Conclusions: As proof of concept, these guidelines will be used in the next phase of our research, which involves designing and developing a game-based physical rehabilitation system.

Introduction

The application of technology in rehabilitation is experiencing significant and rapid expansion [1]. The integration of serious games and technological advancements enhances the rehabilitation process, creating new opportunities to address stakeholders' needs and expectations by (1) enhancing the quality and efficacy of rehabilitation, (2) offering alternatives that sustain patient motivation by mitigating the repetitive nature of traditional rehabilitation, (3) providing tailored therapy levels, and (4) overcoming limitations in resources and facilities associated with conventional rehabilitation methods [2-13]. For example, individuals who have experienced a stroke are motivated to use technologies and games to facilitate their functional recovery [14]. Furthermore, the study by Cruz et al [15] revealed that commercial gaming consoles and off-the-shelf games are more affordable and offer numerous options and variations, which could facilitate the implementation of virtual reality games in clinical practice. However, the usability of virtual reality games is a crucial factor to consider in the design of these interventions. The study by Daoud et al [16] introduced a game-based rehabilitation system that includes 3 exercises and a computerized assessment method. This system evaluates the accuracy of right arm movements during gameplay by analyzing tracking data collected from a Microsoft Kinect sensor. The study by Jayasree-Krishnan et al [17] discussed several barriers to the seamless integration of technological solutions into clinical care, including issues with accessibility

XSL•FO
RenderX

to quality rehabilitation, adaptability to individual patient differences, compliance, and engagement with the rehabilitation process.

In recent years, the implementation of diverse technologies has strengthened telerehabilitation, enhancing rehabilitation processes and ensuring patients receive the necessary services [11,18,19]. Integrating physiotherapy with technologies such as virtual reality and video games enhances the rehabilitation of poststroke patients compared to physiotherapy alone. This approach offers an immersive and interactive platform that boosts patient engagement and motivation during rehabilitation, while also providing a safe environment for practicing and improving physical abilities [2,20,21]. Evidence from a range of studies highlights its potential to improve outcomes for individuals with various physical impairments [2]. Takei et al [22] assessed the safety, feasibility, and acceptability of using the Nintendo Switch video game Ring Fit Adventure for upper and lower limb strength training in older adults with musculoskeletal conditions, alongside conventional physiotherapy over 6 sessions. The authors concluded that this approach is a safe and feasible adjunct to a rehabilitation program, as long as it is supervised, particularly in the initial stages. In the study by Wittmann et al [23], the game "Meteors" was introduced, which involves a virtual robotic arm that replicates the player's arm movements to catch meteors falling onto a planet. In the study by Wittmann et al [24], the game "Slingshot" was used to enhance arm coordination and improve the precision of aiming and extending arm movements. This game focuses on exercising the flexion and extension of the elbow. In this game, scoring is based on performance, and the difficulty level can be dynamically adjusted to maintain the patient's motivation and commitment. In the study by Goršič et al [25], 4 video games were developed for arm rehabilitation. One game involved competitive play, where the patient competed against another individual, such as a friend, relative, or therapist. In addition, there were 2 cooperative games, where the patient and another player worked together to play against the computer, and 1 single-player game where the patient played alone against the computer. The study revealed that competitive games significantly enhanced functional recovery and improved patients' quality of life more than conventional rehabilitation exercises.

In the study by Ma et al [26], a full-body rehabilitation video game was developed using Kinect V2 as an input device. The game accommodates both sitting and standing positions, supporting various movements such as gross motor actions (steps, jumps, and squats) and fine motor gestures (handshakes, palm rotations, and hand opening and closing). This system tracks the player in 3D space and registers real-time data, demonstrating positive outcomes in motor function and the performance of basic daily activities among chronic poststroke patients. The study by [19] argued that successful games in the industry, known for their immersive qualities, incorporate 8 key features: game control technology, display technology, rewards, social elements, avatars, game difficulty, music or sound, and graphical realism. They proposed that future research could explore different game genres, aspects like game narrative and competition, improvements in user interface, and the integration of immersive technologies such as virtual and augmented reality.

The exploration of therapeutic alternatives, combined with new technologies, enables professionals to use a variety of tools for patient rehabilitation and treatment. However, it is crucial to comprehend the functionalities, potential applications, and limitations of these tools [27]. Future research should aim for higher methodological quality, larger sample sizes, and well-defined rehabilitation programs to mitigate inconsistencies in evidence within this field [3,28].

Video games designed for therapeutic use have distinct requirements compared to regular video games. There are differences in user characteristics, where the patient serves as the primary player and the therapist as a secondary user, in contrast to players of regular video games. These users also have different objectives, and the context varies [27]. Considering the patient as the sole end user for any rehabilitation intervention is an aberration and diverges from standard practice, as therapists are primarily responsible for motivating, guiding, and assessing the patient. The study by Krishnan et al [14] revealed that, although individuals who have experienced a stroke were amenable to integrating exergames into their rehabilitation regimen, they noted that these games could not replace the essential role of therapist supervision. Integrating new technologies into clinical practice is complex, as it requires addressing the needs of both clients and clinicians. By considering these factors, technology developers can improve the chances that clinicians will embrace and adopt innovative technologies [29].

The study by Hamilton et al [30] highlighted 2 key factors for optimizing patient engagement: adequate support and a perceived benefit from the technology. It concluded that patients are more likely to engage with technology during rehabilitation when it is personalized by a therapist to fit their specific needs. Therapists and other health care practitioners play crucial roles in both patient recovery and the establishment of an effective rehabilitation system [31,32].

Since rehabilitation aims to restore patient independence and enhance the quality of life, achieving optimal outcomes requires a cohesive multidisciplinary team comprising doctors, psychologists, occupational therapists, nurses, social workers, and physiotherapists collaborating effectively [27]. Despite numerous studies on technology acceptance, there is still a lack of understanding regarding the factors that influence health care professionals' adoption of technological innovations [27,33]. The study by Jung et al [34] argued that although there has been speculation about the roles of therapists in game-based therapy and suggestions regarding varying levels of patient engagement, no comprehensive studies have been conducted to investigate these matters in depth. Understanding how games influence and support the different roles of therapists remains an area for future study [34]. The study by Wu et al [35] argued that, although some serious games have been developed for physical therapy, little work has been conducted through a participatory design approach. The authors highlight the importance of involving diverse stakeholders in the design process to create more effective and user-centric serious games for rehabilitation.

XSL•FO
RenderX

Therefore, effective implementation and use require collaboration from all parties involved in the process, including physicians, nurses, social workers, and other allied health professionals [27]. Thus, the objective of this study is to explore the intentions, needs, and desires of therapists and other practitioners, as well as to examine the factors and determinants influencing the effectiveness and efficacy of game-based physical rehabilitation.

Methods

Ethical Considerations

This study was conducted in accordance with ethical standards for research involving human participants. Ethics approval was obtained from the Ethics and Research Committee, Scientific Research Department, University College of Science and Technology, Gaza, Palestine.

All participants were provided with comprehensive information regarding the study's purpose, procedures, and ethical considerations, enabling them to make an informed decision about their involvement. Informed consent was obtained from all participants, who were explicitly informed of their right to decline or withdraw from the study at any point without any repercussions. Participants' personal information and responses were treated with strict confidentiality. Data were anonymized and stored securely, ensuring that individual identities could not be disclosed in any reports or publications.

Study Design Overview

This study used a design science research methodology, encompassing 2 iterations. The first iteration investigated the therapeutic game requirements and proposed guidelines to guide developers and practitioners in the design of therapeutic games; this iteration will be documented in this paper. The second iteration will use the findings from the first iteration to construct the main artifact, which is a rehabilitation gaming system for physical rehabilitation. The earlier work outlines a more detailed description of the design science research methodology [36,37]. Therefore, in the first iteration, the limited expertise of therapists in using game-based physical rehabilitation for acquired brain injuries significantly prolonged the process of determining the appropriate research strategy. Hence, before any actual game development, conducting a focus group with therapists and related practitioners is a great starting point as it helps generate interesting discussions between physical therapists, occupational therapists, service providers, special educators, psychologists, game designers, software engineers, other practitioners, and the researchers. This process is crucial to understanding how rehabilitation exercises can be translated into a suitable game by identifying the required movements, constraints, difficulty levels, and outputs to design game interventions that align with these exercises. To achieve this objective, the first purpose of the focus group is to evaluate the low-fidelity game prototypes (paper mock-ups) developed and assess how well these prototypes meet the requirements of the rehabilitation exercises. These low-fidelity game prototypes were developed through collaborative team brainstorming sessions and an in-depth review of the literature [38-57]. The second purpose of the focus group is to evaluate the commercial games. The study by Pedraza-Hueso et al [58] determined the feasibility of using the Xbox Kinect gaming console (Kinect Adventure game series) in the rehabilitation of a single patient. This study highlights a usability gap, noting that further research is needed to assess the usability of the Xbox Kinect gaming system in clinical settings and across different patient populations. Whole-body motion capture VR allows a unique opportunity for individuals to experience a heightened sense of realism during task-specific therapeutic activities. However, clinicians need to be able to match a game's components to an individual's functional deficits [59]. Even though none of these games were designed for clinical purposes. The study by Rizzo and Kim [60] stated that "Designers of rehabilitation tasks can benefit from examining the formulas that commercial game developers use." For example, the study by Burke et al [61], discussed that scoring mechanisms as well as mechanisms that maintain player engagement are commonly used in commercial games and can be used similarly in a rehabilitation setting. Therefore, testing commercial games such as the Kinect Adventure game series and Motionsports Adrenaline with therapists can also provide valuable insights into design, usability, and the various mechanisms used to motivate and maintain patient engagement. It can also help identify the missing components that make these games unsuitable for physical rehabilitation. Based on the focus group results, we can then move forward to create high-fidelity prototypes.

Focus Group

The purpose of the focus group was to gather feedback from participants, explore their needs and expectations for a serious game, and gain insights into the requirements for game-based physical rehabilitation. The focus group (Figures 1-3) was held at a designated presentation venue in a hotel in Palestine and was divided into 2 sessions. The first session, lasting approximately 3.5 hours, involved the evaluation of selected commercial games. It began with an introductory briefing by the principal investigator, who outlined the study's objectives. Research assistants initially facilitated the gameplay, helping participants become familiar with the interface. As the session progressed, some participants became comfortable navigating the game menus independently. Following the gameplay, an open discussion was conducted to gather participants' feedback on their experiences and expectations. A scheduled break followed the conclusion of this session.

XSL•FO

Figure 1. Focus group session briefing by the researcher.

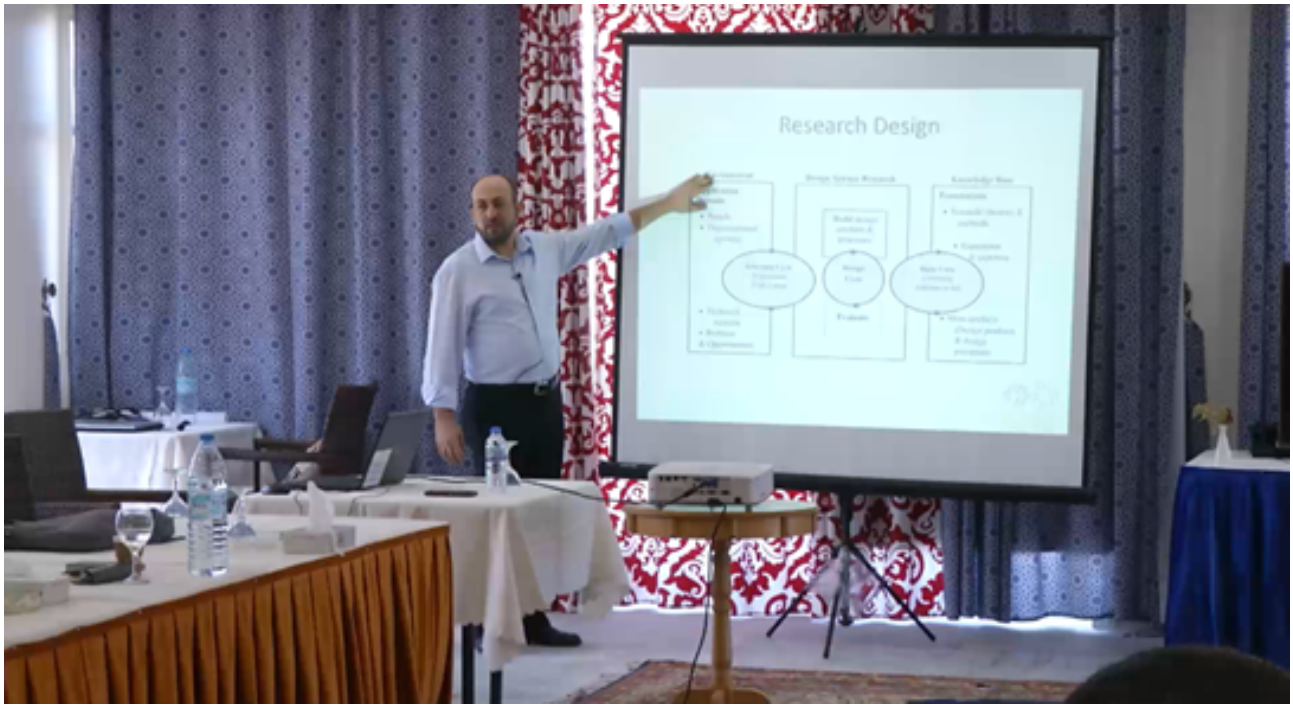

Figure 2. Focus group session. The participants are playing the Kinect Adventures game.

XSL•FO
RenderX

Figure 3. Focus group session. The participants are playing the Kinect Motionsports Adrenaline game.

The second session, held after the break and lasting approximately 4 hours, focused on evaluating the game prototype mock-ups developed by the research team. The principal investigator presented each mock-up sequentially using a projector. Participants were then provided with structured questionnaires, which allowed them to share detailed feedback and offer suggestions for improvement. The completed questionnaires were collected by the research assistants for further analysis. Both sessions were audio- and video-recorded to support detailed qualitative data analysis.

Participants

The focus group comprised 27 participants, including 4 occupational therapists, 10 physiotherapists, 2 game designers, 3 software engineers, 3 special educators, 3 psychologists, and 2 researchers. Table 1 shows the list of focus group participants, encompassing all participant categories.

Table . List of participants.

Role	Participant ID
Occupational therapists	P1-P4
Physiotherapists	P5-P14
Game designers	P15-P16
Software engineers	P17-P19
Special educators	P20-P22
Psychologists	P23-P25
Researchers	P26-P27

Intervention Using Commercial Games

Motion sensing and tracking technologies, such as the high-performance 3D depth-sensing camera Astra Pro Plus, can be used in diverse applications, including robotics, serious games, virtual reality, and augmented reality. Motion-sensing devices, such as the Kinect, fall under the category of gesture-tracking devices, using a user interface known as a natural user interface. Consequently, participants moved around the play area, raised and lowered their arms, and adjusted their body positions to complete the tasks. A total of 2 commercially available games were selected: Kinect Adventures and Motionsports Adrenaline. Kinect Adventures was selected for its entertaining nature and its variety of mini-games, including Space Pop, 20,000 Leaks, Reflex Ridge, River Rush, and Rally Ball. These mini-games offer diverse scenarios and require different body movements. For instance, in 20,000 Leaks, players use their hands and feet to plug holes that appear when fish hit the tank glass. In Rally Ball, players hit a virtual ball toward targets, while in Reflex Ridge, they avoid obstacles while collecting coins. The second game chosen is Motionsports Adrenaline, which offers a range of sports experiences. It includes six distinct mini-games—Wingsuit, Kitesurfing, Kayaking, Mountain Biking, Rock Climbing, and Extreme Skiing—designed to simulate high-stakes stunts that most people would not attempt in real life. Unlike Microsoft's Kinect Sports series, it stands out with a focus on realistic visuals, distinguishing it from many other Kinect games.

XSL•FO
RenderX

Intervention Using Low-Fidelity Paper Mock-Ups

Rabbit Hunting

This game prototype displays several holes, with a rabbit hiding inside one of them. Once the game begins, the rabbit pops out of one of the 5 holes and stays in a hole for a short period of time (depending on the patient's ability), as shown in Figure S1 in Multimedia Appendix 1. The player must hit the appearing rabbit with their hand to score a point. Using motion sensing devices, such as Kinect, the arm movement of the patient is mapped on the corresponding limb of the avatar (a model of a human represented on the screen). Feedback, such as a buzzing sound, an updated score counter, and a change in the rabbit's color, is displayed to the patient on the screen. The game prototype aims to score as many points as possible within a specified time limit, which can be adjusted by the therapist according to the patient's ability. The game becomes more challenging by increasing its speed or introducing a cat that the player must avoid. The therapeutic goals are to improve shoulder, elbow, and wrist movement; enhance multifunctional ability; develop eye-hand coordination; and strengthen muscle power.

Picking the Balls

The game prototype comprises three levels, each designed with increasing difficulty. The patient's arm movements are tracked using motion-sensing devices, such as Kinect, and mirrored by a human avatar displayed on the screen. In the first level (see Figure S2 in Multimedia Appendix 1), the player simply places balls into a basket, with no requirement regarding color or order. Upon successful completion, the player advances to the second level (see Figure S3 in Multimedia Appendix 1), where colored balls are introduced. In this stage, the system prompts the player to pick a ball matching the color shown on the screen. In the final level (see Figure S4 in Multimedia Appendix 1), balls are marked with random numbers, and the player must place them into the basket in either ascending or descending numerical order. In the advanced levels, the patient will be asked which hand to use to pick up the balls. The therapeutic goal is to improve cognitive skills, endurance, eye-hand coordination, awareness, and the range of motion (ROM) of the arm.

Organizing Eggs

This prototype shows an egg appearing in the middle of the screen. Using motion sensing devices, such as Kinect, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. The player has to pick and put each egg in the specified place in the basket as shown in Figure S5 in Multimedia Appendix 1. The player gets a point for every egg put in the right place. The therapeutic goal is to improve motor functioning, balance, strengthen the muscle power in the whole upper limb, and movement of reach, grasp, and release.

Shuffling Shelves

This game prototype intends to work on the patient's cognitive and physical capabilities, as the patient has to grab or pick the book from the upper shelf and put it on the lower one (see Figure S6 in Multimedia Appendix 1), depending on both the book and the shelf's colors. The arm movement of the patient is mapped on the corresponding limb of the avatar (a model of a human represented on the screen) using the motion-sensing device recognition feature. The game begins with a series of colored books appearing on the upper shelf, above the divided and colored lower shelves. After the patient grabs the book and puts it on the suitable shelf, he gets a point. The therapeutic goals include improving endurance and balance, enhancing trunk control, developing right-left discrimination, refining the patient's coordination skills, and promoting arm movements such as extension and shoulder abduction.

Hold the Boat

This prototype focuses on the arm's strength and stability. Using the motion sensing device recognition feature, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. In this game prototype, the patient has to hold the boat and keep moving it to the goal (the end of the channel). Visual cues appear on the screen to guide the player, as shown in Figure S7 in Multimedia Appendix 1. The patient must not only reach the game objects (the boat) but also accompany their movements toward the final destination. This will promote the patient's stability and persistence. The therapeutic goals are to improve grasping, hand awareness, stability, and shoulder ROM.

Reaping the Oranges

This game prototype includes 2 modes: single-player and multiplayer. In the single mode, the patient plays alone, collecting as many oranges as possible from the tree during a certain period of time. Using the motion sensing device recognition feature, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. The player collects the oranges by simply moving their hands to touch the orange on the tree, then placing it in the baskets displayed on the screen, as shown in Figure S8 in Multimedia Appendix 1. The game ends when the time limit is reached. The patient's score is displayed, which is the number of oranges collected during the game. In the multiplayer mode, the goal of the game does not change, but there are two options: competition or collaboration. In the competition, both participants (either 2 patients or a patient and a therapist) must collect as many oranges as possible. The winner will be the one who reaps the most oranges. In the collaboration, both participants must collect as many oranges as possible and place them in shared baskets. The game ends when the time limit is reached or when they reach the target number of oranges, which can be set and controlled by the therapist. In the next game levels, the patients can be asked to use either their right or left arm to place the oranges in the right or left basket, depending on their condition. The therapeutic goal is to strengthen the upper limb, improve eye-hand coordination, range of motion for the arm, "Right-Left" discrimination, weight shifting, abduction, and adduction of the upper limbs of patients, and social interaction. In the next two game prototypes, the objective remained the same as described above, with the difference that the game objects the player must touch would be moving rather than static. This adds complexity, promoting stability and persistence.

XSL•FO
RenderX

Ice Balls

In this game prototype, the patient has to move his hands (stretching his arms at different lengths) to catch ice ball drops from the top of the screen as shown in Figure S9 in Multimedia Appendix 1. The game begins with a small number of ice balls falling slowly from the top of the screen. The arm movement of the patient is mapped on the corresponding limb of the avatar (a model of a human represented on the screen) using the motion-sensing device recognition feature. The more ice balls a player catches, the higher the score is. In the next levels, the number and speed of dropping ice balls increased, and in more difficult places to reach. The therapeutic goal is to improve upper limb movement and coordination, motor planning, timing of reaching, and the supination and pronation movement of the forearm.

Blowing the Bubbles

In this game prototype, the player must move their hand (or both hands). Using the motion sensing device recognition feature, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. The game starts with a girl on the side of the screen generating bubbles, and the player starts collecting points by blowing those bubbles with his or her hand as shown in Figure S10 in Multimedia Appendix 1. The game gets harder by creating more bubbles and making them faster and harder to blow. The therapeutic goal is to improve supination and pronation movements of the forearm, as well as shoulder and elbow muscle power and elbow ROM.

Matching Shapes

This game prototype focuses on cognitive and movement skills. The game starts as several shapes appear randomly on the screen (see Figure S11 in Multimedia Appendix 1). The arm movement of the patient is mapped on the corresponding limb of the avatar (a model of a human represented on the screen) using the motion sensing device recognition feature. The patient must use both arms to select matching shapes or identical symbols. The earlier levels have fewer and simpler shapes, while the advanced levels present more complex shapes. The player gets a point for correctly matching shapes. The therapeutic goal is to improve bilateral hand functioning, movement for the whole upper limb, coordination, and depth perception.

Colored Boxes

This game prototype focuses on cognitive and movement rehabilitation. The arm movement of the patient is mapped on the corresponding limb of the avatar (a model of a human represented on the screen) using the motion-sensing device recognition feature. The patient uses both upper limbs to transport boxes from one side to the other. On the left of the screen, the colored boxes (red, yellow, and blue) gradually depart from one of the 3 levels (the moving belts). The player stands in the middle of the screen using his upper extremities to make a bridge connecting both sides so that the appropriate colored box moves towards the same truck color as shown in Figure S12 in Multimedia Appendix 1. As the game levels advance, the speed of the colored boxes increases. The therapeutic goal is to improve bilateral hand functioning, endurance, coordination of movement in the upper limb, and hand control.

Fallen Apples

In this prototype, the patient raises their hands and moves them left and right, causing the apples to drop, as shown in Figure S13 in Multimedia Appendix 1. Using the motion sensing device recognition feature, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. As the game begins, the trees appear with apples on them, and the player starts moving their hands left and right. A correct movement causes the apples to drop, earning the patient a point. As the levels increase, the difficulty also rises, requiring the player to move their arms to more challenging angles. The therapeutic goals are to strengthen the upper limb, maintain balance, enhance motor planning, and refine movement timing.

Boat Driver

This game prototype relies on the player's ability to use both hands simultaneously. Using the motion sensing device recognition feature, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. The game starts with the boat in a river, as shown in Figure S14 in Multimedia Appendix 1. The player tries to lead the boat to the goal by moving their hands to steer the boat's rudder, aiming to reach a specific point within a given time. Visual cues appear on the screen to direct the player's movement. The game gets more challenging by adding obstacles that the player must avoid before reaching the final destination. The game prototype mechanics focus on improving patients' speed, endurance, eye-hand coordination, rigidity, ROM, and bilateral movement.

Flying for Gold

In this prototype, the player emulates the movement of a flying bird by raising their arms and moving them up and down toward the locations where the golden coins appear. Using the motion sensing device recognition feature, the virtual flying bird on the screen mimics the movements that the player makes. The game starts with the bird appearing on the screen, as shown in Figure S15 in Multimedia Appendix 1, followed by golden coins that appear randomly. The player must collect the coins using the movement mentioned above; the more coins they collect, the higher their score will be. The therapeutic goals are to improve coordination, shoulder movement, and endurance.

The Rowing Boat

The prototype is designed to enable the patient to use both arms simultaneously. Using the motion sensing device recognition feature, the avatar (the virtual character portraying the player on the screen) mimics the movements that the player makes. The game starts with the 2-paddled boat in a river (Figure S16 in Multimedia Appendix 1), and the player starts moving his arms (bilateral movement) to reach a specific point at a given time. Visual cues will appear on the screen to guide the player. The faster the player moves the paddles, the quicker they reach the finish line. In the advanced levels, obstacles are introduced, and the player must navigate around them to reach the destination. The prototype mechanics (targeted exercises) focus

XSL•FO
RenderX

on improving patients' speed, ROM, bilateral movement, body awareness, and reducing rigidity.

The Steam/Air Pump Game

The game begins with the appearance of a pump and a steering wheel. The objective is for the player to rotate the steering wheel or valve multiple times to release steam, ignite a fire, and cook food within a specified time limit, as illustrated in Figure S17 in Multimedia Appendix 1. Points are awarded when the player turns the steering wheel in the correct direction. Visual cues are displayed on the screen to guide the player's movements. The game mechanics are designed to enhance movement speed, reduce joint rigidity, improve ROM, and promote bilateral coordination. Figure S18 in Multimedia Appendix 1 shows an alternative scenario within the Air Pump game prototype.

Results

This section presents the opinions and statements of expert participants regarding the commercial games and game prototypes (mock-ups) that were presented during the focus group. It also includes observations made by the researchers. Therefore, several design implications and recommendations are highlighted.

The participants were excited to test the Kinect-based commercial games, exploring their features and expressing strong enthusiasm for their potential applications. However, the therapist (P4) pointed out that the Kinect Adventures and Motionsports Adrenaline games may not be entirely suitable for patients and would require significant modifications to settings such as speed and difficulty. He added that the extent of a patient's impairment increases the necessity for customizable difficulty settings. Participants (P20 and P22) who tested the adventure game observed a lack of clear initial in-game guidance, which required the facilitator to provide instructions on how to play. Therapists (P1, P2, P6, P11, and P13) agreed that the mock-up prototypes were effective due to their simplicity and focus on specific movements, whereas the commercial games lacked this focus. It is important to note that these games are typically created for healthy individuals and often provide negative feedback upon losing, which may be unsuitable for patients. However, depending on the patient's rehabilitation stage and their motor and cognitive abilities, these games can be a fun alternative to conventional rigorous training, particularly for maintaining a training regimen at home after clinical sessions. Participants (P3, P7, and P14) mentioned that in certain cases, the primary goal is to get patients moving and to create a positive experience with motion. Although correct movement is important, it is not always the primary focus. The commercial games have the potential to motivate patients, serving as a foundation for more advanced exercises. However, to be effective, they need adjustable difficulty levels, minimal distracting elements to maintain focus, simplicity, easy navigation, and clear feedback.

Participants (P4, P6, P10, and P12) emphasized that for a game-based rehabilitation system to be effective, therapists' roles should closely align with their responsibilities in traditional therapy. Once the therapist identifies the therapeutic goals, the game should enable them to assign activities and adjust the exercises to suit the individual impairment characteristics of each patient. In addition, it should enable therapists to track patients' progress and monitor the quality of their exercise movements.

A participant (P19) highlighted that rehabilitation game systems cannot operate independently (as stand-alone applications). They need to be part of a comprehensive framework that involves patients, therapists, clinicians, hospitals, and other relevant stakeholders, due to the multidisciplinary nature of the rehabilitation process. Participants (P5 and P11) believed that the use of rehabilitation games could help reduce therapists' workloads by automating exercise movements and providing monitoring and evaluation of patients' performance. Participants (P17 and P19) suggested expanding the game system to support multiple stations, enabling therapists to work with several patients simultaneously. After each session, patient data would be stored in a database for easy access, review, and performance analysis.

Participants noted that in conventional rehabilitation, therapists used various methods to deliver instructions, including verbal, gestural, and physical approaches. For example, therapists might say, "Move your hand up," and often combine verbal cues with demonstrations of the movements. When patients had difficulty understanding the instructions through verbal or gestural means, therapists provided physical assistance, guiding the patients through the movements until they understood the instructions. Therefore, the game-based system should use multiple methods to communicate instructions and explain game-related rules to patients, particularly those with cognitive impairments. This includes offering audio and visual instructions through text, images, and animations on the screen. In addition, it is important to provide feedback and multiple visual stimuli during gameplay to help direct and maintain patients' focus on the required exercises throughout the therapy sessions. In addition, a participant (P17) mentioned that for the game system to be a viable complement to in-hospital rehabilitation, it should provide clear and sufficient instructions for home-based exercises, allowing patients to participate independently. Another participant (19) suggested including video recording functionality to enable therapists to record themselves while playing the game and demonstrate the correct movements for patients to follow at home. Also, participants (P2) proposed that, following a patient's discharge from the hospital or rehabilitation center, it would be beneficial if the game-based system could record the patient while they practice at home. This would allow therapists to review and evaluate these recordings to monitor the patient's adherence and ensure the exercises are being performed correctly.

A participant (P15) proposed using an avatar to mirror patients' movements, as illustrated in the mock-up prototypes, enabling them to observe their actions in real time. To enhance instructional clarity, a second avatar could be included to demonstrate the correct exercise movements.

When asked about the importance of patients seeing themselves and their actions while exercising, as depicted in most of the presented game prototypes, most therapists appreciated the

XSL•FO
RenderX

visual representation on the screen. The psychologists (P24 and P25) noted that, for youths and children, using a fun character to demonstrate movements on the screen could be beneficial, as many prefer not to see themselves in real images due to potential negative self-perception. A psychologist (P23) added that role-playing in games is impactful because players develop emotional connections with their avatars. As avatars evolve through different stages, they play a key role in sustaining motivation. Important motivational factors include providing diverse avatar options to boost feelings of autonomy, which in turn fosters positive emotions and connections through the avatar's development and advancement (P14). In the Reaping the Oranges mock-up game, a participant (P4) recommended updating the avatar to a farmer. This change would let players take on the role of a farmer, harvesting oranges from a tree to fill a basket. He also suggested adding different game scenarios to involve a variety of physical movements. For example, instead of placing the basket beside the player, the avatar could carry a small basket on their head. In this setup, the player would need to reach up to pick oranges from the tree and place them into the basket on their head. A participant (P9) proposed incorporating different game scenarios for subsequent or advanced levels. For example, oranges could appear on a tall tree that the player's avatar cannot reach by hand. In this case, the avatar could use a small basket, either on its head or held in its hands, to catch the falling oranges before they hit the ground. The avatar would move left or right depending on where the orange will fall, considering the patient's conditions and limitations (P9). He also suggested that with each new game level, the system could change the shape and size of the tree and add animated objects to the environment to increase visual variety. Participants (P7, P11, and P13) suggested that the game system should allow them to choose from a list of available exercises. This way, each patient can be assigned different exercises based on what the therapist wants to evaluate.

A participant (P23) pointed out that consideration should be taken carefully when choosing game themes, as some themes could trigger negative reactions in patients. For example, a car racing game might be uncomfortable for someone who has been involved in a car accident. To address these concerns, it's essential to provide a variety of themes to suit different needs and sensitivities. A participant (P15) proposed that farm life could be an excellent theme for game-based physical rehabilitation, and many others (P1, P2, P11, P13, P15, P16, P20, and P22) agreed with this suggestion. This theme could appeal to a broad range of patients, including elderly individuals who may have connections to rural environments from their youth, as well as younger adults and children. The peaceful and relaxing nature of farm life can instill a sense of purpose in patients, potentially improving their commitment to the rehabilitation process. Furthermore, the theme of farm life aligns with the slow pace of seasonal changes and the growth cycles of crops and animals, reflecting the long-term nature of rehabilitation. This theme emphasizes the need for patients to commit to intensive exercise over an extended period, much like the ongoing care required in farming. For example, various farming activities can be adapted into game exercises targeting different movements, such as shearing sheep, herding flocks, milking cows, sowing seeds, planting trees, weeding, fishing, mending fences, cutting grass, picking fruit, harvesting wheat, chopping wood, feeding chickens, selling corn, irrigating, collecting honey, gathering eggs, watering plants, driving a tractor, trimming hedges, spraying pesticides, raking leaves, and scaring birds. A participant (P3) proposed enhancing the game environment by adding a farmer's house and including more exercises related to activities of daily living (ADLs). Similarly, a participant (P13) emphasized the importance of designing the game system to support the practice of ADL-related movements and tasks. To be effective, game scenarios should replicate real-life activities such as washing dishes, brushing teeth, combing hair, grasping a spoon, holding a cup, shaving, and moving objects. These scenarios should be presented through virtual representations performed by the in-game avatar, incorporating relevant joint movements—such as shoulder abduction and adduction, elbow flexion and extension, and forearm pronation and supination—to interact meaningfully with virtual objects.

A participant (P9) suggested providing a pool of games, each targeting different exercise movements. Another participant (P21) noted that many of the mock-up game prototypes, including The Steam/Air Pump Game, The Rowing Boat, Boat Driver, Colored Boxes, Matching Shapes, Reaping the Oranges, Shuffling Shelves, Organizing Eggs, Rabbit Hunting, and Fallen Apples, could be adapted to fit within a farm life theme under a unified game system. This would provide a variety of game exercises centered around the farm life concept.

Participants (P20 and P23) revealed that the multiplayer aspect of the Reaping the Oranges game, whether through competition, collaboration, or connecting with other patients face-to-face or online, could enhance engagement and enjoyment for many patients. However, it is important to recognize that such interactions may cause stress for some individuals. Therefore, while the game has the potential to enhance the overall experience, it is crucial to consider the diverse preferences and needs of different patients.

A participant (P10) suggested that, given recent technological advancements, it is possible to enable immersive experiences through head-mounted display devices, which are now lightweight and affordable. These devices provide immersive 3D game experiences that can help sustain patient motivation and adherence.

Therapists and other practitioners have been asked about how to transform a physical rehabilitation procedure into a game. It is found that various devices are employed to facilitate therapeutic processes. For instance, during physiotherapy sessions, patients employ various auxiliary devices to facilitate task execution, such as the Shoulder Pulley T Type and the Shoulder Wheel, as depicted in Figure S19 in Multimedia Appendix 1. The shoulder wheel is employed to regain the range of motion in the shoulder joints. Although these devices support the execution of therapeutic movements, they often lack motivational aspects to engage patients. Participants (P3, P10, and P20) noted that integrating gamification with these instrumented devices could fill this gap by turning rehabilitation procedures into interactive and motivating experiences. This

XSL•FO
RenderX

approach represents a valuable opportunity for enhancing therapeutic outcomes and deserves further investigation.

Participants (P22, P24, and P14) argued that adapting existing devices used in physiotherapy sessions and transforming them into game controllers could shift patients' focus from the monotonous repetitions of their exercises to engaging with the game itself. Consequently, actions performed with physical objects in the real world are mapped and reflected in the virtual environment.

The researchers suggested the following game scenarios to demonstrate how these devices can be used: (1) by placing a screen in front of the patients, the Shoulder Wheel can be used to explore a virtual city or world, allowing them to engage with the game and experience tailored stimuli and positive reinforcement. Actions performed by the player using physical objects in the real world are mapped and reflected in the virtual environment. (2) The Shoulder Wheel can also be used for a variety of therapeutic exercises. When operated with both hands, its movements can be integrated into a racing car simulator. Alternatively, when used with one hand, it can be adapted into a firefighter pump game, allowing patients to simulate controlling a water hose to help extinguish a fire. (3) The Shoulder Pulley T Type can be used to simulate the flapping of a bird or the soaring of an aircraft through the skies.

Games based on this setup can be designed to balance patient enjoyment (entertainment value) with an emphasis on the quality of exercise movements (therapeutic value), thereby enhancing both engagement and the effectiveness of the rehabilitation process.

Most participants emphasized that a game-based physical rehabilitation system should offer flexible configuration. It should accommodate diverse cognitive abilities and gameplay preferences by incorporating essential features such as therapy-specific physical movements, adjustable game mechanics, and customizable visual aesthetics.

A participant (P2), who has experience using games in rehabilitation, expressed dissatisfaction with the preprogrammed difficulty levels in games such as adventure games. The participant emphasized the need for more flexible control over game parameters, allowing therapists to adjust the difficulty to suit the individual needs and progress of each patient.

A participant (P16) suggested that developers could take advantage of existing commercial games to create diverse game scenarios. He added that a game like Kinect Adventures: 20,000 Leaks could be modified by simplifying its design, enabling therapists to control aspects such as difficulty level, speed, and range of motion, and to tailor patients' interactions with virtual game objects.

A participant (P14) argued that the game prototypes presented in the Intervention Using Low-Fidelity Paper Mock-Ups section are designed to permit only predefined exercise movements to interact with or play a specific game. For example, in the Blowing the Bubbles game, patients use reaching movements to blow the bubbles. In the Boat Driver game, patients perform circular movements to control the boat. A game system that enables therapists to customize and align different physical movements with game actions (such as using circular motions to maneuver a jet fighter) can enhance the gaming experience for patients and support their rehabilitation goals more effectively.

Most participants believed that a game system with reconfigurable visual elements, tailored to patients' preferences and needs, can enhance their engagement and participation in game-based therapy.

Participants (P4, P7, P22, and P24) noted that patients may react differently to the visual design of rehabilitation games. Individuals with cognitive impairments often struggle to process highly realistic graphics, which can lead to disengagement. In such cases, simplified 2D or cartoon-like visuals may improve comprehension and promote participation in therapy. In addition, older patients or those with negative attitudes toward gaming may view these games as childish and lacking therapeutic value. To address this concern, a participant (P15) suggested that game designs could be adjusted to reflect real-world therapeutic activities, thereby reinforcing their role as serious tools for rehabilitation. Therefore, a game-based system should be able to adjust its visual settings and reconfigure its appearance to match a patient's preferences and needs, as this is crucial for enhancing engagement and participation in game-based therapy. This highlights the need for future research to develop tools that enable therapists to adjust and tailor games to individual patients' preferences and needs.

On the other hand, the controllers of the rehabilitation game system should be designed to enable patients to practice various exercise movements while intentionally suppressing their compensatory behaviors. A participant (P11) suggested that the controller could be configured by the therapist to recognize only the horizontal movements of the patient's hand, or to consider trunk movements as input, thereby reducing trunk-related compensatory actions. Likewise, for stroke patients who unintentionally involve their shoulder or elbow, the game system can allow the therapist to address this by using the compensating joint as an input. Furthermore, the system should be adjustable and flexible, allowing the therapist to choose which hand or side of the patient (left or right) will be used for game interaction.

A participant (P5) suggested implementing a dedicated user interface for therapists to enable efficient control of the game system. This interface would allow therapists to configure game settings. For instance, if a patient begins to show compensatory behaviors during gameplay, the therapist can adjust the game settings to reduce the range of motion or slow down the game pace. This allows the patient to perform movements without severe compensatory behaviors. When patients experience fatigue or pain, therapists can make the games less challenging or pause them. In addition, therapists can have full control over the games to maintain a balance between therapeutic and engagement values.

Another participant (P6) argued that in conventional rehabilitation sessions, therapists must physically interact with patients to correct inappropriate movements. This often requires therapists to stand or sit next to or behind their patients, meaning they need to continuously reposition themselves throughout the

XSL•FO
RenderX

therapy sessions. Thus, a dedicated and portable user interface is essential, allowing therapists to control game-based therapy more efficiently using handheld devices like tablets or mobile phones. This interface would facilitate better interaction with the games and improve the moderation of therapy sessions.

Consequently, based on the earlier discussion, it is evident that there is a need for game systems with high configurability. Such systems would allow therapists to customize therapy programs to better meet individual patient needs. These systems should offer the flexibility required for therapists to tailor therapy programs to each patient's specific needs. However, the increased complexity of game system operations places additional demands on therapists and requires comprehensive training to effectively manage and moderate game-assisted therapy sessions.

Therapists and other practitioners emphasized the importance of proper training to effectively utilize rehabilitation games as a therapeutic tool. For instance, a participant (P1) remarked, "I am motivated to use games with my patients, but I don't know what to do." Therapists explained that improper use of rehabilitation games can result in patient pain or injury, making it challenging for therapists who are new to or lack experience with game-based therapy. Participants (P22 and P25) noted that using rehabilitation games without previous training can make it difficult to determine how to tailor the therapy to meet patients' needs effectively. With proper training, therapists would gain a clearer understanding of their roles, leading to more efficient use of the games and an improvement in the quality of game-based therapy sessions. Therefore, thorough training on the game system is crucial for therapists to let them grasp the system's details and learn the most effective ways to use it. Consequently, it is essential to thoroughly assess and prioritize the usability of the game system for therapists to ensure it is both effective and user-friendly. This underscores the necessity for future research to examine the usability and effectiveness of interactive mechanisms that allow therapists to configure and customize game-based interventions.

On the other hand, therapists revealed that the data collected from the game-based intervention can provide various insights. While the scores at the end of a game session are commonly used to measure performance, additional metrics can be gathered to offer insights into patients' motor and cognitive abilities. These include the following: (1) score: higher scores may indicate better performance in response to challenging tasks; (2) time: longer session durations suggest a greater number of repetitions of the prescribed exercises; (3) level: advancing to higher game levels is associated with increased challenges; (4) distance: Assessing the distance covered by the affected limbs helps determine the level of muscle engagement and effort exerted during the exercise; (5) changes in motion direction: a higher frequency of changes in movement direction might indicate inaccuracies in execution or that the movements were performed without a clear purpose; (6) initial movement range/amplitude: this metric is crucial for evaluating patients' progress and understanding their development over time; and (7) number of sessions: tracking the number of sessions played and any interruptions can help therapists determine whether patients felt uncomfortable with specific games or if they were disengaged and did not complete the prescribed exercises. In addition, one therapist mentioned that electromyography (EMG) sensors could be used to monitor muscle activity during exercises. By recording EMG readings, therapists can assess movement patterns, measure muscle fatigue, identify disorders, and evaluate the effectiveness of exercise interventions.

Movement correction measure: A key factor in the effectiveness of game-based rehabilitation systems is the accurate assessment of patient movements during gameplay sessions. However, according to a participant (P13), the measures taken to prevent incorrect execution of exercises in motion-sensing technology–based games are limited, as patients at risk of injury are typically not permitted to use motion-tracking systems. It remains the therapist's responsibility to evaluate and manage these situations. Another participant (P5) highlighted that some of the major benefits of using this technology include engaging patients, making exercise enjoyable, providing opportunities for social interaction, and offering feedback on exercises. The experts were less worried about the games enforcing or ensuring correct movement and addressing compensatory actions, as they would personally guide and decide when and how patients should use motion games.

According to the discussed metrics, these metrics are expected to provide valuable insights for therapists to evaluate a patient's recovery progress. For instance, low scores and extended playtimes may indicate that patients are struggling to complete the required tasks, which can result in frustration and a negative perception of the game. In addition, covering longer distances with the affected limb and making fewer changes in motion direction suggests that patients are performing movements with greater amplitude, indicating they are in a more advanced stage of recovery. Conversely, if patients cover short distances with frequent changes in motion direction, it indicates that they either struggle to perform wide gestures or exhibit inaccuracies in their movements. Thus, while the patient enjoys the game, these parameters can be collected and stored for later analysis. This allows therapists to monitor and assess the patient's progress and development over time, providing insights into the quality and effectiveness of the game exercises performed. Another therapist suggested developing an online game-based system accessible to both patients and therapists. Therapists would log in to the system to view their patients, and once a specific patient is selected, the therapist could access their records, review collected data, and customize each game's settings as needed to better suit the patient's needs.

Discussion

Principal Findings

The observations, feedback, and suggestions from the focus group were analyzed, leading to the development of several guidelines to inform the design and development of an effective game-based physical rehabilitation system. To increase compliance and ensure patients perform their exercises correctly, the game must maintain patient engagement and provide support during exercises. This can be achieved through appropriate feedback. Instant and clear feedback is crucial for providing a meaningful gameplay experience. It helps patients understand

XSL•FO
RenderX

the outcomes of their actions, reflects their performance in exercises, and offers various in-game achievements. Feedback should include visual, audible, and haptic elements to enhance the user's interpretation of the gameplay and maintain their engagement. In addition, a game-based system needs to facilitate the practice of movements and tasks related to ADLs.

The social aspect of the game system is crucial, enabling patients to play with family members, friends, or other patients. Highlighting this feature enhances the overall experience. In addition, incorporating a tracking mechanism for the quality of the patient's movements in the game system is advantageous. This will effectively support and facilitate the rehabilitation process, encouraging patients to perform the exercises accurately. In addition, a potential game-based system should be capable of tracking patients' progress. This feature could benefit patients by providing positive reinforcement and encouraging compliance and also assist physiotherapists by enabling them to monitor and assess patient development. In addition, simple art styles and graphics, as seen in the mock-up prototypes, can motivate players and make the games more approachable, a feature that participants seemed to appreciate. This cartoon-like, simplistic art style has benefits such as lower processing power requirements and encouraging a more playful state of mind compared to realistic graphics. However, different demographics might respond differently to this style, as many people today are accustomed to games with nearly photo-realistic graphics, such as Call of Duty. People generally tend to prefer familiar styles. On the other hand, since rehabilitation programs typically involve multiple exercises, the game system should be designed to incorporate them. Therefore, the game system should be expandable to include a variety of exercises, supporting the entire rehabilitation process.

Furthermore, the game system should offer significant flexibility and adaptability to suit each patient's specific degree of injury. It is essential for a potential game-based rehabilitation system to allow therapists to customize the game exercises. Since individuals have different needs based on their injury and stage of rehabilitation, customization ensures that the game can better accommodate these unique patient requirements and preferences. Given that the rehabilitation process often extends over a long period, the focus of the training changes throughout this time. Therefore, the game system should include mechanisms for adapting game interventions to accommodate the different stages and focuses of rehabilitation. On the other hand, ensure that patients can concentrate on their exercises rather than dealing with technical details. The findings highlight the need for a rehabilitation game to be simple to install and start. It should be easy to begin without lengthy or complex setup processes. For home use, the game system should prioritize easy installation, fast start-up, and intuitive usability. Table 2 presents a summary and categorization of the design guidelines for game-based physical rehabilitation systems.

XSL•FO
RenderX

Table . Design guidelines for the game-based physical rehabilitation system.

Category	Guidelines
Gameplay design and usability	• Support simplified gameplay mechanics to enhance usability and accommodate patients with varying cognitive and physical abilities. • Integrate multimodal instructional methods, including audio, visual, text, and animation, to support understanding of game mechanics and therapeutic tasks. • Include accessibility features such as simplified controls, multiple visual modes, easy-to-navigate menus, and customizable interface styles to support diverse user needs, allowing the system to cater to different user preferences, cognitive loads, and therapeutic requirements. • Support game-based exercises tailored to the cognitive and physical capacities of patients. • Provide instant feedback and multiple visual stimuli during gameplay to guide and sustain patients' focus on the required exercises. • Use positive reinforcement and reward mechanisms to motivate patients and enhance engagement during therapy. • Support home-based exercise modules that are self-explanatory and include clear, structured instructions to enable independent participation. • Embed clear and intuitive tutorials, supported by visual and auditory cues, as well as explicit in-game guidance, to encourage independent use and reduce the need for external support. • Provide optional multiplayer modes to promote social interaction and engagement when appropriate for the therapeutic context.
Game themes and scenarios	• Provide a variety of themes and scenarios to suit different needs and sensitivities. • Avoid game themes that may trigger distress. Themes should be carefully selected to prevent negative reactions (eg, racing games for car accident survivors) and instead incorporate neutral, calming settings (eg, farm life with seasonal progression) that align with rehabilitation goals. • Incorporate activities of daily living (ADLs), such as fruit picking, brushing teeth, and combing hair, to enhance task relevance and promote functional recovery. • Use stylized, age-appropriate avatars rather than live camera images of patients to enhance comfort and engagement during gameplay. • Offer diverse avatar choices and thematic avatars matching game contexts. • Incorporate avatar customization and progression systems and offer upgrade options to enhance autonomy and sustain patient motivation throughout therapy. • Implement a dual-avatar system, where one avatar mirrors the patient's movements and another, representing the instructor or therapist, demonstrates the correct form to facilitate self-correction.

XSL•FO
RenderX

Category	Guidelines
Therapeutic focus and therapist control	• Implement therapist interfaces that allow dynamic adjustment of exercise parameters such as speed, difficulty, and range of motion during rehabilitation sessions. • Enable therapists to adjust difficulty, customize visuals, and adapt game mechanics to accommodate patient limitations and cognitive impairments. • Allow therapists to target specific motor functions by selecting exercises from a game-based exercise list and assigning them based on individual patient impairments and needs. • Provide a portable, handheld (tablet or phone) interface for therapists to seamlessly control sessions, including real-time form alerts, emergency stop, pause, and override functions to ensure patient safety, correct movement, and efficient session management. • Include tools that allow therapists to translate and map physical rehabilitation movements into game mechanics, ensuring clinical relevance and effectiveness. • Enable the therapist to define movement constraints: the system should be adjustable and flexible, allowing the therapist to choose which hand or side of the patient (left or right) will be used for game interaction. • Provide video recording functionality for therapists to demonstrate exercises remotely. • Enable multiuser support, centralized patient databases, and access for multiple stakeholders or practitioners.
Movement quality, monitoring, and data management	• Incorporate features to track performance metrics, including scores, time, directional changes, movement precision, range of motion, limb engagement, muscle activation, and compensatory movements. • Implement AI-assisted compensatory movement detection with real-time alerts to prevent patients from persisting through pain or incorrect form. • Store data for longitudinal analysis to inform therapy adjustments. • Integrate motion tracking with electromyography (EMG) data to enable comprehensive monitoring of muscle activity during exercises. • Include postsession analytics and progress monitoring dashboards. • Develop comprehensive dashboards for therapists that display and visualize patient progress, compensation behaviors, adherence levels, and movement quality trends over time.
Technology and device integration	• Support the integration of virtual reality or augmented reality and diverse interaction technologies to enhance the effectiveness and engagement of rehabilitation experiences. • Support the integration of EMG biofeedback to track muscle activation, fatigue thresholds, intervention efficacy, and exercise effectiveness. • Gamify existing rehabilitation devices, such as shoulder wheels and pulleys, by transforming them into game controllers that map real-world movements to virtual environments. This allows patients to navigate and interact with the game, thereby enhancing the effectiveness of rehabilitation. • Implement an online platform that supports secure data access and remote configuration.

Limitations

Therapists and health care professionals were actively involved in this phase of the study due to their critical role in implementing effective game-based rehabilitation. Although the inclusion of brain injury survivors (including those with traumatic injuries and stroke) is equally significant, it was beyond the scope of this paper. Their perspectives and participation will be incorporated into future phases of the research and addressed in subsequent publications.

Conclusions

Incorporating serious games and advances in information and communication technologies into physical rehabilitation can enhance the rehabilitation process, offer benefits beyond those of conventional methods, and improve both the effectiveness and efficiency of rehabilitation. The aim is to (1) enhance the effectiveness of game-based therapy for patients who struggle to engage with or benefit from it, and (2) assist therapists by offering a game-based rehabilitation system tailored to their needs. To investigate the factors, determinants, requirements, and actual needs for potential game-based rehabilitation, a focus

XSL•FO
RenderX

group with therapists and other relevant health care professionals is organized. This decision aims to evaluate the ideas with real rehabilitation therapists and practitioners. To effectively discuss the ideas with therapists and other related professionals before starting development, available commercial games are tested, and various paper game mock-ups are evaluated. This approach facilitated productive discussions, validated the direction, and is expected to optimize our development timeline. The focus group discussions yielded several guidelines that will serve as the foundation for the next phase of our research. This phase will involve the design, development, and implementation of a game-based physical rehabilitation system aligned with these guidelines.

Acknowledgments

The authors gratefully acknowledge the focus group participants for their time and for sharing their valuable perspectives. This research was funded by Universiti Teknologi Brunei (UTB). UTB/GSR/2/2023 (19). We thank UTB for the financial support of this research.

Abstract

Background: Decision aids (DAs) are important tools that support shared decision-making (SDM) between clinicians and patients, enabling patients to be more informed and engaged in decisions regarding their care. The use of DAs can increase patient knowledge, reduce decisional regret, and engage the clinician and patient in meaningful dialog. Despite proven effectiveness in enhancing patient-centered care, a gap remains in clinician use of DAs. Known clinician barriers to using DAs include (1) time constraints, (2) concerns about the match between patient need and available DAs, (3) forcing users to leave the electronic health record (EHR) to access DAs, and (4) the burden of manually entering data into the DA.

Objective: This qualitative study identified the needs and requirements of clinicians to inform the design of a clinician-facing, EHR-integrated, Substitutable Medical Applications, Reusable Technologies (SMART; SMART Health IT) on Fast Healthcare Interoperability Resources (FHIR) (HL7) app, the Decision Aid Navigator (DEAN; University of Colorado Anschutz Medical Campus). The Navigator identifies and surfaces DAs that are relevant to a patient's health care conditions (eg, atrial fibrillation), current care (eg, not on anticoagulation), and demographics (eg, check the youngest age for the stroke prevention), and facilitates documentation of SDM discussions and decisions.

Methods: We conducted 13 semistructured interviews with clinicians who were recruited from 4 academic medical centers. Interviews included a demonstration of an initial, mid-fidelity, DEAN app prototype that was designed to address DA use and barriers described in the literature. The interviews focused on clinician context and use of the prototype, affordances and barriers to using the system, and clinician needs and requirements of the system. We used qualitative content analysis to code and reduce the data, using a consensus-making approach, and identify emerging themes.

Results: We identified 3 overarching themes: (1) streamlined functionality may simplify workflow and decrease the burden of DA use and SDM; (2) clinicians need appropriate competencies to effectively use the Navigator and relevant DAs; and (3) trust that the Navigator suggests prevetted DAs. Unanimously, clinicians shared that the DEAN Navigator should be integrated into the EHR. To accomplish this clear priority, clinicians stated that they needed the requisite competencies to successfully use the tool within their workflow and build trust with the tool itself.

Conclusions: Better tools to support and harness the benefits of SDM are needed. Overcoming the barriers of using DAs is paramount. Tools designed and developed to support DA use must be integrated into the EHR efficiently to create an opportunity for uptake of the technology by busy clinicians. If tools like DEAN can streamline the cumbersome process of documenting the use of DAs, more clinicians may potentially use DAs with their patients, given the right context and appropriate DA.

Introduction

Background

Shared decision-making (SDM) and the use of decision aids (DA) tools improve patient-centered outcomes, such as satisfaction with understanding the risks and benefits of health care decisions and less decisional regret [1-3]. SDM is a deliberative process and is defined as: "an approach where clinicians and patients share the best available evidence when faced with the task of making decisions, and where patients are supported to consider options, to achieve informed preferences" [4]. Some believe the SDM process is best accomplished with the use of DAs [5], which are tools specifically designed to provide easily understandable information to facilitate clinician and patient communication and understanding of information to support informed decision-making, as compared to usual care [5].

DAs often elicit a patient's preferences and values and present evidence-based comparisons that are easily understandable to support clinicians and patients in their discussions and decision-making. A 2024 Cochrane review of 209 studies provided strong evidence that patient decision aids, DAs that target health care decisions made by patients, resulted in increased knowledge, more accurate risk perception, congruency between values and care choices, decreased decisional conflict and regret for patients, patient satisfaction with their decision, and improved communication between clinicians and patients [5,6]. In some scenarios, patients were less likely to choose major invasive surgery over conservative care and were more likely to start needed medications [6]. DAs come in many forms, including static text, videos [7], interactive websites [8], and even telenovelas [9], to support various learning preferences, cultures, and attention spans.

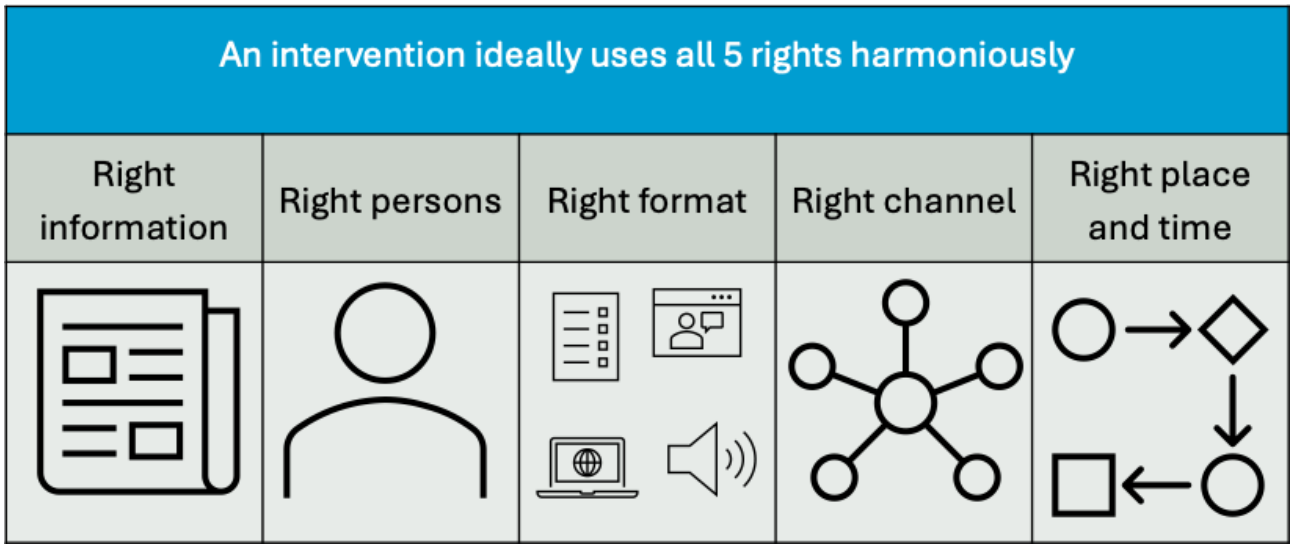
It is essential that patients and their care teams can work together to achieve patients' health goals, patient-centered outcomes, and effective, high-value health care systems. As a primary process of involving patients directly in their care, SDM is explicitly supported both by the National Academy of Health (NAM) (formerly the Institute of Medicine) [10,11] and the Affordable Care Act [12,13]. For instance, Medicare includes requirements for SDM as a condition of reimbursement for implantable cardiac defibrillator [14,15], lung cancer screening [16], and the left atrial appendage closure (WATCHMAN) device placement [15].

Barriers Facing Clinician DA Uptake

Similar to other clinical decision support (CDS) tools, DAs face many implementation barriers, such as increased workload and knowledge demands [17], and organizational factors (eg, culture and priorities) [18]. The result is the slow adoption of DAs and SDM approaches. Stacey et al found that the main barriers for uptake of DAs were (1) lack of funding to support implementation of DAs in clinical practice, including training in using DAs, (2) outdated DAs, and (3) clinician reluctance to use DAs due to increased workload, quality concerns, health record integration issues, manual data entry, and documentation burden [19,20].

Clinician DA use to support decision-making by patients is directly influenced by how cumbersome the process is to access and use the DA within existing clinical workflows [21]. Furthermore, clinicians desire a flexible approach to decision-making with patients [22]. These existing gaps in the literature suggest a need to more fully understand the complex clinical phenomenon and subjective experiences of clinicians to be better able to leverage Health Information Technology (HIT) to support expanded use of DAs.

The 5 Rights of CDS



Osheroff's "The 5 Rights of CDS," shown in Figure 1, outline a framework for effective CDS implementation [23,24]. We applied the "5 Rights of CDS" framework to SDM support, specifically the facilitation of DA use in the SDM process. SDM and DA implementation face many of the same implementation barriers as CDS interventions. The "5 Rights of CDS" address many of the known barriers to SDM and the use of DAs. DAs provide the right information (eg, the relevant, current, and unbiased DA) to the right person (eg, clinician or patient) at the right time (eg, before the decision has been made), in the right format (eg, best format for the clinician or patient given the topic, such as written text or video and the patient's primary language), and in the right channel (eg, within the electronic health record [EHR] patient portal).

Despite the proven benefits of DAs and SDM [6], informatics systems to address the barriers that health systems, clinicians, and patients face when attempting to use DA are lacking. The 5 Rights of CDS and the use of DA are closely aligned with the aim to improve patient care by ensuring that the right information reaches the patient or clinician at the right time. Aligning the principles of the 5 Rights and SDM can improve the quality of care and support patient engagement to make important health decisions.

Based on the documented advantages of using DAs, the 5 Rights of CDS, and the research still needed in making DAs accessible in existing workflows, the objective of this study was to understand clinician needs and requirements for a HIT solution that surfaces relevant DAs. In our proposed solution, DAs are launched in the SMART (SMART Health IT) on FHIR (HL7) [25] Shared Decision Aid Navigator System (DEAN; University of Colorado Anschutz Medical Campus) navigator app and are surfaced in the customized DEAN EHR tab. DEAN was designed and developed as an interoperable SMART on FHIR [25] app and therefore is highly applicable and generalizable.

Figure 1. The 5 rights of clinical decision support (adapted from [23]) .

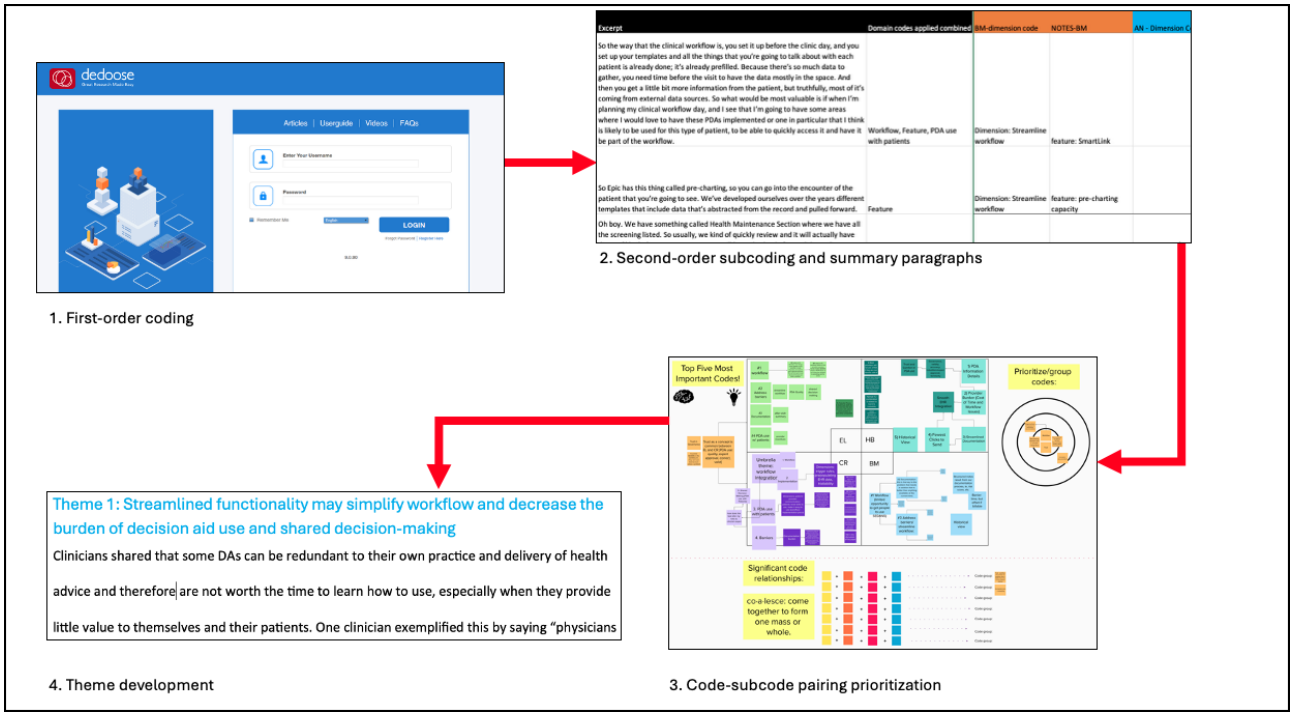
Methods

Overview

We (BM) conducted semistructured interviews (SSI), while other study staff were present to take notes (EL) and assist with facilitation (AS and LS), with clinicians identified at 4 US academic medical centers across the United States using purposive sampling [26,27]. Partners at the academic medical centers identified potential interview participants. We approached individuals via email to gauge interest in participating. Eligibility requirements for the SSI included clinicians with previous DA use experience and at least 20% clinical effort. Interviews continued until we reached thematic saturation, defined as not hearing any substantive new information from research participants.

