent was viewed as acceptable if it was well-trained, lacked bias, and was able to understand them and offer thoughtful answers.

> *As long as it's been well trained, it will be interesting to see what it comes back with. That it's not just a sort of trite responses you get when you're trying to get customer service out.* [pre, P12, female, 48, moderate anxiety]

Postintervention, some participants explained that the downside of a conversational agent was that they could not receive empathy and be understood like they would with a therapist. Nearly all users reported instances where the conversational

XSL•FO
RenderX

agent wrongly paraphrased messages or misunderstood complex thoughts and feelings. This often led to frustration or confusion. Safety messages that appeared when the user did not feel they were needed could lead to frustration and distraction from the session.

> *I think there was a lot of instances where it was clear that whatever I typed it hadn't understood. In a way that's like sitting in a room with a therapist and you tell them something and they just look blank.* [post, P15, nonbinary, 42, severe anxiety]

Some participants found the conversational agent's understanding abilities were less bothersome and less present over time, and some explained that they learned to communicate more effectively with it.

> *I think as the program went on, I got to know the program and I got maybe a bit better myself at finding ways to word things.* [post, P14, female, 53, severe anxiety]

However, others explained that simplifying their answers to ensure the conversational agent would understand impacted their ability to express their emotions.

> *And so you learn to keep it really simple. But that sometimes didn't help, I couldn't really express how I was feeling because the chatbot didn't understand.* [post, P5, female, 68, mild anxiety]

Several participants were not too impacted by these limitations, finding them expected and acceptable for a conversational agent, and not interfering with the overall program's usefulness.

> *You could tell it was looking for specific responses, but that's fine. That's what they do.* [post, P2, male, 33, moderate anxiety]

Postintervention, participants had mixed views on the conversational agent's human-likeness, some finding it human-like and others robotic. Notably, 2 participants valued its neutrality and "ambiguity," neither distinctly human nor robotic, and neither male nor female. However, conversations feeling robotic and preformatted answers could feel restrictive and frustrating, and affected participant's sense of agency, an important need discussed in the next theme.

> *I do think some of the time when you only have one response to give, sometimes I wanted to have choice or say my own thing. If you read back through my data, sometimes you can probably see I'm getting a bit frustrated, if you want to say more sometimes and then you're not given that option. And that sort of forces you out of your own voice and into the voice of whoever programmed it.* [post, P12, female, 48, moderate anxiety]

Theme 4: Guided but in Control

The fourth theme highlights participants' desire to have autonomy and control over how they engaged with the program while also wanting structure and guidance throughout. Being self-directed within a flexible yet structured intervention was valued by participants and was a motivation to participate in the study.

Accessing a time-bound and structured program through an app was seen by participants as useful for personal accountability to help them regularly engage in the work they wanted to do to feel better.

> *I think this would be helpful because I can tap in and out of it as and when. And it's something that's available, the app is always there for you to use. And at the same time there's time frames on it. So, you have to do things by certain dates. So there's a bit of a routine, but also a bit of flexibility.* [pre, P1, female, 35, mild anxiety]

Reminders were also seen as important to support adherence to the program, particularly considering reported engagement challenges such as their mental health, forgetfulness, or external obligations.

> *The reminders did serve, as a prompt to say, OK, just reminding you that you got your next session and you'll be on track to complete the study.* [post, P8, male, 32, mild anxiety]

Accessing a program that is easy to navigate, with a "logical pathway" to follow, was important. Participants also wanted to be guided toward what they should practice and reflect on, through conversational agent prompts and exercises. One participant viewed conversational agents as acceptable only if used within a structured program.

> *The other app I used, I would say something and then the chatbot would reflect that back to me. I'm assuming there is a structured program in the ieso app. So, it's not just going to be stuff I say being reflected back, there would be ideas for me and something for me to follow.* [pre, P13, female, 55, moderate anxiety]

In postintervention interviews, some participants expressed that having more in-app features and sessions to support practice and review content would be helpful, as well as guided support when experiencing symptoms of anxiety, such as meditation or breathing exercises.

> *I think to actually have some, a few recorded meditations that people could turn to relax breathing techniques or relaxation, especially if you're having a bit of a crisis and you need to calm down.* [post, P13, female, 55, moderate anxiety]

In parallel to wanting guidance and structure, autonomy was important to participants.

> *Nothing feels forced upon you. Even the reminders I think are gentle, they're like a little nudge rather than a big old slap.* [post, P16, female, 44, severe anxiety]

Many participants expressed high satisfaction with the intervention's flexibility and ability to fit into their lives, allowing engagement at their own pace, when in the right headspace, and in various settings. Several participants, therefore, saw the program as particularly adapted for people with demanding jobs or caregiving responsibilities.

> *I don't have a lot of time to attend scheduled appointments. So being able to pick something up to*

XSL•FO
RenderX

> *help my own mental health in my own time is more likely to be something I would use in the future than in-person therapy.* [post, P6, female, 44, moderate anxiety]

Many participants desired more control over session timing, duration, and frequency. While some liked time locks between sessions to practice, others found them either too far apart, such that they hindered progress or timely support, or too close together, leaving insufficient time to practice.

> *Having to wait a few more days until the next session, I understand why. But sometimes I was really into a mood where I needed those sessions. And after a few days when the session was available, I wasn't available myself.* [post, P2, male, 33, moderate anxiety]

> *I thought early on it was the sessions are slightly too close together and I thought I didn't always have time to practice.* [post, P10, female, 30, mild anxiety]

Theme 5: Feeling Supported

The final theme describes how participants found the program to be supportive and safe, facilitated by human support.

Clinician involvement in the design of the program provided credibility. Participants were willing to engage as the content was clinically backed and written by humans.

> *I think if it's controlled, it's preprogramed responses written by an expert then, I have a lot of confidence in that system.* [pre, P3, female, 31, severe anxiety]

If users experienced increased anxiety during the study, it was attributed to external stressors and users were able to speak to a clinician. Some users said that negative emotions could sometimes arise, but this was viewed as expected when engaging in such exercises.

> *There were a few moments where it would ask you to think of something negative to practice. But I think that's how those sessions work. And at the end of it, I always felt better. But yeah, there was the odd moment, when it was getting you to think something, but I can't see a way for it to get you to practice and explain it without that.* [post, P10, female, 30, mild anxiety]

Participants valued human support throughout the program.

> *I think it was good that you can just pick it up and do it as and when, while also having some support from real people if and when you needed that.* [post, P1, female, 35, mild anxiety]

Regular calls with research coordinators were beneficial for adherence and engagement with the program, providing gentle reminders or deadlines in addition to app reminders.

> *It helped with accountability knowing that someone was going to call because then if I hadn't done it, that wouldn't be good.* [post, P10, female, 30, mild anxiety]

Importantly, regular check-ins with research coordinators and the option to consult a clinician provided users with a sense of safety and reassurance during the program, and knowing about this human element was a motivating factor to take part in the study. Knowing they could talk to a human was important even when participants did not experience the need for it. Several participants suggested integrating easy ways to contact a human within the app.

> *That was the good thing about those calls [with the research coordinator], you did know there was actually somebody there. I never had to contact a clinician or anything, but it was always very clear that that is an option if that is necessary.* [post, P4, female, 19, mild anxiety]

While most felt supported by the human contact provided, a few desired more frequent clinician interaction and guidance. Some accessed the human support they needed outside of the program, through friends and family, and 1 participant explained that the program itself encouraged and helped them seek social support.

Postintervention, participants expressed that the program's design and content created a supportive and encouraging environment. Several participants described the program as "calming," "relaxing," and "gentle"; the content as "lovely" and "therapeutic"; and the conversational agent as "friendly" and "reassuring."

> *And the acknowledgment at the end, "Let's acknowledge that this may be hard for you," "Are you willing to commit to it?". At that level of acknowledgement, you feel heard. It was like having a cheerleader on your side, you know? That was nice I thought.* [post, P12, female, 48, moderate anxiety]

Discussion

Principal Findings

This mixed methods study demonstrates the overall acceptability of a digital program driven by an AI conversational agent with human support for adults experiencing generalized anxiety symptoms. Quantitative self-reported measures showed that participants found the digital program rewarding and easy to use, and that it both increased access to and enhanced their mental health care. Qualitative interviews provided an in-depth understanding of factors important for DMHI acceptability, giving context to the quantitative findings—such as guiding users, fostering a sense of support, and observing tangible mental health improvements. However, participants frequently reported a lack of personalization and frustrations with the conversational agent's misunderstandings, and there were mixed views on whether it could serve as a substitute for standard care. Using mixed methods enabled a deeper understanding of patient acceptability and offered a new perspective on previously reported outcomes [18], capturing participants' affective and cognitive investment beyond usage metrics [50]. These findings highlight opportunities to optimize and innovate DMHIs to enhance their acceptability and impact on mental health care.

In this study, many participants sought a self-directed and autonomous solution while also wanting to feel supported, highlighting the need to balance structure and guidance with

XSL•FO
RenderX

personal agency in DMHIs. Users appreciated the structured program and wanted more in-app support, such as prompts or worksheets to facilitate reflection and practice. By contrast, some participants wanted increased control over their pace through the program, echoing findings from other conversational agent DMHIs [51]. For example, although time-locked sessions were designed to encourage practice between sessions, many participants preferred having greater control over this. Most participants found the program easy to use, as reflected in a high mean SUS score of 78.6, which exceeds scores reported for other conversational agent DMHIs (63.6-66.2) [19]. The program also met participants' expectations regarding access and flexibility, with 152 out of 203 (74.9%) agreeing that it increased access to care (SUTAQ *Increased Accessibility* subscale).

Despite wanting a self-led digital solution—perceived by some participants as a judgment-free and less intimidating way to access mental health support without talking to a therapist—human support remained crucial for building trust in the program, ensuring safety, and maintaining engagement. Nonclinical research coordinators, who provided motivational support through emails and phone calls, were perceived as helpful in fostering a sense of accountability. Participants also valued having the option to talk to a clinician if needed. This aligns with patient perceptions that DMHIs should involve clinicians and facilitate access to mental health professionals [23,26]. Moreover, this is consistent with findings that DMHIs with human support have lower dropout rates [14] and better outcomes [52], particularly at higher symptom severity [18]. Most participants reported minimal concerns about personnel skills and continuity of care (SUTAQ *Care Personnel Concerns* subscale; mean 2.3, range 1-6), highlighting the acceptability of this support model for real-world implementation. Nonetheless, there were mixed views on the acceptability of the digital program as a replacement for regular mental health care (SUTAQ *Kit as Substitution* subscale; mean 3.3, range 1-6). As individual needs and preferences influence the acceptability of DMHIs, it is essential to ensure that people are offered an informed choice in how they receive care. Moreover, although human support can enhance acceptability, implementations must remain scalable to meet the rising demand for mental health care. In the current program, comparable outcomes to human-delivered care were achieved with up to 8 times fewer clinician hours [18]. Innovative implementation approaches should be explored to further optimize the scalability, acceptability, and engagement of DMHIs that incorporate human support [53,54].

Acceptability can be further enhanced by improving the conversational agent. Being misunderstood by the agent was a significant source of frustration in this study and is a common limitation of tree-based dialogue systems [15,16,51,55,56]. Recent advances in generative AI have transformed human-technology interaction by enabling dialogue systems that emulate fluent human conversation, making users feel heard and understood [57]. Users have reported finding rule-based mental health apps less satisfying than those using generative conversations [58], and recent findings suggest that generative conversational agents may have a greater ameliorative impact on psychological distress than retrieval-based ones [59]. While further research is needed, these preliminary results indicate that using generative AI could enhance engagement and effectiveness in DMHIs. However, generative AI also introduces new patient risks [60,61]. Its integration into DMHIs should therefore be guided by mental health professionals [62], with rigorous frameworks in place to evaluate clinical risk and quality in mental health contexts [63].

Interestingly, despite the conversational agent's limitations, many participants remained engaged because of the content's usefulness. This is consistent with prior research linking perceived usefulness to greater engagement [12] and to the value users place on insights gained from DMHIs [15,56]. In this study, 180 out of 203 (88.7%) participants found the intervention satisfactory (180/203; SUTAQ *Satisfaction* subscale), 164 out of 203 (80.8%) reported that it enhanced care (SUTAQ *Enhanced Care* subscale), and 159 out of 190 (83.7%) found it rewarding and worthwhile (UES *Rewarding* subscale). Postintervention interviews provided further insights into how perceiving benefits—from learning new tools and techniques to observing improvements in symptoms—was key to maintaining engagement, consistent with theory identifying perceived efficacy as a core construct influencing acceptability [20,21]. While prior research on conversational agent–led DMHIs has emphasized the role of factors such as empathy and human-likeness in fostering engagement [19], our findings underscore that expected outcomes and perceived efficacy remain central for individuals using these programs.

Limitations

Limitations of this study are a lack of sample diversity and potential biases arising from the limited perspectives of the clinical and research teams. The program design and interpretation of qualitative data were shaped by the team's cultural context. Given mental health inequities [64] and varying attitudes toward AI [65], research on DMHI acceptability in diverse populations is essential but remains limited [19,66]. Dedicated research is also needed on the personalization and adaptation of conversational agent–led DMHIs to user background, identity, culture, and socioeconomic context [67], as well as on the potential and limitations of generative AI in supporting such adaptation—for example, through language translation and tailoring, metaphor usage, or individualized treatment goals [68]. Co-production with diverse clinicians, researchers, and users with lived experience must be prioritized.

Quantitative findings may be biased toward participants who adhered to the full study protocol. For example, those who completed postintervention questionnaires were more likely to reach the minimum meaningful program dose within 9 weeks (168/203, 82.8%) compared with the full enrolled sample (180/300, 60%). The interviewed subsample, selected preintervention, showed similar engagement to the full sample (14/21, 67%), while those who completed postintervention interviews demonstrated higher engagement (12/16, 75%). Exploring participants' expectations before the study helped mitigate this limitation and provided insights into factors important for acceptability, regardless of engagement. Nonetheless, findings primarily reflect the perspectives of the

XSL•FO
RenderX

most engaged participants. Actionable guidance for DMHI development should therefore focus on enhancing engagement across the broader population. Further research with nonengagers is essential to understand barriers to DMHI acceptability.

Moreover, there are limitations to the validity of the self-reported measures (UES, SUS, and SUTAQ) in this context. Engagement with DMHIs involves different motivations and behavioral processes among users experiencing mental ill health compared with the general digital systems or telehealth services on which these measures were developed and validated, making interpretability in this context challenging [7]. For example, the UES *Focused Attention* subscale (reflecting absorption in the experience) may be less applicable in a DMHI than in a noninterventional system, as suggested by the qualitative analysis, where participants described the program as demanding but rewarding. Additionally, the interpretability of the scales was constrained by the scarcity of suitable benchmarks. To address this, we reported item-level response data to aid interpretation, and qualitative findings provided deeper contextual insights.

Implications for Future Research and Implementation

This study offers insights to inform future research and implementation efforts aimed at enhancing the acceptability, engagement, and usability of conversational agent–led DMHIs. Key areas of focus are balancing user autonomy with structure and guidance, identifying when human support is most beneficial, and reflecting progress back to users to strengthen perceived efficacy and engagement. Real-world implementation pilots will be important to maximize adoption and outcomes [69,70]. The variability in user preferences across these domains underscores the need to explore personalized solutions. Advances in natural language generation using large language models offer powerful tools for creating varied, personalized interactions that surpass the limitations of rule-based dialogue systems [58]. However, their implementation must be approached with caution, ensuring outputs are guided by evidence-based protocols and safeguarded against inappropriate or potentially harmful content. Given users' parallel needs for both structure and effectiveness, future DMHIs should explore safe and engaging ways to integrate generative AI within structured, evidence-based programs that incorporate feedback from lived experience. Finally, the study highlights the need to develop validated measures that capture the unique dimensions of user experience in conversational agent–led DMHIs, enabling more accurate quantitative evaluations of acceptability and engagement and facilitating further research into their relationship with clinical outcomes.

Conclusions

This study provides evidence for the acceptability of a structured, conversational agent–driven digital program with human support for adults experiencing symptoms of generalized anxiety, along with insights to optimize such interventions. Understanding patient acceptability through multiple methods is crucial for enhancing engagement with DMHIs, a key challenge limiting their real-world impact. The findings underscore the importance of design, clinical, and implementation factors in supporting adherence. Importantly, patient expectations of conversational agents are rapidly shifting with the widespread availability of generative AI tools such as ChatGPT. Generative AI has the potential to transform the user experience with DMHIs by enabling dynamic, empathetic, and personalized interactions across modalities and languages. However, rigorous evaluation is essential to ensure patient safety and equitable health outcomes, alongside continued education and research into its acceptability. If integrated safely within structured, evidence-based, and effective DMHIs—shown here to be acceptable to users—this technology could revolutionize the delivery of mental health care and improve patient outcomes globally.

Acknowledgments

We extend our gratitude to the participants in the study and to the dedicated clinicians and support staff involved. We thank Gerald Chan, Stephen Bruso, Andy Richards, Ann Hayes, David Icke, Michael Black, Clare Hurley, Florian Erber, Richard Marsh, Sam Williams, and Jo Parfrey for their support and encouragement. We are grateful to Professor Thalia Eley for introducing us to NIHR BioResource. We thank the NIHR BioResource volunteers for their participation and gratefully acknowledge the NIHR BioResource centers, NHS Trusts, and staff for their contributions. We also thank the National Institute for Health and Care Research, NHS Blood and Transplant, and Health Data Research UK as part of the Digital Innovation Hub Program. The views expressed are those of the author(s) and not necessarily those of the NHS, the NIHR, or the Department of Health and Social Care. This research was funded by ieso Digital Health Ltd.

Data Availability

Owing to the potential risk of patient identification, and following data privacy policies at ieso, individual-level data are not available. Aggregated data are available upon request, subject to a data-sharing agreement with ieso. Data requests should be sent to the corresponding author (PP) and will be responded to within 30 days.

Authors' Contributions

CEP, E Marshall, and ADB conceptualized the study. CEP and PP drafted the paper. PP, CEP, E Millgate, MB, MZ, GW, AC, and JB contributed to data analyses and interpretation. SD, MZ, CEP, and E Marshall conducted the study. All authors contributed to the interpretation of results, revised the paper, and approved the final version.

Abstract

The study explored older adults' perceptions after participating in an online survey about medication decisions, finding that approximately 80% of participants provided positive feedback about the research methodology and their experience.

(JMIR Hum Factors 2025;12:e65684) doi:10.2196/65684

Introduction

Older adults are underrepresented in research, often due to age-related biases and stringent exclusion criteria; this limits generalizability and leaves knowledge gaps [1].

The increasing prevalence of online research has the potential to increase older adult participation, given the rising internet use among this demographic [2]. While research has primarily focused on improving recruitment of older adults, an understanding of their experiences of online research is needed to effectively engage older people [3]. While most surveys include some form of piloting, they rarely capture or share participants' perceptions of the research process. We sought to explore older adults' perceptions after participating in an online experimental survey, given the potential high accessibility of this type of research.

Methods

Overview

We previously reported the main findings from a vignette-based online experiment conducted among adults aged 65 years and older from Australia, the Netherlands, the United Kingdom, and the United States [4]. Participants were recruited for this 15-minute survey through a panel of internet users administered by Qualtrics Research Panels. The study focused on contextual factors influencing how older adults (mean age 71.5, SD 5.1 years) think about deciding to stop a cardiovascular disease medication. In this study, we conducted a content analysis of free-text comments (Textbox 1). The final analysis framework included 17 codes that were subsequently consolidated into 14 themes. Descriptive statistics were used to assess the frequency of each theme.

XSL•FO
RenderX

Textbox 1. Summary of methodology for the content analysis.

1. A vignette-based online experiment was conducted among adults aged 65 years and older from Australia, the Netherlands, the United Kingdom, and the United States using sampling quotas to ensure balanced representation by country and gender. This study was registered at ClinicalTrials.gov (NCT04676282). At the end of the survey, participants were provided the opportunity to leave "any comments about this study."
2. A content analysis was conducted among participants who received the vignette about a hypothetical patient, Mrs EF. Participants from the Netherlands were excluded, as the study team for the content analysis was not fluent in Dutch.
3. Study authors read through the comments to inductively generate codes.
4. Two investigators (SEV and YM) independently coded comments, resulting in >80% agreement.
5. All discrepancies in codes were discussed until consensus was reached.

Ethical Considerations

The online experiment was registered at ClinicalTrials.gov (NCT04676282) and was deemed exempt by the University of Michigan Health Sciences and Behavioral Sciences Institutional Review Board (HUM00183129); by extension, a waiver of consent was granted. All data were collected anonymously. Participants were compensated based on the terms of their panel agreement.

Results

Participants (N=1789) most frequently did not provide any feedback in the free-text comment field (n=784, 43.8%) or wrote that they had no comments (n=487, 27.2%). Three participants (0.2%) gave unclear statements.

Participants' comments (n=515, 28.8%) were primarily positive (415/515, 80.6%), such as that the study was interesting (116/515, 22.5%). Themes and representative quotes are reported in Table 1. Participants said it made them think about their health (80/515, 15.5%) and some participants shared further health information about the study topic (48/515, 9.3%). Participants provided feedback on how to improve the study, categorized as question-specific comments (21/515, 4.1%), general suggestions (12/515, 2.3%), or country-specific comments (3/515, 0.6%). Few participants (16/515, 3.1%) provided negative feedback about the survey.

XSL•FO
RenderX

Table 1. Older adults' feedback about an online survey using a hypothetical vignette by theme, with representative quotes among respondents who provided feedback (n=515).

Themes	Representative quotes (participant code)	Participants, n (%)
Positive feedback (n=415, 80.6%)		
Interesting	• "An interesting study" (919) • "This was an interesting survey to complete" (2200)	116 (22.5)
Thought provoking	• "Interesting and insightful. Made me think a little more about how best to manage my health" (1872) • "Very good survey to ponder thoughts and beliefs" (481)	80 (15.5)
Positive feedback	• "Great stuff. Keep up the good work" (2574) • "Very good" (764)	67 (13)
Thanks for opportunity to participate	• "Thanks" (42)	43 (8.3)
Positive feedback about survey questions or structure	• "Love the format, so easy to see, follow, and understand" (1904) • "Very good questions regarding whether or not to stop a medication when you've been on it for an extended time" (2026)	35 (6.8)
Enjoyed taking survey	• "Enjoyed it" (328) • "Love doing your studies" (287)	34 (6.6)
Unusual study design	• "Very different enjoyed the variety" (540) • "Unusual but interesting" (1853)	19 (3.7)
Interested in results	• "Interested in purpose of results" (1863) • "Very interesting! Now I need to see the final results" (3481)	15 (2.9)
Interested in future studies	• "Great study, I'd do more" (4815) • "Need more like this" (2516)	6 (1.2)
Neutral feedback (n=48, 9.3%)		
Shared personal experience	• "I am afraid of going to see the dr for worries about my health" (1526) • "Thanks; my prescription drugs fall under the Federal Government program where they are funded nearly 100%" (2645)	48 (9.3)
Negative feedback or suggestions for improvement (n=52, 10.1%)		
Question-specific feedback	• "The percentage charts were confusing" (2403) • "One question said check all that apply but only one was allowed" (4279)	21 (4.1)
Negative feedback	• "Boring" (1409) • "Too many generalizations" (1102)	16 (3.1)
General suggestions for improvement	• "Consider adding a progress bar to the survey" (2027) • "Good study could be shorter" (2433	12 (2.3)
Country-specific feedback	• "Some questions are designed for the USA" (1471) • "Prescription insurance? In UK if you are over 65 prescriptions are free" (4075)	3 (0.6)

Discussion

Among older adults who provided feedback about their experiences completing an online survey, approximately 80% (415/515) of the comments were positive. Our findings signal general acceptability of the methodology, and we have implemented the practical feedback to improve our online surveys. We have become more mindful of the survey length, selected straightforward question types, and have conducted pilot testing in all target countries to ensure that questions are appropriate for all participants.

Our study had several limitations. First, less than one-third of the study participants provided any comments. Second, participants were asked if they had any comments, as opposed to more specific questions about their experience taking the survey. Finally, we acknowledge that we coded a single primary theme per comment given the short statements that were provided.

With an aging population who may spend many years in retirement, participating in research can offer benefits such as reducing social isolation and loneliness, fostering a sense of

XSL•FO
RenderX

purpose, and providing mental stimulation, and it may provide monetary incentives [5]. While our online study lacked the social benefit of in-person interaction typical of traditional research, participants reported enjoying the survey; they found it prompted self-reflection on their health, and they expressed interest in the study's outcomes and future research.

Online research is becoming more prevalent; therefore, it is important to make sure this methodology is inclusive of older adults [5]. More than half of adults older than 65 years use the internet, yet they are the least likely to have a home computer [6]. While some researchers attribute this limited use to age-related functional decline, others argue that the main barriers are negative attitudes such as fear, anxiety, and low motivation—barriers that are modifiable. Anxiety about using the internet and digital technologies often leads to self-imposed limitations and low confidence, with older adults frequently underestimating their knowledge and abilities compared to younger users [6]. This underscores the importance of studies like ours that highlight the positive experiences of older adults in online research.

Acknowledgments

This study was funded by award R24AG064025 from the US Deprescribing Research Network via the Northern California Institute for Research and Education through the National Institute on Aging; a Swiss Government Excellence Scholarship (KRW), the Swiss National Science Foundation Scientific Exchanges (grant IZSEZ0_213475/1; KRW), and an Emerging Leader Research Fellowship (2017295) from the Australian National Health and Medical Research Council (KRW). The funders had no role in the design or conduct of the study; collection, management, analysis, or interpretation of the data; preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication. KRW and SEV had full access to all of the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.

Abstract

Background: Telemedicine services have been developing rapidly worldwide. Following the 2018 policy enabling telemedicine for follow-up patients, this service model has gradually gained popularity in China. However, little has been done to understand the policy's implementation across different types of medical institutions or to evaluate its effectiveness.

Objective: This study aims to (1) investigate the patient eligibility assessment process in various types of institutions for telemedicine services in Beijing, (2) elucidate institutions' rationale for adopting such approaches, (3) analyze discrepancies between policy and practice, and (4) provide references for the development of telemedicine services.

Methods: This mixed methods study involved 36 medical institutions in Beijing, determined based on placing in the top 20% for both service volume and service quality in 2023. The study was conducted in 2 phases. First, quantitative analyses were conducted based on the questionnaires collected from each institution's contact to gather information about the assessment process and patient prerequisites. Subsequently, qualitative analyses were conducted through thematic analysis of 36 semistructured interviews with each institution's contact to acquire their considerations of this practice.

Results: These 36 institutions contributed 968,786 telemedicine visits, representing 89.5% of the total service volume in Beijing. In practice, each of the visits underwent a 2-stage eligibility assessment before the physician officially accepted the patient's request. In the first stage, for assessment approaches, 86.2% (25/29) of the nonprofit, tertiary hospitals and 14.3% (1/7) of the private, for-profit institutions automatically assessed patient eligibility, while others did it manually. The assessment was based on the scope of previous visit location, diagnosis of previous visits, and visit interval. For the scope of visit location, 22 hospitals required prior visits to the same institution. For diagnosis, 7 hospitals required patients to have an identical diagnosis. For visit intervals, 11 hospitals required it to be within 6 months. The second stage assessment was conducted by physicians. Compared with policy requirements, nonprofit hospitals had stricter requirements for the scope of visit locations. The main reasons for these discrepancies included distrust in the medical outcomes from other institutions (19/26, 73.1%) and difficulties in handling interinstitutional medical disputes (18/26, 69.2%). In addition, 61.1% (22/36) of the institutions indicated that terminations of telemedicine services were primarily due to the patient's conditions.

Conclusions: This pioneering multicenter, mixed methods study delineated the patient eligibility assessment process for telemedicine services in Beijing. Discrepancies were identified between real-world practice and regulatory prerequisites. The key factors contributing to these variations included the ambiguity of policies and different priorities across institution types. Our findings suggest greater policy clarity, relaxation of regulations for new patients, and strengthened oversight of telemedicine services to improve the quality and accessibility of telemedicine.

Introduction

Background

Telemedicine effectively connects individuals and their health care providers when in-person care is not necessary or not possible. Catalyzed by the pandemic, this novel service model has rapidly expanded and gained broad acceptance [1-3]. Currently, telemedicine is widely implemented in countries such as the United States, Canada, and Australia, with coverage rates reaching 35% - 60% [4-6]. In March 2020, the Centers for Medicare and Medicaid Services in the United States further facilitated adoption by removing the originating site requirement, allowing patients to receive telemedicine services from home [7]. Supported by such policy changes, telemedicine has been particularly useful in stroke treatment, psychiatry, radiology, and other chronic diseases, especially for patients in rural areas [8-11].

Similarly, in China, telemedicine services have been developing at a rapid pace [12]. In 2018, patients with "certain" chronic or common diseases were allowed to use telemedicine for follow-up visits [13], according to the Telemedicine Diagnosis and Treatment Management Measures (trial) formulated by the National Health Commission [14]. However, online initial services, including diagnoses, prescriptions, and referrals for new patients, are still prohibited [15]. By the end of 2022, the policy allowed medical institutions to prescribe medications online via telemedicine for patients presenting COVID-related symptoms. From a safety perspective, determining patient eligibility for telemedicine has remained an important consideration in policymaking. As patient demand for telemedicine continues to evolve, policies should also be updated accordingly to address these changing demands effectively.

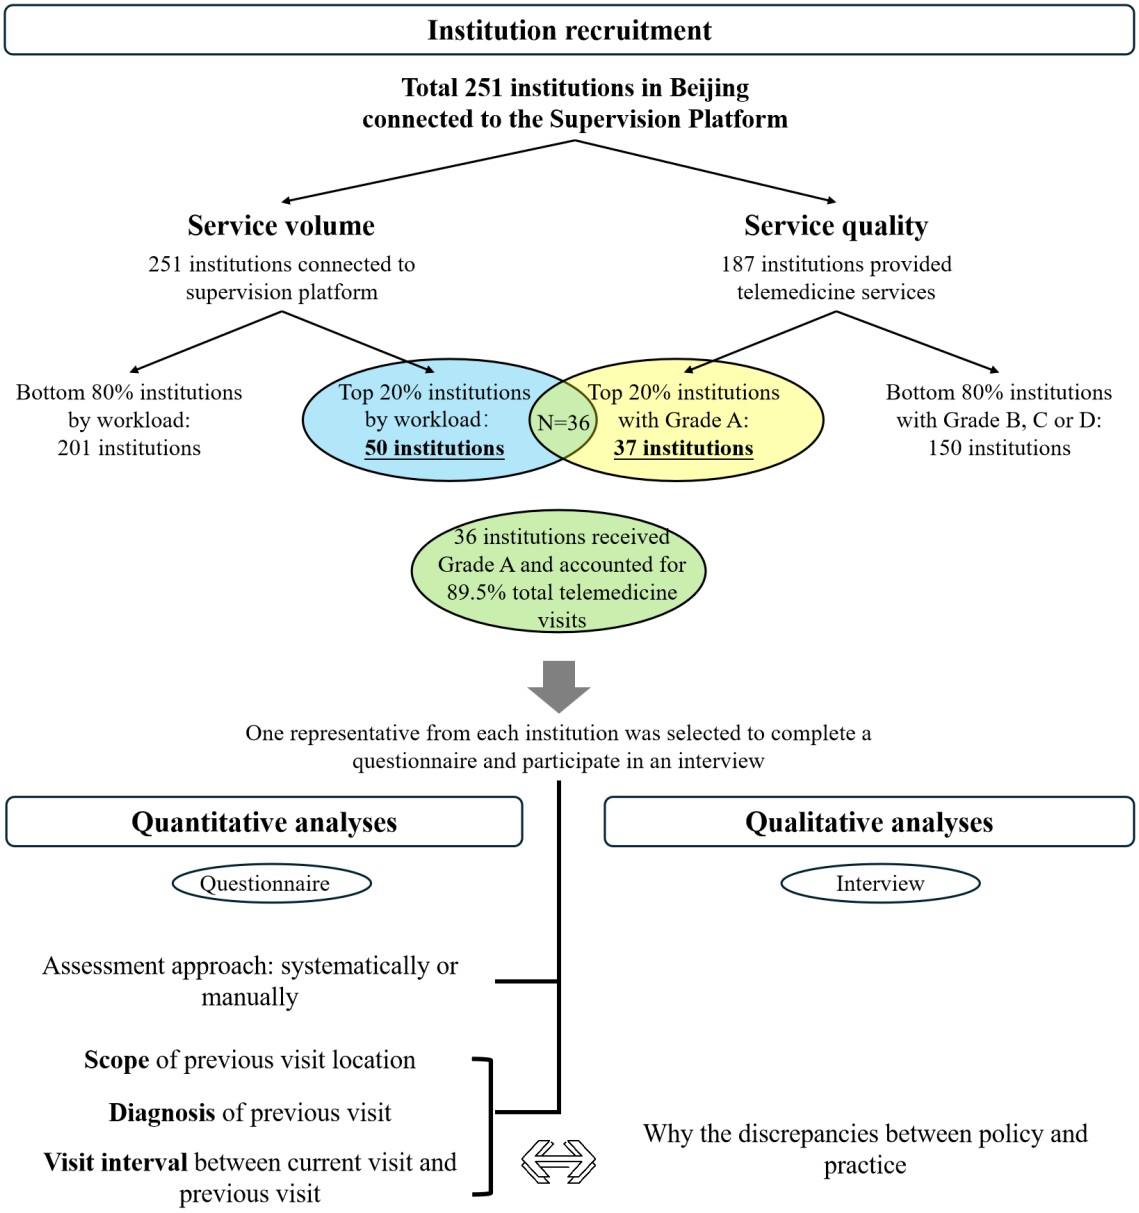
In China, medical institutions are primarily categorized into hospitals and other medical institutions. Hospitals are further classified by function into tertiary, secondary, and first-class levels. Tertiary hospitals serve as regional medical centers with advanced capabilities in clinical care, education, and research, offering high-level specialized care across regions. Secondary hospitals provide medical and health services to multiple communities and undertake limited education and research responsibilities. First-class hospitals focus on preventive and rehabilitative care within a single community [16]. While all types of medical institutions can provide telemedicine services, tertiary hospitals remain predominant, accounting for 61.6% of the telemedicine providers by the end of 2022 [17].

Since the implementation of the telemedicine policy for follow-up patients in 2018, domestic studies have primarily focused on the service volume, operational framework, or organizational implementation [18-20], with relatively few studies evaluating the service process from the perspective of the patient's journey. Currently, only limited research has addressed telemedicine practice variances across different types of institutions [18,21], and extensive research is still needed on institutional implementation considerations and strategies. These research gaps hinder the timely updates and refinements of policies, hence impeding the effective delivery of telemedicine services.

To address this gap, our study investigated institutional approaches to telemedicine follow-up identification in Beijing. Although Beijing is a city with high-concentrated, high-quality health resources [22], its telemedicine services were comparable to those of other provinces and municipalities in terms of service accessibility and provision by tertiary hospitals. The adoption rate of telemedicine among hospitals in Beijing was within the range of 0.700 - 0.840, placing it among the top 10 provinces in China. Similar rates were observed in Jiangsu, Shanghai, Zhejiang, Ningxia, and Xinjiang [23]. In Beijing, about 30% of the tertiary hospitals provided telemedicine services, ranking 16th among 31 provinces [17]. Therefore, Beijing is representative in terms of service volume and the dual-channel service model. Its experience in formulating telemedicine policies positions it as an emerging leader in telemedicine, providing valuable reference for other regions and countries seeking to develop and refine telemedicine policies. While regions should still tailor telemedicine strategies to their own situation and local needs, the experiences from Beijing still offer important guidance for designing region-specific policies.

Aims and Objectives

Based on the analyses of 36 institutions, this study aimed to examine discrepancies between policy and practice in telemedicine follow-up identification. By investigating patient eligibility assessment in Beijing, elucidating institutions' rationale for such approaches, and analyzing the deviations from the national policies, we identified the key issues, proposed strategies to improve the efficiency of telemedicine services, and highlighted potential areas for policy refinement.



Methods

Overview

The reporting of this study followed the checklist of mixed method research studies by Lee et al [24] in *Medical Care Research and Review* (Checklist 1), adopting an explanatory sequential design consisting of 3 phases: institution recruitment, quantitative analyses, and qualitative analyses (Figure 1) [25]. During the institution recruitment phase, based on the total volume and service quality of telemedicine services in 2023, 36 institutions were selected from 251 medical institutions in Beijing. Next, in the quantitative phase, we distributed survey questionnaires to these 36 institutions asking them to specify their prerequisites for providing follow-up visits across 3 dimensions, including scope of prior visit (same physician, same department, same institution, or not specified), diagnostic consistency (identical diagnosis, similar diagnosis, or not specified), and interval between visits (within 6 mo, within 1 y, within 3 y, or not specified). Then, we calculated the frequency of each option to characterize prevailing practices. Finally, in the qualitative research, semistructured interviews were conducted to explore the potential reasons for discrepancies between policy and practice in follow-up determination.

XSL•FO
RenderX

Figure 1. Study flow diagram. The relationship and sequence of mixed methods research components, including institution recruitment, quantitative analyses, and qualitative analyses: the light blue shade indicates the number of institutions selected due to the service volume, the light yellow shade indicates the number of institutions selected due to the service quality, and the light green shade (the intersection of the blue shade and the yellow shade) indicates the institutions recruited for this study.

This design was grounded on 2 rationales. First, integrating quantitative and qualitative data facilitates a synergistic combination of their strengths. The quantitative phase utilized a structured questionnaire to capture the prevalence and distribution of patient eligibility assessment processes for telemedicine services. Concurrently, qualitative interviews offer insights into why the institutional prerequisites for patient assessment functioned. Second, combining quantitative surveys with qualitative interviews enabled data triangulation, thereby enhancing the credibility of our findings on patient assessment prerequisites across different institutions.

Since the study references multiple policy-related concepts, key terms are defined below to clarify the policy context and facilitate the interpretation of the assessment process:

1. Patient eligibility assessment process: This process evaluates whether patients meet the criteria for receiving telemedicine services. It comprises 2 stages: before treatment and during treatment.
2. Prerequisites for patient assessment: In the first stage of patient eligibility assessment, patient eligibility could be assessed either automatically by the system or manually by the physician. The assessment usually covers 3 dimensions, including the scope of previous visit location, diagnosis of previous visits, and visit interval.

XSL•FO
RenderX

3. Scope of previous visit location: Before addressing a patient-initiated request for a telemedicine visit, the scope of requested telemedicine care will be compared to the patient's prior in-person visits to determine whether the encounter involves the same hospital, the same department, or the same physician.
4. Diagnosis of previous visits: Before addressing a patient-initiated request for a telemedicine visit, the chief complaint reported for the current initiated virtual care will be compared with previous in-person visits to assess whether the present diagnosis is identical to or related to the previous diagnosis.
5. Visit interval: The time interval between the current telemedicine visit and the previous in-person visit will be reviewed to determine whether it is within 6 months, within 1 year, or within 3 years.
6. Termination: If the patient's condition does not meet the service requirements set by the proposed institution, such as violating any of the 3 dimensions described above or applying reasons, physicians could stop providing telemedicine services during either the first or second stage of the assessment process.
7. Beijing Telemedicine Service Supervision Platform (referred to as "Supervision Platform"): Developed by the Beijing Municipal Health Commission, the Supervision Platform is a centralized data aggregation platform that requires institutions to upload their telemedicine service information. The Supervision Platform can also automatically calculate the compliance monitoring scores for each institution.
8. Compliance monitoring metrics: Compliance monitoring metrics are built-in indicators within the Supervision Platform to evaluate the quality of telemedicine services. These metrics reflect situations that could lead to point deductions, including 9 qualification metrics, 17 operational metrics, and 8 supervision metrics (Multimedia Appendix 1). For all uploaded telemedicine visits, each recorded violation results in a 1-point deduction. Thus, 1 visit with several quality deficiencies can lead to multiple points deductions.
9. The Beijing Municipal Center for Healthcare Quality Management and Improvement in Internet-Based Medical Services (hereafter referred to as "the Center"): The Center is responsible for telemedicine-related oversight, such as issuing monthly statistical bulletins, conducting inspections, organizing experience-sharing sessions, and providing education and training programs. The Supervision Platform enables the Center to monitor and promptly deliver feedback to institutions.

Institution Recruitment

Based on the total volume and quality of telemedicine services in 2023, research participants were selected from 251 medical institutions in Beijing. Regular inspections by the Center revealed that institutions with higher service volume and quality tended to maintain more consistent assessment standards. Thus, institutions with high service volume and quality were selected for the study.

The volume of telemedicine services referred to the number of telemedicine visits uploaded by medical institutions to the Supervision Platform. A total of 50 institutions ranked in the top 20% by service volume were initially considered from the perspective of service volume.

The quality of telemedicine services was determined based on compliance monitoring scores. The annual average compliance monitoring deduction per visit for each institution was calculated. Institutions were ranked in ascending order based on their scores. The top 20% (n=37) of the institutions received Grade A, indicating the presence of a standardized and efficient management system. These institutions were considered from the perspective of service quality.

We then intersected the top 20% of the institutions in service volume with those by service quality, yielding a final sample of 36 institutions (Figure 1). These 36 institutions consisted of 29 nonprofit tertiary hospitals and 7 private, for-profit institutions. Among them, the 29 nonprofit hospitals included 14 general hospitals, 11 specialized hospitals, and 4 traditional Chinese medicine (TCM) hospitals, covering all categories of tertiary public hospitals in Beijing.

These 36 institutions collectively accounted for 89.5% of the overall telemedicine service volume in Beijing, representing both nonprofit and private, for-profit institutions with high service volume and quality. Therefore, their patient eligibility assessment processes could reflect the mainstream practice of telemedicine services.

Data Collection and Management Procedures

Platform-Based Data Extraction

In August 2024, the institutional information and 2023 service volume data for each of the 36 institutions were obtained from the Supervision Platform.

Questionnaire Survey

The approaches and prerequisites of patient eligibility assessment for telemedicine services in medical institutions were collected through questionnaire surveys conducted in September 2024. Each institution designated a contact for communication with the Center, and their demographic information was compiled in a spreadsheet. A structured questionnaire with 5 questions was designed and distributed sequentially to the contacts of all 36 institutions via Wenjuanxing (an online survey platform), with a 1-week deadline for completion. The survey questionnaire is available in Multimedia Appendix 2. Response progress and data completeness were monitored in real time through the Wenjuanxing administrator interface. Reminders were sent to nonrespondents, and incomplete submissions were flagged for follow-up to ensure data integrity.

Semistructured Interview

The considerations of these prerequisites for patient assessment were collected through semistructured interviews. After completing the questionnaire online, the contacts of the 36 institutions were interviewed individually via telephone calls from November 2024 to February 2025. All participants

XSL•FO
RenderX

provided verbal informed consent. The semistructured interviews were conducted in Mandarin Chinese by the authors YL, XL, HL, and MG. At least 2 of them were present to conduct the interview in each session. All interviewers received professional training in qualitative interviewing and had extensive experience conducting qualitative research. The semistructured interview outline is provided in Multimedia Appendix 3. We recorded the interviews using a digital voice recorder. The interview phase concluded once interviews with all institutions were completed and frequency statistics were compiled. The interviews had an average length of 15 minutes, with an overall length of 526 minutes. Notes were taken simultaneously in Microsoft Word 2019 (Microsoft Corp.), and recordings were transcribed into textual materials within 48 hours after the interviews by the interviewers present on-site. The interviewees were allocated a randomly selected unique identification number.

Data Analysis

Descriptive statistics were used to analyze the quantitative data using Microsoft Excel 2019 (Microsoft Corporation) and SPSS 22 (IBM Corp). The distribution of all categorical variables (eg, type of institution, gender, age, role in the department, and departmental affiliation of the interviewees) was reported as frequencies (n) with percentages (%). The service volume was reported as mean with SD and median with IQR. Frequency distribution plots were generated to visualize the distribution of prerequisites for patient assessment.

Qualitative analysis followed an inductive approach, and the data were systematized and analyzed by manual coding. All textual transcripts were imported into Excel 2019 (Microsoft Corp.). Thematic analysis was employed to generate initial codes from the qualitative data [26]. Three of the authors (YL, XL, and YW) read all of the transcripts and analyzed the data independently.

Initial manual codes were developed respectively, and data segments were assigned to these codes. The codes were clustered into broader themes, which were then merged, split, or discarded following a review of the transcripts after discussion among the above authors. The themes were renamed to accurately reflect their content, resulting in the coding framework (Multimedia Appendix 3). Two of the authors (YL and XL) conducted the coding independently. After completing the coding, both authors compared the coding selections, and when discrepancies occurred, consensus was reached through discussion with a third author (YW) until agreement was reached. The number of recurring themes was recorded and documented. A comparative analysis was performed to evaluate discrepancies between on-the-ground practices and national policy requirements, with gaps and their root causes systematically identified. Reasons for the termination of telemedicine services were further analyzed to determine contributing factors. Finally, the themes were translated into English for reporting purposes.

Ethical Considerations

This study was reviewed and approved by the Medical Science Research Ethics Committee of Peking University Third Hospital (No. IRB00006761-M2024300). The Beijing Municipal Health Commission agreed to use the data from the Supervision Platform for secondary analysis. The interviewees provided informed consent. We filed the survey data while maintaining full confidentiality. The quantitative data were anonymized upon the conclusion of the study via a 2-step process: (1) institutions were categorized and (2) all identifying names were removed. Similarly, the qualitative data were stripped of all identifying details during the transcription process to ensure anonymity. No compensation was provided for participation.

Results

Characteristics of Investigated Institutions

In 2023, 187 institutions provided telemedicine services throughout the year, totaling 1,082,591 visits in Beijing. Among them, the institution with the highest service volume had 164,868 visits, while the institution with the lowest service volume had only 1 visit. The average service volume was 5789.3 visits, with an SD of 21,999.7 visits. The median service volume was 49, the 25th percentile was 13, the 75th percentile was 444, and the IQR was 431.

This research focused on analyzing 36 institutions that distributed questionnaires. The service volume of the 36 institutions can be found in Table 1. The total telemedicine service volume of the 36 institutions included in this study was 968,786, accounting for 89.5% of the total service volume in Beijing. As a result, the services provided by these 36 institutions could reflect the status of telemedicine services in Beijing. The total amount of services in 2023 of the 36 medical institutions was 968,786 (100%), with the highest annual service volume of 164,868 visits and the lowest of 220. The average service volume was 26,910.7 visits, and the SD was 42,043.8. The median of the service volume was 9709.5, the 25th percentile was 2919, the 75th percentile was 29,649.5, and the IQR was 26,730.5.

XSL•FO

Table . Distribution of institutions and service volume, by institution type (n=36).

Type of institution	Institutions, n (%)	Number of services		
		Total, n (%)	Mean (SD)	Median (IQR)
Nonprofit	29 (80.6)	805,917 (83.2)	27,790.2 (41,031.3)	11,163 (31,740)
Tertiary general hospital	14 (38.9)	292,801 (30.2)	20,914.4 (42,644.8)	8414 (9453)
Tertiary specialized hospital	11 (30.6)	386,094 (39.9)	35,099.5 (43,317.9)	13,866 (41,308)
Tertiary TCM[a] hospital	4 (11.1)	127,022 (13.1)	31,755.5 (33,771.8)	27,744.5 (61,829.5)
Private, for-profit	7 (19.4)	162,869 (16.8)	23,267 (49,351.7)	4125 (12,108)

[a]TCM: traditional Chinese medicine.

Among the 36 institutions investigated in this study, 29 were nonprofit hospitals, all of which were tertiary hospitals. They included 14 general hospitals, 11 specialized hospitals, and 4 TCM hospitals. The total telemedicine service volume of the 29 nonprofit hospitals in 2023 was 805,917 (83.2%), with an average service volume of 27,790.2 per hospital. The median service volume of 29 nonprofit hospitals was 11,163, and the IQR was 31,740.

The other 7 institutions were private, for-profit medical institutions, including 1 secondary general hospital, 2 primary TCM hospitals, 2 ungraded general hospitals, 1 first-class TCM hospital, and 1 clinic. The total telemedicine service volume of the 7 private, for-profit medical institutions in 2023 was 162,869 (16.8%), with an average service volume of 23,267 per institution. The median service volume of the 7 private, for-profit institutions was 4125, and the IQR was 12,108.

Characteristics of Interviewees

A total of 36 contacts from 36 institutions specializing in telemedicine services were interviewed for this study (Table 2). These interviewees had experience in outpatient management, engaged in hospital administration, or were responsible for technology-related work. After the implementation of telemedicine services in these institutions, they were assigned operational roles to coordinate and maintain the services. Among the interviewees, 20 were leaders of telemedicine services, and 16 were participants familiar with the work. The average age of interviewees was 40 years.

Table . A summary of interviewees' demographic information (n=36).

Characteristics	Interviewees, n (%)
Sex	
Male	15 (41.7)
Female	21 (58.3)
Age (y)	
30 - 39	19 (52.8)
40 - 49	10 (27.8)
50 - 59	7 (19.4)
Role in the department	
Leader	20 (55.6)
Participant	16 (44.4)
Departmental affiliation of the interviewees	
Affiliated to the outpatient department	16 (44.4)
Independent, office of telemedicine	10 (27.8)
Independent, operation planning department	7 (19.4)
Affiliated to medical administration office	2 (5.6)
Affiliated to the information technology department	1 (2.8)

Patient Eligibility Assessment Process for Telemedicine Services

After patients registered and updated their information on the telemedicine application or WeChat mini-program of each hospital, they could apply for telemedicine services. The institution providing telemedicine services conducted the assessment, which was divided into 2 stages. The first stage took place before treatment. In this stage, the assessment was made automatically by the system or manually by the physician.

XSL•FO
RenderX

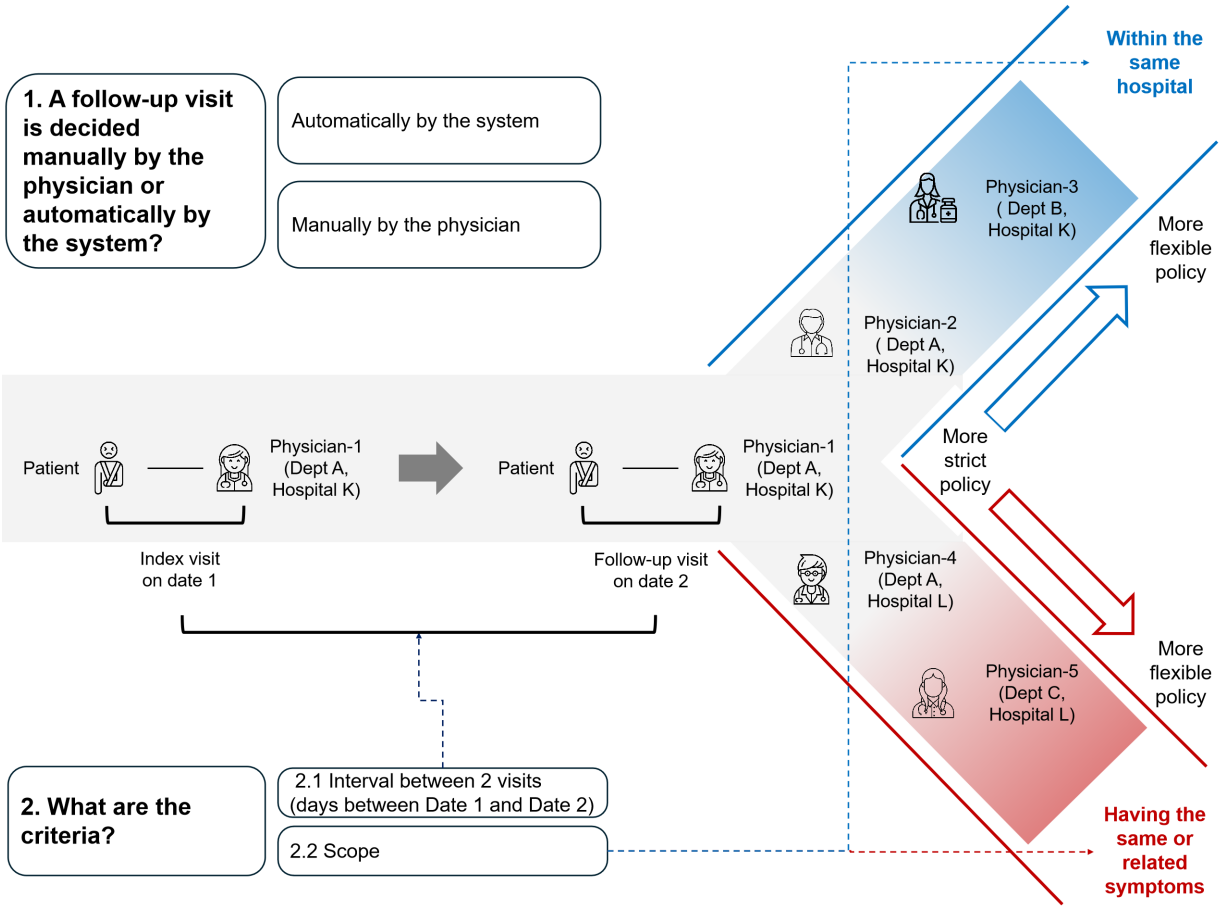
The second stage occurred during treatment. The attending physician determined whether the patient's condition was suitable for telemedicine services. If institutions did not use the system for assessment in the first stage, the 2 stages were combined, and the assessment was left to the physicians. In each stage, specific reasons could prevent patients from receiving telemedicine services. If physicians determined that a patient was not suitable for telemedicine services, they could terminate the session and refer the patient to in-person care. The medical service fee for this session would be refunded.

The assessment approaches of the 36 investigated institutions are presented in Table 3. In the first stage, 72.2% (26/36) of the institutions made assessments automatically by the system, including 25 of the 29 tertiary nonprofit hospitals and 1 of the 7 private, for-profit medical institutions. Among the tertiary nonprofit hospitals, only 4 hospitals selected qualified patients for telemedicine services manually by the physicians, including 1 general hospital, 2 specialized hospitals, and 1 TCM hospital. These hospitals provided a total of 19,465, accounting for 2.42% of the service volume of nonprofit hospitals. Among the 7 private, for-profit medical institutions, only 1 first-class TCM hospital assessed patients automatically by the system. The other 6 private, for-profit institutions assessed patients manually by the physicians for follow-up appointments through telemedicine.

Table . Distribution of assessment approach by hospital type (n=36).

Type of hospital	Auto[a], n (%)	Manual[b], n (%)
Nonprofit	25 (69.4)	4 (11.1)
Tertiary general hospital	13 (36.1)	1 (2.8)
Tertiary specialized hospital	9 (25.0)	2 (5.6)
Tertiary TCM[c] hospital	3 (8.3)	1 (2.8)
Private, for-profit	1 (2.8)	6 (16.7)

[a]Automatically by the system.



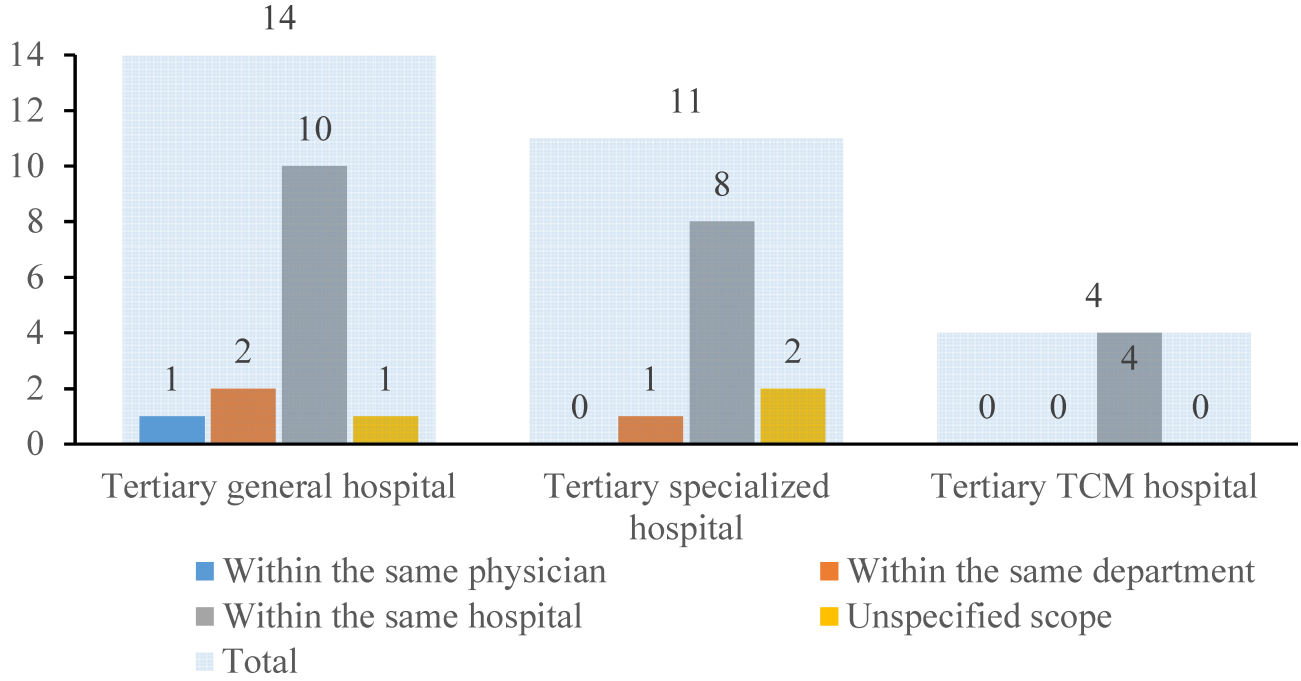
[b]Manually by the physician.

[c]TCM: traditional Chinese medicine.

Regardless of whether the assessment was conducted automatically by the system or manually by the physician, 36 medical institutions investigated in this study assessed patient eligibility from the following 3 dimensions in the first stage. Figure 2 illustrates the patient eligibility assessment process and the 3 dimensions: scope of previous visit location, diagnosis of previous visits, and visit interval. First, whether the previous visit location fell within the scope set by the current institution. Second, whether the previous diagnosis was within the scope defined by the current institution. Third, whether the visit interval between the patient's previous and current visits was within the scope set by the current institution. In this study, we found that medical institutions providing telemedicine services did not necessarily set the requirements for the above 3 dimensions. Considering the ownership type of the institutions, we would discuss the 29 nonprofit tertiary hospitals and the 7 private, for-profit institutions separately.

XSL•FO
RenderX

Figure 2. Patient eligibility assessment process for telemedicine services in the first stage.



Prerequisites for Patient Assessment in Nonprofit Tertiary Hospitals in Beijing

Prerequisites for the Scope of Previous Visit Location

The prerequisites for the scope of previous visit location were categorized into 4 groups: within the same physician, within the same department, within the same hospital, and unspecified scope. Figure 3 shows that 75.9% (22/29) of the nonprofit tertiary hospitals restricted prior visits to the same institution. There was 1 general hospital that required a record of previous visits to the same physician within the hospital. There were 2 general hospitals and 1 specialized hospital that required a record of previous visits to the same department within the hospital. All the TCM hospitals only limited the scope to the same hospital. Additionally, 3 hospitals did not impose any requirements regarding the previous visit location.

XSL•FO
RenderX

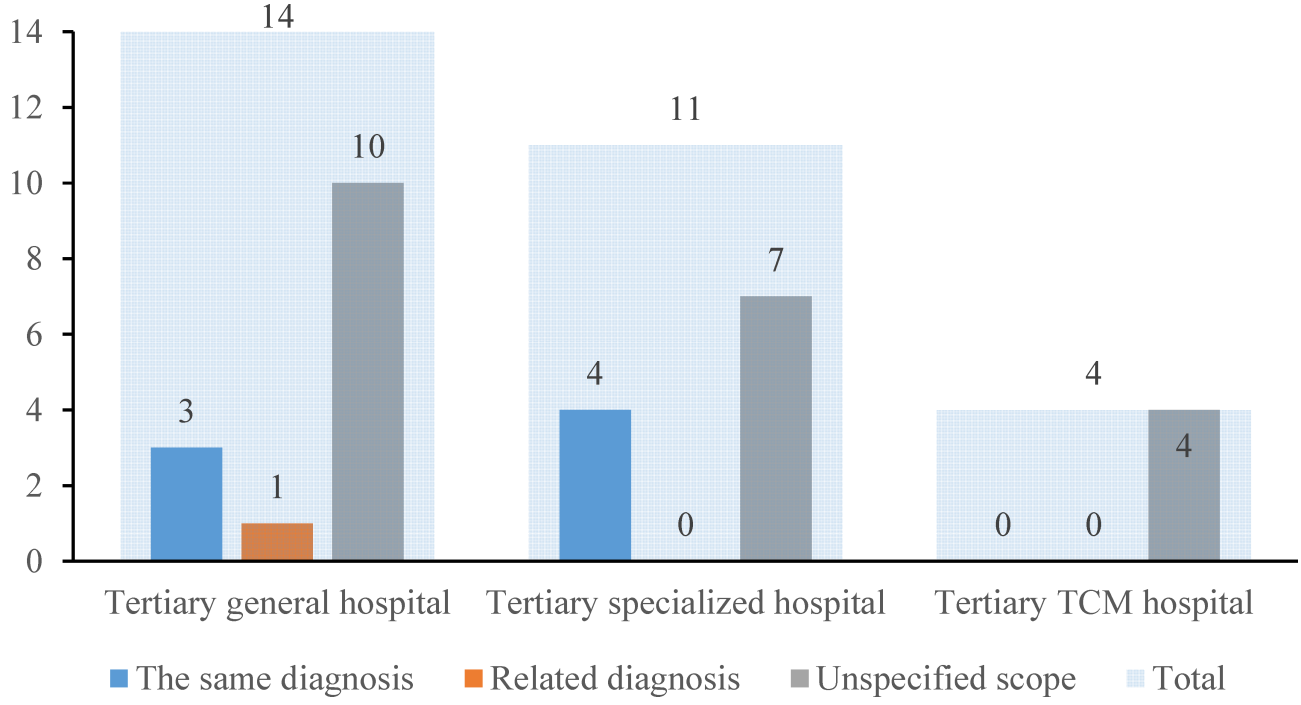


Figure 3. Institution distribution on prerequisites for the scope of previous visit location (n=29). The light blue shade indicates the sum in each type of hospital. The blue, orange, gray, and yellow columns indicate the number of hospitals that required the scope of the previous location to be within the same physician, the same department, the same hospital, and unspecified scope, respectively. TCM: traditional Chinese medicine.

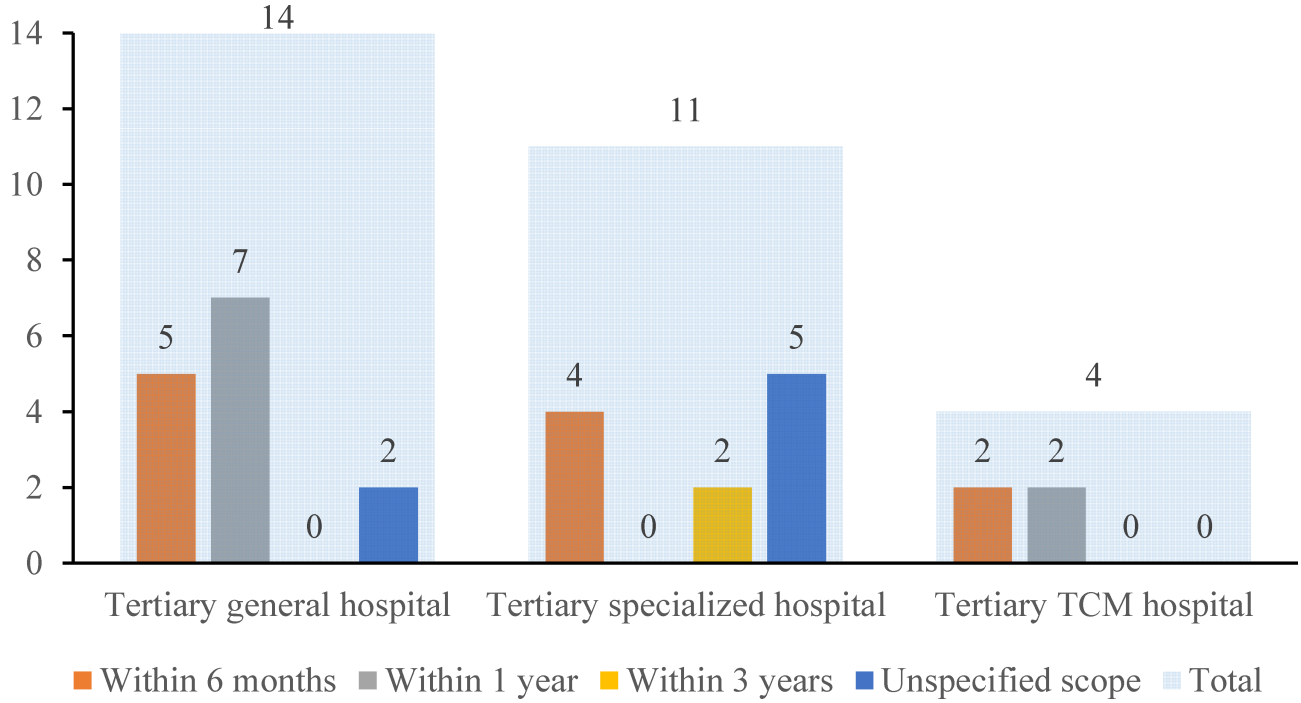
Prerequisites for Diagnosis of Previous Visits

The prerequisites for diagnosis of previous visits were divided into 3 categories: the same diagnosis, related diagnosis, and unspecified scope. Figure 4 shows that 72.4% (21/29) of the nonprofit hospitals imposed no restrictions on the diagnosis of previous visits. There were 3 general hospitals and 4 specialized hospitals that required the diagnosis of the previous visit to match the current diagnosis. One general hospital required the diagnosis of the previous visit to be related to the current diagnosis. TCM hospitals had no restrictions regarding previous diagnosis.

Figure 4. Institution distribution on prerequisites for diagnosis of previous visits (n=29). The light blue shade indicates the sum in each type of hospital. The blue, orange, and gray columns indicate the number of hospitals that required the patients to have the same diagnosis, related diagnosis, and unspecified scope, respectively. TCM: traditional Chinese medicine.



XSL•FO
RenderX

Prerequisites for Visit Interval

The prerequisites for visit interval were divided into 4 categories: within 6 months, within 1 year, within 3 years, and unspecified scope. Figure 5 shows that 37.9% (11/29) of the hospitals restricted the interval to be within 6 months, 31.0% (9/29) of the hospitals restricted it to be within 1 year, and 6.9% (2/29) of the hospitals restricted it to be within 3 years. The 2 specialized hospitals that restricted the visit interval to be within 3 years were both pediatric hospitals. Among the 29 hospitals, 2 general hospitals and 5 specialized hospitals did not have any restrictions regarding the visit interval.

Figure 5. Institution distribution on prerequisites for visit interval (n=29). The light blue shade indicates the sum in each type of hospital. The orange, gray, yellow, and blue columns indicate the number of hospitals that required the visit interval to be within 6 months, within 1 year, within 3 years, and unspecified scope, respectively. TCM: traditional Chinese medicine.

Prerequisites for Patient Assessment in Private, For-Profit Medical Institutions in Beijing

Most of the other 7 private, for-profit institutions did not have any restrictions on the above 3 dimensions. At least 1 secondary general hospital restricted the previous diagnosis to be the same as the current one. This hospital, along with a first-class TCM hospital, required the visit interval to be within 6 months. The other institutions did not have any requirements on the above 3 dimensions to assess whether patients could get telemedicine services. Overall, there were no significant disparities in prerequisites for patient assessment across different types of private, for-profit medical institutions.

Considerations for the Patient Eligibility Assessment

As mentioned by the National Health Commission, patients were required to provide relevant proof of diagnosis from past visits, with no restrictions on the visit interval or the scope of the previous visit location (ie, institution or department) [14]. Physicians providing telemedicine services were responsible for assessing patients. However, in practice, most institutions set requirements in the system for the location of previous visits and the visit interval while having fewer requirements on the diagnosis in the first assessment stage. The reason for imposing such requirements was that obtaining medical records from their own institution was more convenient. The visit intervals were set according to the typical disease progression timelines of the main diseases treated in each department. When telemedicine services restricted the scope of the previous visit location and the visit interval, it became easier to determine eligibility by referencing the patient's diagnosis from a specific institution at a particular point in time.

As shown in Figure 3, 26 institutions required a record of previous visits within their own institution. As they declined to acknowledge or accept previous visit records originating from external institutions, we obtained the following reasons (Table 4) from these institutions through interviews. The primary reason (19 interviewees) was distrust of the medical results provided by other institutions. The second most frequently mentioned reason (18 interviewees) was that it was more challenging to handle medical disputes involving other institutions once they happened. Among these 19 and 18 institutions, only 1 specified that the previous visit must be with the same physician, and 2 required that the previous visit must be within the same department. The third most frequently mentioned reason (10 interviewees) was the system's limitation to access data from other institutions. Notably, these 10 services did not impose additional restrictions regarding whether the previous visit was with the same physician or within the same department. Acceptance was granted as long as the patient had any history of visits within their own institution.

XSL•FO
RenderX

Table . Distribution of reasons for service restrictions in 26 institutions.

Reasons	Institutions, n (%)	Institutions with prerequisites for the scope of previous visit location, n		
		Within the same institution	Within the same department	Within the same physician
Distrust in the medical results provided by other institutions	19 (73.1)	16	2	1
Difficulties in handling medical disputes involving other institutions once medical disputes happen	18 (69.2)	15	2	1
Limited access to data in other institutions through information technology system	10 (38.5)	10	0	0

After the system automatically administered the first assessment stage, physicians would still terminate the telemedicine services in the second stage. Through interviews with the contacts of 36 hospitals, the main reasons for the termination included the patient's condition (n=22, 61.1%), mismatch due to the rules preestablished in the telemedicine system (n=15, 41.7%), and inability to provide the services that the patient hopes to receive (n=13, 36.1%) (Table 5). The proportion of service termination by physicians could be controlled within 2% of the total amount of telemedicine services.

Table . Institution distribution on reasons for the termination of telemedicine services (n=36).

Reasons	Institutions, n (%)
The patient's condition is not suitable for telemedicine services (eg, abdominal pain, trauma, the blood pressure of the hypertensive patient has become so high that physicians cannot refill prescriptions for the patient)	22 (61.1)
Mismatch due to the rules preestablished in the telemedicine system (eg, optometry physicians categorized as ophthalmologists in the system cannot provide services to cataract patients)	15 (41.7)
Inability to provide the services the patient hopes to receive (such as prescribing medications, conducting special examinations)	13 (36.1)
Communication problems due to network issues	7 (19.4)
Not meeting the visit interval required by medical insurance	7 (19.4)
Time conflicts with physicians	5 (13.9)
Insurance fraud committed by patients	2 (5.6)
Unknown	2 (5.6)

Discussion

Principal Findings

This study investigated the current practice of patient eligibility assessment for telemedicine services in Beijing, elucidated institutions' rationale for adopting such approaches, analyzed their differences from national policies, and proposed policy recommendations. First, most nonprofit, tertiary hospitals automatically assessed patient eligibility by the system in the first stage based on the scope of previous visit location, diagnosis of previous visits, and visit interval. Second, compared with national policies, nonprofit hospitals had stricter requirements on the scope of previous visit locations and more lenient requirements on the diagnosis of previous visits. On the other hand, private, for-profit institutions exhibited more relaxed requirements in all dimensions. Third, 2 main reasons for the discrepancies between policy and practice were distrust in the medical results provided by other institutions and difficulties in handling medical disputes involving other institutions once medical disputes happened. Based on the discrepancies, our findings recommend enhancing policy clarity, relaxing telemedicine regulation for new patients, and strengthening telemedicine supervision to improve telemedicine services.

Differences in Prerequisites for Patient Assessment

The quantitative data revealed differences across prerequisites for patient eligibility assessment among various types of medical institutions. Nonprofit hospitals had stricter requirements than private, for-profit institutions on patient eligibility assessment in the above 3 prerequisites. TCM hospitals, which had the highest average volume of telemedicine services, neither restricted prerequisites for the scope of previous visit location to specific departments or physicians nor imposed specific restrictions on patients' diagnoses of previous visits. The main reasons for the flexibility of these hospitals were the holistic view [27] and the personalized treatment approach in TCM, which relies on each physician's own professional judgment

XSL•FO
RenderX

[28]. The general hospital with the highest service volume restricted the current diagnosis to be related to the diagnosis of previous visits, considering the potential variations in the scope of diagnosis and treatment for certain departments across different hospitals. The prerequisites for the visit interval were primarily determined by the disease characteristics among the majority of the patients. We have observed that only 2 hospitals, both pediatric, adopted a 3-year visit interval. As this may be related to the rapid growth of pediatric outpatient visits and relatively long waiting times [29,30], we hypothesize these hospitals seek to transition suitable cases to telemedicine services when appropriate. Most of the other private, for-profit medical institutions did not impose restrictions on the above 3 dimensions.

The qualitative data explained the discrepancies between policy and practice. As for the results of quantitative analysis, the prerequisites for the scope of previous visit location and diagnosis of previous visits showed the gap from policy requirements, while the prerequisites for visit interval were not mentioned in the policies. Our qualitative analysis demonstrated the reasons for barriers to the acceptance of patients based only on external institution visit records. Since determining whether a diagnosis from previous visits aligned with the requirements of the current institution usually involves professional judgment, this assessment cannot be made automatically by the system. Findings from the interviews revealed that the main reasons for the termination of telemedicine service included the patient's condition not being suitable for telemedicine services and mismatches preventing physicians from providing treatment to patients with specific diagnoses.

Reasons for the Discrepancies Between Policy and Practice in Nonprofit Hospitals

The results specified that 2 main reasons had caused the discrepancy in the scope of the previous visit location between policy and practice. The first reason was distrust in the medical results provided by other institutions, and the second reason was difficulties in handling medical disputes involving other institutions once they happened. In practice, service quality and safety were the primary factors that nonprofit hospitals considered. Telemedicine services were only a supplement for traditional brick-and-mortar medical institutions [31]. Therefore, nonprofit hospitals were more cautious in assessments by the system, limiting the scope of previous visit locations to their hospital.

Most nonprofit hospitals did not have restrictions on the diagnosis of previous visits in the first assessment stage. Due to the ambiguity of national policies regarding the requirements of a patient's diagnosis for telemedicine services, it was difficult to quickly assess patient eligibility (except for a few hospitals that limit the scope of previous visit locations to the same department). The physicians always assessed patient eligibility related to the diagnosis of previous visits in the second stage and would terminate services if the patient's condition was not suitable for telemedicine.

Another frequently mentioned reason for differences was barriers to accessing patients' medical information in other institutions. The efficiency of assessment automatically performed by the system was higher than that manually performed by the physician. The system automatically limited the scope of previous visit locations to the same hospital to accommodate the large volume of telemedicine services in Beijing. However, national policies allowed patients to access telemedicine services after their first visit to a brick-and-mortar institution, regardless of the scope of the previous visit location. To be consistent with the policy's requirements, it is necessary to achieve interconnection among health systems in the region. Health information systems, including interoperability with electronic medical records, are a challenge in developing telemedicine services in other countries [32]. Systems that help with initial assessments would quickly capture patients' records at other institutions, reducing physicians' time and effort on evaluation. Beijing had already made a preliminary attempt in this regard. Physicians in 140 secondary and tertiary medical institutions had access to 181 test results and 300 imaging test results in these institutions, and the results were mutually recognized [33]. Access to test results laid the foundation for access to health information records in the future.

Reasons for the Discrepancies Between Policy and Practice in Private, For-Profit Institutions

Private, for-profit medical institutions were more lenient than nonprofit hospitals in assessing patient eligibility. Most of the private, for-profit institutions did not set requirements apart from the policy requirements. However, there was a possibility of relaxing the policy requirements in practical work. Most private, for-profit medical institutions initiated by enterprises took telemedicine services as their primary development direction. When enterprises were the main initiators of medical institutions, they focused on increasing operating income and achieving profitability [18]. Patient eligibility for telemedicine services was always assessed manually by physicians in these institutions, and the actual assessment criteria may have been more permissive than policy requirements. In addition, the private, for-profit medical institutions mainly provided psychological and traditional Chinese medical services, and the telemedicine services were also concentrated on psychological counseling and prescriptions. Physicians focused more on the patients' needs of current telemedicine visits rather than the prerequisites for the scope and diagnosis of previous visits.

International Telemedicine Policies

Telemedicine was once limited only to rural or remote communities but is now increasingly used to expand the geographic reach of health care services and improve access to care [34]. According to the 2023 report on the state of digital health in the World Health Organization (WHO), 78.4% (40/51) of the WHO Europe Member States directly addressed telehealth in their policies or strategies [35]. While the use of telemedicine was generally allowed in most countries, the eligibility requirements for telemedicine service users had changed due to the in-person visits sharply declining during the COVID-19 pandemic. Before March 2020, 36.7% (11/30) of the Organization for Economic Co-operation and Development countries allowed telemedicine only for patients who had an in-person visit in the past, but after March 2020, only 20.0% (6/30) of the countries imposed the requirement [36]. Unlike

XSL•FO
RenderX

most Organization for Economic Co-operation and Development countries, in China, an initial face-to-face meeting between the physician and the patient is still needed before telemedicine services, except for patients with COVID-related symptoms.

The establishment of patient eligibility requirements was primarily intended to ensure the safety of patients engaging in telemedicine services. The comprehensive framework designed by the WHO to enhance and streamline telemedicine services included a clinical risk assessment process. The process specified which services were safe for the patients to use independently and which needed expert medical support [37]. We observed that countries employed 2 methods to ensure safety: establishing telemedicine service lists or relying on physicians' professional judgment. The United States Drug Enforcement Administration allowed patients to obtain prescribed medications through telemedicine appointments, without requiring an initial in-person medical evaluation, except for prescribing controlled medications to new patients [38]. In Japan, it was the physicians' sole responsibility to determine whether telemedicine service was appropriate and safe [39]. Hungary not only restricted the types of telemedicine services but also mandated that physicians make the final diagnosis [39]. In China, the policy has not yet explicitly outlined a list of specific service types for telemedicine. At present, physicians play a key role in determining the services offered to patients and ensuring their safety. Experiences in other countries shed light on how China could refine its telemedicine policies.

Providing telemedicine services to new patients is expected to become a major trend in future health care, with ensuring patient safety as an essential component. A more profound understanding of what visits are appropriate for telemedicine and better triaging of visit types are crucial steps to maintain the quality of care [40]. However, the legal responsibilities of physical medical institutions and physicians regarding issues such as medical risk have not been fully clarified [41]. Supported by the telemedicine service list, the challenges and work-related stress for physicians can be alleviated.

Suggestions for Future Improvement

According to the above analyses, telemedicine policies could be optimized in the following aspects: first, the ambiguous parts of the policies could be clarified. Second, the content of telemedicine services for new patients could be added to the policies. Third, policies for telemedicine services would be made for nonprofit and private, for-profit institutions, respectively.

Explicit policies would help providers implement the requirements stipulated in the policies and make determinations about the applicability of telemedicine services more easily [42]. Although several policy interventions had been implemented at the national level, there was still a lack of specific service standards to direct frontline service delivery [31]. Specific disease names or diagnoses were not defined. A guideline could be made, including a comprehensive list of symptoms or diagnoses provided through telemedicine. Guidelines could also be considered when the most recent in-person visit occurs [42]. For example, the American Medical Association made the Telehealth Services Covered by Medicare and Included in the Current Procedural Terminology Code Set [43]. The United States Drug Enforcement Administration stated that a patient could receive a 6-month supply of buprenorphine through telehealth services; further prescriptions would require an in-person visit [38].

There were already some mature precedents for policymakers to refer to, allowing telemedicine health services for new patients. In the United States, telemedicine services were allowed reimbursement and expanded coverage for telehealth services to new and established patients from March 2020 [44,45]. An in-person visit within 6 months of an initial mental telehealth service is not required through September 30, 2025 [46]. After March 2020, 7 countries relaxed the prerequisite that patients were only allowed to have teleconsultations with physicians they had already consulted in person [36]. In this study, some institutions were found to provide telemedicine services for new patients. The service volume of 1 private, for-profit institution in 2023 was 134,715, ranked third among 36 institutions in this study. In the supervision process, it was found that this institution focused on psychological services and provided telemedicine services for new patients. However, no significant incidents had affected medical quality and patient safety. In the United States, 80% of the mental health treatment facilities that accepted new clients could offer telehealth services [47]. Telemental health use also increased substantially and globally during the pandemic and will remain in use for the foreseeable future [48,49].

In China, from the demand-side perspective, the conditions for opening up telemedicine services for new patients have been met under certain circumstances. Telemedicine services provide access to high-quality medical care, free up resources in overcrowded public hospitals [50], and also help to alleviate the uneven distribution of medical resources [51]. Telemedicine services before and during the COVID-19 pandemic had enhanced the delivery of and access to health care services [52] and increased satisfaction compared with usual in-person care [53]. They allowed unprecedented accessibility for those with mobility or geographical restrictions [54]. Considering the advantages of telemedicine services, there was also a need for new patients to access them.

However, to deal with the potential risks of providing services for new patients, the following measures could be considered. First, standardize the scope of telemedicine services (eg, ordering examinations or tests) for new patients to ensure medical safety [39]. Experts from various specialties would be engaged to develop a telemedicine service list for new patients, detailing diagnostic criteria, disease stages, and specific service items, as well as prohibiting telemedicine in unsuitable cases. Furthermore, developing an interoperable electronic medical record system that enables doctors to access patients' previous medical records and test results would enable physicians to understand patients' conditions more accurately. Second, select the diseases for which the diagnostic and treatment schemes are relatively mature with a high frequency of visits (eg, diseases of dermatology and psychology [47,55]) to meet the patients' needs for privacy protection and reduce the round-trip travel time [50]. Hospitals with high-quality telemedicine services could pilot telemedicine for new patients, starting with 2 - 3

XSL•FO
RenderX

medical specialties that carry low clinical risk. Third, improve the requirements for the professional experience and professional title of physicians who can provide telemedicine services for new patients. Finally, limit the scope of services covered by medical insurance funds. If the patient only needs a medical examination and related consultation, the patient would pay the relevant fees at his or her own expense.

The supervision policies of the services need to be formulated separately due to different initiators of institutions to ensure the quality and safety of services. The primary purpose of telemedicine services initiated by nonprofit hospitals is to expand the scope and intensity of hospital services, while the purpose of telemedicine services initiated by private, for-profit institutions is to increase the number of patients and gain benefits [18]. For nonprofit medical institutions with strict management, policies can appropriately relax the requirements of patient eligibility for telemedicine services and even prioritize providing telemedicine services for new patients. For private, for-profit institutions, policies need to restrict the types of telemedicine services provided by private, for-profit institutions and raise the requirements for the qualifications of physicians in telemedicine services. In addition, since most private, for-profit institutions manually assess patient eligibility by the physician, additional regulation is required (eg, making data of the service process traceable) to ensure the safety and quality of telemedicine services [56]. During regulation, the Supervision Platform can proactively monitor adverse events and quality deficiencies and automatically submit the above results to both medical institutions and the Center on a daily basis. The Center can also organize third-party experts to conduct annual inspections, and institutions that fail to meet the standards will be prohibited from providing telemedicine services.

Limitations

The 36 institutions selected for this study included those with high service quality and large service volumes, but those with lower service volume or quality were excluded. This is because, during routine inspections conducted by the Center, we found that these institutions often lacked stable management systems and assessment processes, making it challenging to reasonably compare their assessment processes with national policy. Therefore, these institutions were excluded from this study, making it impossible to characterize their follow-up criteria.

Additionally, there would be potential social desirability bias in interviews [57]. In an effort to minimize this potential bias, before conducting the interviews, we informed participants about the anonymization of data and ensured that their specific responses would not be disclosed; only the statistically analyzed group information would be made public. We also cross-validated interview results against previous inspection findings to ensure the authenticity of the results.

Finally, the study may have missed considerations and insights from policy formulation and regulatory constraints. Incorporating government perspectives could have enhanced the comprehensiveness of the study. We plan to submit our research results to the relevant government departments to inform policymakers about policy implementation and help elucidate the underlying reasons for the discrepancies between telemedicine policy and actual practice.

Conclusions

This pioneering multicenter, mixed methods study innovatively analyzed patient eligibility for telemedicine services in China, addressing the current gap in telemedicine policy research. The findings faithfully reflect the practices of the patient eligibility assessment process for telemedicine services in Beijing. Furthermore, by integrating quantitative and qualitative analyses, the study uncovered the underlying reasons behind discrepancies between institutional practices and national policy requirements, providing valuable insights about current implementation challenges. These results suggest potential improvements, including relaxing the regulation for new patients' access to telemedicine services, enhancing service delivery processes, and strengthening the robustness of the telemedicine supervisory framework.

Dynamic Indicators of Adherence and Retention in Adults Using a Digital Mental Health App: Longitudinal Observational Analysis From the Brighten Study

Abstract

Background: Making optimal use of mobile health technologies requires the validation of digital biomarkers, which in turn demands high levels of participant adherence and retention. However, current remote digital health studies have high attrition rates and low participant adherence, which may introduce bias and limit the generalizability of their findings.

Objective: This study aimed to identify longitudinal indicators of participant retention and adherence, which may serve to develop strategies to improve data collection in digital health studies and improve understanding of how study cohorts are shaped by participant withdrawal and nonadherence.

Methods: We performed secondary analyses on the Brighten study, which consisted of 2 remote, smartphone-based randomized controlled trials evaluating mobile apps for depression treatment, enrolling 2193 participants in total. Participants were asked, after baseline assessment, to complete 7 digital questionnaires regularly. We assessed adherence to digital questionnaires, engagement (postbaseline participation), and retention rates (the proportion of participants who continued completing questionnaires over time) as outcomes. We investigated the relationship between these outcomes and both static measures (eg, demographics and average questionnaire scores) and dynamic measures (eg, changes in questionnaire scores over time).

Results: The study included 2201 participants, of whom 1093 completed at least 1 nonbaseline questionnaire, with a median completion rate of 37.6% (IQR 15.5%-67.9%). We found significantly higher adherence rates in participants who were less depressed on average over the course of the study (t_{752}=−5.63; P<.001) and in those who perceived clinical improvement (t_{744}=3.78; P=.001). There were significant demographic differences in adherence and engagement, including differences by gender, race, education, income, and income satisfaction. Participants who were more depressed at baseline were more likely to withdraw before completing any nonbaseline questionnaire (t_{1917}=−2.53; P=.01). However, participants who showed improvement in depressive symptoms during the study showed better adherence (Mann-Whitney U=127,084; P<.001) and retention (hazard ratio 0.78, 95% CI 0.67-0.91; P=.002), despite showing greater depressive symptoms at baseline.

Conclusions: We show that participants' clinical trajectory of depressive symptoms, as well as their perception of improvement, are important indicators of engagement, adherence, and retention. Expanding knowledge regarding these longitudinal indicators may improve interpretation of outcomes and help build strategies to improve retention and adherence in future clinical trials.

Introduction

Over the past decade, researchers have dedicated significant effort to identifying clinically useful biomarkers for preventing, diagnosing, and treating psychiatric disorders. Digital biomarkers have garnered considerable attention, as they enable the observation of long-term patterns and trends outside of the hospital or clinic environment, potentially enhancing our understanding of the course of mental illnesses [1,2]. Identifying reliable digital biomarkers has the potential to significantly improve the accuracy of diagnoses, predictions of clinical outcomes (eg, suicidal ideation [3]), and treatment

XSL•FO
RenderX

decision-making regarding psychiatric disorders [4-6]. Furthermore, collecting digital biomarkers is cost-effective [7,8] and allows the possibility to provide patients with feedback through electronic reports, giving them ownership of their own medical data [9-12].

One major challenge for the effectiveness of mobile health technologies is the identification and validation of digital biomarkers [13-16]. This process requires high levels of participant adherence and retention to ensure sufficient data are collected for validation purposes. Active data collection methods, such as digital questionnaires, which are often needed to help validate or contextualize digital biomarkers, intensify this challenge as they demand more time and effort than passive data collection methods such as actigraphy [17,18]. While passive measures may be useful, their validation depends on access to actively collected assessments of patient status. Therefore, understanding the drivers of participant adherence to data collection methods requiring active participation is crucial for the effective design and validation of digital biomarker collection platforms. Eysenbach described the "law of attrition," the tendency for a significant proportion of users to drop out or stop using eHealth mobile apps before completing a trial [19-23]. This dropout may shape the cohort over time in a way that does not represent the initially recruited study population in terms of demographic features, symptomatology, and clinical outcomes, therefore inducing bias in the analyses [16,24].

In studies requiring active remote digital participation, such as completing questionnaires, a few static parameters (ie, those that do not change over the course of the study) have been associated with adherence rates (the degree to which participants follow the study protocol and complete assessments), engagement rates (the proportion of participants who engage in the study after baseline, ie, who complete at least 1 nonbaseline questionnaire), and retention rates (the proportion of participants who continue to complete questionnaires over time). Previous studies suggest that participants who are more depressed at baseline, younger, and less educated tend to have lower assessment adherence rates [16,25,26]. Retention rates can also vary between treatment arms involving mobile apps versus control groups, where control groups with lower engagement requirements may often show better retention, and between ethnic groups [27]. A lower annual income also tends to be significantly associated with poorer study engagement [26].

These static parameters, often of a demographic or symptomatologic nature and considered as averages rather than longitudinal measures, provide meaningful insight into the question of participant engagement in active digital phenotyping. However, there has been less exploration of how dynamic parameters, such as longitudinal symptom change, might affect engagement. Therefore, the objective of this study was to identify novel predictive longitudinal markers of adherence, engagement, and retention to regular self-rated assessments in participants enrolling in a remote digital health study requiring active participation. To do so, we conducted secondary analyses on the Brighten study, a large longitudinal digital intervention study.

Methods

Study Design

The Brighten study consists of 2 completely remote, smartphone-based randomized controlled trials assessing the efficiency of mobile apps for treating depression. The study recruited 2193 participants from the United States through online advertisements, with recruitment for the first version (V1) beginning in August 2014 (recruitment lasted 5 months) and the second version (V2) starting in August 2016 (recruitment lasted 7 months), enrolling 1110 and 1083 participants, respectively [25,26]. Participants were included in the Brighten study if they had a score of 5 or higher on the Patient Health Questionnaire (PHQ)-9 or a score of 2 or greater on PHQ item 10 [28]. The study evaluated 3 interventions over 12 weeks: (1) iProblemSolve (iPST), an app designed by UCSF for problem-solving therapy [25,29,30]; (2) Project: EVO (Akili Interactive Labs), a therapeutic video game; and (3) Health Tips, an app offering strategies to improve mood [28]. The group using Health Tips was considered the control group. In those 2 randomized controlled trials, various questionnaires were sent to participants via smartphone notifications. Most assessments were submitted daily, weekly, or biweekly, but some questionnaires were only sent at baseline. The Brighten study also collected passive digital communication data from the V1 and V2 cohorts, along with passive mobility features from the V2 cohort. While V2 followed a protocol very similar to V1 (same interventions and active data collection methods), it specifically aimed to increase participation among individuals of Hispanic or Latino ethnic backgrounds to assess the feasibility of using digital mental health tools in this population [28].

Intervention Apps

The iPST app implements a 7-step problem-solving therapy model to manage mood: participants select a goal and are guided through a structured action plan. Participants assigned to this app were instructed to use it at least once per week, consistent with typical clinical use [31].

Participants assigned to Project: EVO were encouraged to use it 6 times per week for approximately 30 minutes per day. This video game–based app aimed at enhancing cognitive skills related to depression using adaptive algorithms to adjust difficulty to the user's proficiency [32]. Previous studies of the app's predecessor showed that this dosage improved cognitive control and depressive symptoms in older adults [32,33].

The control group used an app providing daily health tips, such as self-care (eg, showering) or physical activity (eg, walking). Participants in this group were not required to act on the tips, serving as a supportive control condition.

Importantly, all participants, regardless of their assigned intervention, completed their self-rated questionnaires in a separate study app. Our analyses specifically focused on adherence, engagement, and retention with these assessments.

Measures

Demographics such as gender, education level, working status, income satisfaction, last-year income, marital status, race, and

XSL•FO
RenderX

age, as well as parameters regarding study involvement (how they heard about the study, device used, and study version), are provided in Multimedia Appendix 1. These parameters, along with baseline PHQ-9 results, were imputed using MissForest, a nonparametric missing value imputation for mixed-type data, if less than 30% of the data were missing for that specific metric. This threshold was chosen based on validation studies demonstrating the reliability of MissForest under these conditions [34]. Participants were sent 7 questionnaires to complete at a predefined frequency specific to each questionnaire: PHQ-9 [35] (weekly for the first 4 weeks and then biweekly) and PHQ-2 [36] (daily); a 3-item sleep assessment assessing sleep onset latency, sleep duration, and time awake at night (weekly); the Sheehan Disability Scale (SDS) [37] (weekly for the first 4 weeks and then biweekly); the Patients Global Impression of Change (PGIC) Scale [38] (weekly); a survey inquiring about the use of mental health services (weekly); a survey inquiring about study app satisfaction (deployed at weeks 4, 8, and 12); and a survey inquiring about the use of other health-related apps (deployed at weeks 1, 4, 8, and 12) [28]. All questionnaires included in our analyses are provided in Multimedia Appendix 1.

Outcomes

We evaluated 3 key outcomes: adherence, engagement, and retention. To evaluate individual adherence, each participant's average completion rate was calculated as the ratio of completed questionnaires to the total number they were expected to complete. Engagement was binary: participants were considered engaged if they completed at least one nonbaseline assessment and disengaged otherwise. Therefore, disengaged participants, by definition, had a completion rate of 0%. Engaged participants were further divided into high- and low-completion groups, based on the median average completion rate. Based on previous research, engaged participants were also categorized into "improvers" and "nonimprovers" based on the difference between their baseline PHQ-9 score and their latest PHQ-9 score, with a minimum clinically important difference set at 5 points [39]. Therefore, engagement captures a binary distinction (completion beyond baseline), adherence represents a continuous measure of completion, and the subgrouping serves only as a descriptive stratification of engaged participants. Participant retention was determined as the duration for which participants continued completing a specific representative questionnaire (eg, PHQ-9) before they withdrew or stopped responding. It is important to consider that participants in the iPST and Project: EVO intervention groups were asked to use the apps as part of their treatment, but data on their engagement or adherence to the interventions were not available, so treatment adherence was not included as an outcome.

Statistical Methods

To compare engagement and average completion rates across demographic groups, Mann-Whitney U tests were used for 2-group comparisons, and Kruskal-Wallis tests followed by Dunn post hoc tests were applied for comparisons involving more than 2 groups.

A *t* test was conducted on average questionnaire scores and baseline scores between high and low completion groups, evaluating the importance of symptom severity as a static indicator of adherence. A *t* test was also conducted on baseline PHQ-9 scores between the engaged and disengaged groups to assess whether engagement was associated with baseline depressive symptoms.

To assess the potential of symptomatology as a dynamic predictor of adherence, trends in questionnaire scores over time between high and low completion groups were investigated using a repeated measures generalized linear model (GLM).

Elastic net regression with Shapley additive explanations (SHAP) values [40] was used to identify the top 5 predictive features for average completion rate, engagement status (engaged/disengaged), and completion group (high/low), incorporating demographic parameters, average questionnaire scores, and depressive symptom improvement. The models were subsequently retrained without including the study version (V1/V2) as a feature to assess its impact. Model generalizability was assessed by training on passive data from the V1 cohort and testing on the V2 cohort.

To study the impact of depression symptom improvement on adherence, differences in average completion rate and PHQ-9 completion rate between improvement groups were assessed using Mann-Whitney U tests. A robust linear model (RLM) regression was performed with improvement status, controlling for baseline PHQ-9 scores, to predict average completion rate. The RLM was chosen over other regression techniques to handle potential outliers in the data [41].

Cox proportional hazards models were constructed to predict retention, measured as time to last PHQ-9 questionnaire completion, between improvers and nonimprovers, incorporating demographic parameters and average scores from other questionnaires as covariates to evaluate their utility in predicting retention. We chose to study retention for the PHQ-9 rather than globally because completion rates and the frequency with which the questionnaires were sent to participants varied significantly between questionnaires, potentially compromising the reliability and validity of a comprehensive retention measure for survival analysis; the PHQ-9 was chosen as a representative questionnaire given its utility in usual clinical practice. Kaplan-Meier curves were plotted for these models to illustrate assessment retention over time.

Ethical Considerations

Ethical approval for both parent trials (V1: NCT00540865 and V2: NCT01808976) was granted by the Institutional Review Board of the University of California, San Francisco. Participants provided informed consent that included permission for their data to be shared with other researchers for secondary analyses, in line with the National Institute of Mental Health data-sharing policy (NOT-MH-19-033). Our study used only these deidentified datasets and involved no direct interaction with participants.

XSL•FO
RenderX

Results

Outcomes

There were 2201 participants in the dataset. Among them, 1093 were engaged, meaning they completed at least 1 nonbaseline questionnaire, and 1108 were disengaged. In the engaged group, the median average completion rate was 37.6% (IQR 15.5%-67.9%), and the mean was 40.6% (SD 24.2%). Within the engaged group, 548 participants had a mean completion rate higher than the median and were classified as the high completion group (mean 62.3%, SD 11.5%), while 550 participants were classified as the low completion group (mean 19%, SD 9.9%). The average completion rate for the entire cohort was 20.2% (SD 26.5%) for the whole cohort.

Demographics and Study Parameters

Kruskal-Wallis tests and Mann-Whitney U tests showed significant disparities in average completion rate and engagement between groups defined by gender, education, income satisfaction, last-year income, race, device used, study arm, and study version (Table 1). The findings on average completion rate align with previous literature [16,25,26], while the engagement findings are novel, with engagement defined as whether participants chose to remain in the study after completing the baseline assessments.

Table . Significant differences (P<.05) in engagement rates between groups defined by demographics or study parameters.

Category[a]	Engaged (n=1093)	Disengaged (n=1108)	P value[b]
Sex, n (%)			
Male	236 (21.59)	311 (28.07)	.025

[a]Percentages for a given category were calculated on the total number of engaged or disengaged participants. A participant is defined as being “engaged” if they completed at least 1 nonbaseline questionnaire of any kind. Participants who dropped out of the study immediately after baseline, without completing any nonbaseline questionnaire, are classified as “disengaged.”

[b]Bonferroni correction applied.

[c]iPST: iProblemSolve.

Symptomatology

To evaluate the impact of baseline symptomatology and average symptom severity over the course of the study on adherence, we compared baseline questionnaire scores and average questionnaire scores between high and low completion groups. After Bonferroni correction, the mean scores of the PHQ-2, PHQ-9, and PGIC questionnaires collected over the 12-week duration of the study were significantly different between high

XSL•FO
RenderX

and low completion groups (P<.001 for PHQ-2 and PHQ-9 and P=.002 for PGIC). Participants with lower PHfQ-2 scores and PHQ-9 scores (ie, less depressed participants), and participants with higher PGIC scores (ie, those who perceived better clinical improvement since the beginning of the study) were more likely to be in the high completion group. This suggests that participants with lower depression levels and perceived improvement in their clinical condition showed greater adherence compared to those with higher depression levels and perceived worsening of their condition (Table 2). Mean baseline PHQ-9 score was 13.9 (SD 4.8) for the engaged group and 14.4 (SD 5.0) for the disengaged group, with the difference being statistically significant (t_{1917}=−2.53; P=.01). This indicates that participants who were less depressed at baseline were more likely to complete at least 1 nonbaseline questionnaire; however, these baseline scores were not predictive of adherence in subsequent assessments.

Table . Comparisons of questionnaire scores averaged over the 12-week study period between high and low completion groups.

Questionnaire	High completion rate (SD)	Low completion rate (SD)	*t* score (*df*)	*P* value[a]
Mean score				
PHQ-2[b]	4.50 (1.52)	5.20 (1.84)	−6.793 (1019)	1.49×10^{-10}
PHQ-9[c]	9.30 (4.87)	11.27 (5.43)	−5.632 (752)	2.01×10^{-7}
Sleep assessment	7.23 (1.68)	7.43 (2.09)	−1.625 (768)	.837
SDS[d]	21.32 (8.50)	22.80 (9.21)	−2.658 (968)	.064
PGIC[e]	2.66 (0.97)	2.40 (1.07)	3.78 (744)	.001
Baseline score				
PHQ-9	13.75 (4.83)	13.96 (4.86)	−0.709 (1091)	≥.99

Clinical Improvement

To investigate the longitudinal relationship between questionnaire scores and adherence, we conducted a repeated measures GLM model of mean score over time for both high and low completion groups. We found that there was significant improvement in PHQ-2 scores (coeff=−0.01, 95% CI −0.01 to −0.01; P<.001) and PHQ-9 scores (week: coeff=−0.24, 95% CI −0.35 to −0.14; P<.001) over time for both high and low completion rate groups. Daily PHQ-2 scores were not significantly different between the 2 groups (coeff=0.04, 95% CI –0.14 to 0.22; P=.70), but the effect of time on the scores was statistically significant, with participants from the high completion group having a greater decrease in score over time (coeff=–0.012, 95% CI –0.014 to –0.009; P=.001) (Figure 1A). Averages of PHQ-9 score for each weekly (or biweekly) assessment over time were significantly different between the 2 groups (coeff=1.29, 95% CI 0.24 to 2.34; P=.021), but the longitudinal trend was similar (coeff=0.03, 95% CI –0.123 to 0.184; P=.70), with PHQ-9 scores decreasing significantly over time (coeff=–0.24, 95% CI –0.35 to –0.13; P<.001) (Figure 1B). Furthermore, the decrease in sample size regarding completion of PHQ-9 and PHQ-2 was significantly different between high and low completion groups (P_{PHQ-9}=.02 and P_{PHQ-2}<.001), with the sample size from the low completion group decreasing more rapidly. For other questionnaires, such as the sleep assessment, PGIC, and SDS, there was no statistically significant difference in the rate of sample size decrease between the high and low completion groups. There were no significant differences in SDS, PGIC, and sleep assessment scores between the 2 groups, although SDS scores decreased significantly over time for the 2 groups in a similar fashion (coeff=–0.84, 95% CI –1.17 to –0.50; P<.001). The effect of time on sleep assessment scores was found to be different between the groups, but it was nonsignificant (P=.08; Figure 1).

XSL•FO
RenderX

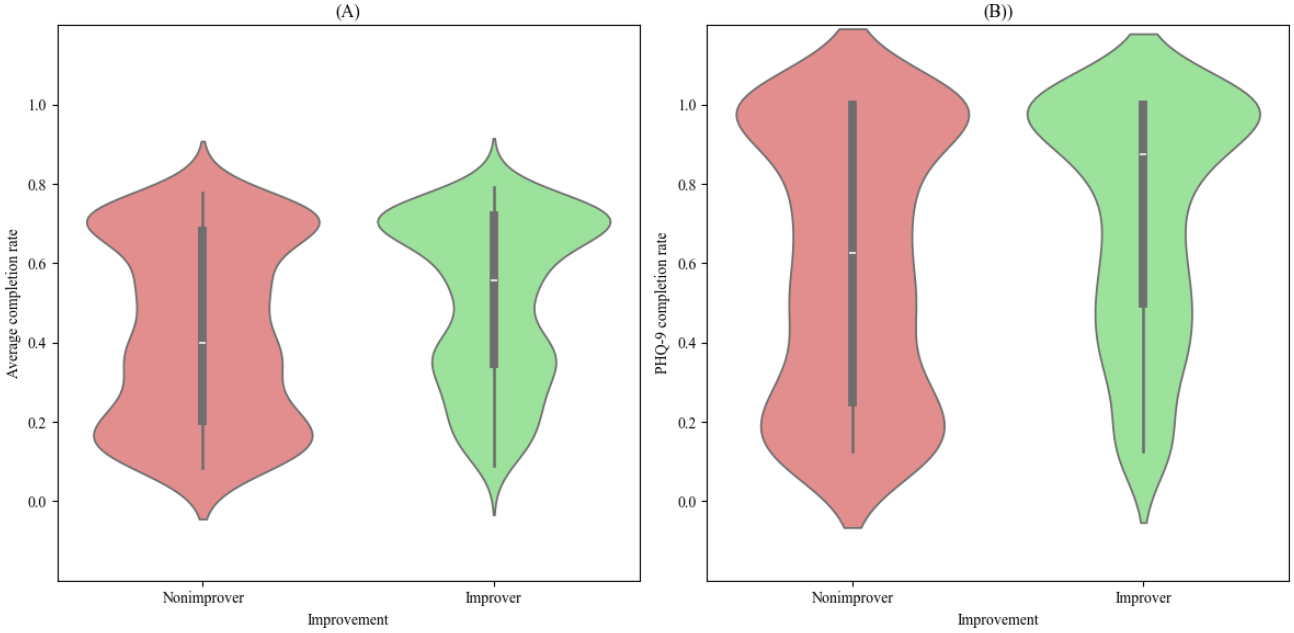

Figure 1. Mean scores over time for high- and low-completion groups by assessment, including sample sizes. (A) Mean Patient Health Questionnaire (PHQ)-2 score over time by completion group, (B) mean PHQ-9 score over time by completion group, (C) mean Patients Global Impression of Change (PGIC) score over time by completion group, and (D) mean Sheehan Disability Scale (SDS) score over time by completion group.

To evaluate the association between clinical improvement regarding depressive symptoms and adherence, we divided the engaged cohort into improvers and nonimprovers. The categorization was based on the difference between participants' baseline PHQ-9 score and their latest PHQ-9 score, using the minimal clinically important difference of 5 points as the threshold for meaningful improvement [39]. There were 410 "improvers" and 513 "nonimprovers." Between those groups, there was a significant difference in average completion rate (improvers: mean 50.7%, SD 20.6%; median 55.5%; nonimprovers: mean 42.6%, SD 22.7%; median 39.9%; and Mann-Whitney U=127,084; P<.001), PHQ-9 completion rate, and baseline PHQ-9 score (P<.001 for all comparisons), with "improvers" having higher baseline PHQ-9 scores than "nonimprovers" (Mann-Whitney U=137,574; P<.001) (Figure 2A and 2B). Mean baseline PHQ-9 score was 15.3 (SD 4.7) for improvers and 12.6 (SD 4.6) for nonimprovers. The RLM regression model showed that the average completion rate of "nonimprovers" was, on average, 8.85% (P<.001) lower than that of "improvers." However, for both groups, baseline PHQ-9 scores were not significantly associated with average completion rates (P=.06; Figure 2).

XSL•FO
RenderX

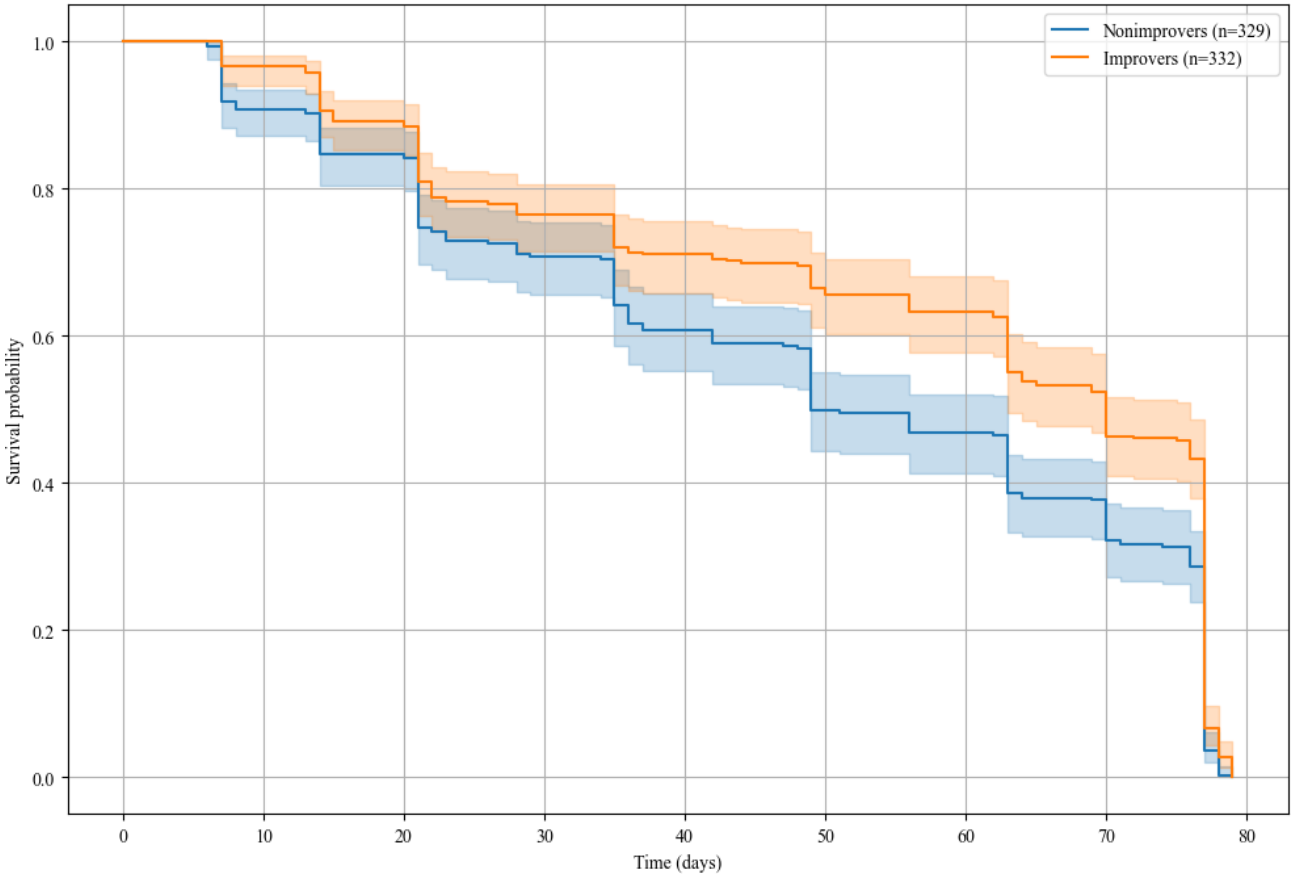

Figure 2. Comparison of adherence between improvers and nonimprovers. (A) Average completion rate (Mann-Whitney U score=127084; *P*<.0001 and (B) Patient Health Questionnaire (PHQ)-9 completion rate (Mann-Whitney U score=125418; *P*<.0001). Average completion rate is defined as the total number of questionnaires completed divided by the total number of questionnaires sent to participants. PHQ-9 completion rate is defined as the total number of PHQ-9 questionnaires completed divided by the total number of PHQ-9 questionnaires sent to participants.

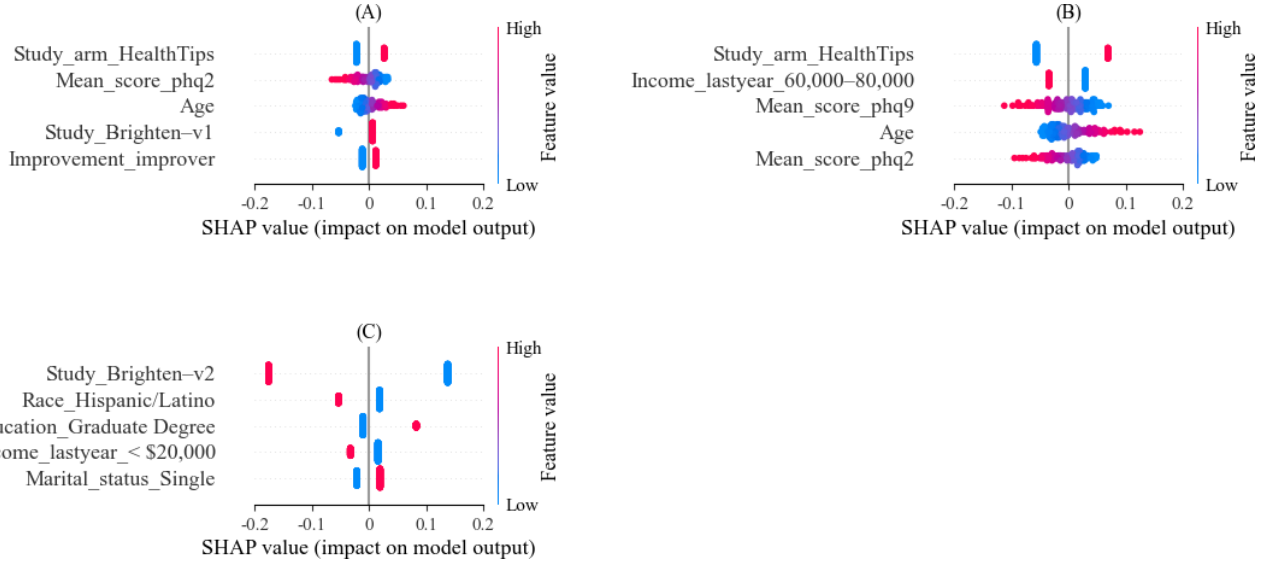
To study PHQ-9 retention, defined as the duration for which participants continued completing the PHQ-9, we performed a Cox proportional hazards model to compare improvement groups, using demographic parameters [1], average scores from other questionnaires, and study version as covariates. The Cox proportional hazards model revealed significant differences in survival probabilities between the 2 groups (hazard ratio 0.78, 95% CI 0.67-0.91; *P*=.002), with the event defined as the day a participant completed their last PHQ-9 questionnaire within 12 weeks from the start of the study. The median survival time was 70 days (mean 56.8, SD 24.7) for improvers (n=332) and 49 days (mean 49.4, SD 25.6) for nonimprovers (n=329), indicating that nonimprovers stopped completing PHQ-9 questionnaires 7.4 days earlier on average compared to improvers (Mann-Whitney U=64632; *P*<.001). We found that age (*P*=.002), mean score of the sleep assessment (*P*=.01), and study version (*P*<.001) were significant predictors of PHQ-9 retention (Figure 3). Cox proportional hazards model based on the PHQ-2 questionnaire is provided in Multimedia Appendix 2.

XSL•FO
RenderX

Figure 3. Kaplan-Meier curves showing retention for improvers versus nonimprovers, with the event defined as the last Patient Health Questionnaire (PHQ)-9 questionnaire completed within the 12-week study duration (n=661). Significant survival differences were observed (improver Coef=−0.25, Exp(coef)=0.78; *P*<.005). Key predictors: age: Coef=−0.01, Exp(coef)=0.99; *P*<.005); mean score sleep: Coef=0.06, Exp(coef)=1.06; *P*=.01); and study Brighten-v2: Coef=0.79, Exp(coef)=2.19; *P*<.005). Bonferroni correction was applied.



Key Indicators of Adherence and Engagement

To assess what features were most statistically useful in predicting average completion rate and engagement, we trained an elastic net regression model on 80% of the data and tested it on the remaining 20%. SHAP values were used to assess the relative importance of each feature and evaluate their contributions to the model's predictions (Figure 4). For predicting average completion rate, the 5 most useful features, in order of importance, were (n=701; mean squared error [MSE]=0.04) (1) being in the control group, (2) having a low mean PHQ-2 score, (3) being older, (4) being in the V1 cohort, and (5) improving in depressive symptoms (Figure 4A).

XSL•FO
RenderX

Figure 4. Top 5 features and their Shapley additive explanations (SHAP) value for predicting compliance metrics using elastic net regression. (A) Top 5 features for predicting average completion rate (n=701; mean squared error [MSE]=0.04), (B) top 5 features for categorizing participants into high and low completion groups (n=701; F_1-score=0.72), and (C) top 5 features for predicting whether a participant will be "engaged" or "disengaged" (n=2201; F_1-score accuracy=0.66).

The 5 most important features associated with being in the high completion group were (n=701; F_1-score=0.72) (1) being in the control group, (2) not being in the US $60,000-US $80,000 annual income group, (3) having a low mean PHQ-9 score, (4) being older, and (5) having a low mean PHQ-2 score (Figure 4B).

The 5 most important features associated with "engaging" in the study were (n=2201; F_1-score=0.65) (1) being in the V1 cohort, (2) not being a Hispanic or Latino person, (3) having a graduate degree, (4) having an annual income greater than US $20,000, and (5) being single (Figure 4C).

To assess the impact of study version (V1/V2) on the models' predictability, we conducted an exploratory analysis excluding it from the features and found that the categorization models (engagement and completion group) performed slightly worse, although the 5 most important features were generally similar (F_1-score decreased from 0.72 to 0.67 for completion group categorization and from 0.66 to 0.60 for engagement categorization). The average completion rate model MSE did not change, although the R^2 decreased from 0.16 to 0.13.

When trained on the V1 cohort and tested on the V2 cohort, the categorization models performed poorly (F_1-score=0.32 for engagement categorization and F_1-score=0.46 for completion group categorization). The model predicting average completion rate had slightly worse predictive performance (MSE=0.04; R^2=0.12).

Discussion

Principal Findings

We found that the subjective perception of a participant's own clinical trajectory (PGIC score) was associated with assessment adherence, with participants who reported a perceived improvement in their clinical condition showing greater adherence. We also found that increased depressive symptoms at baseline were not significantly associated with adherence, but rather with engagement, thus suggesting that more depressed participants were more likely to withdraw immediately after baseline assessment. Furthermore, participants who improved regarding depressive symptoms had greater assessment adherence and retention, despite having higher depressive symptoms at baseline. Previous research has established a link between baseline depressive symptoms and engagement [13]. This study makes novel contributions by exploring the associations between perceived clinical improvement and adherence, as well as the connection between depressive symptom improvement, baseline depression severity, retention, and adherence.

Despite offering monetary incentives, the researchers conducting the Brighten study observed poor engagement and adherence, highlighting the need to investigate this issue further and explore innovative strategies to address this limitation [25]. The demographic parameters we found associated with lower adherence and engagement are similar to what has been found in previous literature (ie, male sex, lower education, lower income, poorer income satisfaction, and Hispanic or Latino race were associated with poorer adherence) [16,25,26]. However, we found that a perceived worsening of clinical condition throughout the study was associated with less assessment adherence, suggesting that a participant's own perception of their change in activity, symptoms, emotion, and quality of life can influence their willingness to complete assessments.

Regarding completion of the PHQ-9 questionnaire, there was a significant difference in retention probability, with participants who improved in depressive symptoms having more chance of continuing to complete assessments than nonimprovers. Age, mean score of sleep assessment, and study version were significant features for predicting retention. Therefore, the global change in depressive symptoms over time was associated with study retention and adherence rate. These findings highlight the

XSL•FO
RenderX

possibility of attrition bias in digital health studies, leading to an overestimation of symptom severity improvement. Furthermore, this kind of bias could lead to misleading conclusions about the effectiveness of treatments and affect clinical decision-making, reinforcing the importance of controlling for attrition rates in digital health studies [42]. However, a possible limitation of the retention analyses is the lack of insight regarding improvement for nonimprovers who stopped completing answering questionnaires early in the study, as they may have eventually experienced symptom improvement that went unrecorded.

The study arm was the most important indicator of assessment completion rate, with participants from the control group having higher completion rates than participants using the Project: EVO app or the iPST app. Moreover, the finding that participants in the iPST group, who were encouraged to use the app once per week, showed higher adherence than those in the Project: EVO group, who were asked to use it 6 times per week, suggests a trade-off between effort and study engagement. Participants required to invest more time in the digital intervention were more likely to skip assessments. We found that baseline PHQ-9 score, although predictive of engagement (serving as an initial "filter" for participants continuing in the study), was not an important indicator of adherence, highlighting the need to focus on clinical trajectories in addition to static measures. In addition, participants who improved significantly in their depressive symptoms had higher completion rates than participants who did not, and their baseline PHQ-9 scores were significantly higher, although, as mentioned, baseline PHQ-9 score is not a direct indicator of completion rate. This suggests that while initial severity is not directly linked to longitudinal adherence, positive clinical progress may encourage consistent assessment completion. In fact, we found that participants who significantly improve regarding depressive symptoms are less likely to withdraw from active completion of assessments than participants who do not. Interestingly, it is also worth considering that the capacity to regularly complete questionnaires might be a potential predictor of future improvement in depressive symptoms.

Limitations

This study presents several limitations. The most important limitation is the lack of data on participants' use of the intervention apps, particularly the project: evo group, whose participants were encouraged to use the app 6 times per week. As a result, we were unable to assess whether engagement with the intervention apps influenced participants' engagement with questionnaire completion. However, our primary interest was in questionnaire completion, as this measure is more directly comparable across digital health studies and thus is the most applicable for broader research contexts. In addition, the GLM repeated measures analysis revealed intriguing patterns and trends in the effect of time and adherence on questionnaire scores, but the rapid decline in sample size over time limits the strength of any conclusions that can be drawn. The elastic net regression models showed only modest performance, with clear potential for improvement. Feature engineering, the collection of larger feature sets, hyperparameter tuning, and time-series transformations are potential strategies that could enhance the accuracy and robustness of the models by improving their ability to recognize underlying patterns, as well as identify temporal dynamics within the data [43-45]. Given the model's limited fit, SHAP value interpretations for top features should be regarded as exploratory. Furthermore, we were not able to generalize the model's predictability across cohorts, highlighting the need for further validation with diverse datasets to ensure its applicability in a realistic transdiagnostic population [46,47]. The limited data available for passively collected variables, such as communication and mobility features, resulted in inconclusive analyses including these variables (refer to Multimedia Appendix 3).

Future Directions

To address adherence and retention challenges in future studies, implementing continuous monitoring systems to identify participants at risk of dropping out could be beneficial [48]. Targeted outreach strategies, such as personalized reminders or support interventions, may help engage these individuals and improve adherence [49,50]. Monetary incentives have also been shown to be effective in increasing adherence and retention rates, though this may be impractical when attempting more naturalistic designs [51-53]. Beyond these approaches, qualitative research is crucial to better understand the underlying reasons for disengagement. Previous user-centered studies indicate that underserved users often cite stigma, cultural mismatch, and usability issues as barriers, while individuals with lower education or digital literacy report practical challenges and a higher perceived time burden when using mobile health apps [54,55]. Conducting more extensive qualitative work would provide valuable insights into how participants perceive their improvement and clinical trajectories, thereby offering a more comprehensive understanding of user challenges and informing strategies to strengthen engagement, adherence, and retention.

Conclusion

Although demographics are useful in predicting adherence, engagement, and retention in digital health studies, we show that dynamic, measurable parameters regarding symptomatology and symptom change are also important in understanding longitudinal patterns of attrition and adherence, and that they play a crucial role in shaping the remaining cohort as long-term studies progress over time [16,24]. We have shown that participants' impressions of their own improvement and the clinical trajectory of participants regarding depressive symptoms are important indicators of engagement, adherence, and retention. Further research is needed to assess the causality and implications of this effect and to determine optimal strategies for countering the bias that this phenomenon introduces into datasets.

Abstract

Background: Digital solutions are gaining increasing importance and present a challenge regarding their introduction and acceptance into professional medical environments. Significant advances have been made regarding the availability, safety, and ease of use of data generated by a multitude of devices and wearables. However, data security and data protection are delaying factors. The underlying analysis focuses on the use and acceptance of digital solutions, and their respective differences between health care professionals and patients.

Objective: This study examines the current use and acceptance of digital solutions among health care professionals and patients. In addition, it derives an outlook on future developments and expectations in the setting of innovative technologies able to penetrate the health market.

Methods: An anonymous web-based survey of 23 multiple-choice and 3 open-text questions was conducted among medical professionals and patients between April and September 2023. In this study, quantitative analysis was performed using Python, with Pandas for data processing and Matplotlib for visualization. Chi-square tests were used to analyze binary categorical data, while Mann-Whitney *U* tests were used to evaluate ordinal data. Additionally, a qualitative analysis was conducted to summarize the results of the open-ended questions.

Results: During 178 days, the survey garnered 2058 clicks, resulting in 1389 participants (67.5% response rate). A total of 1002 participants completed the entire questionnaire, while 387 (27.9%) did not finish. Incomplete responses were excluded from the comprehensive analysis. The sample comprised 271 (27%) physicians and 731 (73%) patients. The study found significant agreement between both groups in adopting and foreseeing the use of digital health tools and telemedicine. Both groups recognized the future importance of digital health without substantial differences.

Conclusions: Overall, attitudes toward digital health and telemedicine were consistent, reflecting a uniform acceptance and expectation of these technologies among health care professionals and patients. The consensus on telemedicine's future role over the next 5 years indicates a unified vision for digital health paradigms. These consistencies between the 2 groups might be future drivers for improvements in accessibility, convenience, and efficiency in health care delivery.

eHealth; digital health; medical data use; information; survey; adoption

Introduction

Digital innovation in health care is accelerating in growth and presence in the media, while the regulatory framework is constantly evolving and adopting. Digitization has found its role in everyday medical life. It is of paramount importance to understand its use and acceptance to improve and continuously develop technology-based health offerings.

XSL•FO
RenderX

First of all, it makes sense to define the term *digital health*: in the search for a unified definition, diverse terminologies and conceptual frameworks are identified in the literature. Fatehi et al [1] conducted a quantitative analysis and term mapping of 95 unique definitions, revealing that digital health is predominantly concerned with the provision of health care rather than the mere use of technology. Their findings highlight a focus on the well-being of individuals at both population and individual levels, emphasizing the use of data and information to enhance patient care. The prevalence of mobile health (mHealth) as a dominant concept within digital health ecosystems was evident, closely interlinked with telehealth and artificial intelligence (AI) applications [1]. In turn, digital health can be subcategorized into a variety of dimensions. eHealth (and its subset mHealth) serves as a foundational category, in which health information technology plays a critical role, focusing on the management and exchange of health information through electronic health records and interoperability systems [2,3]. In the following, these definitions will be assumed for this study.

Developments have been catalyzed by the global COVID-19 pandemic situation [4] and by early legislation in favor of digital health applications (eg, in Germany under the acronym DiGA [*Digitale Gesundheitsanwendungen*]) [5]. Many promises—such as the availability of telemedicine—have been met, while specific needs regarding data storage are strongly underserved [6]. The use and development of digital health applications differ in addressing the needs of professionals versus those of patients. Acceptance is influenced by factors varying in complexity and depth, often driven by fears or lack of understanding. National legal and technical regulations have yielded a desired increase in the development and usage of digital health care solutions. The underlying study examines the current status and the drivers and barriers of this development, which have been found to be major influencing factors in the adoption of digital technologies in health care [7]. Specifically, it analyzes the gaps in the aforementioned categories between patients and professionals. Additionally, it helps understand the current and future needs of digital health and the requirements for offered applications.

A multinational survey among health care professionals and patients focused on this delta, its underlying reasons, and the consecutively arising demand specifically regarding the following five research questions:

1. How do estimations of the future importance of digital health differ between patients and professionals?
2. How do patients and professionals estimate their future use of digital health solutions?
3. Which areas offer specific innovation potential in digital health from the perspective of patients and professionals?
4. Which key obstacles to using digital health solutions do patients and professionals identify?
5. How does the use of web-based access differ toward health data, electronic appointment booking, and telemedicine?

Every nonmedical professional from the general population is considered a patient for research purposes.

Methods

Web-Based Survey

An anonymous web-based survey, adopted from some of the authors' [FS, VF, GME, DP] earlier research in 2018 [8], was conducted between April and September 2023 via the scientific survey platform SoSci Survey [9] hosted on German servers complying with European data protection laws. The survey was initiated with an introductory question distinguishing between patients and physicians, deciding on the further direction of the questionnaire. Depending on the chosen branch, 19 questions for patients and 25 for physicians followed, 3 of which were open-text questions. The questionnaire was provided in German and English and was available for 6 months: 6 April through 30 September 2023. Only fully completed questionnaires were considered for final analysis to guarantee consistent data quality.

The link to the web-based survey was distributed via publications in scientific journals such as *Die Unfallchirurgie*, the networks of the German Society for Orthopaedic and Trauma Surgery (*Deutsche Gesellschaft für Orthopädie und Unfallchirurgie*) and the German Society for Surgery (*Deutsche Gesellschaft für Chirurgie*), and web-based communication platforms such as LinkedIn and university web pages to reach a broad range of participants in both the professional field and among patients.

Participants were asked a set of specific questions regarding their personal and professional use, their acceptance and future expectations toward digital health care, followed by sociodemographic questions, and questions regarding their field of expertise, age, and country of origin. In addition, open-text questions were offered to understand and evaluate individual needs and gain additional insights. The English version of the survey is in Multimedia Appendix 1.

In this study, a quantitative analysis was conducted using the Python programming language, leveraging the capabilities of the Pandas library for data processing and the Matplotlib library for visualization. This approach allowed for a practical assessment of relative frequencies and distribution patterns in the responses of health care professionals and patients. For binary categorical data, such as responses regarding the "use of electronic appointment system," chi-square tests were used to assess the association between the respondents' profession and answers. In cases of ordinal data, including perceptions of the "future importance of digital health" and estimations of telemedicine use in the past and future, the Mann-Whitney *U* test was used. This nonparametric test compares the central tendency of 2 independent samples and is optimally suited for data not conforming to a normal distribution. Responses were numerically coded to facilitate this analysis. The primary objective of this investigation was to compare and contrast attitudes toward and usage of digital health tools, including aspects of telemedicine and web-based health care services. The qualitative data were assessed by a panel of experts (including a physician, a data scientist, and a management expert) and evaluated for underlying trends and overlaps between the questionnaire participants.

XSL•FO
RenderX

Ethical Considerations

This study was approved by the ethics committee of Klinikum rechts der Isar, Technical University of Munich, before distribution. The approval number is 2023 - 146-S-NP. By answering the mandatory questions of the survey and submitting them, the participants provided their consent to the anonymous study. In case they refrained from submitting the answers or refrained from answering specific mandatory questions, their consent was denied. In these cases, data were neither submitted nor recorded in any form. The participants of the survey received no compensation in any form. The privacy and confidentiality of all research subjects' data and identity were maintained at all times, because all data were collected anonymously and no identifying information was submitted at any time.

Results

Analysis of the Replies to the Web-Based Survey

During the 178 days of availability, the questionnaire yielded 2058 clicks, of which 1389 visitors answered the questionnaire and became participants in the study (response rate of 67.5% among visitors). A total of 1002 participants (72.1% of the respondents; 947 of whom were German-speaking and 55 of whom were English-speaking) completed the entire questionnaire, and the remaining 387 (27.9%) participants stopped answering the questionnaire before reaching the last question. The resultant dataset comprised 731 patient-derived responses juxtaposed with 271 physician-sourced answers, offering a representative overview of both primary health care stakeholders.

The study revealed a high level of conformity in perspectives between physicians and patients regarding the adoption and future use of digital health tools and telemedicine. Both groups showed parallel levels of adoption for electronic appointment systems and similar historical use patterns of telemedicine offerings. It yielded a comparable evaluation of the future importance of digital health, with no significant differences observed in their responses. Notably, the analysis indicated a consensus in expectations toward future use over the next 5 years, highlighting a synergistic alignment in the outlook toward digital health paradigms. The general attitude toward digital health and telemedicine yielded no significant differences either, underscoring a uniformity in the acceptance and anticipated future use of these technologies among both groups. Future expectations were aligned, with physicians and patients recognizing the importance and potential of digital health solutions in improving health care delivery. This consensus points toward a collaborative readiness for integrating digital health tools in future health care services, emphasizing the transformative potential of digital technologies in the medical field.

When asked about their “web-based access status to the hospital information system,” 66.1% (179/271) of physicians replied positively (“yes”), while 33.9% (92/271) did not have access (“no”). This result refers exclusively to the answers of the doctors and excludes patient data.

As demonstrated in Table 1, the “use of electronic appointment system” elicited a nonsignificant difference in usage patterns between physicians and patients (chi-square test, P=.16). This lack of statistical significance indicates parallel levels of adoption between the 2 groups.

Table . Proportion of health care professionals and patients using the “electronic appointment systems.”

	Yes, n/N (%)	No, n/N (%)	*P* value[a]
Group			.16
Physicians	159/271 (58.73)	114/271 (41.99)	
Patients	454/731 (62.11)	285/731 (38.97)	

[a]Chi-square test.

The assessment of the perceived “future importance of digital health” is visualized in Table 2. Responses from both cohorts indicated no statistically significant divergence (Mann-Whitney *U* test, P=.13), indicating a uniform recognition of the importance of digital health across the medical community and patient population.

Table . Comparison of the perceived “future importance of digital health” between health care professionals and patients.

	Physicians, n/N (%)	Patients, n/N (%)	*P* value[a]
Response			.13
Very important	181/271 (66.92)	562/731 (76.90)	
Important	65/271 (23.92)	129/731 (17.67)	
Not that important	26/271 (9.43)	47/731 (6.47)	
Not important	5/271 (1.74)	4/731 (0.60)	

[a]Mann-Whitney *U* test.

As delineated in Table 3, historical use patterns of telemedicine similarly showed no statistical difference between physicians

XSL•FO
RenderX

and patients (Mann-Whitney *U* test, *P*=.86), indicating a shared experience regarding the integration of telemedicine into health care delivery over the past 5 years.

Table . Comparison of responses to "use of telemedicine in the last 5 years" between health care professionals and patients.

	Physicians, n/N (%)	Patients, n/N (%)	*P* value[a]
Response			.86
Increased	214/271 (78.97)	578/731 (79.11)	
Remained the same	53/271 (19.61)	140/731 (19.22)	
Decreased	9/271 (3.14)	22/731 (2.98)	

[a]Mann-Whitney *U* test.

Prospective inclinations toward "future use of telemedicine in the next 5 years" are graphically represented in Table 4. The analysis revealed no statistically significant difference in expectations between the 2 groups (Mann-Whitney *U* test, *P*=.10), highlighting a consensus in the projected trajectory of telemedicine's role in future health care services.

Table . Expectations for the "future use of telemedicine in the next 5 years" among health care professionals and patients.

	Physicians, n/N (%)	Patients, n/N (%)	*P* value[a]
Response			.10
Will increase	229/271 (84.67)	647/731 (88.56)	
Will remain the same	36/271 (13.30)	76/731 (10.46)	
Will decrease	8/271 (2.90)	19/731 (2.59)	

[a]Mann-Whitney *U* test.

Collectively, the data shows a conformity in perspectives between physicians and patients regarding the adoption and future use of digital health tools and telemedicine. The absence of statistically significant differences underscores a potentially synergistic alignment in the outlook toward evolving digital health paradigms—in other words, a contextual significance with regard to similarities between the 2 groups. Table 5 provides a comparative statistical analysis of responses on digital health adoption between health care professionals and patients using chi-square and Mann-Whitney *U* tests. We used a significance threshold of *P*<.05 to determine whether the differences between the groups were statistically significant. As shown in the table, none of the *P* values for the comparisons (eg, *P*=.16 and *P*=.13) were below this threshold, indicating that there were no statistically significant differences in attitudes between health care professionals and patients. This suggests that both groups share similar perspectives on the various aspects of digital health adoption presented.

Table . Comparative statistical analysis between the study groups.

Question	Statistical test	*P* value	Significant difference
Use of electronic appointment system	Chi-square	.16	No
Future importance of digital health	Mann-Whitney *U*	.13	No
Use of telemedicine in the last 5 years	Mann-Whitney *U*	.86	No
Future use of telemedicine in the next 5 years	Mann-Whitney *U*	.10	No

Open-Text Questions

This section summarizes answers to the open-text questions, highlighting the most common answers and key aspects focusing on regulated digital medical products.

In Your Opinion, What Can Digitalization Achieve for Patients?

There is a strong emphasis on how digital health solutions can improve patient care and treatment efficiency, with many noting the potential for streamlined treatment processes, quicker and more accurate diagnoses, and a reduction in unnecessary medical tests. Centralized and accessible data management assumes another critical area. Respondents point out the benefits of easily retrievable patient information in an organized format, leading to more informed clinical decisions. This is closely linked with promoting preventive health care and healthy lifestyles, emphasizing the role of digitalization in disease prevention. Reducing the administrative burden on health care professionals is also a significant theme. Digital tools can allow professionals to focus more on direct patient care by minimizing time spent on nonmedical tasks and bureaucracy. Enhancing

XSL•FO
RenderX

communication and decision-making between patients and health care providers is viewed as crucial by study participants. Digital solutions are seen as facilitators of patient empowerment and shared decision-making, highlighting the importance of a patient-centered approach in digital health.

Regarding resource management, digitalization is seen as a potential solution to the shortage of health care professionals, supporting more personalized medicine and aiding in health care research through the provision of comprehensive data for analysis. Accessibility and inclusivity pose key themes, with digital health solutions considered vital for making health care more accessible, especially in remote or underserved areas. The responses collectively underscore the transformative potential of digital health solutions in enhancing health care delivery and patient experience.

Which Development Potential and Opportunities Do You See in the Digitalization of Health Care?

A recurring theme is the potential for digitalization to reduce bureaucracy and thus significantly improve the health care systems' efficiency. This aspect is particularly pertinent in the reduction of regulatory complexity associated with digital medical products. Enhanced data management and accessibility emerge as crucial factors, with many responses highlighting the integration of AI in diagnostics and decision-making, the use of big data for predictive health analytics, and the centralization of patient data. These points resonate with the emphasis on using real-world data and evidence for regulatory surveillance and the development of digital health solutions. Improved communication and coordination through digital tools were seen as crucial for better interdisciplinary and interinstitutional collaboration, reflecting the challenges of diverse regulatory landscapes in health care. The attitude toward innovation in medical devices and diagnostics, especially the role of AI and machine learning, the development of new diagnostic tools, and the application of digital twins and simulation techniques, aligns well with the need for reduced regulation of AI products in health care. Patient-centric approaches are emphasized in the responses, highlighting the need for more personalized medicine and improved patient engagement through digital solutions. This underlines the necessary development of useful, patient-centered, regulated medical products. Regulatory strategy considerations, particularly secure data handling and privacy concerns, are implicit in the responses, reflecting the importance of clear regulations in the development and implementation of digital medical products. Lastly, digitalization is viewed as a solution to health care professional shortages and a means to improve health care access, particularly in remote areas.

Where Do You See the Largest Risks and Disadvantages of the Digitalization of Health Care?

The responses reveal a multifaceted set of concerns, deeply interconnected with the challenges inherent in regulated digital medical products. A primary worry is data security and privacy, with numerous responses highlighting apprehensions about the misuse of personal health information. This emphasizes the need for stringent regulatory and ethical frameworks in the development and deployment of digital medical tools, as perceived by the study participants. Another significant concern is the depersonalization of care. Many participants fear that the rise of digital therapeutics and diagnostics might erode the personal interaction between health care providers and patients, a perceived cornerstone of adequate health care. Balancing technological efficiency with human empathy is, therefore, a key challenge in the realm of digital health. Technological dependency and system vulnerabilities emerge as major concerns. Respondents worry about an over-reliance on technology, potential system failures, and cybersecurity threats, emphasizing the importance of safety and reliability in digital medical products, especially in critical care. Resistance to change is another notable theme, particularly among health care professionals and older patients. This resistance can significantly impact the adoption and effectiveness of digital health solutions. Finally, navigating the complex regulatory landscapes and ethical dilemmas, especially with integrating AI and machine learning in health care, presents its challenges. Robust regulatory strategies and ethical guidelines are seen as paramount in ensuring the responsible and effective use of digital health innovations.

Participant Demography

Considering the age distribution of the participants, the following results were obtained from the questionnaire, as shown in Table 6.

Table . Age distribution between the 2 study groups. Values are shown as absolute numbers and relative frequencies (percentages in squares) of the whole respective population.

	18 - 25 years	26 - 35 years	36 - 45 years	46 - 55 years	56 - 65 years	>65 years
Physicians (n=271), n (%)	9 (3.32)	53 (19.56)	64 (23.62)	71 (26.20)	58 (21.40)	16 (5.90)
Patients (n=731), n (%)	35 (4.79)	166 (22.71)	209 (28.59)	155 (21.20)	111 (15.18)	55 (7.52)

Discussion

Principal Findings

This survey's results indicate alignment between professionals and patients regarding the adoption of technological innovations in health care and emphasize the necessity of improving digital health literacy. The continuous growth of digital health technologies is evident [10], with increasing use among professionals [11], the general population, and research [12], including real-world evidence generation [5]. The COVID-19 pandemic has accelerated digital adoption [13], transforming outdated processes and overcoming patient access barriers at

XSL•FO
RenderX

the “digital front door.” A balance between “techno-optimism” and “techno-skepticism” has emerged [14].

The study’s open-ended responses reflect concerns about data security, privacy, and ethical issues, with both physicians and patients identifying these as central challenges. The depersonalization of care and ethical dilemmas surrounding digital health innovations remain critical concerns. Systematic reviews confirm that digitalization introduces cybersecurity vulnerabilities, such as targeted cyberattacks and risks to patient privacy. Physicians and patients alike perceive these as barriers to effective implementation [15]. Additional studies highlight the ethical dimensions of digital health, including impacts on the patient-physician relationship, informed consent, and potential workforce shifts. Ongoing research is required to ensure that technological advancements do not compromise patient rights or exacerbate health care inequalities [16].

While many individuals rely on the internet as a primary source of health information and for anonymous consultations, skepticism persists regarding web-based data storage and digital data exchange between health care professionals and patients. Research has shown that, while internet users frequently seek health information on the web, they express doubts about the reliability of such information and the security of electronic health data exchange. Nonetheless, positive developments are also noted: physicians report improvements in access to digital health records compared to previous studies [17].

Despite advancements in digital health applications, integrating patient-generated data presents challenges, particularly due to technological limitations such as poor interoperability and data overload. Experts have emphasized the need for regulatory frameworks, ethical guidelines, and improved data governance to facilitate better integration [18]. Additionally, while protective regulations are necessary to ensure data security, the COVID-19 pandemic demonstrated how excessive regulatory barriers contributed to delays in data availability for policymakers. This underscores the need for streamlined data approval processes while maintaining public trust [19].

Germany has introduced the “Law for the Acceleration of Digitization in Healthcare” (DigiG), currently under legislative review. This initiative aims to implement electronic patient case files, digital medication overviews, electronic medical prescriptions, increased use of digital health applications (DiGAs), assisted telemedicine, and a digital medical council comprising experts in data security, information freedom, and information technology [20]. The governing legal frameworks, particularly the European Union’s Medical Device Regulation, impose comprehensive safety, performance, and postmarket surveillance requirements for digital health applications, ensuring high reliability. However, these rigorous conformity assessments may slow innovation. In contrast, the US Food and Drug Administration framework offers a more expedited approval process for digital health technologies, including AI-driven tools, through mechanisms such as the Software as a Medical Device (SaMD) categorization [21]. This regulatory flexibility has facilitated the rapid adoption of AI in US health care [22].

Research has identified various barriers to digital health adoption, including technical difficulties, resistance to change, costs, reimbursement policies, patient age, and education levels. These findings remain relevant, with technological proficiency, perceived usefulness, and accessibility influencing acceptance worldwide. Additionally, interdisciplinary collaboration, cultural factors, and leadership have been recognized as key enablers of digital health implementation [23,24]. Digital booking systems offer potential benefits, but patient and physician attitudes toward these systems remain understudied [25,26]. Our study demonstrates growing interest in digital health solutions and highlights the necessity for a transparent and innovation-friendly regulatory framework.

Age significantly impacts digital health adoption, as older adults face barriers such as limited digital literacy and reluctance toward technological change [27,28]. These challenges must be addressed through targeted interventions, including comprehensive training programs and the development of user-friendly, age-adapted digital health solutions. Integrating digital health education into medical school curricula is critical to preparing future physicians for evolving technological demands, reducing hesitation, and fostering a legal environment conducive to innovation.

Telemedicine adoption requires specific communication skills to maintain strong physician-patient relationships. A systematic review performed by Ritunga et al [29] highlights that effective digital consultations depend on training that addresses the unique challenges of virtual interactions, such as nonverbal communication and empathy. Additionally, as society shifts toward an information-driven model, medical education must balance humanistic aspects, such as the physician-patient relationship, with digital health integration. Experts warn that without proper integration, medical care quality may decline [30]. These concerns align with this study’s findings, reinforcing the importance of digital health training for both professionals and patients.

Legislative changes, particularly at the European Union level, are essential to facilitate health care’s transition from analog systems to modern digital solutions while ensuring privacy protections [31]. “Careful legal consideration has to be applied when considering privacy regulations (…), making every case an individual one,” keeping the patient at the center not only legally but also ethically, reinforcing the importance of individualized health care approaches.

The increasing alignment between physicians and patients regarding digital health adoption has significant implications for future health care delivery. With both groups recognizing the value of digital health tools and telemedicine, integration into routine practice may become more seamless. This shared understanding could reduce resistance, encourage collaboration in designing patient-centered digital solutions, and enhance accessibility, efficiency, and convenience in health care services.

Further research will enable a deeper understanding of drivers and obstacles in digital health advancements. The underlying research deserves a follow-up including a more international study population in the next few years to understand and re-evaluate the described trend patterns on a timeline,

XSL•FO
RenderX

particularly in view of the more and more rapid changes in digital health.

Limitations

Due to the nature of its origin and the involved researchers, our survey has reached mainly answers from German-speaking individuals (94.5% (947/1002) of the survey's participants). The survey distribution via digital means causes a bias toward respondents who are open to digital solutions. Persons unwilling or unable to complete a web-based questionnaire were not considered for technical reasons, causing a systematic bias that might potentially be a limiting factor regarding the generalizability of the presented results. Another limiting factor might be the above-mentioned age demographics of the study: as the majority of study participants belonged to the age groups between 26 and 65 years, the study results might lean toward a comparably high digital literacy among the respondents. Additionally, the German or German-speaking study population presents a limitation with regard to the conclusions drawn for a comparison between physicians and patients worldwide. Overall, 271 professionals versus 731 patients is a logical outcome, as all people are patients in general, whereas a smaller percentage counts as medical professionals.

Future research could benefit from exploring subgroup differences, such as attitudes by age, gender, system access, or professional experience, as well as including other health care professionals like nurses, to provide a more nuanced understanding of digital health acceptance. Practical challenges related to accessing individual nurses in this study will be addressed, and a deeper analysis of qualitative responses based on demographic factors could provide additional insights into specific barriers and facilitators.

Outlook

As also suggested by the replies of the study groups, regulatory aspects must be modified to keep pace with current innovations, allowing for meaningful evaluation, regulation, and dysregulation of new technologies. This aspect is in line with the results of Torous et al [32], who highlighted this urgent need for a steady modification of regulations pertinent to the field of digitalization in health care.

Web-based data availability can lead to misinformation, which needs to be vigorously and continuously counteracted: "To harness the full potential of digital media to support health and well-being as well as to mitigate or counteract the effects of mis- and disinformation, three fundamental skills should be continuously developed: digital literacy, health literacy, and digital health literacy" [33].

In general, perceptions, fears, and resentments must be systematically eliminated to catalyze digital health acceptance and allow for further integration and innovative solutions to benefit patients and professionals. Bureaucratic burdens and technical obstacles must be overcome and transformed from technical barriers into enablers to accelerate acceptance and usage.

Recent developments such as the Data for Health Conference 2023 (DFH23) serve as catalysts for optimistic growth: "With the momentum #DFH23 created, the European Health Data Space (EHDS) as a solid and safe foundation for consented collaborative health data use and the G7 Hiroshima AI process in place, we call on citizens and their governments to fully support the digital transformation of medicine, research and innovation including AI" [34].

Advancements in digital health literacy and enhanced technical reliability will drive openness and catalyze future developments in the patient's interest and, thus, in the interest of sustainable innovation-driven health care systems.

Authors' Contributions

FS, FH, FV, and DP designed the study. FS, FH, and DP conducted the data preprocessing. FH performed the statistical analysis. FS and DP reviewed the statistical results. FS, FH, and DP wrote the manuscript. FS, FH, FV, GME, KFB, RvER, PB, and DP contributed critical revisions to the manuscript and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: As digital technology advances, health-related data can be scientifically analyzed to predict illnesses. The analysis of international data collected during health examinations and health status monitoring, along with data collected during medical care delivery, can contribute to precision medicine and the public good. Understanding citizens' attitudes and predictors of digital health data sharing is critical in promoting data-driven research.

Objective: This study aims to determine the public acceptability of data sharing and the attitudes and influencing factors toward data sharing.

Methods: A cross-sectional web-based survey was conducted in Japan from November 11 - 18, 2023. We analyzed 1000 valid responses. Five factors were investigated as predictors of participants' attitudes toward sharing digital health data for social benefit: (1) individual sociodemographic characteristics, (2) types of health data shared, (3) motivation for sharing data, (4) data sharing concerns, and (5) reasonable access and control over the data. The association of these factors with the respondents' willingness to share was analyzed. We summarized demographic characteristics based on gender, age group, affiliated educational institution, and education history and degree. Continuous variables are expressed as mean (SE). Logistic regression was used to analyze the association between attitudes and acceptability of sharing digital health data and the predicting factors, such as participants' preferences regarding data access and control, underlying concerns, motivations for data sharing, demographic characteristics, and eHealth literacy.

Results: The mean age of the participants and the SD was 52.8 (19.8) years. We identified the factors influencing respondents' willingness to share a wide range of personal digital health data in Japan, including data in medical records, biobank samples, and digitized social communication. Approximately 70% of the participants were willing to share their digital health data. The motives associated with positive willingness to share digital health data were helping future patients (odds ratio [OR] 2.5860, 95% CI 1.8849 - 3.5481; *P*<.001), receiving their own results (OR 2.2261, 95% CI 1.6243 - 3.0509; *P*<.001), and receiving financial benefits (OR 1.8059, 95% CI 1.2630 - 2.5822; *P*=.001). Concerns associated with negative willingness to share data were data being used for unethical projects (OR 0.5104, 95% CI 0.5104 - 0.722; *P*<.001) and agreeing to contract terms that they did not fully understand (OR 0.7114, 95% CI 0.5228 - 0.9681; *P*=.04). Compared with men, women were less willing to share data (OR 0.722, 95% CI 0.539 - 0.967; *P*=.03). Furthermore, the higher one's eHealth literacy, the more positive their willingness to share digital health data (OR 1.0680, 95% CI 1.0450 - 1.0920; *P*<.001).

Conclusions: This study found differences in the types of data people are willing to share. Therefore, the significance of sharing data should be fully communicated to people to motivate them to share their data and contribute to their overall health.

KEYWORDS

digital health data; cross-sectional study; predict factor; Japan; willingness to share personal data; eHealth literacy

Introduction

The progression of digital technology has enabled the comprehensive analysis of health-related data, facilitating the prediction of potential illnesses [1-3]. The exchange of personal digital health data plays a crucial role in shaping policies that enhance digital health initiatives and in the innovation of new treatment and prevention strategies [4]. Personal health data includes medical records and data from medical examinations

XSL•FO
RenderX

[5]. Data from biological samples, such as blood and DNA, are also important types of health data [6]. In addition, family health data, exercise habits, food intake, and lifestyle data are closely related to health [7-9]. The introduction of eHealth records and the development of wearable apps have led to health data digitization [10,11]. Digital health data on heart rate and blood pressure can be collected by mobile devices in several ways. Digital health data, such as social activities, behavior patterns, and location data are useful for the morbidity risk, prevention, and diagnosis of infectious diseases, including COVID-19 and mental health. Other examples of digital health data include travel records made during the COVID-19 pandemic, web-based data on travel locations, and digital health data on social activities [12-14].

Health data can be collected to contribute to the public good when shared, including data collected during health examinations and health status monitoring, as well as data collected during the delivery of medical care. Therefore, biobanks, which collect individual biological samples and use them for public benefit, and databanks, which hold electronic medical records, are being developed [15-18].

As data science develops, it will likely be used for personalized medicine and understanding the social determinants of health. In Japan, the Ministry of Health, Labor, and Welfare has formulated the “Medical Digital Transformation: Vision 2030,” a strategy for promoting medical digital transformation that actively supports the usage of health and medical care data [19]. In Europe, the General Personal Data Protection Regulation governs the use of personal data, including patients’ electronic medical records. This is because informed consent is required for personal data collection and sharing, including secondary use for research purposes.

Digitizing health data and enabling its international sharing are crucial steps in improving health care worldwide. By making medical records accessible across borders, patients can receive accurate diagnoses and appropriate treatments regardless of their location. This is particularly beneficial for travelers and expatriates, as well as people in emergencies, since doctors can quickly access their medical history and provide suitable care without unnecessary delays [20]. In addition to benefiting individual patients, the international sharing of health data plays a significant role in disease prevention and control. By monitoring global health trends, medical institutions and governments can detect outbreaks at an early stage, respond quickly, and implement effective containment strategies. The importance of such efforts was especially evident during the COVID-19 pandemic, where data sharing initiatives helped track the spread of the virus and accelerate vaccine development [21].

The digitization and sharing of health data also benefit medical research. Access to large-scale anonymized datasets allows researchers to develop innovative treatments, improve AI-driven diagnostics, and advance personalized medicine [22]. Moreover, standardized digital records contribute to the efficiency of health care systems by reducing administrative burdens and facilitating better coordination between medical professionals, ultimately leading to improved patient outcomes [23].

Furthermore, sharing health data internationally helps bridge the gap between developed and developing regions, fostering collaboration that promotes equitable health care access and reduces global health disparities [24].

Rare diseases provide a salient example of the benefits of international data sharing. Definitions of rare diseases differ by region: in the United States, a rare disease is defined as one affecting fewer than 200,000 patients nationwide [25]; in Japan, fewer than 50,000 patients nationwide [26]; and in the European Union, conditions affecting fewer than 1 in 2000 people in the general population [27]. Due to the small number of patients in each country, there is limited availability of diagnostic, genetic, and other health data, as well as insufficient specialized knowledge. Consequently, diagnoses may be delayed or missed entirely, hindering the development of effective treatment and prevention strategies. However, international sharing of health data can overcome these limitations by enabling accurate diagnosis and facilitating research on therapies and preventive measures [28].

Despite the many advantages of digitizing and sharing health data, it is essential to address privacy, security, and ethical concerns. Strong data protection measures and international regulations must be in place to ensure that personal health information is shared responsibly and securely [29]. By balancing the benefits of accessibility with the need for confidentiality, the global health care community can create a system that maximizes both innovation and patient protection.

However, digital health data sharing may not be fully understood without examining citizens’ attitudes toward data sharing related to health and medical care [30]. While health data digitization and sharing can facilitate research and create social benefits, public acceptability may be a barrier to its successful implementation [30]. Examining citizens’ attitudes toward and acceptance of sharing digital health data may be useful in formulating policies and guidelines for data management [31]. This can help in the development and implementation of policies to promote medical health research through digital health personal data. Such efforts benefit others through secondary use of large-scale data, drug development, verification of adverse effects, and reflection on health care policy, rather than for personal, individual medical treatment purposes. Existing studies have considered the acceptability of biobanks, eHealth data, and the acceptability of and attitudes toward digital health data [32-35]. Citizens’ attitudes and receptivity to digital health data sharing differ depending on the type of data being shared, and concerns regarding personal data and transparency issues in data sharing may affect data sharing. However, the types of data that can be digitized and contribute to health include not only biobanks and comprehensive medical records but also lifestyle and behavioral habits.

Few studies have been conducted to elucidate the factors that predict willingness to share digital health data. One study considered the attitudes toward the willingness of young people in Brazil and Denmark to register their digital health data [36]. Studies in Australia [37] and Europe [38] have found that citizens prefer sharing health data under government oversight. They express concerns about sharing anonymized health data

XSL•FO
RenderX

for clinical practice or research purposes unless clear provisions are made regarding its intended purpose, limitations on use, and access restrictions [36-38]. Broader citizen consultation on data use, suggesting this trend, has largely been overlooked [39]. However, there is growing evidence of public support for health data sharing [40,41]. Studies indicate that citizens in Australia [42], the United Kingdom, and the United States [43] are willing to share data aimed at improving health outcomes. The determinants of this willingness remain ambiguous, with limited research addressing issues specific to the Asian region, including Japan. This region, with its diverse cultures, social backgrounds, and varying levels of digitalization, may present different predictors of willingness to share digital health data. A comprehensive understanding of the factors influencing citizens' willingness to share health data can help identify challenges and opportunities for establishing data collection systems, thereby improving communication and fostering citizen trust in digital health data.

Methods

Study Design and Setting

This cross-sectional study was conducted via a web-based questionnaire survey administered across Japan by Cross Marketing Inc, an internet research firm. At the beginning of the questionnaire, participants were clearly informed that their personal data would be strictly protected and anonymized. Furthermore, they were explicitly instructed to respond to questions about their attitudes and intentions toward data sharing on the premise that any shared data would exclude personally identifiable data and privacy would be guaranteed. This explanation was included to ensure participants understood that the protection of personal data was a fundamental prerequisite for data sharing scenarios described in the questionnaire.

The survey was developed in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist (Figure 1,Checklist 1). A pilot test was conducted between October 28 and November 6, 2023, to assess the questionnaire's clarity, readability, interface usability, and time burden. The final survey was distributed from November 11 to 18, 2023.

Study Size

A minimum sample size of 385 was calculated using a normal approximation of the binomial distribution, considering Japan's population of 126 million, a 95% confidence level, and a 5% margin of error [44]. Based on previous studies, 1000 questionnaires were collected to improve the validity of the study [36,38,40].

Participants and Sampling

Participants were recruited from Cross Marketing Inc.'s panel and were aged 18 years or older. To ensure demographic representativeness, stratified random sampling was used based on age and gender. Participants were equally allocated into seven age categories (18 - 27, 28 - 37, 38 - 47, 48 - 57, 58 - 67, 68 - 77, and 78 years or older) and by gender, resulting in equal numbers in each age category and gender group. Within each stratum, participants were randomly selected.

Exclusion criteria included discrepancies between registered and self-reported gender or age, extremely short response times, failure to follow instructions, or provision of inconsistent or implausible responses. Out of 23,434 distributed questionnaires, 2203 participants provided informed consent, and after applying exclusion criteria, 1000 valid responses were analyzed. Participant demographics are presented in the Results section (Table 1).

Survey Measures

The questionnaire was developed with reference to previous studies on willingness to share health-related data, including biobank and electronic medical record data, and attitudes toward data repositories. Five factors were investigated as predictors of participants' attitudes toward sharing digital health data for social benefit: (1) individual sociodemographic characteristics, (2) types of health data shared, (3) motivation for sharing data, (4) concerns factors of data sharing, and (5) reasonable access and control over the data (Figure 2) [36-38,45,45]. A pilot study involving 5 academic staff and researchers helped refine the instrument. The selection and formulation of questionnaire items were based on previous studies identifying factors influencing data sharing behavior.

The questionnaire included the following domains, all using uniform response options ("Yes," "No," "Don't know," and "Other" with free-text input). Questions were randomized, and multiple responses were allowed.

Full wording of all items and response options is available in Multimedia Appendix 1 questionnaire.

Figure 2. Predictors of public attitude, personal health digital data for social benefit research model.

XSL•FO
RenderX

Willingness to Share Digital Health Data

Participants indicated their willingness to share various types of digital health data, including physical and mental clinical diagnoses, family health history, genetic and blood test data, dietary and nutritional data, alcohol consumption, sleep status, social communication (frequency and content), physical activity, stress, and geolocation data.

Motivation for Sharing Data

Participants selected motivations such as helping future patients, supporting research, receiving study results, financial incentives, and proposing research topics.

Concerns About Sharing Digital Health Data

Participants selected concerns from a list including privacy risks, data misuse, unauthorized access, and ambiguity in consent terms. The wording related to access restrictions was revised for clarity. Participants chose from options indicating who may access their data (eg, medical professionals, researchers, and family members) and preferences on data control.

Attitudes Toward Access Restrictions

Participants reported preferences on controlling access to their data, transparency in data usage, trust in data controllers, and openness to sharing with public or academic institutions.

Demographics and Health-Related Factors

Data on age, gender, educational attainment, annual household income, marital status, and ownership of digital devices (smartphones, PCs, tablets, smartwatches, and smart home assistants or artificial intelligence [AI] appliances) were collected using predefined categories. Participants also reported previous participation in health research (epidemiological or clinical trials).

eHealth literacy was assessed using the Norman eHealth Literacy Scale (eHEALS), an 8-item, 5-point Likert scale measuring knowledge, comfort, and perceived skills in finding, evaluating, and applying eHealth data [45,46].

Self-rated health status was assessed on a 5-point Likert scale, and responses were grouped into “good” (somewhat good, very good) or “not-so-good” for analysis. Logistic regression analyzed the relationship between health status and willingness to share data.

Participants’ concern about their own and family’s health was measured on a 6-point scale, dichotomized into “interested” or “not interested,” with logistic regression used to assess associations with willingness to share digital health data.

Statistical Analysis

Descriptive statistics (frequencies, means, and SDs) summarized participant characteristics. We used the intention to share digital health data as the outcome variable. Logistic regression analysis was performed to examine its associations with a range of predictor variables, including motivations for sharing data (eg, helping patients and supporting research), concerns about data sharing (eg, privacy risks and misuse), attitudes toward data access (eg, preferences for control and trust in institutions), and sociodemographic and health-related factors (eg, age, gender, education, income, marital status, digital device ownership, and previous participation in health research). Analyses were conducted using SPSS version 28 (IBM Corp), with significance set at $P<.05$.

Ethical Considerations

This study fully complied with the Declaration of Helsinki and Japan’s Personal Data Protection Law [47]. Ethical approval was granted by the Waseda University Ethics Committee (application 2023 - 250), confirming that all protocols and consent procedures were reviewed and sanctioned before data collection.. No personally identifiable information was collected in accordance with both institutional and legal privacy requirements. All persons described are not identifiable and cannot be identified through the details of the story because this research is an anonymous Internet survey.

Informed consent was obtained electronically before participation. Participants received a small monetary incentive (points equivalent to approximately 10 Japanese yen [US$1=147.1 JPY]) via the survey provider’s point system. Low-quality or inconsistent responses were screened and excluded by the research firm.

Results

Characteristics and Attributes of Participants

Table 1 shows participant characteristics. The men-to-women participant ratio is 1:1. The mean age of the participants and the SD is 52.8 (SD 19.8) years. Approximately half of the participants had a university or postgraduate degree in education. In total, 93% of the respondents had a smartphone and 83% had a personal computer. About 80% of the respondents were interested in their health (very interested and somewhat interested).

Association Between Willingness to Share Digital Health Data and Sociodemographic Characteristics

Approximately 70% of respondents were willing to share digital health data. Respondents who were willing to share digital health data were defined as having a positive willingness to share, and subsequent analyses were conducted.

The results of the logistic analysis of the association between positive attitudes toward sharing digital health data and sociodemographic characteristics are shown in Table 2. Compared with men, women were less willing to share data (odds Ratio [OR] 0.722, 95% CI 0.539 - 0.967; $P<.05$).

Those who had more experience participating in research (OR 3.308, 95% CI 1.391 - 7.868; $P<.01$), and had awareness of research data repositories (OR 2.711, 95% CI 1.364 - 5.388; $P<.01$) were more willing to share digital health data. Moreover, owning a smartphone (OR 1.841, 95% CI 1.078 - 3.145; $P<.05$), personal computer (OR 1.658, 95% CI 1.175 - 2.341; $P<.05$), tablet (OR 1.688, 95% CI 1.212 - 2.349; $P<.01$), or smart home assistance appliances (OR 3.384, 95% CI 1.077 - 5.276; $P<.05$) was positively associated with higher willingness to share digital health data. Conversely, there was no association between annual income or education and the willingness to share digital

XSL•FO
RenderX

health data. Logistic analysis of e-health literacy and digital health data sharing suggested that the higher the e-health literacy, the more positive the willingness to share digital health data.

Willingness to share digital health data was significantly associated with a high level of health concern and willingness to share digital health data (OR 2.1871, 95% CI 1.5750 - 3.03710; $P<.001$) but not associated with health status ($P=.73$).

Willingness to Share Digital Health Data and Types of Data That Can Be Shared

The percentage of respondents who indicated a willingness to share shareable data (multiple responses) is shown in Multimedia Appendix 2 Figure S2. The results show that 44%, 33%, 33%, 32%, and 31% of participants were highly motivated to share data regarding physical clinical diagnoses, sleep patterns, blood samples, stress, and food consumption, respectively. Moreover, the content and frequency of social communication tended to be low (11% and 14%, respectively).

Predictors of Motivation to Share Digital Health Data and Positive Willingness to Share

Multimedia Appendix 3 Figure S3 shows the percentage of respondents who indicated each item as a motivation for sharing digital health data. Helping future patients was the most common motivation for sharing digital health data (59%), followed by receiving one's results (48%), supporting researchers (39%), and financial gain (31%).

Table 3 shows the results of the logistic analysis of the association between motives and positive willingness to share data. Motives found to be associated with positive motivation to share digital health data were helping future patients (OR 2.586, 95% CI 1.885 - 3.548; *P*<.001), receiving one's results (OR 2.266, 95% CI 1.624 - 3.561; *P*<.001), and receiving financial benefits (OR 1.806, 95% CI 1.263 - 2.582; *P*=.001).

Table . Logistic regression results regarding a positive willingness to share personal health data and motives and motivation to share data.

Motivations for sharing data	B (partial regression coefficient)	SE	*P* value	OR[a] 95% CI
Helping future patients	0.9501	0.1614	<.01[b]	2.5860 (1.8849-3.5481)
Supporting researchers	0.2607	0.1784	.14	1.2978 (0.9148-1.8412)
Receiving one's own results	0.8003	0.1608	<.001[b]	2.2261 (1.6243-3.0509)

Concerns About Sharing Digital Health Data

The percentage of respondents who selected concerns about their digital health data is shown in Multimedia Appendix 4 FIgure S4 . Of the total respondents, 52% cited unknown use of data for the benefit of others as a concern, approximately 39% agreed to terms and conditions they did not fully understand, and approximately 34% said that data sharing would make them vulnerable to cyber attacks.

Table 4 shows the results of the logistic analysis of the relationship between positive intentions toward digital health data and concerns about sharing. The concern found to be associated with a positive willingness to share data was agreeing to contract terms that were not fully understood (OR 0.711, 95% CI 0.525 - 0.968; *P*=.03). The results showed that those who felt concerned tended to have lower positive intentions than those who had no concerns about their data being used for unethical projects (OR 0.510, 95% CI 0.361 - 0.722; *P*=.001).

XSL•FO
RenderX

Table . Logistic regression results regarding a positive willingness to share personal health data and concerns about sharing.