Interview Guide and Data Collection Interaction

After a review of the literature to understand the already reported barriers and potential facilitators to DA use by clinicians, and alignment with the "5 Rights," we (LS, AS, and BM) developed an SSI guide to elicit insight from potential future users of the Navigator and ensure the same core questions were asked of all the participants while allowing flexibility to ask probing questions on other topics that arose during the discussion (Multimedia Appendix 1).



The SSI began with an elicitation of the participants' perspectives and experiences using DAs and having SDM discussions. This served to kick start the interview and provided the interviewer with the necessary personal context to conduct the remainder of the interview. As the purpose of the SSI was to obtain clinician input on our initial solution to the known barriers to DA use and SDM, we demonstrated a clickable, interactive prototype of DEAN (referred to as the Navigator henceforth) to demonstrate our proposed solution and collect insights from clinicians on how to further refine the prototype to support clinician use of DAs. The demonstration reviewed the known barriers and proposed solutions and facilitated input on the prototype features and functions from a user's perspective. Each interview lasted 1 hour and was conducted on the Zoom (Zoom Video Communications Inc) [28] video conferencing platform. Sessions were recorded and professionally transcribed verbatim for analysis.

Content Analysis Overview

We then conducted a 4-step qualitative coding process to analyze the interview transcripts using the Rapid and Rigorous Qualitative Data Analysis (RaDaR) technique [29-31]. This process included (1) creation and application of first-order codes, (2) application of second-order subcodes for a more nuanced and detailed coding scheme and a reduction of the code-subcode pairings to individual summary paragraphs [29,32], (3) identification and prioritization of relationships in the data, and (4) articulation of salient relationships into qualitative themes describing clinician needs and requirements of the Navigator (Figure 2).

XSL•FO
RenderX

Figure 2. Content analysis overview.

Qualitative Analysis Step 1: First-Order Coding

To accomplish data reduction and thematic development, a codebook was developed that contained the initial a priori codes, ie, first-order codes [33]. We then applied the codes to the interview transcripts to identify expected phenomenon (eg, barriers to the use of DAs) [32] using Dedoose (SocioCultural Research Consultants LLC), a qualitative analysis software [34]. If emergent codes (ie, new codes) were necessary during the coding process, the team defined the emergent code and discussed adding them to the codebook on a consensus basis (agreement from all 5 team members needed for the emergent code to be added). Coding was completed by the core qualitative team (AN, CR, SA, and BM). Each transcript was coded to consensus by 2 team members [33,35,36], a process in which discrepancies are discussed until consensus is reached [37], increasing the rigor of the coding [33,35,37].

Qualitative Analysis Step 2: Second-Order Subcoding and Summary Paragraphs

Once all the transcripts received codes, the Dedoose excerpts were entered into an Excel spreadsheet. Coders then applied more nuanced second-order subcodes. Subcodes were applied independently to Excel excerpts by at least 2 qualitative team members, and consensus was reached (AN, CR, EL, HB, SA, and BM) [36]. Excerpts that received the same code and subcode combination were grouped together and then reduced through synthesis to a single summary paragraph for each pairing.

Qualitative Analysis Steps 3: Code-Subcode Pairing Prioritization

Team members (CR, EL, HB, and BM) then reviewed all the code-subcode pairing summary paragraphs to identify the most relevant pairings to the needs and requirements of clinicians to support DA use. The saliency of the code-subcode pairing was determined by the pairing's information power [38], that is, the richness and relevance of the data in light of the study's objective and questions. Relationships were identified between code-subcode pairings that could be used to articulate the needs and requirements of clinicians for Navigator use.

Qualitative Analysis Steps 4: Theme Development

Mural [39] was used to visualize relevant code-subcode pairings and to interactively coproduce themes (BM, CR, EL, and HB) that characterized and described clinician needs and requirements. We reviewed and finalized the drafted themes ensuring that they accurately reflected our data. Themes were presented to the DEAN team (LS, AS, EL, PR, SS, RE, SA, and CR) for verification of relevance to our research question.

Ethical Considerations

The study was approved by the Colorado Multiple Institution Review Board (COMIRB #22 - 1061) and adhered to all relevant ethical guidelines, including informed consent procedures. We attest to maintaining privacy and confidentiality of research subjects' data and/or identity. The project received a waiver of informed consent. We distributed a postcard consent form outlining the study to all participants prior to data collection. Participants were informed that they could stop their participation at any time. Data were anonymized. Clinicians were compensated $100 for participating in the SSIs.

Results

Overview

Twenty clinicians were contacted to participate in the SSIs, of which 13 participated in them, representing 4 academic medical centers, while 7 did not participate (Table 1). One of the 7 clinicians did not respond, 3 were too busy, 3 did not meet the criteria (1 had no experience with DAs and 2 did not meet the minimum clinical full-time equivalent, FTE requirement of

XSL•FO
RenderX

20%). Interviews were approximately 60 minutes long. The data collected provided data saturation for understanding the needs and requirements of clinicians interacting with the Navigator.

We identified 3 primary themes. Theme 1 describes opportunities identified by the clinicians that may support the uptake of the Navigator. Themes 2 and 3 describe needs and requirements, training and trust, which clinicians reported as necessary to use a technology like the Navigator that surfaces relevant DAs.

20% - 50%	10 (77)
51% - 100%	3 (23)

[a]FTE: full-time equivalent.

Theme 1: Streamlined Functionality May Simplify Workflow and Decrease the Burden of DA Use and SDM

Clinicians shared that some DAs can be redundant to their own practice and delivery of health advice and therefore are not worth the time to learn how to use, especially when they provide little value to themselves and their patients. One clinician exemplified this by saying, “Physicians are already overburdened. Having to bring up another tool, the Navigator, and explain another decision [DA] to the patient takes more time.” Clinicians also shared that while they believed DAs can be valuable, they are not as significant an issue to tackle with their patients as there are more urgent problems the patient is experiencing.

According to the clinicians we interviewed, to combat the burdensome barriers and enable more clinicians to use DAs, the Navigator should address the following requirements: (1) integration into the EHR, (2) data collection burden reduction, and (3) documentation burden reduction. The DA delivery system that centralizes patient EHR data, populates required DA data, allows DAs to open within the EHR, and facilitates documentation of the SDM discussion in the EHR, are components that clinicians cited as desirable.

Too many clicks will be detrimental to the adoption of the DEAN technology. This concern was expressed by a clinician who asked, “If these tools exist, are they going to be within the existing workflow division or are they going to add extra clicks?” Another clinician warned, “All the third-party vendors try to make it seem like it’s seamless. It never is. And busy

XSL•FO
RenderX

clinicians don't fall for the seamless talk," expressing the importance of immediately and consistently demonstrating EHR integration in the existing workflow. Several clinicians recognized that automating tasks (eg, documentation) may increase time in the visit for patient engagement and enhanced patient-clinician relationships, sharing that "The clinician should spend time catching up with the patient, asking how they're doing and having that human aspect to it."

To overcome common barriers, it is not only important that the Navigator is integrated into the EHR, but that the Navigator documentation process be integrated within the EHR note-writing function to make it as easy as possible. Automated note population of DA use with patients was strongly preferred. Some physicians stated they document their use of the DA, including discussing risks with the patients and what they and the patient decided together. "The report, that would then populate into the note, which I think would be brilliant and is a perfect way to include it in the template." However, some find it difficult to balance thorough notes that are simple for patients to understand. In addition, some physicians find it challenging to either write a note with the patient during the visit (which can be very time-intensive) or to remember enough about the visit to write about it later. Templates, or even having the patient come in already engaged with the DA by entering required data, make the documentation process easier for clinicians.

Theme 2: Clinicians Need Appropriate Competencies to Effectively Use the Navigator and Relevant DAs

The use of a DA delivery system, like the Navigator, to support SDM involves interaction with complex technology and health care information. Clinicians communicated that training would be important before using the Navigator. They also felt they needed the knowledge and skills necessary to use the DAs. For clinicians, this includes the training required to access appropriate DAs in the Navigator and use the Navigator within the fast-paced and time-pressured clinical workflows, as well as possessing sufficient knowledge and experience with the clinical content of a DA. Currently, clinicians report being overburdened and learning how to use the Navigator and various DAs to implement the DSM processes into their workflow would be time-consuming. Many clinicians shared that they see many patients in a day and learning a new tool like the Navigator would only add to their busy schedules.

Clinicians identified the need to determine whether a DA is well designed and evidence-based. Alternatively, clinicians would rely on others (eg, a health system governing group or a medical organization) to endorse the DA. Clinicians described the substantial effort expended to adopt a new DA and stay current on the underlying evidence base. Evidence can change rapidly or be based on studies that are unfamiliar to the clinician. "I have very deep knowledge of the CDS tools that I use and understand how well they were validated and who did the studies and how high quality the studies were…we do journal clubs to talk about these tools…There is a depth of understanding and trust that happens before we apply them in clinical practice." Another clinician added, "Some of the other barriers that come up are comfort with the data. Like, you must know the material well yourself to be able to use some of these…and it changes all the time, so you must really be up to date."

Clinicians indicated that competency with the Navigator and specific DAs could be gained through trial-and-error adaptive learning. The opportunity to learn through practice was seen as a strategy to gain the experience and knowledge required to comfortably integrate DAs into clinical workflows. "I think trialability, (eg, using the tool before having to use it with patients) is another way to get over the mental model of adoption." Trialability will add work to the busy clinician's schedule, however, "And if you just gave me a new tool (DA and the Navigator) and say, hey, this is good for head injury patients, I would say, all right, I'll read about it after shift, and I may apply to the future." Relatedly, some clinicians highlighted the Navigator's ability to increase their competence and knowledge, stating, "there's a lot of times when not only am I having trouble explaining a complicated decision to a patient, but there's also actually information in these tools [the relevant DA] that I don't know."

Theme 3: Clinicians Must Trust the Navigator to Implement Use in Their Standard Workflow

A common response to the tool demonstration was that trust in the Navigator is a crucial prerequisite for the successful adoption of DAs. Clinicians are often reluctant to adopt technologies, such as the Navigator, when their benefits are uncertain [40]. Two types of trust were identified by clinicians.

Trust That the Navigator Is Aligned With Clinic Workflow

One clinician recognized the importance that streamlining the busy and burdensome clinical workflow may have on clinician's assessment of the Navigator. Trusting that the Navigator works smoothly within the busy clinical workflow is important because an indirect patient assessment of both the clinician and Navigator may result in, "…we're dealing with time and trust" of the patient. Violation of this expectation could erode clinician trust in the Navigator. Another clinician recognized that the Navigator might streamline the use of DAs, but gaining personal experience with the tool is an essential component for building trust in the system, "…I think after you try these three or four times, then the mental model barrier goes away. You're like, 'Oh, this is kind of helpful. It's not usurping me.'"

Trust That the Navigator Suggests Prevetted DAs They Can Use

Finally, selecting a quality DA and becoming familiar enough with its content to use it effectively during a visit was a concern for clinicians. Physicians feel that they need to establish familiarity with and trust in a specific DA in advance of using the DA during a patient encounter. One clinician shared, "If there were a lot of these [DAs] and I wasn't personally familiar with them, deeply familiar, then I would have difficulty…trying to make sure that I'm comfortable that this information applies to their particular case." Clinicians felt that while information embedded in the Navigator about a DA, such as evidence base or journal citations, could support clinicians' comfort with using a DA, clinicians would still have to become familiar with the DA to trust it enough to put it into practice. However, clinicians

XSL•FO
RenderX

stated that if DAs were prevetted by subject matter experts or committees at the local institution, uptake would be easier because the institution had previously endorsed veracity and use of the DA.

Discussion

Principal Findings

Our findings in Theme 1 reveal that clinicians have concerns about their ability to use DA and have SDM discussions during routine clinical care due to visit length time constraints, which are further impacted by technology that does not fit within their workflow and the need to address the most pressing and medically serious issues during visits. Workflow-concordant technology is essential for adoption and uptake, and clinicians stressed the importance of seamless EHR integration, prevetted and suggested DAs, DAs that do not require duplicate data entry, and the facilitation of the documentation of SDM discussions. While every concern matters, and clinicians and patients should work together to prioritize the visit agenda, clinicians are trained to recognize signs of urgent or life-threatening conditions that must take precedence. For instance, addressing symptoms of a possible heart attack would understandably take precedence over discussing sleep difficulties, regardless of the existence of the perfect insomnia management DA. Clinicians also expressed concerns about redundancy and a lack of value to DAs due to a clinician's expert knowledge of a topic or a simplistic decision. Many clinician recommendations and patient decisions do not require use of a DA, such as the recommendation and decision to take antibiotics for confirmed bacterial pneumonia. This contrasts with the high-stakes decision to have an implantable cardiac defibrillator, which is highly dependent on a patient's desire to lengthen their life and the distress caused by expected and realized electronic shocks. It is an obvious and understandable stance that DAs should only be used when they provide added value to complex SDM discussions. Although research suggests that clinicians recognize that they use paternalistic methods more often than they would prefer and that they have more limited discussions than they feel are optimal, mainly focusing on treatment options but not comparative pros and cons, and patient values and preferences. Many patients would like to be more engaged in their health care decisions [41,42].

Our findings formulated in Theme 2 indicate that clinicians may need to acquire new skills and knowledge to use a tool such as the Navigator and to effectively integrate DA use into existing health care workflows. In a study by Abbass et al [43], who found that lack of appropriate training was a key barrier to technology use, our research participants also commented on the need for both Navigator training and time to become familiar with a DA's content before using it with patients. A qualitative analysis of expert interviews in the context of artificial intelligence [44] described core competencies that clinicians need to effectively use these types of advanced technological tools within their clinical workflow [44]. The competencies identified include basic knowledge about the purpose and application of the tools; how to evaluate the quality, accuracy, and contextual appropriateness of the tools; how to adapt to changes in roles and workflows resulting from implementation; and the need to participate in continuing education related to use.

Similar competencies will be required for DA use in SDM, and with a tool like the Navigator, implementation planning and system training curriculum should account for the additional learning needed to successfully operationalize DAs in real-world settings. When clinicians participate in education opportunities on DAs, they are more likely to share a DA with a patient and engage in formal SDM [45]. With an increased skill set, it may follow that patient satisfaction with DAs and the SDM process would also improve. However, due to the high potential for ongoing changes to DA content, as new evidence and care standards emerge, continuing education will also be required. Continuing education should focus on SDM and DAs as a teachable skill [46].

As explained in Theme 3, while the benefits of DAs have been documented, the lag in widespread "trust" will persist until we can address multiple barriers. When designing and developing HIT that promotes trust, Jones et al [47] recommend designers clearly explain how the technology works, involve end-users in the development of the HIT, provide training and support for targeted end-users, allow for customization by end-users so that they can tailor the way they use the technology, and develop feedback mechanisms so that designers and developers can address system issues [47]. In our interviews, clinicians highlighted issues consistent with the recommendations made by Jones et al [47]. They wanted to trust that the Navigator system and the process of its implementation would work in their existing workflow. Therefore, before clinicians can trust the Navigator, which is mandatory, they need to be assured that the Navigator meets their needs and requirements as outlined in Themes 1 and 2.

The goal of health care technology is to provide greater convenience and clinical task efficiency, yet Abbas et al[43] cite key findings that barriers exist at technological, individual, and institutional levels that prevent widespread trust and adoption of health care technology. Specifically, these findings highlight compatibility, reliability, usability, training, and governance as barriers designers need to overcome to build clinician trust in new technologies [43]. Concerns were shared in the interviews that the Navigator would be vulnerable to these same trust issues and would need to be addressed before uptake.

The results of this study informed the future design, evaluation, and implementation plans of our proposed DEAN system. The rich qualitative data confirmed many of the functional requirements our team had previously identified based on known barriers to DA use and SDM. It also allowed further specification of some functional requirements and advanced the prototype to be used in further user-centered design sessions. For example, we sought to ensure the Navigator interface would integrate with the EHR in a manner consistent with EHR use in clinical care, opening within the EHR and not within an external browser. We also confirmed the need to create a system to support institutional curation of vetted DAs. In response to clinician input, we designed a system that surfaced Suggested DAs based on patients' current problems and medications, in a

XSL•FO
RenderX

manner that was noninterruptive, as clinicians expressed that DA use would be based on agenda prioritization and the need for a formal SDM discussion and the added value of the DA to the discussion. We also planned to streamline the filing of the SDM discussion note to the EHR through a variety of commonly used pathways. Our hope is that data-informed improvements in DA use workflows through the DEAN system, including the Navigator, will support greater uptake of DAs and enhance SDM conversations for clinicians and patients.

Furthermore, we believe the Navigator could lead to more trust on the part of the clinician. For example, the Navigator is designed to have a tile in the interface for each DA. Each DA tile will have an information button that provides readily available information on topics such as the references for the evidence on which the DA was developed and the DA creators. The information button also provides information to indicate the governing person or committee at the institution responsible for vetting and releasing the DA within the Navigator. Finally, we believe that training in Navigator use and time for clinicians to become familiar with the DAs will increase clinician trust of the tool.

Limitations

Some participants conflated the idea of risk calculators with DAs, but the facilitators were able to clarify the difference and provide relevant examples. We only conducted interviews with academic clinicians and community clinicians; practices may have different opinions. If anything, we suspect their time constraints and need to focus on revenue-generating activities may be even greater for community physicians. This could lead to varying stances, such as a clinician never making the time to use a DA and participate in a thorough SDM discussion, or a clinician who welcomes the timesaving and workflow-aligned functionality that the Navigator offers.

Conclusions

Future directions include the further development of the DEAN system, including the Navigator, and other backend systems to support DA curation and documentation of key facts such as DA governing entities, DA authors, evidence citations, evidence in the form of brief written summaries, and DA version date, including when the DA was last updated. Our hope is that the process of including clinicians early in the process of the DEAN system design leads to a tool that is workflow aligned and addresses the major barriers associated with DA use and SDM discussions. This should result in a system that has greater uptake and adoption, ultimately leading to better patient engagement and satisfaction with their medical decisions.

Acknowledgments

The authors would like to thank all the participants that assisted with the user-centered design discovery phase. Research reported in this publication was supported by the Agency for Healthcare Research and Quality (AHRQ) under award number 5R18HS028578-03. Abstract

Background: Mobile health (mHealth) for breast cancer care can greatly benefit patients' symptom management. Although research supports the effectiveness of mHealth, older adult patients with breast cancer often face difficulties using it, hindering them from accessing effective symptom management possibilities. Understanding the preference for mHealth among this population is crucial for providing insights into effective mHealth design.

Objective: This study aimed to better understand the symptom management preference using mHealth for Chinese older adult patients with breast cancer and use the approach of personas to inform the mHealth design.

Methods: This was a descriptive qualitative study. In total, 17 patients with breast cancer aged 60 years and older were recruited from tertiary hospitals in Shanghai, China, using purposive sampling. Data were collected through one-on-one interviews. Content analysis was used to identify the factors that influence participants' symptom management preference using mHealth. The categories of influencing factors of preference informed the persona template and guided the development of the persona.

Results: We identified 3 major categories affecting participants' preference for mHealth, including social interaction patterns, mHealth literacy, and symptoms. The following five personas were developed: (1) Positive Manager, (2) Dependent Parent, (3) Management Isolationist, (4) Image Manager, and (5) Clinician Dependent. We provide insights into how these personas can be used when designing and implementing mHealth for symptom management support.

Conclusions: Key factors influencing symptom management preference using mHealth among Chinese older adult patients with breast cancer and personas developed based on that can foster a better understanding of this population and initiate future mHealth design and implementation.

KEYWORDS

qualitative; mHealth; preference; symptom management; older adults; personas

Introduction

Breast cancer is among the main illnesses that threaten the lives and health of older adult women in China, with a double incidence peak at 45 - 55 and 70 - 74 years of age [1]. The mean age for breast cancer diagnosis in China is 45 - 55 years, which is considerably younger than that in Western countries, where the average age is between 48 and 50 years. However, due to the current unrestrained population aging, a substantial number of older adult patients with breast cancer may emerge. Although only 16.6% of patients with breast cancer were aged 65 years or older in 2018 in China, the incidence rate is estimated to increase to 27% by 2030 [2], leading to growing concerns regarding the management of older adult patients with breast cancer. According to previous studies, older adult patients with breast cancer experience higher rates of comorbidities, poorer performance status, limited social support, and difficulty with transportation, thus leading to different treatment approaches than those provided for their younger counterparts or undertreatment [3]. Older adult patients with breast cancer may face a complicated recovery process, insufficient information access, and a lack of emotional support [4,5].

XSL•FO
RenderX

Fortunately, mobile health (mHealth), which refers to medical and public health practices supported by mobile devices [6], is a promising tool that supports symptom management by providing unprecedented access to specialist clinical diagnostics and treatment advice [7]. Currently, mHealth is providing substantial improvements in human lifestyle behaviors and chronic condition management, facilitating the popularity and accessibility of health interventions [8,9]. Regarding disease management for patients with breast cancer, mHealth has demonstrated great potential for improving lifestyles, managing symptoms, and providing information and emotional support [10-14].

Integrating mHealth solutions for older adults can be significantly beneficial to this population, but the process faces various challenges [15]. For example, many mHealth tools may not be designed considering age-related dilemmas, such as vision or dexterity limitations, thus causing accessibility and usability problems [16]. Furthermore, the older adults from lower socioeconomic backgrounds may face affordability barriers to smartphone access and internet connectivity [17,18]. Moreover, a lack of tailored mHealth designed specifically for their needs can decrease the older adults' willingness to use mHealth, preventing them from adapting to technology and receiving the associated benefits [19,20]. Thus, the successful usage and adoption of mHealth are fairly poor in aging patients, accounting for a large proportion of the customer base for innovative health care devices [21].

Considering the importance of understanding the unique needs of older adult patients with breast cancer, we adopt personas to guide analyses of the needs of this population. The concept of persona was first introduced by Alan Cooper in 1999 [22]. It refers to virtual figures that share specific needs and unique personalities and are categorized based on key information about a target group [23]. Personas are detailed personas that embody the characteristics, behaviors, motivations, goals, and pain points of the identified user segments, thereby enabling more precise interventions [24,25]. Personas serve as the main character in a narrative, a scenario-based approach to intervention design that iteratively generates concepts (in the envision phase), provides feedback to enhance design coherence and appropriateness (in the refine phase), and provides a powerful communication tool to help developers understand the design rationale and prioritize features based on user needs. Considering persona was continuously adopted in different health contexts [20], the age-related challenges in the aging population facing mHealth, in part, can be compensated for by designing senior-friendly mHealth devices using persona.

The specific needs related to mHealth for improving symptom management among Chinese older adult patients with breast cancer have received little focus, and the insufficient use of personas requires further exploration. We typically focus on patients undergoing chemotherapy in this study because of the long duration and cumulative nature of this treatment phase, which is characterized by consistent and increasingly severe side effects such as fatigue, nausea, and immunosuppression. Understanding these patients' unique challenges is essential for developing effective mHealth solutions to improve their symptom management and overall quality of life. Therefore, this study aims to (1) understand the symptom management behavior and preference for mHealth among this population using qualitative data, (2) develop personas representing patients with different symptom management behavior and preference for mHealth, and (3) provide guidance for integrating personas into the design of mHealth.

Methods

Sampling

This study was conducted from April 2022 to February 2023 at the Fudan University Shanghai Cancer Center and Huadong Hospital in Shanghai, China. The purposive sampling method was adopted to enroll participants. The inclusion criteria were as follows: (1) diagnosed with primary breast cancer, (2) aged 60 years and older, (3) undergoing chemotherapy after breast cancer surgery or within 2 weeks of chemotherapy ending, (4) expected survival time of more than 6 months, and (5) know about their own disease status and can express their thoughts and options. The exclusion criteria were as follows: (1) patients currently receiving radiation therapy and (2) patients with vital organ dysfunction. The sample size was guided by the principle of data saturation. Interviews were discontinued after a minimum of 10 sessions, once no new themes emerged across 3 successive interviews [26].

Data Collection

Eligible participants were identified by nurse leaders in the breast oncology departments based on predefined inclusion and exclusion criteria. After briefly introducing the study aims and obtaining verbal agreement from potential participants to be contacted, the nurse leaders referred the interested individuals to the research team.

Before each interview, participants received a detailed explanation of the study from the research team and signed written informed consent forms. General participant characteristics were then recorded, including age, education, chemotherapy stage, primary carer, and whether living with a primary carer.

Subsequently, one of the authors (YZ) and the corresponding author (FW) conducted the face-to-face interviews. YZ is a nursing undergraduate student who took classes in qualitative study, and FL is a lecturer and experienced qualitative researcher with a research focus on breast cancer and imparted qualitative research methodology in the university. Before the beginning of data collection, YZ was trained by FW, covering the principles of qualitative research, techniques of conducting semi-structured interviews (building rapport, active listening, and probing), and mock interview exercises based on the interview guide. Each interview was audio-recorded and lasted 30 - 50 minutes. During data collection, the interviewers summarize and confirm their interpretation of what a participant said during data collection as a member checking to secure the trustworthiness.

Data were collected through semi-structured interviews using open-ended questions. The study aimed to gather qualitative data about participants' behavior and patterns for symptom management and preference for using mHealth; therefore, the

XSL•FO
RenderX

questions were developed carefully around this topic. The original questions were refined after trial interviews with 3 potential patients, and the final interview outlines are presented in Textbox 1. The data from trial interviews were not included in the final data analysis.

Textbox 1. Interview outline around patients' symptom management behavior and preference for using mHealth to manage symptoms.

1. Since starting chemotherapy, how do you feel?
2. What physical, mental, and social interaction changes have you noticed?
3. What are the most dominating symptoms you feel?
4. How do you manage your symptoms? What are the barriers and facilitators of your symptom management experience?
5. Did you get any help to manage your symptoms? Regarding help and resources from your spouse, children, relatives, friends, and health care providers?
6. How do you think about your symptom management skills, attitudes, and experience?
7. How do you think about managing your symptoms using mHealth (eg, knowledge distribution apps, virtual health consultation websites, symptom assessment apps)? Are there any concerns that might discourage you from using mHealth?
8. What features would you find most helpful in mHealth for symptom management?

Ethical Considerations

This study was reviewed and approved by the Institutional Review Board of Fudan University School of Nursing (IRB no. TYSQ2021-03-05). All participants provided informed consent prior to data collection.

Data Analysis

The audio-recorded interviews were transcribed within 24 hours after interview completion. All transcripts were managed and coded using NVivo 12. Data were analyzed using qualitative content analysis, and transcripts were coded inductively [27]. By using inductive coding, the data drove the analytical process, ensuring a comprehensive exploration of patterns and themes based on the interview transcripts. This approach allows the researcher to derive insights and meaning directly from the data rather than imposing preconceived coding categories. YZ and DL analyzed the data independently, and the main steps are as follows: (1) immersing in the data by line-by-line reading of the transcript; (2) selecting the unit of analysis; (3) making sense of the data as a whole; (4) open coding; and (5) group and categorization. After open coding, the preliminary codebook was developed and was iteratively refined through constant comparison and discussion between 2 researchers. Codes were then clustered into subcategories and higher-level categories. Intercoder reliability was addressed through regular meetings to compare coding results and resolve discrepancies via discussion until consensus was reached. Investigator triangulation was implemented by involving 2 researchers in data coding and theme development. Discrepancies were resolved through discussion with the other 2 researchers (CY and FW, with 25 y and 10 y of qualitative research, respectively) to reach consensus. Investigator triangulation was used to ensure a comprehensive and trustworthy exploration of subcategories and categories grounded in the interview transcripts.

Persona Segmentation

After the qualitative data analysis, we identified the categories and subcategories of symptom management behavior and preference for using mHealth to manage symptoms, which could be used as the persona segmentation template. Patients with similar features of categories and subcategories were grouped. Based on these groupings, a persona was created to represent the shared patterns within each subgroup [28]. This ensured that each persona reflected not just individual traits but collective tendencies observed across participants. These personas were sent back to participants for validation to ensure an accurate representation of their characteristics and experiences. Final groupings were refined through team discussions and reviewed by qualitative experts to ensure consistency.

Persona Creation

Subsequently, we designed the persona skeleton, a layout describing the key information that the persona includes [28]. After finalizing the details of each persona, we used visual icons to highlight their key features and enhance vividness. To further humanize the personas, we assigned them names and incorporated representative quotes to reflect each target group's personality and context [25]. The visual elements were hand-drawn by the research team to maintain authenticity and engagement.

Results

Participants

A total of 17 participants were approached and agreed to participate in the interviews. Participant characteristics are outlined in Table 1. The participants had a mean age of 69.6 (range 61 - 80) years. All the participants were female and had undergone radical mastectomy. The most common primary caregivers were their adult children.

XSL•FO
RenderX

Table . Sociodemographic characteristics of the participants.

No.	Age	Education	Chemotherapy stage	Primary carer	Live with primary carer
N1	72	Primary school	2nd-4th cycle	Children	Yes
N2	73	Illiteracy	5th-8th cycle	Children	Yes
N3	66	High school	2nd-4th cycle	Spouse	Yes
N4	68	Primary school	2nd-4th cycle	Children	Yes
N5	79	Illiteracy	5th-8th cycle	Children	Yes
N6	81	Illiteracy	Chemo-ended	Children	Yes

Symptom Management Behaviors and Preference for Using mHealth to Manage Symptom

We identified 3 categories, 7 subcategories, and corresponding descriptions (Table 2). The results describe the symptom management behaviors and preference for using mHealth to manage symptoms among Chinese older adult breast cancer patients.

Table . Symptom management behavior and preference for using mHealth to manage symptoms.

Categories	Subcategories	Description
Social interaction patterns	Living conditions	Living with children or spouse who provide 24/7 care or living alone without a specific caregiver
	Social dynamics	Regular interacting with families or friends or completely being isolated and staying at home
mHealth literacy	mHealth access	Having or not having mobile devices (phone or computer) and Internet connection
	mHealth usage	Knowing or not knowing how to use mHealth devices or with amount of experience
	mHealth interest	Being willing or unwilling to interact with others via mobile devices
Symptoms	Symptom diversity	Experiencing many or only a few symptoms simultaneously
	Symptom severity	Experiencing tremendous or bearable symptom burden

Personas

We classified our findings into 5 personas, with differences in social interaction patterns, mHealth literacy, and symptoms. We typologized the personas as follows: Positive Manager, Dependent Parent, Management Isolationist, Image Manager, and Clinician-Dependent (Table 3).

XSL•FO
RenderX

Table . Persona overview.

Features	Positive Manager	Dependent Parent	Management Isolationist	Image Manager	Clinician-Dependent
					
Age	65	66	81	60	70
Education	High school	Primary school	Illiteracy	College	Primary school
Living conditions	Lives with spouse and children providing care	Lives with children who provide 24/7 care	Lives with spouse	Lives with spouse	Lives with children
Social dynamics	Regular interaction with family and friends	Regularly interacts with family members	Isolated, stays mostly at home	Seeks interactions with patient support groups	Regular interaction with clinicians
mHealth access	Has mobile devices and Internet access	Limited access, often relies on children for tech support	No mobile devices or Internet	Has access	Has mobile devices but prefers clinician support
mHealth usage	Actively uses mHealth, searches for professional health information	Uses mHealth only with children's assistance	Refuses to use mHealth, relies solely on children	Uses mHealth to communicate with peer groups but may need help	Relies heavily on clinicians, limited personal mHealth use
mHealth interest	Interested in web-based clinician interactions and reliable information	Prefers family involvement in mHealth, little personal interest	No interest in using mHealth directly	Prefers engaging with online patient communities for social and emotional support	Trusts only clinician-guided mHealth solutions
Symptom diversity	Experiences multiple symptoms (eg, gastrointestinal issues)	Deals with a mix of symptoms, mainly related to chemotherapy	Experiences chronic pain and discomfort	Focuses on managing self-esteem and emotional symptoms	Multiple symptoms, particularly concerned with treatment side effects
Symptom severity	Manages ssymptoms well but occasionally need support	Struggles with symptom severity	Bears with severe symptoms with willpower	Faces moderate symptom severity but is more focused on appearance	Could bear with symptoms with close clinician guidance
Specific need	mHealth to support chemotherapy-related symptom management, online clinician interaction	mHealth for monitoring by children, simple interface for basic needs	mHealth for children to track appointments and care schedules	mHealth for emotional support, patient-patient communication	mHealth with reliable, clinician-vetted information and consultation options
Design point	Design should focus on providing tips for chemotherapy-related symptom management and ensuring access to reliable professional information, with easy access to online clinician consultations.	Create a simple, user-friendly interface that allows children to monitor patient health and symptom management, ensuring notifications for appointments and medical updates.	Design tools that allow children to remotely manage patient schedules, appointments, and care, with minimal interaction from the patient. Focus on simplifying updates and reminders.	Design should emphasize patient-to-patient interaction for emotional support, with features to help rebuild self-esteem and manage appearance-related concerns.	Provide a trusted, clinician-validated platform with regular updates, symptom management tips, and easy access to clinician consultations.

Persona of Positive Manager

Quotes:*I think I can battle with breast cancer, and I will eventually win. Long days are there (Textbox 2).*

XSL•FO
RenderX

Textbox 2. Persona of positive manager.

Characteristics:

- Social interaction patterns: *I live with my caring spouse and supportive children, who play a crucial role in my daily life and health journey. I am deeply grateful for their presence and support, and I cherish every moment with them. Family and friends are my pillars of support. Regular gatherings and conversations keep me mentally engaged and emotionally fulfilled.*
- mHealth literacy: *Having access to mobile devices and the internet has been a game-changer. It empowers me to stay informed about my health and treatment options, which gives me a sense of control. I actively use mHealth apps to educate myself on managing chemotherapy-related symptoms. The ability to connect with healthcare professionals online reassures me and provides personalized advice. I completed high school and have always valued learning. I find comfort in online interactions with healthcare providers. Their expertise and reassurance help me navigate the challenges of treatment with greater confidence.*
- Symptom diversity and severity: *Dealing with various symptoms, such as digestive issues and occasional fatigue, can be challenging. However, learning how to manage them effectively has been empowering. While I generally manage my symptoms well, there are moments when I need extra support. Knowing I can reach out to my family or healthcare team for guidance makes a big difference.*

Specific preference: Specifically, I require tailored symptom tracking to monitor chemotherapy-related symptoms accurately. Personalized guidance is essential, offering tips on managing issues like gastrointestinal discomfort and fatigue. Regular updates and alerts keep me informed of symptom changes and treatment updates.

Persona of Dependent Parent

Quotes:*I don’t know what to do and have lost hope for the future. Please tell anything to my children (Textbox 3).*

Textbox 3. Persona of dependent parent.

Characteristics:

- Social interaction patterns: I live with my children, who provide around-the-clock care. We have a close-knit family dynamic, and I rely heavily on them for both emotional support and practical assistance. While I interact regularly with my family members, most of my social interactions revolve around family gatherings and caregiving responsibilities.
- mHealth literacy: I have limited experience with technology and rely on my children to navigate mHealth tools. They assist me in using healthcare apps for basic tasks like appointment scheduling and medication reminders. Understanding complex medical information online is challenging for me, so I prefer simplified explanations and direct guidance from my family.
- Symptom diversity and severity: I manage a mix of symptoms related to chemotherapy, including fatigue and occasional digestive issues. These symptoms can be overwhelming at times, impacting my daily activities and emotional well-being. While I strive to cope independently, I often rely on my children’s support to manage symptom flare-ups and seek medical advice when needed.

Specific preference: I require mHealth tools that simplify symptom monitoring and provide clear instructions for managing chemotherapy side effects. Specifically, I need a user-friendly app that allows my children to track my health status, appointments, and medication schedules effortlessly. Timely alerts and reminders are essential to ensure I adhere to treatment plans and receive prompt medical attention for any symptom changes. Access to reliable information and simplified health advice through mHealth would greatly enhance my ability to manage symptoms and maintain my overall well-being.

Persona of Management Isolationist

Quotes:*I am so severely ill. I don’t want to say anything (Textbox 4).*

Textbox 4. Persona of management isolationist.

Characteristics:

- Social interaction patterns: I prefer solitude and spend most of my time at home, away from social interactions. Living alone with minimal external contact, I find comfort in solitude and independence, handling my health challenges mostly on my own.
- mHealth literacy: I don’t use mobile devices or the internet regularly, which limits my access to mHealth tools. I rely solely on face-to-face interactions with healthcare providers or family members for medical information and support.
- Symptom diversity and severity: Managing chronic pain and discomfort is a daily struggle for me. These symptoms significantly impact my mobility and quality of life, requiring ongoing management strategies to cope independently.

Specific preference: I require healthcare solutions that respect my preference for isolation while providing essential medical support. An ideal mHealth tool would allow minimal digital interaction but provide critical health updates and remote consultations with healthcare professionals as needed. This approach would enable me to maintain my independence while ensuring timely medical guidance and support.

XSL•FO
RenderX

Persona of Image Manager

Quotes:*I haven't retired. I have to go back to work with a normal body shape (Textbox 5).*

Textbox 5. Persona of image manager.

Characteristics:

- Social interaction patterns: I actively seek interaction with online patient support groups and communities. These platforms provide me with valuable emotional support and information-sharing opportunities, helping me navigate the challenges of chemotherapy with peers who understand my experiences.
- mHealth literacy: I use mHealth apps to connect with patient communities and access reliable health information. I am comfortable navigating online resources and value the empowerment that comes from educating myself about my health and treatment options.
- Symptom diversity and severity: While managing chemotherapy symptoms, I focus on maintaining my appearance and emotional well-being. I deal with moderate symptom severity, such as fatigue and appearance-related concerns, which impact my self-esteem.

Specific preference: I need mHealth tools that facilitate patient-to-patient interactions and provide emotional support. Specifically, I seek platforms that foster community engagement and offer resources for managing appearance-related symptoms. Access to reliable information and peer support online is crucial for enhancing my resilience and emotional health during treatment.

Persona of Clinician-Dependent

Quotes:

I only rely on health care providers, and I want to contact doctors when I need (Textbox 6)

Textbox 6. Persona of clinician-dependent.

Characteristics:

- Social interaction patterns: I maintain regular interactions with healthcare providers, relying heavily on their expertise and guidance in managing my health. I prioritize direct communication with doctors and healthcare professionals for medical advice and treatment decisions.
- mHealth literacy: While I have access to mobile devices, I primarily use them to facilitate communication with healthcare providers. I prefer direct contact with doctors for accurate medical information rather than relying on digital health tools or online resources.
- Symptom diversity and severity: Managing multiple symptoms related to chemotherapy is a significant concern for me. I depend on clinicians to monitor my symptoms closely and provide tailored treatment plans that address my specific health needs.

Specific preference:

My specific need is a reliable mHealth platform that facilitates direct and timely communication with healthcare providers. I prefer tools that offer secure messaging or virtual consultations with doctors, ensuring I can reach out for medical advice promptly when needed. This direct access to clinicians is crucial for me in managing chemotherapy-related symptoms effectively and receiving personalized care.

Discussion

Overview

This study depicted the differences in symptom management behaviors and preference for using mHealth to manage symptoms among the older adult breast cancer patients in China and, based on the differences, built 5 typical personas: Positive Manager, Dependent Parent, Management Isolationist, Image Manager, and Clinician-Dependent. This study outlines the complete process of persona development, including qualitative data collection, persona segmentation, and creation, building upon previous reviews of persona technologies [28]. The strict adherence to the consensus process [28] and early user involvement [29] suggests that our findings may serve as a valuable reference for future persona development and user-centered design.

The qualitative interviews we conducted focused on our target and special population—older adult breast cancer patients. The combination of cancer and aging renders this population particularly vulnerable, as cancer impacts their physical health while aging contributes to increased comorbidities and a decline in overall resilience [30]. Despite previous studies that have primarily focused on the treatment and survival of this population, few have closely examined their self-management behaviors or actively engaged them in the information age to ensure they fully benefit from modern technologies [31]. Notably, we found only 1 previous paper that recognized the need for health technology in chronic disease management [21], and no existing literature specifically addresses the preferences of older adult breast cancer patients. Therefore, our study identifies 3 key categories—interaction patterns, mHealth literacy, and symptom diversity and severity—that revealed the self-management behavior patterns and preference of mHealth for symptom management of older adult breast cancer patients. This research addresses a critical gap in the literature, highlighting the importance of understanding these factors to enhance mHealth solutions for this vulnerable population.

Following this, we developed 5 personas based on the categories and subcategories identified. This approach adheres to standard persona construction practices by using data-driven classification [28]. Moreover, the personas expand traditional persona content to include social dynamics, mHealth access, mHealth usage, mHealth interest, symptom diversity, symptom severity, specific needs, and design points to enhance richness in understanding older adult breast cancer patients and their context [32].

XSL•FO
RenderX

According to previous studies, the enriched insights gained provide valuable guidance for functional requirements, design, and implementation strategies tailored specifically for this target population [21]. The structure and content of our personas, which incorporate the key features of symptom management, can serve as templates for developing personas for other health consumer target populations [21].

We believe that the personas developed can effectively highlight both common and distinct traits among users. The shared characteristics of the 5 personas should serve as the primary focus for core functionalities, while the unique traits will inform the development of supplementary and optional features. From our research findings, we have initially identified 2 core functionalities: symptom reporting and educational materials.

The symptom self-reporting feature will enable users to log their symptoms daily, facilitating real-time monitoring and proactive management of potential side effects, which is crucial for breast cancer management for older adult patients [33]. For instance, for the Positive Manager, visualizing longitudinal symptom assessments could enhance their understanding of health trends over time. In the case of Dependent Parents, the mHealth product could facilitate a dyad approach where patients and their children both engage with the system, allowing symptom reports to be sent directly to their children via push notifications.

Meanwhile, the educational materials will provide tailored information to enhance users' understanding of their condition and treatment, empowering them to make informed decisions regarding their health. For the Clinician-Dependent, it is crucial to integrate a voice icon and profile icon, enabling medical advice to be easily accessible and conveyed by a trusted physician. Regarding the educational features of the mHealth product, Positive Manager and Imanage Manager are inclined to learn and manage their health and could benefit from self-directed reading materials and a patient support network, while Clinician Dependent, who prefers individualized attention from health care providers, could be offered one-on-one video appointments. Given that the target population consists of older adult patients who often experience memory and comprehension difficulties, the development team must carefully manage the amount of information presented to avoid cognitive overload. A modular approach can effectively cater to users, providing essential knowledge for those who prefer not to delve deeper while allowing for broader exploration through optional modules. Active information seekers, such as the Positive Manager and Image Manager, can benefit from this modular design, which ensures continuous content updates and relevance.

As for the role of personas in the design process, they serve as educational tools for design and usability teams. They provide insights that convey project progress to sponsors and offer a "word picture" that familiarizes team members with target user groups. Personas structure user typification, enhancing communication within development teams. As noted by Hill and Barteck [34], once established, personas become the primary medium for design discussions, aiding in resolving group conflicts by referencing user perspectives. For instance, team members might ask, "What would the Clinician-Dependent think?" while designing the interface and algorithm. Additionally, based on interaction design principles like the double-diamond design, the iterative process often involves usability testing [35]. Personas can help predict who the primary and secondary users will be. For breast cancer patients, spouses and children are typically considered secondary users, as they can facilitate adoption and usage and are often willing to assist primary users in receiving better care. Therefore, detailed personas can serve as a foundation for selecting and screening participants for interactive prototyping and usability testing, directly influencing the solution's design and development [21]. For instance, when considering Dependent Parents, it is crucial to involve their children as secondary users of the mHealth tool, as their experiences and insights are equally valuable.

During the implementation stage, personas serve as essential tools to guide the deployment of mHealth solutions. For the Positive Manager, promotional efforts such as posters and advertisements can effectively reach this group. For the Image Manager, word-of-mouth within social circles is a key avenue for adoption. The Clinician Dependent persona can be introduced to mHealth solutions through doctors or nurses during appointments, making it crucial to integrate mHealth into the clinical workflow. For the Dependent Parent, the focus can be on caregivers who accompany them to appointments, using this relationship as a key promotional touchpoint. Additionally, for long-term adherence, especially with Dependent Parents, their children should be considered the primary channel to improve compliance and ensure ongoing engagement with the mHealth tool.

According to previous studies, personas do not need to be recreated from scratch for every application [36]. Our 5 specified personas—The Positive Manager, The Dependent Parent, The Management Isolationist, The Image Manager, and The Clinician Dependent—can be reused by both researchers and practitioners. With China's rapidly aging population and increasing prevalence of cancer, innovative approaches to patient management are urgently needed [37]. These personas offer valuable insights that can address the current gap in China's user-centered design practice, particularly in mHealth solutions tailored to older adult breast cancer patients. Their reusability makes them adaptable for various health care applications, enhancing design efficiency and consistency across future projects.

Limitations

Our study presents some limitations that should be acknowledged. First, we relied on interviews for data collection, without using focus groups. While one-to-one interviews provided in-depth insights into individual experiences, focus groups could have uncovered collective perspectives and group dynamics, particularly valuable when studying older adult populations. Second, the personas we developed are based on qualitative data, which, while rich in detail, are inherently subjective. The personas were constructed by researchers based on interpretations of the qualitative data, which may introduce some bias. Quantitative approaches to persona development, such as surveys or statistical analysis, could offer more

XSL•FO
RenderX

objective, testable profiles that may provide additional validity and generalizability to the findings [38].

Conclusions

This study identified symptom management behaviors and preferences for managing symptoms using mHealth among older adult Chinese breast cancer patients. Further, we developed 5 personas that reflect the diverse preferences of this population. These personas play a crucial role across multiple stages of mHealth development: helping to determine core functionalities during the planning phase, guiding design and development by aligning product features with user needs, and supporting implementation by facilitating adoption and engagement strategies. Together, these insights contribute to more effective, user-centered mHealth solutions.

Abstract

Background: Digital care platforms that integrate patient-generated health data (PGHD) alongside education and communication tools have been recognized as potential instruments in transforming health care from clinician-centered to a more patient-centered approach. This transformation is driven by the potential of PGHD to provide deeper insights into patients' conditions, facilitate personalized care, improve patient quality of life, reduce inefficiencies in data collection, and empower patients. Yet, actual implementation within clinical settings is still at early stages; therefore, impacts on clinical care remain limited.

Objective: This study sought to explore the benefits, challenges, and opportunities of integrating PGHD into orthopedic care by analyzing the reflections of early adopter surgeons and physiotherapists who have used a digital care management platform.

Methods: This qualitative study used thematic analysis of interviews conducted with surgeons and physiotherapists (n=9) from a clinical unit that was among the first to trial "mymobility," an industry-produced software platform (Zimmer Biomet). The participants were recruited using snowball sampling, and interviews were conducted from June to July 2022. The interviews focused on work practices, use of digital tools, experiences with PGHD, and experiences with the mymobility software. Thematic analysis was conducted using NVivo software (QSR International Pty Ltd), focusing on identifying key themes and insights.

Results: The study identified several benefits of integrating PGHD into orthopedic care, including improved patient education, enhanced communication and assessment, and increased patient motivation and adherence. However, several challenges were also noted, such as increased clinician workload, questionable data utility, lack of patient centricity, and inability to tailor software to clinical contexts. Suggested opportunities included improving dashboard design, personalizing physiotherapy, and using collected data for improving clinical care.

Conclusions: The integration of PGHD into orthopedic care shows promise, largely in areas suggested by the literature. However, significant challenges remain. Future research should focus on addressing solvable challenges, such as improving software user interface design and functionality, while embracing the possibility that some challenges lack clear solutions and will likely require careful balancing of design tensions. The findings highlight the need for ongoing development and refinement of PGHD-inclusive systems to better support clinical practice and patient outcomes.

Introduction

Overview

There are frequent calls within academic literature and popular media to transform health care systems from the traditional "clinician-centered" model to a more "patient-centered" approach, an approach characterized by shared clinical decision-making and increased patient autonomy [1] while also helping to reduce costs through coordinated and accessible personalized services [2]. An important and often asserted mechanism for this transition is increasing the use of patient-generated health data (PGHD) within clinical care. PGHD are information collected by individuals (and informal caregivers) on aspects such as their treatment records, symptoms, biometric data, and lifestyle preferences [3]. The use of PGHD has been promoted for various reasons: providing deeper insight into a patient's condition [4], facilitating

XSL•FO
RenderX

personalization of care [5], improving patient quality of life [6], reducing inefficiencies and insufficiencies in data collected solely at clinical visits [7], reducing retrospective recall bias [8], and empowering patients by helping them to understand their progress [9].

Using PGHD has become increasingly feasible, as technologies for self-tracking of health and wellness data have become affordable and culturally acceptable to consumers [10]. The ease of data collection for patients and ubiquity of these devices are informally influencing clinical interactions, as patients increasingly present their self-collected data during clinical visits [5], and recent studies suggest that clinicians are increasingly open to using PGHD at least as supplementary data within clinical workflows [11] [4].

Despite the potential benefits, there remain extensive known barriers to implementing PGHD within clinical care. For example, West et al [5] identified the nature of the data (structure, completeness, reliability, lack of context, and relevance), selective disclosure, clinician suspicions of underlying patient psychiatric disorders, insufficient clinician time, insufficient clinician expertise, clinician overload, interoperability, and negative impacts to workflow. Other notable barriers include clinician reluctance to assume responsibility for motivating patients to collect data [4], clinician concerns that reliance on PGHD could exacerbate health disparities [6], negative impacts on patient-clinician relationships [12], and resistance to change within clinical culture [7]. Given such diverse challenges, it is perhaps unsurprising that formal integration of PGHD within clinical practice remains limited [13]. Therefore, there remains a lack of knowledge on diverse PGHD-related topics such as how to use PGHD to improve health care outcomes [3], impact on patient-clinician communication within surgical domains [12], best practices to incorporate into clinical workflows [14], and impacts in supporting clinical practice [11].

This study sought to understand work practices, acceptance of digital tools, and attitudes toward PGHD as part of a broader care management platform to gain insights that could guide the design of digital systems that incorporate PGHD alongside other patient support functionalities in orthopedic care. To this end, we conducted interviews with surgeons and physiotherapists who were members of an “early adopter” orthopedic unit that had (1) been given the opportunity to use an early release of industry-produced patient journey software that offered various tools for interacting with patients and their data and (2) participated over several years in the development and deployment of a novel device to enable orthopedic patients to self-collect pain data [15]. Focusing on this context foregrounds real-world exposure and engagement with PGHD, with the reported experiences helping to fill current gaps in knowledge in the clinical use of PGHD, guiding future research on the use of these data in a clinical context.

Background

Total knee arthroplasty (TKA) and total hip arthroplasty (THA) are common elective surgeries for older adults, where an original joint damaged by arthritis or trauma is replaced with metal and plastic implants. Due to high cumulative expenses resulting from this increasingly common procedure, TKA or THA operation is an important target for optimizing care [16]. To this end, fast-track programs that seek to reduce patient time in the hospital have become standard, successfully reducing costly hospital stays without impairing outcomes or increasing readmissions [17]. However, despite the successes of this approach, there remain opportunities for improvement that could potentially be supported with increased use of PGHD. For example, patients who have had a TKA or THA operation frequently have risk factors that can be related to readmission (eg, obesity, cardiovascular disease, diabetes, and lifestyle factors) [16]. Yet, current clinical systems often fail to consider what occurs outside the boundaries of the health care system [18]. This lack of vital information about patients’ comorbidities and lifestyle can hinder timely decisions about surgical scheduling and personalizing patient care, and there is also an urgent need to increase proactive care to enhance patient satisfaction, promote long-term recovery, and reduce unnecessary hospital stays. Given the importance of events occurring outside of the clinical setting for improving outcomes, the importance of engaging patients in collaborative care, and the potential for nonclinical data to inform policies that could improve outcomes, TKA or THA appears as a promising domain for increased PGHD integration.

PGHD and THA or TKA

The adoption and affordability of wearable devices have increased the feasibility of integrating PGHD into THA or TKA care, and there have been numerous studies exploring potential benefits and limitations. Toogood et al [19] used ankle-worn Fitbit step counters to track daily steps in patients who have had their THA operation. They found this method feasible and found that by differentiating activity levels based on factors like age, BMI, surgical approach, and discharge destination, it might be possible to identify slower recovery cases that could benefit from interventions. However, other studies cautioned that while tracking was technically feasible, the resulting data had practical limitations. For example, Crizer et al [20] studied using step counts to monitor preoperative and postoperative recovery but found a weak correlation with patient-reported outcomes. The authors suggested that combining objective measures like step counts with patient-reported outcomes would provide a more comprehensive assessment. Similarly, Bendich et al [21] examined data from wearable sensors worn by patients both before and after total joint surgery. They reported that alterations in sensor data 6 weeks after surgery correlated closely with patients’ reported improvements in well-being; however, the raw sensor data did not directly correspond with patients’ self-reported feelings, suggesting that to effectively predict postsurgery outcomes using sensors, it is essential to analyze how the data evolve over time rather than solely focusing on absolute values. These papers highlight that it is not sufficient to aggregate and report data to clinicians, but rather that meaningful interpretation and context are essential. We found numerous papers that applied tracking devices to support patient monitoring outside the clinical environment. However, we found little research on the reflections of orthopedic clinicians on the use of PGHD and more specifically their experiences with PGHD-inclusive clinical software. In addition, relatively few

XSL•FO
RenderX

studies on PGHD integration have examined the use of patient-generated data from the clinician's perspective rather than the patient's perspective [5], which is important, as clinician engagement has previously been recognized as a significant challenge for integrating patient self-reporting systems into clinical practice [7]. This paper aims to fill these gaps through exploring clinicians' real-world experiences with the benefits and challenges of integrating PGHD into TKA or THA workflows and through analysis identifying opportunities to improve these systems.

Methods

Ethical Considerations

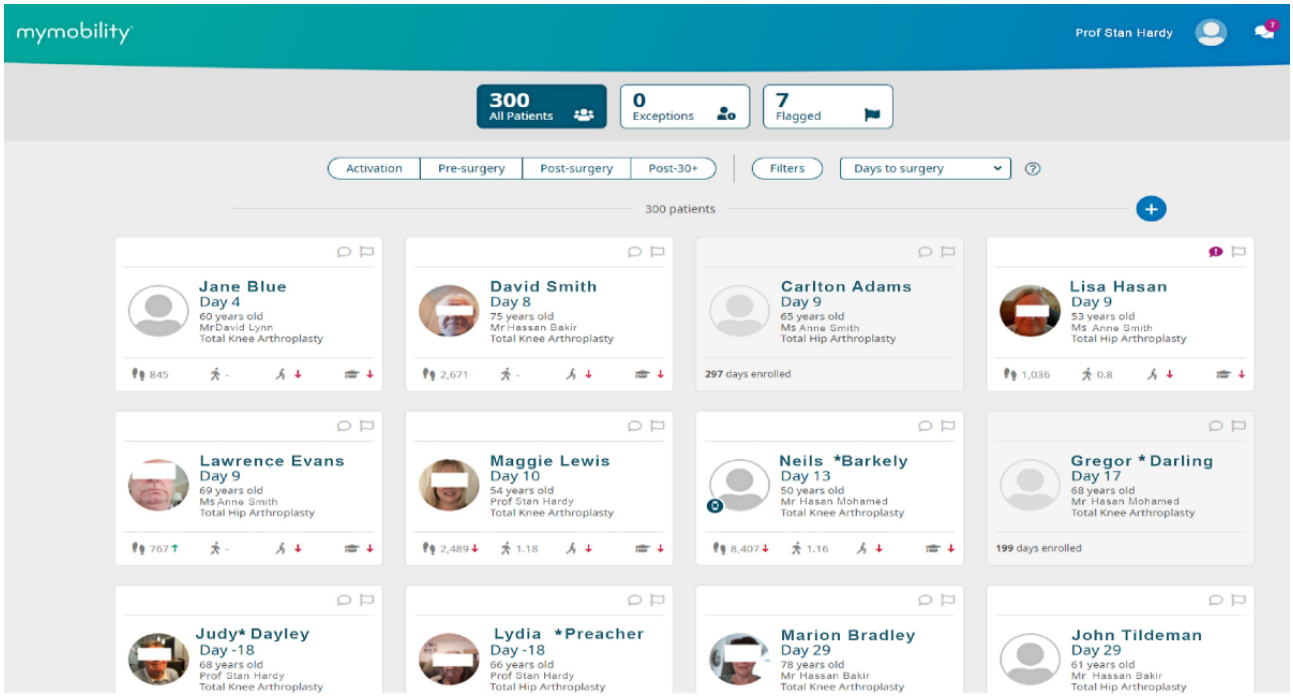
Ethics clearance was granted through the Open University Human Research Ethics board (HREC/3776/Mehta). Preconditions for participation were professional capability in either of the 2 selected clinical roles, experience with TKA or THA, and spoken English. All participants were employed in these roles in the United Kingdom. Participants were assured anonymity. Prior to the interview, participants received an email confirmation of the time and date, as well as receiving a copy of the questions and a consent form that was returned by email. Participation was voluntary, and all participants were informed of their right to withdraw at any time. The interviews lasted from 30 to 60 minutes and were conducted by the same member of the research team (LP). Participants were offered either face-to-face or digital interviews to accommodate their clinical schedules. The interviewees' responses were anonymized according to the ethics committee procedure. Each institution's data protection policy was adhered to, ensuring that data were confidentially stored. All transcripts were transcribed and stored anonymously, and the data were stored on a secure system only accessible to the research team. Interviewees received approximately US $34 honorarium for taking part in the interviews.

Study Design

This study was designed as a formative qualitative investigation to surface early insights from clinicians engaging with PGHD-inclusive digital tools. It was not intended to quantify impact or compare outcomes but rather to inform future system design and identify areas warranting further evaluation through quantitative or mixed methods research.

We chose to interview 2 essential and complementary clinical roles in the TKA or THA domain: orthopedic surgeons who are central to the procedure [22] and physiotherapists whose work has been shown to improve postsurgical recovery [23]. These 2 clinical roles are directly involved in interpreting and responding to PGHD within the mymobility platform (Zimmer Biomet). Surgeons reviewed data to monitor recovery progress and inform follow-up care, while physiotherapists engaged with exercise adherence and symptom reports to adjust rehabilitation plans. Their combined perspectives were essential for understanding how PGHD are integrated into orthopedic workflows. Participants were selected using purposive sampling to capture a range of clinical and implementation perspectives from early adopters of the platform. Recruitment occurred during the COVID-19 pandemic, which introduced additional constraints such as staff unavailability, clinical backlogs, and limited access to nonurgent personnel. These conditions restricted the expansion of the sample. Our team was composed of human-computer interaction professionals (an interdisciplinary field that studies how people interact with digital technologies, with the goal of designing systems that are usable, effective, and aligned with users' needs) and clinicians, a pairing recommended by Cheng et al [24]. Our team also included a change management specialist with experience in digital system implementation. This team member supported interview design and interpretation by contributing expertise on organizational readiness, clinician engagement, and adoption patterns as well as conducting interviews. This team member's perspective helped to frame questions around perceived barriers and enablers in relation to system-wide change processes. Our research was also guided by a sociotechnical systems design (STSD) approach, which seeks to balance human, social, organizational, and technical requirements. This perspective recognizes that digital systems—particularly those introduced into complex clinical environments—often fail when they overlook the interdependent and often hidden dynamics of the social and organizational contexts in which they are deployed [25]. The STSD perspective was used as an interpretive lens for understanding clinician experiences and guiding the interpretation of clinician reflections in relation to their work systems, roles, and digital interactions. It was not applied as a formal evaluative framework, and no inferential claims are made. Given the qualitative nature and small sample size of this study, STSD served to sensitize analysis to the dynamic interplay between human, technical, and organizational factors in digital orthopedic care. Our research group has been collaborating with clinicians within this group since 2016 on the use of tracking devices to assess compliance [26] as well as research and design of tangible devices for patient pain logging [15,27,28]. In addition, members of this unit are participating in early testing of "mymobility," an industry-produced orthopedic care software platform that integrates diverse PGHD from Apple Watch and iPhone into clinical dashboards. These interviews were conducted from June to July 2022, a period when, due to the pandemic, many typically in-person services had been replaced with app-based communication, which by necessity gave clinicians additional exposure to using health-relevant data collected by patients. Drawing on our ongoing relationship with the orthopedic center at Milton Keynes University Hospital, we used snowball sampling to recruit 4 orthopedic surgeons (1 female and 3 male) and 5 physiotherapists (4 female and 1 male; Table 1). All had previous experience with TKA or THA procedures, with experience ranging from 1.5 to 25 years. Clinicians had varying levels of exposure working with PGHD at Milton Keynes University Hospital. While we did not track or analyze the number of patients whose PGHD were reviewed by each participant, all interviewees were directly involved in the early use of the digital platform in clinical care. Participants routinely engaged with patients contributing PGHD as part of their roles, with varying degrees of exposure depending on their clinical responsibilities. The goal of this study was to explore clinicians' perspectives on PGHD integration, not to quantify its use across

XSL•FO
RenderX



patient populations. In the reporting on interviews, S1-4 will be used for surgeons and P1-5 for physiotherapists.

Table . Demographics of participants.

Participant	Age (years)	Sex	Ethnicity	Role	Experience (years)
Surgeon 1	56	Male	Asian	Associated specialist	25
Surgeon 2	46	Male	Asian	Consultant orthopedic surgeon	25
Surgeon 3	45	Male	Asian	Trauma and orthopedic consultant, hip and knee	25
Surgeon 4	53	Female	White	Consultant orthopedic and trauma surgeon	15
Physiotherapist 1	25	Female	White	Rotational physiotherapist	1.5
Physiotherapist 2	56	Female	White	Senior team lead physio in trauma and orthopedics	32
Physiotherapist 3	46	Female	White	Physiotherapist on trauma and orthopedics	12
Physiotherapist 4	29	Male	White	Musculoskeletal and orthopedic outreach physiotherapist	4
Physiotherapist 5	32	Female	White	Specialist musculoskeletal physiotherapist	3

Questions were based on our literature review and previous experience researching the requirements and design of digital systems. The interview questions were piloted and iterated with an advising senior orthopedic surgeon and a physiotherapist. The questions for the semistructured interviews were structured within four sections: (1) current work practices, (2) use of digital tools, (3) experiences with PGHD, and (4) experiences with the mymobility software platform. For the last set of questions, participants were provided with anonymized screenshots of PGHD from the mymobility app for their reference (Figures 1 and 2).

mymobility Software

mymobility [29] is a digital care management platform tailored for orthopedic patients, supporting a variety of procedures through care plans for knee, hip, shoulder, and spine surgeries. This platform seeks to facilitate communication and data sharing between patients and health care providers throughout the surgical process. Key features include:

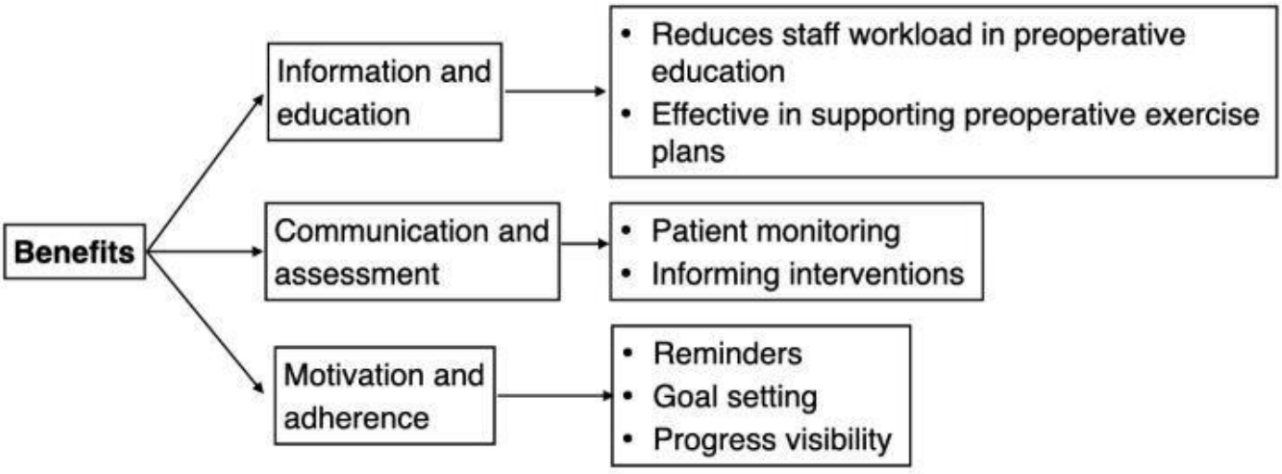
- Patient engagement and compliance: The app seeks to foster patients' engagement in their surgical journey by providing educational materials, procedural information, and personalized exercise plans.
- Data monitoring and insights: Through automated remote monitoring with Apple Watch and iPhone and patient-reported outcomes, the app tracks patient progress, allowing patients' and clinicians' dashboards to view collected data.
- Care team management: Through a unified platform for digital care management and telemedicine, the app seeks to support communication and coordination among patients and care team members.