Concerning factors data sharing	B (partial regression coefficient)	SE	*P* value	OR[a] (95% CI)
Data being used for the benefit of a company or others without one's knowledge	0.2864	0.1467	.06	1.3316 (0.9989-1.7752)
Data being used for unethical projects	-0.6726	0.1770	<.001[b]	0.5104 (0.3607-0.7221)
Agreeing to terms and conditions without complete understanding	-0.3405	0.1572	.03[c]	0.7114 (0.5228-0.9681)

[c]*P*<.05.

Desirable Access Restrictions Related to Sharing Digital Health Data

Multimedia Appendix 5 FIgure S5 shows the percentage of participants' responses regarding their preferred access to digital health data sharing. Receiving information about projects using their data was the most common response (43%), followed by receiving information about who is using their data (35%) and deciding who has access to what parts of their data (31%). However, 13% stated they would not need to be contacted after providing their data and having it anonymized.

Table 5 shows the results of the logistic analysis between positive intentions and each of the access restriction items regarding data sharing. The access restrictions found to be associated with positive intentions were receiving information about projects using their data (OR 2.313, 95% CI 1.700 - 3.147; *P*=.001), giving public or academic institutions access to their data (OR 2.800, 95% CI 1.9248 - 4.0734; *P*=.001), and not receiving information after providing their data (OR 1.929, 95% CI 1.292 - 3.029; *P*=.004).

Discussion

Principal Findings

Internationally, secondary use and third-party provision of personal health-related data have become very important for public health, including surveillance of infectious diseases and the development of preventive methods and treatments [48]. Therefore, it is significant to investigate the factors related to data sharing, such as citizens' attitudes toward, barriers to, and motivations for data sharing. However, research on citizens' personal health-related data sharing is limited [49].

Our study identifies factors influencing citizens' willingness to share a wide range of personal digital health data about health in Japan, including data in medical records, biobank samples, and digitized social communication data. This study showed that approximately 70% of Japanese participants were willing to share digital health data about their health. A survey of public attitudes toward digital research registries among Danish and Brazilian citizens showed that 91% of Brazilian and 70% of Danish citizens had a positive attitude toward digital research registries; our study shows a similar willingness as the results from the Danish participants [36]. Our research focuses on whether people are willing to share data, which directly evaluates behavioral intent. This approach is essential as it provides actionable data for organizations or governments to design effective policies. For instance, it can guide the creation of incentives to promote data sharing or enhance privacy protection measures.

While the Danish and Brazilian study asks about how "comfortable" people feel with data sharing, focusing on emotional aspects, our research directly addresses the question of "willingness to share." This specificity enables deeper insights into both emotional responses and actual behaviors, bridging the gap between attitudes and actions. Our research design, which evaluates the intent to share data, is not limited by cultural or emotional factors. This makes it versatile and applicable across different global contexts. Conducting similar studies in other countries allows us to uncover universal trends and contrasts in data sharing behavior. Our study suggests that helping future patients is an important motivator for sharing health-related digital health data. Furthermore, participants were willing to share their data in the interest of research.

The participants' high level of interest in their health suggested that gaining knowledge about their health is a motivating factor. Moreover, social benefits, such as benefits to future patients and benefits to oneself, were simultaneously motivating for sharing digital health data. Researcher benefits were not found to be associated with motivation for data sharing. A study of attitudes toward sharing health data among United States and United Kingdom citizens also reported a lower willingness to share data for commercial purposes compared to that for public benefit [43].

Based on our analysis, willingness to share digital health data regarding physical illness diagnoses, sleep patterns, food intake, blood samples, and stress was relatively high, while participants had a lower willingness to share social communication data. This may occur because social communication can be considered personal data that citizens may be hesitant to share due to

XSL•FO
RenderX

privacy concerns [50]. However, social communication provides data for research into mental health and infectious disease control; thus, it holds important implications in public health research. Therefore, there is a need to increase public understanding of the importance and significance of digital health data in this area.

Our results suggest that concerns about providing data to unethical projects and agreeing to contract terms that were not fully understood were barriers to the willingness to share digital health data. A study on public attitudes toward the sharing of personal medical records and genomic data in Japan similarly reported concerns about the unauthorized use of data [35]. Although the indicators differ from this study, a link between literacy in the knowledge of genomics, AI, and digital devices, and the sharing of medical records and genomic data has also been noted [35]. Furthermore, trust is important for data sharing [51,52]. Privacy concerns deter data sharing, particularly attitudes toward sharing health data for health policy creation [53].

Aggregating and analyzing multiple types of health data can have significant benefits. We can gain comprehensive insights into health patterns and conditions by combining diverse sources, such as genetic data, clinical records, and lifestyle habits. This approach supports personalized health care, allowing tailored treatments and interventions to address individual needs effectively. Furthermore, the correlation of health data enables predictive analysis, helping forecast potential health issues and promoting preventative measures [54]. Citizens' attitudes and receptivity to digital health data sharing differ depending on the type of data; however, concerns persist regarding personal data protection and transparency in data sharing [55].

While one measure to remove barriers of concern is restricting access to digital health data, our results showed that receiving information about projects that use data, getting information about data users, and granting data access to public or academic institutions are linked to a willingness to share data. These results may suggest that people avoid providing data to unethical projects and wish to exercise their right to self-determination regarding data. Other studies have also identified the importance of controlling the sharing of digital health data [36,37].

Our analysis suggests that the sociodemographic factors associated with willingness to share digital health data are being a man; owning smartphones, PCs, and smart appliances; having experience in participating in health research; and having high digital health literacy. It is necessary to consider measures for sharing digital health data that consider individual characteristics. The association between willingness to share digital health data and educational background reported by Grande et al [56] was not found in our study.

Implications for Policy and Practice

This study identifies factors that make Japanese citizens willing and able to share their data for research. These factors may be applicable not only in Japan but also internationally across borders. An increase in data sharing can contribute to research using big data, for example, the development of diagnostic, preventive, and therapeutic methods for rare diseases for which data are scarce, as well as international surveillance for infectious diseases.

The results of our study suggest that there are differences in the types of data that people are willing to share and that they may be less willing to share data that is related to personal data or not related to their health. Therefore, it is possible to fully explain the significance of sharing through communication with people, motivating them to share, and identifying the possible contributions to their health. Concerns about unethical data use projects and consenting before understanding the full terms of the agreement, identified as barriers to data sharing, can be addressed by disclosing information about the research project when requesting digital health data.

Concerns about unethical data usage and misunderstood consent indicate a demand for stronger ethical governance. Data governance frameworks must incorporate feedback mechanisms, such as providing people with updates about the projects that use their data, thereby enhancing perceived control and accountability.

Receiving this data may contribute to increased confidence in data sharing. Furthermore, ensuring that people have the right to control their data is also key to facilitating data sharing.

The study highlights demographic variations in willingness to share data, suggesting that public engagement strategies must be tailored to specific groups. For instance, women, people with lower eHealth literacy, and those without previous research participation may require more targeted education and reassurance regarding privacy and data control mechanisms.

The willingness of the Japanese public to share health data opens opportunities for international data pooling, particularly in the context of rare diseases and emerging infectious diseases, where domestic data may be insufficient for robust research. These findings support the establishment of cross-border data sharing frameworks that are ethical, secure, and culturally sensitive.

The association between device ownership and willingness to share digital health data suggests that disparities in access to digital technologies may translate into inequities in participation in health research. Policymakers should be aware of the digital divide when designing inclusive health data collection frameworks. These findings underscore the importance of policy measures that enhance public trust in digital health data sharing. Efforts to improve data literacy, transparency in data usage, and the ethical oversight of research projects are vital to increasing citizens' willingness to share their data. Government and academic institutions should consider developing communication strategies that convey how data will be used, who will access it, and the potential social benefits of data sharing.

Limitations and Future Challenges

Two methodological limitations exist in this study. First, the web-based survey could have created the possibility of sampling bias as well as bias in education levels and ownership of digital devices.

Another limitation relates to our sampling design. Although we used random selection within strata defined by age and gender,

XSL•FO
RenderX

this constitutes stratified random sampling rather than simple random sampling. In our analysis, we treated the sample as if drawn via simple random sampling, which may lead to inaccurate estimation of standard errors and affect inferential validity, including the risk of type I error. However, this design was intentionally chosen to ensure adequate representation across demographic subgroups, particularly to explore associations between data sharing intentions and age or gender. Given the total sample size of 1000, we believe the precision of estimates remains acceptable for our exploratory purposes, although results should be interpreted with appropriate caution.

Third, this study was a survey that asked questions about willingness to share digital health data based on future assumptions. However, the study did not explore the perspectives of data providers regarding implementing actual digital health data sharing.

While the quantitative data provides a broad understanding of attitudes, future research should include qualitative approaches, such as interviews or focus groups, to explore the underlying motivations, fears, and expectations surrounding data sharing in greater depth. Therefore, it is important to survey providers during actual data sharing in a future study. Conducting ongoing research into the topic may also be necessary.

Conclusion

This study identified people's receptivity and willingness to share personal digital health data about their health and its influencing factors. Approximately 70% of the respondents viewed sharing digital health data about their health positively. The majority of those with a positive view were motivated to share their data by receiving data about themselves as well as helping future patients. Unwillingness to share digital health data about personal health is a barrier to promoting digital sharing and research for societal benefit. Concerns about data being used in unethical research projects and agreeing to contractual terms and conditions that are not understood were suggested to be associated with reduced willingness to share data. It is also important to improve the understanding of the information of users' institutions, disclosure of information on the projects used, terms of contracts, and access control of data sharing. Furthermore, associations between willingness to share digital health data for public associations with personal characteristics were found regarding gender, interest in health issues, ownership of digital devices, history of participation in research, awareness of digital health databases, and digital health literacy. Therefore, a digital sharing system that considers individual characteristics and provides information regarding the usage of the data could facilitate data sharing.

Abstract

Background: More than half of adults in the United States have at least one chronic medical condition. Remote care strategies, including telemedicine, remote monitoring, and connected health devices, are increasingly used to support chronic condition management and adherence to provider-recommended care plans. Evaluating participant satisfaction and perceived usefulness is essential to understanding program value and potential for sustained engagement.

Objective: This study aims to evaluate participant satisfaction, perceived usefulness, and self-reported health outcomes associated with a clinically deployed Remote Care program for chronic condition management that included nurse and coach follow-up, health monitoring devices, and digital education tools.

Methods: A survey was emailed to 1411 active participants in the Brook Remote Care program between September 23 and December 8, 2023. The survey assessed satisfaction with program features, perceived usefulness, and self-reported health changes. Descriptive statistics were used to summarize the data, and chi-square tests were used to examine differences by age, gender, program duration, and health conditions.

Results: A total of 360 participants completed the survey. Most participants rated the program as useful (320/359, 89%), and 66% (234/357) indicated they were likely to recommend it to others with similar health concerns. Between 68% (216/316) and 84% (277/332) rated specific program features as “good” to “excellent,” with nurse monitoring, health monitoring devices, and program cost receiving the most favorable ratings. Nearly half of participants reported improvements in physical health (155/314, 49%), reduced health-related stress (148/326, 45%), and increased knowledge of their condition (172/360, 48%). Additionally, approximately one-third reported improvements in lifestyle behaviors. Longer program duration was associated with higher satisfaction and greater self-reported health improvements.

Conclusions: Participants reported high satisfaction with a remote care program designed to support chronic condition self-management. These findings support the value of integrated remote care models that combine device monitoring, personalized follow-up, and patient education to enhance patient experience and promote engagement in self-care.

(JMIR Hum Factors 2025;12:e69586) doi:10.2196/69586

KEYWORDS

remote monitoring; patient satisfaction; chronic disease; self-management; telemedicine; digital health

Introduction

Over half of adults in the United States have at least one chronic medical condition [1]. Most follow a medically prescribed treatment plan and adopt self-management strategies, including lifestyle changes and self-monitoring, to improve disease control and clinical outcomes [2]. Many chronic conditions also require frequent medical visits or hospitalization. Remote care, such as telehealth and monitoring with connected devices, offers an alternative to in-person visits, supporting condition management and reducing the risk of acute events and hospitalizations [3,4].

Remote care programs have been shown to reduce mortality, disease complications, hospitalizations, and associated health care costs across a range of medical conditions [5-7]. For example, one study involving patients with chronic obstructive pulmonary disease or congestive heart failure found a 68% and 35% reduction in emergency room visits and hospitalizations, respectively, over a 6-month period (comparing 3 months before and after the intervention) [6,7].

XSL•FO
RenderX

Patient satisfaction is a widely used quality metric, used both to evaluate care and meet regulatory reporting requirements. Understanding how patients experience remote care is essential for assessing its perceived value, ongoing engagement, and potential for broader adoption. A review by Kraai et al [8] reported high satisfaction with remote care, but most studies included in that review were pilot trials with varied designs and no evaluation of remote care offered in a routine clinical setting. A more recent study by Mayo Clinic researchers [9] found that patients receiving remote care for acute conditions, such as COVID-19, were highly satisfied with their care team and the usability of the technology. However, this study focused primarily on an acutely ill population, with 88% being treated for COVID-19, limiting generalizability to chronic care settings.

There remains a need to evaluate patient satisfaction with remote care programs designed specifically for community-dwelling individuals managing chronic diseases. This study aims to contribute to the literature by examining satisfaction and self-reported health changes among insured patients enrolled in a clinically delivered remote care program for chronic condition management.

Methods

Survey Administration

In September 2023, Brook Health emailed active participants (N=1411) in its digital Remote Care program, inviting them to complete a survey (administered via Google Forms) to assess their experience and satisfaction as part of ongoing quality assurance efforts. Two reminder emails were sent approximately 2 weeks apart, followed by a final reminder shortly before the survey closed—3 months after the initial invitation. To be eligible, individuals had to be actively enrolled in the Remote Care program and have an email address on file. Participation was voluntary. To encourage responses, participants were offered the opportunity to enter a drawing for 1 of 5 US $100 Amazon gift cards.

Remote Care Program Description

The Remote Care program was developed and operated by Brook Health, a Seattle-based company that delivers digital health services to support clinic operations, provider-delivered care, and patient well-being. The program includes app-based educational resources and tools; wireless, cellular-enabled monitoring devices (scales, blood pressure cuffs, glucose monitors, and pulse oximeters) that do not require Bluetooth syncing; personalized one-on-one health coaching; and ongoing nurse monitoring to ensure care plan adherence and optimal condition management. Nurses monitored patient data and contacted clinics as needed to escalate care concerns. Patients were referred to the program by their providers and enrolled either onsite at the clinic or from home. After enrollment, patients received information about the program, downloaded the app, created an account, and were provided with digital monitoring devices. Participants received nurse monitoring and coaching calls throughout the program, with the highest frequency of contact occurring during the first month. Program costs were covered by insurance, with participants responsible for applicable copays.

Survey Instrument

The survey assessed participants' perceptions of program usefulness, satisfaction with specific features, and self-reported changes in health and well-being (refer to Textbox 1 for items). Brook developed a custom instrument informed by established digital health evaluation models, with an emphasis on face validity and alignment with program objectives. Acceptability was operationalized through participant experience, including user satisfaction ratings. Designed as a quality improvement tool for real-world implementation, the survey was intentionally brief and written in accessible language to accommodate a diverse patient population. Formal psychometric testing was not conducted. In addition to items assessing specific program components, the survey included a general self-rated health item from the 20-item Short Form Survey and a global health change item modeled after the Global Rating of Change scale, a widely used patient-reported outcome measure [10,11].

XSL•FO
RenderX

Textbox 1. Participant survey questions for the Brook Remote Care Program.

Program ratings

How would you rate the following aspects of the Brook Remote Care program? Very poor, poor, average/acceptable, good, or excellent.

- Ease of enrolling
- Program content
- Nurse interactions
- Coaching
- Devices provided
- Cost of the program
- Program duration
- Results/outcomes

How would you rate the following aspects of Nurse Monitoring in the Remote Care program? Very poor, poor, average/acceptable, good, or excellent.

- Quality of interactions with the nurse
- How often the nurse contacted you
- Amount of time spent on calls with the nurse
- Recommendations made by the nurse

On a scale from 1 to 10, how likely are you to recommend this program to others with similar health concerns? (1=Not all to 10=Extremely likely)

Rate how useful Brook Remote Care has been in helping you to manage your health/health condition? Extremely, very, somewhat, a little, or not at all.

Health ratings

In general, would you say your health is: excellent, very good, good, fair, or poor?

Would you say your health has improved, not changed at all, or worsened since joining Brook Remote Care?

Since joining Brook Remote Care, how do you feel when it comes to stressing about your health status?

While participating in Brook Remote Care, did you...? Check all that apply.

Achieve better control of your health condition

Lose weight

Increase physical activity

Eat healthier

Play a more active role in your health

Reduce medication use

Reduce stress/feel less anxious

Sleep better/more

Become happier

Become more knowledgeable about your condition and management

Spend less time on medical appointment and tests

None of the above/other

How has your use of medications to manage your condition (for which you were referred to Remote Care) changed since joining the program? Check all that apply.

Not on any medications for my condition (never took or stopped taking before starting Brook)

No change in my medication use

I started taking medication(s) for my condition

Changed the type of medication

Decreased amount, strength or frequency

Increased amount, strength, or frequency

XSL•FO
RenderX

Descriptives

How long have you been participating in Brook Remote Care? Less than 1 month, 1-3 months, 4-6 months, 7-9 months, 10-12 months, or more than 12 months.

For which medical condition are you being supported by Brook Remote Care? Congestive heart failure, diabetes, hypertension, weight loss, or other.

Age in years: 18-24, 25-34, 35-44, 45-54, 55-64, 65-74, or 75+.

Your gender: female, male, nonbinary, or transgender.

Ethical Considerations

Participation was voluntary. The following information was included with the survey. “Your responses to this survey are confidential. Your answers will not be shared with your provider or anyone else. Brook Health will only use your responses in aggregate with responses from others who complete this survey. By answering this survey, we presume your approval to use your responses for the following purposes...1) improve existing services, 2) inform the development of new services, 3) create marketing materials, or 4) generate research reports.” To encourage responses, participants were offered the opportunity to enter a drawing for 1 of 5 US $100 Amazon gift cards. This study was reviewed by the University at Buffalo institutional review board and deemed exempt from full review (IRB ID STUDY00008350).

Sample

A power calculation determined that 302 completed surveys were needed to achieve a statistically representative sample with 95% confidence and a 5% margin of error. A total of 441 surveys were received. During data cleaning, 81 duplicate responses were identified and removed; specifically, only the first complete response from each participant (based on the timestamp of submission) was retained. This resulted in 360 unique surveys included in the final analysis, yielding a response rate of 26%.

Descriptive Analysis

Descriptive statistics were calculated for all demographic variables and survey items. Chi-square analyses were conducted to examine group differences in ratings of program features, nurse monitoring, overall program usefulness, likelihood of recommending the program, and self-reported health status and health changes. Comparisons were made across gender (male vs female), age (<65 vs 65+ years), selected health conditions (hypertension, diabetes, obesity, and congestive heart failure), and program duration (<6 months, 7 - 12 months, and 12+ months). In addition, multivariate logistic regression models were conducted to assess whether observed associations remained statistically significant after adjusting for age, gender, and program duration, accounting for potential confounding factors.

Item Scoring

The Net Promoter Score (NPS), a widely used measure of overall program experience, was derived from the question: “On a scale from 1 to 10, how likely are you to recommend this program to others with similar health concerns?” (1=not at all likely; 10=extremely likely). Respondents were categorized as Promoters (scores of 9 - 10), Passives (scores of 7 - 8), or Detractors (scores of 6 or below). The NPS was calculated as the percentage of Promoters minus the percentage of Detractors. Positive NPS values indicate that more participants would recommend the program than not, while negative scores suggest the opposite [12].

Results

Sample Characteristics

Most participants identified as female (223/359, 62%), were aged 65 years or older (251/359, 70%), and had a single chronic condition (220/359, 61%), most commonly hypertension (266/359, 74%). Just more than half (204/3, 57%) had been enrolled in the program for less than 6 months (Table 1).

[a]Multiresponse item. Participants could report multiple health conditions.

Self-Reported Health and Health-Related Changes

Most respondents rated their health as “good” or better (263/358, 74%). Nearly half reported improvements in their physical health (155/314, 49%) and a reduction in health-related stress (148/326, 45%) since enrolling in the program. Reported behavior and condition management improvements included increased knowledge of their condition (172/360, 48%), more active involvement in their care (143/360, 40%), healthier eating (120/360, 33%), improved condition control (116/360, 32%), increased physical activity (112/360, 31%), and reduced stress (96/360, 27%; Table 2).

Increase	40 (11)
Started/changed medication	65 (18)
Not on any/no change	235 (66)

Program Ratings

The majority of participants (320/359, 89%) rated the Remote Care program as "somewhat" to "extremely" useful. Based on responses to the NPS item, 66% (234/357) were classified as Promoters, 20% (72/357) as Passives, and 14% (51/357) as Detractors, yielding an overall NPS of 52, categorized as "excellent." NPS was higher among those with longer enrollment, self-reported health improvements, and individuals managing diabetes or hypertension (Figure 1).

XSL•FO
RenderX

Figure 1. Net Promoter Scores by condition, program duration, and reported health improvements. BP: hypertension; CHF: congestive heart failure.

Program Feature Ratings

All Remote Care program features received favorable ratings, with most respondents rating components as "good" to "excellent." Nurse monitoring, remote monitoring devices, and program cost received the highest "excellent" ratings (>50%). Coaching, educational content, and outcomes were rated more variably, with a broader distribution across "average," "good," and "excellent" ratings. Fewer than 7% of respondents rated any feature as "poor" or "very poor" (Table 3).

Comparative Analyses by Participant Characteristics

Chi-square analyses indicated that self-reported physical health improvements were significantly associated with age (χ^2_1=10.56; *P*=.001) and program duration (χ^2_2=8.72; *P*=.01). Reductions in health-related stress differed by gender (χ^2_1=7.18; *P*=.007) and program duration (χ^2_2=5.99; *P*=.05), with trends also observed for age (χ^2_1=3.62; *P*=.06). Participants enrolled longer reported higher satisfaction across several program components, including ease of enrollment, content, duration, and perceived outcomes (all *P*<.05). Nurse monitoring ratings were also significantly higher among those with longer program participation (χ^2_4=10.49; *P*=.02). No significant differences in program or nurse ratings were found by health condition. A nonsignificant trend suggested men rated nurse recommendations more positively than women (χ^2_4=5.54; *P*=.06), and younger adults rated overall program usefulness slightly higher (χ^2_2=4.87; *P*=.09). Multivariate logistic regression models including age, gender, and program duration were conducted to adjust for potential confounding factors. Multivariate findings were consistent with univariate results, with no substantial changes in the significance or direction of observed associations.

Discussion

Principal Findings

This study found high participant satisfaction with a clinically implemented Remote Care program designed to support chronic condition management through digital monitoring, nurse outreach, and personalized coaching. Most participants reported the program was useful in helping manage their health, and satisfaction was highest among those with longer program engagement. These findings add to a growing body of literature supporting the acceptability and perceived value of remote care solutions for patients with chronic disease.

Participants reported a variety of benefits beyond satisfaction, including improvements in physical and emotional health, condition-related knowledge, and self-management behaviors. These findings are consistent with prior studies showing that remote care can support healthier lifestyles and improved condition control [6,13]. While the observational design limits causal conclusions, the high percentage of participants reporting improvements, particularly in knowledge and engagement, suggests the program may support behavior change in a real-world clinical setting.

XSL•FO
RenderX

Program duration emerged as a consistent factor associated with greater perceived benefit. Participants who were enrolled longer reported more health improvements, higher satisfaction ratings, and stronger endorsement of program features, including nurse support and educational content. While the direction of this relationship is unclear, whether satisfaction encourages continued engagement or vice versa, this aligns with prior research showing satisfaction and engagement are mutually reinforcing and essential to program effectiveness [14].

Few differences in satisfaction emerged across demographic groups. While age and gender were associated with some trends in health perception and nurse rating preferences, program usefulness and satisfaction ratings did not vary significantly by gender, age, or specific health condition. Notably, men, who often engage less with health coaching, rated nurse recommendations particularly favorably, suggesting an opportunity to better tailor outreach or messaging to male participants. Although the association did not reach significance, this pattern may indicate that nurse-led outreach is especially effective for engaging men in self-management—a group often underrepresented in such programs. This warrants further exploration.

Younger adults also appeared to perceive the program as slightly more useful, a pattern that contrasts with previous findings where older adults more often rate remote tools favorably [9]. This may reflect generational differences in expectations for digital health and could inform strategies to optimize engagement across age cohorts. While these trends fell short of statistical significance, they may still carry clinical relevance, particularly given their consistency with prior research and potential value in refining remote care models. In real-world settings with modest sample sizes, patterns like these may not reach conventional significance thresholds yet still highlight meaningful opportunities to personalize care and improve patient experience.

Nurse monitoring was highly rated and is likely a core driver of overall satisfaction. One-on-one nurse interactions may have contributed directly to the reported improvements in condition knowledge, stress reduction, and behavior change. Prior studies support the conclusion that structured remote care with personalized nurse support can enhance self-management and improve outcomes for patients with chronic illness [5,13].

The NPS, an indicator of participant willingness to recommend the program to others, was in the “excellent” range. Importantly, this finding came from a sample with a full range of user experiences, including detractors and passives, not just those who were highly satisfied. This suggests that the program delivered a consistently positive experience across a diverse patient population.

Why This Is Meaningful

Remote care has grown in popularity, especially following the COVID-19 pandemic, as health care systems seek scalable approaches to support chronic disease management [4]. Evidence suggests that remote care and telemonitoring can improve patient outcomes and reduce health care use, including emergency department visits and hospitalizations [5-7]. As these programs become more widely adopted, understanding the patient experience is critical to sustaining engagement and maximizing impact.

This study contributes to the growing body of literature showing high satisfaction with remote care programs [8,9] and extends it by focusing on a clinically integrated program for patients with chronic, not acute, conditions. The consistently high satisfaction and NPSs across diverse subgroups indicate that user-centered remote care models are feasible, scalable, and well-suited for long-term condition management.

Limitations

This study has several limitations. First, outcomes are based on subjective, self-reported data collected from a single group of participants, without a comparison group. This limits our ability to determine whether the observed outcomes were attributable to the program itself or reflect the natural course of condition management.

Second, the survey had a response rate of 26%. It is possible that the experiences and satisfaction levels of survey respondents differ from those who did not respond. However, the distribution of NPSs suggests a range of perspectives was captured. Specifically, 66% (234/357) of respondents were classified as “Promoters,” 20% (72/357) as “Passives,” and 14% (51/357) as “Detractors,” indicating the survey captured both positive and critical feedback about participants’ likelihood to recommend the program.

Third, the high satisfaction ratings related to program cost are likely influenced by the fact that the program was covered by insurance for nearly all participants. This may have bolstered overall satisfaction scores. It is unclear whether participants would have rated the program as highly if they were required to pay out of pocket. Prior research has shown that cost is a frequent barrier to program use [15].

Fourth, while some demographic and health-related differences were observed between survey responders and nonresponders, these were modest and not suggestive of systematic response bias; nonetheless, the possibility of unmeasured differences affecting the generalizability of findings cannot be ruled out.

Finally, the demographic data available for analysis were limited to age, gender, condition, and program duration. We did not have access to important clinical characteristics such as duration of diagnosis or disease severity. Future studies should consider collecting more detailed clinical data to better characterize the participant population and contextualize outcomes.

Because the survey was developed for quality improvement purposes and not psychometrically validated, the reliability and comparability of the findings may be limited. However, the use of face-valid items aligned with program goals supports their relevance for capturing participant experience in real-world care settings.

Conclusions

This study demonstrates that patients managing chronic conditions within a clinically delivered Remote Care program reported high levels of satisfaction, perceived usefulness, and

XSL•FO
RenderX

self-reported health improvements. Longer duration in the program was consistently associated with greater perceived benefit, highlighting the value of sustained engagement.

The findings suggest that remote care programs incorporating regular nurse outreach, connected health devices, and tailored educational content can support patients in managing their health outside traditional clinical settings. As health care systems continue to adopt digital and hybrid care models, understanding patient experience will remain essential to driving meaningful outcomes. Future research should incorporate longitudinal or comparative designs to evaluate the program's clinical effectiveness and long-term impact on behavior change and health outcomes.

Acknowledgments

The authors are grateful to Sarah LaPointe, PhD, for methodological advice and contributing to the survey design. We are also thankful for the contributions of Kelsea Hoover, Jay Burke, Alex Foley, and Cami Woomer for input regarding survey design, data collection, and review of survey results. ChatGPT (OpenAI) was used to assist with language editing and to improve the flow of the manuscript after it was drafted by the authors. All AI-generated suggestions were critically reviewed and approved by the authors prior to inclusion in the final version. No generative AI tools were used to generate scientific content, analyze, or interpret results.

Brook, Inc. provided funding and financial support for this study and publication.

Data Availability

The datasets generated during this study are proprietary and confidential, and therefore are not publicly available, but may be obtained from the corresponding author upon reasonable request.

Authors' Contributions

SMZ contributed to conceptualization, analysis, methodology, writing–original draft, and writing–review & editing. MM assisted with conceptualization, supervision, writing–review & editing. GJJ handled data analysis and manuscript review and editing.

Conflicts of Interest

MM is employed by Brook, Inc, serves as the Chief Medical Officer at Brook, Inc., and has stock options at Brook, Inc. Brook contracted with inZights Consulting (SZ) to serve as independent evaluator on this project and provide consultation on research projects.

Abstract

Background: The use of conversational agents (CAs) in mental health therapy is gaining traction due to their accessibility, anonymity, and nonjudgmental nature. However, understanding the psychological factors driving preferences for CA-based therapy remains critical to ensure ethical and effective application. Variables such as epistemic trust, attachment styles, personality traits, and fear of intimacy appear central in shaping attitudes toward these artificial intelligence (AI)–driven interventions.

Objective: This study aimed to investigate the role of epistemic trust, attachment styles, personality traits, and fear of intimacy in influencing individuals' willingness to engage with CA-based therapy.

Methods: An online survey was administered to 876 psychology students, yielding 736 responses (84.01% response rate). Variables measured included epistemic trust, attachment styles, personality traits, and fear of intimacy. A 5-point ordinal scale assessed willingness to engage in CA-based therapy. The data were analyzed using ordinal logistic regression models, including proportional odds models (POMs), nonproportional odds models (NPOMs), and partial proportional odds models (PPOMs), with residual deviance used to compare model fit.

Results: The PPOM provided the best model fit (residual deviance=3530.47), outperforming both the NPOM (deviance=6244.01) and the POM based on Brant test results indicating violations of the proportional odds assumption (χ^2_{105}=187.8; *P*<.001). In the final model (n=735), epistemic trust significantly increased willingness to engage in CA-based therapy across all ordinal thresholds (odds ratio [OR] 1.75, 95% CI 1.50, 2.03; *P*<.001). Fear of sharing demonstrated a nonuniform effect, with stronger associations at higher levels of willingness (OR 1.086; *P*=.001). Among personality traits, detachment negatively predicted CA preference (OR 0.95; *P*=.001), while psychoticism showed a positive association (OR 1.12; *P*=.003). Being single emerged as a strong predictor of preference for CA-based therapy (OR 3.717; *P*<.001). Attachment styles showed more nuanced effects. While dismissing and fearful-avoidant individuals were descriptively less inclined to engage in traditional human-based therapy, this association was nonsignificant in the case of fearful-avoidant attachment (*P*=.34) and should therefore be interpreted cautiously.

Conclusions: Epistemic trust and fear of intimacy emerged as pivotal factors influencing preferences for CA-based therapy, underscoring the role of interpersonal dynamics and emotional vulnerabilities. The findings suggest that individuals with avoidant attachment styles or maladaptive personality traits are more inclined toward AI-mediated interventions, driven by reduced fear of judgment and increased perceived safety. The relative homogeneity of the sample considered—particularly in terms of age, education level, and cultural exposure—limits the generalizability of these findings to broader or more diverse populations. Nonetheless, these insights highlight the need for ethical considerations and personalized approaches in deploying CA-based mental health tools to balance user reliance with human-centric therapeutic values.

Introduction

Background

In the past few years, the way clinical professionals, patients, and the general population relate to emotional suffering has notably changed. A crucial role in this shift can be attributed to the rise of artificial intelligence (AI) and conversational agents (CAs). These are advanced manifestations of large language models, which are capable of analyzing and extracting knowledge from human conversations, using it to adaptively prompt a real-time answer and consequently creating multiturn human-computer dialogues. The unique ability of CAs to interact with human beings, understand their communication styles, and engage in human-like conversational responses gained notable attention. This is due primarily to their potential applications in the fields of enhancing mental well-being and providing social support [1], with CA-based tools now assuming more nuanced roles, serving not only as companions [2] but also as therapists for individuals seeking emotional support and guidance (for reviews and meta-analyses, see, for example, [3-6]). The rising trend of using CAs for improving mental health can be attributed to various factors. First, the widespread integration of AI-driven technologies in daily life has normalized human-like interactions with machines. CAs, designed with advanced natural language processing capabilities, can engage users in conversations that mimic human interaction, thereby potentially helping alleviate feelings of loneliness [2,7,8]. In addition, their anonymity and nonjudgmental nature may appeal to individuals who might feel hesitant or stigmatized about sharing their emotions with their human counterparts [1,9,10].

However, beyond these technical features, it is imperative to understand the psychological determinants that may drive individuals to rely solely, or primarily, on CA-based therapy, bypassing human interaction. This understanding is crucial for the ethical provision of mental health care, as for some (eg, people with a poor mental capacity or severe mental illness), the prevalent use of CAs may be counterproductive, for example, by eliciting dependence and overreliance on the relationship built with the CA [11,12].

Several psychological factors may influence a person's willingness to communicate exclusively with autonomous agents in order to deal with life-related painful emotions and memories. Among those, 4 factors appear to be of major importance, as pointed out by several reviews on this topic: epistemic trust, fear of intimacy, attachment strategies, and personality domains (for more details on these reviews and meta-analyses, see sections below).

Epistemic Trust in AI

Perceptions of AI capabilities and trust in its effectiveness may play a significant role in shaping individuals' attitudes toward CA-based therapy. Over the past decade, there has been an incremental growth in the number of reviews [13-16] and meta-analyses [17,18] on the factors influencing trust in AI. Riedl [14] suggested that trust in technology relies on "trust propensity," that is, the tendency to believe that the use of AI can be beneficial and that its performance will appropriately and consistently allow it to address specific tasks. However, such beliefs are not necessarily accurate, concealing a logical fallacy deeply rooted in technology idealization [19]. In the case of CA-based therapy, for example, people may overlook the possibility that relying on AI-driven support alone may compromise their capability to think critically and process information autonomously. In addition, they might be exposed to the risk of receiving information that might not be fully accurate and reliable—or might, in some cases, even be dangerous [20,21].

As Alvarado [22] pointed out, AI is primarily an "epistemic technology," designed to enhance human knowledge in different epistemic contexts (eg, inquiry and accurate prediction). To be used epistemologically, though, AI needs to "earn" our epistemic trust, that is, the tendency to believe in shared communicated information and consider the source of information reliable and trustworthy [23].

As a concept, epistemic trust has a long history that precedes the rise of AI. For instance, Fonagy et al [24] have proposed conceptualizing epistemic trust within a broader sociocommunicative perspective as the output of (early) social learning processes. In these processes, several contextual factors (ie, attachment and personality styles, mentalizing capabilities, peers, and sociocultural environment) interact with each other, influencing the way we gradually discern who is knowledgeable and trustworthy [24-26]. In today's world, AI and social media seem to play a pivotal role [27] in becoming a primary source of our knowledge. However, our ability to trust what others say— including CAs—relies on the extent to which we feel safe in our relationships with them [28]. Indeed, individual differences in the propensity to place trust in and engage with AI are underpinned by various subjective factors, including, for example, personality traits and characteristics [29,30], which could help predict the likelihood of individuals opting for AI-based therapy over human-based clinical interventions.

In this study, epistemic trust was conceptualized as the individual's predisposition to perceive the information delivered by a CA as accurate, relevant, generalizable, and safe, and therefore, the CA as a trustworthy communicator. This is in line with different definitions of epistemic trust (eg, [23,31]; reflecting both the tendency to believe in shared communicated information and to consider the source of that information as reliable and trustworthy). In doing this, this study drew from the established use of this concept in clinical psychology, where epistemic trust encompasses both the informational content and the relational qualities of the communicator. In therapeutic contexts, the trust one places in the message and in the person delivering it is widely considered inseparable, as effective psychological interventions rely on both epistemic validity and emotional resonance. Accordingly, our study treats epistemic trust as a relationally embedded construct, capturing both the individual's openness to the information provided by a CA and their implicit trust in the agent as a reliable, nonthreatening source.

Attachment-Based Personality Development and Propensity to Trust AI

Research efforts aimed at understanding attitudes toward AI have primarily concentrated on personality traits underpinning

XSL•FO
RenderX

our preferences and behaviors [32,33], leading to the identification of 2 main theoretical conceptualizations of personality and trust in AI. The first considers personality traits as predictors of trust, while the second sees trust as a mediator between personality and behavioral intentions toward AI systems (for a systematic review of the research status on personality and trust in the context of AI systems, see Riedl [14]). In this regard, the same author [14] proposed a third framework suggesting that the propensity to trust AI is a specific personality trait related to broader personality constructs (ie, the Big Five). This framework also suggests a complex role for emotions and affective states, which are influenced by personality traits and, in turn, influence the development of trust in others and how we relate to them [34].

Similarly, Fonagy and colleagues [35] recently affirmed that "attachment and personality styles are seen as communicative strategies underpinning social learning to ensure adaptation to ever-changing social situations." In other words, deeply rooted aspects of individuals' selves, such as their personality patterns and attachment styles, influence their emotional regulation skills and abilities to relate to others. The quality of our interactions with others, in turn, shapes our inner generalized perception of the availability and trustworthiness of our other people and the overall environment [27,36].

Although research in this field is still in its infancy, recent findings [28] suggest that attachment insecurity can predict a lack of trust in AI. In addition, the same study [28] found that exposure to attachment security cues (but not positive affect) via priming or nudging increased trust levels. In essence, these findings are closely akin to Fonagy's conceptualizations of epistemic trust, personality, attachment, and mentalizing skills, suggesting a possible predictive role of epistemic trust, personality, and attachment in our disposition toward CA-based therapy.

Fear of Intimacy and Avoidance-Based Attachment Patterns

Intimacy involves the capacity to commit oneself to particular affiliations and relationships, and to possess the "ethical courage" necessary to uphold these commitments [37]. Intimate relationships develop in early infant-caregiver relationships, fostering trust in others and instilling the confidence and self-esteem necessary for a child to explore their social environment [38,39]. Difficulties in building intimate relationships during adolescence and early adulthood reflect a lack of emotional integration and have been linked with a wide variety of mental health problems, including general maladjustment and personality disorders [40,41].

Currently, technology often plays a paradoxical role in fostering a sense of "virtual intimacy" while leading to potential social isolation [42,43]. This dichotomy may be underpinned by the coexistence of a desire for connection with a fear of face-to-face interactions, where intimacy and empathy are truly tested [44,45]. This dynamic may also be found in therapeutic relationships, where patients may desire, albeit feel uncomfortable, to open up about their personal lives to mental health professionals [46]. From this perspective, the desire to interact solely with AI to address psychological distress may mask a deep fear of intimacy while simultaneously reflecting the need to understand and make sense of our emotionally painful experiences.

Individuals grappling with the fear of intimacy typically exhibit characteristics rooted in 2 distinct avoidance-based attachment strategies, which correspond to 2 different models of the self: fearful and dismissing [47]. In both cases, others are perceived as untrustworthy and threatening our security. However, individuals with a fearful attachment style consciously desire social connection despite avoiding them due to a depleted sense of self-worth and a deep-seated fear of rejection. They tend not to believe they deserve love and support and mistrust others' intentions. Conversely, subjects who dismiss intimacy possess a positive self-representation and defensively deny their need or desire for intimate social contact. This defensive dismissal serves to protect their self-image and independence [47-49]. This differentiation suggests that both groups may feel more secure in an AI-based relationship and be more prone to trust CAs rather than human beings (eg, therapists), albeit for different reasons: the former (fearfully attached) because of the fear of opening up to someone who might hurt, judge, or reject them, while the latter (avoidantly attached) as they value connections that allow them to preserve their positive self-image and independence [50-52].

In the past few years, an increasing reliance on CAs in mental health therapy has emerged [1], driven by their advanced ability to simulate human-like interactions and their appeal as anonymous, nonjudgmental support systems. While the technical capabilities of CAs have been extensively explored, less is understood about the psychological factors influencing individuals' preference for CA-based therapy over human interaction. Key constructs such as epistemic trust, attachment strategies, personality traits, and fear of intimacy have been identified as critical determinants of this preference.

Considering this, this study aimed to address a gap in the literature by examining how key psychological factors—specifically epistemic trust, personality traits, avoidance-based attachment styles, and fear of intimacy—influenced individuals' willingness to engage with CAs for mental health support. The goal was to contribute to a deeper understanding of the psychological underpinnings that shape preferences for CA-based therapy, with broader implications for the ethical implementation of AI in mental health care. To achieve this, we employed an ordinal logistic regression model to assess the predictive role of these factors in shaping individuals' dispositions toward AI-mediated therapeutic interventions.

Methods

Recruitment and Sample

Data were collected through an online survey distributed to students attending the MSc course "Psychology of Communication" at the Department of Philosophy, Communication and Performing Arts of Rome3 University (Italy). The study was advertised by posting an e-copy of the study flyer on the academic page and Microsoft Teams channel

of the MSc course, reaching out to a pool of 876 students. Participants accessed the survey through a Google Forms link, where they were presented with a Participation Information Sheet (PIS) outlining study details, that is, a concise overview of the study's objectives, participation requirements, data handling procedures, and contact information for the principal investigator, followed by a consent form.

Ethical Considerations

The participants were asked to confirm their agreement to participate by clicking "I agree" on the consent form. Selecting this option to express informed consent redirected participants to another form containing the assessment measures used as part of this study. Participants remained anonymous and could withdraw from the study at any time before data analysis by contacting the principal investigator through email as described in the PIS. The online survey used in this study was designed and implemented in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys [53]) guidelines, ensuring methodological transparency, ethical compliance, data integrity, and robust participant engagement throughout the process. Table 1 reports the CHERRIES criteria and how they were met for this specific study. All procedures performed in studies involving human participants were in accordance with the ethical standards of Italian Psychoanalytical Association (ethical approval 0405/2023) and with the Declaration of Helsinki of 1975, revised in 2013.

Table . CHERRIES[a] compliance.

CHERRIES criteria	Study implementation details
Design	Cross-sectional web survey design using Google Forms.
IRB[b] approval and informed consent process	IRB approval obtained (AIPsi[c] ethical approval 0405/2023); informed consent collected through an online form.
Development and pretesting	The survey was pretested internally by the research team; translated scales were validated via back-translation.
Recruitment process and description of the sample having access to the questionnaire	Participants were MSc students recruited through an e-flyer advertising the study, posted on the MSc course Microsoft Teams channel and University webpage; 876 were invited.
Survey administration	Google Forms used; PIS[d] and consent form provided before questionnaire; anonymity and withdrawal rights ensured.
Response rate	736 out of 876 responded (84.01% response rate); 735 included in final analysis after removing 1 outlier.
Preventing multiple entries from the same individual	Participants could only submit the form once; the survey required institutional login preventing duplicate submissions.
Analysis	Ordinal logistic regression models used; assumptions tested; best-fit model selected (PPOM[e]); power analysis conducted.

[a]CHERRIES: Checklist for Reporting Results of Internet E-Surveys.

[c]AIPsi: Italian Psychoanalytical Association.

[d]PIS: Participation Information Sheet.

[e]PPOM: partial proportional odds model.

Measures

Sociodemographic Information and Willingness to Rely on CA-Based Therapy

Sociodemographic information (eg, age, gender, years of education, and marital status) was collected. To assess the preference for CA-based therapy over human being-based clinical interventions, participants were asked to answer the following question: "On a scale from 1 to 5, how willing are you to participate in psychotherapy sessions solely facilitated by artificial intelligence (AI), without any interaction with a human psychologist?" (scores range from 1=not at all to 5=extremely).

Epistemic Trust

The Italian adaptation [54] of the Epistemic Trust, Credulity and Mistrust Questionnaire (ETCMQ [31]) was used to assess epistemic trust. This is a 15-item self-report measure with a 3-factor structure assessing various forms of epistemic stance (ie, epistemic trust, credulity, and mistrust). Items were adapted and referred specifically to CA-based therapy (ie, When I have a personal problem, I usually ask AI for advice; If I don't know what to do, my first impulse is to ask AI because I trust). In this study, Cronbach α for ETCMQ was 0.95.

Attachment

The Italian translation of the Relationship Questionnaire [55] (RQ [47]) was used to assess attachment styles. It is a 4-item self-report measure that describes 4 prototypical attachment attitudes (secure, dismissing, preoccupied, and fearful), linked on a 7-point Likert scale. In this study, Cronbach α for RQ was 0.97.

XSL•FO
RenderX

Personality Domains

The Italian version [56] of the Personality Inventory for DSM-5—Brief Form—Adult (PID-5-BF [57]) was used to evaluate personality functioning. The PID-5-BF comprises 25 self-reported items designed to assess 5 maladaptive personality domains: negative affectivity, detachment, antagonism, disinhibition, and psychoticism, in accordance with the alternative *DSM-5* model for personality disorders [58]. Participants rate each item on a 4-point Likert scale, with higher scores indicating greater personality dysfunction. In this study, Cronbach α for PID-5-BF was 0.87. As for the Italian version of the RQ [54], the psychometric properties and validation processes of the translated version of the PID-5 are detailed in the original validation studies.

Fear of Intimacy With Helping Professions

Originally developed to assess the comfort of revealing intimate personal details to helping professions, the Fear of Intimacy With Helping Professionals Scale (FIS-HP [46]), is a modified version of the 35-item Fear of Intimacy Scale (FIS) [59]. The FIS-HP has 18 items grouped into 3 factors, each formed by 6 items, named fear of sharing, openness to intimate sharing, and information sharing. Although a validated Italian translation of this scale is not available, in this study, the original FIS-HP [42] was translated into Italian by 2 bilingual psychologists and researchers and then back-translated by an independent translator to verify the equivalence of the translated scale to the original one, in line with the process followed to obtain the Italian standardized version of the 35-item FIS [60]. In this study, Cronbach α for FIS-HP was 0.94.

Statistical Analysis

Power

To determine sample size, we computed an a priori power analysis for logistic regression using G*Power (version 3.1.9.2; Heinrich-Heine-Universität Düsseldorf) [61] as described by Aysel et al [62], which resulted in a recommended sample size of n=683 (α=.05; β=.95; odds ratio [OR] 1.3, 95% CI 1.15-1.47; critical *z* score=1.64).

Data Analytics Strategy

Given the polytomous and ordinal nature of the dependent variable (ie, willingness to address mental health conditions only via CA-based interventions, assessed using 5 categories that may be ordered according to the level of magnitude), we performed an ordinal logistic regressive model using the polr function in the MASS package of R (R Core Team, 2025), following the procedure described by Liang and Zhan [63]. This modeling approach was selected because the POM is particularly well-suited for handling ordinal outcome variables, where the distance between response categories cannot be assumed to be equal. Unlike traditional methods such as ANOVA, which require continuous dependent variables and assume homogeneity of variance across groups, POM retains the ordinal structure of the outcome and models the cumulative probability of being in or above a particular category. This allows for a more accurate and interpretable analysis of ranked responses. Furthermore, POM enables the inclusion of multiple predictor variables—both continuous and categorical—and yields interpretable outputs in the form of ORs, which is particularly advantageous when assessing complex psychological and demographic predictors. Thus, the POM offers a more robust and statistically appropriate framework for evaluating the ordinal response structure inherent to participants' preferences for CA-based therapy [64,65].

Probabilities of the ordinal response variable were transformed into log-odds via logit function, as shown in Equation 1.

Equation 1: Logistic transformation of cumulative probabilities.

$$(1)\text{logit}(P(Y\geq j))=\ln\left[(P(Y\geq j)/1-P(Y\geq j))\right]=\beta 0j+\beta 1jX$$

In logistic regression, log-odds indicate the likelihood of being at or below a certain category level relative to being above it. A positive logit value suggests a higher likelihood of being in or below a particular category, while a negative value indicates a higher likelihood of being above that category. To express odds in terms of predicted probabilities, which are often easier to interpret, we used the transformation formula:

Equation 2: Conversion from log-odds to predicted probabilities.

$$(2)P(Y\geq j)=\exp(\beta 0j+\beta 1jX)/[1+\exp(\beta 0j+\beta 1jX)]$$

Where P(Y≥j) represents the predicted probability of the dependent variable Y being in or below category level *j*, *e* is the base of the natural logarithm (2.718), β_{0j} and β_{1j} are, respectively, intercept and coefficient for the independent variable X. As gender is a dummy variable, we used the following formula:

Equation 3: Predicted probability for dummy variable (gender).

$$(3)P(Y\geq j)=\exp(\beta 0j+\beta 1j\times\text{Gender})/[1+\exp(\beta 0j+\beta 1j\times\text{Gender})]$$

We used the POM, considering the effects of independent variables (IVs) on the dependent variable as equal across all categories. For instance, the OR of each IV is the same for each cut-off – (1) P[Y=1] versus P[Y≥2], (2) P[Y≤2] versus P[Y≥3], (3) P[Y≤3] versus P[Y≥4], and (4) P[Y≤4] versus P[Y≥5]. POM is the most frequently used logistic regression model for analyzing ordinal response variables [64,65]. However, it leads to strong assumptions that, if violated, may lead to incorrect data interpretations [66]. Checking assumptions is crucial to ensuring the validity of statistical analyses and to justify the choice of a model above others [67]. For example, in their review of clinical psychology studies involving linear regression, Ernst and Albers [68] found that only 2% of cases were both transparent and correct in reporting assumption checking, and a further 6% were transparent but incorrect, leading to serious inferential problems [68].

To test the proportional odds assumption (or parallel line assumption), we conducted the Brant test via the Brant R package [69]. If the *P* value of the Brant test is lower than .05, the proportional odds assumption should be considered violated. When data fail to satisfy the proportional odds assumption, a solution is fitting a NPOM or the PPOM [70]. The main difference between NPOM and PPOM is that while the first allows each of the IVs to vary across each category of ordinal response variable, the second just allows to vary only IVs that have violated the assumption.

Results

Out of 876 students, 736 students (84.01% respondents) aged 18 to 85 years completed the survey. As outliers increase data variability and decrease statistical power, 1 participant (male, age 85 y) was manually removed. The final sample consisted of 735 participants (191 males, 25.98%; 543 females, 73.88%; and 1 missing) with a mean age of 27.69 (SD 12.31) years. The single case with missing gender data was handled using multiple imputation, ensuring that no data were excluded from the analyses due to this missing value. Although the age range of the sample was broad (18 - 85 y), the distribution was moderately right-skewed, with a median age of 24 (IQR 19 - 31) years, reflecting the student population from which the sample was drawn. The majority (n=561, 76.36%) were single or in a nonserious relationship, and the remaining 414 (56.3%) were married or in a stable union. On average, participants had 13.84 (SD 3.50) years of education. A total of 76 individuals (10.30%) reported a previous mental health condition, such as anxiety or depression; 127 (17.3%) reported frequent substance use (≥3 times/week) without meeting the criteria for abuse or dependence.

Table 2 shows the POM model results.

The results of the Brant test show that the overall test fails, and the parallel line assumption is not satisfied (χ^2_{105}=187.8; P<.001). Thus, the results of POM should not be interpreted nor generalized, as some predictors might have nonuniform effects across different levels of the outcome variable, necessitating a more flexible modeling approach. In light of this, possible alternative models to explain the data were considered, and Tables 3 and 4 report the results of such alternative models, respectively NPOM and PPOM.

After partially lifting the restriction, both PNOM and PPOM were models found to fit data correctly and may be useful to explain them. To identify the best solution for this purpose, we compared NPOM and PPOM by using residual deviance, which may be considered a measure of discrepancy of a generalized linear model from real observed data [71]. Thus, the lower the value, the smaller the discrepancy and the better the model can predict the value of the response variable. Residual deviance was computed by the VLMC R package [72], which allows for the optimization of the Akaike information criterion (AIC) or Bayesian information criterion (BIC) and overcomes problems related to residuals for polytomous response data by generating data through a Monte Carlo Chain. Results showed that PPOM had a better fit with respect to NPOM (r_D=3530.472 vs 6244.009) and was therefore selected as the chosen model. More specifically, the choice of PPOM over the NPOM was justified by several considerations. First, the residual deviance for PPOM (3530.472) was significantly lower than that of NPOM (6244.009), indicating that PPOM provided a better fit to the observed data. While NPOM relaxed the proportional odds assumption entirely, allowing all predictors to vary across response levels, this approach risked overfitting and reduced parsimony, especially when predictors with no significant nonproportionality were unnecessarily freed. PPOM, on the other hand, selectively relaxed the proportional odds assumption only for predictors that violated it, as identified through the Brant test. This selective relaxation struck a balance between addressing assumption violations and maintaining interpretability, which was a key advantage over the more complex NPOM. By preserving the proportional odds assumption for variables that met it, PPOM simplified interpretation while capturing nuanced effects for predictors like relationship status and fear of sharing. The findings from PPOM offered unique insights. For instance, epistemic trust demonstrated a consistent effect across all response levels, underscoring its robust role as a predictor of preference for CA-based therapy. Fear of sharing, however, exhibited a nonuniform effect that intensified as willingness thresholds increased. Similarly, PPOM revealed a gradient effect for relationship status, where single individuals showed the strongest preference for CA-based therapy at lower thresholds, a pattern that diminished at higher thresholds. Traits like detachment and psychoticism also varied across levels, with detachment exerting a weaker influence at lower willingness thresholds and becoming more pronounced at higher thresholds. These level-specific effects, which were not as clearly identifiable in NPOM, underscored the nuanced contributions of PPOM. Therefore, the model provided a more precise and actionable understanding of the factors influencing CA-based therapy preferences, balancing statistical rigor with interpretability and offering practical insights for targeted interventions.

[a]Logit link values represent log-odds coefficients from the ordinal logistic regression model, indicating the effect of each predictor on the likelihood of expressing greater willingness to engage in conversational agent–based therapy (measured on a 5-point ordinal scale). Positive coefficients indicate a higher probability of choosing more favorable response categories (e.g., “somewhat willing” or “extremely willing”), while negative coefficients reflect a tendency toward lower willingness.

[f]FIS-HP: Fear of Intimacy with Helping Professionals Scale

Overall, our data showed that epistemic trust emerged as a strong predictor of willingness to rely on CA-based therapy. Higher levels of epistemic trust significantly increased the likelihood of choosing AI-mediated therapy (OR 1.745, 95% CI 1.10 - 1.41; *P*<.001). Fear of intimacy, particularly the subdomain fear of sharing, also demonstrated significant predictive power (OR 1.086, 95% CI 1.01 - 1.06; *P*=.001). These findings suggest that individuals with higher epistemic trust and fear of interpersonal vulnerability are more inclined toward AI interventions. Attachment styles showed differential associations with preferences. Secure attachment was not a significant predictor, while avoidant attachment styles—particularly dismissing and fearful—were negatively associated with willingness to engage in CA-based therapy, although these effects were not statistically significant for fearful-avoidant style (*P*=.34), and should be interpreted cautiously. Personality traits, including negative affectivity, detachment, and psychoticism, were significant predictors of

XSL•FO
RenderX

preference for CA-based therapy. For instance, detachment was associated with lower willingness (OR 0.95, 95% CI 0.94 - 1.00; *P*<.001), while psychoticism predicted higher willingness (OR 1.12, 95% CI 1.04 - 1.21; *P*=.003), suggesting that individuals with certain traits may prefer less emotionally intense interaction modalities. Demographic variables also contributed to the prediction model. Men were less likely than women to prefer CA-based therapy, although this effect was not statistically significant (*P*=.11). Education was positively associated with willingness to engage in CA therapy (OR 1.082, 95% CI 1.03 - 1.14; *P*=.002), suggesting that more educated individuals may perceive AI as a viable therapeutic option. Although men were less likely than women to prefer CA-based therapy (OR 0.724, 95% CI 0.49 - 1.08), this effect was not statistically significant (*P*=.11). Finally, relationship status showed robust associations: single participants were significantly more likely to prefer CA-based therapy (OR 3.717, 95% CI 1.73 - 7.97; *P*<.001), as were those married or in stable unions (OR 2.751, 95% CI 1.41 - 5.36; *P*=.003), when compared to those in less defined relationships. In sum, our analyses underscored the multifaceted role of epistemic trust, attachment, personality traits, and demographics in shaping individuals' preferences for CA-based mental health interventions. These findings have implications for tailoring AI-based mental health services to individual needs and addressing potential barriers to their acceptance.

Discussion

Principal Findings

This study examined the psychological and demographic factors influencing individuals' preferences for conversational agent (CA)-based therapy over traditional human-mediated interventions. Using robust statistical approaches, we identified significant predictors, including epistemic trust, attachment styles, personality traits, fear of intimacy, and demographic factors such as gender and education. More specifically, greater epistemic trust significantly increased individuals' willingness to engage with CA-based mental health therapy, highlighting its central role as a precondition for trusting AI-mediated support. Higher levels of fear of intimacy, particularly fear of sharing personal information, also predicted a preference for CA-based support, suggesting that individuals who feel emotionally vulnerable or threatened by interpersonal closeness may gravitate toward less socially demanding therapeutic tools. Personality traits such as detachment and psychoticism were also associated with greater willingness to use AI-mediated therapy, reflecting a preference for emotionally distant or unconventional interaction styles. Attachment styles showed more nuanced effects: individuals with avoidant attachment (both dismissing and fearful) were less inclined to engage in traditional human-based therapy, indirectly favoring CA-based interventions. Demographic predictors such as being single and having a higher level of education further contributed to increased willingness to use CA-based mental health support. These findings align with broader trends in the literature. Recent studies demonstrate that user trust in AI mental health tools is influenced not only by personal traits but also by perceptions of safety, anonymity, and emotional support [3] For example, Abd-Alrazaq et al [71] found that emotional comfort and perceived nonjudgmentality foster trust in CAs - mirroring our finding that epistemic trust and fear of intimacy shape AI preferences. Similarly, a validated model by Lee et al [73] emphasizes the roles of affect, social norms, and habitual use in shaping engagement with well-being chatbots, supporting the notion that behavioral and contextual factors interact with internal dispositions, such as attachment and personality. Furthermore, a recent expert on AI-driven CAs for mental health support [12] raised concerns about user overreliance and the limited emotional depth of chatbot responses, highlighting ethical risks, particularly for individuals whose psychological profiles may predispose them to overuse AI to avoid vulnerability. A scoping review by Rahsepar Meadi et al [74] further underscored the need for transparency, informed consent, and safeguarding in AI therapy design, especially for emotionally avoidant users. Finally, a study analyzing users' reviews of CA-based apps for mental health [75] found that users are more likely to disclose sensitive information to chatbots due to their perceived anonymity, reinforcing our interpretation that individuals with a fear of intimacy or high detachment may favor CAs as emotionally safer alternatives. Together, these converging lines of evidence reinforce our conclusion that psychological vulnerabilities and individual differences significantly influence engagement with AI-based mental health interventions. This underscores the importance of tailoring such tools to users' psychological needs while also addressing ethical, emotional, and relational implications of replacing human intimacy with machine-mediated interaction in mental health care [74]. The following sections delve deeper into the specific roles of epistemic trust, attachment styles, personality traits, and fear of intimacy, providing a more granular analysis of how each contributes to shaping individual engagement with AI-mediated therapy.

Epistemic Trust and the Role of AI

The results underscored the centrality of epistemic trust in shaping individuals' willingness to engage with CA-based therapy. Higher epistemic trust significantly predicted a greater preference for CAs (OR 1.745; 95% CI 1.31–2.32; *P*<.001), affirming its role as a key determinant of trust in AI-mediated interventions. This finding aligns with previous work [68], which emphasized the importance of trust in fostering acceptance of AI technologies. Our results suggest that individuals who perceive AI as a reliable source of information and support are more inclined to rely on it for mental health therapy, echoing the epistemic relationship outlined by Alvarado [22], who highlighted AI's capacity to enhance human knowledge in epistemic contexts. These findings also resonate with the conceptualization of epistemic trust as a product of early social learning [22,69], which influences how individuals assess the reliability of new sources of knowledge, including AI. This study contributes to the growing evidence that AI systems, when perceived as epistemically trustworthy, can be viable alternatives to human therapists. However, it also raises ethical considerations about overreliance on AI and the potential for reduced critical thinking, as highlighted in recent debates on AI's role in health care [70].

XSL•FO
RenderX

Attachment Styles and Fear of Intimacy

Attachment styles, particularly avoidant patterns, emerged as significant predictors of CA-based therapy preference. Individuals with dismissing and fearful attachment styles were less likely to engage with traditional human therapists, likely due to discomfort with emotional intimacy and vulnerability. These findings align with Bartholomew and Horowitz's [43] model of attachment, which posits that dismissing individuals prioritize independence and avoid reliance on others, while fearful individuals desire connection but struggle with trust and fear of rejection. The preference for CAs may reflect a less threatening avenue for emotional expression, consistent with the argument that digital platforms offer "safe spaces" for intimacy without the pressures of face-to-face interaction [75]. Fear of intimacy, particularly fear of sharing, also significantly influenced preferences for CA-based therapy (OR 1.09, 95% CI 1.03–1.14; *P*=.001). This supports previous findings that individuals who struggle with interpersonal vulnerability may gravitate toward less invasive therapeutic options. Ingersoll et al [42] similarly found that fear of intimacy negatively impacts the therapeutic alliance, potentially hindering the effectiveness of traditional therapy. These dynamics underscore the need for CA-based therapies to account for such fears while ensuring they provide adequate emotional support and empathy. Interestingly, while dismissing and fearful-avoidant attachment styles were negatively associated with willingness to engage in CA-based therapy, consistent with their underlying discomfort with closeness or trust, secure attachment did not significantly predict CA preference. This may reflect the adaptive flexibility of securely attached individuals, who are typically comfortable with both intimacy and autonomy [76,77]. As such, they may evaluate AI and human-delivered interventions based more on perceived usability or relevance than on relational needs or avoidance patterns. In this context, their openness to various forms of support may lead to a neutral or balanced preference, rather than a strong inclination toward or against CA-based therapy. Future studies might explore this by directly comparing secure individuals' preferences across therapeutic formats under varying emotional and contextual demands.

Personality Traits and Preferences for AI Therapy

Personality traits, particularly negative affectivity, detachment, and psychoticism, were significant predictors of willingness to engage with CA-based therapy. These traits reflect tendencies toward emotional dysregulation, social withdrawal, and unconventional thinking, which may drive preferences for less interpersonal forms of therapy. The findings align with Marengo et al [30] who noted that personality traits significantly influence how individuals interact with digital technologies, including AI. The association between detachment and CA preference (OR=0.95, *P*<.001) is particularly notable. Detachment often involves avoidance of emotional closeness, making traditional therapy challenging. CAs, perceived as emotionally neutral, may offer a more comfortable alternative. This supports prior research by Matthews et al [27] who remarked that personality traits affect individuals' comfort with AI, particularly in emotionally charged contexts like therapy. Similarly, the significant role of psychoticism (OR 1.12, 95% CI 1.04–1.21; *P*=.003) may reflect the appeal of AI-mediated therapy for individuals with unconventional cognitive styles who might find human interactions overwhelming or judgmental.

Demographic Influences on CA-Based Therapy Preferences

Demographic factors, including gender, education, and relationship status, also played a role in shaping preferences for CA-based therapy. While gender differences were not statistically significant, the trend suggested that men were slightly more inclined toward AI therapy than women. This aligns with previous findings suggesting that men are generally more open to adopting new technologies [28]. Education level was positively associated with willingness to engage in CA therapy, suggesting that individuals with higher education levels may perceive AI as a credible and innovative tool for mental health support. These findings corroborate Glikson and Woolley's [68] assertion that technological literacy influences the acceptance of AI in various domains. Relationship status also emerged as a significant predictor, with single individuals showing a markedly higher preference for CA-based therapy compared to those in stable unions (OR 3.72, 95% CI 2.37–5.82; *P*<.001). This may reflect the increased reliance on digital solutions for emotional support among individuals with less access to intimate interpersonal relationships, consistent with findings by Loveys et al [2] on the role of digital technologies in mitigating loneliness.

Implications for Practice and Policy

The findings have several practical and ethical implications. First, they highlight the need for CA-based therapies to be designed with sensitivity to individual differences, particularly attachment styles and personality traits. For instance, individuals with high detachment may benefit from interventions that gradually build emotional engagement, while those with high epistemic trust may prioritize transparency and reliability in AI responses. Based on these findings, we recommend that developers incorporate adaptive interaction styles into CA systems, such as pacing strategies, tailored disclosure prompts, and emotionally neutral yet supportive communication styles, to accommodate users who struggle with emotional closeness or fear of judgment. Second, our results underscore the importance of addressing the potential risks associated with CA-based therapy. While these technologies offer valuable alternatives, particularly for individuals who struggle with traditional therapy, they also carry risks of overreliance and reduced critical thinking [74]. As discussed by Abd-Alrazaq et al [3], ensuring that CA-based therapies are used as adjuncts rather than replacements for human interaction is critical to maintaining a balanced approach to mental health care. Third, the role of demographic factors suggests that targeted outreach and education efforts may be necessary to increase the accessibility and acceptance of CA-based therapies across diverse populations. For example, addressing technological skepticism among older adults and less educated individuals could help bridge gaps in mental health support. Furthermore, we suggest that mental health practitioners consider screening tools for psychological traits such as epistemic trust, attachment insecurity, and fear of sharing, to help determine whether CA-based interventions are suitable entry points or supportive

XSL•FO
RenderX

complements to traditional therapy. CAs could then be integrated into care in a way that accounts for users' emotional readiness and interpersonal vulnerabilities. Developers might also consider implementing real-time monitoring features within CA systems to detect signs of excessive dependency or emotional withdrawal, prompting referral to human practitioners when necessary. Finally, the findings raise important ethical questions about the integration of AI in mental health care. As highlighted in a recent review [78], the design and implementation of AI systems must prioritize patient safety, privacy, and informed consent. These concerns are echoed in emerging frameworks for responsible AI integration in mental health research, which emphasize transparency, stakeholder inclusion, and regulatory oversight as essential components of ethical deployment [79]. These considerations are particularly important given the reliance on self-reported data and the potential for biases in AI algorithms. Taken together, our findings provide a foundation for designing CA systems that are both ethically responsible and psychologically attuned to the individual needs of users.

Strengths, Limitations, and Future Directions

This study offered a novel contribution to the emerging field of digital mental health by focusing not only on the technological acceptability of CAs, but also on the psychological determinants that underpin individual preferences for AI-mediated therapy. While previous research has highlighted user satisfaction, perceived usefulness, or the technical capabilities of CAs, relatively little attention has been paid to why certain individuals are more psychologically predisposed to prefer AI over human interaction in therapeutic contexts. By integrating constructs such as epistemic trust, fear of intimacy, attachment style, and maladaptive personality traits, this study provides a more comprehensive and person-centered model of CA engagement. This approach fills a critical gap in the literature and offers clinically relevant insights for tailoring CA-based interventions to the psychological needs and vulnerabilities of different user profiles. Nonetheless, while providing valuable insights, this study is not without limitations. The sample was drawn from a specific population (university students), which may limit the generalizability of the findings. More specifically, the participants were all enrolled in a psychology degree program, which likely reflects a cohort that is highly educated, psychologically literate, and potentially more open to digital therapeutic tools than the general population. This homogeneity may have biased responses toward higher levels of epistemic trust and engagement with AI, which could inflate associations between psychological variables and preference for CA-based therapy. As noted in broader critiques of online survey methodology (eg, Andrade [80]), such sampling bias is common and warrants careful consideration when interpreting results. Future studies should replicate this work using more diverse and representative populations to validate and extend the findings. In addition, the reliance on self-reported measures introduces the possibility of response bias, particularly in relation to sensitive topics such as mental health history or substance use. While all participants in this study were aware of what CAs and CA-based therapy entail, due to their academic exposure to topics including the definition, clinical implications, and ethical considerations of AI-mediated therapy, this context should not be conflated with broader public understanding. Although we did not assess participants' personal use of AI tools for psychological support, this was a deliberate methodological choice, as the study aimed to investigate individuals' willingness to engage with CA-based therapy, not their actual behavioral engagement. Nonetheless, individual differences in previous exposure to AI may have shaped interpretations, and this represents an important avenue for future research. Finally, we acknowledge that although the study was grounded in established psychological theory, its cross-sectional design limits the ability to draw causal conclusions. While we refer to associations between constructs such as epistemic trust, attachment style, and CA preference, these relationships should be interpreted as correlational. Longitudinal or experimental designs are needed to determine causal pathways or mediating processes underlying these associations. Looking ahead, while this study focused on individual psychological predictors, future work could explore the interaction between user characteristics and system-specific features, such as CA interactivity, tone, or anthropomorphism. Investigating how these elements jointly influence engagement and outcomes could offer richer insights into optimizing AI-supported mental health interventions across diverse user groups. This priority also aligns with recent reviews (eg, Beg et al [81]) calling for research that connects user characteristics with CA functionalities, including interface style, responsiveness, and therapeutic framing.

Conclusion

This study contributes to the growing literature on AI-mediated mental health interventions by identifying key psychological and demographic predictors of preferences for CA-based therapy. The findings emphasize the importance of epistemic trust, attachment styles, personality traits, and demographic factors in shaping attitudes toward AI in mental health care. While these technologies offer promising alternatives to traditional therapy, their integration must be approached with caution to ensure ethical and effective mental health support. Future research should continue to explore the dynamic interactions between individual differences and technological features, paving the way for personalized and equitable mental health interventions.

Abstract

Background: Mental disorders are the leading cause of disability in young people (aged 12‐30 years), and their incidence constitutes a major health crisis. Primary youth mental health services are struggling to keep up due to overwhelming demand, the complexity and severity of young people presenting for care, and a shortage of qualified mental health professionals (MHPs). Artificial intelligence (AI) tools have the potential to facilitate necessary improvements to diagnosis, triage, and care planning for young people with emerging mental disorders.

Objective: The objective of the present scoping research was to examine beliefs and attitudes underlying MHP acceptance of AI tools in youth mental health services.

Methods: In total, 57 MHPs (mean age 35.35, SD = 9.50 years, 72% female (n = 39)) with experience working with youth populations (age 12-30) took part in study 1 that involved completing a web-based survey about the acceptability of using AI in early intervention services. During study 2, 15 MHPs also participated in 1-hour semistructured Zoom interviews. Attitudes toward the use of 2 novel AI prototypes (both of which provide recommendations for care coordination based on previously published data analyses) in youth mental health were explored. Quantitative data were interpreted using descriptive statistics, and qualitative analysis followed the thematic analysis approach.

Results: MHPs were more likely to agree than disagree that AI will improve youth mental health care overall (eg, n=37, 64% participants somewhat or strongly agree that the field of mental health will improve with AI). Despite voicing concerns regarding data security and privacy, MHPs also acknowledged a need for AI to improve the “signal-to-noise ratio” in services and address delays to care for those with severe and complex problems. Such problems were seen as pervasive across the youth mental health system and emphasize the serious costs of delaying the development and implementation of novel tools. All participating MHPs discussed the potential negative impacts of not adopting novel tools.

Conclusions: MHP acceptance and uptake of novel AI tools in youth mental health services will be driven by a more complex cost-benefit analysis of both adopting and not adopting, rather than solely on their design. The costs of delay are clear, and so researchers and MHPs have a shared imperative to develop useful and meaningful clinical tools and to work jointly on integrating them into practice. Limitations of our sample (including low sample size limiting generalizability) notwithstanding, these findings should inform the future design and implementation of such tools.

KEYWORDS

youth mental health; digital mental health; youth; adolescence; technologies

Introduction

Mental disorders have profound negative effects on young people’s health, well-being, and socio-occupational functioning, and the impacts typically continue throughout their life [1]. Mental disorders are the leading cause of disability among 10- to 24-year-olds and are the leading cause of death among people aged 15-44 in Australia [2-4]. In response to the extreme scale and complexity of these problems, urgent calls have been made to radically transform youth mental health services so that they are able to provide more efficient and personalized treatments [5,6]. For example, in Australia, this has led to the development of *headspace*, an early intervention youth mental health service that can provide multidisciplinary care to young people with emerging mental disorders [7,8]. Similar early intervention

XSL•FO
RenderX

services have also emerged internationally, for example, in Canada, the UK, and Ireland, reflecting that youth mental health is currently a global health crisis [9-12]. Yet, these services are frequently overburdened and under-resourced, creating an urgent need to improve assessment and care coordination, particularly for those with emerging severe and complex problems [5,13,14].

To address this need, there is a rapidly growing interest in the development of artificial intelligence (AI) tools that can provide data-driven solutions to more efficiently and accurately plan appropriate treatments, though such tools are yet to be successfully implemented at scale in youth mental health services [15-21]. Research has shown that there are unique challenges to implementing AI tools in health care settings, including regulatory restrictions and clinical decision systems, along with a lack of trust as compared to other industries, likely because making a mistake in health care settings could have serious consequences, even death [22,23]. Even so, these perspectives fail to consider the potential benefits of improving decision-making systems, particularly in settings that are under-resourced and lack qualified staff. This points to a need for more targeted research focusing on specific challenges and opportunities for implementing unique tools based on the usefulness of the individual tool, characteristics of the setting, and broader contextual factors.

Various frameworks have been proposed to identify factors that may underpin successful implementation of novel technologies. The technology acceptance model (TAM) and the unified theory of acceptance and use of technology (UTAUT) are both widely accepted theoretical frameworks [24-27]. TAM proposes that technology acceptance is linked to perceived usefulness and perceived ease of use and is one of the most widely used and earliest theories in health care industries. UTAT is a broader framework that includes performance expectancy (how much a person believes that using the system will improve job performance) and effort expectancy (the perceived simplicity of using the system) along with cultural and organizational factors such as social expectancy (the perception that others believe the technology should be used) and facilitating conditions (technical or organizational support). Both frameworks are likely to have benefits for understanding this complex problem. While it is important to understand organizational- and system-level barriers, given that this is a unique context facing significant challenges, mental health professionals (MHPs) may also consider factors independent of organizational or social setting. For example, young people often present to mental health services with high levels of risk and low functioning, which may be linked to less trust in novel tools to assist with identifying severe clients, given the potential consequences of mistakes.

So far, there is limited research on the use of tools to assist with multidisciplinary assessment and care coordination in mental health care settings, particularly early intervention services, as current research tends to focus on the use of tools within therapy or as self-help tools [5,6,28]. Broadly, barriers to implementation among MHPs include low perceived usefulness of the tools, poor access to training and supervision, and poor perceived competence and knowledge in using clinical prediction models [29,30]. Additionally, therapist characteristics such as external feedback propensity (the degree to which someone values or is open to feedback) and feedback utilization (the extent to which someone implements feedback) significantly mediate the effectiveness of digital tools on client outcomes [31]. Given these barriers, it is important for design and implementation research to engage with youth MHPs to understand how their acceptance and uptake can be improved.

The present study focused on 2 tools that can be used by MHPs that are intended to improve triage and care coordination of young people with emerging mental disorders. Clients and MHPs can input information regarding clients' multidimensional needs, which is then processed by algorithms developed from data on youth populations presenting to early intervention services. Tool 1 is focused on assessing the level of complexity so that clients can be triaged into short-term therapy or more high-intensity and multidisciplinary treatments [32]. Tool 2 is focused on predicting clients' functional trajectory.[33] Those who have a high likelihood of deteriorating likely require more focused functional supports compared to care as usual. Currently, rough prototypes of these tools have been constructed as proof of concept (and so are not publicly available), and we sought MHP feedback to inform their ongoing design and improvement.

Accordingly, this research explores MHPs' acceptance of two decision-making support tools within a unique context, youth mental health services. The present paper describes 2 studies. Study 1 aimed to assess MHP attitudes toward the use of AI tools within youth mental health services more broadly, and the aim of Study 2 was to gain feedback on MHP acceptance of 2 novel AI tools that have been designed to improve assessment and treatment planning in youth mental health services.

Methods

Two scoping studies were conducted separately, each with unique aims; quantitative and qualitative results were not integrated. Study 1 involved descriptive analyses of general attitudes toward digital tools amongst youth MHPs. Study 2 involved in-depth qualitative analysis of MHPs' attitudes and beliefs. These research studies were not preregistered. Data from the study are available on request.

Recruitment and Informed Consent

We used snowball sampling via social media advertisements (using LinkedIn and Facebook) and referrals from participants or other MHPs that had existing relationships with our team to recruit MHPs who had experience working with young people. MHPs completed a digital consent form and indicated whether they were willing to participate in a one-on-one interview, a survey, or both. Participants willing to participate in a Zoom interview were contacted via e-mail and were reimbursed for participating in both the interview and the web-based survey. Recruitment for surveys was time-limited as this was a scoping study that was intended to inform further development and testing of the digital tools; it was carried out between August 2023 and October 2024. Recruitment for qualitative interviews continued until saturation had been reached in April 2024. Participants were included in the study if they were health

XSL•FO
RenderX

professionals who had provided mental health care to adolescents and young adults (12-30).

Ethical Considerations

This study was approved by the University of Sydney's Human Research Ethics Committee (2021/HE000680). Informed consent was obtained from all participants via web-based forms before participating. All data was deidentified before analyses and no identifying information was included in the current paper. Participants were compensated for completing virtual Zoom interviews.

Study 1: Quantitative Data Collection

We first collected web-based survey data about clinicians' acceptance of decision-support tools in youth mental health care to provide descriptive information about (1) the extent to which MHPs were likely to see digital tools as acceptable and useful, and (2) the potential barriers or facilitators of engagement over and above acceptance of the tools.

Measures

Acceptance of AI-Powered Care Pathways

We adapted 8 items from an existing survey by Cornelissen et al [24] based on the UTAUT, a previous study demonstrated internal consistency and inter-rater reliability of the items, to assess what factors were likely to impact MHPs' acceptance and uptake of AI tools in youth mental health services. Participants were asked to rate statements such as "I believe AI would be useful in my overall performance" on a 5-point scale from "strongly disagree" to "strongly agree."

Potential Impact of Innovations in Artificial Intelligence

We used 10 items to assess MHP's opinions about the potential of future AI to replace key tasks carried out in youth mental health services. These items were adapted from a survey by Doraiswamy et al [34] that assessed psychiatrists' opinions on AI to be more appropriate for youth settings and a range of MHPs, including service managers, psychiatrists, psychologists, etc. The utility of these items has been established in previous studies [35,36]. Participants rated the potential importance of using AI to improve various tasks such as "treatment planning" and "identifying referrals to other services" on a 5-point scale from "not at all important" to "very important."

Facilitators and Barriers to Engagement

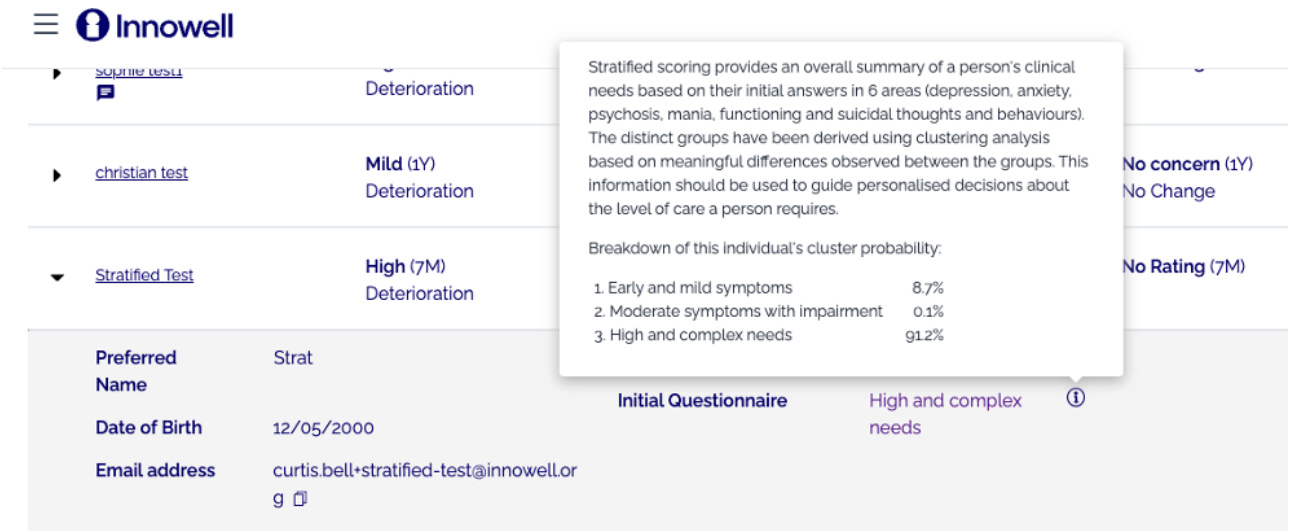
We used 12 items to assess what attributes of novel tools and implementation strategies would most likely impact uptake of novel tools in youth mental health services. Items were adapted from a ranking exercise designed by Leigh et al [37] and were based on a literature search along with expert consensus. Example items included usability, an established research evidence base, and endorsement by colleagues. Participants were asked to rate attributes such as "usability" using a 5-point rating scale from "not important" to "very important."

Procedure

We used web-based surveys to collect quantitative data on the acceptability of AI to health professionals in mental health settings and on the potential facilitators or barriers of implementation and engagement. We used descriptive statistics to compare responses to these items. Given the available sample size, it was not possible to analyze any differences in attitudes between various items. Before analysis, data were screened for valid responses (ie, reported job role fit inclusion criteria for study and location of workplace was in Australia). Given that we used descriptive statistics, participants with missing data were excluded from analyses.

Study 2: Qualitative Data Collection

Participants were initially shown the digital tools and asked to provide initial impressions of the tool before commencing the interview. Semistructured interviews (see Multimedia Appendix 1) allowed us to gain more in-depth information about health professionals' attitudes toward decision support tools within youth mental health settings. Qualitative data collection and analysis followed Standards for Reporting Qualitative Research [38].



Tool 1: Stratified Scoring of Young People's Clinical Needs

Participants were shown a stratified scoring tool that had been embedded within the Innowell platform. The Innowell platform facilitates multidimensional assessments by allowing clients and their MHPs to complete in-depth initial assessments and then track progress during treatment in 5 key domains: (1) overall health, (2) mental health, (3) suicidal thoughts and behaviors, (4) everyday functioning, (5) social connectedness, and (6) drug and alcohol use. This platform has been described in detail in previous publications [39,40].

As shown in Figure 1, the stratified scoring tool is designed to improve identification of subgroups who have complex multidimensional needs to determine appropriate service pathways and care options. MHPs are given an estimate of the probability that a client has (1) early and mild symptoms (low and mixed symptomatology with limited functional impairment), (2) moderate symptoms with impairment (established depressive symptoms and functional impairment), or (3) high and complex needs (very high and complex needs with functional impairment, suicidality, and at-risk mental states (psychosis or mania). The probabilities presented to MHPs are based on a latent class analysis of a cohort of 1284 people aged 12 - 25 years presenting to youth mental health services, that has been described in more depth in a previous publication [32].

XSL•FO
RenderX

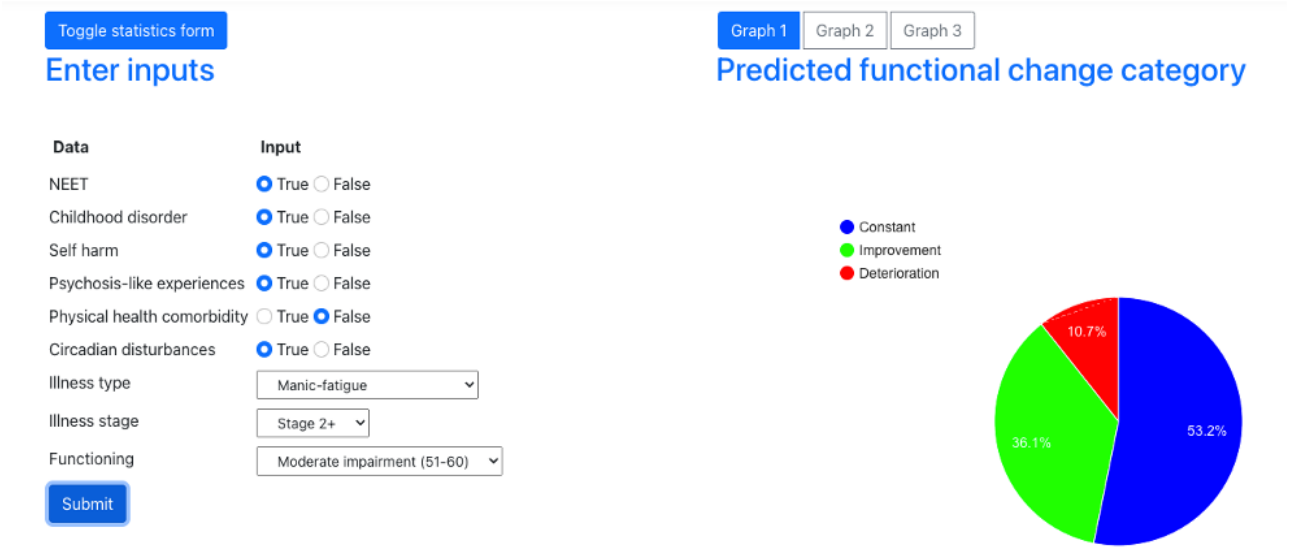


Figure 1. Depiction of tool 1 designed to provide stratified scoring of young people's clinical needs.

Tool 2: Predicted Functional Change

Participants were also shown a tool that predicts a client's functional impairment trajectory over a 3-month period. As shown in Figure 2, the tool shows MHPs the likelihood that a client's functional impairment will (1) remain constant, (2) improve, or (3) deteriorate. The prognostic model was developed from a sample of 718 young people (12 - 25 y) who were engaged in youth mental health care, and it has been described in more detail in a previous publication [8]. In total, 8 factors were used for prediction, including employment, education or training status, self-harm, psychotic-like experiences, physical health comorbidity, childhood-onset syndrome, illness type, clinical stage, and circadian disturbance.

Figure 2. Depiction of tool 2 showing predicted functional change.

Measures

We designed a semistructured interview based on components of TAM that aim to understand why users accept a given technology and how user acceptance can be improved through technology design. According to this framework, acceptance can be measured by behavioral intention to use a novel tool. Interview questions were focused on better understanding 4 key themes, including (1) first impressions of usability, (2) performance expectancy of the tool in decision-making, (3) predicted use within workflow, and (4) professional or ethical concerns.

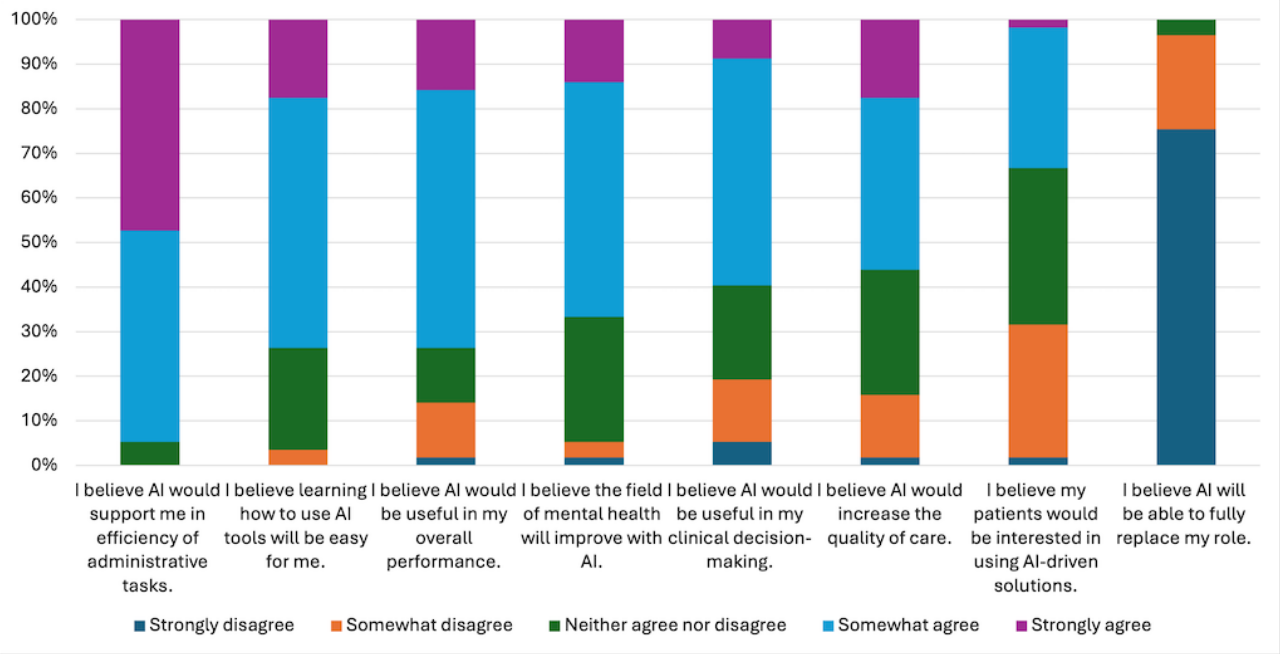
Procedure

Semistructured interviews were conducted via Zoom, video-recorded, and later transcribed. Interviews lasted approximately 60 minutes. Transcriptions of the interviews were analyzed using thematic analysis techniques, with the aim of establishing themes regarding the acceptability of our tools within youth mental health services [41]. Data analysis was both inductive (what was in the data) and deductive (informed by TAM) [24]. Two academic researchers (SM and MC) independently established a list of codes based on transcripts of the interviews. Subsequently, these codes were shared and discussed with a master coder (FI) to establish key themes. A

XSL•FO
RenderX

second round of coding was conducted using a similar process to establish broader patterns of meaning within each theme and refined during a face-to-face meeting with the master coder. Trustworthiness of data coding was established by using two coders and a master coder for triangulation and through an audit trail that can be made available on request.

Results



Participants

The sample consisted of 57 MHPs (mean age 35.35, SD 9.50 years, 72% female (n = 39)) with experience working with youth populations. The majority of participants (45, 81%) came from metropolitan areas compared to rural or regional areas, with a median of 6 - 10 years of clinical experience. In total, 21 participants (37%) had 10 years of experience or less, and 4 participants (7%) had 20+ years of experience. In total, 16 (28%) participants worked only in private settings, 17 participants (30%) worked only in community or hospital settings, while the remainder worked across a variety of settings. All participants completed the web-based survey, while 15 also agreed to participate in one-on-one semistructured interviews.

Quantitative Data Analysis of MHP Acceptance of Novel AI Tools in Youth Mental Health Services

As shown in Figure 3, we first asked participants to rate the perceived usefulness of AI to improve clinical care. In general, participants were more likely to agree than disagree that AI (1) would benefit their overall performance, (n=40, 71%, strongly or somewhat agreed); (2) would improve the field of mental health, (n=37, 64% strongly or somewhat agreed); (3) would be useful in clinical decision-making, (n=33, 58%) strongly or somewhat agreed); and (4) would increase the quality of care (n=31, 54%) strongly or somewhat agreed. Almost all (n=52, 92%) participants strongly or somewhat agreed that AI would improve the efficiency of administrative tasks. Most participants (n=40, 71%) also agreed that AI tools would be easy for them to learn. Even so, participants were unsure whether clients were interested in AI-driven solutions, with (n=20; 34%) reporting they neither agree nor disagree that clients would be interested. Most participants (n=53, 93%) strongly or somewhat disagreed that AI would fully replace their roles.

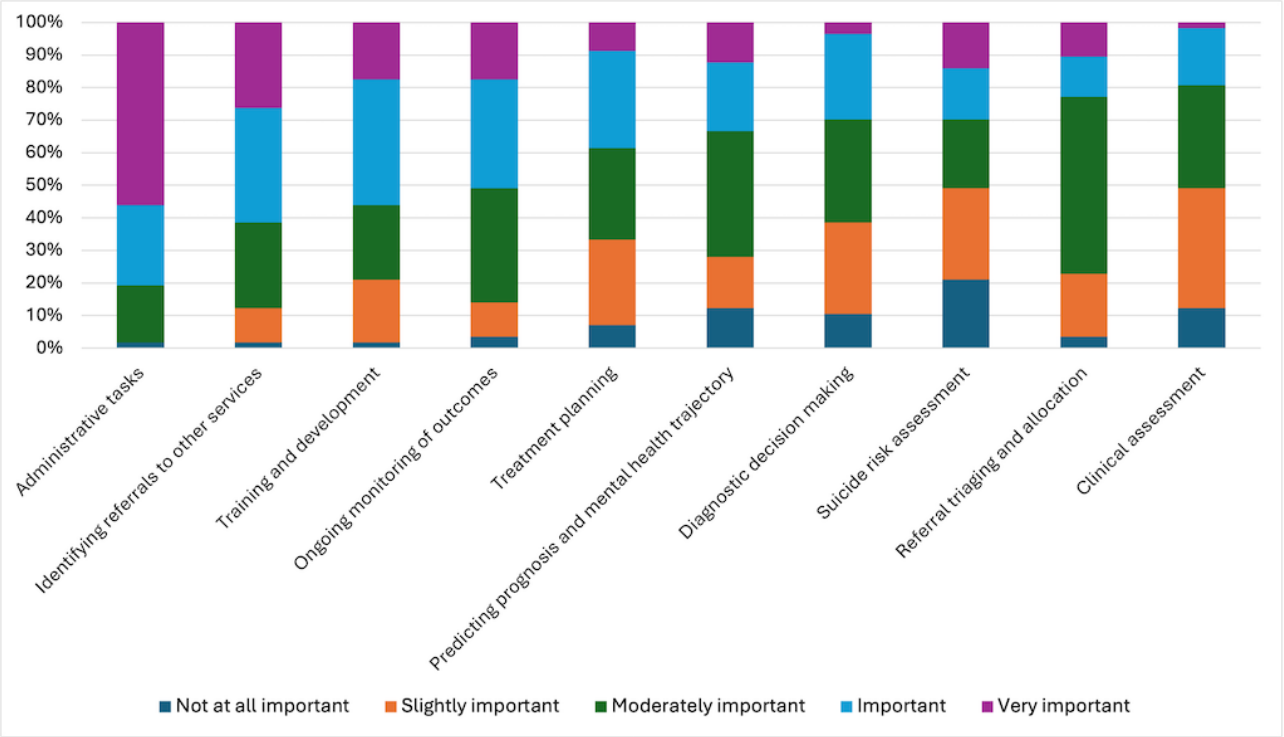


Figure 3. Levels of agreement among mental health professionals regarding the potential of AI to improve aspects of mental health care.

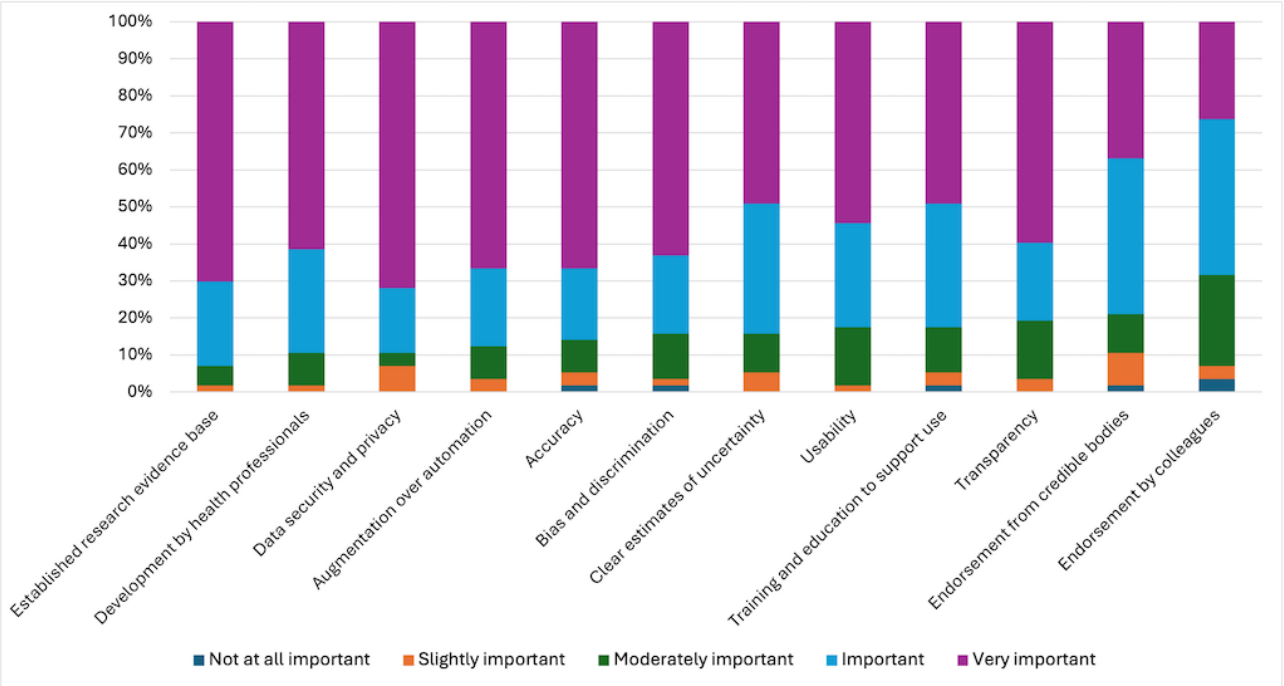
We also asked participants to rate the importance of using AI to improve various clinical tasks (see Figure 4). Participants were least likely to believe that AI was important for suicide risk assessment (42% (n = 24) rating it as not at all or slightly important) and clinical assessment (50% (n=29) rating it as not at all or slightly important) and were most likely to believe that it was important for improving administrative tasks (82% (n=47) rating this as very important or important). Over half (50% (n=29)) of participants believed it was important or very important for AI to improve ongoing monitoring of outcomes, identification of referrals to other services, and training and development. For other items, including referral triaging and allocation, clinical assessment, diagnostic decision-making, and predicting prognosis and mental health trajectory, participant ratings appeared to be more mixed.



XSL•FO
RenderX

Figure 4. Perceived importance of using AI to improve various clinical tasks according to mental health professionals.

Finally, as shown in Figure 5, participants were asked to rate the level of importance of various attributes when considering implementing AI solutions into their practice. All items had high levels of agreement (ie, over 60% (n=34) agree or strongly agree). Over 90% (n=51) of participants saw an established research evidence base, development by health professionals, and data security and privacy as important or very important. Meanwhile, over 80% (n=46) of participants reported that accuracy, augmentation over automation, bias and discrimination, usability, endorsement from credible bodies, clear estimates of uncertainty, transparency, and training and education support were important or very important.

Figure 5. Perceived importance of various aspects of implementing and designing novel digital tools according to mental health professionals.

XSL•FO
RenderX

Qualitative Feedback on AI Prototypes as Proof of Concept

Overall, we found that participating MHPs were highly interested in the development of AI tools. Thus, rather than simply focusing on the prototypes they were shown, discussions focused on the costs and benefits of adopting and not adopting diagnostic and prognostic AI tools in youth mental health services more generally. In line with survey results, participating MHPs were optimistic about the potential improvement to youth mental health care that could be achieved through AI. However, they also appeared to be highly cautious about potential risks to clients and about financial, legal, or training burdens on themselves.

Costs and Benefits of Adopting Novel Tools in Youth Mental Health Services

New Tools Need to Overcome the Non-Negotiable Barriers to Adoption (Costs)

Data fluency was a key concern, as participants often struggled to interpret the results of Tool 1 (see Table 1, Theme 1.1). For example, participants were often surprised by the case study used to demonstrate Tool 1, as the individual was shown to have the greatest probability of being in the low- or high-risk group but no probability of being in the moderate group, which several participants interpreted as an error. One participant noted that for such tools to be implemented, MHPs would need to be well trained in more complex statistical models. By comparison, Tool 2, which used a pie chart to demonstrate predicted trajectories, was immediately seen as more "user friendly," visually appealing, and easy to understand.

XSL•FO
RenderX

Table . Qualitative feedback on artificial intelligence (AI) prototypes from youth mental health professionals.

Themes	Sample excerpts from qualitative data
Costs and benefits of adopting novel AI tools	
Financial costs, time burdens, and safety concerns (costs)	
1.1 Training and other resources needed to understand complex algorithms and establish trustworthiness, reliability, and validity.	"… it's based on probability, right, which is not deterministic, and it's not likely chance. And so it's something we have to get used to, in terms of things not being black and white." [Participant #3, Male] "I don't know if I'm smart enough to understand the algorithms. But I just, I'd be very interested in reading the, like the administration manual, or very dumbed down research paper that I could go, oh, this is why they gave that particular weighting… this was the clinical team and the evidence base that they drew upon." [Participant #17, Male] "I want to know that it has been tested in clinical and community samples, you know, I want to know about its reliability and validity… all that sort of stuff." [Participant #6, Female] "What one person thinks is complex at the beginning of their career, that language is imprecise between people. And so having something standardized and saying, well, 91.2% chance of this… I mean, that seems pretty helpful to me." [Participant #19, Male]
1.2 Data security and privacy	"I'd want to know like how secure it is, like who can access this information?" [Participant #24, Male] "Oh, just feels really intrusive in the person's life and in a way that I wouldn't be comfortable with. So I think that's one thing that's put me off." [Participant #15, Female]
1.3 Professional liability for decision-making	"If the clinician doesn't look at it, kind of like reading a doctor's referral letter, and they miss something, will you be liable?... you should probably be liable, because you're not looking at important information… like that is a professional issue… And on the flip side, if you make a clinical decision or a service decision that is maybe counter to the indications… say there's a coroner's inquest and they say, well, the tool said actually you should have referred and why didn't you?" [Participant #18, Male]
1.4 Ethical concerns about sharing predictive data with clients that may lead to helplessness or reduced self-efficacy.	"I think for people that maybe don't have that sort of level of insight… about their own functioning or their own prognosis… this would be really shocking for them… with someone that was like, oh, yeah, you know… there's nothing wrong with me, or this isn't my fault, or any of those sort of, like core beliefs about what's going on for them. I can imagine them seeing this would be really sort of shocking, or really disarming." [Participant #17, Male] "People feel quite heard and seen by completing these things. And I think that's something if, if that can be made front and centre of these measures… clinicians have their own biases about X, Y, Z, but actually the client experiences, it's helpful… even clients being told that I think that, yeah, helpful message." [Participant #9, Female]

XSL•FO
RenderX

Themes	Sample excerpts from qualitative data
1.5 Financial cost and time burden of implementing novel tool	"Some of the clinicians would be like, I don't have time to… look at all that data before I see someone... And so I can see that that'll be a struggle, like how do you make this really quickly accessible as well." [Participant #5, Female] "Depends about the cost… if it was free, and I knew the data wasn't going to go anywhere, and it was just for me and my practice, I'd use it every day. Okay. If it costs me money, depending on how much… I'd probably say a two out of ten [likelihood of using]. Okay. And if I'm desperate with a complex case… I would, you know, I'd give it like a seven out of ten... If it was a really small fee, I would give it to all my clients prior to them starting." [Participant #18, Male]
Expected use for tools within existing workflows (benefits)	
2.1 Faster identification and referrals of those with severe and complex needs—particularly in large multidisciplinary clinics	"I think it would be very helpful… there have been instances where we have had a few clients come in, and we just weren't the right service for them… emerging psychosis or things like that, which were just not the place for. So I think this would just be so helpful in being able to identify that early on." [Participant #24, Male] "If I ran the headspace center still… I'd be like an eight out of ten [chance of adopting], like working really hard to see how we could bring this into the center." [Participant #19, Male]
2.2 Can supplement rather than replace clinical judgment, which is naturally biased, and dependent on people's training and experience	"Clinical decision making and clinical judgment, has a pride of place… there's kind of entrenched deep problems with that, your biases… I think the clinician has to be pretty open… the statistical tool is probably more accurate than my feeling that someone is suicidal or not… If the test results are coming back and saying 86% chance of being cancer, you should probably agree with that rather than like, your various biases based on your clinical experiences that have selective memories and things like that." [Participant #5, Female]
2.3 Can reduce burden of identifying evidence-based treatments particularly for early MHPs assessing severe and complex clients	"It would be great to have something that could generate a type of like rudimentary treatment plan… your client is presenting with all their history, all this information, and it could like, all the latest research and intervention… that would save so much time, because as a clinician, I think that's where so much of my time is taken just like treatment planning and stuff." [Participant #16, Female] "Seeing what's the best intervention out there, perhaps as a space where AI can help. Okay, ADHD, the first line of treatment is CBT… gathering all the research that's effective there…" [Participant #18, Male]
2.4 "What gets measured gets done"—better information for funders and governments regarding population needs	"Whatever gets measured, gets done…. you get funded by literally the occasions of service you do… if you had this broader sense of, you know, the social occupational functioning and depression, anxiety, and maybe some other things to consider, like if that was all data that you could report back on, to your funders to say this is the targets that we're about… I really like that idea too." [Participant #4, Male] "I think it's really helpful from a service perspective… to look at how they allocate their resources, but it would need some change… you know, are they seeing people [with] early symptoms, are they mostly moderate, you know, what are the what are the breakdown, and people are presenting?" [Participant #9, Female]

XSL•FO

Themes	Sample excerpts from qualitative data
2.5 “Clinicians will do what they always do”	“They just still continue to do what they do, they don’t necessarily take all that information into account as we know… actually feeds back into people’s skills and education.”
	[Participant #5, Female]
	“I don’t know that individual clinician workers actually, necessarily then take that into account in terms of treatment planning. They’ve ticked off the assessment that’s done and then the person is allocated according to what the service can actually provide, not necessarily what the young person needs.”
	[Participant #2, Female]
	“I think it’s up to how much the clinician uses the information again, if a clinician is sensitive to what this data is, is telling them, then I think it can have a significant impact on client outcome. But yeah, I guess, you know, therapy needs to change as a result of this to impact the outcome.”
	[Participant #19, Male]
Costs and benefits of not adopting AI tools	
Irreplaceability of the “human touch” (benefits)	
3.1 Loss of empathy, understanding, and connection	“This is a real person answering the question. There must be some other issues here… physical, family, and help seeking history to complement what’s been responded to - the why.”
	[Participant #15, Female]
	“The AI is not a human being with a culture with understanding and maybe empathy. Of course, we could build it in, we could build it into the AI, but again, you know, at what cost does that have? Like, what risk is that? You know, would I be comfortable speaking to an AI? I don’t know…”
	[Participant #16, Female]
3.2 Skeptical that treatment progress can be predicted by algorithms.	“So I guess I will check you know, if I if I agree with that statistic. And if I, if I did think that too, then I would look at you know, maybe you know, getting them more supports or connected to different resources…”
	[Participant #9, Female]
	“I think because improvement in mental health is so variable… client can have really different goals to begin with, goals can change throughout with treatment… it’s never linear improvement either… like you might not know at the start of treatment that they are on the spectrum and so you could be trying to treat them as such, but it’s like, then they’re not going to demonstrate improvement because there’s that crucial detail that you missed.”
	[Participant #10, Female]
3.3 MHPs pref their own clinical judgment	“This person’s needs haven’t been understood through this data. It’s just their symptoms have been understood… So there’s a need to be really cautious about… how we’re presenting the data, I guess, and what we’re saying the data can and can’t do.”
	[Participant #6, Female]
	“I could see its potential benefits, but… there’s a part of me that’s like… it can never override human judgment… it’s helpful, but I guess it’s not the be all and end all. That’s just my initial sort of reaction… I guess it would sound like a tool that I have to help support my decision making… it’s still up to me to decipher and make sense of the information and to come to my own conclusion about it.”
	[Participant #10, Female]

Themes	Sample excerpts from qualitative data
3.4 "Clinicians will do what they always do"	"They just still continue to do what they do, they don't necessarily take all that information into account as we know… actually feeds back into people's skills and education." [Participant #5, Female] "I don't know that individual clinician workers actually, necessarily then take that into account in terms of treatment planning. They've ticked off the assessment that's done and then the person is allocated according to what the service can actually provide, not necessarily what the young person needs." [Participant #3, Male] "I think it's up to how much the clinician uses the information again, if a clinician is sensitive to what this data is, is telling them, then I think it can have a significant impact on client outcome. But yeah, I guess, you know, therapy needs to change as a result of this to impact the outcome." [Participant #15, Female]
The hidden costs of delay (costs)	
4.1 High demand and high complexity in primary youth mental health services along with "skills shortage" leading to delayed care and referrals	"We have a huge demand for services, we have people presenting with very mixed symptoms, we have them coming into systems where there is very low levels of expertise… I see AI as being a tool which will help to help to improve the signal to noise ratio, will help to be able to discriminate quickly, those people who need to be stepped up into a kind of higher level of care, to more intensive care or monitoring, and those people who can be treated with a kind of briefer, less intense kind of treatment, and they can be triaged accordingly, and then kind of monitored and tracked accordingly." [Participant #5, Female "I think it would be helpful when I'm a bit uncertain about a client in terms of how complex I feel like it is going to be… and whether I'm feeling like, they might need a different service, potentially. Kind of having a bit of a clear line of why we might be referring them on." [Participant #4, Male]
4.2 Service managers and supervisors have poor oversight of less experienced clinicians and not involved in intake assessments	"If you have people with different levels of training and different theoretical models and so on, I think it'd be helpful… that shared data… I could see it being helpful in a supervision setting, too, because it's sort of more objective data that you can bring into the supervisee supervisory relationship, and discuss and reflect on…" [Participant #8, Female] "A really, really clear example I can think of is if there's someone who is reporting psychotic, like experiences and it's a less experienced clinician, that person is going to be more inclined to go or shit they've got psychosis, I need to send them to hospital as opposed to… what is it actually based on? … as that support tool, as an adjunct for that clinical experience." [Participant #4, Male]
4.3 Moral obligation to clients to adapt and improve.	"I think the input we can provide is making sure it's reliable, valid, and so on. But when it comes to preferences, it's not really my own preference… it's really what the folks in front of us want to utilize. And so we need to be open minded to that and not biased." [Participant #17, Male] "If these tools are improving, like health care outcomes, and are more accessible to people… it's about trying to kind of reduce human suffering, like why would you really want to get in the way of that…. if you kind of imagine it in medicine, and they came up with some revolution, yeah, to kind of detect cancer or something, and then doctors, cancer specialists were like, 'Oh, we don't want to do that' … we'd be up in arms about that sort of thing." [Participant #24, Male]

Additionally, almost all users wanted detailed information about how complexity and functioning had been assessed, including understanding psychometric properties of assessment tools, seeing individual items that had led to a particular rating, and having a good understanding of the populations from which the ratings had been derived. Notably, however, improved training

XSL•FO
RenderX

for assessing and identifying severe and complex clients was seen as an important gap, with or without novel tools. One MHP commented that having tools such as this may lead to a more uniform definition of complexity across health services and professionals, which could improve ease of referrals and care coordination.

Participating MHPs also raised concerns about security and privacy (Theme 1.2) and wanted clear information about who would have access to client data before using these tools. In addition, participants had concerns about professional liability if clients received inappropriate care or if risk was not responded to in a timely fashion because of either ignoring or following the advice of tools (Theme 1.3). Several participants reflected on the need for clear guidelines from professional bodies, as well as changes to legislation and insurance policies, before the implementation of these tools could become widespread.

Moreover, when discussing Tool 2, several participants discussed ethical concerns about sharing information about a client's predicted trajectories with clients themselves (Theme 1.4). Participants were particularly concerned about the potentially damaging impacts on a client's hope for recovery, their self-efficacy, and their motivation to continue with treatment. On the other hand, more experienced MHPs were more likely to see this tool as empowering, with one participant noting that they had used a similar tool in their practice and found that "people feel quite heard and seen by completing these things."

Finally, the financial and time burdens of adopting novel tools within health services were frequently cited as a major barrier to implementation (Theme 1.5). Participants suggested that MHPs would only pay a fee for novel technology if they could quickly and easily understand the value of the tool.

Novel Tools Can Address Knowledge Gaps and Will Have Particular Benefits for Severe and Complex Presentations (Benefits)

Participating MHPs generally expected both tools to perform well as a "red flag" system, particularly in large multidisciplinary clinics with high demand for service, to improve efficiency of care coordination, and to help identify those with complex needs more quickly and easily (see Table 1, Theme 2.1). For this reason, participants who worked in private practice were less likely to see the value in the tools, given they did not generally triage clients before seeing them for initial assessments. However, several participants reflected on the difficulty of referring clients within the Australian "Medicare system" and the value of these tools for improving communication with general practitioners and other health professionals.

Despite concerns about the tools' accuracy and reliability, several participants noted the value of having another source of information. They thought the tools could provide valuable insight about complex clients who were not responding to current treatment by assessing whether their current trajectory aligned with expectations (Theme 2.2). Participating MHPs reflected that no tools should be used in isolation; instead, they recommended that such tools should be "triangulated" with other assessment methods and their clinical expertise.

Several participating MHPs suggested that both tools could be improved by providing treatment recommendations, particularly to reduce the burden of care coordination for complex or unique presentations that may require a higher level of training and expertise (Theme 2.3). In a similar vein, participants also suggested that they would prefer these tools to help them identify a client's needs from treatment (ie, need for functional supports), rather than diagnostic information, as this was seen as more relevant for care planning.

As well as helping individual clients to get more efficient care, one participant noted that "what gets measured gets done," suggesting that if tools such as this are implemented in services, it will help funders to better understand client needs and support more diverse support options in youth mental health services other than individual therapy (Theme 2.4).

An important caveat is that participants predicted these benefits would not be realized without adequate training and support for participating MHPs. One participant commented that a lack of experience and expertise in treating severe or complex problems would limit the tools' usefulness (Theme 2.5). They also predicted that the use of the tools would be limited by participants' training in multidisciplinary care more broadly. Indeed, several participating MHPs working in private psychology practices commented that they did not directly address client functioning and did not see Tool 2 as relevant to them.

Costs and Benefits of "Business as Usual" in Youth Mental Health Services

Essential to Preserve Benefits of the "Human Touch" (Benefits)

Even among participants who were highly open to these tools and believed they could be beneficial, there were significant concerns about replacing in-person assessments with digital tools (see Table 1, Theme 3.1). For the most part, participants were worried that digital tools could not display empathy and understanding or build connections with clients. They were also concerned that tools did not consider important contextual information such as family history, social support, or interpersonal communication styles. Additionally, participants were highly skeptical about tools predicting the likelihood of future trajectories (Theme 3.2), as they viewed progress in therapy as highly variable and influenced by a complex range of factors. Most reported that they would mainly use prediction tools retrospectively to assess whether treatments were achieving the intended effects or needed adjustments.

A related problem was that participants ultimately trusted their clinical judgment over and above algorithms to make final decisions about treatment planning (Theme 3.3). When asked, most participants stated they would trust their clinical judgment if they disagreed with the tools. Having said this, 3 clinical supervisor participants wanted to use these tools with less experienced MHPs to help them recognize biases in their thinking. These participants were also more likely to see

XSL•FO
RenderX

"disagreements" with the tools as an important source of information that would enable more reflection and assessment, rather than seeing tool ratings as "right" or "wrong."

Urgent Need to Improve the Signal-to-Noise Ratio in Youth Mental Health Services, and MHPs Cannot Get in the Way of Progress (Costs)

Importantly, most participants also wanted to discuss broader issues in youth mental health services that required urgent improvement through tools such as those used in the present study, indicating that whilst they had concerns about adopting novel tools, they also had concerns about business as usual. Participants frequently commented on issues such as "skills shortage" and the current high demand for services in Australian youth mental health services (see Table 1, Theme 4.1). Participating service managers were concerned that young people were presenting to care earlier in the course of illness (when symptoms are more mixed rather than meeting criteria for specific disorders) and in higher numbers and reported a shortage of skilled health professionals in Australian early intervention services. As such, the tools were seen to improve the "signal-to-noise ratio" within health services by identifying those with more severe disorders earlier and providing more efficient referrals and care coordination to appropriate services.

Additionally, 2 participating service managers cited occasions when clients had been turned away, despite presenting with concerning symptoms, due to lack of knowledge of intake staff (Theme 4.2). For this reason, they frequently discussed how our tools could improve supervision and oversight of less experienced MHPs in their services, particularly those making decisions about referrals and allocation of care.

There were also ethical and moral concerns about "gate-keeping" a client's access to more accurate and comprehensive assessments (Theme 4.3). Two participants made comparisons to medical fields, such as cancer treatment, suggesting that if professionals in these fields were reluctant to adopt evidence-based tools, it would be seen as highly unethical. Participants reflected that the decision to use or not use novel tools should involve clients, particularly if they have been shown to improve outcomes.

Discussion

In sum, MHPs that participated in our study were optimistic that AI would lead to improvements in youth mental health care overall. Despite non-negotiable barriers to adoption, including the financial and cost burdens of learning novel tools, participants found the tools to be useful "red flag" systems that could drastically improve the efficiency of referral and treatment planning processes. These findings highlight both the expected costs and potential benefits of adopting novel tools in clinical settings. Equally, all participating MHPs discussed the impacts of not adopting novel tools (despite not being asked directly), demonstrating the complexity of this decision. Interpersonal relationships with MHPs have important benefits for clients that should be protected. Even so, there are significant risks to clients if youth mental health services do not adopt more intelligent systems that can address the "signal-to-noise" ratio and ensure complex clients receive high-quality care faster.

This work provides a better understanding of how MHPs will make decisions about accepting and adopting novel AI into practice. Digital mental health research has reported consistent problems with widespread implementation of novel tools in youth mental health, partly due to MHP resistance [15-21]. Even so, MHPs in our study clearly saw the utility and value of AI (quantitatively and qualitatively), and this value ranges from reducing administrative burden to helping with referrals, prediction, and treatment planning. These benefits notwithstanding, MHPs identified serious challenges to overcome, including training requirements, infrastructure limitations, and professional liability concerns. Meanwhile, many of the barriers identified are highly solvable—not just in the future, but they must be addressed before widespread adoption can occur. If these barriers are addressed and benefits realized, MHPs clearly acknowledge the value of improved workflows, particularly in high-volume clinics, and predict important benefits for broader mental health system demand. This has the potential to raise the quality of decisions about evidence-based treatments by supporting them with quality information and predictions. Therefore, the costs of delay are clear. Researchers and MHPs have a shared imperative to develop useful and meaningful clinical tools and to work jointly on integrating them into practice.

These findings also demonstrate feasible avenues for improving MHP acceptance and uptake of novel tools. This study identified that usability, development by health professionals, an evidence base, and augmentation over automation are crucial. Again, many of these steps are highly achievable and have been successfully trialed. For example, previous research has found that health professionals are more likely to adopt AI tools when they have seen experienced colleagues integrate them into care and demonstrate potential use [24,31]. Comprehensive literature reviews have also established key steps that may be needed to reduce algorithm avoidance in health care, such as decision autonomy and incentivization [42]. Our results suggest the design of future AI tools should ensure that prognostic information is clearly linked to treatment recommendations and is framed as a means of supporting care planning (eg, by allowing MHPs to assess whether clients are progressing as expected), rather than being seen as deterministic. Given these steps are highly achievable, delaying rapid development and implementation of such tools would be a missed opportunity. There is an urgent need for researchers and MHPs to work together on redesigning current models of care, moving beyond 'business as usual' and toward innovative approaches that better address the complexities of mental health service demand.

Despite these contributions, our research also has limitations that should be addressed. Only 49 MHPs completed our web-based survey. This may reflect that participants who were willing to complete web-based surveys were more interested in AI and therefore more likely to be optimistic about potential future contributions. We also used snowball sampling that may have introduced bias by capturing participants with similar backgrounds and attitudes. Taken together, this limits the generalizability of our findings, and significant further research

XSL•FO
RenderX

is needed amongst youth MHPs. We plan to address this in the future through more comprehensive research in real-world settings on the acceptability, feasibility, and usefulness of our tools. Moreover, we were unable to conduct subgroup analyses with our quantitative data that may help to explain whether AI acceptance is likely to vary based on professional background, experience level, or setting, or whether certain implementation strategies were seen as more valuable. Another limitation is that participants were shown prototypes and were not able to use the tools independently. Survey data suggests that MHPs are overly optimistic about the ease of understanding AI algorithms and so may have overestimated the usability and interpretability of the tools without support from the interviewer. For example, in survey items, MHPs were likely to agree that it would be easy for them to learn novel AI; however, we found that our prototypes were complicated for MHPs to understand, partly because they provided estimates of uncertainty rather than "black and white" information about client status. Addressing both limitations in future research should involve implementing prototypes in youth mental health services as early as possible, to gain more nuanced and diverse opinions from real-world settings.

In conclusion, MHPs recognize the potential of novel AI tools to solve urgent problems in youth mental health. While there are clear and non-negotiable barriers to adoption—including financial costs, potential liability, and training needs—MHPs consider these against the costs of delaying innovation. Problems accessing quality care, particularly for those with severe and complex problems, are pervasive across youth mental health services, creating a need to better handle "signal-to-noise" and to improve efficiency of treatment planning and referral processes. Future research can support MHPs by rapidly developing and implementing novel tools and helping integrate such tools into practice.

Acknowledgments

Thanks to all the mental health professionals who participated in this study and all the staff in the Youth Mental Health and Technology Team, past and present, who contributed to this work. JJC is supported by an NHMRC Emerging Leadership Fellowship (2008196); IBH is supported by an NHMRC Leadership L3 Fellowship (2016346); FI is funded by an NHMRC Emerging Leadership Fellowship (2018157). Abstract

Background: Loneliness is a negative emotional state that is common in later life. The accumulative effects of loneliness have a significant impact on the physical and mental health of older adults. Automatic methods for detection and prediction are an emerging field to support early identification of loneliness.

Objective: This study aimed to qualitatively explore the thoughts and preferences of people aged 65 years and older regarding technologies to detect feelings of loneliness in later life.

Methods: We conducted 60 semistructured interviews with people aged 65 years and older between September 2022 and August 2023. Data were analyzed using a reflective thematic approach on NVivo software (Lumivero).

Results: In total, three themes were identified representing what older adults considered important in a system able to detect loneliness: (1) interest and control of data, which was a priority for older adults; (2) perceived usefulness to address loneliness, which related to the importance of providing recommendations to reduce feelings of loneliness after detection; and (3) personalization as a priority, which included the level of loneliness for which an alert was sent and selection of relevant individuals who would be sent a loneliness alert.

Conclusions: Findings from this in-depth qualitative study provide important perspectives from people with lived experience of loneliness on the context in which a sensor-based loneliness detection system would be most useful and acceptable to older adults. Future research will include such perspectives in the design of innovative technologies enabling the early detection of loneliness and access to timely interventions to tackle loneliness in later life.

loneliness; older adults; preferences; qualitative; technology; mobile phone

Introduction

Loneliness is widely acknowledged to be a serious public health matter [1]. Definitions of loneliness vary, but most authors agree that it refers to a negative emotion linked to poor quality and insufficient social relationships [2-4]. This is usually placed as distinct from social isolation, which refers to an "objective" lack of social relationships. The consequences of loneliness can include poor mental health [5], risk of Alzheimer disease [6], and increased mortality [7]. Aging has long been recognized as associated with loneliness [8], with later life even being expected to be a "time of loneliness" [9]. In the United Kingdom, as many as 1 in 4 people older than 65 years are experiencing moderate to high loneliness [10]. Age-related changes such as retirement, bereavement, reduced social networks, and loss of mobility are well-evidenced as risk factors for loneliness [8,11-14]. Older adults may experience transient loneliness, a temporary feeling experienced from time to time, during such age-related changes.

XSL•FO
RenderX

If loneliness were to be felt consistently over a period of time, it would be defined as chronic loneliness, a state associated with worsening physical and mental health outcomes [15].

COVID-19 substantially impacted the feelings of loneliness and social isolation across the population, acting as a catalyst for many older adults to adopt the use of technologies in daily life [16]. For example, technology has been lauded for its potential to aid people in maintaining existing relationships and increasing communication with neighbors, family, and friends [17]. However, work has identified a multitude of barriers to uptake [18], including trust in the technology [19], and family caregiver concerns related to acting upon risks detected by technologies [20]. Issues of data protection, privacy, and control have been recorded in numerous studies looking at the use of digital technologies in health [21]. Automated technologies have the potential to challenge autonomy, particularly if they notify other people without the immediate consent of the older adult being monitored [22]. Despite such challenges, and with the acceleration of health care digitalization, wearable technologies for health monitoring present a timely opportunity to improve care for aging populations [23]. Due to the rapidly evolving digital landscape, the inclusion of older adults in the design of technology is imperative to avoid digital exclusion [24].

In recent years, using smart technology to identify loneliness has emerged as a potentially useful method of tackling loneliness in older adults [25]. Such technologies would monitor physiological or behavioral indicators of loneliness using sensors, enabling timely detection of loneliness to improve access to targeted intervention [26]. As loneliness is conceptually different from social isolation, which would detect the objective presence or absence of company, loneliness detection technologies are required to include several indicators, including stress, sleep, and activity levels, to enable the passive detection of such a subjective emotional state [27,28]. Specifically, sensor-based approaches measure the behavioral markers of social isolation, such as physical inactivity, poor sleep quality, eating behaviors, time out of home, and phone usage [29]. Numerous works have relayed instances of success using machine learning algorithms able to predict emotions using data such as galvanic skin response [30], electrocardiogram data [31], and electroencephalography data [32]. Behavioral data have also been applied to predicting loneliness [18,26,29]. For example, 1 scoping review found studies measuring daily life patterns to detect loneliness using "smart" technology (eg, ambient sensors to measure motion and touch), smartphones, and wearable sensors [19]. Another review of technology aimed at preventing loneliness in older people found that approaches measuring behavior and movement showed promise as they are usually successful at identifying loneliness [25].

The association between physiological markers of loneliness and the need to tackle loneliness in older populations suggests that it may be fruitful to construct technology capable of identifying loneliness in older adults [33]. Such technologies are required to be both useful and acceptable to older adults to be effective in supporting the reduction of feelings of loneliness. Relevant theoretical frameworks suggest that for technology to be accepted and used by older adults, it must be perceived as easy and useful, and users must have appropriate support and resources [34]. This study aims to gain insight into older adults' general acceptance of loneliness detection technologies to identify the most meaningful priorities for this population, that are applicable to future technology development. Previous work has sought to understand older adults' technology preferences and requirements [24], yet a gap remains in relation to older adults' views on automated detection of loneliness specifically.

The potential to detect loneliness in older adults has numerous potential benefits. A wealth of evidence has suggested that loneliness may be a stigmatized condition [35]. Such negative desirability bias means the ability to detect loneliness without a person needing to seek help [36]. This may be particularly useful for older men who do not identify as lonely but suffer consequences of a similar nature [37]. Timely and accurate identification of loneliness in older adults will enable people to receive the right kind of support at the right time [26]. In general, approaches to alleviate loneliness in older adults include leisure activities (ie, gardening, music, and exercise), therapies (ie, animal, reminiscence, and cognitive), social and community interventions (ie, meal sharing), educational approaches (ie, relationship or skills training), befriending, or system-wide approaches [38]. Such activities can be made available to older adults through referral by primary care professionals through social prescribing initiatives [39].

This paper is part of the "Design for Healthy Aging (DELONELINESS)" project that aims to develop a smart monitoring and communication system with multifunctional electronics built into textiles used as wearables and home furniture to detect and measure loneliness levels in later life [26]. As outlined in previous publications, this system will involve the detection of physiological and behavioral indicators of loneliness in later life using sensor-based technologies. Such technologies will be worn by people aged 65 years and older, with data being inputted into an algorithm modeled to predict feelings of loneliness. Once loneliness is identified, the aim would be to enable users to receive support from family or health and social care professionals or promote engagement in activities to alleviate feelings of loneliness [26].

Including the perspectives of older people is central to the design of such a system [40]. In this paper, we present our qualitative findings on the thoughts and preferences of older adults on technologies designed to monitor and detect feelings of loneliness. Our specific objectives are to (1) describe the context and circumstances in which a smart system might be most useful; and (2) identify the most meaningful way of providing information back to individuals, their carers, or health care or social service providers.

Methods

Study Design

One-to-one semistructured interviews were conducted with participants aged 65 years and older on their experiences of loneliness and preferences for loneliness detection technologies.

XSL•FO
RenderX

Detailed methodology used in this study is available in the published protocol [41].

Ethical Considerations

Ethical approval was obtained from Research Ethics Committees at King's College London (reference LRS/DP-21/22 - 33376) and the University of Sussex (reference ER/FM409/3). Informed consent was sought from all participants. Participants were informed that they could stop their participation at any time. Participants were given a pseudonym following consent to ensure confidentiality. All identifiable information was kept in a password-protected Excel sheet on University OneDrive systems and removed at the point of transcription of interviews to protect the privacy of participants. Participants received a £30 (approximately US $40.47) LoveToShop voucher at the end of the interview as a thank you for sharing their experiences for the study. Interviews were audio-recorded and transcribed verbatim by a professional company.

Recruitment

A stratified sampling technique based on age, gender, accommodation type, and level of digital ability was used. In terms of accommodation type, participants either owned their home, rented, or lived in sheltered accommodation, defined as housing for older adults consisting of private independent units with some shared facilities, emergency alert systems, and a warden [42]. We used the communication preferences of participants during the recruitment process (ie, if older adults had an email, mobile phone, or a landline number) as a proxy measure for the level of digital ability. Eligible participants were required to be aged 65 years and older, have experienced loneliness since reaching 65 years in age, be able to give informed consent, and speak English at a level fluent enough to take part in the interview. Study information was disseminated via research participant websites, organization newsletters related to housing, and through communication to individuals from previous research projects (related to depression and aging) who consented to being contacted about future studies. Interested individuals were invited to contact the research team to obtain study details. All participants provided written informed consent before data collection.

Data Collection

Interviews were conducted between September 2022 and August 2023 by a female qualitative researcher and chartered psychologist with expertise in sensitive interviewing. In accordance with participant preferences, interviews were conducted either in-person (at home or in University offices) or remotely (via telephone or video call using Microsoft Teams software). To describe and stratify a range of experiences, we aimed to interview up to 60 individuals with lived experience in later life [41]. This number was chosen to enable the inclusion of a diverse range of participant characteristics related to loneliness, such as age, gender, accommodation type, level of digital ability, and health status. Characteristic data collected from participants included sociodemographic information (eg, age, gender, ethnicity, and accommodation type). We also included a measure of loneliness severity using the de Jong Gierveld Loneliness scale [43], which has 11 items related to social and emotional loneliness that are totaled to obtain an individual's level of loneliness (ie, not lonely, moderately lonely, severely lonely, or very severely lonely).

The interview topic guide was developed by a multidisciplinary team of psychologists, gerontologists, product designers, and machine learning experts. The first part of the interview focused on the subjective experiences of participants to identify the signs and associated behaviors with loneliness in later life. Findings from this section of the interview have been previously published [33]. The latter half of the interview focused on participants' thoughts and preferences on the role of technology to detect loneliness. In line with theoretical models for technology acceptance [44], the interview topic guide contained specific questions related to older adults' perceptions of the usefulness of technologies. Refer to Multimedia Appendix 1 for complete details.

In relation to technology, we asked about participants' existing use of technologies in relation to their health. We then introduced proposed technologies for measuring loneliness, for example, sensors worn on the body or integrated into a fabric which collect physiological data that may be relevant to loneliness (ie, heart rate and activity levels). We asked participants where on their body or in their home they would be willing to have a device. Finally, we asked about data collected by loneliness detection technologies. Specifically, we asked how useful they would find data collected by the system (ie, sleep, movement, and stress levels) and if these data could be sent to anyone to improve participants' quality of life. We then asked about the benefits and limitations of the data to participants, family members, and health care professionals. Finally, we asked about participants' thoughts on receiving an alert to the risk of becoming lonely, and what participants would hope family members or health care professionals would do if they received a loneliness alert. Refer to Multimedia Appendix 1 for the full interview schedule.

Analysis

Data were analyzed using a reflexive thematic approach by the lead author (J Rees) using NVivo software (version 14; Lumivero) [45]. The early structured themes were constructed by identifying "semantic" themes – surface-level ideas built from the stated perspectives of the participants, but which are not thoroughly interrogated [46]. The generation of initial codes was generally grouped in line with the topic guide questions, for example, usefulness of data, benefits and limitations to data, and thoughts on loneliness alert. We used NVivo to organize our themes into the perspectives of "older adults," "family members," or "health care professionals." These were transformed into "reflexive" themes through several intertwined processes. Specifically, we wrote up "semantic" themes fully into a report, which was then shared with the multidisciplinary project team and discussed in team meetings. Such discussions lead to the refinement of themes, specifically distinctions between theme definitions. Themes were reviewed a final time by the second author (J Ratcliffe), who was involved in drafting this paper but was not present during data collection and analysis. To facilitate an iterative process of theme building and refinement, the themes were critically contrasted with extant

XSL•FO
RenderX

literature [47], specifically the literature on interventions for reducing loneliness. In addition, to extrapolate information on "what works for whom in which contexts" [48], participant characteristics, specifically level of loneliness, marital status, and accommodation type, were considered throughout the write-up stage.

Results

Participant Characteristics

In total, 60 older adults were interviewed with a mean age of 73 (SD 6.7) years, ranging from 65 to 91 years. Most participants were aged between 65-74 years, women, White British, homeowners, and with a moderate level of loneliness (Table 1).

Table . Participant demographic data (N=60).

Characteristics	Participants (N=60), n (%)
Age (y)	
65 - 74	42 (70)
75+	18 (30)
Gender	
Women	42 (70)
Men	18 (30)
Ethnicity	
White or White British	54 (90)
Black or Black British	3 (5)
Asian or Asian British	3 (5)
De-Jong-Gierveld scale loneliness level	
Not lonely	3 (5)
Moderate	36 (60)
Severe	10 (17)
Very severe	11 (18)
Accommodation type	
Own home	43 (72)
Rented	10 (17)
Sheltered accommodation	7 (11)

Marital status varied from widowed (n=20), divorced (n=16), single (n=11), married (n=8), and separated (n=5). The frequency of loneliness also varied from often or always (n=23), occasionally (n=16), some of the time (n=20), and never (n=1). Most participants were degree-educated (n=34). In total, 30% (n=18) of participants did not have children, and 13% (n=8) did not have anyone to contact if they were in trouble or needed help. The majority of participants reported having a long-standing illness or disability (n=50), such as depression, chronic fatigue, arthritis, or hearing loss. Furthermore, 5 participants communicated using their landline numbers only.

Themes

Summary of Themes

In total, 3 themes were constructed to represent older adults' thoughts and concerns regarding a loneliness detection device. First, "interest and control of data" outlined the characteristics of older adults interested in a loneliness detection system and the importance of retaining control over data collected to detect loneliness. Second, "perceived usefulness to address loneliness" highlighted the need to provide suggestions to reduce loneliness in conjunction with an alert about loneliness. Third, "personalization as a priority" relays how participants felt the system needed to be tailored to individuals, particularly regarding (1) the level of loneliness that required intervention, and (2) who the participants felt should be informed they are lonely. Refer to Table 2 for theme outline including supporting quotes.

XSL•FO
RenderX

Table . Themes and selected supporting quotes for thoughts and preferences of older adults for technologies designed to detect feelings of loneliness.

Theme	Supporting quotes
Interest and control of data	• "So it's, well it's just, you know, curiosity about how your body is working. And trying to find patterns and things which is obviously what this is trying to do anyway." [P18, Female, 70, Married, Very Severe] • "Well it's simply because I know I would only get annoyed because I know I'm not doing many steps. Although it's interesting too the way it does your heart rate. Now that's something again I would use it." [P15, Female, 66, Divorced, Moderate] • "Can't be bothered with things like that..I'm not going to make a ridiculous effort at carrying technology around to count them because it's kind of not relevant." [P52, Female, 66, Widow, Not Lonely] • "That's the barrier to me. The information, if it's kept simple, if it's something that's user-friendly to me that's not terribly keen to embrace actively too much technology." [P35, Female, Married, Moderate] • "Yes, some things I might know already but it might show some others that I was not already aware of and that is nice you know, it might not be pleasant, but it is happening and that is good." [P23, Male, 68, Separated, Not Lonely] • "The technology is there. I'd like it all to be used for good but I've no control over whether it is or it isn't and I think for my lifestyle and stuff if you've got nothing to hide it doesn't really matter." [P13, Female, 69, Separated, Moderate] • "I'd be a bit- your terminology, 'at risk of becoming lonely,' that's- a bit kind of- big brotherish, really. I suppose- perhaps it's just the wording, if you said, oh we're concerned for you, it's about time you got out a bit more, then- go and find some friends, go out and have a sing song or go out for a run." [P47, Female, 72, Widowed, Severe]
Perceived usefulness to address loneliness	• "I don't think it would be any use to me. because I know how I feel. I know how I felt yesterday, but I'm feeling better today. No, I don't think it would bother me. I'm not a great one for data. It's more likely to be useful to someone else who's trying to find patterns or (I don't know) reasons for being low." [P8, Female, 65, Married, Moderate] • "I don't know that I could do anything about it, so what's the point in telling you, I don't know. I mean it's because they're going to have someone phoning you up and having a chat with you, you know a silver line chat sort of thing. I don't know if that would make me feel less lonely I suppose you might think well someone could be bothered." [P9, Female, 72, Divorced, Very severe] • "Yes, to have the results but also to have the course of how to break that. It's no point telling me I'm lonely which I already know right. A flashing thing saying please, do this, that might be helpful because there is more directive than giving information that somebody is lonely which they most probably know already." [P49, Female, 72, Divorced, Severe] • "If the algorithms or whatever they call them, if it sees that predicted pattern and it happened once before it says, Oh, last time when you were in that- what actually brought those levels down was that you went and did this." [P35, Female, 68, Married, Moderate] • "For me would be an additional motivator because I've got some concrete evidence, so it would be a motivator to say, Look you're feeling lonely now is the time to make that effort to walk up the pub because there's some music going on tonight, and you know you're going to see so and so." [P32, Male, 70, Widowed, Moderate] • "I don't feel I would need that at this moment in time. I don't but we can't see ahead can we, into the future, and if, when I was, if I was much, much older than I am now then I would probably think it would be a good thing to have but at this moment in time I'm not there." [P55, Female, 73, Single, Moderate]

XSL•FO
RenderX

Theme	Supporting quotes
Personalization as a priority	• "And you could choose the point at which it could be shared, if you like, with those people so that, yes, don't bother to tell them if I'm feeling lonely 10% of the time, but maybe if I'm feeling lonely 50% of the time, then do. But it might be different for other people." [P52, Female, 66, Widowed, Not lonely] • "I think it would be good, because I don't get as much time with my GP as I'd like. I think if she was receiving this information and give her something to study about me, so when I did see her, she could refer back and say, Oh I've noticed your sleep isn't so good. I've noticed you've had these waking moments. But I see that your heart rate's good. So that must be good for you, you know?" [P5, Female, 65, Divorced, Severe] • "When you say you'd alert somebody, who would you alert in my case? I've got no one close that you could send an "I need help" message to." [P43, Male, 70, Widowed, Moderate] • "I really wouldn't want her to be worrying about me, she has her own problems, I think that's something I can cope with. If it's only feeling a bit lonely, I can cope with that, and I really don't think it's worth worrying somebody else. I mean, what are they going to do? Get out of work and rush over just to sit in the house and talk to you, you know I don't know." [P25, Male, 68, Divorced, Very Severe]

Theme One: Interest and Control of Data

Older adults spoke about how health data collected by the system (ie, heart rate, sleep, and activity levels) were interesting, comforting, reassuring, and empowering ("knowledge is power"). These participants all had previous positive experience with using smartwatches. However, some participants were not interested in these data either because they had no present health issues and did not wish to worry about their health ("it is not something you can do anything about anyway") or because of their general disinterest in the use of technology ("I am not a great one for data").

Older adults had varied technological ability, with some using virtual reality and online shopping, whereas others had no WiFi or a sense that there is "too much" technology in daily life. These categories were not mutually exclusive. For example, the oldest participant in the sample (aged 91 y) used technology on a daily basis, including a smartwatch or phone, but felt it isolated her further by reducing in-person interactions, which was especially impactful as she lived in a rural area. Similarly, some participants expressed worry about who would access the data and felt being monitored closely would be intrusive, yet others felt comfortable with data, describing themselves as "open minded" with "nothing to hide." Such perspectives were not associated with the age of the participants or the severity of loneliness.

> *I imagine one of your questions is going to be about the use of data and stuff like that. I'm very comfortable with that…I don't think Big Brother's going to have a huge interest in how many times my heart beats.* [P1, Female, 68, Widowed, Moderate]

The main preference described by older adults was the need to be in control of both the data collected and an alert sent by the system. It was important for older adults to understand which data were being collected and for what purpose. Older adults highlighted how it was important to be aware of the behaviors associated with loneliness and to know why they were being alerted.

> *If the algorithms or whatever they call them, if it sees that predicted pattern and it happened once before it says, Oh, last time when you were in that- what actually brought those levels down was that you went and did this.* [P35, Female, 68, Married, Moderate]

It was important for older adults to feel in control of their data. Participants wished for any data or alerts to be sent to them directly and have the option of contacting other people if they deemed it necessary ("I'd much rather it came through me").

> *The less control you have, the more control you need. So, people will control what they can control. And therefore, it's important that the end user has the control over how things are shared.* [P52, Female, 66, Widowed, Not Lonely]

Theme Two: Perceived Usefulness to Address Loneliness

Most participants described already being aware of their loneliness and did not see the benefit in being alerted about loneliness by the system ("I know I'm lonely I don't need an alert"). Linked with the severity of loneliness, some older adults felt that if you did not notice feelings of loneliness, then a person was not truly feeling lonely.

> *You're aware of the build up. If you aren't aware of it, then you're not of that degree of loneliness, you're just feeling low, can I put it that way? Whereas we can all feel low, and have a bad half hour, a bad day, but loneliness is something else that is different.* [P40, Female, 75, Single, Moderate]

Nevertheless, some thought that the system would be a useful prompt as it provided "concrete evidence" to the early warning signs of loneliness and would either "consolidate" their recognition of loneliness or motivate older adults to engage in behaviors to reduce loneliness. Older adults highlighted how it was important to be aware of the behaviors associated with

XSL•FO
RenderX

loneliness and to know why they were being alerted. One participant compared the system with a "companion" for people who felt alone, whereas others felt the system would have been useful in the past (eg, during widowhood and retirement) or in the future (eg, if cognitive ability reduced). The majority of participants (n=45) lived alone, and this group in particular expressed a concern about falling in the home and suggested that the loneliness sensors could also be used to detect this.

Older adults questioned the use of the system if there was no consequence or follow-up to loneliness detection. Participants felt that if they were to be alerted of loneliness, there would also have to be a recommendation to reduce feelings of loneliness. This requirement was consistently expressed across participants, irrespective of age, gender, marital status, or living situation.

> *If you could tell me how to reduce it, what to do, that would be more important than letting me or anybody else know that I was feeling- I know that I'm feeling it or about to feel it. But it's what to do about it that's the critical thing…There's no point in it otherwise.* [P41, Female, 84, Divorced, Severe]

Theme Three: Personalization as a Priority

Subtheme 3a: Level of Loneliness

Older adults found it important to decide on a level of loneliness at which the alert would be sent to themselves. As participants had a variety of loneliness experiences, this level would need to be tailored to individuals. For example, widowed older adults experienced transient loneliness (ie, more severely at certain times), which may be time-limited, depending on individual grief trajectories. Some older adults experienced severe loneliness, where they were more likely to describe chronic loneliness and thus questioned which level of loneliness would be most appropriate for them. One male participant, who experienced chronic loneliness despite living in shared accommodation, felt loneliness at a consistent level at all times, so he questioned what changes the system would be able to detect.

> *You've got to decide on a level of stress that, you know, like we do on a scale of 1 to 10. You know, if I feel 3 amount of lonely, then don't bother, it will probably pass over, but if I feel 7 or 8 amount of loneliness then please tell me to get off my bum and go out for a walk or something.* [P47, Female, 72, Widowed, Severe]

Participants varied in their responses describing how they would engage in activities to alleviate loneliness following an alert. Some participants described preferring to manage feelings of loneliness on their own, especially for low levels of loneliness ("if it's only a bit lonely I can cope"). When discussing potential interventions following a loneliness alert, participants highlighted the importance of personalization as "every person is going to be different."

Subtheme 3b: Involvement of Others

Participants also discussed the importance of personalization in relation to the involvement of others, specifically health care professionals and family members. For example, some participants had previously experienced suicidal thoughts during times of loneliness and felt it was important for health care professionals to be alerted if they experienced loneliness at that level in the future. However, many questioned whether busy health care professionals, such as general practitioners, had the resources to help with loneliness.

> *…the GP, he can't give me a tablet to stop me being lonely or something like that. Can't come round and spend time with me, you know. They haven't got time to see you in the surgery. So, yes I mean I wouldn't mind the GP knowing I was lonely. But I can't see what advantage there would be there.* [P46, Female, 87, Widowed, Moderate]

Nevertheless, some felt the alert could be sent to health care professionals for severe loneliness or where loneliness was related to physical or mental health issues, such as depression, and some mentioned signposting to counseling and social-prescribing services.

Similarly, older adults felt that loneliness would have to be "severe enough" for the system to contact family members and that this level of severity would differ between individuals.

> *And you could choose the point at which it could be shared, if you like, with those people so that, yes, don't bother to tell them if I'm feeling lonely 10% of the time, but maybe if I'm feeling lonely 50% of the time, then do. But it might be different for other people.* [P52, Female, 66, Widowed, Not lonely]

When participants experienced mild feelings of loneliness, many did not want friends or family members to send the loneliness alert, stating they would feel "embarrassed" or "guilty," and that they could cope with it alone to avoid being a "burden." Some participants expressed not having a problem with family receiving a loneliness alert; however, they questioned what they would be able to do about it if they lived far away. In more severe cases of loneliness, participants thought the loneliness alert could be used as a "conversation starter" during lonely periods where older adults felt less able to initiate social contact. However, others still felt the alert was "too private" to share with others without previous consent from the older adults themselves. Vitally, other participants had no family, so they questioned who they could nominate to receive a loneliness alert. This was especially pertinent for single participants over 80 who felt the alert would be an additional burden to next of kin and relied on safety alert systems in sheltered accommodation in an emergency.

> *When you say you'd alert somebody, who would you alert in my case? I've got no one close that you could send an "I need help" message to.* [P43, Male, 70, Widowed, Moderate]

Overall, involvement of family, friends, and health care professionals in a smart system to detect loneliness was thought to be part of a negotiation as to who the older adult would want involved, at what time, and for what purpose.

Discussion

Principal Results

We constructed 3 themes to represent what older adults considered important in a system able to detect loneliness. "Interest and control of data" highlighted general interest in health data being a personal preference of older adults based on current or previous positive use of technologies. Participants had varying technological abilities but were unanimous in their need to be in control of the data collected and sent by the system. "Perceived usefulness to address loneliness" refers to whether and how the system can be useful to older adults. Many older adults described being aware of feelings of loneliness, especially in severe cases, and thus questioned the usefulness of the loneliness detection system. Participants emphasized the importance of providing recommendations to reduce loneliness following detection to improve usefulness. Finally, "personalization as a priority" refers to the need to work with the individual using the system to determine the level of loneliness that results in an alert, and the consequences of that alert, including the involvement of others to support loneliness, such as friends, family members, or health and social care professionals.

The focus on control echoes concerns over privacy and data protection reported in previous studies on technology use in later life [22,49,50]. Loneliness has been associated with a lack of autonomy [51]; therefore, it is vital that older adults feel in control of the data collected and sent by a loneliness detection system. Trust in technologies can be established through providing feedback in real time and through extensive validation [17,19]. Technology-based approaches for reducing social isolation may not be appropriate for all older adults [52]. As a "digital divide" exists between those with cultural and financial access to technology and those without [24], research has found that lonelier older adults use information and communication technologies less often than their less lonely counterparts [53]. Factors that were found to influence engagement include lack of skills and support to use digital health technologies [54] and a fear or dislike of technology [21]. Ensuring that older adults across a spectrum of abilities feel knowledgeable and confident with the data and associated alerts from the loneliness detection system, is therefore paramount to its use.

The findings of this study suggest a key component of ensuring acceptability of a loneliness detection system is the effective implementation of personalization. Our findings support previous literature, which suggests that digital health systems should make it transparent as to who will gain access to the information collected, and ensure users retain control of who has access to it [55]. A novel finding from our work is the importance of determining an individually selected level of loneliness for which an alert would be sent, highlighting the subjective nature of loneliness [15]. Further consideration is required as to how degrees of loneliness would be measured and reported to the system, for example, self-reporting from older adults or the use of validated loneliness scales [56]. More broadly, our findings on personalization indicate the importance of "user-centered" design in health technology (perspectives that centralize the needs of the user in the design and implementation of the technology) [29,57,58]. This is especially important in the context of culture, which plays an important role in shaping an individual's experience of loneliness [59]. Developing culturally sensitive interventions to reduce feelings of loneliness is an important priority for future research to ensure targeted support is available for older adults.

In relation to the involvement of others in supporting loneliness once detected, older adults emphasized that whoever the system alerted, this should be decided in advance via a clear and transparent set of discussions. Participants tended to refer to general practitioners when health professionals were discussed, a finding that may mirror the trust instilled in doctors by older people [60,61]. Previous research on technology preferences of older adults has identified that if a device was recommended to older adults by a "credible" health professional, it was more likely to be taken up and used [24]. The participants in this study generally held negative attitudes toward alerting family members of loneliness, mirroring concerns from previous research [62]. However, friends or family were not consulted in this study; therefore, it is possible that their thoughts on receiving an alert for loneliness may not align with those of older adults. Perceptions of burden were described as one reason for participant disapproval of family member involvement. Indeed, loneliness has often been linked with guilt, shame, and a perception that others do not care [3,63]. Further research is required on the involvement of family or friends in providing support following an alert from a loneliness detection system, as many loneliness reduction interventions actively involve others [64].

Perceived usefulness is a core component of theoretical models of technology adoption in older adults [44,65]. Participants had varied perspectives on whether and how a loneliness detection system could be useful. Some saw it as potentially useful as a prompt to change their own actions or as an "early-warning" sign before they would have thought to seek help, perhaps even before they realized that they were lonely. Given the stigma of loneliness [3] and the reticence of older men to identify as lonely [63], such a system may be particularly useful for removing the anxiety and uncertainty of doing something about loneliness. Older adults in our study were clear that recommendations to reduce feelings of loneliness once detected were an imperative aspect of such a system. Research has highlighted how there is "no one size fits all" approach to loneliness intervention and that tailored, targeted approaches are required to reduce loneliness (Victor et al [66]). Detailed consideration is required on the selection of appropriate interventions for older adults using a loneliness detection system based on the type of loneliness (ie, emotional or social), severity of loneliness (ie, moderate, severe, or very severe), and reason for loneliness (ie, bereavement or mobility issues). Future research will be required on the acceptability and effectiveness of such recommendations, noting that individual-centered interventions are inherently limited by their lack of capacity to influence the social context of the lonely individual [3].

RenderX

Limitations

This study adds to the emerging literature on sensor-based technologies to detect feelings of loneliness in older adults [18,29]. Our large sample size enabled us to present a variety of perspectives and incorporate a diverse range of participant characteristics, including those who were skeptical or ambivalent about the technology. Despite efforts to achieve an equal distribution of gendered and cultural perspectives, our sample was majority female White-British. Our themes may therefore not represent the views of older adults with different perspectives on technologies, which requires further consideration in future design testing. Our interview sample included people with lived experience of loneliness to provide relevant perspectives and expertise to inform future technology development [67]. It is important to acknowledge that such participants were more open to acknowledging and seeking help for loneliness than some of the prospective target population, who may not readily seek help for loneliness. Social desirability bias may have also influenced how participants spoke about technology. Thus, a gap exists in our knowledge of older adults with reduced help-seeking behavior that may particularly benefit the use of a loneliness detection system. Finally, the perspectives of participants were based on a hypothetical loneliness detection device described by the lead author conducting the interviews. There is no such actual device yet; therefore, potential barriers and enablers identified in related research, such as comfort, cost, and maintenance [68,69], could not be effectively discussed or reviewed. Interpretations of the loneliness detection system may vary among participants, and further user testing would be required to obtain information on acceptability once a device to detect physiological markers associated with loneliness has been developed [33].

Conclusion

Findings from this large qualitative study provide important perspectives from people with lived experience of loneliness on the context in which a sensor-based loneliness detection system would be most useful and acceptable to older adults. It is important to support older adults across a spectrum of abilities and preferences to feel knowledgeable and confident with technologies used by a future loneliness detection system. For older adults to feel in control, transparency on data collected by the system is required in addition to options for personalization related to levels of loneliness, which creates an alert, and which supporters are informed. This should be identified through a clear and full discussion, before they commence using it, of when, why, and who the device should alert in the event of it detecting loneliness. The perceived usefulness of a future loneliness detection system is reliant on activities to reduce feelings of loneliness being recommended following the identification of loneliness. Future research will include such perspectives in the design of innovative technologies enabling the early detection of loneliness and access to timely interventions to tackle loneliness in later life.

Acknowledgments

The authors would like to dedicate this paper to our extraordinary colleague, Anthea Tinker, who passed away in August 2025. Anthea was a dedicated member of the DELONELINESS team, with a wealth of knowledge from her career in gerontology. Above all she was a kind and supportive person who will be greatly missed.

Abstract

Background: The aging population presents challenges for health care systems. Assistive technologies (ATs), such as telemonitoring, fall detection, and self-monitoring devices, offer potential solutions to support older adults and their care. However, successful implementation relies on their acceptance, which remains poorly understood, particularly among nonusers.

Objective: This study aimed to explore older adults' perceptions of ATs, including perceived benefits, adoption barriers, and factors influencing willingness to use these technologies.

Methods: A qualitative study was conducted with 31 participants (aged ≥65 years) with varying levels of health and care needs. Data were collected through 6 focus groups and 6 in-depth interviews and then analyzed thematically using NVivo software.

Results: A total of 7 themes emerged: (1) limited familiarity, with greater recognition of fall detection and self-monitoring devices compared to telemonitoring; (2) perceived benefits, including safety, independence, and chronic disease management; (3) key concerns, including usability, cost, reliability, privacy, and psychological impacts; (4) suggested improvements, including user-friendly designs and training programs; (5) contextual influences identified with independent older adults perceiving greater utility; (6) strategies for ATs' promotion proposed, such as media campaigns, government subsidies, and health care endorsements; and (7) overall willingness to adopt ATs, driven by perceived need, social and health care influence, and ease of use.

Conclusions: Although ATs offer clear benefits, adoption remains limited due to usability, cost, and psychological concerns. Improving accessibility, training, and integration into traditional health care service delivery may facilitate acceptance and use. Future research should focus on inclusive designs and policy interventions to maximize ATs' potential in aging populations.

Introduction

Background

The global population is aging rapidly, posing challenges to health care systems. In Canada, adults aged ≥65 years comprised 14% of the population in 2009 and are expected to reach 23% by 2030 [1]. Providing them with proper care and enabling them to age comfortably at home is crucial, with significant societal and economic implications [2]. Effective management of chronic conditions and health deterioration can improve well-being [3] while reducing costs related to institutional care [4-6].

Assistive technologies (ATs) offer solutions to support older adults' health and independence [3-5,7-9]. Telemonitoring enhances quality of life and security, particularly for those with chronic diseases [4,5,10-15]. Fall detection devices help prevent injuries and allow for timely interventions, reducing long hospital stays [5,8,16]. Self-monitoring devices promote healthier lifestyles by tracking movement and activity levels, providing real-time insights for better care [3,5,17,18].

Nevertheless, concerns remain about older adults' acceptance of these technologies [3,6-8,19-22], as much of the research focuses primarily on technological innovations or those using these technologies. For ATs to be effective, older adults must be inclined to use them, which depends on acceptance [7,22], motivation, and understanding of their use [8]. Placing them at the center of research ensures that these technologies are practical and accessible [23-31]. Nevertheless, studying older adults, particularly the more vulnerable subgroup, is challenging, leading to knowledge gaps, particularly regarding the

XSL•FO
RenderX

perspectives of nonusers [4,32,33]. Prior studies have mostly focused on existing AT users [26,34-37] or specific health conditions such as chronic obstructive pulmonary disease [38-40], hypertension [36,41], heart disease [39] and diabetes [36,42], limiting insights into the broader older population's views [43].

This study aimed to address this gap by investigating how older adults, with various health statuses and experiences, perceive and approach AT types—telemonitoring, fall detection technology, and self-monitoring devices.

Literature Review

Technology-enabled health care is an umbrella term referring to technologies (eg, information and communication, mobile technologies, etc.) that are designed and tailored to provide care, improve the quality of health services, and promote well-being [44]. eHealth is another term that is used in reference to information and communication technologies used for health and encompasses a variety of mobile health apps [45,46] and internet use for health services and information delivery [47,48]. Digital ATs (eg, communication systems, ambient technologies or monitoring devices, mobile apps, etc.) represent the products or systems used to "help maintain or improve an individual's functioning related to cognition, communication, hearing, mobility, self-care, and vision, thus enabling their health, well-being, inclusion, and participation" [49].

ATs present benefits to older adults' care, given their ability to support health care professionals' work (eg, by providing older adults with assistance with activities of daily living), assist older adults in completing tasks that would otherwise not be possible (eg, mobility), and enable older adults to feel safe while independently living at home [50]. In a recent systematic review of randomized controlled trials, ATs were found to be effective for personal disease management (eg, statistically significant positive effects on self-care and health-related quality of life), medication management (eg, statistically significant improvements in medication adherence and a reduction in the number of missed doses), and vision (eg, statistically significant improvements in visual functions with the use of ATs) in older adults [51]. Prior studies have also highlighted other benefits for older adults, including reduced falls [52], more autonomy and independence [53], improved social connection and engagement, and enhanced well-being [54] when using ATs.

Despite the demonstrated benefits and effectiveness of these technologies, older adults' use of ATs remains low, particularly among those with multimorbidity who may benefit most from their use [51]. Previous studies have investigated older adults' acceptance of ATs. For example, Shin et al [55] assessed South Korean older adults' acceptance of ATs using the Senior Technology Acceptance Model. They found that gerontechnology self-efficacy, health contexts and abilities, attitudinal factors, perceived usefulness, and perceived ease of use statistically affected older adults' intention to use ATs [55]. A recently published meta-analysis reviewed the literature that used the Technology Acceptance Model and Unified Theory of Acceptance and Use of Technology (UTAUT) to assess older adults' acceptance of technology [56]. They found that perceived usefulness, social influence, and ease of use all significantly impact older adults' acceptance of ATs, although this relationship is moderated by the type of AT considered [56], with high heterogeneity across the studies considered. As a result, the authors recommended that future research explore the variations in acceptance patterns across different contexts and technologies to lead to a more comprehensive understanding of older adults' AT acceptance [56].

While the existing literature using the TAM, Senior Technology Acceptance Model (STAM), UTAUT, and other behavioral theories has contributed to our understanding of older adults' technology acceptance, there have been calls in the literature for more qualitative research that explores dimensions beyond those included in existing theories [57]. For example, Felber et al [57] discussed that research often quantitatively validates these theories, without consideration of additional issues that are relevant to older adults (eg, loneliness, the fear of ATs replacing human care, etc.). As such, qualitative research would be appropriate to allow additional factors that may influence acceptance to emerge from the data [58]. They are best suited for studies aiming to understand the reasons behind why an older adult may or may not accept a technology and for providing a more detailed understanding of the nuances that are often missed when quantitative approaches are used [57,58]. This study provides new insights into this area of research by exploring how older adults in long-term care (LTC) environments perceive and approach 3 different AT types (ie, telemonitoring, fall detection technology, and self-monitoring devices) using qualitative methods.

Methods

Study Setting

The study was conducted at Perley Health, Ottawa's largest LTC home. Perley Health is a comprehensive community of care that is home to more than 600 seniors and veterans across 450 LTC beds and 139 independent living apartments. It is also a center for research, education, and clinical innovation and offers many programs and services to residents, tenants, and people from across the region. As part of a pilot project from 2018 to 2021, Perley Health had a subacute unit for frail elderly (SAFE), which was a 20-bed specialty care unit that cared for patients recovering from surgery, illness, or other acute health events, who no longer needed to be in hospital but were not ready to go home. Patients typically stayed on this unit for 2 to 3 weeks to access medical and rehabilitative supports and then returned to their place of residence in the community.

Recruitment began in late October 2018 and concluded in April 2019. The process was adapted to participants' autonomy levels. LTC and SAFE residents required multiple visits to build trust, address hesitations, and encourage engagement. For ILA residents, recruitment involved flyers and group sessions to present the study and promote participation.

Study Design and Population

We used a qualitative research design to capture diverse perspectives of older adults with varying levels of independence and care needs and residing in different environments. This approach combined focus groups, encouraging discussion and

XSL•FO
RenderX

interaction [59,60], with in-depth interviews for a deeper exploration of individual experiences [60].

Participants aged ≥65 years were selected through purposive sampling to ensure diversity in health status, living arrangements, and technology familiarity. Inclusion criteria required cognitive capability to be able to provide informed consent, which was usually assessed using the Cognitive Performance Scale [61]. Individuals with moderate to severe impairment were excluded because of their inability to participate.

Data Collection and Analysis

We conducted 6 focus groups (4 - 6 participants each), grouping individuals by autonomy level (eg, ILA vs LTC). Discussions covered experiences with ATs, perceived benefits, challenges, usefulness, willingness to adopt the technologies, and suggestions for improvement. As part of the original study design, we also conducted 6 in-depth interviews with participants who were unable to attend group discussions. These interviews provided deeper insights into specific themes and ensured a balanced representation of opinions.

The 3 ATs explored in this study were selected for their relevance to aging in place and their practical applicability for older adults in institutional or community care settings. Telemonitoring refers to remote systems that track vital signs or health conditions and transmit data to health care providers [62]. Fall detection devices are typically wearable sensors that automatically alert caregivers or emergency services when a fall is detected [63]. Self-monitoring tools, such as GPS-enabled trackers or activity monitors, allow users and family members to track location or daily activity for enhanced safety [64].

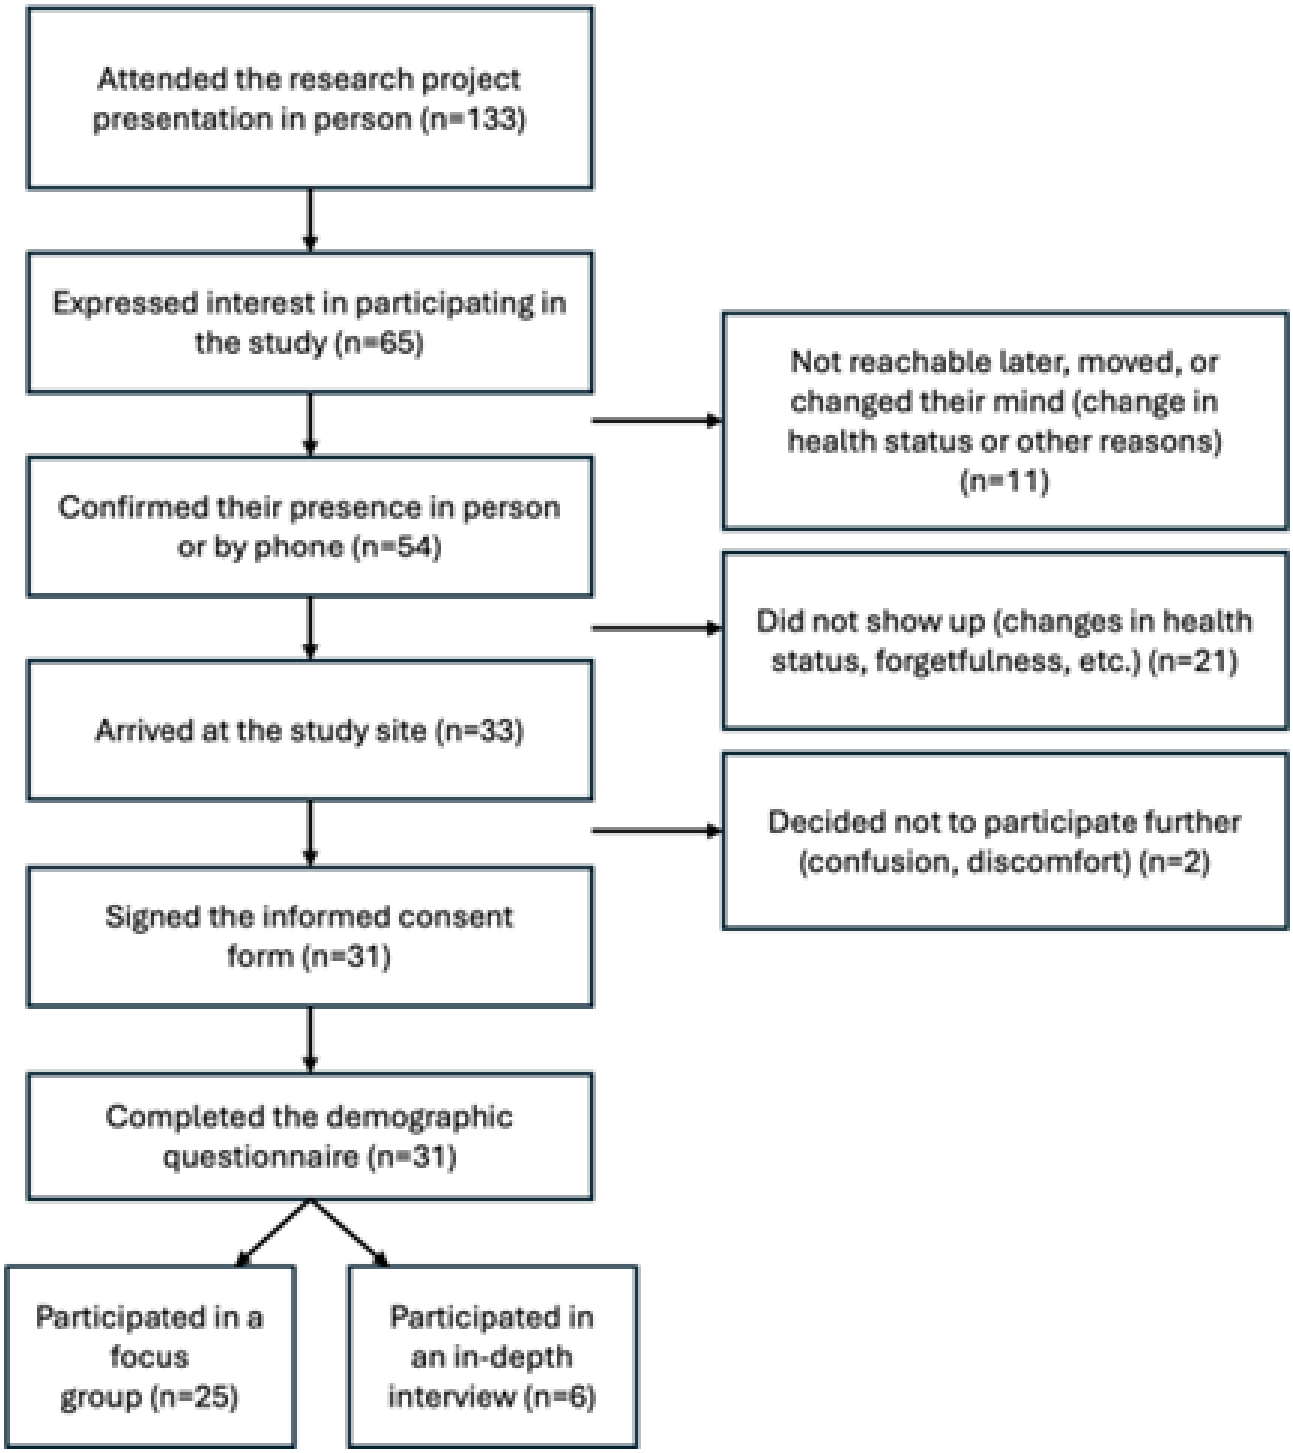
Other digital health tools, such as mobile health apps, virtual reality, or digital twin systems, were not included, as they were considered less familiar or accessible to the study population. The selected technologies reflect those most commonly promoted for older adult safety, autonomy, and chronic condition support in residential and home-based care contexts.