Data Analysis

The anonymized transcribed interviews were analyzed using reflexive thematic analysis (RTA), a qualitative approach that emphasizes the researcher's active role in constructing meaning and identifying patterns across data [30,31]. RTA was selected for its suitability in capturing subjective clinician perspectives without imposing a fixed coding frame, aligning with our study's exploratory and practice-based context. We adopted a realist stance—seeking to report participants' experiences and meanings—while using an inductive, data-driven approach without applying a pre-existing theory or model. The analysis followed Braun and Clarke's [30,31] 6-phase process: familiarization, coding, theme development, theme review, and final definition and naming.

Although the sample was limited (n=9), this reflects the formative nature of the study and recruitment constraints within a single National Health Service site during ongoing pandemic restrictions. While no formal assessment of data saturation was conducted, thematic redundancy across participants suggested that core experiential patterns were robustly captured. Consistent with Braun and Clarke's [30,31] critique of saturation as a criterion borrowed from grounded theory, we recognized that RTA does not seek conceptual closure but rather embraces interpretative plurality and the coconstruction of meaning between researchers and data.

Analysis was conducted with NVivo software (version 12; QSR International Pty Ltd). The interviews were audio-recorded and transcribed. The answers were then collected in subcategories using open coding. Finally, similar open codes were grouped together and discussed in frequent subsidiary meetings with team members. While not all software functions within the mymobility platform are exclusively PGHD-related (education and messaging), and as the software integrates PGHD as a core functionality that can influence these interactions, and as our approach was not sufficiently fine-grained to distinguish between the impact and interactions of each of the features, we report on clinician reflections on these aspects as well.



Results

Benefits

Overview

The mymobility app demonstrated benefits in patient information and education, communication and assessment, and patient motivation and adherence (Figure 3). Participants noted that the app reduced staff workload by providing preoperative information and exercise plans, ensuring that patients were well-prepared for surgery. Remote monitoring capabilities offered insights into patient activities and adherence, aiding clinical decisions and interventions. Additionally, features like reminders and goal setting improved patient adherence to clinical protocols.

Figure 3. Benefits.

Information or Education

Participants viewed the app as a valuable tool for reducing staff workload related to preoperative education. Several noted that it helped patients access key information and prepare for surgery independently. One physiotherapist explained that patients "get all the information ... we normally spend a lot of time going through with them," giving them "an idea of what they're getting

XSL•FO
RenderX

themselves into" (Physiotherapist 3). Another remarked that patients find the preoperative education "very beneficial" (Physiotherapist 5). The app also supported home-based exercise routines, with participants noting that the protocol-based rehabilitation content was "absolutely fine prior to the operation" (Physiotherapist 4) and that it allowed patients to better "understand the exercises" (Surgeon 1).

Communication and Assessment

Clinicians consistently valued the app's capacity to monitor patients remotely, particularly in terms of activity tracking, exercise adherence, and recovery progression. For example, one physiotherapist highlighted how access to pre-operative step counts offered a useful baseline for recovery expectations: "How active they are pre-op will influence their speed of recovery after op" (Physiotherapist 1). Another clinician appreciated the insight into adherence and difficulty with exercises, noting that the app enabled them to "see what exercises they're doing ... and how well they're adhering to it" (Physiotherapist 4).

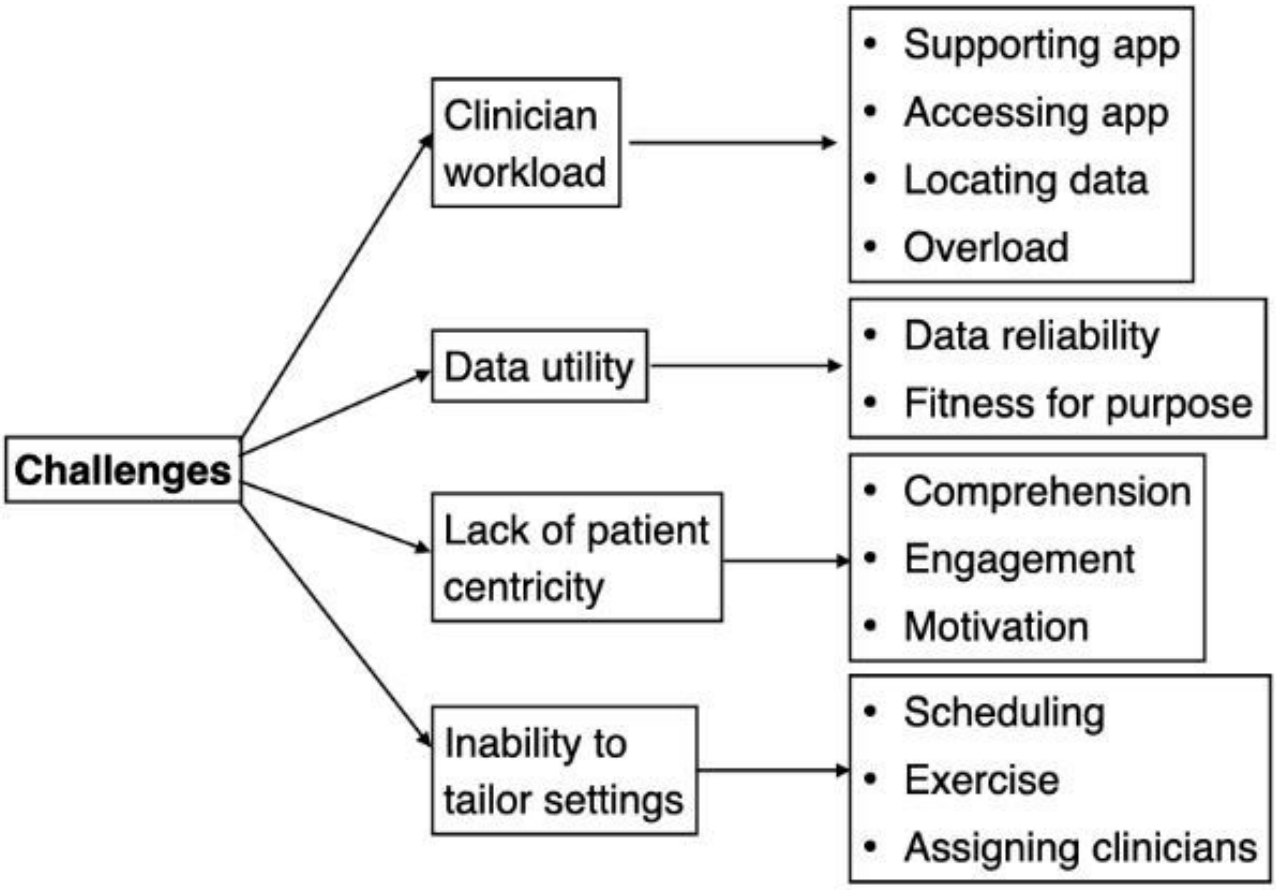
Several participants described the platform as offering an unusually comprehensive overview. One surgeon described it as "brilliant ... it's even doing your gait analysis ... the data we're capturing, it's unbelievable" (Surgeon 3). These data were also used to assess postoperative recovery patterns, helping clinicians gauge improvements or asymmetries over time: "It's quite beneficial to give us a bit more of a guide as to how much load they're putting through their operated limb" (Physiotherapist 5).

Beyond passive monitoring, participants emphasized the potential for the system to inform real-time interventions. One surgeon noted that the data made it easier to detect when patients were deviating from expected progress and intervene earlier if needed (Surgeon 1), while a physiotherapist described how being able to see prior prescribed exercises allowed for better continuity of care and responsive treatment adjustments (Physiotherapist 3). Another surgeon discussed how longitudinal data helped prioritize surgical scheduling for patients with deteriorating function: "We go through the app ... and we are able to assess that they need to be prioritized" (Surgeon 1).

Patient Motivation or Adherence

Participants valued the app's features that supported patient motivation and adherence to rehabilitation protocols. Automated reminders were seen as particularly useful, helping patients follow exercises more consistently: "They seem to adhere a lot better to it when the phone pings at them and tells them to do it" (Physiotherapist 4). Similarly, goal-setting features were appreciated for creating clear expectations and providing structure: "Setting the goals ... is a very good, nice incentive for the patient" (Surgeon 1).

Clinicians also highlighted how progress tracking helped patients maintain perspective during recovery. One physiotherapist noted that visualizing change over time enabled more constructive conversations: "It's really nice to be able to say, 'But look how you were here' ... you actually forget quite how bad you were at the start" (Physiotherapist 3).



Challenges or Weaknesses

Overview

Despite the benefits noted in the previous section, there were also many noted shortcomings, which draw attention to the ongoing challenges in designing and implementing PGHD-inclusive software. In the following sections, we discuss ways in which the software was reported to often increase clinician workload, data utility was often questionable, was ill-suited for patient needs, and the software lacked the flexibility to be tailored to clinical workflows (Figure 4).

XSL•FO
RenderX

Figure 4. Reported challenges.

Clinician Workload or Time

Clinicians reported that the app introduced additional workload and usability challenges. For example, managing patient queries about technical issues, such as step-count tracking, was time-consuming (Physiotherapist 4). Accessing the platform also required logging into multiple systems, which several participants described as cumbersome or unrealistic within the constraints of outpatient care: “It’s too difficult to log on to lots of different things” (Physiotherapist 5).

Beyond accessibility, participants expressed frustration with the fragmentation and volume of data, which often lacked clinical clarity. One surgeon noted, “Too much information and not quite sure what the information it is giving me is ... I don’t even know what double support percentage means” (Surgeon 2). Others echoed this sentiment, describing the system as cognitively overwhelming and poorly integrated into existing workflows. As one clinician put it, “It’s a lot of data” (Physiotherapist 1).

Utility

Beyond issues of access and cognitive load, clinicians expressed doubt about the reliability and clinical utility of patient-generated data. Some were concerned that behavioral data (eg, step counts) lacked the necessary context. As one physiotherapist explained, “If someone’s doing 3000 steps but limping badly and in significant pain, that’s not particularly useful for us” (Physiotherapist 4). Others questioned the accuracy of passive data collection, noting that reduced activity might reflect patients not carrying their phones, rather than a true change in function.

Several participants also highlighted the insufficiency of quantitative metrics alone, emphasizing the continued need for direct clinical assessment: “You have to look at the patient, you can’t just look at the data” (Physiotherapist 2). For many, the data offered limited actionable value, and some felt it had minimal influence on therapeutic decision-making. As one participant concluded, “It doesn’t change our practice in any way, and it almost makes it longer” (Physiotherapist 4).

Lack of Patient Centricity

Clinicians emphasized that the app’s design did not fully account for the cognitive, motivational, and contextual limitations faced by many patients. Some described difficulties with patients who struggled to understand what was being asked of them, especially those with cognitive impairments or who were frail and living in care settings. As one clinician put it, “A lot of the patients we see here are also quite frail, quite elderly ... I think it may just be one too many things for them to manage” (Surgeon 4). Another noted that misunderstandings about the purpose or expectations of PGHD were common: “One of the biggest challenges is everyone’s understanding of exactly what’s being asked of them and how they measure that accurately” (Physiotherapist 5).

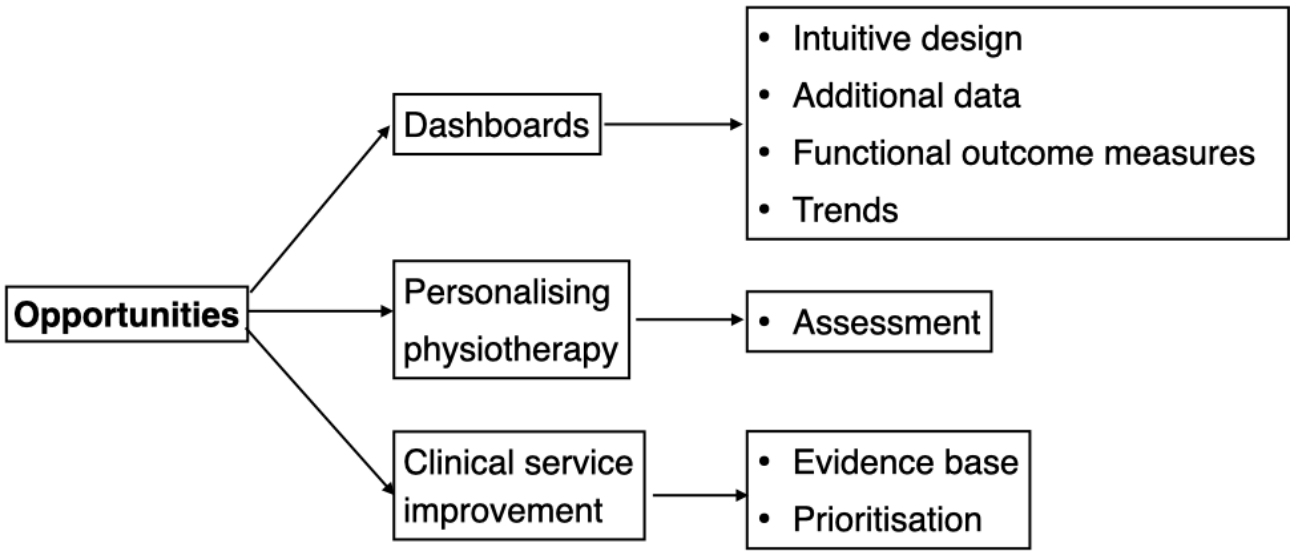
In addition to these accessibility issues, clinicians also reflected on the unintended psychological effects of goal-based metrics and countdowns. While some patients found feedback motivating, others reacted negatively to perceived regressions

XSL•FO
RenderX

or delays. “If they see they’re slipping back,” one physiotherapist explained, “then it’s that defeat ... ‘What’s the point?’” (Physiotherapist 3).

Inability to Tailor to Patient Journey

Clinicians expressed frustration with the app’s limited flexibility to accommodate real-world variations in patient pathways and care team structures. One key issue was the fixed countdown timer, which could become inaccurate after surgery and block access to relevant content: “Her app is now telling her it’s 52 days to her surgery ... but she’s just had it” (Physiotherapist 3). This lack of adaptability also extended to exercise programming. Physiotherapists reported that postoperative exercise options were too generic to meet the diverse needs of patients and could not be tailored to individual recovery trajectories. As one noted, “There’s only two programs ... some exercises are too easy for certain patients, some are too difficult ... there’s no way of changing them” (Physiotherapist 5). In some cases, clinicians advised patients to ignore or delete the app in favor of more appropriate alternatives.



In addition to content rigidity, participants also pointed to deficiencies in role-based functionality. They reported being unable to assign specific clinicians to patients, which led to communication breakdowns and unclear responsibilities. “There’s no way of us assigning ourselves to that patient on the app,” one physiotherapist explained, “so they may still get pinged with exercises we’re not using” (Physiotherapist 5). Surgeons likewise described limited visibility into patient activity between referral and surgery, undermining continuity of care (Surgeon 4).

Opportunities for Improvement

Overview

As well as the benefits and shortcomings noted in the previous section, our analysis suggests several opportunities for enhancing future systems in dashboard design, personalization of physiotherapy, and clinical service improvement. Participants suggested making dashboards more intuitive and informative, with real-time notifications and interest in adding additional data such as heart rate and pain levels. They also emphasized the need for trend identification in patient data to better track progress over time. Personalizing physiotherapy was highlighted as crucial, with tailored exercises based on individual weaknesses and goals, especially after the operation. Finally, the potential of PGHD to improve clinical care and surgical prioritization was recognized, suggesting that more detailed and personalized patient data might enhance treatment outcomes and resource management (Figure 5).

Figure 5. Opportunities.

Dashboard Design

Clinicians proposed several enhancements to dashboard design and data presentation. Many expressed a desire for a more intuitive overview of patients with real-time updates and alerts for significant changes. One surgeon asked, “Why can’t I have [notifications] for my patients?” and described wanting a sidebar dashboard to monitor patient status more easily (Surgeon 2). Participants also suggested visual elements like color coding to draw attention to significant changes in patient mobility (Surgeon 3).

Requests for additional data included heart rate and pain levels, especially during the early recovery phase. “Pain is usually the really big indicator ... in that first six-week period,” noted one physiotherapist (Physiotherapist 4). Others emphasized the importance of context—knowing not just pain scores, but how they relate to exercises, walking aid use, and movement patterns (Physiotherapist 5).

There was strong support for capturing functional outcome measures that reflect daily living. Participants emphasized activities like dressing, standing from a chair, driving, or using public transport as better indicators of recovery than static scores. As one clinician put it, “It’s all about their ability to get on with daily life” (Physiotherapist 3).

Finally, clinicians stressed the value of visualizing patient trends over time. One surgeon explained that even if absolute scores remain low, improvements in mobility or independence may still represent substantial recovery: “Trend is more important than absolute” (Surgeon 4). Another participant noted that

XSL•FO
RenderX

having longitudinal data could significantly improve follow-up consultations after long gaps (Physiotherapist 3).

Personalizing Physiotherapy

Clinicians highlighted the need to personalize physiotherapy plans based on individual patient characteristics, especially postoperatively. “I give different exercises to most of my patients depending on where their weakness is, where their limitation in movement is, and what their goals are,” explained one physiotherapist (Physiotherapist 5). Others emphasized that while protocol-based rehabilitation may suffice preoperatively, postoperative recovery is highly variable. “After the operation, so much depends on what changes ... everyone’s different,” noted Physiotherapist 4.

Clinical Service Improvement

Participants saw potential for PGHD to improve clinical services by informing population-level trends, surgical practices, and prioritization processes. One surgeon noted that, with sufficient data, PGHD could help identify common rehabilitation challenges or communication barriers and enable more targeted support: “We can look into what works for most of the patients ... and target those patients specifically” (Surgeon 1). Others reflected on how such data could prompt critical self-assessment of surgical decisions—for example, identifying stiffness patterns that might relate to prosthetic fit (Surgeon 4).

PGHD were also seen as a tool for refining surgical prioritization. “If their mobility is decreasing rapidly, that’s very important ... so we can try to get them in and have their operation quicker” (Surgeon 1). The dynamic use of deterioration data to rerank patients on waiting lists was described as a promising but underused opportunity.

Discussion

Principal Findings

In this section, we discuss the benefits, challenges, and opportunities raised through our analysis. First, we examine the software’s potential to streamline patient education, improve communication, and enhance motivation. We then explore the hurdles of increased clinician workload, clinician concerns about the reliability or credibility of patient-submitted data, and patient engagement variability. We finally discuss emergent tensions and propose further research to help resolve ongoing challenges.

Benefits

The interviews suggested that the mymobility software with PGHD integration could offer meaningful benefits in the orthopedic care setting. Structured education plans and essential information were appreciated for reducing staff workload and helping patients to prepare for operations. The communication and data sharing functions were useful for monitoring patients and, in some cases, helping to inform interventions. The use of reminders, goal setting, and the ability for patients to view progress over time were noted as showing promise for motivating patients to follow pre- and postoperative care plans. Perhaps most promising for asserting the value of PGHD integration was Surgeon 1 noting that there were specific cases where the shared data had provided evidence for prioritizing care. However, it is important to note that app-based education and preoperative physiotherapy support, some of the more successful noted aspects of the app, do not necessarily require PGHD integration. It remains for further research to determine if PGHD could help with further personalization, for example, with support for comorbidities [32], and if in these cases, benefits would outweigh operational challenges. Physiotherapist 4 noted that the great variance in postoperative outcomes requires in-depth knowledge of the patient’s abilities and progress, which could potentially be supported by greater PGHD integration, though the interviewees expressed concerns that this was more reliably and with less effort accomplished through in-person contact (Physiotherapist 4 and Physiotherapist 2). It is noteworthy and promising that many of the potential benefits of PGHD cited in the literature review were to at least some degree reflected in these interviews and in some cases delivered by the software. As per Cohen et al [4], PGHD did help to provide insights; as per West et al [5], it did help to facilitate care personalization; and as per Caldeira et al [9], the collected data showed promise in motivating and engaging patients. While these benefits might not be universally reported by all clinicians, the responses suggest that this software is making strides in delivering the promised benefits of PGHD integration, and this study provides some empirical evidence that it is viable to integrate PGHD within orthopedic clinical practice.

Challenges

Despite the noted benefits, clinicians reported many barriers to integrating PGHD within clinical care, often echoing the known barriers cited in our review. Particularly problematic were the many ways the app could increase clinician workload, from requiring time to support patients in using the app (Physiotherapist 4), interacting with the platform (Surgeon 2), and locating and making use of data (Physiotherapist 5). Potential benefits of the platform were also complicated by the clinicians’ continued reluctance to trust the validity of PGHD (Physiotherapist 4) and challenges in applying data to decision-making (Physiotherapist 2). Furthermore, clinicians expressed concerns that the need for patients to participate with this approach was unsuitable for many of their patients, echoing the study by Jim et al [6], which noted that the use of PGHD in treatment could increase care disparities. The interviews also highlighted the challenges in tailoring software to reflect individual needs, such as the selection of postoperative exercises or the assigning of clinicians. While the noted interface design shortcomings are likely correctable, the inability to overcome the larger barriers cited within the review is concerning, given the resources likely invested in this software’s design and development. In addition, defining the requirements for the many configurations needed to adequately address personalization of the patient journey likely remains a stubborn problem [33]. This is especially vital, as clinicians noted how this inability to properly reflect the individual patient journey can easily lead to software rejection. Similarly, this leads to another broader question as to how many features should be included within PGHD systems, given how a single deficiency area such as improper notifications can lead to product abandonment.

XSL•FO
RenderX

Opportunities

Clinicians suggested many realizable and relatively standard suggestions for improving product usability, such as making interface terms easier to understand, expanded use of color coding, and indications of how patient progress deviates from norms or expectations. There were also calls for increasing convenience through new features such as notifications of important events and streamlining sign-ins, as well as potentially integrating additional data sources like heart rate, range of movement, pain levels, gait patterns, and increased integration of functional outcome measures to support a more holistic understanding of patients' needs. Such suggestions appear relatively straightforward and reflect established design practices and features within other products. However, other suggestions, such as automated exercise adaptation to individual patient need, might pose greater challenges, given that the clinicians emphasized the importance of human interaction in making these adjustments. While the use of PGHD for clinical service improvement appears especially promising, it might require standardization and trust in PGHD, which might still be culturally lacking at this time.

Design Tensions for Further Research

The software demonstrated capacity to deliver value to clinical care, and many of the noted design deficiencies and suggested improvements are likely amenable to improvement through established iterative human-centered or co-design techniques. Other deficiencies relate to broader societal concerns, which are outside of the ability of software systems to address. In this section, we identify key areas for further research that consist of trade-offs or tensions that might imply conflicting requirements, which cannot be "solved" but rather require design decisions that recognize that trade-offs are inherent. While not necessarily novel, their persistence in this software after significant industry investment suggests that software design alone is insufficient to drive PGHD into the mainstream.

Leveraging Bigger Data Versus Burdening Clinicians

Participants were impressed with the range of available data presented within the mymobility app and even suggested adding additional data. However, they also noted that expansive data could be overwhelming, could increase workload, and that they were often unsure of how to apply such data to their practice. Research question: How can PGHD dashboards be designed to decrease clinician workload? How can the system deliver the right data at the right time to the right clinical role?

Standardization Versus Personalization in Clinical Practice

While standardized protocols and data collection methods are necessary for consistency and reliability, clinicians emphasized the importance of personalized care, particularly in postoperative physiotherapy, where individual patient needs vary significantly. Research question: How can PGHD systems balance the need for standardized data collection and protocols with the flexibility required to personalize patient care effectively?

Comprehensive Versus Targeted Software

Study participants related challenges resulting from accessing information and functionalities from multiple systems, which could support the need for a single comprehensive approach. Yet, participants also noted how one inappropriate feature could lead to system rejection. Research question: What is the appropriate balance in the number of features to include within PGHD-inclusive orthopedic software? How should this be determined?

Adaptive Versus Static Design Approaches

It is recognized that health care is complex with outcomes emerging from multiple interacting systems needing frequent adaption to shifting contexts [34]. This creates a tension between the validation needed to gain regulatory approval for clinical software systems and the dynamic requirements within clinical contexts. Research question: How can clinical software systems be designed that can be validated yet are sufficiently adaptable to variable workflows, preferences, and evolving needs?

Limitations

This study has several limitations. The sample size was limited due to real-world constraints during the COVID-19 pandemic, including staffing shortages and scheduling disruptions. Although we sought diverse perspectives, these logistical challenges prevented broader recruitment and may have introduced selection bias. Additionally, recruitment was limited to a single orthopedic center, which may constrain the transferability of findings. This was due to institutional access constraints and pandemic-related limitations. Future research should explore multicenter participation to capture a broader range of experiences with PGHD integration. Recruitment methods using snowball sampling and existing professional relationships may also introduce selection bias, and the reliance on self-reported data could affect accuracy due to recall bias or socially desirable responses. Additionally, the varying levels of technological familiarity among clinicians and the unique circumstances of the COVID-19 pandemic, which increased reliance on digital tools, may have influenced the results. Future research should address these limitations by including a larger, more diverse sample across multiple health care settings and ideally using random sampling methods to better capture the evolving nature of PGHD integration in clinical practice. Furthermore, as the study was limited to clinicians working with patients who have had TKA or THA operations, the findings may not be transferable to other orthopedic contexts such as trauma, spine, or sports medicine. Future research should investigate the applicability and value of PGHD integration across a wider range of orthopedic conditions.

Conclusions

This study sought to close gaps in knowledge about the real-world application of PGHD integrative software within orthopedic practice. To this end, surgeons and physiotherapists were interviewed to learn more about their experiences and suggestions for improvement. The findings suggest that the mymobility software delivered some meaningful benefits. Structured education plans and the providing of essential information were praised for reducing staff workload and

XSL•FO
RenderX

helping patients prepare for operations. The communication and data-sharing functions showed promise for monitoring patients and informing interventions. Additionally, reminders, goal setting, and progress-tracking features showed the capacity to motivate patients to adhere to pre- and postoperative care plans. Notably, the integration of PGHD helped prioritize care in specific cases, indicating its potential in enhancing clinical decision-making. While some benefits, such as app-based education and preoperative physiotherapy support, do not necessarily require PGHD integration, the software still aligns with literature-reviewed benefits, providing insights, facilitating personalized care, and motivating patients. While there remained a clear need for further interface and interaction design, the software appears to be making strides in delivering on the promised benefits of PGHD within a clinical context.

However, many of the known barriers to PGHD integration remain unresolved. Clinicians reported challenges such as the app increasing their workload by requiring time to support patients in using the app, interacting with the platform, and locating and making use of data. Potential benefits were further hampered by clinicians' reluctance to trust the validity of PGHD and challenges in applying data to decision-making. Additionally, the patient participation required for a PGHD approach posed significant challenges, especially for those who are older or have cognitive impairments. Although the mymobility platform has already been scaled commercially, this study shows that availability does not guarantee seamless clinical integration. Participants described persistent barriers—such as limited time to engage with PGHD, doubts about its clinical relevance, and challenges supporting diverse patient populations—that complicated effective use in practice. These findings suggest that even at scale, PGHD platforms require ongoing refinement of interface design, clinician workflows, and support strategies to ensure meaningful and sustainable adoption.

While many of the perceived benefits and barriers align with prior findings from similar digital health interventions, this study adds value by contextualizing those dynamics within the day-to-day realities of orthopedic care. The role-specific insights from surgeons and physiotherapists offer a practical understanding of how PGHD are actually interpreted, adapted, and applied within clinical workflows.

Future research should explore how to address trade-offs or tensions that may not be fully "solvable" but instead require thoughtful design decisions. Research and development efforts should aim to navigate these complexities in ways that improve usability, utility, and adoption. Further studies should also build on these findings by using quantitative or mixed methods approaches to evaluate the measurable impact of PGHD on clinical workflows, patient engagement, and health outcomes.

Abstract

Background: Readmission avoidance initiatives have been a priority for the Centers for Medicare & Medicaid Services for over a decade; however, interventions are often high-intensity, costly, and resource-intensive, and therefore, rarely scalable or sustainable. Large national payers are in a unique position to leverage data to identify members in real-time who are at high risk of readmission to prioritize the scaled delivery of tailored behavior change techniques to provide an educational intervention to modify health behaviors.

Objective: This study aims to examine the impact of an informatics-driven, multichannel educational messaging campaign implemented to decrease 30- and 90-day acute inpatient readmissions and emergency department (ED) visits among Medicare Advantage members of a large national payer.

Methods: A quality improvement initiative was designed and implemented to provide an evidence-based outreach campaign using human-centered design and behavior change principles to deliver multiple intervention functions, including timely, contextual, and relevant delivery of education, enablement, and persuasion, to reinforce health-promoting behaviors related to planned or unplanned inpatient admissions. Outcomes, including 30- and 90-day acute inpatient readmissions and ED visits, were retrospectively evaluated from Medicare Advantage members enrolled in a large national health plan residing across the United States between May 2020 and July 2022. Leveraging utilization management data, rules-based logic identified members (N=368,393) with a planned acute inpatient procedure (ie, preadmission) or discharged from an acute hospital stay (ie, postdischarge) within 15 days. Members were sequentially assigned to a standard (N=141,223) or an enhanced (N=227,470) messaging group, whereby the standard group received usual outreach and the enhanced group received an educational intervention via a messaging campaign deployed through multiple low-intensity communication channels (eg, text message, email, direct mail) in addition to standard outreach.

Results: Members who received enhanced outreach had fewer relative 30-day acute inpatient readmissions (−4.1%, 95% CI −5.5% to −2.7%; *P*<.001) and ED visits (−3.4%, 95% CI −5.0% to −1.7%; *P*<.001) compared with members receiving standard outreach. Similarly, these findings persisted for relative 90-day outcomes such that members receiving enhanced outreach experienced fewer acute inpatient readmissions (−5.4%, 95% CI −6.5% to −4.3%; *P*<.001) and ED visits (−3.8%, 95% CI −5.0% to −2.5%; *P*<.001) compared with members receiving standard outreach messaging.

Conclusions: Behavior change techniques deployed via educational interventions as low-intensity multi-channel outreach is an effective strategy to reduce avoidable 30- and 90-day inpatient readmissions and ED visits in recently discharged Medicare Advantage members (primarily >65 years).

Introduction

Acute inpatient readmissions pose a significant challenge to the US health care system, affecting patient outcomes, health care costs, and overall quality of care. Despite increasing health system focus on readmission avoidance initiatives, hospital readmissions remain a major burden for health care organizations, payers, and patients. On average, there are ≈3.8 million readmissions per year, contributing to US $452.4 billion in US health care costs, of which Medicare members account for ≈60% [1]. As such, the Centers for Medicare & Medicaid Services introduced the Hospital Readmission Reduction Program (HRRP) in 2012 with the primary goal of addressing excessive hospital readmissions and improving the quality of health care delivery [2]. Key activities of the HRRP include identifying high-risk patients, comprehensive discharge planning, patient education, medication reconciliation, timely follow-up appointments, care coordination with primary care providers, and proactive outreach to patients postdischarge to monitor their health status and address any concerns. Under the HRRP, the Centers for Medicare & Medicaid Services imposes financial penalties on hospitals with higher-than-expected 30-day readmission rates for certain conditions, including, but not limited, to acute myocardial infarction, heart failure, and pneumonia [2].

Now, 10+ years since its inception, there has been a dearth of literature focused on reducing hospital readmissions. Of the existing studies, a majority focus on high-intensity interventions that are costly and resource-intensive, such as home visits and clinician-led telephonic outreach to deliver high-touch member education, discharge planning, care coordination, and transitions of care [3-6]. While such interventions have shown great promise, they are generally not universally sustainable for large-scale implementation. In addition, many readmission avoidance programs primarily focus on specific high-risk groups, leaving a significant portion of the patient population underserved. Thus, there is an unmet need to identify practical and cost-effective strategies that can be operationalized and delivered at scale.

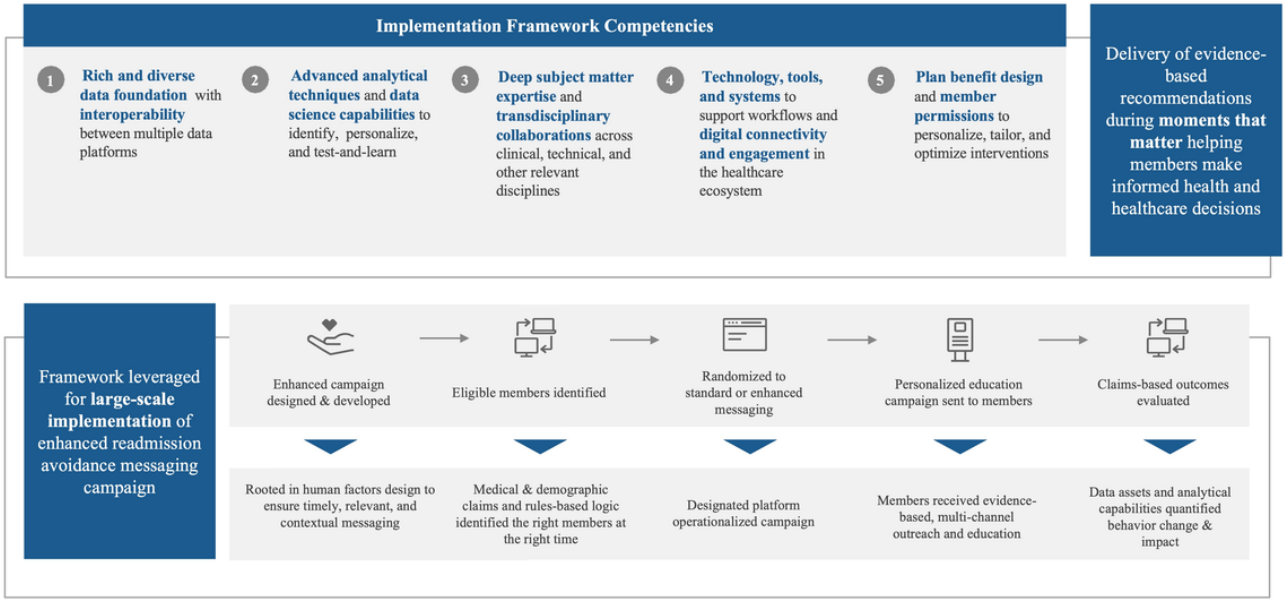
Large national payers hold a unique position in the health care landscape owing to continuous data ingestion of claims and clinical informatics data. Leveraging this rich and diverse data foundation, payers are well-poised to identify members in real-time who are at high risk of readmission to prioritize the frequency and intensity of behavior change techniques and interventions. Combined with clinical expertise and other foundational capabilities (ie, multi-channel tools, interoperability, and plan benefit design), these data-informed insights have great potential to enable the delivery of low-cost interventions to modify members' health behaviors associated with a planned inpatient procedure or following discharge from an acute hospital stay. These tailored intervention functions complement and extend existing initiatives across the health care ecosystem, enhance the patient and member care experience, and effectively optimize the use of health care resources on a population level.

As such, the purpose of this study was to explore the impact of a payer-led quality improvement initiative that used behavior change techniques to deliver low-intensity interventions, primarily an education-based campaign with persuasion and enablement, as an innovative approach to address the persistent challenge of hospital readmissions and related health care use outcomes. Specifically, it was hypothesized that Medicare Advantage members receiving enhanced outreach using a multichannel educational campaign would exhibit lower relative 30- and 90-day acute inpatient readmissions and emergency department (ED) visits compared with members receiving standard of care messaging (ie, usual outreach).

Methods

Study Overview

This study represents a retrospective evaluation of a quality improvement intervention. Briefly, a personalized, evidence-based, informatics-enabled campaign framework was designed and implemented with the overall goal to reduce avoidable hospital readmissions in the Medicare Advantage (primarily >65 years) population. Eligible members were sequentially assigned to a standard or enhanced messaging intervention consisting of evidence-based, multichannel lay education. Administrative claims data were deidentified, aggregated, and analyzed to compare relative changes in 30- and 90-day acute inpatient readmissions and ED visits in a group of Medicare Advantage members that received the enhanced messaging campaign compared with those who received the standard messaging campaign.



Overview of the Campaign Framework

A quality improvement initiative was designed and implemented to provide an evidence-based outreach campaign using behavior change techniques to deliver multiple intervention functions, including education, enablement, and persuasion, to modify health behaviors related to planned or unplanned inpatient admissions. An education-based outreach intervention was designed with the intention of supporting Medicare Advantage members in taking their "next best action" to better health through analytics-informed behavioral changes to modify health behavior before and after hospital admission. The campaign framework was operationalized across six key components (Figure 1): (1) a rich and diverse data foundation; (2) interoperability between multiple internal and external data platforms; (3) application of analytical techniques and data science capabilities, (4) a designated platform to serve as the centralized technology to operationalize campaigns; (5) deep subject matter expertise, and (6) connectivity and engagement

XSL•FO
RenderX

in the health care ecosystem to deliver actionable recommendations for members, providers, or both.

Figure 1. A high-level overview of the campaign framework. Key foundational competencies directly enable the identification, delivery, and evaluation of an informatics-based, readmission avoidance educational messaging campaign for Medicare members of a large national payer. Potential members are identified through rule-based logic that is highly dependent on a rich and diverse data foundation. Model sets are derived from a data warehouse that continuously ingests data from numerous internal platforms with interoperability. Advanced analytics identifies and routes eligible members to a dedicated platform to operationalize the delivery of evidence-based, multichannel outreach and education campaigns (standard or enhanced). Data assets and analytical capabilities facilitate the retrospective evaluation of behavior change and downstream impacts on health care use patterns.

Member Identification

The campaign was deployed to Medicare Advantage members enrolled in a large national health plan with an acute inpatient index event and discharged to a home setting between May 2020 and July 2022. One index admission was associated with each member's study eligibility, which occurs once per 180-day window. Members were excluded from study evaluation if they were discharged to a nonhome setting (eg, skilled nursing facilities, long-term care); enrolled in Dual-Eligible Special Needs Plans; had nonimpactable conditions (ie, trauma, pregnancy); or were admitted for maternity-related or behavioral health events.

Standard Versus Enhanced Messaging Group Allocation

Existing technological capabilities were leveraged to operationalize campaigns. Specifically, a marketing technology application (previously developed in-house in 2018) served as the centralized tool to enable identification, risk stratification, randomization, channel delivery, engagement, and reporting. Briefly, the platform architecture integrates multiple internal, third-party, and other external data, systems, and services. Defined modules enable data input, processing, and campaign deployment. Precise member targeting and agile data science and marketing pods drive rapid and iterative test-and-learn experimentation approaches that support high-volume test cells to evaluate the impact of campaign-related interventions.

Leveraging these standardized processes, members were sequentially assigned to standard or enhanced messaging groups following response adaptive-randomization procedures with dynamic adjustment for covariate imbalance [7]. Briefly, the standard intervention consisted of usual outreach messaging (ie, single-channel, single-time point evidence-based educational messaging) to members with conditions that were high-risk for readmission while the enhanced intervention used member- and condition-informed personalization to augment the mode, frequency, timing and content of educational messaging in an expanded population (Table 1).

XSL•FO
RenderX

Table . Comparison of standard versus enhanced messaging intervention components.

Intervention component	Standard intervention	Enhanced intervention
Population	• High-risk or select conditions	• All eligible members with an acute inpatient index event
Data sources	• Medical and administrative claims	• Daily list of acute inpatient stays • Precertification vendor data • Provider information • Plan benefit structure
Personalization logic	• Member-centric content (see messaging content below)	• Machine learning to optimize member's channel preferences • Just-in-time messaging • Tailored content (see messaging content below)
Channel delivery	• Channels informed by member permissions • Variable; often single channel	• Multichannel (eg, email, direct mail, SMS, and IVR[a]) approach • Provider (PCP)[b] fax notifications
Timing		
Preadmission	• None	• Within 15 d prior to admission
Postdischarge	• High-risk or select conditions	• 3 - 5 d after discharge to home
Recovery	• High-risk or select conditions	• 7 - 30 d after previous message
Frequency	• One time	• Multiple touchpoints
Messaging content	• Clinically relevant (ie, condition-specific) • Informed by evidence-based guidelines	• Behavior change technique groupings (eg, goals and planning, shaping knowledge), and intervention functions (eg, education, persuasion, and enablement) • Multi-component communication campaign (knowledge sharing, reminders, tracker tool, reinforcement of provider follow-up, complications awareness, etc) • Rooted in human-centered design • Condition-specific considerations • Reinforcement of additional plan-enabled resources and support (eg, transportation)

[a]IVR: interactive voice response.

[b]PCP: primary care provider.

Standard Intervention Description

The standard group received the usual outreach messaging. In general, usual member-facing communication leverages a combination of demographic information, health history, and behavioral economics to create personalized, evidence-based awareness and education campaigns. Personalized messaging campaigns are deployed through multichannel modes of communication delivery, including: digital (eg, SMS, multimedia message service, email, interactive voice response [IVR], 1:1 personalized websites or mobile applications); traditional (eg, direct mail, telephonic); or in-person (eg, provider-led, retail brick-and-mortar store) channels.

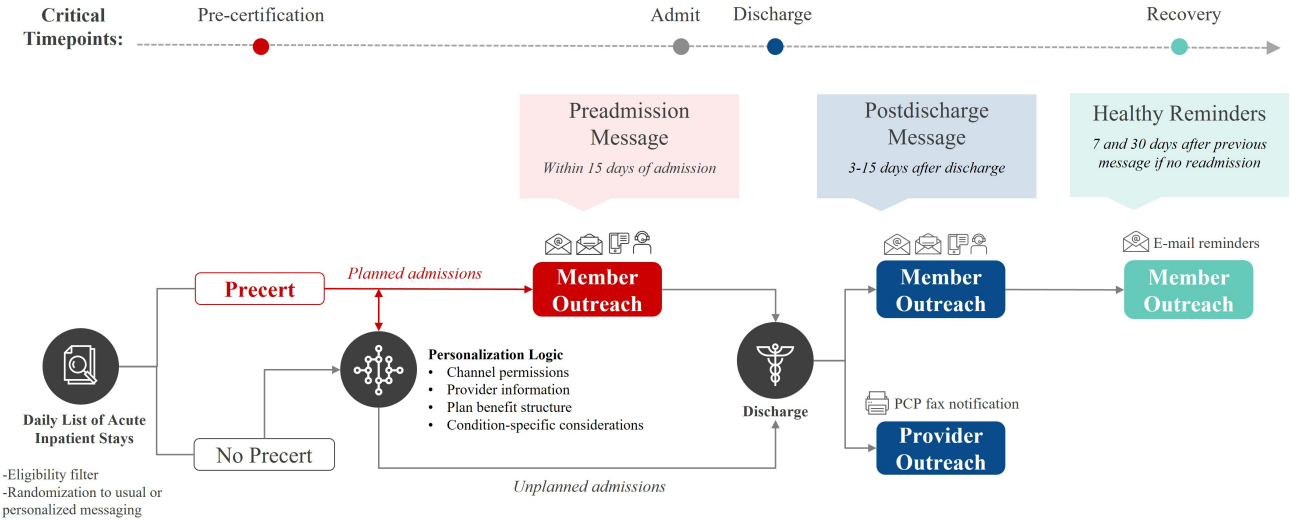
General principles of member-facing campaigns are to (1) serve as a trusted source of evidence-based, credibly sourced health education; (2) provide strategies to overcome barriers to enable decision-making; and (3) deliver personalized, relevant, and timely information that facilitates informed health care decisions. Education-based campaigns are grounded in well-established, evidence-based guidelines and best-practice recommendations for population health (eg, United States Preventive Services Task Force, Centers for Disease Control and Prevention, and American Heart Association). All educational content reinforces or references publicly available health education intended for lay audiences and approved by an internal panel of medical directors with subject matter expertise.

Primary outcomes of member-facing communications vary depending on the use case but are designed to favorably impact clinical outcomes, appropriate health care utilization, medical health care spend, quality metrics, or member satisfaction. For example, many messaging campaigns are designed to favorably augment outcomes related to primary (eg, vaccinations), secondary (eg, screenings), tertiary (eg, disease management),

XSL•FO
RenderX

and quaternary (eg, prevent overmedicalization) care activities. Note that standard outreach communications may differ (ie, frequency, intensity, and type) based on member permissions, plan benefit design, gaps in care, and member risk/need. In the event of potentially redundant outreach initiatives, standard campaigns may be suppressed to facilitate test-and-learn outreach campaigns that are most likely to optimize member outcomes. Specific to this use case, examples of interventions that members may receive include payer-led readmission avoidance program support; postdischarge, telephonic-based, nurse care manager outreach; pharmacist-based medication reconciliation; home health services; remote monitoring; and social support services.

Enhanced Intervention Description



The enhanced group received usual (ie, standard) outreach messaging in addition to personalized readmissions-focused educational outreach using a low-intensity multichannel approach. The enhanced campaign was designed and implemented by a transdisciplinary team composed of experts across data science, clinical, economic, behavioral, marketing, and public health disciplines. Human factors principles were integrated into an agile, rapid-cycle testing framework [8,9] to ensure usability, accessibility, and real-world applicability of readmission reduction interventions for the identified user and context; Medicare members with a recent or planned hospitalization. User requirements for the enhanced intervention were informed by best practices for readmission prevention [2], including recommended transitional care activities (ie, timely postdischarge provider follow-up) and self-monitoring and self-management activities (ie, medication adherence, symptom tracking, and postacute recovery). Human-centered design principles were then applied to enhance local adaptability based on anticipated needs, barriers, and facilitators that were informed by the existing literature [3,9-16] and in-house medical directors with subject matter expertise. These specifications informed the development of the final campaign that was pilot-tested against design requirements prior to large-scale implementation. Continuous feedback loops, including call transcripts, surveys, and evaluations, enabled iterative refinements to messaging, workflows, and intervention delivery, ensuring alignment with user needs and real-world constraints.

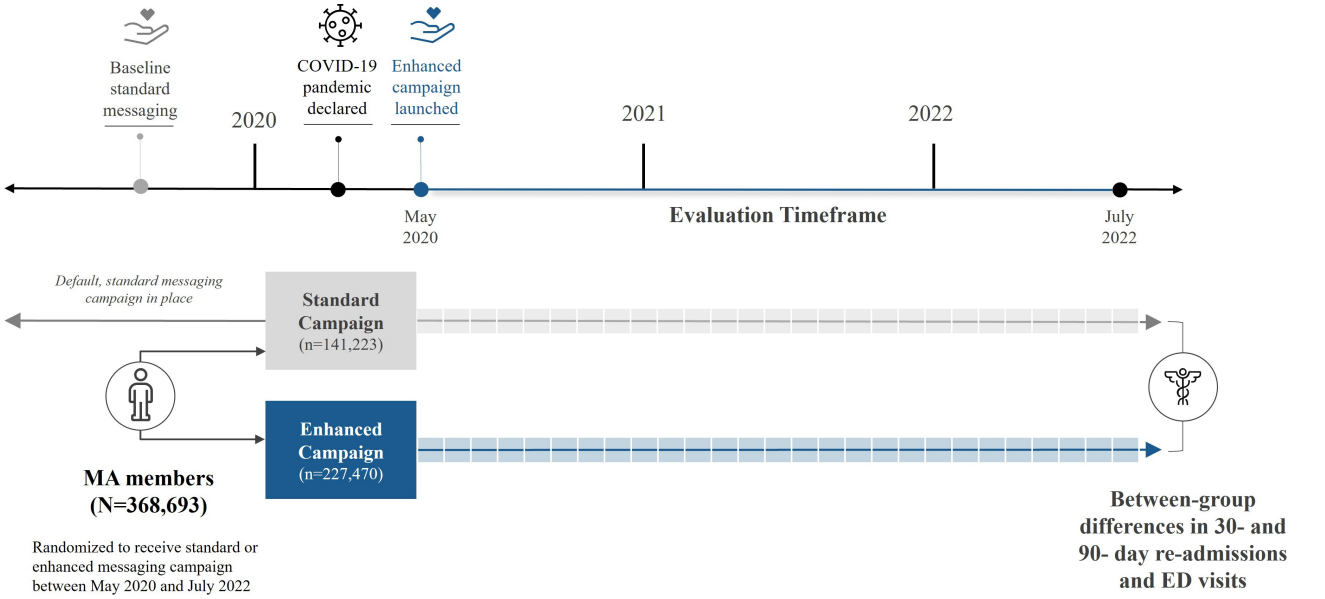
The overall goal of the campaign was to support, empower, and encourage members to engage in clinical actions aligned with guideline-directed care. Personalized, timely outreach at critical touchpoints in a member's journey (ie, preadmission and postdischarge) ensured that messaging was contextually relevant and most likely to translate to goal-concordant behavior change related to planned or unplanned hospital stay. Messaging was grounded in behavioral economics of decision-making, specifically the "foot-in-the-door" technique [17], which facilitates engagement by first encouraging small, manageable tasks (eg, filling out a preadmission checklist or a postdischarge recovery tracker), which often translates to participation with a larger ask, such as avoiding unnecessary health care utilization [17]. Additionally, behavior change technique groupings (eg, goals and planning, shaping knowledge) [18], and intervention functions (eg, education, persuasion, and enablement) [19] were incorporated to reinforce health-promoting behaviors.

The campaign (Figure 2) identified members with a planned acute inpatient procedure (ie, preadmission) using the precertification process or those who were discharged from an acute hospital stay (ie, postdischarge), both within a 15-day event window time span. Just-in-time lay educational messaging was strategically timed to reinforce key recovery actions at critical touchpoints in the member's journey. The outreach strategy used all available communication channels based on member preferences, ensuring inclusivity across digital and nondigital mediums. Preadmission outreach provided timely education on essential preparation steps, including instructions to (1) prepare the home environment, (2) schedule provider follow-up visits and manage prescription fills, and (3) stay on track with recovery plans. Postdischarge outreach supported recovery during the critical 30-day period by delivering tools and information. All members received a recovery tracker calendar with designated fields to record self-reported signs, symptoms, and notes, along with stickers to reinforce daily use. The recovery tracker was designed for portability, enabling members to easily bring to follow-up appointments to facilitate patient-provider communication. Messaging emphasized the importance of provider follow-up, medication adherence, and symptom recognition for complications that would warrant further care. In addition, contact information was provided to facilitate inbound telephonic outreach to assist with potential questions or needs.

XSL•FO
RenderX

Figure 2. Readmissions campaign member flow. Overall campaign logic flow and cadence containing both preadmission (where applicable) and postdischarge messaging and channels. Potential channels for initial member outreach were informed by member permissions and included: e-mail, direct mail, SMS, and interactive voice response (IVR). Provider fax notifications were also sent to all members with a provider on file. PCP: primary care provider.

Examples of enhanced member-facing preadmission and postdischarge messaging can be referenced in Multimedia Appendices 1 and 2, respectively. Human-centered design ensured messaging was accessible and engaging [11]. For example, plain language and large fonts optimized readability and usability, addressing common barriers to comprehension. To accommodate varying levels of digital literacy, all members received direct mail (at minimum), with reinforcement through digital channels (eg, SMS, email, IVR) based on member preferences, ensuring engagement was not limited by access or comfort with technology. Operational efficiencies were implemented to improve the timeliness of direct mail delivery. Creatives were preprinted and mailed daily to ensure arrival within 3 days of identification. Personalization was further enhanced to improve relevance and usefulness using rules-based logic informed by provider relationships, medical and social needs, and plan benefit structure. For example, for members with a provider of record, fax notifications were incorporated to reinforce patient-provider communication and care coordination. Where plan benefits allowed, postdischarge messaging included transportation options and additional support for medical and social needs.



Campaign Evaluation

Data Sources and Study Setting

Retrospective demographic and medical claims data were deidentified, aggregated, and analyzed to determine the impact of the enhanced versus standard educational campaign on primary outcomes for the evaluation timeframe (ie, May 2020 to July 2022). The study design overview is provided in Figure 3. Claims data included ED diagnoses, procedures, sites of care, and provider information. Additional data fields included aggregations of the above information in the forms of medical cases, episode treatment groups, and chronic condition flags. Demographic information collected during health insurance enrollment included self-reported sex, age, plan benefit design, location, and census tract statistics.

XSL•FO
RenderX

Figure 3. Study design overview. The campaign experimentation framework was leveraged to conduct a retrospective analysis of 30- and 90-day outcomes (ie, hospital readmissions and emergency department [ED] visits) between members who received the enhanced messaging campaign compared with a cohort of members who received the standard campaign.

Inclusion and Exclusion Criteria

All participants were enrollees of a Medicare Advantage health plan provided by a large national payer. Inclusion criteria included: (1) receipt of ≥1 standard or enhanced messaging campaign intervention throughout the study evaluation period. Potential participants were excluded if they: (1) did not meet inclusion criteria or (2) were members of a commercial, dual coverage, or indemnity insurance plan.

Ethical Considerations

The Sterling Institutional Review Board reviewed and approved the study (#10132) as an exempt study under 45 CFR 46.104(d)(4). Informed consent was not obtained, as an exemption determination was provided. In addition, a waiver of Health Insurance Portability and Accountability Act authorization for the use and disclosure of aggregated, deidentified member data was obtained. No compensation was provided.

Statistical Analyses

Two-tailed unpaired *t* tests examined between-group differences in baseline characteristics to ensure adaptive randomization techniques effectively achieved balance. Change in acute inpatient readmission rate was calculated as the difference in the average number of readmissions per 100 members (ie, readmission rate) between the standard and enhanced outreach groups. The relative reduction in inpatient readmissions was calculated as the between-group difference in readmission rates divided by the standard outreach group's readmission rate and expressed as a percentage ±95% CI. Change in ED visits was calculated as the difference in the average number of ED visits per 100 members between the standard and enhanced outreach groups. The relative decrease in ED visits was calculated as the between-group difference in ED visits divided by the standard outreach group's ED visit rate and expressed as a percentage ±95% CI.

Secondary analyses explored differences in 30- and 90-day acute inpatient readmissions and ED visits by age brackets (ie,<65 yr, 65 - 69 yr, 70 - 74 yr, 75 - 79 yr, 80 - 84 yr, and >80 yr), geographic region (ie, Midwest, Northeast, Southeast, West), geographic area (ie, urban, suburban, rural), as well as common comorbidities (eg, dementia, diabetes mellitus, low back pain, and obesity).

Covariate balance was confirmed by assessing standardized mean differences for all variables reported. Chi-square tests were used to test the statistical significance of the outreach impact on primary outcomes. Two-tailed unpaired *t* tests were used to explore between-group differences, with statistical significance defined as $P<.05$.

Results

Baseline Characteristics

Table 2 details the baseline characteristics of the standard (N=141,223) and enhanced (N=227,470) outreach groups. On average, the total included study population (N=368,693) was comprised of older adult (mean age:75.3 yr) males (n=181,083 [49.1%]) and females (n=187,610 [50.9%]); a majority of which residing in rural geographies (n=189,594 [51.4%]) with top 3 comorbidities being heart conditions (n=153,353 [41.6%]), diabetes mellitus type 1 or 2 (n=115,432 [31.3%]), and low back pain (n=114,954 [31.2%]). There were no between-group differences in baseline demographic characteristics, risk factors, or comorbidities (all $P>.12$). Of note, mean age was marginally higher in the enhanced (75.4 yr) versus standard (75.3 yr) group ($P<.001$), though this is not considered clinically significant.

Thirty-Day Inpatient Readmissions and ED Visits

Members in the enhanced outreach group experienced a 4.1% (95% CI 2.7% - 5.5%) relative reduction in acute inpatient readmissions compared with the standard outreach group (*P*<.001). In addition, the enhanced outreach group experienced a 3.4% (95% CI 1.7% - 5.0%) relative reduction in unplanned ED visits compared with the standard outreach group (*P*<.001).

Secondary analyses (Table 3) revealed that members between the ages of 70 and 74 years experienced the greatest relative decrease (5.8%) in acute inpatient readmissions, followed by members who were 65 - 69 yr (5.3%), and 75 - 79 yr (4.5%) (all *P*<.05). Members who reside in the Northeast (8.0%) and Midwest (3.4%) experienced a greater relative reduction in acute inpatient readmissions (both *P*<.05) compared with those in the Southeast or West, as did those in suburban (7.6%) compared with members in urban (3.8%) and rural areas (both *P*<.05). Certain comorbidities also demonstrated a relationship with decreased frequency of 30-day readmissions (Table 2), including behavioral health, cancer, diabetes mellitus type 1 or 2, and heart conditions (all *P*<.05).

Ninty-Day Inpatient Readmissions and ED Visits

These trends (ie, 30-day) persisted at 90-days postdischarge such that the enhanced outreach group experienced a 5.4% (95% CI 4.3% - 6.5%) and 3.8% (95% CI 2.5% - 5.0%) relative reduction in acute inpatient readmissions and ED visits, respectively, compared with the standard outreach group (both *P*<.001).

Secondary analyses revealed between-group differences across age, geographic region, geographic area, and comorbidities (Table 3). Similar to the 30-day results, members between the ages of 70 and 74 years experienced the greatest relative

XSL•FO
RenderX

reduction in 90-day acute inpatient readmissions on the order of 8.5% (vs 2.2% - 5.9% for all other age groups). Members with behavioral health, cancer, diabetes mellitus type 1 or 2, heart conditions, low back pain, obesity, Parkinson disease, and renal-related conditions receiving enhanced messaging demonstrated greater reductions in acute inpatient readmissions at 90 days postdischarge (all $P<.05$) compared to members receiving standard messaging (Table 4).

Table . Relative change in 90-day acute inpatient readmissions and emergency department (ED) visits by demographic and clinical characteristics.

Discussion

Principal Findings

This study sought to explore the impact of a payer-led, quality improvement initiative that was designed and implemented to deliver a low-intensity, multichannel educational outreach campaign to modify health behaviors with the goal of decreasing unplanned and avoidable hospital readmissions and ED visits at 30- and 90-days. Consistent with our hypothesis, members receiving the enhanced outreach campaign intervention experienced greater relative reductions in both outcomes compared with the standard outreach group at both 30- and 90-days postdischarge. Put into context, a 4% decrease in 30-day readmissions would translate to approximately US $600,000 in avoidable health care costs for every 1000 members or ≈US $136.5M for the included study sample of 227,470 members (assuming a conservative estimate of US $15,000 per readmission) [1].

The effectiveness of low-intensity, postdischarge follow-up has been examined in previous studies; however, a majority of research has focused on provider-led settings with direct clinician engagement and escalation mechanisms. Bressman et al [20] found that an automated, bi-directional, text-based follow-up intervention from their primary care physician following an index admission translated to 41% lower (adjusted odds ratio) 30-day acute inpatient readmissions or ED visits among 374 patients recently hospitalized (compared with a control, no messaging cohort). Similarly, Patel et al [21] were the first to evaluate the impact of provider-facing secure text messaging on patient outcomes among ≈6400 patients on inpatient services. Patients whose providers were engaged via text messaging to communicate patient information and to help facilitate medical decision-making demonstrated a significant decrease in length of stay on the order of ≈1 day. The larger effect size observed in these studies is likely attributed to differences in setting and intervention design. For example, their interventions were conducted within a single health care system, enabling direct provider engagement and follow-up, whereas this study implemented educational messaging at scale across a nationally distributed MA population. Additionally, the smaller sample size may have influenced effect size estimates by reducing the heterogeneity of outcomes.

This study expands upon the existing literature by evaluating the impact of a payer-led readmission avoidance campaign at scale. Despite the modest relative reductions observed in our study, the large-scale implementation across ≈368k members underscores the potential population-level impact of informatics-driven outreach. The success of the low-intensity multichannel educational outreach campaign is likely multifactorial. Access to extensive claims and clinical informatics data played a critical role in identifying high-risk patients in real-time, enabling the timely deployment of intervention efforts to reduce readmissions. Integrating these data into the outreach campaign enabled precision and effectiveness in reaching the target population. Unlike resource-intensive high-intensity interventions, the low-intensity campaign allowed for engagement with a larger number of members, ensuring that a broader population had equitable access to the necessary support and education to effectively manage their health at a critical moment that matters in their health care journey.

This multichannel outreach campaign embraced a holistic approach to care that was rooted in behavior change. Behavior change technique groupings (eg, goals and planning, shaping knowledge) [18], and intervention functions (eg, education, persuasion, and enablement) [19] were applied to modify health behaviors with the goal of reducing hospital readmissions. Numerous components that combined various self-management techniques, including knowledge acquisition, independent health monitoring, medication adherence, and lifestyle changes, comprehensively addressed member needs in a tailored manner. The multichannel aspect of outreach was designed to reinforce educational messaging that was personalized, contextual, and relevant. Additionally, targeted messaging and outreach efforts were deployed to both members and their providers on record, whenever possible. Specifically, campaign messaging encouraged members to proactively schedule postdischarge follow-up visits and communicate potential complications that would warrant additional clinical support. Simultaneously, payer-led provider alerts regarding their patients' recent hospitalization equipped providers with pertinent information, enabling them to deliver more informed and timely interventions. Overall, this dyadic approach (ie, member-provider) aimed to bridge the communication gap and foster continuity of care by reinforcing the relationship between members and their existing care team.

Last, the low-intensity delivery of communications allowed for broader inclusion of Medicare-insured members across different regions of the United States compared with higher-intensity outreach, which is often cost and labor-intensive. Previous studies examining readmission reduction strategies have found that higher-intensity outreach combining multiple methods is more effective than only using one method, although these methods (eg, home visits, telephone calls, case management) are resultantly more costly compared with the outreach channels deployed in this study [22]. To the best of our knowledge, the study represents the first to investigate the effectiveness of combining multiple low-intensity outreach channels for this use case.

Limitations

There are several limitations to this study. First, the study population is limited to Medicare Advantage members of one large national insurer in the United States with geographic concentrations in the Northeast and Midwest regions. A majority of members in this study self-report primary residence in rural areas (n=189,594 [51%]); notably higher than the average US population (14%) [23], which may limit generalizability to the broader US population. It is possible that differences in access to broadband internet and digital engagement tools may have influenced the effectiveness of electronic messaging, particularly among rural populations. However, the inclusion of multiple outreach channels, including direct mail and provider notifications, helped mitigate these potential disparities. It is difficult to systematically assess differences in access to

XSL•FO
RenderX

technology by geographical location, as multichannel outreach was informed by member channel permissions. In addition, this study was not designed to examine differences in digital technology by geographic location. However, contemporary analysis (Feb 2025) suggests minimal differences in access and preference for digital outreach methods among Medicare Advantage members residing across rural, urban, and suburban locations, with 68% - 69% of members permitting SMS, 75% - 78% permitting email, and 92% - 93% permitting IVR contact across all regions. Interestingly, email open rates (2024 data) indicate slightly lower engagement among rural members (60.5%, $P<.0001$) compared with suburban (64.3%) and urban (62.8%), which may signal potential differences in digital engagement and warrant additional exploration. Nevertheless, this study presents outcomes for a population often underrepresented in the literature and advances our understanding of potential disparities in hospital readmissions.

Second, this study infers readmission and ED visit reductions to be driven by the campaign interventions and does not consider additional (ie, not plan sponsored) interventions. Third, the time horizon may not fully capture the impact of the COVID-19 pandemic on members' behaviors, which continues to evolve. Base rates are unable to be reported due to commercial data use agreements; however, these findings from this large-scale intervention provide valuable insights for designing and implementing future readmission reduction strategies across diverse health care settings. Finally, the possibility always exists that unmeasured confounding variables and potential selection bias may influence outcomes.

Despite the recognized limitations, this study possesses several key strengths. This study represents a retrospective evaluation of a rigorously designed and pragmatic quality improvement intervention. The included study population consisted of a large sample size of 368,693 Medicare Advantage-insured, geographically diverse, older adults across the nation. By focusing on Medicare Advantage beneficiaries, the study addresses a critical population with unique health care needs, contributing to the development of effective strategies to reduce readmissions and improve member and patient outcomes in the population most likely to have gaps in care. The use of claims data enriches the results, providing real-world evidence of outcomes. The integration of additional member data, including plan benefit structure and overlapping programs, enhances the study's precision and effectiveness in minimizing confounding bias. Finally, the campaign's grounded approach in evidence-based practice and health behavior theoretical constructs reinforces the robustness of the intervention and its potential applicability to the generalized population.