To facilitate discussion, participants watched short, brand-neutral, publicly available videos (1 - 2 min each) introducing each technology. These videos emphasized core features, use cases, and benefits while reducing cognitive effort and improving comprehension. Following each video, a series of open-ended and targeted questions were posed using a semistructured discussion guide. These questions were designed to explore perceived benefits (eg, timely interventions and independence), concerns (eg, cost, usability, privacy, and reliability), and potential adoption triggers (eg, health status changes and physician recommendation). Participants were specifically asked whether they believed the technology could enable timely emergency intervention and what limitations or barriers they perceived. The guide also differentiated between those who had previously used the technology and those who had not, allowing for comparison between experienced users and nonusers. Questions were adapted to each device type (telemonitoring, fall detection, and self-tracking) and to the participant's care setting.

Focus groups and interviews lasted up to 1 hour and were audio recorded, with written notes capturing nonverbal cues and context. We transcribed the audio recordings verbatim and analyzed them thematically using NVivo (QSR International, Melbourne, Australia) software. Thematic analysis followed a partially inductive approach: although the interview guide informed the initial structure, codes and subthemes emerged directly from participant narratives. After subclassifying the main themes, a sample of 100 randomly selected coded passages was independently reviewed by 2 research assistants. Discrepancies in interpretation were discussed and resolved collaboratively to enhance coding consistency and validity. To preserve confidentiality and adhere to ethical requirements, participant quotes were not linked to individual identifiers or care settings. As such, quotes are presented without attribution beyond their thematic grouping.

Ethical Considerations

Ethics approval was granted from the University of Ottawa's Research Ethics Board (S-06-18-428). Participation was voluntary, and participants provided written informed consent and were assured of confidentiality of the information collected in the study. To protect identities, pseudonyms were used in transcripts. No compensation was provided.



Results

Overview of Respondents

A total of 133 individuals attended the initial research presentation, with 65 expressing interest. Of these 65, 54 (85.7%) confirmed participation, but some later withdrew due to personal or health reasons or became unreachable. Ultimately, 31 participants completed the study (25 in focus groups and 6 in in-depth interviews; Figure 1).

XSL•FO
RenderX

Figure 1. Recruitment process: This flowchart illustrates the recruitment process for the study, detailing the number of participants at each stage. Of the 133 project presentation attendees, 65 expressed interest, 54 confirmed participation, and 33 arrived at the study site. Ultimately, 31 signed consent and completed the demographic questionnaire, with 25 joining a focus group and 6 participating in an in-depth interview. Drop-off reasons included inaccessibility, health changes, and discomfort.

The study included 31 participants from various care settings: SAFE, LTC, and ILA (Table 1). Of the 6 interviewees, 5 were from SAFE and 1 from LTC. Age varied by living environment, with LTC participants being the oldest. Gender representation was balanced, with 45.2% male and 54.8% female. A significant portion (42%) had university-level education. Most were widowed or single, lived alone (64.5%), and had chronic conditions, with 45.2% reporting comorbidities. Despite health issues, 67.8% rated their health as good or better.

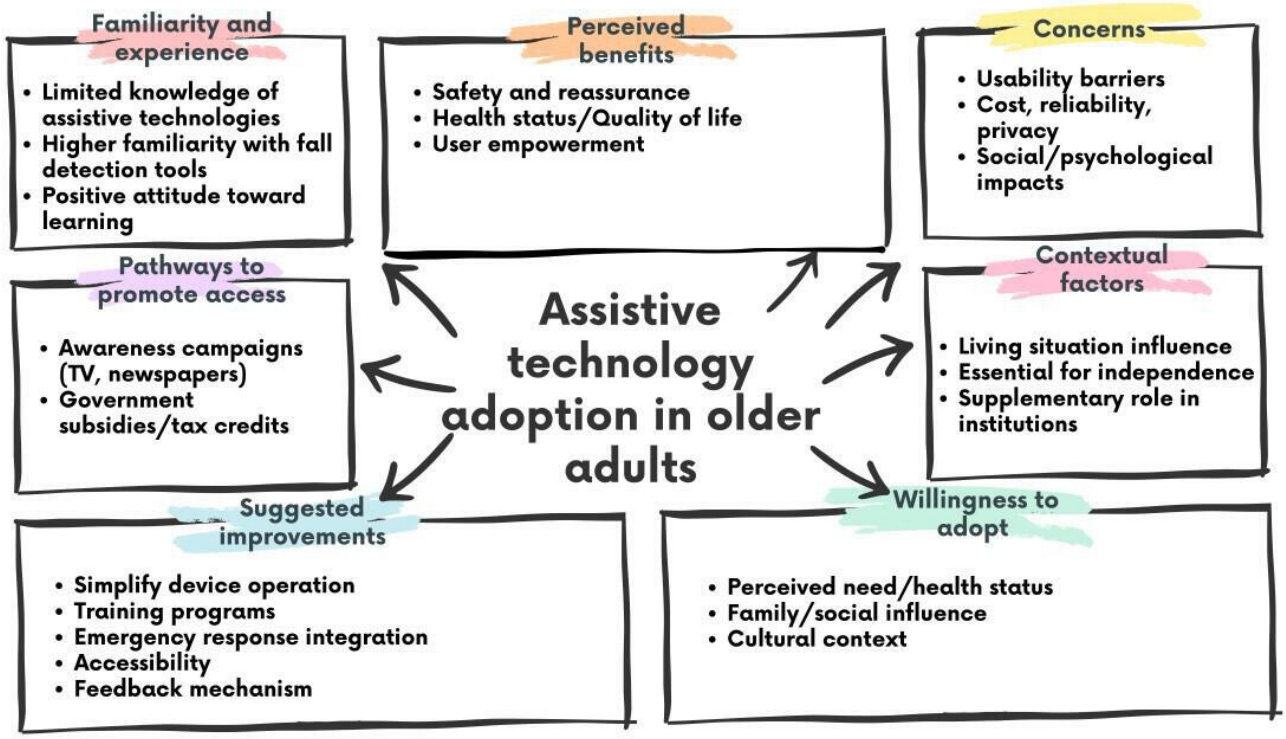
[a]SAFE: subacute unit for frail elderly.

[b]Includes high school, trade, college, and other nonuniversity education.

[c]Includes participants with bachelor's or graduate degrees.



[d]—: not applicable.

Key Findings

We identified 7 overarching themes from the thematic analysis conducted on the data generated from the focus groups and interviews, which are summarized in Figure 2.

XSL•FO
RenderX

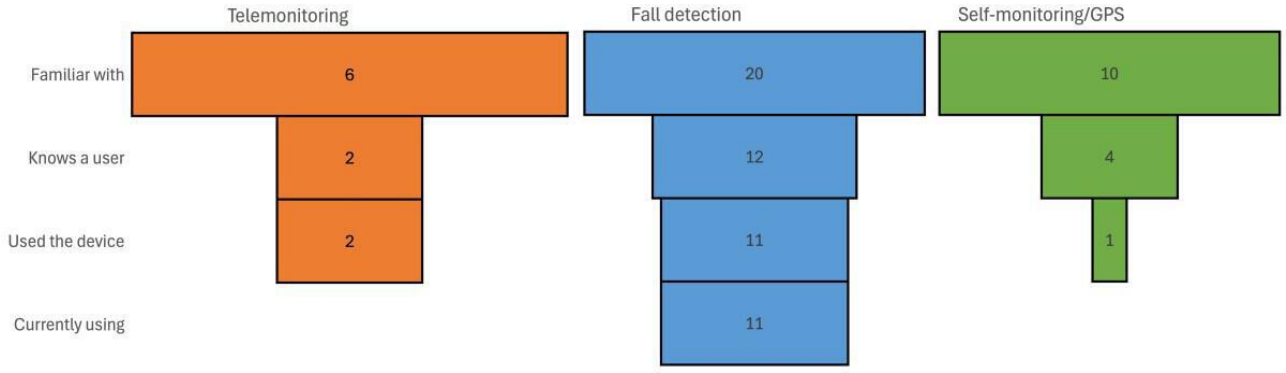


Figure 2. Key themes and subthemes: This diagram highlights factors influencing assistive technology adoption in older adults, including familiarity, perceived benefits, concerns, contextual factors, willingness to adopt, pathways to promote access, and suggested improvements.

Theme 1: Familiarity and Experience With Technology

Most participants had limited prior knowledge of ATs. While many of them followed the news through newspapers and television, they knew little about technologies that could support them. Some participants were eager to learn more, whereas others remained indifferent. As shown in Figure 3, familiarity was highest for fall detection (n=20), followed by self-monitoring/GPS (n=10), and lowest for telemonitoring (n=6). We observed a similar pattern for other measures of exposure, such as knowing a user or having used the device themselves. These differences in baseline familiarity appeared to influence openness and perceived relevance during group discussions. Despite limited experience with these investigated ATs, older adults expressed a positive attitude toward them, for example, “I’m glad to learn there are things like this happening” and “Knowing about these devices motivates us to continue living and maintaining our independence.”

Figure 3. Familiarity with and use of assistive technologies: This chart shows participants’ familiarity and engagement with telemonitoring, fall detection, and self-monitoring devices. Fall detection devices had the highest familiarity and usage, whereas self-monitoring devices had moderate awareness but low current usage. Telemonitoring had the lowest familiarity and minimal adoption.

Theme 2: Perceived Benefits

The participants identified 3 key benefits of ATs presented below.

Safety and Reassurance

Participants commonly perceived that all 3 ATs can reassure users and their families by enabling timely emergency interventions, although they had not personally used these technologies. They valued telemonitoring for its ability to detect abnormalities early and provide prompt feedback. Self-monitoring tools were praised for tracking users’ locations, helping families ensure the safety of loved ones who might become disoriented or lost. Fall detection technology was seen as lifesaving, with 1 participant stating, “Using a fall detector gives the family peace of mind, knowing that their loved one won’t be found on the floor hours later.”

XSL•FO
RenderX

Health Status and Quality of Life

ATs were seen as beneficial for older adults' health by improving chronic disease management (telemonitoring), enabling timely interventions (fall detection), and encouraging active lifestyles (self-monitoring). They also support independence, particularly for those living at home. As 1 participant noted, "This could extend the time they can live at home and do certain activities," instead of being institutionalized.

User Empowerment

Participants felt that telemonitoring's immediate feedback from health care professionals fostered a sense of control and informed decision-making. As 1 participant shared, "If she says in the morning, 'I feel this way,' and the [healthcare professional] responds within an hour, she will know what to do."

Theme 3: Concerns

Despite the perceived benefits, participants raised several key concerns regarding the use of ATs.

Usability

Participants highlighted physical, cognitive, and educational barriers that could limit ATs' adoption and effective use. As 1 respondent noted, "Telemonitoring can only be used by someone who can use it manually, but what if you can't use your hands?," raising concerns that some users may struggle with device operation.

Cost

Many participants saw high expenses as a barrier to widespread adoption and equitable access. As 1 respondent observed, "I see a huge divide between people who can afford this type of technologies and those who can't." This concern about cost reflects broader patterns of digital exclusion among older adults, as noted in recent reviews on health technology disparities [18,65]. Such perceptions may also compound age-related income constraints, underscoring the need for subsidized or publicly funded solutions.

Reliability and Response Time

Participants were concerned about the risk of incorrect or delayed information and the ability to act on it. One respondent questioned, "What happens if there's a problem? Will someone be alerted immediately? The response time matters a lot." The effectiveness of telemonitoring depends not only on the technology but also on the professionals overseeing it. Some were skeptical about whether professionals actively monitored the data, with 1 participant indicating, "It feels like they don't actively monitor the device. For me, it doesn't seem worthwhile," suggesting potential trust-related concerns.

Privacy and Data Security

Most participants were concerned about potential breaches of sensitive information or data being shared with third parties, such as insurers. One respondent also feared that ATs could increase vulnerability to theft, stating, "It could very easily enable someone with malicious intention to access the system and discover that you are not at home."

Social and Psychological Impacts

Participants expressed concerns about the psychological effects of ATs' use, including feelings of dependency and loss of dignity. Many saw these devices as symbols of weakness or reliance on others, potentially impacting self-esteem and personal pride. As one participant noted, "You feel like you don't want to be the person who has to wear that, and yet, in reality, you have to." Participants' emphasis on the psychological burden of using fall detectors echoes findings from Köttl et al [66], where older adults internalized negative stereotypes linked to assistive device use, framing them as "symbols of decline." Our findings further confirm that emotional readiness is just as critical as functional need in ATs' adoption decisions.

Acceptance and Familiarity

The novelty of ATs contributed to hesitation and skepticism among participants. Some were cautious about adopting unfamiliar devices, even when aware of their benefits. As 1 participant remarked, "People might not trust new devices. Anything new is hard to trust, isn't it?"

Theme 4: Suggested Improvements

Participants recommended designing *simpler, user-friendly* devices, as many older adults may struggle with complex technology. They stressed the importance of *training and orientation*, with 1 participant noting, "You can't just hand someone something and leave them to figure it out. There needs to be training or orientation." To enhance emergency response, respondents suggested integrating location-tracking with fall detection devices to ensure faster assistance. As 1 participant proposed, "If they press an alarm, we should be able to locate them, no matter where they are."

Accessibility was another key concern, with many advocating for features that accommodate physical and cognitive limitations, "like using large buttons or voice commands". Reminder systems (for forgetfulness), expanded coverage, and wearable options were also highlighted. One participant remarked, "If they want to change the world, these systems should be everywhere, not just in nursing homes." Finally, participants valued feedback features to confirm help was on the way. As 1 participant stated, "...if it could notify you that your message was sent and someone is coming, that would be reassuring."

Theme 5: Contextual Factors Influencing Use

Perceived usefulness varied by living situation. For older adults living independently, all 3 ATs were viewed as essential for safety, health, and independence. As 1 participant explained, "It's good if you're not in a critical state requiring hospitalization, but you have medical conditions that need monitoring, which can be done remotely."

In institutional settings, these technologies were seen as supplementary to existing care. With professional staff available around the clock, some participants saw telemonitoring and fall detection as redundant. However, others still found value in them, with 1 participant noting, "Even in an institution, I could fall in my room, and staff might not immediately know"

XSL•FO
RenderX

Theme 6: Pathways to Promote Awareness/Access

Awareness campaigns using accessible media were suggested: "Television and newspapers would be good ways to inform people about these options." Government support (ie, subsidies, need-based assistance, and tax credits) to offset costs was discussed as critical. While such support does not currently exist for ATs, participants referenced similar programs in Ontario that subsidize other physician-prescribed medical equipment, such as continuous positive airway pressure machines.

Theme 7: Willingness to Adopt/Use ATs

Many participants initially expressed enthusiasm toward ATs, "This is fantastic!," but this did not necessarily translate into a willingness to adopt them: "My diabetes isn't severe enough right now!" or "You can lead a horse to water, but you can't make it drink." Their willingness to use these technologies depended on several key factors.

Perceived Need and Health Status

Many participants indicated that their willingness to use ATs would increase if their health declined. As 1 participant noted, "I think you have to experience a fall to scare you enough to jump into it faster." Others recognized the potential benefits but felt no immediate need due to stable health conditions.

Family and Social Influence

Family encouragement played a crucial role in AT adoption. Some participants described how their families insisted on using these technologies for peace of mind, even when they were hesitant. As 1 participant shared, "My kids keep pushing me to try it [fall detection bracelet] because it makes them feel better about my safety."

Health Care Recommendations

Guidance from health care professionals significantly influenced ATs' adoption. As 1 participant stated, "If my doctor recommended it, I'd definitely consider it," highlighting the trust placed in medical advice.

Ease of Use and Design

Participants stressed that ease of use was crucial in their decision to adopt ATs. Lightweight, user-friendly, and accessible devices were more appealing, whereas complicated or impractical designs discouraged interest. In addition, limited awareness of how these technologies functioned created barriers to adoption.

Emotional and Psychological Concerns

Participants expressed mixed feelings about being monitored, with some finding it intrusive, whereas others appreciated the security it provided. As 1 participant stated, "It's a bit unsettling to know you're always being watched, but it's also comforting to know help is there if you need it."

Cultural and Situational Context

Social norms and perceived popularity influenced interest in AT adoption. As 1 participant noted, "If other people have it (telemonitoring) and I don't, I feel disadvantaged." ATs were more appealing to those living alone or in rural areas, whereas individuals in assisted living homes or with regular care access showed less interest.

Discussion

Principal Findings

This study explored older adults' perceptions of 3 ATs, namely, telemonitoring systems, fall detection devices, and self-tracking tools. By combining focus groups and in-depth interviews, we gathered nuanced perspectives from individuals with varied health statuses and living environments. This design helped uncover both attitudinal and contextual factors shaping AT acceptance, contributing to an enriched understanding of older adults' engagement with technology.

Perceived Benefits and the Role of Identity

Participants consistently acknowledged the potential of ATs to enhance safety, independence, and chronic disease management. These findings align with the literature, suggesting that older adults are not inherently resistant to technology, but that they appraise its value through the lens of personal relevance and life context [67-71]. Importantly, this study highlights a tension between recognition of benefits and personal adoption—participants often deemed ATs useful "for others," but not necessary for themselves.

This ambivalence may reflect deeper psychological dynamics. Drawing on Socioemotional Selectivity Theory [72], many participants appeared to prioritize emotional satisfaction and autonomy in the present over future-oriented planning. Similarly, internalized ageism, the absorption of negative stereotypes about aging, was evident in language that framed ATs as symbols of frailty or decline. Participants' reluctance to adopt fall detection devices, in particular, often stemmed from concerns about stigma or diminished self-image. These reactions echo prior findings that older adults resist technologies perceived to signal vulnerability [66], underscoring the importance of identity preservation in technology acceptance.

Barriers to Adoption: Beyond Attitudes

Despite generally favorable attitudes, several barriers limited participants' readiness to adopt ATs. Cost emerged as a prominent concern, even in Canada's publicly funded health care context. Consistent with UTAUT2 [73-76], where "price value" influences behavioral intention, participants were highly sensitive to the cost–benefit tradeoff. For many, high device costs were incompatible with fixed or limited incomes. This highlights the need for policy interventions, such as subsidies or expanded Assistive Devices Programs, to enhance financial accessibility.

Usability was another critical barrier. Participants emphasized the importance of accessible, intuitive designs, particularly given potential sensory, physical, or cognitive impairments. These findings reinforce prior research linking effort expectancy (ease of use) to adoption intent [77,78]. Participants suggested adaptive features (eg, voice commands and large buttons) and emphasized the value of hands-on training and orientation sessions. These recommendations support calls for participatory design approaches that incorporate older adults' perspectives into AT development [7,78,79].

XSL•FO
RenderX

Although privacy concerns were noted, they were generally outweighed by perceived safety and health benefits. Still, these concerns merit further investigation. Recent extensions of UTAUT have treated privacy either as an independent predictor [80] or a moderator [81], but its role in older adult populations remains underexplored. Future research should test whether privacy functions differently in this demographic, particularly with respect to self-tracking and location-based technologies.

Willingness Versus Readiness: A Critical Distinction

This study also underscores a conceptual distinction between willingness (attitudinal openness) and readiness (practical ability to act). While participants expressed interest in ATs, this rarely translated into immediate adoption. Readiness appeared contingent on several enabling conditions: digital literacy, health triggers (eg, experiencing a fall), social support, and recommendations from trusted others. This distinction is rarely emphasized in AT literature but is essential for tailoring interventions. Addressing readiness gaps through skills training, caregiver involvement, and experiential exposure to ATs may be just as important as shifting attitudes.

The Influence of Experience and Social Context

Experience with ATs emerged as a powerful enabler. Participants with prior exposure demonstrated higher confidence, clearer expectations, and greater openness to ongoing use. This finding supports evidence from diffusion studies that familiarity reduces perceived complexity and increases trialability [82-84]. Conversely, nonusers often failed to recognize personal relevance, even when their health status suggested potential benefit.

Here, the diffusion of innovation framework [85] offers a useful lens. Health professionals, especially in institutional settings, can serve as gatekeepers, opinion leaders, and change agents. For example, physicians and occupational therapists can assess individual needs, demystify technologies, and provide credible endorsements, thereby influencing both perceived usefulness and social norms [86-88]. Our findings reinforce the importance of leveraging these roles, especially within LTC contexts where allied health professionals routinely assess functional abilities. Promoting ATs through routine care conferences, orientation sessions, and interdisciplinary planning can normalize their use and personalize recommendations.

Implications for Design, Policy, and Practice

Bridging the gap between positive attitudes and actual adoption of ATs requires multipronged strategies that target both systemic and individual-level barriers. Participants emphasized the importance of adaptive, inclusive designs that accommodate cognitive, sensory, and physical limitations. Features such as voice activation, tactile interfaces, and customizable visual displays (eg, font size and button shape) were seen as particularly valuable for enhancing usability. In line with earlier research [7,39,89,90], these design features can help ensure technologies are accessible to a wider range of older adults.

Participants also stressed the importance of training and support. Many felt that simply distributing a device without orientation would be ineffective. Suggestions included hands-on demonstrations, step-by-step tutorials, and reinforcement opportunities through follow-up sessions. For example, in LTC settings, technology vendors could be invited to host demonstration days with staff, residents, and caregivers. For community-dwelling older adults, device trials combined with user support, potentially involving caregivers or trained volunteers, could enhance experiential learning and encourage integration into daily life.

Education and outreach are equally important. Participants advocated for awareness campaigns using accessible media, such as television and newspapers, to reach broader audiences. These campaigns should emphasize the empowering aspects of ATs, helping reframe them as tools for maintaining independence rather than markers of decline. This is particularly critical in combating internalized ageism and reshaping social narratives around aging and technology.

Health care providers, especially physicians, nurses, and allied health professionals, play a pivotal role in recommending and normalizing AT use. Their trusted relationships with older adults position them as effective intermediaries for personalized advice and confidence-building. Strengthening provider involvement through continuing education, clinical guidelines, and structured patient discussions can help increase uptake. In LTC, allied health professionals such as occupational and physiotherapists are well-positioned to incorporate AT assessments into routine care planning. Opportunities for integration include resident orientation, care conferences, and interdisciplinary team meetings. These touchpoints offer natural opportunities to introduce ATs aligned with residents' values, needs, and preferences [91].

Finally, policy interventions are also essential. Public reimbursement schemes, such as Ontario's Assistive Devices Program, could be expanded to include a broader array of ATs and cover maintenance or replacement costs. Such support would help address cost-related concerns, one of the most frequently cited barriers to adoption, and ensure equitable access. Policymakers may also consider embedding AT content into the curricula of health care training programs, ensuring that future providers across disciplines are equipped to assess, recommend, and support AT use among older adults.

Limitations and Avenues for Future Research

This study has limitations that must be acknowledged. First, given its exploratory nature, we used an inductive approach through focus groups and interviews to capture older adults' experiences without restricting responses to predefined frameworks (eg, TAM, UTAUT). This approach enabled novel insights to emerge, although future studies could build on our findings using established models to assess generalizability and validate results in other contexts.

Second, recruitment was limited to individuals with sufficient cognitive abilities to provide informed consent, excluding those with significant impairments. Physical and sensory limitations, such as hearing or vision issues, sometimes disrupted group discussions and required clarification. In some cases, small group sizes—due to cancellations or misunderstandings—reduced discussion depth. However,

XSL•FO
RenderX

in-depth interviews helped address these gaps by capturing additional perspectives. Time constraints also limited exploration of some topics during focus groups, although these were partially mitigated by the interviews.

Third, participants viewed brand-neutral video demonstrations to facilitate discussion, but these may have shaped perceptions based on how the technologies were presented. While the videos offered general overviews, they did not depict specific devices, limiting discussion of their particularities. In addition, themes such as privacy, cost, and emergency response were included in the interview guide, potentially influencing responses. For confidentiality, quotes were not linked to participants' identities or care settings, preventing comparative analysis across environments.

Despite these limitations, the study addressed several gaps in the extant literature. We explored 3 types of ATs relevant to diverse care needs and included 31 participants from LTC, SAFE, and independent living settings, offering broader insights than prior studies with smaller or more homogeneous samples. Unlike studies relying on a single method [83,92-98], our combined use of focus groups and interviews allowed for a richer, more nuanced understanding. Still, we were unable to include participants with cognitive impairment. Future research should address this by involving informal caregivers, who play a key role in decision-making and technology use. Additional research is also needed to explore AT adoption among individuals with greater physical or cognitive limitations. Quantitative studies examining perceived need, prior experience, and external influences (eg, clinician recommendations) could inform strategies to support wider adoption.

Conclusions

Promoting the use of health ATs among older adults requires a focus on improving accessibility, usability, and awareness. This research adds to the growing body of literature on older adults' perspectives on health ATs by offering insights into their attitudes, barriers, and facilitators of adoption. While older adults recognize the benefits of telemonitoring systems, fall detection technology, and self-tracking devices, adoption remains limited and is influenced by factors such as perceived personal need, prior experience, and accessibility. Future efforts should focus on creating adaptive designs, offering experiential opportunities, and implementing accessible pricing models to enhance the adoption of health ATs and maximize their potential to support aging populations.

Acknowledgments

The authors would like to thank all participants for their contributions to this project and the team at Perley Health and Danielle Sinden for facilitating access to the participants and providing the setting for the focus groups.

Funding

This research was supported by a research grant from the Social Sciences and Humanities Research Council (435-2017-1399).

Data Availability

The data gathered during this study are not publicly available and cannot be shared due to confidentiality and original ethics approval restrictions.

Abstract

Background: Mobile health care (mHealth) apps are emerging worldwide as a vital component of internet health care, but there are issues, especially among older adults.

Objective: We aim to investigate the factors influencing the intention to use (ITU) mHealth apps, focusing on those with and without prior mHealth experience.

Methods: A cross-sectional study conducted from August 2022 to July 2023 included Thai citizens aged 45 years or older. Self-reported questionnaires collected data on sociodemographic information, health conditions, smartphone or tablet ownership, and mHealth usage experience. The Thai mHealth Senior Technology Acceptance Model questionnaires with a 10-point Likert scale evaluated mHealth acceptance. A multivariable logistic regression analysis, adjusted for age, gender, education, income, and living area, was performed for 2 subgroups: those who used ITU mHealth apps and those who did not.

Results: Of 1100 participants, 537 (48.8%) intended to use mHealth apps, while 563 (51.2%) did not. The ITU group had a younger average age, higher education levels, higher income, and fewer underlying diseases compared to those who did not intend to use mHealth apps. For those who had never used mHealth apps, having a smartphone was strongly associated with higher odds of ITU (adjusted odds ratio 2.81, 95% CI 1.6 to 4.93; P<.001), while having any underlying disease was associated with lower odds of ITU (adjusted odds ratio 0.63, 95% CI 0.42 to 0.97; P=.034). Higher acceptance levels, characterized by a positive attitude toward mHealth and lower fear of making mistakes, were also associated with higher ITU. For those with prior mHealth experience, acceptance in areas such as perceived ease of use, gerontechnology anxiety, and facilitating conditions was significantly associated with ITU.

Conclusions: Among inexperienced users, a positive attitude toward mHealth significantly enhanced ITU. Conversely, having an underlying disease decreased ITU, indicating a need for tailored mHealth apps. For experienced users, acceptance levels in areas such as ease of use and gerontechnology anxiety were crucial. Future research should explore specific mHealth apps for more targeted insights.

KEYWORDS

mHealth; mobile healthcare; older adults; elderly; aging; questionnaire; smartphone; mHealth usage; intention to use

Introduction

Mobile health care (mHealth) apps, a vital component of internet health care, are emerging worldwide. These apps have attracted a wide range of health care services and are proven effective in solving health problems. The functions of mHealth are diverse, including patient monitoring, diagnosis, personal care, psychological health, educational apps, and social networking [1]. There is growing evidence of the health benefits of mHealth. Mobile devices, with their integrated sensors and features, help health care professionals treat patients with continuous connectivity. These apps are useful for collecting data related to physical activity, human body images, and other health care aspects [2,3]. For example, using mHealth in chronic disease management has shown improvements in symptoms and reduced hospitalizations for patients with asthma, chronic obstructive pulmonary disease, heart failure, and diabetes [4].

XSL•FO
RenderX

However, there are several issues with current mHealth apps, particularly among older adults. Studies show that only 60% of older people intend to use mHealth [5]. Older adults may have physiological changes according to aging such as visual and hearing decline. They may also be unfamiliar with technology and face difficulty learning new skills [6]. Some users experience technical problems with their smartphones when using these apps. Additionally, public awareness of mHealth apps is low, and their usability is not as good as expected [7].

Understanding the factors that affect the intention to use (ITU) mHealth among people with and without prior experience is crucial for enhancing its future usage [8]. Therefore, the primary objective of our study was to investigate the factors associated with ITU, focusing on 2 specific subgroups: those with prior experience using mHealth apps and those without. This study also examined information regarding device ownership, experience with mobile apps and mHealth, and technology acceptance. These findings aimed to gain a better understanding of mHealth usage and identify potential opportunities for implementing mHealth in a community-dwelling population, especially among older adults.

Methods

Study Design

We conducted the cross-sectional study from August 2022 to July 2023 using a nationwide web-based survey and a community survey. The online survey was disseminated through various social media platforms, such as department websites, Facebook, Line, Twitter, and Instagram. The investigator teams, which included medical students and health care personnels from primary care units across 10 subdistricts in Chiang Mai province, distributed the community survey. The respondents to both the online and community surveys used the REDCap (Research Electronic Data Capture; Vanderbilt University) survey platform to self-complete the questionnaires. The STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement guided this study's reporting [9].

Ethical Considerations

The institutional review board of the Faculty of Medicine, Chiang Mai University approved this study's ethical consideration (COM-2565 - 09079). Before participating in this survey, all respondents provided their informed consent in accordance with the screening questionnaire and study information page. Participants were compensated with an incentive of 100 Thai Baht (3 USD) for completing the questionnaires. No identification data were recorded, and respondents were permitted to remain anonymous during the online survey. The community survey used the identification data of eligible participants exclusively for recruitment purposes within each target area. These data were not documented in either the survey form or the study database.

Participants

Study participants were middle-aged Thai citizens aged 45 - 60 years or older at the time of the survey [10,11]. Our study's inclusion criteria required participants to be able to read and communicate in Thai and to have no underlying conditions or diseases that would hinder their ability to complete the survey or use mHealth apps (eg, dementia, active psychological problems, or severe visual impairments). This study excluded respondents who did not complete the survey, spent less than 2 minutes on it, or spent more than 60 minutes on it.

Data Collection

Participant Characteristics

We used self-reported questionnaires to collect data on participant characteristics, including sociodemographic data, underlying health conditions, owning a smartphone or tablet, and experience using the devices and mHealth apps. The initial section of the questionnaires included information regarding mHealth to ensure that the participants comprehended its definition, related concepts, and intended use.

The sociodemographic data included age, gender, marital status (single, married, and separate, divorced, or widowed), living status (alone, with family, and with others), living areas (urban, suburban, and rural), education levels (no education, primary, secondary, high school, vocational training, preuniversity, bachelor's degree, and master's degree), and income per month (<10,000 in Thai Baht, US $ 274; 10,001 - 30,000 in Thai Baht, US $275-$819; and >30,001 in Thai Baht, US $820). The questions inquiring about underlying medical conditions included hypertension, dyslipidemia, diabetes mellitus, chronic renal disease, visual impairments, and hearing impairments. We also gathered data on other related variables, such as wearing glasses or contact lenses, using hearing aids, and a number of current medications.

Experience Using Mobile Apps and mHealth

mHealth apps, or mobile health apps, refer to the practice of medicine and public health supported by mobile devices. The term "mHealth apps" encompasses the use of mobile communication devices such as smartphones and tablets for health care purposes [12,13]. For information on owning and experience using the devices and mHealth, questionnaires asked for smartphone or tablet usage experience (year), owning smartphones or tablets, internet usage experience (year), and previously used mobile apps and mHealth apps.

mHealth Acceptance and ITU

The acceptance of mHealth was evaluated using the Thai mHealth Senior Technology Acceptance Model (STAM) questionnaires. This instrument has been adapted from the 38-item STAM questionnaire [14] and validated for accessing mHealth acceptance in a Thai context. According to the reported psychometric analysis, the Thai mHealth STAM demonstrated satisfactory psychometric properties in terms of validity and reliability. We used instrument items in the following domains as the potential associated factors of an ITU mHealth: attitude toward using, perceived usefulness, perceived ease of use, perceived barriers, gerontechnology anxiety, and facilitating condition. The structure of the Thai mHealth STAM was a 10-point Likert scale. The highest point indicated a high level of acceptance. The participant's ITU mHealth was assessed by the structural question "If there are available mHealth apps for you, do you want to use them? (Yes/No)."

XSL•FO
RenderX

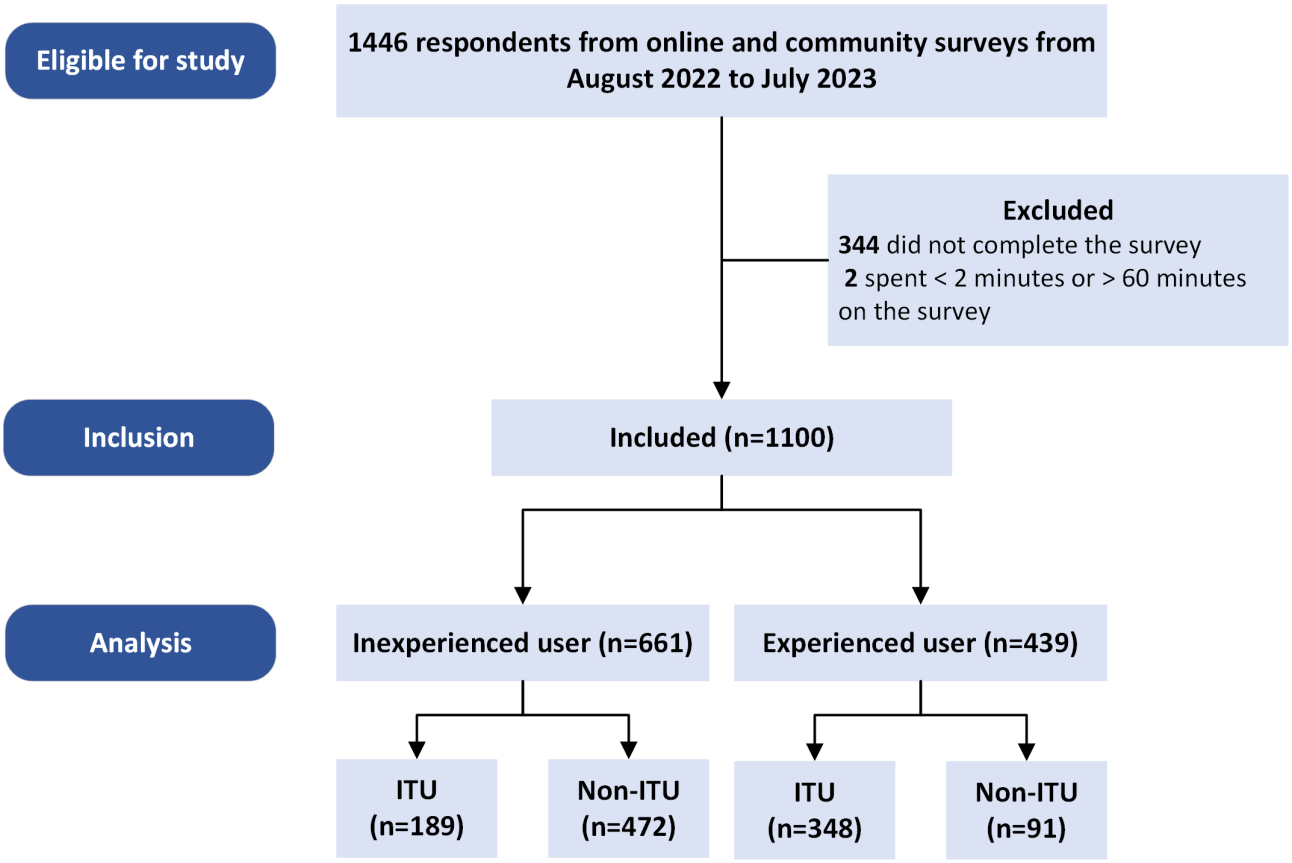
Sample Size

To derive statistics that represent the parameters for the target populations, a minimum sample size of 500 total participants is required. This minimum sample size can accurately detect low to large effect sizes, as suggested by Bujang et al [15]. Based on our primary objective, it aimed to explore the associations between ITU and predetermined variables, including characteristics, ownership, and experience using devices and mHealth, and mHealth acceptance, in 2 specified subgroups of participants: those with experience using mHealth apps and those without. To explore unbiased effect estimates, 18 independent variables were analyzed with adjustments for 5 confounding variables. The sample size calculation, based on the formula n=100+(10 - 50 event per variable)*i*, where *i* refers to the number of independent variables, was conducted to ensure our effect estimates from a multivariable logistic regression had sufficient precision to yield medium to large effect estimates in the subgroup analysis [15]. With 23 independent variables, a minimum sample size of 330 participants per subgroup was needed according to the given formula with 10 per independent variables.

Statistical Analysis

For descriptive analysis, we presented categorical data using frequency and percentage. We described continuous data using a mean with SD, a median with a range (minimum-maximum), or an IQR, as appropriate. The comparison in characteristics, owning and experience using the devices and mHealth, and mHealth acceptance between participants who had ITU and those who did not was examined using an independent 2-tailed *t* test or Wilcoxon rank sum test for continuous data and Fisher exact test for categorical data.

For the analysis of the primary objective, we hypothesized that the factors associated with ITU would be different for participants who had previously used mHealth and those who did not. We performed a multivariable logistic regression for 2 specified subgroups, adjusted for the confounders including age, gender, education levels, income, and living area. The predetermined characteristic variables included having any underlying disease, owning a smartphone, the number of years of experience using it, and an interaction term based on both ownership and experience. We entered each item's mHealth acceptance into the model as continuous data, using a 10-point scale. The magnitude of associations was presented using an adjusted odds ratio along with 95% CIs and *P* value. All statistical analyses were conducted using STATA (version 17.0; Stata Corp, LP). The visualization for this study was created using Microsoft Excel (Microsoft Corporation, 2021). The level of statistical significance for descriptive analysis was set at a *P* value below .05.



Results

Participant Characteristics

Of 1100 participants, the majority were female (776/1100, 62.3%), with a mean age of 62.3 (SD 8.8) years. This study flow diagram is presented in Figure 1. Most of the participants were married and resided with their families primarily in rural, suburban, and urban areas, respectively. For socioeconomic status, 86.2% (948/1100) had a low income (<10,000 Baht, US $274), and 65.9% (725/1100) had the highest education level at primary school. The common underlying diseases were hypertension and dyslipidemia. More than half reported having a vision problem, and 65.2% (n=399) wore glasses or contact lenses. Only 3.3% (4/1100) of respondents required a hearing aid, while 10.9% (120/1100) of respondents reported having hearing problems.

XSL•FO
RenderX

Figure 1. Study flow diagram. ITU: intention to use.

There were 537 participants who had ITU (48.8%) and 563 participants who did not (51.2%). When comparing the participants who had ITU mHealth apps with those who did not, the ITU group had a significantly younger average age, higher education levels, higher income, and a lower proportion of underlying diseases. Furthermore, 94.4% (507/537) and 92% (494/537) of the ITU group reported having experience using a smartphone or tablet and the internet; 91.2% (490/537) and 3.4% (18/537) had owned a smartphone and tablet, respectively. These percentages in the ITU group were significantly higher than those in the non-ITU group. The overall median (IQR) year of experience using the devices was 5 (0 - 10). When comparing the ITU to non-ITU groups, the median years of device usage experience in the ITU were significantly higher than non-ITU (median 6, IQR 3 - 10 versus median 3, IQR 0 - 9, P<.001). In addition, 66.9% of those in the ITU group had experience using mHealth apps, which was a significantly higher proportion than the non-ITU group of 17.4%. The details of participant characteristics are presented in Table 1.

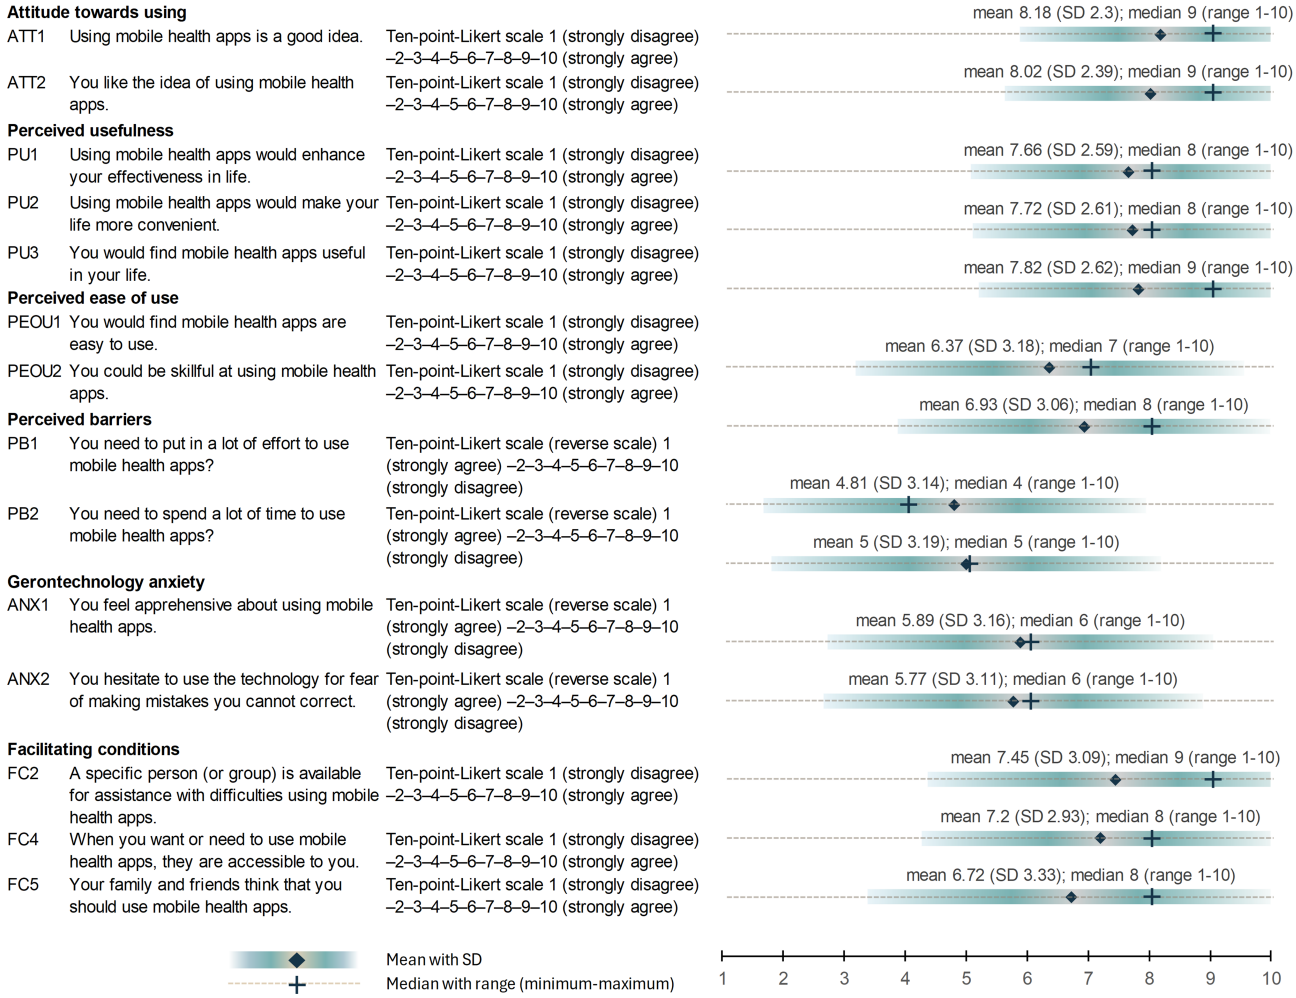
Experience Using Mobile Apps and mHealth

Figure 2 illustrates participants' experience using mobile apps and mHealth. There are many types of mobile apps and mHealth including social media apps, general apps, and mHealth apps. Among the middle-aged and older adults who had previously used mobile apps and mHealth, social media apps had the highest percentages (63.4%), followed by mHealth apps (41.6%), and apps for general purposes (37.5%). The use percentages of almost all mobile apps and mHealth were statistically and significantly higher in the ITU compared to non-ITU groups (*P*<.001), except for mHealth apps with a low use percentage (Samsung Health, Apple Health, and Strava). The use percentages of the top 3 social media apps (Line, YouTube, and Facebook) were greater than other apps. For general purposes, most participants used mobile apps for online banking services, surfing the internet, and shopping. For mHealth, the Ministry of Thai Public Health app, "MorProm," had the highest use (41.6%), followed by the official apps by hospitals (5.9%), while the other mHealth apps from public providers showed a very low use percentage.

Figure 2. Participants' experience using mobile apps and mHealth. ITU: intention to use.

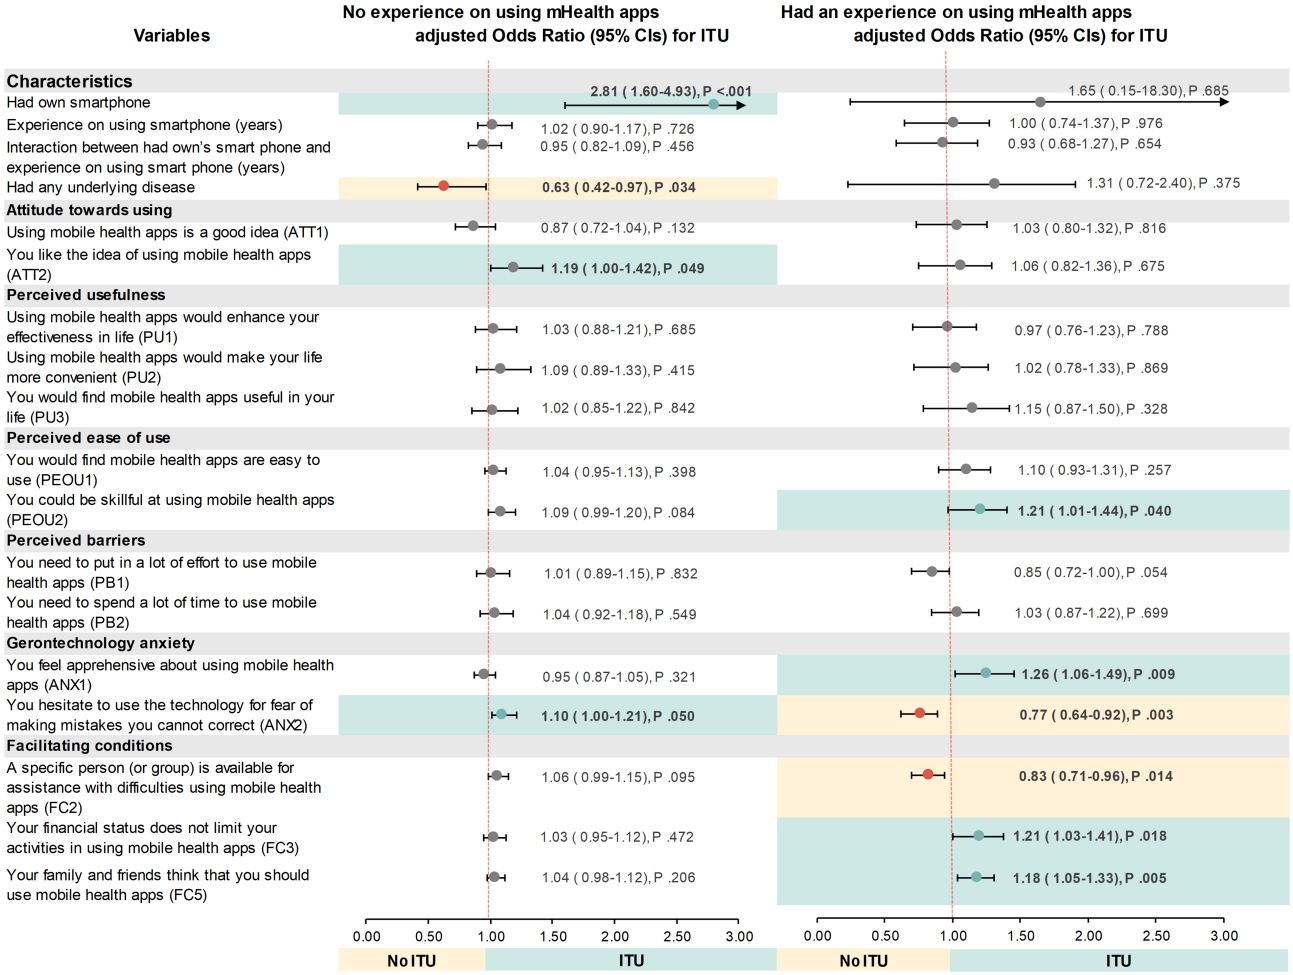


XSL•FO
RenderX

mHealth Acceptance

We assessed the participants' mHealth acceptance using the Thai mHealth STAM questionnaires in the domains, including attitude toward using, perceived usefulness, perceived ease of use, perceived barriers, gerontechnology anxiety, and facilitating condition. Figure 3 displays the structure of the questionnaires and the participants' responses. Overall, participants' acceptance of mHealth fell within the range of agreeable attitudes toward using, perceived usefulness of mHealth apps, and facilitating conditions. On the other hand, we observed responses in the range of neutral to low acceptance across the domains of perceived barriers, gerontechnology anxiety, and perceived ease of use.

Figure 3. Participants' responses to mHealth acceptance questionnaires. ANX: gerontechnology anxiety; ATT: attitude toward using; FC: facilitating condition; PB: perceived barriers; PEOU: perceived ease of use; PU: perceived usefulness.



When compared between the ITU and non-ITU groups, mHealth acceptance levels assessed by the questionnaires showed a significant difference in all items, as presented in Table S1 in Multimedia Appendix 1. Participants who used an ITU mHealth app had higher mean scores in all items. The domain of perceived barriers yielded the lowest mean mHealth acceptance score in both groups.

Factors Associated With ITU mHealth Apps

In this study, we focused on exploring factors associated with ITU mHealth apps in the subgroup of participants who had experience using mHealth apps and who did not. We performed a multivariable logistic regression analysis using predetermined factors including owning a smartphone, experience using a smartphone, underlying disease, and mHeath acceptances. The analysis also adjusted for the confounders consisting of age, gender, education levels, income, and living area. Multivariable analysis results are presented in Figure 4.

XSL•FO
RenderX

Figure 4. Factors associated with intention to use mHealth apps using a multivariable logistic regression. aORs were estimated as adjusted for age, gender, education levels, income, and living area. aOR: adjusted odds ratio; ANX: gerontechnology anxiety; ATT: attitude toward using; FC: facilitating condition; ITU: intention to use; PB: perceived barriers; PEOU: perceived ease of use; PU:perceived usefulness.

For the subgroup of people who had never used mHealth apps before, having a smartphone was substantially associated with higher odds of ITU (adjusted odds ratio 2.81, 95% CI 1.60 to 4.93; *P*<.001), while having any underlying disease was significantly related to a low ITU. Higher levels of acceptance, which are characterized by a higher score of attitudes toward the idea of using mHealth and a lower fear of making mistakes that cannot be corrected when using it, were also significantly associated with a high ITU.

For the subgroup of individuals who had prior experience using mHealth apps, the pattern of associations between predetermined factors varied from the subgroup of those who did not have prior experience. There were no predetermined characteristics relating to ITU. The levels of mHealth acceptance were significantly associated with ITU in the domains, including perceived ease of use, gerontechology anxiety, and facilitating conditions. Perceived ease of use, which individuals could be skilled at using, was significantly associated with a greater odds of ITU. Regarding the level of anxiety associated with mHealth usage, less apprehensiveness about using mHealth significantly increased the odds of ITU. Conversely, a low ITU was associated with a lower fear of making mistakes when using mHealth. Having facilitated support from family and friends to use mHealth and having fewer financial constraints on using mHealth showed a significant positive association with ITU, whereas the support from others was negatively associated with ITU.

Discussion

Principal Findings

To investigate the factors associated with ITU, we found that people who had never used mHealth apps before, having a smartphone associated with a higher ITU, while having any underlying disease was significantly related to a low ITU. Higher levels of acceptance, which are characterized by a higher score of attitudes toward the idea of using mHealth and a lower fear of making mistakes, were also significantly associated with a high ITU. For the subgroup of individuals who had prior experience using mHealth apps, there were no predetermined characteristics relating to ITU. The levels of mHealth acceptance were significantly associated with ITU in the domains, including perceived ease of use, gerontechology anxiety, and facilitating conditions.

Compared to previous studies, several patient characteristics significantly influence the ITU mHealth. Older patients are less likely to use mHealth due to their unfamiliarity with technology. Despite efforts to adopt new technology, many older adult individuals still struggle with it, and the rapid pace of technological advancements leaves them unable to keep up

XSL•FO
RenderX

[16,17]. Additionally, there is a lack of promotion and support for using medical technology among older adults [18]. Socioeconomic status is another crucial factor affecting the ITU mHealth [19,20]. Patients in low-income groups not only lack support for using mHealth, but their daily routines and various burdens also reduce their intention to use these technologies [21]. This is closely related to the level of education [19]; patients with higher educational levels are more likely to understand and recognize the health benefits of mHealth, thus increasing their intention to use it [20]. Chronic diseases also play a role [19]. Patients without comorbidities and those who could effectively manage their chronic conditions tend to have better health management skills and a stronger desire to maintain good health, which positively influences their ITU mHealth [22,23].

Many factors influence the ITU mHealth among people without prior experience. One critical factor is the availability of equipment, such as mobile phones, patient testing devices, personal digital assistants, and other wireless tools. Health care professionals must ensure these facilities are accessible to patients when initiating mHealth services. Providing the necessary equipment and educating patients on its use can reduce inequity, particularly among older populations. The previous studies also showed that when health care systems provide access to such equipment, it enhances user confidence and intention to adopt mHealth, particularly among older adults who may otherwise face barriers due to digital inequality (eg, lacking smartphones or internet access) [24,25]. Empowering patients to access and use smartphones not only enhanced their ITU mHealth but could also improve self-rated, physical, and psychological health levels, as evidenced by the previous studies on the effects of smartphones and smart devices [26-28]. Underlying health conditions also impact the ITU mHealth. Patients with poor health behaviors or low motivation for self-care are less likely to adopt mHealth. The previous studies found that older adults with heart failure [29] and adults with hypertension [30] faced significant barriers to mHealth adoption, including low motivation and limited health literacy, which hindered their engagement with self-management technologies. These support our finding that underlying health conditions may reduce mHealth adoption, as individuals often lack the motivation to use health-promoting technologies. Conversely, some studies suggest that the presence of chronic health conditions can actually motivate individuals to engage with mHealth solutions. The study by Askari et al [31] found that older adults who were able to control their chronic diseases often expressed a greater ITU mHealth, as these tools can provide essential support for self-management and health monitoring. This indicated that while health conditions could pose barriers, they can also motivate the adoption of mHealth solutions, particularly when patients recognize the potential benefits for their health management. Another study also suggested that health conditions could influence older adults' readiness to engage with eHealth resources, with those experiencing chronic illnesses showing a higher willingness to use digital health tools for self-care [32]. This suggests that the context of the health condition is vital in influencing attitudes toward technology use, rather than the notion that poor health behaviors uniformly result in reduced intentions to use mHealth. Confidence in their ability to effectively use mHealth apps is crucial, as a positive attitude toward mHealth increases the likelihood of its use [33]. The positive finding on attitude toward using mHealth is also consistent with the recent systematic reviews on the impact of mHealth interventions, which highlighted that the effectiveness of these interventions is often linked to user confidence and positive attitudes toward technology [4]. To promote mHealth for people without prior experience, health care professionals should educate patients about its benefits and how it can aid in self-care. Additionally, patients must develop eHealth literacy, defined as "the ability to seek out, find, evaluate, and appraise, integrate, and apply what is gained in electronic environments toward solving a health problem." [34].

For participants with prior experience using mHealth, various factors influence their intention to continue its usage. These individuals often possess a positive attitude toward mHealth and recognize its benefits. They may also have experience in overcoming barriers, such as troubleshooting difficulties or correcting errors independently. Consequently, they perceive the benefits of using mHealth to outweigh the risks or challenges. Our finding indicated that perceived self-capability to use mHealth and lower concerns was associated with higher ITU among participants with prior mHealth experience. This finding is aligned with the study by Opoku et al [35], which emphasized that enabling resources, such as the durability and simplicity of mobile technology, significantly influence patients' perceived ease of use of mHealth interventions. This implies that when patients are informed and experienced about the user-friendly nature of mHealth apps, their confidence in using these tools increases, thereby enhancing their likelihood of adoption. In contrast to participants without prior experience using mHealth, those with experience did not avoid using mHealth out of fear of making mistakes. However, the expressed greater concerns about mHealth itself, such as its effectiveness, data security, and privacy, were associated with a low ITU. Our findings align with the studies on experienced users' attitudes toward mHealth [36,37], emphasizing the importance of addressing concerns related to security, privacy, and perceived effectiveness. Therefore, future mHealth interventions should not only focus on enhancing user confidence through health education or instruction by technical and health care providers but also on building trust in technology itself. Additionally, patients, especially older adults, value support from family or caregivers. mHealth for older adults may require assistance at various stages, including tool usage guidance, instructions, and caregiver involvement [16]. Financial considerations also play a crucial role, as increased costs associated with mHealth can affect the ITU for it. To initiate and improve mHealth usage, health care professionals need to identify patients willing to use mHealth, ensure the availability of necessary equipment, and address any financial constraints. Educating patients on the evidence and benefits of mHealth is also essential. Where possible, families and caregivers should be included in the mHealth care plan [38].

The strength of this study lies in its relatively large sample size, which included participants from rural, suburban, and urban areas. This study comprehensively explored various factors

XSL•FO
RenderX

potentially associated with mHealth use, using reliable and validated standard tools to evaluate acceptance. However, some limitations existed. The cross-sectional nature of this study limited establishing causal relationships between the ITU mHealth and associated factors. Further research designs, including longitudinal studies or randomized controlled trials of specific mHealth interventions, are necessary to overcome these limitations and provide a more comprehensive understanding of the factors influencing mHealth usage. Furthermore, the term "mHealth" was defined in a broad and general sense in the questionnaire but was not explicitly specified for participants' conditions. Defining "mHealth" in general could hinder the participants' acceptance and use of mHealth, particularly in the group of participants with underlying diseases and specific health problems. This hypothesis could explain the observed association between having any underlying disease and low ITU in the group of participants who had never used mHealth before. Accordingly, our study primarily aimed to explore mHealth usage in general for community-dwelling adults. Our findings may not generalize enough to provide specific insight into the specific use case of mHealth in a particular population. Hence, we encourage future studies to aim for an in-depth understanding of each type of mHealth and acceptance in the specific context.

Conclusion

This study identified key factors influencing the ITU mHealth and positive attitudes toward using significantly enhancing ITU in both inexperienced and experienced users. Conversely, having an underlying disease was associated with a decrease in ITU, indicating that this group of individuals may require mHealth's specific requirements for their conditions rather than the general purpose. For experienced users, acceptance levels in areas such as ease of use and gerontechnology anxiety were critical. Health care professionals should identify patients open to using mHealth, ensure access to necessary equipment, address financial barriers, and educate patients on its benefits. Future investigations should also explore specific mHealth apps to provide more targeted insights.

Abstract

Background: With the increasing prevalence of digital technology, adolescent internet addiction (IA) has become a global concern. Excessive internet use, especially among adolescents, has been linked to various negative outcomes such as poor academic performance, social isolation, and mental health issues. Conducted among adolescents of Arab origin, our study addressed the limitations of the literature, which predominantly focuses on Western, educated, industrialized, rich, and democratic populations.

Objective: This study aimed to differentiate between essential and nonessential internet use and how they relate to IA in early and middle adolescents, as well as the relationship between subjective happiness with the amount of time spent on nonessential internet use and IA.

Methods: A cross-sectional survey was conducted among 377 students from 16 schools in Qatar. The survey measured essential and nonessential internet use, subjective happiness with nonessential use, and IA symptoms using the Internet Addiction Diagnostic Questionnaire, as well as participant demographics. To explore age-specific associations, participants were categorized into early (age 11-13 years) and middle (age 14-17 years) adolescents. Factorial analysis, multiple regression, and logistic regression were used for statistical analysis.

Results: Nonessential internet use significantly predicted IA in both early (P<.001) and middle (P<.001) adolescents, with early adolescents showing a stronger association. Subjective happiness with nonessential internet use negatively predicted IA only in middle adolescents (P<.001) as greater dissatisfaction led to a higher IA risk. Essential internet use did not predict IA in either group.

Conclusions: Differentiating between essential and nonessential internet use is crucial in understanding IA. This study highlights the importance of developmental differences in shaping IA symptoms. The findings suggest that interventions aimed at addressing IA should be age specific and focus on addressing nonessential use specifically rather than considering internet use and screen time in general as a single entity. Cultural and regional factors also play a role in shaping internet use patterns and IA in the Middle East, necessitating context-specific, culturally sensitive approaches to IA prevention.

internet addiction; internet use; early adolescence; middle adolescence; mobile phone

Introduction

Background

Adolescent internet addiction (IA) has become a growing concern in today's society as the use of technology and the internet has become increasingly prevalent in the lives of young people. According to a study conducted by the Pew Research Center, since 2014 to 2015, there has been a modest increase in the proportion of adolescents who said that they used the internet daily or more often [1]. In a follow-up study in 2022, a total of 97% of adolescents said that they used the internet daily compared to 92% of adolescents who said the same in 2014 to 2015. It is understandable that many adolescents struggle with IA given the widespread use of the internet. Studies have shown that approximately 10% of adolescents are at risk of IA, with even higher rates reported in countries such as Hong Kong, China, and South Korea [2-5]. For example, a survey conducted in South Korea found that nearly 30% of junior high school students were either addicted to the internet or at a risk of IA [6]. While some internet use can be beneficial for educational and social purposes, excessive use can lead to negative consequences such as decreased academic performance, social isolation, and even mental health issues [7-9]. Therefore, it is important to understand the prevalence of IA among adolescents and its contributing factors.

IA is defined as the inability to control internet use, leading to disruptions in everyday functioning and symptoms of withdrawal and tolerance [10]. Although not officially recognized as a disorder in the most recent edition of the *Diagnostic and Statistical Manual of Mental Disorders*, IA has received considerable attention in scientific literature and is regarded as a growing concern [11]. Opinions in the literature differ, with some researchers suggesting distinct diagnostic criteria and subtypes of IA, such as video game and online gambling addiction [12]. However, there is still a lack of consensus regarding the internet's addictive nature and IA diagnostic criteria [13]. While there is still debate regarding the exact nature and criteria for IA, it is clear that excessive internet use can have negative consequences, particularly for adolescents. Understanding the prevalence and factors contributing to IA is important for addressing this growing concern, promoting healthy internet use, and developing appropriate interventions for those who may be affected.

Most psychological research studies predominantly rely on samples from Western, educated, industrialized, rich, and democratic (WEIRD) populations [14]. However, when examining the effects of excessive internet use on adolescent mental health, it is crucial to consider that the experiences of adolescents from non-WEIRD populations may vary owing to many factors, such as different cultural norms and access to technology [15]. This emphasizes the importance of including more diverse samples in research to gain a comprehensive understanding of the global impact of technology on mental health. Cultural context significantly shapes adolescence, with the experiences of young individuals varying widely across different cultures [16]. To address this gap, our study focused on adolescent IA in the Middle East, where limited research on IA has been conducted. In doing so, we aimed to shed light on the specific dynamics of IA in this region and contribute to a more inclusive and comprehensive understanding of this phenomenon.

Qatar has one of the highest internet penetration rates in the world at 99% [17]. The country's internet users have grown significantly from 69% in 2012 to 100% in 2022 [18]. This increase raises the possibility of an increase in IA prevalence rates, as does the spread of mobile device use and the constant release of new technology updates. Furthermore, adolescents may unintentionally be encouraged to spend more time inside streaming online content, playing online games, and spending time on-screen due to Qatar's humid and hot weather, which lasts for more than half the year.

In addition to Qatar's unique technological landscape and climate, broader Middle Eastern cultural factors play a crucial role in shaping adolescent internet use patterns. The region's complex environment, which is characterized by its unique family dynamics, societal expectations, and cultural values, may contribute to the elevated prevalence of IA among adolescents [19,20]. In various Middle Eastern societies, conservative norms that prioritize modesty and restraint frequently conflict with the liberties that online platforms provide. As adolescents navigate their identities and seek communities that are consistent with their evolving values, this cultural tension can motivate them to engage with the internet differently. In addition, it is also argued that the limited opportunities for social interaction outside the home, along with societal pressures to conform, may encourage adolescents to seek connection and validation online, potentially nurturing addictive behaviors [19]. Culturally informed research can inform tailored intervention strategies that address the specific needs of adolescents in the Middle East. For example, studies suggest that effective interventions should involve families and schools, recognizing the significant role that these environments play in shaping adolescents' internet behaviors [21,22].

Excessive screen time is often identified as a prominent indicator of IA, contributing to an unhealthy relationship with the internet and development of negative habits [23,24]. In numerous studies examining adolescent IA, the amount of time spent on the web is commonly regarded as a key factor in determining the presence of IA [25,26]. The COVID-19 pandemic has further heightened the reliance on technology for remote learning and socializing among adolescents [27]. The term *screen time* is frequently used without sufficient attention being paid to the specific activities undertaken during that period. However, this lack of specificity has several methodological limitations. To address these limitations, this study aimed to differentiate between the time spent on essential and nonessential internet use activities, providing a more nuanced understanding of IA in adolescents. However, IA is not just a matter of excessive

XSL•FO
RenderX

screen time; it has also been linked to mental health issues such as loneliness, low self-esteem, sleep problems, depression, social phobia, and anxiety [28,29]. Adolescents who struggle with these conditions may turn to the internet as a coping mechanism, further exacerbating their addiction [30]. Ultimately, IA can have a significant negative impact on adolescents' lives, from decreased academic performance to strained relationships with loved ones [31].

Adolescence is a crucial period for identity exploration and formation during which individuals may encounter situations in which their emerging beliefs and values conflict with societal expectations or their own behaviors, which may lead to cognitive dissonance [32]. This aspect of adolescent development is relevant to the exploration of subjective feelings regarding digital technology use and its association with IA. Cognitive dissonance theory offers an understanding of this relationship by examining potential conflicts arising from adolescents' subjective feelings regarding their digital technology use and addictive behavior. According to the cognitive dissonance theory, individuals experience psychological discomfort when they hold contradictory beliefs, attitudes, or behaviors [33]. In the context of digital technology use and IA, cognitive dissonance may arise when adolescents recognize the negative consequences of excessive digital technology use but continue to engage in it. The literature suggests that subjective positive feelings about one's own life conditions are negatively correlated with IA [34]. It is reasonable to hypothesize that similar correlations may exist between subjective feelings regarding digital technology use and IA. However, there is a lack of specific studies exploring this association. Given this gap in the literature, this study aimed to address this by examining the association between subjective feelings about digital technology use and IA.

Adolescents are growing up in an era characterized by rapid technological advancements, and the use of smartphones has become a common part of their daily lives. This pervasive technology has greatly influenced their interactions with the internet, particularly social networking sites [35]. Consequently, this has had a profound impact on various aspects of their lives, including social dynamics, cognitive development, and emotional well-being. The literature indicates notable distinctions between early and middle adolescents in terms of cognitive and psychological development [36]. It is critical to distinguish between early and middle adolescence when investigating adolescent IA owing to the distinct developmental traits, experiences, and coping strategies that arise throughout these separate phases of adolescence [37]. Early adolescence is a critical period defined by the start of puberty and the transition from childhood to adolescence. This stage is distinguished by rapid physical, cognitive, and social changes, as well as identity exploration and self-concept construction [38,39]. Furthermore, early adolescence is a critical time for the initiation and development of mental health issues [40]. Middle adolescence is characterized by managing the complications of moving into young adulthood [41]. Individuals become more self-sufficient, engage in complex social connections, and gain feelings of autonomy [42]. If these aspects of development are not addressed properly during adolescence, consequences may have a lasting impact in their adulthood. Researchers must examine the diverse vulnerabilities, risk factors, and patterns of internet use among early and middle adolescents while studying IA during these different phases. Early adolescents may be more vulnerable to IA because they are constantly trying new things, including online platforms, to define their identities and connect with friends [39]. Middle adolescence, on the other hand, is characterized by the emergence of more stable patterns of behavior, including internet use, as adolescents approach young adulthood and deal with increasing academic and social demands [43]. Furthermore, research has shown that the characteristics that influence IA change between early and middle adolescence [21]. For example, parental supervision and advice may have a greater effect among early adolescents, but peer influence and social support may become more significant in middle adolescence [44,45]. Furthermore, in middle adolescence, the onset of academic commitment and the need for self-regulation might alter internet use patterns and addiction risks. IA has become a growing concern among adolescents, with symptoms presenting both in relation to oneself and in interactions with others. However, the cognitive development and behavioral patterns of early and middle adolescents differ significantly, suggesting the need for a critical examination of IA symptoms according to age. Although previous research has highlighted the multifaceted nature of IA symptoms, little attention has been paid to the potential differential manifestation of symptoms based on the age of adolescents. Understanding how IA symptoms manifest differently in early and middle adolescence is crucial for tailoring prevention and intervention efforts. Understanding the differences between early and middle adolescence is critical when examining IA. Our study aimed to address the existing knowledge gap by investigating aspects that have not been thoroughly explored in the field of adolescent IA.

Adolescent technology use can be categorized into distinct types depending on type of use: essential and nonessential [46,47]. Activities that are essential for everyday life, such as educational pursuits or personal improvement–related activities, are included in essential use. On the other hand, nonessential use includes leisure activities such as gaming, social media engagement for nonspecific developmental purpose, and other forms of entertainment [46]. Although researchers have investigated the correlations between excessive internet use and IA, there is a noticeable absence of studies that explicitly distinguish between essential and nonessential use patterns. We suggest that the use of the internet for essential activities related to education and personal development can improve efficiency and time management and may not be linked to IA. In contrast, the excessive use of the internet for nonessential activities may help change mood and increase bonding but may also result in diminished productivity and potential adverse consequences [48]. Given this distinction, our study endeavored to examine the distinct effects of essential versus nonessential internet use on adolescents, thereby contributing to resolving a critical gap in the current literature and offering valuable insights for comprehending healthy internet use patterns.

XSL•FO
RenderX

Objectives

While extensive research has been conducted on IA among adolescents, several significant gaps remain. First, there is a lack of studies focusing on non-WEIRD populations, particularly in the Middle East, where unique cultural factors may influence IA. Second, the potential significance of the distinction between essential and nonessential internet use in relation to IA has not been adequately investigated. Third, there is a scarcity of research on the correlation between subjective emotions related to the use of digital technology and IA. Finally, while the developmental differences between early and middle adolescence are well documented, there are few studies that have investigated the potential differences in the manifestation of IA symptoms and their relationship to technology use across these age groups. We aimed to answer the following three research questions (RQs) through this study:

1. Do essential and nonessential types of internet use predict IA in early and middle adolescents? (RQ 1)
2. Can subjective happiness with nonessential internet use predict adolescent IA? (RQ 2)
3. Does the impact of time spent on essential and nonessential internet use, as well as subjective feelings regarding nonessential internet use, on IA differ between the early and middle adolescence stages? (RQ 3)

Methods

Participants

This study involved school students residing in Qatar, and their participation was secured through web-based surveys administered via SurveyMonkey (SurveyMonkey Inc). The survey invitation was sent out to multiple schools in Qatar through an open call using the mailing list of head teachers and educators. One of the authors works at an education policy institute with a network of schools that attend events and participate in research activities. This facilitated outreach. A total of 16 schools accepted the study invitation, comprising an equal number of public (n=8, 50%) and private (n=8, 50%) schools. Public schools in Qatar are government funded and managed by the government and primarily enroll Qatari citizens as they provide free education with Arabic as the language of instruction. These schools are also gender segregated, meaning that male and female students attend separate institutions. Private schools, on the other hand, are funded by tuition fees and managed by private organizations and predominantly enroll expatriate students. These schools follow a variety of government-reviewed international curricula and are typically not gender segregated. Data were collected between March 2022 and May 2022.

Before administering the survey, students were provided with an induction session by their head teacher, who explained the distinction between essential and nonessential internet use. Essential use was defined as internet activities connected to study, academic work, and personal development, whereas nonessential use was defined as activities that do not directly contribute to these aims. This briefing was designed to establish a common understanding among participants, guaranteeing that their answers precisely reflected these definitions. The authors acknowledge the difficulty in standardizing what adolescents consider essential versus nonessential. Therefore, our study and results should be interpreted as reflecting the subjective views and self-reports of the adolescent participants. This interpretation follows an induction on general understanding, which aimed to reduce diversity in perceptions.

We used the formula by Green [49] to calculate the optimal sample size for our research. The formula indicates that a linear regression analysis requires a minimum sample size of 50 plus 8 times the number of independent variables p ($50 + 8 \times p$). This indicates that a minimum sample size of 74 participants was suitable for our study. In addition, to ensure correlation stability [50], our aim was to have a sample size of >250 individuals. This sample size is consistent with recommendations for maintaining statistical power in studies with multiple predictors [49,50]. Furthermore, the male sample was deemed too small to segregate the analysis by gender.

After excluding participants who did not meet the inclusion criteria, such as those who provided incomplete responses, 64.3% (377/586) of the initial students were included in the analysis, which fulfilled the criteria of a 5% margin of error at the 95% CI. Of these 377 students, 86 (22.8%) were male and 291 (77.2%) were female. The gender distribution in our sample reflects the timing of data collection, which coincided with final exams, as well as the demographic characteristics of the responding schools. Specifically, 12% (2/16) of the schools that responded to the survey were predominantly female-only public schools, which significantly contributed to the observed gender imbalance. It is important to note that gender was not included as a variable in our analysis as the study's primary focus was on essential and nonessential internet use. On the basis of the estimates of the sample size and the need for adequate statistical power in our regression analysis, it was not possible to divide the sample by gender for separate analyses.

The average age of the participating adolescents was 13.19 (SD 1.24; range 11-17) years. The participants in the study were requested to explicitly provide their ages. Participants were categorized into 2 groups: early adolescents (aged 11-13 years) and middle adolescents (aged 14-17 years). The classification of adolescents into these developmental phases was determined based on the existing literature [51].

Ethical Considerations

This study was approved by the institutional review board of Hamad Bin Khalifa University (QBRI-IRB 2021-05-094). School permissions were obtained to distribute the survey. The parents and adolescents were informed beforehand of the study, and their written informed consent and assent were collected. Participants were informed about the study's purpose, and their involvement was voluntary, allowing them to skip questions or withdraw from the survey if desired. During data collection, no identifiable information was collected. The researchers ensured that all deidentified data were stored on a password-protected laptop that only the primary investigators of the study had access to. Participants were not compensated for taking part in this study.

XSL•FO
RenderX

Measures

Overview

The survey included questions regarding participants' demographics, digital technology use, subjective happiness with nonessential internet use, and IA. The questionnaire was distributed in both English and Arabic to accommodate language preferences, and the accuracy of the Arabic translation was ensured using the back translation method [52] (see Multimedia Appendix 1 for both versions of the survey). Our study included a comprehensive and multistep procedure for validating the survey questions to establish its reliability and suitability for the adolescent population. We began by conducting think-aloud protocols with a subset of 3 adolescents, asking them to verbalize their thought processes while answering the survey questions [53]. This approach helped us identify potential ambiguities or misunderstandings, leading to revisions in translation that ensured clarity and suitability for the target age group yet without departing from the original meaning of the questions in the English version. In total, 3 authors with extensive expertise dealing with adolescent groups in the Arab area offered expert advice. Furthermore, the questions in the survey were culturally appropriate, did not use any jargon, and were free of unclear language.

Internet Addiction Diagnostic Questionnaire

The Internet Addiction Diagnostic Questionnaire (IADQ) consists of 8 items, each representing a symptom used to identify IA [10]. The questionnaire uses a binary response format, with participants indicating *no* or *yes* to each symptom. The total score on the IADQ ranges from 0 to 8 and is obtained by summing the values assigned to each of the 8 binary questions. The symptoms assessed by the IADQ are *preoccupation* (question 1), *tolerance* (question 2), *unsuccessful efforts to limit or stop Internet usage* (question 3), *withdrawal* (question 4), *loss of control of time spent on the Internet* (question 5), *risk/lose relationships or opportunities* (question 6), *lies to conceal the extent of involvement* (question 7), and *dysfunctional coping* (question 8) [54]. Participants who answered *yes* to ≥5 symptoms were categorized as addicted to the internet (dependent internet users), whereas the others were categorized as nondependent internet users. Previous studies on the IADQ have reported Cronbach α values ranging from 0.60 to 0.72 [55]. The reliability of the IADQ in this study was deemed acceptable, with a Cronbach α value of 0.66 [56] and a McDonald ω value of 0.67. In addition, the research conducted by Lozano-Blasco et al [57] found that using lesser answer categories led to decreased Cronbach α values. The dichotomous character of the questions in the IADQ, which means that they only allow for replies of *yes* or *no*, leads to lower Cronbach α values that are within the acceptable range for dependability. To establish content validity [58], the initial item pool was reviewed by a panel of 3 experts who has extensive experience working with adolescents in the Arab region. This process resulted a questionnaire that comprehensively covered the construct of interest.

Essential and Nonessential Internet Use

Adolescents were presented with a set of questions regarding their use of digital technology for both essential and nonessential purposes on both weekends and weekdays. The weekend is officially observed on Fridays and Saturdays in Qatar. By focusing on weekdays and weekends separately, we aimed to capture any behavioral variations influenced by the shift from weekend to workweek and vice versa. Participants were asked the following questions to encompass four different situations: (1) How many hours do you use digital technology for study purposes daily on weekdays (Sunday-Thursday)? (2) How many hours do you use digital technology for nonessential reasons daily on weekdays (Sunday-Thursday)? (3) How many hours do you use digital technology for study purposes daily on weekends (Friday and Saturday)? (4) How many hours do you use digital technology for nonessential reasons daily on weekends (Friday and Saturday)?

Essential internet use on weekdays and weekends was combined, and their average was used to compute essential internet use time. Nonessential internet use on weekdays and weekends was combined, and their average was taken to compute nonessential internet use time.

Subjective Happiness With Nonessential Internet Use Time

Adolescents were asked to express their feelings regarding the extent of their nonessential use of digital technology. Their responses were collected using a five-point Likert scale: (1) "I am happy with it," (2) "I am somewhat happy with it," (3) "Neither happy nor unhappy with it," (4) "I am somewhat unhappy with it," and (5) "I am unhappy with it."

Statistical Analysis

Multiple linear regression analyses were conducted separately for early and middle adolescents to examine the relationship between nonessential internet use, essential internet use, and subjective happiness with nonessential internet use time and their IA status. The significance level for the statistical tests was set at $P<.05$. All statistical analyses were carried out using JASP (version 0.17.1) [59].

Exploratory factor analysis with oblique (promax) rotation was performed [60]. The determination of the number of significant components to retain for rotation was based on two criteria: (1) the scree plot indicating the number of extracted factors and (2) ensuring that the factor solution allowed for a coherent interpretation of the results.

Results

Descriptive Statistics

The descriptive statistics of the participants are presented in Table 1.

XSL•FO
RenderX

Table 1. Descriptive statistics—internet use patterns and internet addiction (IA).

Variable	Early adolescents (n=242)	Middle adolescents (n=135)
Essential internet use time (h), mean (SD)	2.22 (1.76)	2.96 (2.12)
Nonessential internet use time (h), mean (SD)	4.45 (2.74)	4.52 (2.35)
Subjective happiness with nonessential internet use time, n (%)		
"I am happy with it" (rating of 1)	90 (37.2)	44 (32.6)
"I am somewhat happy with it" (rating of 2)	77 (31.8)	40 (29.6)
"Neither happy nor unhappy with it" (rating of 3)	46 (19)	35 (25.9)
"I am somewhat unhappy with it" (rating of 4)	17 (7)	11 (8.1)
"I am unhappy with it" (rating of 5)	12 (5)	5 (3.7)
IA		
Total IA score (0-8), mean (SD)	3.26 (1.98)	3.47 (2.17)
IA prevalence, n (%)		
Addicted internet users	63 (26)	50 (37)
Nonaddicted internet users	179 (74)	85 (63)

Exploratory Factor Analysis of IA Symptoms

To identify underlying dimensions within the IA symptoms and reduce the data into meaningful factor scores, an exploratory factor analysis was conducted on the dataset. The Kaiser-Meyer-Olkin (KMO) test, a measure of sampling adequacy, was used in this study to evaluate multicollinearity in the data to determine the feasibility of conducting a factor analysis. The overall KMO measure was 0.76, denoting "middling" adequacy. Individual KMO measures were all of >0.68, ranging from the "mediocre" to the "marvelous" categories according to the classification system by Kaiser and Rice [61]. The Bartlett test of sphericity was statistically significant (P<.001), indicating that the data were likely factorizable.

The analysis extracted 2 components, which accounted for 26% of the variance. Our scree plot was compatible with the 2-factor model. We interpreted the 2 factors as representing internal IA symptoms (factor 1; 18% of the total variance)—those symptoms primarily related to the individual's self, such as preoccupation with internet use—and external IA symptoms (factor 2; 9% of the total variance)—those symptoms primarily related to interaction with others. Factor loadings for factor 1 and factor 2 ranged from 0.31 to 0.55 and from 0.33 to 0.78, respectively. Factor scores were derived by adding the scores of individual items within each empirical domain (sum score) and dividing the sum scores by the total number of items (mean item score). The component loadings and uniqueness of the rotated solutions are presented in Table 2.

Table 2. Factor analysis of internet addiction symptoms.

Item	Factor 1 loadings	Factor 2 loadings	Uniqueness
"Preoccupation" (question 1)	0.49	—[a]	0.79
"Tolerance" (question 2)	0.31	—	0.91
"Unsuccessful efforts to limit or stop Internet usage" (question 3)	0.50	—	0.76
"Withdrawal" (question 4)	0.55	—	0.62
"Loss of control of time spent on the Internet" (question 5)	0.50	—	0.77
"Risk/lose relationships or opportunities" (question 6)	—	0.78	0.48
"Lies to conceal the extent of involvement" (question 7)	—	0.33	0.75
"Dysfunctional coping" (question 8)	0.45	—	0.79

[a]The factor does not comprise this item.

Early Adolescents

Predictors of Total IA Scores

Overview

Multiple regression analysis was used to determine factors that predicted early adolescents' total IA scores and internal IA symptoms. No outliers were observed in the data. The Pearson correlation was also used to analyze the associations between total IA, which was the dependent variable, and the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time.

XSL•FO
RenderX

Correlation Analysis of Variables

The correlations between the variables are presented in Table 3.

Table 3. Pearson correlation table between the variables in early adolescents.

	Total IA[a]	Internal IA symptoms	External IA symptoms	Subjective happiness with nonessential internet use time	Essential internet use time	Nonessential internet use time
Total IA	1	—[b]	—	—	—	—
Internal IA symptoms	0.95[c]	1	—	—	—	—
External IA symptoms	0.58[c]	0.30[c]	1	—	—	—

Regression Analysis of Total IA Scores

Table 4 shows the results of the multiple regression that was run to predict the total IA score from the subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time among early adolescents. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.93. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q*-*Q* plot. The multiple regression model significantly predicted the total IA score ($F_{3, 238}$=15.72; $P<.001$; R^2=0.17; adjusted R^2=0.15). Within the model, nonessential internet use time (β=.40; $P<.001$) was the only significant predictor of early adolescents' total IA scores.

Table 4. Multiple linear regression analysis predicting internet addiction in early adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	5.73 (3)	<.001
Subjective happiness with nonessential internet use time	.00923	0.16 (3)	.88
Essential internet use time	.02	0.36 (3)	.72
Nonessential internet use time	.40	6.74 (3)	<.001

[a]R^2=0.17; adjusted R^2=0.15; $F_{3, 238}$=15.72.

[b]Not applicable.

Predictors of Internal and External IA Symptoms

Multiple regression analysis was used to determine factors that predicted internal IA symptoms with the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time, and an ordinal logistic regression model was used to predict external IA symptoms. Table 5 shows the results of the multiple regression that was run to predict the internal IA symptom score from the subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.98. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q*-*Q* plot. The multiple regression model significantly predicted the internal IA symptom score ($F_{3, 238}$=15.95; $P<.001$; R^2=0.17; adjusted R^2=0.16). Within the model, nonessential internet use time (β=.41; $P<.001$) was the only significant predictor of early adolescents' internal IA symptoms.

XSL•FO

Table 5. Multiple regression analysis predicting internal internet addiction symptoms in early adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	6.18 (3)	<.001
Subjective happiness with nonessential internet use time	.00318	0.05 (3)	.96
Essential internet use time	−.00431	−0.07 (3)	.94
Nonessential internet use time	.41	6.86 (3)	<.001

[a]R^2=0.17; adjusted R^2=0.16; $F_{3, 238}$=15.95.

[b]Not applicable.

An ordinal logistic regression analysis was conducted to examine the relationship between the 3 predictor variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) and the outcome variable (external IA symptoms; Table 6). The variables included in the ordinal logistic regression analysis met the assumptions of the statistical model—the dependent variable (ie, external IA symptoms) was treated as an ordinal variable, and the independent variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) were treated as continuous variables. The assumption of no multicollinearity was assessed by examining the variance inflation factors (VIFs), and the result (VIFs<1.1) indicated no multicollinearity. The results revealed that nonessential internet use time was associated with increased external IA symptoms (odds ratio [OR] 1.13, 95% CI 1.02-1.24; *P*=.02). Meanwhile, essential internet use time was not associated with any change in external IA symptoms (OR 1.11, 95% CI 0.96-1.28; *P*=.17). Similarly, subjective happiness with nonessential internet use time was not associated with any change in external IA symptoms (OR 0.99, 95% CI 0.78-1.25; *P*=.94) in early adolescents.

Table 6. Ordinal logistic regression predicting external internet addiction symptoms in early adolescents.

Predictor	OR[a] (95% CI; SE)	*P* value
Subjective happiness with nonessential internet use time	0.99 (0.78-1.25; −0.01)	.94
Essential internet use time	1.11 (0.96-1.28; 0.10)	.17
Nonessential internet use time	1.13 (1.02-1.24; 0.12)	.02

[a]OR: odds ratio.

Binary logistic regression was conducted to examine the relationship between subjective happiness with nonessential internet use time and the likelihood of being a dependent internet user (addicted) compared to a nondependent internet user (unaddicted) in early adolescents. The reference category, representing nondependent internet users, was coded as class 1. The OR of 0.93 (95% CI 0.73-1.20) indicated the effect size. However, the results did not reveal a significant association between subjective happiness with nonessential internet use time and IA (*P*=.58).

Middle Adolescents

Predictors of Total IA Scores

Overview

Multiple regression analysis was used to determine the factors that predicted middle adolescents' total IA scores and internal IA symptoms. No outliers were observed in the data. The Pearson correlation was also used to analyze the associations between total IA, which was the dependent variable, and the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time.

Correlation Analysis of Variables

The correlations between the variables are presented in Table 7.

XSL•FO

Regression Analysis of Total IA Scores

Table 8 shows the results of the multiple regression that was run to predict middle adolescents' total IA score from the subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.83. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q-Q* plot. The multiple regression model significantly predicted the total IA score ($F_{3, 131}=12.96$; $P<.001$; $R^2=0.23$; adjusted $R^2=0.21$). Within the model, nonessential internet use time (β=.31; $P<.001$) and subjective happiness with nonessential internet use time (β=.27; $P<.001$) were significant predictors of middle adolescents' total IA score.

Table 8. Multiple linear regression analysis predicting internet addiction in middle adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	1.16 (3)	.25
Subjective happiness with nonessential internet use time	.27	3.44 (3)	<.001
Essential internet use time	.15	1.90 (3)	.06
Nonessential internet use time	.31	3.94 (3)	<.001

[a]$R^2=0.23$; adjusted $R^2=0.21$; $F_{3, 131}=12.96$.

Predictors of Internal and External IA Symptoms

Multiple regression analysis was used to determine factors that predicted internal IA symptoms with the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time, and ordinal logistic regression was used to predict external IA symptoms. Table 9 presents the results of the multiple regression. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.82. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q-Q* plot. The multiple regression model significantly predicted the internal IA symptom score ($F_{3, 131}=9.15$; $P<.001$; $R^2=0.17$; adjusted $R^2=0.15$). Within the model, nonessential internet use time (β=.29; $P<.001$) and subjective happiness with nonessential internet use time (β=.22; $P=.007$) were significant predictors of middle adolescents' internal IA symptoms.

XSL•FO
RenderX

Table 9. Multiple regression analysis predicting internal internet addiction symptoms in middle adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	2.10 (3)	.04
Subjective happiness with nonessential internet use time	.22	2.76 (3)	.007
Essential internet use time	.10	1.20 (3)	.23
Nonessential internet use time	.29	3.65 (3)	<.001

[a]R^2=0.17; adjusted R^2=0.15; $F_{3, 238}$=15.95.

[b]Not applicable.

An ordinal logistic regression analysis was conducted to examine the relationship between the 3 predictor variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) and the outcome variable (external IA symptoms; Table 10). The variables included in the ordinal logistic regression analysis met the assumptions of the statistical model—the dependent variable (ie, external IA symptoms) was treated as an ordinal variable, and the independent variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) were treated as continuous variables. The assumption of no multicollinearity was assessed by examining the VIFs, and the result (VIFs<1.1) indicated no multicollinearity. The results revealed that all 3 predictors were associated with changes in the external IA symptoms. Nonessential internet use time was associated with an increase in external IA symptoms (OR 1.19, 95% CI 1.03-1.39; *P*=.02). Essential internet use time was associated with an increase in external IA symptoms (OR 1.24, 95% CI 1.05-1.46; *P*=.01). Similarly, a higher unhappiness with nonessential internet use time was associated with increased external IA symptoms (OR 1.75, 95% CI 1.28-2.44; *P*<.001).

Table 10. Ordinal logistic regression predicting external internet addiction symptoms in middle adolescents.

Predictor	OR[a] (95% CI; SE)	*P* value
Subjective happiness with nonessential internet use time	1.75 (1.28-2.44; 0.56)	<.001
Essential internet use time	1.24 (1.05-1.46; 0.21)	.02
Nonessential internet use time	1.19 (1.03-1.39; 0.18)	.01

[a]OR: odds ratio.

A binary logistic regression was performed to assess the impact of subjective happiness with nonessential internet use time on the likelihood of being a dependent internet user (addicted) versus a nondependent internet user (unaddicted). The reference category was coded as class 1, representing nondependent internet users. The OR of 0.66 (95% CI 0.47-0.92) indicated the effect size. The *F*-measure was 75%. The results indicated a significant association between subjective happiness with nonessential internet use time and IA (*P*=.01), suggesting that higher levels of unhappiness were associated with a decreased likelihood of being unaddicted to the internet.

Discussion

Principal Findings

This study aimed to enhance our understanding of adolescent IA by addressing 3 key RQs. First, we examined the significance of differentiating between essential and nonessential internet use in relation to IA, offering a more nuanced view of IA beyond that of total screen time that is found in previous research. Second, we investigated whether subjective happiness linked to time spent on nonessential internet use could predict IA in adolescents. Finally, by studying early and middle adolescents separately, we identified age-specific differences in how time spent on essential and nonessential internet use and the related happiness contribute to IA.

Consistent with the extensive existing literature on IA, our study demonstrated that excessive engagement in nonessential internet activities, such as social media and online gaming, positively correlate with IA overall [62-64]. Furthermore, in our study, essential internet use did not exhibit a significant correlation with IA (*P*=.94 for early adolescents and *P*=.06 for middle adolescents), suggesting that essential internet activities such as remote learning or using the internet for school-required work may not carry the same level of addiction risk. This is similar to the results obtained in other studies [65,66]; Salubi et al [65] found that there was no correlation between essential internet use and IA among 390 surveyed university students in South Africa, whereas Pjevac et al [66] found that IA was lowest among adolescents who mostly used the internet for school purposes. This distinction of the purposes of internet use enables the development of targeted interventions and strategies to effectively address this issue. As digital technology becomes increasingly integral to tasks that once operated without it, acknowledging this technological shift is essential in our evolving digital society. It is necessary to recognize the evolving landscape of digital technology use and interpret digital technology use with caution, as emphasized by Squire and Steinkuehler [67], before delving into the complexities of IA. This caution entails considering the specific activities carried out on the internet, the motivations driving them, and the duration for which they occur.

XSL•FO
RenderX

Our study highlights similarities and key differences in IA between early and middle adolescents as our results revealed that, among early adolescents, nonessential internet use significantly predicted IA and its internal symptoms (related to the self). However, middle adolescents exhibited a more complex relationship with IA as both nonessential and essential internet use, in addition to unhappiness with nonessential internet activities, significantly predicted IA and its external symptoms (related to others).

Our results suggest that early adolescents are more likely to develop IA and experience internal IA symptoms as a result of nonessential internet use, whereas this influence seems to decrease as they get older. This finding is in line with the results of a meta-analysis (of 20 studies) on IA in adolescents reporting that IA is inversely proportional to age [57]. This difference suggests that the impact of nonessential digital technology use on IA may vary according to the developmental stage of adolescents. One possible explanation is that early adolescents are actively navigating their new identity and seeking peer acceptance, which can make them more susceptible to excessive use of digital technology [68]. The pressure to conform to peers' behaviors and expectations may override their ability to exercise self-control and resist the allure of digital technology [69]. Furthermore, in early adolescents, only nonessential internet use increased the likelihood of external IA symptoms. Our results are similar to those of a recent study that examined sociodemographic factors related to IA among a sample of 1664 adolescents in Serbia. The study reported the lowest IA rates among the younger adolescents and among those who used the internet for the purpose of schoolwork [66]. Our results could be interpreted as early adolescents not facing the same academic pressures and responsibilities that drive older adolescents to the excessive use of the internet for essential activities. Instead, early adolescent IA is more related to recreational online activities, underscoring the importance of tailoring preventive interventions to focus on nonessential use, such as social media and gaming, to equip early adolescents to develop healthier digital habits. Parental involvement and supervision play a vital role in preventing IA in early adolescents. Actively engaging with children, establishing open communication channels, and monitoring their digital technology use can create a supportive environment and set boundaries for healthy digital behaviors [27,70]. Emphasizing balance is also essential, highlighting the need for a well-rounded lifestyle that includes academic tasks, physical activities, face-to-face interactions, and nondigital recreational pursuits [71]. Self-control in early adolescents may be enhanced through self-control–training activities and participation in self-control–promoting programs [72].

In contrast to the results for early adolescents, our results demonstrated a more complex relationship between internet use and IA in middle adolescents. Our study found that, while nonessential internet use remains a significant predictor of IA, subjective happiness with nonessential internet activities also plays a role. Specifically, the unhappier middle adolescents were with the time spent on nonessential internet use, the more likely they were to experience IA. These findings are consistent with the findings of a similar study that surveyed a sample of adolescents and young adults (aged 15-24 years) and adults (aged 25-64 years), where dissatisfaction with smartphone use was linked to higher problematic internet use [73]. Our results contribute to the literature as there is a lack of research examining subjective happiness with digital technology use in relation to IA in adolescents.

This can be attributed to the increased academic pressure and the need to manage uncertainty, which drive middle adolescents to spend more time on essential internet activities, such as online educational tasks. The combination of information overload, academic demands, and the desire to avoid having to deal with uncertainty may lead to excessive internet use, further exacerbating IA.

Moreover, middle adolescents exhibited a broader range of factors influencing their external IA symptoms.

While, in early adolescents, only nonessential internet use increased the likelihood of external IA symptoms, in middle adolescents, both nonessential and essential internet use, as well as unhappiness with the time spent on nonessential internet use, increased external IA symptoms. This can be attributed to the intensified academic pressure in combination with information overload, leading them to neglect other aspects of their lives and driving them to the excessive use of the internet to meet academic demands [74,75]. The combination of these factors heightens the risk of IA [76-78]. Furthermore, these academic pressures can further impact social interactions as middle adolescents prioritize academic performance, leading them to show signs of stress in their engagement with others [74,79], manifesting in external symptoms of IA, as observed in our study. Recognizing the unique challenges faced by adolescents at different developmental stages is crucial for effectively tailoring preventive measures and interventions.

While our study focused on examining individual factors related to IA, considering factors related to the specific context in which our results were obtained should not be overlooked and could provide a more holistic understanding of IA among adolescents. Adolescents' internet use and their susceptibility to IA are influenced by cultural values, societal norms, and regional habits. For instance, in the Middle East, where our study was conducted, cultural expectations regarding academic achievement and family roles may contribute to heightened stress and pressure on adolescents [80,81], leading them to spend more time on online activities such as social media and gaming. The emphasis on academic success in our context combined with limited outdoor recreational opportunities due to the extremely hot climate might be driving adolescents to spend more time indoors and engage in online recreational activities, increasing their risk of IA.

In addition, the rapid digital transformation in the Middle East has created new challenges and opportunities for adolescents [82,83]. The increased availability of smartphones and internet access as well as a growing digital culture have made it easier for people to spend long hours on the web. While there are positive aspects of digitalization, it also raises concerns about the potential for excessive use and the development of IA. The addition of environmental factors such as the local affluent culture of convenience, the wide availability of digital devices even at very young ages, and the wide presence of high-speed

XSL•FO
RenderX

internet further influences how adolescents interact with digital technology.

Our study has important implications for the field of IA and for promoting healthier digital technology use habits in adolescents. The findings suggest that interventions aimed at addressing IA should focus on nonessential use specifically, particularly in early adolescents, rather than considering internet use as a whole. Because IA is a complex outcome influenced by multiple physical, psychological, and technological factors rather than a single issue, this targeted approach can help effectively address the factors contributing to IA while considering the developmental factors of adolescents. While there is a dearth of data from the region, there is evidence from a systematic literature review on policy and prevention approaches for disordered gaming and internet use suggesting that, due to the global prevalence of the phenomena and the geographically dispersed nature of preventative programs, it is imperative that prevention efforts be integrated across national borders while taking cultural differences into consideration [84].

The following recommendations are a recapitulation of the evidence produced by the limited international reviews that have examined the effectiveness of programs and interventions in the prevention of IA [71,84-87].

Early identification and intervention are key to addressing IA among adolescents. Schools can implement evidence-based prevention programs specifically targeting IA. These programs can incorporate educational components, skill-building exercises, and peer support networks to help adolescents develop healthy online habits and balance their time between essential and nonessential activities [87]. Comprehensive school-based programs are essential to effectively address IA. These programs should focus on increasing awareness, develop coping strategies, and promoting responsible digital technology use. These programs can be integrated into the school curricula and should include methods to improve self-control and enhance knowledge of the underlying processes that contribute to excessive online activity, such as constant notifications [88,89]. In addition, schools can implement practical digital well-being initiatives, such as mindfulness exercises and the integration of technology breaks into the daily schedule, to promote healthier digital habits. Moreover, promoting digital literacy and responsible digital technology use is crucial for educating adolescents on the potential risks and consequences associated with excessive digital technology use [90]. Given that adolescents' behaviors are largely shaped by other external factors such as their families and external environments [21], schools play a crucial role in extending these preventive programs to parents and caregivers. Understanding children's intentions when interacting with the internet is crucial and emphasizes the need for smarter digital parenting tools that provide enhanced monitoring and guidance. A healthier digital environment can be created by considering intentionality and using smart tools. Devices and programs should be designed to isolate essential and nonessential uses, advising children to avoid installing or visiting purely nonessential social media applications and sites on the same device in which they engage in essential activities.

These recommendations must be supported by designing and enacting policies. Policy makers can design programs targeting the broader environment in which adolescents live, addressing the underlying factors contributing to maladaptive coping, such as reducing academic pressure and improving family support. By reducing dependence on nonessential internet use, these policies, in turn, can empower adolescents to navigate their digital environments more responsibly.

Certain limitations of this study must be considered when interpreting the results. First, due to the cross-sectional design of our study, the generalizability of our findings is limited. Another limitation of our study was that the responses provided by the adolescents were based on self-report, potentially introducing reporting bias. It is possible that the adolescents did not accurately report the time spent on essential and nonessential activities and symptoms of IA. To mitigate the influence of reporting bias, future studies should incorporate objective measures, such as using data on actual screen time, instead of relying solely on self-reported information. Another limitation of this study is that the context of essential and nonessential internet use could have been interpreted by adolescents based on their subjective experiences and perceptions. For example, spending time with friends on social media during the examination period may be considered essential for adolescents who want to receive moral support from their colleagues. Nevertheless, our study left it at the discretion of the participants. The impact of the specific activity or content that adolescents consume or spend excessive time on and the effect it has on them should be scrutinized in more detail and is an area that requires attention. Our sample's gender imbalance, which was characterized by a higher proportion of female participants, may restrict the generalizability of the results to both genders. Furthermore, we adhered to sample size estimates using the method by Green [49] to guarantee sufficient statistical power for our study. The deliberate choice not to segregate the sample by gender was made to ensure that the sample size remained sufficient for obtaining consistent and dependable regression results. The male sample was relatively too small to allow for that option. Although the existing literature on gender differences in IA is inconclusive, with research presenting inconsistent findings [91-95], it is important to exercise caution when interpreting the results of this study due to the higher proportion of female participants. Future studies should aim for a more even gender distribution to comprehensively investigate any disparities in IA between male and female individuals.

The strength of our study lies in its inclusion of a non-WEIRD population, specifically focusing on adolescent IA in the Middle East, where limited research on this area has been conducted. Another strength of our study is that it addresses the research gap by examining both essential and nonessential internet use in the same sample. While previous research has explored the different online activities that contribute to IA [65,96], few studies have specifically investigated the impact of essential and nonessential internet use within a single study. Another strength of our study lies in the separate analysis of IA factors in early and middle adolescents, which allowed us to capture the unique dynamics and influences shaping IA in each age

XSL•FO
RenderX

group, thus enhancing the understanding of IA in relation to developmental stages.

Conclusions

In conclusion, this study sheds light on the complex relationship between digital technology use and IA among early and middle adolescents. For many years, screen time has been widely used as a prominent measure to assess the extent of IA among adolescents. As the digital society continues to evolve rapidly, relying on screen time as a stand-alone criterion fails to provide a comprehensive understanding of phenomena such as IA. Therefore, it is imperative to distinguish between essential and nonessential digital technology use, acknowledging diverse activities and their implications for a better understanding of individuals' engagement with digital technology. The findings of our study provide valuable insights for researchers, practitioners, and policy makers in addressing IA among adolescents. By recognizing the distinct nature of internet activities and considering developmental factors, effective interventions and strategies can be developed to promote healthy digital technology use and prevent IA in adolescents.

Acknowledgments

"Technology Overuse Amongst Adolescents in Qatar: current status, challenges, and recommendations for policy" is a joint project among 3 members of the Qatar Foundation for Education, Science, and Community Development; the Doha International Family Institute; the World Innovation Summit for Education; and the Word Innovation Summit for Health. The statements made herein are solely the responsibility of the authors and do not reflect the statements or opinions of these institutions.

Authors' Contributions

KC conceptualized the study, prepared and analyzed the data, and wrote the paper. MA helped with data preparation and verified the statistical analysis. AA, SA-H, and AB participated in the study conceptualization and design and conducted the data collection. DAH critically reviewed and revised the Conclusions section in the paper. RA participated in all stages and supervised the research. All authors reviewed the paper and provided feedback. All authors approved the final version of the paper.

Conflicts of Interest

None declared.

Abstract

Background: Mental health issues represent a prevalent challenge for employees and their employers, leading to substantial impacts on individuals, society, and the economy. Different employee mental health programs (EMHPs) can support employees in preventing and treating mental health issues. However, the impact of such EMHPs depends largely on the use behavior of employees.

Objective: This study aimed to gain deeper insights into employees' attitude and use behavior regarding EMHPs by investigating (1) employee preference and intention to use EMHPs, (2) factors that predict use, and (3) key facilitators and barriers influencing use.

Methods: An exploratory sequential mixed methods approach was applied, including a scoping review, qualitative interviews, and a quantitative web-based survey. Semistructured qualitative interviews were conducted with 15 employees to gain insights into EMHPs from the employee perspective and inform the creation of a web-based questionnaire. The quantitative web-based survey was conducted to collect representative primary data on employees' perspectives on different EMHPs using 7-point Likert scales. The collected quantitative data were analyzed through descriptive and inferential statistics, including repeated measures ANOVAs and chi-square tests.

Results: The final sample of the web-based survey consisted of 1134 participants and was representative across several sociodemographic characteristics. Analysis of the sample revealed that when given the choice, employees preferred digital (n=666, 58.73%) and self-intervention (n=590, 52.03%) EMHPs. Employees were most likely to use EMHPs focused on prevention (mean 4.89, SD 1.61). Intention to use EMHPs was predicted by age (young: mean 4.59, SD 1.2; old: mean 4.19, SD 1.4; P<.001; Cohen d=0.32), education (academic degree: mean 4.68, SD 1.24; no academic degree: mean 4.26, SD 1.32; P<.001; Cohen d=0.32), and mostly by company culture (positive company culture: mean 4.61, SD 1.27; negative company culture: mean 3.99, SD 1.27; P<.001; Cohen d=0.49). Cost coverage (n=345, 30.42%) and ease of use (n=337, 29.72%) were critical facilitators of use.

Conclusions: Employers can have a positive contribution to employee mental health by starting to offer EMHPs, preferably digital self-intervention programs for prevention; creating and maintaining the right work environment and culture; and ensuring cost coverage for the EMHP.

Introduction

Background

Mental health issues represent a rising global challenge. In this paper, we broadly define mental health issues as any condition affecting an individual's mental health. This definition aligns with the World Health Organization's (WHO's) term "mental health condition" and includes mental disorders as defined by the WHO [1]. According to the WHO, approximately 12% of the global population experience a mental health condition, and every fourth family has a member who is affected by a mental disorder [1,2]. Most of these individuals are employed and therefore represent the active workforce [3]. Data suggest that approximately 20% of employees in industrialized countries experience mental health issues, either through mild symptoms or more serious forms of mental disorders, with prevalence continuing to rise [3,4]. This leads to 3 main adverse effects. First, at the individual level, mental health issues deteriorate the mental health and well-being of employees and negatively impact their quality of life and job performance. Second, at the societal level, mental health issues place a significant burden on welfare systems, which must cover the high costs of treatment and pension requirements. Third, at the economic level, damage arises from decreased productivity, which causes a shrinking economic surplus for individual entities and the respective national economies [1,5,6]. Total annual costs of mental disorders, including health care expenses, costs due to lost productivity, and related economic impacts, are estimated to range between €100 billion and €150 billion (approximately US $110-$170) for countries such as Germany and France [7,8]. On a global scale, these costs amount to approximately US $5 trillion [9].

The workplace itself offers a promising environment for promoting good mental health by preventing mental health issues in early stages or mitigating the effects of existing mental disorders [10-12]. Many programs exist that are explicitly designed or used to support employees [13-16]. As no uniform umbrella term is commonly used for such programs, we refer to these programs as employee mental health programs (EMHPs). In the style of the broader definition of employee assistance programs (EAPs) of the Employee Assistance Professionals Association [17,18], we define EMHPs as any programs or solutions offered and facilitated by employers to support employees in sustaining or regaining good mental health. We consider all solutions independent of whether they stem from company internal units or external service providers. Real examples are manifold as employers offer their employees a diverse range of EMHPs, with the programs coming in different forms and formats [12,18-20]. Among others, there are 3 key dimensions to characterize EMHPs. First, the medium, that is, whether an EMHP is in a digital, analog, or hybrid form. Second, the interaction form, that is, whether an EMHP is self-guided, delivered in a one-on-one setting, or used in a group. Third, the addressed stage of mental health, that is, whether an EMHP is supposed to support employees in preventing mental challenges, treating existing mental disorders, or rehabilitating from past mental health issues [21-24]. Among EMHPs, digital programs are particularly popular and increasingly offered due to their advantages, such as cost efficiency, scalability, and flexibility in terms of time and location [25].

Prior Work

Several scientific studies and meta-analyses have researched the effectiveness of EMHPs. While some studies have not found clear evidence for the effectiveness of EMHPs in improving mental health outcomes [26,27], many other studies suggest that EMPHs can have significant positive effects on employees' mental well-being and thereby improve resilience and work effectiveness [15,18,28,29]. In recent years, studies and meta-analyses researching the effectiveness of digital EMHPs have gained particular attention and provide similar evidence for the potential positive effects of digital programs [20,25,30-33]. These positive effects have also been examined and found for different employee groups, including those in specific professions and across various countries [34-39]. Although both digital and analog EMHPs have been found effective in several studies, researchers note that the impact of these programs depends on the type of EMHP and the specific employee group they target [32,33,40].

Several studies have also identified different general facilitators of and barriers to using EMHPs [24,41,42]. However, only some studies have looked at differences in preference and use behavior based on employee-related characteristics, such as age and gender [43,44], type of profession [42], and education and income [45]. Existing research on predictive characteristics primarily focuses on specific EMHPs and select employee characteristics, leaving a gap in the literature regarding a comprehensive, holistic perspective on how different employee groups prefer and use various types of EMHPs. However, such a holistic view is essential to create transparency on which factors influence EMHP preference and use, particularly for digital ones. A deeper understanding of these predictors would benefit both researchers and practitioners. For researchers, it would help ensure that future research adopts an employee-centered approach. For employers and other stakeholders, it would help provide valuable insights into which EMHPs are most relevant and effective for their targeted workforce, ultimately increasing adoption rates. Greater adoption of EMHPs is likely to improve employees' mental well-being and reduce symptoms, while also mitigating productivity losses. The value of and need for further research to determine suitable mental health resources for employees is also explicitly mentioned by researchers [46]. To the best of our knowledge, no comprehensive study exists that combines research on multiple predictive factors for the use of different EMHP types and relevant facilitators and barriers.

XSL•FO
RenderX

Objectives

Therefore, the objective of this study was to address this research gap by (1) researching preference and intention to use of different types of EMPHs from the employee perspective, comparing digital EMHPs to nondigital ones; (2) examining several predicting factors for potential use of EMHPs; and (3) identifying key facilitators of and barriers to using EMHPs (research questions [RQs] 1-3).

On the basis of the first indications from existing research on EMHPs, as well as on initial evidence from research on the effects of several demographic, sociocultural, program, and other characteristics on intention to use or participation in general health interventions [47,48], we hypothesize that several employee-related factors, such as demographics and personal characteristics, and company-related factors, such as company culture, represent solid predictors for the use of EMHPs. As initial studies have observed different personal preferences for EMHPs among distinct demographic groups [43,44], the predictive value of the several considered characteristics may differ by type of EMHP, especially between digital and nondigital ones.

Methods

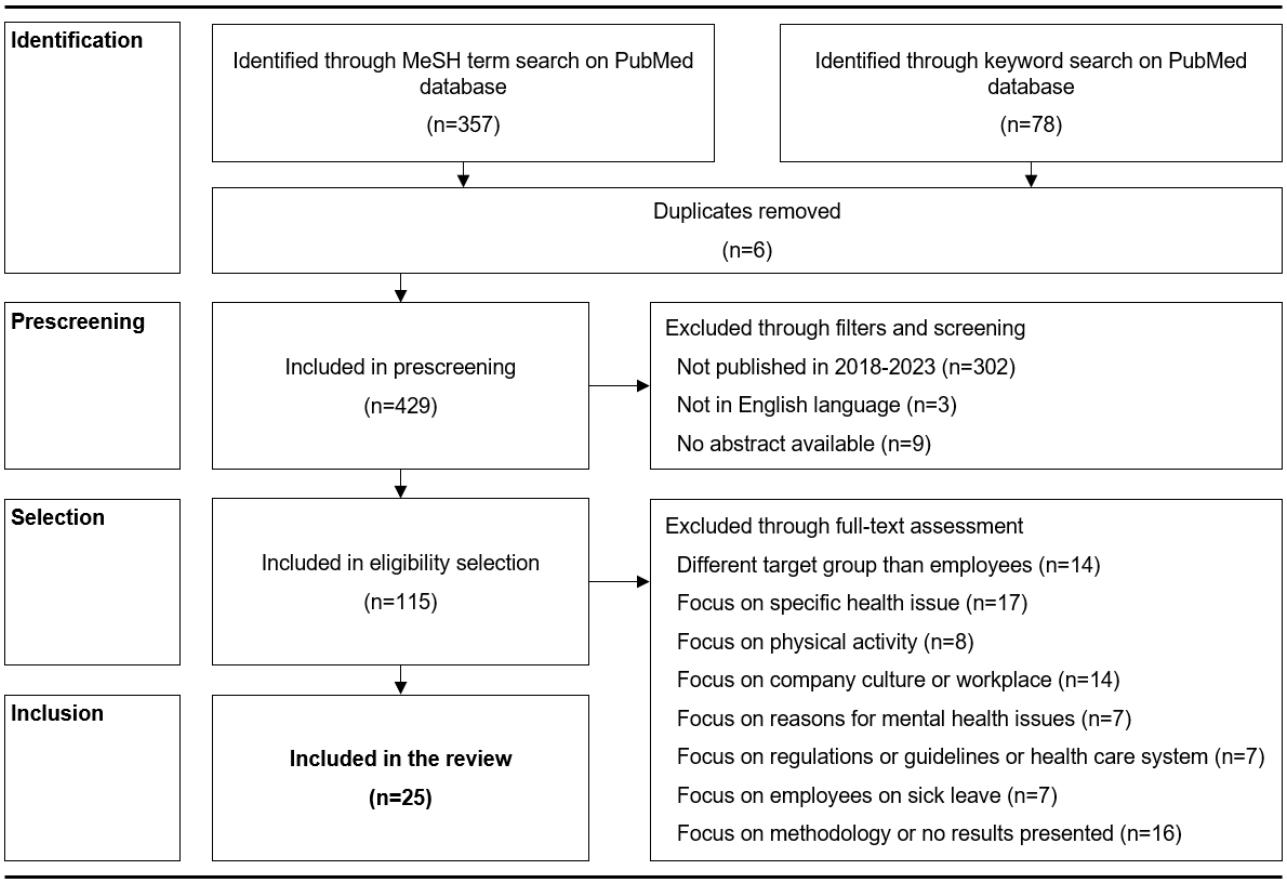
Exploratory Sequential Mixed Methods Approach

We applied an exploratory sequential mixed methods approach with 3 steps. The methodology and results of each step are reported separately, in line with the Mixed Methods Article Reporting Standards. The first step represented a scoping review to identify relevant research on EMHPs. The second step was an exploratory interview study for primary data collection. We conducted semistructured qualitative interviews to collect additional insights into the research topic and illustrate employees' views on EMHPs. The third step was a quantitative web-based survey for primary data collection. For the survey, a closed-format questionnaire was created and validated based on the results of the previous 2 steps.

Ethical Considerations

The Ethics Committee of Witten/Herdecke University raised no ethical concerns with regard to this research project (S-12/2023). All individuals who participated in either the qualitative interview study or the quantitative web-based survey provided voluntary, informed, and written consent to participate in the study and have the results published in a peer-reviewed article. The primary data collection approaches adhered to established ethical standards in scientific research as well as data protection regulations (General Data Protection Regulation). The data collected during the qualitative interview study were factually anonymized in a way that made it impossible, or only possible with disproportionately great effort, to identify individual participants. The data collected through the web-based survey were anonymized using the k-anonymity technique, which ensured that responses were removed if they did not meet the defined anonymity criteria. Additionally, demographic data obtained from the web-based survey such as age were collected in predefined intervals rather than as exact values to further ensure participant anonymity. The participants of the web-based survey received a monetary compensation from the research panel provider that executed the data collection. The research panel provider was remunerated by the authors.

Scoping Review



A scoping review according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines was performed to scope the existing research on EMHPs; refer to the PRISMA-ScR checklist (Multimedia Appendix 1) for further details. The review was conducted in 2 streams with the following 2 search queries performed in the "PubMed" database on January 12, 2023:

1. ((mental health[MeSH Terms]) OR (psychology[MeSH Terms])) AND ((employee assistance program[MeSH Terms]) OR (employer intervention[MeSH Terms]) OR (workplace intervention[MeSH Terms])) OR ((mental health[MeSH Terms]) AND (workplace[mesh terms]) AND (health promotion[mesh terms]))
2. (mental health[Title/Abstract]) AND ((employee assistance program[Title/Abstract]) OR (employer intervention[Title/Abstract]) OR (workplace intervention[Title/Abstract]))

The final set of literature records was identified based on a structured screening process; details are found in Figure 1. Backward and forward snowballing was then applied to reveal further relevant literature records. For snowballing, we allowed the inclusion of relevant records published outside the defined publication period used for the screening process. The overall identified literature was used to create the semistructured interview guide and the web-based questionnaire with its answer options (initial codes).

XSL•FO
RenderX

Figure 1. Overview of the scoping review process. The defined scoping review process included a systematic screening rationale according to the PRISMA-ScR (Preferred Reporting Items For Systematic Reviews And Meta-Analyses Extension for Scoping Reviews) guidelines, resulting in 25 literature records in the final review. MeSH: Medical Subject Headings.

Semistructured Exploratory Interview Study

The interview guide (Multimedia Appendix 2) was designed in an open-ended format to support the exploratory nature of the interviews and was structured along the defined RQs. The interview study aimed to identify the most relevant types of EMHPs, as well as all relevant facilitators and barriers from the employee perspective, to ensure that these were included in the web-based questionnaire. Results from the interviews were also used to illustrate relevant findings from the web-based survey, which, in turn, were interpreted in the context of the interview results. A purposive sampling approach was applied to obtain a representative participant sample of the observed population (employees of employers in Germany). The participants were recruited from the broader network of all authors and selected such that they were well distributed across the 5 demographic and company characteristics—age, gender, education, size of employer, and industry of employer. This ensured representativeness. All participants were informed in writing about the study's purpose and data privacy terms. Selected parts of the resulting interview transcripts were analyzed and used for another research study.

The interviews were conducted in German, either in person or via phone or video call software, during February and March 2023. The interviews were recorded and transcribed in a factually anonymized way so that no participant or company names were stated, and personal data were categorized, for example, into age groups [49]. The transcripts were used to conduct qualitative data analysis through 2 approaches. First, we applied the directed content analysis approach outlined by Hsieh and Shannon [50] to identify the most relevant dimensions of EMHPs, for example, medium or interaction form. Second, we applied the thematic analysis approach described by Braun and Clarke [51] to identify relevant facilitators of and barriers to using EMHPs and relevant mental disorders.

The coding process was structured along 2 iterative coding cycles, and the coding was conducted and reviewed independently by 2 coauthors using the software MAXQDA (VERBI Software Consult Sozialforschung. GmbH) [52]. For both approaches, during the first coding cycle, single words or phrases were either matched with one of the initial codes derived from the scoping review or were defined as a new code. During the second coding cycle, the assigned codes were reviewed and further consolidated or separated depending on the thematic fit. The directed content analysis approach allowed for the prioritization of the most relevant dimensions of EMHPs from the employee perspective based on the frequency of the respective codes, which were limited to 1 per participant to avoid skewed data resulting from participants referring several times to 1 single code.

The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist describes the details of the applied method (Multimedia Appendix 3).

XSL•FO
RenderX

Quantitative Web-Based Survey

Survey Design

The web-based questionnaire (Multimedia Appendix 4) was informed by the results of the qualitative interview study and designed in a closed-ended format. It was structured along the RQs with multiple- or single-choice questions and constructs based on established measures, assessed through 7-point Likert scales (except for mental health status). The questions and constructs represented predicting variables (PV), dependent variables (DV), or collected general information (GI).

Questions and Constructs

Demographic Characteristics (PV)

Data on age, gender, income, and education were collected through standard questions for such web-based surveys (categorical single-choice questions).

Digital Health Care Literacy (PV)

Participants rated their digital health care literacy using the Digital Health Care Literacy Scale by Nelson et al [53].

Mental Health Status (PV)

The current mental health status was assessed through a 3-item short form (Mental Health Inventory [MHI]; MHI-3) of the 5-item (MHI-5) measure [54]. To limit the overall number of questions, the MHI-3 was chosen for its brevity, while still being based on the well-established and widely used MHI-5 [55]. The items of the used MHI-3 were taken from a German version, and answers were collected through a 6-point Likert scale [56]. A mental health score was calculated and used to divide participants into 2 groups (positive or negative mental health status) based on a threshold defined by the scoring method of Rumpf et al [57]. Further, yes or no questions were asked to gain more detail on personal mental health status.

Relevance of Mental Health (GI)

The personal view on the relevance of mental health in society was assessed through a 1-item question. The mental disorders perceived as relevant among employees were assessed based on a multiple-choice question. The answer items were informed by literature and the interview study [58,59].

Company-Related and Profession-Related Characteristics (GI)

The number of employees, the industry of the employer, and the profession type were asked based on single-choice questions. Answer items were derived from established concepts and selectively adapted [60-62].

Company Culture (PV)

Data on company culture were collected through the German "Kurzskala zur Erfassung der Unternehmenskultur" (corporate culture scale, short form) by Jöns et al [63] using the 2 subscales leadership (5 items) and collaboration (4 items).

Intention to Use (DV)

Intention to use was measured as a DV for 9 different types of programs. The first 6 program types were derived from all combinations of the 2 dimensions of EMPHs: medium (digital and analog) and interaction form (self-intervention, bilateral intervention, and group intervention). The additional 3 program types were focused on the different addressed stages of mental health (prevention, treatment, and rehabilitation). All dimensions were clearly defined in the web-based questionnaire (Multimedia Appendix 4) to ensure a uniform understanding of all survey participants; for example, a program was defined as digital if it incorporated any form of digital technology, even if only a single component was digital. Intention to use was assessed with 1 item derived from the intention to use construct developed by Venkatesh et al [64].

Preference (DV)

To assess the unique preference for one of the first 6 programs, a single-choice question was asked.

Factors for Use (Facilitators and Barriers; DV)

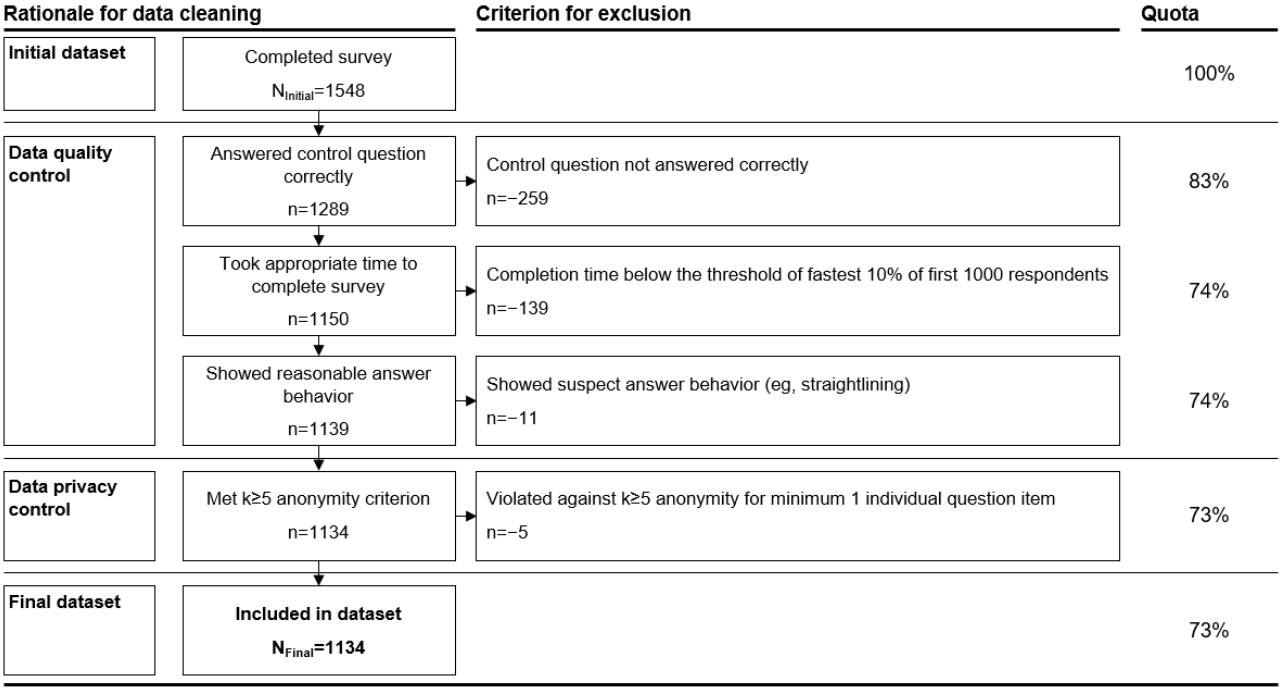
Factors supporting and discouraging the use of EMHPs were assessed through 2 separate multiple-choice questions, each including an "Other" option with a free-text field. The given answer items were based on the scoping review and the qualitative interview study. The latter ensured the comprehensiveness of the selection of relevant facilitators and barriers from an employee perspective.

Offered EMHP (GI)

Participants were asked whether their employers offered any EMHP in the last 12 months and, if so, what type (medium, interaction form, and the addressed stage of mental health) and whether it was used. If participants used the program, their satisfaction was assessed through the 2-item system satisfaction construct by Wixom and Todd [65].

A control question was asked in the middle of the survey to check for participants' attention.

Data Collection



The web-based survey was conducted in Germany in the German language in April and May 2023. A purposive sampling approach was applied to obtain a representative participant sample. Participant recruitment was conducted through a research panel provider that contacted registered panel participants from across Germany via email to invite them to participate in the study. As an inclusion criterion, participants needed to be employed by an employer in Germany for a minimum of 6 months to be able to talk about the mental health support at their current employer. Moreover, during open data collection, quotas were used to ensure a diverse sample with a representative distribution of the survey participants along the sociodemographic characteristics age, gender, and education. Official figures from the German Federal Statistics Office were used as reference values for the distributions to manage the quotas [66,67]. With this and the large sample size, it was ensured that the final sample was representative of the observed population of employees working for employers in Germany. Further details are provided according to the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist (Multimedia Appendix 5).

XSL•FO
RenderX

Descriptive and Inferential Statistical Analyses

After cleaning the survey data (Figure 2), multi-item constructs were tested for reliability using thresholds for Cronbach α based on the study by Blanz [68]. Subsequently, data were first analyzed using descriptive statistics. Second, data were analyzed using inferential statistical analyses. Chi-square tests were conducted to examine the relation between demographic characteristics and actual use of EMHPs and the relation between preference for specific EMHP types and perception of the relevance of influencing factors. Effect sizes were measured using phi (ϕ). Repeated measures ANOVAs were conducted to analyze the difference in intention to use different EMHPs of all participants (within-participants design) [69]. The Greenhouse-Geisser correction was applied when the assumption of sphericity was violated. The Bonferroni correction was applied for multiple comparisons. Effect sizes were measured using partial eta squared for the ANOVAs and Cohen *d* for the pairwise comparisons. One-way ANOVAs were conducted to identify differences in the means of the DV (intention to use) between different groups. Effect sizes of group differences were measured using Cohen *d*. Groups were formed based on relevant independent variables, such as demographics, mental health status (current or past), and company culture. Selected demographic variables were grouped into binary variables (eg, age into young vs old and education into nonacademic vs academic). Assuming interval scale level, the means of variables reported on Likert scales were calculated as arithmetic means [70]. The significance level was set at a *P* value of <.05. SPSS Statistics software (version 29.0; IBM Corp) was used for statistical analyses.

Figure 2. Overview of the data cleaning process. The defined data cleaning process included several data quality control steps and 1 data privacy control step to achieve the final dataset of 1134 participants. Suspect answer behavior means answers with strong patterns that might indicate careless responding, for example, straightlining.

Results

Scoping Review

Through the scoping review, 25 records relevant to the characterization of EMHPs and factors impacting use of such programs were identified (Figure 1). Furthermore, 12 records relevant to the research topic were added through snowballing (an overview of all records can be found in Multimedia Appendix 6 [3-6,10-16,18-21,23-25,28-46]). A total of 45 initial codes for the web-based survey questionnaire were identified, including initial codes for relevant mental disorders.

Semistructured Exploratory Interview Study

The final sample of the exploratory interview study comprised 15 participants. The interview study was concluded after reaching content saturation, which was indicated by recurring responses, confirmation of previously identified themes, and the absence of any new emerging themes [71]. The participants were well distributed across age groups, gender, education levels, industry, and company size (number of employees; Multimedia Appendix 7).

The qualitative interviews identified the most relevant dimensions of EMHPs from the employee perspective, including medium, interaction form, and the addressed stage of mental health. In total, 17 new codes were identified and added to the 45 initial codes derived from the scoping review. The most relevant facilitators mentioned by interview participants included employees needing to be aware of offered EMHPs and employers being willing to fully or partly pay for the offered program, each mentioned by 12 (80%) of the 15 participants. This was followed by the importance of support through culture and leadership, mentioned by 11 (73%) of the 15 participants. The most relevant barrier mentioned during the interviews was that using the EMPH would be too time-consuming, which

XSL•FO
RenderX

would again increase pressure on employees willing to use it, mentioned by 10 (67%) of the 15 participants. This was followed by data protection and privacy concerns, mentioned by 9 (60%) of the 15 participants. As additional thoughts on the topic, 8 (53%) of the 15 participants, when being asked at the end of the interview, stated that they think it was a very critical topic and that more awareness across employers and employees would be needed.

Quantitative Web-Based Survey

Data Sample

The final dataset of the web-based survey included 1134 responses after data cleaning (Figure 2). To the best of our knowledge, this represents the largest survey of employees in Germany in this research context and one of the largest globally.

As targeted by design, the final sample is representative of the German workforce across the relevant demographic characteristics age, gender, and educational degree [66,67], as well as distributed across the company-related characteristics number of employees, industry, and profession (Table 1).

XSL•FO
RenderX

Table 1. Distribution of responses in the final dataset across demographic and company-related characteristics (N=1134).

Variable	Participants, n (%)
Age (years)	
≤29	214 (18.87)
30-39	236 (20.81)
40-49	222 (19.58)
50-59	291 (25.66)
≥60	170 (14.99)
Prefer not to answer	1 (0.09)
Gender	
Woman	523 (46.12)
Man	611 (53.88)
Nonbinary	0 (0)
Prefer not to answer	0 (0)
Education	
None	0 (0)

Measured Constructs

The 4 established constructs used were statistically reliable and internally consistent (Multimedia Appendix 8 [53,54,63,65]) [68]. The company culture measure showed excellent reliability, with a Cronbach α of 0.94 (9 items). The Digital Health Care Literacy Scale showed good reliability (Cronbach α=0.84; 3 items). The MHI-3 showed acceptable reliability (Cronbach α=0.76; 3 items). The EMHP satisfaction construct showed questionable reliability (Cronbach α=0.68; 2 items); however, given that Cronbach α generally is profoundly affected by the number of items and this construct only consists of 2 items, it can still be accepted as reliable [72].

Characteristics of the Sample and GI

MHI-3 suggested that 42.24% (471/1115) of employees had a negative mental health status. Independent of this, 52.84% (585/1107) of employees stated that they had issues with their mental health in the past. In total, 28.61% (321/1122) of employees stated that they pursue activities related to mental health, for example, psychotherapy, meditation, and using a mental health app. The mental health issues perceived as most relevant among employees were burnout (747/1134, 65.87% of participants), depression (717/1134, 63.23%), sleep disorders (704/1134, 62.08%), concentration issues (538/1134, 47.44%), and substance abuse or addiction (344/1134, 30.34%). Overall, employees rated the relevance of mental health in society as high (average score of 5.58, SD 1.56 on a 7-point Likert scale with 7=very relevant; median score of 6, IQR 5-7; 702/1134, 61.9% stated that mental health was “relevant” or “very relevant”).

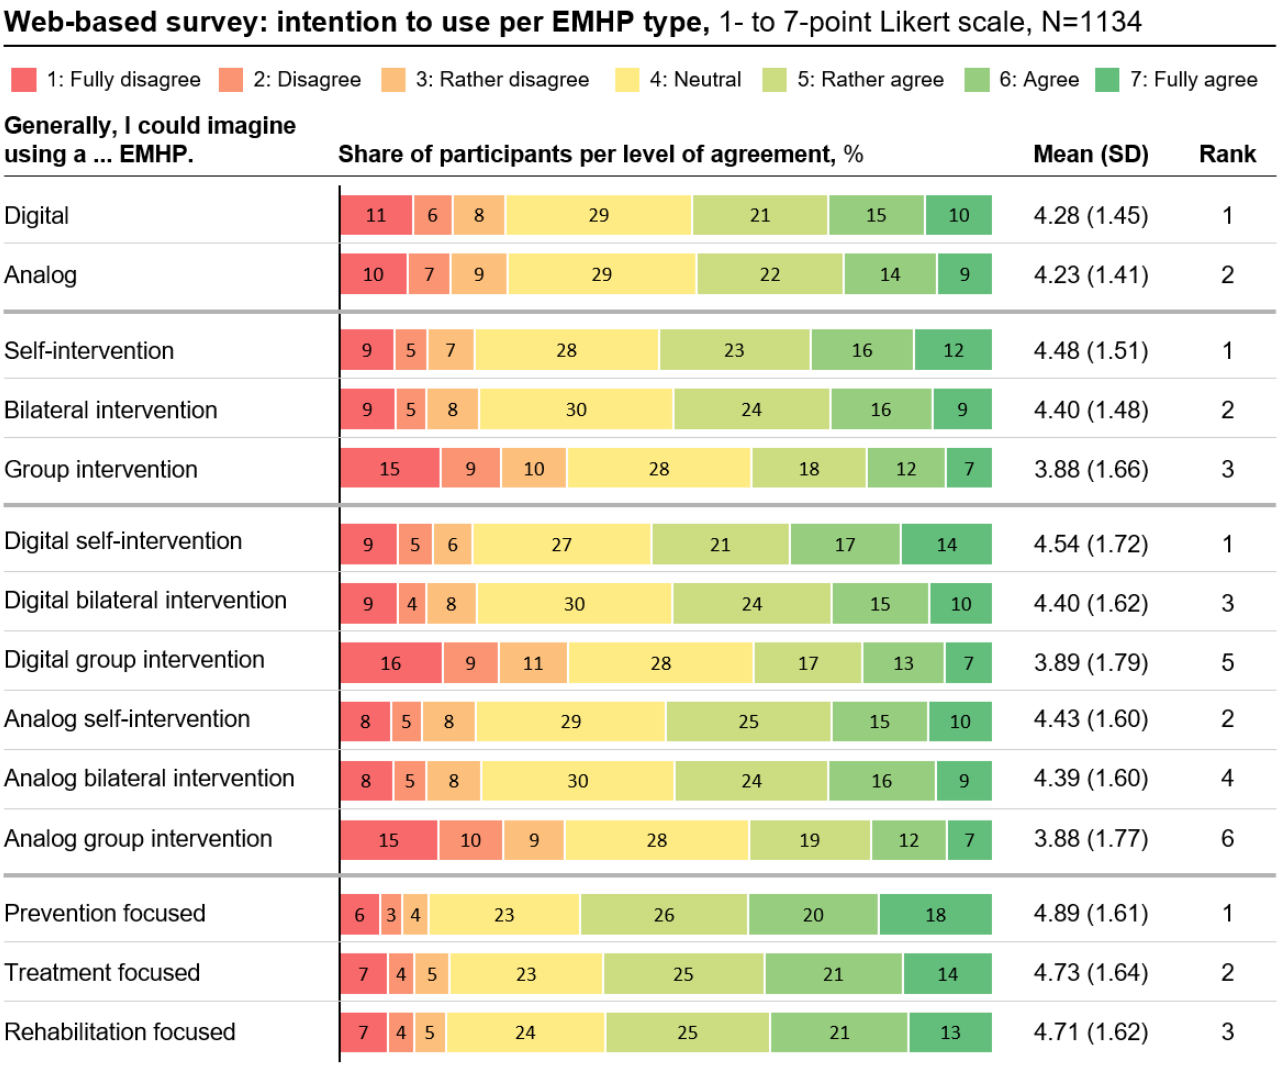
Availability of EMHPs

Overall, 20.37% (231/1134) of participants mentioned that their employers offered at least 1 EMHP. Large companies were more likely to offer a program (117/435, 26.9% vs 30/298, 10.1% at smaller companies). Of the offered EMHPs, 65.8% (152/231) were digitally enabled, while 31.6% (73/231) were analog (6/231, 2.6% of participants did not know). Programs were equally distributed across interaction forms, with 33.3% (77/231) of them being self-intervention, 32% (74/231) bilateral intervention, and 28.6% (66/231) group intervention (14/231, 6.1% did not know). In total, 60.2% (139/231) of the offered EMHPs focused on prevention, 23.4% (54/231) on treatment, and 10% (23/231) on rehabilitation (15/231, 6.5% did not know; Multimedia Appendix 9).

Actual Use of EMHPs

In total, 54.8% (126/230) of employees with an EMHP available through their employer stated that they use it or have used it during the last 12 months. The use rate was higher when digital EMHPs were offered compared to when analog EMHPs were offered (digital: 94/152, 61.8%; analog: 32/72, 44.4%; P=.001; ϕ=0.24; Multimedia Appendix 10). Younger employees (<50 years) had a higher use rate compared to older ones (≥50 years; young: 107/174, 61.5%; old: 19/56, 34%; P<.001; ϕ=0.24; Multimedia Appendix 11). Employees with an academic degree (Bachelor’s, Master’s, or Doctor or PhD degree) had a higher use rate compared to employees without an academic degree (academic degree: 93/139, 66.9%; no academic degree: 33/91, 36%; P<.001; ϕ=0.30; Multimedia Appendix 12). Employees who used offered EMHPs stated a generally high satisfaction with the used program (average satisfaction score of 5.6, SD 1.2 on a 7-point Likert scale; median score of 6.0, IQR 5.0-6.5; 70/126, 55.6% of employees reported a score of ≥6), while there is no significant difference in satisfaction of employees using digital versus analog programs.

Preferred EMHPs



When stating their unique preference, 58.73% (666/1134) of employees stated their preference for digitally enabled EMHPs and 52.03% (590/1134) for self-intervention EMHPs. The most preferred EMHP combination of medium and interaction form was the digital self-intervention program (371/1134, 32.72% of participants), followed by the analog self-intervention program (219/1134, 19.31%) and the digital bilateral intervention program (152/1134, 13.4%), which represents part 1 of RQ1.

XSL•FO
RenderX

Intention to Use EMHPs

Overall, there was medium intention to use EMHPs, with an average of 4.43 on a 7-point Likert scale (median 4.56, IQR 3.89-5.22). However, the SD was high, with an SD of 1.30 (variance 1.68). On average, 50.88% (577/1134) of participants indicated a positive intention to use an EMHP (average score of >4.5 on a 7-point Likert scale), while 31.57% (358/1134) were neutral (average score of >3.5 and <4.5). Regarding part 2 of RQ1, there was no significant difference between the overall intention to use digital and analog programs when they were available. However, intention to use was significantly higher for self-intervention programs and bilateral intervention programs (self: mean 4.48, SD 1.51; bilateral: mean 4.40, SD 1.48) compared to group intervention programs (group: mean 3.88, SD 1.66; P<.001 each; Cohen d=0.40 and Cohen d=0.39, respectively). The difference in intention to use between self-intervention and bilateral intervention programs was also significant (P=.03; Cohen d=0.08). Considering both dimensions, medium and interaction form, intention to use was highest for a digital self-intervention program (digital self-intervention: mean 4.54, SD 1.72; 593/1134, 52.29% of participants indicated a positive intention to use, ie, a score of ≥5). Intention to use for EMHPs focusing on prevention was significantly higher than that for EMHPs focusing on treatment (prevention: mean 4.89, SD 1.61; treatment: mean 4.73, SD 1.64; P<.001; Cohen d=0.13) and that for EMHPs focusing on rehabilitation (rehabilitation: mean 4.71, SD 1.62; P<.001; Cohen d=0.14). Refer to Figure 3 for an overview of the intention-to-use results (details of all repeated measures ANOVAs can be found in Multimedia Appendix 13).

Figure 3. Results of the web-based survey on intention to use per employee mental health program (EMHP) type. Intention to use was assessed by asking the concrete intention to use on a 7-point Likert scale for the 6 EMHP types resulting from the combination of the dimensions medium (ie, digital and analog) and interaction form (ie, self-intervention, bilateral intervention, and group intervention), as well as for the 3 EMHP types based on the addressed stage of mental health (ie, prevention, treatment, and rehabilitation). The reported intention to use each EMHP type by medium and interaction form was calculated by aggregating the intention-to-use data for the 6 combined EMHP types.

Predictors for the Use of EMHPs

Addressing RQ2, it was found that intention to use was higher for younger employees (young: mean 4.59, SD 1.2; old: mean 4.19, SD 1.4; P<.001; Cohen d=0.32). No significant difference in overall intention to use nor regarding digital or analog EMHPs could be observed between women and men. However, women showed a higher intention to use self-intervention programs

XSL•FO
RenderX

(women: mean 4.61, SD 1.49; men: mean 4.38, SD 1.52; P=.008; Cohen d=0.16) as well as prevention and treatment programs (prevention: $mean_{women}$ 5.06, SD 1.51 and $mean_{men}$ 4.74, SD 1.68; treatment: $mean_{women}$ 4.90, SD 1.58 and $mean_{men}$ 4.57, SD 1.68; P<.001 each; Cohen d=0.20 each). Intention to use was higher for employees who held academic degrees (Bachelor's, Master's, or Doctor or PhD degree; academic degree: mean 4.68, SD 1.24; no academic degree: mean 4.26, SD 1.32; P<.001; Cohen d=0.32). Given that digital health care literacy was high across the whole sample (average digital health care literacy score of 6.03, SD 1.18 on a 7-point Likert scale; median score of 6.33, IQR 5.33-7.00; 774/1134, 68.25% of employees reported a score of ≥6), further analyses did not reveal additional insights. Intention to use was higher for employees who had faced mental health issues in the past (mental health issues in the past: mean 4.64, SD 1.14; no mental health issues in the past: mean 4.22, SD 1.41; P<.001; Cohen d=0.32) and for employees with a negative self-assessed mental health status according to MHI-3 (positive mental health status: mean 4.31, SD 1.33; negative mental health status: mean 4.56, SD 1.21; P=.002; Cohen d=−0.19). Employees who perceived their company culture as positive reported a higher intention to use EMHPs (positive company culture: mean 4.61, SD 1.27; negative company culture: mean 3.99, SD 1.27; P<.001; Cohen d=0.49; details of all ANOVAs can be found in Multimedia Appendix 14).

Facilitators of and Barriers to the Use of EMHPs

The most relevant factor for employees impacting the use of EMHPs is whether the employer paid for the program (345/1134, 30.42%). This top facilitator was significantly more relevant for employees who preferred analog EMHPs (160/468, 34.19%) versus those who preferred digital EMHPs (185/666, 27.78%; P=.02; ϕ=−0.07). In line with this, employers not paying for the EMHP was the number 1 barrier (433/1134, 38.18%). Ease of use was the second most relevant facilitator (337/1134, 29.72%), with no difference between employees preferring digital or analog EMHPs. Content quality was another important facilitator if given (259/1134, 22.84%) and an even more relevant barrier if not given (301/1134, 26.54%). The top 5 facilitators and barriers are shown in Table 2, representing RQ3 (details of all chi-square tests can be found in Multimedia Appendix 15).

Table 2. Top 5 facilitators of and barriers to using employee mental health programs (EMHPs) by total participants and differences by preference for medium (N=1134).

	Total participants[a] (N=1134), n (%)	Participants preferring digital EMHPs[b] (n=666), n (%)	Participants preferring analog EMHPs[b] (n=468), n (%)	P value[c]
Top 5 facilitators				
1. EMHP is paid for by the employer	345 (30.42)	185 (27.78)	160 (34.19)	.02
2. EMHP is easy to use	337 (29.72)	198 (29.73)	139 (29.7)	.99
3. EMHP with trustworthy data protection	282 (24.87)	168 (25.23)	114 (24.36)	.74
4. EMHP with easy access	265 (23.37)	153 (22.97)	112 (23.93)	.71
5. EMHP with high content quality	259 (22.84)	164 (24.62)	95 (20.3)	.09
Top 5 barriers				
1. EMHP requires full payment or copayment by the employee	433 (38.18)	250 (37.54)	183 (39.1)	.59
2. EMHP requires too much time	326 (28.75)	202 (30.33)	124 (26.5)	.16
3. EMHP with low content quality	301 (26.54)	173 (25.98)	128 (27.35)	.61
4. Employees feel forced to use EMHP	294 (25.93)	154 (23.12)	140 (29.91)	.01
5. EMHP is too complicated or requires too much effort	265 (23.37)	152 (22.82)	113 (24.15)	.60

Discussion

Principal Findings

Generalizability of Findings

This study analyzed the deployment and use of EMHPs at companies across industries; the preference and intention to use of employees for different EMHPs, including relevant predictors; as well as facilitators and barriers. The representative and exceptionally large sample of the German working population allows for generalization of the findings. Generalizability is enhanced through the fact that no specific sociodemographic subgroup but a broad representative sample of the observed population across several sociodemographic characteristics was investigated. The representative distribution of education levels in the sample further ensured that no employees from a specific socioeconomic status group were underrepresented. The findings of the study are not only generalizable to Germany but may also be transferable to other countries, particularly industrialized nations where mental health

XSL•FO
RenderX

challenges are comparable and employer-employee relationships tend to be similarly structured. Given that a relevant share of participants' employers in this study were large organizations, many of these were likely to operate in several countries across the globe, where the general organizational culture and relationship between employer and employees can be expected to be similar. Moreover, the research on EMHPs generally focuses on the role of the employer as a provider of or at least an access point for mental health services. Therefore, this research is less dependent on the respective health system of a specific country but rather on universal predictors and factors of the relationship between employers and employees. To generate further insights into the transferability of the findings, this survey can be replicated in other industrialized countries by future research.

Prevalence and Actual Use of EMHPs

The fact that employees need support due to increasing mental health issues [16,28,31] is supported by our results, which illuminate the prevalence of past issues and current negative mental health status. While only a fifth of employees have access to EMHPs, more than half of these employees use them. This use rate seems to be high compared to numbers from other studies, indicating use rates for very specific psychotherapeutic consultation services and general EAPs of 1% up to 10% [73] or 39% when looking at intended use [44]. Hence, use rates seem to vary depending on the concrete EMHP. Given that the results of other studies focus on EAPs or consultation services for primarily existing issues, the overall use rates for all EMHPs, including prevention, are expected to be higher, as indicated by our results. Further studies should focus on measured use rates for different types of EMHPs, including prevention-focused programs.

Preferred EMHPs

The found preference for digital programs (666/1134, 58.73% of participants) and for self-intervention programs (590/1134, 52.03%) when choosing one preferred EMHP is in line with the desire for time- and location-wise flexibility and for anonymous use concerning colleagues [24,41]. While patients with existing mental health issues realize the potential advantages of digital programs [74], prior research has found that they prefer face-to-face mental health interventions or hybrid models that include face-to-face contact, presumably due to higher perceived effectiveness [74-76]. However, these studies focused on interventions treating existing mental health issues, for which many do not think that digital programs can replace traditional in-person psychotherapy adequately [77-79]. Furthermore, these studies did not explicitly focus on EMHPs in the work context but on the general population. Given that our study focuses on EMHPs that often also cover prevention purposes [24], the findings do not contradict each other. Instead, they indicate that preference for an intervention involving a mental health professional is higher when facing concrete, particularly severe issues, which was supported by our qualitative interviews:

> *I believe, if my mental state is seriously endangered, then I need a personal conversation, personal support. But if my mental state is somehow not good but not severely bad, then I can imagine using an app for myself, which can help me to feel better.* [Participant 9]

> *For prevention, tips for exercises, general information, or apps, etc, are very important. When there is a concrete need for treatment, then a one-on-one is the best option, with a psychotherapist.* [Participant 7]

However, digital and self-intervention programs are well suited for prevention purposes, especially in the workplace context [44], and digital EMHPs can even be as effective as nondigital ones regarding positive mental health outcomes [30]. A recent study confirms a strong preference for both types of EMHPs, digital self-intervention programs and programs delivered face-to-face [80]. While we acknowledge that preference for a certain EMHP type does not necessarily mean that these preferred EMHPs have higher effectiveness in obtaining the desired outcome, the intrinsic interest to use a specific EMHP is a relevant factor to start using such a program. As digital and nondigital EMHPs can have significant positive mental health effects, starting to use such a program is the most relevant first step, and consequently, the preference should be considered. The importance of intrinsic motivation and fun for starting to use an EMHP was also mentioned during our qualitative interviews:

> *Ideally, using it means fun. The people need a motivation to use it.* [Participant 9]

> *It is an important factor that the UX design is nice and that it is fun.* [Participant 11]

> *It needs to have an entertaining value; something needs to happen. Otherwise, you don't get the people to do it.* [Participant 13]

Intention to Use EMHPs

Overall, we found a medium intention to use EMHPs. However, the detailed results show a strong distribution, indicating opposing views on such programs. One part has a high intention to use both digital and analog EMHPs, while another part is very reluctant. Individuals with a high intention to use EMHPs may be influenced by the increasing awareness of mental health through more research and more coverage in mainstream media, which is also driven by celebrities raising awareness [81,82]. In contrast, other individuals neglect the need, as well as their eligibility, for such programs and for dealing with mental health more openly in general, partly driven by stigmatization, which could explain participants with low intention to use [28,83-85].

Predictors for Use of EMHPs

In line with previous research, intention to use differs substantially by several demographic and personal characteristics [44,45].

Age

Younger individuals tend to be more open toward EMHPs. This may be due to higher awareness and a more open mindset of younger generations toward mental illness, which is found in prior research [42,86]. Conversely, other research suggests that older age is a predictor of help-seeking behavior [87,88]. This

XSL•FO
RenderX

calls out for further research about differences in age concerning awareness and behavior regarding mental health support. Our findings support that younger generations are more open toward the topic and are more likely to use digital programs.

Gender

In contrast to other identified predictors that align with previous research, in this study, we found no evidence for differences in overall intention to use between women and men. However, when looking at specific EMHP types, women showed a higher intention to use programs focused on prevention and on treatment. This suggests that women might have a higher intention to use when presented with the concrete objective of the EMHP. The higher preference of women for self-intervention programs resonates with the findings of Smail-Crevier et al [44], who found that women have a significantly higher preference for self-help interactive programs than men. Further studies focusing on specific EMHPs with clearly defined dimensions, for example, interaction form, are needed to assess differences in preference by gender and gain deeper and solid insights.

Education

Intention to use is also found to be higher for individuals with higher formal education, which is in line with what has been suggested by prior research [45]. This might be explained by higher awareness and understanding of the challenge of mental health issues for individuals and society.

Previous Mental Health Issues

We found that individuals who indicate having had mental health issues in the past show a higher intention to use EMHPs. This suggests that awareness, primarily through lived experience with some mental health issues, increases the likelihood of seeking help and using offered support. Previous research has also found that positive experience with help seeking in the past increases the likelihood of seeking help again [87], which might also be the case for participants of our study, explaining the measured effect.

Mental Health Status

Furthermore, we found that the intention to use is higher for people who have a negative self-reported mental health status. Overall, this seems evident, as the need to use an EMHP is plausibly higher for these individuals than for people with good mental health. However, existing literature offers contrary findings regarding the effect of existing mental health issues on using support services. Some research suggests that when mental health issues reach a certain level of severity, individuals may experience reduced motivation and effort to engage with programs or seek treatment [79]. This effect is especially observable in people dealing with depression [41]. Other studies, in contrast, indicate that support is rather sought when issues already affect social functioning [87,89]. Hence, the severity of a present mental disorder plays a significant role in the resulting use of support services such as EMHPs. Therefore, further research could focus on the intention to use EMHPs based on the severity of mental health issues.

Company Culture

Another predictor of intention to use found in this study is the company culture. Individuals indicating a positive company culture at their workplace have a significantly higher intention to use EMHPs. This finding resonates with existing research on the importance of company culture and the positive effect of supportive leaders [5,13,46]. Notably, company culture emerged as the strongest predictor of intention to use EMHPs in this study, surpassing the effects of both age and education. The authenticity of the employer toward the offered program and the high relevance of the company culture were also mentioned by participants during the qualitative interviews:

> *It is important to feel that the employer means it, that it is a truly honest offer.* [Participant 1]
>
> *I want to have the feeling that this is not a one-time initiative to boost the image. I want to see the true intention of the employer, shown by continuous actions.* [Participant 11]
>
> *I need to have trust that I do not have to fear any negative consequences when I use it.* [Participant 9]
>
> *It is important that you have an environment where people do not judge, where colleagues say, "It is alright to use it, there is nothing condemnable with it."* [Participant 3]

Facilitators of and Barriers to the Use of EMHPs

Having the EMHP paid by the employer is the most relevant facilitator and represents the largest barrier if this is not the case. The reason that cost coverage is an even more important factor for employees preferring analog EMHPs might be that analog programs are usually more expensive than digital ones [25]. While the cost coverage factor is not explicitly mentioned in existing studies on facilitators and barriers, research suggests that it is in the nature of EMHPs to be offered to employees for free or at least at a low cost [42]. A potential expectation attitude of German citizens particularly might stem from the fact that they are used to reimbursed health care services, including psychotherapeutic treatment [76] and apps (specific digital health apps called DiGAs in Germany) [90]. In line with this, the qualitative interviews indicated that if the employer offers a program, employees expect financial support as a basic condition:

> *It needs to be paid by the employer, at least the largest share.* [Participant 10]
>
> *If it costs me personal money, this is a huge barrier.* [Participant 3]
>
> *If it needs to be paid fully or even partially by the employee, there is no more willingness to use it.* [Participant 5]

Further relevant factors are ease of use, easy access, use that should not require too much time, and quality of the content. Hence, convenience, that is, being able to integrate use into everyday life, and the quality of EMHPs are essential for employees, as is indicated by previous studies [14,24,41,91] and our qualitative interviews:

XSL•FO
RenderX

> *Use has to be simple and clearly explained.* [Participant 7]
>
> *Access to the program should be easy.* [Participant 3]
>
> *The time effort should be reasonable. I would like to have it easily integrated into my daily routines.* [Participant 1]
>
> *It not only has to have good content, it also has to be easily understandable and interesting.* [Participant 14]

Employers should ensure these criteria are met to increase the likelihood of use and enhance the impact of EMHPs. They should also consider digital EMHPs, which are generally more cost-efficient, easier to scale, and more flexible than nondigital programs [25].

Limitations

Despite high research standards, this study has some limitations. First, given that quantitative data collection was based on a web-based survey, it is likely that the results overrepresent digitally literate participants [92]. Therefore, participants might have been more prone to using digital EMHPs [93]. However, only a web-based survey of this nature can provide such a large sample representative across several demographic characteristics.

Second, for simplicity, the medium of EMHPs was categorized into a binary set with digital and analog EMHPs, whereas in reality, hybrid forms are available. Despite the existence of hybrid forms, the chosen definition was appropriate for the scope and objectives of our research, and the definitions were clearly presented in the web-based survey.

Third, the survey results relied on self-report measures and question items and the participants' chosen options, which may have led to some skewness in the data. For instance, participants might have indicated their intended and not their actual use behavior when asked, a phenomenon commonly referred to as the intention-behavior gap [94]. In addition, results on the available EMHPs were based on the participants' perspectives and not necessarily on the factual availability of the EMHPs offered by their employers.

Conclusions

Our study contributes to a deeper scientific understanding of employees' perspectives on different EMHPs, including preference, intention to use, predictors for use, and facilitators and barriers. This deeper understanding is relevant for academia and occupational practice. On the basis of our research, academia can drive further scientific studies and findings. Employers who are willing to actively contribute to the mental health of their employees can leverage our findings to choose and facilitate EMHPs, while providers can leverage these findings to create relevant EMHPs that match the employees' needs.

The 3 main implications of the study indicate simple but meaningful actions for employers worldwide. First, because a relevant portion of employees use EMHPs when available and most report satisfaction with them, it is a strong starting point to consider offering an EMHP. Initially, the type of EMHP is not of utmost importance. While starting with digital self-intervention programs focused on prevention may lead to greater acceptance and adoption, given overall preferences, employees generally appear to value the simple availability of any EMHP. Hence, offering any EMHP should potentially create a positive impact. Naturally, the more targeted and tailored the EMHP is, the higher the probability of positive effects. However ultimately, the most important step is to start offering an EMHP.

Second, employers can steer one of the most relevant factors predicting the use of EMHPs—the company culture. This predictor has significant impact on use across all EMHP types. Therefore, employers are advised to create an authentic strategy and communication on offering EMHPs and genuinely support the opportunity to use an EMHP. Conversely, offering an EMHP while having a negative company culture with demotivating communication, leadership, and teamwork styles will likely have no relevant positive effect.

Third, employers should ensure that employees seeking support or willing to act preventatively do not have to pay to use an offered EMHP. Furthermore, they should provide EMHPs that are easy to use, easy to access, and of good quality, as these are the key facilitators of use. Thus, employers should consider offering digital EMHPs, which typically address several of these relevant factors.

Authors' Contributions

BS and LF contributed to the conceptualization, design, and methodology of the study. RH, MZ, and SM contributed to the methodology of the study. BS conducted the scoping review; screened the identified literature records; planned, prepared, and conducted the qualitative interviews; transcribed and analyzed the interview transcripts; planned, prepared, and conducted the quantitative web-based survey; and cleaned and analyzed the data of the web-based survey. RH reviewed the interview guide and the web-based questionnaire, analyzed the interview transcripts, and reviewed the statistical analyses. BS prepared the first draft of the manuscript. All authors reviewed the manuscript. BS edited the manuscript and prepared the final version. All authors approved the final version of the manuscript. LF supervised the research project.

Abstract

Background: Mobile health (mHealth), defined as health care facilitated by mobile devices, offers a promising strategy for enhancing disease management and treatment for patients with chronic conditions. However, there is limited information about how patients with inflammatory bowel disease (IBD) use mHealth and their digital preferences.

Objective: The aim of the study was to investigate the use of mHealth as well as the preferences, obstacles, and eHealth literacy reported by patients with IBD in Germany.

Methods: In April and May 2023, we sequentially enrolled patients diagnosed with IBD, including Crohn disease and ulcerative colitis, to participate in a paper-based survey. The survey included questions on sociodemographic details, health characteristics, mHealth use, internet use, eHealth literacy (measured with the eHealth Literacy Scale), and preferences regarding communication and information.

Results: Of the 200 surveyed participants, almost all (197/200, 98.5%) reported regular smartphone use, and more than two-thirds (139/200, 69.5%) indicated regular engagement with social media. Most of the respondents (168/200, 84%) expressed the belief that incorporating medical apps into their routine could positively impact their health. However, only 25 (12.5%) of the 200 patients acknowledged using medical apps, of which just 2 apps were IBD specific, used by only a few (n=3, 12%). Furthermore, awareness of useful websites or mobile apps tailored for IBD was limited (45/200, 22.5%). Nearly all participants (196/200, 98%) expressed willingness to share app data for research purposes, and most (171/200, 85.5%) consented to transmit app data to their treating physicians. A large majority (175/200, 87.5%) indicated readiness to regularly input data into an app, with a preferred duration of up to 5 minutes (109/200, 54.5%) and weekly input frequency (76/200, 38%). For an IBD-specific app, the most frequently requested functions were electronic prescriptions (110/200, 55%) and a newsletter about new scientific work and clinical studies (94/200, 47%). Usability and security were identified as key app attributes. The internet was the predominant source of health-related information (180/200, 90%). The average eHealth literacy score, measured with the eHealth Literacy Scale, was high (mean 28.9, SD 5.4; range 8-40), with a positive correlation observed between higher eHealth literacy and factors such as younger age and more frequent internet use for health information.

Conclusions: Patients with IBD are well prepared and motivated to use mHealth technologies to better understand their chronic condition and optimize treatment. However, their enthusiasm is tempered by the currently low adoption of mHealth. To fully harness the potential of mHealth in IBD treatment, effective and tailored mHealth solutions, guidance for their implementation, and patient education are needed.

KEYWORDS

eHealth Literacy Scale; mHealth; mobile apps; inflammatory bowel disease; Crohn disease; ulcerative colitis

Introduction

Background

Inflammatory bowel diseases (IBDs), including Crohn disease and ulcerative colitis, are complex, chronic conditions with multifaceted pathogenesis [1,2]. Patients typically require lifelong treatment from a multidisciplinary specialist team, including gastroenterologists, surgeons, rheumatologists, dermatologists, and radiologists [3]. This care includes, apart from regular medical appointments, immunosuppressive pharmacotherapy to maintain remission and prevent relapses [4], which can pose challenges for patients' treatment adherence [5]. The complexity of IBD not only incurs high health care costs [2] but also makes it difficult for patients to understand their illness and manage daily demands, such as monitoring symptoms, implementing appropriate nutrition, and planning activities [6]. Consequently, IBD represents both a substantial economic burden and a patient-level challenge, underscoring the need for modern disease management strategies [3,7].

In today's world, the use of digital media such as computers, smartphones, tablets, the internet, and mobile apps is ubiquitous and plays an important role in the daily lives of many people. One area increasingly affected by these technologies is health. The internet serves as a gigantic source of information, making health information widely accessible; fitness trackers enable individuals to record and document personal health parameters; and digital services such as email allow patients to communicate with health care providers. Consequently, digital technologies are increasingly incorporated into routine health care [8-10]. The concept of mobile health (mHealth), defined by the World Health Organization as "medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices" [11], is a promising approach for managing various chronic diseases, including rheumatoid arthritis [12], diabetes mellitus [13], hypertension [14], and chronic heart failure [15]; for example, electronic medication reminders can improve treatment adherence [16,17], and supportive digital therapy can reduce pain [17] and improve key comorbidities (eg, depression) [18]. In the context of IBD, mHealth has the potential to take disease management to a new level, including improving patients' quality of life and reducing health costs [19]. However, access to mHealth solutions remains extremely limited for patients with chronic IBD [20].

Objectives

The perspectives of patients with IBD on mHealth solutions remain largely unexplored. To effectively incorporate various mHealth solutions into clinical practice, it is essential to understand patients' limitations and needs. This study aimed to examine the use of mHealth solutions as well as the preferences, obstacles, and eHealth literacy reported by patients with chronic IBD in Germany.

Methods

Paper-Based Survey

In April and May 2023, consecutive patients treated at the outpatient clinic for chronic IBD at the University Hospital Erlangen were invited to complete a paper-based survey. This format was intentionally chosen to minimize selection bias by enabling participation regardless of digital literacy or device access.

To create the survey (Multimedia Appendix 1), a broad literature review was performed. Previous mHealth patient surveys in rheumatology served as a starting point [21]. The survey comprised four main sections: (1) sociodemographic and health characteristics, (2) preferences and use of mHealth, (3) eHealth literacy, and (4) communication and information preferences. Foreign terms and explanations of technical terms were provided in footnotes. Inclusion criteria were as follows: patients had to (1) be aged ≥18 years, (2) be proficient in the German language, (3) be physically and mentally capable of completing a structured questionnaire, and (4) have a confirmed diagnosis of either Crohn disease or ulcerative colitis.

The sociodemographic and health characteristics included age, sex, place of residence, educational qualification, diagnosis, duration of illness, patients' global self-assessment of disease activity, and current use of electronic devices (smartphones, tablets, and activity trackers) and social media.

The section on preferences and use of mHealth contained questions about the use of medical apps in general, knowledge and use of IBD-specific apps, and the preferred duration and frequency of actively using an IBD-specific app. Patients were asked to evaluate their preferences for app features on a 5-point Likert scale and the importance of app characteristics on a 10-point Likert scale. In addition, patients' willingness to share recorded app data and overall perceptions of the benefits of medical apps were investigated.

Furthermore, information was gathered on internet use and the perceived utility of the internet regarding health decisions, as well as on web-based services to enhance patient health and on telemedicine, with a focus on patients' digital interaction preferences.

Measurement of the patients' eHealth literacy was carried out using the validated German version [22] of the eHealth Literacy Scale (eHEALS) [23]. This tool has been translated and validated in multiple languages [23-28] and enables systematic capture of differences in eHealth literacy levels. It consists of 8 statements regarding eHealth literacy that are rated on a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree"), yielding a total score ranging from 8 to 40.