Future Research

There are several opportunities for additional exploration. Immediate future research will aim to explore the incremental effect of additional channels. Interestingly, post hoc analysis within the enhanced outreach group revealed that members who received more channels experienced fewer ED admissions than those receiving fewer channels. Specifically, members who received 4 outreach channels had fewer 30-day acute inpatient readmissions and ED visits than members receiving campaigns via one outreach channel, indicating an additive effect of incremental channels ($P<.001$). While interesting, we caution that these results are preliminary and warrant additional evaluation in a controlled, hypothesis-driven study.

In addition, investigating the impact of low-intensity channels based on specific sub-populations, diseases or conditions, and health care settings can provide targeted insights for tailored interventions. As previously mentioned, incorporating more granular data on channel engagement by geographic location could potentially refine multichannel strategies to optimize outreach effectiveness, particularly in rural populations. Future explorations should explore whether reliance on postcharge digital messaging could unintentionally widen the "digital divide" or disparities in access to care. Additionally, exploring best practices in human-centered design that increase member satisfaction, engagement, and resultant clinical and economic outcomes will further optimize and elucidate campaign effectiveness.

Conclusions

Payer-led, personalized educational messaging using multiple low-intensity channels of delivery, including digital health communications such as text message, email, and IVR, can effectively reduce inpatient readmissions and ED visits within 30- and 90-days of discharge among the Medicare Advantage member population.

Acknowledgments

The authors wish to thank Laure Salomon, Josh Weiner, Ali Keshavarz, and Rahul Kak for making this study possible; Shahin Taghikhani and Michael Kolor for their data science support; Szu-Min Yu, Maegan North, Nick Mcburney, Adam Sharaf, Kate Cao, Alexis Cason, Isabella (Ang) Li, Kratika Agrawal, Laurence Chalude, and Carly Levin for their marketing and data engineering support; Dawn Merris, Kirsten Sanderson-Cornelius, Dr Michael Raymond, and Dr Christine Lawless for their business and clinical support; and Dr Dorothea Verbrugge and Mohammad Emami for their publication expertise and guidance. Multimedia Appendix 1
Screenshot displaying enhanced preadmission messaging sent to members via direct mail channel prior to an upcoming hospital stay. Preadmission outreach content focused on priority actions to take in advance of a hospital stay, with emphasis on preparation for the eventual return home (eg, nutritious meal planning, removal of fall risk hazards), scheduling follow-up visits prior to admission, and the importance of medication filling and adherence).
[PNG File, 2608 KB - humanfactors_v12i1e63841_app1.png]

Multimedia Appendix 2
Screenshot displaying enhanced postdischarge messaging sent to members via direct mail following hospital discharge to home. Postdischarge outreach content focused on a member's individual recovery journey by providing a "recovery tracker" calendar for personalized tracking of pain levels, upcoming appointments, and any other key notes to share with their care team at their next follow-up visit. The content reinforced the importance of going to follow-up visits, filling prescriptions and taking them as directed, as well as common warning signs suggestive of a potential complication that would warrant care.

Abstract

Background: The increasing prevalence of mental health disorders among youth underscores the need for accessible and effective interventions. Digital mental health (dMH) platforms like Innowell offer promising solutions by increasing access to mental health care for young people. Innowell is a web-based platform that supports youth mental health by providing personalized measurement-based care in collaboration with a youth's health care providers. However, understanding youth perspectives on these platforms is crucial for ensuring successful implementation and sustained engagement.

Objective: This study aimed to explore youth perspectives on the implementation of the Innowell platform, identifying key factors influencing uptake, engagement, and long-term retention.

Methods: A qualitative descriptive approach was used to examine youth perspectives. Data were collected through 9 focus groups and 1 interview, involving 39 participants aged 15‐24 years from urban (23/39, 59%) and rural (16/39, 41%) communities in Alberta, Canada. Participants were recruited through mental health clinics and community organizations. Thematic analysis was conducted on the transcripts to identify factors that support or hinder engagement with the platform.

Results: Participants emphasized the importance of privacy, security, and personalization in building trust in the platform, with 72% (28/39) reporting that clear communication about data protection would increase their likelihood of use. Progress tracking features, such as symptom trend visualizations and diaries, were identified by 65% (25/39) of participants as critical for sustaining engagement. Ease of use was highlighted, with 58% (23/39) preferring mobile app functionality over web-based interfaces. Dynamic content and personalized notifications were suggested as strategies to maintain long-term use, with 64% (25/39) of participants valuing customizable reminders to encourage daily interactions. Rural participants (16/39, 41%) noted the need for offline functionality due to inconsistent internet access. In addition, participants recommended features such as crisis support, professional communication channels, and access to local mental health resources.

Conclusions: Youth-centered design is essential for enhancing the usability and engagement of dMH platforms like Innowell. Key features prioritized by participants included privacy, security, progress tracking, and personalization. Dynamic and user-friendly interfaces, along with the ability to customize notifications and access professional support, were critical for fostering long-term engagement. Insights from this study provide actionable recommendations for optimizing dMH platforms to meet the mental health needs of young people, particularly in diverse urban and rural settings. Future research should explore implementation strategies tailored to specific user demographics to enhance the scalability and impact of dMH interventions.

KEYWORDS

digital mental health; youth mental health; youth perspectives; engagement and retention; trust and privacy; personalization

Introduction

The number of youth and young adults affected by mental health disorders has increased in the last 10 years [1,2]. Adolescence and early adulthood, ages 12 - 24 years [3], is a peak period of vulnerability for mental ill-health, with 62.5% of mental health disorders emerging before the age of 25 [4]. Mental health conditions of concern include depression, anxiety, eating disorders, bipolar disorder, and substance abuse disorders among others [1,2,4]. Globally, mental health disorders are the leading cause of disability in youth and are the sixth leading cause of disability adjusted life years [5]. The number of youths underdiagnosed or undertreated remains a significant global issue due to barriers to accessing youth mental health services [6,7]. This involves social stigma, limited awareness of available mental health resources [7], and concerns about the therapeutic relationship, including confidentiality and privacy [8,9].

Digital mental health (dMH) has the potential to address the treatment gap of those who do not receive services and increase accessibility of mental health care to youth and young adults [10,11]. The dMH includes both mobile apps and web-based platforms [12] that can augment in-person and traditional mental health services. Youth tend to be more familiar with the digital world and use the internet at progressively younger ages [13]. Given that social interactions and educational commitments are increasingly taking place through digital modes, youth are becoming more inclined to seek mental health support through the internet [14-16]. Research suggests that stigmatizing beliefs surrounding mental illness drive many youth to self-initiate their mental health care by accessing the internet for educational information or assistance regarding mental health concerns, because it is perceived to be more confidential and private than face-to-face services [17]. Of youth aged 13 - 17, approximately 22.2% use internet-based services to seek information regarding behavioral issues [17]. Therefore, there is a growing need for youth-oriented dMH platforms to address some of the challenges of traditional face-to-face mental health care [18,19].

Youth and young adult perspectives on dMH platforms are critical to facilitate retention and uptake of these platforms [20]. Including youth perspectives in dMH research ensures that platforms are accessible, relevant and align with their unique needs and experiences [20,21]. A qualitative study conducted by McKenna et al [22] found that youth valued measurement-based care when embedded in a digital platform and used in their sessions with their therapists because it helped them track their health information between appointments. Generally, dMH platforms have been noted by youth to increase accessibility to mental health care [23], however, the information presented on these platforms must be easy to understand [23]. Youth also noted that dMH may aid self-determination and promote anonymity when asking for mental health support [23].

Despite the benefits of dMH for youth, knowledge regarding the reasons youth use and continue to engage with these platforms is limited [24]. To date, research suggests that reasons for lack of engagement in dMH platforms include limited in-person elements, for example, face-to-face support from a parent, peer or professional [13], privacy concerns [25], technical difficulties [25], and inadequate personalization of the platform [25,26].

A 2019 systematic review and meta-analysis assessing the effectiveness of dMH platforms for youth with anxiety and depression revealed that out of the 34 identified interventions reported, none involved young people in the design process [27]. In contrast, a 2020 review identified 30 platforms that did involve youth design [28]; however, the impact of this has not yet been fully explored as few are widely available for use [29]. One example of a codesigned, personalized, and youth-centered dMH platform that is available in Australia and Canada is Innowell [10,30-32]. The perspectives of youth on the facilitators and challenges in using dMH to access mental health resources and as an adjunct to mental health interventions are scarce.

This study seeks to ascertain the perspectives of youth and young adults regarding the potential barriers and facilitators of using dMH. Understanding what youth expect from a dMH platform can inform recommendations for implementation. To that end, this project asked the following research question: what influences youth engagement with and sustained retention of digital mental health platforms?

Methods

Ethical Considerations

This study is part of a larger multimethod research project aimed at investigating the implementation of a measurement-based care dMH platform for Albertan youth and young adults and was approved by the University of Calgary's Research Ethics Board (REB20-1137) [30,31]. Informed consent was obtained from all participants, and participants under 18 years were required to complete a decision-making capacity assessment to not require parental consent. Participants received instruction to avoid disclosing identifying information, and during transcription any direct identifiers (names, cities, and workplaces) were removed to protect participants' privacy. Focus group participants were compensated for their time at a rate of CAD $25 (US $18.07) per hour.

Recruitment

Recruitment occurred from November 2020 to June 2022. Participants were recruited using self-selected sampling, where participating communities and Innowell testing sites displayed and shared study recruitment posters. Project Leads coordinated with leaders in partnering communities to display the recruitment poster in mental health clinics and community

XSL•FO
RenderX

spaces. In some cases, clinicians discussed the opportunity to participate in the study with their clients aged 15 - 24 years. Interested youth then emailed the study coordinator to express their interest in participating. Inclusion criteria for participants required being between the ages of 15 to 24 years, proficient in written and spoken English, residing in Alberta, and finally, able to use web-based technologies on a computer, tablet, or smartphone. Interested participants were emailed the date and time of the focus group, along with a link to complete the informed consent form and a brief demographics survey to assess participant characteristics. In accordance with the research ethics protocol, a decision-making capacity assessment was administered to participants under the age of 18 years. A perfect score of 4 out of 4 was required to be determined a mature minor, for which parental consent would not be required. If a participant scored lower than 4/4, the missed items were reviewed and retested with a limit of 3 total attempts. Participants without a perfect score after 3 trials were determined to not be mature minors and were ineligible to participate without parental consent. Once the completed consent form was received, the participants were sent a link to join the focus group via Zoom Video Conferencing Software.

Data Collection

Focus groups were conducted as the primary source of data collection. One interview was conducted at the request of the participant. A semistructured interview guide was created to focus on general thoughts and opinions on the Innowell platform and what would support or hinder youth from using it in their community. All focus groups and interviews were facilitated virtually via Zoom Video Conferencing software, audio recorded, and transcribed verbatim by a professional transcriptionist [30,31]. Each focus group lasted up to 90 minutes in length and included 2 to 8 participants. The focus groups and interview included one facilitator and 1 youth research partner note-taker or chat moderator. Participants were first introduced to Innowell through a short video and demonstration of the platform before the focus group discussion. In total, 9 focus groups and one interview were conducted with 39 participants (n=39). Participants represented both urban and rural communities across the province of Alberta, Canada. Sample characteristics are in Table 1.

Table . Demographic characteristics of the participants (N=39) were analyzed.[ab]

		Values
Sex, n (%)		
	Female	25 (64.1)
	Male	7 (17.9)
	Missing	7 (17.9)
Sexual orientation, n (%)		
	Heterosexual	25 (64.1)
	LGBTQIA2S+	10 (25.6)
	Missing	4 (10.2)
Age, n (%)		
	15 - 17 years	21 (53.8)
	18 - 24 years	16 (41.0)
	Missing	1 (2.5)
Ethnicity[c], n		
	Other North American origins	7
	European origins	21
	Asian origins	5
	Other	6
Student or employment status, n (%)		
	Employed	22 (56.4)
	Student	29 (74.3)

[a]"Other" includes sociodemographic information for fewer than five participants to protect anonymity.

[b]Missing includes "prefer not to answer" and "missing" responses. These are combined for clarity and confidentiality.

[c]Values for ethnicity do not equal 100% as participants were allowed to select multiple responses.

XSL•FO
RenderX

Data Analysis

This study used a qualitative descriptive methodology to thoroughly capture the thoughts, perspectives, and experiences of participants who have experiences in health care settings [33,34]. This allowed for the exploration of youth perceptions of challenges and enablers of dMH implementation that are grounded in their lived-experiences of navigating mental health within their communities.

The qualitative analysis of the focus group and interview data was conducted using a 6-stage thematic analysis process: familiarization with the data, generating codes, constructing themes, revising themes, defining themes, and producing the report [30,31,35]. This process followed an iterative codebook approach, allowing for the development of consistency with the generation of codes across focus groups [35]. Three young adult researchers familiarized themselves with the transcripts. They then independently created preliminary codes with support and oversight from the qualitative lead. After coding, they exchanged transcripts and collaborated to resolve any discrepancies, ensuring the validity of the codes through consensus. The coders and the research team then developed themes from the codes. The team engaged in group discussions about the themes, actively documenting their insights to maintain a rigorous and transparent process. Following these 6 steps enhanced the accuracy and credibility of the analysis [30,31]. The sample of 9 focus groups and 1 interview was deemed sufficient based on the concept of "information power," which suggests a qualitative sample's quality relies on its richness, relevance, and depth rather than the number of participants. This approach ensures ample information was gathered to draw meaningful conclusions from the content of the data [30,31,36].

Research Team Positionality

Our team comprises qualitative leads with extensive experience in both research and frontline clinical support, bringing a wealth of knowledge about the complexities of health care settings and a deep understanding of how to effectively support youth. The study team also included youth and young adult coresearchers throughout the entirety of the study, including recruitment, data collection and analysis, and writing the research findings. Youth coresearchers contributed to the research process and offered guidance and knowledge in engaging youth participants. The study team also focused on the power dynamics inherent in conducting focus groups with youth. Recognizing these dynamics, the study team prioritized creating a safe and supportive environment by including a youth coresearcher in every session. The study team also actively encouraged youth to choose their level of engagement, including whether to keep their videos on or off or use the chat, ensuring that their comfort and agency were prioritized in the research process. Through these strategies, we aimed to foster a more equitable dialogue and enhance the validity of our findings.

The Innowell Platform

The dMH platform, Innowell, is an Australian web-based tool youth use in conjunction with their mental health providers [37-39]. Specifics regarding the Innowell platform are described elsewhere [30-32,38,39]. Previous work from the research group has explored the implementation of this platform in school settings, mental health providers' perceptions of using and engaging dMH with youth, and the creation process of an implementation protocol for using dMH in stratified care.

Results

Demographics Summary

The study included participants from various communities across Alberta (withheld to protect anonymity). Participants were aged 15 - 17 years (n=21) and 18 - 24 years (n=16), with one missing response for age. Regarding sex, 7 participants identified as male, 25 as female, and 6 did not report. Sexual orientation was diverse, with most participants identifying as straight (n=25) and 10 as Lesbian, Gay, Bisexual, Queer or Questioning, Intersex, Asexual, 2-Spirited, and other orientations (LGBQIA2S+), combined to protect anonymity. Ethnic backgrounds included European origins (n=21), Other North American (n=7), Asian origins (n=5), six as other or unsure. Regarding employment or student status, 22 were employed and 29 were students. For a full overview of the demographics, see Table 1.

Theme 1: Building Trust—A Digital Safe Space

Confidentiality, Privacy and Data Security

Participants in the study agreed that youth valued and trusted a dMH platform that would grant them the "comfort of …confidentiality and being up front and honest," (FG2). By improving confidentiality and privacy, dMH enables a safe space for youth disclosure of mental health challenges and requests for support. A highly secure and confidential dMH platform would enable youth to access mental health support by reducing the stigma associated with seeking in-person mental health care. One participant stated:

> *There's always that stigma around mental health …[by] having it so that you don't have to be right in-person with the doctor is just a lot easier for people to maintain confidentiality and to be more expressive.* [FG6]

Participants across all focus groups emphasized a deciding factor in their use of dMH would be the strength of data privacy and security features determining how their information is used and stored. As illustrated by one participant, "You have to remind the people that are using this (dMH) that you're not collecting their data" (FG9). Another participant indicated, "I would want to know who can view the information, where the information is going etc," (FG4). To build trust with youth, participants strongly advocated that dMH must clearly state how user data is used and protected. Factors that contributed to building trust in dMH security measures included the appearance and professionalism of the platform. Participants identified that commercial advertisements decreased the platform's appeal, with one stating:

> *I would be hesitant to download that app knowing that I could still be targeted with ads or that information could be leaked to third parties and trying to sell me something with it.* [FG9]

XSL•FO
RenderX

The dMH was seen as having the potential to build safe spaces for youth disclosure if "you have that comfort of some sort of confidentiality and being upfront and honest" (FG2) when providers are onboarding youth to use dMH in their care.

Keeping "Control Over the Situation": Access to Information and Involvement of Others

Participants frequently reported that youth must have jurisdiction over who accesses their personal information on dMH, including providers and parents or guardians. Many participants advocated for reassurance that their information was "protected, nobody else is going to see [their] information [and] it's not going to be shared with anybody outside of [their] clinician and [themselves] or [their] support person" (FG6).

To facilitate this level of privacy, some participants identified "certain healthcare providers that [they] would not want involved in [their] mental health care," and suggested that youth are "able to pick the adults that they were going to be disclosing information to" on dMH platforms (FG1). All participants noted that youth must have control over the level of parent or guardian involvement in dMH. In fact, some participants who reported having a conflictual relationship with their parent or guardian were less inclined to use dMH if family members had any involvement in their care. Overall, youth wanted "control over the situation" to defend their confidentiality and privacy: "...if someone is being added they know they can say, 'Hey, I don't want this person here'" (FG6).

Theme 2: Platform Features to Maximize Youth Engagement

Onboarding or Getting Started With dMH

The participants agreed that youth must be onboarded to dMH to increase digital literacy and trust and generate enthusiasm for dMH's utility in their care. Once receptive to the idea of dMH, participants expressed a preference to receive collaborative onboarding by a provider or dMH expert. One participant imagined receiving a "thorough" walk-through in which they receive a "step-by-step explanation of what you would do [led by] the professionals behind the app" (FG4). Other participants emphasized the need to understand the purpose and the features of dMH to increase the likelihood of engaging with dMH applications. Participants suggested that the onboarding process to dMH be educational, informing youth of "the why behind using it [as] people lose interest when there isn't much detail explained" (FG4).

Progress Tracking

Participants frequently reported the value of tracking their mental health within dMH, including visualizing trends through graphs. One participant noted:

> *I know for myself, I'm really interested in data and trends about myself and my health and being able to broaden that to my mental health is kind of a cool way to introduce it.* [FG9]

Relatedly, a participant noted that seeing progress through dMH tracking may be motivating when a change in their mental health is not perceptible on a day-to-day basis to them and others in their lives.

> *It is about getting better, but it's not always going to be about seeing this dramatic increase and having this weight lifted off your shoulders. I think being able to document things like, "What happened to me today?" Or "how's this week been?" Or "how am I feeling or dealing with whatever's going on?"* [FG6]

A platform feature allowing youth to store and detail personal information, including symptoms and important goals, can serve as an invaluable tool for tracking progress . One participant expressed, "Maybe there could be areas where you could store things and keep things, maybe make a diary page or something" (FG2). This feature would enable users to document their thoughts, feelings, and experiences over time, facilitating self-reflection and self-awareness. Overall, participants noted that they would use dMH regularly if it served to track and enable reflection on their mental health progress and fluctuations in symptoms.

User Experience

Participants throughout the focus groups valued user-friendly design of dMH, including ease of navigation and accessibility. One participant described a facilitator to consistent dMH use as being if "the dashboard itself is easy to understand and navigate" (FG9). Participants expressed a clear preference for an app, or mobile-based, interface compared to a web-based one: "I think it should be an app in the App store because if that is an app in the App Store, it would be accessible to everyone" (FG1). Participants indicated it would increase the chances of discovering dMH, as "youth "looking for meditation [applications] or…games [might] come across it" (FG1). In addition, participants saw potential in the dMH interface facilitating access to mental health education and resources. One participant remarked:

> *It could give you helpful information to make your mental health better and to give you more activities to help you and places to access phone numbers or places to contact if you need help. That would be amazing.* [FG1]

Other participants suggested that dMH could direct youth to local mental health resources and crisis hotlines.

The ability to customize the platform's features and resources to suit a youth's unique needs was also desirable to participants. A participant suggested users be granted the ability to "edit when notifications are sent, when I can talk to someone, who I can talk to and more would be great so it won't be stressful and I can run on my own time"(FG2). A personalized dMH could cater to a wider "variety of people and it can connect [them] with the right resources" (FG4). Another suggested utility of dMH included direct communication with a professional, who "could reach out to you through the app. You could maybe have a personal chat area" (FG2). Other participants expressed interest in dMH platforms with specific features supporting youth in crisis.

> *I think having emergency functions be very accessible would be important as well. Something like a 'chat*

XSL•FO
RenderX

> *now' function that's right on the home screen or close to it so that if someone is in crisis, they can access the help they need.*

This highlights the critical need for in-app support for urgent situations, accessible and emergency functions, complementing the platform's diverse set of resources, including educational materials, links to available mental health services and crisis hotlines.

Theme 3: Sustaining Engagement—Strategies for Optimum User Retention

Barriers to Consistency: The Challenge of Integration

Across all focus groups, participants identified barriers to integrating dMH into their lives. One participant noted, "For me personally, using apps in the past, after a certain point you just kind of get bored of it" (FG6). Another difficulty was prioritizing dMH in the face of other pressing demands and daily routines: "I think that I've had mental health apps in the past, but it's just remembering to do it and having it as a priority it was really tough…." (FG7). Participants identified competing online priorities such as social media as a barrier to using dMH: "Why would I use a mental health app when I can go on Instagram instead. There's nothing enticing me to use the app" (FG6), and "Social media gets in the way of using mental health apps sometimes" (FG3). Overall, these quotes underscore the necessity for dMH platforms to be engaging, easy to integrate into daily routines, and compelling enough to compete with other online activities to ensure sustained user retention.

Suggestions to Reduce Distractions and Maintain Attention

An additional strategy to encourage motivation and continued use of dMH mentioned within the focus groups was the integration of reminder notifications. One participant stated:

> *...if I'm getting notified all the time to maybe update or maybe there's like a quote of the day every day that it'll send me… I think that would be very useful, and something very appealing to the eye.* [FG2]

Another participant provided an example of how notifications and prompts promoted reflection and participation with the platform.

> *I have the app "Calm" on my phone … you can get a notification at the end of the day asking, "How are you feeling at the end of the day?" Sometimes, a lot of the time I just swipe up and sometimes I actually take the time to think about how I'm actually feeling. It's nice for the most part.* [FG3]

However, other participants did not find consistent prompts necessary:

> *Some apps I know I have deleted before if I have set the notifications on and they are just constantly sending me notifications to the point where it gets annoying.* [FG2]

Incorporating timely and personalized notifications could, therefore, play a role in keeping young users engaged and motivated to consistently use dMH platforms, as suggested by one participant.

> *If you check your phone, you see the app which reminds you to do your daily check in or maybe a reminder to do it later in the day around lunchtime or afternoon when you accomplish things or have things that affect your mood. I think that would be very important and useful for people.* [FG2]

The ability for dMH platforms to incorporate additional elements to increase engagement was valued by participants, reflected in a broader sentiment that applications lacking new content tend to be forgotten: "If an app never has anything new on it or different things to try, I find I forget about the app after a while" (FG2). Likewise, one participant noted the power of rewards to attract attention to the dMH platform.

> *People are very motivated by rewards and attention as well. Because like social media—even though you're not getting a specific reward, you're getting attention from others, you're getting communication and it kind of feeds you … so, I think if either some kind of award or like "Congrats you've made it this far! Here's like a little boost of encouragement," or something like that. People like that—that positive reinforcement.* [FG6]

Therefore, incorporating timely, personalized notifications can significantly enhance the appeal and retention of dMH platforms, ensuring they remain a valuable and consistently used resource for young users.

Discussion

Principal Findings

This study aimed to explore youth perspectives on optimizing the implementation of dMH platforms. Three themes were identified from the inductively coded data. The first theme emphasizes the importance of trust in dMH, protecting youth information and creating a safe digital space. The second theme is the identification of specific platform features to enhance the engagement of youth on the platform. The third theme describes the need for dMH platforms to maintain ongoing engagement of youth by removing obstacles to consistent use of the dMH platform and highlighting strategies to reduce user fatigue and boredom.

Theme 1: Building Trust—A Digital Safe Space

Our findings suggest that transparency in a dMH's privacy and confidentiality protections is essential to build youth trust. Other research supports confidentiality's importance for youth across both in-person and digital mental health care settings [8]. Further supporting our results, youths' knowledge of a platform's privacy and security features was identified as a critical factor in increasing engagement with dMH [40]. Despite confidentiality measures contributing to youths' trust in a dMH platform, a study identified this as insufficient for long-term, sustainable engagement from youth [18].

Intertwined with their emphasis on confidentiality, participants valued the power and autonomy to restrict who can see their

XSL•FO
RenderX

mental health information on the dMH platform. Youth most expressed concern about parents and guardians being involved in their dMH care. The findings from our study underscore the critical importance of maintaining youth autonomy and control within dMH platforms, including the ability to selectively involve providers, parents, or guardians. Consistent with our findings, in a preimplementation survey of youth interest in a dMH platform, parental consent was identified as a deterrent for youth participation in dMH [41]. Contrasting to our findings, a study investigating youth attitudes toward parental involvement in dMH reported that youth favored parent access to the dMH patient portal, predicting it would increase accountability and engagement, and enable provider follow-ups [42]. The difference in results may stem from the setting: their study focused on clinical care, where parental involvement is more common, whereas our study was based in community settings, potentially encouraging a greater emphasis on independence and privacy. Our findings suggest that to maximize engagement and effectiveness, dMH platforms should allow users to decide who has access to their data, including the flexibility to invite parents or guardians when it aligns with the youth's preferences and needs.

In line with our finding that that youth value security and privacy measures on dMH platforms, dMH platforms should have robust data security measures to reinforce confidentiality promises. Supporting our findings, a review article identified confidentiality as a "key ethical concern" for users of all ages on dMH platforms [43]. The emotional and psychological effects of data breaches on victims are long-reaching and can include a loss of confidence in the related technology, acute symptoms of posttraumatic stress disorder, and even learned helplessness [44]. Our participants wanted to be informed about dMH's security and privacy measures to build trust in the platform. More investigation is necessary, but dMH platforms should maintain user trust by clearly communicating the security features present on the platform.

Theme 2: Platform Features to Maximize Youth Engagement

Our findings suggest youth prioritize their autonomy when choosing to use dMH platforms but are more inclined to engage if recommended by a trusted individual, including a provider or peer. However, some youth expressed a general resistance to any recommendations about dMH, valuing their own decisions about whether to use dMH. These contrasting findings suggest that eliciting youths' consideration about using dMH must be explored to minimize the risk of rejection and resistance to dMH. Inquiries about dMH from trusted individuals may be followed by youth considering dMH.

Once committed to using a dMH platform, our findings suggest that a positive onboarding experience can facilitate positive user engagement. Youth participants in this study recommend that educational information about dMH and a collaborative approach to engaging youth is critical for increasing the continuous use of dMH. Similar to our findings, a 2023 scoping review of therapeutic dMH platforms for schizophrenia identified thorough initial training including, educational sessions and a hands-on support team as a predictor of user engagement levels [45]. To increase trust in reluctant youth, we recommend that dMH platforms facilitate a virtual orientation process that grants youth the opportunity to practice navigating through the platform and educates them about its intent, and security and privacy features.

Our findings indicated progress tracking features such as graphs and diaries could bolster user motivation and thus lead to higher user engagement. It has been found that increased insight into a user's own personal health, along with empowerment, knowledge, and curiosity may increase engagement with the platform [25]. A research article postulates a psychological mechanism for how digital technologies use progress tracking to increase user motivation and engagement [46]. Another paper described the opportunities and challenges of passive and active progress tracking, arguing that the latter is more conducive to habit formation than a passive, automated one [47]. This suggests that active progress tracking, such as the diary feature suggested by participants , can be more effective in fostering user engagement than passive strategies such as data visualization. Some participants identified the potential for progress tracking to be discouraging for youth whose progress is nonlinear or in a crisis. However, although not contributing to user motivation, progress tracking features could bring youth's attention to unconscious trends of improvement, decline, or stagnation in their mental health.

Our findings suggest an intuitive and accessible user interface is conducive to increased engagement with dMH platforms. Other literature supports our findings, including a qualitative study on the dMH platform Artemis; youth testers preferred a "simple, modern, and consistent" user design and "calming" color schemes instead of identifying technical issues as problematic and disruptive to user engagement [48]. User interface design, content quality, and personalization significantly influence youth engagement [49]. Visually engaging and user-friendly interfaces are crucial in encouraging youth to engage with digital health tools. Our findings indicated that youth preferred an application-based delivery over a web-browser-based dMH platform.

In our findings, participants emphasized dMH, including crisis resources such as a "chat now" feature. In a review of dMH applications' features, a stark 1 out of 31 CBT applications targeting depression were identified that included explicit crisis support features, defined as prominent, identifiable, and intended for use during mental health crises. Such features were not interactive, including a detailed crisis plan or prominent links to suicide prevention hotlines or support centres. This limited presence of crisis support in existing dMH applications aligns with the youth's call for such features on dMH platforms [47].

Theme 3: Sustaining Engagement—Strategies for Optimum User Retention

Participants in our findings highlighted several factors that hindered their ability to consistently use dMH platforms, including the challenges of maintaining engagement, integrating usage into daily routines, and competing with other digital distractions. This decline in engagement over time reflects a common issue with adherence to digital health interventions [50-52]. To that end, designing platforms that offer ongoing

XSL•FO
RenderX

value, such as personalized content, may help foster long-term use. Further, nonpersonalized interfaces can result in frustration and disengagement [13]. A systematic review by Opie et al [53] found that personalized feedback primarily delivered through a dMH internal messaging system from providers to youth was linked to a positive increase in user outcomes.

Participants also identified competition with social media as a barrier to using dMH, as youth often use social media to seek and maintain relationships for educational purposes and entertainment [54]. The immediate gratification and diversity of applications offered by social media can divert attention from health-focused applications. However, by incorporating these aspects, platforms promoting social connectedness enabled by social networks through peer support have been shown to increase engagement [25,53,55]. In contrast, research showed that integrating social media may affect the credibility of the dMH platform [53]. To compete, dMH platforms must offer a similarly compelling user experience. The increased face-to-face interactions facilitated by proper and consistent dMH use by providers can similarly engage youth users. Participants emphasized push notifications and dynamic visual and interactive content would optimize youth retention and engagement (Table 2). Consistent with existing research, participants emphasized the need for customizable, well-timed, relevant notifications that fit naturally into their daily routines [26,56]. In addition, the use of rewards or positive reinforcement to motivate individuals was mentioned within focus groups, which is consistent with previous research on persuasive design techniques [52,57]. However, collecting data for personalized notifications may impact users' privacy without youths' informed consent. Research also suggests that the development of notification fatigue, where users feel overwhelmed by constant alerts, can lead to disengagement or deletion of the platform [58]. Similarly, while not youth-specific, notifications promoted the engagement of users who consistently use the platforms rather than inactive users [59].

Our findings can be situated within a Self-Determination Theory framework, which suggests that human behavior is motivated by 3 innate psychological needs: autonomy, competence, and relatedness [60]. Participants emphasized privacy controls and personalization, which align with Self-Determination Theory. Progress-tracking features and user-friendly design can increase youth's sense of competence. The need for relatedness can be linked to the crisis support and provider communication features suggested by youth for dMH. The satisfaction of these psychological needs may facilitate engagement and long-term retention for youth on dMH.

Practical Recommendations for dMH Implementation

Throughout focus groups, youth participants provided recommendations on how to implement and maintain dMH platforms, including building trust by using these platforms, features that promoted engagement and ways to maintain youth attention and engagement throughout dMH adoption. The themes outlined in this paper offered the ability to provide practical recommendations for implementing dMH platforms in clinical settings for youth and young adults dealing with mental health concerns. Table 2 details the recommendations based on our findings. It is important to note that dMH implementation relies on an individual's access to an electronic device and the internet, which may be feasible in low-resource settings.

XSL•FO
RenderX

Table . Recommendations are based on participant focus groups.

Theme and recommendations		Description
Theme 1: Building Trust		
	Ensuring privacy, control, and security	• Prioritize transparent data usage policies and emphasize the platform's commitment to data security to foster trust among youth. • Empower youth by offering customizable privacy settings that allow them to control who accesses their mental health information. Platforms should provide flexibility for users to selectively involve providers, parents, or guardians, ensuring youth needs are met. • Build trust by clearly communicating privacy policies and data security protocols before onboarding. Highlight confidentiality without overemphasizing security features to avoid triggering concerns about privacy invasions. • Strengthen data security measures to protect youth from the emotional impacts of potential data breaches and foster confidence in the platform's safety.
Theme 2: Platform Features for Engagement		
	Streamlined, collaborative onboarding processes	• Implement a comprehensive, step-by-step onboarding process hosted on the digital mental health (dMH) platform and engaging their provider. The onboarding process should be educational, explaining the purpose and key features of the platform to sustain user interest.
	Progress tracking and a user-friendly interface	• Offer customizable tracking tools like graphs and diaries to help youth monitor their mental health and increase autonomy. Active tracking can foster engagement and support self-reflection. • Platforms should emphasize that progress tracking is not just about linear improvement but also about understanding personal growth, even in times of crisis. • Develop simple and intuitive platforms with customizable features. Allow youth to personalize notifications, communication settings, and resources to suit their needs and preferences. • Mobile-based applications are preferred over a web platform for ease of access.
	Crisis support and professional communication	• Include easily accessible crisis resources. Youth mentioned the importance of timely crisis interventions. Facilitating communication with professionals via the platform can provide an added layer of support, making the platform a go-to resource in times of need.
Theme 3: Sustaining Engagement		

XSL•FO
RenderX

Theme and recommendations	Description
Guided dMH[a] platforms	• Ongoing human guidance and support can improve adherence by providing regular check-ins or nudges as well as personalized feedback from a professional to maintain motivation. • Knowing that professional support is available can help youth build confidence when navigating dMH to promote sustained use. • Regular interaction with a professional or trusted individual can promote a sense of accountability, leading to higher engagement rates as opposed to unguided approaches.

[a]dMH: digital mental health.

Strengths and Limitations

The project's strengths included involving youth from different geographic regions in rural and urban communities where Wi-Fi varied in accessibility. We recruited a diverse sample of youth with respect to geography, sector of involvement, gender, and age. Another important strength is that the focus groups were facilitated by a researcher, youth researcher partner, and implementation lead. A summary of the focus group was shared with participants within 24 hours to receive additional reflections and confirm the accuracy of what was captured from the focus groups.

There are several limitations worth noting. The focus groups were conducted during the COVID-19 pandemic, which may have influenced youths' reflections about using online applications and e-tools via dMH. The increased usage of digital platforms during the pandemic period may have made participants more receptive to dMH compared to prepandemic conditions. The pandemic may have also heightened youth's mental health concerns, influencing their expectations and needs from dMH. This could affect the generalizability of our findings in postpandemic settings. However, the research team probed broadly about the youths' perceptions of dMH before the pandemic to obtain reflections that were not dependent on the context at the time. While the youth had a brief explanation and introduction to the platform before each focus group, all were conducted before youth were onboarded or using the dMH; consequently, the feedback about dMH was general rather than specific to a particular platform like Innowell. In addition, only Albertan youth participated in the focus groups, affecting the generalizability beyond our context.

Conclusions

In this paper, youth perspectives on facilitators of the implementation of dMH perspectives were explored. In total, 3 major themes emerged through thematic analysis. The first, "Building Trust," includes strong confidentiality and robust data security measures as crucial for youth trust in a dMH platform. Second, "Platform Features to Maximize Engagement" includes a thorough onboarding process, a simple and intuitive user interface, and progress tracking to engage with youth users. The third, "Sustaining Engagement," centers on strategies like notifications and reward systems to increase the likelihood that users remain users of dMH platforms. The findings informed recommendations for developing dMH to increase youth uptake of dMH platforms, increase engagement with dMH platforms, and ensure that youth stay committed to dMH platforms.

Acknowledgments

The authors gratefully acknowledge the financial and project support provided by the Alberta Children's Hospital Foundation, Alberta Health, the Partnership for Research and Innovation in the Health System (PRIHS), and Canadian Institutes of Health Research through the Operating Grant: SPOR iCT Rewarding Success.

Authors' Contributions

Recruitment was carried out by MF, LS, and KM. GD and DJ designed the overall study, while GD developed the methods and supervised the preparation and writing of the paper. Data collection was performed by EB, KP, and LN. Coding was conducted by SD, SS, and CEO. The preparation, analysis, and writing of the manuscript were carried out by SD, LV, and EB. KB, JH-G, GH, and MB supported the analysis. All authors carefully reviewed the results and approved the final version of the manuscript.

Abstract

Background: The perinatal period is one of the most vulnerable times a woman experiences. Multidimensional, interprofessional, and personalized support is needed to improve outcomes in women's and children's health while strengthening partner relationships at the same time. Although a vast amount of support services already exist in Germany for psychosocial counseling during the perinatal period, groups who are especially at risk do not take advantage of them.

Objective: Family eNav is an app-based intervention developed by experts in the field of medical and psychosocial support to help young parents navigate through primary and secondary care services in Germany according to their needs. It also empowers patient and parenting perspectives through self-education and symptom monitoring for different settings, for example, mental health and preterm birth. While the intervention will be evaluated in a multicenter, randomized, controlled trial, the focus here lies on the conception of the app, demand among patients, and preuse acceptance.

Methods: During the conception phase, we conducted an explorative study with prospective users and experts in the perinatal psychosocial field to understand the need and preuse acceptance of the intervention. We interviewed 20 participants with a semistructured guide, analyzing their responses using systematic text condensation. Additionally, we conducted a short survey on general questions concerning digitalization within the health care system among the participants.

Results: We established two main themes: (1) access and barriers to health care and psychosocial services and (2) high preuse acceptance of app-based intervention. Health care and psychosocial providers indicated that there is a high demand for their services, which cannot always be met immediately, and at the same time, they are doubtful of reaching those individuals most in need. Prospective users and health and social care providers alike showed great interest in the perinatal navigator and suggested a variety of needs and content requirements to be included. Regionality, availability, and individualized content were underlined as success factors for high user acceptance. Barriers consisted of data protection concerns, as well as denial of their own needs.

Conclusions: Our findings show great acceptance for an app-based intervention on the part of both prospective users and service providers. Feedback on requirements and content, as well as possible barriers, was taken into consideration while developing the app.

Introduction

Pregnancy and early parenthood represent a turning point in life. Sufficient multidimensional support during pregnancy may be beneficial for mother-child relationships [1,2], whereas a lack of support can lead to manifold psychosocial risk factors [3]. Exposure to psychosocial risk factors, such as maternal depression, stress, and low social support, negatively affects pregnancy and child development [4,5]. Maternal and children's health and social inequality are tightly linked [6-9]. Therefore,

XSL•FO
RenderX

improving maternal psychosocial risk factors during this phase represents an important public health aim.

In 2015, a cross-sectional survey in Germany of over 7500 families with small children showed that around 40% of families have three and more stressors, consisting of biographic, perinatal, and psychosocial measures, cumulatively, whereby at least 25% of participants reported that the parenting role was associated with stress [10]. A vast amount of support services already exist in Germany. The ministry for families, seniors, women, and children even offers web-based services through a family portal [11]. For families in troublesome situations, early preventative measures are outlined, from diminishing exposure to violence to promoting a positive environment for development, which are all compiled—and subsidized—within the initiative called "Frühe Hilfen" (translation: Early Help) [12]. Frühe Hilfen conducted several studies on how socioeconomic factors are related to obstacles to using early childhood prevention services. They found that families from lower socioeconomic backgrounds knew less about assistance programs in general and were less likely to actively make use of them. Programs such as home visits or family midwives, who provide support during the first year after childbirth, were more often used by families with lower socioeconomic backgrounds because they were offered to them on the basis of need, and parents did not have to actively look for them [13,14].

Women show a high tendency to search for pregnancy-related information on the web and via smartphone apps [15,16]. The number of health apps for pregnant women that are easy to access and can introduce new ways to perinatal care delivery, especially in low socioeconomic settings, is growing [15,17]. The quality and effectiveness of mobile apps vary tremendously, though, which can lead to mistrust and discontinuance of the app [18,19]. Nonetheless, multiple randomized controlled trials (RCTs) showed health-promoting effects of using mobile health (mHealth) apps, for example, in weight management, gestational diabetes management, and maternal mental health [20,21]. Introducing a digital tool that has been developed with a user- and provider-centered approach opens a realistic opportunity to find evidence-based information and also lowers the threshold for gaining access to this information by digitally interlinking families in need with their regional service providers.

Our research project, Family eNav, is a multicenter health service program funded through the innovation funds of the Joint National Committee (German: Gemeinsamer Bundesausschuss). It was our objective to develop an app-based perinatal guide to better coordinate need-based primary and secondary prevention care and empower patient and parenting perspectives through self-education and symptom monitoring. Intensifying the link between health and social system support through an app-based navigator may ameliorate care for pregnant women and young families, especially those with psychosocial risk factors, and hence may lead to higher quality of life, relieve stress, and strengthen partner and parent-child relationships.

In the conception phase, we tried to develop the content basis for the guide by evaluating the demand for and acceptance of such an app-based intervention. The aim of this study was therefore to gain a deeper understanding of young families' needs and reasons for using services to establish the demand for an app-based perinatal guide. At the same time, we tried to shed light on the provider's perspective on how to successfully integrate an app-based perinatal navigator to determine factors of success and possible barriers.

Methods

Study Design

The study was conducted at the University Hospital of Heidelberg with pregnant women and young mothers, as well as health care experts [22]. Study participants were recruited between November 2021 and March 2022. We used purposive sampling to include all perspectives necessary for the conception of an app-based perinatal guidance program. Overall, we recruited 9 prospective users, among whom 5 users were pregnant and 4 users had infants, and 13 experts from all areas of perinatal services (Table 1). Eligibility criteria for users were older than 18 years of age and fluency in German. To be eligible for participation, service providers had to be involved in the care of pregnant women or young families. We conducted interviews until information saturation was reached.

Semistructured interviews with a mean length of 32.45 (SD 9.54) minutes were held by 3 trained investigators following a previously established interview guide with primarily open-ended questions. At the end of the semistructured interviews, we added a general survey of the participants' perspective on digital health with primarily closed-ended questions, using a scaling system (Multimedia Appendix 1). We performed systematic text condensation on the responses to the questions, which is a descriptive method concentrating on people's experiences rather than the underlying meaning [23]. Through meaning units, we established a coding scheme to form predominant themes in accordance with our research questions. Researcher triangulation was used to increase reliability. Specific quotes were translated into English to underline the main perspectives. The answers to the digital health survey were assessed through descriptive statistics.

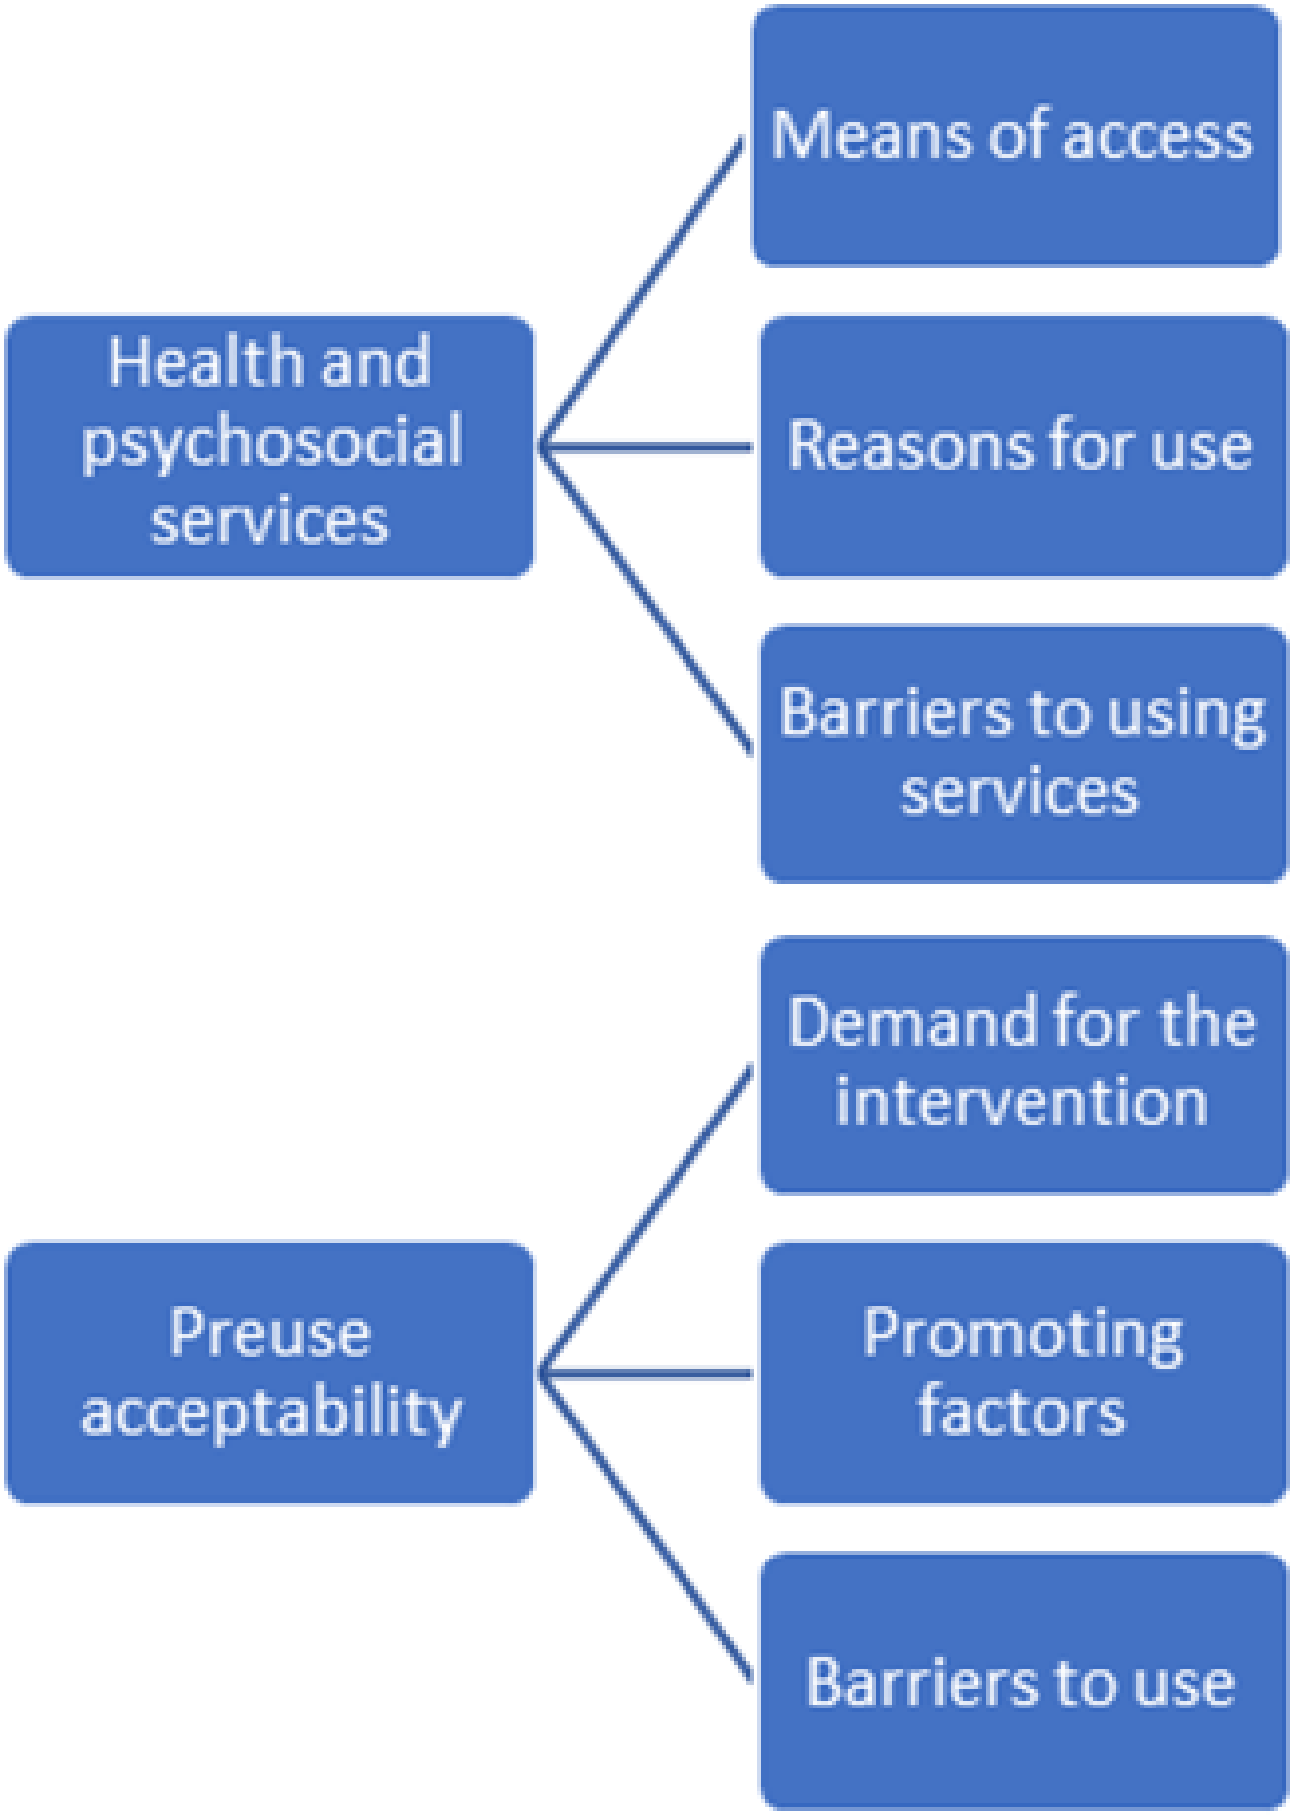
The study aimed to explore the perceived status quo of perinatal services and investigate whether there was a demand for a digital navigator, and also determine preuse acceptance of the planned mHealth intervention study [24]. Second, we wanted to give our prospective users and collaborators a voice within the conception phase of the app. Data were analyzed descriptively.

Ethical Considerations

The study was approved by the ethical committee of the University of Heidelberg (S-344/2022). Informed consent was gathered prior to the interviews. Participants gave oral and written permission to record the interviews and perform data

XSL•FO
RenderX

analyzation. They were later transcribed verbatim. The data were anonymized. Participants did not receive any compensation.



Results

Overview

Through our analysis, we established the following main themes: health care and psychosocial services, and preuse acceptance of an app-based intervention (Figure 1). We listed the most important meaning units for preuse acceptance by comparing the views of our prospective users and experts.

XSL•FO

Health Care and Psychosocial Services: Access and Barriers

Means of Access to Psychosocial and Health Care Services

Internet-based methods, such as search engines, social media, and local home pages to access perinatal services, made up at least 50% of the responses from users and experts. Most experts said they were contacted via email. Conventional methods, such as the telephone or the formal referral system, made up the rest. Numerous experts additionally stressed the importance of word-of-mouth recommendations.

> *I mainly google things or ask colleagues who already were pregnant for recommendations.* [Interview 2]

Reasons for Using and Not Using Services

The willingness to take advantage of health care services during and after the pregnancy was high in our study group. Almost all participants at least tried to take part in activities such as antenatal classes, yoga for pregnant women, baby swimming classes, or courses for family bonding. Reasons for not taking advantage of services were a lack of interest and time, or low perceived value of the service itself, or low perceived qualification of the personnel, lack of knowledge, and higher barriers due to COVID-19 restrictions on services. Some minimized the use of certain services because of disadvantages due to cost and organizational load. Sometimes, a certain level of distrust was shown when services did not show transparently what they offered.

> *Because I think this is what happens to all parents, they just don't have enough time and if they had more time, maybe they would care more about things like this, but especially if they have to search things for a long time, then this is why it fails.* [Interview 7]

Our experts described their situation as being in high demand and even having to work with waiting lists for their services. According to them, the reason is a shortage of personnel and not saturation of demand. They even raised concerns about their outreach to families in need. Most experts see ignorance of their services as the most important reason that they are not used. They stated that barriers to asking for help are naturally high and that the process of finding help is time-consuming; therefore, many families cannot overcome such a barrier. Additionally, they suggested that families in need are often in denial about their own condition or even consider social and health services as a threat that needs to be controlled. Psychological conditions such as lethargy due to depression constitute another barrier to looking for and taking advantage of services. All experts recognized that a digital tool to navigate families would be helpful in lowering access barriers.

> *In our experience, I would say, very paradoxically, the smaller the problem, the higher the parents' willingness to ask for help and vice versa.* [Interview 14]

> *Well, I think the process of looking for help is complicated for postpartum depression, for example, because until you find someone to take you in, there is just not enough capacity in small cities. I think it would help to have some kind of shortcut to a contact person.* [Interview 10]

High Preuse Acceptance of App-Based Intervention

Overview

> *You see, hardly anybody reaches for a book or magazine or something similar while waiting for something. Usually, you have your phone with you.* [Interview 6]

This quote shows the importance of mobile devices in our patients' everyday lives. During our interviews, we saw great acceptance for an app-based intervention on the part of both prospective users and the service providers. As suitable devices, smartphones and handhelds were most often named. Service providers found a computer format more convenient for their daily work.

> *As a provider, the computer would be the most appropriate, but I think for most of the users the mobile phone is most appropriate.* [Interview 16]

We created a mind-map showing the most relevant points concerning the acceptance of our navigator, both from a user and provider standpoint (Multimedia Appendix 2).

High Demand for App-Based Navigator

All our prospective users saw the benefit of an app-based navigator to lower the threshold. They especially mentioned how they missed a sense of direction when looking for specific services. Especially, primipara considered their lack of experience as a source of uncertainty throughout their pregnancy. When those people in their surroundings have had little or have had bad experiences, they see the guidance through an app as a source of trust.

> *Because especially when you are expecting your first child you know zero of what to expect. There is this big unknown territory.* [Interview 6]

Not only do prospective users see the wide range of offers and the inherent lack of transparency here as hindering, but experts, too, emphasized the importance of having clear structures and orientation within health care services to ameliorate pre- and postnatal care.

> *And then we decide within the situation which help systems are needed. And I think, this is like a jungle for women but also for us midwives.* [Interview 13]

Another main improvement this study's participants found in using app-based navigators is time-efficient self-education, which gives them a feeling of security and strengthens their partnerships when sharing new information within the app. Most of our prospective users emphasized that it is important to have one app that combines all aspects of pregnancy, the postpartum period, and early childhood, instead of having a multitude of books and apps for only certain subjects.

> *For example, we bought the book Oh I am growing where all development steps are explained because I did not want to have an app, but now the book is actually just sitting on the bookshelf.* [Interview 7]

XSL•FO
RenderX

Service providers also had a very positive perception of the improvements a future digital navigator could bring. They considered an app where all health-related information could be collected as an improvement in efficiency, making it easier to treat their patients or adequately help their clients. Some of them could envision the app as part of an early warning system, making interventions available sooner to those who need them. Concerning the target group, they thought an app might have a better reach due to the low threshold for gaining information on services and due to the privacy aspect of self-assessing one's need through psychological check-ups and symptom tracking tools. They stated that a digital navigator might be able to lift the burden from some overcrowded postnatal wards and go hand in hand with hospitals' psychosocial support concepts. Like our prospective users, they believe that the app can help give a sense of security and orientation throughout this challenging time.

> *And I would recommend it because it will convey knowledge to parents, mothers, so as to give a little bit of assurance and orientation in this new phase and an important way to network. In the broadest sense of I know where to turn to when I need it and this will indirectly positively influence the children because mothers will feel more confident in their role as mothers or fathers in their role as fathers.* [Interview 14]

Promoting Factors for an App-Based Navigator

Design-wise, our interviewees found a clear-cut structure with a user-friendly interface, as well as easy-to-understand instructions and messages, to be most agreeable. Both experts and prospective users emphasized that anything that would lower the threshold will enhance user engagement.

> *(…)the more I feel at ease, because through colors, font, structure or something else it might leave me with a certain feeling, the more I would be willing to spend time on the app.* [Interview 6]

Both experts and prospective users expressed the need to have a filter function on the displayed services. Filters should include distance and availability of services to promote an efficient search. Prospective users would also look for ratings or comparison tools for services. They would like to have a direct link to the services and information on whether certain offers fall within their insurance benefits. To contact the services, most users would like to have a direct link to the home page or their email address, or telephone number, and some would even prefer to have a direct chat option.

Prospective users listed the following as important content for the self-education part of the navigator: financial aspects such as how to apply for parental benefits; information on the development of the fetus with individual updates according to the gestational age; information on prenatal care, advice on symptoms during the pregnancy, symptom- and weight-tracking tools; calendar function for all doctors' and health care services' appointments and deadlines; checklists for daily questions; information on delivery options and health care providers; support for the postpartum period; and list of postnatal courses, childcare services, information on breastfeeding, activities for babies, and nutritional advice pre- and postpartum.

In addition to the aforementioned content, experts included: relief opportunities for mothers such as family midwives, motherhood nurses, or simple food delivery options; help on finding a midwife and information about their importance; emergency telephone number when dealing with negative feelings after a traumatizing birth or due to postnatal depression; lists of medical doctors and psychologists; lists and information on where to give birth; organizational check lists pre- and postpartum; nutritional and sport advice during pregnancy and nursing period; advice on sleep rhythm and signaling of babies, as well as development milestones; and networking possibilities such as self-help groups.

When asked whether the women wanted to have their partner included in the app, most found it to be helpful. Experts also distinguished the importance of including partners.

> *I think this might be even more important than for myself. As a mother, one is a lot closer to the baby, and therefore, it is easier to find out what is wrong with it. Especially when the father is home alone then he has something like a guidebook. It could be a good back-up to look up things.* [Interview 1]

The last promoting factor that both sides brought up in nearly every interview is the trustworthiness of the information and the contacts that are displayed, and how this might be the key factor for women to continue using and working with the app.

> *The maximum of neutrality and the maximum of transparency and the maximum of the maximum of credibility. This is the basic prerequisite, and this needs to be conveyed.* [Interview 20]

Barriers to App Use

Possible reasons for not using such an app were dominated by data protection concerns, and in some form, a fear of becoming dependent on the smartphone. This was connected to time-consuming installation processes or questionnaires, which could lead to user dissatisfaction or even to withdrawal from the intervention. It was also mentioned that if the information was not kept up-to-date, users would stop using the app soon after realizing this.

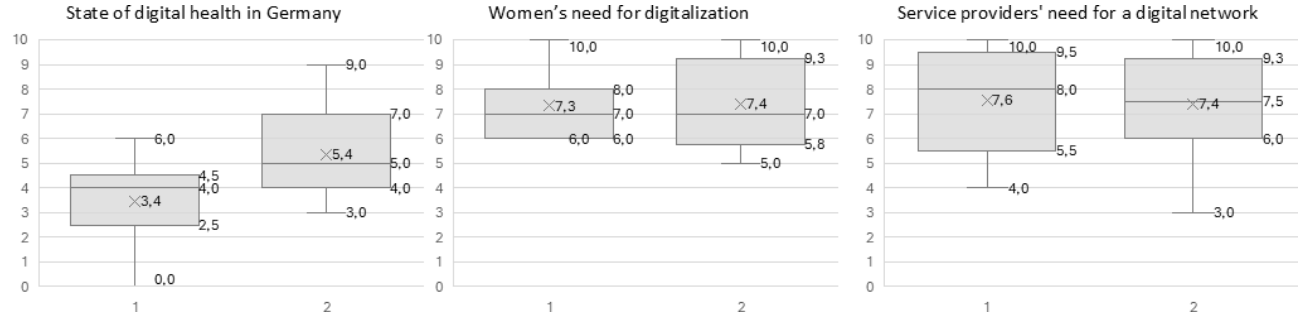
> *I think first and foremost, data protection reasons. I think there are many who might be a little timid in this case. As to maybe their data might be given to third parties or maybe they must disclose too much.* [Interview 8]

Some participants stated that people might not be well informed or generally did not acknowledge their own need for help. Here, experts found lower education status, language barriers, and psychological conditions to be the cause.

> *They think they already know everything and will manage solely on their gut instinct. Otherwise, I do not see a reason because applications are omnipresent and only rarely do people shy away from using them.* [Interview 10]

XSL•FO
RenderX

Others thought that users might miss the personal contact when dealing with their problems through an app. Experts had doubts in particular about video-based therapy options, which they had already had to incorporate in their daily work due to COVID-19 restrictions.



> *Maybe that is just because of anonymity, the nonverbal, the missing conversation.* [Interview 13]

In general, some assessed that the market for app-based interventions might already be saturated. Prospective users said they would not use an app if it were not free of charge. At the same time, none of the prospective users wanted to have advertisements within the app.

Digital Health Survey

At the end of the interview, we asked our participants some general questions about their opinions concerning digital health in Germany (Multimedia Appendix 1). They indicated that the state of digital health in Germany is at least mediocre. However, experts still had a higher opinion than our prospective users, where one even gave a zero, which was outside the given range of 1 - 10. When asked about the need for more digital interlinkage between women and services, both sides estimated that the need is fairly high. Here, opinions did not differ between experts and users (Figure 2). We asked whether not only interlinking providers and users but also providers with providers might be beneficial. All the respondents thought that creating a digital network for service providers would improve access for women. A total of 13 out of 19 respondents thought it would also ameliorate the quality of services, while 6 respondents thought it would not have any effect on the quality. When we asked our service providers specifically, 82% indicated it would enhance their efficiency (Multimedia Appendix 3).

Figure 2. Boxplots of results from the digital health survey; possible answers ranged from 1 to 10 (1 meaning the least and 10 meaning the highest); 1=perspective users, 2=experts; marked within the plot are mean (X), median, and IQRs.

Discussion

Improving Access to Psychosocial Services in Germany

This study showed that most women already access information about perinatal services online and have a high willingness to take advantage of general perinatal services, in particular. Barriers consist mainly of a lack of knowledge, time and affordability constraints, and a certain degree of distrust in the qualification and effectiveness of the services. On the other hand, most experts stated that the services they offered are in high demand, and both pregnant women and young mothers reflected this in their interviews. This outcome can be argued in light of the sociodemographic background of our study participants and the region of Heidelberg, where the annual household average income is approximately €24,400 (approximately US $27,469), which is among the highest in Germany [25]. Our multicenter approach to the RCT, involving centers from low-income areas such as Berlin Tempelhof and more rural areas such as Jena, will provide a more representative study population. The next question we asked is whether the demand is high relative to what is being offered and the capacity of services, or whether services are saturated for other reasons, such as underfunding and understaffing. This fact was explicitly mentioned by some of our experts. While stating that their resources are limited, they also saw an urgent need to reach more families in need, suggesting that their services needed improved access points. This finding compares well with similar studies in Germany showing that there is, in fact, a need to improve access to perinatal services for hard-to-reach subgroups [14,26].

There is a significant amount of evidence pointing in the direction of mHealth for improving access to psychosocial treatments [27]. Furthermore, multiple studies showed that mHealth interventions had positive effects on a large range of psychosocial measurements, including self-management of health, acceptance of pregnancy, anxiety, depressive symptoms, perceived stress, mental well-being, coping, and self-efficiency. It also showed that mHealth interventions positively influenced social support from partners or health care providers. The greatest effect was observed in highly vulnerable pregnant women, leading to the conclusion that a perinatal navigator can effectively help vulnerable groups that we are missing right now [28-31]. In prior studies, interlinking women with service providers or enhancing self-help through mHealth interventions seemed to be the key concept. We took this a step further by asking whether it might be beneficial not only to interlink providers and users but also to connect providers with providers. All the respondents thought that access could be facilitated for women by creating a digital network for service providers. Most of the respondents thought it would also improve the quality of services. When we asked our service providers specifically, 82% indicated it would enhance their efficacy. Creating interdisciplinary networks within perinatal care is an ongoing aim for health care providers and has been shown to be beneficial, for example, in mental health settings [32,33]. So far, interprofessional networks have been based on personal meetings and consultations, and to our knowledge, a telemedical

XSL•FO
RenderX

network has not yet been implemented within perinatal care. We submit that regional interdisciplinary networks can be created and implemented via a mobile navigator and will improve access to and uptake of perinatal services.