Using ranking lists (unique rankings were required), patients indicated their preferences regarding medication reminders, the format of medical information, the design of digitally provided

XSL•FO
RenderX

information, the type of patient diary, and the mode of physician communication.

Statistical Analysis

The examined characteristics were summarized using counts, percentages, means, and SDs. To investigate relationships between continuous variables, Pearson correlation was used. The relationship between the eHEALS score and the frequency of internet use was investigated using the Jonckheere-Terpstra test, with eHEALS score as the continuous dependent variable and internet use frequency as the ordinal independent variable. Relationships between the eHEALS score and binary preferences were examined using logistic regression. The applied statistical tests were carefully selected according to the measurement scales and distributional characteristics of the collected data. All models included adjustments for age and sex. Two-tailed *P* values <.05 were considered statistically significant. Microsoft Excel and SPSS (version 28.0; IBM Corp) were used for data processing and analysis.

Ethical Considerations

This study received approval from the ethics committee of Friedrich-Alexander University Erlangen-Nürnberg (23-63-B) and was conducted in accordance with good clinical practice. Before inclusion in the study, all participating patients provided informed consent for participation, pseudonymized data storage, and processing of the collected data. All participant's data were collected, stored, and analyzed in accordance with applicable privacy regulations. Personal information was pseudonymized, and confidentiality was strictly maintained throughout the study. Participating patients did not receive any form of financial or other compensation for their involvement in the study.

Results

Patient Characteristics

A total of 220 patients were recruited for the study. For the final data analysis, only complete surveys from patients who met all inclusion criteria (200/220, 91%) were considered. The number of patients who declined participation was not recorded. The sociodemographic data of the study sample are presented in Table 1. The mean age was 39.1 (SD 14.0) years, with 49% (98/200) of the patients aged between 18 and 35 years. Sex distribution was nearly balanced. Regarding the use of electronic devices and social media, almost all patients regularly used a smartphone (197/200, 98.5%), more than half (108/200, 54%) regularly used a tablet, nearly one-third (64/200, 32%) used an activity tracker, and more than two-thirds (139/200, 69.5%) regularly used social media.

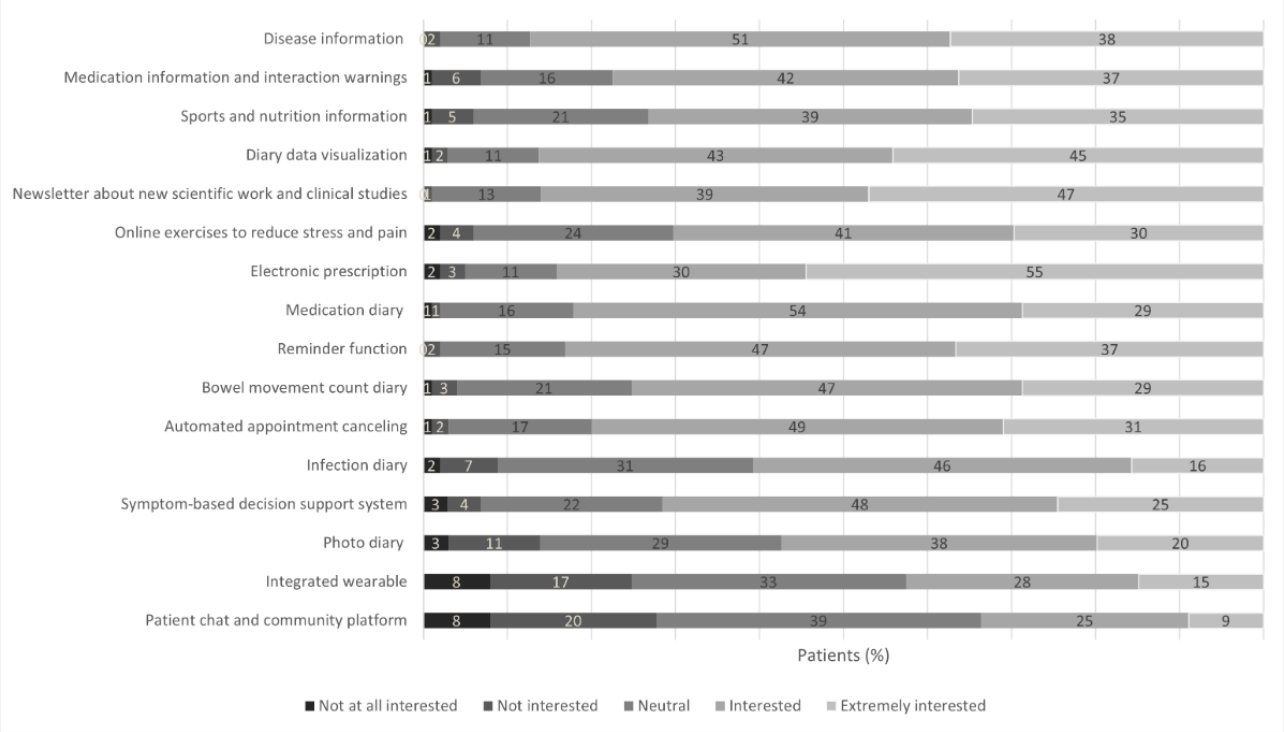
Tablet	108 (54)
Activity tracker	64 (32)
Social media	139 (69.5)
Medical apps	25 (12.5)

mHealth: Use, Knowledge, and Acceptance of Medical Apps and Willingness to Provide mHealth Data

A set of questions assessed patients' preferences and attitudes toward potential mHealth apps and the sharing of health data. An overview of the collected data is shown in Multimedia Appendix 2. Regarding app use, only a small proportion of patients (25/200, 12.5%) reported currently using medical apps. Among these, only 2 apps were IBD specific: CED-Forum (2/25, 8%) and an unnamed IBD app (1/25, 4%). Patients' knowledge of useful IBD-specific digital services (websites and apps) was generally low (45/200, 22.5%). Notwithstanding these findings, more than three-fourths of the patients (168/200, 84%) believed that using medical apps could be beneficial for their health. The potential association between eHEALS scores and the likelihood of expressing the belief that apps are beneficial was investigated using logistic regression adjusted for age and sex. It turned out that our model, using the eHEALS score as predictor, fit poorly, as indicated by the very low explained variance (Nagelkerke R^2=0.09), suggesting that eHEALS scores alone account for little of the variation in patients' perceptions of app benefits.



Almost all patients (196/200, 98%) indicated willingness to transmit app data for scientific research, on condition that data security was guaranteed. Similarly, most of the patients (171/200, 85.5%) agreed to share app data with their physician. Among those who did not agree (29/200, 14.5%), the main reason was the perception that personal contact with their physician was sufficient (17/29, 59%). Other reasons included concerns about not knowing where their data would be stored

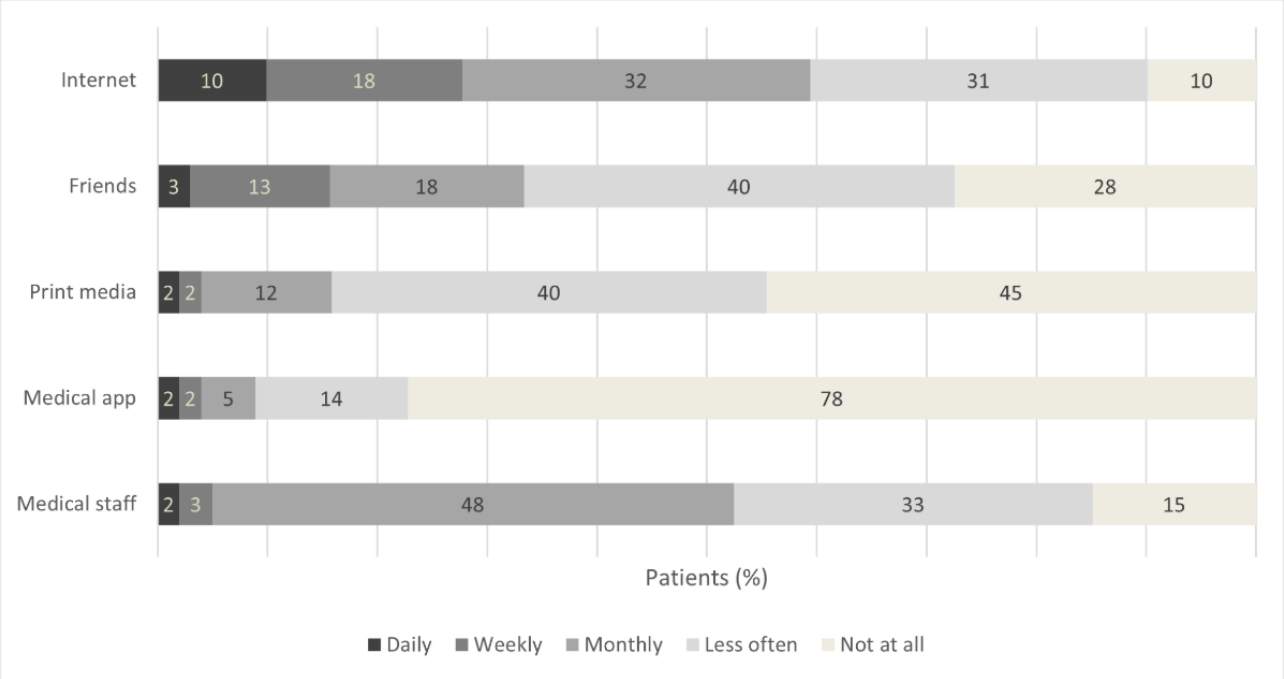
XSL•FO
RenderX

(12/29, 41%), unclear use of the data (11/29, 38%), and insecure data transmission (9/29, 31%). Whereas the majority of patients (188/200, 94%) wished to be notified if an app detected irregularities regarding their health, interest in comparing medication adherence with other patients was low (57/200, 28.5%).

A large proportion of the participants (175/200, 87.5%) were willing to actively input data into an IBD-specific app. Among all patients, weekly data entry was preferred by 38% (76/200), with a duration of 1 to 5 minutes (109/200, 54.5%). When asked to evaluate key attributes of an app on a 10-point Likert scale, patients rated usability (mean 9.0, SD 1.4) and security (mean 8.4, SD 2.6) as the most important (Multimedia Appendix 2). Regarding preferred app features, patients were most interested in electronic prescriptions and a newsletter about new scientific work and clinical studies. By contrast, patients were least interested in direct peer exchanges, such as chats, or integrated wearables (Figure 1).

Figure 1. Patients' app function preferences (responses to "What app functions would you like?").

Internet Use, Perceived Benefit, and Digital Interaction



Another important aspect of our study was to obtain knowledge about patients' internet use, especially regarding health-related information. Almost all patients (193/200, 96.5%) stated that they had used the internet to seek health information, whereas only a small proportion (7/200, 3.5%) had not (Multimedia Appendix 3). The reasons for not seeking health information on the internet included perceiving their physician's information as sufficient (4/7, 57%), considering internet searches unhelpful (3/7, 43%), and other reasons (1/7, 14%). The types of health information patients sought on the internet are illustrated in Table 2. Most patients searched for information about treatment options (165/193, 85.5%) and symptoms (164/193, 85%), whereas information on support groups was least frequently sought (85/193, 44%). Regarding the frequency of internet use for obtaining health information, the most common response was "less often than monthly" (79/200, 39.5%). Comparing the use of different health information sources during the past 3 months (Figure 2), the internet was the most frequently used source (180/200, 90%), with 10% (20/200) using it daily, 17.5% (35/200) weekly, 31.5% (63/200) monthly, and 31% (62/200) less often. More than half of the patients (116/200, 58%) had previously used online support groups to read information (113/200, 56.5%), chat with other patients (17/200, 8.5%), or post information (11/200, 5.5%). Participation in an online health program was infrequent (9/200, 4.5%), and knowledge about the medication website of the German competence network for IBDs was not widespread (29/200, 14.5%).

XSL•FO
RenderX

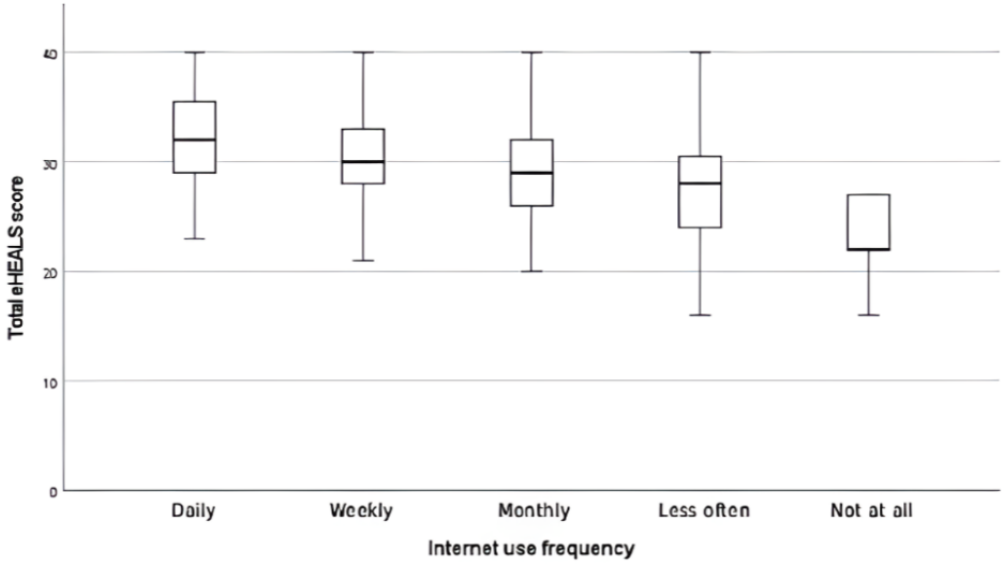
Table 2. Health information previously sought on the internet (n=193; responses to "What health information did you look for on the internet?").

Health information	Patients, n (%)
Treatment options	165 (85.5)
Symptoms	164 (85)
Medication	158 (82)
Diagnosis	144 (75)
Physicians	142 (74)
Disease-specific websites	93 (48)
Support groups	85 (44)
Other	4 (2)

Figure 2. Use of different health information sources (responses to "How often did you use one of the following options to receive health information in the last three months?").

Regarding the perceived benefit of using the internet to make health-related decisions, results were ambiguous with approximately the same number of patients being unsure (81/200, 40.5%) and recognizing the internet as useful (79/200, 39.5%; Multimedia Appendix 3).

Another aspect investigated was patients' digital interaction with their treating physician. Slightly more than half of the patients (105/200, 52.5%) reported having previously communicated with a physician via email. In addition, 71% (142/200) of the patients indicated that they would appreciate the option to communicate with their gastroenterologist via video call. The majority of the patients (159/200, 79.5%) favored electronically filling out medical questionnaires before their appointments, and more than two-thirds (137/200, 68.5%) preferred receiving an electronic medical report rather than a paper report.



eHealth Literacy

eHealth literacy, as defined by Norman and Skinner [23] is "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem." Therefore, eHealth literacy is an important dimension to record patients' handling of digitally provided health information. The mean eHealth literacy score of our patients, measured using the eHEALS tool, was 28.9 (SD 5.4; range 8-40). Male patients had a mean score of 29.0, and female patients had a mean score of 28.3, resulting in a mean difference of 0.7; this difference was not statistically significant (P=.35), as verified by an unpaired, 2-tailed t test (95% CI −0.74 to 2.07). By contrast, age was found to correlate negatively (r=−0.2, 95% CI −0.35 to −0.04) with the eHEALS score. An overview of the distribution of responses to the 8 eHEALS items is provided in Multimedia Appendix 4. The majority of patients agreed or strongly agreed that they know how to use the internet to answer health-related questions (152/200, 76%) and have the skills to evaluate the health resources found on the internet (160/200, 80%); however, concerns were raised regarding the knowledge of available health resources on the internet (41/200, 20.5), and approximately one-third of the patients (69/200, 34.5%)

XSL•FO
RenderX

expressed discomfort about using information from the internet to make health-related decisions. Lower eHEALS scores were found to be associated with a declining frequency of internet use (Figure 3). A Jonckheere-Terpstra test showed a statistically significant trend between lower eHEALS scores and decreasing internet use frequency (T_{JT}=4861.5, z=−4.958; P<.001).

Figure 3. Association of eHealth Literacy Scale (eHEALS) score and frequency of internet use.

Preferences in Communication

Almost all patients (198/200, 99%) wished for the opportunity to raise queries about complaints and treatment between routine medical visits. Preferred methods of contacting the treating gastroenterologist were telephone (81/200, 40.5%), email (61/200, 30.5%), and chat (56/200, 28%; Multimedia Appendix 5). Reminders for regular medication intake were requested frequently (172/200, 86%), with the favored mode being via an app (117/200, 58.5%). The vast majority of patients (196/200, 98%) wished to receive medical information, preferably through an app (92/200, 46%), followed by paper (62/200, 31%) and websites (42/200, 21%). If medical information was provided digitally, patients ranked simple text and images (172/200, 86%) over features based on exchanging information with other patients (20/200, 10%) and game-based learning (8/200, 4%). Acceptance of using a patient diary was high (176/200, 88%), with documentation preference being greatest for an app, followed by paper, and lowest for a website (Multimedia Appendix 5).

Discussion

Principal Findings and Comparison With Prior Work

To the best of our knowledge, this study is the first to provide an in-depth perspective on German patients' views of mHealth solutions in gastroenterology, specifically in the context of IBD. Our findings emphasize that patients with IBD are interested in mHealth technologies and are willing and motivated to use them. For this intention to be realized, two factors are crucial: the availability of the necessary technical requirements, which was found to be remarkably high in our sample, with almost all patients (197/200, 98.5%) regularly using a smartphone and more than half (108/200, 54%) regularly using a tablet; and the possession of digital skills. On the basis of participants' internet use behavior and eHealth literacy levels, it can be assumed that patients with IBD possess these skills. Nearly all patients (193/200, 96.5%) reported using the internet for health matters, underscoring its role as a critical source of health information. Patients in our study demonstrated the ability to find, evaluate, and use such information, as reflected by a mean eHEALS score of 28.9 (SD 5.4; range 8-40). This score indicates high eHealth literacy, considering that a previous study defined a cutoff for high eHealth literacy at ≥26 [29]. Numerous studies in various fields [21,29-33] have examined possible correlations between the dimensions of eHealth literacy and patient characteristics and behaviors. In our study of patients with IBD, younger age was associated with higher eHealth literacy, whereas no effect of sex was observed. Consistent with prior studies [21,29,30,33], lower eHealth literacy was associated with declining internet use frequency. Interestingly, belief in the usefulness of medical apps did not seem to depend on eHealth literacy levels but was overall high, highlighting patients' widespread confidence in the potential of mHealth.

To fully realize this potential, most patients were willing to participate actively by inputting personal health data into IBD-specific apps, sharing them with their treating physicians, and providing them for research purposes. Such active participation ensures electronic data collection of a high standard, both in terms of quality and quantity, which can be of considerable benefit to patients and physicians alike. Prior studies [34-36] have also highlighted the usefulness of patient-generated health data. In addition, patients with IBD expressed clear preferences for digital interaction with their treating physicians, including consultations via video calls, filling out questionnaires online before appointments, and receiving electronic medical reports. These preferences could contribute to improved care by optimizing treatment processes. Despite the overall high enthusiasm for mHealth among patients with IBD, some preferred personal contact with their physician, as reflected by the highest preference for telephone calls for

XSL•FO
RenderX

communication rather than eHealth services. Therefore, offering flexible communication options tailored to patient preferences is important. Furthermore, some of the patients (29/200, 14.5%) expressed reluctance to share data with their treating physicians due to concerns about security and transparency. These concerns must be taken seriously. The responsibility to guarantee data security lies with the various stakeholders involved and is critical not only to avoid undermining patients' confidence in mHealth solutions but also to strengthen it. Further investigation into which specific data security features would make patients feel safe and strengthen their confidence is crucial. In addition, clear communication about data protection measures and transparent handling of data are essential to foster patient trust and encourage wider mHealth adoption.

mHealth apps have the potential to serve as powerful tools and are therefore of particular interest for research. As noted, patients' belief in the usefulness of medical apps was remarkably high, and they were willing to actively use IBD-specific apps by inputting data for up to 5 minutes on a weekly basis. Desired features for an IBD-specific app differed, but preferences were primarily for those that deliver information, such as a newsletter about new scientific work and clinical studies, as well as electronic prescriptions. By contrast, interest in direct peer exchanges and integrated wearables was low, which is partially consistent with prior findings among patients with gastroenterological diseases [37]. Mobile apps can improve treatment adherence [38,39], and, in our study, patients with IBD expressed interest in features such as medication reminders and an app-based patient diary. Usability and security were also identified as key features of an IBD-specific app. Patient perspectives therefore provide valuable guidance for app design. Particular attention should be given to ensuring an intuitive user experience through simple, user-friendly design. App features should be customizable because preferences differ; however, features such as comprehensible information (eg, through simple text and images), electronic prescriptions, medication reminders, and patient diaries seem to be broadly desirable. In addition, the app should minimize demands on data input and guarantee data security so that patients feel safe using it. In line with previous recommendations [20,40,41], involving patients in the app development process is important, as it can enhance acceptance and use [41].

Despite the enormous interest and readiness of patients with IBD, current use of mHealth solutions remains relatively low. Only 12.5% (25/200) of the patients in our study reported using medical apps, of which just 2 were IBD specific (used by 3/25, 12%). Limited availability of IBD-specific apps, as noted in a previous study by our group [20], and the generally low knowledge of IBD-specific digital services likely represent two important factors contributing to the gap between patient interest and actual adoption. Further factors, such as usability concerns and skepticism regarding effectiveness, as reported in studies from other fields [42,43], require investigation in future research. Overall, the high discrepancy points to the need to develop effective mHealth solutions, supported by guidance and recommendations from gastroenterological specialists and societies regarding suitable and reliable sources and services and supported by qualitative patient education to build confidence in using these services, consistent with prior suggestions [42,44]. However, several challenges must be addressed; for example, strict regulations in Germany under the Digital Health Care Act ("Digitale-Versorgungs-Gesetz"), which classify prescribable health apps as medical devices and impose stringent data security demands [45], pose obstacles to the development and implementation of mHealth services. Nevertheless, translating these needs into practice to align with the interest and readiness of patients with IBD is going to be a crucial task and will require collaboration among all stakeholders to enable the implementation of reliable mHealth programs and apps in routine IBD care, thereby fully realizing the potential of mHealth.

Limitations

The main limitations of this study include its cross-sectional design, which does not allow conclusions regarding the evaluation of patients' digital engagement behaviors over time; reliance on self-reported data, which may be influenced by social desirability bias, potentially leading patients to overestimate their digital competencies or willingness to use mHealth tools; and a relatively small, circumscribed sample (outpatients from a single tertiary care center). Moreover, the relatively young mean age (39.1, SD 14.0 y) of the sample may influence findings, as older patients could exhibit different digital health behaviors and face distinct barriers to mHealth adoption. In addition, the number and characteristics of patients who declined participation were not recorded, limiting the assessment of potential selection bias. Therefore, the generalizability of the results may be compromised, as factors such as actual mHealth use could vary from what participants reported.

Conclusions

To the best of our knowledge, this study is the first to comprehensively explore perspectives on mHealth among German patients with IBD. The insights gained have the potential to significantly influence and shape the development and integration of IBD apps. A vast majority of participants not only believed in the possible health benefits of using medical apps but were also motivated and willing to use mHealth technologies and even participate actively by inputting personal health data into apps and sharing them with physicians and researchers. Furthermore, fundamental requirements for successful mHealth use were largely met, as almost all patients regularly used smartphones and demonstrated considerable digital skills, as indicated by a high level of eHealth literacy. Despite these favorable conditions, current use of mHealth among patients with IBD remains limited, likely due to limited availability and awareness of existing apps, usability concerns, lack of perceived necessity, and skepticism about app effectiveness. To close this gap, it is crucial to develop effective mHealth solutions, supported by guidance and recommendations from gastroenterological specialists and societies regarding suitable and reliable sources and services, along with qualitative education on mHealth use. The unmet needs and patient priorities highlighted in this study provide direction for expediting the incorporation of mHealth into standard IBD care.

Abstract

Background: The use of artificial intelligence (AI) methods in palliative care research is increasing. Most AI palliative care research involves the use of routinely collected data from electronic health records; however, there are few data on the views of palliative care health care professionals on the role of AI in practice. Determining the opinions of palliative care health care professionals on the potential uses of AI in palliative care will be useful for policymakers and practitioners to determine and inform the meaningful use of AI in palliative care practice.

Objective: This study aimed to explore the views of palliative care health care professionals on the use of AI for the analysis of patient data in palliative care.

Methods: This was a phenomenological study using qualitative semistructured interviews with palliative care health care professionals with a minimum of 1 year of clinical experience in a hospice in the North West of England. Data were analyzed using inductive thematic analysis.

Results: We interviewed 6 palliative care professionals, including physicians, nurses, and occupational therapists. AI was viewed positively, although most participants had not used it in practice. None of the participants had received training in AI and stated that education in AI would be beneficial. Participants described the potential benefits of AI in palliative care, including the identification of people requiring palliative care interventions and the evaluation of patient experiences. Participants highlighted security and ethical concerns regarding AI related to data governance, efficacy, patient confidentiality, and consent issues.

Conclusions: This study highlights the importance of staff perceptions of AI in palliative care. Our findings support the role of AI in enhancing care, addressing educational needs, and tackling trust, ethics, and governance issues. This study lays the groundwork for guidelines on AI implementation, urging further research on the methodological, ethical, and practical aspects of AI in palliative care.

Introduction

Background

Artificial intelligence (AI) is the science and engineering of creating "intelligent" machines (computers) through developed algorithms that replicate the ability of a machine to think and act like a human [1]. AI involves different methodologies (eg, machine learning, neural networks, deep learning, and natural language processing) that enable a machine to be trained to act autonomously, with or without human instruction [2]. AI has already demonstrated a significant impact in practice by facilitating the interpretation and analysis of large amounts of data contained within electronic health care datasets [3-5]. In health care, AI can facilitate the diagnosis of diseases, support clinical care delivery, and help individuals maintain their independence [6]. AI is increasingly used in palliative care (a discipline that provides holistic, person-centered support for people with life-limiting illness [7]). For example, AI-driven data analysis of electronic health records has been used to identify palliative care needs [8], support clinical documentation [9], identify quality indicators for end-of-life care [10], support symptom assessments [11], and estimate prognosis [12]. Despite the increased focus on palliative care AI, most current clinical AI tools are designed for nonpalliative care populations [8]. The lack of palliative care AI tools is a consequence of limited evidence in populations with serious illness, who often experience complex physical and psychosocial needs [13]. Palliative patients often experience significant morbidity, complex and multifaceted symptoms, and a high risk of mortality, whereas their families face grief and bereavement that extend beyond the patient's death [13]. These unique dimensions of care introduce ethical, practical, and emotional considerations for AI, which are not as prominent in other medical and surgical specialties [14]. For example, the use of AI in prognostication may be more important in palliative care, where sensitive communication about life expectancy directly shapes care planning and emotional preparedness [12,15]. Similarly, the handling of data after death (ie, digital legacy and the rights of caregivers and families) raises questions that are less relevant in acute or curative clinical contexts [16]. Despite the growing body of research on AI in medicine, there is currently limited evidence that addresses these specific complexities within palliative care, which highlights the need for targeted research in this field [17]. Consequently, understanding the views of palliative care practitioners on AI is important to better understand the opportunities, challenges, and implementation issues associated with its use [18]. Therefore, a dedicated study of palliative health care professionals' perspectives on AI is warranted to explore the specific issues affecting this cohort [17,19].

Aim

This study aimed to explore palliative care professionals' views on the use of AI for the analysis of patient data in palliative care.

Methods

Overview

This study involved inductive thematic analysis, a method of analyzing qualitative data in which themes emerge directly from the data without predefined codes or expectations. Inductive thematic analysis was chosen as it provided the researcher with the flexibility to explore participants' perspectives on AI in palliative care [20]. The lead researcher (OA) was a final-year medical student (male) who was supervised by SM and ACN. OA received training and support to conduct the interviews. The study adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [21].

Study Setting

The study was conducted in a hospice in the North West of England, a specialized health care facility providing care for individuals in the advanced stages of a terminal illness or approaching the end of their lives. The hospice provides various services, including a 15-bed inpatient unit, day services, outpatient clinics, community outreach, patient and family support, and bereavement services.

Sampling and Recruitment

Recruitment was conducted between April and May 2022. The study was introduced at a weekly hospice education meeting, giving potential participants the opportunity to ask questions and express their interest in participating. Study advertisements were placed around the hospice, and an email was sent to all staff outlining the inclusion and exclusion criteria for the study. The study material included information about the researcher (OA). Inclusion criteria were palliative care health care professionals working in the hospice with a minimum of 1-year of clinical experience during the study data collection period of April to May 2022.

Data Collection

Over a period of 2 months, semistructured interviews were carried out with palliative care health care professionals. Participants received written information before the interview and provided written consent. Interviews were conducted face-to-face in a meeting room at the hospice. All the interviews were audio recorded using a digital voice recorder. The interviews lasted between 35 and 60 minutes, and the participants were informed that they could pause or discontinue the interview at any time. Each interview began with the researcher providing the participants with background information about the study and a definition of AI. The researcher conducted interviews using an interview guide, which was used to encourage structure across interviews but also facilitated flexibility by allowing participants to talk freely about their experiences (Multimedia Appendix 1). Open questions were used, and the interview schedule was adapted throughout the course of data collection to reflect the emergent themes and concepts (Textbox 1). Field notes and reflections were written throughout the interview process to help make sense of the data during the analysis phase.

XSL•FO
RenderX

Textbox 1. Examples of the interview questions.

- What is your experience with artificial intelligence (AI) currently used within palliative care, if any?
- What do you see as the desired goal or outcome of using AI within palliative care?
- Have you ever been educated on the use of AI within palliative care?
- What are your views on introducing education programs for palliative care health care professionals on the use of AI within palliative care?
- AI in palliative care, like any new health care technology, may raise several safety concerns. Do you have any such concerns?
- AI in palliative care, like any new health care technology, may raise several security concerns. Do you have any such concerns?
- What are some important metrics that should be used when comparing AI tools to traditional tools in palliative care?
- Can you identify a task at work which you currently perform repeatedly, with little or no variations each time?
- What level of trust would you need to allow AI tools to perform this task for you?
- What are some ways this level of trust can be established?
- Is there anything else you'd like to tell me about this topic? If not, do you have any questions?

Interviews were transcribed verbatim by OA. Data were exported to Microsoft Word, and manual thematic analysis coding was used to systematically label the qualitative data extracts to identify patterns and themes. OA used the 6-step thematic analysis proposed by Braun and Clarke [22], which involves (1) familiarization with the data, (2) generation of initial codes, (3) development of initial themes, (4) reviewing themes, (5) defining and naming themes, and (6) writing up the analysis. We used inductive analysis, with line-by-line coding of participants' interviews, to generate codes and organize the data into themes (Multimedia Appendix 2). Coding was carried out by OA. During the data collection phase, OA had regular supervisory meetings (with ACN and SM) to review data analysis, discuss initial findings, and evaluate data throughout the analysis process.

Six individuals contacted OA to consent to participate. None of the participants withdrew from the study. Interviews were analyzed iteratively. By the fourth interview, all key major themes (eg, "general openness toward AI" and "importance of human contact, empathy, and sympathy") were identified. Additional interviews reinforced, rather than expanded upon, these categories. For example, the theme of "confidentiality concerns" emerged in the first interview and was reiterated consistently in interviews 2 to 6 without new subcategories. This redundancy indicated that thematic saturation had been reached with the sample. We determined that further interviews were unlikely to provide new codes, categories, or insights relevant to the research question. Therefore, a consensus was reached to stop data collection on completion of 6 interviews (ie, to stop recruitment of further participants) as the theoretical categories became saturated [23,24].

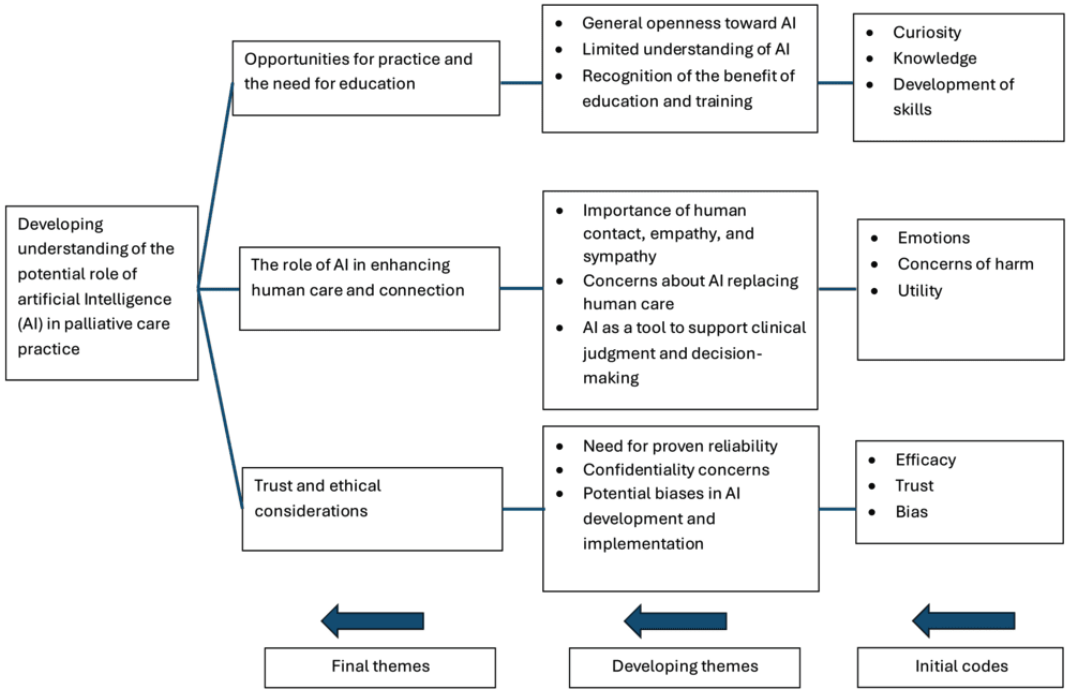
Ethics Statement

The University of Liverpool ethics committee gave ethics approval for this work (reference number 8523). This study was approved by the hospice research governance group. All participants provided written informed consent to participate in this study. All participants were informed of their right to privacy and confidentiality. All participants were informed that their data would be anonymized and that no identifying information would be included in any works related to this study. No compensation was given to participants for participating in the study.

Results

Overview

We interviewed 6 palliative health care professionals, including 1 (17%) nurse, 2 (33%) occupational therapists, and 3 (50%) physicians. A total of 4 (67%) participants were female, and 2 (33%) were male. All interviews were conducted face-to-face and in person (Table 1).



Three themes were developed from the data: (1) opportunities for practice and the need for education, (2) enhancing human care and connection, and (3) trust and ethical considerations (Figure 1).

Figure 1. Thematic map showing the 3 main themes. AI: artificial intelligence.

Opportunities for Practice and the Need for Education

Participants highlighted their openness to consider using AI in palliative care practice. Specifically, participants described their views on how this technology could improve care delivery and efficiency for their patients. Participants spoke of how algorithm-driven health care is increasingly being used in other clinical specialties and how, similarly, AI can be used to improve palliative care:

> *I mean, I think obviously the future is, is going that way, isn't it? You know, artificial intelligence is being developed at all areas.* [Participant 3]

Participants described the lack of AI use in palliative care compared to other medical and surgical specialties:

> *I suppose it's kind of an alien concept, isn't it? I think in terms of technology that we use day-to-day at the moment, we're kind of behind the curve, I would say in, in the NHS [National Health Service], and certainly in this environment. So, I think it's difficult to kind of visualise what that would be like in kind of day-to-day practice.* [Participant 6]

Participants spoke about how AI can potentially improve palliative care. The interviewees provided several examples of possible benefits, such as machine learning–based analyses of electronic health records to identify people needing palliative care, to improve data capture and analysis, and to inform personalized care recommendations:

> *I guess, you know, looking through the hospital records in the hospital. When I see a new patient, I'm manually looking back through the notes to try to find if they've had previous encounters with the palliative care team, how many times they've been in hospital, looking for all the medications to work out what*

XSL•FO
RenderX

> *medications they're on and if any have been stopped.* [Participant 3]
>
> *A good thing would be if something could analyse the entire database every day and say, "look, these are the patients who are flagging up, particularly symptomatic," or "are using lots of PRN [as required] medicines" or, you know, [if] certain keywords trigger [an] urgent review?* [Participant 4]

Participants highlighted that palliative care staff have a limited understanding of the different types of AI applications that may be used in clinical care. Participants expanded on this by describing how better staff education may improve their confidence in using AI in clinical practice:

> *I think for healthcare professionals, like for me, who've maybe not come across so much, or don't understand it so much, it's more about knowing about it, and understanding how we can help use it a bit better.* [Participant 1]
>
> *I think that's only a positive thing. And, I think, to introduce education to help people understand even the basics of what AI is is really important, because I think until we know more about what it is and understand more about what it is, we can't think of the ways in which we can improve care for the patient.* [Participant 1]

Enhancing Human Care and Connection

Participants emphasized the importance of human contact, empathy, and sympathy in palliative care, expressing concerns about AI potentially replacing human care. This was illustrated by the comments of 1 participant:

> *I think in palliative care, you know, our strength is based on human connections.... I don't mean to be like negative towards, kind of, AI technology and stuff, but I think, actually, you know, the majority of my day, when I'm speaking to patients, it's about human connection.* [Participant 6]

Participants identified how AI systems could be potentially designed and modeled to dynamically learn from health care professionals and service users, with the objective to develop algorithms that are meaningful in helping them provide clinical care:

> *I think it should be modelled as if, you know, the algorithm behind it is trying to learn, and it's asking you for confirmation. You know, so it's saying, "this is what I've found," you know, and you then have to decide whether this is useful, or "can you confirm this is correct?", or something like that. It should be this kind of back and forth.* [Participant 4]

Participants described the potential that palliative care health care professionals can routinely use data, informed by AI, to support care and their clinical decision-making (eg, analysis of electronic health record data to identify patients with palliative care needs, automated transcription of consultations, and personalized treatment recommendations). Consequently, the interviewees discussed scenarios in which AI was used to improve and augment the clinical care provided by palliative care professionals. Participants said that AI could be used as a tool to support clinical judgment and decision-making while maintaining a patient-centered approach:

> *I guess if you use the program alongside, like, have a step-by-step approach, so you could use the program or the intelligence alongside, you know, a human in kind of partnership. And then gradually, you just have to learn that trust and become more used to it.* [Participant 2]

Trust and Ethical Considerations

Participants highlighted the importance of health care professionals being confident that AI-driven clinical tools are trustworthy and reliable. The interviewees framed their opinions on the trustworthiness of AI in the context of their clinical responsibility of providing care for people with serious illness (who are often considered vulnerable). Several quotes from the participants illustrated the important role of research in generating evidence to inform meaningful AI use in clinical care:

> *It'd be track record and experience, wouldn't it? So, you probably would want to have enough evidence to show that it made good decisions.* [Participant 5]

Participants stated that confidentiality was important, with several statements highlighting their concerns regarding data privacy and the security implications of using AI in clinical practice. They emphasized the importance of ensuring that patients' data remain secure and protected when using AI to inform clinical decision-making in palliative care:

> *I suppose, privacy and data is the main concern as quite often it is in health care, isn't it? And you know, making sure that data is secure and, you know, things like hacking aren't an issue and people can't access patients' and relatives' private data easily.* [Participant 1]
>
> *I think with any new technology to have to make sure it's secure... And, you know, privacy concerns and breaches of confidentiality- So I think all those things are really important.* [Participant 6]

Participants discussed the risk of bias associated with AI analysis, which could create (and widen existing) inequalities in palliative care. In the interviews, the participants discussed the importance of developing strategies to reduce this risk of bias in AI algorithms and to explore public opinion about the role of AI in clinical practice. Participants described their belief that if AI should be used to improve holistic care for patients and those important to them. Further comments from the interviews highlighted the opinion that the use of AI in palliative care should be inclusive, unbiased, and ethical:

> *If our algorithms have been driven by developers in Silicon Valley in California and most of them are white, male and young, and the modelling has been tested on a particular set of individuals, which don't have certain characteristics, which mean that certain people are not represented, you then might get a*

XSL•FO
RenderX

device or an algorithm which isn't tailored for the needs of certain people. [Participant 4]

General Comments of Participants

Overall, AI was viewed positively by many participants, although many stated that they had not used it in practice. None of the participants had received training in AI, and all stated that they would have liked to have received education on this topic. Participants described their opinions on how data science can improve clinical care; potential ideas included the use of AI to identify people from electronic health records who need palliative care and to use data analytics to evaluate quality of care. Participants highlighted data privacy and ethical issues related to AI use in palliative care, including important related issues such as governance, confidentiality, and consent.

Discussion

Concerning the use of AI in palliative care, it is important to consider the opportunities it offers, the educational needs of staff, the importance of human connections, and practical issues related to trust and ethics.

Importance and Uniqueness of This Paper

This study provides an overview of the views of specialist palliative care health care professionals regarding AI in palliative care, which adds knowledge to the limited evidence base. Our qualitative approach facilitated an in-depth exploration of participants' experiences, which captured their nuances and complexities. The evidence derived from this study improves knowledge about the views palliative care staff have about AI, which will shape its clinical use. Evidence demonstrates that improved staff involvement can improve the effectiveness and success of health care system interventions [25,26].

Relation to Previous Work in This Area

In this study, the staff positively described potential opportunities in which AI could be used to support palliative care, with themes consistent with previous work conducted with generalist staff [27]. In our study, staff identified several hypothetical possibilities where AI could be positively used to improve their practice (eg, predictive modeling, text screening, symptom assessment, and communication), which are consistent with current developments of AI in palliative care [28].

Our findings align with previous research, which recommends that health care professionals receive formal education and training in AI [17,29]. Specifically, previous research advises palliative care education programs to include holistic overviews of AI technologies, ethical considerations, and case studies that highlight the real-world applications and challenges of AI in palliative care [30].

Our findings support previous work, which describes the importance of focusing on human connections in palliative care while ensuring that AI tools are meaningfully used to improve the experience of patients, caregivers, and staff [27]. Consistent with previous research, we highlight the potential problems and bias that may occur from using AI in palliative care, due to limited evidence of patient-centered outcomes measures in palliative care populations [14]. In our analysis, participants described the ethical challenges of using AI in palliative care (reporting themes of promoting transparency and accountability in AI systems, regular ethical review and continuous impact assessments, ensuring patient autonomy and informed consent, and safeguarding data privacy and security) [30]. The ethical themes reported in our study are similar to those in previous research [30,31], illustrating the need to incorporate ethical principles (such as the 4 principles) into decisions involving AI use in palliative care practice [32]. For example, autonomy (Do service users have a choice of how their data are collected, analyzed, and stored?), beneficence (Is AI used in the best interests of individuals or is the benefit mostly for groups, populations, or other stakeholders?), nonmaleficence (How can we ensure people are not harmed from AI in palliative care?), and justice (How can AI tools be used fairly and equitably, in vulnerable people, from different backgrounds, cultures, and geographies?) [33]. Furthermore, our results support the importance of integrating broader ethical theories into practice (eg, consequentialism, deontology, rights-based ethics, and virtue ethics) to provide clinicians and policymakers with a framework to make decisions on how to use emerging technologies in clinical practice [34]. These frameworks can be used to address uncertainty to help stakeholders' (eg, health care professionals, managers, and policymakers) decision-making when considering how to responsibly use AI tools in palliative care [13]. Consistent with previous work, our findings reinforce the view that there is a risk that current AI applications lack engagement with the ethical complexities of real-world use in palliative care, which highlights questions about the adequacy of clinical practice safeguards [15,30].

Limitations

This study is small, focused on one hospice in the North West of England, which means that the findings may not be generalizable to other palliative care settings (eg, home, community, hospital, and nursing homes). Although thematic saturation was achieved with 6 participants, this may have been influenced by the similarities of the participants. We acknowledge that a larger sample incorporating staff from a wider range of roles and professional backgrounds may have yielded more in-depth and diverse data. For example, this study lacks representation of some professional roles (eg, social work, spiritual care, pharmacy, and fundraising), which means there is a lack of data about how AI may impact wider specialist roles in the palliative care multidisciplinary team. Furthermore, our study did not include the perspectives of patients, caregivers, and other relevant stakeholders.

Importance to Policy, Practice, and Research

Decision-makers should consider the perspectives of palliative care staff when developing and implementing AI tools for palliative care. When considering applications of palliative care AI, decision-makers should consider how these innovations will improve care, address human needs, and fulfill ethical and governance requirements. From an educational perspective, it is important that palliative care professionals are trained to safely and effectively use new technologies (eg, AI) in clinical practice. Activities to achieve this objective may include the development of training curricula for undergraduate and

XSL•FO
RenderX

postgraduate students, including content on the opportunities and challenges of AI in health care, ethical considerations of its use, and governance issues [30,35].

Future research on palliative care AI should establish standardized reporting for studies, seek external validation, and consider ethical issues, which are needed to ensure that the clinical application of AI tools is safe, meaningful, and effective [15]. Future research should explore views (on palliative care AI) from different perspectives, including multidisciplinary teams, managers, patients, caregivers, and other relevant stakeholders. Researchers should involve interdisciplinary partnerships and collaboration to facilitate work across essential interconnected themes, such as design, computing, data analysis, ethics, and translational medicine [17,36,37].

Conclusions

This study shows the importance of considering the views of palliative care professionals regarding the potential role of AI in clinical practice. Our findings demonstrate the importance of considering opportunities to meaningfully use AI to improve human-focused care, support staff education, and address practical issues related to trust, ethics, and governance. This study provides a foundation for developing guidelines for AI implementation in palliative care practice. Future research should examine methodological, ethical, and practical issues to ensure that AI best supports palliative care for people with serious illnesses.

Acknowledgments

The authors would like to thank the participants for their valuable input and participation in this study. They would also like to thank the hospice management and research governance group for supporting study recruitment. SS and ACN were funded by Marie Curie, the UK's leading palliative care charity. This study did not receive any funding.

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files).

Abstract

Background: Technology is rapidly reshaping conventional hospital environments into smart spaces, enhancing care, improving clinical workflows, and reducing workloads. However, successful implementation depends not only on the effectiveness of the technology but also on organizational readiness for change.

Objective: This study aimed to identify the key enablers and barriers to readiness for change for a smart hospital ward initiative.

Methods: We conducted a qualitative study to gauge organizational readiness for change for a smart ward initiative. Using purposive sampling, we captured diverse views from clinicians, IT staff, operational support staff, and health care redesign staff. Data were coded deductively under 3 key domains in Weiner's theory of organizational readiness: change efficacy, change commitment, and contextual factors. Subthemes were derived inductively under each domain.

Results: We interviewed 19 participants, including clinicians and support staff. Six subthemes emerged: (1) perceived valence and feasibility; (2) transparency and trust in management; (3) shared understanding and readiness to act; (4) resources, training, and staff capability; (5) innovation culture; and (6) past experiences. Participants viewed the initiative as valuable and were motivated to change, citing that the institution's innovation culture was a key enabler. However, there were key barriers, including unclear timelines, inconsistent training, limited resources, and a lack of infrastructure to support innovation. Concerns about overreliance on technology were also prominent, with staff wary of its impact on clinical judgment and system reliability.

Conclusions: Enabling readiness for the smart ward initiative requires transparent communication of timelines and project awareness, particularly for ground staff, the development of training frameworks, and adequate prioritization of innovation. Alleviating commonly reported technology concerns, such as overreliance, loss of human touch, and system reliability, will also be key to adoption and sustainability.

KEYWORDS

organizational readiness for change; health care innovation; technology adoption; change management; qualitative research

Introduction

Technology is rapidly transforming inpatient care, reshaping conventional hospital environments into smart spaces, including wards [1,2]. "Smart wards," an emerging feature of digitally enabled hospitals, are ecosystems that use interconnected digital systems to enhance patient care, improve clinical workflows, and reduce workload through automation [3,4]. These

XSL•FO
RenderX

ecosystems may incorporate a range of technologies, including real-time patient monitoring, movement detection, and artificial intelligence (AI)–based support tools [4]. Motivated by the challenges of caring for an aging population, a constrained health care workforce, and limited hospital bed capacity [5-7], there is growing investment in smart ward environments. However, the implementation of such technologies requires more than hardware or software; it demands meaningful behavioral and workflow changes among staff.

Alexandra Hospital is the latest hospital to invest in a smart ward concept as part of its commitment to adopting transformative health care technology. The smart ward initiative will include technologies such as continuous vital sign tracking with an integrated dashboard for real-time patient monitoring, a unified communication system for improved team collaboration, inpatient teleconferencing systems for remote consultations and patient education, chatbot agents for patient education, and the integration of AI analytics into clinical systems. The initiative also envisions a centralized virtual workforce that remotely supports inpatient care and ground staff.

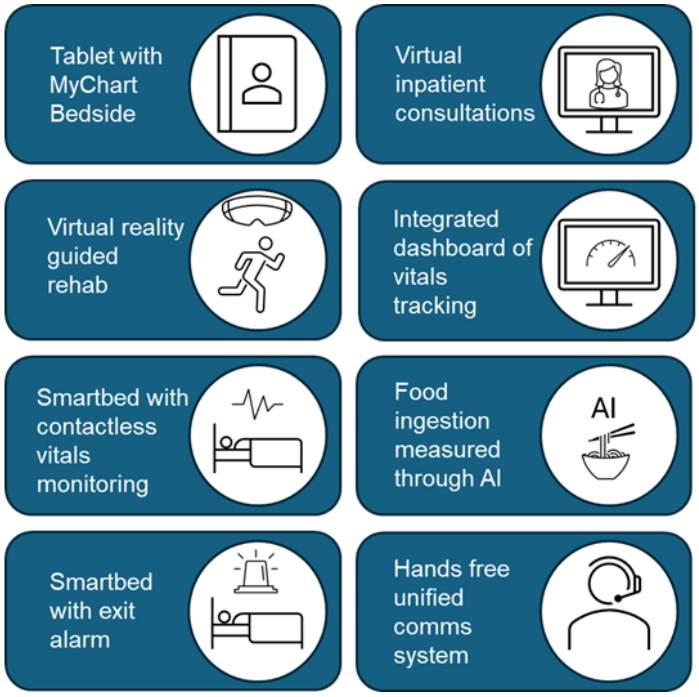
To achieve the smart ward vision, substantial changes in staff behaviors and workflows are required**.** Thus, the successful implementation of technology depends not only on the effectiveness of the technology itself but also on how well an organization and its staff can adapt to these new systems—a concept known as "organisational readiness for change" [8,9]. In the context of digital transformation, such as smart wards, organizational readiness reflects the extent to which staff and systems are collectively prepared—psychologically and behaviorally—to adopt and sustain technological innovations. According to Weiner [9], two key constructs underlie readiness: (1) change efficacy (the shared belief in the organization's capability to execute the change successfully) and (2) change commitment (the collective resolve to implement the change). Multiple factors may influence these constructs, including leadership support, local policy, clear timeframes, resource availability, staff training, and a culture for safe experimentation and learning (ie, sandbox environments) [9-11]. Together, they determine the degree of preparedness in an organization, both psychologically and behaviorally, to implement change [9]. When readiness is high, the implementation of a proposed change is effective, while low organizational readiness leads to resistance to and avoidance of change [9,12-14].

Although several implementation and organizational change frameworks exist; such as the Consolidated Framework for Implementation Research, and Kotter's change model, Weiner's organizational readiness for change model was chosen for its specific focus on the psychological and collective capability to implement change Unlike frameworks that emphasize structural, procedural, or leadership-driven dimensions, this model centers on the shared commitment and confidence of staff to enact change. Through examining how staff perceive readiness for the smart ward and the organizational conditions that support it, the study refines the understanding of how change commitment and change efficacy manifest in high-technology, team-based clinical contexts. Although there is an increasing global interest in smart hospital initiatives, most existing research focuses on the technological infrastructure, digital capabilities, or outcomes of smart technologies [15]. Far less is known about the behavioral and contextual factors that shape successful adoption in a smart ward context. Addressing this gap, this study examines the enablers and barriers to organizational readiness for change as Alexandra Hospital embarks on its smart ward initiative, using the framework proposed by Weiner as the analytical lens.

Methods

We conducted a qualitative study to explore health care staff members' readiness for the smart ward initiative. The project was run during an initial pilot testing phase, in which some, but not all, technologies had been deployed. This study is reported according to the Consolidated Criteria for Reporting Qualitative Research (COREQ) [16].

Ethical Considerations



The study was reviewed and approved by the National University of Singapore Institutional Review Board for Social, Behavioral, and Educational Research studies (NUS-IRB-2023-327). All participants provided written consent to take part in the study. It was emphasized that the study was voluntary and participants could withdraw at any time. Participants received no compensation for taking part in the study. Data were deidentified and participants were assigned a unique ID number.

Setting

Alexandra Hospital, part of the National University Health System, provides care across the continuum, from acute to subacute rehabilitative services. The smart ward initiative, based at Alexandra Hospital, incorporates a suite of technologies (Figure 1). These technologies enhance access to personal health information for patients (via the MyChart Bedside) and clinical data for providers through smart bed systems for continuous vital sign monitoring, automatic bed exit alarms, computer vision, and AI-calculated food consumption, and an integrated dashboard for data analysis and visualization. The initiative also introduces new modes of care, such as virtual reality-guided rehabilitation and virtual inpatient consultations, alongside improved communication through a unified communications system. At the time of this study, some but not all of the technologies had been deployed in the ward.

Figure 1. Summary of the planned smart ward technologies. AI: artificial intelligence.

Participants

We used a purposive sampling approach to capture the views of different departments involved in smart ward development or staff working within the inpatient setting, where the initiative is being implemented. Our inclusion criteria were as follows: staff employed at Alexandra Hospital during the study period; individuals involved in smart ward development or clinicians working within the smart ward; representatives from nursing, medical, IT, operations, or health care redesign departments; the ability to provide informed consent; and the ability to participate in an English-language interview. Exclusion criteria were staff not involved in or exposed to the smart ward initiative (ie, external vendors, temporary or locum staff) and the inability to provide informed consent. The choice of representatives was made as these departments were collectively involved in the design or implementation planning for the smart ward, or represented the main clinical groups affected by the smart ward transformation.

Participants were contacted by email or phone messaging. A research team member (with no direct relationship with the participant) followed up with the potential participant to discuss the project, obtain written informed consent, and arrange a convenient time for the interview. Recruitment continued until data saturation had been reached, defined as the point at which no new codes, themes, or perspectives emerged from successive interviews, and the research team agreed that additional data would not add further conceptual insights. Saturation was assessed iteratively during data collection among the study team. No participants declined to take part, and no participants received compensation to take part in this study.

Materials

The interview guide was informed by the organizational theory of Weiner's implementation effectiveness framework by [9], which is widely used to assess organizational readiness for change in health care settings [17]. This framework was selected because it provides a structured lens to examine the psychological (eg, change commitment) and structural (eg, change efficacy) factors that influence an organization's preparedness to implement change. This makes it particularly suitable for examining health care workers' perceptions before implementing a complex intervention, such as a smart ward. The interview topics included participants' general views, awareness, and understanding of the smart ward initiative; perceived benefits and challenges; and preparedness, including available resources, managerial support, required skills, and value alignment. JS drafted an initial guide and subsequently shared it with the broader project team for feedback. The interview guide was also developed iteratively as new topics emerged during the interviews to ensure responsiveness to participants' experiences. For instance, although we originally asked about the impact of the smart ward on staff-to-patient interactions, many participants also reflected on staff-to-staff interactions. Some also raised questions regarding the suitability of certain patients for the smart ward environment. These topics were subsequently incorporated into later interviews to systematically explore this emerging dimension. Despite these additions, all interviews continued to cover the same foundational domains related to organizational readiness, ensuring comparability across participants.

Procedure

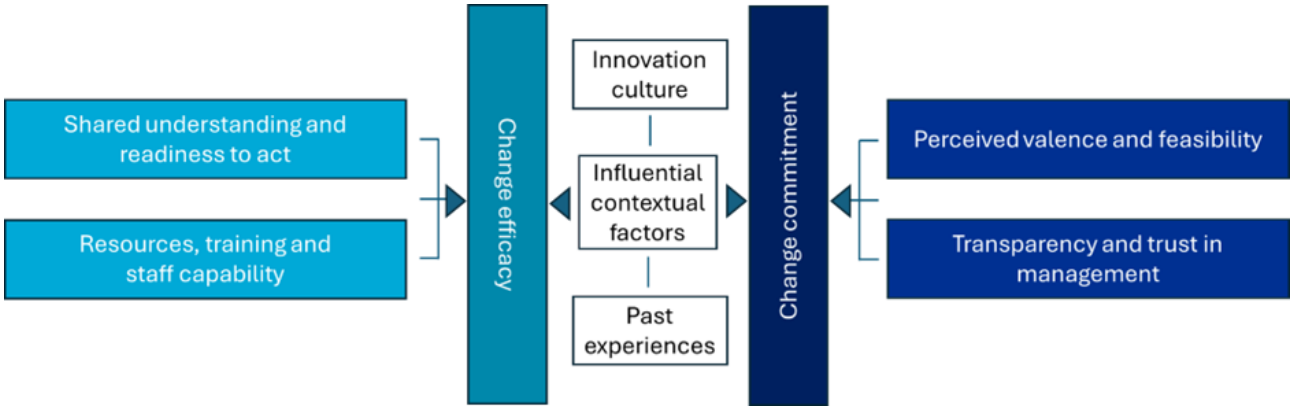
Interviews were conducted in pairs by 4 female health services researchers trained in qualitative methods (JS, HWL, CK, and EHHC) from August 2023 to February 2024. Interviews were conducted using a semistructured interview guide, were audio recorded, and transcribed verbatim. Interviews were conducted in a quiet place that was convenient and acceptable to the participant. On average, the interviews lasted 47 minutes (range 29-69 min).

XSL•FO
RenderX

Data Analysis

We used a framework analysis approach, applying a hybrid deductive-inductive approach [18]. A deductive structure was based on the theory of the organizational readiness for change framework proposed by Weiner, which guided the initial coding. Inductive coding captured emergent insights in each domain. To contextualize the framework to our study, the project team reviewed the original definitions of the framework domains: change efficacy, change commitment, and contextual factors. The team then contextualized these definitions to our study through discussion, drafting a preliminary codebook. Three researchers (JS, HWL, and AA) then independently coded a single transcript sentence by sentence using the draft codebook and met to discuss coding assignments and clarify definitions. This exercise was repeated on a second transcript to resolve any remaining questions. All subsequent transcripts were coded by a single coder (HWL or AA) and checked by a second coder (JS) to ensure consistency. Differences in opinions were mutually reconciled through discussions among the team. Codes were subsequently grouped into subthemes within the framework domains through team discussions, allowing new concepts to emerge while retaining theoretical alignment. All coding and analyses were conducted in Microsoft Word.

Results



We interviewed 19 participants from different professional backgrounds, including clinicians and support staff (Table 1).

Table 1. Participant characteristics (N=19).

Job function	Participants, n (%)
Operations	1 (5)
IT	3 (16)
Nursing	8 (42)
Physician	5 (26)
Health care redesign manager	2 (11)

Results are organized according to the 3 key domains of the theory of organizational readiness for change proposed by Weiner (change efficacy, change commitment, and contextual factors), and 6 subthemes under these domains (Figure 2). We identified several enablers and barriers impacting the smart ward initiative (Table 2). A broader description of the influencing factors is provided in the following section. Additional supporting quotes are included in Multimedia Appendix 1.

Figure 2. Mapping of inductively derived subthemes to the 3 key domains in the organizational readiness for change framework proposed by Weiner [9].

XSL•FO
RenderX

Table 2. Summary of key enablers and barriers by organizational readiness domains (change efficacy, change commitment, and contextual factors) and the 6 subthemes.

	Enabler	Barrier
Change commitment		
Perceived valence and feasibility	• Value perceived • Alignment on value across departments • Perceived as appropriate for general medicine wards	• Slow roll-out • Limited integration • Failure to meet expected needs • Overreliance on technology • Reliability questioned • Alarm fatigue or desensitization
Transparency and trust in management	• Trust in management • Active stakeholder engagement • Minimal expectations for high involvement	• Minimal ground-nurse engagement • Fear of failure or perception that innovation is not a priority • Cultural norms impacting openness
Change efficacy		
Shared understanding and readiness to act	• Good awareness of the initiative • Facilitation of interactions between teams	• Inconsistent communication • Misalignments on purpose
Resources, training, and staff capability	• Ground-up training initiatives • Troubleshooting support	• Delayed training or unclear responsibility for training • Insufficient staff or time to engage with new technology • Need for external funding
Contextual factors		
Innovation culture	• Sandbox culture • Keeping up to date with technology developments • Raising staff awareness of technology	• Complexity of the “sandbox” approach in the clinical setting
Past experiences	• Prior positive experience with technology	• Prior negative experience with technology

Change Commitment: Perceived Valence and Feasibility

Participants broadly agreed that the smart ward initiative held value and had potential to improve efficiency, reduce overtime, and allow more dedicated time for direct patient care. Their comments reflected enthusiasm and a shared sense that the change was desirable:

> *It’s to help us, to make our job easy, to elevate, to help to reduce the workloads.* [Nurse ID 04]

> *Yeah, for sure. I will love to work in an environment like that. Everything is so streamlined. Yeah, that would be good.* [Physician ID 12]

However, during the pilot phase, expectations were often unmet. Many expressed frustrations with implementation delays, lack of system integration, and a failure to reduce workloads. Others shared that pilot testing had resulted in “double work,” with old and new processes carried out simultaneously because the new process was not trusted. Health care redesign staff echoed these concerns, noting early resistance and uncertainty around pilot technology:

> *I think so long already until [smart ward], I think they need to expedite.* [Nurse ID 05]

> *Because we don’t totally trust it right? Because it’s totally new and it hasn’t been totally tested out. So you want to do things the old way as well.* [Physician ID 12]

> *When we tried to implement anything new, there’s always resistance. Because I guess it’s, at first, it’s just umm, they didn’t make sense out of it. It’s like. At first, it’s not going to be everything smooth. It’s going to be a lot more work at the beginning for them. So it’s normal that they may feel hesitant about it.* [HCRD ID 18]

Concerns about overreliance on technology, alarm fatigue, and erosion of human interactions were also common:

> *Yeah, definitely. There are some things that require our own judgment. I mean when we are trained, we need to correlate that to how the patient is clinically, like what are the symptoms, how they look, how they appear, what are some of the signs that they have.* [Physician ID 14]

> *I think it’s helpful but I also don’t know like how reliable it will be, because like. for example, patient is just agitated for a while, then there’s a spike in the heart rate. Then umm, if we’re going send alerts each*

XSL•FO
RenderX

> *time, then it's not going to be helpful.* [Physician ID 16]
>
> *OK, since I can already get my vitals there, right, so it might decrease my bed time interaction.* [Nurse ID 06]

From a systems perspective, IT and operations staff highlighted the need for reliable infrastructure and clear governance to prevent failures and excessive maintenance burdens. Health care redesign staff added that bureaucratic barriers contributed to delays and hindered innovation:

> *While it is important to have all this checks in place [security checks prior to implementation], I'm not too sure that they understand that sometimes it's just a pilot.* [HCRD ID 18]
>
> *Imagine today there's a concept of virtual nursing where one nurse can take after 50 patients over screens.... But if the technology fails, what happens to that 50 patients?* [IT ID 08]

Change Commitment: Transparency and Trust in Management

Perceptions of strategic involvement in the smart ward initiative varied across professional groups. Some ground nurses felt excluded from the design and decision-making process despite being the primary users, contributing to a sense of disconnection. In contrast, physicians were less concerned about their level of involvement, noting that they lacked time to innovate but were open to providing discrete feedback. IT and operations staff reported a more structured advisory role—focused on implementation rather than shaping the initiative's direction:

> *So we need to know everything that is going on in the ward, but when they didn't inform us, we feel like we are not a part of it. So yeah, that's how we feel.* [Nurse ID 04]
>
> *To come up with those ideas and the vision and the direction, I don't think most of us honestly have the time.* [Physician ID 13]
>
> *No, I think we do have quite regular updates and meetings to keep each other informed.* [Operations ID 01]

IT and health care redesign staff generally viewed management as supportive of innovation but recognized that maintaining momentum required constant buy-in. Others felt that innovation was not always a top priority, and that fear of failure among senior management constrained their ambition. Nurses were the most skeptical, describing trust as contingent on seeing concrete results from technological investments:

> *I think sometimes it's the fear to fail that actually hinders the progress.* [HCRD ID 19]
>
> *We have a very strong management that says, no matter what, we will be behind support you, you will get this. You think that other places can have this?* [IT ID 02]

Change Efficacy: Awareness and Shared Understanding

Nurses and physicians valued the initiative's aims but felt uncertain about next steps and timelines, reflecting limited communication and shared understanding. In contrast, IT and redesign staff, who were closely involved in planning, described the project as a concrete realization of digital transformation goals:

> *What is happening now? Are we on to this phase? What phase now? What are we waiting for now? when are the trainings going to be?* [Nurse ID 05]
>
> *Smart Ward is a place that where we can put our dreams into real life.* [IT ID 02]

Health care redesign staff noted that inconsistent communication and technical jargon often hindered cross-departmental engagement, although they actively worked with IT to bridge these gaps. They described ongoing efforts to involve all stakeholders but acknowledged that achieving full transparency remained difficult:

> *You know, sometimes we try to like, you know where we have like new products that we want to bring in, new technology that we want to bring in, we will try to invite everyone.* [HCRD ID 19]
>
> *Actually I think IT and the business right can never have a common language because our language is so much more technical right? We can only start by teaching them. So when they time come to us with the business requirements, we translate that into a technical term and then we share, this is what you call it.* [IT ID 08]

Change Efficacy: Resources, Training, and Staff Capability

All participants recognized the need for adequate resources for technology implementation. Nurses highlighted that insufficient staffing would hinder technology use, while IT struggled to hire and retain skilled staff due to competition with industry roles. Health care redesign staff also called for greater IT resourcing:

> *There are certain personnel in IT that we work with very closely. But if you were to ask me if they are dedicated just solely doing our projects, I don't think so.* [HCRD ID 19]
>
> *It's always difficult because being in public healthcare, right, our pay is relatively lower than private sector. So, you always have this fight with the private sectors that you want somebody good, right? Yeah, but you cannot pay.* [IT ID 08]

IT staff further speculated on the long-term scalability of smart ward, given budget constraints and ongoing operational costs. Others noted the challenge of needing external funding to support their efforts:

> *We are running short of money for public healthcare. Because over the years we have been commissioning more and more IT systems, right and each time we commission an IT system, it actually draw an*

XSL•FO
RenderX

> *operating cost. It increases our operating cost. And if we don't start to consolidate them, some of the systems, right, this will just continue to grow.* [IT ID 08]

> *We ourselves, we are also supposed to look for the funds, for our pilot projects.* [HCRD ID 19]

All teams emphasized the importance of training to ensure competency on the ground but described inconsistent provision and unclear responsibility for ongoing training. This lack of clarity and execution led to a poor understanding of pilot technology and inconsistent user compliance across departments. Health care redesign staff were unconcerned about in-depth training, citing cross-functional support. IT viewed ongoing training as the responsibility of system owners rather than IT itself. Consequently, nursing often initiated in-house training programs, but this did not extend to other departments, creating knowledge gaps across functions:

> *So definitely the team needs to be equipped with skills, like understanding the tech landscape right, the jargon, and basically the landscape, because as an administrator when we have all this data.* [Operations ID 01]

> *Because sometimes the training will come only if the thing is there already.* [Nurse ID 05]

> *Usually we will get the vendor to provide the training to the users before they hand over the system for users to maintain it. So that will be their [system owners] responsibility to share the materials with the staff.* [IT ID 15]

Contextual Factors

Participants generally viewed Alexandra Hospital as a "sandbox" for trials and innovation, which fostered a belief in the feasibility of the smart ward. However, they also recognized that such experimentation is more complex in a hospital environment than in other industries. Several participants emphasized the role of prior technology exposure and mindset in shaping readiness. Those with positive past experiences were more open to change, whereas those with past system failures were more cautious. Strategies such as routine "tech scans" to stay informed and efforts to update staff on technology advancements to boost engagement were seen as beneficial, particularly to encourage those who are comfortable with the status quo:

> *We are designated sandbox [ie, a site for experimentation and testing of innovative ideas] from MOH, okay. We can do, try, trial, and we are not afraid of failing.* [IT ID 02]

> *So I have had to deal with system breakdowns. The backup system was extremely difficult to use for everyone. So it definitely took a toll on everybody.* [Physician ID 12]

Cross-Cutting Influences on Collective Readiness

Differences in staff perceptions reflected not only professional roles but also the hospital's culture. Frontline clinicians, who had less decision-making authority, mainly described the smart ward regarding its day-to-day effects on workload, communication, and patient care. In contrast, staff in IT, operations, and health care redesign, who had greater strategic oversight, tended to focus on systems change factors, including integration, scalability, and long-term feasibility. The hospital's culture of cautious innovation, which encouraged experimentation but was often limited by bureaucratic processes or a fear of failure, also shaped readiness. Taken together, collective readiness for change was shaped not only by perceptions of the technology's value but also by how authority and organizational culture shaped staff experiences and their sense of ownership in the change process.

Discussion

Principal Findings

As technology continues to be deployed in clinical environments, assessing the factors influencing change readiness is essential for its successful implementation and sustained use. We conducted a qualitative study to gauge the organization's readiness to change for the smart ward initiative at Alexandra Hospital. We interviewed a diverse cross-section of health care providers, operational support staff, and the in-house innovation team to identify facilitators and barriers. We found that participants generally saw value in the concept and trusted management. Many appreciated active engagement in the initiative and viewed the hospital's sandbox culture as a key enabler of innovation. However, challenges were evident, including unclear implementation timelines, inconsistent training, and limited resourcing for innovation. Concerns about the overreliance on technology were also prominent, with staff wary of its impact on clinical judgment and system reliability.

A key aspect of change commitment (a core construct of the organizational readiness for change framework by Weiner) is the perception that a proposed change holds value, which is essential for successful implementation [9]. This aligns with the 8-step change model developed by Kotter and the diffusion of innovation theory by Rogers, which emphasizes that if clear benefits are unrecognized, it can lead to a lack of urgency, reduced participation in the process, and may ultimately stall the implementation process [19,20]. In our study, we found that stakeholders from different departments collectively saw the initiative as beneficial, but the underlying perspectives on purpose differed between teams. Similar challenges have been observed in other digital transformation contexts, where divergent stakeholder views have led to misalignment and ultimately constrained implementation efforts [21].

Another driver of change commitment is engagement with stakeholders. Effective and early communication with stakeholders can help build buy-in, address concerns, align expectations, and maintain engagement. In contrast, poor engagement often leads to suboptimal adoption. For example, hospitals that introduced electronic medical records without consulting staff often faced resistance [22]. Conversely, those that involved staff early in technology design and roll-out found that implementation was facilitated [23,24]. Our findings indicated that participants had varying degrees of engagement. Participants closely involved in the initiative viewed the process as collaborative, while some frontline staff felt less informed.

XSL•FO
RenderX

To improve engagement, the nonadoption, abandonment, scale-up, spread, and sustainability framework recommends structured, transparent, and multidirectional communication to engage stakeholders and facilitate adoption [25]. Within the framework proposed by Weiner, such communication can enhance collective change commitment and efficacy by fostering a shared understanding, confidence, and ownership of the change process. Interventions could include workshops, multiple communication channels, tailored messaging, and continuous feedback loops to enhance stakeholder commitment.

Of the contextual factors influencing readiness for change, participants shared that having an innovation culture at Alexandra Hospital is a key enabler for the smart ward initiative. Although relatively new in health care, the "sandbox approach" provides a low-risk environment for testing new ideas or technologies without full implementation [26,27]. This approach may be beneficial when introducing disruptive technology, such as that in the smart ward initiative, as it provides space for learning and experimentation without full implementation [26,27]. The sandbox approach aligns with the model by Weiner, emphasizing that perceived capability (which can be acquired through experimentation) is a core component of change efficacy [9]. However, although there was a belief that a sandbox culture exists at the hospital, the infrastructure to support it was lacking. Clear communication on the purpose and objectives of the sandbox approach could help to establish the support required to achieve a true sandbox environment [28].

Training is another factor in capability development. We found that delayed or inconsistent access to training and a lack of clarity on who is responsible for training led to knowledge gaps on the ground. A lack of training may become problematic, as technology literacy is a known barrier to technology adoption and sustainability [29]. According to the organisational readiness for change model proposed by Weiner, ensuring that stakeholders feel competent and supported is essential for successful implementation, a point also mirrored in the Consolidated Framework for Implementation Research [30]. Effective training overcomes resistance to change by improving awareness, competence, and confidence [20]. These findings align with prior studies showing that insufficient or poorly timed training undermines readiness, while targeted, context-specific programs enhance staff confidence and sustain adoption [25,31]. Efforts should focus on providing timely access to training, defining responsibilities for training delivery, and tailoring content to different stakeholder groups to accommodate varying levels of digital literacy and learning needs [32].

Our findings have several practical implications for hospitals planning or implementing smart ward initiatives. We suggest several practical strategies to support the successful implementation of similar smart ward initiatives. First, efforts should focus on building awareness of the value of such initiatives to ensure a buy-in and consistent understanding. Second, implementation strategies should actively engage staff across all levels, not only clinical leads or innovation champions, to ensure that diverse perspectives are captured and foster collective ownership of change. Third, to operationalize the "sandbox" culture that participants value, institutions should establish concrete support mechanisms, such as a streamlined procurement mechanism, expedited technology safety reviews, and iterative feedback loops to rapidly trial and refine technologies in real-world settings. Fourth, training frameworks should be developed early, with clearly assigned responsibilities for delivery, content tailored to varying digital competencies, and adequate protected time for staff to learn. Finally, leaders should visibly support implementation efforts, actively monitor progress, adapt as needed, and establish mechanisms to surface and address frontline concerns as systems evolve. Together, these actions can improve organizational readiness and enable more effective, inclusive, and sustainable digital transformation in hospital settings.

Strengths and Limitations

We conducted a qualitative study that provides in-depth insights into the readiness of clinicians and support staff members for change. We used an established framework to explore organizational factors influencing technology adoption, which is a clear strength. Our qualitative approach also allowed us to identify context-specific enablers and barriers that may be overlooked in a survey approach. However, the generalizability of our results may be limited, as our data are from a single institution. Although we sought to capture a range of perspectives, the representation from some departments (notably IT and operations) was smaller. In these cases, we included senior management who were directly involved in system-level planning, reflecting the primary function of these departments at this stage of the project. For frontline staff, we recruited a broader sample to capture the experiences and views of those impacted by the smart ward. Although we acknowledge the underrepresentation of some professional groups, thematic saturation was achieved across the main domains of readiness, and the inclusion of both strategic and frontline viewpoints enabled us to interpret the findings holistically. We also cannot rule out sampling bias and the risk of social desirability bias in participant responses. We attempted to mitigate the latter by emphasizing participant anonymity. Another limitation of this study is that we used the organisational readiness for change framework by Weiner to inform the development of the interview guide and to structure the initial deductive analysis. This dual use may have reinforced existing theoretical constructs and constrained the emergence of entirely novel themes. To minimize this risk, we incorporated inductive coding within each domain to capture insights that extend beyond the original framework. Finally, as with all qualitative research, the findings reflect the interpretations of the research team, although efforts were made to enhance rigor through team coding.

Conclusions

By identifying and addressing pertinent factors that influence readiness for change, the enablement of technology implementation is possible. Efforts should focus on project awareness, particularly among ground staff, the development of training frameworks, and the adequate prioritization of an innovation culture. Furthermore, alleviating commonly reported technology concerns, such as overreliance, loss of human touch, and reliability issues, will be key to adoption and sustainability.

Abstract

Background: The virtual nursing delivery model enables the provision of expert nursing care from a remote location, using technology such as audio and video communication, remote monitoring devices, and access to electronic health records. Virtual nurses spend an extensive amount of time on computers to provide care, and little is known about how this workflow may affect and contribute to cognitive fatigue.

Objective: This study aimed to use eye tracking technology and pupil size variation to determine instances of virtual nurse cognitive fatigue during their typical workflow.

Methods: This study examined the virtual nursing workflow by recording and analyzing virtual nurse encounters using eye tracking. This cross-sectional study was conducted during regular 12-hour shifts at a major Southeastern health center in the United States.

Results: The study found that 75% (22/29) of virtual nursing encounters demonstrated a first fatigue instance at 9.8 minutes during patient discharges and at 11.9 minutes during patient admissions.

Conclusions: This study provides valuable insights into virtual nursing workflow design and how it may impact the cognitive fatigue levels of nurses providing inpatient virtual care.

Introduction

Over 25% of US registered nurses may quit by 2027 due to burnout and challenging work environments, contributing to high nurse turnover rates [1]. Nurses experiencing burnout are five times more likely to delay care (eg, documentation and patient discharge) than nurses without burnout, leading to long patient wait times [2]. Incomplete nursing documentation threatens patient care and safety [3]. Patient home medication review, an essential element of patient admission, is commonly missed due to fatigue, a lack of training, competing tasks, and insufficient time [4,5]. A lack of medication review can lead to medication errors, readmissions, and increased healthcare costs [6-8]. In addition, nurse burnout can result in delays in care and promote inpatient complications and poor patient satisfaction [9-11].

Healthcare systems in the United States are swiftly adopting a novel care delivery model, virtual nursing [12]. Virtual nursing provides bedside nurses with remote nursing expertise to reduce their workload and alleviate work-related fatigue [13]. Virtual nursing aims to mitigate burnout by reducing the workload and improving documentation completeness at admission and patient education at discharge [14].

A key consideration in implementing this emerging care delivery model is understanding workflow design, which protects virtual nurses from the unintended consequences of continuous virtual patient encounters [15]. Extended screen time and the use of

XSL•FO
RenderX

electronic health records (EHRs) were associated with an increase in burnout and fatigue in bedside nurses [16]; however, the association between continuous screen time and virtual nurses' fatigue levels, a key factor to the sustainability of this model, is unknown. Pupillometry data, which measures the change in pupil size, measures cognitive fatigue [17]. This study examined the association between using virtual nursing and virtual nurse fatigue using eye-tracking technology.

Eye-tracking technology provides real-time insights into cognitive workload and cognitive fatigue by recording eye movements during different states and activities. Pupil size in particular can be an indicator of cognitive workload, where an increase in pupil dilation corresponds to information processing [18,19]. In instances of cognitive fatigue, pupils exhibit less dilation over time or decreased response to stimuli. As the mental effort to process information increases, pupils constrict, indicating mental fatigue or exhaustion [20].

Methods

Participants, Device, and Measurements

We conducted a cross-sectional study of virtual nurses during regular 12-hour shifts at a Southeastern tertiary hospital. We observed virtual nurses during four times of interest (TOIs): preparation (eg, chart review), admission encounter, discharge encounter, and miscellaneous (eg, documentation). All virtual nurses were previously bedside nurses at the same hospital. At the time of observation, six nurses were on staff at the Virtual Care Center during day shifts. Four nurses were observed over a period of 5 days.

We used a noninvasive screen-mounted eye-tracking device (Tobii® Pro Spark, Tobii AB®, Stockholm, Sweden) to capture pupillometry data of the virtual nurses during their shifts. Our target number of observations (ie, sessions) was based on evidence that suggests a sample size between 10 and 50 observations suffices for reliable and valid results [21-23].

The eye-tracking device was set up at the virtual nurses' workstations on the monitor that displays activity in the EHR. Prior to recording sessions, virtual nurses were oriented with the eye-tracking device and instructed to complete their tasks as they normally would. An initial calibration session was completed with each virtual nurse before recordings began to ensure data quality. Due to fluctuations in shifts and general availability, two of the four nurses had a higher number of recordings and TOIs captured. To help mitigate this as a confounder, we focused our analysis on the encounters and TOIs rather than the individual nurse level.

Ethical Considerations

The Institutional Review Board (IRB) at the University of North Carolina approved this study under IRB number 23 - 0859. Information related to the study was provided to nurses prior to participation, and they were informed they could decline to participate or withdraw at any time. All participating nurses provided verbal consent to the study team members prior to eye-tracking recording. Participating nurses were given a US $25 gift card to thank them for their participation. All data collected was anonymized following data collection to protect participant confidentiality.

Study Outcomes

The primary study outcome was cognitive fatigue measured as changes in pupil size. Secondary outcomes were subgroup analysis of fatigue by nursing tasks and patient acuity.

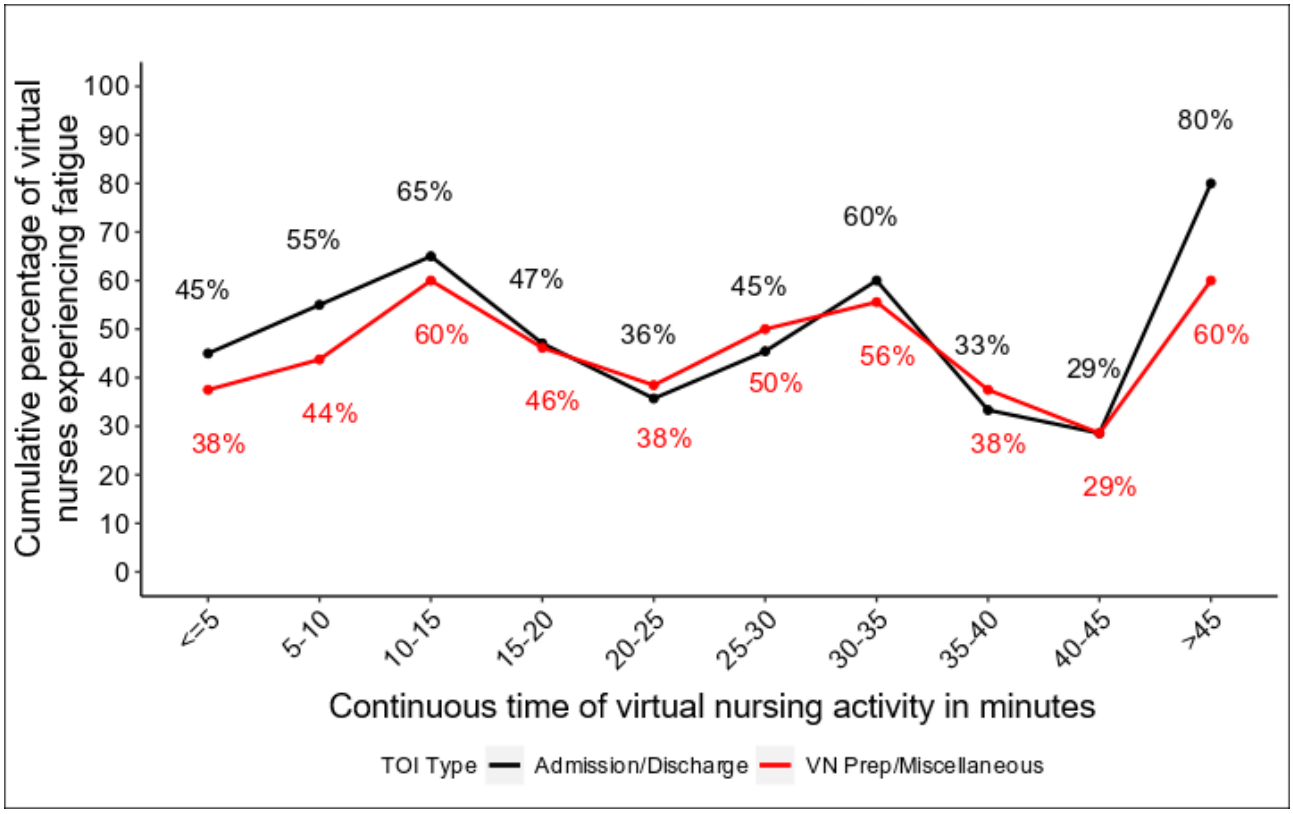
Statistical Analysis

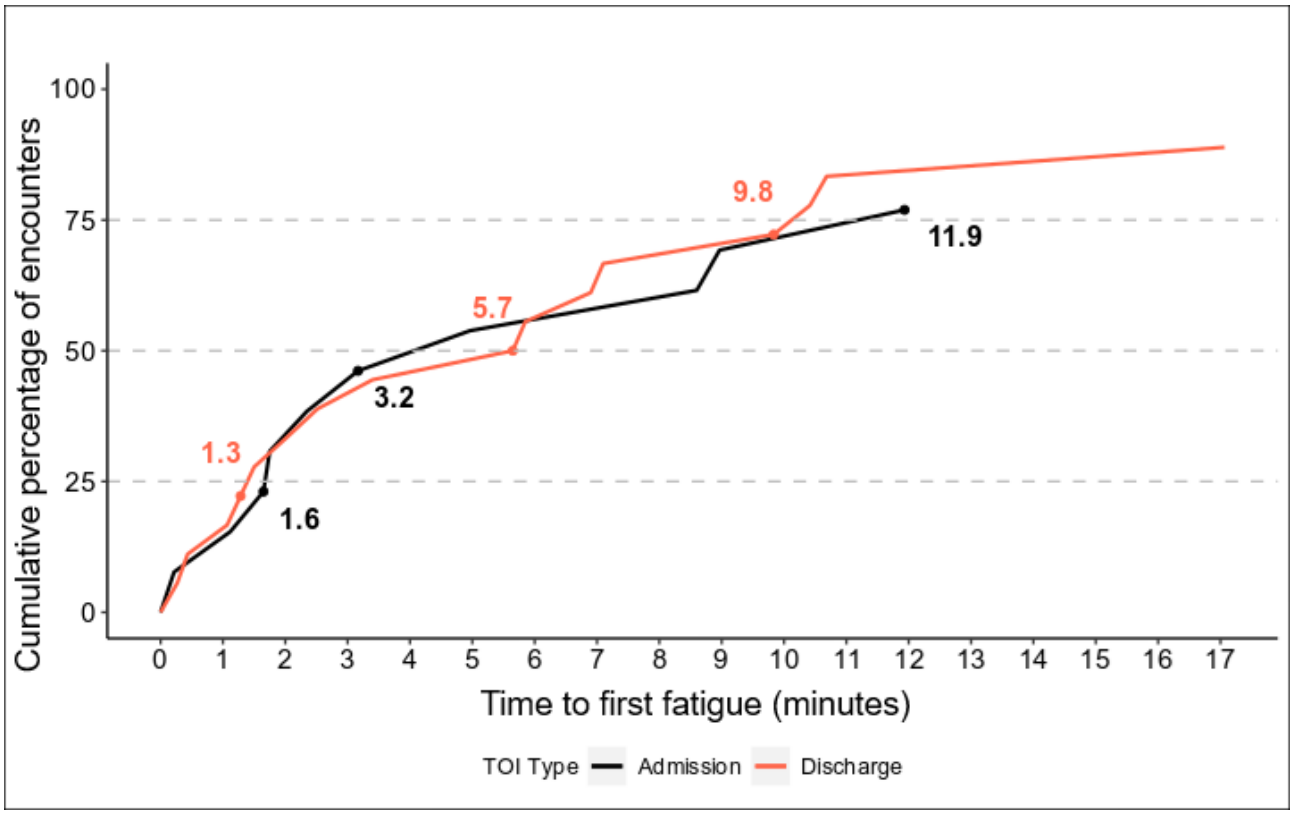
Eye-tracking data were exported, and fatigue counts per minute were calculated by flagging instances where the average pupil size was below the calculated threshold. The fatigue threshold for each recording was calculated by subtracting 1.5 times the SD from the mean pupil size. The Shapiro-Wilk test was used to test for normality and the Mann-Whitney or Kruskal-Wallis tests were used to compare continuous variables. We conducted all analyses with statistical software (RStudio version 2023.12.1; Posit Software, PBC).

To generate figures for visualization, we examined the instances of fatigue in a given recording and tracked them over time. We were most interested in comparing the instances of fatigue during patient encounters (admissions and discharges) and other virtual nursing tasks (preparation and miscellaneous). In Figure 1, the x-axis is represented in continuous time groups of 5 minutes, while the y-axis represents the percentage of virtual nurses who experienced an instance of fatigue in a TOI. As encounter times differ and often decrease over time, the number of recordings that meet a given duration also decreases, leading to a smaller ratio. However, this does not fully explain the higher percentage, as it can also be attributed to a greater number of virtual nurses experiencing fatigue as time progresses. In Figure 2, we note the time to first fatigue in minutes, specifically in patient admission and discharge TOIs, and note the cumulative percentage of virtual nurses who have experienced an instance of fatigue by that period of time. In Figure 3, we compare all recordings of patient encounters and look instead at first fatigue by the level of patient acuity.

XSL•FO
RenderX

Figure 1. Proportion of virtual nurses experiencing cognitive fatigue during virtual nursing sessions over time by 5-minute intervals. TOI: time of interest.





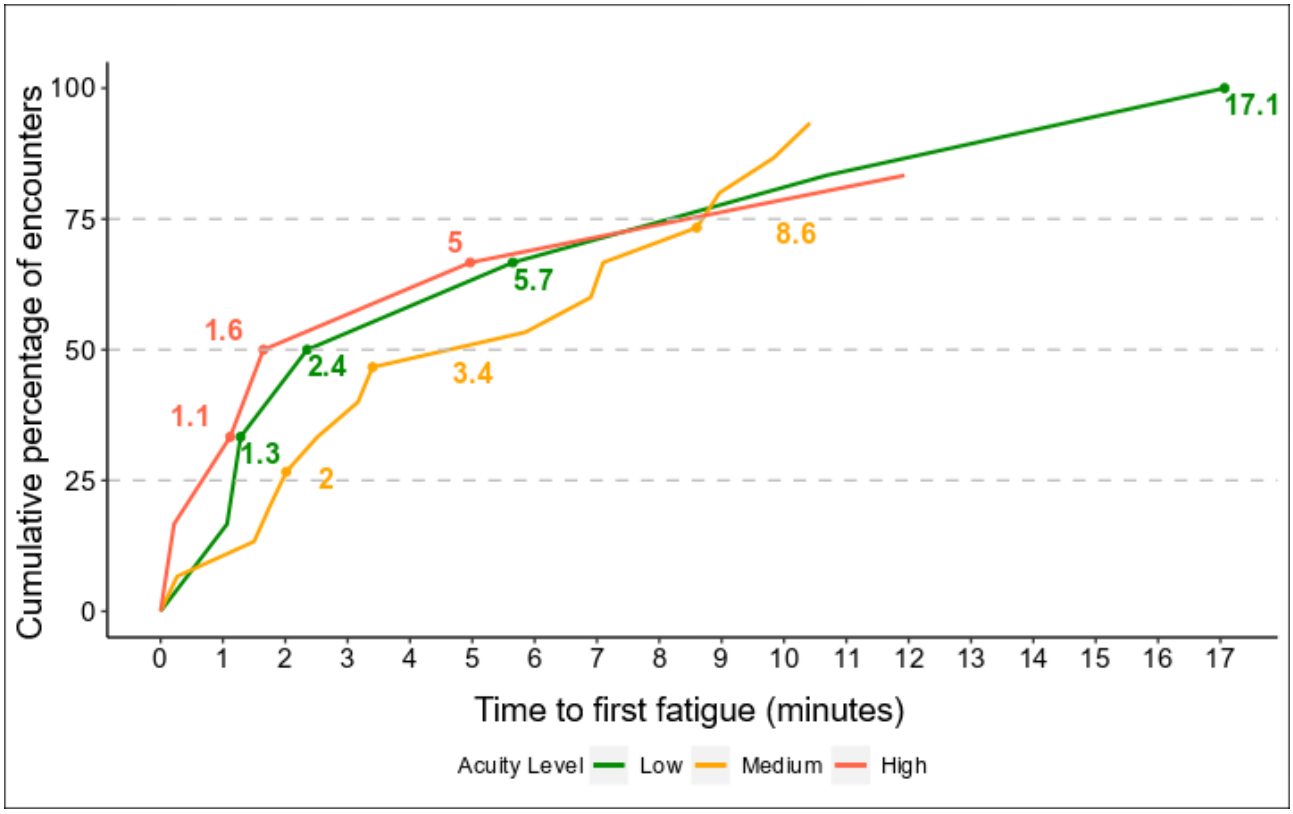


Figure 2. Cumulative percent of virtual nurses experiencing their first cognitive fatigue instance during admission and discharge times of interest (TOIs).

XSL•FO
RenderX

Figure 3. Cumulative percent of virtual nurses experiencing their first cognitive fatigue instance for all times of interest (TOIs) by patient acuity.

To determine patient acuity, we used a combination of factors, including patient age, expected or actual length of stay, principal hospital problem, and severity of the patient unit. These factors were weighted for each patient admission or discharge encounter to determine an acuity rating of low, medium, or high. We used data from the Center for Disease Control National Hospital Discharge Survey [24] to inform this process. The age groups of 18 - 44 years, 45 - 64 years, and >65 years were utilized, with the greatest weight given to patients over 65 years of age. The expected or actual length of stay was categorized into groups of 1 - 3 days, 4 - 6 days, and >7 days, with individuals staying or expected to stay greater than 7 days at the highest acuity. In cases where the principal hospital problem was given (27/29 instances), this was compared to the Center for Disease Control data; the principal hospital problem was compared to the Center for Disease Control data along with the patient's age and length of stay to determine if the patient had lower or higher than the average length of stay. Finally, the severity of the patient unit was taken into consideration, with short-stay units given the lowest acuity, general medical-surgical units given medium acuity, and intensive care units or critical care units given the highest acuity scores.

Results

A total of 22 recordings and over 14 hours of recording time were analyzed, encompassing 83 distinct virtual nursing encounters, Table 1. Of the 83 TOIs, 11 (13%) were admission encounters, 18 (22%) were discharges, 36 (43%) were miscellaneous, and 18 (22%) were preparation tasks. The average (SD) duration was 17 minutes 48 seconds (5.3 minutes) for admissions and 17 minutes 53 seconds (8.9 minutes) for discharges. All four virtual nurses were female, with an average (SD) of 26.3 (7.9) years of nursing experience.

Table . Distribution of workflow tasks for study participants.

	Total observed time	No. of recordings	No. of admissions	No. of discharges	No. of miscellaneous sessions	No. of preparation sessions
Nurse A	6 hours, 8 minutes	11	6	5	18	7
Nurse B	1 hour, 4 minutes	1	0	2	2	1
Nurse C	3 hours, 2 minutes	1	1	3	8	7
Nurse D	4 hours, 27 minutes	9	4	8	8	3
Total	14 hours, 41 minutes	22	11	18	36	18

The average (SD) number of cognitive fatigue instances varied by TOI such that admission encounters had 16.9 (16.4) fatigue instances, discharges had 15 (15.9) fatigue instances, preparation had 4.7 (8.3) fatigue instances, and miscellaneous had 0.42 (1.3) fatigue instances.

XSL•FO
RenderX

Spikes in cognitive fatigue occurred approximately every 15 minutes (Figure 1). For both admissions and discharges, 65% (19/29) of virtual nursing encounters experienced at least one instance of fatigue by 15 minutes, followed by another spike at 30 and 45 minutes. When analyzing the preparation and miscellaneous tasks, we found similar 15-minute interval patterns.

In addition, 75% (22/29) of virtual nursing encounters experienced their first fatigue instance within 9.8 minutes during patient discharges and within 11.9 minutes during patient admissions, Figure 2. Half of virtual nursing encounters (15/29) showed a first fatigue instance within 5.7 minutes during patient discharges and within 3.2 minutes for patient admissions.

We also examined the relationship between patient acuity and fatigue. Of the 29 unique patient admission and discharge encounters, we found that 8 (28%) patients were considered low acuity, 15 (51%) were considered medium acuity, and 6 (21%) were considered high acuity.

Fatigue instances varied by patient acuity (Figure 3). High-acuity patients showed a steeper increase in fatigue than medium and low-acuity patients. Regardless of patient acuity, 75% (62/83) of encounters had their first instance of fatigue within 8.6 minutes.

Discussion

Principal Findings

For the first time, this study quantified the association between the virtual nursing workflow and virtual nurse cognitive fatigue. We report that screen time–related fatigue instances reach maximum levels over 15-minute intervals. This suggests the need to consider more frequent breaks between patient encounters to reduce cognitive fatigue for virtual nurses compared to the standard routine for bedside nurses. We also found that approximately 75% of virtual nurses experience their first fatigue instance after approximately 10 minutes, regardless of the encounter type or patient acuity. By comparison, our previous study suggested that cognitive fatigue occurs after 22 minutes of EHR use by physicians [17].

Suboptimal EHR interface designs and documentation burdens contribute to nurse fatigue [16,25-27]. Virtual nursing can reduce EHR time and the documentation burden for bedside nurses; however, it is paramount to avoid shifting these job stressors to virtual nurses. Virtual nurses who spend extended durations working in the EHR and documenting patient assessments may exhibit cognitive fatigue, a precursor to nurse burnout. This study provides actionable insights into the relationship between using virtual nursing and virtual nurses' cognitive fatigue.

In general, planned and integrated work breaks have been shown to improve the well-being and performance of bedside nurses [28-30]. Our findings support a similar workflow design for virtual nurses that incorporates brief breaks every 15 minutes or between patient sessions. The type of break and its ability to achieve its goals is more important than the frequency of breaks. Prior studies show that breaks should be designed to enable virtual nurses to detach psychologically including active rest and the use of mental health applications [31-33].

For bedside nurses, having an opportunity to rest and physically remove oneself from the work environment can facilitate psychological detachment [31]. However, different work breaks may be needed for virtual nurses as their workflow is primarily computer-based and can become repetitive. One study found that an 8-minute-long virtual reality session during work breaks reduced fatigue among nurses working in high-intensity and cognitively engaging environments [34].

Future research should examine practical work break activities and their impact on virtual nurses' fatigue, including whether different types of breaks (active vs passive) are more effective in reducing instances of fatigue. In addition, future research should use eye-tracking technology to assess the relationship between virtual nursing use and cognitive fatigue among bedside nurses. Although virtual nursing is an emerging care delivery model, there is a critical gap in knowledge around the effect of virtual nursing on organizational and nurse-level outcomes, including nurse burnout.

Limitations

This study was limited by a small sample size of four virtual nurses at one hospital. The study recordings were affected by fluctuations in the virtual nurses' shifts and virtual nurse availability, leading to some nurses having more recorded duration than others. This also resulted in recordings primarily being captured in the middle of virtual nursing work shifts. Future research should examine if instances of fatigue are varied during different times of the shift, including in the beginning and the end of the work shift. The study was limited to a single hospital using the same proficient electronic health record system. Future research should expand on both the nurse sample size as well as the number of institutions to better account for generalizability in the virtual nursing workflow. Additionally, as this study recorded encounters during the live clinical environment and for extended periods of time, eye-tracking accuracy was affected. To ensure an accurate dataset, our analysis only included eye-tracking instances where the percentage of valid pupil data was ≥10%.

To address some of the aforementioned limitations, future research should incorporate larger sample sizes, comparative analyses, and fatigue mitigation strategies to optimize virtual nurse work environments. Future work should incorporate the use of additional measures of cognitive fatigue to ensure accuracy, such as an additional eye-tracker or subjective fatigue surveys for validation. While the study examined patient acuity as a potential confounder, additional contributors to fatigue and confounders may have been unintentionally excluded. Future research should ensure that all contributing factors are addressed in both the recordings and subsequent analyses. In addition, future research should use longitudinal studies to assess the relationship between virtual nursing and virtual nurse fatigue over extended periods to determine potential long-term effects, including exhaustion and burnout. Finally, while the study team used a multifactor approach to assign patient acuity ratings given available data, future research avenues should examine

XSL•FO
RenderX

how fatigue is affected by standardized patient acuity scales, such as the Emergency Severity Index.

Conclusions

This cross-sectional study used eye-tracking methods to understand the effect of continuous screen time on virtual nurses' cognitive fatigue during virtual nursing sessions. The findings emphasize that continuous screen time in virtual nursing tasks contributes to nurses' cognitive fatigue and that specific workflow designs are required to reduce screen time–related fatigue. Health systems implementing virtual nursing should consider frequent breaks away from computer workstations to alleviate the effect of continuous screen time on virtual nurses' well-being. These breaks could incorporate instances of active rest or the use of mental health applications, which have been shown to reduce burnout and fatigue in bedside nurses and other healthcare providers. Findings from this study have direct policy implications and suggestions for more effective workflow redesign.

Acknowledgments

We sincerely thank the nurses and team at the UNC Virtual Care Center for their time and participation. We also thank the following UNC SON students for their assistance: Christiana Akinyemi, Kyndall Estep, Josh Saucedo, Alex Vo, and Linnea Week.

Abstract

Background: Dispensing errors significantly contribute to adverse drug events, resulting in substantial health care costs and patient harm. Automated pill verification technologies have been developed to aid pharmacists with medication dispensing. However, pharmacists' trust in such automated technologies remains unexplored.

Objective: This study aims to investigate pharmacists' trust in automated pill verification technology designed to support medication dispensing.

Methods: Thirty licensed pharmacists in the United States performed a web-based simulated pill verification task to determine whether an image of a filled medication bottle matched a known reference image. Participants completed a block of 100 verification trials without any help, and another block of 100 trials with the help of an imperfect artificial intelligence (AI) aid recommending acceptance or rejection of a filled medication bottle. The experiment used a mixed subjects design. The between-subjects factor was the AI aid type, with or without an AI uncertainty plot. The within-subjects factor was the four potential verification outcomes: (1) the AI rejects the incorrect drug, (2) the AI rejects the correct drug, (3) the AI approves the incorrect drug, and (4) the AI approves the correct drug. Participants' trust in the AI system was measured. Mixed model (generalized linear models) tests were conducted with 2-tailed *t* tests to compare the means between the 2 AI aid types for each verification outcome.

Results: Participants had an average trust propensity score of 72 (SD 18.08) out of 100, indicating a positive attitude toward trusting automated technologies. The introduction of an uncertainty plot to the AI aid significantly enhanced pharmacists' end trust (t_{28}=–1.854; P=.04). Trust dynamics were influenced by AI aid type and verification outcome. Specifically, pharmacists using the AI aid with the uncertainty plot had a significantly larger trust increment when the AI approved the correct drug ($t_{78.98}$=3.93; P<.001) and a significantly larger trust decrement when the AI approved the incorrect drug ($t_{2939.72}$=–4.78; P<.001). Intriguingly, the absence of the uncertainty plot led to an increase in trust when the AI correctly rejected an incorrect drug, whereas the presence of the plot resulted in a decrease in trust under the same circumstances ($t_{509.77}$=–3.96; P<.001). A pronounced "negativity bias" was observed, where the degree of trust reduction when the AI made an error exceeded the trust gain when the AI made a correct decision (z=–11.30; P<.001).

Conclusions: To the best of our knowledge, this study is the first attempt to examine pharmacists' trust in automated pill verification technology. Our findings reveal that pharmacists have a favorable disposition toward trusting automation. Moreover, providing uncertainty information about the AI's recommendation significantly boosts pharmacists' trust in AI aid, highlighting the importance of developing transparent AI systems within health care.

Introduction

Background

Pharmacists play a pivotal role in ensuring patients receive the correct medications as prescribed by health care providers. This involves a critical verification task, where pharmacists must match the medication dispensed in filled bottles with the prescription labels. Dispensing errors, defined as instances when patients receive the wrong drug or dosage, significantly contribute to preventable adverse drug events, leading to approximately 700,000 emergency department visits and 100,000 hospital admissions each year [1]. Several challenges contribute to these errors including, but not limited to, limitations in current technology; lack of standardized procedures; and the high cognitive workload imposed on pharmacy staff, who often manage numerous tasks simultaneously [1-4]. To enhance patient health outcomes, reduce unnecessary health care costs, and alleviate the burden on pharmacists, it is essential to develop and implement reliable tools that minimize the risk of dispensing errors [5].

Since the 1990s, the implementation of barcode scanning systems has been advocated as a means to reduce medication errors [6]. The adoption of such systems within pharmacies and broader health care environments has led to a notable reduction in medication errors [7-10]. Nevertheless, research indicates that barcode scanning systems are not immune to workarounds and human errors [11-13]. Moreover, these systems do not adequately address the challenges faced by overburdened pharmacists [14-17].

In response to these challenges, pill counting and verification or recognition systems using image classification technologies have emerged [18-21]. Innovations like Eyecon and VIVID use vision-based methods to count medications placed on the tray. More recently, advancements have been made in automated pill identification through feature engineering. For example, Yu et al [22] and Yu et al [23] proposed an automatic pill recognition method based on pill imprints, achieving an accuracy of 86.01% and 90.46%, respectively. Caban et al [18] used a modified shape distribution technique to determine the shape, color, and imprint of a pill to identify the drug. The proposed technique was evaluated with 568 of the most prescribed drugs in the United States and achieved a 91.13% accuracy.

The advent of deep learning has further enhanced the capabilities of automated pill recognition systems [5,24]. For instance, Larios Delgado et al [5] developed a pill recognition method using 2 deep learning models. They used a deep convolutional neural network model for pill blob detection to isolate the pill from the background and then passed the output to a deep learning–based classifier to identify the 5 most likely pills with 94% accuracy [5]. Similarly, Wong et al [25] proposed a deep convolutional network model and achieved a mean accuracy of 95.35%. Lester et al [24] trained a ResNet-18 deep learning model to predict the labeled features of a medication product using an image showing medication inside a filled prescription bottle. In a test set containing 65,274 images of 345 unique oral drug products, the overall macroaverage precision, that is, the mean of precision values for each class, was 98.5%.

Despite the impressive strides in model accuracy, realizing the potential of these technologies is only possible if people establish appropriate trust in them. Trust in automation, defined as "the attitude that an agent will help achieve an individual's goals in situations characterized by uncertainty and vulnerability" [26], is one of the most crucial factors determining the use of automation [27,28]. There is a growing body of research examining people's trust in autonomous and robotic technologies in various domains, including transportation [29-31], health care [32,33], education [34], and defense [35,36]. In addition, researchers have developed various methods to enhance people's (proper) trust in automation or autonomy [37,38], including the use of various graphical representations [37,39-42].

For example, a military perimeter defense experiment conducted by Mercado et al [43] aimed to investigate the role of intelligent agent transparency on operator trust. Participants were tasked with selecting optimal routes for unmanned vehicles, assisted by an artificial intelligence (AI) agent. The AI agent operated at three levels of transparency: (1) basic details only; (2) basic details supplemented with reasoning and rationale; and (3) comprehensive information, including basic details, reasoning, rationale, and uncertainty indication, in a text description. They observed a positive correlation between transparency levels and participant trust. They concluded that providing operators with the agent's reasoning process and uncertainty metrics fostered a deeper understanding of the system's capabilities, thereby enhancing trust and increasing usability [43]. This finding emphasizes the importance of transparent AI systems in supporting effective human-machine collaboration.

Another study investigated the impact of visual explanations on human trust in machine learning systems [40]. Participants performed leaf classifying tasks with or without visual explanations. The leaf examples were presented in 2 formats: images and feature charts. Results revealed that providing visual explanations enhanced trust and confidence in participants' decision-making. Interestingly, the feature charts were designed with intentional omissions of detailed explanations of features to prevent information overload. However, this simplification led participants to struggle to interpret the charts, and expert users expressed a need for more comprehensive feature descriptions to inform their decisions [40]. This insight reveals the importance of integrating visual explanations with a thoughtfully managed information load for appropriate human trust.

XSL•FO
RenderX

Signal detection theory (SDT) is commonly used to study trust in automation by modeling the reliability of automated systems used by human operators. SDT evaluates how AI systems distinguish signals from noise, categorizing the state of the world as either "signal present" or "signal absent." Based on SDT categorization, AI performance results in 4 outcomes: hit (error flagged correctly), miss (error not flagged), false alarm (FA; no error, but flagged incorrectly), and correct rejection (CR; no error and no flag). Correct identifications (hit and CR) increase trust, while incorrect ones (FA and miss) decrease trust [44,45]. Research indicates that FAs typically reduce trust less than misses, prompting designers to design more liberal systems (ie, more willing to flag an error) with higher rates of FAs to ensure potential issues are flagged [46-48]. In the context of pill dispensing, FAs may lead to minor disruptions, while misses could lead to dispensing errors, indicating that a more liberal AI system prioritizing safety by minimizing misses is beneficial.

Objectives

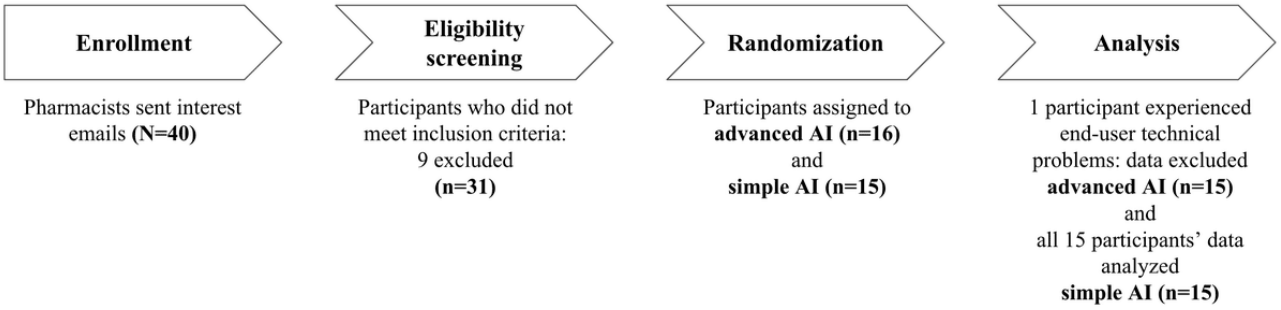
This study, therefore, aimed to explore pharmacists' trust in automated pill verification technology, which is designed to assist with the critical task of medication dispensing. Specifically, we aimed to study the role of presenting AI uncertainty information on pharmacists' trust in the system. The primary hypothesis was as follows:

- H1: Presenting AI uncertainty information of predicted probability in a visualization format will increase AI transparency, leading to enhanced pharmacists' trust in pill verification technology.

Beyond this primary focus, we also explored how pharmacists' trust behavior varied across different AI performance patterns categorized by SDT. Drawing from these arguments, we derived the following hypotheses:

- H2: Misses would result in a more significant decline in trust compared to FAs.
- H3: Furthermore, given the differing consequences associated with the 4 SDT patterns, we speculate that presenting AI uncertainty information might have varying effects depending on the specific type of patterns.

Methods



Ethical Considerations

This research was exempt from institutional review board oversight by the University of Michigan (HUM#00213493). Before participating, participants signed an electronic informed consent form, and all data were collected anonymously. Participants received US $150 upon completion of the study.

Recruitment and Participants

Recruitment emails were dispatched to pharmacists through the Minnesota Pharmacy Practice-Based Research Network and the University of Michigan College of Pharmacy Pharmacist Preceptor Network. To meet the inclusion criteria, pharmacists were required to (1) be licensed pharmacists in the United States, (2) be aged at least 18 years, and (3) have access to a laptop or desktop computer with a webcam. Pharmacists who (1) require assistive technology to use the computer; (2) wear eyeglasses with more than one power; (3) have uncorrected cataracts, intraocular implants, glaucoma, or permanently dilated pupils; and (4) have eye movement or alignment abnormalities (eg, lazy eye, strabismus, nystagmus) were excluded from participation in the study (Figure 1). A total number of 30 licensed pharmacists in the United States completed the study. Table 1 shows the demographic information.

AI Model

The AI model used in this study is a Bayesian neural network that predicts the National Drug Code (NDC), a unique identifier assigned by the Food and Drug Administration to catalog drug products in the United States [49,50]. The Bayesian neural network used a technique known as random dropout [51], applied to a ResNet-34 convolutional neural network architecture [52] to estimate the probability associated with each NDC (ie, each class). The model produced 50 different predictions, where each prediction is a probability vector that quantifies the probabilities that an input belongs to each of the NDCs. The predicted NDC was then attained by finding the highest average probability derived from the 50 predictions.

To train the AI model, we acquired a dataset of 432,974 images from a mail-order pharmacy in the United States. This pharmacy uses a robotic system that counts pills, fills and labels the bottle, captures the images of the contents, and seals the bottle with a cap. The image dataset consists of 1 year's worth of robot-captured images of oral medications, such as tablets and capsules, inside prescription bottles filled by the robotic system. Each image in the dataset is associated with an NDC label and various attributes of color, shape, size, manufacturer, tablet scoring, and imprint. The number of images available for each NDC varied, ranging from 3 to 12,105, with a median of 540 (IQR 257-1291). The medications featured in these datasets were classified into 12 different colors and 7 distinct shapes. The detailed classification is shown in Table 2.

Experimental Testbed and Stimuli

In the experiment, participants performed a pill verification task with the help of an imperfect AI aid that recommends whether to accept or reject a filled medication. The participant's task was to verify whether the filled medication matched the reference image. If the reference image and filled medication did not match, the correct action was to click "reject." If the reference image and filled medication matched, the correct action was to click "accept."

The user interface was designed following pharmacists' feedback from a focus group study conducted by the research team [50]. The interface displayed an image of a filled medication, a reference image, prescription information, and AI aids. There were 2 types of AI aids powered by the same AI model: one aid augmented with an uncertainty plot indicating the degree of certainty (or uncertainty) of the AI recommendation, and the other aid without this feature. Both AI aids recommend the action the pharmacist should take, using 4 checkboxes. A recommendation to accept was indicated when all four checkboxes turned green (Figure 2); otherwise, the recommendation was to reject. For the AI aid with the uncertainty plot, an additional histogram was integrated (Figure 3). The histogram displayed the distribution of the 50 probabilities for the predicted NDC, generated by the 50 predictions. The purpose of the histogram was to provide a visual representation of the certainty or uncertainty level associated with the AI's NDC prediction.

With the help of an AI aid, participants performed a block of 100 pill verification trials. The experimental stimuli for the 100 trials, including the reference NDC and the filled medication, were carefully selected from the dataset of 432,974 images. The selection process ensured a broad representation of colors and shapes (Table 3), while blurry images were excluded to maintain clarity. To minimize learning effects, each reference NDC was intentionally shown no more than twice throughout the experiment.

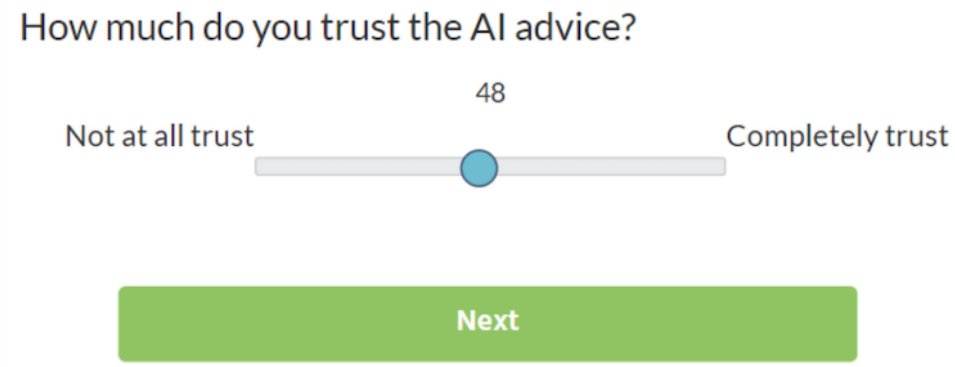
Furthermore, the AI aid was not perfect for the 100 trials, that is, it occasionally offered incorrect recommendations. Based on SDT, we mapped out the relationship between the AI's recommendation and the true state of the world [53]. In the context of this experiment, a signal in the world was an incorrectly filled medication. The extent to which the AI recommended rejecting an incorrectly filled medication reflects its ability to detect the signal. The combination of the state of the world and the AI's recommendation resulted in four potential outcomes: (1) the AI rejects the incorrect drug (hit), (2) the AI approves the incorrect drug (miss), (3) the AI rejects the correct drug (FAs), and (4) the AI approves the correct drug (CRs), as shown in Figure 4.

Figure 4. Four potential AI performance patterns according to signal detection theory. AI: artificial intelligence.



XSL•FO
RenderX

Benchmarking prior literature [54], the base rate was set to be 24%, that is, 24% of the trials contained wrongly filled medication. The AI accuracy was set as 82% to ensure that the AI would be perceived as useful while providing sufficient misses and false alarms [55]. By combining the filled image accuracy and AI accuracy, there were 60 cases of the AI approving the correct drug, 22 cases of the AI rejecting the incorrect drug, 2 cases of the AI approving the incorrect drug, and 16 cases of the AI rejecting the correct drug.

After each trial, participants received performance feedback indicating the correctness of their decision to accept or reject, as well as whether the prescription bottle was correctly or incorrectly filled (ie, "Your decision was correct. The medication was correctly filled"). Following this step, participants reported their trust in the recognition AI on a visual analog scale, with the leftmost point labeled "Not at all trust" and the rightmost point labeled "Completely trust" (Figure 5) [44,56,57].

Figure 5. Participants reported their trust in the recognition AI on a visual analog scale. AI: artificial intelligence.

Experimental Design

The experiment used a mixed subjects design. The between-subjects factor was the type of AI aid, distinguished by the presence or absence of an uncertainty plot. The within-subjects factor was the four potential outcomes: (1) the AI rejects the incorrect drug, (2) the AI rejects the correct drug, (3) the AI approves the incorrect drug, and (4) the AI approves the correct drug (Figure 4).

Half of the participants used the AI aid without the uncertainty plot, and the other half used the AI aid with the uncertainty plot. Each participant completed 2 blocks of 100 trials each. One block involved using the AI aid (either with or without the uncertainty plot), and the other block required participants to perform the task manually. The order of the 2 blocks was counterbalanced. Additionally, benchmarking prior literature [45], the trial sequence was fixed for the 100 trials in each block.

As this study is focused on the pharmacists' trust in AI, data from the manual task block were excluded from the analysis, concentrating the study's findings on interactions involving the AI aid.

Measures

Trust propensity

Before the experiment, we measured participants' trust propensity using the 6-item survey used by Merritt et al [58]. Trust propensity is "a stable, trait-like tendency to trust or not trust others" [59], and the propensity to trust machines reflects a person's tendency to trust machines in general rather than in a particular machine.

End Trust

End trust, *Trust*(*100*), is the participant's final trust rating after interacting with the AI help scenario.

Average Trust

Average trust denotes the mean of moment-to-moment trust ratings collected throughout the experiment.

Trust Change

After each trial *i*, participants reported their *Trust*(*i*) in the AI. We calculated a trust change as follows.

$$\text{Trust change } (i) = \text{Trust}(i) - \text{Trust}(i-1), \text{ where } i=2, 3, \ldots, 100.$$

Since the moment-to-moment trust was reported after each trial, 99 trust changes were obtained from each participant.

Experimental Procedure

The experiment was conducted remotely with interested participants who met the inclusion criteria. Each interested individual was phone screened to determine their eligibility. Before each experiment, participants had a brief web-based meeting with a member of the study team to ensure that the physical environment, including lighting conditions, was suitable for the experiment. Subsequently, the pharmacists were directed to Labvanced's website on their computer and presented with a 15-minute video tutorial that explained how to perform a simulated medication verification task using the testbed interface. Pharmacists were informed that the objective of the task was to determine whether an image of a filled medication

XSL•FO
RenderX

bottle matched a known reference image. The tutorial also explained the 2 AI aids.

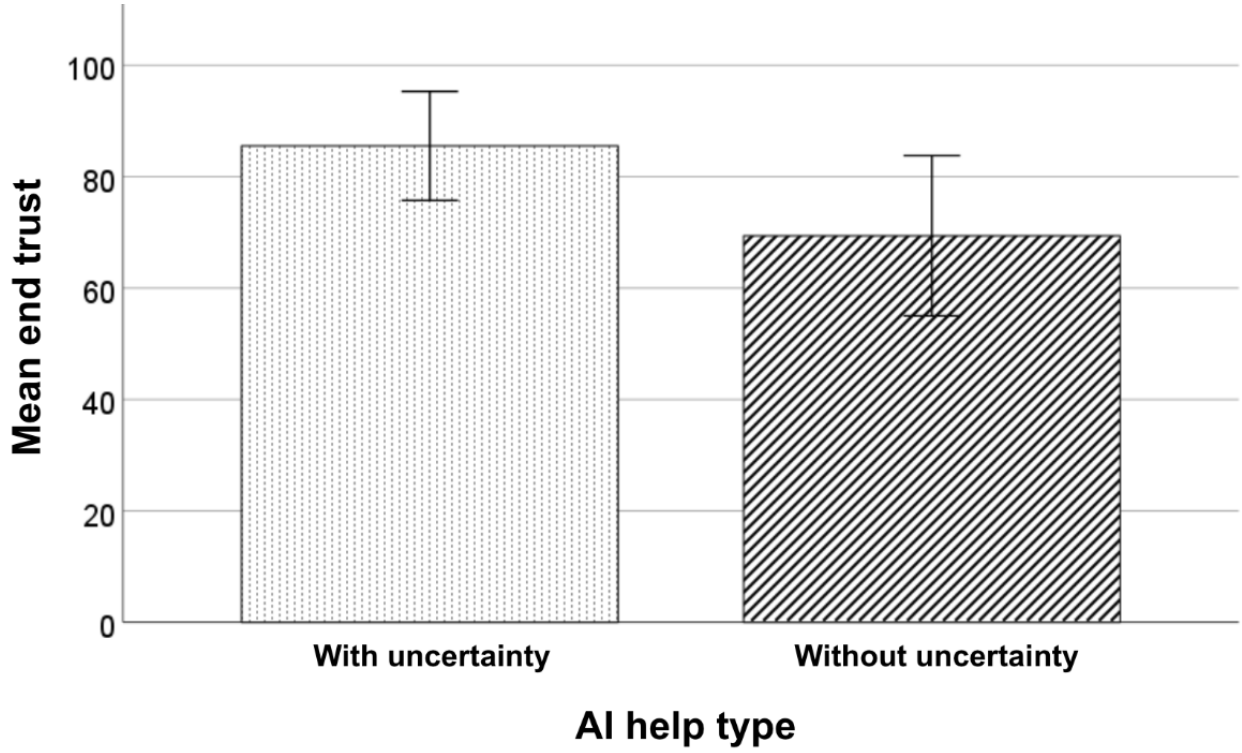
Before engaging in the verification task, participants were directed to complete a demographics survey and a trust propensity survey [58]. Additionally, they went through a set of calibration procedures for the eye-tracking software. Participants then completed a block of 100 verification trials using an AI aid—either with or without the uncertainty plot—and another block of 100 verification trials manually, conducted in a counterbalanced order. Upon completion of the 200 trials, participants filled out a postexperimental survey and answered nonmandatory free-response feedback questions. All participants finished each block within the time limit of 60 minutes.

After completing all the tasks and surveys described earlier, participants were invited to a 30-minute debriefing session with one of the study team members. Study team members described 6 concepts of automation evaluation: observability, predictability, directing attention, exploring solution space, adaptability, and calibrated trust [60], and provided an example scenario for each concept. After each description and example, the participants were asked to provide their thoughts on how the concept relates to our system.

Statistical Analysis

Participants' trust propensity, end trust, and trust change when using both types of AI aids were analyzed. First, we conducted a descriptive analysis of the participants' trust propensity. Then, to test our directional hypothesis that AI aids with uncertainty will result in higher end and average trust, we conducted a 1-tailed *t* test. Finally, we analyzed how trust increased and decreased after participants experienced each of the 4 AI performance patterns using mixed-linear models with random intercept. Regression 2-tailed *t* tests were conducted to compare the means between the 2 AI aids for each AI performance pattern. The Kenward-Roger method was used to estimate degrees of freedom. Mixed model (generalized linear models) tests were conducted using the R (version 4.2.2; R Foundation for Statistical Computing) *lme4* package [61]. All statistical significance was determined at the α=.05 level and analyses were carried out using R statistical software [62].

Results



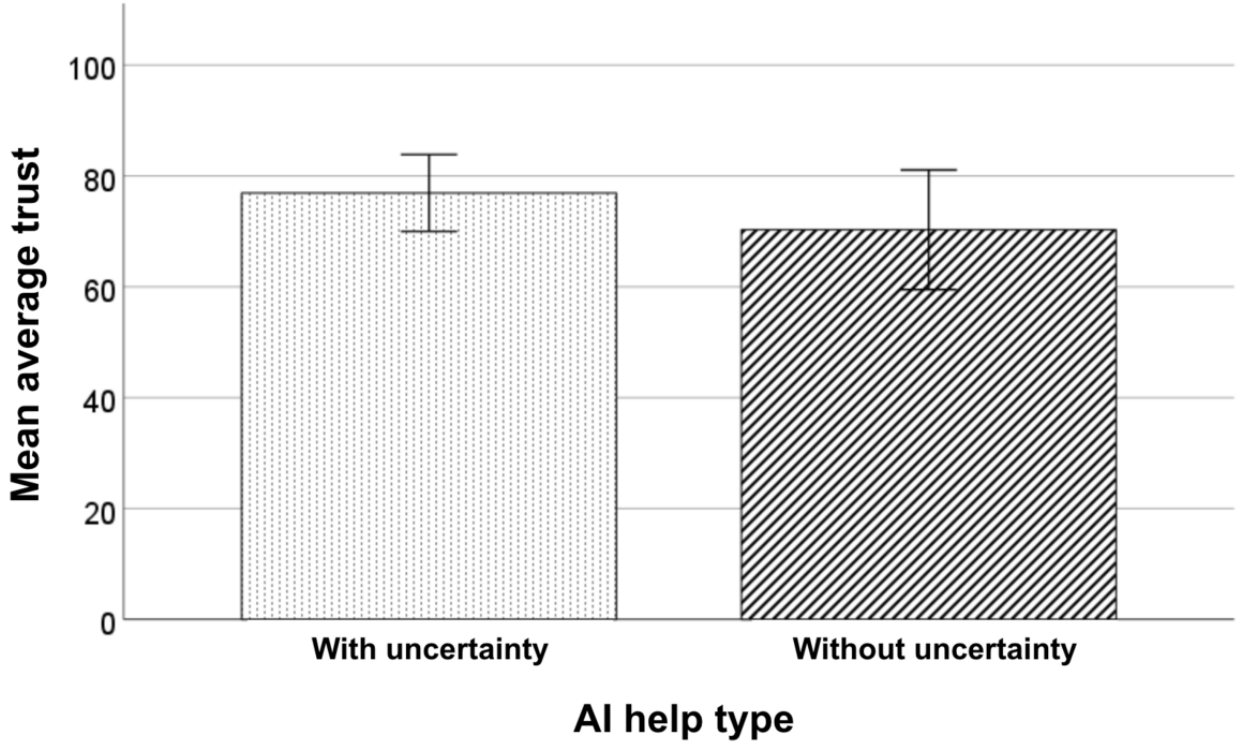
Trust Propensity

Participants had an average trust propensity score of 72 (SD 18.08) out of 100, indicating the participants generally had a positive attitude toward trusting automated technologies. There was no significant difference between the 2 AI aids (t_{28}=–0.854; *P*=.20; Cohen *d*=.312).

End Trust Toward AI Aid

The 1-tailed *t* test indicated that participants trusted the AI aid with the uncertainty plot significantly more than the AI aid without the plot at the end of the experiment (t_{28}=–1.854; *P*=.04; Cohen *d*=–.677; Figure 6).

Figure 6. Mean end trust by AI aid help type (with or without the uncertainty plot). The error bars represent a 95% CI. AI: artificial intelligence.



Average Trust Toward AI Aid

Participants showed a slightly higher average trust in the AI aid in the with-uncertainty condition (mean 76.92, SD 13.42) than in the without-uncertainty condition (mean 70.29, SD 20.88; Figure 7). However, the difference did not reach statistical significance (t_{28}=–1.036; *P*=.16; Cohen *d*=–.378).

XSL•FO
RenderX

Figure 7. Mean average trust by AI aid help type (with or without the uncertainty plot). The error bars represent a 95% CI. AI: artificial intelligence.

Trust Change

Figure 8 shows the trust change after participants experienced the 4 AI performance patterns. When the AI approved the correct drug, there was a significantly greater trust increment when participants used the AI aid with the uncertainty plot compared to the one without ($t_{78.98}$=3.93; *P*<.001; Cohen *d*=.214); When the AI approved the incorrect drug, there was a significantly greater trust decrement using the AI aid with the uncertainty plot ($t_{2939.72}$=–4.78; *P*<.001; Cohen *d*=.712). Interestingly, when the AI rejected the incorrect drug, we observed a decrement of trust for participants using the AI aid with the uncertainty plot ($t_{509.77}$=–3.96; *P*<.001; Cohen *d*=.312). When the AI rejected the correct drug, both AI help types showed a decrease in trust and there was no statistical difference between them ($t_{856.57}$=–0.68; *P*=.49; Cohen *d*=.045). Overall, participants using the AI aid with the uncertainty plot displayed a large magnitude of trust adjustment. In addition, we observed a significant "negativity bias" in that the magnitude of trust change when the AI made an error (ie, the AI approves the incorrect drug or the AI rejects the correct drug) was significantly larger than the magnitude of trust adjustment when the AI provided correct recommendations (generalized linear model test; *z*=–11.30; *P*<.001).

To examine variation in pharmacists' trust behavior across different AI performance patterns categorized by SDT, we initially combined the data from both the with and without uncertainty help scenarios. Trust decreased significantly more when the AI approved the incorrect drug compared to when the AI rejected the correct drug (t_{509}=–4.687; *P*<.001; Cohen *d*=.475). This trend was observed in the with-uncertainty AI help scenario (t_{254}=–4.91; *P*<.001; Cohen *d*=.758). However, in the without-uncertainty AI help scenario, although there was a greater trust decrease in trust when the AI approved the incorrect drug than when the AI rejected the correct drug, the difference was not statistically significant (t_{254}=–1.14; *P*=.255; Cohen *d*=.014).

As we measured participants' trust toward AI continuously, we calculated the autocorrelation between the trust ratings. Autocorrelation measures the relationship between a variable's current value and its past values in a time series. Figure 9 shows the mean autocorrelation as a function of time separation between the ratings. For both AI aids, the correlation decreased as the time separation increased. The AI aid with the uncertainty plot had a lower mean autocorrelation compared to the aid without the uncertainty plot (Figure 9).

Discussion

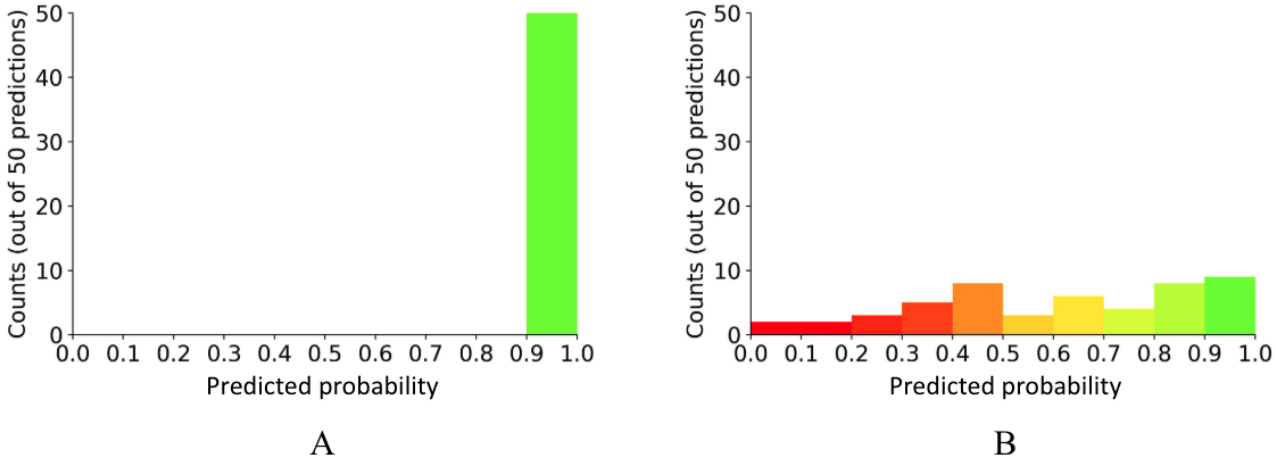
Principal Findings

This study aimed to investigate pharmacists' trust in automated pill verification technology and how the presentation of AI uncertainty information would influence them. Overall, the findings revealed that pharmacists have a favorable disposition toward trusting automation, and including the AI's uncertainty information increases pharmacists' trust in the AI recommendation *(*Figure 6*)*.

Comparison With Prior Work

The propensity to trust automation refers to an individual's general inclination to trust automated or autonomous systems, shaped by their past experiences and future expectations [58,59]. Research has shown that levels of trust propensity vary among

XSL•FO
RenderX



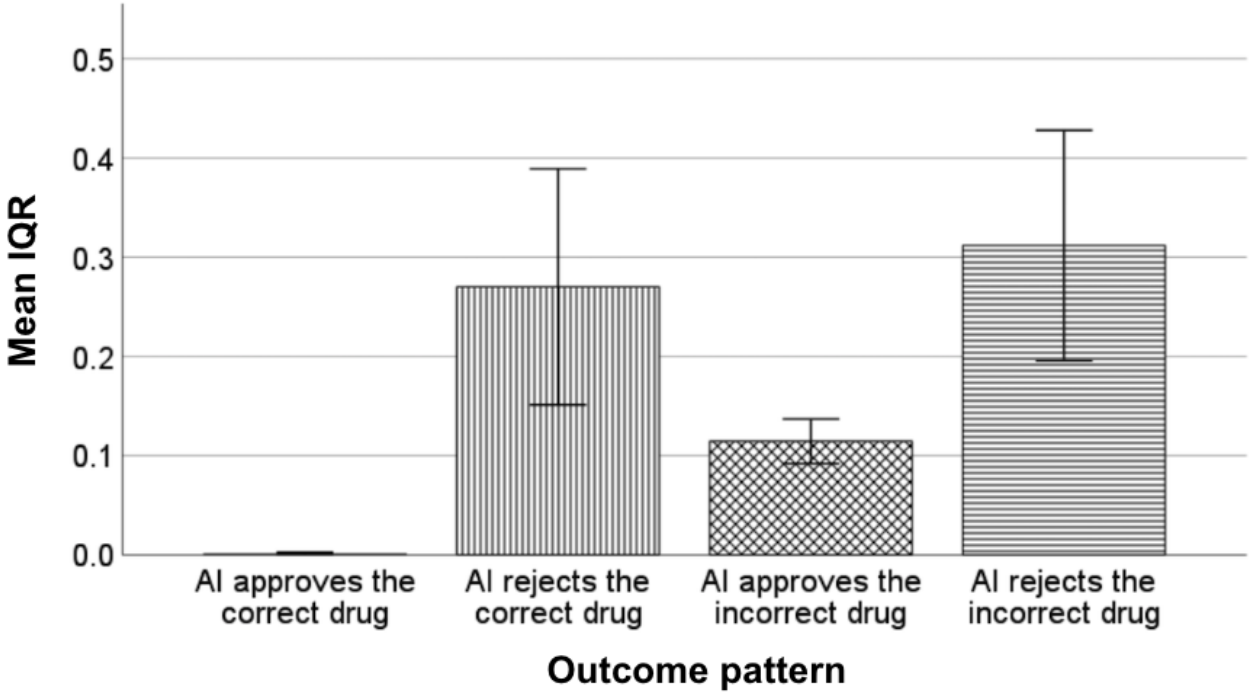
individuals. For example, an early study by Merritt et al [58], which included 69 college students (average age of 25 years), found an average trust propensity of 3.56 (SD 0.6) on a 7-point Likert scale [59]. More recently, Montag et al [63] surveyed 289 participants aged between 18 and 70 years and reported their propensity to trust automation to be 4.98 (SD 1.06) after converting to a 7-point Likert scale. Similarly, Miller et al [64] reported a trust propensity score of 4.97 (SD 1.21) from a smaller cohort of 28 participants aged between 18 to 60 years. Another investigation by Yang et al [65] with 75 adults (mean age 23.0) split into 3 groups reported trust propensity scores of 72.6 (SD 14.8), 69.4 (SD 10.4), and 69.4 (SD 14.4), equivalent to average scores of 5.08 (SD 1.89), 4.86 (SD 1.62) and 4.86 (SD 1.86) on a 7-point Likert scale.

In line with these findings [63-66], our study revealed that pharmacists generally have a favorable disposition toward trusting automation, with an average rating of 72 (SD 18.08) on a 100-point scale, or 5.03 (SD 2.09) on a 7-point Likert scale. This positive attitude may be attributed to the frequent use of automated technologies, such as barcode scanners and pill counters in their daily work [6,7]. Additionally, as expected, no significant difference was observed between the groups using different AI aids because the participants were randomly assigned to use either of the AI aids.

Examining pharmacists' end trust, our findings reveal that the AI aid with the uncertainty plot significantly enhanced the end trust scores. We attribute this enhancement to the increased transparency achieved through the presentation of a histogram showing the distribution of 50 predicted probabilities. While AI advancements promise to improve human performance, a prevailing issue is the perception of AI as a "black box." This lack of transparency contributes to a lack of trust in AI and can undermine team performance [66-68]. The higher end trust observed in participants using the AI aid with the uncertainty plot indicates that making the AI more transparent by revealing its decision-making process can foster a higher level of trust in automation. Participants 14 and 24 captured this sentiment well stating: "As soon as the uncertainty plot became red and yellow, I slowed down, which could be helpful because sometimes slowing down when there is uncertainty, just knowing there's uncertainty, is enough" (P14) and "if the uncertainty plot was all green bar and AI thought it was doing a 100% accurate job then it was easier to make my decision" (P24).

Regarding the dynamics of trust, that is, moment-to-moment trust change, when AI approved the correctly filled bottle, we noted trust increments for both AI aids. Furthermore, the inclusion of uncertainty information led to a larger increment in trust compared to when such information was absent. When the AI mistakenly approved the incorrect drug, we observed a significant trust decrement for both AI aids, potentially attributed to the adverse outcome associated with the wrong medication. Furthermore, the trust decrement was significantly larger when the uncertainty information was shown. This pronounced trust decrement could have resulted directly from the distribution of the histogram: participants were shown a histogram indicating a high level of certainty (Figure 10A). Therefore, participants may have perceived the error made by the AI aid as a "confident" error and therefore reduced their trust even more. Studies examining likelihood alarms reported that highly likely alarms (ie, "confident" alarms) engender a greater decline in momentary trust upon automation failures [57,69].

Figure 10. Uncertainty plots with (A) narrower and (B) wider IQRs. IQR is a measure of statistical dispersion, or how spread out the data points are.



Our study also offers additional validation of prior findings regarding the SDT modeling of trust [47,48]. When the AI mistakenly approved the incorrect drug (miss), a greater trust decrease appeared compared to when the AI rejected the correctly filled bottle (FA). However, the difference was statistically significant only in the with-uncertainty AI help type. This finding may provide further evidence that "confident" AI errors lead to a greater trust decrement [57,69].

Intriguingly, when the AI rejected an incorrectly filled bottle, the absence of uncertainty information resulted in an increase in trust, whereas the presence of such information led to a decrease in trust. Such contrasting results could have stemmed from the uncertainty plots influencing the participants' decision-making process. When the AI approved the correct drug, all uncertainty plots presented to participants showed a consistent solid green bar (Figure 10A). However, when the AI rejected the incorrect drug, the IQR of the uncertainty plot was broader, indicating the lack of certainty (Figure 11). A total of 16 (73%) out of 22 uncertainty plots displayed a wider spread with mixed color bars (Figure 10B). This ambiguity might

XSL•FO
RenderX

unintentionally cause the human participants to doubt the capability of the AI aid with the uncertainty plot, resulting in a decrease in their trust, as evidenced by P18's statement: "When the checkboxes were not all green and the histogram had a bunch of colors (variability), I was even less trusting of the AI tool." This perspective is also supported by P25, who noted: "When the uncertainty plot had some red, it made me double check and decreased my confidence for sure."

Figure 11. Mean IQR by outcome pattern. The error bars represent a 95% CI. AI: artificial intelligence.

Finally, when AI rejected the correctly filled bottle, trust decrements occurred, with no significant differences between the 2 AI aids. If this circumstance happened in the real world, the pharmacists would reinspect the filled prescription. It will likely lead to an increased workload, fatigue, and stress, which could potentially lead to a lower quality of work and a higher frequency of errors [70,71]. However, P21 offered a contrasting viewpoint that more flagging would be better than AI approving the incorrect, highlighting: "I didn't lose as much trust when AI rejected the correct drug. I feel like AI should be there as a cautionary tool."

The observed trends in the moment-to-moment dynamics of trust indicate a greater degree of trust adjustment when participants were assisted by the AI with the uncertainty plot. This observation is further confirmed by the autocorrelation analysis. Specifically, the trust autocorrelation plot (Figure 9) reveals a lower autocorrelation between trust ratings when the uncertainty information was presented. This suggests that current trust levels were less influenced by past trust levels, implying more significant changes in trust from moment to moment. Pharmacists relied less on previous trials and more on the information presented in the present trial, highlighting the advantages of a more transparent display.

In addition, for both AI aids, participants displayed a larger trust decrement due to incorrect automation predictions. Even though these observations may seem alarming initially, they align with the prior literature addressing negativity bias. The study suggests that failure in automation typically has a more significant negative impact on trust than a positive impact from successful automation [56,65].

Limitations and Future Directions

We acknowledge several limitations of this study and propose directions for future research. First, as a pioneering investigation in this domain, we did not strictly control the interquartile range of the uncertainty plot (Figure 11). Future investigation should systematically examine the effects of presenting different distributions within the uncertainty plot on pharmacists' trust. Exploring similar variations in the IQR among different outcome patterns could provide a deeper understanding of how outcome patterns could impact trust while avoiding potential confounding factors.

Second, the uncertainty plot used in this study displayed the distribution of only 1 (2%) out of 50 probabilities for the predicted NDC. Future research should consider incorporating additional contextual information to enhance the interpretability of these distributions. A notable challenge identified was that users unfamiliar with statistical representation found the uncertainty plot difficult to understand. P11 suggested simplifying the uncertainty presentation because "it would be a little bit too much for some people not as comfortable with statistics or technology." Nonetheless, there is potential for pharmacists to become more comfortable with these plots with prolonged use and training, as evidenced by P30's remark: "I started skeptical because it's something I'm not familiar with, but as I got more examples of it, my trust built up quickly." Consequently, researchers should continue to develop alternative visualization techniques that provide a more comprehensive and intuitive representation of the AI's uncertainty, while maintaining a low complexity to accommodate users with varying degrees of statistical proficiency.

XSL•FO
RenderX

Third, this exploratory study was limited by a small sample size, which may have impacted the statistical power of the analyses on trust propensity, end trust, and average trust. This limitation likely contributed to the lack of significance observed in some results. However, despite being underpowered, our analysis still revealed a significant difference in end trust, indicating a large effect size. Regarding trust change, to maintain the AI's perceived usefulness while still providing enough examples of both misses and FAs, we incorporated only 2 trials of the AI approving the incorrect drug (miss) and 16 trials of the AI rejecting the correct drug (FA), setting the accuracy at 82%. The statistical power to detect significant differences may have been compromised by the small sample sizes. Future research should aim to include larger participant pools to enhance the generalizability and robustness of the findings.

Finally, this study only focused on pharmacists' trust and trust change and did not include the analysis of accuracy and reaction time. Even though focusing on trust alone is an accepted practice [53], a more comprehensive analysis linking performance with trust would likely reveal the relationship between performance and trust calibration.

Conclusions

Dispensing errors are significant contributors to adverse drug events, which lead to considerable health care expenses and harm to patients. Despite progress made in developing automated technologies to aid pill verification, pharmacists' trust in these systems has not been thoroughly investigated. Our research represents an initial exploration into pharmacists' trust in automated pill verification technology, marking a significant step in understanding the integration of such systems into health care settings.

Our findings reveal that pharmacists have a favorable disposition toward trusting automation, which can likely be attributed to their frequent use of automated technologies in their daily work. Moreover, providing uncertainty information about the AI's recommendation significantly boosts pharmacists' trust in the AI aid, highlighting the importance of transparency in AI development. The dynamics of trust vary depending on the AI's performance. Pharmacists using the AI aid with the uncertainty plot had a significantly larger trust increment when the AI approved the correct drug and a significantly larger trust decrement when the AI approved the incorrect drug. Intriguingly, the absence of the uncertainty plot led to an increase in trust when the AI correctly rejected an incorrect drug, whereas the presence of the plot resulted in a decrease in trust under the same circumstances. In addition, a pronounced "negativity bias" was observed, where the degree of trust reduction when the AI made an error exceeded the trust gain when the AI made a correct decision.

Abstract

Background: Due to the rising prevalence of Alzheimer disease and related dementias, easily deployable tools to quantify risk are needed. Smartphones and smartwatches enable unobtrusive and continuous monitoring, but there is limited information regarding the feasibility, adherence, and acceptability of digital data collection among racially diverse older adults.

Objective: This paper examined the feasibility, adherence, and acceptability of a 4-week combined smartwatch monitoring and ecological momentary assessment (EMA) study in a racially diverse sample of older adults.

Methods: A total of 44 older adults (aged ≥55 y) with either mild cognitive impairment or healthy cognition completed an informed consent comprehension quiz, baseline cognitive testing, training regarding digital data collection, and questionnaires. Participants were instructed to wear a Garmin Vivosmart 4 smartwatch for 23 h/d for 4 weeks, sync 2 smartphone apps (Garmin and Labfront) daily, and complete a daily EMA survey with automated prompts for surveys and charging. Training time, smartwatch adherence (eg, wear time), daily EMA survey response rate, and performance on the consent quiz were quantified. Associations between feasibility and adherence metrics and participant factors were evaluated. Self-reported usability of the apps and smartwatch was collected at study end.

Results: Consent comprehension quiz scores were high (mean 97.33%, SD 6.86% correct), and training sessions lasted on average 17.93 (SD 6.89) minutes. During the 4-week study, participants wore the smartwatch for an average of 21 h/d (SD 1.53) and showed an average response rate of 94% (SD 9.58%) to daily EMA surveys. In unadjusted bivariate analyses, age, race, and cognition were associated with feasibility and adherence measures, but only age and race remained significant in multivariate models. After accounting for all participant factors, older age was a significant predictor of longer training time, and Black race was a significant predictor of lower daily wear time. On the usability survey, all participants (45/45, 100%) indicated willingness to participate in future smartwatch studies, >80% (37/45) had a positive experience, and >90% (41/45) were satisfied with smartphone app syncing.

Conclusions: Smartwatch monitoring, requiring daily wear, smartphone syncing, and daily EMA survey completion, is highly feasible in older adults because adherence to daily wear and EMA surveys was high, as was general satisfaction on usability surveys. Although older participants may require more training on smartwatch and smartphone procedures and automated prompting during the study period, longitudinal monitoring with the Garmin Vivosmart 4 smartwatch and Labfront app is acceptable and feasible for collecting nearly continuous data in Black and White older adults, including those with mild cognitive impairment and those without.

Introduction

Background

With the prevalence of Alzheimer disease (AD) and AD and related dementias (ADRD) increasing alongside the aging population and the availability of new treatments, there is a need to quantify risk and detect cognitive decline at the earliest stage [1]. It is estimated that only a small minority of older adults with mild cognitive decline are accurately identified early [2], missing an opportunity for early intervention. Missed or delayed diagnoses are even more common in Black and African American older adults, who are also at increased risk for AD/ADRD [3]. Personal digital devices such as smartwatches have been proposed as a potential tool for the early detection of AD/ADRD. Although recent data show that smartwatches have been increasingly adopted by older adults [4], the utility of personal digital tools for AD/ADRD monitoring is dependent upon consistent smartwatch use and syncing with associated software. This study examined the feasibility of and adherence to daily smartwatch wear and ecological momentary assessment (EMA) survey completion in a racially diverse sample of older adults enrolled in a 4-week study. We also investigated older adults' comprehension of study details that are relevant to informed consent. The participant characteristics associated with smartwatch adherence and the comprehension of consent were explored to optimize adherence and ethical research conduct in future studies.

Observable yet subtle cognitive, sensory, and motor changes precede and predict the clinical manifestations of AD/ADRD [1,5] and may be measured by sensors in commercially available smartwatches; for example, the Garmin smartwatch has been validated against conventional clinical measures of sleep [6], activity [7,8], and heart rate variability [7], which are associated with dementia risk [9-11]. The Garmin Vivosmart 4 smartwatch also has shown positive results in a 2-week feasibility study of stress in adults undergoing psychotherapy [12]. Thus, digital measures of stress, low heart rate variability, reduced physical activity, and sleep alterations have great potential as low-cost digital biomarkers for AD/ADRD that may be measured continuously, longitudinally, and passively, requiring relatively little effort.

EMA questionnaires delivered directly to participants via their personal digital devices enable high-frequency data collection in the participants' natural setting. EMA can be useful for contextualizing passive metrics [13]; for example, EMA data may facilitate the interpretation of atypical data as clinically significant or not (eg, elevated heart rate due to a cardiac event vs a day at an amusement park). EMA data also provide insight into participants' immediate perceptions and mood states without the confounds of recall bias [14]. There is potential for passive and EMA data collection via personal digital devices, but limited data exist on the feasibility and adherence of device use for health monitoring in older adults. In addition, the extent to which cognitive ability level influences adherence is not known. Adherence to daily EMA surveys and key tasks, such as wearing, charging, and syncing digital devices, is crucial for valid and reliable measurement and requires cognitive resources. This raises an important question: are those who could benefit the most from digital health monitoring more likely to show poor adherence?

Our review of the literature identified few studies on the feasibility and adherence of smartwatch use in digital health research. The results of the available studies suggest several important moderating factors, including the study procedures and participant factors. In-person studies and study designs that include interaction with a member of the study team show much higher retention and adherence than fully remote studies [15]. Adherence also varies depending on task demands, with different adherence rates for smartwatch wear versus syncing versus EMA completion. Adherence to wearable device use, which is relatively less demanding, versus the completion of daily EMA surveys has been estimated to be approximately >90% and 70%, respectively, in studies that are not fully remote [16-19].

Participant factors also play a role in retention and adherence. Although age is commonly considered a barrier to the adoption and acceptability of smartwatches due to low digital literacy [20], empirical data aggregated across several studies of smartwatch data show that older age was associated with greater retention [15]. A study requiring older adults with healthy cognition to wear a Fitbit device for 30 days during waking hours reported high rates of adherence to daily wear (89% of study days) and syncing (85% of study days) [21]. Other studies have demonstrated the effects of race, sex, and memory ability on adherence such that White participants [15], women [22], and people with better memory abilities [21] are more adherent when asked to engage in digital health research studies that involve interacting with a smartphone app.

In addition to the importance of learning about smartwatch adherence and feasibility, it is also crucial to understand older adults' comprehension of informed consent procedures for studies using novel technology. With the large amount of health data collected from a smartwatch and the need for long-term data storage, it is vital for older adult participants to fully understand data privacy and security limitations and the associated risks of study participation. Older adults also may be more wary of sharing personal health information in the context of digital health research. To assess older participants' understanding of informed consent procedures, interactive quizzes have been developed for use in fully remote studies [23]. For this study, which included face-to-face interactions with members of the study team, a 10-item comprehension quiz was modeled after a quiz used by Hackett et al [13] that was designed according to published guidelines [24,25]. The consent quiz focused on the novel technology used in the study (eg, where participants' data are stored and the right to request digital data to be deleted at any time). Hackett et al [13] reported high accuracy rates on a similar quiz in a sample of older adults and significant associations between quiz scores and education level.

XSL•FO
RenderX

Quiz scores also varied by race, with Black participants scoring lower than White participants.

Objectives

In this study, feasibility and adherence were evaluated over a 4-week monitoring period that required wearing the smartwatch daily (23 h/d), charging it, syncing apps, and completing EMA surveys. Feasibility and adherence were assessed by tracking participant retention and measuring the following: (1) time required to complete study training on syncing apps and completing EMA surveys, (2) the comprehension of informed consent information, (3) daily smartwatch wear time, (4) adherence to smartwatch daily wear, and (5) the completion of daily EMA surveys. We also investigated associations between feasibility and adherence measures and participant characteristics (demographics, cognition, and self-reported functional and cognitive decline). Finally, we explored participants' perceptions regarding the usability of the Garmin Vivosmart 4 smartwatch and the study-related apps (syncing process). To address these aims, we recruited a racially diverse sample of older adults, including those with mild cognitive impairment (MCI) and those without. It was hypothesized that older age, worse cognitive function, and greater self-reported functional decline would be associated with lower daily wear time, adherence to wear time, and survey completion, as well as lower comprehension of consent.

Methods

Participants

A total of 47 community-dwelling older adults aged ≥55 years classified as having healthy cognition or MCI were recruited from the Temple University Cognitive Neuropsychology Laboratory cohort in Philadelphia, Pennsylvania. This cohort includes >200 adults who have participated in ongoing federally funded studies since 2020 and represent the racial, ethnic, and economic diversity of the Philadelphia area. Participants met the following inclusion criteria: (1) oral and written fluency in English (to complete study questionnaires and measures) and (2) no history of large vessel stroke, Parkinson disease, major traumatic brain injury, seizures, schizophrenia, or significant neurological conditions other than dementia. The exclusion criteria included (1) current psychiatric disorder (eg, bipolar disorder or major depressive disorder), (2) intellectual disability, and (3) severe motor and sensory deficits precluding the use of a computer touchscreen. Participants from the laboratory cohort were contacted and screened for the following inclusion criteria for this study: (1) aged ≥55 years, (2) cognitive status classified as healthy or MCI, (3) current smartphone user (Android or IOS), and (4) not currently wearing a smartwatch or willing to wear only the study smartwatch during the study period. The exclusion criteria included (1) a diagnosis of dementia and (2) scheduled surgery or travel during the 4-week study period. Approximately 80 participants from the laboratory cohort were contacted as part of the recruitment efforts. The most common reasons for nonparticipation were not having a smartphone or a lack of interest in completing a month-long study.

Of the 47 participants recruited for this study, 1 (2%) was excluded because they required a walker for mobility, which precluded accurate step count recording, and 1 (2%) was excluded from the analyses of feasibility and adherence because their smartphone malfunctioned, and they required the monitoring period to be extended. Moreover, 1 (2%) of the 47 participants dropped out after 1 day, citing discomfort from the smartwatch band being too tight. Thus, of the 47 enrolled participants, 3 (6%) were excluded, resulting in a final sample of 44 (94%) participants for the feasibility and adherence analyses. The participant who extended their monitoring period because of the smartphone malfunction was retained for the usability analyses.

Ethical Considerations

This study was approved by the Temple University Institutional Review Board (Protocol Number: 29712). All participants provided written informed consent and received a US $50 gift card as compensation for their time. Data storage and procedures were Health Insurance Portability and Accountability Act–compliant and only approved study personnel had access to study data.

Procedures

Overview

Participation in the study involved 3 phases. First, participants completed an initial in-person study visit lasting 2 to 4 hours, which included comprehensive cognitive testing, training for the study, and questionnaire completion. Second, participants wore the smartwatch for 4 weeks, answered daily questions on their smartphone, and synced the smartwatch with a smartphone app once a day. Finally, all participants completed a debriefing session. More details of each study phase are provided in the following subsections. Textbox 1 shows the study timeline. The cognitive tests administered during study visit 1 are listed in Table 1.

XSL•FO
RenderX

Textbox 1. Study timeline.

Study visit 1

- Informed consent and comprehension quiz
- Installation of Garmin and Labfront apps
- Study training on syncing and daily survey
- Questionnaires and cognitive testing

4-wk monitoring period

- Participants engage in daily activities as usual
- Wear smartwatch for 23 h/d
- 9-question ecological momentary assessment survey once a day
- Sync Labfront and Garmin apps once a day to securely collect and transmit deidentified data

Study visit 2

- Uninstall apps and unpair smartwatch
- Debriefing questionnaire
- Payment of US $50

Table 1. Cognitive domains and corresponding neuropsychological measures.

Cognitive domains	Neuropsychological measures
Attention	• Trail Making Test part A [26] • Digit Span Forward [27]
Executive function	• Trail Making Test part B [26] • Digit Span Backward [27]
Language	• Letter fluency (S and P) and category fluency (animals) [28] • Boston Naming Test, 30-item version [29]
Processing speed	• Salthouse Letter Comparison Test [30] • Salthouse Pattern Comparison Test [30]
Episodic memory	• Hopkins Verbal Learning Test: immediate recall, delayed recall, and recognition trial [31] • Brief Visual Memory Test–Revised: immediate recall, delayed recall, and recognition trial [32]

Initial Study Visit

Participants completed the following during study visit 1, which lasted 2 to 4 hours: (1) informed consent and 10-item consent comprehension quiz on the specific features of the study (eg, data security and privacy; refer to Multimedia Appendix 1 for the quiz items); (2) gold standard cognitive tests (Table 1) and questionnaires; (3) installation and configuration of study apps and training on wearing a Garmin Vivosmart 4 smartwatch daily (23 h/d of wear; 1 h/d of charging time) for 4 weeks, syncing the smartwatch, and completion of a daily EMA survey. At the end of the first study session, a follow-up visit was scheduled for a date at least 4 weeks later. Further details of the procedures during the initial session are provided in the following subsections.

Smartwatch Data Collection

At the initial study visit, 2 apps (Garmin and Labfront) were downloaded onto the participant's smartphone to facilitate deidentified passive (raw sensor) and active data collection for the daily survey. The Garmin app facilitated data collection from the smartwatch sensors. The Labfront [33] app is a research platform that collects and organizes the Garmin smartwatch data and enabled the study team to monitor adherence and data collection in real time and remotely through a user-friendly study dashboard. The Labfront app was also used to deliver the daily EMA surveys.

A Garmin account was created for each participant using the Garmin Connect mobile app on their smartphone with deidentified information. The Labfront Companion app was then downloaded to the participant's smartphone. The Labfront app uses a randomized 6-digit ID to connect the participant's smartwatch to the app and to connect the Garmin and Labfront accounts. The Garmin smartwatch connects to the Garmin and Labfront apps via Bluetooth. Daily in-app Garmin and Labfront syncing required a Wi-Fi network or an LTE cellular data connection. Once the Garmin and Labfront apps were connected,

XSL•FO
RenderX

data were available for real-time download by the study team in CSV format. Daily syncing of the apps enabled the aggregation of minute-by-minute data.

Participants were asked to wear the Garmin Vivosmart 4 smartwatch for 23 h/d on their nondominant wrist for 4 weeks and to charge it for approximately 1 h/d. Alarms were set in participant smartphones twice daily at times of the participant's choosing to serve as reminders for the following: (1) charging the watch in the morning and (2) syncing the Garmin and Labfront apps and completing the daily survey on the Labfront app at night before going to sleep. To minimize the influence of external cues as well as behavior and health tracking information on participant behavior, all notifications were disabled on the study smartwatch, and additional features were removed from the Garmin app at the initial study visit.

Standardized training procedures with training criteria were used to teach participants how to charge the watch, sync the apps, and complete the daily survey. The training included demonstrations and a practice run during which participants were required to independently complete all daily study steps. Repetitions were recorded for practice runs, and the training session was timed. At the end of the training, participants were given a binder to take home and refer to during the study. The binder contained detailed instructions on how to charge the watch, sync the apps, and complete the daily survey during the study. The contents of this training binder are available in Multimedia Appendix 1.

4-Week Monitoring Period

Participants were told to go about their daily life during the 4-week monitoring period while wearing the smartwatch for 23 h/d and to charge it for 1 h/d. Sleep duration, beat-to-beat heart rate variability, and physical activity data such as step count were collected but are not reported in this paper. Participants were also asked to complete the daily EMA survey delivered to their smartphones through the Labfront app. The EMA survey included 9 questions (Multimedia Appendix 1). The purpose of the EMA survey was to guide the subsequent interpretation of smartwatch data (estimated time to complete the survey: 5 min).

During the course of the study, adherence was monitored through Labfront software by study personnel. If participants were nonadherent for >4 consecutive days, which was defined as wearing the watch for <16.67 h/d or not completing the daily surveys, they were contacted by the study team to determine the reason for nonadherence and to possibly reschedule the follow-up study session to extend the study period and obtain at least 28 days of data collection. The duration of the monitoring period (in days) was tallied for each participant. It is important to note that only 1 (2%) of the 47 enrolled participants required an extension of the monitoring period due to >4 consecutive days of missing data caused by a malfunction of their smartphone. Consequently, this participant was excluded from all feasibility and adherence analyses. For some of the participants (18/44, 41%), the monitoring extended beyond 4 weeks because the follow-up visit could not be scheduled on the study end date due to scheduling conflicts; in these cases, the follow-up visit was scheduled as soon as possible but no more than 1 week later.

Follow-Up Visit

After the study period, participants returned for a brief second visit (study visit 2) during which we collected data on their study experience, the usability of the apps and smartwatch, and barriers to future participation in wearable device research. At this visit, smartwatches were synced a final time to capture any aggregate-level data that had not been previously uploaded to the app. Subsequently, deidentified data obtained during the monitoring period were downloaded in CSV format for each participant from the Labfront researcher user interface for processing and analysis.

Measures of Participant Characteristics

Cognitive tests and questionnaires used in standard clinical evaluations for cognitive decline were administered during study visit 1.

Cognition and Clinical Classification

IQ was estimated with the Hopkins Reading Test [34]. The 5 cognitive domains and 10 cognitive tests that were administered are listed in Table 1. Scores from each of the 10 tests were standardized (T score) after adjusting for demographic variables (age, education, sex, and estimated IQ score [28]). Clinical classification (ie, healthy cognition vs MCI) was based on published criteria [35] that define MCI as T scores of ≤40 (<1 SD) on both measures from at least 1 cognitive domain. A total composite score and cognitive domain–specific composite scores were calculated by averaging demographically corrected T scores (refer to Table 1 for all neuropsychological measures). These neuropsychological tests are used widely in research and clinic settings, have been extensively validated, and show strong psychometric properties [28].

Self-Reported Cognitive and Functional Decline

The average score from the Everyday Cognition (ECog)–short form [36] was used to estimate self-reported functional decline across a range of abilities (eg, memory and language), with scores ranging from 1 (no decline over the past 10 y) to 4 (worse decline over the past 10 y). The optimal cut score for distinguishing between healthy cognition and MCI is 1.32. The original validation study estimated a Cronbach α value of 0.96 [36].

Smartwatch Feasibility and Adherence Measures

Training Time

The amount of time spent training (in minutes) during study visit 1 was recorded. Training procedures were standardized (Multimedia Appendix 1). Training began with a review of procedures for charging the watch and ended when the examiner observed that the participant independently demonstrated charging the watch, syncing the apps, and completing the daily survey.

Comprehension of Consent

Comprehension of consent was assessed using a 10-item quiz (Multimedia Appendix 1), which included questions on study-specific risks, data privacy, and security. The following is an example item: "The Garmin/Labfront apps collect the *content* of my texts and phone calls" (correct answer: no). To

XSL•FO
RenderX

ensure informed consent, if participants answered any item incorrectly, study personnel immediately provided feedback to clarify the correct response.

Smartwatch Adherence

The total number of days that participants did not wear the watch was tallied, and 2 measures were used to evaluate adherence to the instruction to wear the watch for 23 h/d. First, the average daily wear time (in hours) per participant across all possible days of wear was collected. Wear time was derived from minute-to-minute heart rate data; therefore, wear time reflects the accumulation of heart rate data from the watch. Weekly averages of wear time were also computed (weeks 1, 2, 3, and 4) to examine adherence over time.

On the basis of published recommendations [37], daily watch data were considered valid if the participant wore the smartwatch for at least 16.67 hours that day. Therefore, watch adherence also was assessed as the "percentage of valid smartwatch days" during the monitoring period, calculated as the number of days the participants wore the watch for ≥16.67 h/d divided by the total number of days they were in the study.

EMA Survey Adherence

Adherence to the daily survey was calculated as the number of daily surveys completed divided by the total number of days that each participant was in the study. This percentage ranged from 0% to 100%, with 100% indicating perfect adherence.

Usability Measures

A self-administered usability survey was completed by participants at the follow-up visit (study visit 2) to provide qualitative information on smartwatch use. The survey questions focused on the smartwatch and Labfront and Garmin smartphone apps, which were used for daily EMA surveys and syncing. Participants were also asked to report their likelihood of participating in another future study that included the smartwatch and daily surveys. This survey was administered to 45 (96%) of the 47 enrolled participants, including the participant whose monitoring period was extended.

Statistical Analyses

Descriptive statistics were used to characterize feasibility: average daily wear time, study training time, percentage correct on consent comprehension, the percentage of completed EMA surveys, the percentage of valid smartwatch days, and responses to the study debriefing questionnaire. To examine univariate associations between feasibility and adherence measures and participant characteristics, Spearman correlations and Mann-Whitney *U* tests were used for continuous and categorical variables, respectively, with Bonferroni correction applied to interpret statistical significance. Friedman rank tests for 1-way repeated measures of ANOVA were used to analyze whether wear time differed from week 1 to week 4, with Bonferroni correction applied to interpret statistical significance. Nonparametric statistical tests were used due to the skewed distributions of the variables of interest. Multiple linear regressions were conducted to examine multivariate associations between demographics (ie, age, sex, race, and education) and cognitive variables (ie, ECog, cognitive composite scores, and cognitive status) on all feasibility and adherence measures. Separate models were conducted for each cognitive variable to avoid multicollinearity. As the dependent variables were not normally distributed, we used bootstrapping (5000 replications) to estimate robust SEs and CIs for coefficients, leading to more reliable testing of significance.

All analyses were conducted using SPSS software (version 28.0; IBM Corp) or, for bootstrapped regressions only, R (version 2023.12.1+402; R Foundation for Statistical Computing).

Results

Participant Characteristics

A total of 44 older adults ranging in age from 55 to 83 years participated and were included in the feasibility and adherence analyses. On average, participants were college educated with estimated IQ scores in the high average range (Table 2). Self-report of cognitive and functional decline was well within the normal range (ECog; range 1-2.5). The cognitive composite T score ranged from 35.40 to 63.40. The sample comprised mostly women (26/44, 59%) and primarily individuals identifying as Black or African American (11/44, 25%) or White, non-Hispanic (31/44, 70%). Of the 44 participants, 8 (18%) met the Jak-Bondi criteria for MCI. The participants were relatively active, with an average of 5999.74 (SD 2872.38) steps per day. Of the 44 participants, 17 (39%) owned a smartwatch before the study, with most owning a Fitbit device (n=9, 50%) or an Apple Watch (n=9, 50%). Those who currently or previously owned a smartwatch reported the main motivations for use as activity monitoring, followed by improving fitness and improving health. Of those who had not owned a smartwatch, most (17/44, 39%) indicated that they would consider buying one after their study experience.