High Preuse Acceptance Promising for RCT Outcomes

All of our study participants gave positive feedback and showed high preuse acceptance. Most pregnant and postpartum women have already used apps during their pregnancy. Promoting factors for app use from the user's perspective were time-efficient self-education concerning evidence-based information, positive feedback mechanisms through symptom tracking, direct and easy contact opportunities to regional perinatal and psychosocial services, and networking possibilities. Providers estimated a destigmatization of risk factors, the low threshold for information, and for access to specific services, as well as the chance to better monitor high-risk pregnancy, as success factors for a perinatal app-based navigator. On the subject of perinatal and postpartum depression, a study from Varma et al [34] showed comparable results on acceptance and utility. Especially during the COVID-19 pandemic, we saw an increased interest in the subject of telemedical monitoring. Several studies showed that virtual visits and communication through telemedicine are highly accepted on both the patient and provider sides of health care [35-37]. Barriers to app use expressed by future users were mainly unawareness, data protection concerns, complexity of app use, hidden costs, or in-app advertisements, as well as the already high number of apps on the market. Providers added language barriers, low education profile of users, and mismatch of app design, denial of necessity, and psychological lethargy, as well as a general digital skepticism, to this list. Similar barriers to telehealth uptake, including level of education, telehealth literacy, and unawareness, were found in a multinational review by Kruse et al [38]. What differs from other studies is our family-centered approach in a multidisciplinary context, allowing multiple entry points, as well as a personalized solution for women and young families navigating through this phase.

Limitations

There are several limitations to this study. The first and perhaps greatest limitation concerns our study participants' socioeconomic status and level of education, which is only partly representative of the foreseen cohort of women with psychosocial risk factors from hard-to-reach socioeconomic niches. Furthermore, all participants were from the same geographic area, which might lead to results not being generalizable nationally. Nonetheless, tailoring the app to the needs of prospective users and health care providers should help the intervention to be more successful. Testing the mHealth intervention in a multicenter setting will help with representative data. Another limitation is the small sample size, which is characteristic of qualitative research methodology. To validate the data, we used researcher triangulation. Interviews were conducted by two investigators, and data interpretation was done in a team of three. By introducing a small survey with closed-ended questions, we were able to triangulate common notions on digital health.

Conclusions

This study demonstrated high acceptance of an app-based perinatal navigator both from the users' perspective and the psychosocial and health care providers' points of view. It also showed that creating better networks between users and providers, but also between providers and providers, will help improve access and quality of care. Feedback on requirements and content, as well as possible barriers, informed our concept and helped in creating all parts of the self-education guide. All information was curated by a team of health care professionals from different specialties, including midwives, gynecologists, psychologists, and pediatricians. The results from this study underscore the necessity for a multicenter RCT on the perinatal navigator.

Acknowledgments

This study is funded as part of a multicenter randomized controlled trial, called Family eNav (01VSF20002), through the innovation funds of the Joint National Committee (German: Gemeinsamer Bundesausschuss). For the publication fee, we acknowledge financial support by the University of Heidelberg.

Authors' Contributions

KK transcribed, curated, analyzed, and interpreted data for the work. KK is responsible for drafting the paper and agrees to be accountable for all aspects of the work. VS and KB drafted the interview guide and are responsible for recruitment and interviewing the study participants. VS and KB were part of the data curation and interpretation of the work. MW, MA-D, and DS helped conceptualize the study design, as well as reviewed the process and final draft, and gave important contextual information. SW, as principal investigator of Family eNav, gave the idea to the project, as well as conceptual assistance for this exploratory study. SW reviewed the data and gave important input for the interpretation of the data. All coauthors examined the manuscript, made corrections, and approved it for publication.

Abstract

Background: With the increasing prevalence of type 1 diabetes alongside limited health care resources, the need for more sustainable health care services is apparent. Central to ensuring the standard of diabetes care while simultaneously optimizing resource utilization is improved patient-clinician communication and the provision of individualized care. Digital outpatient solutions incorporating patient-reported outcome measures (PROMs) have been introduced in diabetes outpatient care over recent years; however, features and delivery methods differ, and existing studies on their use and perceived clinical value are limited. Furthermore, clinicians' acceptance has been suggested as a key factor in the sustainability of digital solutions. Thus, to support the implementation of digital outpatient solutions perceived as valuable by clinicians and patients, we need more knowledge about how they are accepted and utilized in clinical practice.

Objective: This study investigates how clinicians and patients with type 1 diabetes accept and utilize a digital outpatient solution to support individualized care in the context of full-scale implementation at a diabetes specialist outpatient clinic. Furthermore, we aim to explore the synchronous interaction between patients and clinicians when they are allowed to prepare through the filling and reviewing of asynchronous PROMs before consultations.

Methods: This qualitative study uses interpretive description as a methodological approach. The digital outpatient solution features various components, including PROM questionnaires, asynchronous chat, remote consultations, e-learning, and information distribution. Data were collected through semistructured interviews with 10 clinicians and 20 patients with type 1 diabetes and observations of consultations. The data from the patient and clinician interviews (267 A4 pages) were analyzed separately before being jointly analyzed in the context of the findings from the observations (40 A4 pages).

Results: Our analysis resulted in the following three main themes that describe the interplay between clinicians' and patients' acceptance, utilization, and perceived clinical value of a digital outpatient solution: (1) clinicians' acceptance of the digital outpatient solution influences patients' acceptance, (2) variations in the use of different features influence the extent of individualized care, and (3) clinicians' and patients' utilization influences perceived care efficiency and quality. Those who demonstrated higher acceptance and more extensive utilization reported that the solution was more valuable in enhancing individualized care efficiency and quality.

Conclusions: This study highlights the interplay between clinicians' and patients' acceptance, utilization, and perceived clinical value of a digital outpatient solution in diabetes specialist outpatient care. Our findings suggest that when clinicians and patients understand why and how digital solutions are used, such solutions can enhance care efficiency and quality, contributing to sustainable health care. Future research should aim to gain an in-depth understanding of clinicians' and patients' acceptance, as well as the effectiveness of change management strategies when implementing digital outpatient solutions in diabetes specialist outpatient care.

Introduction

Background

As of 2022, about 8.75 million individuals worldwide were living with type 1 diabetes [1], a number predicted to increase to between 13.5 and 17.4 million by 2040 [2]. The rising global prevalence of type 1 diabetes, combined with limited health care resources, poses significant challenges to health care systems worldwide in their effort to provide high-quality care [3]. This escalating pressure calls for more sustainable health care services to ensure high diabetes care standards while simultaneously optimizing resource utilization. Thus, facilitating efficient communication between patients and their health care providers, emphasizing patients' individual needs, and providing timely support will be increasingly important in the immediate future. Emerging digital solutions designed to promote patient communication and evaluate health status to individualize care offer opportunities and potential strategies to navigate this successfully [3,4].

An important aspect of diabetes care involves educating and supporting patients in developing sufficient self-management skills [5]. Diabetes self-management, which includes maintaining blood glucose levels within the target range, adopting a healthy lifestyle, and managing potential psychological issues, can help minimize the risk of complications and improve quality of life [6,7]. However, patients' required self-management support level varies significantly, underlining the need for person-centered and individualized care [5]. Patient involvement becomes increasingly important, and digital solutions can be tailored to enable patients to participate actively in their treatment and self-management. One way of involving patients is through digital patient-reported outcome measures (PROMs), which entail collecting health information directly from patients without interpretation by a health care professional [8]. Relevant PROMs in type 1 diabetes may encompass patients' perceived glycemic control, self-management activities, and diabetes distress. PROMs can provide a comprehensive understanding of patients' needs and provide valuable information for clinicians when delivering person-centered and individualized care [9,10]. Simultaneously, PROMs can foster a self-reflection process within patients, leading to increased engagement in their treatment and self-management [9].

In recent years, digital outpatient solutions with PROMs have been developed and examined in diabetes specialist outpatient care [11-13]. However, according to a scoping review, these solutions' features and delivery methods vary [4]. Some digital PROM-based outpatient solutions that aim to individualize care seem to focus on the psychological aspects of living with type 1 diabetes [14,15], while others also include other factors, such as glucose monitoring, self-management activities, and lifestyle [13,16]. The delivery methods range from patients completing the PROMs at a touch screen at the clinic to utilizing web-based solutions [4]. Furthermore, the literature on how the solutions are used is limited, mainly comprising small pilot and feasibility studies [4], underscoring the need for further research.

DigiDiaS—Individualizing Diabetes Care Through a Digital Solution

In November 2021, a multicomponent digital outpatient solution was implemented at the diabetes specialist outpatient clinic at Akershus University Hospital in eastern Norway through the DigiDiaS project [17]. The solution mainly relies on PROMs entailing glucose monitoring, diabetes distress, and self-management activities. However, it also incorporates additional features aimed at individualizing care and supporting communication between clinicians and patients with type 1 diabetes, such as asynchronous chat and video consultations. For patients, use of the solution is voluntary and requires their consent upon app download. As of April 2024, 1354 out of approximately 1800 patients with type 1 diabetes had been included in the digital outpatient solution. All clinicians at the outpatient clinic utilize the digital outpatient solution, comprising diabetes specialist nurses and physicians working with type 1 diabetes patients.

For digital solutions aiming to individualize care to be implemented successfully, they must be accepted and utilized by both clinicians and patients, and clinicians' acceptance has been suggested as a key factor in new digital solutions' sustainability [18,19]. Acceptability, a core concept in digital health [20], can be defined as a multifaceted construct reflecting the extent to which people delivering or receiving a health care intervention consider it appropriate [19]. This acceptability can, in turn, influence utilization in the sense of user engagement and intervention effectiveness [20]. While previous research states that patients in diabetes outpatient care generally seem to welcome the use of digital PROMs [14,16,21,22] and the opportunity to self-report concerns [23,24], clinicians' acceptance and perceptions of such measures' usefulness vary [11,12,16]. Thus, we need more knowledge about how digital solutions are being accepted and utilized by clinicians and patients in diabetes specialist outpatient care [4]. Furthermore, no prior research has explored the synchronous interaction between clinicians and patients after asynchronous preparation using PROMs in a digital solution [4]. Consequently, the clinical value of using digital PROM-based solutions in diabetes care has yet to be established in terms of enhancing care quality and sustainable utilization of health care resources.

Objective

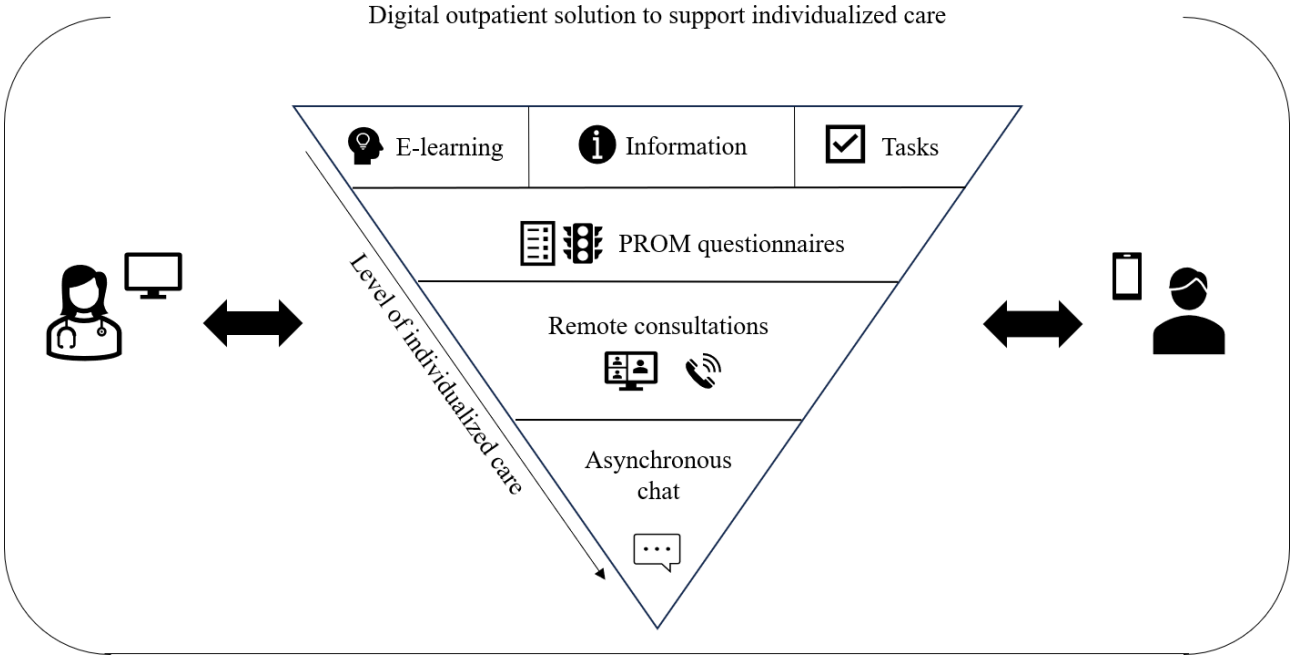
This study investigates how clinicians and patients with type 1 diabetes accept and utilize a digital solution to support individualized care in the context of full-scale implementation at a diabetes specialist outpatient clinic. Furthermore, we aim to explore the synchronous interaction between patients and

XSL•FO
RenderX

clinicians when they are allowed to prepare through the filling and reviewing of asynchronous PROMs before consultations.

Methods

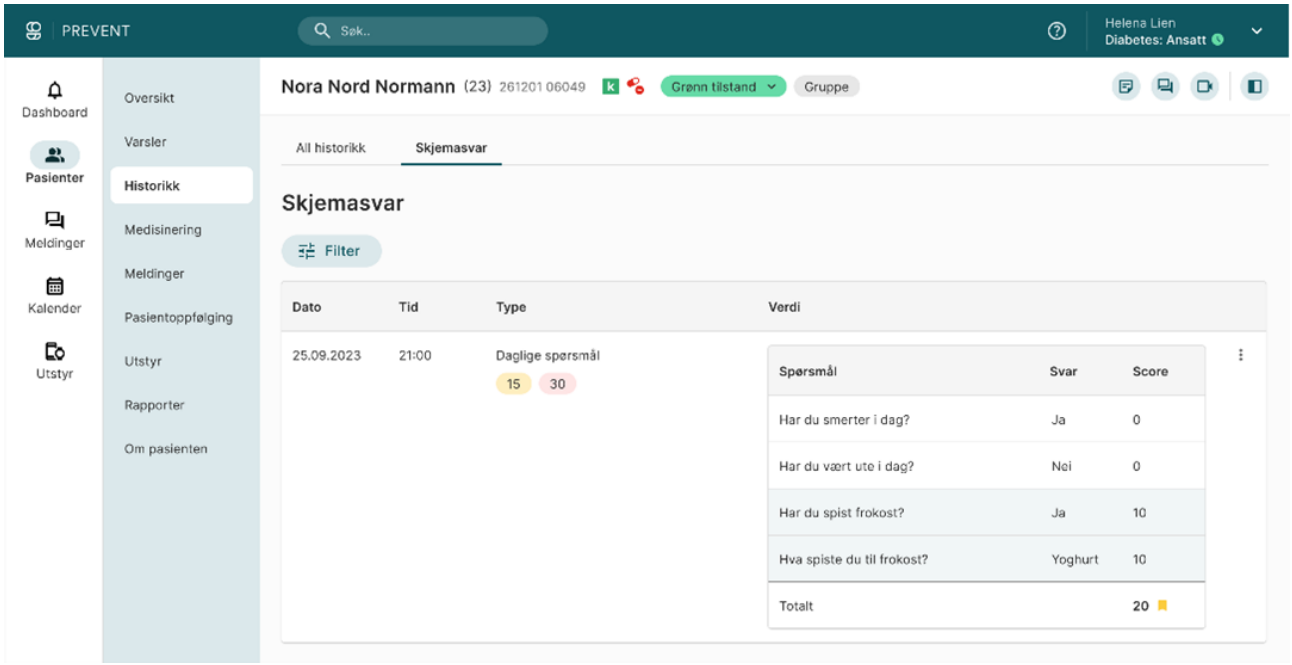
Design



This qualitative study uses interpretive description as a methodological approach, comprising a framework developed to conduct research arising from clinical practice and aiming to improve practice [25]. The interpretive description process is inductive and pragmatic, providing flexibility to adapt the research process to the specific research questions [25]. Our study is embedded within a larger multimethod prospective observational study investigating digital PROMs in diabetes specialist outpatient care [17].

The Multicomponent Digital Outpatient Solution

The previously detailed solution [17] was facilitated via Dignio Connected Care, offering web-based software used by clinicians and an app for patients [26], along with JOIN Norsk Helsenett, which provides a platform for video consultations [27]. Clinicians received training on the use of the digital outpatient solution, with ongoing support provided during and after the implementation process. Clinicians use the web-based Dignio platform to review completed PROM questionnaires from patients before a scheduled consultation, assign tasks, provide e-learning, and distribute digital information to individual patients and groups. During the outpatient clinic's operating hours on weekdays, diabetes specialist nurses asynchronously respond to chat messages from patients, consulting a physician if necessary. On the patients' side, the solution's app enables them to complete assigned PROM questionnaires before consultations, receive information and e-learning, cancel consultations, reschedule or change upcoming consultations at the outpatient clinic to phone- or video consultations, and chat asynchronously with their clinicians as needed. The chat feature is mainly used by patients to report and ask questions about nonacute medical issues (self-initiated patient-reported outcomes) and submit practical queries. Should immediate assistance be required, patients are instructed to either call the clinic directly or dial the national emergency number.



The PROM questionnaire sent to patients before consultations is a modified and translated version of the DiabetesFlex Care PROM questionnaire originating from Denmark [13]. The questionnaire is multidimensional and is triaged based on preset thresholds using a traffic light system, which indicates patient responses' severity [13]. Norwegian adjustments to the Danish version were made based on a user involvement study conducted at Akershus University Hospital, involving patients, diabetes specialist nurses, endocrinologists, management, and researchers [23]. In addition to PROMs, the questionnaire contains open text boxes for subjective responses. Figure 1 illustrates the digital outpatient solution's different features. Figure 2 shows a screenshot of the web-based digital platform used by clinicians, while Figure 3 displays screenshots of the app used by patients.

Figure 1. The digital outpatient solution aims to individualize care through improved patient-clinician communication. Each feature can be used based on an individual patient's need for support. The triangular presentation illustrates the different levels of individualized care that each feature promotes, from uniform to highly individualized features. For example, while e-learning is a uniform feature received by those patients in need, the asynchronous chat is highly individualized and tailored to address a specific question at hand. PROM: patient-reported outcome measure.

These screenshots are from a demo user and are intended to illustrate the design.

Participant Recruitment

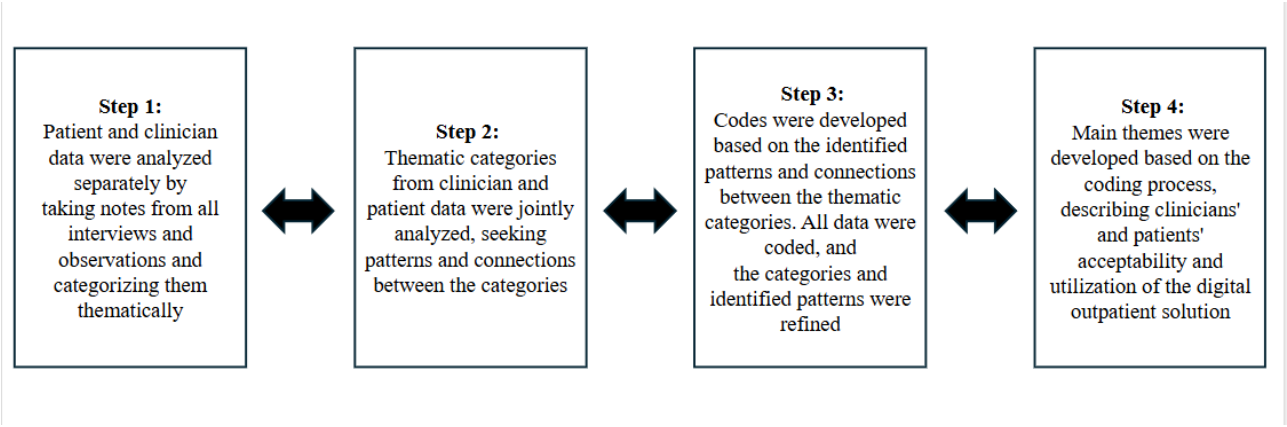
Clinicians working with patients with type 1 diabetes at the outpatient clinic were recruited through convenience sampling [25], and the clinic manager invited them to participate. They were recruited based on availability, as we wanted to interfere as little as possible with clinical practice. All 10 clinicians invited to participate in the study, comprising 6 diabetes specialist nurses and 4 physicians, consented to participate. This represented approximately half the physicians and all the diabetes specialist nurses at the outpatient clinic, excluding the clinic manager and 1 newly hired nurse. Patients invited were adults with type 1 diabetes who had consented to use the digital outpatient solution and had completed the PROM questionnaire before their next consultation. Patients were recruited through purposive sampling [25] to ensure variation in gender, age, ethnicity, and frequency of digital interactions. Information about the study was sent to patients via the digital outpatient solution before their next upcoming consultation. At the start of the consultation, their clinician asked whether they wanted to participate. Of the 23 patients invited to participate, 20 consented. Written consent was obtained from all study participants.

Data Collection

The first author collected data through observations and semistructured interviews between August 2023 and April 2024. An observation guide (Multimedia Appendix 1) and interview guides (Multimedia Appendices 2 and 3) were developed based on informal observations that the first author conducted at the outpatient clinic between February and March 2023, as well as aspects of the Method for Assessment of Telemedicine

XSL•FO
RenderX

framework [28]. The guides were reviewed in a reference group comprising a user representative, researchers, clinicians, and management from the outpatient clinic. The observation guide facilitated insight into how the digital outpatient solution was used to individualize care, while the interviews sought to capture both clinicians' and patients' perspectives on their utilization of possibilities provided by the digital outpatient solution.



Scheduled consultations involving all participating patients and 6 out of 10 participating clinicians were observed. The observed consultations took place at the clinic (17), over the phone (2), or via video (1). Observations of remote consultations were conducted on-site, in the same room with the clinician at the outpatient clinic. Observation notes (40 A4 pages) were written down manually in the observation guide, digitally recorded, and stored. The notes in the observation guide contained descriptions of the type of consultation, topics discussed, context, use of PROM responses during the consultations, and analytical thoughts.

Individual semistructured interviews with clinicians were conducted before the observations, whereas patient interviews were conducted within 2 weeks after the observed consultations. The interviews were conducted at the clinic, over the phone, or via video based on participants' preferences regardless of whether they were clinicians or patients. During the interviews, participants were asked questions about their attitudes toward the use of health technology in general, experiences with the implementation of the digital outpatient solution and using different features, the solution's perceived usefulness, and potential improvements. Clinician interviews lasted between 28 and 52 minutes (median 37 minutes), and patient interviews lasted for 20-47 minutes (median 28 minutes). All interviews were transcribed verbatim (267 A4 pages).

Data Analysis

Data analysis was conducted in line with interpretive description [25]. We concurrently collected data and conducted a constant comparative analysis. This made the process dynamic by moving back and forth between the different steps of the analysis, as illustrated in Figure 4.

Figure 4. Illustration of the dynamic process of the constant comparative analysis.

The analysis aimed to inductively explore how clinicians and patients utilize a digital outpatient solution to individualize care. Through our interpretation process, we revealed a strong link between acceptability and utilization. In the final step of the analysis, 3 main themes were developed based on the coding process that describe clinicians' and patients' acceptance and utilization of the digital outpatient solution. The theoretical framework for acceptability was used to determine that the findings pertain to acceptance and utilization [19]. The first author conducted the analysis, with ALJ, HH, and AT contributing to analytical discussions during each step. These themes were discussed further with the remaining authors. NVivo 14 software (Lumivero) was used to manage and code the data [29], supplemented by visual exploration techniques to identify connections and patterns in the data. The visual exploration process involved positioning the thematic categories in relation to each other to identify patterns in clinicians' and patients' acceptance and utilization of the digital outpatient solution.

Credibility

To ensure the credibility and epistemological integrity of our study, we have provided a comprehensive description of the study design and analysis process [25]. We aimed to establish representative credibility through prolonged engagement with the outpatient clinic prior to data collection. Furthermore, we enhanced the credibility of our findings by triangulating data, collecting information from multiple sources [30]. By thoroughly describing our results, we aim to demonstrate our analytic logic and interpretive authority to ensure trustworthiness [25].

Ethical Considerations

The study was assessed by the Norwegian Agency for Shared Services in Education and Research (reference no. 456954) and the data protection officer at Akershus University Hospital (22/09709 - 13). The project did not require approval by the regional committees for medical and health research ethics (reference no. 407539).

We used a service for sensitive data (TSD), developed at the University of Oslo, which was designed for storing and processing sensitive data in compliance with the Norwegian Personal Data Act and Health Research Act [31]. Written consent was obtained either on paper and stored securely, or digitally via Nettskjema [32], requiring a governmental ID portal

XSL•FO
RenderX

login to access the information, and stored in TSD. All interviews were audiorecorded using the Nettskjema-diktafon app [33], a solution that immediately transfers all audio files encrypted for storage in TSD. MAM transcribed the interviews using the f4transkript program [34]. AT reviewed all recordings and transcripts throughout the analytical process, informing the interpretations. The privacy and confidentiality of research participants' data and identities were maintained.

Results

Participants' Characteristics

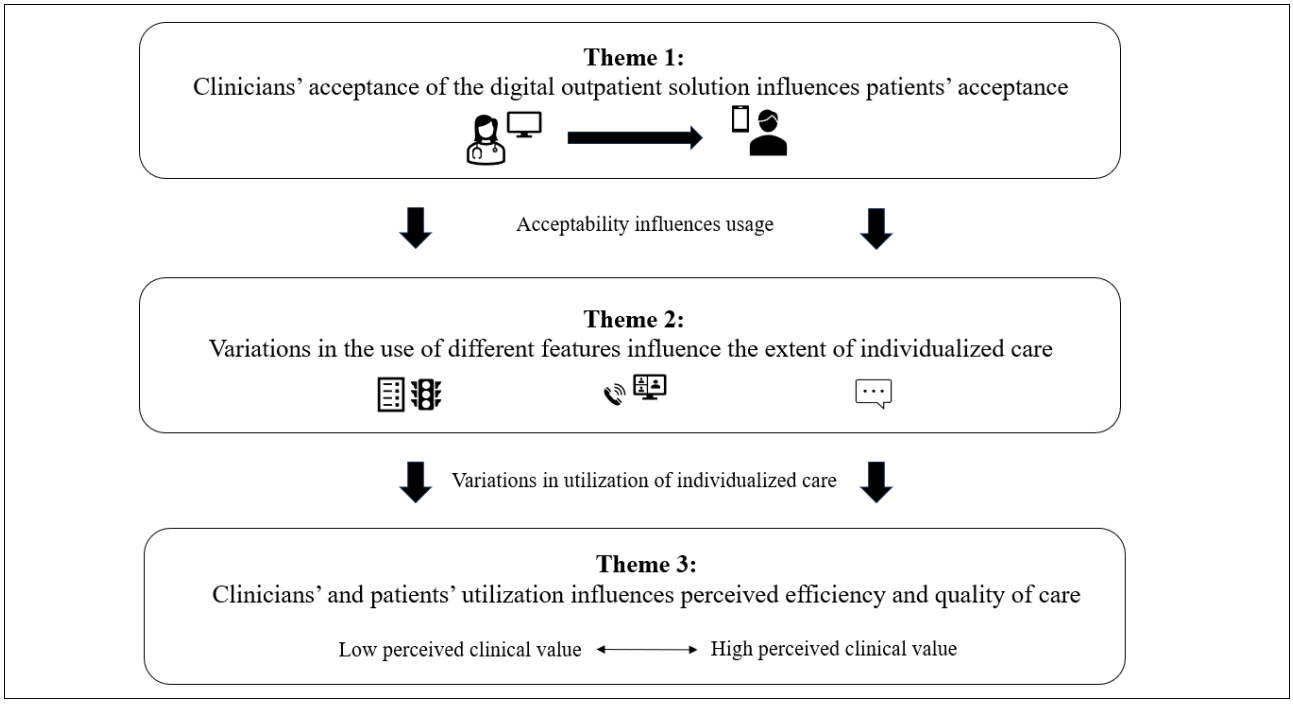
The patients' characteristics, including their use of the digital outpatient solution, are shown in Table 1, and the clinicians' characteristics, including their diabetes care experience, are shown in Table 2.

Table . Characteristics of patients and their use of diabetes technology and the digital outpatient solution (N=20).

Characteristics and usage	Values
Gender (female), n (%)	10 (50)
Age (years), median (minimum-maximum)	36 (18 - 65)
Diabetes duration (years), median (minimum-maximum)	21 (1 - 50)
Glucose monitoring, n (%)	
Continuous glucose monitor	19 (95)
Glucometer	1 (5)
Treatment, n (%)	
Insulin pump	12 (60)
Insulin pen	8 (40)
Number of completed PROM[a] questionnaires, median (minimum-maximum)	1 (1 - 7)
Number of chat conversations, median (minimum-maximum)	2 (0 - 11)
Has used remote consultations, n (%)	12 (60)

[a]PROM: patient-reported outcome measure.

Table . Characteristics of clinicians and their diabetes care experience (N=10).



Characteristics and diabetes care experience	Values
Gender (female), n (%)	9 (90)
Diabetes specialist nurse, n (%)	6 (60)
Physician, n (%)	4 (40)
Nurses' diabetes care experience (years), minimum-maximum	5 - 25
Physicians' diabetes care experience (years), minimum-maximum	5 - 15

Overview of the Identified Patterns

Our analysis identified three main themes that comprise a pattern describing the complex dynamics of how clinicians and patients accept and use the digital outpatient solution to support communication and individualize care: (1) clinicians' acceptance of the digital outpatient solution influences patients' acceptance, (2) variations in the use of different features influence the extent of individualized care, and (3) clinicians' and patients' utilization influences perceived care efficiency and quality. Figure 5 provides an overview of how the 3 themes are connected. Notably, the participants did not emphasize the possibility of assigning and receiving tasks, information, and e-learning, so it was not a focus of the analysis.

XSL•FO
RenderX

Figure 5. Illustration of how clinicians and patients accept and use the digital outpatient solution to support individualized care.

Clinicians' Acceptance of the Digital Outpatient Solution Influences Patients' Acceptance

This theme describes how a variation was observed in how clinicians and patients accepted the digital outpatient solution, with an interplay between the two. Specifically, clinicians' acceptance seemed to shape patients' understanding of the solution's use and, subsequently, their acceptance.

Clinicians' understanding of the digital outpatient solution's potential and their confidence in using its different features varied. They also expressed variations in their personal commitment toward mastering the digital outpatient solution's features and adjusting their existing workflows. Some clinicians felt confident using the PROM questionnaires, chat, and remote consultations, viewing them as positive means to support individualized care:

> *I really like it. Both the digital outpatient solution and I absolutely love video consultations because they shorten the time spent during consultations and we stay more on topic. And with the apps we use, we have access to much more data than before.* [Clinician 1]

Conversely, other clinicians expressed uncertainty about using some features of the solution. While most felt comfortable using the chat and remote consultations, some were uncertain about how to use the PROM questionnaires before and during consultations, questioning whether the benefits outweighed the additional preparation time required of them and their patients:

> *I feel it is a very comprehensive and somewhat time-consuming questionnaire for patients to fill out. I'm a bit worried that patients might find it to be too much work.* [Clinician 10]

Furthermore, clinicians' own understanding and acceptance of the solution seemed to affect how they introduced the solution to patients. Clinicians who indicated a solid understanding of the solution's possibilities to individualize care expressed that they spent time explaining the various features to patients, during which they emphasized how it could enhance patients' self-management awareness and improve communication with their clinicians. Patients who felt well informed about the solution's potential also indicated higher acceptance levels:

> *As we talked, he realized that this was his tool, and he could expect that I had read his responses before consultations. So, it suited him very well. He also understood that it was a way to make him more aware of his disease… Of course, it creates an expectation that I, as a clinician, should keep myself updated on their responses, but with him, I also experienced a positive expectation, that now we are talking, we can clear big and small problems out of the way early.* [Clinician 3]

However, clinicians expressing less familiarity with the solution's possibilities often focused on the chat feature as a means for patients to communicate with the clinic between consultations. Some reported that they did not mention the use of PROM questionnaires at all when presenting the solution to patients. This led to uncertainty among patients who received these questionnaires before consultations without adequate information about their purpose:

> *It was a bit like, what is this, I thought…and it seemed that you had the option to decline to fill out the questionnaire. I believe there was an option to not fill out the questionnaire without losing the appointment. But I thought, OK, I'll just fill out the form, it's probably a questionnaire they have. But I thought the information was poor.* [Patient 14]

Simply receiving the questionnaire without any clear instructions about its intended use was insufficient to gain patients'

XSL•FO
RenderX

acceptance. Clinicians' and patients' acceptance of the digital outpatient solution influenced further to what extent they used the different features to improve communication and individualized care.

Variations in the Use of Different Features Influence the Extent of Individualized Care

This theme describes how clinicians and patients used PROM questionnaires, the option for remote consultation, and the chat feature to individualize care. It outlines the variations among participants' use, as well as the interplay between clinicians' and patients' usage patterns.

PROM Questionnaires Can Facilitate Individualized Consultations Through Mapping Needs and Reflection

The most pronounced differences in use of the solution were related to use of patients' PROM responses and how these responses influenced consultations. While some clinicians admitted to forgetting to review the patients' PROM responses before a consultation occasionally, most clinicians made it a routine part of their consultation preparation. Some clinicians used PROM responses to tailor consultations and set agendas, ensuring that the patient's needs were emphasized. When PROM responses were used actively, patients reported feeling more engaged in their treatment, with increased opportunities to discuss their concerns and priorities. This also included discussing positive PROM responses, as this could serve as a motivational factor in patients' self-management process:

> *I have previously felt that these consultations are a bit "so-so". We talked about blood glucose monitoring and maybe not so much more. So, you don't really know, and maybe the clinician doesn't know either, which direction the conversation will take. So, the fact that I have already thought about what I want to discuss, and they are aware of my thoughts and feelings, has added great value to my consultations.* [Patient 8]

When patients reported challenging issues through the questionnaire, clinicians could address these concerns specifically, improving their communication with their patients. However, some clinicians used the PROM responses less often during the consultations, which led their patients to question the value and purpose of the information they provided through the questionnaire:

> *What then is the value of the questionnaire? It was not mentioned and none of the elements I reported were brought up... so I question the value of it. Questionnaires for the sake of questionnaires?* [Patient 6]

If clinicians did not address patients' PROM responses during the consultations explicitly, we observed that most patients did not bring it up. However, patients noted that this lack of use made it more challenging to engage actively in their consultations. Still, most patients used the PROM questionnaire as a tool for reflection to some extent to inform and guide their self-management process and prepare for consultations.

Consultations Tailored to Needs and Personal Preferences

With the digital outpatient solution's implementation, most patients experienced a notable shift toward more individualized consultations. In addition to the use of PROM questionnaires, which affected the consultations' content, the shift was facilitated by patients being asked whether they wanted to meet remotely with their clinicians by either phone or video. Both clinicians and patients agreed that certain matters, such as physical checks or discussing difficult or complex issues such as mental health challenges, were best addressed in person. However, many found remote consultations more convenient for simpler requirements, such as support when starting to use a new insulin pump:

> *I have used it in the follow-up when patients have started using an insulin pump. Initially, a physical meeting is required to get started with the pump, but the subsequent follow-up is conducted digitally. This is possible because patients have uploaded their pump data. This allows us to see all the necessary information while they are at home, enabling us to make necessary adjustments.* [Clinician 1]

However, both clinicians and patients expressed personal preferences regarding using remote consultations. While some preferred communicating remotely and used it regularly, others had a strong preference for in-person consultations:

> *I have always chosen to decline that option because I prefer to speak with people face-to-face. I have used video meetings a lot for work and other settings, and that's not a problem, but I feel much more comfortable face-to-face.* [Patient 10]

Patients regularly chose between physical attendance at the clinic and video or phone consultations based on needs or personal preferences.

Chat Messages Facilitate Individualized Care When Needed

Most patients used the chat feature, which all the diabetes specialist nurses used consistently, facilitating targeted care within a short time frame. Chat was highlighted as the most frequently used feature of the digital outpatient solution. For clinicians, chat presented an opportunity to maintain contact with patients and even reduce consultation frequency if adequate follow-up could be conducted via chat:

> *We reach more patients when they have the opportunity to send a message. We dare, in a way, to schedule their next consultation in half a year because they can write to us in the meantime if they need to.* [Clinician 1]

When confronted with complex patient inquiries via chat that warranted comprehensive written responses or extensive dialogue with the patient, clinicians found transitioning to immediate remote consultations useful in providing the necessary support. These chat-initiated remote consultations, serving as an extension of the chat interaction, enriched the overall communication process:

XSL•FO
RenderX

> *When the patients write messages, we see how extensive the issue is, whether it's a short question, or if it's a question that requires having a conversation around what the patient is wondering about. So, I often ask if we can have a conversation instead of answering a dissertation...And there is a lot of good feedback on that. I also think we can resolve issues quickly so that they don't have to wait until their next scheduled consultation to get answers. So, I believe that we are promoting health more in the way we are working now.* [Clinician 3]

The patients found it easier to contact the clinic through chat. Moreover, patients reported that chat supported their self-management, as they used it to address urgent concerns immediately instead of waiting for their next consultation or calling the clinic. Many patients viewed phone calls as a barrier, and they experienced a lower threshold for writing their questions in chat. Patients and clinicians used the chat feature for a range of queries, from addressing practical questions about upcoming consultations to discussing treatment-related matters, such as insulin adjustment. Chat also provided a sense of security for patients, knowing that help was just a message away:

> *It certainly helps me to have the reassurance that I can simply send a message instead of having to call and wait for a response and all that, so it's very convenient. Let us say I'm at work and wondering about something, I can just send a message, and I know I'll get a response soon. Especially when I don't have the opportunity to be on the phone, it's a great comfort knowing there's someone there to help.* [Patient 4]

Although some patients had used chat only once or twice, or not at all, they reported a sense of security from knowing that they had the option to send a chat message when necessary. This underscores the chat feature's latent value, demonstrating its significance even when not used actively.

Clinicians' and Patients' Utilization Influences Perceived Care Efficiency and Quality

Both clinicians and patients acknowledged the digital outpatient solution's potential clinical value in enhancing efficiency by streamlining communication and improving care quality through individualized follow-up based on patients' needs. However, the extent of the perceived clinical value varied among clinicians and patients and was reflected in how they utilized different features of the solution. Clinicians' and patients' utilization, that is, their practical and effective use of the digital outpatient solution, appeared to influence their experiences regarding the solution's benefits, with those demonstrating extensive utilization typically perceiving the solution as more valuable. Furthermore, this theme describes clinicians' and patients' perspectives on how the different features can contribute to enhanced care efficiency and quality.

The most prominent differences in clinicians' and patients' perceived clinical value were related to the PROM questionnaires. When utilized, both clinicians and patients found that the questionnaires helped focus on patient-identified key areas for managing their life with type 1 diabetes, simultaneously making consultations more efficient by prioritizing topics. From the patients' perspective, the PROM questionnaires were also viewed as the clinic's acknowledgment of the complex nature of living with type 1 diabetes. This comprehensive focus on all aspects of living with diabetes was believed to enhance care quality by enabling the patients to address challenging issues more comfortably:

> *It's easier to sit and write it on the phone than to bring it up in a consultation because the questionnaire is a lot about your thoughts and feelings, and it is not always easy to talk about… and when you are in a consultation, they often ask you how you are doing and then you usually just say that it's going well even though it's not.* [Patient 11]

However, patients stressed that the extent to which clinicians utilized their responses was crucial in perceiving the questionnaire as valuable from the patients' perspective. Although not all patients experienced remote consultations, most recognized their clinical value in increasing efficiency. Some patients also expressed a wish to try remote consultations in the future, particularly if circumstances prevented them from meeting clinicians in person at the outpatient clinic. Both patients and clinicians appreciated remote consultation's potential to increase efficiency and flexibility. Patients clearly benefited from a reduction in travel time, while some clinicians valued the possibility of working remotely. Both parties also noted that remote consultations tended to be more concise, without the usual small talk evident during in-person consultations. However, this led to a few clinicians expressing concerns about potentially missing important information, with some worrying that care quality provided remotely was not as high as in person. Most patients did not share the same concern, as they would choose clinic consultations for issues they felt were better discussed in person.

Both clinicians and patients emphasized the chat feature's role in elevating care efficiency and quality. Clinicians found that chat reduced the volume of calls to the clinic, allowing them to respond at their convenience, rather than being interrupted by calls during other tasks. Although responses from the clinic could take a few hours or even a couple of days, patients perceived the overall process as more efficient and flexible than calling. Furthermore, chat enabled clinicians to give more thought-out advice, differing from the immediate responses provided over the phone and enhancing the perceived quality of the responses provided to patients:

> *After nearly two years of using the solution, we appreciate receiving written questions, as it allows us to respond at our convenience. This also allows us to thoroughly consider our response and consult with a colleague before replying if necessary. I think this is a good approach.* [Clinician 4]

Patients appreciated the chat feature's value in offering an accessible way to receive reassuring responses to their questions, thereby easing everyday management of their condition. Both clinicians and patients viewed the chat feature, largely driven by patient-initiated conversations, as a key element of the digital

XSL•FO
RenderX

outpatient solution for individualizing care to meet patients' needs.

Discussion

Principal Findings

This qualitative study provides insight into how clinicians and patients accept and utilize a digital outpatient solution in a diabetes outpatient clinic differently, highlighting an interplay between their usage patterns. Specifically, clinicians' acceptance seems to shape patients' understanding and acceptance of the solution's resources, subsequently influencing clinicians' and patients' use. Furthermore, this seems to influence clinicians' and patients' perceived clinical value of the solution's different features. Those demonstrating higher acceptance and more extensive utilization perceived the solution as more valuable, recognizing its potential to enhance care efficiency and quality.

To our knowledge, no extant literature has highlighted the interplay between clinicians' and patients' acceptance, utilization, and perceived clinical value of digital outpatient solutions during full-scale implementation in diabetes specialist outpatient care. The literature mostly encompasses pilot and feasibility studies, with an emphasis either on the patients' or the clinicians' perspective [4]. Although the literature in this field is limited, studies have indicated that patients generally embrace PROM-based digital outpatient solutions [16,22], whereas clinicians often express ambivalence and challenges related to time, resources, and care quality [11,12,16]. Our findings particularly align with how clinicians express ambivalence about using digital outpatient solutions, revealing variations in satisfaction and use of the solution. Moreover, our study goes further than extant studies in exploring the complex interplay between clinicians and patients, specifically by demonstrating that clinicians' acceptance influences patients' acceptance and their collective utilization of the solution. This interplay underscores the important role of clinicians' understanding and acceptance of the digital outpatient solution for successful implementation [19].

The importance of clinicians' acceptance has been emphasized in literature examining telehealth services in different contexts [18]. Regarding this specific multicomponent digital solution, our findings suggest that both clinicians and patients perceived combining different features to improve the efficiency and quality of individualized care as clinically valuable and appropriate for implementation in clinical practice [19]. However, variations in acceptability across individuals seemingly affect clinicians' and patients' perceived clinical value of each feature, influencing their utilization in the sense of user engagement and intervention effectiveness [20]. For instance, most participants used the chat feature and found it valuable for individualizing care, aligning with extant literature arguing that a chat feature can strengthen clinician-patient relationships in type 1 diabetes care [35]. Remote consultations were used based on individual preferences and needs and were valued particularly for their role in enhancing communication efficiency, a benefit also reported in earlier literature [36]. However, we observed wide variations in use and perceived clinical value of PROM questionnaires. Extant literature has argued that PROMs' usefulness in clinical practice depends on patients reporting their concerns, clinicians' proficiency in utilizing information, and both patients and clinicians perceiving them as useful [37]. This suggests that the effectiveness of using PROMs to individualize care depends on clinicians' and patients' ambition and capacity to leverage opportunities that PROMs offer. Without active engagement from both clinicians and patients, PROM questionnaires can be perceived as a burden rather than an asset, adding to workloads without enhancing perceived clinical value.

Implications for Clinical Practice

Overview

To ensure successful implementation, it is crucial to address both human factors and organizational change [38]. We argue that an in-depth understanding of human factors, such as users' acceptance, is essential when implementing a digital outpatient solution in diabetes care. Based on our findings, we emphasize the importance of clinic management in addressing the challenges and implications that clinicians and patients encounter during implementation, as these factors can significantly impact the solution's sustainable utilization.

Importance of User Acceptance and the Clinicians' Role in Implementation

Based on our findings, which underscore the important role of clinicians' acceptance in the sustainable utilization of the digital outpatient solution, we argue that clinicians should be a prioritized group during implementation. When clinicians accept and understand how the digital outpatient solution can be utilized, they are in a better position to provide the necessary information for patients to start using it. Extant literature has recognized clinicians' role in implementing digital outpatient solutions successfully [18] and has suggested further exploration of workflow changes that clinicians encounter when implementing digital solutions in diabetes care [4]. Furthermore, clinicians' role has also been highlighted in the context of other diagnostic groups, such as epilepsy, in which it has been argued that PROM-based follow-up represents substantially changed outpatient care and that implementation success is highly dependent on clinicians' daily management of the solution [38].

The Need for Organizational Involvement and Strategy

Ensuring clinicians' acceptance and competence to provide the necessary information and education to patients about how to utilize digital outpatient solutions seems to require organizational strategies that emphasize education, training, and ongoing support throughout and after implementation. As part of the implementation of this digital outpatient solution, all clinicians underwent training and were offered ongoing support as needed. Nevertheless, the persistence of some clinicians' hesitance to change implies that more comprehensive organizational involvement may be necessary for optimal implementation. Strategies that address clinicians' individual support needs might help foster more universal acceptance among clinicians.

Furthermore, our findings indicate that the extent of organizational involvement required for implementation to be

XSL•FO
RenderX

successful can differ, depending on the effort required from clinicians and patients to adapt to the new practices. In this study, the implementation of the chat feature and offering patients the choice of remote consultations were viewed as particularly valuable. However, the implementation of PROM questionnaires required considerable changes in clinicians' workflow and their care delivery methods, while concurrently requiring increased patient involvement. Extant literature has highlighted the need for clinicians to adapt their care methods when implementing PROMs in diabetes care [12] and that the efficiency of using PROMs in clinical practice seems to increase in line with clinicians' and patients' understanding of why and how they are used [37]. Consequently, we suggest that more structured education and follow-up from clinic management are needed on the use of PROM questionnaires, compared with other, more easy-to-use features of the digital outpatient solution, such as the chat feature and remote consultations.

Change management, a systematic approach to managing the human elements of change [39], could inspire strategies to ensure utilization when implementing a digital outpatient solution. This approach involves a set of processes designed to guide an organization through a transition [39] and has been applied in other contexts implementing digital services [40], as well as other settings in health care services [41]. We propose that using a change management approach adapted to the specific context could facilitate future implementations of digital outpatient solutions in diabetes specialist outpatient care. However, implementing change notably often requires more time and resources than anticipated, particularly under pressure [42]. Given the increasing patient population in diabetes care [2], as well as the constraints of limited health care resources, potential implementation challenges should be considered before introducing new digital outpatient solutions in diabetes specialist outpatient care. Thoughtful consideration of potential implementation challenges and proactive planning for their resolution could enhance the likelihood of successful implementation.

Limitations

Despite providing valuable insights, this study has some limitations. The data, collected from 1 single diabetes outpatient clinic and specific to 1 particular digital outpatient solution, may not present patterns transferable to other settings or digital solutions. However, we did find that patients and clinicians were reporting similar experiences in other studies, although the content and delivery methods in their digital outpatient solutions differed [11,12,16,22]. These studies were also conducted in Scandinavian countries, providing a patient population and health care setting comparable with our study.

Another potential limitation is that some of the clinicians interviewed in this study also participated in the user involvement study previously conducted at Akershus University Hospital [23], which aimed to develop this digital outpatient solution and the care trajectory. The clinicians' involvement in the solution's development process may have influenced their attitudes and understanding of its use. This implies that not all clinicians may have had the same foundation or knowledge to utilize the solution, potentially contributing to observed variations in acceptance, utilization, and perceived clinical value. Still, this variation in clinicians contributes to bringing different perspectives with the digital solution into the study, and the findings emphasize the importance of understanding why and how such solutions are used for their effective utilization.

All patients recruited for this study had used the solution to some extent, having completed at least 1 PROM questionnaire. We chose to focus on this group to gain insight into the utilization of the different features. However, we acknowledge a limitation in that we have not considered patients who have accepted using the digital outpatient solution but have not done so for various reasons. Understanding the barriers that these patients face in using the solution could provide valuable insight, potentially helping to facilitate a smoother transition to digital follow-up for patients currently not using the solution.

Finally, as this is a qualitative study, we are gaining deep insight into how the solution is utilized in clinical practice. Although our sample size concerning the clinicians could have been larger, it still contained 96 A4 pages of transcribed data. This shows a high degree of information power [43]. However, using a mixed methods design or further investigating patients' and clinicians' acceptability and utilization quantitatively could deepen our understanding and enhance the validity and reliability of our findings.

Conclusions

This study explored the interplay between clinicians' and patients' acceptance, utilization, and perceived clinical value of a digital outpatient solution in diabetes specialist outpatient care. We identified variations in the use of the solution's features, suggesting that certain features might require greater knowledge and efforts from clinicians and patients to be utilized efficiently, particularly the use of PROM questionnaires. Our findings imply that when clinicians and patients understand why and how such solutions are used, they can enhance care efficiency and quality, contributing to sustainable health care services. We argue that an in-depth understanding of clinicians' acceptance is essential when implementing a digital outpatient solution. Furthermore, using a change management approach, adapted to the specific context, could facilitate future implementations to ensure sustainable utilization. Future research should look deeper into clinicians' and patients' acceptance, as well as use of change management strategies when implementing digital outpatient solutions in diabetes specialist outpatient care.

Acknowledgments

The authors want to thank the members of their reference group for their valuable insight into the study's development, as well as all the clinicians and patients who consented to participate. This study has received funding from Akershus University Hospital

and Oslo Metropolitan University. Sikt AI chat, a GPT technology that ensures privacy and data security [44], was used for language improvements during manuscript preparation.

Data Availability

The datasets generated in this study are available only in Norwegian, and as they are part of a larger and ongoing study, data are currently not publicly available. Please contact the corresponding author for further information. The Norwegian version of the DiabetesFlex questionnaire can be made available upon request to TS. The English version 1 is published elsewhere [13].

Authors' Contributions

All authors contributed to the study design. TS and MAM recruited the participants, and MAM conducted data collection and transcribed all the material. AT reviewed the transcripts and MAM conducted the data analysis, with ALJ, HH, and AT contributing to analytical discussions. TS and JAW ensured that the content was relevant for clinical practice. EÅ reviewed the content in light of his knowledge of digital solutions in diabetes care. MAM drafted the manuscript, and all authors reviewed and edited the content. All authors take responsibility for the final manuscript's content.

Abstract

Background: Latino adults with type 2 diabetes (T2D) have higher rates of diabetes medication nonadherence than non-Hispanic White adults. REACH (Rapid Encouragement/Education And Communications for Health) is a text message platform based on the information-motivation-behavioral skills model that addresses barriers to adherence and was shown to improve adherence and glycated hemoglobin (HbA1c) levels, but it is only available in English.

Objective: This study aimed to report the multiphase, stakeholder-driven adaptation of the REACH barriers to diabetes medication adherence content to a Latino population (REACH-Español).

Methods: This was a qualitative study using focus groups. We identified potentially eligible patients (≥18 y old, Latino ethnicity, Spanish-language preference, and T2D diagnosis) using a Mass General Brigham Hospital query. Eligible patients were invited to participate in a focus group conducted in Spanish between April 13 and November 9, 2023. A total of 5 focus groups were conducted. Focus groups 1‐3 centered on ranking 40 barriers to diabetes medication adherence (derived from REACH and the extant literature), whereas focus groups 4‐5 centered on translation and cultural modifications of the original SMS text message content associated with each of the REACH barriers. Barriers were mapped onto information-motivation-behavioral constructs. We used descriptive statistics to summarize participant characteristics. Focus groups were audio-recorded, professionally transcribed, and analyzed with thematic content analysis using NVivo (Lumivero).

Results: In total, 22 participants attended the focus groups. The mean (SD) age was 63.2 (11) years, 55% (n=10/22) were female, and the mean HbA1c level was 8.5%. All participants were born in Latin America or the Caribbean and spoke Spanish as their preferred language, and 54.5% (12/22) had completed middle-school education or less. Among the top 10 ranked barriers, 50% (n=5) corresponded to information, 20% (n=2) to social motivation, 20% (n=2) to behavioral skills, and 10% (n=1) to personal motivation. Personal motivation barriers (medication burden and fear of side effects) and behavioral skills (forgetting to take medication) emerged as important themes in the focus groups.

Conclusions: A stakeholder-driven approach to intervention adaptation identified and prioritized relevant barriers to diabetes medication adherence among Latino adults with T2D and facilitated the adaptation of the REACH platform to a Spanish-speaking population.

Introduction

Suboptimal medication adherence, generally defined as taking less than 80% of prescribed medications [1], is reported by nearly 50% of adults with type 2 diabetes (T2D) [2,3] and is associated with poor glycemic management [1,2,4] and higher risk of all-cause mortality [5]. Rates of suboptimal diabetes medication adherence are higher in racial and ethnic minority populations [6,7], particularly among individuals with lower English language proficiency [8]. An estimated 60% of Latino adults with limited English language proficiency report nonadherence to diabetes medications, compared with 52% of Latino adults with English proficiency and 38% of non-Hispanic White individuals [8]. Unique barriers to diabetes medication adherence have been reported by Latino adults with T2D [8-18], including negative perceptions regarding diabetes medication use (particularly insulin) [9,12,18], misunderstanding of the ongoing need for glucose-lowering pharmacotherapy once glycated hemoglobin (HbA1c) has improved [17], and challenges with regimen complexity even with the use of a Spanish-language interpreter [8,19]. While interventions that address patient-reported barriers to diabetes medication adherence can improve glycemic management [20,21], interventions that address barriers to diabetes medication adherence of relevance to Latino adults with T2D are lacking.

Among numerous behavioral theories that explain medication adherence behavior [22], the information-motivation-behavioral skills (IMB) model is an important theory-based model for conceptualizing and addressing domains associated with diabetes medication adherence [23,24]. The IMB model is built on three key components that influence behavior change, that are (1) information (ie, accurate knowledge about the disease and medications), (2) motivation (ie, beliefs and attitudes plus social support and social norms), and (3) behavioral skills (ie, objective and perceived abilities) [23,25]. When applied to diabetes medication adherence behavior, the IMB components allow for the identification of barriers to medication adherence in each domain [25]. Several interventions that have incorporated this model to address self-reported barriers to medication adherence have shown improvements in diabetes medication adherence and glycemic management among adults with T2D, including among Latino adults [21,23]. However, patient-centered tools for Latino adults with T2D based on the IMB model that are scalable and that do not rely on in-person educational sessions, which can be resource-intensive, do not yet exist.

REACH (Rapid Encouragement/Education And Communications for Health) is an innovative text message tool based on the IMB model that delivers text message content tailored to individual patient-reported barriers to diabetes medication adherence [21,26]. REACH delivers daily diabetes self-management 1-way texts, daily 2-way texts that ask about medication adherence, and weekly texts that provide adherence feedback and encouragement based on responses to 2-way texts. REACH was shown to improve diabetes medication adherence (by an average of one-third to one-half day per week over 12 months), reduce barriers to diabetes medication adherence (including cost-related barriers), improve dietary behavior and physical activity, and significantly reduce HbA1c at 6 months compared with usual care (0.74% reduction among patients with baseline HbA1c≥8.5%) [21]. However, despite its efficacy, scalability, and high participant engagement [27], REACH has not been adapted to other contexts. REACH could serve as an important clinical tool to address barriers to diabetes medication adherence among Latino adults with T2D. In this study, we used a multistage, stakeholder-driven, iterative method of language adaptation to adapt the original REACH barrier content to a Latino, Spanish-speaking population with T2D, focusing on identifying barriers to diabetes medication adherence of relevance to this population.

Methods

Study Design, Setting, and Participant Eligibility

We conducted a qualitative study by carrying out focus groups at the Massachusetts General Hospital (MGH) Chelsea HealthCare Center, one of the MGH Community Health Care Centers that serve a patient population in the greater Boston area that is majority Latino or Spanish-speaking [28]. Eligible participants had a T2D diagnosis (based on diagnostic codes, confirmed with electronic health record review), were ≥18 years old, were taking at least 1 glucose-lowering medication, and reported Spanish as their preferred written and spoken language. We excluded patients with auditory or communication difficulties.

Participant Recruitment

We searched the MGH Research Patient Data Registry to identify individuals who received care at MGH within the previous 2 years and who were ≥18 years old, had a diagnosis of T2D, and had registered Spanish as their preferred language. A total of 3709 patients met this criteria, of whom 500 lived in the city of Chelsea. We mailed out opt-out letters to 350 of these participants (selected randomly), followed by telephone calls to screen for the eligibility criteria described above. Among 30 eligible patients willing to participate in the study, 22 unique participants attended one of the focus groups 1 - 5. A total of 10 participants who attended focus groups 1 - 3 also attended either focus group 4 or 5. The reason for participation in multiple focus groups was to engage patients in the iterative process of content adaptation, which took place in two steps: (1) identification of barriers to diabetes medication adherence of relevance to the study population (focus groups 1 - 3) and (2) adaptation of SMS text message content addressing the relevant barriers. Enrollment occurred between March and November of 2023. Given that the original REACH content was created with input from communication experts who edited the text messages to be readable and understandable (ie, written at the

XSL•FO
RenderX

sixth-grade reading level or below) [26], the adaptation of REACH barrier content was also guided by an emphasis on reading appropriateness for the study population. Thus, for eligible patients interested in participating in the study, we conducted a health literacy screening to tailor the focus group activities to the literacy level of the study population. We used the 1-item Brief Health Literacy Screening Tool (BRIEF) questionnaire ("How confident are you filling out medical forms by yourself?"), which has been validated for Spanish-speaking populations as a quick assessment of health literacy [29].

Ethical Considerations

Participants received US $50 for focus group attendance. The Mass General Brigham Institutional Review Board approved all aspects of the study (protocol 2022P002678). At the beginning of each focus group, participants received an IRB-approved information sheet, which outlined the objectives of the study, procedures, benefits and risks, confidentiality, as well as an emphasis on voluntary participation. All participants agreed to participate in the focus groups.

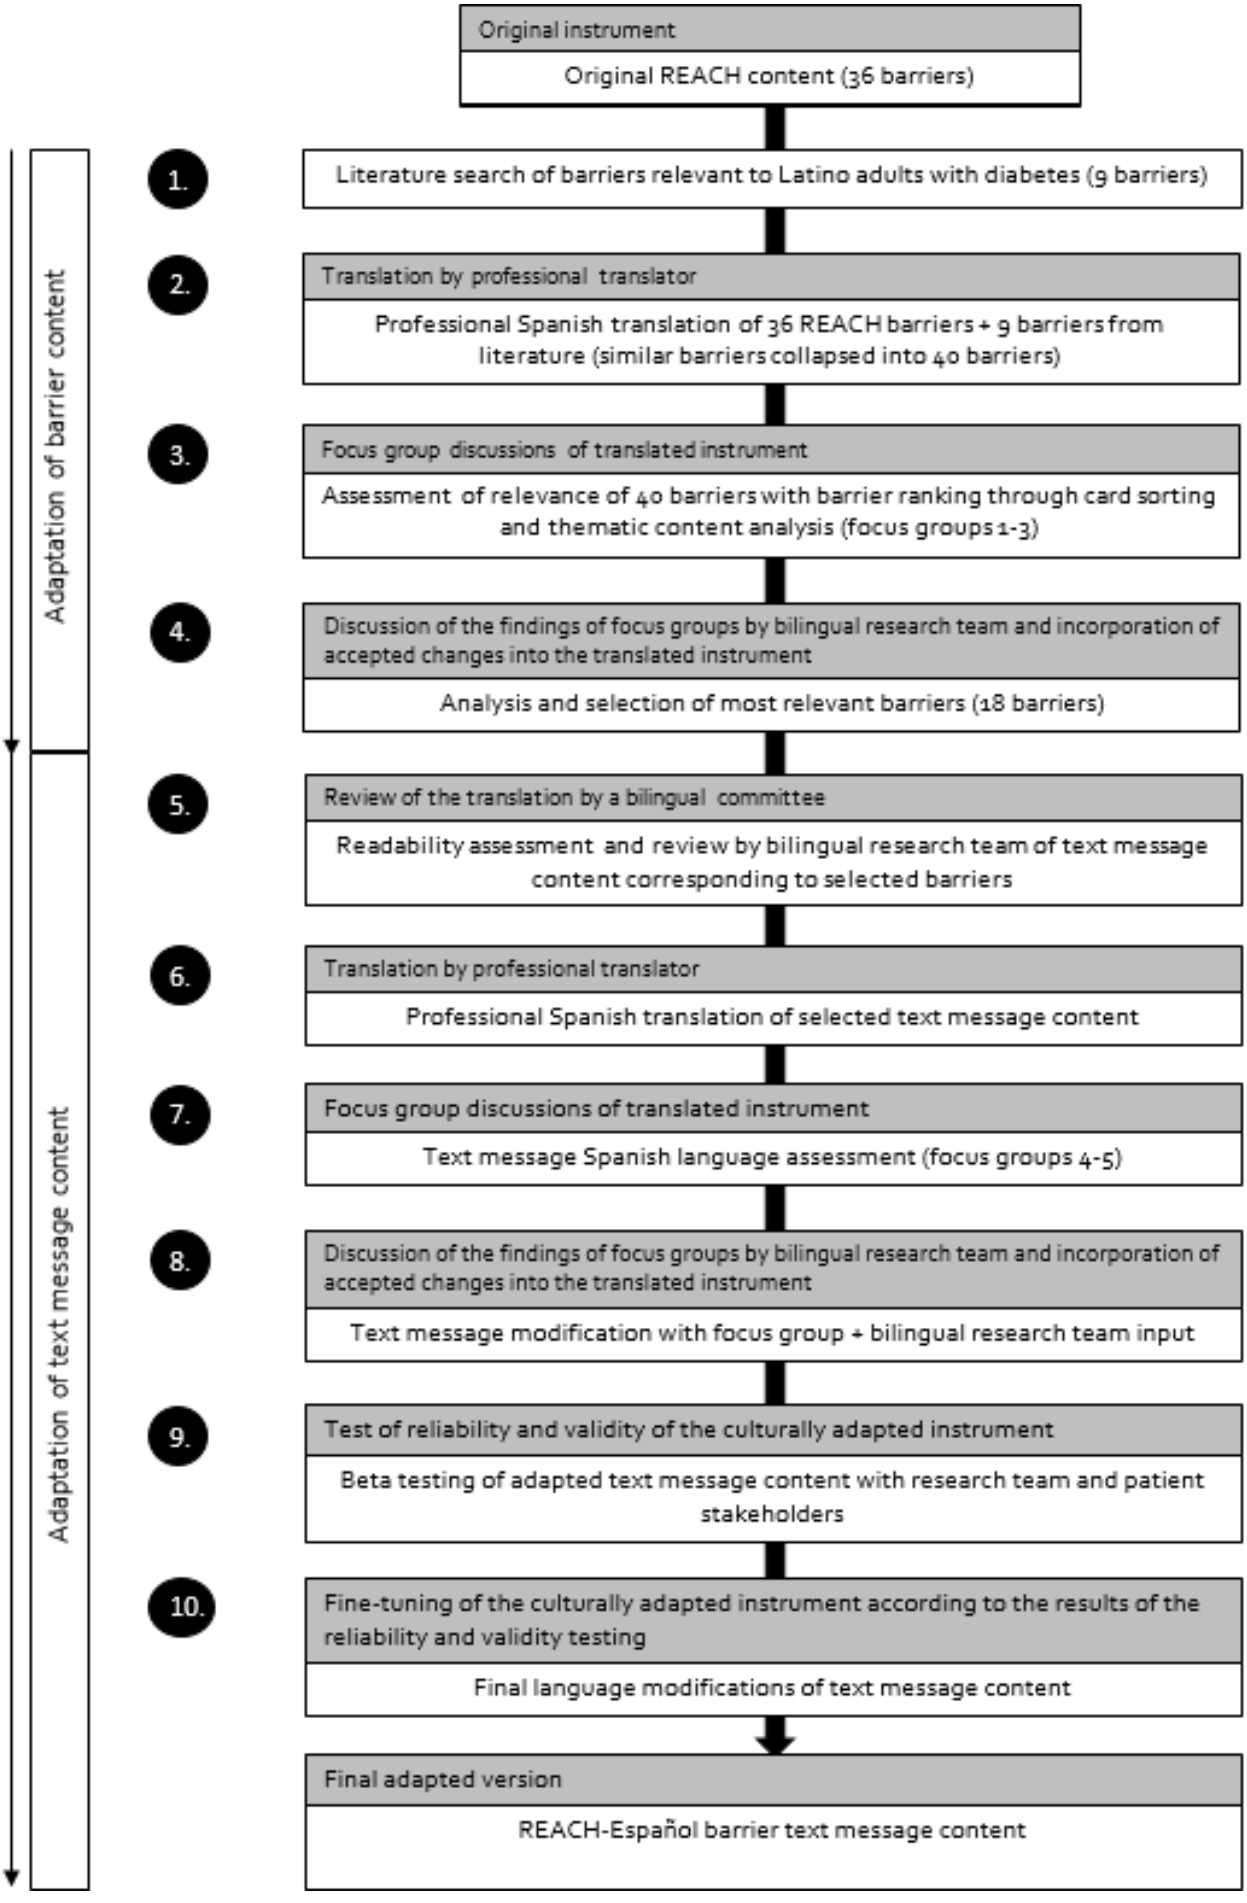
Measures

At the start of each focus group, participants were asked to fill out a sociodemographic and diabetes history questionnaire. The data that were collected through this questionnaire were age, sex, ethnicity, country of birth, preferred language, educational attainment, household income, health insurance, and diabetes history (age at diagnosis, diabetes medications, and complications).

REACH Barriers to Diabetes Medication Adherence

The development of the REACH barrier content has been described in studies by Nelson et al [25,26]. The REACH study team conducted a thorough review of published studies describing patient-reported barriers to adherence to glucose-lowering medications. The literature review yielded 68 barriers to taking oral glucose-lowering medications and 7 barriers to taking insulin; similar barriers were collapsed, resulting in 36 adherence barriers [25]. A 2-step interactive procedure was subsequently used to rank these barriers among adults with T2D. Each of the 36 barriers was mapped to the IMB constructs, and content experts drew on identified studies to develop SMS text messages addressing each barrier [26]. For instance, the barrier "My daily medicine routine is too complicated to keep track of" generated 21 SMS text messages to address this concern, such as "to help keep things simple, take your medications at the same time you're doing something else, like brushing your teeth or eating meals."

Adaptation Methodology



Description

To ensure that the REACH-Español barrier content was culturally and linguistically appropriate for the target population, we were guided by the multistage, iterative method for cross-cultural adaptation proposed by Matías-Carrelo et al [30] This multistage method relies on the linguistic review of the translated instrument by incorporating input from multiple stakeholders, including both a multinational bilingual committee composed of bilingual (English-Spanish) researchers familiar with the instrument and stakeholders from the populations being studied. This adaptation methodology aims to maintain the content, semantic, and technical equivalence. It is superior to the translation and back-translation method, which may not yield cultural equivalency of the content being translated, nor capture key sociocultural factors [30]. In this study, two groups of bilingual stakeholders reviewed the SMS text message content being translated (1) a bilingual research team and (2) focus group participants. Figure 1 summarizes the 10-step adaptation process used in this study (the Matías-Carrelo et al [30] framework is shown in gray and the corresponding adaptations in white).

Literature Review of Barriers and Translation

We conducted a systematic review of published studies describing patient-reported barriers to diabetes medication adherence in Spanish-speaking adults with T2D. We identified an additional 9 barriers relevant to Spanish-speaking adults that were not included in the original REACH barrier list (Multimedia Appendix 1). We collapsed similar barriers, resulting in 40 barriers to diabetes medication adherence with potential relevance to Spanish-speaking adults with T2D (Multimedia Appendix 2).

Barrier Translation

The 40 barriers' names were professionally translated into Spanish (Multimedia Appendix 1).

Barrier Assessment

To assess the relevance (and irrelevance) of the 40 barriers to diabetes medication adherence among Latino adults with T2D, we conducted 3 focus groups. Our screening for health literacy at recruitment showed that 33% of participants interested in attending one of the focus groups had low health literacy ("not at all" confident in filling out medical forms by yourself). Therefore, we tailored the focus group activities to a lower health literacy level by focusing on nonwritten activities and using visual props and cues to guide the discussion (Multimedia Appendix 3). We used a 2-step interactive process adapted from the original REACH barrier development process [25]. In the first activity, we encouraged an open discussion by asking participants to think about "things that make taking diabetes medications difficult" and to share these with the group; we wrote each item on a whiteboard as the discussion progressed. In the second activity, we asked participants to rank each of the 40 barriers to diabetes medication adherence referenced earlier, according to personal relevance. To make the activity easy to follow, we used a "traffic light" model of 3 colored envelopes and asked participants to place each written barrier name (eg, "I worry that taking diabetes medicines for a long time will be bad for me") into a folder, based on its relevance to them (Multimedia Appendix 3): red (never), yellow (sometimes), or green (always). Focus groups were audio-recorded and professionally transcribed in Spanish.

Barrier Analysis and Selection

Upon completion of the barrier ranking activity, barriers that were placed in the red "never" envelope received a score of 1, those placed in the yellow "sometimes" folder received a 2, and barriers placed in the green "always" folder received a 3. We then calculated the proportion of participants that reported each barrier as sometimes or always (Multimedia Appendix 4). We retained 23 barriers that were reported as relevant ≥33% of participants (mean proportion for all barriers was 32%) plus 1 barrier (regimen complexity) that emerged as an important theme in the focus groups. We then combined barriers with similar content (19 barriers) and removed 1 barrier ("I think brand name medicine works better than generic medicine") because of some recent recalls of generic glucose-lowering medications which may have affected perceptions at the time [31], resulting in 18 final barriers for REACH-Español.

Review of Existing Barrier Text Message Content

To adapt the text message content corresponding to each barrier in a Spanish-speaking population, we selected the most relevant barriers that were identified in focus groups 1 - 3. We reviewed the original REACH text message English content corresponding to each of the selected barriers and conducted a readability check of each text message using the Flesch-Kincaid readability grade level test, ensuring that the language used was grade 6 or lower.

Text Message Content Translation

The text message content corresponding to each of the 18 barriers was professionally translated into Spanish.

Text Message Spanish Language Assessment

To ensure that the Spanish text message content was culturally and linguistically appropriate for the target population, we invited the same group of participants that attended focus groups 1 - 3 to attend 1 of 2 additional focus groups (focus groups 4 - 5). To solicit participant feedback in the focus groups, we projected each text message on a Microsoft PowerPoint presentation and gave each participant a green ("Yes) and a red ("No") paddle (Multimedia Appendix 5). We asked participants to approve or disapprove of messaging according to ease of understanding by raising the paddle when each text message was projected and read aloud. We discussed messages that received "No" votes.

Text Message Content Modification

Following the completion of focus groups 4 - 5, we excluded text messages not well-received by participants (not relevant, tone did not resonate). Then, our bilingual research team modified specific language based on participant feedback, with a focus on selecting language that was more broadly understood by Spanish-speaking participants from diverse geographic and cultural backgrounds with distinct dialects. Focus groups were audio-recorded and professionally transcribed in Spanish.

Beta Testing

The revised text message content was sent to our digital health partner, MEMOTEXT, which will deliver the text messages to participants in the pilot study of REACH-Español. To ensure that the text message content delivery worked as intended and to subject the content to one more round of language modification, we conducted beta testing of the text message content. Beta testing entailed having the research team members as well as 3 patient stakeholders (participants who attended focus groups 4 or 5) receive and interact with the REACH-Español text message content over the course of 4 weeks. All members of the beta testing process provided input on a weekly basis on either technical or linguistic aspects that required modification. Patient stakeholders provided their impression of the program via an exit interview.

Fine-Tuning

Throughout the beta testing process, we identified several technical issues, mostly pertaining to the sent time of the text messages (ie, too close to bedtime, welcome text message sent after content message). MEMOTEXT revised the platform throughout the beta testing process based on user feedback.

XSL•FO
RenderX

After all user input was incorporated, a final version of the REACH-Español text message content was created.

Analysis

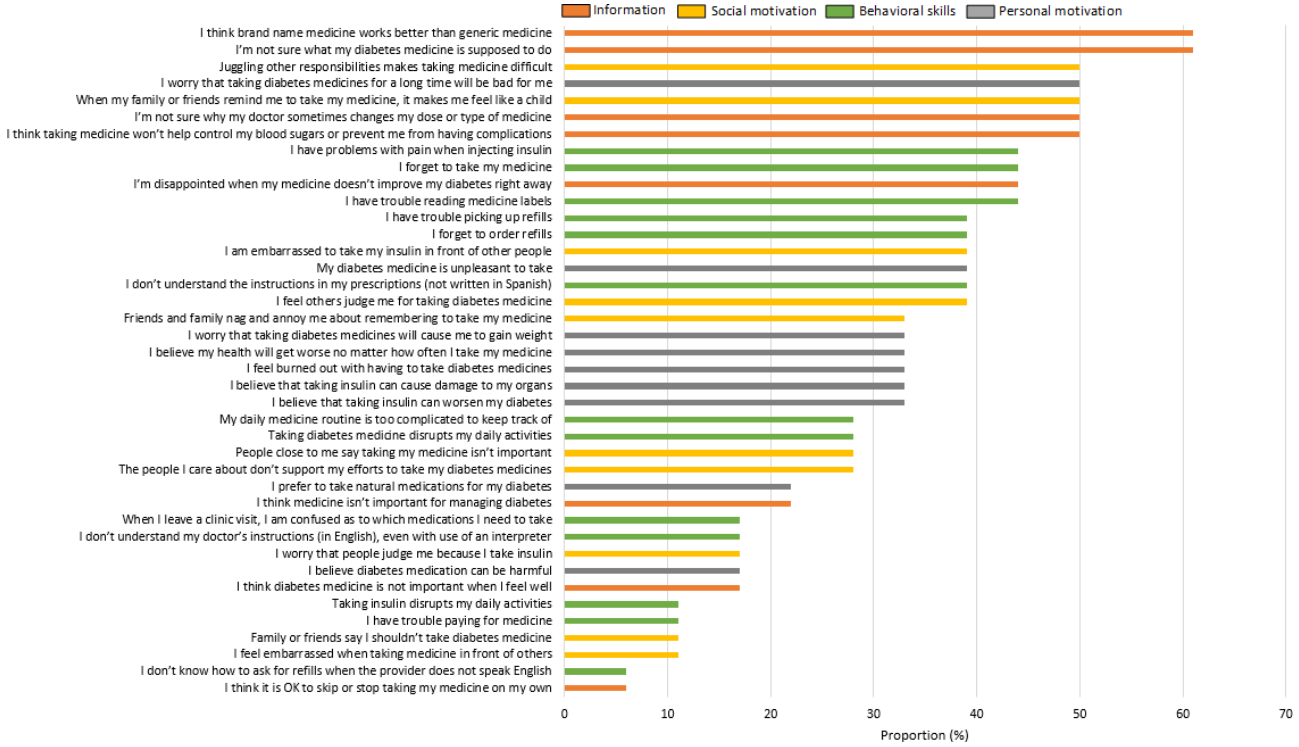
We used descriptive statistics (means, SDs, and proportions) to summarize participant characteristics. For the qualitative analysis, an "open-coding" approach (inductive) was used first to identify themes in the transcripts (in Spanish) from focus groups 1 - 3. Themes were then categorized as barriers and facilitators to diabetes medication adherence. Second, we used deductive coding to map the codes into the IMB construct. Coding was conducted by native Spanish-speaking research team members. Analyses were conducted using Microsoft Excel and NVivo 14 (Lumivero).

Results

Focus Group Participants

A total of 22 participants attended focus groups 1 - 5. The first 3 groups were attended by 18 participants; 10 of these participants also attended either focus group 4 or 5. Table 1 summarizes the demographic and clinical characteristics of the study participants. The mean age was 63.2 (SD 11) years, 55% (10/22) were female, 59% (13/22) were categorized as having high health literacy (based on the 1-item BRIEF questionnaire), although 55% (12/22) reported an educational attainment of elementary or middle school only. Over two-thirds (16/22 73%) of participants were born outside of the United States, largely in Central America. Participants had a mean (SD) diabetes duration of 20.3 (12) years. In addition, 59% (13/22) of participants reported insulin use.

Table . Characteristics of the focus group population.



Characteristic	Overall (n=22)
Age (y), mean (SD)	63.2 (11)
Sex (female), n (%)	10 (55)
HbA_{1c}, mean (SD)	8.5 (1)
HbA_{1c}<7%, n (%)	2 (9)
HbA_{1c}>7%, n (%)	20 (91)
Age at diabetes diagnosis (y), mean (SD)	44.2 (13)
Diabetes duration (y), mean (SD)	20.3 (12)
Number of diabetes medications, mean (SD)	2.9 (1)
Insulin use, n (%)	13 (59)
Health literacy quintile, n (%)

Barrier Selection

Multimedia Appendix 2 shows the list of 40 barriers to diabetes medication adherence that were assessed for relevance in focus groups 1‐3. Barriers are shown in order of higher to lower proportion of participants reporting each barrier as relevant sometimes or always. Figure 2 shows the list of 40 barriers, categorized into the IMB model and ranked according to the proportion of participants who reported the barrier as relevant sometimes or always. Among the top 10 barriers, 50% (n=5) corresponded to the information category, 20% (n=2) to the social motivation category, 20% (n=2) to behavioral skills, and 10% (n=1) to personal motivation.

Figure 2. Proportion of participants who reported each diabetes medication adherence barrier as relevant sometimes or always (barriers were shortened to improve readability, please refer to Multimedia Appendix 4 for full barrier wording).

Barriers to Diabetes Medication Adherence Based on Thematic Analysis

Table 2 outlines the key themes that emerged in focus groups 1‐3 based on participant quotes, grouped into barriers to diabetes medication adherence, and mapped into the IMB model. In total, 5 themes emerged in response to the question "What are some difficulties that come to mind when taking your diabetes medications?" In order of relevance (higher or lower number of times mentioned), most participants agreed that medication burden was one of the most important barriers to diabetes medication adherence, followed by fear of side effects or of new medication, difficulty or confusion with medication changes, forgetting to take medications, and frustration with diagnosis or lack or improvement.

XSL•FO
RenderX

Table . Diabetes medication adherence barriers reported by focus group participants (what are some difficulties that you encounter when taking your diabetes medications?).

Barriers to diabetes medication adherence: What are some difficulties that you encounter when taking your diabetes medications?			
Themes	Participant Quotes	IMB[a] category	Existing REACH[b] barrier
Medication burden			
Too many medications and exhaustion with taking medications daily	"It's not difficult to take medications, it's just that we are disgusted by having to take so many medications." (Female, 62 y old, El Salvador) "I am exhausted with having to take medications every day." (Female, 45 y old, Guatemala) "Sometimes I don't want it….there is a rejection, a rejection [of the medication]." (Female, 45 y old, El Salvador)	Personal Motivation	I feel burned out with having to take diabetes medicines
Interferes with daily activities	"Yes, [it interferes] with daily chores…if the next dose is close enough, then I skip it and inject the following dose."(Male, 63 y old, El Salvador). "Well, sometimes it's very difficult to wake up, knowing that you won't be drinking a cup of coffee with bread, but something else, to take the diabetes pills." (Female, 74 y old, Puerto Rico)	Social Motivation	Taking diabetes medicine disrupts my daily activities/ Taking insulin disrupts my daily activities
Regimen complexity	"It's very difficult because I take ten medications in the morning and eight at night." (Male, 63 y old, El Salvador). "In my case, I have to take two pills in the morning and two at night…and the daytime ones, I can't get used to taking them. I take all four at night." (Male, 63 y old, El Salvador)	Behavioral skills	My daily medicine routine is too complicated to keep track of
Juggling other responsibilities	"I have difficulty taking the medications because I start working at 7AM, so if I am late for work I don't take any medications until my break time, around 10am…and then the other medications I take at 9PM, when I come back from work." (Female, 45 y old, Guatemala)	Social Motivation	Juggling other responsibilities makes medicine difficult
Fear of side effects or of new medications			
Low blood sugars	"And there are times when it [blood sugar] drops suddenly and it gives me anxiety to find something to eat because I feel like as he [other participant] mentioned, tremulous, it's horrible." (Male, 56 y old, Guatemala)	Personal Motivation	N/A[c]
Side effects	"Perhaps I will not feel it now but I will feel it [side effects] over time." (Male, 65 y old, Guatemala)	Personal Motivation	I worry that taking diabetes medicines for a long time will be bad for me
New medications	"You are taking a risk, if you take the medication, it alleviates something but it will damage something else." (Female, 63 y old, Puerto Rico)	Information	N/A

XSL•FO
RenderX

Barriers to diabetes medication adherence: What are some difficulties that you encounter when taking your diabetes medications?			
Themes	Participant Quotes	IMB[a] category	Existing REACH[b] barrier
Organ damage	"Because you know that there are medications that damage the kidneys and then the doctor tells you, I'm sorry, it was the medication [that caused the kidney damage], so you live in fear." (Female, 71 y old, Puerto Rico)	Personal Motivation	I believe diabetes medication can be harmful.
Difficulty or confusion with medication changes			
Medication changes	"I had a problem with the insulin because, I mean, my sugar was very high so the doctor said 'we are going to do an experiment,' they did an experiment with me that they put me until a certain level and that's where it [the dose] remained." (Male, 65 y old, Guatemala) "Because they have me like a guinea pig, like playing with me, making experiments…sincerely don't know what to do." (Male, 56 y old, Guatemala)	Information	I'm not sure why my doctor sometimes changes my dose or type of medicine
Medication instructions	"Í would leave [the clinic] and would write down the [medication] changes but then I would lose the paper…so I wouldn't know if I had to put 35 [units] in the morning or 38 in the afternoon…and since I had a visit every 3 mo, I would suffer very much." (Male, 77 y old, Guatemala)	Information	When I leave a clinic visit, I am confused as to which medications I need to take
Forget to take medications			
	"In reality, it's not difficult to take the medications…the problem is that I forget to take the medications because of my age." (Male, 77 y old, Guatemala) "Yes, I have one difficulty in taking my medications. That is, I am very forgetful." (Male, 54 y old, El Salvador)	Behavioral skills	I forget to take my medicine
Frustration with diagnosis or lack of improvement			
Treatment doesn't work	"At times I feel very frustrated because so many medications that you are taking and the sugar does not go down….that puts me depressed." (Female, 62 y old, El Salvador)	Information	I'm disappointed when my medicine doesn't improve my diabetes right away
Difficulty accepting diagnosis	"I have diabetes since the last two years. I come from a family with diabetes. I got divorced and in the process, the diabetes appeared. So, I started taking the metformin because I didn't want to accept it. It was something very hard and I have difficulty accepting it." (Female, 45 y old, Guatemala)	Personal motivation	N/A

Facilitators to Diabetes Medication Adherence Based on Thematic Analysis

Multimedia Appendix 6 shows the 5 themes that emerged in response to the question, "What motivates you to take your diabetes medications." In order of relevance (higher to lower), fear as motivation was an important facilitator, followed by belief in treatment benefit, personal responsibility, and will to take medications, family support and medication organization, and getting used to the medication.

Language Modification of Text Message Content

Focus groups 4 - 5, which centered on eliciting feedback on the translated text message language content, generated rich discussion. A total of 111 text messages (related to barriers 1 - 8) were reviewed in focus group 4 and 100 text messages (related to barriers 9 - 18) were reviewed in focus group 5. Participants were generally enthusiastic about the text message content and provided feedback on wording that seemed confusing, too complex, or less likely to be understood by broad Spanish-speaking audiences. For instance, the word "comprimidos" was changed to "pastillas" and the preferred word for refills was "reposiciones" instead of "prescripciones." In total, 12 messages were excluded since patients did not like the tone, felt that they were difficult to understand, or felt that they were not relevant. Some examples of these excluded text messages included "If taking your diabetes medications is unpleasant, try to push through. Remember that not taking them may make you feel worse" and "What advice would you give your friends who forget to refill their medications? Use those tips for yourself too!"

Beta Testing Patient Stakeholder Input

In the final step of REACH-Español content adaptation, 3 patient participants who had attended one of the focus groups were invited to participate in the beta testing process over the course of 4 weeks. At the end of beta testing, the following patient stakeholder input was provided:

> *The texts are very important because when you are old, you know things from experience, but you forget things that are important. Like that the test strips need to be in a hermetically sealed box. The text messages are very helpful with remembering to take the medications. [Male, 77 years old, Guatemala]*

> *The texts are helping to remind me to take my medications. When I look and I see the message [any of the messages], I run to take my medication. The texts are very clear. It's really helping me. [Female, 45 years old, Guatemala]*

> *The content is helpful. For example, learning about what food to eat to raise a low blood sugar. It's helping to remind me to take my medications. I think this program is best for older people who have the time and attention to follow the advice. [Male, 63 years old, El Salvador]*

Discussion

Principal Findings and Comparison With Previous Works

In this study, we outline the multistage process used to adapt the REACH text message content [26], which addresses patient-reported barriers to diabetes medication adherence, to a Latino population. The adaptation process centered on the theory-based IMB skills model for medication adherence and engagement of patient stakeholders to identify barriers to diabetes medication adherence with specific relevance to Latino adults with T2D (with Spanish-speaking preference). We found that among the top 10 most commonly reported barriers to diabetes medication adherence among Latino adults with diabetes, 50% (n=5) corresponded to information gaps, 20% (n=2) to social motivation, 20% (n=2) to behavioral skills, and 10% (n=1) to personal motivation. In contrast, our thematic analysis showed that personal motivation barriers (medication burden and fear of side effects) were the highest concern for focus group participants, followed by behavioral skills (forgetting to take medications), and information barriers (difficulty or confusion with medication changes and frustration with diagnosis or lack of improvement). These findings suggest that using the IMB model as a framework to identify barriers to diabetes medication adherence is useful in this population and that different qualitative approaches (open discussion vs ranking exercise) can provide complementary data to inform the adaptation process of tailored interventions.

By engaging focus group participants in an interactive barrier ranking exercise conducted through card sorting, we were also able to select highly relevant barriers to diabetes medication adherence and exclude those with lower salience from the study.

XSL•FO
RenderX

Through this exercise, we found that the priority of some barriers differed in this population compared with the original REACH intervention. For instance, "I'm not sure what my diabetes medicine is supposed to do" was reported as relevant by 61% (11/18) of participants in this study, whereas this barrier was relevant only for 16% (38/237) of participants in the REACH development study [25]. Similarly, "I am not sure why my doctor sometimes changes my dose or type of medicine" was relevant to 50% (9/18) of participants in this study, whereas only 15% (36/237) of participants in the REACH development study reported that this barrier was relevant. These findings underscore the importance of stakeholder-driven adaptation approaches given that core intervention components (in this case, the list of barriers), differed across populations.

We also found that the iterative process of translating and modifying the original intervention content with stakeholder input (bilingual research team, focus group participants) enriched the adaptation process by incorporating language diversity and nuance. By eliciting input from participants through interactive focus group activities, we were able to capture both the thematic and linguistic or cultural relevance of the content being translated. For instance, we excluded certain text messages that did not resonate with the audience. We revised the language with modifications considered more broadly understood across Spanish-speaking Latin American and Caribbean populations. Choosing language wording with a broader reach was particularly important in this study given the heterogeneity of the Spanish language across Latin America and the Caribbean. Our observations are consistent with previous studies that have highlighted the importance of engaging bilingual stakeholders (including patients) throughout the language adaptation process [30,32,33].

Although barriers to diabetes medication adherence have been previously reported in the Latino population [8,10,11,17,19,34], most studies have not used a theoretical framework to identify such barriers. The IMB model has been empirically validated as a framework to identify barriers to diabetes medication adherence [23], but only 1 intervention based on the IMB model has documented its use in Latin American adults with diabetes [35]. Our study supports the use of the IMB framework to better ascertain barriers to diabetes medication adherence among Latino adults, which can be helpful in the development of interventions to address these barriers. Our qualitative analysis also highlights the importance of treatment complexity in this patient population and underscores the need for interventions that can identify and reduce treatment burden and regimen complexity. Although these challenges to diabetes self-management have been well described [36-39], scalable interventions that can reduce the treatment burden are lacking, particularly in the Latino population.

Digital health technology can improve diabetes medication adherence behavior [21,40] and HbA1c [21,40,41] and is recommended by the American Diabetes Association to support diabetes self-care [42]. However, among the 90 (approximately) digital health apps currently available for diabetes self-management, only one-third are available in Spanish, of which 94% (90/96) have a readability level above that recommended for patient education material [43]. Some digital medication adherence support platforms are currently under study in Latino and Spanish-speaking populations [44,45]. However, none of these platforms provide educational content tailored to patient-reported barriers to diabetes medication adherence. The REACH-Español platform adapted in this study offers this key innovation, in addition to health literacy–informed content, which could facilitate broader engagement of prospective participants and long-term medication adherence.

Our study has the key strength of having adapted an intervention with iterative input from stakeholders who could be representative of the population most likely to use the intervention. This user-centered approach is recommended in diabetes digital health research [46,47] to ensure that end user perspectives are represented in the development of interventions and content is tailored to user needs. However, our study also has several limitations. First, the sample size was relatively small, although we achieved thematic saturation for barrier selection after conducting 3 focus groups. Second, we recruited participants from a single health center and did not have representation from every Latin American and Caribbean country, which could limit the generalizability of our findings. In addition, although the barriers to diabetes medication adherence selected in this study were based on relevance to the focus group participants, the order of relevance may differ in other Latin American populations living elsewhere in the United States or with a different insulin usage profile. For instance, "I have trouble paying for my medicine" was not a highly ranked barrier but this may be an important barrier in other areas of the country with lower insurance coverage. Thus, should the REACH-Español content be adapted to other contexts, using the IMB model to identify population-specific barriers could be helpful. Finally, the focus of this study was to adapt the barrier-specific text message content. While text message content pertaining to diet and physical activity was directly translated from English to Spanish, the content did not undergo the stakeholder-driven adaptation process described here, which will be the subject of a future study.

Conclusions

In this study, we report the multiphase, stakeholder-driven adaptation of the REACH digital health platform text message content, which addresses barriers to diabetes medication adherence, to a Latino population with T2D. We found key barriers to diabetes medication adherence that were relevant to this population, largely related to information gaps. These findings can contribute to the fields of patient-important outcomes and treatment burden to guide respectful and meaningful patient engagement in the management of T2D. Furthermore, engaging a diverse group of bilingual stakeholders (bilingual research team, focus group participants) early and throughout the iterative adaptation process was integral to ensuring content and linguistic relevance of the text messages in the REACH-Español platform. The feasibility, acceptability, usability, and preliminary efficacy of REACH-Español is under study in a 6-month pilot randomized controlled trial, which could broaden our understanding of the role of tailored, digital health interventions on improving diabetes self-care among Latino adults with T2D.

Abstract

Background: Digital health education can enhance the quality of life of patients with heart failure by providing accessible and tailored information, which is essential for effective self-care and self-management.

Objective: This work aims to develop a mobile health knowledge transfer concept for heart failure in a user-centered design process grounded in theoretical frameworks. This approach centers on enhancing the usability, patient engagement, and meaningfulness of mobile health education in the context of heart failure.

Methods: A user-centered design process was employed. First, semistructured stakeholder interviews were conducted with patients (n=9) and medical experts (n=5). The results were used to develop a health knowledge transfer concept for a mobile health app for heart failure. This concept was implemented as a digital prototype based on an existing German mobile health app for patients with heart failure. We used this prototype to evaluate our concept with patients with heart failure in a study composed of user testing and semistructured patient interviews (n=7).

Results: Stakeholder interviews identified five themes relevant to mobile health education: individualization, content relevance, media diversity, motivation strategies, and trust-building mechanisms. The evaluation of our prototype showed that patients value the adaptation of content to individual interests and prior knowledge. Digital rewards such as badges and push notifications can increase motivation and engagement but should be used with care to avoid overload, irrelevance, and repetition.

Conclusions: Our findings emphasize the importance of tailoring mobile health education to the specific needs and preferences of patients with heart failure. At the same time, they also highlight the careful implementation of motivation strategies to promote user engagement effectively. These implications offer guidance for developing more impactful interventions to improve health outcomes for this population.

Introduction

In 2019, heart failure affected more than 56 million people worldwide [1]. The diagnosis of heart failure entails severe health consequences for patients and significant financial resources for public health systems [2]. In light of an aging population, heart failure is becoming increasingly important in society and requires new approaches for prevention, management, and therapy to mitigate health impact [3,4].

Heart failure requires a high level of active patient involvement [5]. Self-monitoring of physiological parameters, medication intake, nutrition, and physical activity are crucial factors in preventing the hospitalizations of patients [6,7]. In this context, health literacy plays a major role since high levels of health literacy in patients with heart failure promote patient empowerment, self-care practices, and medication adherence [8-10]. Health literacy can be described as the capacity of a person to access and understand health-related information, place it in context, and use it responsibly to promote and

XSL•FO
RenderX

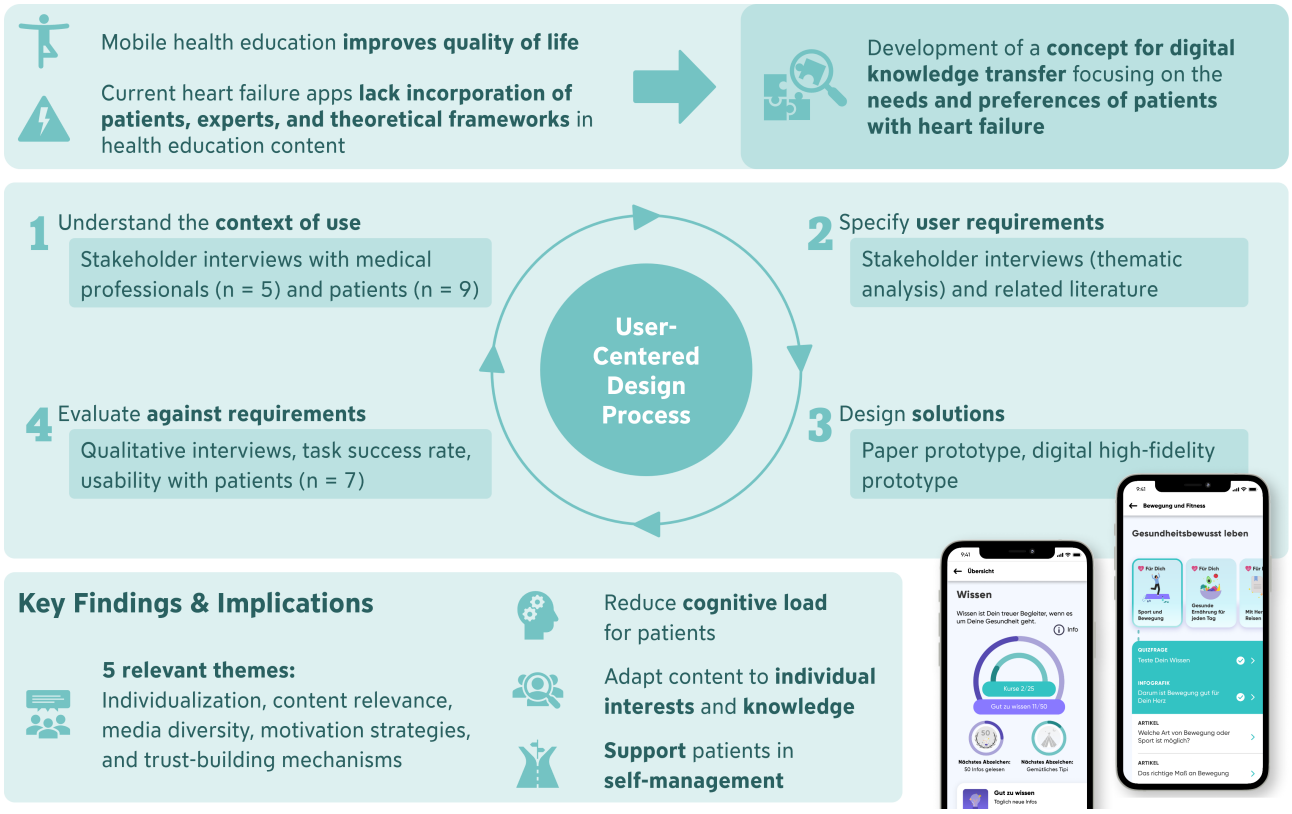
maintain good health [11]. With a focus on heart failure and other cardiovascular diseases, The American Heart Association concludes that health literacy is crucial for effective treatments for cardiovascular diseases and acknowledges information technology as a potential path to improving health literacy [12]. In the long-term, low health literacy is associated with an increased risk for hospitalizations and death in patients with heart failure [13].

To effectively deliver information to patients and achieve learning effects, mobile health technology offers great potential. This applies to populations with low health literacy in particular [14-16]. As smartphone access has become widespread across various demographic groups, including those with lower socioeconomic status, they provide an accessible platform for delivering tailored health interventions to underserved populations [17,18]. Enhancing health literacy requires attention not only to disease-specific content but also to digital health literacy, empowering users to navigate health-related inquiries online effectively [14,19,20]. However, several barriers have been identified, including the access to apps, the readability of content as well as the usability of digital health services [14,21]. In the context of heart failure, evidence about the effects of mobile health for promoting health literacy is still limited. Allida et al identified no increase in heart failure knowledge through digital educational content and unclear evidence on self-efficacy, self-care, and health-related quality of life [22]. In contrast, several recent studies demonstrated positive effects on quality of life, hospitalization rates, and self-management abilities [23-25]. However, despite the potential benefits, these approaches lack the incorporation of theoretical frameworks for engaging, appealing, and effective knowledge transfer. Furthermore, patients with heart failure are hardly involved in the development process of mobile health interventions.

Thus, the aim of this work was to develop a concept for a sustainable and engaging knowledge transfer with a specific focus on the needs and preferences of patients with heart failure. Theoretical frameworks for mobile health knowledge transfer and the involvement of end-users throughout the design process build a strong foundation for an engaging, user-friendly, and effective mobile health intervention. A digital prototype served as a tangible representation of our concept, which we evaluated with patients with heart failure.

Methods

Study Design Overview



The foundation of this work was the user-centered design process, a common method in interaction design [26]. It emphasizes the involvement of the potential end-users throughout the developmental phases to ascertain that the resulting concepts align with their needs, preferences, and experiences of the target group. This iterative approach often incorporates techniques such as user interviews, focus groups, prototyping, and usability testing to refine the design based on continuous feedback. The graphical abstract (Figure 1) provides an overview of the methodology used.

First, we used current literature and semistructured qualitative interviews to understand the context of use and derive requirements. Based on the findings, possible design solutions were drafted as a paper prototype. Thereafter, a digital high-fidelity prototype was implemented. This digital prototype was then evaluated in a study focusing on the identified requirements of the target group.

The exemplary app we used for the prototype design is the ProHerz app (ProCarement Gmbh, Germany), a medical-grade mobile app for heart failure. This app is intended to support patients in managing their health by tracking vital signs and medication intake. Additionally, the company provides a ‘CareCenter,’ where, depending on the product used, medical experts regularly monitor the patients’ health parameters and stay in personal contact via messages and phone calls.

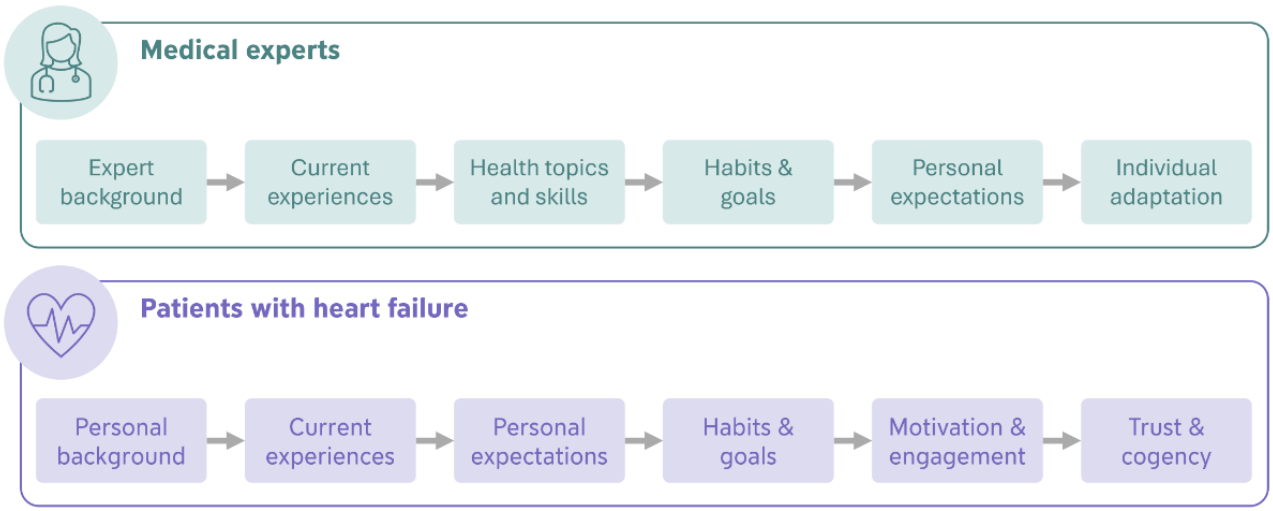
Stakeholder Interviews

Recruitment

Qualitative semistructured interviews were conducted with patients (n=9) and medical experts (n=5). This approach is a flexible data collection method that combines predefined questions with the freedom to explore emerging topics to further enhance the understanding of participants' experiences and perspectives [27]. All patients were recruited from the ProHerz user base. Thus, all were patients with heart failure and previous experience with the ProHerz app. We chose this group because of their experience using a mobile health app for self-management. To allow for meaningful comparisons of feedback, our recruitment strategy aimed to include participants with varying levels of experience using the ProHerz app, aligning with best practices in end-user and usability testing. Medical experts were recruited through ProCarement, where they interact with the ProHerz users in their daily work. All experts were nurses with long-term experience in heart failure care. Their close exchange gives them a broad perspective on patients' characteristics, needs, and skills.

Procedure

The interview guidelines were based on our research aims and current literature. Both stakeholder interviews covered similar aspects (Figure 2). The guidelines aimed to identify patients' specific needs and requirements regarding content and features within a mobile health knowledge transfer.



The interviews with the medical experts targeted explicitly at their perspective on essential knowledge and skill requirements that should be covered in a mobile health knowledge transfer concept. Besides, specific features, content presentation, and adaptation strategies for individual patient needs were discussed.

In the patient interviews, we inquired about experiences with specific features, their current interactions with the ProHerz app, and their expectations regarding knowledge transfer within a mobile health app designed for heart failure. Furthermore, the interviews included discussions on patients' health-related routines and goals and identifying requirements for trust-building and cogency. Additionally to the interview, patients were asked to complete the European Health Literacy Survey Questionnaire (EU-HLS-Q16) to assess their health literacy level [25,26]. Through this tool, participants rate general tasks related to health literacy based on their level of difficulty.

All interviews with medical experts were conducted via Microsoft Teams. Patient interviews were conducted in person.

XSL•FO
RenderX

Figure 2. The topics included in the interview with both stakeholder groups.

Prototype Development

The development of the knowledge transfer concept was based on the findings from the interviews and related literature.

We incorporated the framework of Riegel et al to structure the topics [28]. The content categories in the prototype are oriented toward the three self-care processes for heart failure: maintenance, symptom perception, and management. Information in the prototype was structured based on the principles for effective e-learning by Clark and Mayer and the recommendations for designing health-literate mobile apps by Broderick et al [29,30]. This included, for example, dividing information into manageable units, using different types of media, and writing in a conversational style.

Additionally, we considered possible cognitive limitations of users in the context of heart failure [22,31-34]. According to the Cognitive Load Theory, a reduction of cognitive load is able to improve learning outcomes. The theory describes three types of cognitive loads in the context of learning: intrinsic, extraneous, and germane cognitive load. We aimed at reducing the extraneous cognitive load by simplifying navigation, avoiding unnecessary elements, and ensuring a clear, uncluttered interface design. The intrinsic load was managed by sequencing information into smaller units aligned with the complexity of topics. The germane load was supported by including interactive elements such as quizzes or visual aids, encouraging active engagement.

Personalizing health education to address individual needs has been shown to improve health outcomes in areas such as physical activity, nutrition, and adherence to screening recommendations [35]. In the context of health education for heart failure, users face unique challenges through varying levels of health literacy and cognitive impairments [13]. As such, a personalized approach that takes relevant individual factors into account can meet diverse needs of patients, ensuring information is both accessible and relevant [22]. For this reason, we decided to incorporate the possibility of adapting the contents based on a short survey participants answered in the beginning.

The derived themes of the interviews were brought together with findings from the health literacy assessment that additionally revealed the needs of patients. We drafted a workflow for the mobile knowledge transfer and implemented this as a low-fidelity paper prototype.

For the first usability test, we embedded the paper prototype in Useberry (Useberry User Testing Technologies IKE, Greece). Useberry is a tool to test the usability of the paper-based prototype digitally. We aimed to find usability issues as early as possible in our design. For this initial testing, we invited healthy participants through personal contact. At this stage, the priority was gathering quick insights from users who were familiar with mobile apps to identify basic usability issues before moving on to the larger-scale user testing with patients with heart failure. This reduced the burden and required time and effort of the actual patients. Test users (n=5) were asked to perform different navigation-related tasks within the prototype. Outcome measures were the task completion rate and the recorded clicks.

After this initial usability testing, the paper prototype was then transferred into a digital high-fidelity prototype using Figma (Figma GmbH, Germany). This prototype included an example questionnaire for individualizing the information content based on the date of diagnosis, implanted devices (pacemaker and defibrillator), smoking habits, topics of interest, the preferred media formats and the New York Heart Association (NYHA) functional class (Figure 3). The NYHA classification is a commonly used system for categorizing the severity of heart failure based on physical activity limitations caused by cardiac symptoms. It ranges from Class I (no limitations) to Class IV (highest limitations) [36]. After the questionnaire, the basic landing page of the app was presented with an additional link to the health knowledge section. The main part of our prototype was the knowledge section with an overview and link to the available courses and the short information messages. Additionally, badges for learning-related achievements can be found there. Finally, an example course was implemented on the topic of sports and exercise (Figure 4).

Concept Evaluation

Recruitment

For evaluating the knowledge transfer concept, we recruited patients with heart failure (n=7), who were already experienced in using a mobile health app. Therefore, all participants were recruited from the user base of ProCarement. Four participants already took part in the previous stakeholder interviews conducted as part of this study.

XSL•FO
RenderX

Procedure

After being instructed about the study procedure, participants were asked to complete 11 tasks with the digital prototype. Due to feasibility reasons, patients accessed the prototype on a computer interface. This approach allowed participants to interact with the app more comfortably during the evaluation, while also enabling researchers to observe user interactions in detail and collect qualitative feedback efficiently. Tasks included small, simple tasks and more complex, time-consuming tasks. An overview of all tasks is listed in Table 1. Afterwards, semistructured interviews were conducted to obtain the participants' overall impression and to identify features and characteristics that have the potential to improve engagement and increase health literacy.

Table . Tasks given to participants in the evaluation of the digital prototype of the health knowledge transfer concept.

No.	Description
1	Navigate to the questionnaire for individualization
2	Complete the questionnaire for individualization
3	Navigate to the knowledge section
4	Navigate to informative notifications, read the first unread notification
5	Navigate to the educational courses
6	Navigate to the course category 'symptoms'
7	Navigate to completed courses
8	Select a course within a course category
9	Navigate to recommended courses and select a recommended course
10	Complete one educational course
11	Navigate to the overview of badges

Analyses

All qualitative data obtained during interviews were analyzed using thematic analysis based on the approach of Braun and Clarke [37]. This method involves identifying, analyzing, and reporting patterns (themes) within the data, allowing for a rich and detailed interpretation of the participants' experiences and perspectives. The process includes familiarizing oneself with the data, generating initial codes, searching for themes, reviewing themes, and defining and naming them to ensure a comprehensive understanding of the qualitative insights.

Ethical Considerations

All presented substudies were approved by the institutional review board of the Friedrich-Alexander-Universität Erlangen-Nürnberg (approval no. 22 - 233-S), and we obtained written informed consent from all participants. The collected data were pseudonymized after collection to ensure participant confidentiality and data protection.

Results

Stakeholder Interviews

Demographics

The stakeholder interviews with patients and medical experts were conducted in August 2022. We recruited 9 patients with a mean (SD) age of 67 (7) years. Patients received their diagnosis between 15 and 3 years prior to this study. All patients were using the ProHerz app for at least 4 months (Table 2). Seven identified as women, and 2 identified as men. Additionally, 5 medical experts were recruited (Table 3) with work experience between 6 and 11 years.

Table . Characteristics of patients with heart failure included in the stakeholder interviews.

Interviewee ID	Age (y)	Identified as	Years since heart failure diagnosis	Months of app experience with ProHerz

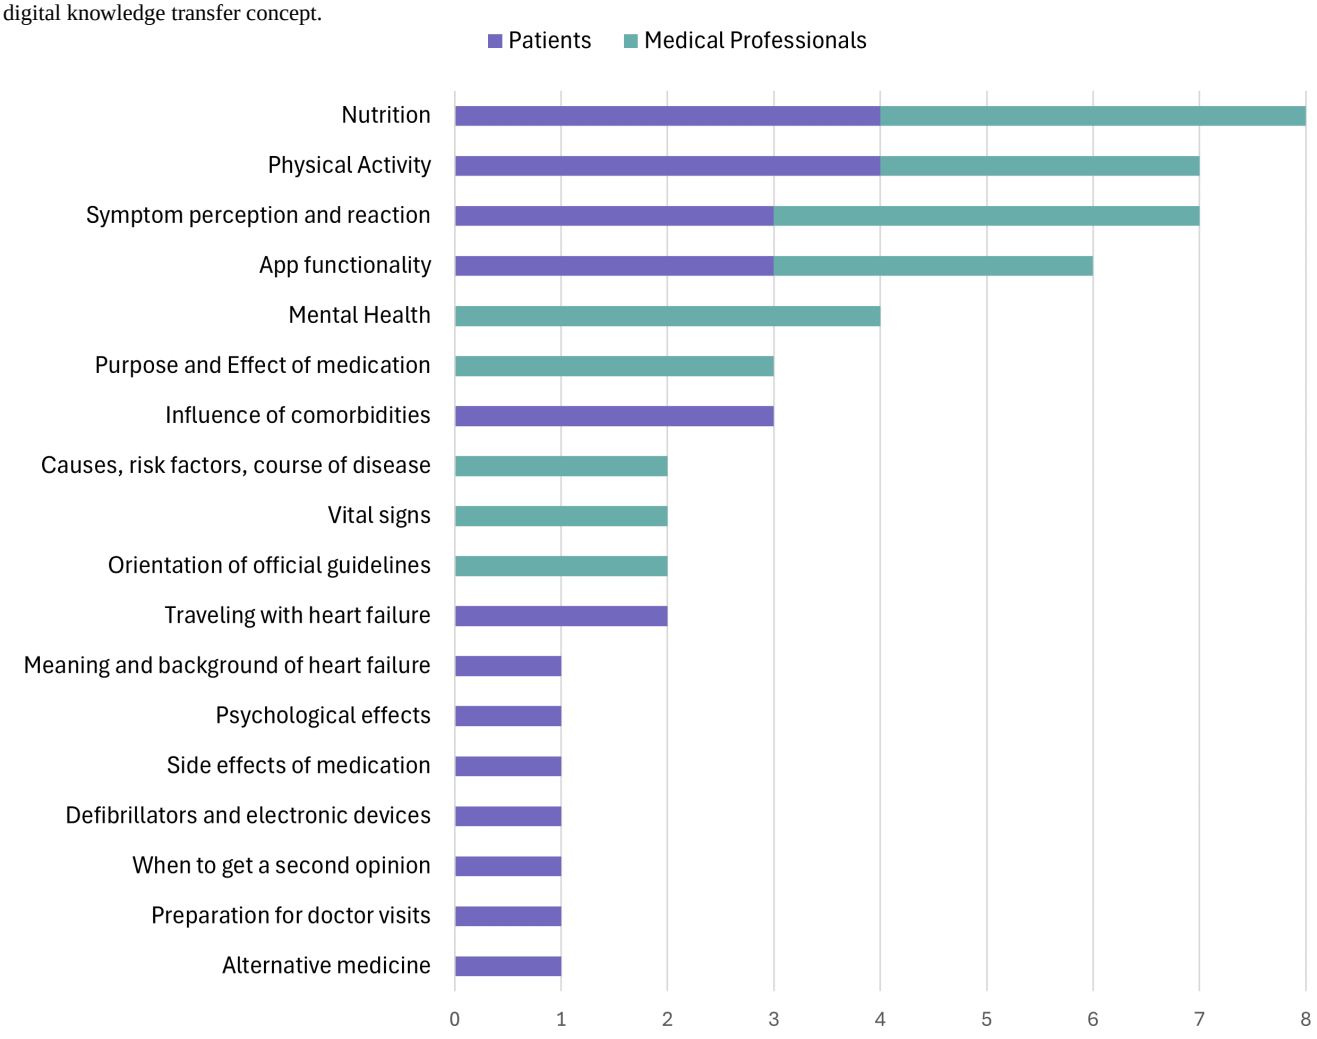
Table . Characteristics of medical experts included in the stakeholder interviews.

Interviewee ID	Identified as	Expert experience	Years of work experience with patients with heart failure
Expert 1	female	Heart failure nurse, licensed practical nurse	11
Expert 2	male	Licensed practical nurse	6
Expert 3	female	Licensed practical nurse	6
Expert 4	female	Bachelor of Science in Nursing, specialist in anesthesia and intensive care	9
Expert 5	male	State-qualified nurse	8

Thematic Analysis

We derived five themes relevant to a knowledge transfer concept from the stakeholder interviews with patients with heart failure and medical experts.



Individual Adaptation of Health Information

The interviews revealed a positive perspective towards the adaptation of content and push notifications to the different levels of knowledge of the users (4/5 experts, 2/9 patients). Our results suggest individualization based on different information such as the NYHA class, walking distance, app usage duration, physical condition age, prior knowledge, or personal preferences that could be determined for example through a quiz within the app.

Relevant Health Topics for Patients With Heart Failure

Several relevant health topics were identified within the stakeholder interviews (Figure 5). Health topics most requested by both patients and medical experts included nutrition (4/5 experts, 4/9 patients), physical activity (3/5 medical experts, 4/9 patients), symptom perception and reaction (4/5 medical experts, 3/9 patients), and app functionality (3/5 medical experts, 3/9 patients).

Figure 5. Health topics mentioned in the stakeholder interviews with patients and medical experts and that were considered relevant to be included in a digital knowledge transfer concept.

XSL•FO
RenderX

Diversity of Media Formats

Most of the interviewed patients (7/9 patients) preferred information in text format. For example, 1 participant stated, "you can read it two or three times if you say it's something that's difficult to absorb, maybe a text would be better" (P5, translated). Additionally, videos were perceived as useful by all medical experts but only desired by 2 patients. Related to the presentation of the information, patients mentioned using fewer technical terms and more simple language (2/9 patients) and shortly highlighting the most important aspects (2/9 patients). This can support easy comprehension of contents, which was also mentioned as a factor for the trustworthiness of health information (3/9 patients).

Promotion of Motivation, Engagement, and Joy

Medical experts (4/5 experts) suggested a reward system to increase engagement with the information contents. However, it should be ensured that this reward system is suitable for the specific target group of users (2/5). Three patients also mentioned the wish to receive positive feedback for progress within the app. Personal interest in the content was also mentioned (3/9) to have a positive influence on engagement.

Credibility and Trust

From the interviews with patients, we identified several factors related to the credibility of information. Positively perceived was the specification of authors (3/9 patients), especially if the authors are physicians (2/9 patients) or authors with an academic background (2/9 patients). In addition, the provider of the mHealth app should have a good reputation (3/9 patients). Factors restraining trust and credibility could be advertising (1/9 patients), authors without medical background (1/9 patients), or irrelevant information (1/9 patients).

Health Literacy

Health literacy levels based on the EU-HLS-Q16 were between 10 and 16 with an average (SD) score of 13.6 (2.1). Participants mostly had difficulties deciding on preventive actions based on media information (5/9 patients) and determining whether information about health risks in media is trustworthy (4/9 patients).

Evaluation of the Digital Prototype

Demographics

We evaluated the proposed digital prototype of the knowledge transfer concept with 7 patients with heart failure (Table 4). The mean (SD) age was 65 (6) years. Patients received their diagnosis between 2 and 24 years prior to this study. All patients were using the ProHerz app for at least 5 months. Four participants identified as women, and 3 as men. This group was less diverse in terms of ProHerz experience, which was a result of recruiting participants based on availability and willingness to participate.

Table . Characteristics of patients included in the evaluation study of the knowledge transfer concept.

Interviewee ID	Age (y)	Gender	Years since heart failure diagnosis	Months of app experience
P1	60	female	5	9
P2	58	female	3	5
P3	75	female	3	15
P5	63	female	4	16
P10	59	male	9	15
P11	71	male	2	15
P12	69	male	24	10

Usability

The mean task completion rate was 84%; 5 of the 11 tasks given during the study were completed by all participants. The lowest completion rate occurred with task 4, which was completed by 4 of 7 participants (Table 5).

XSL•FO
RenderX

Table . Task completion rate for all tasks performed by the participants within the usability testing.

No.	Description	Completion rate (%)
1	Navigate to the questionnaire for individualization	100
2	Complete the questionnaire for individualization	100
3	Navigate to the knowledge section	100
4	Navigate to informative notifications, read the first unread notification	57
5	Navigate to the educational courses	71
6	Navigate to the course category ‘symptoms’	71
7	Navigate to completed courses	71
8	Select a course within a course category	71
9	Navigate to recommended courses and select a recommended course	86
10	Complete one educational course	100
11	Navigate to the overview of badges	100

Interview Results

The thematic analysis of the semistructured interviews with patients within the evaluation of our proposed concept resulted in 3 main themes.

Knowledge Transfer

In the evaluation of the digital prototype, the majority of participants (4/7 patients) classified the prospective range of information as valuable. The organization and structure of contents received positive feedback from most participants (5/7 patients). Specifically, the clear arrangement of information (3/7 patients) and the definition of specific categories (2/7 patients) were highlighted. Patients also perceived the individual adaptation as positive, because personally irrelevant content would be hidden (4/7 patients).

To further improve the concept, participants indicated the necessity to update contents in response to potentially evolving needs over time due to lifestyle or health condition changes (2/7 patients).

Motivation and Engagement

A majority (5/7 patients) expressed an intention to utilize the course content in the future. Notably, reminders about feasible health-promoting measures were identified as a motivational factor by 3 out of 7 patients, with a specific emphasis from 2 participants on messages related to physical activity.

Concerns were raised about the potential negative impact of irrelevant, repetitive, or overly frequent notifications (4/7 patients). Conversely, aligning information with individual interests was identified as a key factor in promoting joy and sustaining engagement among users.

Patients expressed joy while answering the quiz questions, which may have contributed to a more engaging experience (2/7 patients). There was a suggestion to place quiz questions at the end of a course to assess the comprehension of the content effectively.

Participants generally responded positively to medical staff monitoring of progress, considering it a supportive element in their engagement with the course. However, 1 participant viewed social comparison negatively. Furthermore, intangible rewards, such as badges, were not universally well-received, with 1 out of 7 participants expressing a negative opinion, stating that it is solely virtual and not a real reward (P11).

Ease of Use

Out of 7 patients, 3 patients explicitly mentioned the app as easy to use. Other participants did not comment on this aspect, neither positively nor negatively. Concerns regarding the ease of use included potential initial overload when first using the app and potential individual difficulties with the technology and navigation.

Discussion

Principal Findings and Implications

In this study, we developed a concept for mobile health knowledge transfer for patients with heart failure. We grounded this concept on the requirements of patients with heart failure and current theoretical frameworks. From the patient and caregiver perspectives, we derived five central themes for a health knowledge transfer concept.

Our findings contribute to the understanding of user preferences and content organization in digital health interventions targeted at users with heart failure. The integration of diverse methodologies, including qualitative interviews, usability testing, and participant feedback, fortifies the study’s comprehensiveness, providing insights into user engagement, health literacy promotion, and the practical implications for digital health interventions. The results of this study represent an important step toward the development of a mobile health knowledge transfer tool for heart failure patients. By identifying relevant features and characteristics, this work provides a foundation for further refinement and testing, ultimately aiming to support health literacy and improve patient outcomes. It

XSL•FO
RenderX

becomes evident that a concept should focus on individualization, topic relevance, media diversity, motivation strategies, and trust-building mechanisms to optimize its impact on health literacy and engagement of patients with heart failure. Based on the findings, identified in the stakeholder interviews, we developed a concept for knowledge transfer in a digital health app for patients with heart failure.

We evaluated our concept with a digital prototype and identified features and characteristics that are perceived as supportive in increasing health literacy, that can promote motivation, engagement, and joy, and that are able to convince patients of a mobile health knowledge transfer. Most prominent was the wish for content that is individually adapted and balanced regarding the topics covered as well as media formats used to present those topics.

The results of the prototype evaluation presented both encouraging feedback and areas for refinement. Participants highlighted the app's structured design and ease of navigation, emphasizing that these features facilitated a straightforward user experience and enhanced the clarity of the presented information. The quiz elements, in particular, were frequently mentioned as engaging and motivating, showcasing the potential of interactive components to sustain user interest and reinforce learning. These positive responses suggest that the app effectively addressed some of its primary goals, including improving knowledge transfer and supporting patient engagement.

Conversely, the feedback also identified challenges that should be addressed in future iterations. Participants expressed concerns of getting overwhelmed, potentially hindering comprehension. This may reflect concerns about managing excessive information or complex interactions within the app, particularly in the context of their health condition. For users with chronic conditions like heart failure, the introduction of too much content or functionality in a single interface could exacerbate feelings of being overwhelmed and lead to disengagement or frustration [38]. Furthermore, badges and achievements were mentioned to be not motivating despite research showing the positive effects of such gamification elements [39,40]. Older users or those less familiar with gamification might find such features irrelevant or even patronizing if they do not see clear value in them. Other gamification elements such as progress bars, interactive storylines, or more useful rewards may be more effective in motivating users. Therefore, future iterations could explore the inclusion of a simple setup and customization menu to enable or disable features such as gamification and other user-preferred functionalities.

Accessibility is a critical consideration in designing digital health systems to ensure they meet the needs of diverse users. While none of the participants in our study raised concerns or reported difficulties with accessibility, indicating that the system was well-received by the target population, it is important to account for potential challenges in broader user groups. Features such as larger fonts, high-contrast visuals, simplified navigation, and optional audio support can further enhance usability, particularly for individuals with age-related changes in vision, hearing, or varying levels of digital literacy.

The high rates of completion for most tasks suggest that the interface and navigation design are intuitive, enabling users to locate and interact with the desired functions efficiently. This aligns with the positive feedback received during the interviews conducted within the evaluation. However, with a few tasks having a lower completion rate, some aspects of the design need further refinement in future iterations. Factors such as differences in technology familiarity, cognitive load, or previous experience with the ProHerz app could have contributed to these discrepancies. Interactive tutorials to onboard users and a further adaptation of content may be able to better account for different requirements, levels of experience, or cognitive abilities. In particular, task 4 with a completion rate of only 57% was the most problematic task for participants. The participants were not able to locate the button to navigate to the informative notifications. The reason for this is most likely the design of the progress bar on the same page (Figure 3, right) that users expected to be the button to the next page. Ensuring more consistent visual cues for interactive elements could further reduce the potential for misinterpretation and enhance the overall user experience.

Comparison With Prior Work

The need for individualization is in line with the findings of Giordan et al [41], calling for further customization especially related to the educational level and digital literacy of users. Our results additionally highlight the need for customization regarding personal interests and lifestyle and the importance of regular adaptation to changing circumstances in the life and knowledge of users. Future applications require new strategies to individually adapt educational content that can change over time. This can include regularly soliciting user feedback through surveys, using quizzes to assess understanding, or adaptive learning algorithms based on user behavior within the mobile app [42].

The topics covered in our knowledge transfer concept are in line with the recommendations of the European Society of Cardiology. They included information about heart failure, symptom monitoring, self-management, medication, fluid intake, implantable devices, physical activity, nutrition, smoking, sleep mental health, and traveling [43]. The information was presented using different media formats, which relates to current literature emphasizing the benefits of this approach. A variety of formats can support users with different health literacy levels and can deepen the learning effects [29,43,44].

Strengths and Weaknesses

Several limitations apply to this study. Firstly, the participant pool featured a restricted number of individuals, all German-speaking and residents in Germany. Moreover, participants were well-acquainted with the ProHerz app, potentially influencing their perspectives and feedback, especially regarding the ease of use. Given the advanced health literacy levels of the participants, our findings may not comprehensively represent the needs of individuals with lower health literacy. The initial usability testing was conducted with a convenience sample due to limited patient availability; therefore, results from this group need to be interpreted with caution. During the evaluation phase, 4 participants already

XSL•FO
RenderX

were part of the stakeholder interviews in the first phase of this study due to limited participant availability. Lastly, all participants accessed the app on a laptop rather than a mobile phone, introducing a potential discrepancy, as some users reported difficulties with computer usage and the overall interaction experience may be different. These limitations underscore the necessity for cautious interpretation and highlight avenues for future research refinement.

Our study combines several strengths: we were the first to conceptualize a mobile health knowledge transfer within a user-centered design approach. By prioritizing patient needs and requirements, and involving healthcare professionals to ensure relevance and meaningfulness, the study sets a precedent in fostering impactful and patient-centric digital health interventions. The incorporation of theoretical frameworks for mobile health education enriches the conceptual foundation, contributing to the overall robustness of the study and its potential impact on the enhancement of patient-centered care.

Conclusions

We were the first to develop a mobile health knowledge transfer for heart failure grounded on theoretical frameworks within a user-centered design process.

By addressing individual health literacy levels, cognitive challenges, and personal preferences, this knowledge transfer concept can help patients better understand and manage their condition. The active involvement of healthcare professionals ensures that the resulting intervention is meaningful and aligned with relevant healthcare aspects. The findings also emphasize a discrepancy between what healthcare professionals perceive as important for patients and what patients themselves prioritize, particularly when it comes to identifying relevant healthcare topics. Our results are paving the way to more personalized and effective mobile health education for individuals managing heart failure. The concept can be used as a foundation for other digital platforms and mobile health apps to provide tailored educational content and supporting clinicians in delivering consistent, patient-specific information in home settings.

Future research opportunities should focus on longitudinal studies to assess the sustained impact of this knowledge transfer concept on health literacy, self-care behavior, and patient outcomes. In this context, validated usability scales alongside user interviews should be incorporated during iterative development processes, while also addressing potential biases in design and testing to ensure more robust and generalizable findings. Additionally, possible strategies for better individualization of health information should be further explored. To better understand the impact of personalization, future studies could incorporate a comparison of user experiences before and after customizing the app, providing valuable insights into how individualization influences usability and user satisfaction. This presents an opportunity to investigate adaptive learning algorithms that dynamically tailor content based on user progress and preferences.

Acknowledgments

This project is supported by the Bavarian State Ministry of Health and Care, project grant number PBN-MGP-2010-0004-DigiOnko. The authors would like to acknowledge the financial support from Deutsche Forschungsgemeinschaft and Friedrich–Alexander Universität Erlangen-Nürnberg within the funding program Open Access Publication Funding.

Authors' Contributions

MF conceived the study, developed the study design, analyzed data, assisted in interviews, and wrote the manuscript draft. SB and JR assisted in developing the study design, interview conduction, and data analysis. KMJ, MN, and HL assisted in writing the manuscript. PT, SE, BME, and HL initiated and supervised the project. All authors reviewed the final manuscript.

Conflicts of Interest

JR, SE, and PT are employees of ProCarement GmbH. All other authors declare no conflicts of interest.

Abstract

Background: Long COVID is an often debilitating condition affecting millions of people. Its diverse clinical presentations make effective diagnosis and management at the primary care level difficult, while specialist services for long COVID face extensive wait times. An electronic consultation (eConsult) program in Ontario developed a long COVID specialist group to allow primary care providers (PCPs) prompt access to specialist advice for patients with long COVID.