Percentage of completed daily surveys	94.00 (9.58)

[a]MCI: mild cognitive impairment.

[b]ECog: Everyday Cognition.

Retention Rate and Duration of Monitoring Period

A total of 47 participants were enrolled, of whom 1 (2%) dropped out after 1 day citing discomfort from the smartwatch band being too tight. All other participants (46/47, 98%) completed the study. However, 2 (4%) of these 46 participants were excluded from feasibility data analysis: 1 (50%) was excluded because their monitoring period was extended to 46 days due to a smartphone malfunction, and they did not complete the EMA survey for 1.5 weeks during the originally scheduled 28-day study; consequently, they were asked and agreed to extend their monitoring period. As a result, this participant was excluded from the analytic sample used for feasibility and adherence analyses. No other participants extended their monitoring period for reasons other than scheduling conflicts. Another participant was excluded due to mobility issues. Thus, the final analytic sample for the feasibility analyses comprised 44 participants.

The number of days monitored with the smartwatch ranged from 27 to 35. The mode for study days was 27 days,

XSL•FO
RenderX

corresponding to exactly 4 weeks because the date of the initial study visit was excluded from analyses. The average number of days in the study was 29 (SD 3.46) days. Feasibility and adherence measures were computed using all available monitoring days.

Feasibility and Adherence

Average feasibility and adherence measures are shown at the bottom of Table 2.

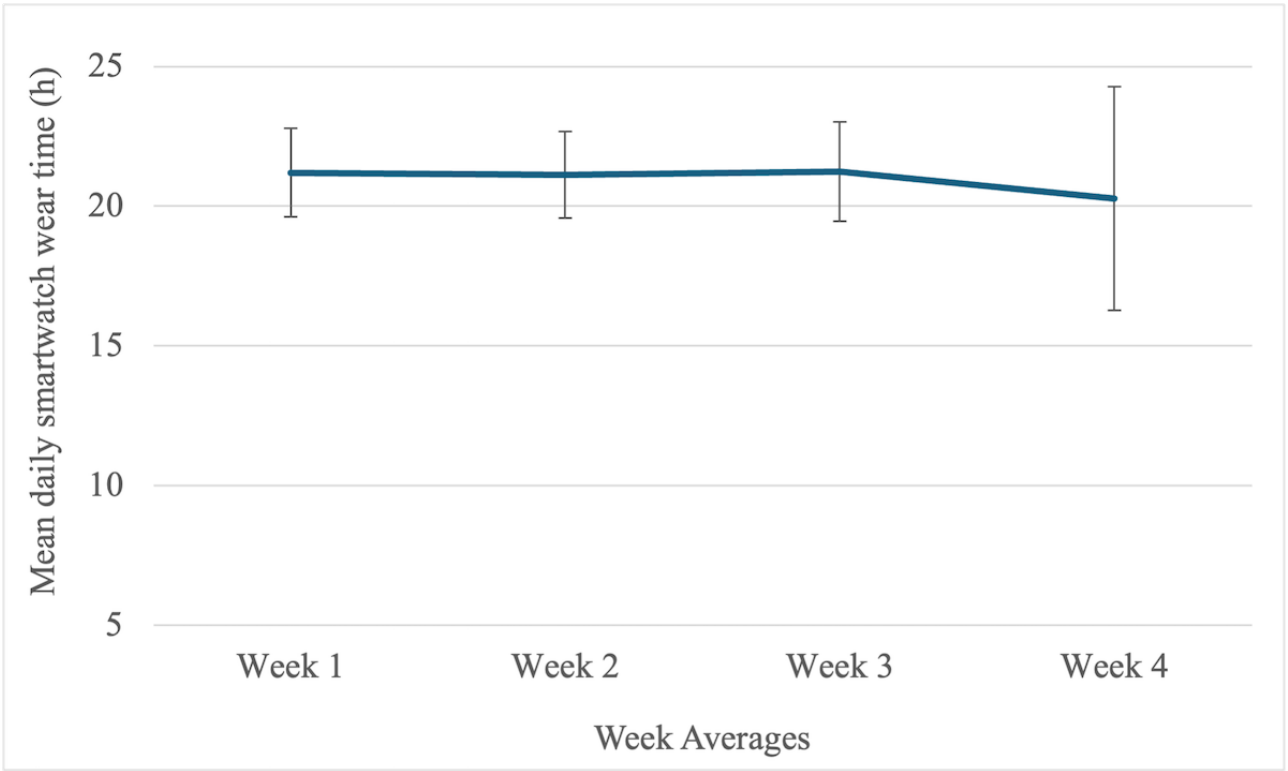
Comprehension Quiz

On average, participants obtained a score of 97% (range 70%-100%) correct on the consent comprehension quiz, approaching a perfect average score. The most frequently missed response was indicating "yes" to "Using the Garmin and Labfront apps will help improve my cognitive functioning."

Training Time

Participants took an average of 17.93 (range 12-53) minutes to complete the study training during study visit 1. Training time was mostly spent independently practicing study tasks, such as syncing apps.

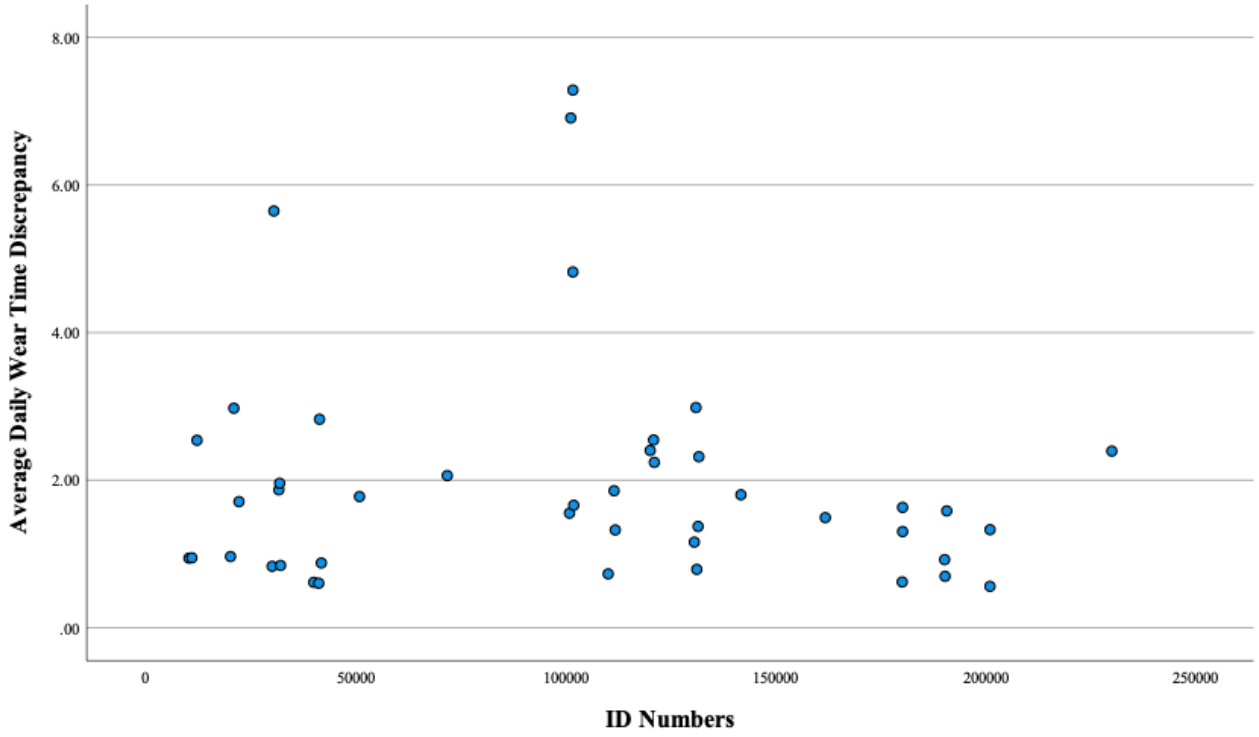
Smartwatch Adherence



Of the 44 participants, 11 (25%) did not wear the watch for at least 1 entire day (n=9, 20% missed only 1 d; n=1, 2% missed 2 d; and n=1, 2% missed 4 d). All participants wore the watch for ≥16.67 h/d for ≥14 days during the monitoring period. Of the 44 participants, 5 (11%) had ≥27 days of wear time that exceeded 16.67 h/d. On average, participants exceeded 16.67 h/d of wear time on 92% (range 53%-100%) of total study days. As the monitoring period extended beyond 4 weeks for some participants due to scheduling conflicts, watch adherence measures also were calculated over 27 days, with the average percentage of days exceeding 16.67 h/d of wear time remaining unchanged at 92% (range 55%-100%).

On average, participants wore the watch for 21 (range 15.71-22.44) h/d across the 4-week study period. Of the 44 participants, 3 (7%) had an average wear time of <18 h/d, 2 (5%) had an average wear time of <16.67 h/d, and 39 (89%) wore the watch for ≥20 h/d on average.

The distribution of average watch wear time per week is shown in Figure 1. Pairwise 2-tailed *t* tests showed no significant difference in average wear time across the 4 weeks (refer to Multimedia Appendix 1 for full results).



As shown in Figure 2, on average, 91% (40/44) of the participants wore the watch for at least 19 h/d, within 4 hours of the required 23 h/d. In fact, on average, participants on average wore the watch for 21 h/d, within 2 hours of the required 23 h/d.

Figure 1. Daily wear time across participants was averaged across weeks 1 to 4 in the study. The y-axis represents the mean daily smartwatch wear time in hours. The error bars represent –1 to +1 SD.

XSL•FO
RenderX

Figure 2. Average wear time discrepancy for the entire sample. The y-axis represents each participant's average daily wear time subtracted from the required 23 h/d. The x-axis shows participant ID numbers from the feasibility analyses. Each dot represents a participant.

EMA Survey Adherence

On average, participants completed surveys on most study days (94%; range 58%-100%). Of the 44 participants, 3 (7%) completed <70% of the surveys, while 41 (93%) completed >85% of the daily surveys.

Correlations Among Smartwatch Feasibility and Adherence Metrics

As shown in Table 3, a greater percentage of daily surveys completed was significantly associated with longer study training time, but the *P* value for this association did not survive Bonferroni correction (ie, *P*=.005 and below). Correlations between the 2 measures of smartwatch adherence and between smartwatch adherence measures and the percentage of daily surveys completed were significant and survived correction for multiple comparisons. The correlations indicated that participants who completed a higher percentage of daily surveys also wore the watch for longer durations and had more days of valid smartwatch wear time.

Associations Between Participant Characteristics and Feasibility and Adherence Metrics

As shown in Table 4, only age and self-reported cognitive and functional decline (ECog) were significantly associated with feasibility and adherence metrics. Specifically, older participants required longer study training times, and participants who reported greater cognitive and functional decline (ECog) had lower daily average wear time. However, these significant correlations did not survive Bonferroni correction (P=.003). No other correlation coefficients were statistically significant (Table 4).

[a]ECog: Everyday Cognition.

There were no significant sex differences in consent comprehension, training time, watch adherence measures, or the percentage of daily surveys completed (data reported in Multimedia Appendix 1). Participants with MCI and those with healthy cognition differed on only 1 measure (data reported in Multimedia Appendix 1): participants with MCI (median 20.64, IQR 2.74 h) had significantly lower daily wear time than participants with healthy cognition (median 21.53, IQR 1.18 h; U=71.00; P=.03). This result is consistent with the significant correlation between ECog and daily wear time reported in Table 4, suggesting an association between lower cognitive abilities and less smartwatch wear time.

Between-group analyses comparing Black and White participants were not statistically significant, except for daily wear time (data reported in Multimedia Appendix 1). Black participants (median 20.76, IQR 0.91 h) had significantly lower daily smartwatch wear time than White participants (median 21.83, IQR 1.02 h; U=74.00; P=.004).

Multivariate associations between participant characteristics and feasibility and adherence metrics were investigated using multiple regression analyses with bootstrapping to estimate the significance of the coefficients. Separate regressions were run, including one for each cognitive variable (cognitive composite scores, ECog, and cognitive status; refer to Multimedia Appendix 1 for all tables), to avoid multicollinearity. The results showed that race remained a significant predictor of daily wear time, even after controlling for age, sex, education, and measures of cognition, with White participants having longer daily wear times than Black participants. Multivariate analyses also showed that age was significantly associated with training time even after controlling for sex, education, race, and measures of cognition, with older age associated with longer study training time. By contrast, associations between the measures of cognition and feasibility and adherence metrics were not statistically significant in regression analyses, including demographic variables (age, sex, education, and race).

Usability Survey

The results of the usability survey are shown in Table 5 (Garmin smartwatch) and Table 6 (Labfront smartphone app). Overall, participants expressed favorable views of both the smartwatch and the smartphone apps and especially enjoyed their involvement in research. When asked, “Would you wear this Garmin smartwatch without being asked to wear it as part of the study?” 55% (25/45) of the sample reported “yes.” However, all participants indicated they were likely (11/45, 24%) or very likely (34/45, 76%) to participate in a future study asking them to wear a Garmin smartwatch daily. Of the 45 participants, 36 (80%) either somewhat or strongly agreed that they had a positive experience using the Garmin smartwatch during the study period (Table 5). Most of the participants (31/45, 68%) reported that the smartwatch was comfortable or very comfortable. Most of the participants (32/45, 71%) were satisfied or very satisfied with the functioning of the watch. The majority of the complaints about the smartwatch were regarding low battery life (17/45, 38%), followed by discomfort (8/45, 18%) and technical issues (8/45, 18%). Of the 45 participants, 17 (38%) reported no complaints about the smartwatch. Participants suggested the following improvements for the watch: changing wristband material (18/45, 40%), increasing

App usability and overall experience are reported in Table 6. Of the 45 participants, 41 (91%) were satisfied or very satisfied with the syncing process of both apps (Garmin and Labfront). Of the 45 participants, 35 (78%) indicated that they agreed or strongly agreed that the Labfront app was easy to use and that they felt very confident using it. Importantly, 64% (29/45) of the participants had a positive or extremely positive experience with the Labfront app. Moreover, 71% (32/45) of the participants indicated that the Labfront app was easy to use or extremely easy to use (Table 6).

Discussion

Principal Findings

Overall, the results demonstrated that our longitudinal study requiring daily wear of a smartwatch and daily EMA survey completion in a racially diverse sample of older adults was feasible with excellent adherence. Participants with cognitive impairment and those without wore a commercially available smartwatch during waking and sleep hours for 4 weeks for an average of 21 h/d and showed an average response rate of 94% to daily EMA surveys. Only 1 (2%) of the 47 enrolled participants refused to complete the study after informed consent due to discomfort with the watch fit. On the basis of the results of our consent comprehension quiz, participants had no difficulty understanding the study procedures and risks, and completed smartwatch and app training in 18 minutes on average. After consent and training, participants remained in the study for at least 28 days. Average wear time did not decline significantly over the course of the study and on average never fell below 20 h/d. Although there are no benchmark standards for indicating good smartwatch adherence, a recent systematic review of activity trackers to monitor physical activity suggested that 3 valid days of at least 10 h/d may be a good adherence threshold for a week-long study [38]. Another study defined a "valid day" as one that includes at least 16.67 hours of data or at least 600 one-minute epochs of nonzero heart rate values [37]. In our study, participants wore the study watch for >16.67 h/d on 92% of the days on average. Thus, our results exceed the recent suggestions for adherence and validity and show strong support for the feasibility and adherence of our protocol to monitor older adults.

Smartwatch feasibility and adherence metrics were associated with each other as expected, and EMA survey adherence also was related to smartwatch adherence measures. However, feasibility and adherence metrics were differentially related to participant factors, indicating the importance of measuring adherence to each feature of a smartwatch and EMA study separately. EMA survey adherence was not related to any participant characteristic and was uniformly high, possibly because participants received smartphone reminder alarms to complete the daily survey and sync the apps at predetermined times at night before bedtime. There was no comparable alert to prompt participants to wear the smartwatch during the day or night. Future studies should consider adding prompts to facilitate smartwatch adherence.

In contrast to past studies [21], we observed no associations between participant's sex or education level on any measure of adherence and feasibility in our diverse sample. Smartwatch adherence was associated with race such that White participants wore the smartwatch for more hours per day (daily wear time) than Black participants during the study period. The effect of race remained significant, even after controlling for other demographic variables, including age, education, and cognition. The reason for the race difference is unknown but may be explained by different beliefs, attitudes, or daily habits between the racial groups. As wear time is measured using the photoplethysmography sensor, which relies on the absorption of infrared light into the skin, it is possible that the measures might have been less accurate for people with darker skin tone. If replicated, cultural factors and potential sensor limitations related to skin tone, which might explain racial differences in adherence, should be systematically explored. Although Black and White participants differed in daily wear time, race did not influence the percentage of days that reached the 16.67-hour threshold for "valid" wear time. Thus, the race difference in daily wear time was small and potentially inconsequential. Furthermore, race was not associated with any other feasibility and adherence measure.

Although cognitive ability level (both self-reported cognitive decline and MCI status) was associated with daily wear time in bivariate analyses, the effect of cognition was not significant in multiple regression models. These results contrast with past research that has shown cognitive ability to be related to adherence; for example, memory ability was related to adherence in a study requiring the daily syncing of a Fitbit device in a sample of older adults without cognitive impairment [21]. Our study protocol, including training and supports during the monitoring period (eg, the take-home binder and twice daily alarms [in the morning to charge the watch and at night to sync the apps and complete the surveys]) may have helped participants with cognitive difficulties adhere to the smartwatch wear requirements and EMA survey.

Age was not associated with watch or survey adherence, which is consistent with the results from a recent smartphone digital phenotyping study [15]. However, similar to a recent study from our laboratory [13], we found that age was associated with training time such that older participants required longer training times in the laboratory to learn how to sync the study-related apps and complete the daily EMA survey on their smartphone. The training required participants to independently complete each activity (syncing apps, charging the smartwatch, and completing the EMA survey) while a member of the study team observed, answered questions, and provided feedback. On average, participants took <20 minutes to complete the training. Older participants may have taken longer to complete the training due to lower digital literacy; they may have required more practice and may have asked more questions during the training. Although the number of people aged >65 years owning smartphones in the United States has steadily increased over the past decade, digital literacy is generally lower in older adults. The longer training time and the take-home binder, which summarized the training for review during the study period, may have consequently minimized age effects on smartwatch and daily EMA survey adherence. Smartwatch studies that incorporate a "human in the loop" have been found to have higher adherence than fully remote studies [15]. Even if a study is conducted fully remotely, providing some contact with study personnel (via teleconference) or training resources (in the form of a training binder, video tutorial, website, or web-based helpline) could be quite beneficial to increasing adherence, especially for older adults with low digital literacy.

Participants generally demonstrated solid knowledge of the informed consent information, including issues related to data security and privacy that are relevant to research using wearable devices; for example, responses to the study consent quiz

XSL•FO
RenderX

showed that participants understood that the study apps were Health Insurance Portability and Accountability Act–compliant and that they had control over their data such that they had the right to delete their study data at any time. In contrast to a study on smartphone digital phenotyping that found that education and race were associated with quiz accuracy [13], percentage correct on the consent comprehension quiz was not significantly related to any of the participant demographic factors, possibly because the scores on the quiz had little variability (ie, ceiling effects). Similar to a past study [13], the most frequently incorrect question concerned the potential benefits of the study, with many participants incorrectly reporting that their participation would improve their cognitive abilities. In these cases, the comprehension quiz enabled the study team to explain that wearing the smartwatch had no clear benefit and possibly preclude participants' disappointment at the end of the study.

Smartwatch usability reports were largely very positive, with most of the participants (37/45, 82%) agreeing that they had a positive experience using the Garmin Vivosmart 4 smartwatch in the study as well as high satisfaction regarding its comfort and functioning. This is in line with past research showing that the Garmin Vivosmart was rated as the most usable and acceptable smartwatch compared to 5 other smartwatches by older adults in a small study [39]. Although participants indicated that they needed to charge the Garmin Vivosmart 4 smartwatch daily, they were generally satisfied with battery life. Regarding app usability, almost all participants were satisfied with the syncing process of the Labfront and Garmin Connect apps (42/45, 93%), felt that the Labfront app was easy to use (35/45, 78%), and reported a positive experience using the Labfront app (29/45, 64%). There are currently no other studies examining the usability and acceptability of the Labfront and Garmin Connect apps.

Regarding the usability of the smartwatch and apps, participants were generally satisfied with the smartwatch and reported that they would wear it again in another study. It is important to consider that most of the participants (44/45, 98%) reported having to charge the watch daily, and low battery life was the most frequently cited complaint about the smartwatch. Thus, in future studies, participants should be trained and prompted to charge watches and other digital devices, and they should be informed about battery limitations to preclude complaints and dissatisfaction. Multiple chargers, including portable batteries, may be offered to participants to improve usability. Despite minor complaints regarding charging, most of the participants (37/45, 82%) reported a positive experience during the study using the smartwatch. Participants also reported high satisfaction and ease of use of the Labfront and Garmin apps, which were used for daily syncing to enable sensor and EMA data to be transmitted to the research team. Taken together, our findings are generally in line with prior research showing good acceptability and usability of wearable devices in research studies involving older adults [21].

Limitations

Although our sample included older adults of different races, the sample was relatively small and highly educated. Furthermore, only 8 (18%) of the 44 participants had MCI; therefore, analyses comparing participants with MCI and those with healthy cognition were underpowered. However, cognitive effects on adherence were also examined with a composite test score and self-reports of cognitive and functional abilities (ECog). Moreover, our monitoring period was limited to a 4-week period; therefore, the conclusions may not generalize to longer periods. Importantly, our study incorporated several supports for participants such as in-person training, a take-home binder, contact with study personnel, and reminder alarms set for times specified by participants. These study features likely influenced the high adherence to smartwatch wear and EMA survey completion in our study compared to fully remote studies with little to no support from study personnel. In addition, our study's EMA survey imposed minimal demands because it was required only once daily and completed at a time preferred by participants.

Conclusions

This study demonstrated the feasibility of a combined smartwatch monitoring and daily EMA study requiring nearly 24-hour wear time daily for a month in racially diverse older adults, including those with cognitive impairment and those without. Smartwatch feasibility and adherence metrics were not significantly intercorrelated and were differentially related to participant characteristics. The inclusion of a guided training for older adult participants on study procedures as well as a take-home binder and smartphone reminder alarms to complete study steps (syncing apps, charging the smartwatch, and completing the daily EMA survey) may have contributed to strong adherence and feasibility in this study, regardless of cognitive impairment. Participants reported high satisfaction regarding the usability of both the Garmin Vivosmart 4 smartwatch and Labfront app. Overall, longitudinal monitoring using a commercially available smartwatch with a daily EMA survey is acceptable and feasible for collecting nearly continuous data in Black and White older adults, including those with cognitive impairment and those without.

Abstract

Background: In 2024, Zhejiang Province introduced a new policy offering free influenza vaccinations to individuals aged 60 years and older. However, the vaccination willingness among the newly eligible 60-69 years age group remains ambiguous in comparison to those aged 70 years and older.

Objective: This study aimed to evaluate the willingness of individuals aged ≥60 years in Zhejiang Province, China, to receive free influenza vaccines under a newly implemented policy. It further explored their sources of influenza-related health information and identified key determinants of vaccination hesitancy across age subgroups.

Methods: A cross-sectional survey was conducted using multistage convenience sampling via on-site questionnaires. Structured questionnaires were administered to 7162 eligible participants aged ≥60 years from March to May 2024. Valid responses (n=7103; response rate: 99.18%) were analyzed via logistic regression and Kruskal-Wallis tests.

Results: Overall vaccination willingness was 73.15% (5196/7103), with 11.71% (832/7103) refusal and 15.14% (1075/7103) hesitancy. Key predictors of hesitancy included male gender (odds ratio [OR] 1.27, 95% CI 1.05 - 1.54), ages 60 - 69 years (OR 1.46, 95% CI 1.06 - 2.02), corporate employment (OR 0.75, 95% CI 0.58 - 0.98), and absence of chronic diseases (OR 2.06, 95% CI 1.44 - 2.96). The 60 - 69 year age group demonstrated lower awareness of the free policy (61.9% vs 73.72% in the ≥70 years group; H=61.25, *P*<.001) but higher engagement with social media (WeChat [Tencent Holdings Limited]: H=345.44; TikTok [ByteDance Ltd]: H=294.66; *P*<.001) for health information.

Conclusions: Despite high willingness, knowledge gaps persist, particularly among adults aged 60 - 69 years. Targeted dissemination of policy information via social media platforms (eg, WeChat and TikTok) and community-driven campaigns is recommended to enhance vaccination uptake. This approach may serve as a model for regions implementing similar policies. Future studies should track actual vaccination uptake postpolicy and explore artificial intelligence–driven social media interventions to boost engagement.

KEYWORDS

influenza vaccine; vaccination willingness; older adults; health policy; China

Introduction

Influenza, a prevalent seasonal acute respiratory infectious disease, exhibits an escalating incidence rate in China [1]. The virus is characterized by its high antigenic variability and rapid transmission, resulting in annual epidemics. Globally, influenza is responsible for approximately 390,000 deaths annually, with two-thirds of these fatalities occurring among older adults [2]. In China, individuals aged ≥60 years account for 80% of the nation's influenza-associated excess respiratory mortality [3]. Within Zhejiang Province, surveillance data from 2009 to 2021 indicate 990,016 reported cases and 8 deaths, with estimated actual cases 12.11-fold higher than reported [4]. Influenza vaccination—recognized as the most cost-effective intervention for preventing respiratory infections by the Chinese Center for Disease Control and Prevention [5]—reduces disease burden, hospitalizations, and mortality in older adults [6,7]. A 2013 meta-analysis of 95 studies confirmed vaccination prevents 28% of complications, 39% of influenza-like illnesses, and 49% of confirmed cases in this demographic [8].

The influenza vaccination uptake among the older population in China has traditionally been low. For instance, during the 2011 - 2012 flu season, only 4.3% of individuals aged ≥60 years in 9 Chinese cities were vaccinated against influenza [9]. This rate further declined to 3.8% in the 2014 - 2015 flu season [10].

XSL•FO
RenderX

However, in recent years, there has been a marked increase in the vaccination rate among older adults, attributable to the Chinese government's heightened emphasis on vaccinations for older adults. This surge is particularly noticeable in the aftermath of the COVID-19 outbreak and the introduction of free influenza vaccination policies by certain local governments. In the 2020‐2021 and 2021‐2022 periods, free influenza vaccinations were offered in 195 and 226 counties and districts, respectively, leading to vaccination rates of 45.7% and 32.9% among the older populations in these regions [11]. Despite this progress, the influenza vaccination rate among older adults in China remains below the World Health Organization's target of 75%.

In China, influenza vaccines were categorized as Category II, necessitating voluntary self-funded vaccination by residents [12]. This classification contributed to the low uptake of influenza vaccination. However, with China's economic progression, policies granting free influenza vaccinations to individuals aged ≥60 years were first introduced in major cities, including Beijing, Shanghai, and Shenzhen [13-15]. Extensive research confirmed that these measures substantially elevated both the willingness and rate of influenza vaccination among older adults. As a result, the initiative extended to other regions, encompassing areas within Zhejiang and Shandong provinces [16,17]. Notably, Zhejiang Province was among the pioneers in this endeavor. Specific counties and districts, such as Taizhou and Ningbo [18,19], began offering complimentary influenza vaccinations to those aged ≥60 years from 2017, aligning with local government initiatives for public welfare. By 2020, Zhejiang had fully adopted the policy for residents aged ≥70 years [16], and by 2024, it was expanded to cover all residents aged ≥60 years in the province [20].

Several studies have examined influenza vaccination willingness in Chinese regions with similar policies. In Beijing (free for ≥60 years since 2007), willingness reached 76.61% post policy implementation [21]. Shanghai reported 80.6% willingness among adults ≥50 years [22], while Hangzhou (Zhejiang's capital) observed 85.98% uptake in the ≥70 year age group under free vaccination [16]. Lower willingness was noted in non–first-tier cities (eg, 60.7% in Chongqing [23] and 53.66% in Kaifu District, Changsha [24]). These studies consistently identified policy awareness, income level, and prior vaccination history as key determinants. However, no prior study has assessed the newly eligible 60‐69 year age group in a province-wide free vaccination program, highlighting the necessity of this investigation.

Despite the existing circumstances, the influenza vaccination rate among individuals aged ≥60 years in Zhejiang Province was a mere 21.76% [25] prior to the introduction of the universal free influenza vaccination policy for this age group. The potential impact of this policy on vaccination rates, particularly among those aged between 60 and 69 years old, remains uncertain. However, an individual's willingness to receive the flu vaccine is a critical factor influencing vaccination rates; the stronger the willingness, the higher the likelihood of actual vaccination [26,27]. Given this context, our study aims to (1) analyze the willingness to receive the influenza vaccine and its determinants among individuals aged ≥60 years in Zhejiang Province under the free vaccination policy in 2024, (2) investigate the ways from which different age groups of older individuals acquire knowledge about influenza prevention and treatment, and (3) identify the primary reasons why different age groups of older individuals are willing or unwilling to get vaccinated against influenza.

Methods

Study Setting, Sampling and Recruitment Procedure

Zhejiang was a province located in the southeastern part of China with a population of 66 million at the end of 2023. Among this population, approximately 14 million individuals were aged ≥60 years, representing about 21.5% of the total population. In addition, Zhejiang had experienced the second-largest influx of migrant workers in China and remained a significant province for this demographic group. This situation further increased the risk of infectious disease transmission among them.

The policy was announced via government portals in January 2024. After 2 months for policy dissemination, a questionnaire survey was administered from March to May 2024 to the selected participants. Inclusion criteria were as follows: (1) aged ≥60 years, (2) residents of the selected community or village, and (3) individuals who were informed about the study's content and purpose and voluntarily agreed to participate. Exclusion criteria included (1) plans to be away from the community or village for more than 3 months in the upcoming year, (2) cognitive impairments that hindered normal communication, and (3) lack of cooperation with the study and poor compliance (Multimedia Appendix 1).

Measures

The instrument was developed based on the World Health Organization flu vaccine hesitancy scales. Cognitive testing was conducted with 20 older participants in January 2024, followed by a pilot survey in 2 communities (n=200). Cronbach α improved from 0.68 to 0.765 after revising items with poor discrimination (item-total correlation <0.2).

The self-developed questionnaire was composed of 3 different parts, including sociodemographic information, knowledge on influenza prevention and treatment, and reasons for willingness or unwillingness to receive influenza vaccination (Multimedia Appendix 2).

Sex, age, ethnicity, marital status, family structure, education, occupation, income, chronic illness status, and history of influenza vaccination were included in sociodemographic information.

The section of knowledge on influenza prevention and treatment consisted of 11 items, segmented into 3 categories: basic knowledge of influenza, knowledge on preventing influenza, and understanding of influenza vaccination. The fundamental knowledge contained 7 single-choice questions. The influenza prevention knowledge had 1 multiple-choice question, while the influenza vaccination knowledge comprised 3 questions, with 2 being single-choice and 1 a multiple-choice. Each correct answer in the single-choice section was allocated 1 point, whereas a completely accurate response in the multiple-choice

XSL•FO
RenderX

section was given 2 points. Incorrect answers, whether due to overselection, underselection, incorrect selection, or omission, were not awarded any points. The maximum possible score was 13, known as the influenza prevention knowledge score. Each of the 7 items had a content validity index greater than 0.8 and the overall Cronbach α coefficient was 0.765. The Kaiser-Meyer-Olkin measure was 0.855 and the Bartlett test *P* value was less than .01, indicating adequate reliability and validity.

The section of reasons for willingness or unwillingness to receive influenza vaccination consisted of 3 questions: "How do you learn about health information?," "Why are you willing to get a flu vaccine?," and "Why haven't you received the flu vaccine?" The 3 questions mentioned above were all presented in a multiple-choice format for respondents.

The following were also taken into consideration during data collection:

- Occupation: for older respondents, if they are retired, record the occupation they were engaged in before retirement. If they are still working, record their current occupation.
- Income: personal monthly income refers to the total amount of taxable income earned by an individual within a tax month. For older respondents, sources of income include both wages (or pensions) and other types of income combined.
- Chronic diseases refer to conditions that have been definitively diagnosed by a physician, including hypertension, diabetes mellitus, hyperlipidemia, chronic obstructive pulmonary disease, bronchitis, stroke, coronary artery disease, and tumors.

Data Analysis

A database was constructed using EpiData 3.1 software (EpiData Association), with data entry executed in duplicate to ensure accuracy. Statistical analysis was performed using SAS Viya Long-Term Support 2024.03 (SAS Institute). Descriptive analysis was used to examine demographic characteristics, and the Kruskal-Wallis (H) test was used for this purpose. ANOVA (*F* test) was conducted to compare scores related to influenza prevention and treatment knowledge. Multivariate logistic regression analysis was implemented to identify factors that influence vaccination intention. A *P* value less than .05 was deemed statistically significant.

The dependent variable is influenza vaccination willingness (positive=1; hesitation=2; negative=3). The term "positive" is used to denote survey participants who explicitly stated their willingness to receive the influenza vaccine. The term "hesitation" refers to those who demonstrated hesitancy, while "negative" pertains to individuals who clearly expressed their unwillingness to receive the vaccine. The independent variables consistently included in all models are as follows: sex (male=1; female=2), age (60 - 69 years old=1; 70 - 79 years old=2; aged ≥80 years old=3), marital status (unmarried=1; married=2; unmarried or divorced or widowed=3), family structure (solitary living=1; living with spouse or children=2; living with spouse and children=3; other=4), education level (primary school or lower=1; middle school=2; high school or technical school=3; college or higher=4), occupation (agency or institutional personnel=1; medical staff=2; farmers corporate staff=3; sole proprietors=4; other=5), chronic illness status (none=1; 1 to 2=2; 3 or more=3), history of influenza vaccination (yes=1; no=2), and income (less than 2000 RMB [approximately US $281]=1; 2000 - 4999 RMB [approximately US $281-$703]=2; 5000 - 10,000 RMB [approximately US $703-$1407]=3; more than 10,000 RMB [approximately >US $1407]=4; unclear=5). All conversions from RMB to US $ are based on the average exchange rate on March 1, 2024 (US $1=7.1066 RMB).

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki. Informed consent was obtained from all participants or their guardians. Each participant received a small gift valued at 100 RMB (approximately US $14) as compensation. Surveyors recorded responses without personal identifiers; data were anonymized during electronic entry using coded IDs. The study protocol was approved by the ethics committee of the Zhejiang Provincial Center for Disease Control and Prevention (2022-016-02).

Results

Demographics and Univariate Analysis of Vaccination Willingness

In 2024, a total of 7162 individuals were surveyed, yielding 7103 valid responses, reflecting a response rate of 99.18%. The gender distribution was nearly equal, with 3566 males and 3537 females. Approximately 91.9% (6533/7103) of the participants were between the ages of 60 to 79 years, while only 8.0% (570/7103) were aged 80 years or older. Over half of the respondents (4577/7103, 64.4%) had an educational level at or below primary school, and more than 80% (5969/7103) reported an average monthly income of less than 5000 RMB (approximately US $703).

The univariate analysis results revealed that factors such as sex, age, marital status, family structure, education, occupation, income, chronic illness status, and influenza vaccination history significantly influenced respondents' willingness to receive the influenza vaccine. Of these, the most influential factor was found to be influenza vaccination history. Respondents with a history of influenza vaccination demonstrated a higher willingness to be vaccinated compared to those who had never been vaccinated (n=3572, 86.7% vs n=1624, 54.5%) against influenza. Age was identified as the second most influential factor. Respondents aged 70 - 79 years expressed the highest willingness to receive the vaccine (n=2389, 78.1%), while those aged 60 - 69 years showed the least willingness (n=2371, 68.3%). Medical staff showed the highest willingness to be vaccinated compared to other occupational groups (n=176, 81.9%). Furthermore, respondents with chronic diseases were more likely to express a willingness to receive the influenza vaccine, although they also had a higher proportion of unwillingness to be vaccinated (Table S1 in Multimedia Appendix 3).

XSL•FO
RenderX

Multivariate Analysis of Vaccination Willingness

A multivariate logistic regression analysis was performed, using the willingness to receive the influenza vaccine as the dependent variable and indicators that demonstrated statistically significant differences in univariate analysis as independent variables. The findings revealed that the 60 - 69 year age group, medical staff, individuals with chronic illnesses, and those who had a history of influenza vaccination were all contributing factors to the willingness to receive the influenza vaccine. Notably, residents with a history of influenza vaccination were 7.82 times more likely to express willingness to receive the influenza vaccine compared to those without such a history (odds ratio [OR] 7.82, 95% CI 6.52 - 9.39; $P<.001$) (Table 1).

Comparison of Influenza Prevention and Treatment Knowledge Scores

The results showed that the scores for influenza prevention and treatment knowledge among respondents aged 60 - 69 years was 6.5 (SD 3.19); among those aged 70 - 79 years, it was 6.1 (SD 3.24), and among those aged ≥80 years, it was 5.2 (SD 3.37). There was a statistically significant difference in the scores of influenza prevention and treatment knowledge among different age groups (F_2=45.55, *P*<.001), with older age groups having lower scores.

XSL•FO
RenderX

Access to Health Information

The findings indicated that television, doctors, and family members were the main ways of obtaining health knowledge. Compared to the 70 - 79 and ≥80 year groups, individuals in the 60 - 69 year age group exhibited a higher propensity for leveraging new media platforms such as WeChat (Tencent Holdings Limited; H=345.44, *P*<.001) and TikTok (ByteDance Ltd; H=294.66, *P*<.001) as primary ways for acquiring health information. Despite high social media use (WeChat: n=1366, 39.34%), the 60 - 69 year group's policy awareness showed no correlation with platform engagement (*r*=0.04, *P*=.11), suggesting ineffective information diffusion (Table S4 in Multimedia Appendix 4).

Reasons for Willingness to Receive Influenza Vaccination

A questionnaire survey was conducted among respondents who were willing to receive the influenza vaccine. The findings indicated that the predominant reason influencing participants' willingness to receive the influenza vaccine was "awareness of the free vaccine policy." Awareness of the free policy was 70.16% (2013/2869) overall but significantly lower in those aged 60 - 69 years (n=867, 61.9% vs n=2002, 73.72% in ≥70 year group; *P*<.001). In addition, statistically significant differences among different age groups were noted for the reasons "active promotion by the community" (H=6.740, *P*=.03) and "awareness of the advantages of getting vaccinated" (H=33.125, *P*<.001). No other reasons demonstrated a statistically significant difference (Table S5 in Multimedia Appendix 5).

Reasons for Unwillingness to Receive Influenza Vaccination

The results indicated that "concerns about the necessity of vaccination," "not previously acknowledged or recognized," and "concerns about the effectiveness of vaccines" were the 3 primary reasons for respondents not willing to receive the influenza vaccine. These reasons did not show any statistically significant differences among different age groups. In comparison, respondents in the ≥80 year group were more concerned about the safety of the vaccine (H=10.96, *P*=.004). Those in the 70 - 79 year age group were more likely to refuse the vaccine due to contraindications (H=28.40, *P*<.001), while those in the 60 - 69 year age group were more concerned about the burden of vaccination (H=6.96, *P*=.03) (Table S6 in Multimedia Appendix 6).

Discussion

Principal Findings

This study indicated that the willingness to receive the influenza vaccine among residents aged ≥60 years in Zhejiang Province was 73.15%, which was lower than the vaccination willingness rates among the older population in first-tier Chinese cities such as Beijing and Shanghai [21,22]. It was also lower than that of Hangzhou, the capital city of Zhejiang Province, but higher than that of other non–first-tier cities in China [23,24], as well as higher than similar survey results from countries such as the United States and Italy [28,29]. On one hand, after 3 years of the COVID-19 pandemic, China had unprecedentedly intensified its publicity efforts on respiratory infectious disease prevention, significantly improving residents' knowledge, attitudes, and behaviors regarding respiratory infectious disease control [30]. On the other hand, the economic burden of influenza vaccination affected residents' willingness to get vaccinated, especially for low-income middle-aged and older individuals. Whether the vaccine was free played a crucial role in their decision to get vaccinated [31].

This study found that older individuals who were female, aged ≥70 years, had a history of influenza vaccination, and had chronic diseases were more willing to receive the flu vaccine. This finding was consistent with some domestic studies [32,33]. The history of influenza vaccination was the most significant factor influencing the willingness to vaccinate among the older adults [26,34,35]. The willingness to vaccinate among the older adults who had previously received the influenza vaccine was 7.823 times higher than that of those who had not. Prior recipients may perceive reduced infection severity, but causality between vaccination history and economic burden relief remains unproven. Age was another important factor. Compared to those aged ≥70 years, the willingness to receive the vaccine was lowest among those aged 60 - 69 years, who also had the highest proportion of hesitation responses. The primary reason was likely due to the recent implementation of a free influenza vaccination policy for this age group in Zhejiang Province, which many were still unaware of. The free vaccination policy was one of the most crucial factors driving vaccination rates, especially among low-income older populations [36]. When examining reasons for willingness to vaccinate, it was found that the proportion of those aware of the free vaccine policy in the 60 - 69 year age group was significantly lower than in other age groups, further explaining their lower vaccination willingness. However, encouragingly, the 60 - 69 year age group had a higher acceptance of the influenza vaccine and better recognized its benefits.

To assess knowledge levels about influenza prevention and treatment across different age groups, an 11-question questionnaire was designed. Analysis showed that the 60 - 69 year age group scored highest on the knowledge assessment, yet they had the lowest willingness to vaccinate, contradicting previous study in Hangzhou [16]. This discrepancy might be attributed to the limited number of questions in their questionnaire (consisting of merely 5 questions), which could introduce randomness. To ensure the questionnaire's accuracy and reliability, it was repeatedly revised until both its reliability and validity were satisfactory. Another analysis revealed that despite higher educational levels, better mental health, and stronger memory among the 60 - 69 year age group, their unfamiliarity with the newly introduced free vaccination policy contributed to their lower vaccination willingness compared to those aged ≥70 years.

This study found that television, medical staff, and family members are the main ways for older adults to obtain health information. In China, traditional media such as television remains the primary source of health information for older adults [16]. Despite this, their trust in doctors is higher [37]. It is recommended that medical staff should be encouraged to

XSL•FO
RenderX

strengthen the promotion of influenza vaccine policy and related prevention knowledge among older adults, in order to better help them establish a positive willingness to get vaccinated against the flu and thus make the decision to receive the influenza vaccine. What is different is that compared to those aged ≥70 years, the 60 - 69 year age group more often obtains health information through television, while the ≥80 year age group more often relies on family members for health information. Therefore, for the newly implemented policy in Zhejiang Province of free influenza vaccination for those aged 60 - 69 years, it is advisable to promote this policy to the older adults through local mainstream television media. This would not only increase the coverage of the promotion but also enhance its authority and credibility. It is worth noting that with the widespread proliferation of the internet in China, new media represented by WeChat and TikTok have risen strongly. According to statistics, from 2010 to 2020, over a 10-year period, the number of internet users aged ≥60 years increased from 8.67 million to 60.54 million, with the proportion of older internet users in the older population increasing from 4.9% to 23.8% [38]. Compared to those aged ≥70 years, the 60 - 69 year age group is far more active on WeChat or TikTok every day. This also suggests that for the 60 - 69 year age group, the way of obtaining health information is gradually changing, and new media is playing an increasingly important role.

From the analysis of reasons for willingness to receive influenza vaccination, apart from "awareness of the free vaccine policy," "active promotion by the community" also plays a crucial role in encouraging older individuals to get vaccinated. Compared to those aged ≥70 years, individuals in the 60 - 69 year age group are more likely to believe that receiving the influenza vaccine can benefit their health. They also pay more attention to the necessity of getting vaccinated [39]. On the other hand, those aged ≥70 years are more concerned about the safety of the influenza vaccine [40]. This highlights the importance of enhancing community promotion of the free influenza vaccination policy, as well as disseminating information about the necessity and safety of the influenza vaccine, to increase the willingness to vaccinate among older adults, particularly those in the 60 - 69 year age group. Future implementation research should examine digital outreach efficacy through platforms such as TikTok or WeChat, particularly in low-resource settings.

This study has some limitations. First, the sampling method used in this study was a multistage convenience sampling approach to obtain respondents. The selection process favors individuals more likely to be accessible or compliant, skewing the results toward higher vaccination willingness. Second, the investigators were generally doctors from local hospitals or community health service centers (township health clinics), who were relatively familiar with the respondents. During the survey process, respondents might tend to provide more positive responses, which could potentially overestimate their willingness to receive influenza vaccination. Third, some questions were answered based on recall alone, such as influenza vaccination history and chronic illness status, which might lead to recall bias. Finally, the cross-sectional survey method used in this study might affect the generalizability of the results.

Conclusions

Targeted dissemination via social media (eg, TikTok or WeChat) for the 60 - 69 year age group and community-driven policy education are critical next steps. This approach may serve as a model for regions implementing similar policies. Future studies should track actual vaccination uptake and test artificial intelligence–optimized messaging through digital platforms.

Acknowledgments

We thank all residents who participated in the implementation of this project. We also thank the staff from the survey sites for their field investigation and colleagues in the Institute of Immunization Program, Zhejiang Center for Disease Control and Prevention for their technical support. This work is supported by the Chinese National Sci-Tech Plan Project and the Zhejiang Provincial Government.

Generative artificial intelligence was not used for any part of the article.

Data Availability

The dataset generated from this research has undergone anonymization and is available for scholarly purposes from the corresponding author on reasonable request. Nevertheless, it is imperative to acknowledge that data dissemination is subject to constraints imposed by the Ethics Committee of the Zhejiang Provincial Center for Disease Control and Prevention, which restricts extensive public distribution. Furthermore, the participant consent procured does not encompass unrestricted public sharing of the dataset.

Authors' Contributions

LW, JX and XZ conceived and designed the study; YZ, YX, and XY collected the data; YZ, XY, and SR analyzed and interpreted the data; and LW, JX and XZ helped draft, read, and approve the final manuscript.

Abstract

Background: In blended care, digital mental health interventions (DMHIs) integrate with face-to-face psychotherapy provided in person or via telehealth. To incorporate DMHIs into routine care for depression and anxiety, it is important to understand the needs and expectations of mental health professionals for blended DMHIs.

Objective: The study objective was to partner with Australian mental health professionals in the design of a transdiagnostic, cognitive behavioral therapy–based blended model of care for adults experiencing depression and anxiety.

Methods: Participants were Australian health professionals who treat adults with depression and anxiety. The participatory design process included a web-based survey (N=258), one-on-one interviews (N=14), and a 2-part focus group (N=6). Quantitative and qualitative data were collected through the web-based survey. In-depth qualitative feedback from interviews and the 2-part focus group was subjected to reflexive thematic analysis.

Results: Mental health professionals found blended care with face-to-face therapy more acceptable than telehealth and blended care with telehealth, with standalone DMHIs being the least preferred option. The most common ways in which mental health professionals thought a DMHI could integrate with face-to-face psychotherapy included homework completion (129/178, 72.5%), skills practice to support in-session therapy (128/178, 71.9%), and psychoeducation (127/178, 71.3%). Mental health professionals expect the blended DMHI to be easy to use, flexible, protective of client data, and to include evidence-based content from several therapeutic modalities (eg, cognitive behavioral therapy and mindfulness). Other preferences included mental health professionals being able to prescribe specific program modules to their clients, track the treatment progress of clients, and receive alerts if their clients' symptoms worsened. In terms of implementation, mental health professionals were concerned about the time and effort needed to use blended care. They suggested that ongoing training and support would help mental health professionals implement blended care with their clients. Monitoring client risk and progress via a web-based dashboard and downloadable summaries was also important.

Conclusions: Designing DMHIs that support psychotherapy for adults with depression and anxiety has the potential to increase access to evidence-based treatment. Involving mental health professionals in DMHI design is expected to increase their acceptance of DMHIs and facilitate the integration of these digital products into routine care.

Introduction

Background

The global impact of mental disorders continues to grow annually, with significant health, social, and economic consequences [1,2]. Shortages in the mental health workforce and funding for services also impact access to evidence-based care worldwide [3]. Depression and anxiety are two of the most prevalent mental disorders globally, and psychotherapies are currently recommended as first-line treatments for both disorders, either alone or in combination with pharmacotherapies [4,5]. Cognitive behavioral therapy (CBT) has the strongest evidence base for reducing depressive and anxious symptoms, with recent research confirming moderate to large effects on depressive disorders across more than 400 randomized controlled trials (RCTs) [6] and large effects on anxiety symptoms across 66 RCTs [7]. Transdiagnostic psychotherapies are effective for depression and anxiety and are increasingly favored by the clinical community, as these psychotherapies target the shared symptoms, causes, and maintaining factors of co-occurring disorders, such as depression and anxiety [8-11].

Digital Mental Health Interventions

Unfortunately, most adults who meet diagnostic criteria for depression and anxiety do not access treatment [12,13]. Digital mental health interventions (DMHIs) help to overcome several barriers to accessing treatment (eg, waiting lists, high out-of-pocket costs, and lack of access to skilled mental health practitioners) [3,14]. DMHIs typically include psychotherapy-based content and may be especially beneficial for people who cannot access psychotherapy delivered by a mental health professional. Originally, DMHIs were delivered by computer (eg, CD-ROM) [15,16], but they have now evolved to the point where DMHIs can include artificial intelligence [17]. Today, DMHIs primarily consist of mobile apps and internet-based programs delivered on digital devices, such as smartphones, tablets, laptops, and desktop computers. Self-guided DMHIs enable individuals to self-manage depressive and anxious symptoms with evidence-based skills (eg, CBT) via automated, self-paced modules. Guided DMHIs work similarly but are used with remote support from a health care professional or a paraprofessional, such as a trained coach. Several meta-analyses [16] show that self-guided and guided DMHIs, particularly internet CBT-based programs, significantly improve symptoms of depression (83 studies; Hedge g=0.52, 95% CI 0.43 - 0.60 [15]) and anxiety (47 studies, Hedge g=0.80, 95% CI 0.68 - 0.93) [18]. Early evidence suggests that mobile DMHIs could also be used to effectively treat depression and anxiety, albeit with smaller effect sizes than digital CBT delivered via the internet or computer software [19].

Despite decades of research evidence, the uptake of DMHIs into practice is limited due to high dropout rates and poor user engagement of clients, especially in self-guided formats [20,21]. Acceptance of DMHIs by mental health professionals is another important factor influencing their inclusion in routine clinical care, as health professional endorsement can impact whether a client is willing to use a DMHI [20] and if DMHIs are considered a suitable option for referral [22]. Issues that impact DMHI acceptability by mental health professionals include concerns about program credibility [23,24], DMHI accessibility for people with digital, writing, or reading difficulties [22,25], and the appropriateness of DMHIs for people with severe mental health difficulties [26,27]. Moreover, safety concerns about DMHIs are linked to low acceptability and a reduced likelihood that health professionals will incorporate these products into routine practice [14,26,27]. For example, a qualitative study with Australian psychologists (N=10) [26] found that they preferred face-to-face psychotherapy over standalone DMHIs and were concerned that DMHIs increased the risk of severe symptoms being missed (eg, suicidality) and lacked personalization and human connection, especially self-guided DMHIs.

Combining DMHIs with face-to-face psychotherapy (blended care) can address the limitations that affect DMHI acceptability when integrated into routine clinical care [23,25,26]. Blended care extends upon guided DMHIs by using the DMHI to facilitate in-person or telehealth assessment and treatment led by a mental health professional. The DMHI may be combined with psychotherapy within a treatment plan or supplement psychotherapy as an adjunct, either in-session or between sessions. Much of the existing research on blended care has focused on models of care that support mental health professionals who deliver psychotherapy, such as therapists and psychologists. Blended care can be defined or implemented in several ways; however, one commonality between blended approaches is using DMHIs to enhance psychotherapy and ensure that DMHIs are used as effectively as possible. Examples include reinforcing psychoeducation, symptom tracking, or helping clients to practice skills learned in face-to-face therapy sessions. Findings from Germany, the Netherlands, and Denmark indicate that blended care was acceptable to CBT-based therapists and psychologists before and during the COVID-19 pandemic [28-31]. Research conducted before the COVID-19 pandemic also found that blended care is more acceptable to health professionals and care providers than standalone internet treatment for depression across all levels of severity [32].

Evidence for Blended Care

To date, most research on blended care, especially for depression, was conducted in Europe before the COVID-19 pandemic. Blended care has been tested in several RCTs and pilot trials across Europe in high-income countries, such as Germany, Denmark, Sweden, and the Netherlands, with promising results [25,33-37]. European research also shows that local mental health professionals value blended DMHIs that are flexible to use [38,39], can be customized to suit client needs [28,31,40], and help clients with symptom tracking and homework completion between therapy sessions [28,38]. Adequate training and minimizing the time burden of DMHI use with clients is also important to European mental health

XSL•FO
RenderX

professionals [28,31,38-40]. The European research suggests that blended care is scalable and could enhance mental health professionals' acceptance of DMHI use in routine care, as well as improve client engagement by increasing DMHI uptake and adherence. However, both before and during the COVID-19 pandemic, mixed results were found for blended RCTs outside of Europe in other high-income countries, such as the United States, Japan, and Australia [25,33,41-43]. There is a need to investigate whether the European findings generalize to blended care in non-European countries.

Access to mental health treatment varies worldwide [3], and, by extension, a blended care approach must be tailored to the specific mental health system of a country to function optimally. In the case of Australia, most people with depression and anxiety are provided a mental health treatment plan by their general practitioner, who then refers the person to other health professionals as needed [44]. An Australian with depression or anxiety may receive support from psychiatrists, social workers, or occupational therapists; however, psychotherapy is usually delivered by a psychologist in the private mental health system, with government payments providing partial rebates for up to 10 therapy sessions per calendar year [44,45]. Australian psychologists also currently prioritize CBT due to this therapy being recommended as first-line treatment for depression and anxiety [4,5]. In principle, blended care could work in Australia, as several research studies show the combination of DMHIs with psychotherapy sessions or health professional support may improve symptoms of depression [46-48], anxiety [48], panic disorder [49,50], comorbid depression and alcohol use [51], and hoarding disorder [52]. However, several of these studies have small sample sizes [46,48,52] or no control group for the condition that includes a DMHI combined with psychotherapy or health professional support [47,49,50].

Participatory approaches, including co-design, involve partnering with the intended target audience during the creation of interventions to identify potential issues early and ensure the intervention design reflects their preferences [53,54]. This type of research has been extensively used in DMHI research [54]; however, to date, only 1 participatory [39] design study from Germany has examined the needs and expectations of mental health professionals for blended care using participatory principles. Behr and colleagues [39] consulted with psychotherapists and people with lived experience of mental illness during the COVID-19 pandemic to design a transdiagnostic and transtheoretical internet-based DMHI for blended care. Many of the preferences expressed by psychotherapists aligned with other European blended care studies. However, Behr and colleagues [39] also found that psychotherapists wanted the blended DMHI to protect client data and privacy, contain scientifically sound content, and facilitate the therapeutic relationship with clients. More participatory research on blended care is needed to (1) optimize how the DMHI is deployed to support psychotherapy and (2) ensure the blended care model is adapted to the specific country's mental health system.

Rationale, Objectives, and Aims

Prior research on blended care may have used DMHIs that were not designed to support psychotherapy (ie, they are self-guided and do not integrate with psychotherapy). This puts increased pressure on mental health professionals, and the example of Behr and colleagues [39], along with other European research on blended care [38,40], shows that participatory research is needed to ensure that blended DMHIs align with the preferences of mental health professionals and integrate into existing treatment pathways. Moreover, differences between mental health treatment systems could have contributed to mixed results in blended care trials conducted outside Europe [25,33,41-43]. In addition, even in a high-income country like Australia, there is an estimated 32% shortfall in the mental health workforce [55], further highlighting the need to adapt blended care models to specific mental health systems. This study is part of a larger project to create a transdiagnostic DMHI for Australians with depression and anxiety that could be used self-guided or integrated into routine clinical care. Because most Australians with depression and anxiety are treated in the private mental health system [44], it is currently unknown (1) if blended care would be acceptable to Australian mental health professionals, (2) what their preferences for blended care are, and (3) if blended care would work with the current government reimbursement model for psychotherapy sessions.

To our knowledge, this will be the first Australian study to use participatory design principles to design a new CBT-based blended care model for depression and anxiety with mental health professional input. Phase 1 involves 2 multistage participatory design studies that include web-based surveys, qualitative interviews, and a 2-part focus group with mental health professionals and Australian adults with lived and living experiences of depression and anxiety. Results from the participatory design study with people with lived experience are reported separately in Part 1 of this manuscript series [56]. For mental health professionals, our main aim was to determine their needs and expectations for a DMHI to be used with their clients in blended care. The present findings will inform the creation of a DMHI that addresses clients' needs [56], is acceptable to mental health professionals, and can be integrated into routine treatment for depression and anxiety as part of a CBT-based blended model of care. A secondary aim was to identify factors affecting the training, support, and resources that mental health professionals would need to implement the DMHI into their clinical practice.

Methods

Participatory Design Approach

A mixed methods convergent parallel design [57] was used, which included a web-based survey, qualitative interviews, and a 2-part focus group with a convenience sample of mental health professionals. Throughout data collection, participants were encouraged to discuss any DMHIs they used in practice, not just those created by the Black Dog Institute. Stage 1 involved a web-based survey designed to capture the perspectives of a diverse range of Australian health professionals who provide mental health care to adults with depression or anxiety in their

XSL•FO
RenderX

clinical practice (eg, general practitioner, mental health nurse, social worker, psychologist, and psychiatrist). The web-based survey was created in line with the Checklist for Reporting Results of Internet E-Surveys [58]. In stage 2, a subset of mental health professionals participated in one-on-one web-based qualitative interviews to collect more focused data to address the study aims and conclusions [57]. Finally, in stage 3, a small sample of psychologists was recruited for a 2-part focus group to provide more targeted feedback on implementing the new blended care model. Five psychologists external to the research team served as health professional advisors throughout stages 1-3. The health professional advisors were consulted regularly throughout each stage to confirm and double-check the findings, and all 5 participated in a 2-part focus group for the study. To further mitigate potential bias, the core research team also worked with a diverse range of nonresearchers, including user experience, IT development, innovation, and service delivery professionals before, during, and after data collection. Questions for the web-based survey, interview, and focus group were developed via collaboration between the core research team, health professional advisors, and user experience experts.

Ethical Considerations

Ethical approval was received from the University of New South Wales Human Research Ethics Committee (HC200541). All mental health professionals provided informed consent for the use of their data for research purposes. If participants wished to withdraw their consent, they could contact the research team. All participant data from the web-based survey, interviews, and focus group sessions were deidentified, recoded, and stored in a password-protected file only accessible to the research team. Participants could enter a prize draw to win an Aus $100 (US $65) online gift card for completing the web-based survey. A prize draw was selected as the reimbursement method to minimize the likelihood that a participant would complete the web-based survey solely for compensation. Survey respondents were randomly invited to complete one-on-one interviews and were reimbursed with an Aus $30 (US $20) online gift card. Due to the high level of group interactivity required for a 2-part focus group compared to the interviews, participants were reimbursed with an Aus $200 (US $130) online gift card for attending both 1-hour sessions.

Stage 1: Web-Based Survey

The web-based open survey took approximately 20 minutes and was created with Qualtrics software (version 2020; SAP Inc). Eligibility criteria for health professionals included (1) that they provide mental health care to adults with depression or anxiety, (2) were 18 years of age or older, (3) were fluent in English and (4) were currently living in Australia. The web-based survey was advertised between October and December 2020 via the Black Dog Institute website, the Black Dog Institute health professional network, social media (eg, Facebook [Meta Platforms Inc] and Instagram [Meta Platforms Inc]), existing professional organizations, and peak clinical bodies for mental health professionals (eg, the Australian Psychological Society). To participate, health professionals were directed to the Black Dog Institute website to access a web link for the Qualtrics (2020) survey. The web-based survey began with a participant information sheet and consent form, which included details on the purpose of the research study, eligibility criteria, reimbursement, participant data storage, and the estimated time required to complete the survey. The web-based survey included questions on participants' demographics, clinical practice details, past and current use of DMHIs, and their needs and expectations for a blended DMHI (refer to Multimedia Appendix 1). The web-based survey also included 2 questions from Topooco et al [32] focused on the challenges health care professionals and clients face when integrating digital technology into psychotherapeutic treatment for depression and anxiety (also refer to Multimedia Appendix 1).

Stage 2: Interviews

A subset of survey respondents was randomly invited via email to participate in one-on-one interviews between November 2020 and March 2021. Interviews were conducted until data saturation was achieved. The interviews explored mental health professionals' attitudes toward DMHIs and their views on blending these programs into routine clinical care. Apart from their participation in the web-based survey, there were no pre-existing relationships between participants and the researchers. Interviews were run online using Zoom videoconferencing software (Zoom Communications Inc), and lasted, on average, 53 (SD 12) minutes. The interviews were semistructured and followed a script developed by the research team based on relevant literature and findings from the web-based survey. No personal details about the researchers were disclosed to participants apart from their involvement in the overall project. Interviews were facilitated by either KO or FT. Open-ended questions were used to prompt discussion during the interview (refer to Multimedia Appendix 1). All interviews were audio-recorded and later transcribed by KK.

Stage 3: Focus Group

A 2-part focus group was conducted online using Zoom videoconferencing software, with each session lasting approximately 1 hour. The eligibility criteria were the same as those for the web-based survey. However, only psychologists were included, as they were the most common type of mental health professional recruited for the web-based survey and interviews. A 2-part focus group was advertised via email in July 2021, and the 2 sessions were run in July and August 2021, respectively. A convenience sample of 5 health professional advisors and 2 psychologists from the Black Dog Institute psychology clinic was recruited. The researchers were familiar with 7 participants because they worked at the same workplace, but there were no pre-existing personal relationships. One psychologist's data was excluded from data analysis as they could only attend one of the two focus group sessions. To minimize bias, the sessions were designed by service delivery and user experience professionals without clinical training (FT, CF, and VC) with input from the research team. Session 1 was led by CF, while Session 2 was led by KO, FT, and VC. KK attended both sessions as the note-taker. The focus group script (refer to Multimedia Appendix 1) included questions on factors affecting the implementation of the new blended care model, such as how the psychologists would use blended care with therapy sessions, the training and support needed to implement

XSL•FO
RenderX

blended care, and the features to include in an online program dashboard designed for health care professionals as part of the blended care system. Both sessions were audio-recorded and later transcribed by author KO.

Reflexivity Statement

To reduce potential biases, the core group of researchers involved in thematic analysis included 2 clinical psychologists who were also researchers (JMN and KO) and 3 nonclinician researchers (RKM, KK, and JATM). 2 service design professionals external to the research team assisted with qualitative data collection (FT and CF). 4 members of the core research team had prior experience with reflexive thematic analysis (JMN, KO, RKM, and KK). The 2 clinicians (JMN and KO) had experience in psychotherapy and digital mental health treatment for individuals with clinical depression and anxiety. All 3 nonclinician researchers (RKM, KK, and JATM) had experience with digital mental health research. One nonclinician researcher (RKM) also had experience working with staff and health professionals from substance use and mental health services. All coauthors reviewed the final coding framework for the thematic analysis conducted for the interviews and the 2-part focus group. This included 4 clinical psychologists who were also researchers (SL, MB, PB, and LK), a psychologist who was also a researcher (AEW), 2 user experience professionals (VC and KV), 2 service design professionals (FT and CF), and a public health researcher (NC). We acknowledge that our past clinical and research experiences, as well as our familiarity with the literature, may have introduced biases and assumptions that inadvertently influenced the thematic analysis of the interview and focus group transcripts. The core research team minimized this with regular meetings to discuss the data to ensure transparency and check that our themes and subthemes were grounded in the collected data.

Data Analysis

Descriptive statistics were performed with SPSS software (version 26.0; IBM Corp). For the web-based survey results, descriptive statistics were calculated based on the actual number of participants who responded to a specific question. Reflexive thematic analysis was selected to examine qualitative data from the one-on-one interviews and a 2-part focus group, as this method was appropriate for answering the research questions [59]. For the interviews, KK cleaned and checked the transcripts against the original audio after each interview and focus group session. Authors (KK, KO, and RKM) then read the interview transcripts several times and, after familiarization, used a general inductive approach to generate the initial set of codes. These codes were then categorized using Microsoft Excel to create the initial coding framework. The coding framework was revised iteratively by authors KK, RKM, and JATM until consensus on themes and subthemes was achieved. All disagreements were resolved through discussion with the research team (including KO, JMN, and AEW) until consensus was reached. The same approach was followed to analyze the focus group transcripts. The transcripts were read several times by KO and RKM, who generated the initial set of codes and then revised the coding framework iteratively with JMN.

Results

Stage 1: Web-Based Survey

Demographics

Of the 258 participants who provided consent, 157 (60.9%) completed the web-based survey. The average age was 47 (SD 13.74; range 18 - 78) years, and most participants were women (n=200, 77.5%), spoke English as a first language (n=227, 88%), and lived in a major Australian city (n=175, 73.8%; Table 1). Statistical comparisons revealed no significant differences in the demographics of participants who completed the full survey versus those who did not (see Multimedia Appendix 2).

XSL•FO
RenderX

Table . Sample characteristics for the web-based survey.

Demographic characteristics	Participants, n (%)
Gender (N=258)	
Women	200 (77.5)
Men	58 (22.5)
English primary language at home (N=258)	227 (88)
First Nations Australian origin (N=258)	4 (1.6)
Residential location in Australia (N=258)	
Major cities	175 (73.8)
Regional or remote	62 (26.2)
Current role[a] (N=239)	
Registered psychologist	45 (18.8)
General practitioner	43 (18)
Clinical psychologist	37 (15.5)
Social worker	28 (11.7)
Mental health nurse	26 (10.9)
Counselor	20 (8.4)
Trainee psychologist	11 (4.6)
Psychiatrist	5 (2.1)
Other current role[b]	36 (15.1)
Current work setting[a] (N=239)	
Private practice	119 (49.8)
Not-for-profit organization	49 (20.5)
Outpatient	38 (15.9)
Inpatient	28 (11.7)
University	25 (10.5)
Other work setting[c]	29 (12.1)

[a]Percentages do not add up to 100% as respondents were allowed multiple responses.

[b]Other current roles included occupational therapist, peer support roles, and other types of nurses (apart from mental health).

[c]Other current work settings included government, hospitals, justice settings, and schools.

Practice Details

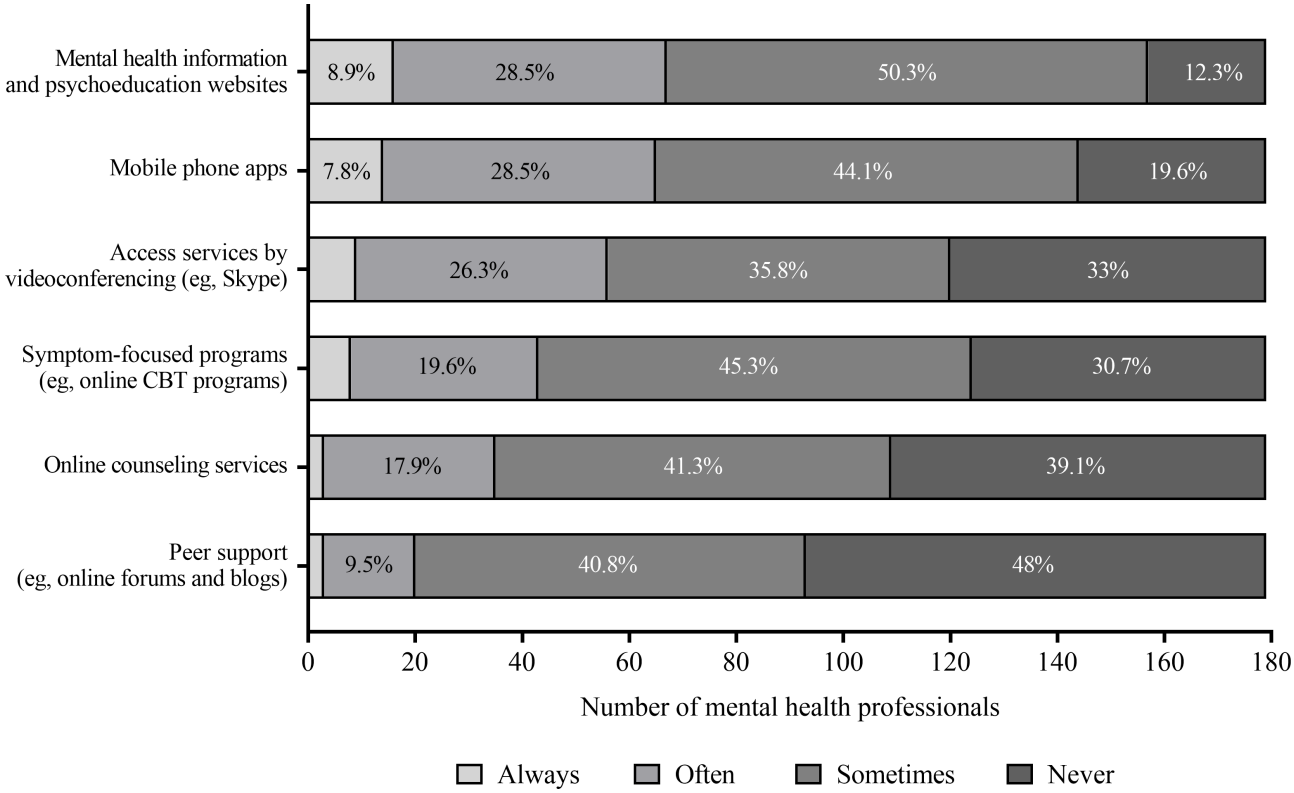
A total of 239 participants provided data on their current work role and work setting. The most common work roles were registered psychologists (n=45, 18.8%), general practitioners (n=43, 18%), and clinical psychologists (n=37, 15.5%; Table 1). The percentage of different work roles and work settings was largely consistent among participants who did or did not complete the full survey (refer to Multimedia Appendix 2). Participants mostly worked in private practice (n=119, 49.8%), not-for-profit organizations (n=49, 20.5%), and outpatient settings (n=38, 15.9%; Table 1). Across 239 participants, most (n=127, 53.1%) had 10 or more years of experience as mental health professionals, with an average of 15 (SD 11.89; range 0-49) years. Table 2 shows that the most common mental health conditions treated by participants were anxiety (199/221, 90%), depression (190/221, 86.1%), and trauma and stress-related disorders (152/221, 68.8%). The most common psychotherapies used to treat depression and anxiety were CBT (178/216, 82.4%), acceptance and commitment therapy (116/216, 53.7%), and mindfulness-based cognitive therapy (115/216, 53.2%; Table 2).

XSL•FO
RenderX

Table . Counts and frequency percentages of the most prevalent mental health issues treated by mental health professionals and the most used treatment modalities when working with adults experiencing depression and anxiety.

Practice details	Participants, n (%)
Most prevalent mental health issues[a] (N=221)	
Anxiety disorders	199 (90)
Depressive disorders	190 (86)
Trauma- and stressor-related disorders	152 (68.8)
Personality disorders	97 (43.9)
Substance-related and addictive disorders	80 (36.2)
Bipolar and related disorders	80 (36.2)
Schizophrenia spectrum and other psychotic disorders	55 (24.9)
Obsessive-compulsive and related disorders	51 (23.1)
Feeding and eating disorders	35 (15.8)
Most frequent treatment modalities[a] (N=216)	
Cognitive behavioral therapy	178 (82.4)
Acceptance and commitment therapy	116 (53.7)
Mindfulness-based cognitive therapy	115 (53.2)
Solution focused and brief therapy	82 (38)
Dialectical behavior therapy	64 (29.6)
Interpersonal psychotherapy	39 (18.1)
Schema therapy	38 (17.6)
Family therapy	26 (12)
Humanistic approach	23 (10.6)
Couples therapy	20 (9.3)
Psychodynamic approach	19 (8.8)
Eye movement desensitization and reprocessing	12 (5.6)
Psychoanalysis	11 (5.1)
Gestalt approach	10 (4.6)
Jungian approach	6 (2.8)
Other treatment modalities[b]	20 (9.3)

[a]Percentages do not add up to 100% as respondents were allowed multiple responses.



[b]Other common treatment modalities included peer support, physical activity, lifestyle advice, acupuncture, and hypnosis.

Use of Digital Mental Health in Practice

Figure 1 (data labels show the frequency percentage) shows how often particpants recommended different types of DMHIs to clients (see Multimedia Appendix 3 for counts). Participants were most likely to always or often refer clients to mental health information and psychoeducation websites (67/179, 37.4%), mobile phone apps (65/179, 36.3%), and videoconferencing services (eg, Skype [Microsoft], Zoom [Zoom Communications Inc]; 56/179, 31.3%). The 3 most common DMHIs that participants would suggest to clients with depression and anxiety were This Way Up (Clinical Research Unit for Anxiety and Depression at St Vincent's Hospital and the University of New South Wales), Smiling Mind (Smiling Mind Pty Ltd), and Headspace (Headspace Health).

XSL•FO
RenderX

Figure 1. Counts of what type of digital mental health interventions were referred to clients in participants' clinical practice (N=179). CBT: cognitive behavioral therapy.

Is There a Need for Digital Mental Health in Routine Care?

Most participants (135/178, 75.8%) reported a need for an online mental health program that could be integrated into routine care. Among the remaining 43 participants, 9 (5.1%) disagreed and 34 (19.1%) were unsure.

Digital Mental Health Preferences

Routine Care

Table 3 shows that participants preferred integrating DMHIs into routine care for depression and anxiety by referring clients to homework exercises to do in between sessions (129/178, 71.3%), specific modules to support skills learned in therapy (128/178, 71.9%), and psychoeducation (127/178, 76%). Other commonly preferred ways of integrating DMHIs into routine care included using DMHIs to assist clients with relapse prevention (117/178, 65.7%), tracking symptom changes over time (116/178, 65.2%), and supporting clients who had run out of sessions and could not afford to pay (113/178, 63.5%; Table 3).

XSL•FO
RenderX

Table . Counts and frequency percentages for integrating DMHIs into routine care, challenges faced by health care professionals and clients when digital technology is integrated with psychotherapy, and factors affecting whether blended care is suitable for a client.

Digital mental health preferences, challenges, and client factors	Participants, n (%)
Ways the program could integrate into routine care[a] (N=178)	
Refer client to homework exercises	129 (72.5)
Refer client to specific program modules	128 (71.9)
Psychoeducation	127 (71.3)
Relapse prevention once treatment is complete	117 (65.7)
Assessments to track symptoms	116 (65.2)
Support clients who run out of sessions and cannot afford to pay	113 (63.5)
Use in-session to explain or practice skills	107 (60.1)
As a prequel to therapy	88 (49.4)
Challenges for health care professionals[a] (N=158)	
Low motivation because of critical attitude toward digital technology	73 (46.5)
Not skilled in digital technology	72 (45.9)
Difficulties adapting treatment methods to digital technology	70 (44.6)
Low clinical effectiveness	57 (36.3)
Adherence of the health care professional is low	45 (28.7)
Degree of accessibility and cost of internet	41 (26.1)
Use of digital technology is too time-consuming	32 (20.4)
Other challenges	26 (16.6)
Challenges for clients[a] (N=158)	
Difficulties with applying self-help strategies	73 (46.5)
Not skilled in digital technology	72 (45.9)
Low client adherence	70 (44.6)
Low motivation because of critical attitude towards digital technology	57 (36.3)
Degree of accessibility and cost of internet	45 (28.7)
Low clinical effectiveness	41 (26.1)
Use of digital technology is too time-consuming	32 (20.4)
Other challenges	26 (16.6)
Client factors for blended care[a] (N=157)	
Access to a computer, tablet, or phone	128 (81.5)
Online modules relevant to main symptoms or diagnosis of patient	126 (80.3)
Access to the internet	123 (78.3)
Intelligence and cognitive functioning of client	118 (75.2)
Access to a private, safe place to complete program	112 (71.3)
Competence in using digital technology	111 (70.7)
Absence of severe suicidality	109 (69.4)
Absence of psychotic symptoms	100 (63.7)
Absence of acute medical need that hinders client's ability to participate in treatment	94 (59.9)
Absence of severe substance use	82 (52.2)
Other factors	22 (14)

[a]Percentages do not add up to 100% as respondents were allowed multiple responses.

XSL•FO
RenderX

Program Inclusions

Of the 178 participants, 142 (79.8%) described what they wanted to be included in a blended DMHI. Several suggested evidence-based content from common therapeutic modalities, such as CBT, acceptance and commitment therapy, dialectical behavior therapy, and mindfulness. Participants were also keen for the DMHI to support face-to-face therapy, for example, “flexibility to ’build’ your own exercises with clients or tailor them.” Supporting clients with skills practice and symptom monitoring was also important, for example, “validated assessment measures”, and “sleep tracking and thought monitoring.”

Challenges of Digital Mental Health

The most common challenges identified by participants for health care professionals were low motivation due to negative attitudes toward digital technology (73/158, 46.5%), not being skilled in digital technology use (72/158, 45.9%), and difficulties with adapting treatment methods to digital technology (70/158, 44.6%; Table 3). The 3 top challenges identified for clients were difficulties with applying self-help strategies (73/158, 64.6%), not being skilled in digital technology use (72/158, 63.9%), and low client adherence (70/158, 62%; Table 3).

Blended Care Approaches to Treatment

Client Factors

The most important factors that participants thought would affect the suitability of blended care for a client were access to a computer, tablet, or phone (128/157, 81.5%), modules relevant to the client’s main symptoms and diagnosis (126/157, 80.3%), internet access (123/157, 78.3%) and the client’s intelligence and cognitive functioning (118/157, 75.2%; Table 3). Other important client factors included access to a private, safe space to use the DMHI (112/157, 71.3%), and competence in DMHI use (111/157, 70.7%). Most participants considered the absence of severe suicidality (109/157, 69.4%), psychotic symptoms (100/157, 63.4%), acute medical needs affecting the client’s treatment (94/157, 59.9%), and severe substance use (82/157, 52.2%) to be important client factors for blended care as well.

Acceptability

Participants (N=157) rated acceptability with a 100-point scale (0=Not at all, 100=Extremely acceptable) for (1) standalone digital programs, (2) telehealth sessions, (3) blended care with digital programs and face-to-face sessions, and (4) blended care with digital programs and telehealth sessions. Participants found blended care with digital programs and face-to-face sessions the most acceptable treatment option (mean 71.61, SD 25.48), followed by telehealth sessions (mean 68.38, SD 23.72) and blended care with digital programs and telehealth sessions (mean 64.65, SD 25.86). Standalone digital programs were the least acceptable option to participants (mean 38.81, SD 25.86).

Sharing of Client Information

Most participants preferred client information to be shared with them via a secure email account (99/157, 63.1%) or sent to a secure web portal where they could log in and see the information (91/157, 58%). A minority wanted their client’s information shared with them via SMS text messaging to a nominated phone number (15/157, 9.6%) or through another information sharing method (16/157, 10.2%), such as a printable report or via an existing practice management system. Some participants were not sure (14/157, 8.9%) or did not mind (11/157, 7%) how client information was shared with them. The types of client information that participants wanted to share and receive from the blended DMHI included program adherence and completion, symptom tracking with validated and subjective (eg, sleep and mood) measures, and client feedback on treatment (eg, benefits, difficulties, or questions they have). The preferred time interval between receiving client information from the DMHI varied. Most participants preferred a weekly or fortnightly interval, and others wanted to tailor the interval to the client or treatment timeline, for example, “every week to begin with, moving to larger intervals as treatment progresses.”

Stage 2: Interviews

Demographics

A total of 14 mental health professionals participated in the one-on-one interviews. Their mean age was 46 (SD 13; range 26 - 73) years. Half of the participants were female (7/14; 50%), and the other half were male (7/14; 50%). Overall, 11/14 (79%) participants lived in major Australian cities, and 3/14 (21%) lived in regional or remote areas of Australia. The sample consisted of registered psychologists (5/14, 36%), clinical psychologists (5/14, 36%), mental health nurses (3/14, 21%), and a counselor (1/14, 7%). Participants had worked as mental health professionals for an average of 16 (SD 9.95; range 4 - 35) years. Participants worked in private practice (5/14, 36%), outpatient settings (4/14, 29%), universities (4/14, 29%), and not-for-profit organizations (2/14, 14%).

Thematic Analysis Findings

Overview of Findings

Six key themes were identified related to blended care for depression and anxiety: (1) blended care preferences, (2) promote client engagement, (3) prioritize client safety and duty of care, (4) minimize burden on time-poor clinicians, (5) program is credible and trustworthy, and (6) client barriers to using program. Illustrative quotes for each subtheme within the 6 themes are provided in Table 4.

XSL•FO
RenderX

Table . Thematic analysis themes and subthemes with example quotes.

Themes and subthemes	Example quotes
1. Blended Care Preferences	
Supports Skills Practice, Psychoeducation, and Lifestyle Changes	"If we're able to provide them with resources, [like] psychoeducation material...alongside the therapy that we're doing, it increases the support provided to the client." [Participant 71]
Helps Clinician Monitor Treatment Progress	"...I also want to know whether they're finding therapy effective and helpful and what they find helpful and what they don't find helpful." [Participant 14]
Prescribe Program Modules to Clients	"In a perfect world, a way to digitally prescribe it for people to track their progress, and then to be able to facilitate...not just like the way they engage with it, but in session tools." [Participant 15]
Walk Through Program Content in Session	"My preference...is to work through a program with a client, to have some oversight on what they're doing, to review the content with them, to answer any questions that they have." [Participant 8]
Trial the Program from the Client's Perspective	"If I were to give it to somebody or lead someone to it, I would want to do it myself, first of course." [Participant 3]
2. Promote Client Engagement	
User-Friendly and Inviting Interface, With Minimal Text	"I like that it's very simple and easy, a lot of the communication around concepts is done visually and in videos, there's no long slabs of text." [Participant 15]
Flexible with Lots of Variety	"It's important to have lots of different...ways of delivering information. So, whether it be...printed, video, audio and animated or something like that...it kind of keeps your interest and it's kind of interesting and stimulating, you're not just reading realms of stuff." [Participant 12]
Program Content Adjusts to Meet Client Needs	"The other thing that I think would be really, really helpful is if there was some way that you know this online program is personalized...because I think sometimes if you mention a whole lot of stuff, you know, clients find it a little bit trite, you know, like eat well and you know look after yourself. It's not really meaningful to them." [Participant 14]
Interactive Activities and Features	"...a bit interactive with a quiz or a little video or somebody talking about their experience, you know, that's just short and sweet, you know, a three-minute video and practical things." [Participant 24]
Relatable and Encouraging Stories Shared by Real People	"...having stories where people share their story, that can be very powerful." [Participant 48]
3. Prioritize Client Safety and Duty of Care	
Directs Clients to Crisis Support When Needed	"If there [were]...links to crisis services that are available and perhaps, you know, if people are screening as really high, knowing that they're going to get some kind of automated message to remind them to seek support immediately...that's really important." [Participant 9]
Helps Monitor Client Safety	"Hmm, if they are feeling worse...maybe that's the possibility of the clinician being alerted if their scores are really low...then the clinician could do a follow-up call, or like a check-in." [Participant 12]
Supports Maintenance of Professional Boundaries	"...we'll organize to call [the client] or send a text or we'll organize for a crisis service to ring or...and you work out with them what, you know, that's a bit of a negotiation process about what they'd be comfortable with and what you're obliged to do under your duty of care." [Participant 39]
Not Suitable for Clients with Severe Mental Distress	"With the population I work with, no, I mean if I was working with a more severe population, I might be a little bit less willing to use online programs without more support." [Participant 10]
4. Minimize Burden on Time-Poor Clinicians	
Quick Reference Guides and Resources	"So, I think first of all, helping clinicians have a quick and easy way of understanding what the content of a module or whatever it is, so they know if it's appropriate." [Participant 15]

XSL•FO
RenderX

Themes and subthemes	Example quotes
Integrates with Existing Client Management Systems	"I don't know if it's going to come into it, but also not being easily able to refer like say, for example, some of our clinicians they've got electronic medical records and databases already set up like if there was an easy trigger in those systems to kind of alert someone to refer to another service." [Participant 83]
Web-Based Program Dashboard	"If there is a clinician dashboard kind of interface, being able to have access to that, so I can see before the session, 'okay, great, they have completed this task.'" [Participant 8]
5. Program Is Credible and Trustworthy	
Evidence-Based and Reputable	"I'd want it to be, you know, peer-reviewed...and it's gone through all the you know research, efficacy, validity, all that sort of stuff, so I'd want it to have all that as the foundation." [Participant 33]
Secure and Protects Client Privacy	"...maybe a button with 'would you like your clinician to be able to see this?', 'yes or no', something that they can control, so they can say yes, just before the session and then after the session, they can hide it again if they don't want the clinician to have ongoing access." [Participant 10]
6. Client Barriers to Using Program	
Program Cost	"I think once you put a cost on it, you can lose a lot of people." [Participant 24]
Digital Interventions Not Appropriate for Some Clients	"The ability to engage with the app and take on board information that's there with the reading and the content requires a level of cognitive functioning and, you know, self-awareness and conscious thought. If all those are getting scrambled for you, then this isn't going to work." [Participant 62]

Theme 1: Blended Care Preferences

Theme Overview

This theme refers to how mental health professionals envisioned the blended care program would work for clients receiving routine clinical care for depression and anxiety.

Supports Skills Practice, Psychoeducation, and Lifestyle Changes

Participants emphasized the importance of modules in the program supporting skills taught in face-to-face therapy, such as psychoeducation and healthy lifestyle content (eg, sleep hygiene, physical exercise, and nutrition). Including this content would allow clinicians to assign psychoeducation and skills practice activities to clients between sessions, freeing up therapy sessions for more challenging and tailored skill development.

Helps Clinician Monitor Treatment Progress

Several participants wanted to track whether clients found their therapy sessions helpful and monitor the severity of client symptoms across sessions to indicate progress. Participants suggested including measures for client-reported outcomes and experiences in the program (eg, outcome rating scale and session rating scale). Some participants were also interested in viewing which modules and activities clients had completed in the program.

Prescribe Program Modules to Clients

Participants preferred to prescribe specific modules or activities in the program so that their clients were assigned content and activities relevant to their needs or which assisted clients in practicing a skill they were currently learning with their therapist.

Walk Through Program Content in Session

When using a DMHI, participants wanted to guide clients through the content during therapy sessions to help familiarize them with the program and help clients feel more comfortable using it. Participants also thought that demonstrating how the program worked to their clients would address practical barriers, such as client reporting of technical issues.

Trial the Program From the Client's Perspective

Participants preferred to trial the program from the client's perspective before recommending it. This feature would allow participants to verify the program's quality, ease of use, and content before recommending the program to clients.

Theme 2: Promote Client Engagement

Theme Overview

User engagement with the blended care program was an important consideration for interviewees. Theme 2 includes the features, functionality, and content within a DMHI that mental health professionals suggested would enhance client engagement with the program.

User-Friendly and Inviting Interface With Minimal Text

Most participants believed that the program should be easy and intuitive for clients to use and stay engaged with. Some participants suggested that the onboarding experience for clients should be simple and include minimal registration questions. Other suggestions included using clear and friendly language to explain concepts and avoid "long slabs of text." It was also important that the program was designed with an aesthetically pleasing interface (eg, colorful, comic-style graphics and animations).

XSL•FO
RenderX

Flexible With Lots of Variety

Many participants thought clients would stay engaged with the DMHI if it was flexible, modular, and included a range of content, options, and functionality. Participants also believed clients would like to choose which module or activity they wanted to complete rather than having one suggested. Some participants thought that transdiagnostic content would be more engaging for clients than disorder-specific content and recommended including transdiagnostic modules that address multiple concerns common for people with anxiety and depression (eg, perfectionism, rumination, self-esteem, and procrastination).

Program Content Adjusts to Meet Client Needs

Some participants thought content personalized to clients' needs would help them stay engaged with the program. For example, if a client indicated they wanted to improve their relationships with others or manage procrastination, the program would show information or modules relevant to these topics in response.

Interactive Activities and Features

Several participants believed interactive activities and features would enhance client engagement, such as practical activities that require users' active input, such as quizzes and chatbots. Other suggestions included videos, audio tracks, diagramming tools, and activities, such as behavioral activation or exposure stepladders where their client could input content relevant to them.

Relatable and Encouraging Stories Shared by Real People

Some participants believed that incorporating other people's experiences of mental ill health and treatment into the program would enhance client engagement. These participants thought a video would be a good way to include these stories and that the examples should be relevant and encouraging for clients.

Theme 3: Prioritize Client Safety and Duty of Care

Theme Overview

This theme focuses on participant perspectives about the importance of prioritizing and safeguarding client safety while also assisting mental health professionals in setting clear boundaries around their duty of care to clients.

Directs Clients to Crisis Support When Needed

A common concern was ensuring clients could access crisis support if they were feeling unwell or experiencing suicidal ideation while using the DMHI. Most participants wanted contact details of emergency and mental health support services included (eg, Lifeline and Suicide Call Back Line), while others endorsed a more personalized approach where a user input (eg, endorsing suicidal thinking) would trigger messages or risk alerts, such as advising the client to seek help immediately and then directing them to crisis support information.

Helps Monitor Client Safety

Participants wanted the program to help monitor client safety and alert the clinician if their client's symptoms worsened or they endorsed indicators of elevated suicide risk. A common suggestion was to use validated questionnaires to flag if a client's symptoms were worsening. Some participants thought the DMHI could prompt mental health professionals to check in with their clients or reassess their treatment plans.

Supports Maintenance of Professional Boundaries

Participants expressed concern about their increased duty of care between therapy sessions when using a DMHI with clients (eg, being required to contact clients at risk outside of sessions). Some also thought the program could help mental health professionals manage their duty of care and client safety. This included (1) guiding discussions about duty of care with clients, (2) setting boundaries around the mental health professional's availability, and (3) clarifying which client information would be shared with mental health professionals. Participants thought that this could be facilitated through the onboarding content of the DMHI and automatic notifications about elevated client risk to mental health professionals.

Not Suitable for Clients With Severe Mental Distress

Some participants felt a DMHI, even when used with blended care, would not be appropriate for high-risk clients or those experiencing severe distress. Examples included clients who were suicidal, experiencing significant challenges with perceptions of reality (eg, psychosis and personality disorder) and those with severe distress or functional impairment (eg, severe depression).

Theme 4: Minimize Burden on Time-Poor Clinicians

Theme Overview

This theme describes how DMHIs can reduce the burden on mental health professionals who may already be short of time.

Quick Reference Guides and Resources

Many participants thought simple, quick, easy-to-use guides and resources would help them decide whether the DMHI was appropriate for clients. Several participants specified that short overviews of content or program modules, the program structure, and details to pass on to the client (eg, time commitment) would be helpful. The preferred medium for quick reference guides and resources was varied and included written summaries, short videos less than 2 minutes long, booklets, and brochures.

Integrates With Existing Client Management Systems

Some participants wanted the blended DMHI to integrate with existing software and client management systems used in their practices. Examples included sending questionnaires or referring clients to the program digitally via client management systems that mental health professionals already had in place to avoid the need for additional record-keeping and the risk of duplicate records.

Web-Based Program Dashboard

Several participants wanted access to a dashboard to view their clients' progress, including completion of modules or activities and symptom scores. The dashboard could also be used to recommend modules or activities to clients using the program, and it would be helpful to quickly view their clients' data before or during a therapy session with them.

XSL•FO
RenderX

Theme 5: Program is Credible and Trustworthy

Theme Overview

This theme emphasizes the importance of a DMHI being credible, reliable, and safe for clients.

Evidence-Based and Reputable

Most participants would only recommend DMHIs to their clients if the product had been scientifically evaluated or had demonstrated effectiveness and was developed by organizations or individuals they trusted.

Secures and Protects Client Privacy

The DMHI needed to be confidential and protect client data. Participants wanted transparent information about where the client data were stored and who could access it, including in the DMHI. Participants also thought clients should be able to turn clinician access to their data on and off.

Theme 6: Client Barriers to Using the Program

Theme Overview

The final theme refers to barriers that prevent clients from using a DMHI.

Program Cost

Most participants believed cost was a barrier to their clients accessing DMHIs and that their clients would want to check the efficacy and suitability of DMHIs before paying for access. Another perspective was that some individuals with mental illness were struggling financially and that DMHIs should be included in treatment costs. Participants also felt uncomfortable with clients paying for DMHIs, considering the already high costs of therapy. However, some acknowledged that cost could indicate to clients that a program has a high level of quality and credibility. Overall, participants emphasized the importance of keeping the costs of DMHIs low.

Digital Interventions Not Appropriate for Some Clients

Participants believed that DMHIs would not suit clients who lack access to technology (ie, no mobile phone, computer, or internet access), have poor literacy skills, have cognitive impairments or intellectual disabilities, face psychosocial vulnerabilities (ie, domestic violence and child protection concerns), or require the additional empathy and validation that an in-person therapist can offer.

Stage 3: Focus Group

Demographics

In total, 6 psychologists participated in the 2-part focus group. The mean age was 35 (SD 10; range 26‐54) years. All participants spoke English as their primary language and lived in major Australian cities. Most participants were female (n=5, 83%), and 1 (17%) was male. Overall, 5 (83%) participants were clinical psychologists and 1 (17%) was a provisional psychologist. The participants had worked as mental health professionals for an average of 10 (SD 10; range 1‐28) years and worked in private practice (n=4, 67%), not-for-profit organizations (n=4, 67%), and outpatient settings (n=2, 33%). All psychologists nominated depressive and anxiety disorders as two of the most common mental health issues they treated in their clinical practice. Other common mental health issues treated by participants included trauma and stressor-related disorders (n=5, 83%), personality disorders (n=4, 67%), bipolar and related disorders (n=3, 50%), and obsessive-compulsive and related disorders (n=3, 50%). All psychologists commonly use CBT to treat depression and anxiety. Other treatment modalities included acceptance and commitment therapy (n=4, 67%), mindfulness-based cognitive therapy (n=4, 67%), and schema therapy (n=4, 67%).

Thematic Analysis Findings

Overview of Findings

Five key themes were identified that related to the resources, support, and training needed to implement blended care into routine care for depression and anxiety: (1) user-friendly resources, training, and support; (2) practical and flexible training; (3) comprehensive implementation support; (4) monitor client progress and risk; and (5) tailor client content and access.

Theme 1: User-Friendly Resources, Training, and Support

Psychologists emphasized that resources, support, or training for the blended care system should be user-friendly and facilitate the use of blended care with clients. Psychologists also emphasized that any digital components of a blended care system, such as a web-based dashboard or portal, should be simple, quick, and easy to integrate into their regular clinical practice.

Theme 2: Practical and Flexible Training

Psychologists thought training should be ongoing as they used the blended care system and focused on understanding what is included in the program (eg, clinical techniques). Like interviews, the psychologists raised concerns about client confidentiality and how the limitations of duty of care when using DMHIs should be communicated to clients. They suggested that this should be covered in any training provided to mental health professionals for the blended care DMHI. Psychologists also wanted various training resources to be provided, including workshops, written summaries, Frequently Asked Questions, and video-based guides. Receiving professional development credit for an educational module (eg, on blended care) was also considered an important incentive.

Theme 3: Comprehensive Implementation Support

The psychologists believed that one-on-one and peer support would be needed to implement blended care. For one-on-one support, they suggested the DMHI support team should regularly check in with mental health professionals using the blended care system and include “Frequently Asked Question” and “Help” sections in a web-based dashboard to provide contact details on how and who to contact for help. Additionally, they recommended facilitating peer support through access to a clinician chat group or message board.

Theme 4: Monitor Client Progress and Risk

Psychologists wanted to be able to view and track client progress via a web-based dashboard included in a blended care system. Preferred metrics included questionnaire scores, client responses, and the number of activities completed. Flagging and receiving

XSL•FO
RenderX

notifications about at-risk clients based on symptom severity was also essential. Another suggestion was to include a downloadable snapshot of the client's DMHI use and other data that could be exported to and saved in other practice management software.

Theme 5: Tailor Client Content and Access

The psychologists valued the ability to select, schedule, and personalize DMHI content for clients. This included searching for activities with clinical terms (eg, behavioral activation), assigning specific activities to clients, tailoring reminders to suit client needs, and sending content and activity links directly to clients. Having control over the digital "unlinking" of a client during therapy closure or handover to another mental health professional was also important.

Discussion

Principal Findings

This was the first participatory design study to investigate Australian mental health professionals' needs and expectations of a new transdiagnostic, CBT-based blended DMHI that could be integrated into routine care for clients experiencing depression and anxiety. Participants wanted the blended DMHI to be easy to use, flexible to use with clients, and provide a broad range of tailored content to engage and sustain client interest, including evidence-based content from several therapeutic modalities, such as CBT, acceptance and commitment therapy, and dialectical behavior therapy. Participants also provided detailed feedback on the sharing of client data, including a preference for this to occur via a secure email account or web portal, as well as the types of client data that would be most helpful to share. Factors affecting mental health professionals' acceptance of a blended DMHI, as well as the types of training, support, and resources needed to implement blended care, were also identified. Incorporating features that support the monitoring of client safety into DMHIs and ensuring that DMHIs are free or of low cost for clients could enhance the acceptance of blended care by mental health professionals. Overall, our findings indicate that blended care for depression and anxiety would be feasible and acceptable for Australian mental health professionals to implement, especially psychologists.

Blended Care Needs and Expectations

Blended care, where a DMHI is integrated with in-person or telehealth sessions, was considered more acceptable than standalone digital interventions. Many of our findings on the needs, preferences, and expectations of mental health professionals for a DMHI that could facilitate blended care align with results from our participatory design study with people with lived and living experiences of depression and anxiety [56] and research with European mental health professionals [28,30,31,38-40]. CBT was the most used therapeutic modality when treating adults with depression and anxiety; however, acceptance and commitment therapy and mindfulness-based cognitive therapy were also common. Given that most participating mental health professionals were experienced CBT-based psychologists, further research will be needed to adapt the blended care system to the needs of other types of mental health professionals. Consistent with the views of people with lived experience [56], participants also expected the blended DMHI to be evidence-based, credible, and protective of client data. These results align with 2 prior blended care studies [28,39] and existing research [22,24,27,60,61] conducted before and during the COVID-19 pandemic, which showed that mental health professionals value DMHIs with strong evidence bases and prioritize client privacy and data security.

A novel finding from this study is mental health professionals' views on sharing client data, as only 1 blended care study [39] has previously reported this. Behr and colleagues [39] found that psychotherapists believed clients should have control over what data their psychotherapist can see in a DMHI. Our results build upon these findings by providing specific details on how mental health professionals wanted this data sharing to occur. In this study, most participants preferred to receive client information through a secure email account or online portal on a weekly or fortnightly basis and wanted to view data on clients' progress through the DMHI program, mental health symptoms, and feedback on their treatment. Both our results and those of Behr and colleagues [39] show that mental health professionals value maintaining the security of client data when sharing data with treatment providers. Further research is needed to validate these findings, given the predominance of psychologists in this study and psychotherapists in the Behr and colleagues [39] study. Despite this, the data sharing findings align with qualitative research by Atik and colleagues [28] on blended care, who found that clients were not concerned about sharing personal data within a DMHI, provided their data were used only for treatment purposes. However, these 2 studies [28,39] and our study were conducted during the COVID-19 pandemic; therefore, further replication is needed to ensure that these findings were not due to the unusual circumstances of this worldwide event.

Participants in this study believed blended care could enhance psychotherapy by helping to track a client's treatment progress and providing clients with psychoeducation and skills practice that support in-session therapy. Similarly, other blended care studies found mental health professionals, who primarily consisted of psychologists and psychotherapists, prefer blended DMHIs that allow clients to track their symptoms and complete homework between therapy sessions [28,29,38,62]. Further, Cerga-Pashoja and colleagues [38] reported that mental health care workers who deliver low-intensity psychological interventions (ie, UK psychological well-being practitioners) wanted blended care to help facilitate continuity between therapy sessions. The current results indirectly support this desire for treatment continuity, as mental health professionals suggested the inclusion of a web-based dashboard that would allow them to recommend program content and review client progress between and before therapy sessions. Relatedly, mental health professionals wanted the blended DMHI to assist with the monitoring of client symptoms and flag if these worsened or indicated suicidality, further contributing to a sense of treatment continuity and mental health support between therapy sessions.

XSL•FO
RenderX

Blended Care Acceptability

Consistent with previous research [28,39,60] conducted before and during the COVID-19 pandemic, mental health professionals thought that the blended DMHI should direct clients to immediate support if they were feeling unwell or in crisis. Mental health professionals in this study were also wary of using blended care with highly distressed clients or clients with high suicide risk. which is in line with previous research [22,32]. This is despite research evidence indicating that blended care is feasible for treating severe mental illness and may also improve treatment adherence in this population [33]. One reason for the current findings could be that mental health professionals working in private practice, especially psychologists, were well-represented throughout all 3 stages of the participatory design study. These participants may have been more cautious about working with high-risk clients compared to other mental health professionals, as they could be sole traders operating their own private practices or be part of a small business. Other factors influencing participants' willingness to use DMHIs with clients were client suitability and cost. In line with previous research [22,30], mental health professionals thought blended care might not be appropriate for people with poor digital literacy, limited access to digital technology, or comorbidities that could hamper treatment engagement (eg, cognitive impairment and domestic violence). Prior research also supports our finding that mental health professionals preferred DMHIs to be free or low-cost for clients [26,60]. This highlights the importance of using participatory approaches in DMHI research, especially with practitioners who treat the mental health condition in question, and ensuring sustainable funding models are available for ongoing maintenance and support for blended care systems.

Mental health professionals were also concerned about the time and effort needed to implement blended care with clients. This concern has previously been raised in European studies conducted before the COVID-19 pandemic with CBT-trained mental health professionals working at mental health services that use blended care [30,31,38,40]. However, blended care can also save mental health professionals' time by allowing the DMHI to cover some aspects of face-to-face therapy, such as psychoeducation, or using the DMHI to continue contact with the client for aftercare and to maintain treatment gains without additional face-to-face therapy sessions [25]. Ensuring these time-saving qualities are realized is key to enhancing the acceptability of blended care models [30,39]. In this study, mental health professionals made several suggestions for minimizing the workload associated with implementing blended care and the types of training and resources that would support them using a blended DMHI with clients. Strategies included trialing the DMHI from the client's perspective, supplying quick reference guides and resources (eg, written summaries and short videos), and providing a web-based dashboard that could be used to view client progress and prescribe therapeutic content. Mental health professionals also reported a need for ongoing one-on-one and peer support when using blended care with clients and training to help them understand the therapeutic content in the blended DMHI.

Limitations

This study has several limitations that should be noted. This study occurred during the first and second years of the COVID-19 pandemic (ie, October to December 2020 and July 2021). During this time, the demand for mental health professionals increased while mental health service delivery was disrupted due to quarantining restrictions and physical distancing rules [3,23]. This forced many mental health professionals to switch from face-to-face to telehealth service delivery. It is possible that mental health professionals were more motivated than usual to participate in the research due to the sudden need for many to transition to telehealth service delivery. This may have also influenced our finding that blended care was more acceptable than standalone DMHIs. However, our results do align with a European survey conducted before the COVID-19 pandemic [32], which found that a range of stakeholders involved in depression treatment thought blended care was more acceptable than standalone internet-based treatment for mild, moderate, and severe depression. Further research will be needed to disentangle the effects specific to the COVID-19 pandemic on the blended care system in the future.

The generalizability of our results may also be limited, as the sample was predominantly female and English-speaking and was comprised of individuals who resided in major Australian cities, were psychologists, and worked in private practice within a high-income country. These demographics are consistent with research showing that psychotherapy for mental health treatment within Australia is primarily delivered by psychologists working in private practices [45]. However, further research should consider how the blended care system could be adapted for use by other types of mental health professionals, including those not working in private practice and those in rural, regional, or remote areas of Australia. This could increase the accessibility of blended care for people who may not be able to afford to cover the gap in payments for psychotherapy within the current Australian mental health system. Another limitation of this study is the focus on a transdiagnostic model of care. For highly comorbid mental health diagnoses with shared cognitive, emotional, and biological mechanisms, like depression and anxiety, transdiagnostic approaches have many benefits [7-11]. However, as also mentioned by participants in this study, this approach may not be appropriate for all clients. There is still a need for diagnosis-specific treatment, as some symptoms experienced by a client with a diagnosis, such as bipolar disorder, may not be addressed by a transdiagnostic intervention for depression and anxiety [9].

Future Directions

The findings from this study and the participatory design study with people with lived and living experiences of depression and anxiety [56] have been used to create a new Australian blended model of care for depression and anxiety. The present results have been incorporated into a co-design and prototype testing process for a web-based health professional portal that forms part of the myNewWay blended care digital system. The new system also includes a CBT-based and transdiagnostic mobile app for people receiving treatment for depression and anxiety [56]. Phase 2 of the larger Australian project involved refining

XSL•FO
RenderX

and evaluating both digital products for use as part of routine care for depression and anxiety. This included an implementation clinical trial with Australian psychologists and their clients. Findings from this clinical trial will inform the development of a workflow model for integrating the new blended care system into a mental health professional's practice without increasing their workload or compromising quality of care.

Conclusion

The present findings indicate that Australian mental health professionals who deliver psychotherapy value blended DMHIs that facilitate their clinical practice. Given the similarities between the present findings and the European blended care research [28,30,31,38-40], some elements of optimal blended care may be universal and replicable in mental health care systems in other countries. However, it is important to recognize that blended care will not solve the issue of mental health workforce or funding shortages [3]. Moreover, the increasing incorporation of artificial technology into DMHIs may further complicate the implementation of blended care in the future [17]. Blended care could be an option for leveraging the convenience and accessibility of DMHIs in a way that supports evidence-based treatment and the current workforce while longer-term solutions are sought for these larger system-level issues. Our results, as well as those of others using participatory principles [39,60], further highlight the importance of involving mental health professionals in DMHI design and development. Designing DMHIs that work with, rather than against, existing care pathways for depression and anxiety is crucial for improving access to mental health treatment.

Abstract

Background: Digital mental health platforms often consist of many different forms of self-care exercises. To our knowledge, whether the number of choices presented to the users affects their uptake and experiences and poses negative consequences (ie, not choosing any exercises, choice dissatisfaction) for users, especially those experiencing anxiety and depressive symptoms or unpleasant state emotions, has not been empirically investigated.

Objective: This study investigated the impact of choice set size on practice decisions, completion, satisfaction, and subjective experiences, as well as potential moderators including depression and anxiety symptoms, state emotions, and motivational and decisional attributes on these choice outcomes.

Methods: Participants were recruited through university mass email and social media, and 652 participants were included in our analyses. Participants completed questions regarding anxiety and depressive symptoms, state emotions, and other psychological attributes. Then, they were randomly assigned to 1-choice, 4-choice, and 16-choice conditions, in which they may choose a self-care activity to practice or decide not to practice. Finally, they completed questions regarding completion, satisfaction, engagement, attitude, and perceived improvement in psychological state.

Results: Presenting multiple choices resulted in a higher likelihood of practice (odds ratio 3.12, 95% CI 2.08 to 4.67 and 3.83, 95% CI 2.55 to 5.76; $P<.001$) and better decision satisfaction (16-choice vs 1-choice: $d=0.36$, 95% CI 0.17 to 0.56, $P<.001$; 4-choice vs 1-choice: $d=0.24$, 95% CI 0.05 to 0.43, $P=.03$) compared with presenting with a single choice. Tentative evidence indicates anxiety symptoms and state emotions were meaningful moderators. Specifically, for individuals with more anxiety symptoms and intense negative emotions, presenting a larger choice set (16 choices) resulted in more positive chosen exercise satisfaction, better attitudes toward chosen activity, and higher perceived improvement in mental health state after the activity, when compared with presenting with smaller choice sets (anxiety: $\beta=-0.38$, 95% CI −0.69 to −0.06 to −0.51, 95% CI −0.84 to −0.18; state emotions: $\beta=-0.31$, 95% CI −0.66 to 0.03 to −0.60, 95% CI −0.92 to −0.28). No evidence was found for the moderating effect of motivational and decisional attributes.

Conclusions: The moderation results were contradictory to prior research and our expectation that a larger choice set may result in worse outcomes than a smaller choice set for people who were experiencing higher levels of psychological distress. We speculated that a possible reason for these findings may be that people with more anxiety symptoms and unpleasant emotions may have a stronger need to reduce these uncomfortable symptoms and emotions, and when presented with more choices on self-care activities, there may be a higher possibility that these self-care activities can address their distress.

Introduction

Background

To maintain and enhance positive mental health, practicing mental health self-care regularly is essential in our daily lives. With the proliferation of digital mental health apps and platforms, numerous exercises derived from approaches such as cognitive-behavioral therapy and mindfulness-based interventions [1,2] become easily accessible. These activities can be guided through audio or visual instructions or completed using worksheets. While having more exercises available may cater to different needs of service users, presenting too many choices on the platform may negatively influence the likelihood of practice, engagement, and satisfaction, especially for people experiencing anxiety and depressive symptoms or unpleasant emotions [1]. Are users more motivated to do mental health self-care exercises, and are their experiences more satisfactory and engaging if they are given fewer or a larger number of choices? Moreover, are these choice decisions and the related completion of practices, engagement, satisfaction, and experiences moderated by users' present psychological distress, emotional states, and individual differences in motivation and decision-making?

While numerous studies have explored the effects of different choice quantities in economic and consumer decision-making contexts [3-7] and some digital health studies have investigated the efficacy of choice provision versus the absence of choice or tunneling [8-10], research comparing a higher number of choices over a low number of choices in health-related settings is scarce. Only a handful of studies have addressed this comparison in health-medical contexts [7,11,12], and to our knowledge, there is no such study on digital mental health self-care. Making choices for mental health self-care is different from many other consumer behaviors. In previous research, consumer behaviors often involve commercial transactions over the buying of daily goods (ie, pens, jam), with multiple dozens of choices in the large choice set [4]. Often, when research involves making health-oriented decisions, the number of choices is generally lower (under 20 choices) compared with other consumer behavior domains [11,12]. Unlike other consumer behaviors, these choices may have more bearing on well-being and health and may be considered as more consequential than daily goods choices for most people. With the increasing popularity of digital mental health, research on choices of mental health self-care may have informative implications for personalization of self-care offerings and understanding of the public's choices over mental health-related self-care activities.

More Choices-Are-Better Perspective

Multiple theories in psychology and economics suggest that individuals tend to experience greater satisfaction when presented with multiple choices compared with having only one option available or a limited number of choices. The availability of multiple choices is believed to support feelings of autonomy, a fundamental human need that boosts motivation based on Self-Determination Theory [5,13,14]. Relatedly, having multiple choices can enhance perceptions of freedom in decision-making and elevate choice satisfaction [3,4,15]. Such beneficial effects have been observed in some health-related contexts such as illness screening and physical exercise [16]. Classical economic models also suggest that a higher number of choices increases the likelihood of individuals identifying and selecting options that match their personal preferences and goals [3,4,17,18].

However, with Chinese cultures emphasizing a culture of deference and compliance to authority [19,20] while Chinese people generally have lower mental health literacy [21,22], but higher levels of mental illness stigma [21,23], they may prefer being told which choice to opt for or may benefit more from a smaller choice set in terms of mental health self-care (see studies by Chernev et al [4], Misuraca et al [5], and Mogilner et al [24] regarding the association between lower expertise/familiarity and better outcomes with a smaller choice set). Thus, understanding how Chinese people respond to different choice sets in a digital mental health platform for self-care under a mix of this theoretical and cultural backdrop has important implications for how researchers and mental health practitioners could promote public mental health in Chinese societies.

Overchoice Effect or Too-Many-Choices Perspective

Contrary to traditional economic beliefs that more choices lead to better outcomes, some studies over the past 2 decades have indicated that an abundance of choices might diminish the likelihood of purchase and dampen choice satisfaction under certain circumstances [4,25-27]. Some individuals may find themselves overwhelmed by an excess of options, leading to decision-making challenges and dissatisfaction due to limitations or exhaustion in cognitive resources and capabilities [5,26,28]. Being presented with many choices, individuals may experience an increase in cognitive costs in processing more information, making judgments and decisions [4]. This phenomenon of negative repercussions from an excessive array of choices is often referred to as "choice overload" or "overchoice" [7,29,30]. However, while numerous studies, meta-analyses, and reviews have investigated this topic, the findings remain mixed, sometimes inconclusive, and controversial [4,30]. The overchoice effect may manifest under specific conditions, such as increased decision complexity and choice set intricacy [4], and may affect individuals with certain psychological attributes, such as prevention regulatory focus [31] or in emotional states such as anxiety [5,32]. In the mental health realm, for individuals with anxiety or depressive symptoms and state unpleasant emotions, it is worthwhile to examine how choice autonomy, which aligns with personal recovery and self-determination, and cognitive overload, which may be particularly relevant for people experiencing psychological distress, may affect decisions, engagement, and experiences with different choice set sizes.

Anxiety, Depression, and State Emotions as Potential Moderators

One of the individual difference moderators that may be relevant is the experience of anxiety. Studies by Hu et al [32] found that individuals experiencing high levels of anxiety were more prone to facing decision difficulties and delaying choices when confronted with a larger array of options. Hu et al [32] posited that anxiety demands more cognitive resources, thereby reducing the capacity for processing information and rendering judgments

XSL•FO
RenderX

based on more information within larger choice sets, so a lower number of choices may be preferred by people experiencing high levels of anxiety. This heightened challenge when encountering a larger choice set in decision-making might lead individuals to postpone choices or not choose any option and perhaps experience lower satisfaction [32-34].

Related to but distinct from anxiety, we are not aware of any study on the potential moderating effect of depression in choice set size effects. Existing research indicates that many individuals experiencing depression often contend with fatigue [35,36] and may experience amotivation [36]. Similar to cognitive resource limitations among individuals with anxiety [32], people with depression may find it challenging to process information involving more choices due to diminished energy and motivation levels. Individuals with depression may avoid activities that demand extensive cognitive resources [37-39] or encounter difficulties and unpleasant experiences when engaging in complex tasks or decisions that require heightened cognitive engagement [38,40,41]. Thus, when the number of choices is high, one may anticipate that individuals exhibiting more depressive symptoms may be more likely to experience the overchoice effect.

Although the above-discussed studies about anxiety and depression were conducted outside the digital mental health context, concerns have been raised by digital mental health researchers regarding the potential negative impact of offering users a wide array of choices, suggesting the possibility of triggering the overchoice effect [1,42,43]. Notably, Valentine et al [1] contended that individuals with depression and anxiety disorders may encounter cognitive challenges, such as difficulties in concentration, rendering them more susceptible to experiencing the adverse effects of overchoice and disengagement when confronted with excessive information and numerous options. It is imperative to investigate whether limiting the number of self-care choices presented, particularly for individuals with heightened levels of anxiety and depression, would lead to better outcomes than presenting an extensive number of choices.

In addition to anxiety and depressive symptoms, individuals' current emotional states may affect their choice preferences. Drawing from the rationale applied to anxiety and depressive symptoms, it is hypothesized that individuals reporting higher levels of anxiety or depressive symptoms, or stronger unpleasant emotions, would benefit more from a restricted number of choices (1 choice or 4 choices) compared with a larger choice set (16 choices), including greater uptake, engagement, and completion of the chosen activity as well as satisfaction with the decision.

Tailoring the Number of Choices Based on Individual Differences in Regulatory Focus and Choice Preferences

In addition to testing the potential interactions between the number of choices and mental health conditions and emotional states, it may be valuable to investigate the moderating effects of dispositional individual characteristics. One pertinent characteristic worth considering is regulatory focus, as proposed by Higgins [44], which pertains to the motivational orientations in goal pursuits and decision-making processes. Regulatory focus can be categorized into prevention focus that emphasizes safety and the prevention of losses or errors, and promotion focus that emphasizes seeking advancements, gains, and growth opportunities.

Research by Tuan Pham and Chang [45] found that individuals with a predominant promotion focus tend to view options selected from a larger choice set more favorably than those from a smaller set. This inclination was attributed to the proactive nature of promotion-oriented individuals, who are eager to capitalize on opportunities that may be more abundant in wider choice sets [45]. Furthermore, promotion-focused individuals often aim to maximize gains and pursue idealistic goals, making them more likely to find an option that aligns with their preferences in a larger selection. Another related explanation is that promotion-focused individuals tend to strive for maximizing gains and are more idealistic [46,47], and a higher number of choices is more likely to consist of an ideal option that matches well with the preference of the decision maker [3,4,17]. In contrast, Polman [31] found that prevention-focused individuals are more affected by choice overload. They worry about making mistakes and are vigilant about "bad options." With more choices, they perceive a higher risk of encountering these "bad options." Therefore, presenting fewer choices may be better for prevention-focused individuals. Given the above findings, it is hypothesized that for predominantly promotion-focused individuals, presenting a larger choice set will be more beneficial than presenting a smaller choice set, whereas for predominantly prevention-focused individuals, presenting a smaller choice set will be better than presenting a larger choice set.

Apart from regulatory focus, a relatively simple potential method of choice-set-individual-characteristics tailoring was tested by directly asking participants their preferences and perceived difficulty in making decisions when given many choices. For people who prefer many choices and perceive making decisions as less difficult [48], we expect that a higher number of choices (19) will be more beneficial in enhancing their practice likelihood, completion rates, decision satisfaction, choice satisfaction, and engagement compared with a lower number of choices (1 choice or 4 choices). In contrast, for people who do not prefer many choices and people who perceive making such decisions as difficult, a lower number of choices (1 choice or 4 choices) may be better than 16 choices. Broadly speaking, accommodating or matching individual preference is generally associated with engagement, choice satisfaction, and completion rates in mental health contexts [49,50]. This method of tailoring may seem intuitive, simple, and feasible to implement if shown to be effective.

Summary of Hypotheses

To summarize, we investigated both symptoms of psychological distress and state emotions, as well as psychological attributes as moderators. We hypothesized the following for practice likelihood, completion of exercise, satisfaction, and engagement:

- For people experiencing lower levels of anxiety, a higher number of choices (16) will result in better outcomes than

XSL•FO
RenderX

lower numbers of choices (1 or 4). For people experiencing higher levels of anxiety, a lower number of choices (1 or 4) is expected to result in better outcomes than a higher number of choices (16).
- For people with fewer or no depressive symptoms, a higher number of choices (16) will lead to better outcomes than lower numbers of choices (1 or 4). For people experiencing more depressive symptoms, a lower number of choices (1 or 4) will result in better outcomes than a higher number of choices (16).
- For people with more intense pleasant emotions, a larger choice set (16) will result in better outcomes than a smaller choice set (1 or 4). For people experiencing more intense unpleasant emotions, a smaller choice set (1 or 4) will lead to better outcomes than a larger choice set.
- For people who are predominantly promotion-focused, a larger choice set (16) is more likely to result in better outcomes than a smaller choice set (1 or 4). For people who are more prevention-focused, a smaller choice set (1 or 4) will lead to better outcomes than a larger choice set (16).
- For people who prefer many choices and perceive making decisions as less challenging, a wider choice set (16) will lead to better outcomes than a smaller choice set (1 or 4). For participants who do not prefer many choices and perceive making decisions as more difficult, a smaller choice set (1 or 4) is more likely to result in better outcomes than a larger choice set (16).

Methods

Open Science Disclosures

We preregistered our 3-condition experiment in the Open Science Framework (OSF), with the template by Van't Veer and Giner-Sorolla [51]. The preregistration document, data files, code, outputs, and materials of our study are available in OSF (Table S2 in Multimedia Appendix 1 [31,52-67] contains links).

Sample Size Determination, Recruitment, and Participants

We are not aware of any empirical study regarding choice set size in digital mental health exercises or investigating individual difference moderators on the impact of choice set size in mental health decision-making and experiences. Thus, our power analysis was not based on effect sizes of prior studies. We determined the minimum sample size through power analysis based on an effect size of f=0.18 (a small to medium effect based on Cohen [68]) that we consider as practically meaningful to detect while considering resource constraints, monetary and time costs, and number of potential participants [69]. We conducted the power analysis with G*Power (version 3.1; Heinrich-Heine-Universität Düsseldorf) [70]. With an expected alpha of 0.00167 (0.05/30, since we expected to adjust alpha with Holm correction to account for the number of hypothesis testing), 3 conditions, and a power of 80%, a minimum sample size of 575 would be required. Accounting for potential attrition and exclusion of participants not meeting validity testing, our target sample size was set as 675.

We recruited participants through the university subject pool and the social media platforms (Facebook and Instagram). We stated in the advertisement and the introductory page of the study that participants should understand Chinese and should be 18 years or older. The number of participants who were randomized to one of the conditions (1-choice, 4-choice, or 16-choice conditions) was 675.

The number of participants who completed at least one dependent variable measure and passed at least one validity check question (thereby included in our analyzed sample) was 652 (1-choice: 216 participants, 4-choice: 220 participants, 16-choice: 216 participants). A total of 23 participants were excluded due to not completing the experiment or not passing at least one validity check. The mean age of the analyzed sample was 21.77, with a SD of 12.41. A total of 40.03% of participants were women, 57.66% were men, and 2.31% of participants did not disclose gender.

Procedures and Measures

The randomized 3-condition experiment was conducted through Qualtrics. To measure pre-existing characteristics or states, participants first completed scales on anxiety and depressive symptoms, emotional states, and psychological attributes (regulatory focus, preferences, and difficulties in making choices). In mental health self-care, it is reasonable to first gauge participants' distress experience (as measured by anxiety and depressive symptoms) and their present emotional state at the time of engaging in a mental health platform, as this may affect their decision-making and we may adjust based on these potential moderators. This also simulates digital mental health contexts in which pre-existing states or psychological attributes are measured for personalization purposes. The effects of different choice set sizes on emotional states, anxiety, or depression were not tested, so such measures were presented before choice presentations only. Participants were randomized to either 1-choice, 4-choice, or 16-choice conditions, in which they chose to practice with one of the mental health exercises or chose not to practice. After that, participants responded to outcome variables including satisfaction, engagement, and subjective experiences. The entire experiment takes around 20 to 25 minutes. Details about the scales and measures are reported in the following.

Choice Set Sizes

Rationale

In the context of mental health self-care, we anticipated a possibility that for a proportion of participants experiencing moderate to severe levels of depression, they may be amotivated to make choices on their own [36]. Moreover, in the Chinese culture, many people were socialized since very young to be deferent to authorities and exercise conformity or compliance [19,20]; thus, some Chinese people may find making choices more challenging or prefer simply to be told what to do. As such, we included a single-choice option. We are aware that the choice set size literature generally focuses on comparing various levels of choice sets with a smaller number of multiple choices to a very large number of choices (meta-analysis by [4]); however, we are unaware of any study that focused on choice

XSL•FO
RenderX

set sizes for mental health-related self-care exercises. In light of the clinical and cultural considerations, we decided to include a single-choice condition to investigate whether providing a single choice may be better for a subgroup of participants. Participants can still opt out of not practicing self-care, even with this single-choice option.

As to our decision of including 4-choice and 16-choice as the other 2 experimental conditions for investigation, we acknowledged that these choice set sizes contain fewer options than some consumer behavior studies that involve products such as pens and DVDs [4] and the decision does not have much implication for their health. However, our choice set sizes were similar to studies that involve health decision making and a study that found support for the overchoice effect among people with higher levels of anxiety (eg, [12,32,71], also see Chernev [4] meta-analysis regarding the number of choices in different studies). Health-related decisions generally involve less familiar and more complex information compared with consumer decisions like buying food and other daily life products. A 4-choice condition is considered a relatively manageable size, similar to other studies using smaller choice sets [12,32]. As to a larger choice set, presenting participants with 30 or more choices on mental health self-care appears unrealistic and may not even be appropriate in light of the generally low levels of mental health literacy and unfamiliarity of the public with mental health self-care among Chinese [21,22]. Moreover, considering the user interface of presenting various choices on mobile apps, the maximum number of presenting a 16-option choice set is deemed more suitable in real-world implementation. Although the exact number of choices is not definite, we deemed comparing a single, manageable few, and relatively large choice sets in digital mental health contexts to be realistic and meaningful, as any of these choice set sizes has potential implementation implications on a mental health mobile app. Due to research constraints (eg, number of participants to be recruited, funding), we could not include more than 3 conditions with a greater number of choices.

Anxiety Symptoms

Participants completed the Generalized Anxiety Disorder-7 (GAD-7) [72], which measures anxiety symptoms over the past 2 weeks and consists of 7 items with 0 to 3 Likert scales (0=Not at all, 1=Several days, 2=More than half the days, 3=Nearly every day). Sum scores were used, with higher total scores indicating more severe levels of anxiety symptoms. GAD-7 has been validated in both general and clinical populations and has shown adequate internal consistency, construct validity, and convergent validity [72-74]. With our sample, GAD-7 has an internal consistency of α=.922.

Depressive Symptoms

Depressive symptoms over the past 2 weeks were measured using the Patient Health Questionnaire (PHQ-9) [75], with 9 items and 0 to 3 Likert scales (0=Not at all, 1=Several days, 2=More than half the days, 3=Nearly every day). The score is the sum of all items, and higher scores indicate more severe levels of depressive symptoms. PHQ-9 has been validated in both clinical populations and general populations and has demonstrated good reliability, construct validity, and convergent validity [76,77]. In our sample, PHQ-9's internal consistency was α=.876.

State Emotions

Apart from measuring anxiety and depressive symptoms, state emotions were measured by using 8 emotions with 2 emotions from each quadrant of the Circumplex Model [78]. The emotions measured include tired, sad (unpleasant and lower arousal), tense, distressed (unpleasant and higher arousal), happy, excited (pleasant and higher arousal), relaxed, and calm (pleasant and lower arousal). 5-point scales adapted based on The Positive and Negative Affect Schedule [79] were adopted (1=very slightly or not at all, 2=a little, 3=moderately, 4=quite intense, 5=very intense, slight changes in wording for 4th and 5th point). The internal consistency of the pleasant emotions subscale was α=.708, and the unpleasant emotions subscale was α=.834 in our study. For the analyses, we averaged the pleasant emotions and the unpleasant emotions to calculate composite scores for pleasant emotions and unpleasant emotions. We then calculated the difference between pleasant emotions and unpleasant emotions, in which a positive score implies more intense pleasant emotions (compared with unpleasant emotions), whereas a negative score implies more intense unpleasant emotions (compared with pleasant emotions).

Regulatory Focus

Promotion and prevention orientations in regulatory focus were measured using Gomez et al [80] Health Regulatory Focus Scale (HRFS). The scale consists of eight 7-point scale (1=strongly disagree, 7=strongly agree) items (5 promotion items and 3 prevention items). We replaced "health" with "mental health" in the items so that the items are more relevant to mental health. An example of promotion focus is "If I see a good opportunity to improve my mental health, I take advantage of it right away," and an example of prevention focus is "When I implement a mental health behavior, it's because I want to protect myself from getting sick." The scores are calculated by averaging promotion items and prevention items. HRFS demonstrated an advantage in predictive validity within health behavior contexts over general regulatory focus scales [52,53]. It also has adequate internal consistency, test-retest reliability, convergent validity, and discriminant validity [80]. In our study, HRFS showed internal consistency of α=.887 in promotion focus and α=.698 in prevention focus.

Perceived Difficulty of Making Choices and Preference for Choices

Perceived Difficulty of Making Choices (PDMC) and Preference for Choices (PFC) were measured with scales constructed and adopted by Feldman et al [48], which were positively associated with the Free Will and Determinism Scale [81]. Both scales consist of 2 items each with 7-point scales (1=strongly disagree, 7=strongly agree). An example item of PFC is "In each decision I face, I prefer to have as many options as possible to choose from," and an example item of PDMC is "It's very hard for me to choose between many alternatives." Scale scores were calculated by averaging the items. The scales have not been formally validated. PFC scale shows an internal consistency of α=.785, and the internal consistency of PDMC is α=.690.

XSL•FO
RenderX

While we focused on preregistered confirmatory moderators in this manuscript, we included additional psychological attributes, notably Need For Cognition [82] in the same data collection, and the full list of these scales is reported in Multimedia Appendix 1 [31,52-67]. (We may conduct exploratory analyses with such variables for separate manuscripts and we welcome researchers to conduct secondary exploratory analyses [eg, machine learning methods, see discussion] with our open dataset.)

After completion of the above measures, participants were randomized to either (1) 1-Choice condition, (2) 4-Choice condition, or (3) 16-Choice condition. Each condition consists of an array of mental health self-care exercises with brief descriptions about the tasks involved and the purpose of each exercise. All exercises have the same purpose in improving mental well-being and reducing psychological distress and last for a few minutes. They are commonly used exercises in mindfulness-based, self-compassion-based, and cognitive-behavioral interventions, which are evidence-based approaches demonstrated to improve mental well-being and reduce anxiety and depressive symptoms [83-85]. In a previous randomized controlled trial conducted among Chinese in Hong Kong [84], brief mobile app-based mindfulness-based, self-compassion-based, and cognitive-behavioral interventions were found to be equivalent and effective in improving mental well-being and reducing psychological distress.

Half of the exercises involve writing tasks, and half of the exercises are experiential, based on audio/video. Examples include mindful awareness of emotions, mindful breathing (mindfulness), self-compassion letter-writing, self-kindness meditation (self-compassion), problem-solving, and absorbing activities (cognitive-behavioral). The order of the exercises was randomized to prevent order effects, and the choices of the single-option and 4-choice option (2 writing, 2 experiential) were randomized from the 16 choices. More details regarding the exercises and each condition are reported in the Multimedia Appendix 1 [31,52-67] "Details regarding Different Choice Sets and Exercises" section, with screenshots on Qualtrics, titles, and descriptions of all exercises presented or randomized. The Qualtrics QSF file is shared on OSF [86], in which people can download and upload the file on Qualtrics to view the experiment with exercises in the Chinese language.

After choosing "choose later," "do not want to practice," or choosing and involving in one of the exercises, participants were presented with the following variables. Variables designated as primary are variables for which we have specific hypotheses, and secondary are variables that are exploratory, as indicated in our preregistration.

Manipulation Check

We included a manipulation check: "The previous page has many mental health exercise choices," with a 7-point scale (1=Strongly Disagree, 7=Strongly Agree), to test if the choice set size manipulation results in perceived differences in the number of choices across conditions. This question was presented neutrally to avoid negative or positive connotation regarding many choices, as there may be an impact on subsequent responses to the dependent variables if such a question was framed positively (diverse choices) or negatively (too many choices).

Decision Satisfaction (Primary)

Participants completed 2 items on decision satisfaction, which were based on Benoit and Miller's [54,83] items. They included one item on satisfaction with the number of options and one item on satisfaction with decision experiences (the process). An example of a decision satisfaction item is "Are you satisfied or unsatisfied with the number of options just a moment ago?" Both items have 7-point scales (1=very unsatisfied, 7=very satisfied), which is the same as Benoit and Miller [54]. The internal consistency of the scale is α=.721.

Chosen Exercise Satisfaction (Primary)

Two items from Benoit and Miller [54,83] were used to measure chosen option satisfaction, including one item on the degree to which participants are satisfied or unsatisfied with the chosen exercise and one item on the degree to which participant believes the chosen exercise fulfills personal preferences. An example item is "Are you satisfied or unsatisfied with your chosen exercise just a moment ago?" The 2 items have 7-point scales (1=very unsatisfied, 7=very satisfied; 1=completely unable to fulfill my preference, 7=strongly fulfill my preference). The scale had an internal consistency of α=.763 in this study.

Completion (Primary)

Participants were asked whether they completed the exercise with a single question ("Did you complete the exercise just a moment ago?") with three options: (1) did not choose any of the exercises, (2) completed, and (3) not completed. Only data from participants who chose one of the exercises were analyzed.

Engagement (Primary)

A single question on the degree of engagement in the exercise ("What was your level of engagement in the exercise just a moment ago?") was used, with a 7-point scale (1=not engaged at all, 7=very engaged). Only data from participants who selected one of the exercises were analyzed.

We also included the following secondary measures for exploratory purposes. We did not have specific hypotheses as we are unaware of any study in the number-of-choice literature with such dependent variables, and at the preregistration stage, we perceived such variables as more distal compared with the primary measures we included. Despite that, we believed including these items would be worthwhile for several reasons. These measures are simple and not lengthy, particularly relevant in mental health contexts, and may inform future studies in the number-of-choice literature.

Attitudes Toward Chosen Exercise (Secondary)

Three items measuring participants' attitudes toward chosen exercise were used, with one item each on liking, perceived helpfulness of the exercise, and desirability of the exercise. All these items are measured with 7-point scales (1=not desirable at all for me, 7=very desirable for me; 1=strongly dislike, 7=strongly like; 1=not helpful at all, 7=very helpful). An example item is "Do you think that the exercise you just did a

XSL•FO
RenderX

moment ago was helpful for you?" The internal consistency was α=.903.

Perceived Improvement in Psychological State (Secondary)

Participants who chose one of the exercises also completed an item regarding their perceived improvement in mental state ("Do you think your mental state has improved or not due to the exercise a moment ago?). This item is measured with a 7-point scale (1=no improvement at all, 7=very substantial improvement).

Apart from the above secondary variables, 2 additional secondary items on behavioral intention in practicing the exercise in the future and engaging in our digital mental health platform were included. In retrospect, we consider these items to be too distal or not well-designed. These items are included in the shared datasets (Table S1 in Multimedia Appendix 1 [31,52-67] contains links), and other researchers may conduct analyses with such variables, while understanding the limitations of such variables.

After the first survey, participants were sent a link in which they could optionally click on to practice or not, with the same number and combination of options as the first survey. Two weeks later, they fill in questions regarding their experiences with similar measures as the first survey. As very few (lower than 15%) of participants engaged in practice after the first survey, and most of the items require participants to have chosen or practiced exercises after the first survey to be valid, a very low number of responses received in the follow-up survey (<100 participants) can be analyzed. As a result, our analyses in the results section focus on participants' practice decisions, completion, and experiences of decision making and practices in the first survey, and the potential moderation effects.

Ethical Considerations

We obtained ethics approval from the Chinese University of Hong Kong Survey and Behavioral Research Ethics Committee (number: SBRE-23 - 0081). Participants provided informed consent via the web before the experiment, and the consent form indicated that they could withdraw from the experiment at any time. We emphasized in the consent form that participants would get compensated for their time regardless of whether they engaged in self-care exercise or not. Participants did not need to provide their names, and we noted in the consent form that their data would be confidential, anonymized, and deidentified. These practices may reduce social desirability bias in consumer research [87,88]. The datasets shared on OSF are anonymized and deidentified. Each participant was compensated with $50 Hong Kong dollars (equivalent to US $6.42) for completing the study, as transparently stated in the consent form.

Results

Notes Regarding Validation Check and Reported Results

We only reported results of participants who passed at least 1 validity check in the main manuscript. This procedure was not preregistered, but we believe this would be necessary to ensure the quality of the analyzed responses. For transparency purposes, we report results of all participants who were randomized to one of the conditions and completed one of the dependent variables in Multimedia Appendix 1 [31,52-67] (including participants who failed both attention checks). The results are highly similar.

Manipulation Check

A one-way Welch ANOVA was conducted to test whether the manipulation was successful, in other words, whether there were significant differences in levels of agreement on the presence of many choices between participants in different conditions. Welch's ANOVA was adopted instead of Fisher's ANOVA as it is robust against unequal variances [89]. Results indicate that the manipulation was successful with substantial differences in perceived number of choices between conditions and are reported in the Manipulation Check Results section in Multimedia Appendix 1 [31,52-67].

Alpha Adjustment for Multiple Testing

Alpha Adjustment Methods

As preregistered, to address risks of false positive results due to testing with multiple moderators and multiple dependent variables, the Holm sequential alpha adjustment method [55] was adopted for tests associated with our confirmatory hypotheses (with primary outcome variables). With the Holm method, the *P* values for each family were ranked from smallest to largest. For the lowest *P* value in the family, the alpha is adjusted by dividing 0.05 by the total number of tests in the family (0.05/m). For the second lowest *P* value in the family, the alpha is calculated by dividing 0.05 by m-1. For the third lowest *P* value, then adjusted alpha=.05/m^{-2}, etc. As preregistered, the tests were divided into 2 families, each with different research objectives [90]. In Family A, tests were divided in relation to anxiety and depressive symptoms as well as state emotions (potential moderations of GAD-9, PHQ-7, and state emotions, with primary outcome variables listed above). In Family B, tests were divided in relation to potential moderation of chronic traits in motivation and decision making (HRFS, PDMC, and PFC).

Regarding our secondary (exploratory) dependent variables, we did not preregister any alpha adjustment method. For exploratory analyses, two approaches are common: (1) not adopting alpha adjustment [90-92], (2) adjusting alpha with less conservative and more powerful approaches such as Benjamini-Hochberg False Discovery Rate method [93,94]. We contemplated both approaches and decided to adopt the Benjamini-Hochberg method due to the substantial number of tests involved. With the Benjamini-Hochberg procedure, *P* values are ranked from smallest (order of 1) to largest. The adjusted alpha is calculated by rank/number of tests * 0.05. To illustrate, when the number of exploratory tests in a family is 24, the adjusted alpha for the lowest *P* value would be 1/24 * 0.05=0.00208333333, whereas the adjusted alpha for the 5th lowest *P* value would be 5/24 * 0.05=0.01041666666. Similarly, such tests were classified into families [90]: (1) comparison between different numbers of choices (main effect), (2) potential moderation of anxiety and

XSL•FO
RenderX

depressive symptoms and state emotions, (3) potential moderation of psychological attributes.

Practice Exercise Decision

Using Jamovi [95], we conducted a logistic regression to compare participants' likelihood of practicing (in the first survey) between 3 conditions. The chi-square goodness-of-fit test indicates nonequal distribution in practice decisions between conditions, χ^2_2=50.8, *P*<.001. Compared with the 1-choice condition (54/216, 24.8%), participants in the 4-choice condition (113/220, 50.7%) were substantially more likely to practice (ie, choose an exercise option), odds ratio (OR) 3.12, 95% CI (2.08-4.67), *P*<.001 (below adjusted alpha of .00416666666). Similarly, participants in the 16-choice condition (121/216, 55.8%) were much more likely to choose an exercise option, OR 3.83, 95% CI (2.55-5.76), *P*<.001 (below adjusted alpha of .00208333333), compared with participants in the 1-choice condition (54/216, 24.8%). However, we found no significant differences in practice likelihood between participants in the 16-choice condition (121/216, 55.8%) and the 4-choice condition (113/220, 50.7%), OR 1.23, 95% CI (0.84-1.79), *P*=.29.

Completion of Exercise

Another logistic regression was conducted to compare participants' likelihood of completing chosen exercises between conditions. We found no support for differences in distributions of completion between conditions, χ^2_2=1.08, *P*=.583. The completion rates between conditions were not significantly different, 16-choice (106/139, 76.3%) versus 1-choice (90/112, 80.4%): OR 0.79, 95% CI (0.43-1.44), *P*=.44; 4-choice (111/137, 81.0%) versus 1-choice (90/112, 80.4%): OR 1.04, 95% CI (0.56-1.96), *P*=.90; 4-choice (111/137, 81.0%) versus 16-choice (106/139, 76.3%): OR 1.33, 95% CI (0.75-2.37), *P*=.34.

Decision Satisfaction

One-way Welch ANOVA was conducted, and differences in decision satisfaction between conditions were found, $F_{2, 432.00}$=7.42, *P*<.001. Games-Howell *t*-tests were subsequently conducted. Participants in the 16-choice condition (n=216, mean 4.80, SD 1.13) had higher decision satisfaction compared with participants in the 1-choice condition (n=216, mean 4.41, SD 1.05), $t_{427.85}$=3.77, *P*<.001 (below adjusted alpha of .00625), *d*=0.36, 95% CI (0.17-0.56). Tentative evidence indicates that participants in the 4-choice condition (n=220, mean 4.66, SD 1.06) have higher decision satisfaction than participants in the 1-choice condition, $t_{433.91}$=2.52, *P*=.03 (above adjusted alpha of .00833333333), *d*=0.24, 95% CI (0.05-0.43). The difference between the 16-choice condition and the 4-choice condition did not reach significance, $t_{430.87}$=1.36, *P*=.37, *d*=0.13, 95% CI (−0.06 to 0.32).

Other Immediately Measured Variables

Results from Welch's ANOVAs showed no evidence for significant differences in other dependent variables, including chosen exercise satisfaction, engagement, attitude toward chosen exercise, and perceived improvement in mental state between conditions with different numbers of choices. Results are reported in Table 1.

Table . ANOVAs for chosen exercise satisfaction, exercise engagement, attitude toward chosen exercise, and perceived improvement in mental state.

Dependent variables	*F* test (*df*), *P* value	16-Choice versus 1-Choice Games-Howell *t* tests (*df*), *P* value	4-Choice versus 1-Choice Games-Howell *t* tests (df), *P* value	16-Choice versus 4-Choice Games-Howell *t* tests (*df*), *P* value
Chosen exercise satisfaction	1.52 (2, 285.75); *P*=.22	1.74 (277.78); *P*=.19	0.85 (274.24); *P*=.67	0.93 (305.82); *P*=.62
Exercise engagement	0.98 (2, 246.61); *P*=.38	−1.00 (231.85); *P*=.58	−1.35 (237.95); *P*=.37	0.42 (268.80); *P*=.91
Attitude toward chosen exercise	0.34 (2, 243.07); *P*=.71	0.49 (228.05); *P*=.88	−0.28 (226.13); *P*=.96	0.82 (270.46); *P*=.69
Perceived improvement in mental state due to exercise	0.77 (2, 243.16); *P*=.46	1.04 (230.87); *P*=.55	0.01 (225.33); *P*>.99	1.09 (270.00); *P*=.52

Number of Practices After the First Survey

Furthermore, we found no evidence for differences in the number of practices (after the first survey) between participants in different conditions, $F_{2, 410.19}$=0.13, *P*=.88. In other words, the differences in the number of practices after the first survey were not significantly different, 16-choice versus 1-choice, $t_{330.39}$=0.50, *P*=.87; 4-choice versus 1-choice, $t_{391.77}$=0.18, *P*=.98; 16-choice versus 4-choice, $t_{410.70}$=0.32, *P*=.95.

Moderation Analyses of Anxiety and Depressive Symptoms as Well as State Emotions

The following analyses were conducted with RStudio linear regression (lm) function [96].

Linear Regressions With Anxiety Symptoms as the Potential Moderator

Findings from linear multiple regressions with anxiety symptoms (GAD-7) as the moderator found no support for significant moderation for decision satisfaction and exercise engagement. For chosen exercise satisfaction, attitude toward chosen exercise, and perceived improvement in mental state, we found tentative evidence for moderation. Results are summarized in Table 2. Simple slope analyses for chosen exercise satisfaction, attitude toward chosen exercise, and perceived improvement in mental state were conducted. A tentative moderating effect (with *P* values below .05 but above adjusted alpha) was found. People who experienced higher levels of anxiety symptoms, such that these participants in the 16-choice condition tended to experience higher chosen exercise satisfaction, more positive

XSL•FO
RenderX

attitudes toward chosen exercise, and more perceived improvement in mental state due to chosen exercise, compared with corresponding participants in the 4-choice and 1-choice conditions (Table 3).

Table . Interaction results (linear regressions) with anxiety symptoms as the potential moderator.

Dependent variables	β (95% CI)	*P* value
Decision satisfaction	• 16-Choice versus 1-Choice * GAD:[a] β=–.18 (–0.37 to 0.01) • 16-Choice versus 4-Choice * GAD: β=–.11 (–0.30 to 0.08)	• 16-Choice versus 1-Choice * GAD: *P*=.06 • 16-Choice versus 4-Choice * GAD: *P*=.25
Chosen exercise satisfaction	• 16-Choice versus 1-Choice * GAD: β=–.30 (–0.53 to –0.08) • 16-Choice versus 4-Choice * GAD: β=−.25 (–0.47 to –0.03)	• 16-Choice versus 1-Choice * GAD: *P*=.009 (above adjusted alpha of .00142857142) • 16-Choice versus 4-Choice * GAD: *P*=.02 (above adjusted alpha of .00151515151)
Exercise engagement	• 16-Choice versus 1-Choice * GAD: β=−.08 (–0.34 to 0.18) • 16-Choice versus 4-Choice * GAD: β=−.03 (–0.28 to 0.21)	• 16-Choice versus 1-Choice * GAD: *P*=.55 • 16-Choice versus 4-Choice * GAD: *P*=.78
Attitudes toward chosen exercise	• 16-Choice versus 1-Choice * GAD: β=−.33 (–0.59 to –0.08) • 16-Choice versus 4-Choice * GAD: β=−.29 (–0.53 to –0.05)	• 16-Choice versus 1-Choice * GAD: *P*=.01 (above adjusted alpha of .00714285714) • 16-Choice versus 4-Choice * GAD: *P*=.02 (above adjusted alpha of .01428571428)
Perceived improvement in mental state	• 16-Choice versus 1-Choice * GAD: β=−.36 (–0.61 to –0.10) • 16-Choice versus 4-Choice * GAD: β=−.29 (–0.52 to –0.05)	• 16-Choice versus 1-Choice * GAD: *P*=.006 (above adjusted alpha of .00178571428) • 16-Choice versus 4-Choice * GAD: *P*=.02 (above adjusted alpha of .01785714285)

[a]GAD: Generalized Anxiety Disorder.

Table . Simple slope analyses with Generalized Anxiety Disorder-7 (GAD-7) as the potential moderator, chosen exercise satisfaction, attitudes toward chosen exercise, and perceived improvement in psychological state as dependent variables.

GAD-7 level	Chosen exercise satisfaction, β (95% CI)	Attitudes toward chosen exercise, β (95% CI)	Perceived improvement in mental state, β (95% CI)
−1SD (lower anxiety)	• 1-Choice versus 16-Choice: β=.12 (–0.22 to 0.45); *P*=.49 • 4-Choice versus 16-Choice: β=.15 (–0.17 to 0.46); *P*=.36	• 1-Choice versus 16-Choice: β=.28 (–0.08 to 0.65); *P*=.13 • 4-Choice versus 16-Choice: β=.19 (–0.14 to 0.53); *P*=.26	• 1-Choice versus 16-Choice: β=.23 (–0.13 to 0.60); *P*=.21 • 4-Choice versus 16-Choice: β=.15 (–0.18 to 0.49); *P*=.38
Mean	• 1-Choice versus 16-Choice: β=−.20 (–0.43 to 0.04); *P*=.10 • 4-Choice versus 16-Choice: β=−.11 (–0.34 to 0.11); *P*=.31	• 1-Choice versus 16-Choice: β=−.06 (–0.31 to 0.19); *P*=.66 • 4-Choice versus 16-Choice: β=−.10 (–0.34 to 0.13); *P*=.39	• 1-Choice versus 16-Choice: β=−.13 (–0.38 to 0.12); *P*=.31 • 4-Choice versus 16-Choice: β=−.14 (–0.37 to 0.10); *P*=.26
+1SD (higher anxiety)	• 1-Choice versus 16-Choice: β=−.51 (–0.84 to –0.18); *P*=.002 (above adjusted alpha of .00138888888) • 4-Choice versus 16-Choice: β=−.38 (–0.69 to –0.06); *P*=.02 (above adjusted alpha of .00147058823)	• 1-Choice versus 16-Choice: β=−.39 (–0.75 to –0.04); *P*=.03 (above adjusted alpha of 0.025) • 4-Choice versus 16-Choice: β=−.40 (–0.74 to –0.06); *P*=.022 (above adjusted alpha of .02142857142)	• 1-Choice versus 16-Choice: β=−.49 (–0.85 to –0.13); *P*=.007 (above adjusted alpha of .00357142857) • 4-Choice versus 16-Choice: β=−.43 (–0.76 to –0.09); *P*=.01 (above adjusted alpha of .00892857142)

Logistic Regressions With Anxiety Symptoms as the Potential Moderator, Practice Decision, and Completion as Dependent Variables

Logistic regressions were conducted to test the moderation of anxiety symptoms (GAD-7) in the impact of different numbers of choices on practice decision and completion. With practice decision as the dependent variable, we found no evidence for moderation, OR (GAD-7 * 4-choice versus 16-choice)=0.88 (95% CI 0.59-1.30), *P*=.52; OR (GAD-7 * 1-choice versus 16-choice)=0.91 (95% CI 0.60-1.38), *P*=.65. With completion as the dependent variable, we found no support for moderation, OR (GAD-7 * 4-choice versus 16-choice)=0.97 (95% CI

XSL•FO
RenderX

0.55-1.72), *P*=.93; OR (GAD-7 * 1-choice versus 16-choice)=0.98 (95% CI 0.54-1.79), *P*=.96.

Linear Regressions With Depressive Symptoms as the Potential Moderator

No support of depressive symptoms as moderation was found for various dependent variables, except attitudes toward chosen exercise. The interaction results are summarized in Table 4.

Table . Interaction results (linear regressions) with depressive symptoms as the potential moderator.

Dependent variables	β (95% CI)	*P* value
Decision satisfaction	• 16-Choice versus 1-Choice * PHQ:[a]β=−.07 (–0.26 to 0.13) • 16-Choice versus 4-Choice * PHQ: β=.01 (–0.18 to 0.20)	• 16-Choice versus 1-Choice * PHQ: *P*=.51 • 16-Choice versus 4-Choice * PHQ: *P*=.91
Chosen exercise satisfaction	• 16-Choice versus 1-Choice * PHQ: β=−.19 (–0.42 to 0.05) • 16-Choice versus 4-Choice * PHQ: β=−.19 (–0.42 to 0.04)	• 16-Choice versus 1-Choice * PHQ: *P*=.12 • 16-Choice versus 4-Choice * PHQ: *P*=.11
Exercise engagement	• 16-Choice versus 1-Choice * PHQ: β=−.03 (–0.30 to 0.23) • 16-Choice versus 4-Choice * PHQ: β=−.05 (–0.30 to 0.20)	• 16-Choice versus 1-Choice * PHQ: *P*=.80 • 16-Choice versus 4-Choice * PHQ: *P*=.69
Attitudes toward chosen exercise	• 16-Choice versus 1-Choice * PHQ: β=−.18 (–0.44 to 0.08) • 16-Choice versus 4-Choice * PHQ: β=−.25 (–0.50 to –0.01)	• 16-Choice versus 1-Choice * PHQ: *P*=.18 • 16-Choice versus 4-Choice * PHQ: *P*=.04 (above adjusted alpha of .02857142857)
Perceived improvement in psychological state	• 16-Choice versus 1-Choice * PHQ: β=−.25 (–0.51 to 0.01) • 16-Choice versus 4-Choice * PHQ: β=−.23 (–0.48 to 0.01)	• 16-Choice versus 1-Choice * PHQ: *P*=.07 • 16-Choice versus 4-Choice * PHQ: *P*=.06

[a]PHQ: Patient Health Questionnaire.

Specifically, the moderating effect of depressive symptoms on the number of choices (16-choice versus 4-choice) on attitudes toward exercise was inconclusive, with the *P* value below .05 (*P*=.04) but above the adjusted alpha based on Benjamini–Hochberg correction. Simple slope analysis using the PROCESS Macro function in R by Hayes [97] with +1SD value in depressive symptoms (PHQ=13.49) showed that participants in the 16-choice condition (mean=4.71) had more positive attitudes toward exercise compared with participants in the 4-choice condition (mean=4.27), β=.37 (95% CI 0.01-0.72), *P*=.04 (above adjusted alpha of .02678571428). Other regression coefficients at different levels of depressive symptoms were not significant.

Logistic Regressions With Depressive Symptoms as the Potential Moderator, Practice Decision and Completion as Dependent Variables

For practice decision, we found no support for interaction between depressive symptoms and number of choices, PHQ-9 * 4-choice versus 16-choice: OR 1.10 (95% CI 0.75-1.61), *P*=.63; PHQ-9 * 1-choice versus 16-choice: OR 1.32 (95% CI 0.87-2.01), *P*=.19. Additionally, we found no evidence for interaction between PHQ-9 and number of choices on completion of exercises, PHQ-9 * 4-choice versus 16-choice: OR 1.16 (95% CI 0.65-2.07), *P*=.62; PHQ-9 * 1-choice versus 16-choice: OR 1.35 (95% CI 0.73-2.50), *P*=.35.

Linear Regressions With State Emotions as the Potential Moderator

For decision satisfaction and engagement, no evidence for the moderation of state emotions was found. For chosen exercise satisfaction (primary dependent variable), we found conclusive evidence for the moderation of state emotions (*P*<.001, below adjusted alpha) when comparing the 16-choice condition with the 1-choice condition and found tentative evidence for the moderation of state emotions (*P*=.04) when comparing the 16-choice condition with the 4-choice condition. For secondary dependent variables, including attitudes toward chosen exercise and perceived improvement in psychological state, we found tentative evidence for the moderation of state emotions, and such results are reported in Table 5. Building on the moderation findings, simple slopes analyses were conducted. For people who are experiencing more intense unpleasant emotions, participants in the 16-choice condition tend to experience higher chosen exercise satisfaction compared with participants in the 1-choice condition, whereas there is tentative evidence of higher chosen exercise satisfaction for people in the 16-choice condition compared with participants in the 4-choice condition. Furthermore, we found support that participants who experienced more intense unpleasant emotions in the 16-choice condition experienced more positive attitudes toward the chosen exercise, compared with participants in the 4-choice condition, and tentative evidence for differences in chosen exercise

XSL•FO
RenderX

satisfaction between the 16-choice condition and the 1-choice condition. Moreover, we found tentative evidence that people with more intense unpleasant emotions in the 16-choice condition experienced more subjective improvement in mental state compared with participants in the 1-choice condition. We report more details of simple slope analyses in Tables 6 and 7.

Table . Interaction results (linear regressions) with state emotions (continuous) as the potential moderator.

Dependent variables	β (95% CI)	*P* value
Decision satisfaction	• 16-Choice versus 1-Choice * State Emotions: β=.17 (–0.01 to 0.36) • 16-Choice versus 4-Choice * State Emotions: β=.01 (–0.17 to 0.20)	• 16-Choice versus 1-Choice * State Emotions: *P*=.08 • 16-Choice versus 4-Choice * State Emotions: *P*=.88
Chosen exercise satisfaction	• 16-Choice versus 1-Choice * State Emotions: β=.41 (0.18 to 0.64) • 16-Choice versus 4-Choice * State Emotions: β=.23 (0.01 to 0.45)	• 16-Choice versus 1-Choice * State Emotions: *P*<.001 (below adjusted alpha of .00135135135) • 16-Choice versus 4-Choice * State Emotions: *P*=.04 (above adjusted alpha of .00161290322)
Exercise engagement	• 16-Choice versus 1-Choice * State Emotions: β=.18 (–0.08 to 0.44) • 16-Choice versus 4-Choice * State Emotions: β=.14 (–0.11 to 0.38)	• 16-Choice versus 1-Choice * State Emotions: *P*=.19 • 16-Choice versus 4-Choice * State Emotions: *P*=.27
Attitudes toward chosen exercise	• 16-Choice versus 1-Choice * State Emotions: β=.36 (0.10 to 0.62) • 16-Choice versus 4-Choice * State Emotions: β=.29 (0.05 to 0.53)	• 16-Choice versus 1-Choice * State Emotions: *P*=.007 (above adjusted alpha of .00535714285) • 16-Choice versus 4-Choice * State Emotions: *P*=.02 (above adjusted alpha of .01607142857)
Perceived improvement in mental state	• 16-Choice versus 1-Choice * State Emotions: β=.32 (0.07 to 0.58) • 16-Choice versus 4-Choice * State Emotions: β=.17 (–0.07 to 0.41)	• 16-Choice versus 1-Choice * State Emotions: *P*=.014 (above adjusted alpha of .01071428571) • 16-Choice versus 4-Choice * State Emotions: *P*=.16

Table . Simple slope analyses with state emotions as the potential moderator, chosen exercise satisfaction, attitudes toward chosen exercise, and perceived improvement in mental state as dependent variables.

State emotions	Chosen exercise satisfaction, β (95% CI)	Attitudes toward chosen exercise, β (95% CI)	Perceived improvement in mental state, β (95% CI)
−1 SD (stronger unpleasant emotions)	• 1-Choice versus 16-Choice: β=−.60 (–0.92 to –0.28); *P*<.001 (below adjusted alpha of .00131578947) • 4-Choice versus 16-Choice: β=−.35 (–0.67 to –0.03); *P*=.03 (above adjusted alpha of .0015625)	• 1-Choice versus 16-Choice: β=−.40 (–0.75 to –0.05); *P*=.03 (above adjusted alpha of .02321428571) • 4-Choice versus 16-Choice: β=−.40 (–0.75 to –0.06); *P*=.02 (above adjusted alpha of .01964285714)	• 1-Choice versus 16-Choice: β=−.44 (–0.79 to –0.09); *P*=.02 (above adjusted alpha of .0125) • 4-Choice versus 16-Choice: β=−.31 (–0.66 to 0.03); *P*=.07
Mean	• 1-Choice versus 16-Choice: β=−.18 (–0.41 to 0.05); *P*=.12 • 4-Choice versus 16-Choice: β=−.12 (–0.34 to 0.10); *P*=.30	• 1-Choice versus 16-Choice: β=−.04 (–0.29 to 0.21); *P*=.73 • 4-Choice versus 16-Choice: β=−.11 (–0.35 to 0.12); *P*=.36	• 1-Choice versus 16-Choice: β=−.11 (–0.37 to 0.14); *P*=.38 • 4-Choice versus 16-Choice: β=−.14 (–0.38 to 0.10); *P*=.25
+1 SD (stronger pleasant emotions)	• 1-Choice versus 16-Choice: β=.24 (–0.10 to 0.57); *P*=.17 • 4-Choice versus 16-Choice: β=.12 (–0.19 to –0.43); *P*=.46	• 1-Choice versus 16-Choice: β=.31 (–0.05 to 0.68); *P*=.10 • 4-Choice versus 16-Choice: β=.18 (–0.15 to 0.51); *P*=.28	• 1-Choice versus 16-Choice: β=.21 (–0.16 to 0.58); *P*=.26 • 4-Choice versus 16-Choice: β=.03 (–0.30 to 0.37); *P*=.84

Table . Means of 1-Choice, 4-Choice, and 16-Choice conditions at different levels of state emotions.

	1-Choice	4-Choice	16-Choice
−1 SD (stronger unpleasant emotions)	• Chosen exercise satisfaction: 4.13 • Attitude toward exercise: 4.22 • Perceived Improvement in psychological state: 3.57	• Chosen exercise satisfaction: 4.41 • Attitude toward exercise: 4.21 • Perceived improvement in psychological state: 3.75	• Chosen exercise satisfaction: 4.80 • Attitude toward exercise: 4.71 • Perceived improvement in psychological state: 4.18
Mean	• Chosen exercise satisfaction: 4.48 • Attitude toward exercise: 4.50 • Perceived improvement in psychological state: 3.91	• Chosen exercise satisfaction: 4.56 • Attitude toward exercise: 4.42 • Perceived improvement in psychological state: 3.87	• Chosen exercise satisfaction: 4.69 • Attitude toward exercise: 4.55 • Perceived improvement in psychological state: 4.07
+1 SD (stronger pleasant emotions)	• Chosen exercise satisfaction: 4.84 • Attitude toward exercise: 4.78 • Perceived improvement in psychological state: 4.25	• Chosen exercise satisfaction: 4.71 • Attitude toward exercise: 4.62 • Perceived improvement in psychological state: 4.00	• Chosen exercise satisfaction: 4.57 • Attitude toward exercise: 4.40 • Perceived improvement in psychological state: 3.95

Logistic Regressions With State Emotions as the Potential Moderator

With practice decision as the dependent variable, the regression indicates no support for moderation, OR (State Emotions * 4-choice vs 16-choice)=1.03 (95% CI 0.70-1.50), *P*=.89; OR (State Emotions * 1-choice vs 16-choice)=0.92 (95% CI 0.61-1.40), *P*=.71. With completion as the variable, we also found no evidence for moderation, OR (State Emotions * 4-choice vs 16-choice)=0.85 (95% CI 0.47-1.53), *P*=.59; OR (State Emotions * 1-choice vs 16-choice)=1.18 (95% CI 0.64-2.16), *P*=.60.

Moderation Analyses of Individual Characteristics

Linear Regressions With Health Regulatory Focus [80] as the Potential Moderator

Interaction results of health regulatory focus with different dependent variables were all nonsignificant and are summarized in Table S3 in Multimedia Appendix 1 [31,52-67].

Logistic Regressions With Health Regulatory Focus [80] as the Potential Moderator With Practice Decision and Completion as Dependent Variables

With logistic regression, we found no evidence for moderation of health regulatory focus on the impact of number of choices in practice decision, OR (HRFS * 4-choice vs 16-choice)=1.01 (95% CI 0.70-1.47), *P*=.95; OR (HRFS * 1-choice vs 16-choice)=0.77 (95% CI 0.50-1.20), *P*=.26. With completion as the dependent variable, we also found no support for moderation of health regulatory focus, OR (HRFS * 4-choice vs 16-choice)=0.94 (95% CI 0.51-1.72), *P*=.84; OR (HRFS * 1-choice vs 16-choice)=0.67 (95% CI 0.35-1.28), *P*=.22.

Linear Regressions With PFC and PDMC [48] as the Potential Moderator

With PFC as the potential moderator, we found no support for any interaction effects with all continuous variables. Results are summarized in Table S4 in Multimedia Appendix 1 [31,52-67]. Additionally, we found no evidence for moderation with PDMC with all continuous variables (Table S5 in Multimedia Appendix 1 [31,52-67]).

Logistic Regressions With PFC and PDMC [48] as the Potential Moderator

With practice decision as the dependent variable, we found no evidence for moderation with PDMC as the potential moderator, OR (PDMC * 4-choice vs 16-choice)=0.86 (95% CI 0.58-1.27), *P*=.45; OR (PDMC * 1-choice vs 16-choice)=1.23 (95% CI 0.82-1.85), *P*=.31. With completion as the dependent variable and PDMC as the potential moderator, the results also indicate no significant moderation, OR (PDMC * 4-choice vs 16-choice)=1.05 (95% CI 0.57-1.92), *P*=.88; OR (PDMC * 1-choice vs 16-choice)=0.98 (95% CI 0.53-1.79), *P*=.95. Additionally, we found no support for moderation of preferences for choices with practice decision as the dependent variable, OR (PFC * 4-choice vs 16-choice)=0.98 (95% CI 0.66-1.44), *P*=.91; *OR* (PFC * 1-choice vs 16-choice)=0.79 (95% CI 0.52-1.20), *P*=.27. Finally, we found no evidence for moderation of PFC with completion of exercise as the dependent variable, OR (PFC * 4-choice vs 16-choice)=0.92 (95% CI 0.50-1.67), *P*=.78; OR (PFC * 1-choice vs 16-choice)=1.02 (95% CI 0.56-1.84), *P*=.96.

Discussion

Principal Results: Comparing Different Numbers of Choices (Overall Effects)

Our investigation delved into potential differences in various outcomes across different numbers of choices. Participants in 4-choice and 16-choice conditions appeared more likely to practice one of the mental health self-care exercises and reported higher levels of decision satisfaction, compared with participants in the single-choice condition. These findings align with existing studies that underscore the positive impact of providing multiple choices, fostering increased active involvement and satisfaction among participants in health interventions [16].

The rationale behind these results might be elucidated using the self-determination theory. Individuals might be more inclined

XSL•FO
RenderX

to engage in mental health behaviors when granted autonomy to make a choice when given multiple options [5,13-15]. The provision of multiple options caters to the fundamental human need for autonomy and the freedom to choose, possibly leading to heightened decision satisfaction in the multi-choice conditions compared with the single-choice condition. Conversely, individuals presented with only one option, including Chinese people, may experience a sense of choice deprivation and feel less satisfied with the insufficient number of choices [98].

Another plausible explanation rooted in classical economic models suggests that in conditions offering multiple choices, participants are more likely to discover an exercise aligning with their preferences, thus increasing the likelihood of selection [3,4,18]. In contrast, the singular exercise choice provided may not resonate with participants' preferences, leading to lower exercise selection rates. However, our findings found no support for significant differences between the multiple-choice conditions and the single-choice condition in other outcomes, such as satisfaction with the chosen exercise, engagement levels, and completion rates. This lack of differentiation could stem from these variables predominantly reflecting experiences with the specific chosen exercise, with the benefits of multiple-choice provision potentially not extending to these more distal variables.

While our study revealed distinctions in 2 outcome variables between the single-choice and 4-choice conditions, as well as between the single-choice and 16-choice conditions, in terms of overall effects, we did not observe any significant differences in dependent variables between the 4-choice and 16-choice conditions. These findings align with the meta-analysis on choice set size conducted by Scheibehenne et al [30], which reported a negligible mean effect size when comparing higher versus lower numbers of choices. Similarly, our results are consistent with the meta-analysis by Chernev et al [4], which found no substantial differences in outcomes, including satisfaction and option selection, when comparing larger and smaller choice sets, among studies examining potential moderators. The average effect sizes of main effects, particularly in studies testing potential moderators, often tend to be minimal or statistically nonsignificant [4]. While some studies find support for the overchoice effect (eg, [26]), others (eg, [99]) found better outcomes with a higher number of choices, underscoring the variability of effects across different contexts [4].

The reasons behind minimal differences between the 16-choice condition and the 4-choice condition remain unclear, and our findings contradict concerns by some digital mental health researchers who suggested a higher number of choices may backfire [1,42]. It is possible that discomfort or indecisiveness (not selecting any of the choices) due to many-choice comparison is less likely to occur in decision-making contexts where making a choice does not involve any financial costs, including the context of our experiment. However, it is unclear if our findings are generalizable to digital mental health platforms that require payments for audio, video, and written exercises. In contexts where people need to pay the prices, the overchoice effect may be more likely to occur, possibly due to counterfactual thinking, anticipated and experienced regret, or other uncomfortable emotions regarding the monetary costs [4,11,26,100-102]. That said, we are unaware of studies that compare the impact of choice set sizes in decision-making contexts with and without monetary considerations. These explanations are speculative, and further research, comparing digital health self-care choices that do not require payment versus self-care choices that require payment, is warranted to delve deeper into these nuances and test these conjectures.