Objective: This study aims to assess patterns of service use, response times, impact, and clinical content of eConsult cases submitted to an eConsult long COVID specialist group in Ontario.

Methods: This study is a mixed methods analysis of eConsults submitted by PCPs to the long COVID specialist group of 2 eConsult services (Champlain eConsult BASE and Ontario eConsult) between June 1, 2021, and July 31, 2022. Data sources included the use data collected automatically by the services, responses to a mandatory closeout survey, and the content of PCP questions and specialist responses (Champlain eConsult BASE service only). Clinical questions or responses were analyzed using 2 validated taxonomies. Descriptive statistics were used for survey responses and use data.

Results: A total of 40 PCPs submitted 47 eConsults through Champlain eConsult BASE and 197 PCPs submitted 228 cases through Ontario eConsult. The median specialist response time was 0.6 (IQR 0.19-2.36; mean 1.7, SD 2.29) days. The 5 most common symptoms of long COVID were fatigue (14/47, 30%), dyspnea (7/47, 15%), cough (6/47, 13%), altered sense of smell (ie, anosmia and parosmia; 6/47, 13%), and cognitive changes (6/47, 13%). The five main question categories asked by PCPs were: (1) management of chronic symptoms of COVID-19, (2) need for additional work-up or follow-up testing, (3) community resources to support or manage patients with long COVID, (4) diagnostic clarification, and (5) guidance regarding COVID-19 vaccination.

Conclusions: The long COVID groups provided rapid access to a multispecialty service that facilitated the avoidance of unnecessary face-to-face referrals. An assessment of eConsults highlighted 5 common question types, providing insight into potential gaps in knowledge among PCPs that could help guide medical education and policy.

Introduction

The COVID-19 pandemic has had an unprecedented impact on health care systems and economies worldwide. As of November 2023, there have been over 700 million reported cases of COVID-19, resulting in over 6.5 million deaths [1]. As the pandemic began spreading, the potential for long-term morbidity from COVID-19 became apparent. The World Health Organization reports that 10% - 20% of those infected with COVID-19 report incomplete recovery months beyond the acute illness—a condition commonly referred to as long COVID or post-COVID-19 condition [2].

A recent Statistics Canada survey reported that 14.8% of respondents with a previous positive test or suspected infection for COVID-19 experienced ongoing symptoms at least 3 months after infection [3]. Potential symptoms of long COVID are varied, and people often experience symptoms across multiple organ systems.

Primary care is ideally positioned to diagnose and provide management for patients with long COVID. Unfortunately, given its diverse clinical presentations and limited empirical evidence guiding management, many primary care providers (PCPs) lack the specialized knowledge to effectively identify and manage long COVID. In certain jurisdictions, long COVID specialty clinics have been established to support primary care. However, demand and wait times for these clinics make timely access a challenge. There is a need for innovative tools to support PCPs in identifying and delivering care for those with long COVID.

One solution to these challenges is electronic consultation (eConsult), which allows PCPs to ask clinical questions regarding their patients to specialists using a secure web-based platform. In response to the pandemic, an eConsult service operating in Ontario, Canada, launched a long COVID specialist group, allowing PCPs to connect with specialists across multiple disciplines with expertise in long COVID to help with the diagnosis and management of their patients. Previous studies assessing this eConsult service in Ontario have demonstrated improved access to specialty care, reduced need for face-to-face specialist visits, cost savings, and high physician satisfaction [4-8].

In this study, we examined eConsult cases submitted to a long COVID specialist group in Ontario to assess patterns of service use, response times, the impact on the need for formal face-to-face referrals, and the content of clinical questions being asked.

Methods

Study Design

This study is a mixed methods analysis of eConsults submitted by PCPs to the long COVID specialist group between June 1, 2021, and July 31, 2022.

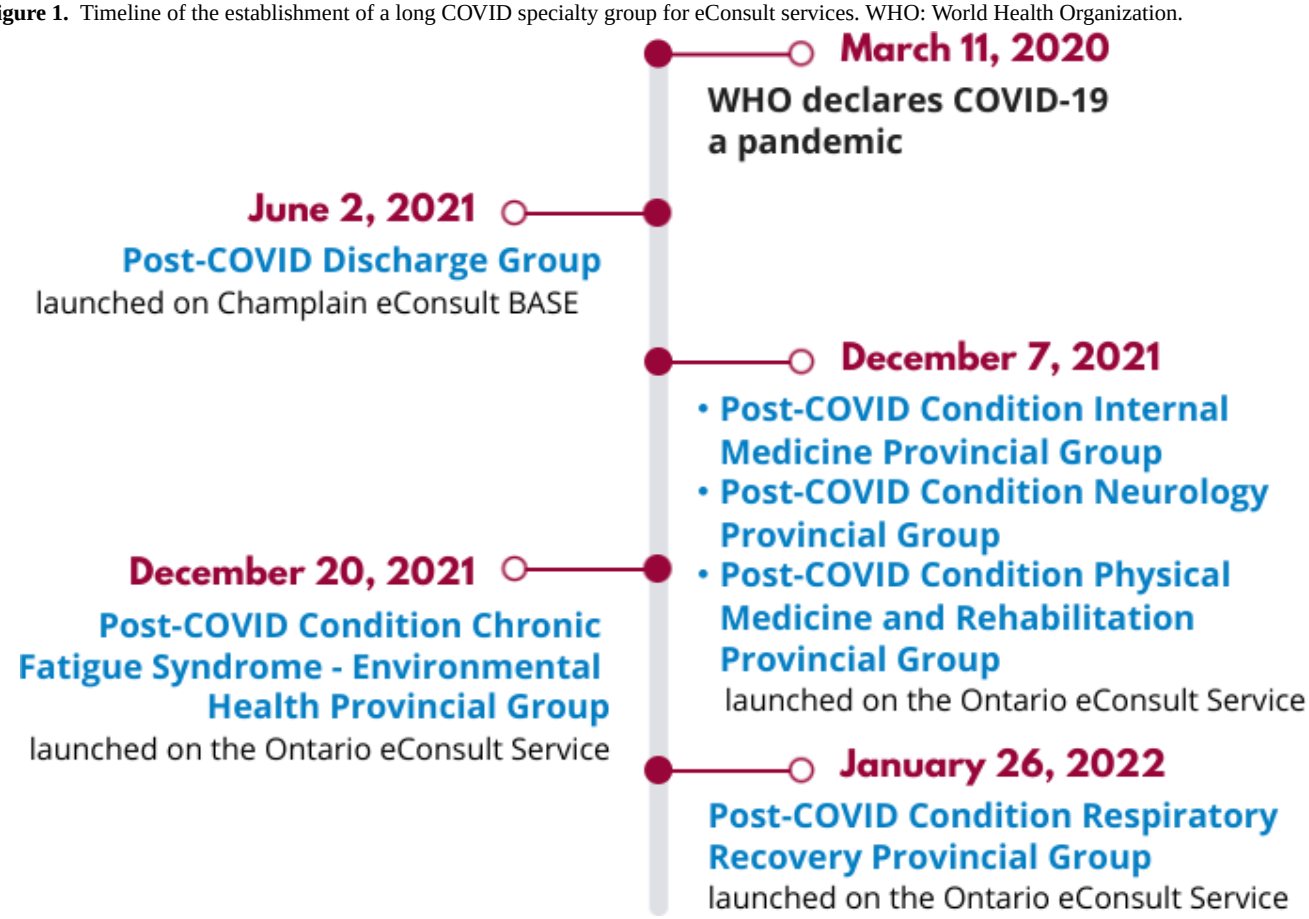
Ethical Considerations

This study received ethics approval from the Ottawa Health Science Network Research Ethics Board (REB protocol 2009848 - 01). The Ottawa Health Science Network Research Ethics Board waived informed consent for the study due to its retrospective, cross-sectional nature, so individualized patient consent was not obtained. All nonanonymized data were stored on secure servers that are accessible only by approved users who signed a privacy and confidentiality form.

Participants

Participants in the study were PCPs who were registered to 1 of the 2 eConsult services and who submitted at least 1 eConsult to the long COVID group within the study timeframe.

eConsult Services



Two multispecialty eConsult services currently operate in Ontario under the umbrella of Ontario eConsult. The first service, the Champlain eConsult BASE (Building Access to Specialists through eConsultation) service, was initially piloted in 2010 across the Champlain region of eastern Ontario, which includes Ottawa and its surrounding communities and has a population of around 1.3 million people. The second service, the Ontario eConsult Service, made eConsult available to all PCPs across Ontario in 2018. Both services are funded through the Ontario Ministry of Health. On June 2, 2021, a long COVID specialty group was established on the Champlain eConsult BASE service. Later in the year, a similar service was made available on the Ontario eConsult Service, providing PCPs with access to five different long COVID specialty subgroups that were rolled out between December 2021 to January 2022: (1) Post-COVID Condition Internal Medicine Provincial Group, (2) Post-COVID Condition Neurology Provincial Group, (3) Post-COVID Condition Phys Med/Rehab Provincial Group, (4) Post-COVID Condition Chronic Fatigue Syndrome—Environ Health Provincial Group, and (5) Post-COVID Condition Respiratory Recovery Provincial Group.

Measures considered when recruiting specialists to eConsult BASE-managed groups include the specialist's experience, level of interest, and ability to maintain an adequate case volume, as well as maintaining equity across and within regions or organizations. The services leveraged existing eConsult specialists and recommendations from peers to identify eligible specialists.

In total, 19 specialists were available to respond to long COVID questions during the study period (5 on the Champlain BASE and 14 on the Ontario eConsult service) from various specialty backgrounds, including internal medicine, infectious disease, neurology, physiatry and respirology (Figure 1).

XSL•FO
RenderX

Figure 1. Timeline of the establishment of a long COVID specialty group for eConsult services. WHO: World Health Organization.

PCPs initiate an eConsult by logging onto a secure web portal and selecting the specific specialty service from a dropdown menu. The PCP fills out a structured electronic form and submits the case along with any pertinent attachments (eg, laboratory or imaging data). The case is assigned to a specialist from the chosen group, who responds within 7 days (the median specialist response time is typically 1 day [5]). When a case is closed, the PCP completes a mandatory close-out questionnaire that gathers information about the case's outcome, whether a referral was originally contemplated and whether it was ultimately avoided as a result of the specialist's advice, and the case's educational value and capacity to serve as material for continuing medical education by using a 5-point Likert scale (Multimedia Appendix 1).

Data Collection and Analysis

We computed descriptive statistics to examine the overall use of the long COVID specialist group from June 1, 2021, to July 31, 2022. Data from both the Ontario eConsult and Champlain eConsult BASE services were analyzed to determine the total number of cases submitted to the long COVID specialty group. Time stamps for each eConsult were assessed to examine the response interval for specialist responses, and the total self-reported time billed was used to determine the amount of time each specialist spent responding to the eConsult.

Following the established methodology, case transcripts of PCP questions from eConsults submitted through the Champlain eConsult BASE between June 1, 2021, and July 31, 2022, were retrospectively reviewed. Case-level data were accessible for Champlain eConsult BASE but not for Ontario eConsult. Two investigators (MQ and JS) reviewed cases retrospectively using 2 validated taxonomies: the International Classification for Primary Care, version 2 and Ely et al's taxonomy of generic clinical questions. The International Classification for Primary Care, version 2 was used to classify clinical topics and patient-presenting symptoms. The taxonomy of generic clinical question was used for question classification. In many cases, a single eConsult case had multiple questions, and patients often presented with multiple symptoms; therefore, each case was not restricted to a single clinical question or presenting complaint or symptom.

We performed a descriptive analysis of all eConsult close-out questionnaires completed by the PCPs. Specifically, we sought to determine the PCP's course of action after the eConsult (eg, face-to-face referral avoided and face-to-face referral still needed) and to gain insight into the nature of the advice given to the PCP (eg, new advice given and advice confirmed course of action initially contemplated).

Results

Overview

A total of 40 PCPs submitted 47 eConsults through Champlain eConsult BASE between June 1, 2021, and July 31, 2022, and 197 PCPs submitted 228 cases through Ontario eConsult between December 1, 2021, and July 31, 2022. These cases comprised 0.2% (n=23,067) of the total number of closed cases submitted to Champlain eConsult BASE and 0.5% (n=45,494)

XSL•FO
RenderX

of all Ontario eConsult closed cases during their respective time frames.

The median time for a specialist to respond to the eConsult was 0.6 (IQR 0.19 - 2.36; mean 1.7, SD 2.29) and the average time the specialist billed in responding to each eConsult was 27.5 (SD 18.53; median 20, IQR 15-45) minutes.

Clinical Content of eConsults

The retrospective taxonomy analysis assessed the clinical questions PCPs asked in the 47 cases submitted through Champlain eConsult BASE. Patients had a median age of 43 (IQR 6-65) and presented 24 unique symptoms across cases (Table 1).

Table . Percentage of patients with reported symptom or finding.

Symptom or finding	Patients (n=47), n (%)
Fatigue	14 (30)
Dyspnea	7 (15)
Altered smell (anosmia, parasomnia)	6 (13)
Cough	6 (13)
Cognitive changes	6 (13)
Chest pain	5 (11)
Palpitations	3 (6)
Altered taste (dysgeusia, ageusia)	3 (6)
Congestion	3 (6)
Alopecia	2 (4)
Myalgia	2 (4)
Rash	2 (4)
Paresthesia	2 (4)
Headache	2 (4)
Tremor	2 (4)
Insomnia	2 (4)
Fever	1 (2)
Eye pain	1 (2)
Tinnitus	1 (2)
Arthralgia	1 (2)
Back pain	1 (2)
Abdominal pain	1 (2)
Edema	1 (2)
Asthenia	1 (2)

The 5 most common symptoms were fatigue (14/47, 30%), dyspnea (7/47, 15%), cough (6/47, 13%), altered sense of smell (ie, anosmia and parosmia; 6/47, 13%), and cognitive changes (6/47, 13%). The five main question categories asked by PCPs were: (1) management of chronic symptoms of COVID-19, (2) need for additional work-up or follow-up testing, (3) community resources to support or manage patients with long COVID, (4) diagnostic clarification, and (5) guidance regarding COVID-19 vaccination (Table 2; sample questions in Multimedia Appendix 2). The most common topics pertained to guidance on the management of chronic symptoms of COVID-19 (22/47 cases, 47%), the need for additional work-up or follow-up testing (20/47 cases, 43%), suggestions for community resources to help support or manage patients with chronic COVID-19 (9/47 cases, 19%), and diagnostic clarification (7/47 cases, 15%).

XSL•FO
RenderX

Table . Content of clinical questions asked of post-COVlD-19 condition specialists by electronic consultation (eConsult).

Content topic	eConsult cases (n=47), n (%)
Management of chronic symptoms of COVID-19	22 (47)
Need for additional work-up or follow-up testing	20 (43)
Community resources to support or manage patients	9 (19)
Diagnostic clarification	7 (15)
Guidance related to COVID-19 vaccination	7 (15)
Necessary to refer to specialist	6 (13)
Interpretation of testing	4 (9)
Other	3 (6)

Outcome of eConsults

PCPs completed the post-eConsult questionnaire for 268 of the 275 cases submitted on both the Champlain eConsult BASE and Ontario eConsult services during the study timeframe. Through eConsult, PCPs were able to confirm a course of action that they had initially contemplated in 35% (95/268) of cases and received advice on a new or additional course of action in 59% (157/268) of cases (Table 3). In 38% (102/268) of cases, PCPs had initially contemplated a face-to-face referral but found it unnecessary after the eConsult, while an actual face-to-face referral was needed in only 24% (64/268) of cases (Table 4).

Table . Impact of electronic consultation (eConsult) on PCP[a] course of action.

PCP survey answer	Responses (n=268), n (%)
I got good advice for a new or additional course of action	157 (59)
I was able to confirm a course of action that I originally had in mind	95 (35)
I got good advice for a new or additional course of action that I am not able to implement[b]	5 (2)
I did not find the advice very useful[c]	5 (2)
Other	6 (2)

[a]PCP: primary care provider.

[b]Response option available only for the Champlain eConsult BASE Service.

[c]Response option available only for the Ontario eConsult Service.

Table . Impact of electronic consultation (eConsult) on need for face-to-face referral.

PCP[a] survey answer	Responses (n=268), n (%)
Referral was originally contemplated but now avoided at this stage	102 (38)
Referral was not originally contemplated and is still not needed	88 (33)
Referral was originally contemplated and is still needed	57 (21)
Referral was not originally contemplated, but eConsult process resulted in a referral being initiated	7 (3)
There was no particular benefit to using eConsult in this case[b]	2 (1)
Other	12 (4)

[a]PCP: primary care provider.

[b]Response option available only for the Ontario eConsult Service.

Discussion

Principal Results

This study demonstrates the considerable potential of an eConsult service to support PCPs navigating the complexity and diversity of long COVID symptoms. By facilitating quick, low-barrier access to specialist advice, eConsult empowered PCPs to provide the best possible care for patients with long COVID while avoiding long wait times for specialist referrals. PCPs were able to get prompt specialist advice from a specialist with a median response time of just over 12 hours. The main question types identified in the study related to (1) the management of chronic symptoms of COVID-19, (2) the need for additional work-up or follow-up testing, (3) community resources to support or manage patients with long COVID, (4)

XSL•FO
RenderX

diagnostic clarification, and (5) guidance regarding COVID-19 vaccination. A face-to-face referral was not needed after the majority of eConsult cases, so patients could be given an expert-guided treatment plan without waiting to see a specialist. To our knowledge, this is the first study to examine an innovative electronic solution to help support PCPs in managing long COVID.

Limitations

This study has several limitations. First, the taxonomy analysis used data from a single health region in Ontario, which may impact the generalizability of our findings. As mentioned above, we only had access to case-level data from the Champlain eConsult BASE service and not the Ontario eConsult service. The Champlain region is a culturally and linguistically diverse region and our findings were externally validated by specialist team members who answered eConsults from across Ontario and confirm the nature of the questions identified in this study are representative of common questions asked across the province. Furthermore, this study only examined eConsults submitted to the long COVID group and it is possible that relevant COVID-19 cases were submitted to other specialty groups such as infectious disease. Finally, neither service collects detailed demographic information about the PCPs using the service, so we were unable to report any of this information in our results section.

Comparison With Prior Work

With studies and data continuing to emerge about long COVID, there remain significant challenges in diagnosing and managing patients with this condition (O'Hare et al [9]). A systematic review conducted by Macpherson et al [10] found patients commonly expressed concerns about the lack of knowledge about long COVID, and often found they received conflicting or inconsistent advice from providers. There is currently no effective validated treatment for long COVID [11]. This challenge with management was evident in our findings, as approximately half of the questions PCPs posed were related to advice on management, and one-fifth inquired about community resources to support with management. Furthermore, 59% of PCPs surveyed reported receiving new advice that changed their management plans.

Recognizing the burden of long COVID, many jurisdictions worldwide have implemented multispecialty long COVID clinics and rehabilitation centers. Previous studies have shown that these rehabilitation programs can have a positive impact on various patient outcomes [12,13], such as increased quality of life, reduced fatigue, improved functional status, and better mental health [13]. Unfortunately, the demand for such clinics is high, with many reporting long wait times. Digital strategies such as eConsult provide a means for quicker access to support patients and initiate management. They also have the potential to reduce demand by allowing the PCP to provide guided care; approximately 40% of PCPs surveyed highlighted that a face-to-face referral was not needed as a result of the advice they received through eConsult. This may lessen the backlog of seeing long COVID specialists by decreasing the number of unnecessary in-person referrals. Additionally, we were able to quickly adapt the eConsult service to implement long COVID groups, whereas setting up specific specialty clinics requires greater coordination, time, and cost.

One of the other challenges in identifying and managing long COVID relates to its diversity of presentation; the Public Health Agency of Canada has reported over 100 different symptoms associated with long COVID. In the 47 eConsults examined in this study, 24 unique symptoms were reported, with the 5 most common being fatigue, dyspnea, cough, altered sense of smell (ie, anosmia and parosmia), and cognitive changes. These findings are in line with other international studies. For example, a UK-based study conducted by Carfi et al [14] also noted fatigue as the most common long COVID symptom (51%), followed by dyspnea (35%), arthralgia (25%), and concentration difficulties (25%). This diversity in presentations can lead to challenges with diagnosis, which is particularly important as the symptoms of long COVID overlap with other serious and possibly life-threatening complications associated with COVID-19, such as pulmonary embolism, myocarditis, and organizing pneumonia. Several publications have reported delays in the diagnosis of life-threatening conditions such as pulmonary embolism as they were mistaken for symptoms of COVID-19 (Yousefazai and Bhimaraj [15]; Melazzini et al [16]). In total, 15% (7/47) of PCP questions related to diagnostic clarification, while 43% (20/47) of eConsults asked about the need for additional testing to rule out other conditions. This highlights the importance of getting timely advice to confirm the diagnosis and avoid delays in the diagnosis of possibly life-threatening conditions. The diversity of presentations also demonstrates the need for a multidisciplinary approach to providing support for patients with long COVID. To address this need, Ontario eConsult established 5 unique subgroups that PCPs can select (ie, internal medicine, neurology, physical medicine or rehabilitation, chronic fatigue syndrome, and respirology) involving providers from various specialties to better support PCPs and their patients in getting helpful and appropriate advice in a timely manner.

Conclusions

The long COVID groups available through the Champlain eConsult BASE and Ontario eConsult services provided rapid access to a multispecialty service that facilitated the avoidance of unnecessary face-to-face referrals. Long COVID is a multisystemic condition that is often debilitating, with a significant impact on one's quality of life and mental health. Given the lack of knowledge around long COVID, limited timely access to specialized long COVID clinics, and the possibility of delayed diagnosis of life-threatening conditions associated with COVID-19 (eg, pulmonary embolism), there is an urgent need for innovative digital solutions such as eConsult to better support PCPs to provide patients with timely access to specialty advice. An assessment of eConsults highlighted 5 common question types, providing insight into potential gaps in knowledge among PCPs that could help guide medical education and policy.

Abstract

Background: Digital self-monitoring tools, such as the experience sampling method (ESM), enable individuals to collect detailed information about their mental health and daily life context and may help guide and support person-centered mental health care. However, similar to many digital interventions, the ESM struggles to move from research to clinical integration. To guide the implementation of self-monitoring tools in mental health care, it is important to understand why and how clinicians and clients adopted, adapted, and incorporated these tools in practice.

Objective: Therefore, this study examined how clinicians and clients within a psychiatric center appropriated an ESM-based self-monitoring tool within their therapy.

Methods: Twelve clinicians and 24 clients participated in the piloting of the ESM tool, IMPROVE. After utilizing the tool, 7 clinicians and 11 clients took part in semistructured interviews. A thematic framework analysis was performed focusing on participants' prior knowledge and expectations, actual use in practice, and potential future use of ESM tools.

Results: Many participants experienced that the ESM tool provided useful information about clients' mental health, especially when clinicians and clients engaged in collaborative data interpretation. However, clinicians experienced several mismatches between system usability and their technical competencies, and many clients found it difficult to comply with the self-assessments. Importantly, most participants wanted to use digital self-monitoring tools in the future.

Conclusions: Clinicians' and clients' choice to adopt and integrate self-monitoring tools in their practice seems to depend upon the perceived balance between the added benefits and the effort required to achieve them. Enhancing user support or redesigning ESM tools to reduce workload and data burden could help overcome implementation barriers. Future research should involve end users in the development of ESM self-monitoring tools for mental health care and further investigate the perspectives of nonadopters.

Introduction

To improve access to and facilitate person-centered mental health care, digital technologies are increasingly being deployed to collect and share health-related data, deliver care, and support individuals in managing their health [1,2]. The experience sampling method (ESM; also termed ecological momentary assessment) is a structured diary technique that enables individuals to collect detailed information about their mental health in their daily lives [3]. Using smartphone apps, the ESM prompts individuals to complete brief self-assessments multiple times daily, assessing their emotional states, behaviors, and psychological symptoms. By allowing individuals to collect this information and share it with their clinicians, the ESM can ensure that therapeutic decisions are aligned with clients' everyday experiences and needs. For example, by providing insights into which activities an individual commonly engages in, and how they respond to different daily life situations and stressors, clients and clinicians can make shared decisions about the focus of treatment [4].

Despite its potential, the ESM, similar to many other digital mental health interventions [5,6], struggles to move from

XSL•FO
RenderX

piloting and trialing to actual clinical implementation. To address this research-to-practice gap, scholars have made calls to adopt user-centered design strategies for developing digital mental health tools [7]. User-centered design emphasizes the importance of conducting in-depth analyses of users' goals, needs, and context of use to inform technology design [8]. Nonetheless, most evaluations of digital health technologies focus primarily on quantifiable, technical aspects such as system performance, usability scores, and cost benefits [9,10]. However, an often overlooked but crucial step in implementing the ESM and self-monitoring tools is understanding how and why people integrate these technologies into their daily practices [11]. For example, what are the goals people hope technologies will help them achieve, what difficulties do individuals encounter when using new technologies, and what strategies do they apply to overcome technology use obstacles?

Studying the situated use of the ESM can provide essential knowledge into how users appropriate and make sense of these tools [12,13]. Technology appropriation can be examined in three main stages [13]. The first stage involves users' prior knowledge and expectations, which determine their initial willingness to adopt the technology. Expectations about potential benefits (eg, simplifying tasks) and the effort required (eg, time spent on training) are particularly crucial in shaping the initial interest [14,15]. In the second phase, users explore and evaluate the technology's capabilities, while becoming familiar with its functions. They adapt their practices to integrate the technology (eg, maintaining an internet connection), and adapt the technology to suit their needs (eg, disabling certain features or altering settings) [13]. They will test the technology's applicability in different situations and determine what features are most useful to them. Finally, if users find that the technology has added value and helps them achieve their goals and tasks, they might develop new routines and workflows that allow them to integrate and use the technology in their daily practice, thus moving into the third stage of persistent use [13].

To date, the appropriation of ESM tools in health care has largely been overlooked. While one study has examined how individuals with back pain appropriated ESM tools for pain management [16], there is a lack of research in the field of mental health care. As a consequence, we have a limited understanding of how individuals with mental illnesses and their clinicians interact with and make sense of digital ESM tools, and what might lead them to adopt or abandon these technologies. However, understanding this is vital for facilitating successful implementation [15,17]. To address this knowledge gap, we undertook a pilot implementation study, using the ESM tool "IMPROVE," a clinical prototype tool informed by research examining clinicians' and clients' design preferences [18,19]. IMPROVE was used as a part of therapy following a 3-step intervention, in which clinicians and their clients could (1) personalize the tool to clients' specific problems and situations, (2) self-monitor clients' mental health and daily activities via an app, and (3) review the collected data in summarized graphs in an online dashboard. To inform the further development and implementation of clinical ESM tools, this paper aimed to evaluate participants' (1) prior knowledge and expectations, (2) actual use in practice, and (3) potential future integration of ESM-based self-monitoring tools. Addressing these gaps in the literature will provide valuable insights into why and how clients and clinicians in mental health care choose to adopt or abandon digital self-monitoring tools in therapy.

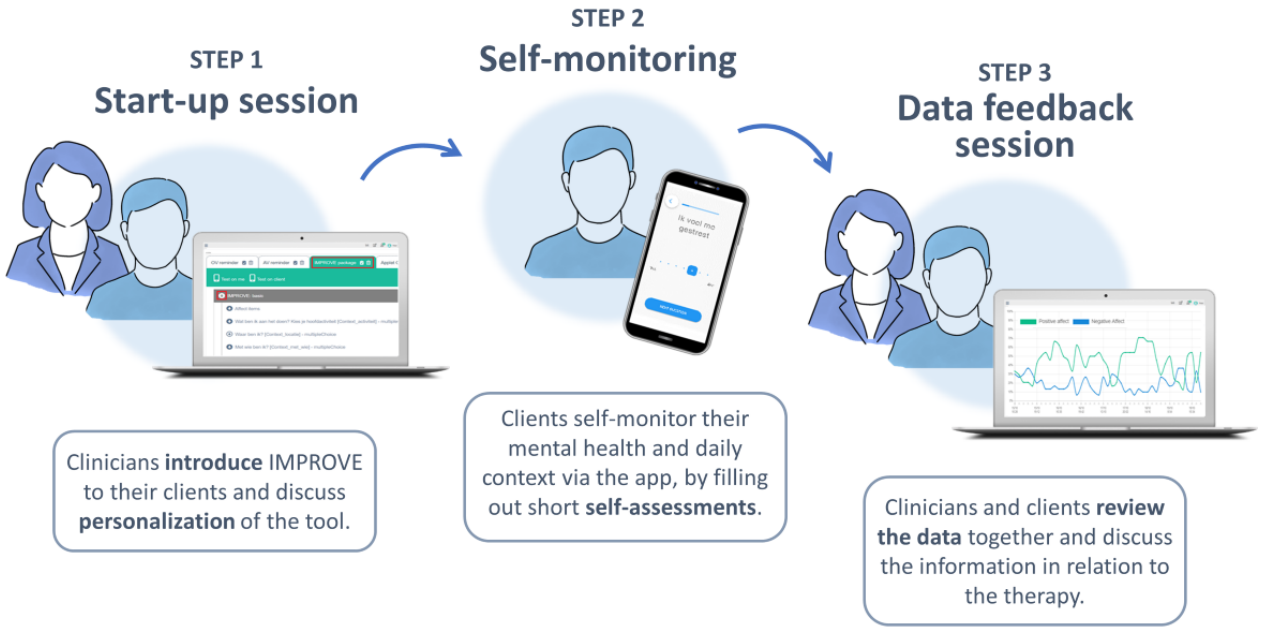
Methods

Ethical Considerations

All participants provided written informed consent, and all procedures were approved by the medical ethics committee of KU Leuven (S64244). Participants were given a study ID to ensure anonymity, and interviews were pseudonymized during the transcription by removing personally identifiable information and replacing them with pseudo codes. Finally, participants were allowed to freely use the IMPROVE tool after completion of the study but were not given additional compensation.

Study Design and Recruitment

We conducted a pilot study within the University Psychiatric Center KU Leuven in Belgium in which we involved clients and clinicians in testing and evaluating IMPROVE. The research team was unable to access the clinic directly, due to COVID-19 restrictions. Therefore, invitations to participate were emailed to all psychiatrists and psychologists affiliated with the psychiatric center (N=142). The study aimed to enroll 12 clinicians, and initial invitations were followed by up to 2 reminder emails. For those interested, online informational sessions with the research team were organized. Participating clinicians were asked to recruit at least 1 client from their practice. By allowing clinicians to select clients, the referred sample provided a practical representation of the clients with whom clinicians were likely to use the tool within a real-life context.



The inclusion criteria were kept broad to reflect the diverse reality of clinical practice. To be eligible, clinicians needed to be certified mental health professionals and proficient in Dutch, which was the language the intervention was designed in. Clients had to be 18 years or older and also proficient in Dutch. To replicate real-world implementation, clients were asked to use their own smartphones. As a result, only clients owning a smartphone with at least 3G coverage were eligible to participate.

IMPROVE was run on the digital platform m-Path [20]. To enable clinicians to use IMPROVE, they received a manual with instructions on using the tool in their practice (Multimedia Appendix 1: IMPROVE training manual) and were invited to join an online training session. Clinicians and their clients were then requested to complete the 3-step intervention (Figure 1). In the first step, clinicians introduced IMPROVE to their clients and assisted them in downloading the app on their smartphones. They also discussed personalization of the tool, such as adding symptom-specific questions or adjusting the notification schedule. In the second step, clients self-monitored their mental health for 6 consecutive days. They received 10 semirandom notifications daily, prompting them to complete brief self-assessments on mood and context. Additionally, they received a morning notification to assess their sleep and an evening notification to evaluate the day. In the third step,

XSL•FO
RenderX

clinicians and clients reviewed the collected data together, exploring factors such as clients' activities, mood variability, and mood-context interactions.

Figure 1. Overview of the steps included in the IMPROVE intervention.

Data Collection and Analysis

Due to COVID-19 measures, data were collected remotely via online surveys in RedCap (Research Electronic Data Capture, Vanderbilt University) [21] and through Skype interviews (Version MSO; Skype Technologies). In some cases, poor connections affected the quality of the interview recordings; however, the overall data collection was not hindered by remote methods. Demographic information was collected at study enrollment and participants who completed the intervention were invited to participate in a semistructured interview (Multimedia Appendix 2: Interview guides). Interviews were audio recorded and transcribed verbatim. We performed a thematic analysis [22] in which we first conducted top-down content-coding of the transcripts using a thematic framework that identified interview material related to clinicians' and clients': (1) previous knowledge and expectations, (2) actual use in practice, and (3) potential future integration of the IMPROVE tool (Table 1). Hereafter, we performed additional inductive in vivo coding and used pattern and focused coding to create labels for the in vivo codes and compiled them into additional subthemes [23]. LdT undertook all primary and secondary coding, which was then revised by the coauthors and discussed in multiple peer debriefing sessions [24]. After each session, the coding categorizations and labels were modified and refined based on feedback from coauthors. To explore the potential impact of the different themes on the discontinued use of IMPROVE, additional information was extracted from informal participant contact records kept by the research team.

Table . Thematic framework for top-down coding of interviews.

Theme	Description
Prior knowledge and expectations	Participants talk about any prior experiences or knowledge they have regarding the ESM[a] or self-monitoring tools (analog or digital). Participants talk about their motivations and expectations related to using the ESM or self-monitoring tools and participating in the study.
Actual use in practice	Participants talk about how they used the IMPROVE tool and how they judged these experiences. Mentioning eg, what purpose they used it for, when, and how often they used it.
Potential future integration	Participants talk about their interest in using the IMPROVE tool (or similar tools) in the future. Participants talk about potential changes that they find would be relevant for future use and integration of the IMPROVE tool.

[a]ESM: experience sampling method.

Results

Participant Characteristics

Nineteen clinicians expressed interest in participating in the study, of whom 12 were enrolled. While a systematic record of the number of clients approached by clinicians was not maintained, at least 29 clients were invited, with 24 agreeing to participate. Of the enrolled participants, 8/12 clinicians (67%) and 17/24 clients (71%) completed the intervention; among these, 7/8 clinicians (88%) and 11/17 clients (65%) subsequently participated in an interview. A demographic summary of interview participants can be consulted in Multimedia Appendix 3: Demographic summary.

Thematic Analysis

A complete overview of the themes and subthemes of the analysis and how frequently they were mentioned by participants can be found in Multimedia Appendix 4: Overview of themes. Tabulated in vivo code summaries of participants' individual experiences can be found in Multimedia Appendix 5: Individually summarized experiences. Additionally, illustrative summaries are displayed in text boxes.

Previous Experience and Expectations

Individuals' experiences and expectations are important indicators of their initial willingness to adopt technologies. While only 1 clinician had experience using digital self-monitoring tools, most clinicians and some clients had experience using analog self-monitoring or diary techniques. Some clinicians also had experience with different forms of digital tools within their practice (eg, online training platforms, video consultations, and virtual reality). Similarly, several clients had experience using mental health apps, eg for practicing breathing techniques and cognitive-behavioral therapy exercises. Despite their limited experience, clinicians generally expected that IMPROVE would offer benefits over analog registration methods, allowing them to more easily collect and summarize information about their clients. However, several clinicians also anticipated that there would be challenges and limitations for using the tool. The most commonly mentioned was that low digital literacy could be a barrier for both clients and clinicians (Clinician 0100 Textbox 1). Clinicians' motivation for testing the tool was primarily driven by curiosity and the conviction that they need to master digital tools, as these are becoming increasingly dominant in the health care sector. Interestingly, most clients were primarily motivated by a wish to help and contribute to research but also expressed a curiosity toward what digital mental health tools might offer (Client 0501 Textbox 2). Some clients hoped that IMPROVE would allow them and their clinicians to get a better understanding of their mental health problems.

Textbox 1. "Might use digital self-monitoring tools in the future"– selected participants' experiences.

CLINICIAN 0100:

Prior knowledge and expectations

- I had no experience with digital self-monitoring, but I am currently testing VR technology in therapy. I have previously worked with analog self-registration in therapy.
- I expected it would be technically challenging to work with the tool.
- I want to try using new methods in therapy and I was eager to try the tool.

Actual use in practice

- It was difficult to find things in the dashboard and I needed help from the research team to use the tool. After a while using the platform got easier, but it required a lot of time to get started.
- It was difficult to draw conclusions about my clients' data, but I asked my client for clarifications when I was not able to interpret their data.

Potential future integration

- The tool gave me more information about what happens in clients' lives.
- I might use the tool again if it is made easier to use.

CLIENT 0503:

Prior knowledge and expectations

- I had no experience with self-monitoring apps.
- I hoped to gain more insight into my mental health.

Actual use in practice

- Assessment frequency was high, but okay for 1 week.
- I think I responded to almost all notifications, but I sometimes missed notifications because I forgot my phone. Also, when I was not feeling well I didn't respond to the notifications.
- Identifying, labeling, and scoring emotions on a scale are difficult.
- My therapist had difficulties operating the dashboard, so we didn't go into detail with the data.

Potential future integration

- I might use the tool again, but it is tiring to do for a long time.
- I prefer using the tool as a part of therapy, but I would like to have access to the data myself.

CLIENT 0802:

Prior knowledge and expectations

- I have no experience with health apps, but I use analog methods to keep track of my mental health.
- Digital tools allow you to do more than analog tools, so I thought it would be interesting to try.

Actual use in practice

- The number of notifications was okay, but I sometimes missed notifications because I was working or sleeping.
- Using the tool during the therapy session made it easier to recollect things that had happened.

Potential future integration

- I might consider using the tool again.

XSL•FO
RenderX

Textbox 2. "Not likely to use digital self-monitoring tools in the future"– selected participants' experiences.

CLIENT 0501:

Prior knowledge and expectations

- I had no experience with self-monitoring apps.
- I was hesitant to participate because I do not like self-assessments.
- I thought it was worth trying and I wanted to contribute to improving mental health care.

Actual use in practice

- It was difficult always to remember to have my phone with me.
- Notifications were sometimes disturbing and the assessment frequency was too high.
- It was important to me that I did not miss notifications; therefore, fear of missing notifications would sometimes stress me.
- Self-reflection was sometimes difficult and confronting.
- It was interesting to look at my data.

Potential future integration

- I don't find it likely that I will use the tool again.

Actual Use in Practice

Participants' willingness to test the IMPROVE tool was influenced by their initial expectations that digital self-monitoring would provide them with benefits and advantages. Below we describe how clinicians and clients used the tool in practice and how they evaluated its capabilities and contextual fit.

Step 1: Start-Up Session

Clinicians generally found that the time investment required to learn to use IMPROVE was too much considering the time they had available. Experiencing time constraints was also one of the most common reasons reported by clinicians who did not complete the intervention. Personalizing clients' questionnaires in particular asked for extra time and effort from clinicians. Despite emphasizing that the personalization of the IMPROVE questionnaires made the tool more relevant, clinicians made limited use of the available personalization options. Most clients also expressed that personalization of the tool is desirable but that clinicians did not discuss this with them.

Furthermore, while most clinicians were convinced that using the IMPROVE tool would become easier with practice, many clinicians indicated that the complexity of the tool was too high. In particular, clinicians found that navigating the dashboard was not intuitive and that it was difficult to find things and set up the clients' questionnaires. Thus, many experienced that they did not have adequate competencies to make full use of the tool; "I constantly felt I was doing something wrong," 1 clinician explained. However, at the same time, clinicians made limited use of the training manual and expressed a wish for more in-person support. This was also reflected by several clinicians contacting the research team for additional support after the initial training (Clinician 0100,Textbox 1). Interestingly, some clinicians resolved their need for support by organizing training sessions with colleagues.

Step 2: Self-Monitoring

The majority of clients reported that they made an effort to comply with the notifications, but many found that the frequency of the self-assessments (10 notifications per day) was too high. A few clients indicated that they would consciously skip assessments because they did not consider it important to respond to all notifications. Conversely, some clients also mentioned that missing notifications would make them feel guilty and annoyed, or that the thought of missing assessments made them nervous and stressed (Client 0501, Textbox 2). Although clients reported that completing the assessments did not take them long, many experienced difficulties responding to the notifications within the fixed 15-minute response window. Several reasons for this were voiced, of which being occupied with work and other daily activities was the most frequent (Client 0802, Textbox 1; Client 0601, Textbox 3). Having an irregular day rhythm or sleep schedule that did not match the notification schedule, needing to carry one's phone and ensure an internet connection, and feeling unwell or tired were also factors that made complying difficult. Importantly, clients who dropped out of the study also reported a lack of time, difficulties complying with the assessments, notifications stress, and feeling unwell as reasons for not completing the intervention.

XSL•FO
RenderX

Textbox 3. "Likely to use digital self-monitoring tools in the future"– selected participants' experiences.

CLINICIAN 0600:

Prior knowledge and expectations

- I have no experience with digital self-monitoring, but I have used analog self-monitoring techniques in therapy.
- I think digital tools are easier to use than analog self-monitoring methods. Digital tools are used more and more, and we need to offer clients tools that can help them achieve their goals.

Actual use in practice

- It takes time and effort to learn to use the tool.
- I didn't personalize my client questionnaire, because I wanted to start with the basics.
- I monitored my clients' responses and contacted them if I could see they weren't responding.
- There was a lot of data; I started with simpler visualizations and gradually added things. If I didn't know the client beforehand, I would not be able to make sense of the data.

Potential future integration

- The tool provided more details and an overview and allowed us to go more in-depth with problems that we already knew were there. We used the tool to identify what was important for the client.
- I will certainly consider using this tool again with my clients.

CLIENT 0601:

Prior knowledge and expectations

- I had no experience with health apps.
- I had no specific expectations and I'm generally skeptical about health apps, but I wanted to help research.

Actual use in practice

- I responded to as many notifications as I could, but I missed a lot because I was busy. I didn't consider it a problem that I missed some notifications. I also had to remember to bring my phone and connect it to 4G.
- It is sometimes difficult to assess whether your mood changed and how much.
- I was amazed to see what came out of the data. My therapist was able to do a lot with the data, despite my low compliance.

Potential future integration

- The tool provided useful information and allowed me to get to know myself better.
- I would be interested in using the tool again, but I would like to have access to the data myself.

CLINICIAN 1200:

Prior knowledge and expectations

- I used digital self-monitoring tools before in therapy.
- Digital self-monitoring tools are easier to use and give better insight into clients' lives than other methods. However, self-monitoring can be difficult for some clients.

Actual use in practice

- Setting up the tool took a lot of time.
- It was interesting to look at the data, but the many visualizations were somewhat overwhelming.

Potential future integration

- The tool quickly provides you with an overview of how your client is doing.
- I would like to use the tool again, but it should be made less burdensome for clients. It would be interesting to monitor clients for a longer period to evaluate their progress and the effect of treatments.

CLIENT 1201:

Prior knowledge and expectations

- I had no experience with mental health apps.

XSL•FO
RenderX

- I expected the tool would make it easier for my therapist to understand my problems.
- I think there is a need for more mHealth in mental health care and that this tool might help me and others.

Actual use in practice

- There are too many notifications and they are sometimes disturbing. People should be allowed to snooze notifications if they are busy.
- I did my best to respond to the notifications. On good days, it is okay to complete the assessments, but on bad days, it is difficult.
- My therapist identified moments when I was feeling bad and tried to understand these.

Potential future integration

- The tool can make you aware of what you need to work on, and it makes it easier to monitor the effects of your treatment.
- I would like to keep using the tool to check how I am doing.

Several clients found the practice of labeling and rating their emotions difficult. Some indicated that they were unsure whether they completed the self-assessments correctly and expressed a need for more guidance from their clinicians on how to respond to the assessments. Several clients also expressed a wish for more open questions that would allow them to describe their experiences in more detail, as they did not find that the default questions were sufficiently able to capture their experiences. Interestingly, while clinicians were not instructed to do so, some monitored their clients' responses during the self-monitoring week as a form of remote monitoring of clients (Clinician 0600, Textbox 3).

Step 3: Data Feedback Session

To get the most out of the data feedback session, most clinicians reviewed their clients' data in preparation for the session. Many felt that preparation was necessary for them to understand the data and be able to discuss it with clients. Many clinicians found it challenging to interpret and navigate the graphs, which they often perceived as overwhelming. This generally led clinicians to be selective in the data they would review and discuss with clients. All clinicians reviewed the data with their clients and some also encouraged their clients to give their interpretation of the data or to provide further clarification (Clinician 0100, Textbox 1*)*. Similarly, clients indicated that the support of a clinician was crucial for them to make sense of their data. While most clients reported that they could understand the graphs, they also indicated relying on their clinician to help them interpret the data. These findings indicate that, despite challenges, most clinicians could provide useful feedback to their clients based on the self-monitoring data.

Potential Future Integration

Despite encountering challenges, both clinicians and clients described that the IMPROVE tool provided them with useful insights. Next, we will explore how these experiences influenced participants' willingness to integrate and use digital self-monitoring tools in their future practice. Clinicians and clients were generally open to using digital self-monitoring tools again. Participants who expressed the greatest interest in continued use more often experienced an added value of using IMPROVE (see Textbox 3). This included having access to more detailed information about clients' mental health, which helped create an overview and clarity, and identify focus points to discuss in therapy. Clinicians who had initial positive expectations and believed digital tools were important in supporting mental health care were also more willing to use digital self-monitoring again. The clinicians who were more hesitant reported more difficulties using IMPROVE and expressed a greater need for support (see Textbox 1).

Clients who expressed a low interest in using digital self-monitoring tools in the future also reported negative reactivity in the form of stress and increased negative emotions during self-monitoring (see Textbox 2). Interestingly, all these clients had high compliance during the self-monitoring. However, clients overall reported that the assessment frequency should be lowered to make future self-monitoring less burdensome. Moreover, some clients and clinicians expressed an interest in using the tool for extended periods to monitor progress and the effects of therapy. Finally, clients and clinicians also expressed a desire to adapt the self-assessment further and monitor factors more specific to the individual client.

Discussion

Principal Findings and Implications

To guide the successful implementation of digital self-monitoring tools in mental health care, it is pivotal to understand how people react, respond, and adapt to these technologies. We examined how clinicians and clients in a psychiatric center appropriated the ESM-based self-monitoring tool IMPROVE within their therapeutic practices. In line with existing theories, our results indicate that clinicians' and clients' willingness to adopt and integrate digital self-monitoring tools into their practice depend on the perceived balance between added benefits and the effort necessary to accomplish these [17]. The main benefits identified in our study included better information about clients' mental health, while system usability and assessment burden demanded extra effort from participants. Below we discuss the potential implications of this for the implementation of the ESM tools in clinical practice.

While some struggled more than others, all interviewed participants managed to reach a basic level of use of the IMPROVE tool within the intervention period. Furthermore, we observed a great interest and curiosity towards digital mental health tools, especially among clinicians. Many clinicians experienced that using IMPROVE added value and generated more clarity and focus in the therapy, by providing more detailed

XSL•FO
RenderX

information about the clients' mental health. Several clients also experienced these benefits. Our findings suggest that a collaborative effort between clients and clinicians is key to maximizing the experienced benefits of the ESM tools. While many clinicians struggled to construct a frame for the interpretation of clients' data, several turned to their clients to help make sense of the data. Clients also stressed the importance of having a clinician support them in interpreting their data and doubted whether they would be able to do this themselves. Other studies similarly highlighted the value of patients providing clinicians with additional information about patient-generated health data to unveil the subjective meanings of the data [25]. This indicates that collaborative data interpretation is an essential component in the clinical application of the ESM tools, which boosts the perceived usefulness of the tool. Therefore this component should be emphasized and strengthened in future implementation initiatives.

Most participants in our study expressed willingness to use the ESM or similar tools in the future, although many emphasized the necessity of making changes and improvements to the tool. This aligns with previous findings that clinicians and clients are generally interested in the ESM-based self-monitoring [18,19,26]. However, the need for further adaption was reflected by participants encountering several challenges in using and integrating IMPROVE into their practice. Many clinicians experienced difficulties navigating the tool's functionalities, which made it difficult for them to start using the tool and apply more advanced features, such as personalizing clients' questionnaires. Clinicians, therefore, expressed a need for more in-person support. Unfortunately, these types of usability issues are common in digital health tools [27]. A study examining usability problems of eHealth applications found that system navigation, interface design, and lack of built-in guidance and support accounted for 69% of users' usability issues [27]. Furthermore, consistent with other research [28,29], our study indicated that technology literacy and attitude can influence willingness to use digital tools. More anthropological field research on mental health care workers' existing technology habits and literacy might help inform the system design of the ESM tools and understand users' context and capabilities. Similarly, engaging end-users in co-design processes could help tackle usability issues that could lead users to abandon the tools. Finally, our results show that adequate support for clinicians and clients is needed to facilitate the implementation of the ESM tools in mental health care. Especially in the early adoption phases, users should be supported in familiarizing themselves with the tools and integrating them into their work routines. Potential solutions could include more built-in guidance functions in the tool or establishing additional structures (eg, service centers) that can provide direct user support.

Furthermore, our findings emphasize that self-monitoring demands a lot of clients, and can be difficult and burdensome for people with mental health problems. While clients expressed a wish to comply with the self-assessments, they often found it practically challenging. In line with other self-monitoring studies [30], we found that competing activities (eg, working) and technical issues (eg, device or internet access) were the most common reasons for missing assessments. To comply with the assessments, several clients had to change their phone habits, eg, ensuring that they always had their phone with them, and had notifications and internet connection on. As it is known that existing habits are important predictors of technology acceptance [17], this need to change habits can become a threat for sustained clinical implementation of ESM tools. Furthermore, some clients reported negative reactivity to self-monitoring, which was associated with less interest in using the tool again. Other studies also found that while self-monitoring can be motivating and helpful, it can also become a stressful activity that clients feel obliged to comply with [31]. This highlights the need to investigate how self-monitoring tools can be made less burdensome for users while still producing valuable information. Potential solutions could include the integration of passive monitoring [32,33] or adaptive assessment schemes that allow for periods with lower and higher assessment intensity [34,35].

Limitations

The findings of the study should be interpreted considering the following limitations. One limitation is that the study relied on referral sampling, which might have influenced the representativeness and diversity of the sample. Furthermore, the study was conducted in a large psychiatric center of a university in Belgium. Clients and clinicians within different health care settings or with different demographic backgrounds might have different experiences of using digital self-monitoring tools. Another limitation is the potential overrepresentation of people with a positive attitude towards digital mental health tools. Several clinicians for example recruited clients who they expected were interested in using digital tools and had the necessary technical literacy. Furthermore, none of the participants who dropped out of the intervention participated in the interviews. However, using contact records data, we established that some of the challenges experienced by participants who were interviewed were also reported as reasons for dropout by participants who did not complete the intervention. Future research should aim to better understand the views of nonadoptors, identify the main reasons for nonadoption, and work towards tackling these barriers in the design and implementation of ESM self-monitoring tools.

Conclusion

ESM-based self-monitoring can provide clinicians and clients with useful information about how clients' daily life activities correspond to fluctuations in their mental health. These benefits seem to increase when clinicians and clients engage in collaborative interpretation and sense-making of the clients' data. Therefore, ESM tools have a clear potential to support a person-centered approach to mental health care rooted in clients' daily life experiences. However, our study highlights that the effort required by clinicians and clients to integrate ESM tools into daily practice remains substantial due to system usability challenges and the burden of repeated assessments. Addressing these issues in future ESM tool developments will be crucial for successful implementation. One potential solution to tackle these barriers is enhancing user support. Another is modifying key features of ESM tools to better suit users and their contexts, such as reducing the frequency of assessment and data information load. Engaging end-users directly in this process

XSL•FO
RenderX

through user-centered design approaches may ensure a better fit between the tools, their context of use, and user goals and ultimately facilitate better adoption.

Acknowledgments

The authors would like to thank all clinicians and clients for participating in the study and contributing to this work. We also thank Merijn Mestdagh and Stijn Verdonck for programming the necessary software functionalities on the m-Path software platform. In addition, the authors would like to thank Silke Apers, Daphne Tuyaerts, and Tessa Biesemans for their contribution to data collection and Ana Teixeira and Daphne Tuyaerts for their help in designing the study. Finally, the authors would like to thank the Leuven IMMERSE patient advisory board members for providing feedback on the interpretation of the study results. This project received funding from the European Union's Horizon 2020 research and innovation program (777084; DynaMORE project and 945263; IMMERSE). GK is supported by the Research Foundation–Flanders (12ZZM21N and 1204924N).

Data Availability

To avoid potential identification of study participants, the complete interview transcripts will not be made publicly available.

Authors' Contributions

LT, GK, JW, MW, and IMG were involved in designing the study and setting up the data collection. Data analysis was undertaken in a collaboration between LT and LU. The first manuscript draft was written by LT with the support of GK. All authors contributed to the critical review of the manuscript and approved the final version.

Abstract

Background: First Nations children and youths may have unique ways to convey their health needs that have not been recognized by health providers. This may contribute to the disparity between high rates of mental health and physical pain and low rates of treatment for the conditions they experience. Evidence suggests that a colonial history has resulted in poor experiences with the health care system, lack of trust with health providers, and miscommunication between clinicians and patients. Contemporary ways, using both Indigenous and Western knowledge, are needed to bridge the gap in communicating pain.

Objective: The aim of this qualitative study was to test the usability and clinical feasibility of the Kids Hurt App with First Nations youths and clinicians working with youths.

Methods: Using a Two-Eyed Seeing approach, the Kids Hurt App was developed using concepts from validated mood and pain assessment apps combined with community-based research that gathered First Nations youths and clinicians perspectives on quality, intensity, and location of pain and hurt. The Kids Hurt App contains 16 screens accessible on any web-based device.

Results: In total, 3 rounds of low-fidelity testing (n=19), 2 rounds of high-fidelity testing (n=20), and 2 rounds of clinical feasibility testing (n=10) were conducted with First Nations youths (10 - 19 years) to determine the relevance, validity, and usability of the Kids Hurt App. High-fidelity testing was also conducted with 15 clinicians after completing the high-fidelity youth sessions. Youths had constructive suggestions that were used to improve the app in subsequent rounds of version testing. There was one main discrepancy between youths and clinicians related to preference for how best to visually convey pain. The youth's preference was maintained in the app.

Conclusions: All youths in all rounds of testing indicated that they would use the Kids Hurt App if it was available to them in a health care setting, with most clinicians noting that the app would be useful in practice.

Introduction

Overview

Indigenous peoples in Canada are comprised of 3 distinct groups: First Nations, Inuit, and Métis. They reside across Canada, from large cities to small isolated communities [1]. In comparison to non-Indigenous peoples, Indigenous peoples are the fastest-growing cohort in Canada with a significantly younger population [1]. Indigenous children younger than 14 years of age represent 25.4% of the total Indigenous population, while the same age group in the non-Indigenous population only compromises 16% [1]. Repeated reports of racism in health care, such as those in the In Plain Sight report describing Joyce

XSL•FO
RenderX

Echaquan's fatal health care experience in Quebec [2], combined with research findings [3,4] suggest that health care providers need to understand the structural and historical factors that contribute to the current racial disparities faced by Indigenous peoples [5]. A legacy of colonialism and present-day racism is a determinant of health that is unique to Indigenous peoples so efforts need to be made to create better understanding, appropriate assessment, and improved care for health conditions such as pain [6].

While 1 in every 5 Canadian people experiences chronic pain, this number is significantly higher in Indigenous communities, and most types of pain are more prevalent in Indigenous peoples [7]. Indigenous children are particularly vulnerable to experiencing pain. In one study examining pain diagnoses, a large sample of First Nations children (n=2631) who were compared to an age-, sex-, and location-matched sample of non–First Nations children, demonstrated that the First Nations cohort experienced significantly more physical pain–related diagnoses for 10 of the 13 pain indicators studied [7]. Further to this, while ear- and throat-related diagnoses were the 2 most diagnosed pain conditions for both groups, the First Nations cohort was significantly less likely than the non–First Nations cohort to visit a specialist for these same conditions, demonstrating inequities in diagnosis and treatment [7]. Additionally, these data showed that children (0 - 9 years) who had a physical pain diagnosis were more likely to have a mental health diagnosis in adolescence, a finding only evident in the non–First Nation cohort who were seemingly able to access mental health care [7].

Cultural variances in pain expression have also been found between Indigenous and non-Indigenous children and youths [8,9]. Latimer et al [8] concluded that Mi'kmaq children were stoic and hid their pain. Children reported that they would not cry when enduring pain and preferred instead to be "brave" or "tough it out" [8]. These findings led researchers to conclude that health clinicians may not have ways to accurately assess or document the level of pain a child or youth is experiencing. Similar findings of stoicism were reported in Indigenous peoples in Australia, with participants often being described as quiet about their pain and not reporting pain due to higher pain tolerance, fear of Western medicine, or intercultural communication difficulties [10]. Clinicians are trained to use numerical or face pain scales to assess pain; however, only minimal research has been done to determine if these self-report pain scales are culturally appropriate for use with Indigenous children, and indeed to our knowledge, none in First Nations children [11,12]. Community members reported that numerical pain rating assessment scales are confusing, and it is difficult to attach hurt or pain to one measure such as a face or number [9]. The evidence suggests that there is a clinical practice gap in assisting Indigenous youths to convey their pain to health providers. This study endeavored to find a culturally appropriate mechanism to support youths in sharing their pain and to address reports of a lack of clinician's ability to recognize pain, which creates a barrier to appropriate health care [13]. In response to these needs, the Kids Hurt App [14] was cocreated with Indigenous and clinical partners. It was created with the notion that Indigenous peoples have many effective ways of communicating knowledge that include visual images and storytelling. This led the developers to explore how both Indigenous and Western ways could be used to develop a better assessment tool that puts the technology in the hands of the youths. The aim of this qualitative study was to test the usability and feasibility of the Kids Hurt App with First Nations youths and clinicians working with youths.

Background

Two-Eyed Seeing

The project used a Two-Eyed Seeing (TES) approach, a term coined by Elders Murdena and Albert Marshall, which recognizes the benefit of seeing Indigenous knowledge and experience from one eye while also seeing strengths from another eye's perspective that is different from one's own [15]. The Western perspective is most typically how health care is currently delivered. When both eyes are used, the ultimate benefit is achieved by effectively enhancing the health of Indigenous peoples through the practical sharing of knowledge [16].

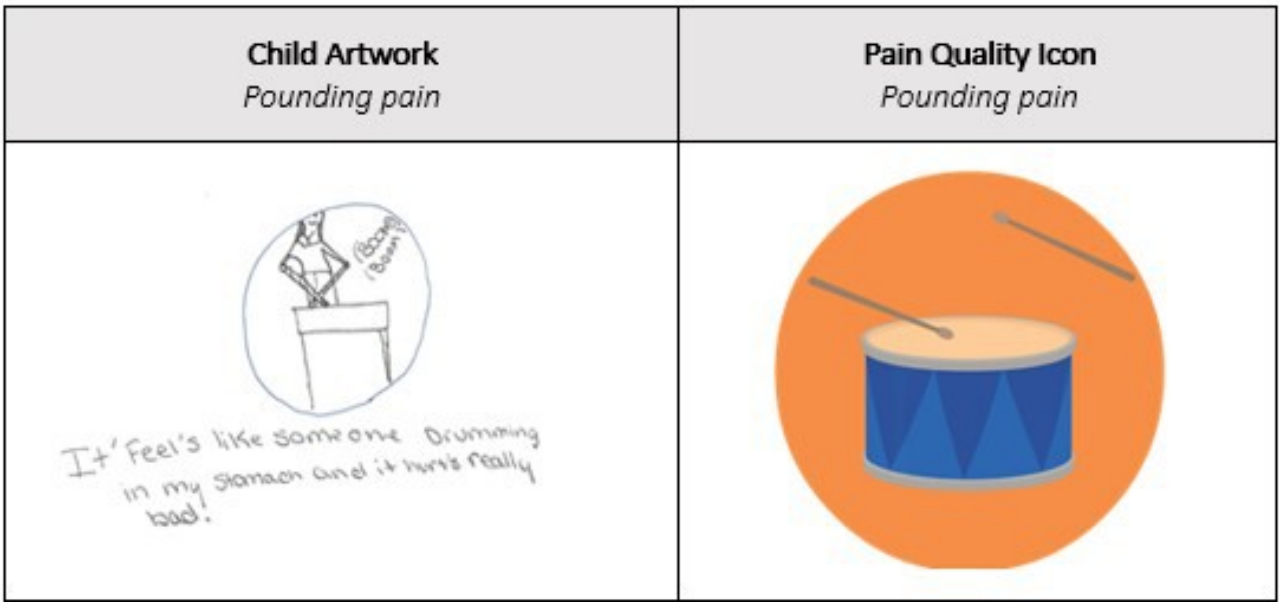
Digital Health Interventions for Indigenous Children and Youths

Although there is a growing body of literature on digital health and app-based interventions to manage pain in children and youths, research on the development and usability of app-based interventions for Indigenous peoples is limited. In a review of digital health solutions for Indigenous mental well-being across Canada, the United States, Australia, and New Zealand, Hensel et al [17] indicated that co-designed app-based interventions had been shown to reduce anxiety and depression symptoms and contribute to well-being. The Aboriginal and Islander Mental Health Initiative for Youth App, or AIMhi-Y, was developed in consultation with Indigenous youths from Australia and the Torres Strait Islands [18]. The youths identified apps as a potential way to mitigate barriers to accessing help and highlighted the need for a strength-based approach [18,19]. A randomized controlled trial found that iBobbly, a suicide prevention app developed in consultation with Indigenous youths living in Australia, had only a minimal, nonsignificant impact on psychological well-being outcomes, although qualitative data indicated the app was helpful and that construct validity issues may have been the reason why there was not a significant impact [20]. To date, there is no research on the development or usability of apps for Indigenous children and youths in Canada [21].

Development of the Kids Hurt App

The Kids Hurt App was developed by the Aboriginal Children's Hurt and Healing Initiative for children aged 10 - 19 years. Funding for the app development and testing was received from the Canadian Institutes of Health Research (FRN# 162455 & SCA-145102), Indigenous Health Nursing Research Chair, Dalhousie University (FRN# 167603), and IWK Health Foundation. The Aboriginal Children's Hurt and Healing Initiative is a broad partnership, consisting of Indigenous community leaders, clinicians, elders, youths, researchers from universities, and health delivery systems. In keeping with Ownership, Control, Access and Possession (OCAP) principles

XSL•FO
RenderX



[22], the app is owned by communities involved in this research study. OCAP is a registered trademark of the First Nations Information Governance Centre and describes the principles of ownership, control, access, and possession to ensure that First Nations have control over data processes including ownership and how their information is used. The app was developed to facilitate pain communication between clinicians and Indigenous youths in a culturally safe manner. It is not meant to replace the history-taking step of a health care interaction but rather serves to augment the quality of communication exchange by giving youths an opportunity to share their pain story in a comfortable, culturally safe way.

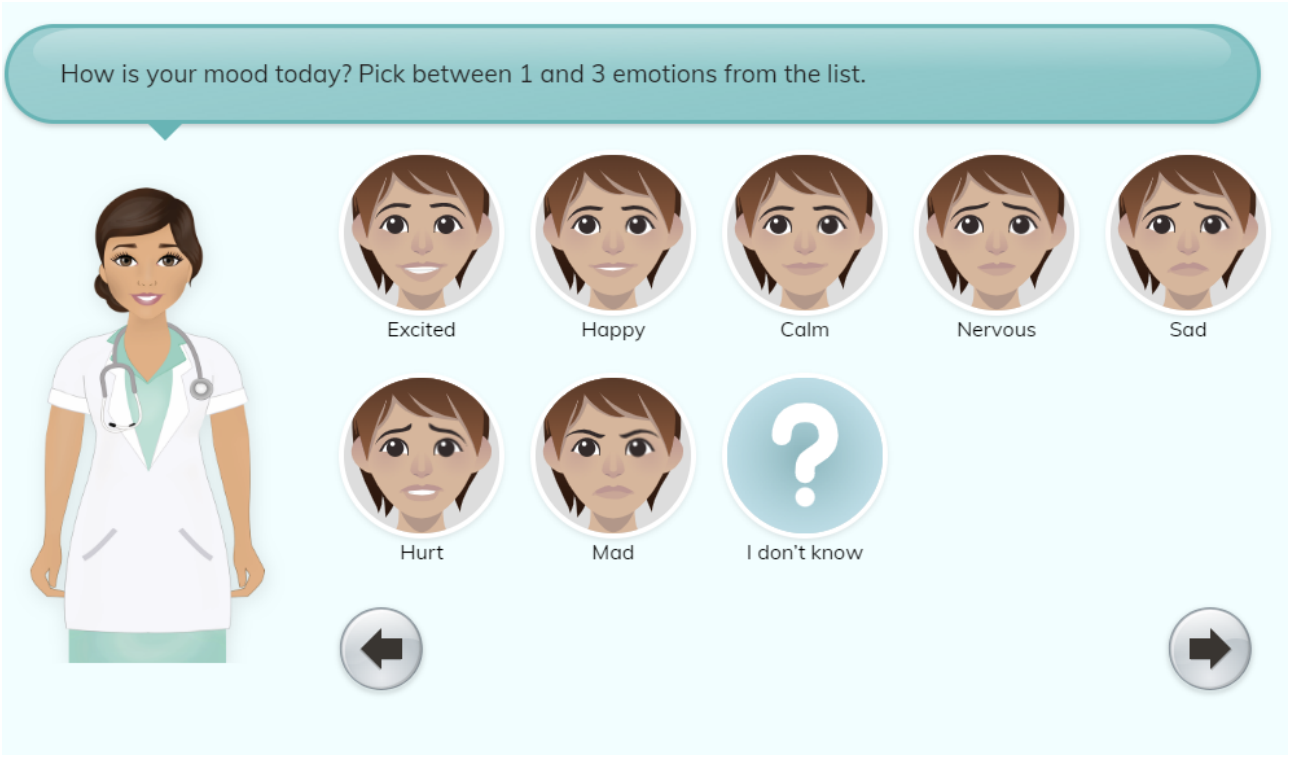
The app was developed using TES to ensure both Indigenous and Western concepts and content were included. In total, 16 "screens" or interfaces were developed. Multimedia Appendix 1 provides an example of the final 16 screens developed. Previous versions of these screens were used throughout various stages of testing.