Principal Results: Tentative Evidence for Moderations of State Emotions and Anxiety

Contrary to our hypotheses, recent findings in the broader overchoice literature beyond mental health contexts [32], and concerns raised by digital mental health researchers [1,42], our study unearthed tentative evidence suggesting that individuals with heightened anxiety levels and stronger negative emotional states may actually experience greater satisfaction, exhibit more positive attitudes toward the selected exercise, and perceive greater psychological improvement when presented with a higher number of choices (16 choices), as opposed to those offered a single choice or 4 choices. Our expectations were rooted in the notion that individuals experiencing intense anxiety and unpleasant emotions might struggle with decision-making in larger choice sets due to limited cognitive resources and heightened difficulties, leading to unpleasant experiences when choosing from a wider array of options [1,32,38,39,41]. However, our findings diverged from this anticipated direction, prompting a reflection. How can we interpret these unexpected results, and are these results reliable?

Our moderation findings are tentative, but we believe such results are likely reliable despite some uncertainties. While for several dependent variables, our results (moderation of anxiety symptoms and state emotions) reached conventional statistical significance of $P<.05$, most of the results did not retain significance following alpha corrections. There exists a possibility that these findings could be attributed to chance, particularly considering the inclusion of multiple potential moderators and a range of primary and secondary dependent variables. Despite this uncertainty, the likelihood of these results being false positives is relatively low, given the medium to large effect sizes observed for the aforementioned dependent variables, based on the benchmark outlined by Fey et al [103]. Notably, effect size serves as a robust indicator of the replicability of research findings [104]. Moreover, a common thread among the variables with $P<.05$ results is that they are all regarding participants' subjective perceptions and sentiments (satisfaction, attitude, and perceived psychological improvement) concerning the selected exercise, rather than behavioral measures like practice decision and completion. Moderations of both anxiety symptoms and emotional states concerned these same subjective dependent variables, suggesting that moderations of anxiety and emotional states for such outcomes likely exist.

For participants with high anxiety and stronger unpleasant emotions, the higher satisfaction, more positive attitudes, and more subjective improvement in mental state with such exercises under a larger choice set may stem from a higher probability of matching their preferences and needs. This resonates with

XSL•FO
RenderX

economic models and studies positing that individuals have a higher probability of finding options that cater to their specific preferences and goals when faced with more choices, as previously discussed [3,4,17]. Crucially, this could also be attributed to the heightened desire of individuals with elevated anxiety levels and unpleasant emotions to alleviate their uncomfortable feelings. A selection pool of 16 exercises is more likely to include self-care activities that effectively address their needs, in contrast to single or limited 4-choice sets. Individuals may perceive only a small fraction of exercises (perhaps one or a few) as beneficial for their personal well-being. When the choice set comprises only 1 or 4 exercises, the chances of encountering an emotion-relief method that precisely aligns with their individual needs are considerably lower. This disparity underscores the potential advantages of a larger choice set over a smaller choice set in matching personal needs, preferences, and goals for individuals experiencing high anxiety and unpleasant emotions.

Related to the heightened need to address uncomfortable emotions, when people experience unpleasant mental health and emotional states, mental health–related exercises may be perceived as more personally relevant. Based on dual process models such as the Elaboration Likelihood Model and Heuristic-Systematic Information Processing Theory, heightened perceived personal relevance can result in higher effort in information processing [105,106]. It is possible that such heightened effort in information processing and more elaborate processes in thinking and decision making may increase the likelihood of participants choosing exercises that can better satisfy their emotional needs and help address their distress, through considering more options effortfully and deciding systematically with a larger choice set. In contrast, smaller choice sets may not align well with such more elaborate and effortful processes.

Conversely, individuals with lower levels of anxiety and unpleasant emotions may not have any need to further regulate their mental health at the time of the experiment and thus may consider mental health exercises as less personally relevant. Consequently, the utility of a larger choice set may hold less significance or may be perceived as irrelevant to them. As such, they may expend less cognitive effort in processing information and weighing different options, which is consistent with dual process models discussed above. Given that practicing these self-care exercises may be considered less relevant to this group of participants, the number of choices presented may yield minimal, if any, discernible effects. This rationale may explain why we did not uncover substantial differences in both behavioral responses and subjective experiences among individuals with lower levels of anxiety and unpleasant emotions across varying choice set sizes.

It is hard to interpret the absence of evidence for the moderating effect of depressive symptoms, as null findings do not necessarily imply the absence of effect. One interpretation is that, as the direction of findings is consistent with anxiety and state emotions, moderation may exist but was not detected due to relatively small effect sizes. Therefore, the moderation effect of depressive symptoms was nonsignificant. Further research with a larger sample size and a wider range of anxiety and depressive symptoms is needed.

Limitations, Strengths, and Future Research Directions

The above explanations regarding the moderations of anxiety symptoms and state emotions are speculative. The study did not delve into testing potential mediating mechanisms, and future research can explore factors such as perceived need to alleviate unpleasant emotions, perceived personal relevance of mental health self-care exercises, and elaboration in processing and deciding on mental health exercises. Through such mediated analyses, mechanisms of the phenomenon can be better understood. Additionally, it remains possible that the moderation findings can be better elucidated by a third variable linked to anxiety and unpleasant emotions, such as fear of missing out [107,108]. Subsequent studies can incorporate these variables to further investigate and validate these potential explanations.

Given the tentative nature of our moderation findings and the lack of significance in most results following alpha corrections, it is imperative to conduct replications and extensions to ascertain the replicability, reliability, and generalizability of the findings. These efforts can involve close or very close replications (directing repeating our work with similar/same designs), or conceptual replications [109] within the realm of digital mental health platforms or diverse contexts like other digital health arenas or consumer decision-making scenarios. Future research initiatives can aim to investigate whether these effects are specific to the digital mental health domain or if they hold broader generalizability and applicability across various decision-making contexts.

An intriguing avenue for conceptual replications-extensions, or follow-up studies, involves investigating the impact of recommendation statements when presenting varying choice sets (ie, a single choice, 4 choices, or 16 choices) on decision outcomes. For instance, investigating how phrases like “We strongly recommend you to practice the following exercise(s)” influence individuals’ choices and experiences compared with conditions without such recommendation language may yield valuable insights. Notably, our study did not incorporate recommendation wordings in any of the conditions, and it is plausible that the inclusion of such language would lead to increased engagement, decision-making, satisfaction, and other subjective outcome variables [1]. Introducing recommendation wordings in select conditions can also enhance the ecological validity of the results, considering that recommendation systems are increasingly common in digital mental health platforms [1,110]. Exploring the influence of recommendation statements within the context of different choice set sizes can provide a deeper understanding of how decision-making processes and subjective experiences are influenced in digital mental health settings and beyond.

Related to recommendations, another worthwhile direction is to compare different numbers of choices with and without tailored recommendations, which have been commonly adopted and researched in digital mental health contexts [1,110,111]. Studies can test if tailored recommendations that are based on prior behavioral data, demographics, mental health states, and other psychological attributes and offered a lower number of

XSL•FO
RenderX

choices may outperform a higher number of choices that are not tailored, as such fewer number of choices may be able to align with service users' needs and preferences better without providing a large amount of information. Studies that involve the intersection of choice set size and tailored recommendations [111] will require a much larger sample size due to a much higher number of conditions but can be feasible in digital mental health platforms where there are many service users. Another method that has been adopted in digital health studies and can be considered in testing the effects of various conditions over time is micro-randomized controlled trials, in which service users or participants are randomized sequentially and multiple times [112,113]. Further research can help us understand if more choices are really needed to achieve matching of needs, or if a lower number of choices of tailored recommendations can already satisfy users' needs. It is possible that when comparing subjective experiences and behavioral outcomes across conditions, mental health states and psychological attributes (eg, trait reactance, [114]) may moderate such effects.

Another worthwhile direction in replications-extensions or follow-up studies is to investigate other choice set sizes. As mentioned in the introduction, the 3 choice set sizes were chosen as such sizes were potentially suitable for different subgroups of participants and feasible to implement in real-world mobile apps. Over 30 choices are perhaps overwhelming due to lower mental health literacy of most Chinese people [21,22], as there may be too much unfamiliar and technical information to process and understand (see studies by Chernev et al [4], Misuraca et al [5], and Mogilner et al [24] regarding higher likelihood of overchoice effect among people with lower familiarity or expertise with the options). However, it is possible that such a number of choices may be suitable for a proportion of participants with higher digital mental health self-care related knowledge, since studies in the broader choice set size literature have shown that people with higher expertise regarding the options benefit more from a larger choice set [4,5,24]. While such a choice set size of over 30 choices does not seem suitable in a mobile app, it can be feasible in a web page in a computer. Another possibility is that a number between 4 and 16 may outperform other numbers of choices for a proportion of participants, perhaps because a smaller choice set does not optimally satisfy needs and preferences, but a larger choice set is also suboptimal due to increased cognitive costs and diminishing marginal benefits, whereas a medium choice set may satisfy needs well with limited cognitive costs (see studies by Grant and Schwartz [115], Liu et al [116], and Reutskaja and Hogarth [117] regarding inverted-U relationship between number of choices and outcomes). Further digital health studies can examine this speculation of an inverted-U relationship. That said, including more conditions with different choice set sizes will require more participants, and these decisions involve dilemmas given considerations for power analysis, number of participants, and real-world constraints in data collection.

Another worthwhile area for improvement in future replications, extensions, and follow-up studies is to include a question on perceived quality to test if the perceived quality of exercises is similar or varies between conditions. Given that exercises in the 1-choice and 4-choice conditions were randomly chosen from the exercises that were also presented in the 16-choice condition, it is likely that perceived quality would not vary much. That said, perceived quality between conditions may influence the results, and future studies can explicitly account for this.

Furthermore, researchers may consider investigating decision-making dynamics, task completion rates, user experiences, and mental health outcomes over extended periods within a digital platform, where individuals repeatedly engage with self-care or health-related options. Conducting such longitudinal studies would necessitate larger sample sizes to ensure adequate statistical power, as sustained engagement in self-care exercises or digital interventions is not common among most individuals [118,119]. These studies can be effectively carried out in real-world digital platforms with a substantial user base, ensuring sufficient statistical power and enhancing ecological validity, while examining generalizability and applicability.

In addition to pursuing replications-extensions or follow-up studies involving primary data collection and analyses, another valuable direction for research involves conducting secondary data analyses with our datasets shared on the OSF (Table S1 in Multimedia Appendix 1 [31,52-67] contains links). Given the tentative nature of our findings, exploring the data with different statistical methods may lead to different findings, offer fresh perspectives, and potentially uncover new insights. Researchers can consider using methodologies like the Personalized Advantage Index [120] and machine learning techniques such as Random Forests to delve into potential moderators and enhance personalization strategies [56]. Moreover, while our manuscript primarily focused on preregistered confirmatory moderators and hypotheses, as well as a few exploratory outcome variables, we included additional measures of psychological attributes such as Need for Cognition [82] in our data collection (Multimedia Appendix 1 [31,52-67]). We welcome and encourage researchers to conduct secondary analyses based on our dataset and are open to potential collaborations in this regard.

Implications

Presenting a higher number of choices does not appear to be counterproductive for most individuals with higher levels of anxiety symptoms, depressive symptoms, or intense state unpleasant emotions. For individuals experiencing elevated anxiety and depression symptoms or unpleasant emotions, there is currently no empirical evidence supporting the reduction of presented choices if there are initially 10 - 20 options shown. Instead, our findings tentatively indicate that offering a greater number of choices (16 options) may actually enhance the subjective experiences of individuals with high anxiety and intense unpleasant emotions. This could stem from an increased likelihood of aligning with and addressing their mental health needs with a larger choice set. However, we cannot definitively ascertain the outcomes of presenting individuals with an even larger number of choices (eg, over 30 choices, see Chernev et al [4] meta-analysis), and caution is advised for digital mental health developers and designers when presenting dozens of options.

XSL•FO
RenderX

In the realm of digital mental health platforms, many already incorporate measures like GAD-7 for assessing anxiety, where our findings find support for moderations based on anxiety symptoms. Tailoring the number of choices to individual anxiety levels may be beneficial. Furthermore, our moderation results concerning state unpleasant emotions suggest that including measures of current emotional states may be valuable. Developers of digital mental health platforms also need to consider the impact of adding additional items, such as 8 new state emotion measures, to existing assessments, as this may deter some participants from completing them. One potential strategy could involve including 1 to 3 state emotion items that exhibit stronger or more consistent moderation effects compared with others. Digital mental health platforms may include multiple state emotion items for a period of time. After that, based on behavioral, satisfaction, and subjective experiences data and corresponding moderation analyses (eg, through machine learning methods such as Random Forest [56]) with the initially included emotions, they may choose 1 to 3 state emotions that show stronger moderation effects to increase the likelihood that people fill in such measures and to facilitate personalization for a higher proportion of participants.

Conclusions

Our research found support for the advantage of having multiple exercise choices (4 choices or 16 choices) in enhancing the likelihood of practicing self-care and decision satisfaction, surpassing such outcomes of the single choice condition. More importantly, contrary to our expectations, prior findings [32], and concerns regarding the impact of a larger choice set in the digital mental health field [1,42], we found tentative evidence that for people with more anxiety symptoms and more intense unpleasant emotions, presenting them with a higher number of choices (16 choices) would be more beneficial for their subjective experiences of the chosen exercise (ie, satisfaction, attitude, perceived improvement in mental state) than presenting them with a lower number of choices (4 choices or 1 choice). This unexpected finding could be attributed to the higher probability of encountering exercises that align with participants' mental health needs, preferences, and effectively address their emotional distress within a more extensive choice array.

In light of these intriguing findings, we advocate for further investigations into the underlying mechanisms at play, replication and extension studies to examine the reliability and generalizability of our findings, perhaps with additional choice set size conditions, secondary analyses using our open dataset, and additional research on the intersection between tailored recommendations and choice set size, as well as impact of choice set size in decision-making contexts without monetary considerations. Moreover, we highlight the potential of tailoring the number of choices based on individuals' anxiety symptoms and current emotional states within digital mental health platforms. We call for further investigation aimed at deepening our understanding of how choice set sizes can be potentially tailored to enhance engagement, user experiences, and outcomes in digital mental health environments.

Acknowledgments

We used Poe AcademicWriterBot [121] in copy-editing the English language to improve the manuscript's readability. We adapted some of these suggestions. We also thank Hoi Ching Yu and Yuxuan Zheng for their help with pretesting the Qualtrics surveys. The digital mental health self-care exercises included as choices in the study are from Jockey Club Tour Heart+Project, a digital mental health platform, developed and led by the corresponding author WWSM.

Funding

This study is funded by the internal grant from Mental Health Research Center (MHRC) of the Hong Kong Polytechnic University (Project ID: P0040456) as well as the General Research Fund from Research Grants Council (RGC) of Hong Kong SAR, China (Reference number: 14606623). The Jockey Club Tour Heart+Project is funded by the Hong Kong Jockey Club Charities Trust (SN: 2024 - 0077) for the Jockey Club TourHeart 3.0: Advancing Precision Mental Health Care Through Generative Artificial Intelligence.

Data Availability

The datasets, analysis files, and code with outputs of this study are available on the Open Science Framework, with links available in Table S1 in Multimedia Appendix 1.

Authors' Contributions

SKY, WWSM, and FHTL contributed to conceptualizations of the study. SKY, FHTL, and JCML contributed to the design of the experiment, whereas all authors helped with pretesting the Qualtrics survey and providing suggestions. JCML was responsible for data collection of the study. WWSM was responsible for the supervision of the project. SKY conducted analyses and wrote the initial draft of the manuscript and revised the manuscript based on suggestions. WWSM made many changes to the manuscript, and GMHC and CWL provided some suggestions for changes to the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Paramedics face frequent exposure to trauma and intense occupational stress, often under conditions of limited psychological support and ongoing stigma. Digital mental health interventions have the potential to offer accessible, confidential, and tailored support. However, their acceptability and design must be informed by the lived experiences of paramedics to ensure effectiveness.

Objective: This study aimed to explore the experiences of trauma exposure among UK paramedics in the workplace and their views on the design and delivery of digital mental health interventions.

Methods: Semi-structured interviews were conducted with 22 UK paramedics. Participants were recruited through purposive and snowball sampling. Interviews were transcribed verbatim and analyzed using reflexive thematic analysis. Ethical approval was obtained, and trauma-informed principles were applied throughout data collection and analysis.

Results: Five key themes were identified: (1) It Has to Feel Easy to Use*:* highlighting the need for digital tools that reduce cognitive burden and are accessible during unpredictable shifts; (2) Make It Fit My Needs: calling for interventions specifically designed for paramedics, with lived-experience-informed language and delivery; (3) We Need to Talk to Each Other: describing a strong desire for peer connection while recognizing barriers such as stigma and shift pressures; (4) I Need to Know It's Safe: emphasizes the importance of anonymity, data privacy, and psychological safety; and (5) Support Needs to Feel Human: reinforcing the value of integrating digital tools with human connection and professional services. Participants expressed strong support for an app-based solution that offers anonymity, rapid accessibility, and flexibility, while preserving opportunities for human interaction.

Conclusions: Paramedics face unique mental health challenges that are not adequately addressed by existing services. Digital mental health tools offer promise if they are carefully co-designed to reflect the realities of frontline work. Anonymity, usability, peer connection, and integration with existing support systems are critical to engagement. These findings offer actionable insights for the development of trauma-informed, context-sensitive digital mental health interventions for emergency service workers.

Introduction

Frontline workers, including paramedics, firefighters, police officers, and emergency health care staff, operate in some of the most high-pressure environments, frequently encountering life-threatening emergencies, traumatic incidents, and high-stress situations [1,2]. The cumulative exposure to critical incidents places these workers at significant risk of developing mental health conditions such as posttraumatic stress disorder, anxiety, depression, and burnout [3,4]. While all frontline workers experience occupational stress, research consistently shows that paramedics report some of the poorest mental health outcomes among emergency responders, including elevated levels of psychological distress, emotional exhaustion, and suicidal ideation compared to their counterparts in firefighting and law enforcement [5,6].

Paramedics face unique challenges that exacerbate their vulnerability to mental health difficulties [7]. They frequently operate under relentless workloads with little opportunity for recovery between challenging and often traumatic calls. Paramedic work requires responding to unpredictable situations with limited resources at any hour of the day. In these high-pressure, uncontrolled settings, paramedics are often

XSL•FO
RenderX

required to make complex decisions while also managing the effects of sleep deprivation and disrupted circadian rhythms caused by shift work [8,9]. The unpredictability of their role, such as never knowing the severity of an incident before arriving on the scene, further compounds stress levels. Additionally, paramedics often work in isolated environments, providing care in ambulances, homes, or public settings without immediate access to team support [10]. This lack of structured debriefing opportunities can lead to cumulative emotional distress, as paramedics must frequently suppress their emotions to remain professional in high-stakes situations [11].

Another significant challenge is moral injury, a psychological distress experienced when actions taken in the line of duty conflict with personal values or ethical standards [12]. Paramedics frequently witness unavoidable suffering, resource limitations, and cases where they are unable to save a life, leading to profound feelings of guilt, self-doubt, and helplessness [13]. Furthermore, paramedics often provide end-of-life care in uncontrolled environments, making their experiences emotionally intense and personally distressing [14]. This repeated exposure to human suffering, combined with high-performance expectations and limited emotional support, places them at heightened risk of long-term psychological harm [15].

In addition to physical trauma cases, paramedics are frequently dispatched to mental health-related emergencies, including suicide attempts and death by suicide, self-harm incidents, and acute psychiatric crises [16]. These callouts present unique stressors, as paramedics must navigate complex interactions with individuals in extreme distress, often with limited mental health training or specialist support [17,18]. Attending suicide-related incidents has been shown to significantly impact paramedics' mental well-being, particularly when required to interact with grieving families or manage high-risk patients without adequate resources [19]. The emotional toll of these callouts, combined with the stigma surrounding mental health within emergency services, contributes to burnout, compassion fatigue, and secondary traumatic stress among paramedics [20].

Another critical issue paramedics face is exposure to workplace violence and assaults. Paramedics frequently encounter aggressive patients, intoxicated individuals, or bystanders who may become physically or verbally abusive [21]. This occupational hazard is further exacerbated by working alone or in unpredictable environments where immediate backup may not be available. Exposure to workplace violence not only increases the risk of physical injury but also significantly contributes to long-term psychological distress, fear, and hypervigilance [22]. Studies have shown that repeated exposure to aggression and violence leads to elevated rates of posttraumatic stress disorder, anxiety, and depressive symptoms among paramedics, further compounding the already high levels of occupational stress they experience [10,23,24]. Despite policies aimed at protecting emergency responders, many paramedics feel unsupported when reporting incidents of violence, contributing to a culture of normalization and underreporting [25].

Despite these challenges, many paramedics do not seek professional mental health support due to stigma, fear of judgment, and concerns about confidentiality [26]. Prior research has identified that paramedics are less likely than other emergency responders to disclose psychological distress, fearing that such admissions could lead to professional consequences, social isolation, or doubts about their fitness to work [11]. Traditional face-to-face mental health support services, while available, remain underused due to perceived stigma, logistical barriers, and a culture that often prioritizes resilience over emotional well-being [27].

Such issues highlight the urgent need for tailored mental health support for paramedics [28]. Digital mental health interventions present a promising avenue for overcoming barriers to traditional face-to-face support by offering accessible, confidential, and flexible options for managing psychological distress [29]. However, for such interventions to be effective, they must be designed with direct input from end users to ensure relevance and usability [30]. Cocreation is increasingly recognized as a critical component in the development of digital mental health interventions, ensuring they are relevant, engaging, and responsive to the needs of the end user [31]. By involving paramedics in the design process, digital interventions can be tailored to align with their unique work environments, stressors, and coping mechanisms. Research has shown that interventions developed in collaboration with users have higher adoption rates and greater long-term efficacy compared to those designed without user input [32]. For paramedics, cocreation is particularly vital as they face distinct challenges such as exposure to trauma, high-pressure decision-making, and limited opportunities for structured mental health support. Generic digital interventions may fail to address the realities of their work, leading to disengagement and limited effectiveness. Additionally, cocreation fosters a sense of ownership and trust in the intervention, reducing potential stigma associated with help-seeking. When end users see their insights reflected in the final digital intervention, they are more likely to perceive the intervention as relevant and beneficial to their well-being [33]. Given the demanding and often unpredictable nature of paramedic work, it is crucial that digital mental health interventions are not only evidence-based but also practical and person-centered.

This study aims to explore paramedics' perspectives on digital mental health interventions and identify key design considerations to inform the development of tailored support systems [34]. It seeks to understand paramedics' experiences with workplace trauma and their perspectives on the acceptability of a digital mental health intervention. The research also aims to contribute to the growing body of literature on digital mental health interventions for frontline workers. This study addresses the following research questions:

1. What are paramedics' experiences with workplace trauma, and how do they currently manage their mental health?
2. What features and functionalities do paramedics consider essential for a digital mental health intervention?

XSL•FO
RenderX

Methods

Study Design

This study used a qualitative design using in-depth, semi-structured interviews to explore paramedics' experiences with workplace trauma and their perspectives on digital mental health interventions. A qualitative approach was chosen to generate detailed insights into participants' mental health needs and intervention preferences, allowing for a deeper understanding of lived experiences that quantitative methods may not capture. Grounded in a constructivist epistemology, this approach emphasizes the coconstruction of meaning between researchers and participants and acknowledges the active role of the researcher in interpreting the data. It aligns with the participatory and trauma-informed principles underpinning this study, ensuring sensitivity to the emotional content of interviews and valuing the voices of participants throughout the analytic process [35].

Recruitment

Recruitment was conducted through professional networks, paramedic organizations, and web-based forums to ensure a diverse sample that captured a broad range of experiences within emergency medical services. A combination of purposive and snowball sampling was used. Purposive sampling enabled the targeted recruitment of participants with relevant professional backgrounds and trauma exposure, while snowball sampling allowed existing participants to refer colleagues with similar experiences, broadening the reach and diversity of the sample. Recruitment strategies included direct invitations disseminated via paramedic organizations, participant referrals through word-of-mouth, and digital flyers shared on professional social media platforms. Individuals were eligible to participate if they resided in the United Kingdom, were aged 18 years or older, had been employed in a paramedic role for at least 6 months, and self-identified as having experienced trauma in the workplace at the time of this study. Interested participants were provided with an electronic participant information sheet detailing this study's purpose, procedures, and ethical safeguards. Following written informed consent, interviews were scheduled at times convenient to each participant.

All interviews were conducted via Microsoft Teams to ensure accessibility, data security, and consistency in data collection [36]. A total of 22 paramedics working in emergency medical services were recruited through purposive and snowball sampling [37]. This sample size was sufficient as qualitative research prioritizes depth, richness, and variation in experiences over numerical representativeness [38]. Studies on first responders and trauma have drawn meaningful conclusions from similar sample sizes [39-41], demonstrating that a focused cohort can yield transferable, contextually grounded insights [42]. Purposive sampling ensured that participants had direct lived experience relevant to the research aims, while snowball sampling enhanced inclusivity by recruiting those hesitant to engage in trauma-related research [43,44].

Data Collection

A semi-structured interview guide was developed to facilitate in-depth exploration of participants' experiences, drawing on previous research related to occupational trauma and mental health in emergency services [45,46]. The guide was designed to prompt discussion on key areas, including encounters with workplace trauma, access to and experiences with existing mental health support, perceived organizational and cultural barriers to seeking help, and preferences for digital mental health interventions tailored to paramedic needs. Questions were open-ended and designed to elicit rich, narrative data while allowing for flexibility based on individual experiences. The guide was refined iteratively during the early phases of data collection, with minor modifications made to reflect emerging themes and to enhance sensitivity to the language and challenges specific to the paramedic context. This adaptive approach ensured the interviews remained responsive to participants' perspectives while maintaining consistency across core thematic areas. All interviews were conducted remotely using Microsoft Teams, allowing for flexible scheduling and increased accessibility for participants working variable shift patterns. This web-based format also aligned with trauma-informed practices by enabling participants to choose a safe and private environment in which to share their experiences.

Interviews were conducted over 18 months and ranged in length from approximately 40 to 75 minutes (mean 58.2, SD 10.2). All interviews were conducted remotely, allowing participants to join from a private setting of their choice. The final sample size (n=22) was determined based on the richness, relevance, and diversity of the data, consistent with the principles of reflexive thematic analysis [42]. Rather than aiming for data saturation, we drew on the concept of information power to guide sample sufficiency, prioritizing depth, variation, and the capacity of the data to meaningfully address the research questions. The dataset was judged to provide rich, nuanced insights into paramedics' lived experiences of workplace trauma and preferences for digital support, with recurring patterns and interpretative depth evident across the interviews.

Ethical Considerations

This study forms part of a broader program of research exploring trauma exposure and psychological support needs among frontline workers in the United Kingdom. It specifically focuses on the views and experiences of paramedics regarding the acceptability and design of digital mental health interventions, with distinct aims and analyses from prior related research [28]. Given the sensitive nature of workplace trauma, ensuring the well-being and safeguarding of participants was a key ethical consideration. This study received ethical approval from the University of Strathclyde Ethics Committee (UEC22/92). Informed consent was obtained before participation, and ethical approval was granted by the institutional review board. Participants were informed of their right to withdraw at any stage without repercussions. Data were anonymized and stored securely, per GDPR and institutional data protection policies, to protect participant identity and confidentiality. Participants were offered a £20 (US $23.29) gift voucher as a thank-you for their time and contribution to the interviews. Additionally,

XSL•FO
RenderX

signposting to mental health support services was provided to all participants, ensuring access to professional help if discussing traumatic experiences triggered distress [47]. Researching trauma-related topics requires careful ethical handling, and efforts were made to create a psychologically safe space where participants could share their experiences without fear of judgment or harm [48]. This study also emphasized the importance of participatory methods and lived experience perspectives in shaping digital mental health interventions. By centering paramedics' voices, this study aligns with the principles of participatory research, ensuring that digital interventions are not only theoretically sound but also practically applicable to frontline workers' needs. Additionally, researcher well-being was considered, given the emotionally demanding nature of trauma-related research. The research team received specific training, led by a Health and Care Professions Council–registered clinical psychologist, on conducting sensitive research and applying trauma-informed principles. This included prioritizing self-care, reflexive journaling throughout the research process, and recognizing signs of secondary trauma exposure. To further safeguard well-being, interviewers were limited to 1 interview per day, followed by a structured debrief with the research lead. Additionally, a structured debriefing process was implemented to provide access to professional supervision and peer support [49,50]. Reflexive meetings were held regularly throughout the research process, fostering a team approach to addressing challenges, ensuring ethical consistency, and supporting both participant and researcher well-being [51,52].

Analysis

All interviews were one-to-one and were audio-recorded and transcribed in full verbatim. The data were then managed in NVivo (version 12, QSR International) and analyzed using a reflexive thematic approach, following the framework by Braun and Clarke [53], which is particularly suited for studies exploring complex psychological and social phenomena [54]. This approach builds upon the earlier thematic analysis framework of Braun and Clarke [55], adopting a more explicitly reflexive and interpretative approach. It emphasizes the researcher's active role in meaning-making [56]. Themes are not viewed as pre-existing within the data but are constructed through deep engagement and iterative interpretation [57]. This began with the process of familiarization and immersion within the data, generating initial codes organically and fluidly. Initial codes were logged, with records of how each theme evolved through discussion and refinement. Regular team meetings were held to review and challenge coding decisions, ensuring that the analysis was grounded in the data while allowing for flexibility in interpretation. Any discrepancies in theme development were resolved through collaborative discussion in the research team, ensuring that final themes were coconstructed rigorously and reflexively [58].

A value-based approach to qualitative research was applied, ensuring a commitment to ethical transparency, reflexivity, and participant-centered analysis [59]. This framework emphasizes the importance of researcher subjectivity and the co-construction of knowledge, aligning with the study's focus on participatory research and lived experience perspectives. Recognizing the limitations of rigid, universal evaluative tools for qualitative research, the Big Q Qualitative Reporting Guidelines were considered to ensure that methodological choices aligned with qualitative research values rather than externally imposed standards rooted in postpositivist traditions [59]. This framework prioritizes methodological congruence, reflexivity, and the interactive nature of knowledge production. To ensure transparency and rigor in the research process, an audit trail was maintained throughout data collection, analysis, and interpretation. This involved systematically documenting all key decisions made at each stage of this study, providing a structured record of the rationale behind methodological choices and analytic interpretations.

Results

Participant Characteristics

The final sample consisted of 22 paramedics. Participants ranged in age from 23 to 59 years (mean 38.22, SD 9.28), with professional experience ranging from 1 to 38 years (mean 13.11, SD 6.93). Thirteen (59%) participants identified as male and 9 (41%) as female. The majority (82%, n=18) identified as White British, while 4 (18%) participants identified as belonging to ethnic minority backgrounds. Most participants were based in England (64%, n=14), with the remainder in Scotland (36%, n=8). All participants self-identified as having experienced occupational trauma that had negatively impacted their mental health and well-being. See Table 1 for a full breakdown of demographic characteristics.

Table . Participant characteristics. Names are pseudonyms. Ethnicity categories adapted from UK Office for National Statistics classifications.

Name	Gender	Age (years)	Service (years)	Ethnicity
Billy	Male	30	5	White British
Harry	Male	34	10	White Scottish
Gillian	Female	47	21	White British
Garry	Male	51	10	White Scottish
Mike	Male	40	2	White Scottish
Jan	Male	28	3	White Other (Polish)
Nathan	Male	50	21	White Irish
Terry	Female	44	17	White Scottish
Sam	Male	51	15	White British
William	Male	39	5	White Scottish
James	Male	37	12	White British
Rachel	Female	36	11	White Scottish
Paul	Male	45	20	White Irish
Laura	Female	33	8	White Scottish
Jane	Female	48	25	White British
Emma	Female	29	6	White British
David	Male	41	14	White Scottish
Sarah	Female	42	19	White British
Leigh	Female	46	23	White Scottish
Eric	Male	50	18	White Other (Polish)
Rebecca	Female	35	9	White British
Luke	Male	38	16	White British

Themes

The themes presented below reflect the diverse and often deeply personal ways in which paramedics make sense of their experiences of occupational trauma. Given the subjective and multifaceted nature of psychological trauma, participants were invited to self-define their experiences, enabling the analysis to capture a broad spectrum of emotional and psychological responses. This approach respected individual interpretations of what constitutes trauma and ensured that the analysis remained grounded in participants' own meanings and language. Five key themes emerged from the analysis, capturing the experiences and preferences of paramedics regarding digital mental health interventions. These themes illustrate their needs for usability, personalization, social support, privacy, and human connection (Table 2).

XSL•FO
RenderX

Table . Summary of themes identified in the thematic analysis.

Theme	Description
It Has to Feel Easy to Use—Navigating Acceptability and Usability	• Intervention must be simple and intuitive. • Should reduce cognitive load postshift. • Quick access is crucial for usability.
Make It Fit My Needs—The Importance of Customization and Personalization	• Tools should be tailored to paramedic experiences. • Generic interventions were seen as ineffective. • Relevance drives engagement.
We Need to Talk to Each Other—Social Connection and Peer Support	• Peer support is highly valued. • Digital tools can enable safe, structured connection. • Reduces isolation and builds validation.
I Need to Know It's Safe—Confidentiality, Privacy, and Safety	• Concerns about stigma and data breaches. • Security and trust are prerequisites for use. • Anonymity must be guaranteed.
Support Needs to Feel Human—Integration With Existing Services	• Digital tools should complement, not replace, human support. • Facilitate access to professional help. • Include guided check-ins and support pathways.

Theme 1: It Has to Feel Easy to Use—Navigating Acceptability and Usability

Acceptability was closely linked to usability for many participants, who emphasized that any digital intervention must feel simple, nonintrusive, and easy to engage with during or after demanding shifts. Paramedics described the cognitive burden of their work, noting that complex or time-consuming tools would be impractical in high-pressure environments. Many highlighted that their workload and unpredictable schedules often leave little energy for engaging with structured mental health support.

> *Getting five minutes to breathe is rare now. We used to have time to gather ourselves, but not anymore.* [Rachel]

> *You deal with something traumatic, but before you've processed it, you're already at the next job.* [Luke]

These accounts reflect the high workload pressures paramedics face, with limited opportunities for decompression or reflection. Digital interventions, therefore, were seen as acceptable only if they were intuitive, low-effort, and seamlessly integrated into the rhythm of shift-based work.

> *You can't go through life just dealing with trauma on adrenaline… I have to have a way of bringing that down and managing that.* [Paul]

Some paramedics reported becoming emotionally desensitized over time, reflecting a gradual numbing that made it harder to recognize when support was needed.

> *It's trauma after trauma. Eventually it just becomes normal, and that's when you realise you've stopped feeling it.* [Leigh]

This emotional distancing may contribute to reduced help-seeking unless support is easily accessible and presented in a way that feels informal and manageable.

Participants expressed that traditional face-to-face mental health support often felt inaccessible, both logistically and psychologically, due to stigma and confidentiality concerns. In contrast, digital interventions were viewed as potentially acceptable because of their on-demand nature and discretion.

> *I wouldn't go to a therapist, even if I needed to. It's just not what we do. But if I could check in with something that doesn't feel like a big deal, I'd probably use it.* [Nathan]

> *Going through work to get help feels risky. But if I can do it quietly, that changes everything.* [Rebecca]

A key factor influencing acceptability was that the intervention should not require additional cognitive or emotional effort, particularly at the end of long or emotionally draining shifts.

> *If I've had a long shift, I don't want something that's going to take brain power. It has to be quick and easy.* [Jane]

Some participants also saw digital tools as a proactive way to manage stress before it became overwhelming, valuing short, in-the-moment strategies.

> *Even a short breathing exercise or prompt could stop it spiralling after a tough job.* [Laura]

In sum, usability was seen as foundational to acceptability. Tools that were easy to navigate, unobtrusive, and offered brief, practical support were more likely to be welcomed and used.

Theme 2: Make It Fit My Needs—the Importance of Customization and Personalization

Beyond usability, participants consistently emphasized the importance of personal relevance and individual fit in shaping how acceptable an intervention would feel. In this context, acceptability was not just about simplicity or ease of use, but about feeling seen, understood, and supported in a way that resonated with paramedics' specific experiences. When discussing the acceptance and needs for an appropriate

XSL•FO
RenderX

intervention, participants noted the importance of "specific" [Rachel] help, comprising needs unique to paramedics. It was noted that others "just don't get it" [Leigh].

Participants felt that credible support should be tailored to paramedics specifically, as they felt they are "different from other first responders" [Eric] and "other members of society" [Rebecca]. Participants stated that creators of an intervention should have a strong knowledge and preferably, experience of life as a paramedic, which can be evidenced by comments such as:

> *You need people designing this who understand our reality. Otherwise, it just won't connect.* [Nathan]
>
> *There's no substitute for lived experience. We spot it straight away when something feels off.* [Emma]

Participants viewed themselves as different from other occupations, given the nature of their working environment, and therefore stated they required an intervention "that's tailored for an individual" [Leigh]. All participants stated that they would be more likely to speak of mental health concerns and seek help if they could speak to someone with "real insight into the job" [Rachel].

Additionally, participants suggested they were more likely to access help if it could be "completely anonymous" [Eric], given the stigmatization prevalent within the occupation:

> *If people don't know it's you, you're far more likely to be honest.* [David]

Regarding anonymity, all participants suggested that an identifiable method of intervention would prevent them from accessing help. Overall, acceptability was high across participants for an intervention, with all participants stating they would be accepting of an anonymous and specific intervention:

> *Even something small, like a quick check-in after a shift, if it's anonymous and for us, I'd use it.* [Laura]
>
> *If nothing changes, we're just going to lose more people. This kind of support has to be built in.* [Rachel]

Participants reflected the timely need for an intervention comprising the detailed characteristics to prevent "experienced people from burning out and leaving for good" [Emma]. Hence, all participants suggested that a digital intervention in app form would be beneficial, given that it could be specific to them, constantly accessible, and confidential, as voiced by Eric:

> *Having it on our phones would make it feel like a normal part of the job (pauses) something we all use, not something secret or awkward.* [Eric]

Furthermore, in discussing potential technological barriers, participants described digital tools as familiar and well-integrated into their working lives, with 1 noting it was "second nature now" [Sam]. As such, acceptability was not about the presence of technology per se, but about how well it aligned with paramedics' specific needs and values:

> *We use tech every day. It's not strange anymore. If anything, it makes sense to use it for our mental health too.* [Rebecca]

Participants emphasized that interventions were more likely to be accepted if they could be tailored based on personal needs, emotional state, or shift patterns. This capacity for customization fostered a sense of personal relevance and ownership, making the intervention feel trustworthy and worth engaging with:

> *You're more likely to keep going back if it feels like it's built for you.* [Sarah]

Theme 3: We Need to Talk to Each Other—Social Connection and Peer Support

A strong theme that emerged was the need for social connection, particularly among colleagues who understand the unique pressures of the role. Participants spoke about how workplace trauma is often managed informally through discussions with peers, yet increasing work demands have reduced these opportunities. For instance, 1 paramedic shared how important it was to debrief but noted that opportunities to do so were limited:

> *There are fewer and fewer chances to talk things through. That's when you start carrying things on your own.* [Luke]

However, some expressed concerns about the diminishing support culture in their work environment:

> *The support bit, it's just not there.* [Leigh]

The need for peer support was reinforced by the recognition that sharing experiences with colleagues who "really get it" [Mike] provides comfort and validation:

> *If you're involved, first responders and stuff, you have an understanding of what you've been through* [David]

Despite this, some participants highlighted a reluctance to open up about their struggles, especially within a "macho culture" that discouraged vulnerability:

> *You certainly wouldn't admit it to your colleagues. It was a stiff upper lip culture, you know, just get on with it* [Terry]

Given these concerns, digital interventions were seen as a potential way to facilitate peer connection in a safe and anonymous environment. Some participants suggested that a digital platform could provide structured opportunities to connect with others who have shared similar experiences, while still allowing individuals to maintain privacy:

> *I wouldn't want to sit in a room and talk about it, but if there was something online where you could connect with people who've been through the same, that would be different.* [Rebecca]

Others highlighted the potential for digital interventions to offer moderated peer forums or guided group discussions, ensuring that support remains professional and constructive:

> *It would have to be somewhere safe, not just a big free-for-all chat where people bring each other down. Maybe something that's monitored, or with prompts to help guide discussions.* [James]

XSL•FO
RenderX

The ability to share experiences without fear of judgment was seen as a crucial element in increasing engagement with peer support mechanisms. Digital tools that allow for anonymous peer check-ins or shared reflections were regarded as particularly valuable:

> *Sometimes you don't need someone to fix it, you just need to know someone else has been through it too. If an app could help with that, I'd use it.* [Luke]

Theme 4: I Need to Know It's Safe—Confidentiality, Privacy, and Safety

A major concern for participants was data security and confidentiality. Many reported that stigma and fears of professional consequences prevented them from seeking help. The pressure to appear resilient and the fear of being judged or deemed unfit for their role created barriers to accessing mental health support. Participants highlighted that any digital intervention must prioritize absolute anonymity to encourage engagement.

> *There's a fear. There's a big fear… About our professional registration, because you've got a mental health condition… because if you speak, you're fired.* [Gillian]

> *There are people with the attitude that if you suffer from mental health problems, then this is obviously not a job for you… you're clearly not cut out for it.* [Garry]

Ensuring anonymity was seen as crucial, as paramedics were concerned that seeking support through formal channels might lead to professional repercussions or workplace stigma:

> *You want to be sure it's completely anonymous. That's the only way I'd open up.* [Jan]

Digital interventions were perceived as a potential solution, offering a confidential and secure platform where paramedics could access support without fear of being identified. Participants suggested that digital tools should include features such as encrypted communication, anonymous logins, and discreet access options to protect their privacy. Additionally, some paramedics expressed the need for clear information on how their data would be stored and who would have access to it:

> *You'd have to be upfront about what happens with any data. If I'm putting anything in, I want to know it's not going anywhere else.* [Laura]

Several participants described how the long-term effects of trauma can be overwhelming, making it even harder to seek help. They acknowledged that while digital interventions could not replace professional therapy, they could provide an important first step for those who are hesitant to engage with traditional mental health services. By incorporating stringent privacy protections and offering an anonymous space for processing emotions, digital interventions were viewed as potentially bridging the gap for paramedics who might otherwise avoid seeking mental health support due to concerns about stigma and confidentiality.

Theme 5: Support Needs to Feel Human—Integration With Existing Services

Although participants expressed a willingness to engage with digital interventions, they stressed that technology should not replace human-led mental health support. Many emphasized that digital tools should be used as a supplement rather than a substitute for direct peer or professional support. While digital interventions offer accessibility and confidentiality, participants acknowledged the value of human connection in processing trauma and stress. One paramedic highlighted how the lack of structured support left them feeling exposed:

> *Sometimes it's just a few words from a person that makes all the difference. The app can't do it all.* [Sarah]

Participants expressed a strong need for interventions that offer structured and ongoing support, ensuring that paramedics feel genuinely seen and supported in their mental health journey. They recognized that digital tools could help fill gaps in existing support services, but were cautious that such tools must integrate seamlessly with professional and peer-based systems.

> *I think having a digital app for trauma is the right thing. I think building such an app, it's something that needs to be built for the people that you're wanting to use it.* [Harry]

Many paramedics emphasized that for a digital intervention to be truly beneficial, it should facilitate bridging the gap between self-help and professional support. They suggested that digital tools could provide structured pathways to connect users with trained professionals when needed, ensuring that those who require more intensive intervention are not left without options:

> *I'd use something like a digital app if I knew there was a way to reach out to a real person if I needed it. Just knowing that's there makes a difference.* [James]

Another key aspect raised by participants was the need for human elements within the digital space to create a sense of connection and validation. Some suggested that interventions could incorporate recorded messages from experienced paramedics or psychologists to guide them through difficult moments:

> *If I could hear from someone who's been in my shoes, even if it's just pre-recorded guidance, that would feel more real than just reading generic advice.* [David]

Participants also highlighted the need for structured check-ins and follow-ups to ensure ongoing support, rather than a 1-time or reactive approach:

> *It shouldn't just be something you use once when you're in crisis. It should check in with you, like, "How are you doing?" and offer reminders to engage with it.* [Emma]

These insights reinforce the idea that while digital interventions can provide essential support and accessibility, they should not function in isolation. Instead, they should act as an entry point into broader mental health care, offering both immediate coping

XSL•FO
RenderX

strategies and seamless integration with existing services. By incorporating human-centered elements such as guided support, personalized check-ins, and links to professional care, digital tools can become a valuable and sustainable resource for paramedics navigating workplace trauma.

Discussion

Principal Findings

This study explored paramedics' experiences of workplace trauma, their approaches to managing mental health, and their perspectives on the acceptability and design preferences for digital mental health interventions. Thematic analysis identified 5 key themes that offer novel and context-specific insights into how digital tools can be designed to address the unique challenges faced by paramedics. These findings contribute to a growing body of research advocating for trauma-informed, user-centered approaches in digital mental health interventions for emergency service workers.

First, participants emphasized that digital interventions need to be easy to use, with a simple, intuitive design that does not add to their cognitive load after stressful shifts. They highlighted the importance of quick access and ease of navigation, aligning with previous research indicating that digital mental health interventions must be designed for seamless usability to encourage engagement [34].

Second, participants expressed a strong preference for customization and personalization, with a tool that adapts to their individual coping styles, schedules, and emotional states. They noted that existing mental health resources often fail to address the distinct challenges of their role, reinforcing findings that user-centered digital interventions lead to higher adherence and satisfaction [60]. Participants also emphasized that their work schedules are unpredictable, meaning the intervention should be flexible, allowing them to engage with support at a time that suits them rather than being restricted to set hours or appointments.

Third, participants highlighted the importance of social connection and peer support, valuing the opportunity to connect with colleagues who understand the unique pressures of their role. They suggested that digital interventions should facilitate safe and structured peer interactions, aligning with research demonstrating the critical role of peer support in promoting resilience among first responders [61-63]. The ability to share experiences with others who have been through similar situations was seen as particularly beneficial, as it reduced the sense of isolation that many paramedics reported experiencing.

Fourth, concerns around confidentiality, privacy, and safety were significant, with participants voicing worries about data security and the need for absolute privacy to overcome fears of stigma or professional consequences. Many preferred an anonymous platform to reduce concerns about disclosure, echoing previous studies that highlight the importance of privacy in emergency workers' engagement with mental health interventions [11]. They expressed particular concerns about their professional registration and career security, with some fearing that seeking support through formal occupational health routes could have negative consequences. A digital intervention designed with strong privacy protections was seen as a way to reduce these concerns and encourage engagement. However, with the need for anonymity comes an ethical requirement to ensure adequate support and safeguarding. Recent research on safeguarding of users of mental health apps has emphasized the importance of ensuring that platforms clearly highlight their limitations and capacities concerning identifying risk and referring individuals to outside care opportunities, in addition to any built-in interventions [64].

Finally, participants stressed the need for digital interventions to complement, rather than replace, human-led mental health support. While digital tools offer accessibility and discretion, participants recognized the value of professional guidance and structured follow-ups to ensure sustained engagement. Research supports a blended approach that integrates digital mental health tools with professional and peer-based support systems to maximize effectiveness [65]. Participants noted that digital interventions could serve as an important first step in seeking help, but that access to human support, whether through structured debriefs, therapy, or informal check-ins, remained a crucial component of effective mental health care. This aligns with earlier work whereby emergency workers have emphasized the importance of personal engagement in their training and education [66].

Strengths, Limitations, and Future Directions

This study makes a valuable contribution to the existing body of knowledge by providing in-depth insights into paramedics' experiences of workplace trauma and their perspectives on digital mental health interventions. A key strength of this study lies in the use of robust qualitative methodology, which enabled the generation of rich, contextually grounded findings. However, this study has some limitations. The sample consisted of 22 paramedics, which, while appropriate for qualitative research, may not fully capture the diverse experiences across different ambulance services and geographic locations. Additionally, participants self-selected into this study, which may have resulted in the inclusion of individuals who are more willing to engage in discussions about mental health, potentially limiting the generalizability of findings. Future research should aim to recruit a larger and more demographically diverse sample to explore a broader range of perspectives and experiences. Particular attention should be given to increasing representation of ethnically and culturally diverse paramedics, as this is essential not only for producing inclusive and representative findings but also for informing the effective transcreation and localization of digital interventions. This will contribute to more accessible, relevant, and equitable interventions, ultimately reducing disparities in mental health outcomes and supporting health equity across emergency service settings.

While purposive and snowball sampling allowed the research team to access a diverse range of paramedics with direct experience of workplace trauma, it is acknowledged that there is potential for self-selection bias. Participants who chose to take part may have been more open to discussing mental health or more comfortable with technology, compared to those who did not volunteer. As such, the sample may not fully reflect the

XSL•FO
RenderX

perspectives of paramedics who are more reluctant to engage in conversations about mental health or who may be more skeptical about digital interventions. This should be considered when interpreting the findings, particularly concerning the anticipated uptake of digital tools across the broader paramedic workforce.

Another limitation is that this study focused solely on paramedics, whereas other emergency responders, such as firefighters and police officers, also experience similar mental health challenges. Comparative studies across different frontline professions would help identify both shared and profession-specific needs for digital interventions. Additionally, this study explored user preferences but did not evaluate an actual digital intervention. The research team is currently undertaking a program of work focused on the co-design, development, and real-world testing of a digital tool, Sentinel, to evaluate its feasibility, usability, and impact on mental health outcomes among first responders [67]. By incorporating paramedic feedback throughout the development process, Sentinel aims to address usability, personalization, peer connectivity, and confidentiality concerns. The intervention will be piloted with paramedics to evaluate its effectiveness and integration into existing mental health support systems. Furthermore, customized versions of Sentinel will be expanded to support other frontline professionals, including firefighters, police officers, and emergency health care staff, recognizing both the common and unique stressors they encounter. Additionally, the platform will offer resources for the families of frontline workers, acknowledging their vital role in providing support and the importance of addressing their specific needs to help foster stronger community and familial resilience [68]. Future studies will examine how these adaptations enhance mental health support across various high-pressure occupational settings, leading to a scalable, evidence-based intervention for frontline workers [69].

The findings of the current study have clear implications for ambulance services and policymakers seeking to improve the mental health of frontline staff. Services should consider investing in digital tools that are co-designed with paramedics, offer confidentiality, and are accessible outside of traditional working hours. Importantly, such tools should not operate in isolation but be embedded within wider organizational strategies that promote psychological safety and reduce stigma around help-seeking. Embedding trauma-informed support into routine practice, through education, peer-support systems, and leadership engagement, can help foster a culture where mental health conversations are normalized and proactively supported. Policy makers can play a key role in endorsing the development and adoption of such interventions across emergency services, ensuring that funding mechanisms and regulatory guidance align with the psychological needs of high-risk occupational groups.

While future technological innovations hold promise, the immediate priority lies in developing usable, human-centered digital support grounded in the lived experience of paramedics. Artificial intelligence, wearable data, and real-time analytics may offer longer-term opportunities to enhance personalization, tailor content delivery, and monitor distress signals [70]. However, any integration of such technologies must be approached cautiously, with strong attention to ethical considerations, including data privacy, informed consent, and algorithmic bias [71]. Crucially, future research must ensure that artificial intelligence–driven tools remain grounded in cocreation and usability principles, as interventions designed with direct user input are more likely to be trusted and effective in real-world settings [72,73].

To support scalability and implementation, structured frameworks such as RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance), the UK Medical Research Council guidance on complex interventions, or the technology acceptance model could be used to guide development and evaluation [74-78]. These frameworks can help developers attend to issues of accessibility, human interaction, and long-term sustainability, ensuring that digital interventions are both usable and adaptable to diverse frontline professions. Ultimately, while innovation in digital health is advancing rapidly, this study underscores the critical value of listening to paramedics themselves. Future work should continue to center on the voices of frontline workers to ensure that digital mental health tools are responsive, acceptable, and fit for purpose in the demanding realities of emergency service work.

Conclusions

This study highlights the importance of designing digital mental health interventions that are user-friendly, personalized, confidential, and integrated with existing support services. The findings provide critical insights into the specific needs of paramedics, particularly concerning their frequent exposure to workplace trauma, and outline key design considerations for digital mental health tools. Given the high levels of trauma-related psychological distress among paramedics, tailored digital solutions have the potential to offer accessible, flexible, and trauma-informed support. Future research should prioritize cocreating and rigorously evaluating digital interventions with paramedics and other emergency responders to ensure real-world usability and clinical relevance. By integrating end user feedback and addressing the psychological impact of trauma directly, digital mental health tools can enhance engagement, promote well-being, and provide frontline workers with timely support to navigate the emotional demands of their work. Through ongoing collaboration and refinement, trauma-informed digital interventions have the potential to transform the accessibility and effectiveness of mental health care for paramedics and other frontline professionals.

Acknowledgments

We would like to thank all the paramedics who participated in this study for sharing their experiences and insights.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the sensitive nature of the qualitative interview content and confidentiality agreements with participants. Anonymized data may be made available to qualified researchers upon reasonable request to the corresponding author, subject to approval by the relevant ethics committee and completion of a data sharing agreement.

Conflicts of Interest

NC is the Chief Scientific Officer of Sentinel, serves on its executive board, and holds a minority equity stake in the company. She leads the clinical strategy and research direction of the platform. AK and WH are also members of the Sentinel research and development team. Although Sentinel is referenced in the future directions of this paper, it was not evaluated in this study. All aspects of study design, data collection, and qualitative analysis were conducted independently of any commercial interests. The authors provide this disclosure in the interest of transparency. All other authors declare no competing interests.

Abstract

Background: Nowadays, mobile health technology has been increasingly used for treatment and prevention at all levels of health care. Associating this technology with the promotion of healthy salt consumption—both cost-effective and cost-saving public health strategies—can reduce this risk factor that contributes significantly to the increase of noncommunicable diseases worldwide.

Objective: We aim to assess the usability and the efficacy of a mobile app intervention—"Sal na Medida" app—on the promotion of a healthy salt intake among adults, based on the Behavior Change Wheel framework. Additionally, to investigate if intention, self-efficacy, and habit variables mediated the effect of intervention on salt intake behavior.

Methods: An experimental, randomized, and longitudinal study that evaluated the intervention effect with assessments at baseline, postintervention (1 mo), and at follow-up (2 mo). Sociodemographic and clinical data were collected from participants recruited at primary health care centers. The behavior of salt intake and per capita salt consumption were the primary outcomes. Psychosocial variables of intention, self-efficacy, and habit were assessed as possible mediators. Usability was evaluated after 1 month and 2 months of using the app.

Results: Eighty-six participants were randomized in the intervention group (IG; n=43) or control group (CG; n=43). Most of the participants were female (IG: n=36, 84% and CG: n=37, 86%). Usability of app intervention scored 77.8 points (on a scale of 0 to 100) among IG participants. There was a significant reduction in salt intake in IG according to the variables of per capita salt and the behavior of salt intake. Furthermore, at the end of the follow-up, individuals in IG were 63% more likely to have a lower salt intake than those in the CG. The regression analysis showed an increase in intention and the perception of self-efficacy, and a more pronounced reduction in the habit of using more than 3 g of salt/day in preparing meals in IG when compared to CG. Habit and self-efficacy were identified as mediators of the intervention's effect.

Conclusions: The theory-based mobile app intervention for reducing salt intake has shown promise both in terms of usability and efficacy among adults. Conducting further studies to assess its potential for implementation on a larger scale would be valuable for determining its real-world impact and feasibility.

Introduction

Background

Recent literature indicates that excessive salt consumption worldwide is responsible for approximately 3 million deaths—more than half of all diet-related deaths—and 70 million disability-adjusted life years (DALYs), which accounts for two-thirds of DALYs [1]. In Brazil, the economic burden is particularly significant, with an estimated annual cost of US$ 102 million due to public hospitalizations [2]. These detrimental outcomes could be prevented or at least mitigated by adhering to the World Health Organization's recommendation of a daily salt intake of 5 grams (roughly 2 grams of sodium) [3]. Additionally, the World Health Organization's global action plan for the prevention and control of noncommunicable diseases 2013‐2020 has prioritized salt reduction as 1 of 9 voluntary global targets [4].

To reduce the problem of salt overconsumption, it is crucial to understand the different sources of salt intake, which can differ across countries and regions. In South Asia, most salt intake comes from added salt during cooking and discretionary use at the table [5]. In the Eastern Mediterranean Region, bread and dairy products are the primary sources of salt consumption [6]. In Europe and North America, processed and ultraprocessed foods contribute the most to salt intake [7]. In Brazil, table salt and salt-based spices account for approximately 74.4% of the total household sodium availability [8], with about 70% of the salt consumed coming from the addition of salt to home-cooked meals [9].

Reducing salt intake in household diets offers significant health benefits [10-12]. A 10% reduction in salt consumption could prevent 5.8 million DALYs annually due to cardiovascular disease, at a population-weighted average cost of US $1.13 per capita [13]. To achieve this reduction in salt intake, various behavioral initiatives are used, including health education interventions, public awareness campaigns, and multicomponent strategies [14].

However, interventions grounded in established theories and frameworks tend to produce more effective health outcomes, since theories allow us to identify effective intervention content and processes through which it is expected to influence behavior, and also to understand the mechanisms by which the interventions work [15]. In this way, the Behavior Change Wheel (BCW) guide [16] has been broadly used to design health interventions due to its comprehensive methodology aimed at fostering behavior change. In the field of eating behavior, the BCW framework has been successfully applied in intervention studies [17,18].

Considering the findings from previous studies on salt intake behaviors in Brazil [8,9,19], which highlighted the excessive use of salt in food preparation, the need to develop an intervention to reduce salt consumption became apparent, which led to the development of a theory-based intervention using a rigorous methodological approach, the BCW, as a guiding model, to ensure the effectiveness of the intervention.

The process of intervention design based on BCW is detailed in a previous study [20]. During the development of the intervention, it was possible to identify, by means of a literature review, that the behavior of salt addition during food preparation was the main source of the overall daily salt intake of adults and elderly Brazilians [8,9,19]. In turn, this behavior was determined by intention, self-efficacy, and habit [21]. To address these determinants and by applying the BCW steps, we were able to identify the behavior change techniques: goal setting (behavior), problem-solving, goal setting (outcome), action planning, commitment, feedback on behavior, self-monitoring of behavior, social support (unspecified), social support (practical), instruction on how to perform the behavior, information about health consequences, demonstration of the behavior, prompt or cues, behavioral practice or rehearsal, credible source, and adding objects to the environment [20].

Another critical step in the intervention development is to identify the most effective method for delivering the intervention. A review of the literature revealed the potential benefits of mobile apps and the efficacy, reliability, and association with improved health outcomes of mobile app-based interventions on eating behaviors [22-24], and specifically in interventions related to salt consumption [25]. This evidence informed our decision to use a mobile app as the delivery method for the intervention [20].

Subsequent to the intervention development process, the next step is to evaluate the effect of the intervention. Therefore, this study shows the results of the efficacy and usability assessment of a mobile phone app intervention to promote healthy salt intake behavior among adults, focusing on behavior change in adding salt during food preparation.

Objective

This study aimed to assess the usability and the efficacy of a mobile app intervention, named "Sal na Medida" app, on the promotion of a healthy salt intake behavior among adults, based on the BCW framework. Additionally, it aimed to investigate if intention, self-efficacy, and habit serve as mediator variables of intervention effects.

Methods

Trial Design

This is a randomized controlled trial, with 2 parallel groups (intervention [IG] and control group [CG]). This study was conducted between October 2021 and August 2022, part of a large study developed in three modules: (1) intervention design, (2) development of "Sal na Medida" app, and (3) implementation and evaluation of the intervention efficacy and app usability. Details of the protocol of this study, with data from modules 1 and 2, have been previously described [20]. This paper adheres to the CONSORT (Consolidated Standards of Reporting Trials) guidelines for reporting randomized trials (Checklist 1) [26]. The trial was registered at The Brazilian Clinical Trials Registry (RBR-4s8qyyq) [27], date of registration: January 28, 2022.

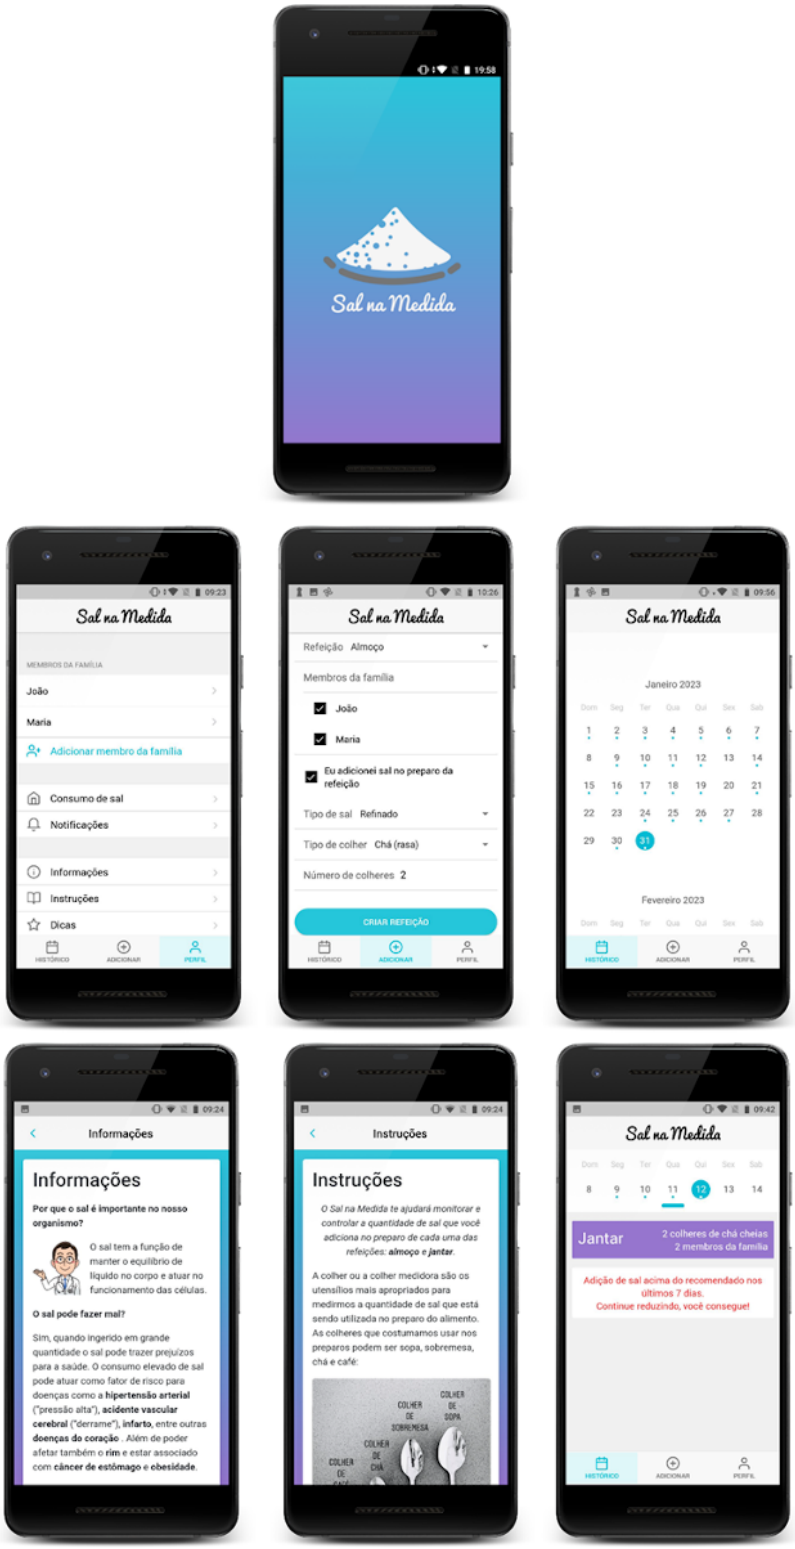
XSL•FO
RenderX

Participants

Participants were recruited from primary health care centers (PHCC) in a Brazilian city with a population of 51,000 people, located in the interior of São Paulo state. Inclusion criteria comprised individuals aged 20 to 59 years with adequate oral and reading skills. Participants were also required to possess sufficient digital literacy to operate the app independently or with assistance from an adult or family member. Exclusion criteria included individuals without access to a mobile phone equipped with the Android operating system. Individuals who met all the inclusion criteria and did not present any exclusion criteria were invited to participate by either the researcher or the Community Health Agent, who serves as the link between the PHCC and the families within the covered area.

Intervention

The intervention, delivered via a mobile app, was developed using the BCW [16], as detailed in a previous study protocol [20]. The intervention development was based on the results of previous studies that identified, in the Brazilian population, a high salt intake and its sources of consumption [8,9,19] and that identified that intention, self-efficacy, and habit were the key psychosocial determinants of salt intake behavior [21].



To address these determinants and by applying the BCW framework, we selected corresponding intervention functions, that is, broad categories of things one can do to change behavior, which included education, persuasion, incentivization, modeling, enablement, and training. Building on these intervention functions, specific “active ingredients” were identified to facilitate behavioral change, referred to as behavioral change techniques. These techniques included—problem solving, goal setting (outcome), action planning, commitment, feedback on behavior, self-monitoring of behavior, social support (unspecified), social support (practical), instruction on how to perform the behavior, information about health consequences, demonstration of the behavior, prompts or cues, behavioral practice or rehearsal, credible sources, and adding objects to the environment [20].

The prototype of the mobile app, named “Sal na Medida” app, was pretested among potential users, and the final version was produced.

In the app, the behavior change techniques described above were incorporated. Each day, participants record the number of people who had meals at home. For each meal, they enter the number of individuals who consumed it, as well as the number and type of salt spoons used. Additionally, the app provides information on the recommended daily salt intake, the health risks of excessive consumption, tips for reducing salt intake, and demonstrations—through text, images, and videos—to support better understanding. Throughout this process, the app offers feedback on whether the participant is meeting the recommended daily salt intake goal (Figure 1).

XSL•FO
RenderX

Figure 1. The “Sal na Medida” app screenshots.

After the app was installed on the Android (Google LLC) phones of the participants in the IG, they received instructions on how to use it, and then they were followed up for 2 months. Participants in the CG did not receive any intervention. However, as they were under the usual care of the primary care center, they may have been exposed to general advice on salt intake that is usually given during consultations with health professionals.

Outcomes

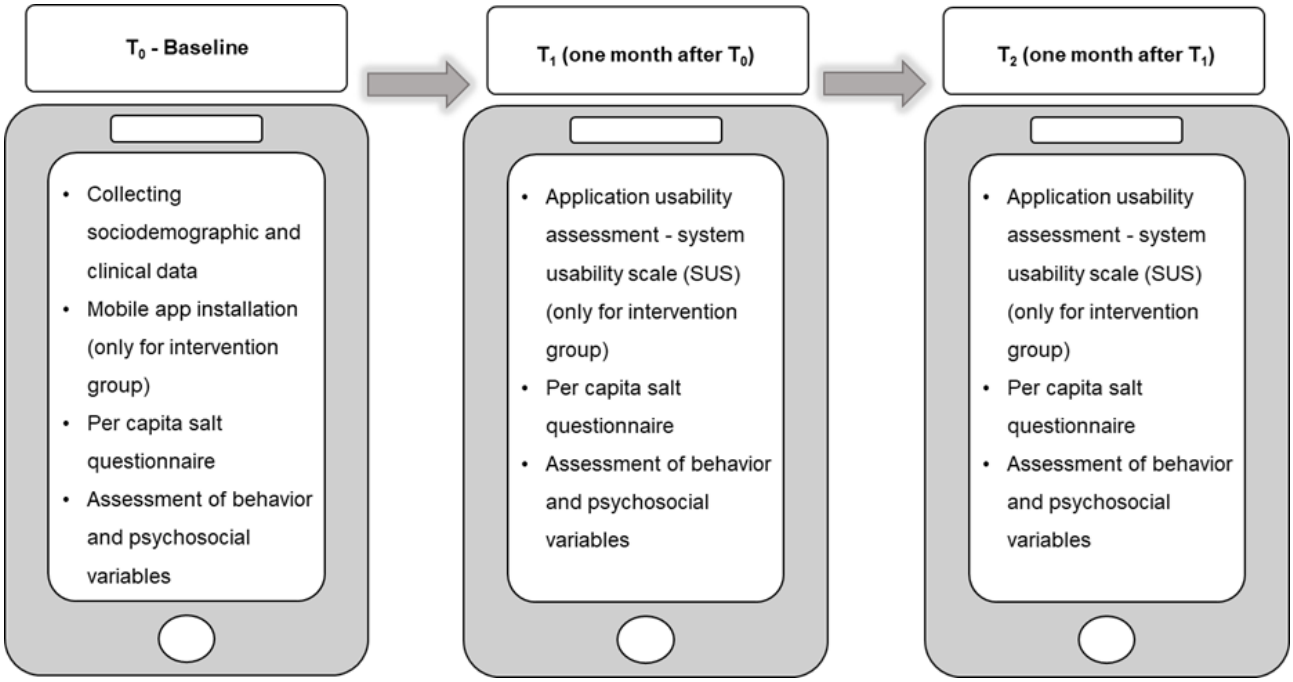
Primary Outcomes (Salt Intake Variables)

- Per capita salt: this is a self-reported questionnaire that estimates the discretionary sodium intake from salt used at the table and during home food preparation, developed and used in previous Brazilian context studies [9,19,21,28]. It measures the amount of salt consumed per person daily based on reports of the amount of salt used per month in

XSL•FO
RenderX

the household (1 kg packages), taking into account the number of people living in the house and the number of meals each person eats at home.
- Behavior of salt intake: the instrument used in this study was developed in a previous study [29] as a subjective tool for collecting data on salt consumption, specifically regarding the behavior of adding salt to food. It includes a question with 5 response options, assessing the behavior of adding a maximum of 3 g of salt per day during cooking.

Secondary Outcomes (Psychosocial Variables)



Psychosocial variables were assessed using a validated instrument developed in a previous study [29].

- Intention: participants' motivation for adding a maximum of 3 g of salt per day during cooking was estimated using a scale comprising 6 items, with each item rated on a 5-point scale (1-completely disagree to 5-completely agree). A high score indicated a high intention to perform the behavior.
- Self-efficacy: participants' confidence in their ability to add a maximum of 3 g of salt per day during cooking was assessed by means of the mean of 3 items rated on a 5-point scale (1-completely disagree to 5-completely agree). The higher the score, the greater the perception of self-efficacy to perform the behavior.
- Habit: evaluation of participants' habits regarding salt intake during cooking was conducted using a scale consisting of 10 items, each assessing the extent to which they used more than 1 level teaspoon of salt per day (equivalent to more than 3 g of salt), assessed on a 5-point scale (1-definitely not to 5-definitely yes]. Higher scores on the scale indicate a greater habit of using more than 3 g of salt per day during cooking.
- System Usability Scale (SUS): a reliable and widely used tool for assessing the usability of various products and services, including software, websites, and mobile applications [30]. It consists of a 10-item questionnaire with 5 response options for respondents (1-completely disagree to 5-completely agree). A higher score indicates better usability. The scale was applied at T_1 and T_2 only for IG participants.

Data Collection

This study was conducted over 3 waves of data collection during a 2-month follow-up period (Figure 2). At baseline (T_0), sociodemographic and clinical variables were obtained from participants in both IG and CG. Variables including per capita salt, behavior of salt intake, and the psychosocial factors (intention, self-efficacy, and habit) were evaluated at T_0, T_1, and T_2 for both groups. The SUS was applied to the IG at T_2.

Figure 2. Data collection plan: control and intervention group.

Sample Size

The sample size was estimated using the G* Power software (version 3.1.9.4; Heinrich-Heine-Universität Düsseldorf), based on the objective of comparing quantitative outcomes between IG and CG, in the 3 periods of data collection. Repeated measures ANOVA was used with a significance level of 5%, 80% power, and an effect size of 0.25, which is considered a moderate degree of effect size [28]. A minimum sample of 86 participants was estimated (each group consisted of 43 participants).

Randomization

Participants were randomly allocated to either the IG or the CG using a randomization procedure with variable block sizes. The randomization sequence was generated by a statistician, independent of the research team, using a web-based tool. The principal investigator was responsible for enrolling participants

XSL•FO
RenderX

and assigning them to their respective groups according to the predefined randomization sequence and order of enrollment.

Statistical Methods

Qualitative data were described using frequencies and percentages, and quantitative data as measures of central tendency (mean and median) and dispersion (SD, maximum, and minimum).

To evaluate the efficacy of the intervention on primary outcomes (salt intake variables), a linear regression model via generalized estimating equations modeling was used to make comparisons between groups and times.

Regression analysis with generalized linear models was used to assess the prediction of per capita salt at T_1 and T_2 by the psychosocial variables of habit, self-efficacy, and intention measured at T_0.

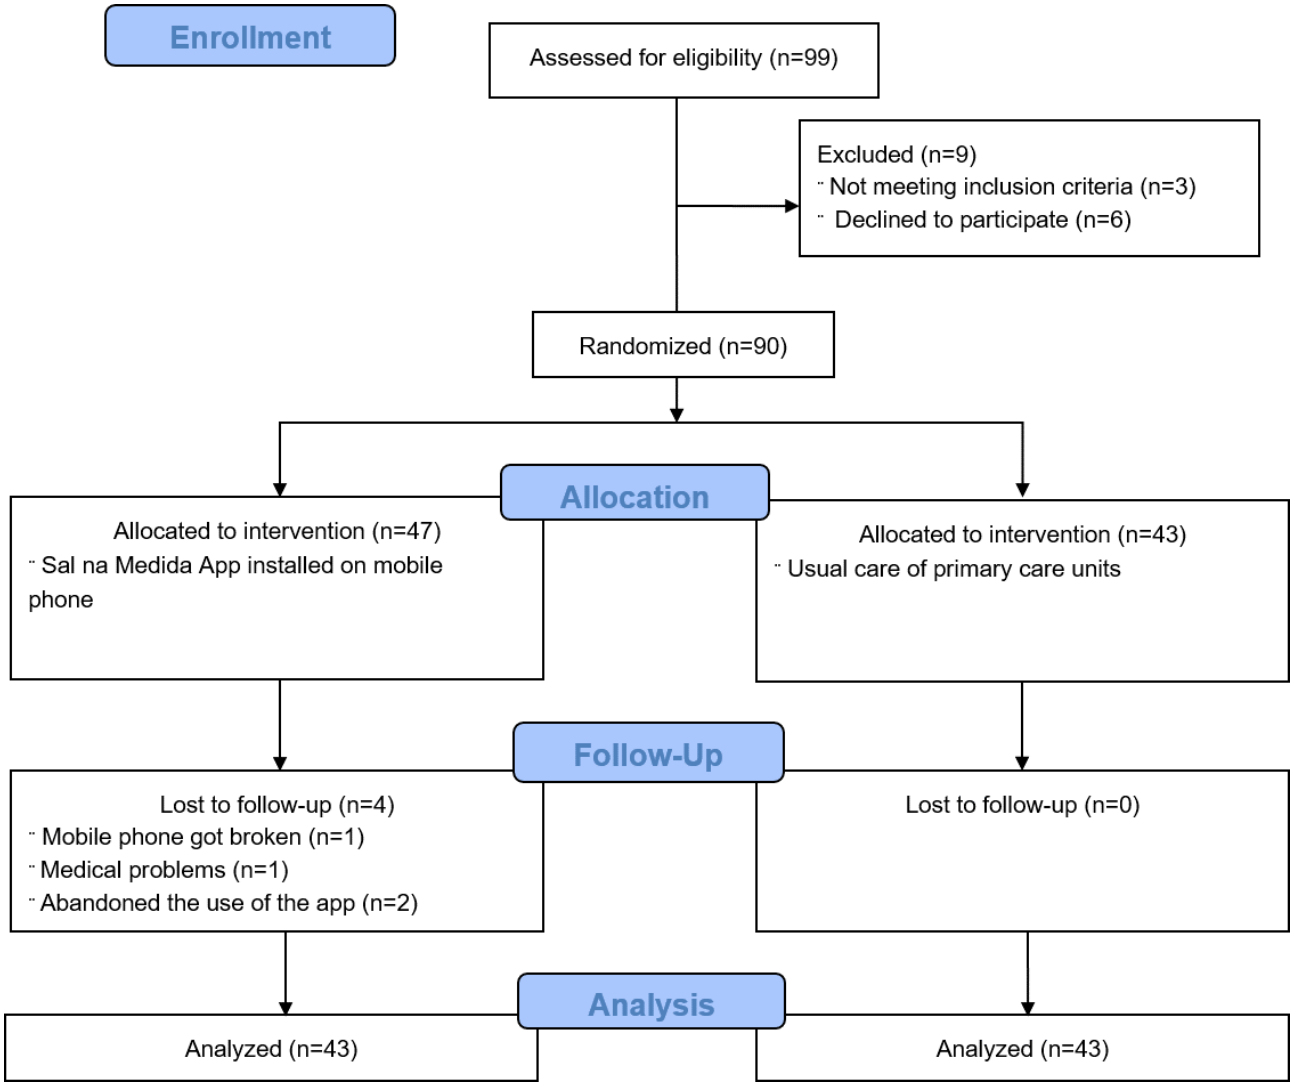
The app's usability was evaluated by the mean (SD) obtained by the SUS at T_2. The SUS scores were classified as: above 90 points and the app is considered to have the best possible usability, 81 to 90 points and it is considered excellent, 71 to 80 points as good, 60 to 70 points as 0kay, and below 60 points and the degree of usability is not acceptable [31].

To assess the mediators of the effect of the intervention, mediation analysis using linear regression models was used via generalized linear models and modified Poisson regression models with robust variance. The results of the linear regression and Poisson models are presented using the estimates of the regression coefficients and relative risk, respectively, with CI values and *P* values. In the mediation analyses, the results of behavior at T_0 were considered as a control variable.

A significance level of 5% will be adopted. Statistical analyses were performed using the SAS (version 9.4; IBM Corp) program.

Ethical Considerations

This study was approved by the Research Ethics Committee of the university to which the researchers are connected (10937419.0.0000.5404), accredited by the National Research Ethics Commission, in compliance with Resolution 466/2012/CNS/MS. The procedures followed were in accordance with the ethical standards outlined in the Declaration of Helsinki. Written informed consent was obtained from all participants. All necessary measures were undertaken to ensure participant privacy, including the use of anonymized data, secure data storage, and strict confidentiality protocols throughout the research process.



Data entered by IG participants into the "Sal na Medida" app was securely stored in the Firebase Realtime Database per Google's privacy policy [32].

Results

A total of 90 participants were recruited, and 86 (95%) of them completed this study after 2 months of its beginning (IG n=43; CG n=43). Four participants who did not complete the study, who were predominantly female 75% (3/4), with an average age of 40.2 (SD 13.6) years and a mean of 11 (SD 2.4) years of schooling (Figure 3).

XSL•FO
RenderX

Figure 3. Flow diagram of the study.

Sociodemographic and clinical characterization data, as well as comparative and association analyses applied to the 2 groups, are presented in Table 1.

XSL•FO

[c]*P* value obtained with the chi-square test.

[d]Not available.

Only for the age variable, there was a statistically significant difference (*P*<.001) between the means of participants in the IG (34.2, SD 9.4 y) and the CG (43.4, 9.9 y). For this reason, the analyses were adjusted according to the age variable. In both groups, there was a predominance of female (IG: n=36, 83.7%; CG: n=37, 86%), White (IG: n=28, 65.1%; CG: n=20, 46.5%), and active (IG: n=40, 93%; CG: n=42, 97.7%) participants. Considering the clinical data, there were no significant differences between groups.

The results regarding the intervention's effect on per capita salt intake indicated that, at baseline (T_0), there was no significant difference between the IG and CG (IG=4.6, SD 2.7 g; CG=5.3, SD 4.0 g). At T_1, 30 days after the baseline, both groups showed a reduction in salt intake (IG=3.9, SD 2.6 g; CG=4.7, SD 3.4 g). Finally, at the end of the intervention, the IG showed a further reduction in salt consumption, while the CG remained stable (IG=3.5, SD 2.3 g; CG=4.7, SD 3.6 g; Table 2).

Table . Description of variables of salt intake (per capita salt and behavior) and psychosocial determinants (intention, self-efficacy, and habit) at T_0, T_1, and T_2.

Variables	Intervention group (n=43)			Control group (n=43)		
	T_0	T_1	T_2	T_0	T_1	T_2
Per capita salt, mean (SD)	4.6 (2.7)	3.9 (2.6)	3.5 (2.3)	5.3 (4.0)	4.7 (3.4)	4.7 (3.6)
Intention, mean (SD)	4.0 (0.2)	4.1 (0.3)	4.2 (0.4)	3.9 (0.1)	3.9 (0.2)	3.7 (0.7)
Self-efficacy, mean (SD)	4.0 (0.2)	4.1 (0.3)	4.2 (0.5)	3.8 (0.4)	3.8 (0.5)	3.6 (0.7)
Habit, mean (SD)	3.4 (1.2)	2.3 (0.9)	1.8 (0.8)	3.2 (1.3)	2.1 (1.2)	2.6 (1.2)
Behavior (1 to 3)[a], n (%)	24 (55.8)	7 (16.2)	3 (7)	21 (48.9)	16 (37.2)	15 (34.9)
Behavior (4 to 5)[a], n (%)	19 (44.2)	36 (83.7)	40 (93)	22 (51.1)	27 (62.7)	28 (65.1)

[a]Behavior 1, 2, 3, 4, and 5 = use of a maximum of 3 g of salt/day in meal preparation—never, rarely, sometimes, on most days of the week, or every day, respectively.

In the regression analyses, the intragroup results confirmed that, at the end of the intervention, IG participants had a significant reduction in per capita salt intake (mean difference =−1.08 g; *P*=.01). In contrast, although the CG also showed a decrease in salt intake at T_2, this difference was not statistically significant (mean difference =−0.55 g; *P*=.22). There was no statistically significant intergroup difference at T_2 (Table 3).

[a]Linear regression via generalized estimating equations.

To assess the effect of the intervention on the behavior variable of salt intake, participants were considered to have achieved the desired behavior if they reported scores of "4" or "5," indicating that they used a maximum of 3 g of salt per day in meal preparation on most days of the week or every day, respectively.

We found a significant change in the scores among IG participants. At T_0, the majority (n=24, 55.8%) reported never, rarely, or occasionally using a maximum of 3 g of salt per day during meal preparation. By the end of the intervention (T_2), this percentage increased significantly, with 93% reporting consistent adherence to this behavior on most or all days of the week (Table 2).

Regression intergroup analyses showed that, at T_2, participants in the IG had a 63% higher probability of adhering to this behavior compared to those in the CG (*P*<.001; Table 3). Additionally, the intragroup analysis revealed that, after the intervention, IG participants were 111% more likely (*P*<.001) to consistently use a maximum of 3 g of salt per day when preparing meals on most days or every day (Table 4).

Table . Effect of the intervention on the salt intake variables (behavior) at T_0, T_1, and T_2. Analyses adjusted according to the age variable.

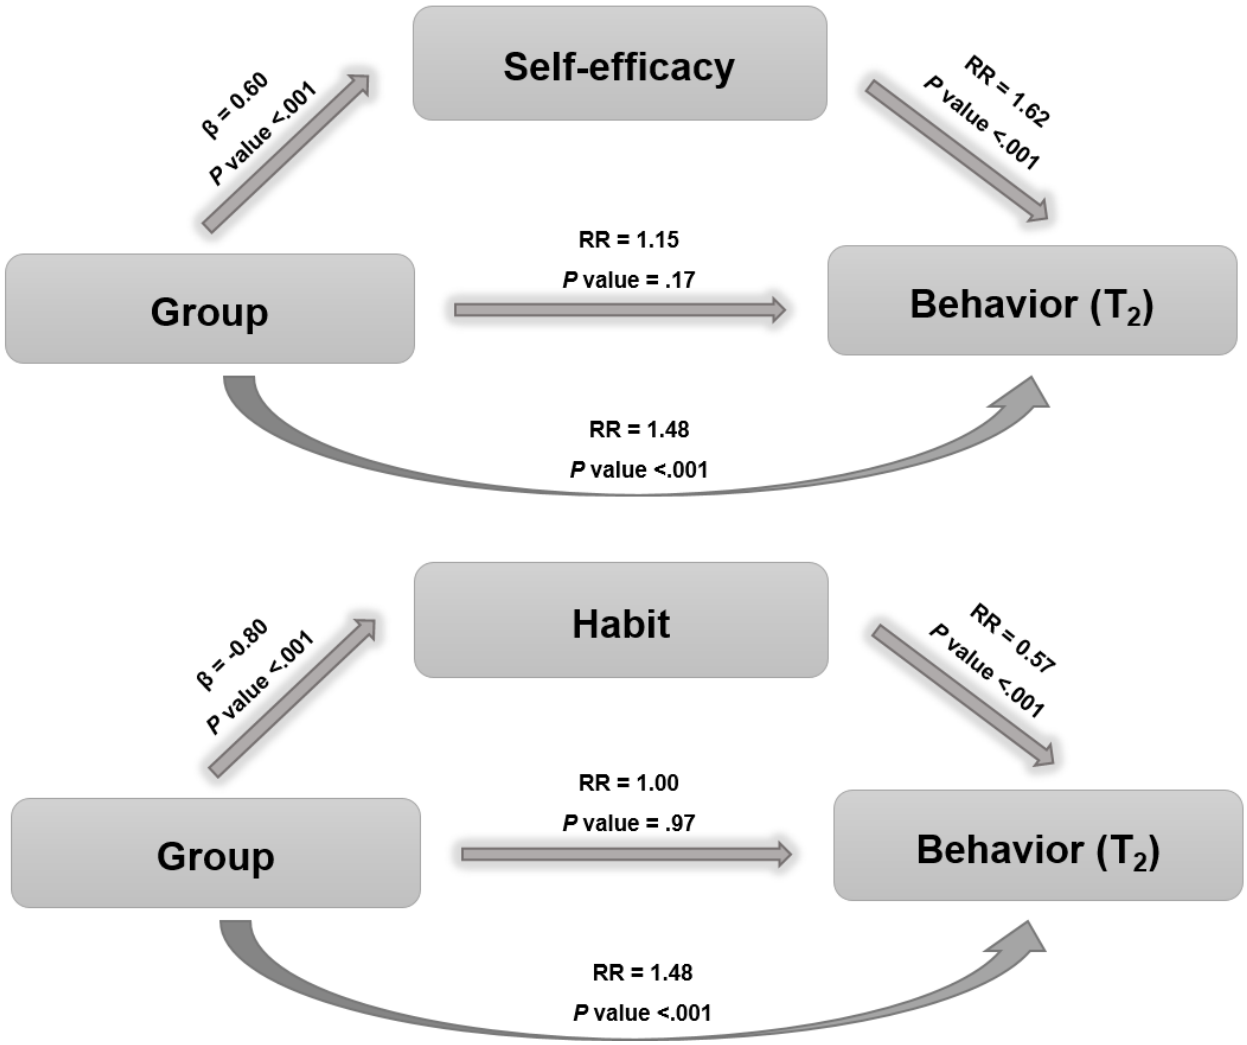
Behavior	Relative risk[a]	95% CI	*P* value[b]
Intervention-control (T_0)	0.99	0.63 to 1.56	.95
Intervention-control (T_1)	1.52	1.15 to 2.03	.004
Intervention-control (T_2)	1.63	1.26 to 2.11	<.001
T_1/T_0 (control group)	1.23	1.03 to 1.47	.02
T_2/T_0 (control group)	1.27	1.05 to 1.54	.01
T_2/T_1 (control group)	1.04	0.92 to 1.17	.56
T_1/T_0 (intervention group)	1.89	1.39 to 2.58	<.001
T_2/T_0 (intervention group)	2.11	1.52 to 2.92	<.001
T_2/T_1 (intervention group)	1.11	1.01 to 1.23	.04

[a]It was estimated the risk of presenting the result "4 and 5."

[b]Poisson model modified via generalized estimating equations.

Concerning secondary outcomes, that is, the psychosocial determinants of behavior, the IG participants showed, after the intervention, a slight increase in the mean of intention (mean T_0=4.0; mean T_2=4.2) and in the self-efficacy (mean T_0=4.0; mean T_2=4.2). As for the habit of using more than 3 g of salt per day in the preparation of meals, there was a decrease in the average score of this variable in both groups, but in IG, the decrease was more pronounced (mean T_0: 3.4; mean T_2: 1.8) when compared to the CG (mean T_0=3.2; mean T_2=2.6; Table 2).

The intragroup regression analysis indicated that, at the end of the intervention, IG participants reported an increase in the intention to use a maximum of 3 g of salt per day in preparing meals (mean difference=0.16; *P*=.02). When comparing the groups, at T_2, the IG showed higher intention when compared to CG (mean difference=0.51; *P* value<.001; Table 3).



For self-efficacy, after the intervention, there was an increase in the scores of this variable in the IG (mean difference=0.21; *P*=.02) and a decrease in the CG (−0.23; *P*=.0494). In the intergroup analysis, after the intervention, the IG presented higher self-efficacy when compared to the CG (mean difference=0.66, *P*<.001; Table 3).

Regarding the habit of using more than 3 g of salt per day in meal preparation, a significant reduction was observed in both the CG (mean difference=−0.55; *P* value <.001) and IG (mean difference=−1.60; *P*<.001). However, at T_2, the reduction was significantly greater in the IG compared to the CG (mean difference=−1.03; *P*<.001; Table 3).

Mediation analyses found that self-efficacy and habit mediated the effect of the intervention. The analyses show that the intervention led to an increase in participants' perception of self-efficacy, which in turn contributed to improving the behavior of salt intake, that is, the increase in self-efficacy led to a higher frequency of the behavior of using no more than 3 g of salt per day. Additionally, the intervention resulted in a decrease in the habit of adding large amounts of salt when cooking, which also served as a pathway through which the intervention influenced the behavior of salt addition (Figure 4).

XSL•FO
RenderX

Figure 4. Mediation analysis. Analyzes adjusted according to the behavior T_0. It was estimated the risk of presenting the result "4 and 5"(use of a maximum of 3 g of salt/day in the preparation of meals on most days of the week or every day, respectively). β: coefficient; RR: relative risk.

The usability of the application evaluated in the IG indicated a mean score of 77.8 (SD 12.7). The average score on the SUS scale of the individuals after the intervention was 77.8, which indicates good usability of the application.

Discussion

Principal Findings

The “Sal na Medida” app was developed to contribute as a public policy strategy to change the behavior of adding large amounts of salt during home food preparation by adults in the general Brazilian population. Our results showed a substantial positive impact on participants’ salt intake behavior throughout the intervention and indicate that the “Sal na Medida” app is an important method for changing the behavior of salt addition in home-cooked meals and proved to be a good alternative in promoting healthy salt intake.

The improvement in the behavior among participants in the IG from baseline to the end of the intervention was quite significant. While the majority initially reported limited salt addition only occasionally or rarely at baseline, postintervention 93% reported consistently adhering to the maximum 3 g of salt per day during cooking. This highlights the efficacy of the intervention in promoting healthier salt intake behavior. Furthermore, the chances of an individual performing the healthy salt intake behavior using the mobile app were 63% higher than for people who did not use this tool.

When evaluating other review studies, we found many have been using mobile apps to change eating habits [22,23], but still, few have been in the area of salt intake specifically. As we found several sources of consumption of this nutrient, strategies were applied to reduce the consumption of high-sodium foods by offering an alternative to low-salt foods in these places where processed or ultraprocessed foods are sold or consumed [33,34]. In another study, despite adding information about using less salt when cooking or at the table, this guidance was provided by a health professional in a face-to-face visit, and the app was used only, as well as in previous studies, to encourage individuals to make choices with low sodium content in industrialized foods [35].

Another finding of our study is with respect to the mediation analyses, which revealed important insights into the mechanisms through which the intervention was successful in changing the salt intake behavior. Specifically, we found that the positive effect of the intervention on salt intake behavior was mediated by 2 psychosocial variables: self-efficacy and habit. This means

XSL•FO
RenderX

that as individuals gained confidence in their ability to control their salt intake, they were more likely to adopt this behavior; additionally, breaking the automaticity in the use of salt, that is, making a conscious behavior, people are able to achieve the desired behavior. So, understanding these mediating factors clarifies the mechanism through which the intervention influences the desired results [15].

Despite providing advice and knowledge about healthy salt recommendations, interventions are generally aimed at a specific public, with the disease already triggered and with the aim of not aggravating this condition, as in cases of hypertension [34,35] or cardiovascular disease [33] or even controlling the associated symptoms, such as high blood pressure, and not the general population to prevent these diseases.

In terms of health prevention, such a tool is essential to promote public policies at the first level of health care, as actions aimed at reducing the addition of salt aim to prevent the onset and worsening of chronic noncommunicable diseases, impacting health as well as the economy [36]. Intervening in this behavior is part of several government initiatives, as this behavior of salt consumption above the recommended level is not unique to Brazil, but also to other countries in the Americas [37]. The Pan American Health Organization, together with the International Development Research Center, developed a report for Latin American countries with social marketing to help reduce salt, but it has been insufficient to implement or adopt salt reduction strategies in local communities [37].

In Brazil, there are ongoing policies, such as voluntary targets for reducing the sodium content in processed and ultraprocessed foods, the front labeling of warnings that was approved by Brazilian Health Regulatory Agency (Anvisa) and includes the alert for excess sodium [38], in addition to the recommendations of the Food Guide Brazilian, when it comes to the use of small amounts of culinary ingredients [39].

Finally, in evaluating the app usability, it is possible to identify how easily and efficiently users can interact with an app to achieve their goal. The usability score of the “Sal na Medida” app showed good usability, which is a good indication. Higher usability leads to greater user acceptance and improved health outcomes, making it a crucial factor in evaluating digital health applications [40]. Although the study involved a younger adult sample—who might generally be more tech-savvy and thus could have influenced the app’s usability score—a systematic review on educational technology usability using the SUS found no significant correlation between SUS scores and participants’ age [41]. The “Sal na Medida” app was tested with the population that uses primary health care services in Brazil, which has the potential to be another alternative tool in the future.

Strengths and Limitations

A recent review on mobile health technologies to reduce salt makes 3 recommendations for future interventions in this area [25], in which the “Sal na Medida” app is included.

First, to create innovative and interactive mobile health technologies. Given that this study addresses a previously unexplored source of salt consumption in mobile apps—one that contributes to exceeding recommended daily intake limits—along with its demonstrated good usability and the ability to be used independently without professional assistance, the “Sal na Medida” app represents the first tool to integrate these concepts.

Second, to design interventions in primary care and associate them with salt reduction targets. Our study is aligned with specific public health recommendations for reducing salt intake, particularly by promoting behavioral changes in excessive salt use during meal preparation, and, additionally, it was conducted with adults recruited from PHCCs in a Brazilian city. Thus, the “Sal na Medida” app is promising with regard to its impact on reducing salt intake at the population level, especially in a specific geographical context. Although it was developed specifically for reducing salt consumption in food preparation, the app contains strategies that involve replacing foods with high sodium content with natural foods. This behavioral change can trigger changes in other behaviors related to salt intake, such as the consumption of processed foods.

The third and final item is to develop large-scale clinical trials with a robust design, incorporating an outcome variable (24 h urine sodium). We conducted a randomized controlled study, targeted at a specific behavior of salt intake, and the intervention was guided by the BCW [16], a robust framework. As the focus of the study was on behavior change—specifically reducing the amount of salt added during meal preparation—and on encouraging participants to adopt this behavior as a lasting habit in their daily lives, the 24-hour urine sodium was not assessed as a quantitative variable in this study.

The study also had some limitations. The system required the participants’ smartphones to have only Android because the app is not available in iOS (Apple Inc). Another limitation was the impossibility of blinding researchers and participants for data collection after the intervention, which could cause potential bias in the responses of individuals.

Another study limitation is the use of a self-reported questionnaire to estimate per capita salt intake. The literature points to the lithium-tagged salt method as the gold standard for measuring discretionary salt intake. However, studies using this method are often limited in size due to the significant burden it places on participants [42]. The self-reported per capita salt questionnaire used in this study was used in previous studies in the Brazilian context [9,19-21,43,44] because it allows us to capture the main source of salt consumption for this population. The 24-hour urinary sodium excretion is the gold standard for objectively quantifying salt intake; however, this method does not allow identification of the source of salt intake and has several limitations, such as intraindividual variability in urinary excretion due to factors like diet, hydration status, physical activity, stress, and renal function; inconvenience and burden for participants to collect the 24-hour urine sample, which may lead to incomplete collection; and high costs of analyses [45].

Finally, future studies investigating the long-term effects of the “Sal na Medida” app on maintaining behavior change are necessary, as the follow-up period in this study was limited to 2 months. Additionally, future research should include older

XSL•FO
RenderX

adults to evaluate the intervention's efficacy and the app's usability within this population.

Conclusions

The "Sal na Medida" app intervention demonstrated a positive impact on salt intake behavior, enhancing participants' intention and self-efficacy perception toward reducing salt use during home-cooked meal preparation, while also decreasing the habit of adding excessive salt. Achieving a change in behavior and integrating healthy habits of salt intake into the routine of families during meals is the goal of the "Sal na Medida" app. The next phase involves scaling up the app for broader implementation.

Abstract

Background: Digital interventions are effective in promoting healthy behaviors and are recognized as one of many strategies for achieving healthier populations. These interventions often include goal-setting, but the practical application and fidelity of goal setting, especially when targeting multiple health behaviors, remain underexplored. In a factorial randomized trial, we included goal-setting as one of six behavior change components in the digital intervention "Buddy," targeting university and college students' alcohol, diet, physical activity, and smoking behaviors. However, we found no strong and consistent evidence of an effect of goal-setting alone on any of the outcomes, highlighting the need to investigate how participants used this component.

Objective: This case study of Buddy aimed to gain insight into participants' interactions with the goal-setting component. Specific objectives were to identify the characteristics of participants who used this component and to analyze participants' self-authored content.

Methods: This study combined fidelity and effectiveness findings and involved 1704 participants from 18 universities and colleges in Sweden. Self-authored goals and challenges were analyzed using summative content analysis. Logistic and negative binomial regression analyses were conducted to estimate the odds of setting a goal, selecting or self-authoring a challenge, to estimate the odds of setting a goal with respect to a specific behavior, and to estimate the frequency of selecting or self-authoring different behavioral challenges.

Results: Of the 850 participants given access to the goal setting and challenges component, 427 (50%) set at least one goal and 403 (47%) selected or self-authored at least one challenge. A total of 607 goals were set, with most participants setting one goal (336/427, 79%). Goals primarily targeted physical activity (n=302), dietary behavior (n=140), and multiple health behaviors (n=53), typically combining physical activity with diet, alcohol, smoking, or sleep. Other goals included study performance, mental health, sleep, and mobile phone use (n=73). Fewer goals concerned alcohol (n=19) or tobacco (n=17). Participants selected 1506 challenges from 41 premade challenges, with dietary behavior challenges being most popular (667/1506, 44%). An additional 170 challenges were self-authored. Participants' baseline characteristics were associated with the odds of setting goals targeting specific behaviors and the frequency of selecting or self-authoring challenges targeting specific behaviors.

Conclusions: Our analyses suggest that, while goal-setting is theoretically grounded, and participants used Buddy in ways that suited their personal needs, this did not translate to measurable behavior change in the study population. The self-authored content showed how participants used the component and provided insights into how they articulate behavior change in terms of personal goals, challenges, strategies for action, motivation plans, and rewards. Future research should explore the conditions under which goal-setting may be more or less effective, to better understand its nuances and potential benefits.

Introduction

Improving unhealthy behaviors using digital interventions is one of many potential public health strategies for achieving healthier populations. Behavioral changes can reduce the incidence and burden of noncommunicable diseases, including cancers, cardiovascular diseases, and diabetes [1-5]. Individual-level public health interventions can support the adoption of healthy behaviors, including reducing alcohol consumption, eating a healthy diet, engaging in regular physical activity, and smoking cessation. In this context, digital interventions have proven effective in facilitating behavior change across various health behaviors [6-13]. Digital interventions offer scalable and easily accessible support designed to strengthen individual skills and capabilities, for example, by guiding individuals in setting goals for behavior change. However, few digital interventions have addressed multiple health behaviors simultaneously, despite the frequent co-occurrence of unhealthy behaviors [14,15].

In the context of behavioral interventions, goal-setting is recognized as a key behavior change technique [16]. It is commonly operationalized in interventions to focus on both behavioral goals, such as "go for a walk," and outcome-oriented goals, such as "lose weight." The rationale for this approach is grounded in the goal-setting theory developed by Locke and Latham [17,18], which focuses on the motivational aspects of setting goals. The theory emphasizes that specific and challenging goals, coupled with feedback, may lead to increased effort and improved task performance compared to easy, vague, or nonspecific goals, such as "doing one's best." The utility of setting goals is dependent on the individual's commitment to the goal, possession of the necessary skills to attain it, and absence of conflicting goals. Building on this theory, social cognitive theory [19,20] expands the scope of goal-setting by asserting that health behaviors are influenced not only by an individual's goals but also by their understanding of potential health risks and benefits associated with the behavior, their belief in their capability to perform these behaviors (perceived self-efficacy), their expectations of the outcome of their actions, and the perceived facilitators and barriers.

Complementing these theoretical frameworks, interventional research provides further insight into the efficacy of goal-setting within digital health interventions. Studies suggest that interventions are particularly effective when key intervention components include goal-setting, along with action planning, practicing behavior, behavior substitution, habit formation, and problem-solving [21-27]. For instance, a meta-analysis by McEwan et al [28], which included randomized controlled trials where participants set goals for physical activity, reported a medium-sized positive effect of goal-setting (Cohen *d*=0.55; 95% CI 0.43-0.67). Furthermore, a review by Epton et al [29] evaluated the effects of goal-setting across a range of behavior outcomes, including health-related goals (eg, weight loss), sporting goals (eg, performance in sports), cognitive goals (eg, problem-solving), and educational goals (eg, increasing study time). The review found small but robust effect sizes (Cohen *d*=0.34; 95% CI 0.28-0.41), suggesting that goal-setting can be beneficial in various behavioral contexts beyond health behavior change.

While goal-setting has been extensively researched, most studies focus on single-behavior interventions with clearly defined behavioral targets such as smoking cessation or physical activity. In contrast, this study investigated its application within the context of a digital multiple health behavior change intervention, which has not been thoroughly examined in previous research. This approach allowed us to explore how participants interpreted and used goal-setting when behavioral goals were not predefined by the intervention, offering insights into its real-world implementation. Based on its theoretical grounding and wide use in other health behavior interventions, we included goal-setting as one of six potentially effective components in a multiple health behavior change intervention [30]. This digital intervention, called Buddy, targeted university and college students' alcohol, diet, physical activity, and smoking behaviors. The intervention was designed to be open and flexible, allowing participants to use its components based on their individual needs. Our findings revealed no strong and consistent evidence of goal-setting alone impacting any of the measured health behaviors (Asberg et al, unpublished data, 2025). When goal-setting was combined with self-monitoring, there was limited evidence of positive effects on alcohol consumption and smoking 2 months postrandomization, but these effects did not persist at later follow-ups.

If goal-setting is to be an effective component of digital interventions, it is essential to ensure that the component is delivered and received by participants as intended. Evaluating this implementation fidelity can help identify any deviations from the protocol, such as when an intervention component is not delivered or used as planned [31]. Deviations may compromise the impact that an intervention may have; thus, identifying them and revising protocols is important. Despite this, the practical application and fidelity of goal-setting within both digital and face-to-face interventions are rarely evaluated [32,33].

Considering that the evidence we collected did not indicate an effect of goal-setting on behavior, and that the use of goal-setting is understudied in digital multiple behavior interventions, we aimed to explore how participants used this component. To investigate this interaction, we conducted a case study of Buddy with the aim of gaining a deeper understanding of participants' interactions with the goal-setting component of the Buddy intervention. The specific objectives were to identify the characteristics of participants who used this component and to analyze participants' self-authored content.

Methods

Study Design

This study combined quantitative and qualitative data collected from a factorial randomized trial of Buddy, which invited participants from 18 geographically dispersed universities and colleges in Sweden (representing approximately 50% of all) to take part in a behavior change intervention. Participants were recruited through posters, leaflets, email, websites, social media,

XSL•FO
RenderX

and via Student Health Care staff. Interested students registered by texting a dedicated number. Students were eligible for inclusion if they were 18 years or older and met at least one of six criteria for unhealthy behaviors, in accordance with national public health guidelines. These included: (1) having consumed 10/15 (woman/man) or more standard drinks of alcohol in the past week (with one standard drink defined as 12 grams of pure alcohol); (2) having consumed 4/5 (woman/man) or more standard drinks of alcohol on a single occasion at least once in the past month; (3) having consumed less than 500 grams of fruit and vegetables on average per day in the past week; (4) having consumed two or more units of sugary drinks in the past week (one unit defined as 33 cl); (5) having spent less than 150 minutes on moderate and vigorous physical activity the past week; or (6) having smoked at least one cigarette in the past week. Students were excluded if they lacked sufficient proficiency in Swedish to complete the registration or did not have access to a mobile phone, as all study information and intervention materials were delivered digitally in Swedish.

The trial was part of the MoBILE (Mobile Health Multiple Lifestyle Behavior Interventions Across the Lifespan) research program [34], which aims to study digital health interventions across the lifespan, and was designed to evaluate the components of Buddy, of which, goal-setting was one. Buddy is based on previous research of digital health interventions among Swedish university students [35-42], on social cognitive models [43,44], and behavior change techniques [16]. For details of the factorial trial and the intervention, please see the protocol [30].

A screenshot of the goal-setting and challenges component of Buddy is presented in Figure 1. The Buddy intervention aimed to support health behavior change by enhancing self-regulatory skills and capacity through goal-setting and planning. By providing a structured approach, participants were encouraged to set goals and challenges for behavior change in any area they chose and were reminded of these throughout the week via text message. The intervention was accessible to participants over a period of 4 months, with weekly reminders sent on Sundays to access the intervention.

Participants were prompted to set one or more goals for their future behavior, which included: (1) Setting a goal for the upcoming week, participants self-authored what they wanted to achieve; (2) Action-planning, participants formulated two strategies or activities that they planned to use to progress toward their goal; (3) Coping-planning, participants identified and prepared for potential motivational struggles by formulating their approach to self-motivation when faced with barriers; and a (4) Reward-planning, participants selected rewards for themselves upon achieving their goal.

Participants could also create their own challenges or choose from a library of ready-made challenges for the coming week. The challenges were shorter descriptions of tasks, for example, “I will start every day with a 15-minute walk.” Participants were informed that they could return to the system to set new goals and challenges.

XSL•FO

Figure 1. Interface of the goal-setting and challenges module in Buddy, showing where participants could self-author goals for the upcoming week (upper section), and select premade challenges addressing alcohol, diet, physical activity, and smoking. Translation: Goal-setting and challenges. Clearly defining your goals is an important step when aiming to make lasting changes in your life. Here, you can create a weekly plan by setting goals and accepting challenges. Throughout the week, you will receive text message reminders to help you stay on track with your plan. Set a goal. My goal for the upcoming week is to: ...For example, engage in physical activity for at least 60 minutes a day, or limit alcohol consumption to no more than 5 units per week. Accept challenges! Tap on the different health behaviors below and choose up to 5 challenges. If you prefer, you can also create your own challenges by tapping the pencil icon. We will send you text message reminders about your challenges throughout the week. Come back next week to select new challenges!

Ethical Considerations

The study received approval from the Swedish Ethical Review Authority on December 15, 2020 (Dnr 2020‐05496). All participants provided informed consent prior to participation. Data were anonymized before analysis to ensure confidentiality. No financial compensation was provided to participants. The trial was preregistered in the ISRCTN registry on January 28, 2021 (ISRCTN23310640).

Data Analysis

Qualitative Analysis

We conducted a qualitative content analysis using a summative approach, as outlined by Hsieh and Shannon [45], to analyze how participants interacted with the goal-setting and challenges component of the Buddy intervention. This approach involved both the quantification of specific content and the interpretation of its contextual meaning, allowing us to explore not only what participants wrote about, but also how they articulated themselves when setting goals and challenges across different health behaviors. The qualitative data consisted of user-generated, self-authored text entries submitted by participants within the intervention. These entries included both self-authored goals and challenges. The self-authored goals were structured entries composed of 5 sentences: one goal formulation, two strategies for achieving the goal, one motivational statement, and one reward. Each goal entry was approximately 60‐80 words long, whereas the self-authored challenges were formulated more succinctly, typically ranging from 2 to 15 words.

All qualitative data were exported from the platform and imported into NVivo12 Plus (Lumivero) for structured coding. We began the qualitative analysis of goals by identifying keywords related to the health behaviors that participants intended to change. Based on these keywords, we grouped the goals according to the targeted behavior, for example, goals related to physical activity were placed in one group, while those related to alcohol use were placed in another. Goals addressing multiple behaviors were categorized independently. Within each behavior group, we then coded the goals by focusing sequentially on content related to strategies, motivations, and finally rewards. This phase involved multiple rounds of coding and iterative refinement through comparing and contrasting codes to ensure attention to detail, accuracy, and consistency. Finally, we developed categories for strategies, motivations, and rewards within each behavior group.

Quantitative Analysis

We used logistic regression to estimate the odds of setting a goal and selecting or self-authoring a challenge. We also used logistic regression to estimate the odds of setting a goal with respect to a specific behavior (among those who had set a goal). We used negative binomial regression to estimate the frequency of selecting or self-authoring different behavioral challenges (among those who had selected or self-authored a challenge). All models included baseline characteristics of participants as covariates, including age, sex, BMI, total weekly alcohol consumption, frequency of heavy episodic drinking per month, number of cigarettes smoked per week, minutes of moderate and vigorous physical activity per week, average daily fruit and vegetable intake, weekly sugary drinks consumption, self-perceived stress, and psychosocial measures (importance, confidence, and know-how).

We used Bayesian inference to estimate the parameters of the regression models, with Student *t* priors centered at 0 with 3 degrees of freedom and a scale of 2.5 (a half-Student *t* prior was used for the dispersion parameter of the negative binomial models). We report the median of the posterior distribution as a point estimate of the association, along with 95% compatibility intervals (CI) defined by the 2.5 and 97.5 quartiles of the posterior distribution. We also report on the probability of an association (POA) as the proportion of the posterior distribution that is above or below the null in the direction of the median.

Results

Overview

The results are presented in four parts, illustrated in Textbox 1. The first part presents an overview of interactions with the component and the characteristics of the study population. The second part provides a detailed summary of the self-authored goals and challenges. The third part explores the associations between participants' characteristics and setting goals and challenges, as well as the associations between participants' characteristics and setting goals and challenges targeting specific behaviors. Finally, the fourth part presents the analysis of participants' self-authored content regarding goals and challenges.

Interactions With the Component and Participant Characteristics

From April 13, 2021, to October 18, 2023, we randomized 1704 participants to the factorial trial. In Table 1, baseline characteristics are presented for the entire study population. Access to the goal-setting and challenges component was given to 850 participants, of whom 427 (50%) set at least one goal and 403 (47%) selected or self-authored at least one challenge. A total of 607 goals were set by 427 participants, the majority of whom set one goal (336/427, 79%), 13% (55/427) set two goals, and 8.4% (36/427) set three or more goals. Additionally, 28 participants started setting a goal but did not fill in the entire form. A total of 1506 challenges were selected from 41 premade challenges, with dietary behavior challenges being the most popular (667/1506, 44%), followed by physical activity (635/1506, 42%), alcohol (154/1506, 10%), and smoking (50/1506, 3%). An additional 170 challenges were self-authored by participants. A complete list of the premade challenges available for selection is provided in Multimedia Appendix 1.

Table . Baseline characteristics of randomized participants.

Variables	Participants (N=1704)
Sex, n (%)	
Female	1400 (82.16)
Male	304 (17.84)
Age (years), mean (SD)	28 (6.9)
BMI (kg/m^2), n (%)	
Under (<18.5)	60 (3.52)
Normal (18.5 - 24.9)	844 (49.53)
Over (25.0 - 29.9)	458 (26.88)
Obese (≥30)	342 (20.07)
Alcohol, mean (SD)	
Total weekly alcohol consumption	3.7 (5.2)
Frequency of heavy episodic drinking	1.8 (2.7)
Smoking	
Number of smokers (smoked ≥1 cigarette per past week), n (%)	218 (12.79)
Number of cigarettes last week, mean (SD)	3.5 (16.6)
Physical activity	
Weekly moderate and vigorous physical activity (minutes), mean (SD)	207 (214)
Dietary behavior, mean (SD)	
Average daily fruit and vegetable consumption, portions per week	1.3 (1.1)
Sugary drinks, cans per week	2.7 (4.1)
Candy and snacks, portions per week	6.5 (6.4)
Stress, mean (SD)	
Self-perceived stress[a]	7.8 (2.9)
Psychosocial measures, median (IQR)	
Importance[b]	8 (7-10)
Confidence[b]	6 (5-8)
Know-how[b]	6 (5-8)

[a]4-item perceived stress scale with total score ranging from 0 to 16.

[b]Single item with 1-10 response options.

Setting Goals and Selecting or Self-Authoring Challenges

Table 2 shows that most participants set goals for physical activity (n=302) and dietary behavior (n=140). The goals highlighted the interconnectedness of health behaviors as participants set goals targeting multiple behaviors (n=53), typically combining physical activity with other behaviors like diet, alcohol, smoking, and sleep. Participants took the opportunity to set other kinds of behavior goals that focused on a variety of miscellaneous aspects (n=72), such as study-related performance, mental health, sleep, physical body, and mobile phone use. Meanwhile, fewer participants set goals for alcohol (n=19) and tobacco (n=17), including both smoking and snus.

When contrasting the self-authored goals (Table 2) with the self-authored challenges (n=170) in Table 3, similarities emerged regarding the choice of behaviors and activities to be conducted. Challenges, like goals, were primarily about physical activity (n=60), dietary behavior (n=30), mental health (n=19), tobacco use (n=14), study performance (n=12), sleep routines (n=8), leisure activities (n=6), alcohol consumption (n=5), and physical health (n=4). These challenges mirrored the goals' structure, being articulated as clear directives, intentions, or actions formulated in the first person singular, such as "I shall" or "I shall not." For example, "I will run every weekday morning this week," "Eat salad with every meal," "No smoking before 18.00," and "I will only drink on Friday and Saturday between 19 - 22."

XSL•FO
RenderX

Table . Focus of self-authored goals.

Focus of self-authored goals	Number of self-authored goals (n=607)
Physical activity	302
Dietary behavior	140
Miscellaneous[a]	72
Multiple health behaviors[b]	53
Alcohol consumption	19
Tobacco including snus	17
Unspecified	4

[a]Include performance goals, positive mental health goals, sleep behavior goals, physical body goals, and mobile phone use goals.

[b]Include diet and physical activity goals, combination of behaviors (three or more), physical activity and alcohol goals, physical activity and smoking goals, physical activity and other routine goals, and alcohol or smoking and diet goals.

Table . Focus of self-authored challenges.

Focus of self-authored challenges	Number of self-authored challenges (n=170)
Physical activity[a]	60
Dietary behavior[b]	30
Mental health: stress reduction, meditation, reflection, gratitude, and self-compassion	19
Tobacco use: reduce and refrain from cigarettes and snus	14
Study performance behavior: time and task commitment for completion	12
Sleeping routines: establish sleep routines	8
Leisure activities: prioritize leisure activities	6
Alcohol consumption: restrictions on consumption	5
Physical health and well-being: prioritize activities for physical health	4

[a]Number of days exercising per week (n=30), amount of exercise per day (n=16), and specified type of activity (n=14).

[b]Eat regularly and eat more vegetables (n=23) and reduce snacking (n=19).

Participant Characteristics and Setting Goals and Challenges

Table S1 in Multimedia Appendix 2 shows associations between baseline characteristics and setting a goal. These analyses reveal that the odds were smaller for men to write a goal compared to women (odds ratio [OR] 0.44, 95% CI 0.30-0.66; POA>99.9%). In addition, those with higher consumption of candy and snacks had higher odds of writing a goal; however, the association did not appear as strong (OR 1.03, 95% CI 1.00-1.05; POA=98%). Those who rated the importance of changing their health behaviors as higher at baseline also had higher odds of setting a goal (OR 1.09, 95% CI 1.00-1.18; POA=97.4%). Finally, although the evidence was weaker, smoking more cigarettes per week at baseline was associated with higher odds of setting a goal (OR 1.12, 95% CI 0.96-1.32; POA=92%).

Table S2 in Multimedia Appendix 2 shows associations between baseline characteristics and selecting or self-authoring a challenge. As was the case for goal-setting, men had a lower odds of selecting challenges compared to women (OR 0.46, 95% CI 0.30-0.67; POA>99.9%). There was also evidence, albeit weaker, that those who rated higher importance of change had higher odds of interacting with challenges (OR 1.07, 95% CI 0.98-1.16; POA=93.6%). Additionally, there was some evidence suggesting that individuals with high BMI (obese) were more likely than individuals with normal BMI to interact with the challenges component (OR 1.32, 95% CI 0.89-1.97; POA=91.4%).

Participant Characteristics and Behavior Targeted in Goals and Challenges

Overview

Tables S3-S16 in Multimedia Appendix 2 show associations between participants' characteristics and setting goals targeting specific behaviors, and the frequency of selecting or self-authoring challenges targeting specific behaviors. These analyses were done among participants who had set a goal or selected a challenge, respectively. Here, we give a summary of the findings presented in the tables.

Man Versus Woman and Age

When comparing men versus women, the strongest associations were found concerning setting goals targeting alcohol and diet, with the odds being lower for men. This pattern was also evident for selecting challenges related to alcohol and diet, where men selected fewer of these compared to women. In addition, men

XSL•FO
RenderX

selected fewer challenges related to physical activity than women. Older participants had higher odds of setting goals targeting alcohol consumption and selected fewer challenges relating to diet.

Alcohol Consumption

Participants who reported a higher weekly consumption of alcohol at baseline had lower odds of setting goals targeting diet and higher odds of setting goals targeting multiple health behaviors and miscellaneous goals. The multiple health behavior goals concerned combinations of behaviors such as physical activity, diet, alcohol, and smoking, while miscellaneous goals concerned behaviors not specifically targeted by the intervention, such as sleep. Those with higher weekly alcohol consumption also selected more challenges relating to alcohol consumption, but fewer challenges relating to physical activity. More frequent heavy episodic drinking at baseline was associated with selecting more alcohol-related challenges and writing fewer self-authored challenges.

Smoking

Participants who reported being more frequent smokers at baseline had higher odds of setting tobacco-related goals and had lower odds of setting goals for all other behaviors (except for multiple health behavior goals). These participants also selected more smoking challenges and fewer diet challenges.

Dietary Behavior

Participants with a higher fruit and vegetable intake at baseline had higher odds of setting goals related to physical activity and were less likely to set goals related to alcohol, diet, and tobacco. Similarly, these participants selected more physical activity and smoking challenges, but fewer diet challenges. Participants who reported a higher weekly consumption of sugary drinks had higher odds of setting multiple health behavior goals. Finally, participants who had higher candy and snacks intake at baseline selected more diet and self-authored challenges.

BMI

Participants with higher BMI (overweight and obese) had lower odds of setting goals targeting alcohol, as well as selecting fewer alcohol-related challenges, compared to those with normal BMI. Participants in the highest BMI category (obese) had higher odds of setting goals relating to diet and lower odds of setting goals targeting multiple health behaviors. Participants with lower BMI (<18.5) were more likely to set goals targeting diet but selected fewer challenges for diet compared to those with normal BMI. The participants in the underweight category were also less likely to set goals targeting tobacco. Participants in the edge BMI categories (underweight and obese) selected fewer challenges relating to physical activity and smoking, compared to those in the normal BMI category.

Physical Activity

Participants with higher levels of physical activity at baseline had higher odds of setting goals targeting diet and miscellaneous goals, and lower odds of setting physical activity goals. They also authored more of their own challenges and selected fewer physical activity challenges.

Stress Levels

Participants who experienced higher levels of stress relative to the group mean had higher odds of setting miscellaneous goals and lower odds of setting goals targeting alcohol. These participants also selected more smoking-related challenges.

Psychosocial Measures

Participants who rated the importance of changing their behavior as higher relative to the group mean at baseline had higher odds of setting goals targeting alcohol consumption and self-authored fewer challenges. There were no marked associations between confidence in being able to change with goal-setting and challenges. Finally, those who rated their knowledge of how to change their behavior higher relative to the group mean had lower odds of setting goals targeting alcohol and smoking and more frequently self-authored challenges.

Participants' Self-Authored Content From Buddy

The content of the self-authored goals and challenges was qualitatively analyzed. The coding process resulted in a total of 2412 codes. They focused primarily on health improvement, behavior modification, and self-improvement. A summary of all self-authored goals, strategies, motivations, rewards, and challenges can be found in Multimedia Appendix 3.

Participants Articulated Goals Differently Depending on Health Behavior

Goals related to alcohol, tobacco, and physical activity were often quantifiable, focusing on aspects like quantity, frequency, type, or duration. Physical activity goals were typically more specific, detailing activity duration or training frequency. Dietary behavior goals, while also specific, focused more on restrictions, as well as establishing desirable healthy patterns. As expected, considering the complexity of diet, these goals, unlike other health behaviors, included both preventive measures, such as avoiding unhealthy food products, and promotive aspects like incorporating healthy food choices. This contrasted with physical activity goals, which solely promoted increased activity, and alcohol and tobacco goals, which were purely preventive, such as limiting, reducing, or abstaining from the behavior.

> *In the upcoming week, my goal is to...*
>
> *...not drink alcohol on weekdays (Alcohol)*
>
> *...not smoke more than 4 cigarettes a day (Tobacco)*
>
> *...go for a walk every morning before studying (Physical activity)*
>
> *...not eat sugar and swap to fruit and berries instead... (Diet)*
>
> *...study at least 4 hours a day (Miscellaneous)*
>
> *...consume 500 grams of vegetables daily and work out 5 times (Multiple)*

Participants Intend to Use Proactive Strategies Such as Planning and Preparation

When formulating goals, participants were asked to formulate strategies to achieve their goals. Planning, preparation, and prioritization were central to all behaviors and were pronounced as specific, detailed, and proactive strategies on how to achieve

XSL•FO
RenderX

goals. This involved setting new routines, being mindful, and focusing on goal-oriented activities.

Participants articulated diverse activities and combinations of strategies. Dietary strategies included meal planning and availability of healthy alternatives, preparation of healthy food, and bringing fruit or lunch boxes to university. Physical activity strategies involved scheduling activities, making room for exercise in one's study schedule, adjusting routines, setting reminders, and finding motivational tools such as podcasts or social support. Alcohol and tobacco strategies involved heightened awareness of what is important to them and planned modifications to habits, such as slowing drinking pace, not carrying cigarettes, leaving parties earlier, or making environmental changes like avoiding alcohol-related activities.

> *In the upcoming week, I will undertake these two actions to progress towards my goals...*
>
> *...buy fruits to eat instead and eat proper breakfast, lunch, and dinner (Diet)*
>
> *...by going to bed on time and making a lunchbox the day before (Physical activity)*
>
> *...make some plans for Saturday night instead of going to the pub (Alcohol)*
>
> *...chew gum, drink tea, and do breathing exercises (Tobacco)*
>
> *...to go to bed on time and not sleep too late during the day (Miscellaneous)*
>
> *...schedule training and say no to cigarettes (Multiple)*

Physical activity strategies were typically action-oriented, specific, and time-framed, closely aligning with the goals. For instance, a goal to walk 20 minutes per day could involve the strategy to go for a morning and a poststudy walk. Conversely, dietary, tobacco, and alcohol strategies involved a broader range of activities like distractions, restrictions, substitutes, and limitations of unhealthy alternatives, as well as planning and preparing for healthy choices. For example, a typical goal to limit drinking involved the strategy to abstain from drinking before going out or swapping to alcohol-free alternatives. A typical goal to avoid unhealthy food involved the strategy to abstain from buying and replacing dessert with fruit and berries instead. Physical activity was also articulated as a strategy to achieve dietary, alcohol, and tobacco goals, such as being physically active as a means to divert attention from snacking, smoking, or drinking.

Participants Motivate Themselves With Health Benefits, Self-Encouragement, and Goal Focus

When formulating strategies, participants were asked to formulate how to motivate themselves when faced with barriers to achieve their goals. Participants' motivational self-talk, across various health behaviors, was expressed in a similar manner, primarily focusing on well-being, health benefits, self-encouragement, and goal orientation. The self-talk emphasized both short- and long-term well-being and health benefits. For tobacco, the focus was mainly on the long-term benefits, while physical activity and alcohol were more focused on short-term well-being, such as "feeling better afterwards, or the next day." Participants recalled and expressed previous experiences of feeling good when adopting a healthy behavior. For example, "I always feel better after exercising" (Physical activity), "I will be feeling so much better if I don't snack and avoid sweets" (Diet), "This will bring me energy" (Multiple), "I will avoid anxiety the day after if I drink moderately" (Alcohol), "Smoking is harmful to me and my asthma will improve without it" (Tobacco), and "I will feel good from exercise and less screen time. It will help" (Miscellaneous).

Participants used self-encouraging positive affirmations like "you can do it" to motivate themselves. In the context of physical activity, this included pushing oneself to work hard with a just-do-it attitude, overcoming barriers, and reminding themselves of the necessity of effort for success. For diet, tobacco, and alcohol goals, the focus shifted to reminding oneself that there are better alternatives, encouraging perseverance, and strengthening one's capability to combat craving, all with the aim of making oneself proud. Overall, participants reminded themselves of their capability and determination with affirmations like "I can and I will. They also reassured themselves of their past accomplishments, reinforcing their belief in their capabilities and the manageability of the task.

> *If it feels tough, I will tell myself that...*
>
> *...get a grip, it goes quickly and it's fun! (Physical activity)*
>
> *...I actually prefer and feel better with good, cooked food (Diet)*
>
> *...I feel much better during the week if I don't drink (Alcohol)*
>
> *...that you cannot afford it, and that I have succeeded in several demanding challenges before (Tobacco)*
>
> *...you can do it, you are goal-oriented and wonderful (Miscellaneous)*
>
> *...you must keep your promises to yourself so that you can trust yourself (Multiple)*

Regarding goal orientation, participants reminded themselves to stay focused on the goal, its significance, and why it is important, for example, the long-term benefits, self-improvement, or success with a task or studies. For miscellaneous behaviors, participants also highlighted the importance of self-value, personal sustainability, and life balance by encouraging themselves to focus on the task and dedicate time for health.

Participants Plan to Reward Themselves With Shopping, Indulgence, and Self-Appreciation

To meet their goal, participants were asked to articulate how they would reward themselves when achieving their goal. These rewards varied, but overall included shopping, indulging in something to eat, and engaging in enjoyable activities. Regardless of health behavior, participants also planned to express self-appreciation by acknowledging and recognizing their progress and effort. This often took the form of symbolic gestures like "a pat on the back," applause, a hug, or a sense of pride.

XSL•FO
RenderX

Shopping was a popular reward, with participants planning to buy clothing, beauty products, craft materials, electronics, or home decor. Some participants planned to indulge in culinary treats, such as cooking their favorite meal, dining out, or purchasing "special items" like sushi, exotic fruits, or barista coffee. Among those who set goals related to tobacco and alcohol, some planned to reward themselves with the ability to drink or smoke. Engaging in enjoyable activities was also a common reward. These activities ranged from socializing, movie nights, and gaming to outdoor activities like walking in nature or self-care activities like taking a day off from studying. Some planned to treat themselves with a visit to the hairdresser, a tattoo artist, or a massage, while others planned a trip. Some participants planned to save or invest the money they would have otherwise spent on unhealthy behaviors.

Discussion

Principal Findings

We conducted this study to gain insight into the fidelity of a digital multiple lifestyle behavior intervention by investigating participants' interactions with a goal-setting and challenges component. The self-authored content shed light on how participants used the goal-setting component and provided insights into how participants articulate behavior change in terms of personal goals, challenges, strategies for action, motivation plans, and rewards. Overall, our findings indicate that participants who engaged with the intervention component did so as intended, demonstrating the feasibility of incorporating goal-setting into a multiple health behavior intervention. Despite this, as mentioned earlier, in our analyses of the effects of goal-setting on behavior, we found no strong evidence that the component was effective (Asberg et al, unpublished data, 2025). This may partially be explained by the use being heterogeneous, with many not using the component at all, and individual characteristics determining engagement within the component. However, the combined findings of fidelity and effectiveness suggest that while components of behavioral interventions may be grounded in theory and used as intended, this does not always translate to behavior change. This calls for further research to explore the conditions under which goal-setting may be more or less effective, to better understand its nuances and potential benefits.

Our findings show that participants' baseline characteristics were associated with setting goals targeting specific behaviors and the frequency of selecting or self-authoring challenges targeting specific health behaviors. These associations were in line with what was anticipated and intended; for instance, participants with higher alcohol consumption focused on alcohol, while smokers prioritized smoking cessation. Meanwhile, despite Buddy's strong emphasis on alcohol, diet, physical activity, and smoking, those experiencing stress concentrated on goals and challenges concerning managing studies, mental well-being, sleep, and mobile phone use. Our findings also suggest that participants who already practice some healthy behaviors, such as consuming fruits and vegetables or engaging in physical activity, were more inclined to focus on other health areas where they may not be following guidelines. Overall, our findings suggest that participants used the intervention component to address their personal needs for support in changing unhealthy health behaviors.

When analyzing the content of the goals and challenges set by participants, we found that strategies, motivations, and rewards focused on proactive activities like planning, preparation, and prioritization. Participants were motivated by reminding themselves of the health benefits, self-encouragement, and maintaining a focus on their goals. These motivations had both a short- and long-term perspective. Participants supported themselves with positive affirmations, such as "you can do it," and richer messages of self-improvement, self-worth, and sustainable life balance.

Comparison With Prior Work

Previous studies have shown that goal-setting can lead to improved outcomes in various health behaviors. For instance, a web-based intervention [46] showed that weekly goal-setting can increase fruit and vegetable consumption among university students over time, but no corresponding impact on physical activity levels was observed. Researchers suggest that while goal-setting can be beneficial in initiating new behaviors, it might not be as effective for enhancing behaviors that individuals are already practicing. In a factorial trial [47], researchers compared adaptive goals versus static goals, and the effect of immediate versus delayed financial rewards on increasing physical activity. The result indicated that static goals initially increased daily step count but subsequently declined physical activity levels over time. Conversely, those with adaptive goals showed a smaller initial increase but maintained a more consistent level of activity throughout the 4-month intervention period. Notably, the activity levels of the static group eventually fell below those of the adaptive goal group, even with the incentive of immediate rewards.

In a study by Padovano et al [48], the relationship between daily goal-setting and its impact on alcohol consumption was investigated among individuals with alcohol use disorder. The study revealed that the most commonly selected goal was complete abstinence ("I have a plan to not drink"; n=858, 31%), followed by moderation goals ("2 or fewer drinks"; n=604, 22%), or ("5 or fewer drinks"; n=618, 22%). The odds of drinking were reduced by 89% when an abstinence goal was set (OR 0.11, 95% CI 0.08-0.15). Additionally, the study observed that those who more frequently set abstinence goals were the ones who drank more per drinking occasion. These formulations align with the self-authored alcohol and tobacco goals in this study, which were framed in a preventive manner—limiting, reducing, or abstaining from the behavior—and were predominantly formulated by participants with higher alcohol and smoking behaviors.

Similarly, the self-authored goals in this study, particularly those related to physical activity, aligned with the self-authored goals set by participants in a digital weight-loss intervention [49]. In that study, participants were encouraged to set weekly behavioral goals and share their goals and accomplishments on a shared social media platform. Findings indicate that goals expressed in repeating terms, or as both measurable and repeating terms (eg, "My exercise goal is to walk for at least 15 minutes a day

XSL•FO
RenderX

this week") were associated with greater weight loss. These repeating term goals, for example, articulating the number of training days per week, to eat fruit every day, to meditate, or to study for a specified number of hours per day, were also articulated among the students in this study.

Limitations

This study has a number of limitations that should be considered. First, associations between baseline characteristics and use of the component are not causal and should not be interpreted as such. These analyses describe who among the participants did what, but not why they did so. Second, the study did not assess whether interaction with the goal-setting component translated into behavior change. To establish causal relationships and better understand the impact of goal-setting on health behaviors, future studies could randomize participants to different goal-setting strategies—such as predefined versus self-authored goals to evaluate their differential effects on behavior change outcomes. Third, half of the participants with access to the goal-setting and challenges component did not choose to engage with it. While we do not expect all participants to interact with digital interventions that have low barriers to entry, it remains an important question to investigate reasons why the remaining participants, despite signing up for Buddy, did not use this module. Future studies could include follow-up with nonusers to better understand barriers to interaction, such as lack of time, perceived relevance, or competing academic or personal demands. Gaining insights into these factors could inform the design of digital interventions that better align with users' contexts and needs.

Moreover, among those who did engage with the goal-setting component, the majority set one or two goals (n=391, 92%). This could be due to various reasons, including satisfaction with the initial goal or behavior change progress, which might have eliminated the need to set other goals. The process of self-authoring goals may be cognitively demanding, and not all participants are likely to benefit equally from a goal-setting component. Some may find the task of setting and achieving goals difficult, overwhelming, or simply outside the scope of their current priorities. Additionally, the absence of feedback on progress or positive reinforcement from Buddy may have contributed to a lack of motivation to set new goals. Without encouragement to revisit or revise their goals, participants may have disengaged over time.

Conclusions

Our analyses of self-authored content from the goal-setting and challenges component in a digital intervention for multiple health behavior change provided insights into how participants articulate behavior change in terms of personal goals, challenges, strategies for action, motivation plans, and rewards. Participants set goals related to both single and multiple health behaviors, which is in alignment with the intended purpose of Buddy. Furthermore, participants used Buddy in ways that suited and supported their personal behavior change needs, sometimes extending beyond the scope of the lifestyle behaviors that Buddy targeted. Future research should explore the conditions under which goal-setting may be more or less effective, to better understand its nuances and potential benefits.

Acknowledgments

This study was funded by the Swedish Research Council for Health, Working Life, and Welfare (grant 2018 - 01410; Principal Investigator: ML).

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

This study is part of the MoBILE (Mobile health multiple Behavior Interventions across the LifEspan) research program, which was designed by ML and MB. KÅ, MB, and ML contributed to conceptualization. Formal analysis was done by KÅ and MB. ML and MB contributed to funding acquisition. KÅ contributed to the investigation, and KÅ and MB contributed to the methodology. MB and ML supervised the study. Validation was done by MB and ML. Writing—original draft was done by KÅ, and all the authors contributed to writing—review and editing.

Conflicts of Interest

MB owns a private company (Alexit AB) that develops and distributes eHealth solutions to the public and private sectors. Alexit AB played no role in developing the intervention, study design, data analysis, data interpretation, or writing of this report.

Abstract

Background: Strengthening shared decision-making in mental health care may improve the quality of services and treatment outcomes, but its implementation in services for severe mental disorders is currently lacking.

Objective: This study aims to explore the feasibility and acceptability of iTandem (University of Oslo), a mobile app designed to promote shared decision-making in the treatment of psychotic disorders. In addition, the study aims to investigate mechanisms that potentially contribute to the intended effect of the app. iTandem is a therapy supplement that facilitates patient involvement in decisions regarding treatment goals and focus areas. It is designed for personalized use and contains 8 optional modules: sleep, medication, recovery, mood, psychosis, activity, substance use, and feedback concerning therapy.

Methods: Patients undergoing assessment or treatment for psychotic disorders and their clinicians were recruited for the study. Patients and clinicians jointly used iTandem as part of standard treatment in a 6-week trial. We used a mixed-methods study design with a clear emphasis on qualitative methods. Feasibility and acceptability were assessed through descriptive statistics based on preintervention and postintervention questionnaires and app usage data, in addition to text responses to open-ended items. We conducted a reflexive thematic analysis of postintervention interviews to elaborate these measures and to explore mechanisms potentially contributing to achieving shared decision-making when using iTandem.

Results: A total of 9 patients and 8 clinicians completed the trial. The participants evaluated iTandem as a user-friendly and acceptable tool, but there were considerable variations in how the app was integrated into treatment and in perceptions of its clinical value. The thematic analysis suggests that iTandem has the potential to facilitate shared decision-making through supporting cognition and shifting the patient's role. We also identified scaffolding structures, an analogy of personalized support, as a precondition for these mechanisms and for the overall feasibility and acceptability of iTandem.

Conclusions: iTandem was generally perceived as a feasible and acceptable tool in the treatment of patients with psychotic disorders. Our findings suggest that nonclinical aspects, such as support structures, are important to the feasibility and acceptability of such digital interventions and patients' aptness for digitalized treatment in general. Future research should explore related nonclinical aspects further instead of defining potential target groups based on diagnoses and symptom severity alone.

Introduction

Background

The clinical integration of technology into health care services has been suggested as a strategy to enhance both treatment efficiency and service user satisfaction [1,2]. Moreover, shared decision-making (SDM) has become a core principle in the design of new person-centered services within mental health care [3,4].

SDM involves mutual involvement and collaboration between the patient and service provider, enabling a shared understanding to explore and decide on therapeutic alternatives throughout the course of treatment, in accordance with patient needs and preferences [5,6]. To achieve a shared understanding of the clinical condition, as well as relevant factors that should be included in the decision-making process, delivering information in a tailored and accessible format is crucial [7,8]. Although the body of available literature is inconclusive, studies indicate that higher levels of patient involvement in mental health care services result in improved treatment outcomes related to both clinical recovery and patient satisfaction [9,10]. Thus, mental health care services are making efforts to develop and distribute publicly available communication tools that promote SDM implementation in routine health care, both in Norway [11,12] and internationally [4].

However, the process is slow, and mental health care services have so far implemented SDM only to a limited extent [13,14]. The research literature indicates that SDM is especially lacking in the treatment of severe conditions, such as psychotic disorders [15,16]. According to a Norwegian study, patients with psychotic disorders report that they are not involved in their treatment as much as they prefer [17]. These findings are mirrored in the international literature [16,18,19]. Nevertheless, a recent study found that receiving information and feeling understood are fundamental care needs of individuals who have experienced a psychotic episode for the first time [20]. Both of these aspects are core elements of SDM and underline the potential clinical value of implementing SDM in this patient population.

There are several obstacles to the implementation of SDM in the treatment of patients with psychotic disorders. Many patients endure cognitive and negative symptoms, which comprise problems such as reduced memory, levels of engagement and interest, and difficulties expressing emotions and needs [21-23]. The presence of such symptoms may impede patients from pursuing a role as active agents who take part in informed dialogues with clinicians. In addition, research has revealed stigmatizing views toward persons with psychotic disorders among mental health service providers [24] and that clinicians expect that patients with psychotic disorders are less able and less willing to engage in a collaborative approach to treatment [25,26]. A possible consequence is reduced effort from the service provider to achieve SDM. Another consequence is that patients perceive the stigma from service providers and feel disempowered [27], which further complicates their opportunities to experience SDM. Furthermore, the services delivered to people with severe mental disorders are complex and resource-intensive activities [28,29]. Patients are typically followed for longer periods of time, and services should be able to adjust the goals and content of the treatment according to changing needs. Without strategies to maintain a focus on common goals, this might be challenged in a protracted course with changing clinicians, departments, and patient contexts [30-33].

The discrepancy between the ideal of SDM-based clinical practices and the current situation in severe mental health care exposes a need to develop novel strategies to enhance patient involvement. Integrating digital tools may offer a flexible and personalized approach to targeting SDM [34]. Highly accessible digital tools, such as mobile apps, offer functionality that can overcome some of the obstacles to SDM. Apps can facilitate the collection of real-time data points, providing rich information about specific aspects of the user's life, which can be of importance for the process of recovery. In addition, this functionality can reduce the demands on memory and help users convey relevant information during therapy sessions [35,36]. Several app interventions developed for patients with psychotic disorders have been evaluated as feasible and acceptable by users, such as Actissist (University of Manchester), FOCUS (University of Washington Psychiatry & Behavioural Sciences), and PRIME (Personalized Real-time Intervention for Motivation Enhancement; Regents of the University of Minnesota) [37-40]. However, few mobile apps directly target SDM in mental health [34]. The existing SDM apps offer functionality such as mapping clinical decisions and weighing the benefits and disadvantages connected to them [41] or prompting evaluations of therapy sessions and monitoring of health parameters, which can be used to support decision-making [42,43]. Despite the relevant functionality and promising user experiences, adoption and diffusion of such apps remain low in routine clinical settings [44,45]. A user-centered approach that involves service providers and patients from early exploratory stages is necessary to ensure feasibility and clinical benefit, which facilitates diffusion in everyday clinical settings [46].

The idea of the mobile app examined in this study developed from a previous innovation project in which persons with lived experiences stated that they missed alternative ways of collaborating with services and that there is a lack of tools to strengthen the focus on treatment goals during and between treatment sessions [47]. This insight sparked an iterative and person-centered process of concept and software development, involving a thorough mapping of the needs of patients with severe mental illness and their therapists. The outcome was iTandem, a mobile app designed to enhance the patient's voice in decisions concerning focus areas and treatment goals. Before planning the present exploration of the feasibility and acceptability of iTandem in clinical settings, the app was beta-tested, and its functionality was refined according to feedback from patients and clinicians.

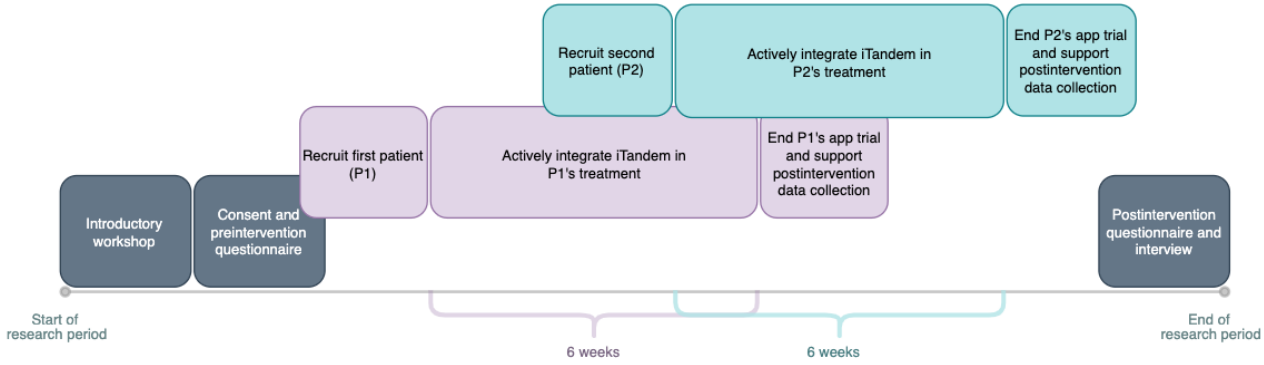
Study Aim

We aim to explore the feasibility and acceptability of the mobile app iTandem [47] in the treatment of patients with psychotic disorders from the perspectives of both clinicians and patients.

XSL•FO
RenderX

In addition, we aim to explore mechanisms that potentially contribute to achieving SDM when using iTandem.

Methods



Setting and Recruitment

The study took place at 2 clinical sites at Innlandet Hospital Trust in Norway from December 2022 to May 2023. Innlandet Hospital Trust is part of the public specialist health care services and offers both inpatient and outpatient treatment. The catchment area is geographically large and mainly rural. The hospital trust serves people from a broad range of social strata, and many patients live far away from the specialized services.

One of the sites is a specialized unit for the assessment and treatment of early psychosis. The other site is a psychosis treatment clinic at a district psychiatric center. All the clinicians who participated in the study were invited by the heads of their respective units.

The core project group (consisting of authors MS, SRA, KLR, and GEB) arranged an introductory workshop for clinicians, and the overall aims of the study were explained. The research activities and a timeline of the project are described in Figure 1. Demonstration videos covering the different functionalities of iTandem and providing examples of how to inform and recruit patients were presented. Based on previous user testing, clinicians were advised to guide patients to reduce the selection of modules to 2 - 3 to avoid overload. Written instructions for recruitment and how to access a visual report of app data were handed out, including references to the project website [48]. Guided role-play exercises were offered to the clinicians. However, the role-play training was not carried out because the clinicians did not perceive it to be necessary. Clinicians were encouraged to contact the project coordinators (MS and GEB) when they needed support. GEB was a local coordinator.

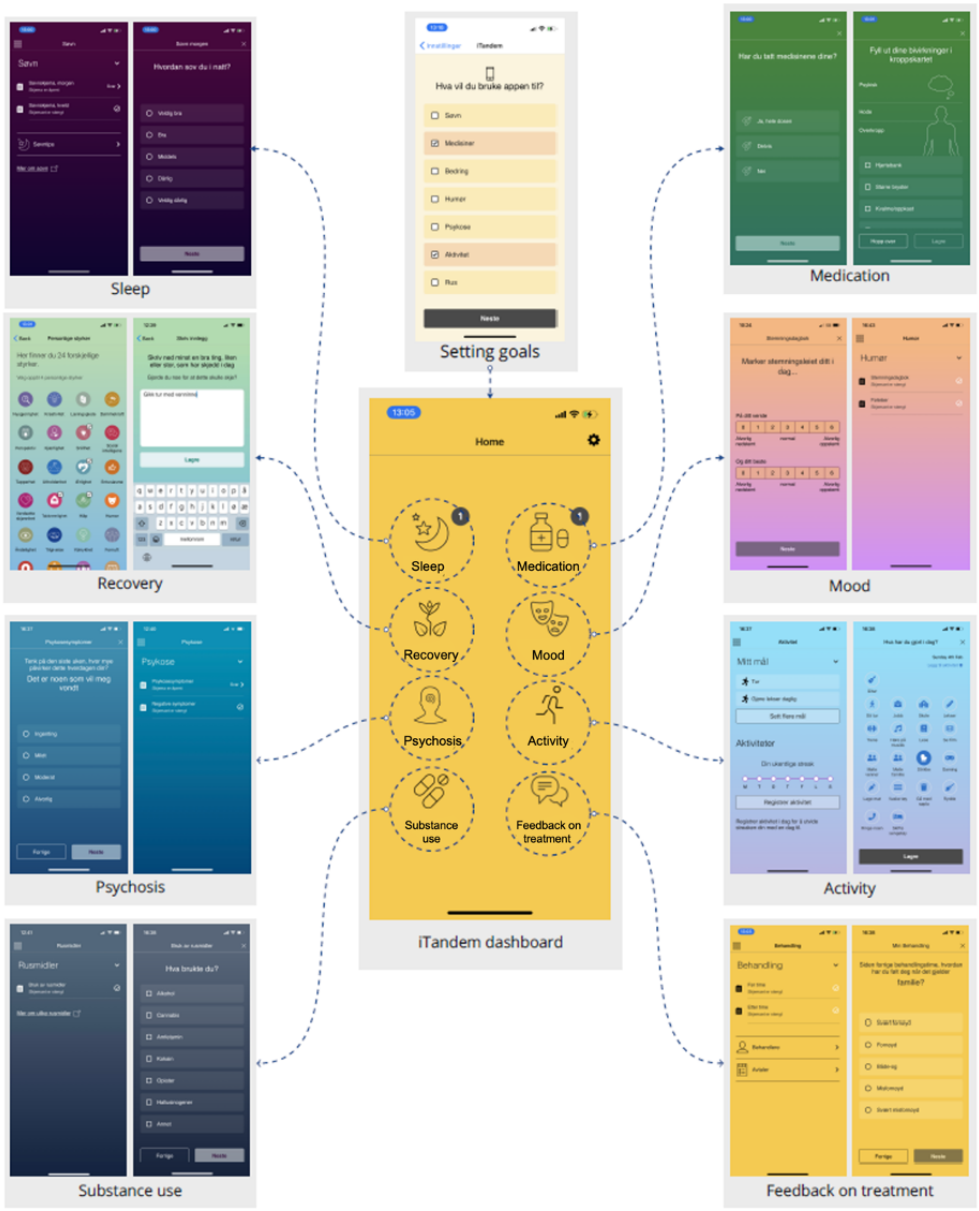
Figure 1. Research activities and project timeline for clinicians participating in the study.

Initially, 10 clinicians agreed to take part in the study. They participated in an introductory workshop and signed an informed written consent form. Eight completed the trial, while the remaining 2 clinicians left the study due to lack of engagement in patient recruitment and personal reasons, respectively.

Patients were invited by their clinicians to participate in the study during routine consultations. The inclusion criteria for patients were as follows: currently undergoing assessment or treatment for a psychotic disorder, age 18 years and older, having access to a smartphone, being able to download the iTandem app, and being willing and able to consent. The first inclusion criterion, concerning the presence of a psychotic disorder, was based on clinician ratings. Experienced clinicians working at the clinical sites of this study assessed and diagnosed patients using the *International Classification of Diseases, 10th Revision* diagnostic criteria for schizophrenia, schizotypal, and delusional disorders (F20-F29). The 2 clinical sites offer services exclusively to patients diagnosed with a psychotic disorder and patients undergoing assessment based on indications of a psychotic disorder. Therefore, all patients included in the study met this criterion.

The convenience sample of patients first comprised 14 patients from both outpatient and inpatient units. During the trial, 5 left the study. Two patients did not complete the trial because their therapists were absent from the clinic for much of the trial period due to vacation or sick leave. One patient agreed to participate but never began using the app actively. One patient was discharged and left the study, while another patient did not attend the sessions within the trial period.

Six patients and all 8 clinicians agreed to participate in interviews. A total of 2 patients and 2 clinicians were interviewed in person, 2 patients were interviewed over the phone, and the remaining participants were interviewed through a secure video platform. The interviews were performed by MS and KLR.



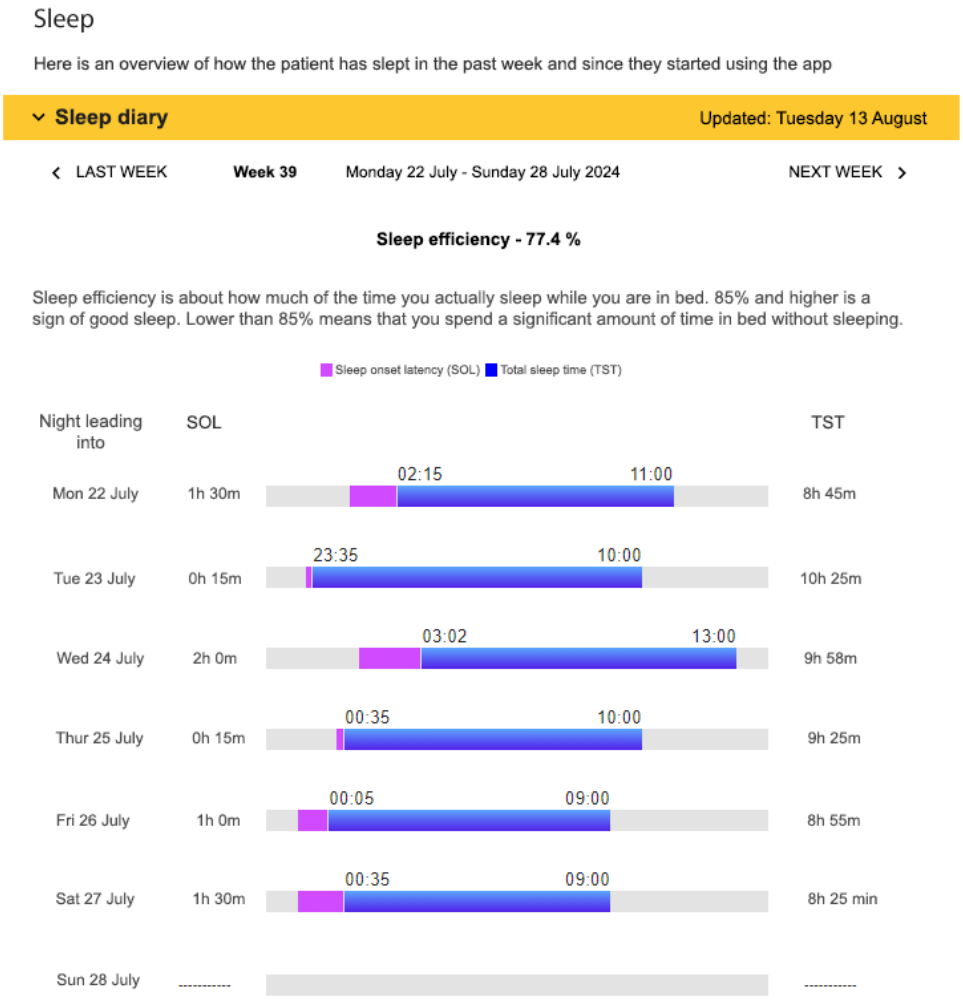
Intervention

The iTandem mobile app [47] is developed by the Early Intervention in Psychosis Advisory Unit for Southeast Norway and the app development team at the Information Technology Department at the University of Oslo. iTandem is designed as a supplement to typical treatment. The purpose of integrating the app in treatment is to enhance therapeutic communication and accentuate the needs and preferences of patients in treatment for severe mental disorders or addiction. Since iTandem is designed for personalized and need-based use, there are no generic recommendations concerning the ideal combination of modules or how long the app should be an integrated part of treatment. However, the trial period of this study was set to 6 weeks.

XSL•FO
RenderX

iTandem is administrated by patients, while their clinicians have access to a digital report that summarizes the app data. iTandem contains 8 optional modules assessing sleep, medication, recovery, mood, psychosis, activity, use of substances, and feedback concerning treatment (Figure 2). The contents of the different modules are described in detail elsewhere [47]. The app prompts patients to register data regularly. The time intervals between notifications depend on which modules the user has activated. For instance, the sleep module entails a sleep diary that requires data registrations in the morning and in the evening. When this module is activated, the user receives notifications twice a day. In contrast, the psychosis module sends out weekly prompts, as the symptoms tracked with this module change more slowly and over a longer period of time.

Figure 2. The dashboard and modules of the iTandem app.



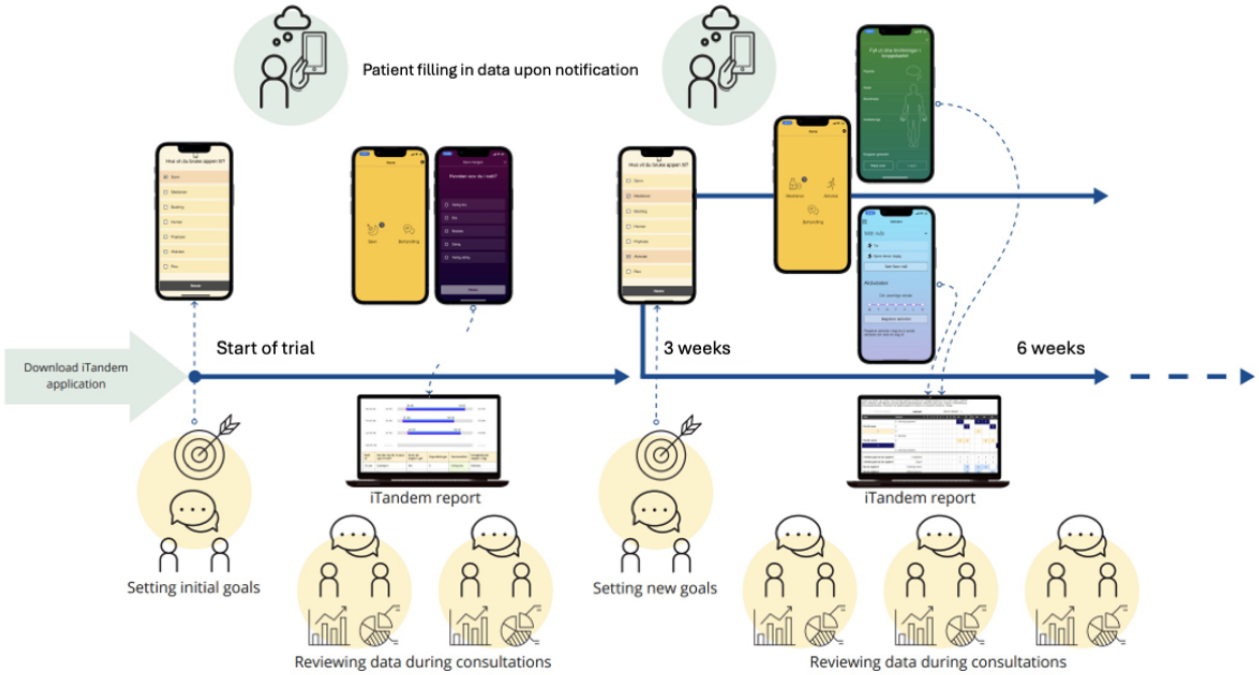
In this study, patients consented to participate in the 6-week trial via a web-based form with guidance from their therapists. Thereafter, patients downloaded the iTandem app on their personal smartphones and discussed with their therapists which of the modules would be most meaningful to their condition and current life situation. This conversation represents the beginning of an SDM-based approach, directing the focus of ongoing treatment in accordance with patient needs and preferences. Patients and clinicians were encouraged to change the selection of modules during the six-week trial period if they experienced that a treatment goal was achieved or perceived other modules as more useful.

The data registered by patients during the trial period were transferred directly to Tjenester for Sensitive Data, a service for storing and processing sensitive data at the University of Oslo. These data comprised the basis for an automatically generated digital report with visual representations of the active modules. Clinicians accessed the report through a secure web

XSL•FO
RenderX

portal. Figure 3 demonstrates how the sleep module is represented in the report, summarizing a week of data registration.

Figure 3. The sleep module is visualized in the report. The content has been translated into English.



Night leading into	Did you take anything to help you fall asleep?	Daytime naps	Awakenings during sleep	Sleep quality	Daytime functioning
22.July	No	No	1	Medium	Medium
23.July	Sleep medication	No	0	Good	Good
24.July	No	No	2	Bad	Bad
25.July	Sleep medication	Yes, 20-60 min.	0	Medium	Good
26.July	No	Yes, < 20 min.	0	Very good	Very good
27.July	Sleep medication	No	0	Very good	Very good
28.July					

In the introductory package, the clinicians were instructed to share and discuss the report with their patients during the treatment sessions of the trial period. The project group presented various potential areas of application, such as monitoring fluctuations of symptoms and side effects from medication, identifying connections between different aspects of the patient's condition and daily life, and guiding ongoing clinical interventions in accordance with reliable patient data over time. Figure 4 demonstrates the process of integrating and actively using the app and report during the trial.

Figure 4. Flexible integration of iTandem throughout the trial period.

Study Design

A mixed-methods research design placed within a pragmatic paradigm [49] was applied to explore iTandem's feasibility and acceptability and the mechanisms potentially involved in achieving SDM. The study places a heavier emphasis on qualitative methods, prioritizing active researcher interpretation and broad exploration of individual experiences from a small sample of participants. The quantitative methods of the study comprise some instruments providing reliable data that can easily be compared to benchmark values. Other measures that are typically operationalized in a largely quantitative manner within similar research contexts involve more qualitative assessments in this study.

The research design applied here largely resembles a convergent design with a side-by-side comparison approach [49], since the data collection and analyses are mainly conducted separately before integrating the findings in the discussion, where the qualitative elements elaborate and nuance the quantitative results. However, the quantitative data are also used to guide the qualitative methods earlier in the analytic process.

Quantitative Data and Methods

The quantitative data include responses to the web-based preintervention and postintervention questionnaires and app usage data. All 9 participants and 8 clinicians completed the preintervention and postintervention assessments, except for one clinician who did not fill out the postintervention questionnaire. Descriptive analyses were conducted using SPSS Statistics 29 to depict the groups of participants, identify tendencies in the data material, and create a foundation for the qualitative exploration of feasibility and acceptability. The following quantitative measures were included in the study:

Demographics and Participant Background Information

In preintervention questionnaires, patients reported gender, age, treatment level (inpatient or outpatient), and duration of treatment. Clinicians reported gender, age, which service they worked in (inpatient, outpatient, or both), and patient diagnoses.

Usability

User-friendliness (ie, technical feasibility) was measured using the System Usability Scale (SUS) [50]. Separate items constructed by the project group mapped occurrences of technical errors.

Acceptability

Acceptability was assessed with postintervention closed-ended questionnaire items. Both groups were asked whether they experienced the intervention as clinically valuable and to what extent the digital tool had been used during the trial period. In addition, patients reported whether the intervention was experienced as comfortable and safe and which modules they had chosen. App usage data supplemented the patient acceptability measure with indications of whether the participants were engaging actively in iTandem or not. These data were obtained manually by observing and documenting the number of data points registered by each of the participants in the different modules, providing insight into broad tendencies of app activity across the sample.

Qualitative Data and Methods

The main data source in the current study was the qualitative data material. It comprised both text responses to open-ended items in the preintervention and postintervention questionnaires and individual semistructured postintervention interviews. All 8 clinicians and 6 of the patients participated in interviews. The number of words in the 14 interview transcripts ranged from 2304 to 6574, with a median of 3603 words.

XSL•FO
RenderX

A reflexive thematic analysis was conducted using NVivo 14 (Lumivero). The purpose was to gain a deeper understanding of the feasibility and acceptability measures and to explore these data further, identifying mechanisms that potentially contribute to the intended effect of the iTandem intervention:

Feasibility

Feasibility was explored in postintervention interviews. Both groups were asked similar questions about how the iTandem intervention fit into the current clinical setting, what factors may impact a successful implementation, and their thoughts on the future use of apps in long-term follow-up. All participants were asked about potential areas of improvement related to the tool and its implementation. The patients' postintervention questionnaires included text response items mapping experiences with the specific modules they had used, which were used as an indication of whether the different modules had been applied as intended.

Acceptability

The postintervention interviews provided oral accounts of the participants' enthusiasm, satisfaction, potential negative events, and experience value from taking part in the trial. The patients' open-ended questionnaire items prompted the patients to share perceived health effects, as well as positive and negative aspects of the intervention.

The thematic analysis of this study is largely based on Braun and Clarke's reflexive thematic analysis, applying essentialist and experiential theoretical assumptions [51]. The data collection and analysis of the study were guided by the overall aims of the research project, broadly exploring the feasibility and acceptability of iTandem, as well as mechanisms related to SDM. However, the thematic analysis applied here is essentially inductive rather than theory-driven.

MS conducted the analysis. KLR and SRA contributed in stages 1, 4, and 5. The authors involved in the analysis had several explicit discussions concerning aspects that may have had an impact on the methodological choices and results of the study, such as roles, backgrounds, and motivations in the project. KLR and SRA were central actors in the development of the app. KLR, SRA, and MS hold relatively optimistic views on the potential value of digitalization and SDM in health care. These contextual and personal factors impact all stages and decisions of the research project. Furthermore, the participants' accounts represent subjective interpretations of experiences within specific environments, which are accepted and included in the analysis. Thus, principles of reflexiveness, attention to context, and an experiential approach to data are integral in this application of thematic analysis [52]. The 6 steps of thematic analysis were conducted in a dynamic manner, moving back and forth between the stages described below, especially from the third to the sixth phases:

Data Familiarization

MS conducted verbatim transcriptions of the 14 interviews. MS, KLR, and SRA read and reread the interviews and noted their first thoughts about each interview and the dataset as a whole. The group shared ideas and reflected on the content of the data material. This workshop, as well as the other collaborative activities described in later phases, is not a standard element in Braun and Clarke's reflexive approach. The purpose of the discussions was not to get closer to objectiveness, as this is not considered an ideal in the reflexive form of thematic analysis [51]. Instead, this was done to spark creativity and reflexiveness in the analytic process. The transcripts were imported to NVivo. Electronic memos based on the initial thoughts about the data material were created and connected to each interview.

Coding

MS coded the dataset systematically in NVivo. The coding was conducted in accordance with the guidelines for reflexive thematic analysis, where one subjective coder is sufficient to achieve high-quality output, while aiming for interrater reliability using a second rater would represent a deviation from this branch of thematic analysis [51]. No coding frameworks were applied, and no parts of the data material were excluded from the coding process. Although ideas concerning the research questions emerged in these early phases, MS made efforts to direct the same level of attention to all parts of the texts in all interview transcripts to maintain an inductive approach. However, the process can be said to have been influenced by theory to some extent, as the authors had hypotheses related to the research questions and had experience with the same kind of data material from a previous beta test. Furthermore, the interviews were semistructured, which led the accounts in a specific direction, although question formulations were open, and participants were encouraged to communicate their thoughts without restrictions. This phase resulted in a total of 340 semantic codes.

Generating Initial Themes

MS combined different codes into groups that represented units of similar meaning in NVivo. Examples of headings of such code groupings are "Target group" and "Prerequisites of experiencing clinical value." In this phase, the titles of the candidate theme structures were still descriptive and topic-like rather than conveying shared meaning about essential aspects of the data set.

Developing and Reviewing Themes

Maintaining an experiential approach to the data, MS went through the tentative themes and the associated data extracts in NVivo to ensure that the themes reflected what the participants had said. As a result, the themes were merged or reconstructed into new tentative themes. In a new workshop, the groups of codes were presented on paper to KLR and SRA. The authors used this as a starting point to adjust themes and structure them in relation to each other. Some were left out as they were deemed not contributing to the research aims. MS also studied the questionnaire material to evaluate whether the tentative themes reflected the participant perceptions provided outside an interview context. This phase resulted in 3 preliminary themes on core mechanisms potentially involved in facilitating SDM through iTandem.

Refining, Defining, and Naming Themes

The themes were reviewed again by MS, KLR, and SRA, given titles, and connected to the most representative quotes of the data material. The group also worked on descriptions of each

XSL•FO
RenderX

theme that communicated the intended meaning clearly. As the analytic process was carried out in an iterative manner, MS repeated phases 3, 4, and 5. After another round of consulting with the other authors and reviewing and refining the themes, the final set of themes was completed.

Producing the Report

MS initiated the write-up in parallel with previous phases of the analytic procedure, long before themes were finalized. Thus, the data analysis, literature search, and writing processes interacted throughout this research project.

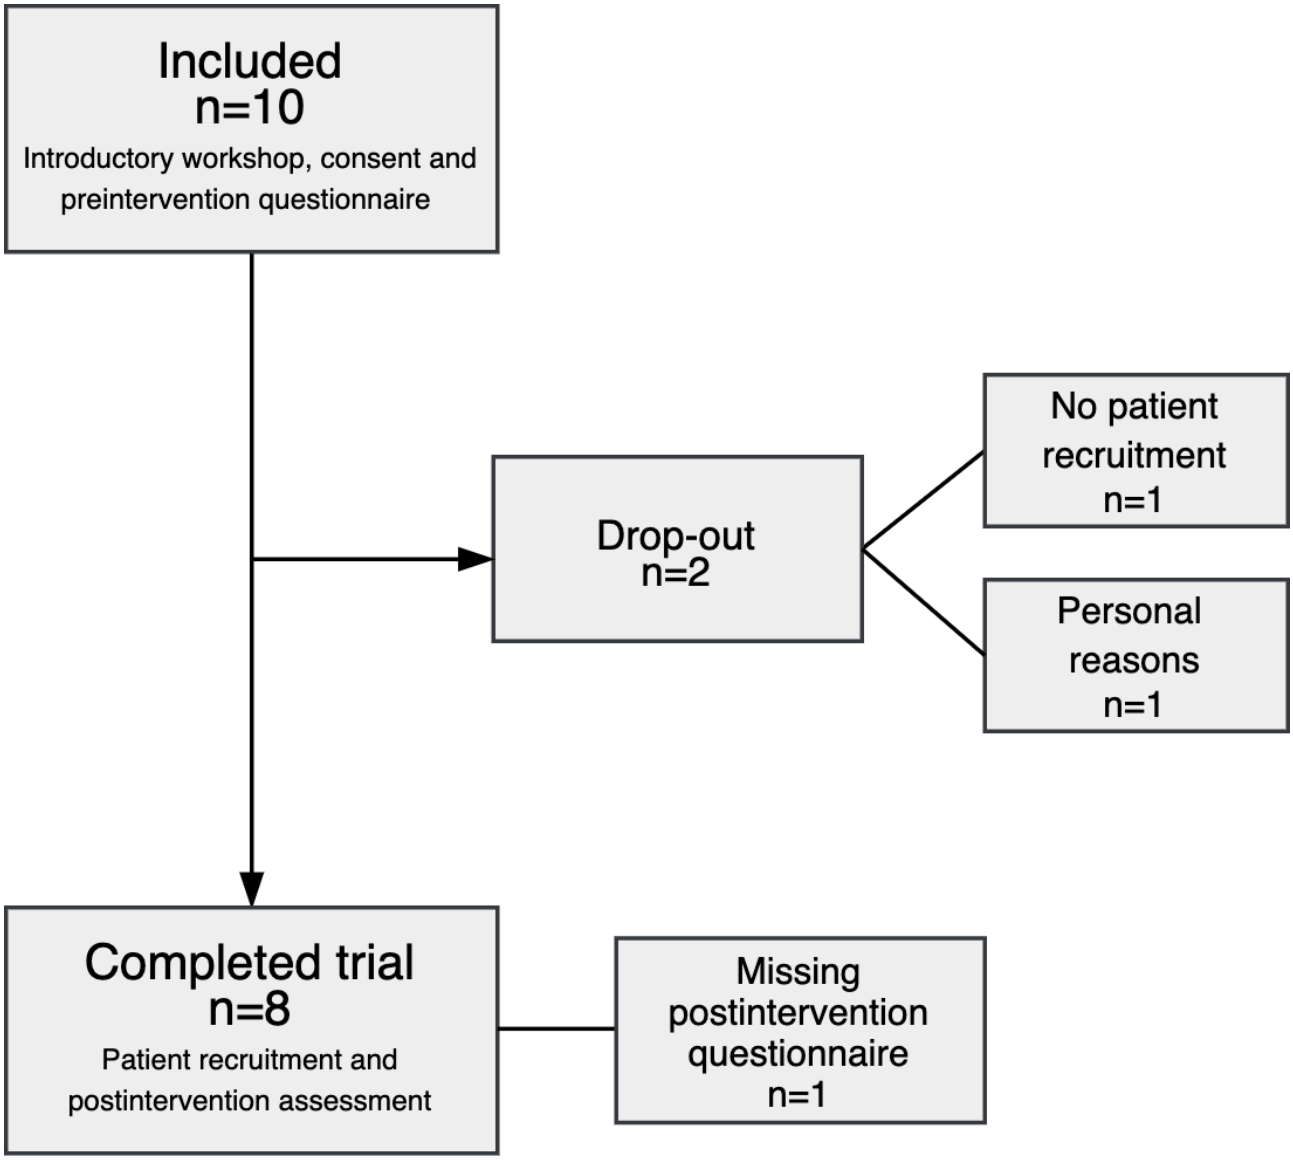
Service User Involvement

Service user representatives were involved in all stages of this study, from early app development to designing the assessment tools for data collection and writing this paper. Early Intervention in Psychosis Advisory Unit for Southeast Norway, at which several of the article authors are employed, has its own board of service user representatives. In addition, the researchers in this project discussed the research design with a user representative employed at Innlandet Hospital Trust. During the writing process, the authors discussed the interpretation of findings with 2 service user representatives from the Bipolar Association Norway and refined the manuscript according to feedback on themes.

Ethical Considerations

The patients participating in this study were recruited based on their status as patients in service for severe mental disorders and can be defined as members of a vulnerable population. Involving vulnerable persons in research requires careful ethical considerations, including the protection of the participants' interests and obtaining freely given informed consent. These principles were integral in the design of the study and in the introductory workshop for the clinicians. During the introductory workshop and the further communication with clinicians, they were instructed to clearly explain both benefits and risks related to participation to their patients, as well as stressing that all elements of the study participation were voluntary and that withdrawing would not result in any negative consequences. All participants gave consent to participate in the study through a digital form after receiving information about the project presented verbally and in a text document. The project obtained approval from the data protection officer at Innlandet Hospital Trust (23839981) and Oslo University Hospital, the institution responsible for data processing (22/20426). Importantly, this study primarily investigates digitalized service delivery and user experiences, rather than mental health conditions and treatment outcomes. The Regional Ethics Committee evaluated the study to be outside of their mandate, as the research did not primarily aim to collect and analyze health data or develop new knowledge about health or disease (523626).

Results



Quantitative Data

Participant Background Information and Demographics

Eight clinicians completed the study (Figure 5). The clinicians reported the following gender identities: 4 males, 4 females, and 0 other identities. The age range was 27 - 63 years old (mean and median 45 y old). A total of 4 clinicians provided outpatient services, 2 inpatient services, while the remaining 2 clinicians worked in both inpatient and outpatient services.

XSL•FO
RenderX

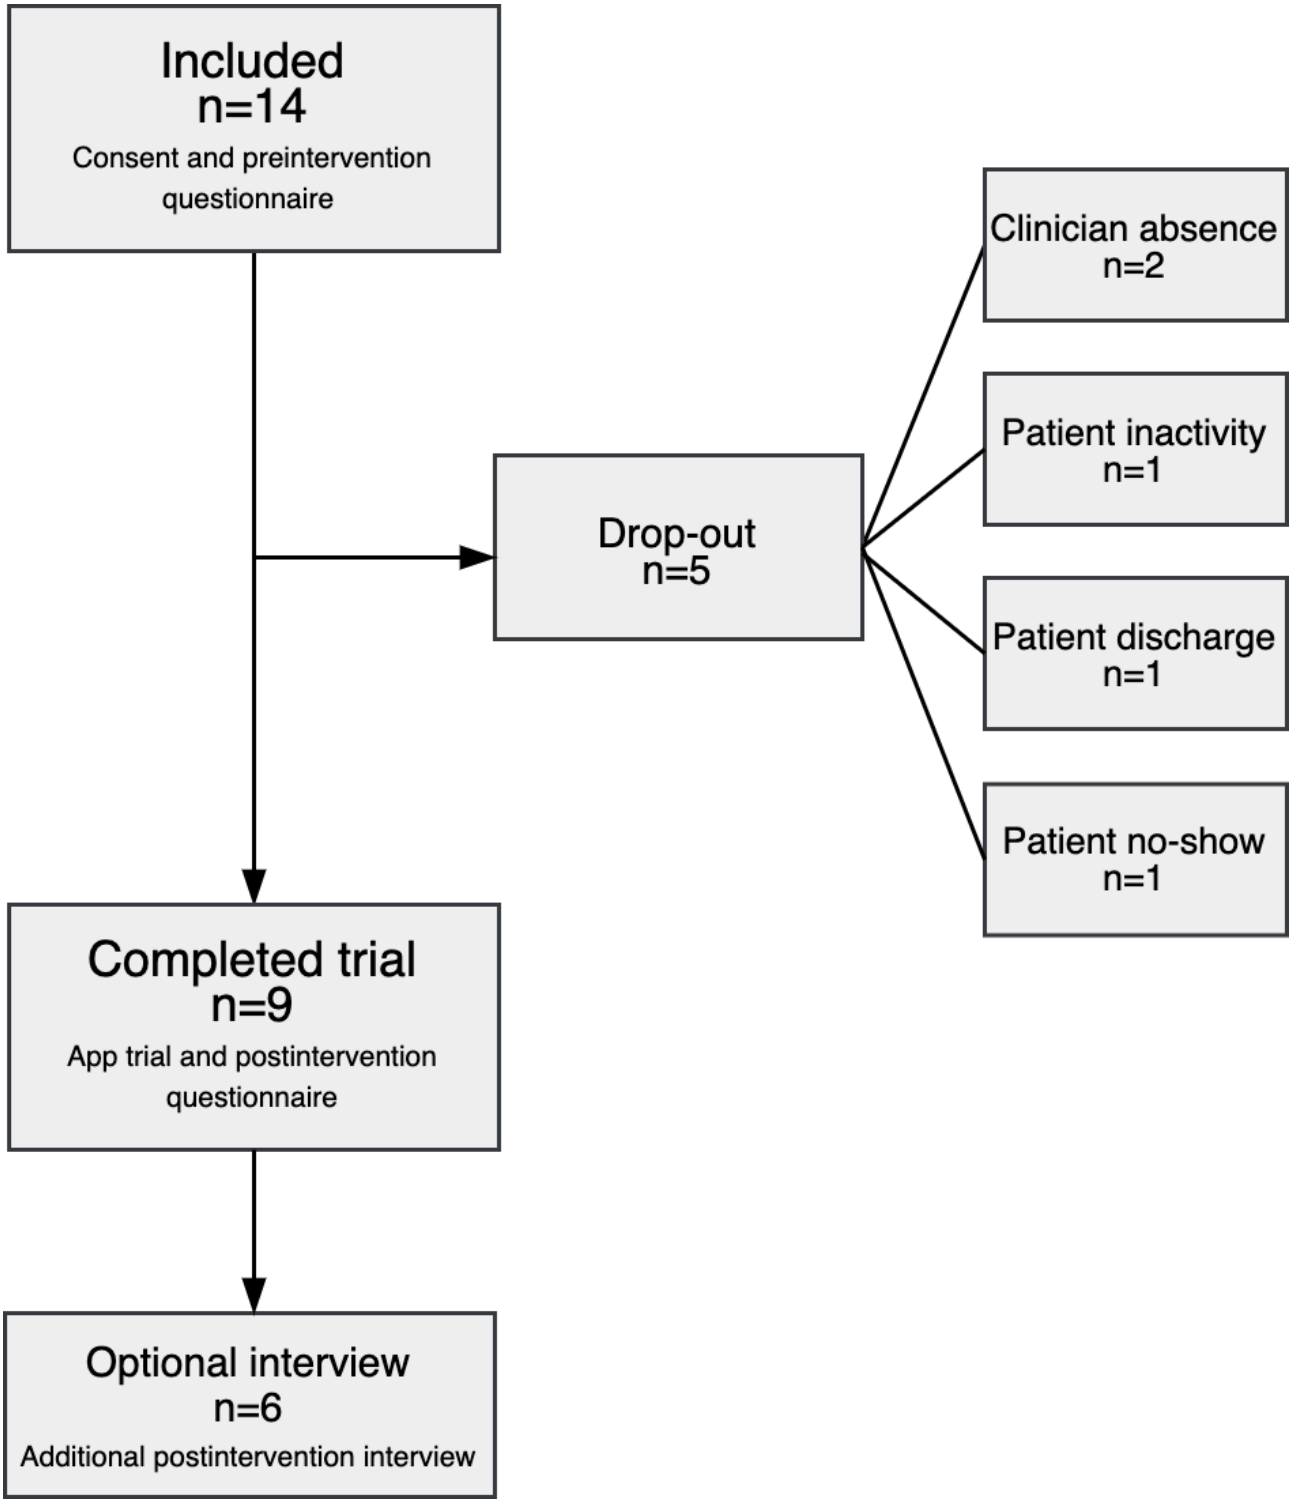


Figure 5. Flowchart of the clinicians recruited to the study.

Nine patients completed the study (Figure 6). The patients reported the following gender identities: 7 females, 2 males, and 0 other identities. The age range was 18 - 43 years old (median 27 y old). Eight out of 9 received outpatient services. The duration of treatment in mental health care services was 0-200 months (median 16 mo). All patients were undergoing assessment or receiving treatment for schizophrenia, schizotypal, or delusional disorders (F20-F29). Two were diagnosed with additional stress reaction disorders and/or a developmental disorder.

XSL•FO
RenderX

Figure 6. Flowchart of the patients recruited to the study.

Usability

iTandem was rated as above average in terms of user-friendliness, with SUS mean scores of 75.0 by patients and 82.1 by clinicians, out of 100.

Additional items covering experiences of technical errors revealed occasions where clinicians were denied access to the report or where the report's representation of one of the app modules contained errors.

Acceptability

The levels of engagement varied across the sample. Most patients engaged with 3 or more modules (Table 1). The introductory package to clinicians recommended limiting the number of modules to one or two, but some patients chose more. Patients displayed a preference for modules related to general health and well-being over symptom-oriented modules. Activity and Sleep were the most popular modules, selected by 8 of the 9 patients.

XSL•FO
RenderX

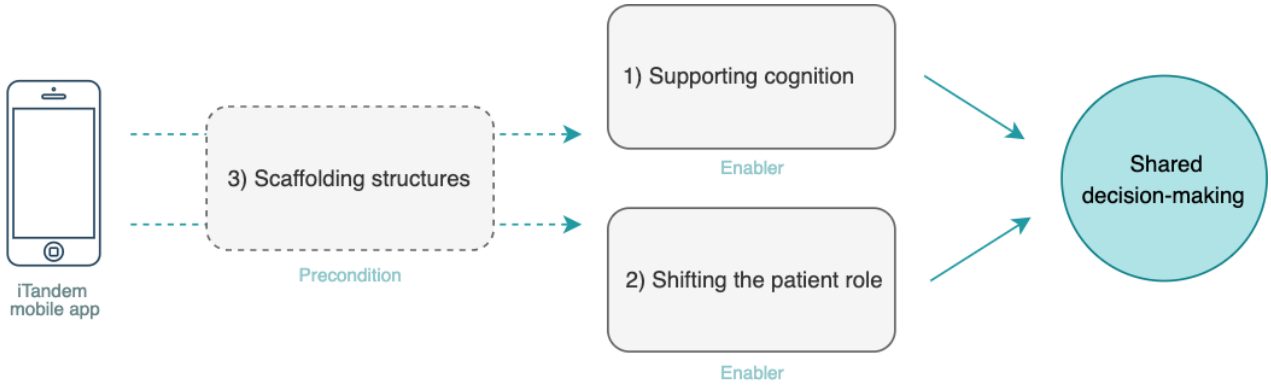
Table . Joint display of patients' questionnaire responses.

Participant number	Selected modules	Report brought up in sessions	Experience of using report in sessions	Experience of sharing personal data	Perceived health effect
103	Sleep, mood, activity	Once	Useful	Ok	Positive: "I became more aware of my feelings and mood … I realized how much I accomplished to do each day. I used the app less after a while because I managed to maintain a good structure in my everyday life. But I liked it a lot in the beginning."
105	Sleep, mood	Several times	Useful	Ok	Positive: "Provides me with an overview."
107	Sleep, recovery, activity	Once	Ok	Un-comfortable	Negative: "I became a bit more paranoid and felt watched."
108	Sleep, recovery, mood, activity, medication, psychosis	Several times	Useful	Safe	Positive: "Maybe a bit, nice to have a routine with the app."
109	Recovery, activity	Every time	Useful	Ok	Positive: "More aware of activities, that it doesn't have to be that many every day, but that I still manage some things."
112	Sleep, mood, activity	No	No experience	Ok	Positive: "It was nice to get an overview of sleep and feelings, and for instance I became more aware that I often go to bed too late in the night."
113	Sleep, mood, activity, psychosis	Several times	Useful	Safe	Neutral: "No."
114	Sleep, recovery, mood, activity, medication, psychosis	Once	Ok	Safe	Neutral: "I don't know."
115	Sleep, mood, activity	Several times	Ok	Ok	Neutral: "It has not made any big differences to my mental health. It has been the same regardless (…)"

Responses to questionnaire items targeting experienced value from the iTandem intervention revealed distinct differences between patients (Table 1). Five out of 9 patients reported that reviewing the report in sessions felt useful. The same number of patients reported that they experienced positive health effects from using iTandem. Three patients reported neutral experiences with both items. One incident was identified as an adverse event related to the iTandem intervention. One patient participating in the study (#107) experienced increased levels of paranoid thoughts and a feeling of being watched through the digital tool. This patient also reported that sharing data through the report system was experienced as uncomfortable. The patient discussed the problems with their clinician and stopped using iTandem.

Questionnaire data showed that some clinicians were not able to maintain an active focus reviewing the report regularly in treatment sessions (Table 1). Their evaluations of clinical value from the intervention varied. The variation in responses seemed to correspond with the levels of app activity and experienced value from the perspectives of their respective patients.

Qualitative Data



Feasibility and Acceptability

Through the reflexive thematic analysis, the following themes, which represent potential enablers for SDM in the iTandem intervention, were generated: Supporting cognition and Shifting the patient role. The third theme, Scaffolding structures, was

XSL•FO
RenderX

constructed as a precondition for these processes (Figure 7) and suggested as a precondition for the overall feasibility and acceptability of iTandem.

Figure 7. Themes generated through qualitative analysis and their suggested role in promoting SDM using the iTandem app.

Theme 1: Supporting Cognition

The first theme elaborates on how the iTandem intervention served as an aid for cognitive tasks within the treatment context for both patients and clinicians. Participants recognized bias and limitations regarding their own memory, their capacity to communicate inner states, and their ability to follow a structure in both treatment sessions and over a course of treatment. The data registration made by patients in iTandem, together with the clinicians' use of the report, were viewed as compensatory activities. In addition, several participants expressed that the intervention supplied the treatment with new clinically relevant information and that they had the experience of getting an overview of aspects related to their condition and general well-being.

Graphic representations of the patient data were automatically generated in the report, offering a more accessible format for summarizing and communicating complex information. Thus, iTandem helped translate data about the patient into something easily comprehensible and provided the therapy with more concrete reference points. Participants valued that the visual report provided an overview of parameters related to health and general well-being:

> *When patients register their sleep, you access a graph where the information from sleep over time is a lot more comprehensible. It makes it more tangible.* [Clinician #209]

> *It is nice to get to see the patterns, get it documented instead of writing it down or trying to remember it. That does not work.* [Patient #108]

Some participants talked about the value of iTandem as a tool for clinicians to maintain structure and focus on the patient's chosen therapeutic project over time. iTandem was also perceived as an aid to promote a more nuanced presentation of the lives of patients. Moreover, iTandem facilitated the search for positive elements in patients' everyday lives:

> *I used iTandem as a reminder for myself to maintain structure and keep track from one session to the next. I think it worked well for remembering to bring up topics. (…)*

> *Taking in the nuances in everyday life can be a problem for many patients. One event might be experienced as bad, and the patient focuses on this event only. And then, [with iTandem], it might become evident that there had been better moments during the past week.* [Clinician #207]

Theme 2: Shifting the Patient Role

The second theme covers how the iTandem intervention had the potential to cause a push toward a more active and empowered patient role in therapy. The intervention entailed a direct opportunity for patients to take part in decisions regarding their treatment focus. A patient account reveals that this was experienced as unfamiliar, but the alteration of the patient role resulted in a feeling of involvement and empowerment. Furthermore, when maintaining activity in the selected focus areas over time, the patient experienced increased commitment and agency:

> *I felt that I was very involved in deciding what we would focus on. Although it was difficult to express myself firmly, it helped me to think "Okay, this is what I want to focus on, this is what I want." (…) I liked using the app. In a way, I felt more—I don't know the exact word, but—I felt that I had to actively use it to get better. Well, there was no pressure, but I felt that it was my responsibility too.* [Patient #109]

With iTandem, the course of treatment was supplemented with an alternative path for patients to engage in their treatment. Several patients exerted strong digital skills and explored the tool independently. They quickly became comfortable in navigating iTandem, sometimes to a greater degree than the clinicians. Thus, iTandem also represented an area of mastery and a means to show competence and reduce the experience of hierarchies that characterize traditional health care contexts. Furthermore, although most participants across the sample underlined the need for patients and clinicians to know each other well before introducing digital tools in treatment, some talked about technology as a means to relate to and disclose important issues in therapy:

> *They grasp it immediately. They are used to apps. I had briefly mentioned the name of the app before I was going to introduce it in the session, and the*

XSL•FO
RenderX

> *patient had already registered and started exploring the app.* [Clinician #211]
>
> *I think [disclosing feelings through an app] is easier. But it depends on who the person is. If it is a friend, I can speak freely. But I don't feel like I always can do that with a therapist.* [Patient #112]

Perceiving digital communication as an equivalent or superior alternative to the traditional therapeutic conversation might break with assumptions regarding what high-quality and safe therapeutic communication is for patients in mental health care. Thus, it demonstrates a change in the views of different patient roles and underlines the importance of mapping needs, preferences, and personal traits to create beneficial conditions for secure therapeutic relationships and hearing patient voices.

Theme 3. Scaffolding Structures

The third theme refers to support structures that acted as prerequisites for the 2 processes described above and for the participants' evaluation of iTandem as feasible and acceptable. All the participants talked about social and/or technological structures that had significantly impacted their experiences with iTandem throughout the trial. Examples of scaffolding included the digital infrastructure enabling the operation of iTandem, encouragement to maintain app activity during the trial, and pragmatic strategies to compensate for reduced levels of functioning caused by invasive symptoms.

For some, scaffolding was necessary from the initial use of iTandem. One patient endured paranoid thoughts directed toward digital devices, which made it impossible to use a personal smartphone. To solve this, a relative lent their phone to the patient. The patient expressed positive experiences with the intervention, even though the intensity of paranoid thoughts persisted throughout the trial. Other patients struggled with understanding text and symbols in iTandem and needed guidance from close ones to interpret the content:

> *I am positive [toward using the app]. I have not installed it on my phone, I have used [a relative's] phone. I might have to disclose that first. I have a problem with apps on my own phone.* [Patient #108]
>
> *I needed to ask my partner at times because I have difficulties understanding the meaning of the tasks.* [Patient #114]

Moreover, the act of clearly conveying the purpose of the intervention was a central scaffolding prerequisite for both groups. When there was a lack of communication about purpose and use, patients did not necessarily perceive the intervention as helpful, and the clinician was not using the tool to focus the treatment.

Scaffolding structures, such as a safe therapeutic alliance and an attentive clinician, seemed central to the process of enabling a shift in the patient role. Work within the recovery app module provided an example of how scaffolding acted as a precondition for this relational dynamic. The recovery module prompted patients to register positive everyday happenings and personal strengths. These activities appeared to represent a highly relevant focus area in the treatment of several patients and incited encouraging experiences for some. However, without scaffolding, such as the presence of reassurance and guidance from a clinician, the app intervention was not feasible and did not result in experiences of SDM-related processes. The differences across the sample are exemplified by the following quotes:

> *I would say that [the recovery module] was the most positive aspect. I got a new perspective on which strengths I actually possess. Especially for someone who doesn't think they have any…I actually have some.* [Patient #109]
>
> *With "good experiences" and "personal strengths," it's all about positive things concerning yourself, you know. You are meant to come up with positive things about yourself, and that is not something I do.s So that part is difficult for me.* [Patient #115]

Discussion

Principal Findings

This study aimed to explore iTandem's feasibility and acceptability and the mechanisms potentially contributing to SDM in treatment for psychotic disorders based on a 6-week app trial and data from questionnaires and interviews. The findings reveal largely positive evaluations of user-friendliness and acceptability. SUS scores from both patients and clinicians place iTandem's usability higher than the benchmark mean score of digital health apps [53]. However, there were substantial differences in how much the app was used and in perceived clinical value, including its contribution to SDM. These variations were explored further through the qualitative analysis. The qualitative findings suggest that the app has the potential to initiate cognitive and relational mechanisms that are central to enabling SDM in therapy. These processes, as well as evaluations of iTandem as feasible and acceptable, often relied on personalized support over time or "scaffolding."

Our results suggest that a digital tool like iTandem can offer an alternative channel to communicate inner states, as well as a platform where the information is made accessible for both the patient and clinician. Thus, iTandem facilitates a common recognition of clinically relevant issues incited by the patient. The findings fit well with existing literature underlining how cognitively demanding SDM processes can be for patients [54] and highlighting the importance of building a shared understanding to succeed in implementing SDM [7]. Importantly, the provision of information alone is insufficient as a means of driving SDM. In the absence of cognitive aids that help patients apply complex information to their own situation, information does not necessarily contribute to moving the patient toward experiencing more empowerment [55]. Existing literature has pointed out the value of multidimensional information tools in facilitating both the involvement and apprehension of health information in severe mental health contexts [56]. In accordance with this literature, the participants in our trial expressed appreciation for the tables, graphs, and other visual cues of the iTandem intervention. Nevertheless, research on digital SDM tools for mental health care [34,57] has little focus on cognitive mechanisms and the formats of information from the perspectives of both clinicians and patients.

XSL•FO
RenderX

An enhanced focus on tools that aim to compensate for limited cognitive capacity may be useful in the further development of digital interventions aimed at strengthening SDM. This may be of even greater relevance to patient populations that struggle with cognitive and negative symptoms [21-23] and their clinicians.

The integration of iTandem caused a movement in the patient role toward increased agency and involvement. The change was facilitated by the introduction of a digital patient-administered approach to relating to and actively impacting the direction of therapy. As the iTandem app entails personalization at the operational level, it is simple for users to tailor the use of the app based on individual preferences [26]. Interestingly, the results revealed a tendency toward preferring modules related to general health and well-being over modules dealing with illness-related symptoms or drug use. This tendency was found in both the quantitative and qualitative data material, and although it is not statistically valid, it may represent the relevance of a holistic and resource-focused approach to treatment. This is in line with a desire for more recovery-oriented mental health care services [58], where we move our clinical focus from only monitoring a reduction in severity of symptoms toward more person-centered treatment goals reflecting what the patients find important for their well-being [59,60]. Thus, efforts to strengthen SDM with flexible and person-centered methods harmonize with the recovery movement of mental health care [9,57].

The patient role shift also accentuates the complex relational processes underlying SDM. Previous research has conceptualized SDM as a method of care [5,6]. This perspective underlines that SDM should be approached as an intrinsic value in therapeutic settings, not a practical procedure. Operationalizing SDM by using digital tools such as iTandem can help us overcome some of the barriers we have been facing until now, especially in vulnerable populations. However, patients hold different preferences regarding roles in the therapeutic relationship, the desire for control in health care settings, and the degree to which they would like to involve themselves in decisions about their own condition [13,61].

The participants' accounts indicated that various social and technological support structures acted as prerequisites for experiencing the 2 processes discussed above and for the overall feasibility and acceptability of iTandem. There exists evidence that speaks for the value of several types of support in severe mental health care, such as the involvement of relatives in treatment [62,63] and social support in more general terms [64-66]. This literature underlines the general relevance of scaffolding for patients with severe mental health conditions, which proved to be a central concept in our findings. In addition, the importance of supportive social dynamics has been recognized in models from implementation science [67-69]. However, the emphasis in the implementation literature is often on more formal and impersonal support structures, such as the availability of resources and organizational backing. The concept of scaffolding structures in this study is more sensitive to subtle individual differences in social and practical needs, rooted in a person-centered approach.

Importantly, there are prerequisites that are more fundamental than the scaffolding structures discussed above. The target population of iTandem is characterized by a lower level of digital competency and financial status than the general population [70,71]. Although previous research has shown high rates of smartphone ownership within the population [72], there still exists a minority that lacks the required financial means and digital skills, for whom interventions like iTandem remain inaccessible. The presence of paranoid thoughts directed toward technology has been identified as another barrier [72]. Although this barrier does not apply to most patients, the one adverse event in our trial demonstrates the relevancy of recognizing this subgroup. In our trial, the therapist reported the adverse event after it was successfully handled in the treatment sessions and the symptom level had been normalized. The clinician also informed the project group that the therapeutic alliance had maintained cooperation despite the emergence of paranoid thoughts directed toward iTandem. Therefore, we perceived the event's level of seriousness as moderate and the negative reaction as reversible, and no interventions were initiated. Nevertheless, such adverse incidents expose a need for strategies to uncover and handle negative participant reactions. Guidelines addressing this are currently emerging [73], underscoring the importance of improving future practice.

In the digital mental health field, conditions such as depression and anxiety have been the main areas of focus [74,75]. Our study suggests that digital tools also have the potential to compensate for unmet needs associated with patients with psychotic disorders, such as cognitive and negative symptoms and a pronounced lack of participation in clinical decision-making. Thus, mental health care services should also offer such tools to this patient population. Existing research on interventions that share some of iTandem's functionality supports this notion [34,76]. For instance, the computer-based decision-making tool TReatment E-AssisT (TREAT; RoQua Inc.) improved clinical discussions by uncovering more clinically relevant topics that aligned with the needs of patients with psychotic disorders [77]. However, the tool did not significantly affect the levels of SDM [78]. This optimistic but inconclusive evidence of digital tools and SDM [34,76] encourages further research on the mechanisms involved. Our study also invites further research on individual differences that are not related to psychopathology, such as the preferred degree of control and decisional impact, tech-savviness, and the digital habits of patients. In addition, we recommend exploring clinicians' perspectives on SDM and digitalization. Finally, research investigating the feasibility of these concepts at service, economic, and societal levels is needed. We will address some of these knowledge gaps in an ongoing study that includes iTandem and uses a modified study design and new outcome measures.

Limitations

This is a small study, and the limited number of participants makes it impossible to draw firm conclusions. In addition, technical problems with the report that occurred during the study represent a limitation, as there were cases where interruptions obstructed participants from carrying through the intervention as planned. Another limitation is the possible weaknesses in the

XSL•FO
RenderX

introductory workshop. We did not insist on doing role-play to make clinicians more familiar with how it should be introduced when they were reluctant. We believe this could have helped them convey the essential recommendations regarding the need to limit the number of app modules employed by patients. There are also ethical concerns related to the recruitment procedure. Since clinicians recruited their own patients, there is a risk that patients felt obligated to participate because of the pre-established relationship. Importantly, during the introductory workshop for clinicians, the project group communicated the importance of fully informed consent and the option to permanently leave the trial for all participants. The clinicians were also instructed to underscore the voluntary nature of participation when recruiting patients to the study. Nevertheless, research staff will be responsible for patient recruitment in the new trial. Moreover, the study is based on the conception that SDM and clinical app implementation are generally wanted in health care services, and a final limitation is that this stance is not challenged. The mixed methods design is, however, a strength of this study. A pragmatic combination of quantitative and qualitative methods provided the study with a comprehensive and nuanced understanding of the participants' experiences with iTandem and SDM. The qualitative emphasis allowed us to collect rich data, although the sample was small. Participants perceived the threshold to respond to questionnaires as lower than that of being interviewed; thus, we were able to collect information, even from those who were reluctant to speak with us. Another strength is the naturalistic setting and the inclusion of user perspectives of both patients and clinicians during development and testing.

Conclusions

Patients with psychotic disorders and their clinicians generally perceived iTandem as a feasible and acceptable supplementary tool for treatment. The app has the potential to serve as an aid for cognition and to facilitate a shift of the patient role toward a more active position in clinical settings. The study suggests that the feasibility and acceptability of iTandem depend on some fundamental prerequisites, including appropriate support structures. We recommend not excluding this patient population from accessing digital interventions based on the severity of the diagnoses and invite further research on how nonclinical individual differences impact experiences with digital tools and SDM. We also encourage research on the digitalization of mental health care and SDM that explores service, economic, and societal domains.

Acknowledgments

We want to thank all the service users and clinicians who participated in the trial. We also want to thank Jonathan Romm for creating illustrations for this paper.

Abstract

Background: While the health benefits of physical activity are well-known, adherence to regular physical activity remains a major challenge. Just-in-time adaptive intervention (JITAI) has been proposed as one method to increase physical activity by delivering an intervention at a time when individuals are more likely to make behavioral changes. However, most studies that have implemented JITAI have used uniform intervention criteria (UIC) across participants rather than personalized intervention criteria (PIC) for the individual.

Objective: The objective of this paper was to examine the effectiveness of using JITAI implemented with PIC to increase physical activity.

Methods: Healthy university students wore a wrist activity monitor for 2 weeks. Participants were divided into 2 groups, which received JITAI to promote physical activity according to either PIC or UIC. In the first week, the mean distance moved and sedentary time per hour for each participant were calculated to derive PIC. UIC was obtained from a 2-week study with a different sample (n=47) conducted under the same conditions. In the second week, JITAI prompts were sent every hour if both of the following criteria were met: the distance moved was shorter, and sedentary time was longer than PIC or UIC. Differences in changes in physical activity as a result of implementing interventions according to PIC and UIC were analyzed using multilevel models.

Results: We analyzed data from 28 healthy university students (18 - 23 y old, female n=12). Both PIC (P<.001) and UIC (P<.001) significantly increased physical activity in the first hour after JITAI was received. In that first hour, PIC increased physical activity more than UIC; more calories were burned (P=.02), more steps were taken (P=.007), and distance moved was increased (P=.003). However, over the course of the week, the use of JITAI did not significantly increase physical activity levels.

Conclusions: Our results appear to suggest that PIC-based JITAI is more effective than UIC-based JITAI, consistent with the idea of a need for precision health approaches. Further research is needed to develop effective long-term intervention designs with sustainable effects.

Introduction

The benefits of physical activity for prevention and management of chronic diseases and mortality have been well established [1-3]. To promote physical activity for better health, the World Health Organization (WHO) has recommended 150 - 300 minutes of moderate-intensity aerobic physical activity per week, or 75 - 150 minutes of vigorous-intensity aerobic physical

XSL•FO
RenderX

activity throughout the week, or an equivalent combination of moderate- to vigorous-intensity activity [4]. However, a pooled analysis of 507 population-based surveys (n=5.7 million) found that 31.3% of adults worldwide do not meet this recommended amount of physical activity [5]. Low levels of daily physical activity have become a global health problem, and methods to increase physical activity using mobile health (mHealth) have started to be implemented [6-8].

mHealth is defined as health care services supported through the use of mobile devices such as mobile phones [9]. The aim of mHealth is to enhance users' health and well-being through mobile devices and other wireless technologies by monitoring and analyzing their health status, providing support for disease prevention and treatment, and management and introduction of interventions for disease in everyday environments [10]. Previous studies incorporating mHealth interventions have shown beneficial effects in promoting health behaviors and support for behavioral change (eg, increasing physical activity [9,11,12]).

Just-in-time adaptive intervention (JITAI) is an intervention design that adapts the timing, type, and intensity of intervention support to changes in an individual's status and behavior [13]. The goal is to provide support at the timing and in the context that the individual most needs and is most likely to accept it. JITAI has shown promising effects for improving physical activity in research settings. For example, van Dantzig et al [14] found that when they encouraged a 5-minute break after 60 minutes of continuous sitting, the amount of sedentary time decreased. Finkelstein et al [15] found that reminders promoting exercise sent when participants took 15 or fewer steps per hour significantly decreased sedentary behavior compared to when they did not receive reminders. Bond et al [16] found that 3-minute break reminders after 30 minutes of sitting decreased sedentary time and significantly increased the amount of time spent doing light physical activity compared to no reminder. Fiedler et al [17] found that delivering the prompt when the participant was inactive for more than 60 minutes significantly increased moderate to vigorous physical activity (MVPA). Mair et al [18] showed the feasibility of using personalized smartphone-delivered JITAI in elderly people. JITAI was tailored to the individual based on real time physical activity, daily physical activity goal, time of day, and weather conditions [18].

In most JITAI studies to date, however, the criteria for the intervention have been uniform (eg, 15 steps fewer per hour and sitting continuously for 30 or 60 minutes), and have not reflected the different activity patterns of the individual [12,18]. Uniform intervention criteria (UIC) do not accommodate varying levels of preexisting physical activity, and as such may not be the most effective way to promote uptake. In this study, we compared the effects of increasing activity in groups that received physical activity interventions using UIC versus groups that received an intervention using personalized intervention criteria (PIC) tailored to the individual's activity patterns. We hypothesize that the intervention using PIC is more effective in increasing physical activity than the intervention using UIC.

Methods

Participants

A total of 31 healthy university students in Japan aged 18‐23 years old participated in the study. Healthy university students under 30 years of age were eligible to be included in the study. Participants who had current medical problems or were using medication that could influence physical activity were not eligible to participate. This prospective 2-week randomized comparative study took place between December 2022 and January 2023. The participants were randomly assigned into 2 groups in a 1:1 ratio by using a random number table (integers 0 and 1): PIC group, which received the intervention with personalized intervention criteria, and UIC group, which received the intervention with uniform intervention criteria. While a within-persons design was considered (both PIC and UIC in a single individual), due to the time limitations and potential mixing of effects of both types of intervention criteria, a between-persons design was used. Details are reported in the CONSORT-EHEALTH V 1.6.1 checklist (see Checklist 1).

Ethical Considerations

The study was approved by the institutional review board at Shizuoka University, Japan (19‐8). Participants provided written informed consent after receiving a full explanation about the purpose of the study, methods, and precautions for participation in the study. Participants who completed the study received an Amazon gift card worth JP ¥5000 (approximately US $35).

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee. Participants provided written informed consent. All data used in this study were anonymized to protect participants' privacy and ensure confidentiality.

Assessments

Questionnaires

Participants completed a questionnaire before the 2-week study to collect their age, sex, height, weight, medical history, and drug use. Participants who had current medical problems or used medication were excluded from the study.

Activity Monitor

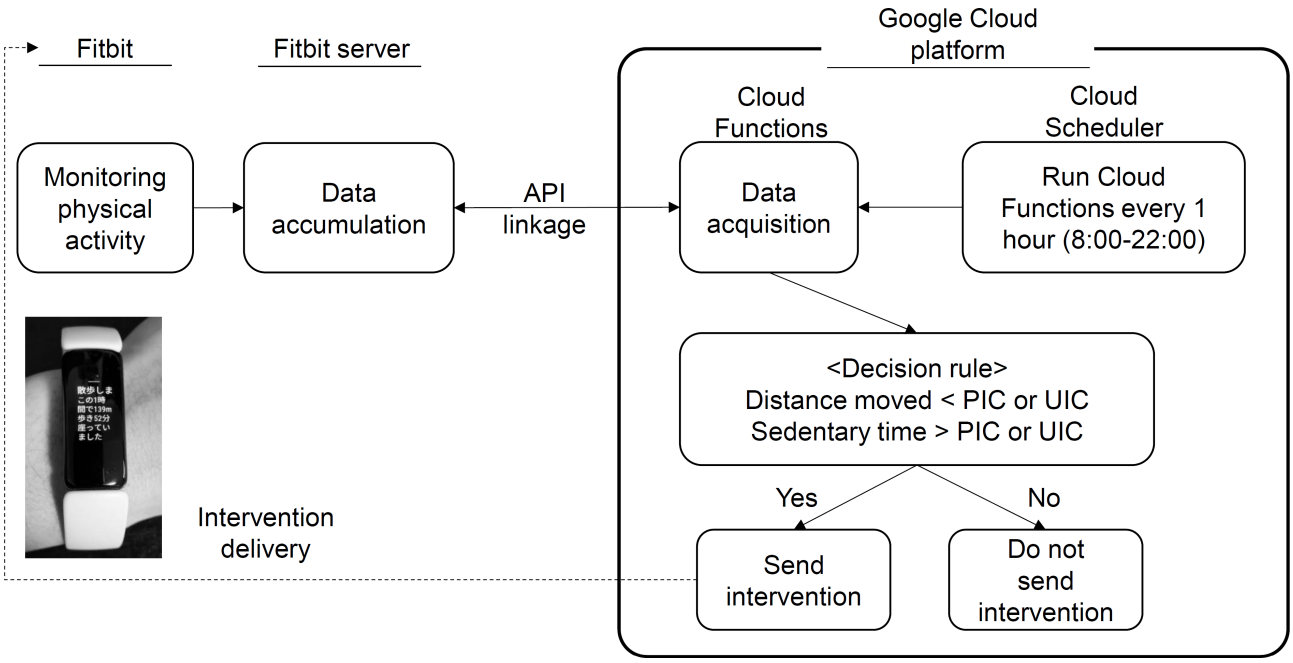
Physical activity was measured using a wrist-worn wearable activity monitor (Fitbit Inspire 2). The active monitor estimates sedentary time (minutes), lightly active time (minutes), fairly active time (minutes), very active time (minutes), calories (kcal), steps (n), and distance moved (m). Steps are calculated by the 3-axis accelerometer, while distance moved is automatically calculated based on the number of steps and the participant's stride length. Time spent at different activity levels are also calculated by the activity monitor (sedentary time, lightly active time, fairly active time, and very active time). Activity monitor and participant's smartphone were synchronized via Bluetooth by installing the Fitbit app on their smartphones, and activity data were recorded on the Fitbit server via the smartphone. The activity monitor was worn on the nondominant wrist at all times

XSL•FO
RenderX

during the study period. Participants were instructed to remove the monitors when showering or bathing.

Intervention

Intervention Criteria (PIC vs UIC)



The intervention criteria used were distance moved (m) and sedentary time (minutes). For distance moved, 1 SD lower than the mean (mean distance, SD) was used, and for sedentary time, 1 SD longer than the mean (mean sedentary time + SD) were used. The reason for extending the intervention criteria to include SD rather than using only the mean of physical activity was to ensure that interventions are not triggered when activity levels differed only slightly from the mean. That is, interventions might be too frequent and difficult to adhere to if the threshold was strictly set at the mean values.

Set points for interventions were determined differently for the 2 groups. PIC group received interventions based on individual activity data measured during week 1. The UIC group received interventions based on group data from a 2-week preliminary study conducted a year earlier using the same devices looking at physical activity in a sample of university students (n=47). The UIC were determined using a different sample because the timing of the study period was different for each participant; participants were recruited and participated during different dates so the UIC could not be calculated at the start of the intervention period for all participants.

Intervention Structure and Flow

Figure 1 shows the intervention structure and flow. The intervention was performed using the tools "Cloud Functions" and "Cloud Scheduler" of the Google Cloud platform via the Fitbit application programming interface (API). Cloud Functions is a serverless runtime environment used to build and connect cloud services and to run the process of retrieving physical activity data from activity monitor, calculating intervention criteria with the physical activity data and delivering feedback to participants as an intervention for increasing physical activity. Cloud Scheduler is a scheduling function for processing functions at a specific time, and was used to repeatedly run the process as needed. Cloud Scheduler was set up to trigger Cloud Functions at the 34-minute mark every hour (ie, 10:34 AM, 11:34 AM, 12:34 PM…) to evaluate the physical activity in the past hour (ie, 9:34 AM-10:33 AM, 10:34 AM-11:33 AM, 11:34 AM-12:33 PM…). Cloud Functions were used to retrieve 1-minute interval data from the Fitbit server through the Fitbit API. When both (1) "Distance moved" was less than the intervention criteria and (2) the "Sedentary time" was longer than the intervention criteria, participants were notified. Intervention decisions were based on data on distance moved and sedentary time in the past hour.

Figure 1. Intervention structure and flow. API: application programming interface; PIC: personalized intervention criteria; UIC: uniform intervention criteria.

Intervention Timing

An intervention decision was made once per hour by the programmed Cloud Scheduler of the Google Cloud platform, and the intervention message was delivered when the intervention criteria met the predefined conditions (ie, UIC or PIC). The intervention schedule was run from 8:00 AM to 10:00 PM.

Intervention Contents

The intervention consisted of sending an email to the participant's email address. The email included a message encouraging physical activity and stating the participant's distance moved and sedentary time in the last hour. One message (in Japanese) was chosen at random each time from the following 5 messages: "Would you like to take a walk?" "Would you like to exercise?" "Move your body!" "Let's exercise!" and "Let's move a little!" The Fitbit app on the smartphone allowed

XSL•FO
RenderX

email notifications, and when the email was received, the activity monitor vibrated, and the contents of the email were displayed on the Fitbit screen.

Statistical Analysis

Analysis was performed using SAS 9.4 (SAS Institute Inc). The physical activity data acquired are longitudinal and repeatedly measured from individuals, and thus have a hierarchical structure. We used multilevel modeling, a widely used analytical method for such data structures [19]. We specified 2 different sets of models to examine the effectiveness of using JITAI implemented with PIC to increase physical activity. Model set A was specified to examine the effects of PIC or UIC on physical activity after the intervention. To examine the change in physical activity after 1 hour of intervention by different intervention criteria, the mean level of physical activity was estimated for the group using UIC and the group using PIC at the hour before and the hour after the intervention. The physical activity types estimated were sedentary time (minutes), lightly active time (minutes), fairly active time (minutes), very active time (minutes), calories (kcal), steps (n), and distance moved (m). We ran 7 different models, using each of these physical activity parameters as dependent variables. The intervention group (ie, PIC group and UIC group) and before or after intervention (ie, the hour before and the hour after the intervention) were used as independent variables.

Model Set A

Level 1 model (within-participant):

$$(1)\text{Physical Activity}ti=\beta 0i+\beta 1i\times(\text{Before or After Intervention}ti)+\varepsilon ti$$

Level 2 models (between-participants):

$$(2)\beta 0i=\gamma 00+\gamma 01\times(\text{Intervention Group}i)+\gamma 02\times(\text{BMI}i)+\gamma 03\times(\text{Sex}i)+\upsilon 0i$$

$$(3)\beta 1i=\gamma 10+\gamma 11\times(\text{Intervention Group}i)+\upsilon 1i$$

where "*Physical Activity*$_{ti}$" indicates the dependent variable (sedentary time, lightly active time, fairly active time, very active time, calories, steps, or distance moved) at the *t*th recording for the *i*th participant; β_{0i} is participant i's intercept; β_{1i} is participant i's slope; γ_{00} is the average intercept across all participants; γ_{01}, γ_{02}, γ_{03}, and γ_{11} are all participants' slopes; γ_{10} is the slope of β_{1i}; ε_{ti} is the within-individual residuals; υ_{0i} and υ_{1i} are the random effects of intercept and slope, respectively. The random or fixed effect of slope was determined by comparing Akaike information criterion (AIC) to find the best-fitting parameters for each. As an example, we have shown Equation 3 which has a random effect of slope (υ_{1i}). To test the differences before or after intervention in mean level of physical activity, we added a categorical variable representing "*Before or After Intervention*$_{ti}$" into the right-hand side of Equation 1. In addition, to test the difference in mean level of physical activity between PIC and UIC groups, we added a categorical variable representing "*Intervention Group*$_i$" into the right-hand side of Equations 2 and 3. The slope (γ_{11}) of an interaction term between "*Before or After Intervention*$_{ti}$" and "*Intervention Group*$_i$" represents the difference in physical activity for the group using UIC and the group using PIC at the hour before and the hour after the intervention in the combined multilevel model. In Equation 2, BMI and sex were adjusted for in the Level 2 (between-participants) models.

Model set B was specified to examine changes in physical activity from Week 1 (without intervention) to Week 2 (with intervention) associated with the different intervention criteria (UIC or PIC). A total of 7 separate models were specified using the hourly mean of each physical activity parameter (as above) as a dependent variable. Intervention group and week were specified as independent variables.

Model Set B

Level 1 model (within-participant):

$$(4)\text{Physical Activity}ti=\beta 0i+\beta 1i\times(\text{Week 1 or Week 2}ti)+\varepsilon ti$$

Level 2 models (between-participants):

$$(5)\beta 0i=\gamma 00+\gamma 01\times(\text{Intervention Group}i)+\gamma 02\times(\text{BMI}i)+\gamma 03\times(\text{Sex}i)+\upsilon 0i$$

$$(6)\beta 1i=\gamma 10+\gamma 11\times(\text{Intervention Group}i)+\upsilon 1i$$

where "*Physical Activity*$_{ti}$" indicates the dependent variable (sedentary time, lightly active time, fairly active time, very active time, calories, steps, or distance moved) at the *t*th recording for the *i*th participant; β_{0i} is participant i's intercept; β_{1i} is participant i's slope; γ_{00} is the average intercept across all participants; γ_{01}, γ_{02}, γ_{03}, and γ_{11} are all participants' slopes; γ_{10} is the slope of β_{1i}; ε_{ti} is the within-individual residuals; υ_{0i} and υ_{1i} are the random effects of intercept and slope, respectively. The random or fixed effect of slope was determined by comparing AIC to find the best-fitting parameters for each. As an example, we have shown Equation 6 which has a random effect of slope (υ_{1i}). To test the change in physical activity from Week 1 without intervention to Week 2 with intervention, we added a categorical variable representing "*Week 1 or Week 2*$_{ti}$" into the right-hand side of Equation 4. In addition, to test the difference in mean level of physical activity between PIC and UIC groups, we added a categorical variable representing "*Intervention Group*$_i$" into the right-hand side of Equations 5 and 6. In Equation 5, BMI and sex were adjusted for in the Level 2 (between-participants) models. In an effort to compare intervention effects more precisely, we used the hourly averaged physical activity to minimize variation due to factors such as sleep length and the time participants did not wear the activity monitor.

For all analyses, data were excluded when participants were sleeping and not wearing the activity monitor. A $P<.05$ was considered significant. The Tukey-Kramer method was used to adjust for multiple comparisons.

Results

Participant Characteristics

While 31 participants were recruited for the study, 3 participants did not participate for more than 4 days during their 2-week periods and were excluded from the analysis. There were no significant differences in characteristics between the intervention groups, except for in BMI (Table 1).

XSL•FO
RenderX

Table . Participant characteristics. Two-sample *t* tests were performed to compare the age, height, weight, and BMI between the PIC and UIC groups. χ^2 tests were performed to compare the sex distribution across the two groups.

[a]PIC: personalized intervention criteria.

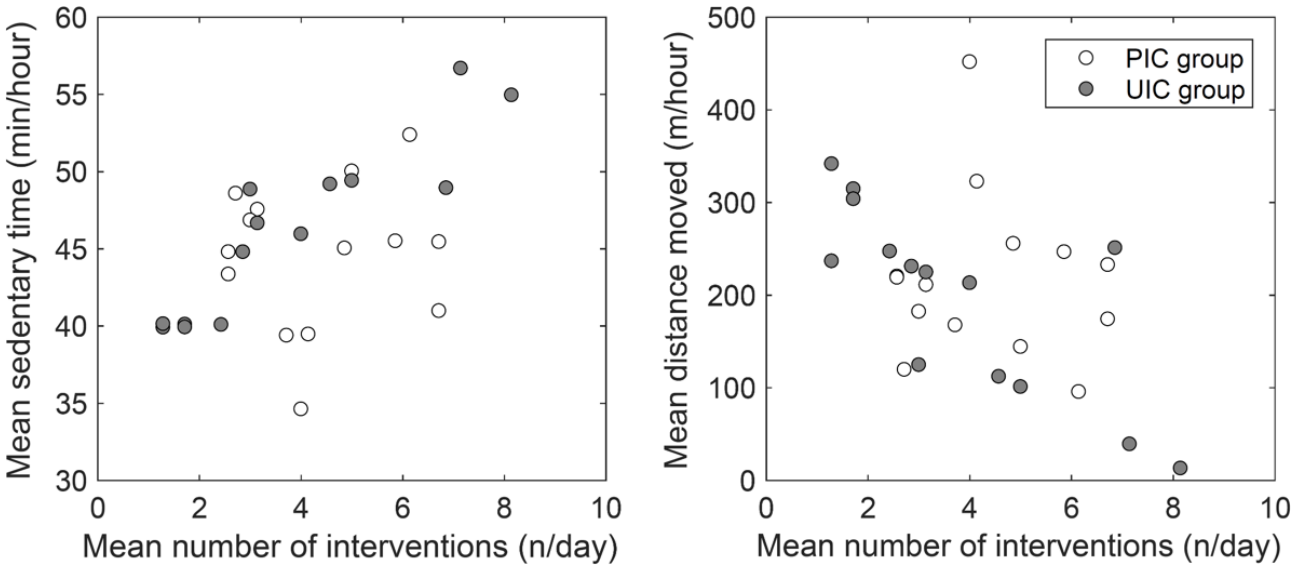
[b]UIC: uniform intervention criteria.

[c]Not applicable.

The PIC group received interventions based on individual activity data measured during week 1. The UIC group received interventions based on group data from a 2-week preliminary study conducted a year earlier using the same devices looking at physical activity in a sample of university students (n=47; see Table 2).

Table . Participant intervention criteria.

ID	Distance moved (m)	Sedentary time (min)
PIC[a]1	151	50
PIC2	127	52
PIC3	125	52
PIC4	164	46
PIC5	263	41
PIC6	105	51
PIC7	93	55
PIC8	152	50
PIC9	148	50
PIC10	140	51
PIC11	39	56
PIC12	18	57
PIC13	57	55
PIC14	294	42
UIC[b] (n=14)	139	52



[a]PIC: personalized intervention criteria.

[b]UIC: uniform intervention criteria.

The mean number of interventions for the PIC group was 4.4 per day (SD 1.5; range 1.3 - 8.1), and the mean number of interventions for the UIC group was 3.8 per day (SD 2.3; range 2.6 - 6.7). No significant difference in the mean number of interventions was found between the PIC and UIC groups. However, some participants in the UIC group who had higher average levels of physical activity received a lower number of interventions (ie, a mean of 1 - 2 interventions per day) to increase activity, while some participants who had lower average physical activity levels received a higher number of interventions (ie, a mean of 7 - 8 interventions per day; see Figure 2).

XSL•FO
RenderX

Figure 2. Mean number of interventions per day in accordance with physical activity level in personalized intervention criteria (PIC) versus uniform intervention criteria (UIC) group.

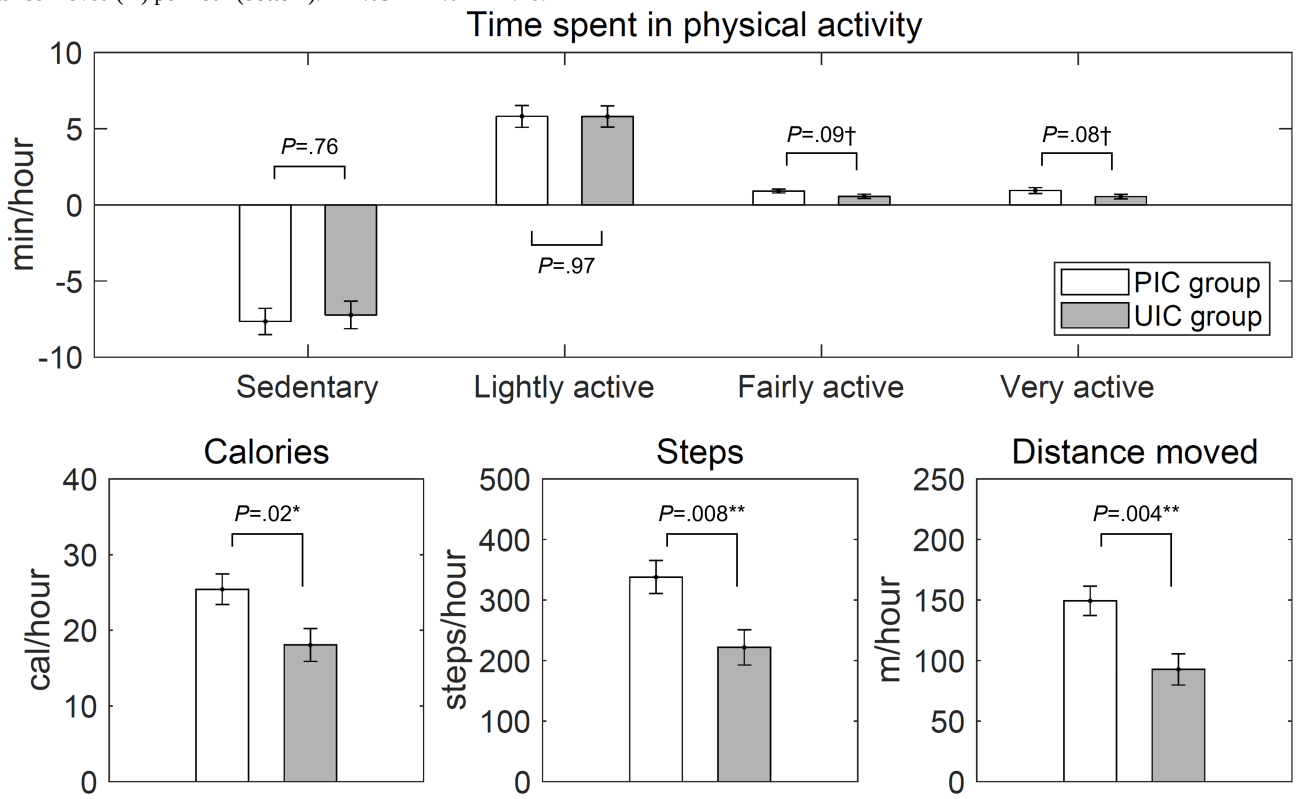
Model Set A: Effects of PIC and UIC on Physical Activity for the Hour Before and the Hour After the Intervention

In model set A, the best models for sedentary time and lightly active time used random intercepts and slopes, while the best models for fairly active time, very active time, calories, steps, and distance moved used random intercepts and fixed slopes. For both the PIC and UIC groups, sedentary time significantly decreased after the intervention (PIC group: before *B*=55.83, SE=0.54; after *B*=48.21, SE=1.07; *P*<.001 and UIC group: before *B*=57.11, SE=0.58; after *B*=49.88, SE=1.10; *P*<.001; see Table 3). The other 6 physical activity types (ie, lightly active time, fairly active time, very active time, calories, steps, and distance moved) significantly increased after the intervention in intervention groups (*P*<.001; see Table 3). See Table S1 in Multimedia Appendix 1 for detailed information.

Table . The change in physical activity 1 hour after the intervention as affected by differences in intervention criteria.

Physical activity	PIC[a] group			UIC[b] group		
	Before intervention	After intervention	*P* value	Before intervention	After intervention	*P* value
Sedentary time (min), mean (SE)	55.83 (0.54)	48.21 (1.07)	<.001	57.11 (0.58)	49.88 (1.10)	<.001
Lightly active time (min), mean (SE)	4.02 (0.53)	9.80 (0.94)	<.001	2.95 (0.56)	8.76 (0.97)	<.001
Fairly active time (min), mean (SE)	−0.04 (0.10)	0.86 (0.10)	<.001	0.08 (0.11)	0.65 (0.11)	.003
Very active time (min), mean (SE)	0.01 (0.12)	0.95 (0.12)	<.001	0.04 (0.13)	0.59 (0.13)	.01
Calories (kcal), mean (SE)	74.54 (3.08)	99.83 (3.08)	<.001	68.97 (3.24)	87.10 (3.24)	<.001
Steps (n), mean (SE)	66.35 (28.70)	403.35 (28.70)	<.001	63.80 (30.48)	285.67 (30.48)	<.001
Distance moved (m), mean (SE)	26.82 (12.52)	175.70 (12.52)	<.001	27.06 (13.31)	119.85 (13.31)	<.001

[a]PIC: personalized intervention criteria.



[b]UIC: uniform intervention criteria.

Calories burned (PIC group: *B*=25.29, SE=2.03 and UIC group: *B*=18.13, SE=2.18; *P*=.02), Steps taken (PIC group: *B*=336.99, SE=27.45 and UIC group: *B*=221.88, SE=29.45; *P*=.008), and distance moved (PIC group: *B*=148.89, SE=12.19 and UIC group: *B*=92.79, SE=13.07; *P*=.004) showed significant differences in the increase in physical activity the hour before and after the intervention between the PIC group and the UIC group (Figure 3). Specifically, the number of calories burned per hour was estimated to increase by 7.16 kcal more in the PIC group than in the UIC group after the intervention. Steps taken increased by 115.11 steps and distance moved increased by 56.10 m in the PIC group compared with the UIC group. There were no significant differences in change observed between

XSL•FO
RenderX

groups in the other activity types (see Table S1 in Multimedia Appendix 1 for details).

Figure 3. Changes in physical activity from the hour before to the hour after the intervention in personalized intervention criteria (PIC) versus uniform intervention criteria (UIC) group. The values represent time spent (min) doing physical activity (top), calories burned (kcal), steps taken (steps), or distance moved (m) per hour (bottom). $^{*}P<.05$ $^{**}P<.01$ $^{\dagger}P<.10$.

Model Set B: Effects of PIC and UIC on Physical Activity From Week 1 Without Intervention to Week 2 With Intervention

In model set B, the best models for lightly active time, fairly active time, calories, steps, and distance moved used random intercepts and slopes, while the best models for sedentary time and very active time used random intercepts and fixed slopes. In both PIC and UIC groups, there were no significant changes in physical activity (all parameters) between week 1 and week 2 (see Table 4). See Table S2 in Multimedia Appendix 1 for detailed information.

Table . The change in physical activity from week 1 without intervention to week 2 with intervention as affected by differences in intervention criteria.

Physical activity	PIC group			UIC group		
	Week 1	Week 2	*P* value	Week 1	Week 2	*P* value
Sedentary time (min), mean (SE)	43.01 (1.36)	42.26 (1.36)	.55	44.82 (1.36)	45.38 (1.36)	.76
Lightly active time (min), mean (SE)	14.01 (1.19)	14.52 (1.12)	.92	12.81 (1.19)	11.94 (1.12)	.69
Fairly active time (min), mean (SE)	1.48 (0.21)	1.75 (0.29)	.67	1.35 (0.21)	1.70 (0.30)	.50
Very active time (min), mean (SE)	1.44 (0.19)	1.41 (0.19)	≥.99	1.06 (0.19)	1.02 (0.19)	≥.99
Calories (kcal), mean (SE)	116.91 (4.36)	119.06 (5.81)	.94	106.99 (4.34)	105.32 (5.80)	.97
Steps (steps), mean (SE)	590.46 (58.36)	564.56 (62.62)	.94	525.15 (58.00)	497.16 (62.50)	.93
Distance moved (m), mean (SE)	257.31 (26.14)	245.49 (27.81)	.93	230.32 (25.98)	214.77 (27.75)	.85

Discussion

Principal Findings

In this study, we examined the differences between in the impact of interventions based on personalized intervention criteria and uniform intervention criteria on physical activity in daily life. We found that in the first hour after JITAI was delivered, physical activity in the PIC group increased more than in the UIC group. However, the use of JITAI (both criteria) did not significantly increase physical activity over the whole study period.

There was a significant difference in increase in calories burned, steps taken, and distance moved between the PIC and UIC groups. This indicates that interventions based on PIC were more effective, suggesting that interventions to promote physical activity need to use individually developed intervention criteria based on physical activity in daily life. It has been reported that low feasibility of intervention suggestions is likely to lead to dissatisfaction [20,21]. It is possible that the setting of individually optimized intervention criteria that presented highly feasible goals (eg, proper number of interventions; see Figure 2) based on their physical activity level may have made it easier for them to change their behavior. Further studies need to identify the optimal number of interventions per day to promote physical activity.

Interestingly, in contrast to previous studies, we did not observe differences in overall physical activity between the first week without intervention and the week with intervention in either group. This may be due to the length of the intervention period used in this study. A previous study using UIC showed found an increase in physical activity after 21 days of intervention [16], while another study that sent contextually tailored intervention messages for 6 weeks showed an increase in the number of steps, although the increase diminished over time [22]. Taken together, it is possible that a longer intervention period is needed to effectively promote increased physical activity. A possible additional factor explaining this was that all but one participant had never worn activity monitors before, and simply wearing the monitors during the first week might have affected their baseline activity levels [23]. Future studies may need to set a burn-in period to precisely identify the baseline of physical activity before starting intervention.

This study had several limitations. Participants were university students, and the number of participants was small (n=28). Considering the sample size and the limited number of personal characteristics available to include as covariates (ie, age, BMI, and sex), it is possible that group differences (PIC vs UIC) may be related to other hidden third variables. Further studies need to examine the effectiveness of JITAI using PIC in larger samples with more personal characteristics, especially for participants who have low average levels of physical activity (eg, obese and elderly people who need more personalized intervention criteria). In addition, the variables of physical activity (ie, sedentary time and distance moved) we used for intervention were limited and in the future, more criteria could be used to determine thresholds to trigger interventions, and more sophisticated approaches to determine intervention decisions (eg, machine learning classification) could be used with additional physical activity features. A technical limitation was that the time of the intervention decision could not be randomized and was fixed. In future JITAI research, a finer grained approach ensuring that it is possible to intervene at the timing when the intervention criteria are met might lead to more optimal timing of the intervention. Finally, this study was limited to 2 weeks in duration and did not include any follow-up. Programs for increasing physical activity require the promotion of long-term behavioral changes. Further studies need to consider maintenance of benefits and sustainability of programs over longer periods of time.

Conclusion

We found that personalized intervention criteria were more effective than uniform intervention criteria in increasing physical activity levels, supporting the idea that precision health approaches tailored to the individual may lead to beneficial effects on health. The findings of this pilot study warrant further investigation; JITAI PIC programs need to be assessed over longer durations and in different populations.

Abstract

Background: Binge drinking, which is linked to various immediate and long-term negative outcomes, is highly prevalent among US college students. Behavioral interventions delivered via mobile phones have a strong potential to help decrease the hazardous effects of binge drinking by promoting safer drinking behaviors.

Objective: This study aims to evaluate the preliminary efficacy of bhoos, a novel smartphone app designed to promote safer drinking behaviors among US college students. The app offers on-demand educational content about safer alcohol use, provides dynamic feedback as users log their alcohol consumption, and includes an interactive drink tracker that estimates blood alcohol content in real time.

Methods: The bhoos app was tested in 2 independent pre-post studies each lasting 4 weeks, among US college students aged 18 - 35 years. The primary outcome in both trials was students' self-reported confidence in using protective behavioral strategies related to drinking, with self-reported frequency of alcohol consumption over the past month examined as a secondary outcome.

Results: In study 1, bhoos was associated with increased confidence in using protective behavioral strategies. Students also endorsed the high usability of the app and reported acceptable levels of engagement. Study 2 replicated findings of increased confidence in using protective behavioral strategies, and demonstrated a reduction in the self-reported frequency of alcohol consumption.

Conclusions: Bhoos is a personalized, accessible, and highly scalable digital intervention with a strong potential to effectively address alcohol-related behaviors on college campuses.

Introduction

Overview

Binge drinking, defined as consuming more than 5 standard drinks for men or 4 for women within a 2-hour period [1,2], is highly prevalent among US college students. This is concerning because binge drinking is linked to various immediate and long-term negative outcomes, including lower academic performance, a higher incidence of sexual assault, drunk driving, motor vehicle accidents, organ damage, and premature death [2-5]. Additionally, research shows that college students consume more alcohol than their noncollege-attending peers [6,7], which is troubling given that excessive drinking during late adolescence and early adulthood is a strong predictor of alcohol use disorders later in life [8]. Therefore, taking proactive steps to address binge drinking among college students is critical to reducing both the short- and long-term consequences in this population.

Alcohol Interventions in US Colleges

A common approach adopted by US colleges and universities to address hazardous drinking among students involves programs that focus on changing attitudes, increasing knowledge, and modifying behaviors related to alcohol use. Programs like the Brief Alcohol Screening and Intervention for College Students [9,10] typically include brief motivational counseling sessions aimed at reducing students' positive alcohol expectancies, increasing their awareness of the consequences of drinking, and enhancing their readiness to change [11-15]. Despite the

XSL•FO
RenderX

widespread implementation of such alcohol education and intervention programs, national data show that binge drinking rates among college students have remained relatively stable for over a decade [5], highlighting the ongoing difficulty in effectively addressing this public health issue.

Delivering Alcohol Interventions Through Smartphone Apps

Safer drinking interventions delivered through smartphones may offer distinct advantages in addressing binge drinking among young adults due to their ubiquity, high use, constant presence, and engaging features. Among all US demographic groups, college students have some of the highest rates of smartphone ownership and use [16]. Capitalizing on this widespread adoption provides an opportunity to develop personalized interventions that can effectively engage students and help regulate their alcohol consumption. Compared with in-person interventions, smartphone app-based alcohol interventions are highly accessible, cost-effective, scalable for large student populations, and can offer personalized feedback based on users' behaviors [17-19].

Researchers have begun exploring the use of smartphone apps to deliver alcohol interventions both in the general population [18-20] and among college students specifically [21-25]. Reviews generally support the feasibility and potential of app-based interventions for addressing outcomes of problematic drinking in college students, though results have been inconsistent across studies [21,23]. One potential reason for this inconsistency may be the lack of sufficient tailoring or personalization for US college students, given that incorporating strategies like gamification to personalize digital interventions may increase user engagement and improve outcomes [26,27]. For example, providing users with dynamic feedback about their drinking, such as their estimated blood alcohol level, may help them to better regulate their alcohol consumption during a night out with their friends to avoid negative consequences. Furthermore, providing users with graphical displays of their current and past alcohol consumption patterns may help them understand how their drinking has impacted other aspects of their lives, such as their academic performance and personal health.

Our team conducted a formative study to gain a detailed understanding of US students' preferences for interventions and their patterns of smartphone use [28]. Based on our findings and through conducting iterative user-centered design testing, our team developed bhoos (see below for a detailed description of the app and its functions). Similar to other app interventions, bhoos provides on-demand psychoeducational content about safer alcohol use. A novel feature of bhoos, however, is its just-in-time approach. Through an interactive drink tracking feature, students can log their consumption of alcohol in real time, enabling the app to provide dynamic feedback on recommended safe drinking behaviors based on estimated real-time blood alcohol content [28]. The primary goal of bhoos is therefore to promote safer drinking behaviors, in large part by increasing students' confidence in engaging in protective strategies, with the potential secondary outcome of reducing overall alcohol consumption.

The Current Studies

We investigated the feasibility and preliminary impact of bhoos in 2 pre-post studies conducted among students at a mid-Atlantic university in the US over a 4-week period. The hypothesis for study 1 was that bhoos would lead to an increase in students' confidence in using protective behavioral strategies (ie, behaviors that are used while drinking to reduce alcohol use or limit alcohol-related problems) from baseline to postintervention. A secondary hypothesis was that bhoos would lead to a reduction in self-reported alcohol consumption from baseline to postintervention. Study 1 also evaluated the impact of small monetary incentives on drinking outcomes and how students use the app to log their drinks. As study 1 was the first to test bhoos in college students, we examined students' engagement with the app and their ratings of its usability. Focus groups were conducted at the end of study 1 to gather feedback on the app from participants. Study 2 was conducted as a replication of self-reported drinking outcomes in study 1 to determine the potential of testing bhoos in a future randomized trial.

Ethical Considerations

Both studies reported in the manuscript were approved by the University of Virginia Institutional Review Board for Social and Behavioral Sciences (IRB-SBS #4020, 5334). All participants provided informed consent. Data are deidentified. Participants in study 1 received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $45). Participants randomized to receive added incentives in study 1 received an additional sum, up to US $30, based on their completion of 3 engagement milestones: US $10 for downloading the app, US $10 for logging 1 drink or dry day, and US $10 for logging a "streak" of 3 consecutive days of drinks or dry days. Participants in study 2 received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $25).

Study 1

Methods

Study Overview and Participants

Study 1 consisted of 3 phases. The first phase evaluated the bhoos app in a simple pre-post trial design. The second phase randomized (1:1) participants to receive small additional monetary incentives or not for using the bhoos app in a second pre-post trial. The third phase consisted of focus groups to capture impressions of the app by a subset of participants from the second phase.

For all phases of study 1, college students were eligible to participate if they met the following criteria: (1) aged 18 to 35 years, (2) current enrollment verified via a university email address, and (3) currently owned and used a smartphone. Students were enrolled using traditional, online, and social media methods. Recruitment spanned June through September 2021. Recruitment materials instructed applicants to complete a web-based interest form including contact information, demographic information, and questions to determine initial

XSL•FO
RenderX

study eligibility. Research coordinators verified student status and identity with the university's internal people search. Eligible verified applicants were invited to participate, signed a web-based consent form, and were enrolled in the study.

The phase 1 group included 83 participants (mean age 20.8 years, SD 1.6 years; 68% self-identified as female; 58% self-identified as White, 16% self-identified as Asian or Hawaiian/Pacific Islander, 4% self-identified as Black, 12% self-identified as multiracial, 4% prefer not to answer, and 6% chose to leave the item blank), and phase 2 group included 172 participants (mean age 20.1 years, SD 1.8 years; 60% self-identified as female; 48% self-identified as White, 19% Asian or Hawaiian/Pacific Islander, 8% Black, 11% multiracial, 1% prefer not to answer, and 13% chose to leave the item blank). Assessments occurred at baseline and postintervention, 28 days later. All participants received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $45). Participants in the phase 2 group who were randomized to not receive added incentives (n=86) were only provided compensation for completing the baseline and postassessments. However, those randomized to receive added incentives (n=86) received an additional sum, up to US $30, based on their completion of 3 engagement milestones: US $10 for downloading the app, US $10 for logging 1 drink or dry day, and US $10 for logging a "streak" of 3 consecutive days of drinks or dry days (see bhoos description, below).

To improve the app for future trials, the third phase of the trial included a subset of participants (n=18) from the phase 2 group who were invited to be part of debriefing focus groups that occurred 9 - 12 months after the initial pre-post trial. A total of 5 focus groups were conducted and qualitative information was collected regarding participants' general impressions of the app, what features of the app they liked most/least, and the degree to which the app helped them manage their drinking.

Intervention: Bhoos

Bhoos (pronounced [booz]) is an app whose name is a play on the word "booze," slang for alcohol, and the nickname for University of Virginia students, "hoos." The app provides on-demand educational content about safer alcohol use and dynamic feedback to users as they log their alcohol consumption in real time. Users can log the type of alcoholic drink they are consuming and each drink entry is time-stamped. The app provides real-time estimates of the user's blood alcohol concentration (estimated blood alcohol concentration) based on their self-identified sex, weight, and number and type of alcoholic drinks logged. In-app notifications are pushed to users based on their estimated blood alcohol concentrations, including information about recommended actions to stay safe and avoid overdrinking. Users can view their current and past drink history through a built-in dashboard. To encourage engagement with the app, users can establish a streak of logins whenever they log consecutive drinking days or dry days (ie, days in which users logged no alcoholic drinks). To encourage engagement, the app also allows users to rate activity level or sleep quality as a secondary health behavior. Materials about safe drinking tips and staying healthy can be accessed directly from the main page. Users can also learn about health-related resources in and around the university through the app on demand. The app design and content were informed by formative research and a think-aloud process with the target population prior to this trial [28].

Measures

Baseline Alcohol Use Severity

The 10-item Alcohol Use Disorders Identification Test (AUDIT) is the most widely used self-report measure of unhealthy alcohol use [29]. Scores range from 0 to 40, with higher scores indicating more unhealthy alcohol use. Prior studies on college students have suggested cutoff scores for low-risk drinkers (<7), hazardous drinkers (8-15), and alcohol-dependent drinkers (>15). Participants completed the AUDIT at baseline (Cronbach α=0.78) to characterize their alcohol use over the past year.

Alcohol Consumption in the Past Month

We used a modified 3-item measure based on the Daily Drinking Questionnaire [30] to assess students' self-reported drinking behavior. Students were initially asked "How often did you drink during the last month?" with response options ranging from 1 (did not drink at all) to 7 (once a day or more). Responses were analyzed as a single-item measure of the average number of days per week in the last month involving alcohol consumption, with higher scores indicating more days per week that involved alcohol consumption. Students who responded that they had drank at least once a month (ie, a score of ≥2) were then asked 2 follow-up questions: "Think of a typical weekend evening (Friday or Saturday) during the last month. How many standard drinks did you drink on that evening?" and "Think of the occasion (any day of the week) you drank the most during the last month. How many standard drinks did you drink?" Students responded to each of these questions by typing a number into an open field. Because these questions were intended to assess for average and maximum alcohol consumption, respectively, we analyzed responses to them as separate items.

Protective Behavioral Strategies

A modified version of the 20-item Protective Behavioral Strategies Scale [31-33] was administered at baseline (α=0.92) and postintervention (α=0.93) to assess students' confidence in using protective behavioral strategies, or behaviors adopted while drinking to limit their alcohol consumption or limit alcohol-related problems. Specifically, the instructions were modified from the original version to ask students to select the response option that "best fits your confidence level" for using various protective strategies when drinking. Participants responded to each item on a modified scale from 1 (extremely not confident) to 7 (extremely confident), with scores ranging from 20 to 140 [34,35]. Higher scores indicate more confidence in using protective behavioral strategies such as stopping or limiting alcohol consumption, changing the speed or frequency of drinking, and reducing the risk of serious harm by using a designated driver, going home with a friend, or protecting one's drink from adulterants.

XSL•FO
RenderX

App Usability

The 10-item System Usability Scale (SUS) [36] was administered postintervention to assess the usability of the bhoos app. The SUS provides a global view of subjective assessments of usability. We customized the items to specifically mention bhoos. Sample items include "I think that I would like to use bhoos frequently" and "I thought bhoos was easy to use." Responses to each item range from 1 (strongly disagree) to 5 (strongly agree). Possible scores on the SUS range from 0 to 100, with a higher score indicating higher overall usability of a system or program. The SUS has been used in roughly 3500 surveys within 273 studies evaluating a range of systems, interfaces, and programs [37]. Internal consistency of the SUS was good (α=0.84).

Plan for Analyses

To determine whether students' self-reported drinking outcomes differed across the 2 phases, including the incentive conditions in phase 2, 1-way ANOVAs were conducted using the phase 1, phase 2 incentivized, and phase 2 nonincentivized groups as within participants variables and difference scores for the drinking outcomes as the dependent variables. Difference scores in drinking outcomes between the baseline and postintervention time points served as the dependent variables. Next, for each of the phase 1 and phase 2 groups, paired *t* tests were conducted to obtain estimates of short-term changes in drinking and attitudinal measures from baseline to follow-up. Box-Cox transformations were performed for the drinking outcomes where there was evidence of nonnormality of data based on skewness (outside of −1 and +1) or kurtosis (outside of −2 and +2) being outside of the conventional acceptable ranges. The pattern of findings did not change when using transformed or raw variables. Analyses of self-reported drinking outcomes were performed using IBM SPSS Statistics (version 26.0.0). App use is described using descriptive statistics. Qualitative feedback from focus groups was reviewed by members of the study team (KI, CF, NA, and CC), and recurring themes were identified.

Results

Baseline Alcohol Use Severity

To characterize the sample, we examined AUDIT scores for all participants in study 1. Of the 234 students who completed at least the baseline measures, 133 (59%) were classified as low-risk drinkers (AUDIT Score ≤7), 93 (40%) were classified as hazardous drinkers (AUDIT Score between 8 and 15), and 8 (3%) were classified as alcohol dependent drinkers (AUDIT score >15).

Evaluating the Impact of Study Phases on Self-Reported Outcomes

There was no significant effect of the study phase or incentives on any of the self-reported drinking outcomes, for the average number of days per week in the last month involving alcohol consumption ($F_{2, 232}$=0.294, *P*=.75, η^2=.003), typical weekend evening drink consumption in the last month ($F_{2, 165}$=0.662, *P*=.52, η^2=.008), the maximum number of drinks consumed in the last month ($F_{2, 175}$=0.005, *P*=.99, η^2=.00), or protective behavioral strategies ($F_{2, 232}$=1.469, *P*=.23, η^2=.013). Table 1 contains all results of self-reported drinking outcomes, separately for each phase and incentive condition. Below, we report self-reported drinking-related outcomes overall for those in phases 1 and 2 combined, followed separately for each phase and incentive group.

Table . Self-reported drinking outcomes for study 1.

	Average number of days per week drinking in the last month, mean (SD)				Average number drinks per weekend in the last month, mean (SD)				Max number of drinks on one occasion in the last month, mean (SD)				Protective behaviors, mean (SD)			
	Pre	Post	*t* test (*df*)	*P* value	Pre	Post	*t* test (*df*)	*P* value	Pre	Post	*t* test (*df*)	*P* value	Pre	Post	*t* test (*df*)	*P* value
Phase 1	3.66 (1.31)	3.71 (1.34)	0.54 (75)	.59	3.64 (1.68)	3.61 (1.75)	0.11 (60)	.91	5.68 (3.16)	5.94 (3.12)	0.79 (65)	.43	98.20 (21.01)	100.30 (20.18)	0.98 (75)	.33
Phase 2 (no incentive)	2.99 (1.35)	3.01 (1.36)	0.22 (74)	.83	3.21 (2.06)	2.89 (1.95)	1.35 (50)	.18	4.53 (3.36)	4.59 (3.65)	0.27 (53)	.81	106.19 (24.74)	111.91 (23.28)	2.29 (76)	.03
Phase 2 (incentive)	3.05 (1.52)	2.99 (1.27)	0.55 (81)	.59	3.76 (1.92)	3.93 (2.75)	0.12 (52)	.91	5.93 (3.05)	5.98 (4.48)	0.64 (54)	.52	106.14 (26.05)	108.52 (24.56)	0.89 (80)	.38

Protective Behavioral Strategies

Overall, there was a significant increase in students' confidence in using protective behavioral strategies in drinking from baseline ($Mean_{pre}$ 103.58, SD 24.26) to postintervention ($Mean_{post}$ 106.97, SD 23.20; t_{233}=2.393, *P*=.02), such that students reported more confidence engaging in more protective behaviors while drinking to limit alcohol-related problems from drinking from baseline to postintervention.

As seen in Table 1, despite an increase in students' self-reported confidence in using protective behavioral strategies from baseline to postintervention for all 3 groups, the effect was not significant for students in the phase 1 group (t_{75}=0.98, *P*=.33), and the phase 2 incentive group (t_{80}=0.89, *P*=.38). There was,

XSL•FO
RenderX

however, a significant increase in confidence in using protective behavioral strategies for the phase 2 no incentive group (t_{76}=2.29, P=.03).

Alcohol Consumption in the Past Month

Overall, there was no significant change to the average number of days per week in the last month involving alcohol consumption, from baseline ($Mean_{pre}$ 3.23, SD 1.43) to postintervention ($Mean_{post}$ 3.25, SD 1.39; t_{232}=0.07, P=.95). There were also no significant changes to students' average number of drinks per weekend in the last month from baseline ($Mean_{pre}$ 3.52, SD 1.90) to postintervention ($Mean_{post}$ 3.44, SD 2.20; t_{164}=0.85, P=.40), nor were there significant changes to students' maximum number of drinks consumed in the last month from baseline ($Mean_{pre}$ 5.43, SD 3.46) to postintervention ($Mean_{post}$ 5.51, SD 3.83; t_{173}=0.20, P=.84).

As seen in Table 1, there were no significant changes to students' self-reported drinking frequency in the past month from baseline to postintervention for students in the phase 1 group (drinking frequency in the past month, t_{75}=0.54, P=.59; the average number of drinks per weekend in the last month, t_{60}=0.11, P=.91; the maximum number of drinks consumed in the last month, t_{65}=0.79, P=.43). This was also the case for the phase 2 no incentive group (drinking frequency in the past month, t_{74}=0.22, P=.83; the average number of drinks per weekend in the last month, t_{50}=1.35, P=.18; the maximum amount of drinks consumed in the last month, t_{53}=.27, P=.81), and the phase 2 incentive group (drinking frequency in the past month, t_{81}=0.55, P=.59; average number of drinks per weekend in the last month, t_{52}=0.12, P=.91; the maximum amount of drinks consumed in the last month, t_{54}=0.64, P=.52).

Usability of Bhoos

There was no significant effect of the study phase or incentives on self-reported usability of bhoos ($F_{2,\ 234}$=0.097, P=.908, η^2=.001). Usability scores for students in phase 1 ranged from 22.5 to 100 (mean 71.22, SD 17.21). Scores for students in the phase 2 nonincentive group ranged from 35 to 100 (mean 71.75, SD 16.96), and 37.50 to 100 (mean 72.38, SD 15.69) for those in the phase 2 incentive group. The average usability score (mean 71.80, SD 16.54) placed bhoos in the third quartile of all programs evaluated by the SUS [37].

Engagement With Bhoos

Nearly all participants (93.33%, 238 of 255) in study 1 downloaded the app. The majority of participants (85.49%, 218 of 255) logged at least 1 drink or dry day. Roughly two-thirds (160 of 255) of the participants logged at least 1 alcoholic drink, whereas nearly 3-quarters (189 of 255) logged at least 1 dry day. Slightly more than half (145 of 255) logged at least 1 streak. On average, participants used the app for 12.67 days (SD 9.96 d) of the 28 days of the intervention period.

Overall, providing added incentives did not seem to impact how students used the app to log their drinks. Among those in the phase 2 group, students randomized to receive incentives logged, on average, 11.16 drinks (SD 8.92) while those randomized to receive no added incentives logged, on average, 13.04 drinks (SD 16.62), t_{130}=0.924, and P=.357. Moreover, students randomized to receive incentives logged, on average, 15.50 dry days (SD 9.39) while those randomized to receive no added incentives logged, on average, 15.90 dry days (SD 8.81), t_{169}=0.282, and P=.78.

Qualitative Feedback From Focus Groups

The feedback obtained from focus groups revealed several common themes. Students found the bhoos app to be visually appealing and user-friendly. They expressed that the drinking chart within the app raised their awareness of their drinking habits over time, and they appreciated the ability to review their drinking history within the app. However, some students felt that the psychoeducational content within the app was too static, and they suggested that incorporating videos would be beneficial. Additionally, many students expressed a desire to track a broader range of secondary behaviors, including mood and stress.

In response to this feedback from the focus groups, we made several iterative improvements to the bhoos app in preparation for the next pilot study (study 2). Specifically, we enhanced the psychoeducational content by adding 4 short videos on relevant topics, including information on helping an intoxicated friend, knowing the signs of alcohol overdose, learning about alcohol tolerance, and understanding standard drink amounts. We also included more information on safety tips while drinking. We refined the app's functionality for users to track their mood or stress to identify patterns related to drinking events. Last, known bugs and glitches that students reported while using the app were addressed, enhancing bhoos' overall performance and reliability.

Discussion

Collectively, the results from study 1 provide preliminary support for the feasibility and usability of bhoos among college students in the United States. While the students in this sample did not report a reduction in drinking frequency, findings indicate that they were more confident in their ability to engage in protective behaviors while drinking, potentially enhancing their safety. Both app engagement data and mixed methods results confirm the usability of bhoos, while providing added monetary incentives did not seem to impact any of the observed outcomes or how students used bhoos to track their drinking. The qualitative feedback from students was instrumental in identifying areas for app improvement to enhance usability and engagement. Building on these findings, study 2 was conducted to examine whether the impact of bhoos on drinking-related outcomes would be replicated in an independent sample of college students.

Study 2

Methods

Study Overview and Participants

Eligibility criteria were identical to study 1. College students were recruited over the 2022 Fall semester using advertisements in dining halls. Although the initial goal was to enroll up to 200

XSL•FO
RenderX

students, the recruitment timeline was hampered by the continuation of the COVID-19 pandemic and a tragic event that occurred on university grounds on November 13th, 2022 (a shooting on University grounds that resulted in the murders of 3 students). The latest baseline questionnaires were completed before the event and enrollment of new participants was halted after the event. Participants who completed baseline questionnaires were permitted to complete the study and complete the postintervention questionnaires. In total, 43 students were recruited (60% students self-identified as women; 24 students self-identified as White, 12 students self-identified as Asian or Native Hawaiian, 2 students self-identified as Black, and 5 students self-identified as multiracial). Once again, assessments were administered at baseline and postintervention, 28 days later. All participants received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $25). An added incentivization group was not included in study 2.

Measures and Plan for Analyses

The same self-report measures were administered in study 2 as in study 1. Specifically, baseline alcohol use severity was assessed by the 10-item AUDIT [29] (α=0.82). Alcohol consumption in the past month was assessed at baseline and postintervention with the 3-item measure used in study 1. Each item was treated as a separate single-item scale. The modified 20-item Protective Behavioral Strategies Scale [31-33] was administered at baseline (α=0.90) and postintervention (α=0.91) to assess students' confidence in using protective behavioral strategies. Finally, the usability of the bhoos app was assessed postintervention using the SUS [36] (α=0.75).

Paired *t* tests were used to investigate short-term changes in drinking and protective behaviors from baseline to follow-up. Due to the limited sample size, if the normality assumption was not met some analyses were computed again with the paired Wilcoxon Signed Rank Test. This did not change the interpretation of any of the results]. Analyses were performed using R (version 4.3.3; R Core Team). App use is described using descriptive statistics.

Results

Baseline Alcohol Use Severity

Of the 43 students, 25 (58%) were classified as low-risk drinkers (AUDIT Score ≤7), 11 (26%) were classified as hazardous drinkers (AUDIT Score between 8 and 15), and 6 (14%) were classified as alcohol dependent drinkers (AUDIT score >15).

Protective Behavioral Strategies

As expected, there was a significant increase in students' confidence in using protective behavioral strategies after using bhoos from baseline ($Mean_{pre}$ 107, SD 17.19) to postintervention ($Mean_{post}$ 113.37, SD 15.87; t_{31}=-2.79, *P*=.01), such that students reported confidence in engaging in more protective behaviors while drinking to limit alcohol-related problems from drinking after the intervention compared with before.

Alcohol Consumption in the Past Month

There was a significant decrease in the average number of days per week drinking alcohol in the last month from baseline ($Mean_{pre}$ 2.32, SD 1.27) to postintervention ($Mean_{post}$ 2.06, SD 1.15; t_{33}=2.32, *P*=.031). Among students who reported drinking, there was no significant change to their typical weekend evening drink consumption from baseline ($Mean_{pre}$ 3.83, SD 2.80) to postintervention ($Mean_{post}$ 3.87, SD 2.30; t_{29}=0, *P*=.92), nor was there a significant change to the maximum number of drinks they consumed in a single occasion the last month, from baseline ($Mean_{pre}$ 5.17, SD 4.07) to postintervention ($Mean_{post}$ 5.34, SD 4.50; t_{28}=0.24, *P*=.82).

Usability of Bhoos

Usability scores ranged from 55 to 98 (out of a possible 100). Overall, students reported higher usability of the revised version of bhoos (mean 77.93, SD 11.92) than in the original version tested in study 1. The average score placed bhoos in the upper 75% (fourth quartile) of all programs evaluated by the SUS [37].

Discussion

Collectively, the findings from study 2 reproduce the drinking-related results from study 1. Specifically, the findings of study 2 replicate the finding that bhoos is associated with an increase in confidence in using protective behaviors while drinking. It is worth noting that students in study 2 also reported reduced frequency of drinking, which may have resulted from improvements to the app from study 1, which is supported by our finding that students rated the app as more usable in study 2 than in study 1.

Overall Discussion

Principal Findings

Developing effective, accessible, and scalable interventions to address excessive drinking among college students is critical due to the significant public health concerns posed by alcohol misuse on college campuses. In 2 studies, we observed promising and consistent results regarding the impact and usability of the bhoos app, which effectively promoted confidence in using protective behaviors related to drinking among US college students.

The results suggest that bhoos' features, such as drink tracking and dynamic feedback, help to encourage responsible drinking behaviors, including monitoring alcohol intake, planning for safe transportation after drinking, or seeking help when needed. The ability to provide personalized, real-time feedback increases the relevance of the app to the individual needs and experiences of its users. By offering recommendations based on the user's drinking patterns and risk factors, bhoos may engage users more effectively than a generic one-size-fits-all program which enhances the likelihood of behavior change. Moreover, this more personalized approach to providing risk feedback aligns with the principles of Motivational Interviewing [38,39] and follows proven strategies for promoting behavior change [40-42]. Smartphone app-delivered interventions like bhoos offer several advantages over traditional approaches, including

XSL•FO
RenderX

the ability to deliver actionable feedback at critical moments. Additionally, they provide the potential for widespread accessibility and scalability. College students, in particular, maybe the most receptive to mobile apps for obtaining information and support for health-related decisions, given their high smartphone use [16]. The ease of dissemination and the low cost of smartphone apps make them a practical option for broad implementation on college campuses.

Limitations and Future Directions

The findings from our studies should be considered in light of several limitations. First, the reliance on infrequent and static measures of drinking behaviors introduces the possibility of recall bias. Moreover, the primary outcomes of both studies reflected students' confidence in using various protective behaviors while drinking and not the actual behaviors they engaged in. Future research could benefit from incorporating more ecologically valid approaches, such as ecological momentary assessment, perhaps administered within the app, to assess for actual protective behaviors related to drinking while limiting recall bias. Additionally, the pre-post design of our study limits our ability to evaluate the efficacy of bhoos, which could be better assessed through a randomized controlled trial. The short time frame between baseline and postassessment (4 weeks) restricts our understanding of the long-term sustainability of the app's effects. Future studies should explore the app's impact over longer periods, such as a full college semester. Moreover, a large percentage of students in both studies were White and female which may limit the generalizability of our findings to minorities and men. Finally, the tragic shooting that occurred on university grounds may have influenced students' drinking behaviors in study 2, although the extent of this impact is unclear. Future studies should examine how such events, and events more broadly (eg, political elections, performance of University athletic teams), affect student drinking behaviors.

General Conclusion

In summary, preliminary findings across 2 studies indicate that bhoos shows strong potential as a tool for promoting protective behaviors related to alcohol use among college students. While these studies help advance highly accessible and scalable approaches to address the consequences of binge drinking by US college students, further research is needed to fully understand the app's role in comprehensive alcohol harm reduction efforts within this population. Its personalized approach, combined with its accessibility and scalability, suggests that bhoos could be a valuable addition to the range of interventions available to address alcohol-related issues on campuses.

Acknowledgments

The authors thank the Board of Visitors and the President of the University of Virginia for funding this project through the Strategic Investment Fund. The authors also appreciate the support and guidance of the Executive Committee for the project "Reducing the Burden of Addictions in Virginia": Dr Robert Klesges, Dr Lee Ritterband, Dr Nassima Ait-Daoud Tiouririne, Dr Karen Ingersoll, Dr Christopher Holstege, and Dr Margaret Shupnik. Finally, the authors thank the undergraduate research assistants for this study: Grace Biegger, Aasritha Natarajan, David Vann, and Shruti Vachhani. We would also like to thank our development team, Gabe Heath, Nicole Le, and Brendan Murphey, for the design and development of the bhoos app intervention.

Abstract

Background: Artificial intelligence (AI) chatbots have been customized to deliver on-demand support for people with mental health problems. However, the effectiveness of AI chatbots in tackling mental health problems among the general public in Hong Kong remains unclear.

Objective: This study aimed to develop a local AI chatbot and compare the effectiveness of the AI chatbot with a conventional nurse hotline in reducing the level of anxiety and depression among individuals in Hong Kong.

Methods: This study was a pilot randomized controlled trial conducted from October 2022 to March 2023, involving 124 participants allocated randomly (1:1 ratio) into the AI chatbot and nurse hotline groups. Among these, 62 participants in the AI chatbot group and 41 in the nurse hotline group completed both the pre- and postquestionnaires, including the GAD-7 (Generalized Anxiety Disorder Scale-7), PHQ-9 (Patient Health Questionnaire-9), and satisfaction questionnaire. Comparisons were conducted using independent and paired sample *t* tests (2-tailed) and the χ^2 test to analyze changes in anxiety and depression levels.

Results: Compared to the mean baseline score of 5.13 (SD 4.623), the mean postdepression score in the chatbot group was 3.68 (SD 4.397), which was significantly lower (*P*=.008). Similarly, a reduced anxiety score was also observed after the chatbot test (pre vs post: mean 4.74, SD 4.742 vs mean 3.4, SD 3.748; *P*=.005), respectively. No significant differences were found in the pre-post scores for either depression (*P*=.38) or anxiety (*P*=.19). No statistically significant difference was observed in service satisfaction between the two platforms (*P*=.32).

Conclusions: The AI chatbot was comparable to the traditional nurse hotline in alleviating participants' anxiety and depression after responding to inquiries. Moreover, the AI chatbot has shown potential in alleviating short-term anxiety and depression compared to the nurse hotline. While the AI chatbot presents a promising solution for offering accessible strategies to the public, more extensive randomized controlled studies are necessary to further validate its effectiveness.

Trial Registration: ClinicalTrials.gov NCT06621134; https://clinicaltrials.gov/study/NCT06621134

Introduction

An estimated 1 in 7 people in Hong Kong experience a common mental disorder in their lifetime, with anxiety and depression being the two most common mental health issues in Hong Kong, accounting for 19% and 14% among the generation population, respectively [1,2]. Nearly three-quarters of individuals experiencing a mental health disorder do not seek professional help for various reasons such as high cost of services, fear of judgment, or stigma [3]. To address these potential problems, artificial intelligence (AI) chatbots have been incorporated into digital interventions, particularly web- and smartphone-based apps, to enhance user experience and optimize individualized mental health [4,5]. Chatbots can provide a safe and confidential space for people to seek help for their mental health concerns. Additionally, they are available at any time throughout a study, making them a convenient option for those who may lack access to traditional mental health services or require support beyond regular business hours. Further efforts toward strengthening implementation of chatbots are needed, and their application to the general public should be explored to improve perceptions of general mental health and increase awareness of the importance of premedical interventions in the future [6].

Chatbot models have been developed in various countries and are widely used in psychology and clinical practice. For example, Tess, a psychological AI service, has been tailored to provide immediate assistance to caregiving specialists, individuals receiving care, and family caregivers within a nonprofit organization in the United States and Canada [7]. Among university students, chatbot applications have showed a significant decrease in anxiety symptoms [8]. Anna, an AI-driven chatbot, simulates the function of a therapist and offers gamified versions of evidence-based activities drawn from various therapeutic approaches. Participants who engaged in activities facilitated by Anna provided more detailed responses containing a higher number of positive relational terms [9]. A review of users' opinions, satisfaction, and attitudes regarding depression and anxiety chatbot apps found that users felt supported and confident while they used apps that were easy to navigate, affordable, and free of cost [10]. In Hong Kong, the first AI-driven Cantonese psychological support tool, the Pai.ACT mobile app, was developed for parents of children with special education needs [11]. However, there is currently a lack of evidence on the effectiveness of AI chatbots in tackling mental health problems in the general public.

Given the risk of anxiety and depression in Hong Kong and the limited availability of mental health services during the epidemic, this study aimed to compare the effectiveness of the developed AI chatbot with that of a conventional nurse hotline in alleviating psychological anxiety and depression in the general public. Additionally, this study also aimed to understand user satisfaction with chatbot usage and gather preliminary data for larger randomized controlled trials to advocate for the AI chatbot as a psychological support tool for individuals seeking information on the chatbot platform.

Methods

Recruitment

This study was designed as a randomized controlled trial (RCT) with two parallel groups. Participants were parents recruited through two school principal's networks. The inclusion criteria included (1) being able to use smartphones proficiently to interact with the AI chatbot, (2) being fluent in Chinese language used in the study to effectively communicate with the AI chatbot, and (3) providing an electronic consent form. Parents who were unwilling or unable to commit to the entire research process and had difficulties in reading and understanding Chinese were excluded. Invitation letters were sent to kindergarten and primary school principal groups from chief schools, and 124 parents responded to this study and provided an electronic consent form. Participants were then randomly allocated in a 1:1 ratio to either the AI chatbot or the nurse hotline group using block randomization with blocks of four. Participants immediately filled out the posttest questionnaires after communicating with the AI chatbot or nurse. Those who did not respond immediately received reminders until they completed the posttest questionnaires. Participants with risky mental health problems were followed up by phone calls and were encouraged to ask to connect with necessary medical services and mental health clinical departments.

Ethical Considerations

This study was approved by the Institutional Review Board of the University of Hong Kong/Hospital Authority Hong Kong West (approval number: UW21-344). Informed consent was obtained from all participants in the study, ensuring that they were fully aware of the nature and possible consequences of their participation. Participants were informed that they had the right to opt out at any time without penalty. The original consent and approval covers secondary analysis without additional consent. Data collected from participants were deindentified to ensure privacy and confidentiality. Identifying information, including names, initials, or hospital numbers, was removed from all datasets to protect participant identities. Participation was voluntary, and individuals were informed that no financial or material incentives would be provided. Consolidated Standards of Reporting Trials (CONSORT) reporting guideline was adhered to in this study [12].

AI Chatbot Development Procedures

The development of the AI chatbot involved 7 key steps. First, the developer analyzed requirements by understanding common queries and focusing on providing accurate information to the public and assisting nurses. Relevant data was then collected from credible sources, and natural language processing (NLP) algorithms were used to train a robust model on diverse questions and answers. By integrating large language models, the chatbot could provide detailed responses. Next, the developer designed and developed the backend infrastructure, including databases, application programming interfaces, and integration with University of Hong Kong's website and WhatsApp. Extensive testing and validation ensured the chatbot's accuracy and user-friendliness, with a beta version tested by selected users. Finally, the chatbot was deployed on University of Hong

XSL•FO
RenderX

Kong's website and made accessible through WhatsApp, with a nurse hotline version developed to assist health care professionals in handling public inquiries.

The AI chatbot system comprises several essential components to provide accurate and relevant information. It begins with context identification, where the chatbot analyzes keywords and phrases to understand the user's query, ensuring accurate interpretation and relevant response. Next, the system conducts query analysis using NLP techniques to determine the user's intent and extract specific details such as dates, locations, and vaccination information. The query response system then leverages the trained NLP model and large language model–generated responses to provide accurate and contextually appropriate answers tailored to users' needs. Finally, the chatbot relies on a regularly updated and comprehensive dataset containing the latest information on COVID-19 vaccinations, government regulations, and health care procedures, ensuring the delivery of reliable and accurate responses.

Questionnaires

The Patient Health Questionnaire-9 (PHQ-9) is a self-assessment tool consisting of 9 questions that measure the frequency and severity of depressive symptoms over the last 2 weeks. Each question is derived from the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (*DSM-IV*) criteria and is rated on a scale of 0 (not at all) to 3 (almost daily) [13]. The Generalized Anxiety Disorder Scale-7 (GAD-7) is a 7-item self-report scale that evaluates the frequency and severity of anxious thoughts and behaviors during the last 2 weeks. Items are based on the diagnostic criteria of the *DSM-IV* and scored from 0 (not at all) to 3 (nearly every day) [14]. The service satisfaction survey is a 3-item questionnaire for participants to report their degree of satisfaction after using the two platforms. The rating score ranges from 0 to 10, representing an increasing satisfaction from not at all likely to extremely likely. Based on the standardized cutoff that determines the severity of anxiety and depression, participants were divided into two groups: the no-risk group (total score<4) and the risk group (total score>4) [15].

Statistical Analysis

Quantitative variables were tested for normal distribution using the Kolmogorov-Smirnov test. Normally distributed continuous variables were expressed as mean (SD) and categorical variables were expressed as numbers and percentages. A per-protocol analysis was performed for all outcomes when comparing the 2 groups. The independent *t* test (2-tailed) was employed to compare the preanxiety or predepression, postanxiety or postdepression, pre-post difference scores, and service satisfaction between the AI chatbot and nurse hotline groups, respectively. The paired *t* test (2-tailed) was used to compare scores before and after group chat. Linear regression was conducted to analyze the difference in posttest scores between the AI chatbot and nurse hotline groups adjusted by pretest scores. Categorical variables were compared with the χ^2 test. All analyses were conducted using SPSS software (version 29.0; IBM Corp).

Results

From October 2022 to March 2023, all the participants (N=124) answered prequestionnaires, and 62 (62/62, 100%) participants in the AI chatbot group and 41 (41/62, 66.1%) in the nurse hotline group completed both the pre- and postquestionnaires (Figure 1). Comparisons within groups before and after the test are displayed in Table 1 and Figure 2. Compared to the mean baseline score of 5.13 (SD 4.623), the mean postdepression score 3.68 (SD 4.397) was significantly lower in the chatbot group (*P*=.008). Similarly, a reduction in anxiety score was also observed after using the chatbot test (pre vs post: mean 4.74, SD 4.742 vs mean 3.4, SD 3.748; *P*=.005).

Figure 2. Comparison of anxiety and depression scores within groups pre- and postintervention. GAD-7: Generalized Anxiety Disorder Scale-7; PHQ-9: Patient Health Questionnaire-9; ns: nonsignificant. **P<.05.

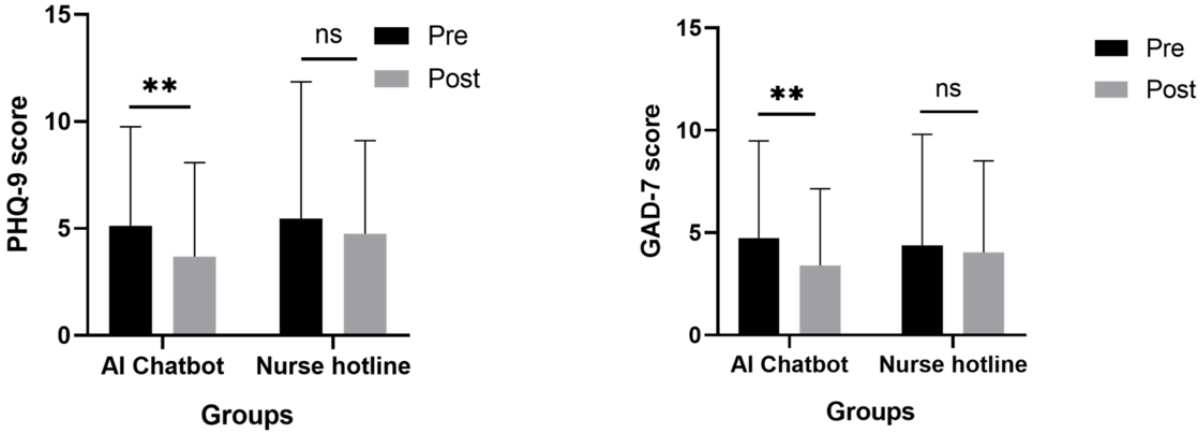

Table 2 shows there were no statistically significant differences at baseline between groups in depression (P=.76) and anxiety scores (P=.71). Although the postdepression and postanxiety scores in the chatbot group were slightly lower than those in the nurse hotline group, there was no statistical difference (all Ps>.05). No statistically significant difference was observed in service satisfaction between the 2 service platforms (P=.32). In the nurse hotline group, there were no notable differences in depression and anxiety scores before and after the test.

Table . Comparison of the before and after PHQ-9[a], GAD-7[b], and service satisfaction scores between the AI chatbot and nurse hotline groups.

Variables	AI chatbot scores (n=62), mean (SD)	Nurse hotline scores (n=41), mean (SD)	P value[c]
Pre–PHQ-9	5.13 (4.63)	5.46 (6.4)	.76
Post–PHQ-9	3.68 (4.40)	4.76 (4.35)	.43
Pre–GAD-7	4.74 (4.74)	4.37 (5.44)	.71
Post–GAD-7	3.40 (3.75)	4.05 (4.46)	.22
Service satisfaction	16.11 (6.88)	17.39 (5.59)	.32

[a] PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Scale-7.

[c]Independent t test.

No significant variations were observed in the pre-post score differences for either depression (P=.38) or anxiety scores (P=.19) between the 2 groups (Table 3).

Table . Comparison of the pre-post anxiety and depression score differences between the artificial intelligence (AI) chatbot and nurse hotline groups.

Variables	Groups		
	AI chatbot (n=62), mean (SD)	Nurse hotline (n=41), mean (SD)	P value
Pre-post differences			
PHQ-9[a]	−1.452 (4.203)	−0.707 (4.161)	.38
GAD-7[b]	−1.339 (3.635)	−0.317 (4.15)	.19

[a]PHQ-9: Patient Health Questionnaire-9.

[a]PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Scale-7.

Based on the PHQ-9 and GAD-7 cutoff, the pre- and postscores were categorized into no-risk group and risk groups. No significant differences were observed in the prevalence of anxiety and depression before and after using the nurse hotline or AI chatbot (Table 5).

Table . Comparison of the anxiety and depression prevalence before and after using the nurse hotline and artificial intelligence (AI) chatbot among participants.

Groups	No-risk group (score≤4), n (%)	Risk group (score>4), n (%)	*P* value
Pre–PHQ-9[a]			
Nurse hotline (n=41)	27 (65.9)	14 (34.1)	.20
AI chatbot (n=62)	33 (53.2)	29 (46.8)	
Post–PHQ-9[a]			
Nurse hotline (n=41)	26 (63.4)	15 (36.6)	.33
AI chatbot (n=62)	45 (72.6)	17 (27.4)	
Pre–GAD-7[b]			
Nurse hotline	27 (65.9)	14 (34.1)	.34
AI chatbot	35 (56.5)	27 (43.5)	
Post–GAD-7[b]			
Nurse hotline	27 (65.9)	14 (34.1)	.47
AI chatbot	45 (72.6)	17 (27.4)	

[a]PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Scale-7.

Discussion

Principal Results

This study is among the first in Hong Kong to compare the effectiveness of AI chatbots and nursing hotlines in addressing mental health–related inquiries. The AI chatbot proved effective in reducing anxiety and depression during the COVID-19 outbreak and was comparable to the conventional nursing hotline. It suggests the potential use of AI chatbots as a complementary approach in mental health interventions, particularly when AI chatbots can provide timelier and uninterrupted 24-hour support to users in need during the challenging periods such as a pandemic.

Previous research comparing the effectiveness of the AI chatbot and humans in improving mental health is controversial. Our study found that both the AI chatbot and nurse hotline had similar effects in alleviating depression and anxiety. The results are consistent with another study comparing the text-only chatbot and voice-based digital human interactions as responders to mental health questions, which reported that the text-only chatbot was more user-friendly, although there were no significant differences in electroencephalography measurements [16]. No differences were observed in another RCT comparing the effects of AI chatbot (ie, ChatGPT-3.5) and nurse education on preoperative anxiety reduction among groups [17]. However, one study comparing physician and AI chatbot responses to patient questions posted on a public social media forum found that the chatbot generated higher quality and empathetic

XSL•FO
RenderX

responses to patient questions than physicians [18]. Additionally, the follow up process took less time for the nurse hotline group compared to the chatbot group. This was primarily because participants in the nurse hotline group were quicker in responding to follow up questionnaires while the chatbot group typically required more than one attempt to gather responses. It is feasible to use the AI chatbots to provide instant information to users about mental health knowledge and basic strategies to dissipate their temporary anxiety and depressed mood. However, the AI chatbot can only be a facilitator, and humans will not be replaced in the long-term professional treatment. The sample size in the above-mentioned studies is very small, which may have limited the power of statistical analysis. Therefore, more RCTs with larger sample sizes are necessary to confirm differences between the AI chatbot and human-based services.

Our study showed a significant reduction in the levels of anxiety and depression after using the AI chatbot. This finding is supported by a study from Argentina, which showed a substantial decrease in anxiety symptoms in university students using *Tess* [8]. Another study reported that the use of the Elomia chatbot for 4 weeks resulted in a significant decrease in the symptoms of anxiety and depression along with reduced negative effects [19]. AI chatbots can offer information to users in a quick and easy format. They can also be programmed to answer specific questions about a certain condition, such as what to do during a medical crisis or what to expect during a medical procedure. The AI chatbot could lower the barriers to care by helping patients access help more quickly and efficiently [20]. AI chatbots appear to have a positive impact on depression and anxiety in a wide range of populations, including university students [8], short-course treatment patients [21], and preoperative patients [17]. The potential benefit of chatbot–assisted mental health support is that it can provide helpful information about depressive moods, especially for users who have difficulty in communicating emotions to other humans [22]. Besides, the chatbot offers real-time relief, emotional support, and instant messages on basic knowledge about health-related questions. AI chatbots can help reduce anxiety and depression by providing accessible, anonymous, consistent, and immediate emotional support. They serve as a valuable supplement to conventional therapy and mental health care, offering users a safe space to express their feelings and find effective coping strategies.

Our study differs from previous ones by addressing a research gap in the broader population. Earlier studies primarily concentrated on specific groups, such as college students aged 18-33 [8], younger individuals aged 19-23 [19], and older adults aged 60 years [17]. The sample size in our study (N=124) aligns with past studies, which typically included approximately 100 participants. A study with a larger sample size of 412 younger participants [19] also found AI chatbots to be effective in alleviating anxiety and depression symptoms. Notably, our study was conducted during the COVID-19 pandemic, unlike previous studies, which were conducted under normal circumstances. Hence, additional research is necessary to understand the efficacy and impact of AI chatbots across different age groups, demographics, and environmental contexts.

Our study was carried out during the COVID-19 outbreak, revealing that AI chatbot interventions are versatile and can be applied in various situations, such as during future pandemics or for disseminating information to prevent other diseases. There is great potential in AI chatbot designing and application during an epidemic like COVID-19 [23]; AI chatbots not only help in reducing depression and anxiety at any given time but also can be embedded into the health care systems, to help patients describe their symptoms and provide preliminary guidance on whether they need to seek medical attention [24]. This can assist in triaging patients based on the severity of their symptoms. They can help patients book appointments with health care providers, reducing the burden on administrative staff. AI Chatbots can send reminders to patients to take their medications on time, improving medication adherence [24]. They can provide ongoing emotional support and coping strategies for individuals dealing with mental health issues like anxiety, depression, and stress. This can complement traditional therapy and make mental health care more accessible. Chatbots can also deliver personalized health education to patients, helping them understand their conditions, treatment options, and preventive measures.

The findings of this study comparing AI chatbots and nurse hotlines in alleviating the levels of anxiety and depression during the COVID-19 pandemic can be generalized to a certain extent, given that the general population was the target group. This broad target population ensures that the results are applicable to a wide range of individuals who may have experienced similar mental health challenges during the pandemic. However, the generalizability may be limited by factors such as the specific characteristics of the sample used in the study, including their demographics and the severity of their anxiety and depression symptoms. Additionally, the dynamic nature of AI chatbots, which can be influenced by various factors such as the phrasing of questions and ongoing optimization processes, may also affect the generalizability of the results. The study's design and methodology provide a solid foundation for replicability. The use of an RCT framework, which is a robust design for evaluating interventions, increases the likelihood that similar studies can be conducted with comparable results. The clear documentation of the study's procedures, including the recruitment process, data collection methods, and statistical analysis techniques facilitates replication by other researchers. Furthermore, the study's focus on a common and significant issue—mental health during a pandemic—ensures that there is a continued interest and relevance in conducting similar studies. However, replicability may be challenged by the need for access to similar populations and resources, as well as the evolving nature of AI chatbot technology, which may require adaptation of the intervention for future studies.

Although AI chatbots have a potential complementary function in mental health and health-related fields, certain drawbacks must be considered. For example, the safety and privacy concerns remain unclear [25]. Chatbots are unable to deliver the emotional support and personal bond that a certified mental health expert may provide. They cannot deliver a diagnosis or management strategy for mental health disorders. Therefore, it is crucial to use AI chatbots as a complement to, rather than a

XSL•FO
RenderX

substitute for, specialized mental health services. Moreover, further refinement to the AI chatbot is necessary for establishing an integrated system for recognition-alert-reporting system for mental health problems. After early detection and identification of depression and anxiety, the AI chatbot should be designed to automatically send self-regulation advice to the users to handle their negative emotions as well as send reminder messages to encourage them to seek medical services. Additionally, the question coverage of the AI chatbot is limited; it covers common mental health–related questions that may overlook the scope of other health problems. The scope of the population using chatbots should be expanded among the public. Further studies are required to draw solid conclusions about the effectiveness and safety of chatbots.

Limitations

One of the limitations of our study is the small sample size. Toward the end of the COVID-19 outbreak, there was a notable lack of enthusiasm among parents to participate in this study. Only two school principal groups were involved, which may have introduced a selection bias. Additionally, the study period was too short to recruit sufficient participants; however, the preliminary results showed a significant reduction in anxiety and depression after using the AI chatbot, supporting the applicability of using AI chatbots to relieve negative emotions during the next epidemic crisis. Demographic data and other confounding factors were not collected due to privacy concerns; these factors will be included in the following larger randomized control study.

Conclusions

The AI chatbot is as effective as the nurse hotline in answering mental health–related questions. Besides, the AI chatbot can reduce short-term anxiety and depression levels compared to the nurse hotline. The developed AI chatbot shows promise as a complementary tool to provide available intervention strategies to the public, particularly for families with limited access to mental health services. This study provides insights into the potential application of using AI chatbots to provide immediate information to the public and mitigate public emotional distress during future epidemic emergencies.

Abstract

Background: Hybrid work is the new modus operandi for many office workers, leading to more sedentary behavior than office-only working. Given the potential of digital interventions to reduce sedentary behavior and the current lack of studies evaluating these interventions for home office settings, it is crucial to develop digital interventions for such contexts involving all stakeholders.

Objective: This study aimed to reach expert consensus on the most feasible work strategies and the most usable digital elements as a delivery method to reduce sedentary behavior in the home office context.

Methods: A modified Delphi study including 3 survey rounds and focus groups was conducted to achieve consensus. The first Delphi round consisted of two 9-point Likert scales for assessing the feasibility of work strategies and the potential usefulness of digital elements to deliver the strategies. The work strategies were identified and selected from a scoping review, a systematic review, and 2 qualitative studies involving managers and employees. The median and mean absolute deviation from the median for each item are reported. The second round involved 2 ranking lists with the highly feasible strategies and highly useful digital elements based on round 1 responses to order the list according to experts' preferences. The weighted average ranking for each item was calculated to determine the most highly ranked work strategies and digital elements. The third round encompassed work strategies with a weight above the median from round 2 to be matched with the most useful digital elements to implement each strategy. In total, 4 focus groups were additionally conducted to gain a greater understanding of the findings from the Delphi phase. Focus groups were analyzed using the principles of reflexive thematic analysis.

Results: A total of 27 international experts in the field of occupational health participated in the first round, with response rates of 86% (25/29) and 66% (19/29) in rounds 2 and 3, respectively, and 52% (15/29) in the focus groups. Consensus was achieved on 18 work strategies and 16 digital elements. Feedback on activity progress and goal achievement; creating an action plan; and standing while reading, answering phone calls, or conducting videoconferences were the most feasible work strategies, whereas wrist-based activity trackers, a combination of media, and app interfaces in smartphones were the most useful digital elements.

XSL•FO
RenderX

Moreover, experts highlighted the requirement of combining multiple levels of strategies, such as social support, physical environment, and individual strategies, to enhance their implementation and effectiveness in reducing sedentary behavior when working from home.

Conclusions: This expert consensus provided a foundation for developing digital interventions for sedentary behavior in home office workers. Ongoing interventions should enable the evaluation of feasible strategies delivered via useful digital elements in home office or hybrid contexts.

sedentary behavior; office work; home office; hybrid work; technology; Delphi

Introduction

Background

Workplace sedentary behavior (SB) is associated with poorer health and work-related outcomes, such as musculoskeletal disorders, reduced mental and occupational well-being, job dissatisfaction, and fatigue [1-4]. According to the World Health Organization, the workplace is one of the main settings to reduce SB in the adult population [5], with office workers, who spend an average of 77% of their working day sitting [6], being a key target group [7]. After the COVID-19 pandemic, hybrid work, alternating work in the office and at home, has become the new work paradigm for many desk-based jobs [8-10]. Hybrid work results in even higher levels of SB than working solely in the office [11], increasing the risk of musculoskeletal health problems, mental health issues, and reduced work productivity [11,12].

Developing strategies to reduce and break up workplace SB, replacing it with activities other than sitting, such as walking or standing, has been the focus of recent studies [13,14]. In particular, the use of digital strategies in desk-based jobs (eg, delivered via mobile phone, activity tracker, or desktop computer) has the potential to provide scheduled prompts, deliver information, give automated tailored feedback, and mediate organizational support and social influences [15]. Recent evidence has highlighted the capability of digital interventions to reduce workplace SB and its associated harmful effects on health and work-related outcomes among office workers [16-18]. However, this research has focused on the traditional office environment, with a dearth of research available on the use of digital interventions to reduce of employees' SB while working remotely or undertaking hybrid work [19,20].

Multicomponent digital interventions that combine environmental and organizational changes and provision of information and counseling have been reported as more effective than single-component interventions in reducing occupational SB among office workers [16,21]. In addition, the grounding of interventions in a theory of behavior change is key in the success and behavior maintenance of multicomponent interventions [22-24]. Given the limited evidence base on the effectiveness of interventions targeting hybrid work, it is crucial to develop multicomponent digital interventions grounded in sound theory of behavior change to reduce occupational SB among home office workers.

Objectives

To contribute to a successful implementation of an intervention and, thereby, to its effectiveness, involving stakeholders such as researchers, experts in the addressed topic, and the target population in the development of interventions is necessary to identify needs, priorities, and potential solutions [25]. A previous qualitative study identified which factors influenced employees' ability to reduce SB when working from home from the employers' perspective, whereas additional qualitative evidence identified the factors influencing the reduction in SB from the employees' perspective [26]. This study aimed to go beyond the existing research gaps to incorporate expert opinions to gain a complete picture of all stakeholders and reach consensus on the feasibility of digital work strategies to reduce SB in a home office context. Therefore, the aim of this study was to reach expert consensus on the most feasible and usable digital work strategies as a delivery method to reduce SB in a home office context.

Methods

Design

A modified Delphi study was used to elicit a consensus from a spectrum of experts in the field of occupational health. It is a flexible approach combining quantitative and qualitative data. Qualitative data can be collected before, after, or between Delphi rounds [27,28]. This study encompassed 3 survey rounds and subsequent web-based focus group sessions. This study is part of the initial modeling of a multicomponent intervention and of a larger European project (ie, the Click2Move program) aimed at tackling the challenge of occupational sedentarism in hybrid office workers.

This study was based on the recommendations of the Conducting and Reporting Delphi Studies guidelines [29] and the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [30].

Ethical Considerations

This project was approved by the Research Ethics Committee of the University of Vic–Central University of Catalonia (250/2023). This study was conducted in accordance with relevant guidelines and regulations. The invitation email contained general information about the study and a link with further details of the participant information statement, including assurances of anonymity and confidentiality and emphasizing that participation was completely voluntary and participants

XSL•FO
RenderX

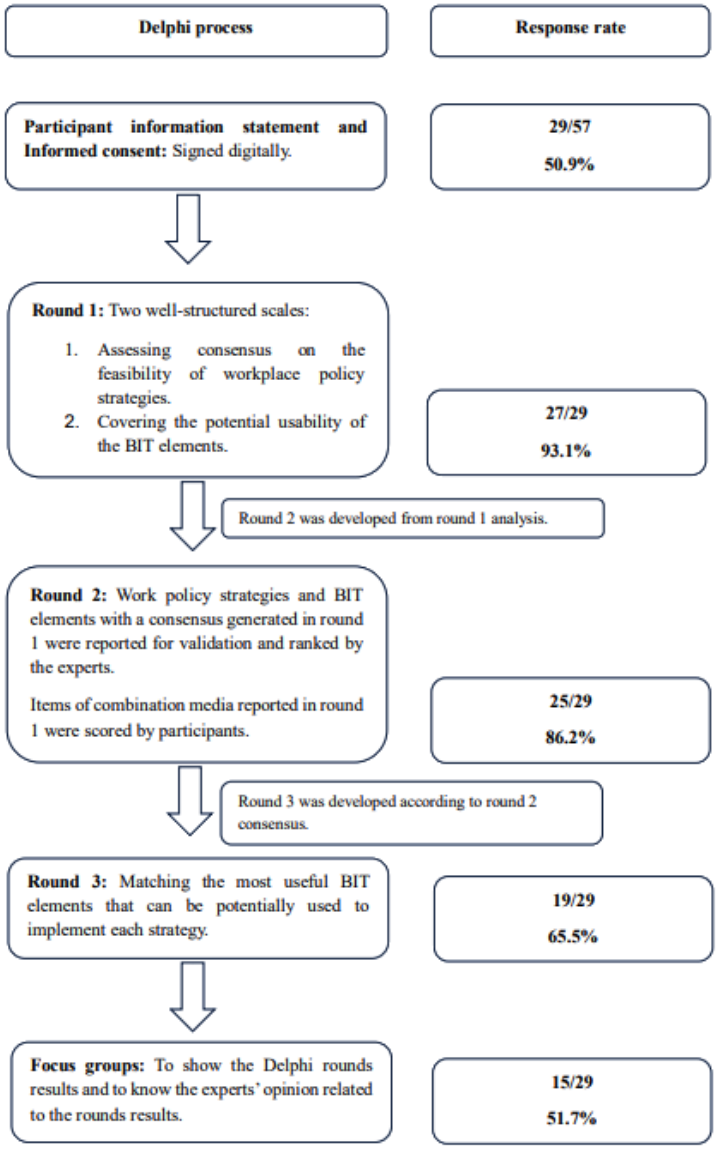
could withdraw at any time without any consequences. In compliance with ethical research practices, digital informed consent was obtained from all participants before initiating the survey. No incentives were provided to the participants for their involvement.

Participants and Recruitment

International experts (N=57) identified as leading or established researchers in the field of occupational health (with a specific focus on modification of physical activity [PA] behavior in the workplace), well-being, or computer- or desk-based jobs specialists identified by the research team were invited via email to participate. The experts were selected through a search of published articles that identified highly active authors in the field, whereas the job specialists were identified from professional networks of the involved institutions. The exclusion criterion was not being able to understand and communicate in English.

To maximize participation in the Delphi survey, a reminder email was sent within 1 week. After completing the 3 Delphi rounds, participants who signed the informed consent form for the Delphi study (29/57, 51%) were invited via email to participate in a focus group.

Procedure



Delphi Survey

Overview

In total, 3 survey rounds were conducted using the LimeSurvey software (LimeSurvey GmbH; Multimedia Appendix 1), which were piloted by 4 members of the research team to ensure the appropriateness of the questionnaire items, wording, and functionality and identify any issues or gaps. No changes in wording were made to the Delphi surveys. If participants agreed to take part, they received an automatic email with the link to the first survey. Participants had 10 days to complete each round of the survey. Individual responses were anonymized, and all participants were invited to complete the second and third rounds of the survey regardless of their participation status in the previous rounds. Attrition was prevented through a short period between rounds and by providing feedback on study findings. A summary of the entire Delphi process is provided in Figure 1.

XSL•FO
RenderX

Figure 1. Delphi process. BIT: behavioral intervention technology.

Round 1

Round 1 was carried out between January 13 and 23, 2023. Participants were provided with an explanation of the survey and were asked to provide demographic information (ie, age, gender, and employer organization). Two 9-point Likert scales were used.

The first scale assessed participants' opinions on the feasibility of work strategies (n=36) for reducing SB when working from home. The work strategies had been selected from a scoping review of the vast majority of real-life PA strategies implemented [31], a systematic review of effective digital interventions to reduce SB [21], and 2 qualitative studies that further explored the perceptions of managers and employees on the factors influencing the ability of employees to reduce their SB in a home office context [26]. The strategies were classified based on the Behavior Change Wheel (ie, environmental planning and service provision, 9/36, 25% of the strategies; regulation, guidelines, and restriction, 15/36, 42% of the strategies; and communication and social support, 12/36, 33% of the strategies) [32].

Participants were invited to score each work strategy. Scores ranging between 1 and 3 suggested a lack of feasibility, scores between 4 and 6 suggested neutral feasibility, and scores between 7 and 9 suggested high feasibility. This scoring was based on the 9-point Grading of Recommendations Assessment, Development, and Evaluation methodology [33]. The feasibility scores considered the 4 dimensions of feasibility: social validity or acceptability, integration into the existing system, practicality, and adaptability (Table 1) [34].

The second scale covered the potential usefulness of the technology-based behavior change elements according to the behavioral intervention technology (BIT) model (ie, messaging and social support [n=6 elements], push notifications [n=5 elements], information delivery [n=9 elements], report and visualization [n=4 elements], digital log [n=3 elements], and passive data collection [n=7 elements]) [35]. Scoring was based on the 9-point Grading of Recommendations Assessment,

XSL•FO
RenderX

Development, and Evaluation scale divided into 3 categories: not useful (1-3), neutral (4-6), and highly useful (7-9) [33]. Participants were also invited to provide additional items or observations through an open-ended question for each strategy or BIT element category.

Table 1. Feasibility dimensions for the strategies and the related research question for each dimension.

Dimension	Research question
Social validity or acceptability	Is the strategy appropriate, reasonable, fair, and potentially effective for home-based work?
Integration into the existing system	To what extent are the strategies aligned with the infrastructure of home office settings?
Practicality	Can the initiative be implemented using the available resources, time, training, and materials in home-work offices?
Adaptability	Is the initiative flexible enough to fit across the diverse needs of home office work?

Round 2

Round 2 started on February 6, 2023, and finished on February 16, 2023. Work strategies from round 1 were ranked based on the *highly feasible* scores for work strategies and *highly useful* scores for BIT elements. A total of 35 work strategies (rather than 36) were ranked in round 2 based on recommendations from round 1 (a similar approach was implemented for work strategies and BIT elements). In this second round, participants were asked to place each work strategy in order of preference considering the most feasible strategies to reduce SB when working from home. The same procedure was followed for the BIT elements. Additional items that appeared in the first survey were scored based on the round 1 approach (ie, the 9-point Likert scale).

Round 3

Round 3 was launched on February 17, 2023, and could be answered until February 27, 2023. According to the preferred order of the items ranked in round 2, participants were asked to match the most useful BIT elements that could potentially be used to implement each of the work strategies to reduce SB when working from home. The work strategies included in this round were those with a weight above the median.

Focus Groups

To explore in more depth the experts' opinions and understand their perspectives, focus groups took place.

Focus groups were conducted in English or Spanish by a researcher (AC or IP-S) and a moderator (IP-S, JB-R, or AMS-M) with previous experience facilitating focus groups. The focus groups were held on the web using Microsoft Teams in April 2023. The focus groups lasted a total of 60 minutes. The size of the groups was small (4 participants on average) due to scheduling difficulties and time zone differences among countries.

A guide was developed based on the 3 Delphi rounds (Multimedia Appendix 2). However, the researchers did not follow it in full detail, using the freedom to explore thoughts and ideas based on the responses from each group. First, there was a brief welcome and introduction to explain the aim of the focus group, obtain consent for the recording of the session, and introduce each participant. The results of every Delphi round were then shown. Subsequently, experts were asked about what factors they thought made some strategies more feasible than others considering the 4 dimensions (outlined in Table 1) and what factors may enhance participation among the BIT elements. The last element of the focus group covered the need for any adaptation before the implementation of the strategies in the hybrid work model. The focus groups were recorded, transcribed verbatim, and translated into English if necessary to be analyzed later.

Data Management and Analysis

Study uptake was calculated as the proportion of participants who accessed the round 1 Delphi survey to that of all potential participants identified. Retention rate referred to the proportion of completed responses for each round and participation in the focus groups. In round 1, responses to the Likert scale in the *highly feasible* or *highly useful* category (score from 7 to 9) were calculated. The median and mean absolute deviation from the median (MAD-M) for each item were also reported to assess the strength and extent of agreement. Medians of 7 to 9 were defined as strong support, medians of 4 to 6 were defined as moderate support, and medians of 1 to 3 were defined as no support. The MAD-M describes the variation in the median values [36]. In round 2, we calculated the weighted average ranking for each item to determine the most highly ranked work strategies and BIT elements for reducing SB among home office workers. The respondents' most preferred choice had the largest weight, and the least preferred choice had a weight of 1. For achieving consensus, the order-weighted average process was followed through the aggregation of the strategies evaluated in the previous round to be validated in round 2 [37]. Items that achieved consensus were those that were ranked with a weighted average above the median. The additional items that emerged from round 1 were assessed through a 9-point Likert scale in round 2, and the median and MAD-M were calculated. In round 3, the matched items for each work strategy and BIT element were reported, as well as the percentage of respondents.

The focus group analysis was conducted using the principles of reflexive thematic analysis [38,39]. First, a researcher (IPS) familiarized themselves with the data, reading and rereading carefully each transcript to obtain a general impression of the main opinion of the experts and identify repeated concepts. Subsequently, according to the subjectivity of the researcher, an initial open coding process was generated from interesting features and relevant data searching for evidence for themes, namely, patterns of shared meaning underpinned by a central organizing concept. Reflexive thematic analysis was approached

XSL•FO
RenderX

in an inductive, semantic, and realistic way. In other words, the construction of codes and themes was directed by the content of the data but not by a topic summary. Codes, concepts, and the core category were recoded and relabeled if necessary after each step until the codes provided the intended depth of the insights. The analytic outputs obtained from the codes and through the active engagement of the researcher with their data were then conceptualized in potential themes and subthemes. Finally, the themes were reviewed, defined, and named. At the end of each step, data were shared with an experienced supervisor (CV-C) for reflecting on how the data were initially coded and consider things that might have been overlooked. MAXQDA 2022 (VERBI GmbH) was used for the analysis.

To ensure a robust analytical process, we considered key aspects of quality and rigor. The first aspect was reflexivity, which involves critical reflection of researcher perspectives and its integration within the analysis and interpretation of the data to develop themes [40]. The study team comprised researchers with expertise in PA and SB in the workplace who have experienced working from home since before or after COVID-19 pandemic. IP-S, who carried out the analysis, is a Spanish physiotherapist and osteopath PhD student who has been working from home for 3 years; CV-C, the supervisor during the analysis, is an experienced nutritionist with a background in health promotion and qualitative research who has been working from home since the COVID-19 pandemic. Second, confirmability, the objectivity of the findings [41], was attained through a critical friend approach whereby an experienced supervisor reviewed interpretations and introduced alternative perspectives, increasing objectivity and confirming the accuracy of the findings. Third, dependability, the reliability and consistency of the study [41], was attained through detailed research procedures (ie, rigorous data collection techniques and well-documented procedures and analyses). Credibility was then built on the reflexivity and triangulation of the data, incorporating more than one researcher in the analysis process [42]. Furthermore, a critical friend approach was used whereby an experienced qualitative researcher, CV-C, critically analyzed the preliminary themes and ensured that the selected quotes provided support for the themes developed. Finally, transferability was enhanced through the transparent and detailed descriptions of the participants and research process [42].

Results

Participant Characteristics

A total of 51% (29/57) of the invited experts expressed their interest in participating in the study through the digital informed consent form. Of these 29 participants, 27 (93%) completed the first round, 25 (86%) completed the second round, and 19 (66%) completed the third round. Of those 29 participants, 15 (52%) joined the focus groups.

Most of the first-round Delphi respondents and focus group participants identified as women (16/27, 59% and 8/15, 53%, respectively), with 48% (13/27) of first-round respondents aged between 36 and 45 years.

A wide variety of countries across Europe were represented. However, non-European countries such as Australia (5/29, 17% of the participants) were also represented.

Delphi Survey

Feasibility of Work Strategies

Round 1

Multimedia Appendix 3 shows the results of round 1, which considered the 36 work strategies divided into 3 categories. A total of 69% (25/36) of the work strategies were ranked as highly feasible.

In total, 7 environmental planning and service provision work strategies were rated as highly feasible with strong support. Activity trackers (20/27, 74%; median 8, MAD-M 1.41); workstation accessories (19/27, 70%; median 8, MAD-M 1.59); and relocation of home office supplies such as the bin, printer, or water source (19/27, 70%; median 8, MAD-M 1.30) were the 3 work strategies considered as highly feasible for reducing SB when working from home. Active workstations equipped with treadmills were reported to be unfeasible (19/27, 70%; median 2, MAD-M 1.48).

In total, 53% (8/15) of the work strategies regarding guidelines, regulations, and restrictions were rated as highly feasible with strong support. Self-monitoring of sedentary and activity behaviors (20/27, 74%; median 8, MAD-M 1.30), substitution of sedentary tasks (eg, reading, answering a phone call, or participating in a videoconference) with standing or incidental movements (20/27, 74%; median 7, MAD-M 1.37), and creating an action plan (20/27, 74%; median 7, MAD-M 1.11) were the most highly useful. The least feasible strategy was the locking or blocking of the screen or keyboard for specific durations (11/26, 42%; median 5, MAD-M 2.19).

Regarding the communication and social support work strategies, feedback on activity progress and achievement of goals (22/27, 81%; median 7, MAD-M 1.74); providing information to increase awareness and knowledge (20/27, 74%; median 8, MAD-M 1.37); and the provision of awards, rewards, or incentives by the company to achieve goals (19/27, 70%; median 7, MAD-M 1) were ranked as the most feasible for reducing SB when working from home. Most of the work strategies included in this category (10/12, 83%) were rated by the respondents as highly feasible, and none of them were considered unfeasible. No new items emerged from open-ended questions.

Round 2

The ranking list of the work strategies with the weighted average (range 14.6-0.48) is reported in Table 2. Most items reported as highly feasible when working from home in round 1 (18/25, 72%) were scored above the median (3.64) in round 2, with the exception of self-selected reminders (3.24); active breaks such as stretching, walking, or strengthening exercises (2.36); real-time records (2.32); high or height-adjustable chairs (1.96); exercise accessories (1.52); and social networking for sharing experiences (0.48).

XSL•FO
RenderX

Table 2. Ranking of highly feasible work strategies (results of round 2).

Strategy	Weighted average score
Feedback on activity progress and goal achievement	14.6
Create an action plan—increase standing breaks or replace sitting time, how long, how often, when, and how (eg, when the phone rings)	13.04
Standing while reading, answering phone calls, or conducting videoconferences	13.04
Providing information to increase awareness and knowledge of the dangers associated with prolonged sedentary behavior and the potential benefits of reducing it or breaking it up	12.88
Self-monitoring sedentary and activity behaviors (ie, activity tracker or a diary log)	10.76
Short breaks (5-10 min) approximately every 60 min of sitting time	10.36
Scheduling (blocking) 5-10–min breaks between meetings on the calendar	8.6
Information and support about the strategies and goals and reminders	8.04
Setting tailored goals for reducing sitting time	7.24
Activity demonstrations to perform during the breaks	7.12
Height-adjustable desks or desk platforms	6.92
Relocation of home office supplies (eg, bins and printers)	6.8
Incidental moving while reading, answering phone calls, or conducting videoconferences	5.76
Awards, rewards, or incentives to achieve goals or recommendations	5.48
Standing desks	4.6
Point-of-choice or point-of-decision prompts	4.4
Workstation accessories (seated footrests, standing footrests, or sit-stand antifatigue mats for standing desks)	4.24
Motivational messages from managers	3.64
Wellness coaches supporting the employees during breaks	3.48
Self-selected reminders to achieve goals	3.24
Blocking the screen or keyboard for breaking up sitting time unless conducting a meeting	3.24
Active workstation with underdesk stepper or pedaling device	2.52
Short breaks (5-10 min) approximately every 30 min of sitting time	2.48
Team or individual activity challenges	2.4
Active breaks, such as stretching, walking, or performing strengthening exercises for ≥10 min	2.36
Scheduling (blocking) snack breaks on the calendar	2.32
Real-time records or feedback	2.32
Active lunchtime, such as Pilates, yoga, walking, or cycling	2.04
High chairs or height-adjustable chairs	1.96
Social comparison	1.68
Exercise accessories, such as rubber bands, wooden sticks, or mats	1.52
Active workstation equipped with treadmill	1.44
Short breaks (5-10 min) approximately every 40 min of sitting time	1.36
Competition among peers	0.92
Social networking for sharing experiences	0.48

Usefulness of BIT Elements

Round 1

Multimedia Appendix 4 shows the results of round 1 considering the usefulness of the BIT elements divided into 5 categories.

In total, 33% (2/6) of the BIT elements from the messaging and social support category were ranked as highly useful with strong support: social challenge features (20/27, 74%; median 7, MAD-M 1.22) and gamification (14/26, 54%; median 7, MAD-M 1.78). None of the messaging and social support items were considered not useful. Smartphone app and desktop application interfaces were identified to be the 2 most useful

XSL•FO
RenderX

BIT elements within the push notification category (12/27, 44%; median 7; and MAD-M 1.41 for smartphone app interface and 15/27, 56%; median 7; and MAD-M 1.18 for desktop application interface). The other 3 push notification elements were ranked as highly useful or neutral with medians between 5 and 6, indicating moderate support. A combination of different media was the preferred item in the delivery of information category (14/24, 58%; median 7, MAD-M 1.71), with the other elements within the category receiving moderate support and being considered neutrally or highly useful. A total of 15 new combined digital items, such as videos and images, moving images on websites, or reminders combined with social challenges, emerged from open-ended responses to the combination of media element in the information delivery category. Blending was considered more useful than isolated media. Real-time data (19/27, 70%; median 7, MAD-M 1.48) and data summaries via the app interface (14/27, 52%; median 7, MAD-M 1.67) were considered the most useful in the report and visualization category. The 2 remaining items (data summaries via email or SMS text message and websites) were ranked as neutral. The 3 most useful BIT elements to track activity were wrist-based activity trackers (17/26, 65%; median 7, MAD-M 1.69) and using a mobile phone diary (17/27, 63%; median 7, MAD-M 1.41) or smartphone sensors (13/26, 50%; median 7, MAD-M 1.61). The only element considered as not useful to track activity was waist-based activity trackers (10/26, 38%; median 5, MAD-M 1.85).

Round 2

Overall, BIT elements reported as highly useful to support work strategies were ranked at the top in each category (Table 3). In the messaging and social support category, items ranked above the median score (2.52) coincided with highly useful items in round 1 (ie, social challenge features and gamification), but chats (eg, WhatsApp groups) were added to the top of the ranking. SMS text messages were added to the 2 BIT elements in the push notification category considered as highly useful in round 1, which were scored above the median (2.00) in round 2. In addition to combination of media, videos, interfaces in smartphone apps and desktop applications (same as in the push notification category), images, and websites were among the items scored above the median (3.24) in the information delivery category. The new items that emerged from the open-ended responses in round 1, specifying potential combinations of media for information delivery described as highly useful, were a combination of mobile phone apps and desktop applications; a combination of personalized messages, reminders, and social challenges; a combination of videos, text, and images within an interactive website; and a combination of a mobile app with social media (Table 4). In the report and visualization category, the 2 items ranked as highly useful in round 1 remained above the median (2.32) in round 2. The median of the BIT elements to track activity was 3.56. In round 2, a total of 2 more items were added as highly useful to the 3 identified in round 1: leg-based activity tracker and computer software. In total, 17 BIT elements were considered highly useful in round 2.

XSL•FO
RenderX

Table 3. Ranking of highly usable behavioral intervention technology (BIT) elements (results of round 2).

BIT element to communicate information	Weighted average scores (SD)
Messaging and social support	
Social challenge features (cooperative activities, eg, reach 10,000 steps among all members of the department)	5.16
Gamification features (competition among colleagues)	4.48
Chats (eg, WhatsApp groups)	3.28
Emails	1.76
Calls	1.4
Forums	1.64
Push notifications	
App interface—text and sound and vibration in smartphones	4
Application interface—computer screen notification in desktop computers	3.08
SMS text messages	2
Chats	1.64
Emails	1.52
Information delivery	
Combination of media	7.6
Videos	6
App interface—smartphones	4.44
Images	4.36
Application interface—desktops	3.24
Websites	3.24
Emails	3.16
SMS text messages	2.36
Audios	1.44
Report and visualization	
Real-time data via app interface	2.96
Data summary via app interface	2.84
Data summary via email or SMS text message	1.8
Data summary via website	1.24
BIT elements to track activity	
Mobile phone diary (manual entry)	7.72
Web-based questionnaire (manual entry)	3.52
Computer software diary (manual entry)	1.6
Passive data collection	
Wrist-based activity tracker	8.6
Leg-based activity tracker	3.64
Smartphone sensors	3.6
Computer software	3.6
Waist-based activity tracker	3.28
Electronic workstation	3.08
Cushions on chairs	2.04

Round 3

After the description of the priorities of the expert panel, the BIT elements that were considered most suitable for implementing each of the work strategies are shown in Multimedia Appendix 5, including the 18 highly feasible work strategies and 16 rather than 17 highly useful BIT elements because social challenge features were considered within the gamification features in round 3.

The use of wrist-based activity trackers was identified as useful by 63% (12/19) of respondents for self-monitoring sedentary and activity behaviors. Using a computer software was considered useful to schedule 5- to 10-minute breaks between meetings (9/19, 47%), whereas a desktop application interface was considered useful to support strategies such as short breaks every 60 minutes of sitting time (6/19, 32%). Videos were described to be useful when delivering activity demonstrations to perform during the sitting breaks (9/19, 47%). Other BIT elements identified were gamification features, such as social challenges, which are used for providing awards and rewards and offering incentives (8/19, 42%). However, setting tailored goals (8/19, 42%); creating an action plan (6/19, 32%); standing while reading, answering calls, or conducting videoconferences (6/19, 32%); providing feedback on activity progress (4/19, 21%); and motivational messages (4/19, 21%) were mainly recognized to be best delivered through a smartphone app. Providing information and support was considered to be best delivered through a combination of media or a smartphone app (5/19, 26% each). Combination of media was also chosen by most of the respondents as the most useful mode for providing information to increase awareness and knowledge (5/19, 26%) and for promoting incidental movement (3/19, 16%).

XSL•FO
RenderX

Environmental strategies such as height-adjustable desks (11/19, 58%), relocation of home office supplies (5/19, 26%), standing desks (9/19, 47%), and workstation accessories (9/19, 47%) did not correspond with any BIT elements according to most of the respondents. For point-of-choice or point-of-decision prompts, there were no corresponding BIT elements to support their implementation according to most of the respondents for this strategy (4/19, 21% of the sample), although 16% (3/19) considered that this strategy could be delivered via computer software.

Focus Groups

Overview

A total of 2 indicative themes were generated from the analysis of the focus groups regarding the experts' perceptions in relation to the Delphi results on the potential feasibility and usefulness of strategies and digital elements to reduce SB in a home office context. The first theme referred to the integration of the digital strategies for reducing SB when working from home, which included 3 subthemes: social influences, physical environment, and individual factors. The second theme was related to the adaptability of the strategies to reduce SB in the office and home context.

Theme 1: Integration of the Digital Strategies for Reducing SB When Working From Home

Overview

This theme involves the importance of combining multiple levels of strategies to facilitate and maximize the strategies' implementation and their effectiveness in reducing SB when working from home. According to the experts, while organizational-level factors such as organizational support or policy changes may not be immediately feasible on their own, they are essential for achieving sustainable change. The same was considered true for information provision—it alone is not enough to motivate behavior change, although it is an important factor at the individual level to increase individuals' knowledge. In addition, environmental changes are required to promote less sitting and more movement during working hours. Therefore, experts highlighted that the following implementation levels need to work in tandem to achieve sustainable behavior change.

Social Support

Experts explained the need for the company to support the culture of active and healthy workplaces to motivate the employees' behavior change. Social support may be achieved by aligning the company policies and culture with the support of the manager (eg, motivational messages) to be able to increase the integration of digital strategies for reducing SB when working from home:

> *[I]t is based on what the management or the philosophy of the company or the company policy wants to refer to their workers. If those at the top are not proactive in...the chain, it will decrease.* [E13; focus group 4; paragraph 43]

While the target behavior is contextualized within the domain of working from home, participants identified interaction with colleagues as a relevant factor to motivate employees toward behavior change. For example, social modeling may motivate home office workers to reduce their SB by sharing activities around the sitting time breaks. However, social interaction can be perceived negatively if a competition component is present in the strategies. This may be due to competing against people whom they do not know or due to the bottom position of some workers during the challenges. Therefore, cooperative challenges may be the solution, in which every worker contributes to the challenge without a competition element:

> *[W]hen people find themselves in an environment where they've got to adapt behaviourally, seeing what can be done and observing how others might do it, can be quite powerful...we are social animals, monkey see, monkey do and that social modelling element to me jumps out as really quite important and not to be lost.* [E01; focus group 1; paragraph 44]

Physical Environment

The home office context was seen by some participants as a limiting factor in engaging in sufficient PA during work hours due to the reduced space compared to the office context. For example, having (normally) no more than 1 floor at home, implying the use of stairs, or the lack of large spaces for walking are barriers to be active while working at home. Although applying physical changes such as standing desks may be a solution to break up sitting time at work, it appears to be a less feasible strategy in the home office context due to the expensive cost for the companies:

> *I'm a big advocate of standing desks, standing workstations in terms of being effective but I appreciate that in this situation it's probably not feasible for them to be incorporated in the home-office.* [E10; focus group 3; paragraph 7]

Nevertheless, experts highlighted the importance of combining these environmental changes with prompts or reminders for the success of the behavior change integration when working from home. Regarding point-of-decision prompts, experts highlighted that mobile phone notifications were more feasible for reducing SB than desktop notifications because they cause less disturbance:

> *[W]hen we moved into our new offices a few years ago, we all got standing desks and just observing...I don't see anybody using. So, if there's something for me in there about prompting/reminders, do you know?... So, I think the prompting is really important.* [E011; focus group 3; paragraph 11]

Individual Factors

Experts mentioned the difference in literacy between *PA* and *sitting time*, believing that workers may understand the term *PA* more easily than the term *sitting time*. This may be due to the lack of knowledge on the importance of reducing sitting time behaviors, which could be perceived as a barrier when only reporting sitting time feedback. Therefore, educational material or information, one of the highlighted strategies to be used together with social support and physical environment strategies to achieve SB reduction when working from home, delivered through a combination of media (ie, smartphone, desktop, and

XSL•FO
RenderX

websites), was considered the most adaptative medium to increase the employees' knowledge. Experts emphasized that the information delivered must be simple and short, especially with the use of videos:

> *I think the combination of media is probably the way forward because I guess different organisations will also have different ways of rolling out information. I know a lot of companies nowadays that they all have their own company app, and they do a lot of communication via their app that all their employees have access to.* [E10; focus group 3; paragraph 42]

Furthermore, feedback on the respondents' own behavior was identified as a key strategy to motivate individuals and achieve behavior change. The best frequency at which to deliver feedback could be in real time as this adapts to each individual's schedule. However, a daily summary feedback approach was also considered helpful in combination with real-time feedback:

> *For the summary—daily maybe? But I probably go for the combination of the two, so you probably have some sort of summary data to share with them but still, it's nice to see at the moment what you did.* [E05; focus group 2; paragraph 67]

Theme 2: Adaptation to the Home Office Environment

This theme refers to the flexibility of the strategies to fit the diverse needs of hybrid work. All the experts mentioned the capacity of the strategies to be adapted to all environments without the need to be changed to fit in the home or office context:

> *I think you want to have the same or approach or whatever you use for say, remote working, I would also use for hybrid working because I guess a lot of strategies are going to be the same...So, I think you could maybe just replicate or duplicate what you're doing here for the hybrid workers.* [E10; focus group 3; paragraph 64]

However, some strategies need to be adapted to each individual depending on the type of work they perform. For example, walking while on a call may be a good strategy for a call center, but it might not work in another type of job. Therefore, it is valuable to provide different strategies to allow everyone to choose their preferred one to change their behavior:

> *[D]ifferent populations need a different approach, right? So very much dependent on the type of work that people are doing, you're going to have to approach them differently. So, the task set is going to help determine what options you actually have to still do your work but would be doing it sitting down all the time.* [E05; focus group 2; paragraph 29]

Therefore, experts highlighted the importance of providing a list of strategies that can be adapted to employees' needs for reducing sitting and moving more during their working hours:

> *So instead, you look towards providing a menu of strategies that you know are effective or have at least been shown to be feasible and acceptable and not shown to have any harm and you know, have benefits maybe in terms of cultural elements of it and that a lot of those would be applicable for the home environment but would also be applicable obviously for the workplace environment.* [E02; focus group 1; paragraph 65]

Summary

In general, no dissonance was found among the responses of the different experts. Strategies such as feedback, social modeling, breaks every hour, prompts via mobile phone every hour, educational material, and organizational support (eg, motivational messages) were the most discussed and considered the most feasible. Other strategies such as physical changes (ie, height-adjustable desks) were considered unfeasible despite being ranked higher in the Delphi rounds. Finally, although certain strategies such as the creation of an action plan, standing while reading and answering calls, blocking 5 to 10 minutes between meetings, or setting tailored goals for reducing sitting time obtained high scores in the Delphi rounds, these topics were discussed less among the experts during the focus groups.

Discussion

Principal Findings

This study achieved international expert consensus on 18 potentially feasible work strategies to reduce home office SB delivered through 16 potentially useful digital elements. These results seem to be transferable to both office and home settings based on experts' responses. Moreover, the experts highlighted the importance of multiple factors (ie, social, individual, and environmental) working in tandem to facilitate and maximize the strategies' implementation, as well as to achieve behavior change.

Comparison With Prior Work

Wrist-based activity trackers were identified by most of the experts (12/19, 63%) as useful for self-monitoring activity and SB. Previous research has highlighted the feasibility and usability of these devices for self-monitoring SB as well as workers' acceptability of these approaches in the office context [43,44]. In addition, these strategies have demonstrated effectiveness in reducing SB in such settings [44]. Some studies have highlighted limitations in recognition of postures and step detection when using wrist-based devices compared to leg-based devices [45-48]. However, few experts considered leg-based activity trackers for self-monitoring activity and SB due to the discomfort they may cause. This suggests that future interventions incorporating activity trackers with the aim of reducing SB should first validate the devices for their subsequent implementation and effectiveness evaluation in home office settings.

In the literature, computer visual feedback on activity patterns is considered to be an enabling factor for increasing motivation and awareness among office workers [49]. However, experts preferred smartphone apps as they are able to provide real-time feedback on activity progress. In addition, feedback may be an indication of progression toward a defined goal [43]. In this study, experts stated that smartphone apps could be a useful tool for setting tailored goals. Evidence has demonstrated the

XSL•FO
RenderX

effectiveness of smartphone apps in reducing SB and promoting PA in office settings [16]. Hence, smartphone apps may be a potential mode of delivery for setting tailored goals and providing feedback on the move, which should be evaluated in future home office environment interventions.

Previous research has demonstrated that short activity breaks (ie, walking) every 30 minutes result in reductions in office SB time [50] but also in reductions in fatigue and improvements in energy and mood [51]. However, in this study, experts considered breaks every 60 minutes more feasible. According to recent literature, a possible explanation may be related to the fact that workload and time pressure were identified by employees as the most common barriers for reducing and breaking up SB [52], making it difficult to stop more frequently. Moreover, replacing SB with active working tasks (eg, incidental moving while reading and answering calls) may overcome these barriers [49]. Working remotely increases opportunities to perform active tasks or even other light-intensity PA that may increase the potential benefits of reducing SB and its harmful health effects among office workers [9,10,53]. Experts reflected on the importance of providing clear instructions and modeling through video demonstrations as a key digital element to enhance active breaks among employees when working from home. This may have implications for future studies evaluating the most effective active break duration through video demonstrations and the implications of these breaks regarding SB time and its health effects in home office contexts.

On the basis of experts' responses, there is a literacy gap between the terms *PA* and *SB*, with activity trackers largely focused on PA instead of SB [52]. Therefore, educational material may be a key aspect to increase knowledge for behavior change and reduce the lack of understanding of SB and its subsequent health implications, which was highlighted by experts. Educational material is an essential and effective strategy for workers to increase awareness of SB's health consequences [52,54]. In our findings, a combination of media was preferred to deliver information to increase awareness and knowledge. Therefore, it is recommended that future studies include educational material to increase knowledge and awareness among home office workers.

Despite the relevance of knowledge and awareness to achieve behavior change, social and organizational support is a factor noted by workers in the current literature for facilitating and encouraging movement in the workplace [55-57], as well as by managers in the home office setting [26]. Home office work is more related to negative emotions than office work due to the isolation and loneliness; therefore, social support is even more important in this context [58]. Gamification features, including social challenges, were identified as a useful digital element to deliver strategies such as awards, rewards, or incentives to achieve goals or recommendations for reducing SB among home office workers. This strategy could provide social support and motivation. Motivational messages from managers are also an organizational support strategy, which experts suggest could be delivered through smartphone apps. Thus, future studies should evaluate the acceptability of these social and organizational strategies among both managers and employees, as well as their effectiveness in the home office context.

Environmental work strategies such as standing desks, height-adjustable desks, or workstation accessories were mostly not matched with any digital element. Moreover, experts recognized work strategies such as height-adjustable desks as unfeasible in the home office environment, primarily due to the associated costs. Recent evidence has demonstrated the high cost of such desks (eg, standing desks or height-adjustable desks) compared with nondesk interventions [59]. Workstation accessories (eg, desk platforms) or relocation of office supplies are less expensive strategies [60] that were deemed more feasible and usable by experts and may be implemented in home office settings. Therefore, home office interventions may include environmental work strategies in a similar way to office interventions but with a lower associated cost.

On the basis of the findings presented in this paper, physical environmental strategies need to work in tandem with social support and individual strategies to achieve behavior change. A recent systematic review showed that theory-based interventions, a relevant step in multicomponent intervention development [25], that include social, physical, and individual elements are more effective than non–theory-based interventions [21]. Furthermore, stakeholder engagement (eg, consultation or coproduction among researchers, experts on the topic, and the target population) should be encouraged throughout the development process [25]. Recent studies have highlighted the need for a top-down approach whereby managers should provide support to employers [26]; hence, the implementation of strategies should be an organizational initiative. Although evaluating effectiveness on outcomes has traditionally been the primary focus of interventions in this discipline, in particular to encourage their adoption in the real world, the feasibility, acceptability, cost-effectiveness, and scalability of interventions is increasingly important to ensure the translation of findings from research to practice [25,61]. This study provides new insights for future research on the design of home office interventions aimed at reducing SB based on the learned experiences of occupational health experts. However, we were not able to cover the entire audience's perspective, so new qualitative studies exploring the perspectives of different stakeholders (eg, end users) may further inform about the feasibility and usability of digital workplace strategies.

In addition, experts considered that no adaptations would be needed to transfer these home office strategies to hybrid work, the current modus operandi for many desk-based workers. However, the experts who participated in this study were mainly from high-income countries; therefore, such perceptions may vary among people from other regions. Hybrid work presents opportunities for promoting PA by providing flexibility to integrate occupational, leisure, lifestyle, and incidental activities [9] but also for improving health and well-being [62]. Hence, the results of this study may be transferable to hybrid work in high-income countries, whereas hybrid work should receive greater consideration in future interventions given cultural variability.

Strengths and Limitations

The main strength of this study is the novelty of the home office context to deliver strategies for reducing SB through digital

XSL•FO
RenderX

elements. The fact that focus groups were conducted after a Delphi study enabled us to elicit additional views and opinions on the Delphi results from the experts' perspectives, consolidating the consensus. Nevertheless, we did not share the analytical categories, interpretations, or conclusions from the thematic analysis with the experts, which may affect the analysis's credibility. The entire study was conducted in a rigorous manner, with high participant response rates and representation from international experts. However, some strategies may have been overlooked due to the nonsystematic search approaches used, and most of the international experts were from high-income countries, limiting the applicability of these findings to those communities. Some other limitations were present in the study. First, despite the rigor in the methodology used to engage experts, not all responses were complete, meaning that data were sometimes missing from some questions. Second, as is the case in any Delphi survey, the data gathered were based on subjective opinion and the expertise of the participants. Third, experts acted as representatives of the stakeholders; thus, the inclusion of other stakeholders such as end users would also have been important to address other, more diverse perspectives.

Conclusions

This study presents the consensus of international experts on feasible work strategies and useful digital elements as a mode of delivery of these work strategies to support the reduction in SB in home office or hybrid contexts. Consensus was achieved on 18 work strategies and 16 BIT elements. Future interventions should implement and evaluate the effectiveness of these strategies but also their feasibility and acceptability in home office settings.

Abstract

Background: Chronic insomnia, or insomnia disorder, is a major health issue with a prevalence of up to 15%. The recommended first-line treatment is cognitive behavioral therapy for insomnia (CBT-i), which, unfortunately, remains insufficiently accessible. Digitalization has the potential to reduce health care access inequalities by offering more flexible and accessible care options. Digital CBT-i (dCBT-i) has been shown to be as effective as in-person CBT-i, highlighting its potential for broader implementation.

Objective: This study aimed to develop an evidence-based dCBT-i program grounded in theoretical and clinical knowledge, designed for efficient integration into health care systems, and to establish it as the first prescribed digital treatment in France.

Methods: The program was constructed based on validated CBT-i theory and practice, incorporating the latest scientific data on CBT for insomnia. It was designed as a robust multicomponent therapy, integrating an initial standardized assessment and daily intelligent adaptation to enable digital phenotyping and provide personalized treatment.

Results: We developed an innovative digital solution that combines scientific rigor with practical application. The program includes a standardized initial evaluation and dynamic personalization through intelligent algorithms. These features allow for the adaptation of therapy based on patient progress and needs, ensuring individualized care.

Conclusions: The development of this dCBT-i program represents a significant milestone in digital health care, offering a scalable solution to the accessibility challenges of traditional CBT-i. Future steps involve conducting clinical studies to further evaluate its effectiveness and optimize its implementation within health care systems.

Introduction

Insomnia is a major health complaint, with a prevalence up to 50% in primary care patients undergoing current treatment for either independent insomnia or insomnia comorbid with another disease, posing a risk of worsening comorbid medical conditions without addressing insomnia [1]. Chronic insomnia, or insomnia disorder, has an estimated prevalence of approximately 9% to 15% based on criteria from the Diagnostic and Statistical Manual of Mental Disorders (Fourth Edition; DSM-IV) and the International Classification of Sleep Disorders [2]. Moreover, insomnia affects 85% of patients with a mood disorder during depressive phases, and more than one-half of the patients will retain insomnia symptoms after remission [3,4]. Insomnia disorder is defined by sleep dissatisfaction for at least 3 months and 3 nights per week despite adequate opportunity for sleep, with difficulty initiating sleep, maintaining sleep continuity, early morning awakening, or poor sleep quality and with daytime dysfunction and significant impairment in areas of functioning [5,6].

The latest European Insomnia Guideline suggests that cognitive behavioral therapy for insomnia (CBT-i) is the reference and first-line treatment for insomnia disorder, with sustained improvements over time [7], and multicomponent CBT-i is strongly recommended [8]. Another important aspect of recent research involves distinguishing between response and remission rates. Response is typically defined as a significant reduction in Insomnia Severity Index (ISI) scores, while remission is generally defined as achieving a final ISI score ≤7. Studies have shown that 70% to 80% of patients respond positively to CBT-I, with about 50% of patients showing a clinically meaningful reduction of symptoms, while remission was attained by approximately 40% of patients receiving CBT-i and outcomes were often improved at the 6-month follow-up for both response and remission [7,9-12]. In addition, patients who do not respond well to CBT-i often have insomnia associated with a mood disorder and with insomnia complaints often masking disruptions in the biological clock or a state of “hyperarousal” [1,7,13]. However, CBT-i has been shown to be effective in treating insomnia comorbid with a mood disorder [14] and to also have an effect on psychiatric symptoms comorbid with insomnia disorder [15,16], and mindfulness techniques (often integrated into the emotional regulation component of CBT-i) were found to reduce hyperarousal [17-20].

CBT-i has largely been proven effective but is not sufficiently accessible as they are too few CBT-i therapists available and the treatment can be expensive [7,21-24]. Digital CBT-i (dCBT-i) could make treatment more accessible. Digitalization of CBT-i was first proposed in the 1990s, and the first proposal to introduce dCBT-i into the health care system as a preliminary step before in-person orientation was made in 2009 [25]. There are now numerous programs with proven efficacy and technological advances that allow for adaptation and personalization of content, while some obstacles still reside, including patient adherence and the perception of individualization [21-24,26-28]. Some programs are fully automated, while others are guided (mixing human and digital interaction) or only used as a tool to support in-person care [29].

To make CBT-i more accessible, fully automated treatments seem to be more relevant, but they are considered less engaging and associated with poorer adherence. The latest technological advances, encouragement for therapeutic adherence, and digital phenotyping to create a sense of treatment personalization should allow innovative, fully automated programs to be as engaging as in-person care [21-24,26-28,30]. dCBT-i has already been proven effective at reducing insomnia severity, with many studies reporting significant reductions in ISI [31] scores after treatment compared with control groups. For instance, a study reported an average difference in ISI score of 7.6 points, while a meta-analysis of 33 randomized controlled trials (RCTs) found a mean difference of 5.0 points between treatment and control groups [32,33]. dCBT-i was also found to have a significant effect on quality of life and cognitive functions, and efficacy was also demonstrated for mild insomnia or insomnia comorbid to a mood disorder [34-38]. dCBT-i was also found to have a reducing and protective effect on comorbid psychiatric symptoms [39-44] and a preventive effect on sleep disturbances after a stressor such as during the COVID-19 pandemic [45].

Digital interventions could significantly reduce access inequalities by introducing less stigma, being more flexible, and being less expensive for the patient than in-person therapy [23,34,46]. dCBT-i could then be a perfect solution to the challenge of access, as it was proven to have the same efficacy as in-person CBT-i. As highlighted in a recent meta-analysis, dCBT-i may be a viable alternative when in-person care is not available [47]. However, some issues still remain. First, many interventions exist, but less than 15% of the available “care apps” are based on strong theoretical models [23,48]. Second, adherence is an important challenge with this type of care, as less than 30% of users participate in digital programs in their entirety [30,49,50]. Finally, evidence-based, valid programs are not always made available to the public, as they must be implemented in the health care system [51].

In this context, our goal was to describe the 2-year development of an evidence-based digital program that could retain CBT-i efficacy while being accessible, engaging, and ready to be implemented in the French health care system, as already accomplished in other countries [52,53]. We further sought to develop an innovative digital solution grounded in the latest scientific data on CBT-i, with a robust multicomponent therapy approach. This solution integrates an initial standardized assessment and daily intelligent adaptation, where digital phenotyping and algorithms adjust the treatment based on daily monitoring of the patients’ behaviors, optimizing the treatment in real time and providing personalized solutions. This cutting-edge treatment is grounded in the latest scientific data and uses technological tools to offer individualized and evolving treatment based on a robust standardized assessment of the patients’ sleep complaints. Furthermore, algorithmic possibilities and artificial intelligence (AI) should allow the treatment to evolve continuously and adapt to the changes in the patients’ daily lives, making the treatment even more patient-centered and tailored to its specific needs than most traditional CBT-i protocols.

XSL•FO
RenderX

Methods

Program Overview

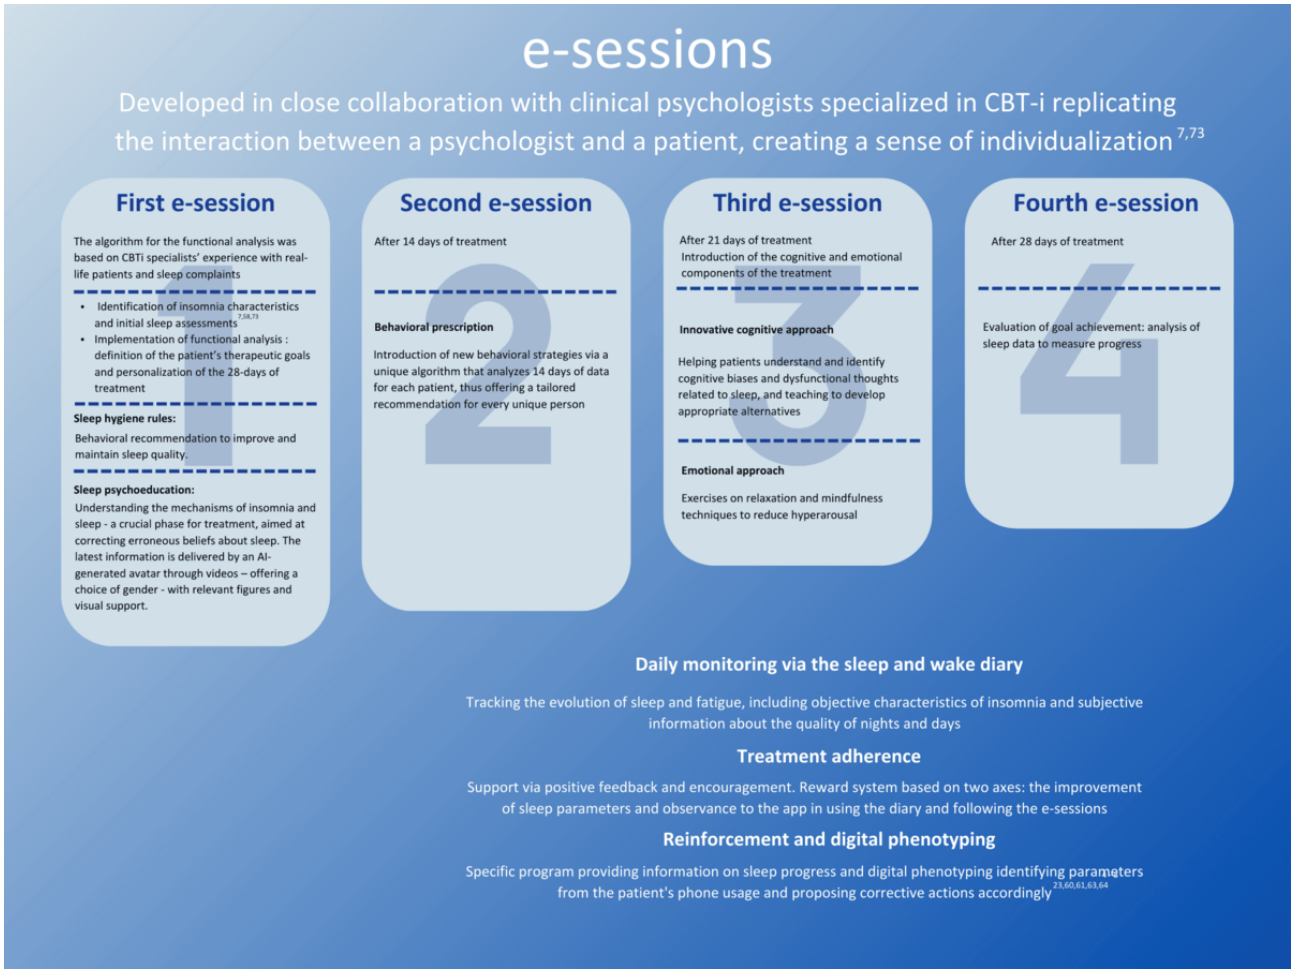
We developed a digital program tailored for French patients diagnosed with insomnia disorder by their medical practitioner, integrating data from the evidence-based CBT-i literature, user research, and clinical expertise. The development process followed the latest guidelines provided by various authors specializing in digital intervention issues and the treatment of insomnia disorder [7,8]. To make the app useful and safe, we followed the ASPECTS (Actionable, Secure, Professional, Evidence-based, Customizable, Transparent) guidelines and the various steps used in evaluating an app [54].

Our method should allow prescribers to integrate into their care useful data and information about their patient from our intervention such as a sleep diary and daily patient habits.

The French guidelines for safety and privacy were followed, and the data will be secured and protected according to those guidelines.

Various experts (eg, legal advisors, scientific and medical professionals, sleep practitioners, psychologist specializing in CBT-i, digital and user experience design specialists) whose credibility and capability were assessed were included in the process.

We conducted a deep literature review, and the entire program was based on CBT-i as described in the literature. In addition, dCBT-i is already evidence-based [7].



The program is flexible and adaptable to its users, and the app should be easy enough to be engaging, which will be determined though user research and planned studies. The program provides transparency to users about how it works and collects data. Electronic sessions (e-sessions) mimic real-life CBT-i consultations where the patient is introduced to fundamental tools and information, and every recommendation is explained well to the patient in order to develop good treatment adherence.

The program was built according to known psychological models of change in order to “reflect the psychological chronology of the change process” [55].

Finally, the program is personalized for each patient using numerous tests and algorithms, which define a tailored treatment pathway for the patient's insomnia.

The digital medical device Noxxea will undergo clinical validation to demonstrate its effectiveness and safety of use with patients with insomnia. The method incorporates traditional pillars of insomnia management through several e-sessions designed to replicate the interaction between a psychologist and a patient (Figure 1).

Figure 1. Key components of the digital insomnia treatment program. AI: artificial intelligence; CBT-i: cognitive behavioral therapy for insomnia; e-session: electronic session.

XSL•FO
RenderX

The first e-session involves identification of the patient's insomnia characteristics and initial sleep assessments, based on the requirements of an in-person clinical evaluation and traditional theoretical models of insomnia [7,56]. Implementation of functional analysis involves personalization of a 28-day treatment based on this analysis and defining the patient's therapeutic goals. The algorithm was based on CBT-i specialists' experience with real-life patients and sleep complaints.

Daily monitoring via the sleep diary includes use of the sleep and wake diary. The diary tracks the evolution of sleep and fatigue, including objective characteristics of insomnia and subjective information about the quality of nights and days.

Sleep hygiene rules include behavioral recommendations to improve and maintain sleep quality.

Sleep psychoeducation helps to understand the mechanisms of insomnia and sleep. This is a crucial phase for treatment, aimed at correcting erroneous beliefs about sleep. The latest information is delivered by an AI-generated avatar in videos with relevant figures and visual support.

The second e-session (after 14 days) is the mid-treatment assessment, which evaluates the first 14 days of treatment. The behavioral prescription introduces new behavioral strategies via a unique algorithm that analyzes 14 days of data for each patient, thus offering a tailored recommendation for every unique person.

The third e-session (after 21 days) involves cognitive and emotional restructuring. Although this approach is quite rare in digital formats today, it remains essential for CBT-i. Thought management was finally made possible in dCBT-i through a specific module based on Beck's cognitive restructuring techniques [57]. It enables patients to understand cognitive biases and dysfunctional thoughts, identify automatic thoughts related to sleep, and learn to respond to them with appropriate alternatives. Another module offers exercises on relaxation and mindfulness techniques to reduce hyperarousal.

The final assessment (after 28 days) evaluates achieved goals, including an analysis of sleep data to measure progress.

To ensure adherence to treatment, a reward system was developed based on 2 axes: improvement of sleep parameters and adherence to entering the agenda and e-sessions in the app.

Regarding reinforcement and digital phenotyping, throughout the treatment, the patient receives reinforcement through a specific program providing information on sleep progress, thus facilitating engagement. An essential aspect of the app is the use of digital phenotyping, which identifies parameters from the patient's phone use and proposes corrective actions accordingly.

The inclusion of digital phenotyping is a key element of the method that allows for further adaptation and personalization of treatment and makes it as close to in-person care as possible. In 1982, evolutionary biologist Richard Dawkins highlighted the arbitrary nature of many phenotypic delineations and introduced the concept of the "extended phenotype" [58]. This concept suggests that phenotypes should include all effects a gene has on its environment, not just biological processes like protein biosynthesis or tissue growth. Both animals and humans modify their surroundings, and these modifications, along with associated behaviors, are expressions of their genomes, forming part of their extended phenotype. Dawkins used the dam-building behavior of beavers as an example of an extended phenotype. With the increasing integration of personal technology into human lives, a novel concept called digital phenotyping was introduced in 2015 by Jain et al [59] and further developed by Torous et al [23,60,61] in psychiatry. Digital phenotyping involves real-time collection of data and markers of human behavior to identify the "digital signature of a pathology." It assumes behaviors can be quantified through data from connected tools like smartphones, digital sensors, and wearable devices to derive an "e-semiology" [62]. Two types of data are considered. "Passive" data are automatically collected in real time without user input, using tools like accelerometers and GPS to detect psychomotor retardation or motor agitation. Deviations in GPS coordinates from typical travel patterns, such as reduced activity, increased time spent at home, or chaotic journeys to unusual locations, may indicate pathological behaviors. Mobile phone–based sensing software measures heart rate, heart rate variability, galvanic skin conductance, and blood pressure, which are regarded as potential biomarkers of certain psychiatric conditions. Supplementing this with "active" data is essential, as metrics like screen time, number of calls, and usage hours provide valuable indicators of psychosocial functioning [23,60,61]. Additionally, analyzing language (verbal and paraverbal) and emotional arousal offers insights into the valence of messages during social interactions, indicating the user's mood and mental state. Digital phenotyping can also help minimize cognitive biases, such as confirmation or self-serving biases, by collecting objective information through passive data, for instance. This approach is highly promising for mental disorders and allows for optimal therapeutic personalization, almost in real time, and enables the enhancement of patient empowerment [63,64].

Noxxea Development

Several steps described here were carried out to create this innovative solution based on the latest scientific data.

Treatment development was first discussed with experts in the field in order to take patient needs into account from the beginning. As a result, there was a dynamic interplay between scientific research and product development.

An acceptability study validated certain ergonomic aspects of the app and the usefulness of generative AI for sleep solutions (M Villechevrolle, unpublished data, May 2025). A study involving 582 users was conducted to gather their concerns and feedback. It used the script method, allowing for both qualitative and quantitative analysis of user reactions. The findings were then integrated into the ongoing development of the app to enhance user trust and ensure data privacy.

The most important aspect of the development was to remain as close to in-person treatment as possible.

Translating CBT-i into a digital format requires maintaining the relational aspect of therapy. Indeed, in psychotherapy, a

XSL•FO
RenderX

form of therapeutic alliance is essential, and it is not yet fully known how that translates to a digital program [30]. Flexibility and personalization of treatment seem fundamental—for instance, dCBT-i with a therapist or direct context with a practitioner or therapist-guided dCBT-i had greater effects on sleep parameters and treatment adherence than dCBT-i without a therapist [38,65-67]. Programs are effective even without support, but better results with digital programs are found when the users have a sense of support and individualized care [22,68-71]. This may also help explain why a recent network meta-analysis of various CBT-i delivery methods found that both guided and unguided dCBT-i achieved medium effect sizes, while smartphone-based CBT-i did not show significant effects compared with the control group [7,47].

Therefore, a significant effort was made to develop a form of communication within the app that was as close to an in-person consultation as possible. The participant can choose the avatar's gender, and support is offered through positive feedback and encouragement via the app. A reward system was developed to engage the patient and help him or her identify changes and improvements. Every item of text and dialogue was written by clinical psychologists specializing in CBT-i in the same way a therapist would talk to his or her patient, and the e-sessions were developed to recreate a sense of individualization and the 4 to 8 validated sessions of CBT-i [7,72].

Nonetheless, we prioritized chronobiological regulation with emotional and cognitive aspects to stay true to the description and validation of CBT-i in the literature, which does not require the same relational demands in terms of therapeutic alliance as in-person psychotherapy (which typically requires a higher number of sessions and is often more suitable for resistant insomnia). The program was thus developed according to the components described in sleep recommendations and many studies using this form of treatment for sleep disorders [7,72,73].

Psychoeducation and Sleep Hygiene

The program must address the sleep hygiene "rules." Therefore, explanations about recommendations, habits, sleep functioning (roles and functions as well as circadian patterns), and changes in sleep patterns across the lifespan are given and integrated into the treatment.

Behavioral Treatment

A sleep calendar is introduced at the beginning of the treatment to collect at least 10 nights of sleep data in the first 2 weeks of treatment, allowing the calculation of individualized sleep parameters and habits. Sleep restriction and stimulus control are the main behavioral strategies used in the program. These components were developed in close collaboration with the scientific committee and translated into a digital format within the app in accordance with established CBT-i guidelines. Sleep restriction is thus personalized for each patient according to an individualized sleep calendar, and stimulus control is personalized using patient-reported data, the chronotype, and routines assessed at the start of the program. Personalized video content targeting chronobiological rhythms and behavioral habits further supports the tailoring of treatment to each patient's specific needs.

Relaxation Component

Many different relaxation strategies as well as mindfulness meditations are introduced within treatment as ways to reduce somatic tension, arousal, or intrusive thoughts. Patients are encouraged to explore them during their treatment.

Cognitive Component

Cognitive strategies are introduced as ways to identify and challenge misconceptions and faulty beliefs about sleep and state during the day. Patients are introduced to the concepts of cognitive control at bedtime and cognitive restructuring to learn to challenge thoughts. They are encouraged to explore these strategies within the framework of behavioral change.

Developing this program was challenging due to the need to incorporate sleep medicine recommendations using a digital intervention while designing it to closely resemble an individualized care format. The presented treatment not only offers sleep education, which is predominantly present in therapeutic education programs in institutions or digital platforms, but also integrates an individualized functional analysis adapted for digital use. It guides the patient toward a form of cognitive therapy similar to that provided in CBT-i treatment.

Results

The Noxxea program is now fully developed, and several steps are planned for its clinical evaluation, including an RCT scheduled for 2025 that will evaluate the program against a waiting list control group.

Digital Phenotyping Research

Collaboration with the mathematics department at the Pasteur Institute and the Institut National de la Santé et de la Recherche Médicale (INSERM) research laboratory (Decision and Bayesian Computation, Computational Biology & Neuroscience Department, Centre National de la Recherche Scientifique [CNRS] Unité Mixte de Recherche [UMR] 3571 – Jean Baptiste MASSON) will allow analysis of data to enhance the treatment's algorithms and improve efficacy at predicting and preventing insomnia relapse. This work will mainly focus on digital phenotyping: Approximately 50 data points will be collected and analyzed to aid with the detection, prediction, and prevention of chronic insomnia relapses. The digital phenotyping initiative is central to the innovative dCBT-i and has the following 3 main objectives: validate the initial selection of the 4 key tracking data points chosen for the first version of the treatment; analyze and evaluate the 70 passive and active data points collected to determine interaction models that enable detection of symptoms, prediction, and prevention of insomnia relapse, as well as the isolation of additional data that could enhance the efficacy of a new version of the treatment and improve adherence; and test a second version of the treatment by validating the selection of new tracking data points.

Effectiveness of Real-World Implementation and RCT

We will evaluate the efficacy and compare it with that of in-person CBT-i in the same population. The WHAT (work,

XSL•FO
RenderX

help, accessible, trusted) criteria can be used to evaluate a digital intervention, and we will need to evaluate the following [51,74]:

- Work: To evaluate efficacy, we plan to conduct an RCT.
- Help: A clinically significant effect in the target population would help conclude that it can be a useful addition to in-person CBT-i.
- Accessible: Technical quality will be continuously assessed (by professionals and users).
- Trusted: Risk management and adherence to national and international standards and guidelines will be assessed and continuously updated to the latest requirements.

Discussion

This dCBT-i treatment is built according to European recommendations and guidelines and follows closely what is done in person. The goal is not to replace in-person care but to offer an alternative when in-person care is not available given that not all individuals with insomnia disorder can receive the recommended treatment in France. Ideally, it will be covered by the national health insurance system as it is a first-line medical treatment for a major health issue.

The digital form of insomnia disorder treatment incorporates validated and recommended behavioral, cognitive, and emotional techniques for insomnia, closely mirroring the CBT-i treatment offered traditionally while being even more tailored to patients' individual needs. It is meant to be a medical treatment prescribed by a health care professional following an evaluation and a precise diagnosis, addressing the dual challenge of considering therapeutic adherence and support in its development while individualizing the behavioral and cognitive components of the treatment for greater effectiveness. The innovative program presented here followed those demands, as well as safety and security guidelines for digital health interventions while being grounded in the latest technological advances and scientific data on CBT for insomnia. It would offer access to an evidence-based multicomponent treatment and is intended to be integrated into the health care system as such. In line with expert recommendations, the Noxxea solution could ideally be part of a stepped care model that adapts to the severity of the condition and the patient's needs, with dCBT-i proposed as a first step delivered through multiple pathways, such as being prescribed by a doctor or accessed directly by the patient [51].

Authors' Contributions

All authors contributed to the development of the method. ES drafted the article, and all authors reviewed, revised, and approved the final manuscript.

Conflicts of Interest

ES, SB, SM, and PAG received consulting fees from Di&Care, which is developing the digital cognitive behavioral therapy for insomnia (dCBT-i). CP and AD are employed by Di&Care. All authors agreed to disclose these relationships.

Abstract

Background: Digital mental health interventions (DMHIs) are effective in reducing symptoms of depression and anxiety. Low user engagement and uptake of DMHIs observed in previous research may be addressed by involving the intended target audience in the design of the DMHI from the outset.

Objective: This study is phase 1 of a multiphase project aimed at designing, developing, and evaluating a blended DMHI for depression and anxiety in Australia. Our objective was to partner with adults with lived and living experiences of depression and anxiety on their needs and expectations of a new transdiagnostic DMHI for depression and anxiety. This included identifying strategies that would help increase their engagement with the DMHI and their preferences for integrating the DMHI with psychotherapy.

Methods: A mixed methods participatory design approach was used to collect quantitative and qualitative data via a web-based survey (n=324) and semistructured interviews (n=21). Feedback was collected on participants' needs and expectations for the DMHI, including accessibility, content, features, functionality, format, data sharing, preferred clinical support pathways, and barriers to and facilitators of user engagement. Qualitative interview data were analyzed using reflexive thematic analysis.

Results: Most participants (190/257, 73.9%) preferred a DMHI delivered as a smartphone app that could be used at any time of the day. Ease of use and a well-designed interface were important, as was a positive, encouraging, and uplifting DMHI look and feel. Other preferences included symptom tracking, diverse therapeutic content, and features that facilitated social connection and peer support (eg, online community and stories of lived and living experience). Participants also suggested several strategies to enhance engagement with the DMHI, including personalization, reminders, short and achievable activities, and goal setting. Participants reported a strong interest in sharing information from their DMHI with mental health professionals (to facilitate therapy), especially regarding changes to their emotions.

Conclusions: Transdiagnostic DMHIs for depression and anxiety have great potential to improve access to affordable, evidence-based mental health support. Involving people with lived and living experiences of depression and anxiety in the design, development, and conceptualization of DMHIs may improve uptake, acceptance, engagement, usability, and ultimately, treatment outcomes.

participatory design; depression; anxiety; smartphone; digital intervention; blended care; transdiagnostic

Introduction

Background

Globally, depression and anxiety are two of the most prevalent mental health disorders. In 2019, an estimated 280 million people were living with a depressive disorder, while >300 million people were living with an anxiety disorder [1]. Depression and anxiety commonly co-occur, with comorbidity rates as high as 50% [2]. These disorders are associated with a decreased quality of life due to poor physical health, disability, and reduced life expectancy [3], as well as lower workforce productivity and high economic costs [4]. Fortunately, there are many effective treatments for depression and anxiety that either target specific disorders or use a transdiagnostic approach [5]. However, several barriers affect access to treatment. These include high out-of-pocket costs and inconsistencies in the quality and type of care received [1]. Concerns about seeking help in person due to negative beliefs and stigma surrounding mental illness also play a role [6]. In addition, long waiting times persist due to a shortage of trained mental health professionals and inadequate funding of mental health services [1,6].

Digital Mental Health Treatment

Digital mental health interventions (DMHIs), such as smartphone apps or online programs, address many of the barriers to face-to-face mental health care. DMHIs allow people to access psychotherapy skills and content in their own time and empower them to self-manage their symptoms [7-11]. Due to these advantages and the need to minimize face-to-face contact during the COVID-19 pandemic, many DMHIs have been developed and implemented quickly in recent years [12]. DMHIs can be used in a self-guided format (ie, without human support) [8,9], guided format (ie, with remote support from a health professional or coach), or together with face-to-face therapy sessions in person or with telehealth in a "blended" format (blended care) [12-14]. Evidence supports the efficacy of DMHIs, particularly those based on cognitive behavioral therapy (CBT), in reducing symptoms of depression and anxiety [15,16]. A 2021 meta-analysis [15] found that compared to control conditions, both guided and self-guided DMHIs significantly reduced depressive symptoms across 83 studies, with a medium pooled effect size (Hedges g=0.52; 95% CI 0.43-0.60). For anxiety, a recent meta-analysis [16] reported that compared to inactive controls, guided and self-guided DMHIs significantly reduced anxiety symptoms across 47 studies, with a large pooled effect size (Hedges g=0.80; 95% CI 0.68-0.93). While most studies have evaluated internet-delivered DMHIs (ie, delivered on websites), smartphone apps targeting depressive and anxiety symptoms have also shown positive results, with small to medium pooled effect sizes for anxiety (Hedges g=0.26; 95% CI 0.21-0.31) and depression (Hedges g=0.50; 95% CI 0.40-0.61) [17,18].

Despite this evidence showing that smartphone apps and internet-based interventions are effective in improving symptoms of depression and anxiety, DMHIs are not typically integrated into routine mental health care [19]. There are several reasons for this, including a lack of practitioner confidence and training in integrating these tools into practice, difficulties in personalizing these interventions, and a lack of integration with practice management software and electronic health records [20]. There is promising preliminary research into the combination of DMHIs with face-to-face therapy in blended care for depression and anxiety [14,21,22]. However, research on the efficacy and effectiveness of blended care is limited compared to the evidence base for self-guided and guided DMHIs [8,9,23] and is confined mainly to Europe and North America [14,24]. In practice, many existing DMHIs have high attrition rates and low user engagement, especially when accessed in stand-alone self-guided formats [25,26] and in "real-world" naturalistic settings outside of controlled research studies [27]. For example, a review by Linardon and Fuller-Tyszkiewicz [26] found that the dropout rate of users participating in studies that included smartphone apps for depressive or anxious symptoms was 36% and 21%, respectively. Dropout rates are even higher in naturalistic community settings. For instance, studies have shown that completion rates of DMHIs in naturalistic settings are at best half of what is found in clinical trials of the same intervention [28-30]. Several factors contribute to low DMHI engagement, including technical issues, motivation issues, and a lack of user-driven design [11,25,31,32]. Reviews of the existing literature also show that various features, functionality, and design considerations can promote user engagement with DMHIs. These include the perceived usefulness; positive impact and relevance of DMHIs; content that promotes good mental, physical, and cognitive health [33,34] and social connection [25,31]; design aspects (eg, ease of use and interface); personalized content and choice [35-37]; data security and privacy; and therapist guidance [25].

Limitations of DMHIs for Depression and Anxiety

These findings provide guidance for improving participant engagement and reducing attrition for DMHIs overall, which is especially relevant given the increased availability of DMHIs following the COVID-19 pandemic. However, an often-overlooked issue is how DMHIs should be integrated into routine clinical care for depression, anxiety, and other mental disorders [9]. Many existing self-guided and guided DMHIs include linear, one-size-fits-all programs for a specific disorder (eg, major depressive disorder) or multiple disorders (eg, transdiagnostic programs for mixed anxiety or anxiety and depression). In this model, programs follow a mostly set structure, delivering a series of modules that are completed in the same order for each person. While this approach has benefits [38], the downside is that the DMHI cannot be individually tailored to suit a person's goals, needs, symptoms, and problems.

XSL•FO
RenderX

This lack of personalization negatively affects user engagement [11,25] and is a barrier for mental health professionals using these programs in practice [39]. Another important clinical consideration is that people experiencing severe depression and anxiety symptoms, and frequent suicidal ideation, use DMHIs once they are released into the community, although the programs are often not designed for these clients (eg, myCompass and THIS WAY UP) [40-42]. The needs, preferences, and expectations of people with varying symptom severity and suicidal risk levels need to be considered at the outset when developing interventions for depression and anxiety. Another factor affecting the inclusion of DMHIs in routine clinical care is that many of these interventions have been designed as "self-help" or "stand-alone" products [8,43,44]. This has contributed to the low uptake of DMHIs in practice and limits their potential use, reach, and benefits for people with depression and anxiety at various stages of care (eg, before, during, and after seeking in-person therapy).

Incorporating the needs of the intended target audience directly into DMHI design and development can potentially help address poor user engagement, high attrition, and the lack of integration of DMHIs into clinical practice. Participatory design approaches, such as co-design and co-creation, actively incorporate multiple stakeholders' perspectives into defining a problem and collaborating with them on potential solutions [45,46]. In digital mental health, participatory design involves partnering with the intended target audience during DMHI design, development, refinement, and evaluation to ensure the product or service reflects their needs. Unfortunately, in DMHI research that uses participatory approaches, these details are often inconsistent, use varied terminology, or are not reported clearly [45,46]. Moreover, the few existing DMHI studies that use co-design principles have been limited to young adult samples (aged 18-34 years) or mental health professionals, with very few in adults aged ≥35 years [45]. Using participatory design and co-design principles to create DMHIs that fit into routine care may help adults with anxiety and depression, along with their mental health professionals, adopt blended care more easily [21]. However, to date, only 1 European study [47] reports the participatory design process during the development of a blended care intervention with people with lived experience of mental illness and psychotherapists. In that study, people with lived experience preferred a DMHI that was gentle and compassionate rather than performance based and they valued having the autonomy to choose modules themselves or have them selected by their therapist. It was also important that the DMHI included crisis support, transparent data security, and confidentiality information. Finally, people with lived experience preferred inclusive, varied, concise content delivered in various formats (eg, text, images, and videos) to ensure the DMHI was accessible to many people.

Rationale, Objectives, and Aims

Blending digital and face-to-face therapy is a promising approach for integrating DMHIs into routine mental health care [14,21,22,24]. However, to date, only 1 study has used participatory design to incorporate the needs of people with lived experience of mental illness into the design of a blended care intervention [47]. Blended care interventions can address the limitations of DMHIs, especially stand-alone options; hence, there is a need to further investigate the utility of the blended care approach. For depression and anxiety, the option of mental health professional involvement would add an extra layer of clinical safety and permit better tailoring of DMHI use for people experiencing depression and anxiety. This study is part of a larger Australian research project that aims to design, develop, and evaluate a new transdiagnostic DMHI for adults with depression and/or anxiety (ie, myNewWay) [48]. The intervention is intended to address limitations of existing DMHIs and be suitable for use as part of blended care. Australian research on blended care is limited; however, preliminary results align with studies in other countries [14,21,22,24] and indicate that blending digital and face-to-face therapy may improve symptoms of depression [49-51] and anxiety [51]. To the best of our knowledge, there are also currently no transdiagnostic blended care models in Australia designed with target audience input and tailored to the specific needs and preferences of adults with depression and anxiety.

This study is 1 of 2 related participatory design studies in which we partnered with people with lived and living experiences of depression and anxiety and mental health professionals in the design of the new blended care DMHI. This paper reports on the findings of people with lived and living experience. Findings from mental health professionals are reported separately in part 2 of this manuscript series [52]. The DMHI will be transdiagnostic rather than diagnosis specific, as transdiagnostic approaches are acceptable, feasible, efficient, and effective for treating multiple symptoms and diagnoses within 1 treatment program [5,40]. We will use findings of this study to co-design and then develop a program that will be engaging, safe, and effective for people with varying severity levels, including those experiencing suicidal ideation. The program could be personalized to individual goals and needs and integrated into face-to-face or telehealth mental health care. We also wanted to ensure that the DMHI met the needs of adults with lived and living experience by including relevant therapeutic content and sustaining their interest with appealing design features and functionality, especially given that user engagement is associated with better treatment outcomes [15,53] and more cost-effective treatment [54,55].

Conducting participatory design within an Australian context is important to ensure that the new blended care model aligns with the needs and expectations of adults living with anxiety and depression. In Australia, adults with depression and anxiety are treated in the private mental health system and can access up to 10 psychotherapy sessions per calendar year with partial government rebates [56]. Blending DMHIs with this existing treatment pathway could increase the quality of care, and, thereby, enhance recovery by providing access to evidence-based resources for depression and anxiety before, during, and after psychotherapy. Given that most blended care research has been conducted in Europe and North America [14,24], conducting research outside these cultural contexts also helps to show which elements of blended care may be universal and which elements are not. The first aim of this study was to examine the needs and expectations of participants regarding the content, features, functionality, and look and feel of the

XSL•FO
RenderX

DMHI. This also includes how people with depression and anxiety want to access the DMHI, their preferences for content delivery, and the overall blended model of care. With respect to the blended care model, we asked about the types of therapeutic guidance and human-based support they would like to receive while using a DMHI that blends with psychotherapy, as well as their preferences for sharing data from the DMHI with health professionals. Understanding participants' preferences for including guided components within a DMHI will ensure that it meets their needs and leverages the potential benefits of guided DMHIs for depression and anxiety [15]. Our second aim was to identify factors that would affect engagement with the new blended DMHI, which could be addressed in the design of the interface, functionality, or content of the intervention to maximize sustained engagement with the DMHI.

Methods

Participatory Design Approach

A mixed methods convergent parallel design [57] was used for this study, which included a convenience sample of people with lived and living experience. This approach ensured that both a broad range of perspectives (ie, web-based survey) and in-depth insights (ie, qualitative interviews) were represented to achieve the study aims and conclusions [57]. Stage 1 was the web-based survey, which assessed participants' experiences and attitudes toward DMHIs and the barriers and facilitators to their use. The survey was developed in accordance with the Checklist for Reporting Results of Internet E-Surveys [58]. For stage 2, a subset of survey respondents completed one-on-one online qualitative interviews on their preferences for the DMHI. For people with lived and living experience, stage 3 included co-design sessions and prototype testing of designs based on findings from stages 1 and 2; however, these results are not reported in this paper. The survey and interview questions were developed by the research team, which included health professionals, people with lived experience, user experience and user interface experts, and those with knowledge of implementation research (Multimedia Appendix 1). The data collection methods used in stages 1 and 2 are consistent with prior participatory design research in digital health [45]. In addition, 5 people with lived experience of depression and anxiety served as lived experience advisors during stages 1 to 3. The lived experience advisors took part in each stage of the broader project, including both the survey and qualitative interviews conducted in this study.

Ethical Considerations

All research procedures received ethics approval from the University of New South Wales Human Research Ethics Committee (HC200541), and all participants provided informed consent before participating. If participants wished to withdraw their consent, they could contact the research team. Participant data from the online survey and interview was deidentified and replaced with a number and saved in password protected file accessible only by the research team. Participants were given the option to enter a draw to win an Aus $100 (US $65) online gift card for taking part in the online survey. For the interview, participants were reimbursed with an Aus $30 (US $20) online gift card.

Stage 1: Web-Based Survey

The web-based 20-minute open survey was distributed between October and December 2020. The survey was advertised via the Black Dog Institute website and social media (eg, Facebook and Instagram) and the Black Dog Institute Lived Experience Resource Network. Interested participants were directed to the Black Dog Institute website, which outlined the eligibility criteria for the study and included a link to the web-based survey hosted on Qualtrics (version 2020; SAP Inc) software. At the start of the survey, respondents read the participant information sheet and consent form outlining the purpose of the research study, eligibility criteria, where their data were stored and who had access to it, the length of time to complete the study, and their reimbursement incentive. Eligibility criteria were that participants were aged >18 years, could speak English, currently lived in Australia, and had current or previous experience with anxiety or depression. The web-based survey included questions (Multimedia Appendix 1) on participant demographics, their mental health treatment history, current technology use, their experiences with DMHIs, and preferences for a new DMHI targeted at reducing symptoms of depression and anxiety. Participants were asked what features in the DMHI they would find helpful, how they would like any content displayed, and their preferred medium for accessing the DMHI (eg, smartphone and laptop). Participants' current levels of depression, anxiety, and stress were also assessed using the validated 21-item Depression Anxiety Stress Scale (DASS-21) [59]. The DASS-21 is reported to have sound psychometric properties [60]. Respondents rate each item on a 4-point Likert scale (never=0 to almost always=3), with higher scores indicating more severe levels of depression, anxiety, or stress.

Stage 2: Interviews

The interviews were conducted with Zoom videoconferencing software (Zoom Communications, Inc) and lasted 60 minutes on average (SD 10.52 min; range 35-74 min). The semistructured interviews included open-ended questions (Multimedia Appendix 1) that assessed attitudes toward and experiences with DMHIs, preferences for features and functionality, and suggestions for improving engagement with DMHIs. A clinical psychologist (KO) and the user experience designer (KV) facilitated interviews. All interviews were audio-recorded and later transcribed by the project officer (KK).

Data Analysis

Quantitative data from the web-based survey were analyzed using SPSS (version 26.0; IBM Corp). Descriptive statistics were calculated for closed-ended survey questions. Sample counts and percentages were provided for each survey question. Reflexive thematic analysis was adopted for qualitative data because this methodology was appropriate for answering the research questions [61]. Following each interview, transcripts were checked and cleaned against the original audio by KK. KK (project officer), KO (clinical psychologist), and RKM (project officer) read the transcripts several times, and after familiarization, they used a general inductive approach to

XSL•FO
RenderX

generate the initial set of codes. The 3 authors have experience with digital mental health and thematic analysis. Codes were categorized in Microsoft Excel (version 2024) to create the initial coding framework, which was revised iteratively by KK, RKM, and JATM (research assistant with experience in digital mental health and thematic analysis) for consensus on final themes and subthemes. Any disagreements on codes were resolved through discussion with the research team (including KO, JMN, and AEW, who are psychologists) until a consensus was reached.

Results

Stage 1: Web-Based Survey

Overview

Of the 331 adult participants who provided consent, 324 (97.9%) supplied their demographic information, and 231 (68.3%) participants completed the full survey. The demographic, mental health, and treatment characteristics of 324 participants are presented in Tables 1 and 2. The sample had an average age of 46 (SD 16.4; range 18-80) years, was predominantly female, spoke English as their first language, was born in Australia, and lived in a major Australian city. A total of 209 (68.3%) of 306 participants rated their digital literacy as good to very good, with the rest rating it as acceptable (n=65, 21.2%) or poor (n=12, 3.9%). Approximately half (156/306, 51%) of the participants spent 1 to 3 hours online daily, and >40% (131/306, 42.8%) spent >4 hours online daily. A small number of participants (19/306, 6.2%) spent <1 hour online daily.

[a]Percentages do not add up to 100% as respondents were allowed multiple responses.

[b]GP: general practitioner.

[c]MHP: mental health professional.

[d]Results for the 21-item Depression Anxiety Stress Scale (DASS-21) were calculated based on the number of participants who responded to these questions (n=308).

Mental Health and Treatment

Most participants (198/318, 62.3%) had experienced both depression and anxiety (Table 2). A total of 191 (60.1%) of 318 participants were currently receiving mental health treatment, and 285 (85.3%) participants had received mental health treatment in the past. Medication was the most common form of current and past treatment, followed by therapy with a psychologist or psychiatrist (Table 2). The distribution of participants (308/324, 95.1%) who scored in the normal, mild, moderate, severe, and extremely severe ranges for the 3 DASS-21 subscales can be seen in Table 2. Approximately 80% (247/308) of participants had elevated depression scores, 70% (216/308) had elevated anxiety scores, and 64% (197/308) had elevated stress scores on the DASS-21 subscales (scored in the mild to extremely severe ranges).

Current and Past Use of DMHIs

Only 52 (17%) of 306 participants were currently using DMHIs, while 131 (42.8%) had used them in the past. The most commonly used DMHIs among 139 participants were mindfulness meditation apps (n=79, 56.8%), followed by CBT-based apps (n=30, 21.6%) and forums (n=13, 9.4%). The most frequently used apps were Headspace, Smiling Mind, and Calm. Of the participants who had never used DMHIs (155/306, 50.7%), the 3 most common reasons were a lack of awareness, a belief that these products are not useful or necessary, and not having found a DMHI that was helpful to them.

Preferences for Digital Mental Health

Product Promotion or Awareness

Almost 70% (177/256) of participants preferred finding out about a DMHI via a health professional recommendation, followed by social media or Google search (Table 3).

XSL•FO
RenderX

Table 3. Participants' preferences for promotion and access.

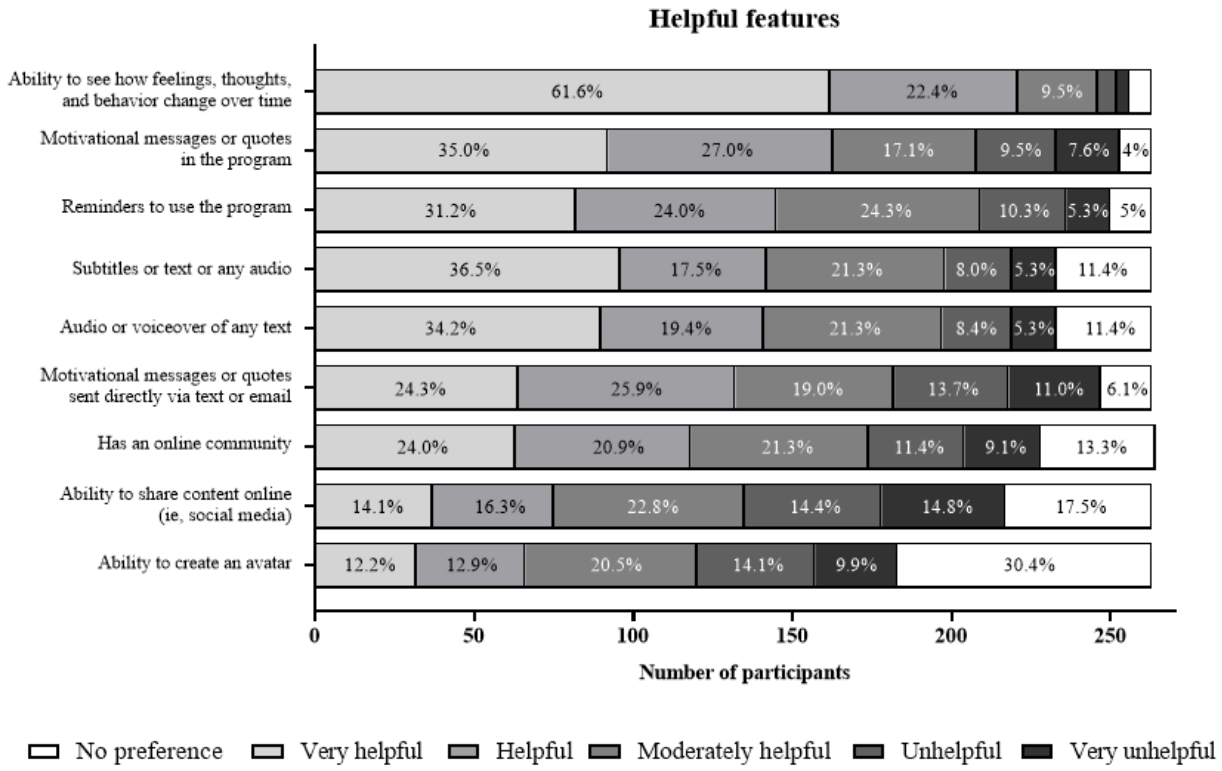
[a]DMHI: digital mental health intervention.

Access to Product

Most participants (190/257, 73.9%) reported wanting to access a DMHI via a smartphone app, while a third preferred (85/257, 33.1%) using a laptop (Table 3). Most participants wanted to use a DMHI when they felt the need to use it (164/257, 63.8%), in the evening (96/257, 37.4%), or just before bed (73/257, 28.4%; Table 3).

Willingness to Pay



Only 40 (16.5%) of the 242 participants were willing to pay for a DMHI, whereas most said maybe (n=142, 58.7%), and the rest said no (n=60, 24.8%). Of the 182 participants who responded yes or maybe, the median amount they would pay monthly for a DMHI was Aus $10.00 (US $6.5; IQR Aus $5.00-$15.00). The majority (125/176, 71%) were willing to pay between Aus $1 to $10 (US $0.65-$6.5) per month, while some participants (12/176, 6.8%) were willing to pay >Aus $50 (US $32) per month.

Preferred Features

Figure 1 shows which DMHI features participants considered the most helpful (ie, rated as helpful or very helpful). The most popular features were the ability to track thoughts, feelings, and behaviors over time (221/263, 84%), motivational messages (163/263, 62%), reminders (145/263, 55.1%), subtitles (142/263, 54%), and audio voiceover (141/263, 53.6%). Features viewed as moderately helpful included motivational messages sent directly to the user via email or text and the inclusion of an online community, while the least helpful features were having an avatar and the ability to share content online in general.

XSL•FO
RenderX

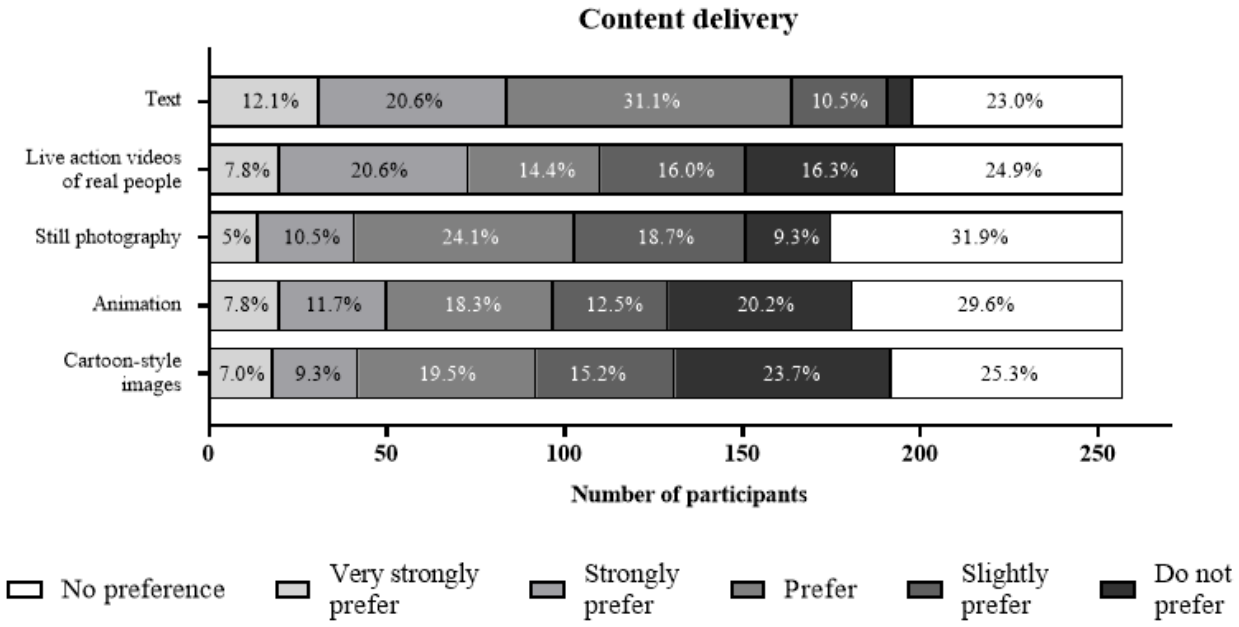


Figure 1. Participant preferences for the features of digital mental health interventions they find most helpful (n=263). Data labels show the frequency percentages.

Preferred Format of Content Delivery

Figure 2 indicates that text, still photography, and live-action videos of real people were the preferred forms of content display (ie, rated as very strongly prefer, strongly prefer, or prefer). Although there was a wide range of preferences for content display types, most participants preferred not to see information displayed in cartoon-style images (61/257, 23.7%), animation (52/257, 20.2%), or live-action videos of real people (42/257, 16.3%; Figure 2).

Figure 2. Participant preferences for preferred content delivery methods (n=257). Data labels show the frequency percentages.

XSL•FO
RenderX

Engagement With DMHIs

Participants commonly reported that if the DMHI were effective and helped them feel better (eg, “effectiveness in making me less anxious,” “I feel it is helping me,” and “success in feeling better”), it would help them stay engaged. Some participants also suggested that being able to visualize their progress and the use of rewards, challenges, and achievement milestones would encourage users to keep coming back to the DMHI (eg, “check ins to see progress” and “rewards for logging in every day”). Participants also thought personalized and tailored content, such as “choose your own path based on your mood” and “options to turn off what you use and don’t use,” would encourage them to keep using the DMHI. Other engagement strategies included reminders and notifications (eg, “to be able to set a reminder and task to help with motivation and skills”) and having a well-designed layout (eg, “colorful,” “interactive,” “simple,” and “visual and no text blocks”).

Sharing Information

Participants rated psychologists, general practitioners, and psychiatrists as individuals they were most likely to share information with via a DMHI (Table 4). Participants were relatively confident in sharing information with a counselor, a friend, or a family member and less confident when sharing with a social worker, carer, or teacher. When participants were asked about what information they would like to share via the DMHI with others (ie, psychologist, friend, or teacher), most preferred to share how they were feeling over time, followed by specific program activities, whether they felt worse or better, and their goals (Table 4). Participants also rated what types of information they were most likely to share specifically with a mental health professional. The top-rated responses were how they felt over time, when they felt better or worse, their goals, and certain activities they completed within the DMHI (Table 4). Most participants (155/241, 64.3%) preferred communicating with mental health professionals via a chat box inside the DMHI, while some (86/241, 35.7%) preferred face-to-face appointments, phone calls, or SMS text messaging (Table 4).

XSL•FO
RenderX

Table 4. Information sharing preferences by participants for digital mental health interventions (DMHIs).

	Participants
People I would share information with[a], mean (SD)	
Psychologist	67.60 (35.81)
General practitioner	60.33 (34.54)
Psychiatrist	56.64 (40.20)
Counselor	53.42 (38.39)
Friend	52.32 (36.75)
Family member	48.69 (36.48)
Social worker	34.01 (36.74)
Carer	27.45 (35.64)
Teacher	16.48 (27.95)
Types of content I would share[b,c], n (%)	
How I am feeling over time	169 (67.9)
Certain activities I complete in the program that I choose to share	123 (49.4)
When I am feeling worse	119 (47.8)
When I am feeling better	111 (44.6)
My goals	100 (40.2)
What I use within the program	61 (24.5)
All the exercises and activities I complete in the program	53 (21.3)
When I use the program	40 (16.1)
Other types of content	19 (7.6)
Types of content I would share with a mental health professional[a], mean (SD)	
How I am feeling over time	73.71 (30.97)
When I am feeling worse	70.42 (34.08)
When I am feeling better	68.67 (35.05)
My goals	64.49 (34.59)
Certain activities I complete in the program that I choose to share	62.05 (34.75)
What I use within the program	55.37 (36.47)
When I use the program	52.87 (37.82)
All the exercises and activities I complete in the program	47.92 (36.58)
How I would communicate with a mental health professional[b,c], n (%)	
Chat box inside the program	155 (64.3)
Face-to-face appointment	102 (42.3)
Phone call	98 (40.7)
SMS	84 (34.9)
Video call	43 (17.8)
Other communication method (eg, email)	8 (3.3)

[a]Ratings were made using a 100-point scale (0=would never share and 100=extremely likely to share).

[b]Percentages for types of content (n=249) and how the participant preferred to communicate with a mental health professional (n=241) were calculated based on the number of participants who responded to these questions.

[c]Percentages do not add up to 100% as respondents were allowed multiple responses.

XSL•FO
RenderX

Stage 2: Interviews

Demographic Information

A total of 21 adults participated in one-on-one qualitative interviews. Most of them (13/21, 62%) were female participants and aged 41 years on average (SD 16.4; range 21-68 years). Most spoke English as their first language (13/21, 62%), were born in Australia (11/21, 52%), and were from major Australian cities (18/21, 86%). Of the 21 participants, 14 (67%) had experienced both depression and anxiety, 3 (14%) had experienced depression only, 1 (5%) experienced anxiety only, and 3 (14%) experienced another mental health problem.

Thematic Analysis Findings

Eight key themes related to DMHIs were identified: (1) promotes user engagement; (2) friendly, pleasant look and feel; (3) content is multifaceted and interesting; (4) sense of connection with real people; (5) features that facilitate progress; (6) safe, trustworthy, and effective; (7) data security is important; and (8) must be low cost or free. All themes, subthemes, and illustrative quotes for each subtheme are listed in Table 5.

XSL•FO
RenderX

Table 5. Themes and subthemes from the thematic analysis, along with example quotes.

Themes and subthemes	Example quotes
1. Promotes user engagement	
Easy to use and simple to navigate	"It just all needs to be easy. I hate learning new technology platforms, I hate it, so easy as possible." [Participant 4]
Personalize content and activities to user needs	"There needs to be tailored kind of options for people, different ways that they can engage with it just to keep it interesting." [Participant 5]
Reminders and notifications	"I really liked the fact that it gave you reminders to use it, that was great, and you could set it to what time of the day you'd like it to remind you." [Participant 36]
Short and achievable activities	"Maybe kind of breaking up into small tasks. So that there's a clear plan how to start to work, whatever the user wants to achieve." [Participant 9]
Goal setting to support a sense of progress	"So you can set up goals...so like basically this is what I want to become or like this is what I want and it's like a journey." [Participant 12]
2. Friendly, uplifting look and feel	
Streamlined and attractive graphic design	"It felt like it had a kind of color scheme, it looked professional." [Participant 1]
Warm, gentle, and inviting tone	"The app comes up and says gently to you, 'welcome back' or 'welcome, glad to see you.'" [Participant 9]
Short, positive, and encouraging messages	"And I also get like motivating notifications every day like small quotes or something, it makes me feel good." [Participant 12]
3. Content is multifaceted and interesting	
Provides options for wellness practice that support recovery	"I think things that are like mindfulness and exercise and things that can be part of anyone's regular routine when they're recovering would be valuable." [Participant 29]
Broad variety of content to prevent boredom	"So variety would be really good for the app as well because yeah people if they know exactly what's going to happen every time they do it, they'll just get bored of it, I think." [Participant 56]
Program incorporates different treatment approaches	"Like ACT...and DBT as well, like, I think a lot of people connect with those better...because it seems like every single app on the market is literally all about CBT and mindfulness." [Participant 36]
Searchable information about mental health	"I think it would be good if there was kind of an inventory of mental illnesses that a person can look up and read the description on the symptoms and things certain things like that and maybe suggestions on what to do if you suspect that you might have it." [Participant 1]
4. Sense of connection with real people	
Personal stories shared by real people	"I think having if possible, some form of personalized stories or...there is a section there where you can read about other people who are like you and know that you're not alone." [Participant 63]
Online community support	"So I think overall, the online forums I found the most, the most useful, probably because of that connection with other people with peers, basically." [Participant 4]
5. Features that track and aid progress	
Mood-tracking feature	"I liked the feature where you could input other things that are going on like how much sleep you had...you can put all that stuff and then you could sort of look and see correlations between your mood and these external factors." [Participant 36]
Visualize changes in mental health over time	"You can step back from it and sort of view the data on you and then, you know, work on it from there, because it just feels like it's this evolving thing that you know comes and goes." [Participant 51]
Reflective journaling	"Maybe somewhere to sort of record or reflect on how far you've come or what you want to achieve, or like sort of like a reflection journal could be quite valuable as well." [Participant 29]
Share treatment progress with their psychologist	"I don't think I would use it necessarily like in (my psychologist's) office, but maybe even just to sort of like talk about with her of like how I'm progressing, what I'm doing for my own like mental health." [Participant 52]
6. Safe, trustworthy, and effective	
Tips and activities to help feel better immediately	"If there is something that I could, if I am feeling, not necessarily in crisis, but if I am feeling not okay for any reason, that I can dip into like say a certain section and know ok, I can do this." [Participant 5]
Confidence in the credibility of the program	"Knowing where it's coming from and who is being provided by." [Participant 24]

XSL•FO
RenderX

Themes and subthemes	Example quotes
Access to crisis support information if needed	"There's a kind of list of hotlines that come up that I can access at any time in case of a crisis, so I think that's really nice." [Participant 1]
User-created plan when feeling unwell	"Inviting the user to list what they like to do to keep the head above water. I like to watch comedy, pursue my interest in things like that. I look to my brother, play with my pets. Yeah, having that as a list and just go alright, here's a couple of things that you can do, but the benefit of that is that these are things you have indicated that you want to do in the past, this is your stuff." [Participant 9]
7. Data security and control over information sharing	
Control over sharing sensitive information	"Because I want to have control over that...I've got the utmost trust in my GP and we work out what's going to go on. I don't want somebody else to have knowledge or understanding of my history and come at me cold when I don't have a relationship with that person." [Participant 19]
Transparent information about data privacy	"Transparency is very important, and that element of trust thing comes in as well that you know you feel comfortable about dealing with an organization or service provider that you know is there for your own understanding and benefit." [Participant 27]
Positive about sharing data with a trusted health professional	"I know that if my psychologist found it useful that I have personally I think she's you know, she's a very trusted professional for me. If there is that comfort level there, I think it's definitely like a great feature like for her to see where I'm at." [Participant 63]
8. Must be low cost or free	"Yeah, I think I didn't want to pay for anything because I wasn't sure if it was going to work and to be honest, I didn't use it frequently." [Participant 27]

Theme 1: Promotes User Engagement

Easy to Use and Simple to Navigate

Participants indicated that they wanted a DMHI that was easy to follow, intuitive, and straightforward to navigate. Suggestions included having a fast and easy sign-up process and clear navigational icons and features. Participants also mentioned negative past experiences with products that were too clunky, slow, and frustrating to navigate. This was thought to be particularly problematic for people with mental health issues who are feeling unwell or stressed.

Personalize Content and Activities to User Needs

Many participants emphasized personalization as a key feature for maintaining user engagement with DMHIs. Some expressed a preference for having a program that was responsive to their needs. This included the user choosing the activities or content to complete based on how they were feeling on the day and the DMHI's ability to suggest content and activities to the user based on their interactions with the DMHI (eg, mood-tracking scores).

Reminders and Notifications

Participants mentioned liking reminders and notifications in apps or programs they had previously used, as this feature helped them stay on track with managing their mental health. Some preferred daily check-in reminders or notifications that could be updated at times that suited the individual's schedule, while others valued the option to customize the content shown in the reminders and notifications.

Short and Achievable Activities

There was a clear preference for activities in the DMHI to be short and quick to complete. Some participants said that being able to complete a few smaller tasks would help foster a sense of accomplishment. Participants also suggested that if an activity needed to be longer, it could be divided into smaller tasks to prevent the activity from becoming too time consuming.

Goal Setting to Support a Sense of Progress

Participants emphasized the importance of being able to track their progress within the DMHI. Suggestions included unlocking a new stage or section in the intervention and being rewarded, offering daily challenges the user could engage in, or setting up various goals the user could work toward.

Theme 2: Friendly, Uplifting Look and Feel

Streamlined and Attractive Graphic Design

Overall, participants wanted a DMHI that was visually appealing with a professional-looking color scheme and images. However, opinions varied about the preferred colors and designs. Some participants preferred bright and vibrant colors, while others wanted soft and calming colors. Presenting information graphically (eg, pie charts and icons) was also mentioned as a desirable design feature.

Warm, Gentle, and Inviting Tone

The language and tone of the content within the digital product were important. They preferred the language and tone to be empathetic, calm, and encouraging. Participants also specifically mentioned that they did not want any language or tone that could be interpreted as forceful, overpowering, or aggressive. For example, some participants preferred the DMHI to have a friendly tone, akin to how a therapist would speak to them.

Short, Positive, and Encouraging Messages

Many participants wanted to see brief, uplifting, and inspiring messaging displayed throughout the DMHI. Participants suggested these messages could be included in notifications or shown when a user first opens the DMHI to help someone feel welcome, create a sense of connection, and validate that they made the right decision to engage with the program.

XSL•FO
RenderX

Theme 3: Content Is Multifaceted and Interesting

Provides Options for Wellness Practices That Support Recovery

Several participants wanted a DMHI that incorporated a range of wellness techniques, skills, and practices. Suggestions were diverse and included sleep hygiene, exercise guidance, spirituality resources, breathing techniques, information on healthy living, meditation exercises, and gratitude journaling. Participants wanted these components to maintain long-term recovery and sustained engagement with the DMHI.

Broad Variety of Content to Prevent Boredom

Participants stressed the importance of offering a wide range of up-to-date and relevant content in the DMHI that addresses the various experiences and situations that users might encounter. This breadth and variety of content would also ensure the user could always find something new and interesting, preventing boredom and sustaining their interest in the DMHI in the long term.

Program Incorporates Different Treatment Approaches

Many participants had used CBT-based apps and programs in the past. These participants expressed that CBT was not suitable for all individuals and wished to see other therapeutic modalities, such as dialectical behavior therapy, acceptance and commitment therapy, and mindfulness, included.

Searchable Information About Mental Health

Some participants reported that a DMHI should include an information section where users could search for mental health information. For example, 1 participant suggested an inventory of mental health conditions accompanied by descriptions of their symptoms. Another participant mentioned the value of a search section to access articles or advice, allowing users to search for specific topics related to their struggles.

Theme 4: Sense of Connection With Real People

Personal Stories Shared by Real People

Several participants mentioned that they valued connecting with others who were also experiencing mental health challenges. Participants suggested that these personal stories could be shared via the DMHI through video or written accounts, either by reading stories or participating in an online forum. Some participants expressed a desire to provide support to others dealing with anxiety and depression, drawing on their past positive interactions and helping others in other apps and forums.

Online Community Support

Some participants reported that being able to interact with an online community of other individuals facing mental health challenges would enhance their engagement with the DMHI and help reduce feelings of loneliness. However, some participants highlighted the importance of ongoing safety monitoring and moderation if an online community was included in the DMHI.

Theme 5: Features That Track and Aid Progress

Mood-Tracking Feature

Most participants preferred to monitor their mood over time using the DMHI. Some participants suggested that it would be helpful to have the ability to track other factors, such as sleep, coffee intake, and menstrual cycles, within the mood-tracking feature to observe how these variables relate to changes in mood.

Visualize Changes in Mental Health Over Time

Several participants preferred to view their tracking data collected by the app visually to see how their mental health changed over time. They also wanted to view their data plotted at different calendar frequencies, such as weekly, monthly, or yearly intervals.

Reflective Journaling

Some participants recommended including a section for recording and reflecting on achievements and progress. They believed this would be valuable for their recovery and allow them to reflect on their progress and growth.

Share Treatment Progress With Their Psychologist

Some participants were keen to share their data from the DMHI with their psychologist to inform them of their progress between therapy sessions and initiate discussion in their sessions.

Theme 6: Safe, Trustworthy, and Effective

Tips and Activities to Help Feel Better Immediately

Participants mentioned that it would be useful to have a section in the DMHI where users could access tips and activities to help calm them down when they were feeling overwhelmed (eg, panicking or anxious). Suggestions included easy meditations, mood-lifting activities, and breathing exercises.

Confidence in the Credibility of the Program

Several participants emphasized that the content of the DMHI should be backed by scientific research and evidence. Some participants also highlighted that the intervention should be developed by a reputable organization and in collaboration with mental health professionals and researchers.

Access to Crisis Support Information if Needed

Some participants thought it was important to include crisis support information, such as mental health hotline numbers and websites.

User-Created Plan When Feeling Unwell

A few participants suggested that the DMHI should offer users the option to create a plan for challenging times or when life feels overwhelming. These participants recommended that the plan include options for pursuing personal interests and listing strategies or activities that they found helpful when they felt unwell.

XSL•FO
RenderX

Theme 7: Data Security and Control Over Information Sharing

Positive About Sharing Data With a Trusted Health Professional

Many participants were comfortable sharing data from the DMHI with a trusted health professional. Participants also highlighted several benefits of sharing the data with their health professional, such as streamlining information sharing, allowing the health professional to monitor their client's mood between sessions, and storing and sharing homework digitally with the health professional. All these benefits were thought to enhance face-to-face therapy.

Control Over Sharing Sensitive Information

Participants emphasized the private and personal nature of their mental health journey. Consequently, many participants thought it was important to have control over what information they could share from the DMHI and the ability to choose whom they could share it with. Participants also felt that sharing information should be an optional feature included in the DMHI and that this feature could be managed by the client.

Transparent Information About Data Privacy

A few participants were concerned about where the DMHI's data would be stored and who would oversee the data. These participants emphasized that it was important for the DMHI to be transparent with this information.

Theme 8: Must Be Low Cost or Free

Nearly every participant interviewed expressed reluctance to pay for a mental health DMHI. Some reported that the high cost of in-person therapy would mean that the cost of an app would be an additional financial burden for people seeking mental health treatment. Other participants hesitated to pay for a DMHI without knowing whether the intervention was effective.

Discussion

Principal Findings

The objective of this study was to use participatory design to incorporate the perspectives of people with lived and living experiences of depression and anxiety into a new DMHI that could be integrated into clinical practice as part of a blended care model. To the best of our knowledge, this research is the first Australian study to partner with adults with living and lived experiences of depression and anxiety and use participatory design to conceive a blended care DMHI. Our mixed methods approach also provided valuable insight into our participants' needs, preferences, and expectations of DMHIs and clarified how the new DMHI could be integrated with psychotherapy in a blended care model. Survey data highlighted how respondents wanted to access the DMHI and their preferences for features, content delivery, and sharing of information via the DMHI. Interview findings converged with survey data but also provided in-depth detail on preferred content and features and how to sustain engagement with the new DMHI. To date, the study findings have informed the designs for a new Australian blended care digital system called myNewWay [48], which includes a mental health smartphone app that can be used alone or as part of blended care.

DMHI Needs, Preferences, and Expectations

Survey findings indicated that participants preferred accessing a DMHI via a smartphone app, rather than on a computer or tablet. This preference and other findings may reflect the opinions of people who are familiar with digital technology, as the level of digital literacy was relatively high in the study sample. Two important factors for addressing the needs, preferences, and expectations of people with lived and living experiences of depression and anxiety were ensuring that the DMHI was well designed and easy to use. Qualitative interviews also highlighted that including a variety of therapeutic content was important to people with lived and living experiences of depression and anxiety. These findings are consistent with DMHI research conducted before, during, and after the COVID-19 pandemic [11,31,47,62], indicating these 3 factors should be considered in the design of DMHIs for depression and anxiety. Though no clear trends in the graphic design of the DMHI were identified in surveys and interviews, participants wanted the overall esthetic, tone, and feel of the DMHI to be positive, encouraging, and uplifting. This is an important consideration given that past research has found that the esthetic qualities of DMHI design are linked to better usability and user-friendliness [11,62].

Participants were keen for a DMHI to be user-friendly, simple to navigate, and lacking in technical issues, given that (a lack of) ease of use was often associated with past negative DMHI experiences and disengagement. However, most participants were currently using or had used DMHIs, which aligns with the relatively high levels of digital literacy in the study sample. Future research should give special consideration to defining whether these qualities can be addressed in a similar way for people with higher or lower levels of digital literacy. In addition, a novel finding from qualitative interviews that builds upon previous work is that DMHI users preferred to receive short, positive motivational messages within the DMHI or via push notifications (if app based). This finding is aligned with research conducted before the COVID-19 pandemic [63], which found short motivational messages to be the most commonly used component of the myCompass self-help program. While this preference for short, positive motivational messages may be specific to conditions before the COVID-19 pandemic and DMHI users with high digital literacy, existing literature does suggest that the language used in DMHIs should be hopeful and confident [64]. Moreover, people with depression and anxiety may be experiencing concentration and working memory problems alongside any mental health symptoms or co-occurring issues, further supporting the notion that the length of messages should not be overly long.

In this study, the appeal of the DMHI was also connected to whether the product helped to improve their mental health symptoms and well-being. These results support the findings of the systematic review by Borghouts et al [25], who found that the perceived effectiveness of a DMHI will affect whether a user engages with it. Participants also suggested that the DMHI could help them monitor their mental health symptoms via a

XSL•FO
RenderX

self-tracking feature (ie, mood and sleep), which is consistent with previous research [31,62]. One point of differentiation between this study and past research is that interview findings showed which aspects of self-tracking were most preferred, including the visualization of changes over time, reflective journaling, and the ability to share progress with a mental health professional. In qualitative interviews, participants also expressed a strong preference for diverse DMHI content that referred to wellness practices in addition to a wide range of therapeutic techniques, such as healthy eating, physical exercise, and gratitude practices. This desire for diverse and comprehensive content may have stemmed from many participants' previous experiences with DMHIs that focus on a single therapeutic modality, such as CBT or mindfulness. Participants also wanted the DMHI to include features that help facilitate social connections, which again was most evident in the qualitative interview findings. This is unsurprising, given the importance of social connectedness in positive mental health outcomes [33], especially for depression [34]. Features that support social connectedness were also desired as an inclusion in past DMHIs [11,25], and the need for isolation during the COVID-19 pandemic may have exacerbated this need. Suggestions included incorporating an online community where DMHI users could connect with peers with similar experiences or being able to read or listen to personal stories of people who had overcome mental health challenges.

In line with our secondary aim, participants identified 4 strategies in surveys and interviews that could enhance user engagement with a DMHI: personalization, reminders, goal setting, and including short and achievable activities within the DMHI. Consistent with previous research [11,31,62], participants wanted to personalize a DMHI to suit their needs and set goals. Unlike other studies that saw personalization as customizing the interface (ie, colors, theme, and music) and reminders, qualitative interviews showed that participants viewed personalization as the ability to pick and choose the content and activities or have the DMHI suggest them based on their responses. These findings are especially important, given that a lack of DMHI personalization is a common barrier to user engagement [25] and a common source of user dissatisfaction [11]. Participants preferred a modular, flexible design that could be individually tailored over a less flexible linear program where all users received the same content. Consistent with previous research [35,36,62], participants suggested using custom reminders to engage and maintain user interest in the DMHI in both surveys and qualitative interviews. For example, by allowing users to customize when reminders are delivered or by prompting the user to check in with the DMHI throughout the day. Furthermore, the finding from qualitative interviews that short and achievable activities would facilitate engagement with a DMHI was unique, yet important to consider, as users of DMHIs may be experiencing anxiety and depression and associated symptoms, such as rumination, fatigue, and low energy, which may hinder their ability to engage with longer activities. On the basis of their systematic review, Borghouts et al [25] proposed that shorter module durations were associated with better user engagement in self-guided DMHIs. However, this finding was only based on 2 studies, suggesting that more research is needed to verify this finding.

Integrating DMHIs Into Routine Care

The study findings provide insight into participants' preferences regarding whether and how they would use a DMHI with health professionals in a blended model of care. However, it is important to note that these findings represent the views of people who tended to have high digital literacy and were either currently using or had used DMHIs. Participants were open to sharing their information with health professionals via the DMHI, and there was no clear preference for a DMHI to be self-guided or guided in surveys and qualitative interviews. These findings are in line with the potential need for a program to be used flexibly, either in a self-guided or guided format, throughout their mental health recovery and navigation through mental health treatment. Survey data indicated that participants were also comfortable with and positive about sharing data from a DMHI with a trusted health professional, such as a psychologist, general practitioner, or psychiatrist. These findings extend prior research by highlighting that participants wanted autonomy and control over what information they could share, which is especially relevant given the rapid acceleration of remote care via DMHIs and other digital technology during the COVID-19 pandemic [12]. Several participants expressed concerns about how the data collected by the DMHI would be used, stored, and accessed. These results align with a blended care qualitative study [65], which found that clients were not concerned about sharing personal data via an app if their data were kept secure, anonymous, and private. Previous research on user perceptions of stand-alone DMHIs [25] and blended DMHIs [47] also confirmed that data security, confidentiality, and transparency affect user uptake of DMHIs both before and during the COVID-19 pandemic.

Other factors that impacted whether someone was willing to use a DMHI were the product's credibility, cost, the inclusion of crisis support, and immediate distress management. In qualitative interviews, participants emphasized that a DMHI should be backed by scientific research and developed by a reputable organization, consistent with previous research that showed that inadequate information about credibility can affect user trust in a DMHI [11]. The inclusion of a crisis support section was highlighted as important in this study, as well as in the European user-centered study by Behr et al [47]. The inclusion of this feature can act as an additional safety feature when the program is released into the community, especially if it is used by individuals with higher symptom severity and frequent suicidal ideation in a self-guided format. The addition of distress management tools that can help an individual feel calmer in the moment may also be helpful for people with varying severity levels and assist with developing emotion regulation and distress tolerance. Finally, in both surveys and qualitative interviews, we found that participants were reluctant to pay for a DMHI and strongly believed it should be free or offered at a very low cost (ie, Aus $1-$10 [US $0.65-$6.5]). This corresponds with existing research indicating that many studies have found that participants prefer free DMHIs [11], highlighting the need for future DMHIs to be accessed free of charge or at a low cost. Future research should explore the drivers of this low willingness to pay for DMHIs and understand whether it is due to the low perceived value of these

XSL•FO
RenderX

interventions, general expectations that mental health care should be free, or other factors. Future research also needs to explore the optimal funding and business models to support the ongoing maintenance required to successfully integrate DMHIs into routine clinical care, especially given the higher availability of DMHIs overall following the COVID-19 pandemic.

Limitations

Two main limitations may affect the generalizability of the findings of this study. The first limitation was the nature of the sample recruited for the study. Although the sample included people with a wide range of symptom severity, it predominantly consisted of female, English-speaking, and city-dwelling individuals, with most having previously received mental health treatment. Most participants had good self-rated digital literacy (229/306, 74.8%) and spent >1 hour per day online (287/306, 93.8%), and >40% (131/306) had also used DMHIs in the past. Their opinions may not be representative of the general community, who may be eventual users of DMHIs, especially those who do not usually use digital products or those who have never accessed mental health support. The second limitation was that recruitment for this study took place during the COVID-19 pandemic. Due to the need for many people to isolate before COVID-19 vaccines were widely available, the digital provision of mental health services was expedited during this time [12] (eg, telehealth). Whether the findings generalize to the mental health care system after the COVID-19 pandemic is unknown, and further research will be needed to verify this for this study and other DMHI research conducted before the COVID-19 pandemic.

Conclusions and Future Directions

This study provides clear insights into the needs, preferences, and expectations of adults with lived and living experiences of anxiety and depression for a transdiagnostic DMHI. Although our results are most relevant for people with high levels of digital literacy and experience with DMHIs, our findings highlight the importance of using mixed methods approaches to incorporate lived experience feedback into DMHI design and development. For people comfortable with digital technology, therapeutic interventions that improve mental health symptoms and are perceived as helpful, engaging, and effective are most desirable. Specific features that could enhance user engagement for a DMHI targeted at depression and anxiety include reminders, a self-tracking feature for symptoms, and content that facilitates social connection and peer support (eg, online forum and personal stories). The DMHI for depression and anxiety should also include access to support and resources that users can access when feeling unwell or in crisis. The potential for detection of severe symptomology, such as suicidality in depression, also supports the utility of a DMHI that a person can use as part of a blended care model with a mental health professional.

To date, findings from the participatory design study have been applied in subsequent parts of the larger Australian research project [48]. Designs for the new DMHI were subjected to a co-design and prototype testing process, which was then used to develop a smartphone app that is part of the myNewWay blended care digital system. The smartphone app provides therapeutic content and symptom management strategies primarily based on CBT, including psychoeducation, cognitive restructuring, emotion awareness and acceptance, goal setting, problem-solving, behavioral activation, exposure, relaxation, and mindfulness. Results from the participatory design study with mental health professionals were used similarly and informed the development of a health professional portal [52]. Phase 2 of the larger Australian research project involved an implementation clinical trial to evaluate the myNewWay app and Health Professional portal when used alongside psychological therapy for depression and anxiety. Currently, the myNewWay blended care system is being updated based on feedback from clients and psychologists involved in the clinical trial. The blended care system will also undergo further evaluation in a randomized controlled trial to compare the effectiveness of blended care with myNewWay to the self-guided use of the smartphone app for improving symptoms of depression and anxiety.

Acknowledgments

The authors thank Nyree Gale for her support with the Black Dog Institute Lived Experience Resource Network. Abstract

Background: Sleep duration plays a crucial role in cognitive health and is closely linked to cognitive decline. However, the relationship between sleep duration and cognitive function in the Chinese population remains poorly understood.

Objective: This study aims to evaluate the association between sleep duration and cognitive function among middle-aged and older adults in China.

Methods: Using data from 15,526 participants in the 2020 China Health and Retirement Longitudinal Study, we used 3 composite indicators, encompassing episodic memory, mental acuity, and overall cognitive function to evaluate cognitive performance. Sleep duration per night, self-reported through face-to-face interviews, was also obtained. Adjustments were made using multiple generalized linear regression models, accounting for demographic, lifestyle, and health-related covariates.

Results: Among the 15,526 respondents analyzed, 53.02% (8232/15,526) were female and 46.98% (7294/15,526) were male, with an average age of 61.5 (SD 9.27) years. Those reporting sleep durations of 4 hours or less (β=−1.85, 95% CI −2.07 to −1.62), 5 hours (β=−0.55, 95% CI −0.78 to −0.33; *P*<.001), 9 hours (β=−1.78, 95% CI −2.17 to −1.39), and 10 hours or more (β=−3.01, 95% CI −3.39 to −2.63) per night had a significant negative relationship with cognitive function. In the adjusted model, the negative impact of long sleep (≥10 hours) on overall cognitive function became more pronounced (β=−3.01, 95% CI −3.39 to −2.63; *P*<.001), followed closely by extremely short sleep (≤4 hours; β=−1.85, 95% CI −2.07 to −1.62; *P*<.001).

Conclusions: This study reveals an inverted U-shaped relationship between sleep duration and global cognitive decline, indicating that cognitive function should be closely monitored in individuals with both short and long sleep durations. Consequently, public health strategies should prioritize the promotion of moderate sleep to mitigate the cognitive risks associated with aging, particularly in culturally specific contexts.

Introduction

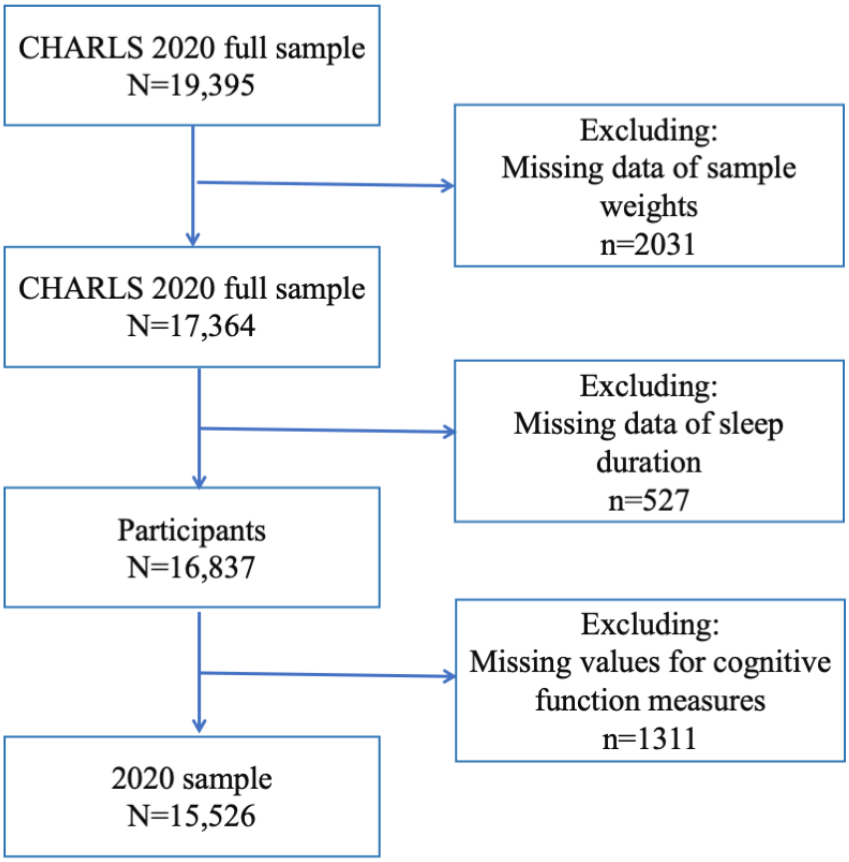
Background

Cognitive impairment poses a significant challenge in the context of global aging, profoundly affecting societal development and individual well-being [1]. In China, approximately 30% of the middle-aged and older population, representing over 260 million people, experience cognitive decline [2-4], which undermines autonomy and imposes substantial economic burdens on families and society [5,6]. Among various influencing factors, sleep duration has emerged as a potential mitigator of cognitive decline, with both insufficient and excessive sleep being associated with impaired cognitive performance [7,8].

Studies conducted in the United States, such as the English Longitudinal Study of Aging (ELSA) and the Health and Retirement Study, have revealed that both short and long sleep durations adversely affect cognitive function [9,10]. Specifically, the ELSA study found that older adults who sleep less than 5 hours per night have significantly lower cognitive scores compared with those who sleep for 7 hours [11,12]. Various mechanisms have been proposed to explain these findings, including impairment of the brain's ability to clear metabolic waste due to insufficient sleep and the reflection of underlying health problems through excessive sleep [13-15]. However, these studies are predominantly focused on Western populations, and their findings may not be entirely applicable to other cultural contexts. In China, research on the relationship between sleep duration and cognitive function is relatively scarce and often relies on single cross-sectional data [16,17]. Furthermore, systematic evaluations of this relationship, particularly with respect to sex and age differences, are lacking. In addition, most existing studies are limited to specific age groups or fail to account for the moderating effects of demographic factors such as sex and age [18]. Thus, it is crucial to conduct a more comprehensive assessment of the complex relationship between sleep duration and cognitive function.

Objectives

Given the distinctions in historical ethnic, economic, and sociocultural background, Chinese adults had different sleep patterns contrasted with other countries [19,20]. This study uses nationally representative data from the China Health and Retirement Longitudinal Study (CHARLS) to systematically examine the relationship between sleep duration and cognitive function. By subdividing cognitive function into mental intactness and episodic memory, this study provides evidence to support improving the cognitive health among middle-aged and older people. We hypothesized that both short and longer sleep durations are strongly associated with cognitive decline.



Methods

Study Design

This cross-sectional study used data from the 2018 survey of CHARLS, conducted between 2018 and 2020, which surveyed residents aged 45 years or above in 28 provinces across China [21,22]. The CHARLS focused on aging-related issues in China, the largest upper-middle-income country, and aimed to align with leading international research studies to ensure cross-study comparability of results [23]. Initiated in 2011, the CHARLS conducted follow-ups every 2 or 3 years, including in 2013, 2015, 2018, and 2020, to collect a nationally representative sample of the middle-aged and older adults in China, using a multistage stratified sampling technique with 450 villages distributed in 150 counties in 28 provinces. In this study, we used the latest CHARLS wave in 2020, with 19,816 individuals, to investigate the associations between sleep duration and cognitive function. Figure 1 shows a schematic flow diagram of the study sample [24].

Figure 1. The flowchart of the study sample from the 2020 China Health and Retirement Longitudinal Study (CHARLS).

Ethical Considerations

The CHARLS study protocol adhered to the principles of the Declaration of Helsinki and received ethical approval from the institutional review board of Peking University (ethical approval number IRB 00001052-11015) [25]. As this study involved a secondary analysis of existing data sets, ethical approval was not required under the research ethics policies and procedures of the London School of Economics and Political Science. This cross-sectional study follows the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline. All CHARLS participants provided written informed consent before data collection [26].

Cognitive Function

To evaluate cognitive performance, we used 3 composite measures based on the framework of the Health and Retirement Study and other cognitive function research, which include the word recall test, the Telephone Interview of Cognitive Status, and a pentagon-drawing test. The word recall test assessed episodic memory by requiring respondents to immediately recall 10 Chinese nouns (immediate recall; just read to them in any order) and then recall the same list with 4-minute delay (delayed recall). The episodic memory score was calculated as the average of immediate and delayed recall scores, ranging from 0 to 10. The Telephone Interview of Cognitive Status and a pentagon drawing test were used to assess mental intactness, focusing on time orientation, numerical ability, and visuospatial skills. Participants performed tasks such as serial subtractions, identifying the current data (month, day, year, and day of the week and season) and replicating a drawing of overlapping pentagons [27,28]. The scores from these tasks were combined into a single mental intactness score, ranging from 0 to 11. The global cognitive function was calculated as the sum of the episodic memory and mental intactness scores, with higher scores indicating better cognitive performance [29,30].

Sleep Duration

Drawing upon data from the ELSA conducted in England, CHARLS gathered self-reported sleep duration figures during face-to-face interviews using an open-ended format. Specifically, participants were queried about their average sleep hours per night over the past month: “In the past month, how many hours of sleep have you had on average per night?” In alignment with the previous CHARLS sleep study [31-34], responses were subsequently categorized into 7 sleep duration groups (≤4, 5, 6, 7, 8, 9, and ≥10 hours per evening). Daytime napping patterns were assessed through the question: “In the past month, how long have you napped on average after lunch?” leading to 4 napping duration categories: nonnappers (0 min), short nappers (<30 min), moderate nappers (30-90 min), and extended nappers (>90 min). In line with the previous CHARLS study on sleep, we divided respondents into 3 sleep duration categories in the analyses. The specific categorization is as follows: a sleep duration of 7 to 8 hours is considered the standard sleep group, less than 7 hours is considered the short sleep group, and more than 8 hours is considered the long sleep group [35].

Consistent with the approach adopted in a previous CHARLS on sleep patterns, we classified participants into 3 sleep duration

XSL•FO
RenderX

categories for analysis. The detailed categorization criteria are outlined as follows: individuals with a sleep duration of 7 to 8 hours are the standard sleep group, those sleeping less than 7 hours are the short sleep group, and those with a sleep duration exceeding 8 hours are the long sleep group.

Covariates

The CHARLS used a structured questionnaire to collect comprehensive sociodemographic and health-related data. The covariates considered potentially influential in shaping the associations included age; sex; educational attainment (elementary school and below, secondary school, and college and above); marital status (married vs others); residence (rural vs urban); smoking and drinking status (never vs current); visual and hearing impairment; self-reported general health status (ranging from very good to very poor); self-reported life satisfaction (spanning from completely satisfied to not at all satisfied); daytime napping habits; depression; and chronic disease condition (none, mild, and severe). In addition, sample weights were considered during the analysis to adjust for the representativeness of the sample.

Statistical Analysis

In this study, ANOVA was used for numerical variables, while ordered *t* test and chi-square tests were conducted for discrete variables to compare respondent characteristics among different sleep groups, specifically short sleepers, standard sleepers, and those with long sleep disorders. Continuous variables were summarized with means and SDs, while categorical variables were reported in terms of counts and percentages. To maximize statistical power, the sample size for analysis was allowed to vary based on the quantity of valid responses for each cognitive metric. For the continuous cognitive measures, a generalized linear model with a Gaussian distribution and an identity link function was used. A comprehensive suite of covariates, encompassing demographic factors such as age, sex, educational attainment, marital status, and lifestyle attributes, including smoking and alcohol consumption, were incorporated into our analytic framework. In addition, measures of functional independence based on activities of daily living, urban versus rural residency, self-assessed health status, life satisfaction, depressive symptomatology, and the presence of chronic medical conditions were included as covariates to mitigate potential confounding effects. Statistical significance was set at 2-sided $P<.05$. All data analyses were conducted using Stata (version 18.0; Stata Corp).

Results

Sample Characteristics

The characteristics of the surveyed individuals are shown in Table 1. The study sample included 15,526 respondents, including 8232 female participants (53.02%) and 7294 male participants (46.98%), with an average age of 61.5 (SD 9.27) years. Among them, 7808 individuals (N=15,526, 50.29%) belonged to the standard sleep group, 6034 (N=15,526, 41.92%) to the short sleep group, and 1084 (N=15,526, 6.98%) to the long sleep group. In terms of the cognitive function composite score, participants in the standard sleep group demonstrated the highest mean score of 11.03 (SD 4.34), followed by the short sleep group with a mean score of 10.32 (SD 4.52). Conversely, the long sleep group recorded the lowest mean score of 8.40 (SD 4.67). Regarding the mental intactness composite score, a similar pattern emerged, with the standard sleep group scoring highest (mean 6.81, SD 2.96), followed by the short sleep group (mean 6.35, SD 3.06) and the long sleep group recording the lowest score (mean 5.27, SD 3.14). In the domain of episodic memory, the standard sleep group achieved a mean score of 4.22 (SD 2.06), outperforming the short sleep group (mean 3.97, SD 2.08) and the long sleep group (mean 3.13, SD 2.19). Collectively, these findings underscore the superior performance of the standard sleep group across cognitive function, mental intactness, and episodic memory domains, compared with both the short and long sleep groups. Notably, the long sleep group consistently shows the lowest scores across all 3 cognitive domains, hinting at a potential association between sleep duration and cognitive health.

Trajectories for Sleep Duration Across Cognition Status

Figure 2 displays the trajectories of cognitive scores across different sleep durations, including cognitive function, mental intactness, and episodic memory. Overall, in 2020, the relationship between sleep duration and the scores of the selected population in cognitive function, mental intactness, and episodic memory exhibited an inverse U-shaped pattern.

XSL•FO
RenderX

Figure 2. Trajectories of cognitive scores across groups with different sleep durations.

In Table 2, in the unadjusted analysis, compared with individuals sleeping for 7 hours, those in the long sleep group (≥10 hours) exhibited the most significant negative impact on cognitive function (β=−1.85, 95% CI −2.17 to −1.52; *P*<.001). Subsequently, the 9-hour sleep group demonstrated the second-highest negative effect with β=−0.85 (95% CI −1.02 to −0.64; *P*<.001). Unhealthy sleep patterns had a detrimental influence on mental intactness than on episodic memory. Specifically, in the very short sleep group (≤4 hours), the negative effect on mental intactness was β=−0.61, whereas for episodic memory, it was β=−0.22. Intriguingly, no significant association was observed between cognitive function, episodic memory, and mental intactness with sleep duration in the 6-hour sleep group (*P*>.05). Upon adjustment, the long sleep group (≥10 hours) showed an exacerbated negative impact on overall cognitive function, with β increasing from −1.85 to −3.01, 95% CI −3.39 to −2.63; *P*<.001). The second most significant negative effect shifted from the 9-hour sleep group to the very short sleep group (≤4 hours) in the adjusted model with β=−1.85 (95% CI −2.07 to −1.62; *P*<.001). Consistent with the unadjusted findings, unhealthy sleep continued to have a greater adverse effect on mental intactness compared with episodic memory. The 6-hour sleep group maintained a nonsignificant association with cognitive function (*P*>.05).

Discussion

Principal Findings

This nationally representative study, using the CHARLS database, reveals a statistically significant inverse U-shaped association between sleep duration and cognitive function. The findings reveal that the standard sleep group had the optimal cognitive scores, episodic memory, and mental intactness, whereas groups with either short or long sleep durations were significantly associated with cognitive decline, with long sleep having a more pronounced negative effect.

These findings align with those from major international studies, such as the ELSA and the Health and Retirement Study, which also identified the detrimental effects of both short and long sleep on cognitive function [12,36]. The consistent inverted U-shaped relationship between sleep duration and cognition suggests a universal phenomenon, albeit influenced by cultural and social contexts. However, it is important to recognize that cultural and social contexts may partly explain the observed variations in findings across different populations. For instance, in Chinese culture, familial support and older adult lifestyles may exacerbate the negative effects of prolonged sleep duration. The emphasis on close family bonds in Chinese society could inadvertently lead to excessive care or protection of older adults [37], potentially reducing their physical activity levels and contributing to cognitive decline. In addition, traditional health beliefs that promote prolonged rest as beneficial may further amplify the prevalence of long sleep among older adults in China [38]. These factors, coupled with a slower pace of life and lower levels of social engagement in some Chinese populations, present a unique cultural framework that differs from Western populations, where long sleep durations are less prevalent [39]. Thus, the findings of this study impart profound insights into how cultural and social factors influence the interplay between sleep duration and cognitive function, offering perspectives that are infrequently explored in the realm of international scholarly research.

From a mechanistic perspective, the adverse consequences of short sleep on cognitive function are well-documented. Short sleep may hinder the elimination of cerebral metabolic waste, including β-amyloid, a neurotoxic protein linked to Alzheimer disease [40,41]. Inefficient removal of such waste materials can disrupt neuronal function and impair cognitive processes. Moreover, sleep deprivation interferes with the equilibrium of neurotransmitters, including dopamine and serotonin, which are critical for mood regulation, attention, and decision-making [13]. These disruptions can culminate in impairments in executive function and emotional regulation, both integral aspects of mental well-being. Furthermore, hormonal dysregulation associated with insufficient sleep, such as elevated cortisol levels, has been shown to exert neurotoxic effects on the hippocampus, an essential brain region for memory consolidation. Moreover, decreased levels of growth hormone during sleep deprivation may also hinder tissue repair and neuronal regeneration, further compromising brain health [42].

XSL•FO
RenderX

The severity of short sleep's impact varies across different cognitive domains. Mental integrity, along with episodic memory, suffers from sleep deprivation; however, the disruptions to mental integrity appear more profound and systemic. Insufficient sleep not only impairs attention, executive function, and emotional stability but also exerts broad effects on mental health and cognitive capabilities, mediated by chronic stress and heightened inflammatory processes, ultimately leading to structural damage in the prefrontal cortex and neurotransmitter imbalances [43]. Conversely, while the impact on episodic memory is notable, it is relatively confined to specific processes such as memory formation and consolidation, often stemming from hippocampal dysfunction and increased susceptibility to memory interference. Therefore, the systemic nature of sleep deprivation's effects on mental integrity renders then more comprehensive and extensive when compared with its effects on episodic memory [44]. In contrast, long sleep duration is frequently associated with underlying health conditions that may indirectly contribute to cognitive decline. For instance, prolonged sleep has been linked to elevated inflammatory markers like C-reactive protein and metabolic dysregulation [45,46]. These biological responses could reflect the presence of chronic illnesses or suboptimal health states adversely affecting cognitive function. In addition, sex differences in physiological, hormonal, and social factors may further exacerbate cognitive disparities associated with long sleep [47,48]. Specifically, variations in estrogen levels and their neuroprotective effects could partly account for differing cognitive outcomes between men and women. Socially, women may encounter distinct roles and stressors that interact with sleep patterns, potentially influencing cognitive health in unique ways [49]. These findings highlight the need for a sophisticated appreciation of the interplay between biological, social, and sex-specific factors with sleep duration in influencing cognitive outcomes.

Since the declines are primarily centered on mental intactness, the resulting downstream consequences on instrumental activities of daily living warrant explicit consideration, particularly for older adults living alone. Low scores in these domains map onto tangible challenges in everyday life. Impairments in mental intactness, encompassing attention, and sequencing and visuospatial copying abilities, are closely tied to instrumental activities of daily living, which include managing medications and finances, keeping appointments, using the phone, navigating public transport, or following multistep cooking and home-safety routines. Deficits in episodic memory further undermine an individual's capacity for new learning and recall. This, in return, affects their adherence to treatment plans, remember emergency contacts, or recall whether gas or electric appliances have been turned off. Together, these impairments heighten risks that go far beyond a mere reduction in independence, which includes medication errors, missed or duplicate doses, falls resulting from disorientation, wandering or getting lost outdoors, malnutrition due to irregular meals, fire hazards, and vulnerability to financial scams. These risks are particularly pronounced among older adults living alone, underscoring the need for proactively identifying at-risk sleepers at both the clinical and community levels.

The study's strengths lie in its use of nationally representative data from the CHARLS, bolstering the external validity and generalizability of the findings. The substantial sample size reinforces the robustness of the results, enabling an in-depth analysis of sleep duration and its correlation with cognitive function among middle-aged and older adults. Importantly, this research contributes significant scientific evidence to inform sleep-based interventions aimed at promoting cognitive health. Translating these strengths into action, we outline implementable strategies for prediction, public communication, and prevention that public-sector and primary-care services can adopt now.

These findings provide a solid foundation for developing predictive models. They motivate nonlinear specifications (eg, restricted cubic splines or categorical cut-points at ≤4, 5, 6, 7 [reference], 8, 9, and ≥10 hours) combined with demographic, health, and psychosocial covariates already collected in population surveys and primary care. Models can be trained to estimate individual risk of low global cognition and domain-specific deficits (especially attentional or executive components captured by mental intactness), enabling risk stratification, providing early warning signals for clinicians, and targeting of behavioral counseling for those who stand to gain the most.

The study also offers data to support public awareness initiatives. Given the clear, nonlinear risk signal at both extremes of sleep duration and the relative sparing at approximately 7 hours, public health messaging can be framed in plain language (eg, "both insufficient and excessive sleep are linked with worse thinking and attention in later life"), while emphasizing that attention or executive skills appear especially vulnerable to chronic unhealthy sleep habits.

While acknowledging its strengths, several limitations merit recognition. First, the cross-sectional design of this study precludes the establishment of causal relationships between sleep duration and cognitive function, necessitating longitudinal studies to ascertain whether sleep duration directly influences cognitive trajectories over time or if other factors mediate this relationship. Second, the reliance on self-reported sleep data may introduce information bias, potentially affecting the accuracy and reliability of the results. Incorporation of objective sleep measures, such as actigraphy or polysomnography, could yield more precise assessments in future studies. Third, the relatively smaller sample size in older age groups may have contributed to increased variability in the findings, diminishing the statistical power to detect significant associations in this subgroup. Finally, the study did not account for other potential confounding factors, such as dietary habits, genetic predispositions, or environmental influences, which may play crucial roles in shaping the observed relationships and warrant further exploration.

In prioritizing future research endeavors, longitudinal study designs should be used to confirm causal relationships and examine potential mediators and moderators of the relationship between sleep duration and cognitive function. For instance, biomarkers indicative of inflammation and metabolic health could provide valuable insights into the underlying biological mechanisms. Similarly, lifestyle variables, including physical

XSL•FO
RenderX

activity, social engagement, and dietary habits, could elucidate the broader context of sleep-cognition interactions. In addition, comparative analyses across diverse cultural milieux could augment our comprehension of how sociocultural factors shape these relationships, ultimately guiding the development of tailored interventions to foster cognitive health in various populations.

Conclusions

In summary, this study reveals that moderate sleep duration is significantly protective of cognitive function in middle-aged and older adults. The identified risks associated with both short and long sleep underscore the necessity for individualized sleep health interventions tailored to personal characteristics. Public health policies should account for sex and age disparities to implement effective interventions aimed at enhancing cognitive health in aging populations, thereby alleviating the societal and economic burdens associated with global aging.

Acknowledgments

This work was supported by grant zyyzdxk-2023249 from the high-level traditional Chinese medicine key subject construction project of the National Administration of Traditional Chinese Medicine-Evidence-based Traditional Chinese Medicine, grant B2025019 from the Hebei Administration of Traditional Chinese Medicine, and grant YLZLXZ24G033 from the National Health Commission. The authors thank the China Health and Retirement Longitudinal Study team for providing data and simple training in using the database.

Authors' Contributions

HR and JL conceived the research design. GG and YJ conducted the data analysis and drafted the initial version of the manuscript. JD, XZ, and XL offered insights pertaining to the presentation of the findings and critically reviewed the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Attention-deficit/hyperactivity disorder (ADHD) is a prevalent neurodevelopmental disorder affecting 3%-7% of children globally. Alternative treatments are needed to address the limitations of traditional pharmacotherapy and nonpharmacotherapy, such as drug side effects and substantial time and financial costs. In this light, digital therapeutics for childhood ADHD are emerging as an effective alternative, with the benefits of potentially being free from serious side effects associated with software-based treatments and facilitating easy home use without constraints on time or space.

Objective: This study aims to evaluate whether a 4-week digital treatment program can improve symptoms, problem behaviors, and neurocognitive functions in children with ADHD, independent of medication status, while also gauging participant satisfaction with the program.

Methods: We recruited 22 Korean children aged 6-12 years with a diagnosis of ADHD. During the preintervention visit, we collected data on ADHD symptoms, relevant behavior scales, and neurocognitive assessments. Participants then used the program 5 times per day, 5 days a week for 4 weeks at home. At the postintervention visit, we collected the same data as during the preintervention visit and gathered additional feedback on their experience over the 4 weeks.

Results: A total of 19 participants were included in the statistical analysis, showing significant decreases in scores across various categories. These included the Korean ADHD Rating Scale (Total: P=.004; Inattentive: P=.004; and Hyperactive-impulsive: P=.01) and Korean Conners' Parent Rating Scale (Total: P<.001; Impulsive-hyperactive: P=.001; and Conduct Problem I: P=.04). Significant improvements were also noted in the Stroop word (P=.004), color (P<.001), and color-word (P<.001) scores. No significant differences in treatment effects were found between medicated and unmedicated participants. Caregiver and child satisfaction surveys yielded mean ratings of 4.3 and 4.1 out of 5, respectively.

Conclusions: A 4-week gamified intervention improves attention and hyperactivity-impulsivity in children with ADHD, irrespective of medication status, demonstrating its potential effectiveness and acceptability as a treatment option. As this is a small pilot study and underpowered, larger studies with appropriate control groups are needed in future research.

Introduction

Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental disorder characterized by persistent hyperactivity, impulsivity, or inattention that disrupts daily functioning [1]. The condition is heterogeneous, typically characterized by persistent patterns of inattention, hyperactivity/impulsivity, or a combination of both [2]. Most diagnoses occur early in life, with estimates indicating that approximately 3%-7% of children globally are diagnosed with ADHD [3,4]. Both in Korea and internationally, there has been a steady increase in ADHD diagnoses, primarily among children and adolescents [5,6].

In addition to the hallmark symptoms of persistent inattention and hyperactivity, ADHD can lead to cognitive and functional impairments in affected children, including challenges with response inhibition and working memory [2]. It also results in diminished academic performance and strained peer or family relationships, adding further distress to those affected [7]. Moreover, if not addressed, childhood ADHD can persist into adulthood, continuing to disrupt everyday life [8-10].

Child ADHD management strategies are categorized into pharmacological and nonpharmacological approaches. Although prescribed medication is frequently used to alleviate ADHD symptoms [10], parents often hesitate to medicate their children due to potential or actual side effects. These side effects commonly include decreased appetite, sleep disturbances, and stomach problems [4]. Furthermore, selecting the optimal medication for a particular patient can be time-consuming [10,11]. Nonpharmacological approaches include parental training, cognitive behavioral therapy, and cognitive training. These treatments can burden parents because they are both time-consuming and costly [12]. In addition, the scarcity of professional trainers makes access to nonpharmacological ADHD care more challenging. These limitations of traditional treatments have spurred the development of new ADHD treatments using advanced digital technologies.

Digital therapeutics (DTx) are defined as health software intended to treat or alleviate a disease, disorder, condition, or injury by generating and delivering a medical intervention that has a demonstrable positive therapeutic impact on a patient's health [13-15]. They offer high accessibility in terms of both time and location [16] and considerably reduce concerns about side effects due to their noninvasive nature. Moreover, it demands less supervisory effort than other behavioral therapies, since embedded algorithms can automatically adjust the usage instructions and program difficulty according to the user's level.

Gamification is an additional strategy used by DTx to enhance user engagement and experience [17,18]. Given that children with ADHD often display heightened novelty-seeking behaviors [19], they generally favor game-based activities. Presenting therapeutic interventions in a gamified format can greatly improve adherence to treatment regimens.

Previous research has consistently shown that various multitasking tasks can mitigate ADHD symptoms [20,21]. However, the widely used dual n-back task is recognized for its high level of difficulty and complex rules. These characteristics can make onboarding challenging for children—particularly those with ADHD—leading to early dropout, and sustaining motivation for continued training can be difficult. Given these challenges of conventional interventions, some researchers developed a gamified intervention as an alternative treatment. One of the most notable approaches was EndeavorRx, a Food and Drug Administration (FDA)-cleared DTx, developed by Akili Interactive for children with ADHD, which is effective in mitigating inattentive symptoms [21-23]. It was developed by incorporating gamified cognitive training that involved multitasking Go/No-Go tasks and sensory-motor tasks [24]. The results showed that digital-based multitasking tasks, focusing on perceptual discrimination and sensory-motor coordination, were effective in enhancing attention in both older adults and children with ADHD [21,24].

Notably, the driving task effectively increases cognitive load while maintaining an engaging experience for children. Nevertheless, this type of multitasking approach also presents limitations, particularly in providing finely tuned difficulty adjustments. By implementing a difficulty adjustment system, it is possible to engage a broader range of age groups at different stages of cognitive development. This approach also helps address cultural differences related to disparities in access to digital technologies.

Therefore, we present a gamified DTx named "StarRuckus" (eMotiv). It aims to reduce core ADHD symptoms through the simultaneous execution of n-back and driving tasks, including a personalized difficulty adjustment algorithm to ensure training benefits [21,25,26]. It functions as an enhanced version of the Go/No-Go task (0-back task), allowing for the customization of difficulty levels through varying n levels [27,28]. While difficulty adjustment in Go/No-Go tasks typically involves manipulating factors such as stimulus presentation time, the number of stimuli, and the number of discriminative targets, the n-back task allows for additional parameters, including the n level and the inclusion of lure stimuli.

To the best of our knowledge, this study is the first to implement multitasking that combines an n-back task with a driving task as a cognitive training intervention aimed at improving ADHD symptoms. Computerized multitasking working memory training is recognized for its effectiveness in alleviating core symptoms of ADHD, such as inattention [29] and hyperactivity-impulsivity [20]. Multitasking n-back training strengthens the right inferior frontal gyrus, an area exhibiting structural [30,31] and functional deficits in children with ADHD [32,33]. Furthermore, multitasking driving training can enhance neural activity efficiency in the prefrontal cortex [24,34], thereby improving attention in children with ADHD [21,26,35].

XSL•FO
RenderX

Another distinctive feature of StarRuckus is its focus on the reward system within its gamification elements, setting it apart from other DTx interventions. After providing a personalized difficulty level tailored to each user, the system delivers differentiated in-game rewards based on performance outcomes. These rewards can be collected and used to unlock additional content, such as character purchasing and town customization.

This pilot study explored the effectiveness of StarRuckus as a potential treatment for children with ADHD, both medicated and unmedicated, while assessing its appeal to both children and their caregivers. We evaluated improvements in symptomatology and behavior scales as well as cognitive-neurological indicators before and after a 4-week intervention with StarRuckus. In addition, feedback on usage experience and safety was gathered from children and caregivers. Through this study, we aimed to provide preliminary evidence supporting the efficacy and acceptability of StarRuckus as a DTx.

Methods

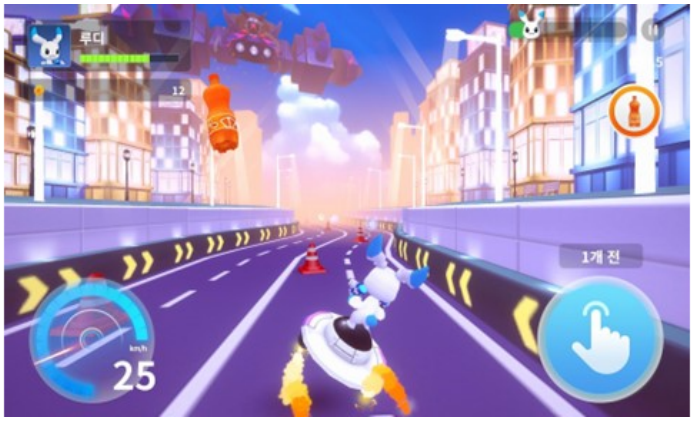
Participants

Two cohorts, 1 taking medication and 1 without medication, were included in the study. The participants in both cohorts agreed not to alter their medication status during the study, understanding that any change could result in their withdrawal. Although this agreement was not binding, participants were permitted to change their medication status after consulting with their doctors. They were also required to report any medication changes during the study. Inclusion criteria for the participants consisted of (1) a confirmed *DSM-5* diagnosis of ADHD; (2) age between 6 and 12 years; and (3) either consistently taking medication for ADHD for at least 30 days or not taking psychotropic medication for at least 3 days to allow for a washout before baseline measures. Exclusion criteria for the participants included (1) current comorbid psychiatric diagnoses listed in *DSM-5* with marked symptoms; (2) initiation of behavior therapy within the last 4 weeks or plans to change or start behavior therapy during the study; (3) motor conditions reported by parents that prevent the use of digital interventions; (4) color blindness as reported by caregivers; (5) uncorrected visual or auditory impairments; and (6) any other medical condition that might confound the study data.

Procedures

Participants were recruited from a community child center and a web-based community for caregivers of children diagnosed with neurodevelopmental disorders. Children and caregivers willing to participate completed a web-based survey to check eligibility. In addition, caregivers had to provide clinic-issued documentation as proof of their children's medical histories. If children were eligible for the study, caregivers were contacted to provide instructions about the course of the study.

The study consisted of 3 phases: a preintervention visit, the intervention period, and a postintervention visit. At the preintervention visit, participants and their caregivers received detailed information about the research purpose, eligibility criteria, procedures, potential risks and benefits, and confidentiality aspects. After comprehending the study protocol, they provided informed consent. Subsequently, the caregiver and child were placed in separate rooms for data collection. While parents completed questionnaires regarding their children's behavior, the children engaged in several neurocognitive tasks primarily focused on attention and working memory. Upon completion of the data collection tasks, children tested StarRuckus for approximately 10 minutes, with supervision to ensure compliance with the rules. At the conclusion of the preintervention period, tablets preinstalled with StarRuckus were lent to the participants for use during the intervention period. Throughout the intervention phase, participants had to complete 5 daily sessions, each lasting about 20-25 minutes, 5 days a week for 4 weeks. Compliance was electronically monitored by researchers, and reminder text messages were sent to parents when they were likely to fall short of the required session counts. In addition, caregivers and participants were instructed to report any adverse events to investigators in real time. The postintervention visit mirrored the preintervention visit, including neurocognitive tasks for the participants and questionnaires for the parents. Following data collection, satisfaction and inconvenience questionnaires were completed, incorporating reports of any adverse events. The children's questionnaires were designed for readability, and researchers assisted the children with any difficulties.



Digital Intervention

StarRuckus (Figure 1) is a gamified training program designed for children aged 6 to 12. It is a digital application available for download on both Android (Google LLC) and iOS (Apple Inc) platforms, aimed at mitigating ADHD symptoms in children. The program includes two main tasks: (1) a continuous visuomotor driving task and (2) an n-back task [36], which engages working memory. In the driving task, users maneuver the character by tilting the device left or right. The primary objective of this task is to dodge as many obstacles as possible while collecting target points. The n-back task, a working memory exercise, challenges participants to identify whether each presented stimulus matches one shown several steps earlier in the sequence [37,38]. The maximum difficulty level in the app goes up to 4-back. Once all 5 sessions are completed, the training program ends automatically.

In a cognitive training program, it is crucial to maintain a level of difficulty that aligns with the users' skill levels. The adaptive algorithm of StarRuckus adjusts task difficulty in real time based on individualized performance metrics tailored to each task type. For instance, in n-back tasks, increased difficulty may involve raising the n level or modifying stimulus parameters, such as increasing lure frequency or shortening stimulus duration. In driving tasks, difficulty can be modulated through speed changes. When users demonstrate improved performance, the system gradually introduces more challenging levels. Conversely, if performance declines, the difficulty is reduced to keep the tasks manageable and maintain engagement.

XSL•FO
RenderX

Figure 1. StarRuckus in-game screenshot.

In addition to providing internal rewards through a gamified treatment designed to entertain children, the program included various in-app rewards to maintain participant engagement. For example, children were able to build their own villages with the resources gained during the training process. They could also use these resources to outfit new space vehicles and characters.

Measures

Korean ADHD Rating Scale

A Korean ADHD Rating Scale (K-ADHD-RS) was used, originally developed by DuPaul in 1991 [39]. The K-ADHD-RS, comprising 18 questions, is a prevalent measure for assessing symptoms of ADHD. There are 2 subscales, 1 for inattention and 1 for hyperactivity. The Korean version, validated and proven reliable in 2002 [40,41], is extensively used in Korea to support ADHD diagnosis in children. In the scale, 0 corresponds to “rarely or never,” 1 to “somewhat,” 2 to “often,” and 3 to “always or very often.”

Korean Conners’ Parent Rating Scale

We used the Korean Conners’ Parent Rating Scale (K-CPRS), originally developed in 1970 [42,43]. It is a widely recognized tool for assessing problematic behaviors in children. Although analogous to the original, the Korean edition features a different distribution of questions across factors. According to the factor analysis results of the Korean edition [44], our assessment focused on 5 identified factors: Impulsive-hyperactive, Conduct Problem I, Conduct Problem II, Psychosomatic, and Anxiety [45].

ADHD Diagnostic System

The ADHD diagnostic system (ADS) is a computerized attention test designed to facilitate the diagnosis and assessment of treatment effects for ADHD. It is a type of continuous performance test [46,47] and features both ADS visual and auditory (ADS-A) modules, each containing 3 distinct stimuli (1 target and 2 nontargets). The proportion of targets was controlled to appear at 22% in the first part, 50% in the second part, and 78% in the final part of the task, respectively. Participants were instructed to press the spacebar when the target stimulus appeared and to ignore nontarget stimuli. Key outcome measures in our analyses included omission error, commission error, response time (RT), and RT SD [45].

Stroop Color and Word Test

In this study, we used the Korean version of the Stroop Color and Word Test [48], validated for children aged 5-14 years and originally developed in 1978 [49]. The Stroop test, primarily assessing selective attention and processing speed, consists of 3 card sessions: Word, Color, and Color-Word. Each session presents 100 stimuli, and children are timed to read them as quickly as possible within a 45-second limit. Specifically, children are instructed to read black words denoting color names (red, green, and blue) in the first session, name the printed color marked with “XXXX” in red, green, and blue in the second session, and name the printed color instead of the incongruently printed word in the final session. Raw scores from the word, color, and color-word sessions, along with the interference score, were recorded for data analysis.

Digit Span

The digit span (DS) test, a subcomponent of the Wechsler Intelligence Scale for Children-Fifth Edition [50], was administered using the Korean standardized version in this study [51]. The DS test, which involves memorizing a sequence of digits beginning with 2 digits and increasing by 1 digit at each step through 2 trials at each level until both are incorrect, was generally used to evaluate working memory and consists of 3 subtasks: DS Forward, DS Backward, and DS Sequencing. In the forward task, the examiner reads numbers aloud, and the participant recalls them in the order presented. The backward and sequencing tasks follow a similar procedure to the forward task but require participants to recall the sequence in reverse order or reorder the digits numerically, respectively. These tasks are generally more challenging than the forward task as they necessitate manipulating and reorganizing the received information. Scoring was based on the total number of successful trials across all subtasks.

Statistical Analysis

Behavioral and cognitive outcome measures were analyzed using open-source statistical libraries in Python (version 3.9.12; Python Software Foundation). Depending on the Shapiro-Wilk normality test results, either a 1-sample *t* test (parametric) or a Wilcoxon rank-sum test (nonparametric) was performed. A 2-tailed significance level of $P<.05$ was considered statistically significant, and Cohen *d* effect sizes were calculated.

Ethical Considerations

This study received approval from the Public Institutional Review Board designated by the Ministry of Health and Welfare, Korea (approval no P01-202305-01-007). Written informed consent was obtained from caregivers of all participating children, and assent was obtained from children when appropriate. Participants were informed about the study purpose, procedures, potential risks, and their right to withdraw at any time without penalty.

Results

Overview

The study is reported in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile HEalth Applications and onLine TeleHealth) checklist (Multimedia Appendix 1).

Participants Flow

A total of 22 Korean participants were enrolled in the study following screening. During the intervention, 1 participant withdrew with parental consent. Two participants experienced changes in their medication status: 1 resumed medication during the study after not taking any at the preassessment, and another changed their medication type. A total of 19 participants completed the study, as shown in the participant flowchart (Figure 2). Table 1 presents the demographic and clinical characteristics of the participants at baseline.

Figure 2. Flowchart of participants.

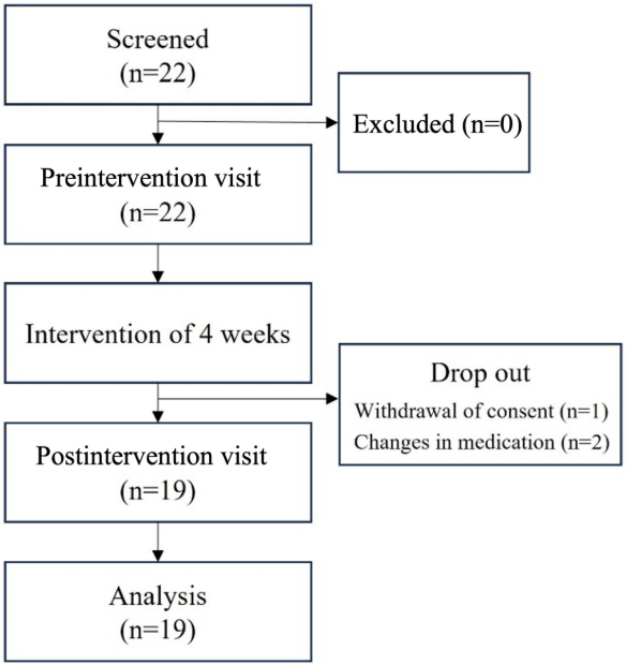

Table 1. Demographic and clinical characteristics of the participants.

Characteristic	Count
Sex , n (%)	
Male	14 (73.7)
Female	5 (26.3)
Age (years), mean (SD)	8.5 (1.5)
IQ[a], mean (SD)	99.4 (16.7)
Medication, n (%)	
On medication	10 (52.6)
No medication	9 (47.4)

Parent Rating Scales

K-ADHD-RS

For the K-ADHD-RS, an ADHD symptom measure rated by parents, a paired *t* test assessed changes in the Total, Inattentive, and Hyperactive-impulsive scores before and after 4 weeks of intervention. There were statistically significant reductions in Total (*P*=.004; effect size *d*=0.69, 95% CI –9.27 to –1.99), Inattentive (*P*=.004; effect size *d*=0.77, 95% CI –5.27 to –1.15), and Hyperactive-impulsive scores (*P*=.01; effect size *d*=0.47, 95% CI –4.22 to –0.62; Table 2).

Table 2. Changes in attention-deficit/hyperactivity disorder (ADHD)-related symptoms and challenging behaviors of participants following the digital intervention.

Measure and factor	Pre mean (SD)	Post mean (SD)	*P* value	Effect size *d*
K-ADHD-RS[a]				
Total	28.00 (8.78)	22.37 (7.55)	.004[c]	0.69
Inattentive	15.74 (4.45)	12.53 (3.84)	.004[c]	0.77
Hyperactive-impulsive	12.26 (5.42)	9.84 (4.79)	.01[c]	0.47
K-CPRS[b]				
Total	43.84 (14.57)	34.79 (10.34)	<.001[c]	0.72
Impulsive-hyperactive	14.00 (5.94)	10.26 (4.61)	.001[d]	0.70
Conduct problem I	9.00 (4.05)	7.53 (3.27)	.04[c]	0.40
Conduct problem II	0.21 (0.52)	0.26 (0.55)	.71[d]	-0.10
Psychosomatic	2.95 (2.50)	2.00 (2.34)	.15[c]	0.39
Anxiety	8.42 (3.76)	7.26 (3.11)	.06[d]	0.34

[b]K-CPRS: Korean Conners' Parent Rating Scale.

[c]*P* value derived from the *t* test.

[d]*P* value derived from the Wilcoxon signed-rank test.

K-CPRS

Postintervention changes in the Total score and the Impulsive-hyperactive, Conduct Problem I, Conduct Problem II, Psychosomatic, and Anxiety subscales from the K-CPRS, which assesses childhood behavior problems, were analyzed. Significant improvements were observed in Total (*P*<.001; effect size *d*=0.72, 95% CI –13.84 to –4.26), Impulsive-hyperactive (*P*=.001; effect size *d*=0.70, 95% CI –5.68 to –1.80), and Conduct Problem I (*P*=.04; effect size *d*=0.40, 95% CI –2.90 to –0.05) scales (Table 2).

Neurocognitive Tests

ADS

For the ADS in the visual and auditory domains, postintervention changes—including omission error, commission error, mean of correct RT, and SD of correct RT for both visual and auditory tasks—were analyzed. Apart from a decrease in auditory commission error, which approached significance (*P*=.05; effect size *d*= 0.59), no other statistically significant or notable changes were observed (Table 3).

[c]RT: response time.

[d]*P* value derived from a *t* test.

[e]In the case of the Stroop Color Word Test, statistical analysis excluded a participant who refused to undergo the test.

[f]DS: digit span.

Stroop Color and Word Test

Scores for the Word, Color, and Color-Word tasks, as well as the Interference score, were evaluated. One participant who did not complete the Stroop task on the postintervention visit was excluded from analysis. Scores for Word (*P*=.004; effect size *d*=-0.45, 95% CI 2.24-10.21), Color (*P*<.001; effect size *d*=-0.45, 95% CI 2.52-6.48), and Color-Word (*P*<.001; effect size *d*=-0.45, 95% CI 1.87-5.68) exhibited significant improvements. The Interference score did not show a statistically significant change (Table 3).

DS

In the WISC-DS, total scores for DS Forward, Backward, and Sequencing were analyzed. No statistically significant changes were noted in the DS tasks (Table 3).

Medication Status Subgroup Analysis

As an exploratory analysis, we compared changes in outcome measures between participants taking medication (n=10) and those not taking medication (n=9). Independent *t* tests (or Mann-Whitney U tests, as appropriate) revealed no statistically significant differences in treatment effects between the medicated and unmedicated groups across all outcome variables. These findings suggest that the observed benefits of the digital intervention were independent of concurrent pharmacological treatment.

Satisfaction and Acceptance

Satisfaction and Acceptance Reported by Children

The mean compliance score of the study participants during the intervention, calculated as the proportion of completed sessions to the total number of instructed sessions, was 81.8% (SD 21.8). For this calculation, only fully completed sessions were counted as compliant. For example, if a participant was instructed to complete 5 sessions per day, 5 days a week, for 4 weeks (totaling 100 sessions) and completed 80 full sessions, their compliance rate was calculated as 80%. Partial completions were not counted in the compliance score.

Participants completed an 11-item questionnaire assessing the digital intervention program's difficulty, learnability, enjoyment, likability, and desire for more play at the postintervention visit. The overall average rating was 4.3 on a 5-point Likert scale (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and

XSL•FO
RenderX

5=strongly agree). The mean ratings for task difficulty and learnability were 3.7 (SD 0.9) and 4.7 (SD 0.6), respectively. Enjoyment had a mean rating of 3.8 (SD 1.4), while the average likability for narrative structures, rewards, and sound effects was 4.1 (SD 0.9). The desire for more play received a mean rating of 3.9 (SD 1.2). Refer to Table 4 for additional results.

Table 4. Children's ratings of satisfaction and acceptance with the digital intervention.

Dimension and question	Mean (SD)
Difficulty	
Found the game easy to play.	3.7 (0.9)
Learnability	
Understood the gameplay mechanics.	4.7 (0.6)
Enjoyment	
Enjoyed playing the game.	3.8 (1.4)
Likability	
Liked the appearance of the characters.	4.1 (1.2)
Desired to collect the characters in the game.	4.5 (0.6)
Liked the appearance of the space vehicles.	4.0 (1.3)
Desired to collect the space vehicles in the game.	3.8 (1.3)
Appreciated the game's storyline	3.9 (1.1)
Appreciated the rewards obtained from playing the game.	4.7 (0.6)
Enjoyed the sound effects in the game.	3.7 (1.2)
Continuity	
Look forward to continuing the game.	3.9 (1.2)

Satisfaction and Acceptance Reported by Caregivers

At the postintervention visit, caregivers completed a survey about their intervention experience. The survey included four items: (1) the extent to which their children enjoyed playing StarRuckus, (2) the presence of perceived risks to their children, (3) their willingness to continue using the program, and (4) the program's ease of use. On a 5-point Likert scale (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree), the mean rating for enjoyment was 4.0 (SD 1.2), for the absence of perceived risks was 4.4 (SD 0.8), for willingness to continue was 3.6 (SD 0.8), and for ease of use was 4.5 (SD 0.6). The overall mean rating across the 4 items was 4.1 (SD 0.9). In addition, caregivers reported whether children experienced discomfort while using StarRuckus. Reported issues included arm pain (n=2), emotional reactions (n=2), and eyestrain (n=1) as intervention-related discomforts. Children who experienced arm pain reported that the tablet felt heavy. Regarding emotional reactions, 1 child felt frustrated with increasing task difficulty, and another became upset due to unsatisfactory outcomes despite considerable effort in the game. The child with eyestrain reported occasional glare or continuous blinking during app usage.

Discussion

Principal Findings

This study aimed to examine the feasibility and acceptability of the digital intervention StarRuckus, which targets the reduction of ADHD symptoms. Data on symptom and behavior scales, neurocognitive indicators, and user experience feedback were collected. The results of K-ADHD-RS and K-CPRS parental reports demonstrated significant changes in total scores and some subscales compared with baseline, with a moderate effect size indicating symptom improvement and associated behavioral or functional difficulties in children with ADHD.

Although the study lacked a control group, the observed improvements in behavioral symptoms are consistent with findings from previous controlled trials of digital cognitive interventions, which reported similar benefits beyond placebo or practice effects [21,23,52]. These precedents support the interpretation that the improvements observed in this study may reflect genuine intervention-related changes rather than nonspecific factors alone.

Although most results from neurocognitive tasks (ADS visual, ADS-A, and Stroop test) showed no significant changes, 3 subtasks of the Stroop test exhibited a significant increase in performance. Also, the commission error of ADS-A showed a marginally significant tendency to decrease. Furthermore, safety, user convenience, and satisfaction were confirmed by questionnaires administered to parents and children during the postintervention period, with no major adverse events leading to dropout. These findings provide preliminary evidence that gamified digital interventions could be an effective and safe treatment option for children with ADHD, regardless of medication status.

In the context of cognitive training, the transfer effect, a phenomenon where the outcomes of one learning event influence another, is a principal issue [53]. These effects appear within

XSL•FO
RenderX

the realm of cognitive functions, or they may extend to behavioral aspects or symptoms. The current results provide preliminary evidence of transfer effects on behavior or symptoms in ADHD, in contrast to neurocognitive outcomes. Concerning the subjective and behavioral outcomes based on parental reports, our findings support a reduction in both inattention and hyperactivity-impulsivity symptoms of ADHD. These results are consistent with previous studies. Such studies have shown that digitalized cognitive training, including game-based therapeutics, can reduce the behavioral symptoms of ADHD [52,54,55]. Moreover, improvements were noted in the Conduct Problem I subscale of K-CPRS following the use of StarRuckus. Since we used K-CPRS, which differs in item composition and subscale names compared with the original version, interpreting these results requires caution. The Conduct Problem I subscale of K-CPRS, concerning oppositional behaviors and bad habits [40], involves argumentative and defiant behaviors, fidgeting or squirming, emotional dysregulation, and sleep problems. These symptoms are prevalent in ADHD and frequently co-occur with oppositional defiant disorder [3,56]. Indeed, exploratory findings from previous studies have suggested that computer-assisted cognitive training may yield symptomatic improvements in oppositional defiant disorder or conduct disorder itself [57,58]. Other evidence indicates that the efficacy of such training in alleviating ADHD symptoms is not substantially influenced by the presence of comorbid conditions, such as disruptive behavior disorders [59]. However, since the information was gathered by nonblinded raters and there was no control group, we cannot eliminate the possibility that parental overestimation may have influenced the results. A randomized controlled trial conducted by a blinded rater is needed for further investigation.

The current results provide insufficient evidence of transfer effects within neurocognitive functions. Based on the literature on digitalized cognitive training that targets executive functioning in children with ADHD, these findings can be attributed to several factors. First, the results of this study may have been influenced by the low ADS scores at baseline, as suggested by the exploratory analysis, which showed that many participants' ADS performances were below the clinical threshold. Among the 8 indicators yielded by ADS, 13 (68%) participants out of 19 had none or only 1 deficit. These findings may partly relate to the heterogeneity in the cognitive profiles of ADHD [60,61]. Therefore, considering the observed improvements in subjective and behavioral outcomes, it is essential to use multiple cognitive outcomes to identify the underlying cognitive functioning in heterogeneous ADHD participants. Similarly, a previous study demonstrating the efficacy of ADHD digital interventions included children whose Test of Variables of Attention and Attention Performance Index scores, targeted by the intervention, met the inclusion criteria at baseline and found significant improvement in Attention Performance Index scores after training [21]. Second, it is possible that our cognitive training did not result in transfer effects within cognitive abilities such as auditory working memory and interference control. There is currently no consensus on the transfer effects of multitasking training. Finally, due to the small sample size of this study, there may not have been sufficient power to yield significant results. Therefore, future research involving measures targeting various domains of neurocognitive functions, brain signals, brain imaging, or mediating research could further elucidate the mechanisms of transfer in multitasking training. In addition, future studies with larger sample sizes may be necessary.

Although the current results provide preliminary evidence of transfer effects on behavior or symptoms in ADHD, they offer insufficient evidence for transfer effects within neurocognitive functions. Nevertheless, previous research suggests that the multitasking working memory training mechanism in this study likely involves updating and dual processing, which are central executive components of working memory considered vital for behavioral transfer in ADHD. Furthermore, a marginally significant reduction in ADS commission errors and an increase in 3 Stroop Test subtasks may suggest enhanced inhibitory control and processing speed, indicating potential cognitive transfer effects. These gains in inhibitory control, a primary deficit in children with ADHD [62], align with findings from previous studies [20,37]. These findings are further supported by overlapping neural systems, which may explain how working memory training leads to improvements in inhibition [63,64]. In addition, although the corpus of research is limited, several studies demonstrate that working memory training enhances processing speed in ADHD [65,66]. In this study, relatively simple cognitive tasks were used, and test-retest intervals of several weeks were applied; thus, the influence of practice effects may have been reduced [67]. However, the 2 factors previously mentioned do not eliminate practice effects. Therefore, further research with control groups is essential to verify hypotheses related to inhibitory control and processing speed.

While the small sample size limited statistical power, exploratory subgroup analyses indicated no significant differences in treatment outcomes between medicated and unmedicated participants. This finding provides preliminary support for the feasibility of using DTx both as a standalone and as an adjunctive intervention. Nonetheless, adequately powered future studies with stratified randomization are needed to more conclusively evaluate differential effects by medication status.

To promote high treatment adherence among children with ADHD, StarRuckus was developed as a gamified digital therapy, incorporating elements designed to foster internal motivation and maintain engagement in therapeutic activities. Notably, children rated the affinity of game components (eg, characters, space vehicles, and storyline) highly in terms of satisfaction and acceptance. In addition, there was a strong correlation between the children's enjoyment and their desire for continued use (Pearson r=0.74; P<.001). This finding suggests that children who enjoyed the program for 4 weeks were more inclined to continue playing. Consequently, the game format is likely to encourage sustained engagement with the treatment.

StarRuckus was designed to maximize the advantages of gaming while minimizing its disadvantages, such as addictiveness and violence. It incorporates a playtime restriction that limits daily usage to 5 sessions per day. In addition, the story and audiovisual components are free from violent content. Notably,

XSL•FO
RenderX

the item indicating the absence of risk factors in the program received a high average score (mean 4.4, SD 1.2 on a 5-point scale). Furthermore, digital programs, through their convenient usability, minimize the effort required for parental guidance. In the case of StarRuckus, parents reported that the program was easy to operate (mean 4.5, SD 0.6 on a 5-point scale), while children indicated a strong understanding of the task rules (mean 4.7, SD 0.6 on a 5-point scale).

The caregivers' willingness to continue using the program received relatively low scores (mean 3.6, SD 0.8 on a 5-point scale). A similar pattern emerged in a preceding study of a digital intervention for children with ADHD [35], where 80% of parents found the program valuable, yet 40% were hesitant to continue the intervention (approximately 37% of parents responded "neutral" or "disagree" when asked if they wanted their child to continue using the program in this study). Researchers hypothesized that this reluctance might stem from the program's perceived difficulty. Our study conducted a correlation analysis between the caregivers' desire to continue and the children's reported enjoyment, revealing a negative correlation of –0.29, which was not statistically significant (Pearson r=–0.29; P=.22). To better understand why caregivers of children with ADHD report high satisfaction yet exhibit reluctance to continue use, future research should include structured interviews to explore their motivations and concerns more deeply.

Among the 7 of 19 (37%) caregivers who were "neutral" or "disagree" about continuing the use of the program, only 1 reported discomfort (eyestrain) during participation. This suggests that discomfort did not notably influence their decision to continue using the program. In addition, no participant dropped out of the study due to discomfort.

Limitations

This study has several important limitations that should be considered when interpreting our findings. First, the study had a small sample size. Second, and perhaps most critically, we had no control group, which makes it difficult to definitively attribute the observed improvements to our intervention rather than to natural progression, placebo effects, practice effects, or other external factors. The unblinded nature of our assessments further introduces the possibility of subjective bias, particularly in parent-reported outcomes. The improvements observed in behavioral measures and cognitive tasks could be influenced by practice effects or heightened parental attention during the intervention period. To solidify our understanding of the intervention's efficacy, additional randomized controlled trials with appropriate control conditions (eg, waitlist, placebo, or active comparator) and larger participant cohorts are essential, with outcomes assessed by blinded raters. Finally, the heterogeneity of ADHD severity was likely due to participants' differing times of diagnosis. Therefore, future studies need to use cohorts with controlled heterogeneity, enabling researchers to determine which ADHD subpopulations are most likely to benefit from our intervention.

Conclusions

This is the first study to demonstrate the potential of a gamified multitasking training program that combines the n-back task and the driving task to improve core symptoms in Korean children with ADHD. In this preliminary investigation, we assessed the feasibility and appeal of a gamified DTx for children with ADHD, considering both medicated and nonmedicated groups. In both cohorts, the 4-week intervention was associated with reductions in core ADHD symptoms, including inattention and hyperactivity-impulsivity, and received favorable user feedback. StarRuckus, the digital program that is not bound by time or location and is readily accessible at home, holds promising potential to serve as both a substitute for and a supplement to conventional ADHD treatment strategies. While the preliminary results we observed provide an initial foundation for further research into this approach, our study design, which includes a small sample size without a control group, limits conclusions about causality and generalizability. Future studies should implement robust randomized controlled trials with appropriate control conditions, larger and more diverse samples, blinded assessments, and longer follow-up periods to further validate these preliminary findings and reveal the underlying mechanisms of the intervention's effectiveness.

Acknowledgments

Abstract

Background: Telepsychiatry has gained considerable attention, particularly during the COVID-19 pandemic. Although various factors influence the choice between online and offline modalities, differences among populations remain underexplored.

Objective: This study aims to compare adults seeking mental health support online and offline in private clinics.

Methods: In this cross-sectional study, we assessed differences in sociodemographic factors, internet accessibility and usability, previous help-seeking history, personality traits assessed using the Arabic Big Five Personality Inventory, and levels of self-stigma measured using the Self-Stigma of Seeking Help Scale.

Results: In total, 259 participants were included (136 online and 123 offline). The online group had a higher proportion of university graduates (P=.02), employed individuals (P<.001), and those with better internet access (P=.03) and higher internet usability (P=.001). The offline group showed higher levels of conscientiousness (P=.003). The primary reasons for choosing online therapy were ease of access and time-saving. Logistic regression identified previous use of online psychiatry as the strongest factor associated with choosing online services (odds ratio [OR] 28.90, 95% CI 11.739-71.165; P<.001). Employment (OR 5.01, 95% CI 1.781-14.080; P=.002), better internet usability (OR 1.69, 95% CI 1.069-2.664; P=.03), and agreeableness (OR 1.16, 95% CI 1.001-1.351; P=.05) were also significant factors. In contrast, previous in-person visits (OR 0.11, 95% CI 0.048-0.269; P<.001), openness (OR 0.85, 95% CI 0.748-0.975; P=.02), and conscientiousness (OR 0.86, 95% CI 0.758-0.971; P=.02) were negatively associated with online preference.

Conclusions: This study highlights key differences between online and offline mental health help seekers, enhances our understanding of treatment modality preferences, and paves the way for future research.

KEYWORDS

help-seeking behavior; online therapy; personality traits; self-stigma; telepsychiatry

Introduction

Telepsychiatry refers to the delivery of psychiatric assessment, consultation, and treatment services through telecommunication technologies that support real-time interactive communication between clinicians and patients. It is mostly implemented through videoconferencing, enabling direct face-to-face interactions at a distance. Online therapy, more broadly, encompasses any form of professional mental health support conducted over the internet, including text-, audio-, or video-based communication [1,2]. It has gained significant attention and adoption during the COVID-19 pandemic, which disrupted traditional face-to-face mental health service delivery [3]. Telepsychiatry has demonstrated the ability to perform

XSL•FO
RenderX

various functions, such as monitoring, surveillance, mental health promotion, and treatment programs, as efficiently and effectively as in-person care [4].

Research on help-seeking preferences has revealed that several factors can influence individuals' choices between online-based therapy and offline mental health help-seeking. Mental health literacy, gender, age, and location of residence have been identified as influential factors [5,6]. Online and offline users may differ in educational level, social support, social withdrawal, family attachment, and technological awareness [7]. Some individuals may lean toward face-to-face interactions, driven by personality traits and concerns about efficacy and privacy [8-10]. In contrast, online interventions are favored by many because they offer increased accessibility, overcoming barriers such as stigma, distance, and transportation issues [11-13].

Cross-cultural factors can significantly influence the preference for offline consultation or telepsychiatry; cultural background and identity can affect comfort with technology and acceptance of telepsychiatry [14]. Some patients prefer telepsychiatry, especially ethnic minorities and immigrants, to connect with mental health professionals who have the appropriate language and cultural background, regardless of location [15].

According to Andersen's Behavioral Model of Health Services Use [16], the use of health services is shaped by 3 categories of factors, which can be applied to understand decisions about online mental health services. Predisposing factors, such as age, sex, and education, may influence individuals' attitudes toward telepsychiatry. Enabling factors, including employment status, income, internet accessibility, and the ease of accessing therapists online, can facilitate or constrain the use of digital platforms. Need factors, such as privacy concerns and the preference for saving time, may further motivate individuals to choose online therapy over traditional in-person care. However, most studies comparing online and offline mental health help-seekers to better understand these factors have been conducted in Western populations, with few studies comparing populations from developed and developing countries [16-18]. Studies conducted in the Arab world, including Egypt, have primarily focused on readiness to use digital mental health services, as well as knowledge, attitudes, perceptions, and satisfaction with these services [19-21]. Nevertheless, there remains a gap in the literature addressing the factors that influence individuals' choices between telepsychiatry and traditional in-person therapy in the Arab world [22].

Therefore, this study aims to address this gap by examining differences between online and offline mental health help seekers in Egypt, focusing on socioeconomic factors such as educational attainment, income level, and employment status, along with personality traits. Additionally, this study assessed differences with regard to the self-stigma of seeking help. In this study, we define "online help seekers" as individuals receiving therapy through videoconferencing platform, whereas "offline help seekers" are those attending in-person sessions at outpatient clinics. By undertaking this investigation, we aim to provide valuable insights into the field of telepsychiatry and mental health services.

Methods

Study Design and Participants

This cross-sectional study was conducted using a self-administered survey for both online and offline participants. Inclusion criteria were adult Egyptians aged 18 years or older, residing in Egypt, who sought mental health help either through an online telepsychiatry platform (Shezlong) or offline at private outpatient clinics, without psychotic features. To control for migration as a potential confounding factor, the study was limited to participants from a single country, ensuring that each participant could choose between online and offline therapy. To maintain comparability, only private clinics were selected for the offline group, aligning with the private nature of the online service. The study was guided by the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines [23].

Sample Size

The required sample size was determined using MedCalc version 18.2.1 (MedCalc Software Ltd). We based our calculation on a previous study that reported a mean agreeableness score of 4.67 (SD 1.17) among individuals preferring online mental health services and 5.13 (SD 1.10) among those preferring offline services [24]. Assuming a significance level α=.05, a power of 80%, and equal group allocation (1:1 ratio), the minimum sample size required was 190 participants. To ensure sufficient power and account for potential data loss, the sample size was rounded up to 200 participants, with 100 in each group.

Recruitment

For online help seekers, a total of 7 therapists expressed interest in inviting their clients to participate. Each therapist sent a link to the online survey at the end of the session. For offline participants, a total of 6 therapists working in private clinics provided a hard copy of the survey following clinic consultations. A consent form was placed on the first page of the online survey, and only participants who provided consent proceeded to the subsequent pages, where they answered the age question to confirm eligibility based on predetermined inclusion criteria. Due to cultural sensitivity toward written consent, initial oral consent was obtained from offline participants, after which those who agreed to participate completed a paper-based survey that began with a written consent statement. Data were collected randomly from January to June 2024. To minimize selection bias, therapists were instructed to approach all eligible clients during the recruitment period.

There are notable sociodemographic differences between public and private sector help-seekers in Egypt. Additionally, there is no equivalent public sector online mental health service with comparable reach or accessibility, as the only existing platform remains in a limited beta phase. Moreover, the private sector accounts for a substantial portion of outpatient mental health care use, even among lower-income individuals, due to perceptions of better quality and accessibility compared with public services. Therefore, we focused exclusively on the private

XSL•FO
RenderX

sector for the comparison between online and offline help-seekers [25].

Data Collection Tools

The participants completed a self-administered questionnaire. The overall instrument demonstrated acceptable internal consistency in our sample (Cronbach α=0.674). The questionnaire consisted of the following sections: demographic and social factors, internet accessibility and usability, previous history of online or offline help seeking, reasons for preferring online therapy, the Arabic Big Five Personality Inventory, and the Self-Stigma of Seeking Help (SSOSH) scale.

Demographic and Socioeconomic Factors

Demographics included age, sex, educational status, last educational attainment, and marital status. Other variables included residence, monthly salary, breadwinner status, and receiving charity. Participants who were employed were asked about employment type (part time or full time), work shift (rotational or fixed), working location, salary range, and work sector.

Internet Accessibility and Usability

Internet accessibility was assessed as yes or no, and internet usability was measured on a Likert scale from 1 to 5, where 1 represents the lowest and 5 the highest.

Previous History of Online or Offline Help Seeking

History of online or offline help seeking was assessed by asking about previous experience with offline help seeking through clinics or online through videoconference, with a yes or no response.

Reasons for Preferring Online Therapy

Online participants were asked to rate the strength of each reason for preferring online therapy using a Likert scale, where 0=no, 1=moderate, and 2=strong. The options were: ease and comfort, saving time, cost savings, feeling of confidentiality, lack of nearby therapists, availability of many therapists to choose from, preferred therapist is available online only, and others (please specify).

The Arabic Big Five Personality Inventory

A 25-item questionnaire was used to assess the 5 major personality traits: neuroticism (N), extraversion (E), agreeableness (A), openness to experience (O), and conscientiousness (C). Sample items include: “I am a sociable person,” “I am an anxious person,” “I like new ideas,” and “I am organized and disciplined.” The reliability of this inventory ranged between 0.70 and 0.83, while validity ranged from 0.49 to 0.86 [26,27]. Respondents rated each item on a 4-point Likert scale: 1=no, 2=some, 3=much, and 4=always. Each trait’s total score ranges from 5 to 20, with higher scores reflecting stronger expression of that trait. In the current sample, internal consistency was assessed using Cronbach α. The Arabic Big Five Personality Inventory demonstrated acceptable overall reliability (α=0.658). Subscale reliability coefficients were as follows: extraversion (α=.790), neuroticism (α=0.757), agreeableness (α=0.909), openness (α=0.839), and conscientiousness (α=0.820).

SSOSH Scale

The SSOSH consists of 10 items on a Likert scale from 1 to 5, where 1=strongly disagree and 5=strongly agree. Items 2, 4, 5, 7, and 9 are reverse scored, and higher scores indicate greater of self-stigma [28]. Sample items include: “I feel inferior if I go to a therapist for help” and “Seeking help from a professional does not threaten my self-confidence.” The translated Arabic version is available on the official website of the Self Stigma Research Collaborative at Iowa State University [29]. In the current sample, Cronbach α for the SSOSH was 0.398, indicating low internal consistency.

Statistical Analysis

The collected data were wrangled, coded, and analyzed using SPSS software (version 25; IBM Corp) and R (R Foundation for Statistical Computing) to generate a correlation heatmap of the Big Five traits and SSOSH scale. Quantitative variables are expressed as mean (SD), whereas categorical variables are expressed as n (%). An independent 2-tailed *t* test was used to estimate differences in continuous variables between the online and offline groups, whereas the chi-square test and Monte Carlo exact probability were used to assess the difference in categorical variables, with column proportions analyzed for significant variables. Pearson correlation was used to assess the relationship between the Big Five traits and the SSOSH scale. A multivariable logistic regression model was conducted using important significant variables, the Big Five traits, and the SSOSH scale to identify the significant factors associated with preference for online consultations. Odds ratios (ORs) and 95% CIs were reported. Statistical significance was set at $P<.05$. Cronbach α values were calculated to evaluate the internal consistency of the psychometric scales used in the current sample.

Ethical Considerations

Ethics approval was obtained from the Ethics Committee of Al-Azhar Faculty of Medicine (registry number Psych._84 Med.Research._Prevalence Depression/Pts.-MS._00000084). All procedures involving human participants were conducted in accordance with the ethical standards of the institutional research committee of Al-Azhar Faculty of Medicine and the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. The process of obtaining informed consent, described above, was implemented for both online and offline participants using electronic and written formats, respectively. Participants’ privacy and confidentiality were safeguarded throughout all study phases, with anonymized data used for analysis and reporting. Online participants were offered a 10%-20% discount for a future online therapy session as a token of appreciation, whereas offline participants received no compensation.

Results

Demographic Characteristics

A total of 304 eligible participants were approached, of whom 259 agreed to participate, yielding a response rate of 85.2%. The study included 259 participants, with 136 in the online group and 123 in the offline group. The majority of participants

XSL•FO
RenderX

were female, representing 80.9% (110/136) in the online group and 73.2 % (90/123) in the offline group. The mean age was similar between groups, with the online group having a mean age of 28.92 (6.35) years and the offline group having a mean age of 29.21 (9.55) years.

Significant differences were observed in the current educational level between the 2 groups (*P*=.003). The online group had a lower percentage of students (22/136, 16.2%) compared to the offline group (35/123, 28.5%) but a higher proportion of graduates (114/136, 83.8%) compared to 68.3% (84/123). When considering the highest level of education achieved, the offline group had a higher proportion of participants with secondary education or less (16/119, 13.4%) compared to the online group (6/137, 4.4%), whereas the online group had more participants with a university degree (109/136, 80.1%) compared to 68.1% (81/119), a statistically significant difference (*P*=.02). There were no significant differences in marital status between the groups, with the majority of participants being single, particularly in the online group (96/136, 70.6%) compared to 61.8% (76/123; Table 1).

Table 1. Demographic characteristics.

Variable	Online group (n=136)	Offline group (n=123)	Test statistic	Effect size	*P* value
Sex			2.2 (1)[a]	0.092[b]	.14
Male, n (%)	26 (19.1)	33 (26.8)			
Female, n (%)	110 (80.9)	90 (73.2)			
Age in years, mean (SD)	28.92 (6.35)	29.21 (9.55)	–0.284 (251)[c]	0.0358[d]	.78
Current education level, n (%)			—[e]	0.205[b]	.003[f]
Not educated[g]	0 (0)	4 (3.3)			
Student[g]	22 (16.2)	35 (28.5)			
Graduate[g]	114 (83.8)	84 (68.3)			
Highest education level achieved (n=256), n (%)			7.6 (2)[a]	0.173[b]	.02
Secondary or less[g]	6 (4.4)	16 (13.4)			
University degree[g]	109 (80.1)	81 (68.1)

[f]Monte Carlo exact probability.

[g]Significant difference between both groups.

[h]No significant difference between both groups.

Social and Economic Characteristics

The social and economic characteristics of the participants revealed notable differences between the online and offline groups. A significant difference was observed in working status, with a higher proportion of participants in the online group being employed (105/136, 77.2%) compared to the offline group (69/123, 56%), indicating a difference of 21.2% (*P*<.001). This association reflected a moderate effect size (Cramer V=0.224). Both groups predominantly resided in urban areas, with the online group showing 96.3% (131/136) compared to 91.1% (112/123) in the offline group, although this difference was not statistically significant. The proportion of participants who were breadwinners was also comparable between the groups, with 15.4% (21/136) in the online group and 22.8% (28/123) in the offline group.

Working conditions indicated that both groups had similar distributions, with the majority working full-time, and there were no significant differences in workplace (office-based vs remote) or working time (fixed vs rotational shifts). Participants were engaged in various sectors, including health, technology,

XSL•FO
RenderX

communication, governmental services, and entrepreneurship. Income levels also showed no significant differences, with 22.3% (23/103) of the online group earning more than 20,000 Egyptian pounds (US $419.03) compared with 25.8% (17/66) in the offline group (*P*=.25) (Table 2).

Table 2. Social and economic characteristics. A currency exchange rate of EGP £1=US $0.02078 is applicable.

Internet Access

Regarding internet access, the online group demonstrated a higher connectivity rate, with 97.8% (133/136) having internet access compared to 91.9% (113/123) in the offline group (*P*=.03). Additionally, the online group reported better internet usability, with a mean score of 4.57 (0.64) compared to 4.14 (1.25) in the offline group, indicating a significant difference (*P*=.001) (Table 3).

Table 3. Internet access and history of psychiatric visit.

Variable	Online group (n=136)	Offline group (n=123)	Test statistic	Effect size, Cramer V	*P* value
Having internet access, n (%)			4.8 (1)[a]	0.135	.03
Yes[b]	133 (97.8)	113 (91.9)			
No[b]	3 (2.2)	10 (8.1)

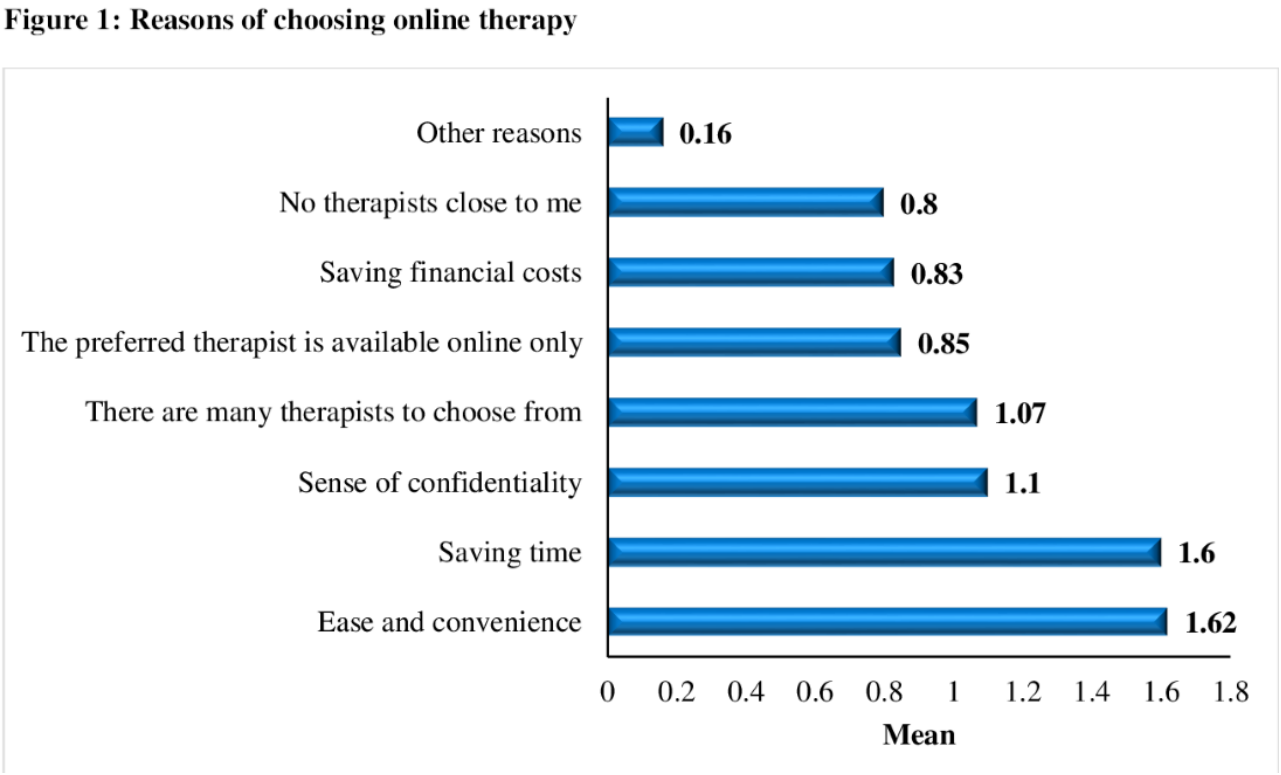
[a]Chi-square test (degrees of freedom).

[b]Significant difference between both groups.

[c]2-tailed *t* test (degrees of freedom).

History of Psychiatric Visit



This study examined the history of psychiatric visits for each group. The offline group had a 37.2% higher rate of clinic visits, with almost three-quarters reporting such visits (90/123, 73%) compared to only 36% (49/136) in the online group (*P*<.001). Similarly, the online group demonstrated a significantly higher use of online video consultations, with 78.7% (107/136) receiving this service compared to only 16.3% (20/123) in the offline group (*P*<.001). This finding was associated with a large effect size (Cramer V=0.623) (Table 3).

Reasons for Choosing Online Therapy

Figure S1 in Multimedia Appendix 1 shows the primary reasons participants chose online therapy, with the top 4 factors being ease and convenience (mean 1.62, SD 0.55), saving time (mean 1.6, SD 0.58), sense of confidentiality (mean 1.1, SD 0.82), and availability of many therapists (mean 1.07, SD 0.76; Figure 1).

XSL•FO
RenderX

Figure 1. Reasons of choosing online therapy.

Big Five Personality Trait

With regard to personality traits, the only statistically significant difference between the groups was found in conscientiousness, with the offline group scoring higher than the online group (mean 13.44, SD 3.47 vs mean 12.15, SD 3.47; *P*=.003), reflecting a moderate effect size (Cohen *d*=0.37). No significant differences were observed for the other personality traits, including extraversion, neuroticism, agreeableness, and openness, which showed similar levels between the 2 groups. Among the personality traits, agreeableness had the highest mean in both groups. In the online group, openness was the second highest, whereas conscientiousness was the second highest in the offline group (Table 4).

Table 4. Big Five personality traits and the Self-Stigma of Seeking Help (SSOSH).

Variable	Online group (n=136), mean (SD)	Offline group (n=123), mean (SD)	2-tailed *t* test (*df*)	Effect size, Cohen *d*	*P* value
Extraversion	11.37 (2.79)	11.98 (3.27)	–1.635 (257)	0.201	.10
Neuroticism	12.57 (3.04)	12.74 (3.16)	–0.431 (257)	0.055	.67
Agreeableness	15.18 (3.51)	15.45 (3.12)	–0.635 (257)	0.081	.53
Openness	12.84 (3.71)	13.04 (3.68)	–0.440 (257)	0.054	.66
Conscientiousness	12.15 (3.47)	13.44 (3.5)	–2.982 (257)	0.37	.003
SSOSH	19.96 (5.68)	22.96 (6.48)	–3.973 (257)	0.492	<.001

SSOSH

The offline group showed a higher level of SSOSH, with a mean score of 22.96 (6.48) compared to the online group (mean 19.96, SD 5.68), reflecting a significant difference (2-tailed t_{257}=–3.973; *P*<.001) and a moderate-to-large effect size (Cohen *d*=0.492) (Table 4). We examined the correlation between personality traits and SSOSH in both the online and offline groups. Several significant correlations were identified in the online group. Extraversion showed a weak negative correlation with SSOSH (*r*=–0.199; *P*=.02), while openness exhibited a stronger negative correlation (*r*=–0.287; *P*=.001). Additionally, conscientiousness was also negatively correlated with SSOSH (*r*=-0.192; *P*=.03) (Table 4).

In the offline group, openness was the only trait that significantly correlated with SSOSH (*r*=–0.226; *P*=.12). These findings suggest that openness is consistently associated with lower self-stigma across both groups, whereas extraversion and conscientiousness appear to play more prominent roles in the online group (Table 5).

XSL•FO

Table 5. Correlation between the Big Five traits and the Self-Stigma of Seeking Help (SSOSH) scale among online and offline groups (Pearson r and *P* value).

Group	Extraversion	Neuroticism	Agreeableness	Openness	Conscientiousness
Online (n=136)					
r	–0.199	0.149	–0.143	–0.287	–0.192
P value	.02	.08	.10	.001	.03
Offline (n=123)					
r	–0.083	0.140	–0.052	–0.226	–0.113
P value	.36	.12	.57	.01	.21

To account for the increased risk of type I error due to multiple comparisons, the Benjamini–Hochberg procedure was applied to control the false discovery rate at 0.05 across bivariate tests. Seven variables remained statistically significant after correction: SSOSH scores, history of psychiatric visits (both clinic-based and online), working status, ease of internet access, current education level, and conscientiousness. Other variables, including highest level of education and internet access, did not remain significant after correction (Table S1 in Multimedia Appendix 1).

Logistic Regression Analysis of Factors Affecting Choosing Online Sessions

Logistic regression analysis revealed several significant factors associated with choosing online mental health services. Multicollinearity among predictors was assessed using variance inflation factors; all values were below 1.52, indicating an acceptable level of collinearity (Table S2 in Multimedia Appendix 1). The model demonstrated a good fit, as indicated by a nonsignificant Hosmer–Lemeshow test (χ^2_8=3.9; *P*=.86), and explained a high proportion of variance in the outcome (Nagelkerke R^2=0.662). After adjustment for confounders, a history of online psychiatric consultation was the strongest factor (OR 28.90, 95% CI 11.739-71.165; *P*<.001), followed by a history of in-person psychiatric consultation, which was negatively associated with choosing online services (OR 0.11, 95% CI 0.048-0.269; *P*<.001). Being employed (OR 5.01, 95% CI 0.327-2.739; *P*=.002) and higher internet usability (OR 1.69, 95% 0.445-56.969; *P*=.03) were also significant factors. Among the personality traits, higher agreeableness (OR 1.16, 95% CI 1.001-1.351; *P*=.05) was positively associated with choosing online therapy, while higher openness (OR 0.85, 95% CI 0.748-0.975; *P*=.02) and conscientiousness (OR 0.86, 95% CI 0.758-0.971; *P*=.02) were negatively associated. Other factors such as education level, internet access, and SSOSH scores were not significant (Table 6). A marginal OR plot was constructed to show the adjusted effects of the statistically significant factors identified in the logistic regression model (Figure S2 in Multimedia Appendix 1).

[d]SSOSH: Self-Stigma of Seeking Help.

Discussion

Overview

The internet has become increasingly important as primary channel for delivering remote therapy. Over the past 20 years, there has been significant growth in online platforms supporting individuals with various mental health conditions [30,31]. However, research has primarily focused on comparing the efficacy of telepsychiatry with offline methods [32,33], with less emphasis on the individual factors that influence the choice of online options. The personal and psychological factors associated with choosing online therapy over offline therapy remain insufficiently explored.

This study aims to provide preliminary data on the differences between individuals who prefer online versus offline mental health services, with a focus on the relationships between sociodemographic characteristics, previous mental health experiences, personality traits, self-stigma, and the preferred modality of help-seeking. Multivariable logistic regression analysis identified a history of online psychiatric consultation as the strongest factor associated with online preference, followed by employment, ease of internet use, and agreeableness. Conversely, previous offline psychiatric visits, along with higher levels of openness and conscientiousness, were significantly associated with a preference for offline care.

We found that the online group was more likely to be graduates, employed, hold a university degree, and have greater internet access and usability. This suggests that telepsychiatry may be more widely adopted when internet access is better and education levels are higher. A national survey in Egypt found that individuals with higher education and current employment status demonstrated greater awareness of and a more positive attitude toward telemedicine [34], aligning with broader research that links telemedicine use to higher educational levels, better internet access, and greater digital literacy [35,36]. Another study on Egyptian students reported that unfamiliarity with electronic mental health is among the most commonly perceived barriers [37]. Additionally, graduates and employed individuals often face time constraints and must balance multiple responsibilities, making the flexible nature of online therapy an appealing option.

This study revealed no significant difference in income levels between the online and offline groups. Globally, individuals with lower income levels face greater challenges in accessing mental health services [38]. However, participants in both groups in this study had already accessed private mental health care, suggesting that they likely have the financial resources to afford such services, which may minimize the impact of income disparities between the groups. In addition, several other factors influence the decision to seek mental health care in the Arab world, including mental health stigma, negative perceptions and attitudes toward mental illness, low mental health literacy,

XSL•FO
RenderX

family dynamics, structural barriers related to the health care system, and service accessibility [39,40]. Such factors have also been identified in studies conducted in Egypt, where help-seeking behaviors are often affected by strong social stigma and reliance on informal support [41,42].

We found that more than 90% of both the offline and online groups reside in urban areas, indicating that rural residents are less likely to seek mental health help, whether online or offline. Egyptians living in rural areas tend to have lower levels of mental health literacy, higher levels of stigma, and limited internet access, all of which may contribute to reduced help-seeking rates compared with urban residents [43-45]. Additionally, there is an unequal distribution of mental health services across Egypt, where the majority of psychiatric facilities and specialists are concentrated in urban centers. As a result, individuals living in rural areas face limited access to mental health care, both online and offline [46]. This pattern is commonly seen in other countries as well; rural populations often face logistical challenges, including a shortage of mental health professionals, significant distances to health care facilities, and lower levels of mental health literacy, which hinder their ability to recognize mental health issues and the importance of seeking help [47-49].

This study found that the offline group had a statistically significant association with previous clinic visits, whereas the online group had a similar association with use of video-based online therapy. Notably, this was the strongest factor associated with choosing online therapy in the logistic regression, with OR 28.90 (95% CI 11.739-71.165). This pattern may be explained by the mere exposure effect, whereby individuals develop a preference or bias toward familiar options due to increased comfort, perceived safety, and reduced cognitive effort [50]. Previous literature suggests that when individuals have experience using online services, they are more likely to prefer these platforms when seeking help for mental health problems [10,51]. However, choosing face-to-face counseling over online therapy may be attributed to unfamiliarity with online counseling and concerns about privacy and security [52,53]. Additionally, the association may reflect the persistence of the initial factors that led individuals to choose online therapy, such as the need for privacy, scheduling flexibility, time efficiency, or work-related constraints.

The strongest reasons for choosing online therapy over offline were ease and convenience, time saving, and a greater sense of confidentiality. This trend is common, as online therapy is perceived as beneficial due to its flexibility, allowing clients to schedule sessions without needing to travel, saving both time and money [54,55]. This convenience is especially helpful for individuals balancing work, family, or other commitments [56]. Additionally, confidentiality is a primary motive for choosing online therapy, as it offers greater privacy, especially for individuals dealing with stigmatized issues [57].

Agreeableness was the most prevalent trait in both groups in this study. Agreeable individuals are more likely to have a positive attitude toward seeking professional help and recognize the need for information and treatment [55,56], with a lower likelihood of holding stigmatizing beliefs about mental illness [57]. In many Arab countries, patients tend to favor a paternalistic model of the doctor-patient relationship, where the physician is expected to take the lead in decision-making, with little involvement from the patient, a tendency that aligns with a high level of agreeableness [58,59]. Moreover, high agreeableness has been commonly observed in studies conducted on Arab populations, including Egyptians, reflecting cultural values of collectivism and social conformity [58-60].

The logistic regression analysis in this study identified associations between specific personality traits and the preference for telepsychiatry. Higher levels of agreeableness showed a marginal association with choosing online therapy, while higher levels of openness and conscientiousness were negatively associated. Previous studies have shown that individuals high in agreeableness may demonstrate greater acceptance of online therapy and a higher capacity to adapt to new situations that require online therapy [61,62]. Moreover, their heightened sensitivity to social evaluation from others may make them prefer the privacy offered by telepsychiatry, as accessing care from home helps minimize exposure to potential stigma associated with attending in-person clinics [63].

Unexpectedly, higher openness was negatively associated with the preference for telepsychiatry. While openness is generally linked to creativity and a willingness to explore new experiences [64,65], individuals high in this trait may favor offline therapy, potentially due to its greater opportunity for in-depth emotional connection and self-disclosure [66]. This aligns with clinical observations from Shezlong, where many clients tend to keep their cameras off during initial video sessions—an act that may reflect lower levels of openness.

Conscientiousness was statistically higher in the offline group and negatively associated with telepsychiatry. This trait is associated to a strong sense of responsibility, self-discipline, and a goal-oriented mindset [67]. Seeking help in the clinic may require higher levels of commitment, punctuality, and adherence to structured appointments compared with the flexibility of online therapy. Currently, the literature lacks direct studies on personality traits and telepsychiatry use. Most research focuses on broader help-seeking behaviors or general telehealth adoption [68,69].

Self-stigma was higher among the offline group. Previous research has demonstrated that higher levels of self-stigma are associated with a reduced likelihood of seeking offline psychological help [70,71]. A systematic review conducted in the Middle East found that both public and self-stigma serve as major barriers to accessing mental health care, with many individuals turning to family members or traditional healers before seeking professional help [67]. Addressing these cultural nuances through targeted awareness campaigns and community-based initiatives may help reduce stigma and promote help-seeking behavior across age groups [72,73].

Although self-stigma was lower among the online group, it was not independently associated with the choice of online help when controlling confounding variables in the logistic regression analysis. The relation between self-stigma and help seeking has not been sufficiently investigated in the context of online help-seeking or telepsychiatry. A previous study from China

XSL•FO
RenderX

reported a negative association between self-stigma and the willingness to seek online help, though it did not include a comparison group of offline help-seekers [70]. Another Swedish study found that self-stigma significantly predicted the intention to seek online help among college students and primary care patients [39]. The inconsistency in previous literature suggests that the dynamics of self-stigma in digital contexts may differ from traditional settings and warrant further investigation.

The absence of a significant association between self-stigma and choosing online therapy in the logistic regression in this study might be attributed to several factors. First, other variables such as perceived effectiveness of online therapy, accessibility, and technological proficiency may play a more substantial role in the decision-making process. Second, the relationship between self-stigma and help-seeking behavior is complex and may be influenced by additional factors, such as cultural norms and individual differences [74,75].

The study showed that openness was the only trait negatively associated with self-stigma in both the online and offline groups. Self-stigma occurs when individuals internalize prejudiced beliefs prevalent in society, leading to feelings of shame and reduced help-seeking behavior [71]. Research demonstrates that openness to experience is associated with cognitive flexibility and a lower tendency to accept rigid stereotypes or prejudices, which may in turn reduce the internalization of stigmatizing beliefs about mental health and lead to lower levels of self-stigma [76,77].

Additionally, individuals with high openness are more willing to disclose psychological distress, as they tend to view self-exploration and emotional vulnerability as opportunities for personal growth rather than sources of self-stigma [78]. In Egyptian and broader Arab communities, individuals often express psychological distress through physical symptoms rather than verbalizing emotional difficulties, in an effort to avoid the perceived weakness and social stigma associated with mental illness and help seeking, which is often viewed as socially unacceptable. Mental health issues are frequently associated with shame, leading families to conceal a relative's psychiatric diagnosis for fear of damaging their social standing or marriage prospects. This stigma is further reinforced by cultural norms that place a high value on endurance and emotional restraint, discouraging open discussion of mental health struggles [40,79].

There are inconsistent results regarding openness and self-stigma, with previous research showing no direct association between them [74,75]. The complex relationship between self-stigma of seeking help and personality traits is rarely studied in the context of telepsychiatry. Therefore, further investigation is needed to understand how factors associated with self-stigma operate across online and offline settings. Understanding these factors associated with self-stigma is essential due to the high levels of mental health stigma, which pose a significant barrier to help seeking, especially in Egypt and the Arab world [80].

Implications and Future Research

This study has significant implications for clinical practice and underscores the need for future research. Understanding the personal and psychological factors that influence the preference for online therapy can help mental health professionals tailor their services to better meet the needs of patients. The significant differences in self-stigma and personality traits between online and offline help seekers highlight the importance of exploring these factors further, particularly as online therapy emerges as an increasingly vital modality for mental health support, likely to expand in popularity and accessibility. Consequently, future research should focus on replicating these findings among diverse populations and with larger sample sizes to enhance their generalizability. Importantly, this study opens the door for investigating differences between actual offline and online help seekers, necessitating further studies to address the existing knowledge gap surrounding help-seeking behaviors. By expanding this research, we can gain deeper insights into the complexities of mental health service use, ultimately contributing to a more comprehensive understanding of the motivations behind choosing different modalities for support.

Strengths and Limitations

This study aimed to compare actual online and offline mental health help seekers in terms of sociodemographic factors, personality traits, and self-stigma, rather than merely assessing preferences and intentions, by focusing on individuals who sought mental health care. The findings serve as preliminary data for further research and contribute to the representation of Egyptian and Arabic populations in the literature. Despite its strengths, the study has several limitations. The relatively small sample size and recruitment from one online platform and a few private clinics may restrict the generalizability of the findings to the broader population of mental health service users. Additionally, the use of convenience sampling may introduce selection bias, as participants who engage with the study may differ systematically from those who do not. Furthermore, conducting the study in only one country limits the ability to draw broader conclusions applicable to diverse cultural contexts, highlighting the need for future research to replicate these findings in different settings and populations.

Conclusions

In conclusion, this study provides key insights into the differences between individuals who prefer online versus offline mental health services. Logistic regression analysis identified several significant factors associated with online service preference. The strongest factor was a history of online psychiatric consultation, highlighting the role of previous exposure in shaping treatment choices. Employment status and ease of internet access were also positively associated with choosing online therapy. In contrast, a history of in-person consultations and higher levels of openness and conscientiousness were associated with a preference for offline services. Higher agreeableness showed a marginal association with choosing online therapy. These findings suggest that treatment modality preferences are influenced by a complex interplay of previous experiences, sociodemographic factors, and personality traits. Tailoring mental health interventions to these factors may enhance service accessibility and engagement. Future research should aim to validate these findings in more diverse populations and explore additional cultural and structural influences.