The first app screen asks users their gender and age (see Screen 1 in Multimedia Appendix 1), with the subsequent screen providing them with the option to create an avatar or choose a predesigned one (see Screen 2-3 in Multimedia Appendix 1). First Nations youths were involved in the development of the avatar designs through initial content validity testing to ensure that visual representation was present. Once an avatar is chosen, it is prompted to answer a series of responses to physical and emotional pain prompts. The inclusion of both physical and emotional pain prompts provides an example of how TES [15] was used throughout the development of the app. Earlier design ideas for the app had only physical pain prompts; however, community feedback suggested that incorporating both physical and emotional pain prompts would better represent the Indigenous holistic view of health, which involves "a healthy balance of 4 elements or aspects of wellness: physical, emotional, mental, and spiritual" [23]. While this version of the Kids Hurt App does not incorporate all 4 wellness aspects, emotional and physical pain were chosen because they were the most reported types of pain in previous research [7]. Future app iterations are expected to include spiritual and mental dimensions. There is also evidence that physical and emotional pain are interconnected, and the app presents an opportunity to highlight this for both youths and clinicians.

Additional incorporation of TES [15] involved the use of the International Association for the Study of Pain assessment tool guidelines [24] in the development, ensuring three key assessment features were embedded into the app: (1) pain location (see Screen 4-6 in Multimedia Appendix 1), (2) pain quality (see Screen 7 in Multimedia Appendix 1, and (3) pain intensity (see Screen 8 in Multimedia Appendix 1). Pain quality icons were conceptualized based on previous art-based research with Indigenous youths [8,9] as well as the Iconic Pain Assessment Tool [25] and the Pain Quality Icon (QuILT) [26] as illustrated in Figure 1.

Figure 1. Pain quality icon development.

Pain intensity was initially captured using 2 scales: a 10-point "face scale," mimicking the Faces Pain Scale—Revised (FPS-R) [27], and a newly developed "Jar of Hurt," building on the concept of the "Pieces of Hurt" tool [28] and respecting the nation's language and word for "pain" which is "hurt" [8]. A jar was used as a common, everyday item that would provide the imagery of filling something up with pain or hurt. In addition, details of *where* users were when they got hurt (ie, school) and *what* they were doing (ie, playing) were also included with options based on common places of injury noted in the First Nations Regional Health Survey [29].The inclusion of the *where* and *what* aspects of the app allowed the incorporation of storytelling (see Screen 9-10 in Multimedia Appendix 1), an approach with significant cultural ties for Indigenous populations [30].



After completing questions regarding the user's physical pain, users are then prompted to provide information on their emotional pain through a series of similar screens (see Screen 11-14 in Multimedia Appendix 1). Emotional pain icons were initially chosen based on 22 common emotions identified from

XSL•FO
RenderX

20 validated mood apps (Multimedia Appendix 2). Through the initial content validity testing with First Nations youths, these 22 emotions were narrowed down to 8, which were identified as most likely to be used to describe their emotional mood. The resulting 8 emotions, both "negative" and "positive," provided a range of options and avoided bias in responses (Figure 2). Emotional pain questions focused on users' current emotional state (happy, sad, and anxious), intensity of those emotions (using the 10-point Jar of Hurt), and any physical symptoms that may be associated with their emotional pain (ie, chest tightness).

Upon answering both the physical and emotional pain questions, information is presented on a final storyboard screen (see Screen 15 in Multimedia Appendix 1).

Figure 2. Emotional pain icons.

Methods

Study Design

Once an initial version of the app was finalized three types of testing took place: (1) low-fidelity testing, (2) high-fidelity testing, and (3) clinical feasibility testing. This testing or development strategy mirrored the process published by Stinson et al [31].

Ethical Considerations

Prior to project initiation, the study was approved by both an Indigenous and tertiary pediatric hospital research ethics board (Mi'kmaw Ethics Watch & IWK Health Research Ethics Board; #1017831). Informed consent was obtained from all participants or their parents or guardians prior to taking part in study procedures. Youth participants received a CAD $10 (US $6.98) gift card after completing the testing. Clinician participants were not compensated. Data were deidentified immediately following data collection sessions.

Participants

First Nation youth participants were recruited through social media platforms and community organizations or contacts to complete low-fidelity, high-fidelity, and clinical feasibility testing. Clinicians recruited from a First Nation Health Centre and a pediatric health center unit specializing in emotional or physical pain–related services (rheumatology, pain clinic, etc) also completed high-fidelity testing. Eligibility criteria for youth participants included (1) self-identifying as Indigenous, (2) residing in a First Nation community, and (3) being between 10 and 19 years of age.

Data Collection

Overview

The study took place over a 5-year period between April 2017 and March 2022. Significant delays were experienced due to the COVID-19 pandemic. All youth data collection sessions were completed within the youth's Indigenous community to ensure that local support resources were available if a youth felt distressed. A trained mental health clinician was available as a resource for each session, and smudging was offered for youths who took part in the clinical feasibility sessions.

Low-Fidelity Testing

Low-fidelity testing is a qualitative usability approach where youths were able to view a paper-based version of the app. Youths completed a demographic survey prior to reviewing the app screens. In total, 3 rounds of low-fidelity testing took place. During each round, youths were shown paper-based screenshots of the Kids Hurt App and asked what they liked and disliked about the design through a series of semistructured questions.

XSL•FO
RenderX

Sessions were audio-recorded and transcribed for clarity and accuracy. After each round of testing, feedback was reviewed and integrated into the app. Screenshots of the updated version of the app were then shown to the next round of participating youths until no further changes were suggested based on the methods of Stinson et al [31].

High-Fidelity Testing

High-fidelity testing is similar to low-fidelity testing; however, participants were able to review a fully functioning version of the app rather than paper-based screenshots. Youths completed a demographic survey prior to using the app, and all sessions were audio-recorded and transcribed. Two rounds of high-fidelity testing were completed with participating youths to determine functionality and acceptability and to allow for any suggested revisions to be shared. The app was viewed on an iPad, and the youths worked through the app in the presence of the research assistant. At the start of each session, youths were asked to complete the app by themselves and to talk out loud about any likes, dislikes, or difficulties. The length of time it took for youths to complete the app from start to finish was recorded. Then, they were asked to go through the app for the second time with the research assistant who asked them semistructured questions. Once finished, they were asked open-ended questions on their overall thoughts regarding likes, dislikes, ease of use, and whether they would use the app in a health care setting if it was available. Feedback from each round was incorporated until no further changes were suggested (2 rounds). Interviews with the youths were audio-recorded in each of the 2 rounds to maintain the integrity and accuracy of the findings.

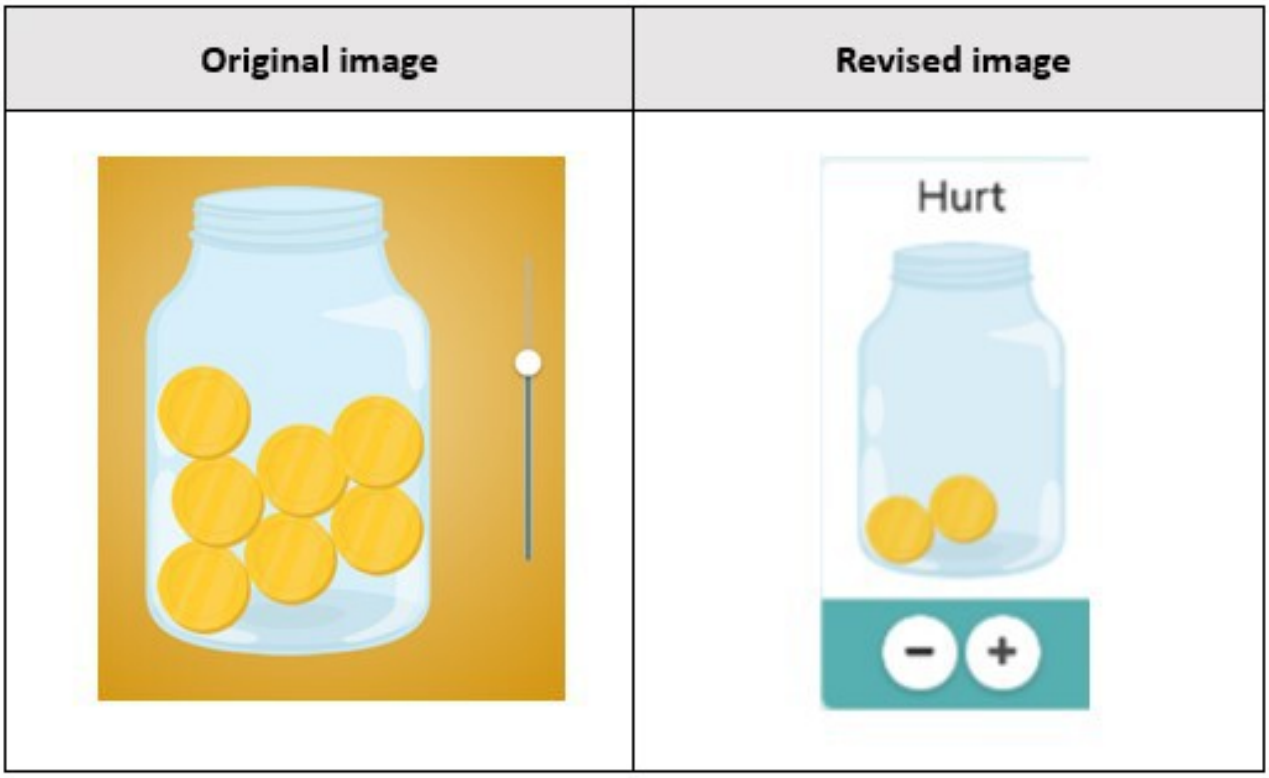
After the youths completed the high-fidelity testing, clinicians were then invited to take part in high-fidelity testing. Clinicians were invited to use the app and then answer a series of questions either through a digital survey or during a focus group. Focus group sessions were transcribed to ensure data accuracy. Questions assessed the clarity and importance of the various app components and also allowed space for participants to provide suggestions on what they would like to change or add for each screen. Demographic questions were also asked to determine participant's profession and types of experience.

Clinical Feasibility Testing

Clinical feasibility testing was completed with youths to help determine if the app works well, if it is easy to use, and if youths found it relevant for use in their care. Youths were asked to work through the app with the research assistant present and then answer a series of questions in a digital survey format. Questions ranged from demographic questions to those regarding the app's usefulness as well as functionality. Once an initial 5 youths had completed their review of the app, changes were incorporated, and an additional 5 youths were invited to take part. After 2 rounds of clinical feasibility testing with very positive results and minimal changes, it was determined that a third round was not needed.

Data Analysis

Demographic survey responses from all rounds of testing were analyzed using the SPSS Statistics (version 24; IBM Corp) database system to provide an overall breakdown of age and gender. Field notes and transcribed interviews were reviewed to determine any changes needed for subsequent rounds of testing. Revisions associated with more large-scale app functionality that were unable to be incorporated between testing rounds, such as incorporating a feature to track pain over time, were added to a database for future recommendations.



Results

Low-Fidelity Testing

A total of 19 youths participated in 3 rounds of low-fidelity testing (round 1: 7 youths, round 2: 6 youths, and round 3: 6 youths). In total, 63% (n=12) of the participants were identified as female. The average age for all participants was 13 (SD 2.46) years. In the first round of low-fidelity testing, 1 participant suggested that the Jar of Hurt scale should use a plus or minus button to increase or decrease the amount of hurt rather than the original "slider" option (Figure 3). In subsequent rounds, youths were shown both the slider and the plus or minus option and asked their preference. The majority of youths (n=11) preferred the plus or minus option. The directions for describing how to use the Jar of Hurt were also identified during low-fidelity testing as needing clarification. A total of 6 of the 19 youths identified this issue. "I don't know, it's a little confusing. It sounds complicated" (Female, 14 years). The language was simplified, and it was agreed that it would be further reviewed in the high-fidelity rounds.

XSL•FO
RenderX

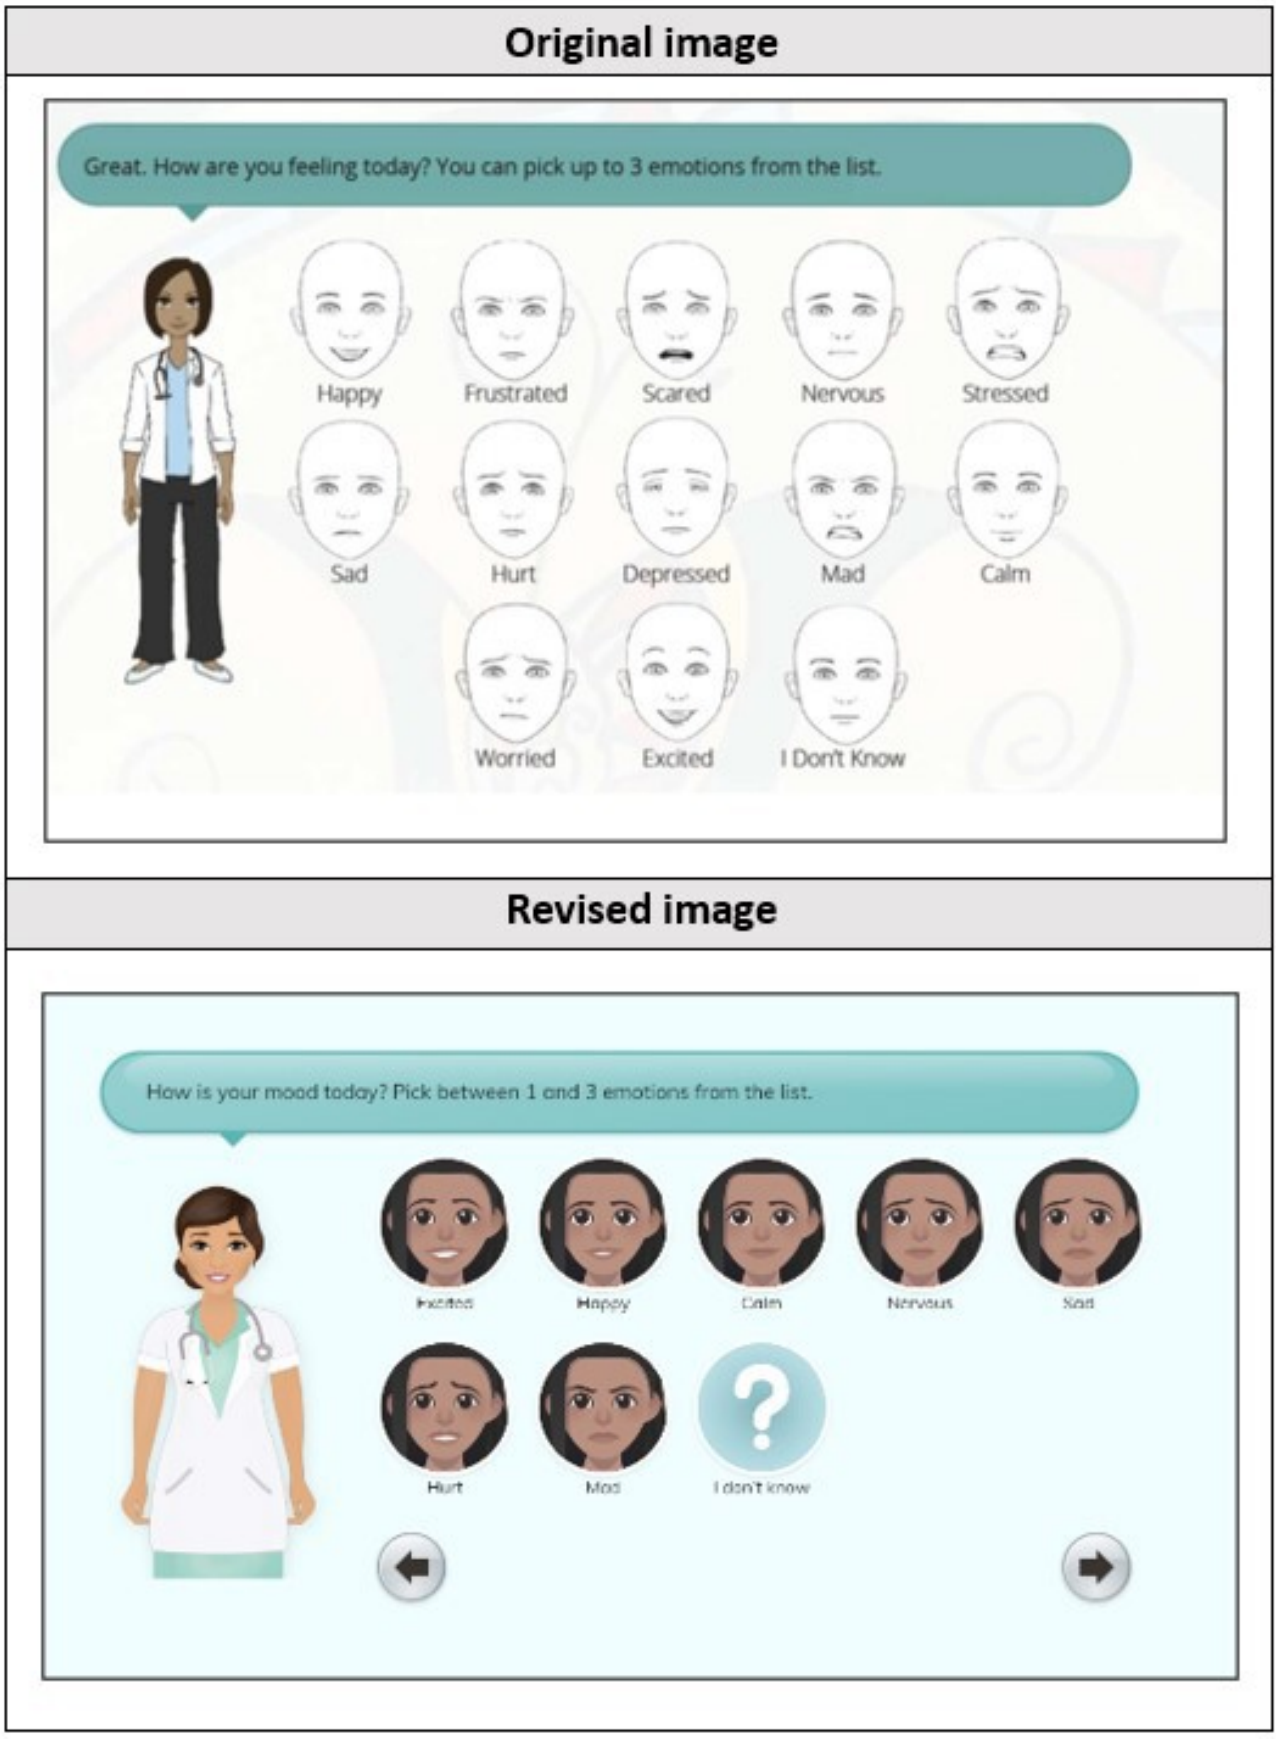


Figure 3. Jar of Hurt—plus or minus button addition.

The final noted change from low-fidelity testing was an overall dislike of the way the emotion face icons looked. One youth described the faces as “creepy.” To address this, the facial icons were redesigned to look like the user’s avatar rather than a generic face as illustrated in Figure 4.

XSL•FO
RenderX

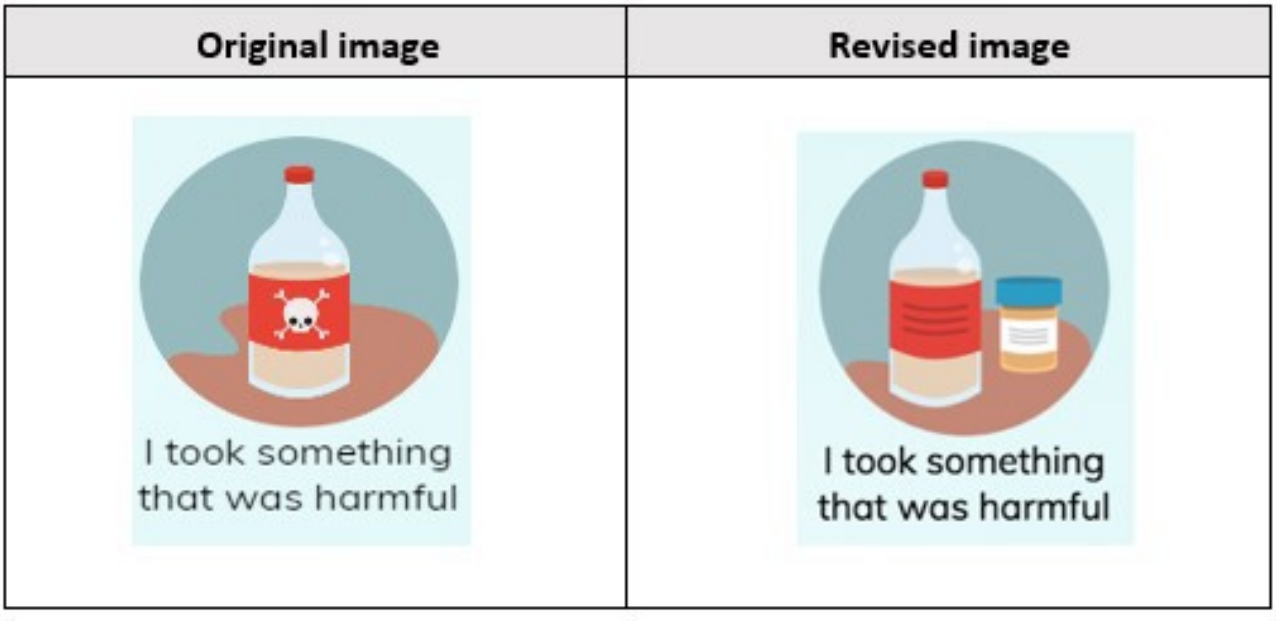
Figure 4. Emotion faces—revised. Original image depicts 10 emotions rather than the finalized 8 emotions, as this was an initial mock-up screenshot for testing purposes only.

XSL•FO
RenderX

High-Fidelity Testing

A total of 20 youths participated in the 2 rounds of high-fidelity testing (round 1: 10 youths and round 2: 10 youths). In total, 70% (n=14) of participants were female, and the average age for youth participants was 16 (SD 2.46) years. The average time it took youths to complete the app was 3.61 minutes (216.6 seconds; SD 48). All youth participants identified enjoying the app and agreed it would be helpful to them.

> *It was pretty helpful. I know when you go to your doctor, you don't really want to open up. Sometimes you're nervous. At least the app helps explain how you feel.* [Female, 17 years]



Confusion remained regarding the use of the Jar of Hurt with 2 of 10 youths in the first round of testing describing it as confusing. As a result, examples of an empty jar and a full jar were added beside the plus or minus buttons to provide a visual of how to increase or decrease the amount of pain or hurt (see Screen 7 and 8 in Multimedia Appendix 1). After this change was implemented, no confusion was noted in the remaining high-fidelity testing round.

Participants also suggested revisions to the "I took something harmful" icon in the "how you were hurt" section. Initially, this icon included a skull and crossbones to symbolize poison; however, youths suggested that something more representative of drugs or alcohol should be included.

> *I think this would be something chemical, based on the picture and skull thing. But I think something that can be added is maybe drugs or alcohol. Because the person may not always feel comfortable saying it but hitting it on the button without thinking and if it's right in front of you, they may be honest.* [Female, 18 years]

This icon was revised to better reflect youth participant's perception of which icons are most relevant to them (Figure 5).

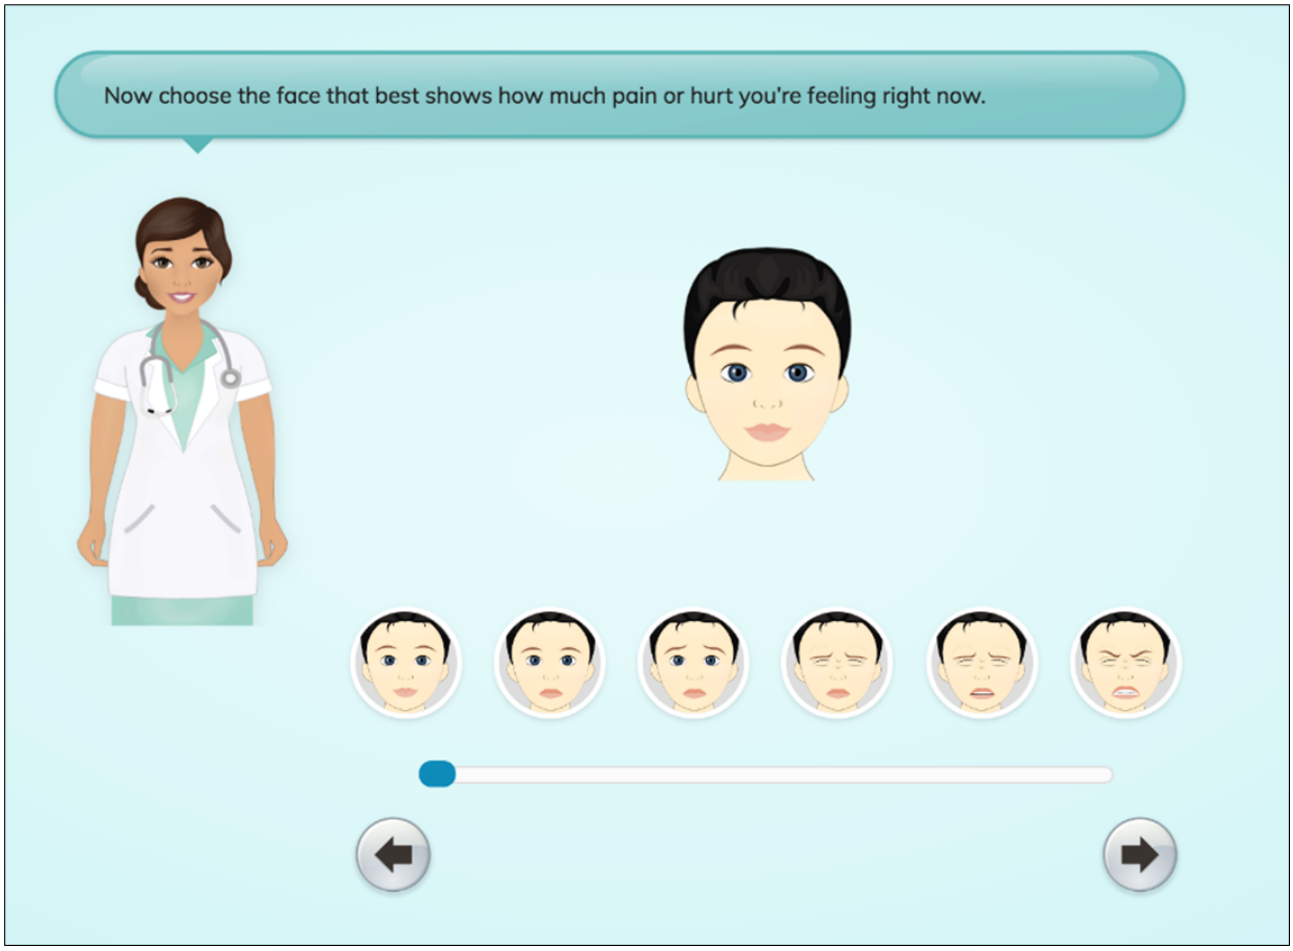
Figure 5. "Harmful" icon changes.

A final revision resulting from the youth high-fidelity sessions was determining a preference for which scale to use to represent the quantity of pain. Youths were shown a scale with facial images similar to those in the FPS-R and superimposed in the avatar [27] (Figure 6) and the Jar of Hurt scale (Figure 7) and asked which they felt would best allow them to quantify their pain. The majority (n=12, 60%) preferred the Jar of Hurt scale. One youth shared their reason why:

> *If you had to choose one option, I would say the jar scale would be a lot better. Because maybe some people, they know how to hide it. Their pain. So, I'd say the jar scale is a lot better.* [Male, 16 years]

XSL•FO
RenderX

Figure 6. Faces Pain Scale—Revised expressions avatar adapted faces scale.



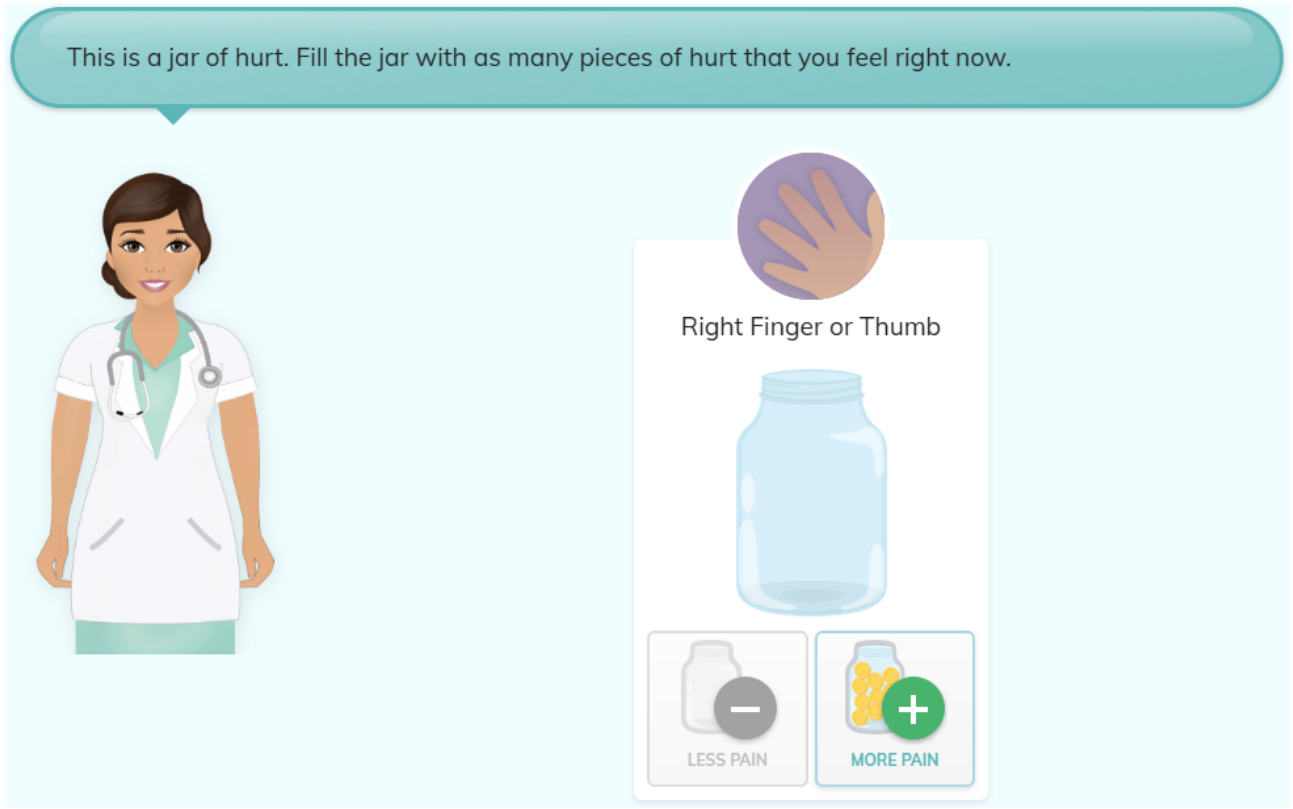


Figure 7. Jar of Hurt scale.

XSL•FO
RenderX

In addition to youths, a total of 15 clinicians participated in high-fidelity testing. In total, 10 clinicians completed this through a digital survey, and 5 participants took part in a focus group session. Most survey respondents were nurses (n=7, 70%), and focus group participants included physicians, physiotherapists, nurses, and psychologists.

In total, 14 of 15 clinicians found the app to be moderately or extremely useful. Like youths, clinicians were asked to identify their preference between the Jar of Hurt or the FPS-R adapted scale (Figures 6 and 7) through the survey questions. A total of 7 of the 9 clinician respondents identified a preference for the FPS-R adapted scale.

On 2 different screens, clinicians suggested adding an "other" option. For the quality of pain screen, 4 of 5 clinicians from the focus group felt that an "other" option should be included to allow users to add their own quality of pain descriptors. Similarly, for the emotional pain screen, all clinician participants suggested adding an "other" option to allow users the flexibility of adding any emotion they felt, even if not in the presented list. These additions were made in subsequent versions of the app.

Clinical Feasibility Testing

A total of 10 youths completed clinical feasibility testing (round 1: 5 and round 2: 5). Results from the clinical feasibility testing were very positive, with 80% (n=8) of respondents identifying that they found the app easy to use and 90% (n=9) saying they would use the app in a hospital or health care setting. No technical errors were found. Participants suggested that the Jar of Hurt method was more geared toward younger youths but also noted that they were happy to use the scale either way. Suggestions for change were mainly larger design changes identified as "future changes" including having a text or email function to send results to themselves or their care providers, having the ability to track changes in their pain or hurt over time, and including translation in their Indigenous language.

Discussion

Principal Findings

In this study of clinicians and First Nations youths, 3 types of testing occurred in the development of the Kids Hurt App: low-fidelity, high-fidelity, and clinical feasibility. For the 2 groups of participants, each subsequent round of testing reduced the app modifications. Overall changes were minor, but important observations were thought to increase the usefulness of the app for users.

Recent literature has identified that app-based interventions may remove barriers to accessing care for youths [18,32,33]. Apps are accessible and may mitigate confidential concerns and concerns about stigma. Smartphone-based apps may be particularly useful, as authors from one study found that smartphones are a mainstream technology and are an advantage within the health care system [34]. While existing research suggests that Western pain assessment tools are not appropriate for Indigenous peoples [10], this study demonstrates how an app can be developed collaboratively and engage youths to share their pain respecting both Indigenous and Western knowledge systems. All youths stated that they would use the Kids Hurt App if it was available in the health care setting. Youths reaffirmed that they often found it difficult to articulate their feelings and felt that the app could help them communicate their needs. This app allows them to share their pain and help facilitate enhanced communication.

One notable finding in this study was the process of determining which pain scale to use, the "Jar of Hurt" scale or the "face scale." In the initial development stages of the app, the "Jar of Hurt" concept was chosen based on previous research regarding the "Pieces of Hurt" tool [28]. While this research was completed with younger children than our target population, the concept of using objects rather than faces was appealing based on previous research indicating that Indigenous children are often stoic in their expression of pain and may hide their pain rather than displaying it outwardly through facial expressions [8]. Through high-fidelity testing, 60% (n=12) of youths preferred the "Jar of Hurt" scale over the "face scale," and while it was noted in clinical feasibility testing that the scale was more geared toward younger youths, participants identified being happy to use the tool, regardless of that. Clinician preference was strongly noted for the face scale likely because of its similarity to the FPS-R scale, a well-known pain measurement tool [27]. However, given that the app was developed to provide youths with a valid way to convey their pain and hurt and to develop an alternative to Western pain assessment tools, the "Jar of Hurt" was maintained as the preference for conveying pain intensity. This finding highlights the importance of taking the time to validate patient indicators of pain consistent with different age groups and populations.

Improved Health Care Experience

During a typical patient visit, a clinician obtains the patient's history, current pain experience, and future needs in a short amount of time [35]. This can be challenging if a patient finds it difficult to articulate their pain and hurt for a range of reasons, such as stoicism or power dynamic, further causing delay in timely and appropriate care [34,36]. In this study, participants identified the app as "easy to use" and were able to complete the app screens in an average of 3.61 minutes (216.6 seconds; SD 48). The youths' suggestions for app improvement, such as the Jar of Hurt being a better way to capture pain instead of a face that may hide pain, provide some indication that the Kids Hurt App may facilitate better communication, and consequently health care experience, by allowing Indigenous youths to convey their pain through an app. Other comments such as the youths who indicated pushing a button might be easier than talking could imply that the app offers a nonthreatening and safe way for youths to share their stories. Research has shown that youths have high technological literacy and are comfortable using eHealth apps [37,38]. In a generation where technology is fluent, the Kids Hurt App can give youths a voice in the health care system, in a medium they are comfortable with, to personally advocate for their physical and emotional pain care.

Limitations

At the time of testing, the app was not yet available in the youth participant nation's language. The current version of the app [14] is fully translated into Mi'kmaw. Communication between

XSL•FO
RenderX

the provider and patient should always be clear and effective, and having health information accessible in one's primary language is important [39]. Thus, we recommend that the app be available in the nation's primary language in any further testing. An additional limitation is that testing was only completed with 2 First Nation communities so results cannot be assumed to be accurate for all Indigenous nations.

Conclusions

Culturally safe care acknowledges the attitudes, knowledge, and behaviors of another's culture in a respectful manner. If a provider encounters an Indigenous patient, it would be important to understand the patient's unique historical legacies, ways of communicating, and any potential intergenerational trauma that may influence pain report [40]. Implications of creating and using an app that has been codeveloped by the end users (First Nations youths) increase the usefulness of the app and provide a space for the provider and patient relationship to be optimized for best care outcomes. The short app completion time is an indication of the minimal effort it takes to offer a culturally appropriate alternative to pain self-report and may reduce miscommunication and repeat visits for the same condition. Future research will include testing the app with non-Indigenous youths as well as in various health settings such as mental health, tertiary, primary care, and emergency departments. Further development of the app related to youth's self-report of effective strategies that reduce pain and hurt is planned. The Kids Hurt App is a culturally safe and evidence-based communication tool that may allow First Nations youths to comfortably share their pain and hurt stories. Each nation may be different in its communication and will need to review the app for usability and feasibility in its own communities.

Acknowledgments

The authors would like to thank the First Nations youths and the clinicians for taking the time to support the development and testing of the Kids Hurt App.

Abstract

Background: It is widely accepted that the COVID-19 pandemic has accelerated the era of online health care delivery, including within community palliative care. This study was part of a larger project involving a collaboration between universities, health care services, government agencies, and software developers that sought to enhance an existing telehealth (video call) platform with additional features to improve both patient and health care professional (HCP) experience in a palliative care context.

Objective: The aim of this study was to understand palliative care patients' and HCPs' experiences of telehealth delivery in a palliative care context in Victoria, Australia. For the purposes of this study, telehealth included consultations by both video and telephone calls. By better understanding users' experiences and perceptions of telehealth, we hoped to determine users' preferences for new telehealth enhancement features.

Methods: A total of 6 health care professionals and 6 patients were recruited from a major tertiary hospital network's palliative care unit in Victoria, Australia. Participants were asked to generate 3 - 5 photographs depicting their telehealth experiences. These photographs were used as visual aids to prompt discussion during subsequent one-on-one interviews. Intertextual analysis was conducted to identify key themes.

Results: A total of 3 overarching themes emerged: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. Patients (n=6) described telehealth as supporting their physical and psychological comfort and maintaining connection with HCPs, yet there were specific situations where it failed to meet their needs or impacted care quality and delayed treatment. HCPs (n=6) recognized the benefit of telehealth for patients but reported several limitations of telehealth, in particular due to lack of physical examination opportunities. Participants indicated that 2 types of connection were imperative for effective telehealth delivery: technical connection (eg, good internet connectivity or clear phone line) and interpersonal connection (ie, good rapport and therapeutic alliance between the HCPs and patients). Often technical connection issues impeded the development of interpersonal connection between the HCPs and patients in telehealth.

Conclusions: The findings presented in this study combined with other co-design activities, which are outside the scope of this paper, indicated the potential value of a telehealth enhancement feature that generates patient-facing clinical consultation summaries. Our team has developed a video telehealth enhancement feature (or "add-on"), which will enable clinicians to distill key actionable advice and self-management guidance discussed during teleconsultations for a take-home summary document for patients. The add-on's prototype has also been subjected to an initial simulation study, which will be reported in a future publication.

Introduction

In Australia, chronic illness continues to be a major challenge in health care [1] with more than three-quarters (78.6%) of Australians impacted by at least one chronic condition [2]. Many of these chronic conditions are life-limiting [3], and thus patients may benefit from palliative care [4]. The 2018 National Palliative Care Strategy recommends the approach of using palliative care as a "means to improve the quality of life of patients and their families affected with life-threatening illnesses through the prevention and relief of suffering by means of early identification, assessment, and treatment of pain and other problems" [5]. Studies have shown that palliative care improves quality of life by improving independence, providing symptom relief and pain control, and supporting the physical, emotional, and spiritual needs of patients, their carers, and loved ones [6-9]. Furthermore, palliative care is linked with a significant decrease in health care use and prolongment of survival [10].

Specialist palliative care in Australia is delivered using different models of care depending on the geographic location and available resources [11]. Many of these models of care were transformed during the COVID-19 pandemic to promote physical distancing [12,13]. One such approach for the delivery of specialist palliative care in Australia was a move to telehealth to limit hospital attendance and in-home visits [12]. The implementation of telehealth in palliative care in Australia demonstrated promise beyond the pandemic, with the potential to improve communication, facilitating more equitable access to palliative care (especially for those in rural and regional areas), avoiding lengthy travel to hospitals or clinics (particularly when patients are very unwell), and potentially assisting with timely symptom relief [14]. However, for continued sustainability and success of telehealth models, telehealth needs to adapt and evolve based on feedback from patients and health care professionals (HCPs) [15].

The importance of user involvement in the implementation of palliative care services has been recognized and prioritized by researchers to improve productivity, quality, and relevance of care [16]. The aim of this study was to understand palliative care patients' and HCPs' experiences of telehealth delivery in a palliative care context in Victoria, Australia. For the purposes of this study, telehealth included consultations by both video and telephone calls. This study was part of a larger project involving a collaboration between universities, health care services, government agencies, and software developers, which sought to enhance an existing telehealth (video call) platform with additional features to improve both patient and HCP experience. By better understanding users' experiences and perceptions of telehealth, we hoped to determine users' preferences for other telehealth enhancement features.

Methods

Participants

Palliative care professionals and patients were recruited from the Monash Health Supportive and Palliative Care Unit at a tertiary hospital network in Victoria, Australia. HCPs, including palliative care medical and nursing staff, and interpreters involved in the Unit's use of telehealth were invited to participate by email. The Unit has video telehealth palliative care clinics for oncology patients. In addition, during COVID-19 outbreak, the Unit provided a telehealth outreach service when in-person home visits were not possible.

Patients aged 18 years and older, with conversational English proficiency, currently using telehealth to access palliative care were invited through email invitations and postcards. A total of 6 patients and 6 HCPs participated in the study. All participants lived in Victoria and spoke English as their primary language. The patients' ages ranged between 54 and 61 years old. In addition, 4 of the 6 patient participants identified as female and 2 identified as male. The HCPs' ages ranged between 33 and 62 years old, with 5 identifying as female and 1 as male. The duration in their health care roles ranged from 6 months to 8 years. Their roles were 'doctor' (n=3), 'interpreter' (n=2), and 'nursing clinical coordinator' (n=1). Our 6 patient participants have been deidentified as P009, P012, P013, P014, P015, and P016, and HCP participants as HCP001, HCP003, HCP 004, HCP005, HCP010, and HCP011.

Data Collection

The study used a qualitative photo interviewing technique [17,18]. Participants were requested to generate 3‐5 photographs based on certain prompts and share them with the research team. HCPs were asked to click photographs to depict their everyday work life in the context of telehealth models of care, what telehealth represents in their work, general experiences, and opportunities for improving current telehealth models. Similarly, patients were asked to generate photographs to illustrate their experience of receiving health care through telehealth, what telehealth represents for them as patients and their everyday lives, and opportunities for improving telehealth models of care. Multimedia Appendix 1 and Multimedia Appendix 2 shows the specific instructions provided to both HCPs and patients.

Participants emailed their photographs to a member of the research team. Subsequently, telephone interviews, lasting between 30 and 45 minutes, were conducted with each HCP and patient participant. During the interviews, participants were asked to elaborate on what each of the photos meant for them and how the photographs related to their experiences of telehealth. During the interviews, use of participant-generated photographs helped trigger participants' memories and invoke their deeper consciousness, values, attitudes, and personal

XSL•FO
RenderX

meanings of telehealth [19-21]. The visual aids also helped the researcher and participant reach a shared understanding of the topic [22]. All the interviews were audio-recorded and transcribed verbatim by a professional transcribing company. The interview transcripts were deidentified, and photos blurred to protect participants' identities. The anonymized transcripts were imported into Microsoft Word and the photos inserted at the point where they were discussed during the interviews, allowing for an intertextual analysis in which the participants' photos and words could be viewed together [23].

Data Analysis

A multistep data analysis process was conducted, involving intertextual analysis wherein participants' words and photos were viewed together and analyzed using a 3-step process involving (1) preview, (2) review, and (3) cross-photo comparison [23]. In the first "preview" stage, the first author reviewed all the photos and identified recurring motifs. These motifs were recorded in a PowerPoint slide deck and shared with the research team at a meeting for feedback and further interpretation. Subsequently, a more in-depth "review" was conducted wherein one researcher coded all the interview transcripts with relevant themes and subthemes in more granular detail. The emergent codebook was shared and workshopped with the research team to further distill the emerging patterns.

The final stage in the data analysis process was "cross-photo comparison." During this phase, the research team discussed the similarities and differences within and across participant groups (eg, within patient participants' or within HCPs' accounts, or across patients' and HCPs' accounts). Often the patients' and HCPs' accounts provided contrasting experiences of the same facet of telehealth use (referred as "counter-examples"). For example, where patients valued the convenience of telehealth and being able to liaise with their doctors from anywhere, HCPs found patients' use of telehealth in certain places (eg, public spaces) disruptive and uncongenial to the therapeutic process. To organize the emergent themes, a storyboard was developed by the first author containing illustrative quotes and photographs from both patients and HCPs. This story board has been provided in Multimedia Appendix 3 . The storyboard was presented to the research team and subsequently, manuscript development commenced.

Ethical Considerations

Ethics approval for the study was obtained from the Monash Health Human Research Ethics Committee (project identification number 79681). All participants were provided plain language summaries of the research project, and what their participation would entail. All participants provided informed written consent. They also had the option to stop the interview at any point. Only approved members of the research team had access to the identifiable participant information. All interview transcripts were deidentified before the commencement of the data analysis process. Photos generated by participants showing any humans were also blurred to preserve participants' privacy.

Results

Overview

A total of 3 themes were identified: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. It should be noted that while these themes are presented as distinct categories, they are not necessarily mutually exclusive. In addition, in some cases the themes included counter-examples, as mentioned above.

Comfort (Or Lack Thereof) Afforded by Telehealth

For some participants, telehealth afforded them greater physical and psychological comfort. However, for some others, telehealth hampered their physical and psychological comfort. Therefore, this theme elucidates how telehealth use impacted patients' and HCPs' physical and psychological comfort.

Physical Comfort

Palliative care patients often experience physical discomfort, including pain and fatigue, which in turn impacts their ability to visit clinics for in-person consultations. Patient participants advised that they had arranged their homes in ways that minimized their discomfort. Telehealth enabled them to remain in this environment, unlike in-person appointments, which lead to physical exertion due to travel and wait times, with this issue compounded for rural patients.

Patient participant P015 captured this theme when discussing a photo (Figure 1) of the room where they spent most of their time. They reported being "in pain 24/7" and explained how telehealth helped minimize their discomfort:

> *...You can actually see how close my bed; my chair is to my office desk. And so, I just use the walking frame, I get to the chair very easily. I sit in my chair, I'm listening to a bit of music, or I'm just watching TV…I'll sit in the wait in the chair, waiting for the doctor to come in.* [P015]

XSL•FO
RenderX

Figure 1. Patient home office for telehealth consultations (P015).

By contrast, some HCPs associated telehealth with physical discomfort. HCPs working in the palliative care outreach service during the pandemic, as opposed to the Unit's dedicated telehealth clinics, reported that private rooms were not always available. Therefore, telehealth appointments were often conducted in shared workspaces, which could be noisy and distracting, impacting their ability to effectively conduct quality consultations with patients. For example, HCP001 included a photo of the shared office space (Figure 2) where they often conducted telehealth consultations and stated:

> *It gets very loud because we're [all] talking… So then anybody else talking on the phone, someone else has to talk up to talk over the top of that, and then anybody having a conversation with each other in the office has to talk up.* [HCP001]

XSL•FO
RenderX

Figure 2. Palliative care service shared office space (HCP001).

Psychological Comfort

Alongside physical comfort, telehealth provided patients with psychological comfort by reducing the stress associated with in-person appointments. Participants reported a variety of psychological stressors associated with in-person appointments, which were mitigated by using telehealth, for example, travel and wait times, risk of exposure to COVID-19 in hospitals, forgetting key questions for their doctors, and financial stress, particularly for rural patients who may need to make overnight accommodation arrangements for brief appointments. P013 provided a photo of a piggybank (Figure 3) and stated:

> *…going to appointments, car wear and tear, fuel for my daughter, parking fees, petrol... [With] telehealth, [I] don't have to spend that money… [the money saved could be spent on] all the bits and bobs that they keep chucking at me to take.* [P013]

XSL•FO
RenderX

Figure 3. Piggy bank (P013).

The psychological comfort associated with the freedom to stay in one's chosen location and receive health care from the comfort of their own homes is also illustrated in P014's photo (Figure 4) and quote as follows:

My bush family are my reason for living out here … This is my family. Because of telehealth, I get to stay home and enjoy them. You know, I don't lose a day or two being on the road away from them. I know it's only animals but for some people, you know, animals are our family. [P014]

XSL•FO
RenderX

Figure 4. Life in 'the bush' (P014).

For some outreach service HCPs, however, the sudden large-scale transition to telehealth in the aftermath of the COVID-19 outbreak, led to some psychological discomfort at their perceived inability to provide their usual standard of care. Given their professional training had primarily been in face-to-face care, they felt ill-equipped to efficaciously transition to online care. HCP005 provided a photo of themselves holding their stethoscope up to the camera (Figure 5), demonstrating the limitation of physical examination in telehealth consultations. HCP005 said that the return to more in-person consultations was "almost a relief" post–COVID-19 pandemic. They further elaborated:

> *…often to be thorough in your assessment, as a doctor, you've been trained [to] do your history, examination and do investigations. I guess telehealth takes away … what we're trained to do.* [HCP005]

XSL•FO
RenderX

Figure 5. Health care professional (HCP) uncomfortable about limitations of telehealth (HCP005).

Connection Considerations in Telehealth

Participants indicated that 2 types of connection were imperative for effective telehealth delivery: technical connection (eg, good internet connectivity or clear phone line) and interpersonal connection (ie, good rapport and therapeutic alliance between HCPs and patients). Often technical connection issues impeded the development of interpersonal connection between the HCPs

XSL•FO
RenderX

and patients in telehealth. This theme illustrates how technical connection and interpersonal connection impacted the participants' telehealth experiences.

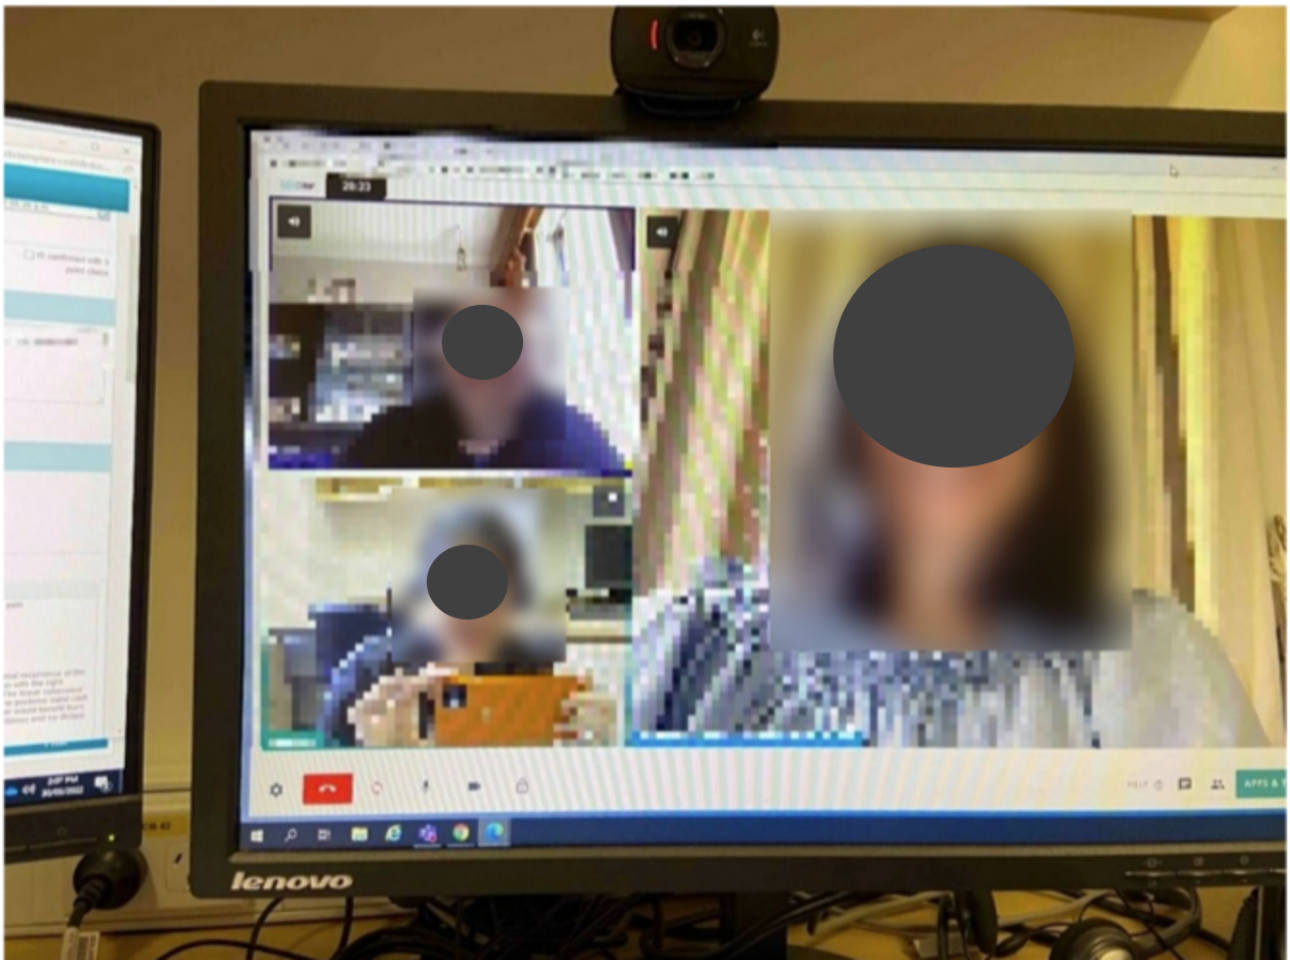
Technical Connection

The technical aspects of connection included the skills required to use the technology, internet and mobile phone connectivity, and specific hardware and software concerns. HCP participants noted that their patients had first been introduced to the telehealth model of care during the pandemic with varying levels of technological proficiency. Patients with limited technological proficiency needed to build their confidence and skills over time, with support from HCPs, support staff, and family members. HCPs described situations where no one had checked whether or not a patient's computer had required microphone and video capabilities. Internet connectivity and bandwidth issues were also reported by both patients and HCPs. HCPs, in particular, due to their volume of telehealth calls, reported a lot of time lost to troubleshooting connectivity issues, which impacted the time available for clinical conversations. Often participants had to transition to telephone calls. For example, P012 shared an image of their landline home phone (Figure 6), describing it as follows:

> *It is the most reliable tool in my house. It never drops out. Whereas the Internet … the internet on my computer can be slow or drop out or whatever at a telehealth appointment. And my mobile phone drops out, it's unreliable as well. But this phone is not unreliable. So if I lose a connection with any of the doctors, I know I can ring them on that phone … and it's not going to drop out. That's really important … So the landline is a good back up source for me for telehealth. I always have it sitting there in case something happens.* [P012]

XSL•FO
RenderX

Figure 6. Landline home phone as back-up (P012).

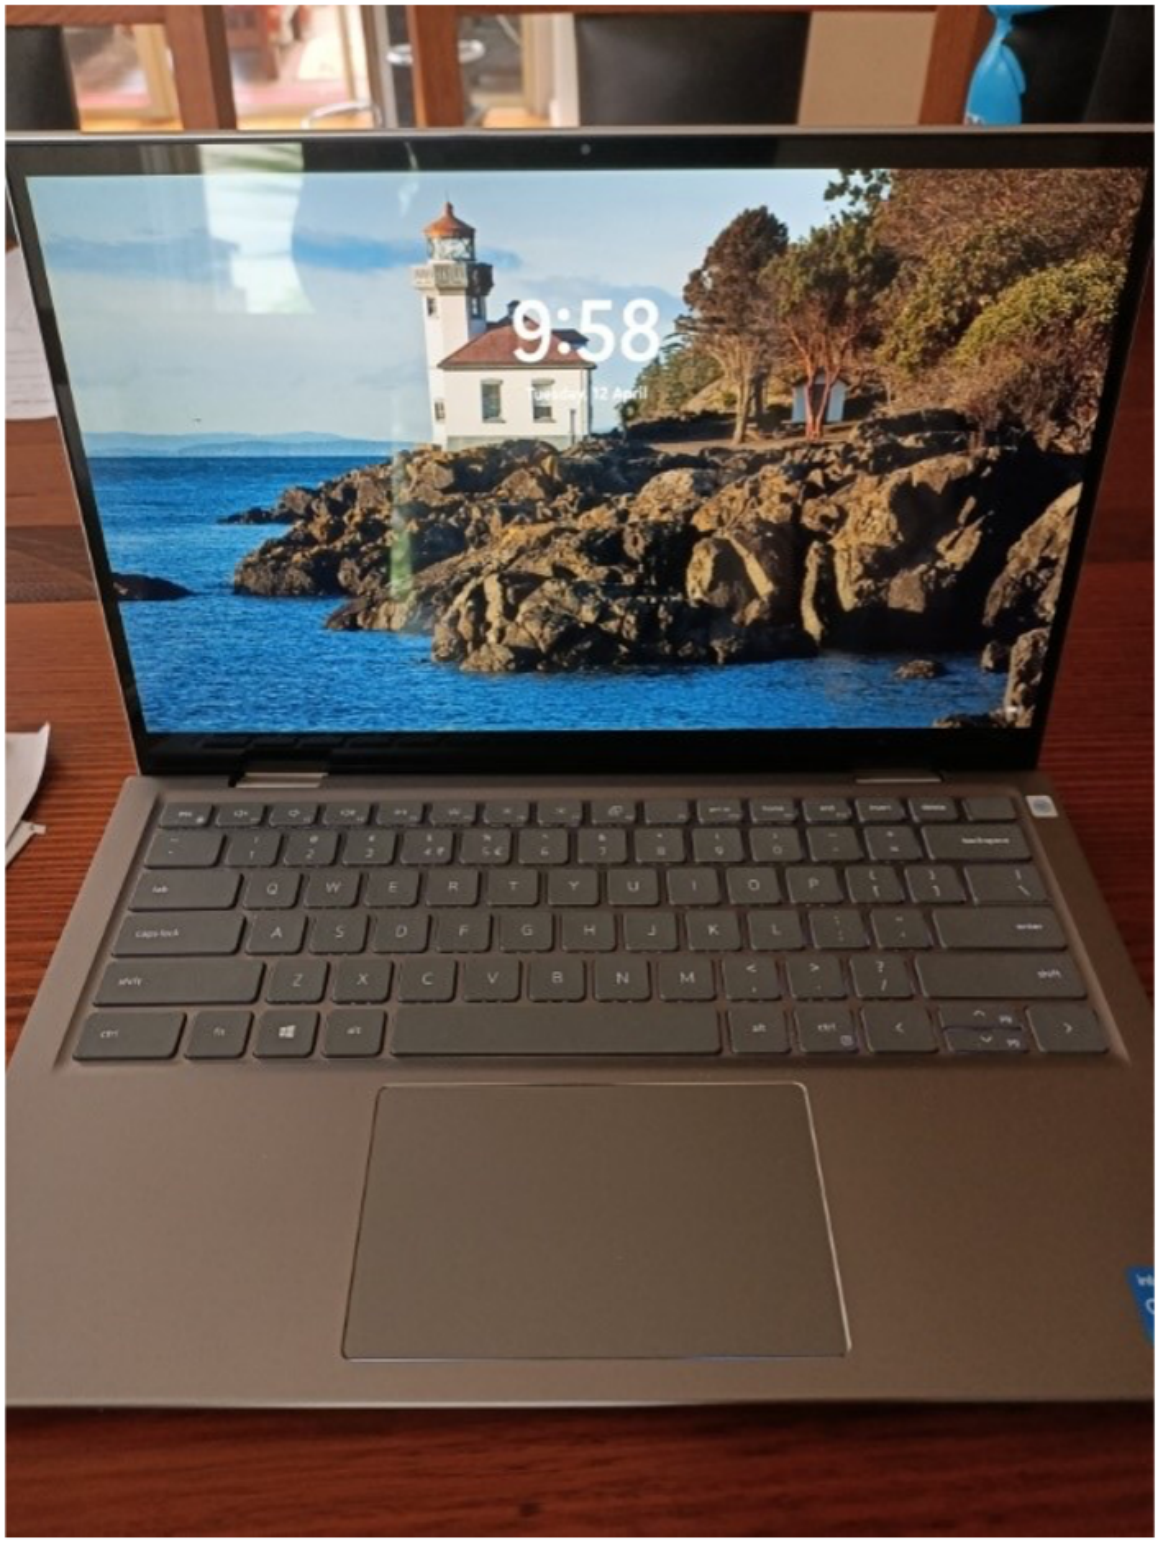


Nevertheless, participants also reported that in the absence of connectivity issues, and with the appropriate skill level to use, and availability of the right technology, telehealth can be very useful and seamless. For example, HCP003 illustrated a good experience of using telehealth involving both a patient and their carer in Figure 7, and recounted:

> *… essentially showing how we can make it work when everyone is capable of using telehealth. On the right … that's actually the patient's son … But it just shows how it can work. So … having patient caregiver in telehealth, it is all very possible. The video worked well the audio worked well ... there was no barrier there.* [HCP003]

XSL•FO
RenderX

Figure 7. Positive experience of telehealth (HCP003).



Interpersonal Connection

Participants expressed a general preference for video consultations over telephone consultations because of more opportunities for eye contact, and reading of facial expressions or other nonverbal cues. The notion of power dynamics between HCPs and patients also emerged, with some participants stating that conducting the consultations over telehealth made patients feel more relaxed and open, as opposed to feeling nervous in front of their HCP in person. P012 provided an image of their laptop (Figure 8), which they used for video consultations and stated:

> *I've noticed for me that I open up and talk more ... But when I'm in his rooms, I'm intimidated when I'm in person with him, face to face. I'm more conscious of myself and self-conscious. Whereas over the computer I'm not. I'm really confident and I just pour everything out.* [P012]

XSL•FO
RenderX

Figure 8. Patient's laptop used for video consultations makes them feel more relaxed (P012).

The type of technology used for video consultations also played a role in the quality of the clinical conversations. As previously mentioned, participants sometimes had to rely on backup options such as mobile phones or landlines for consultations due to technological failures, which also impacted the quality of their telehealth consultations. HCP011 shared a photo of an outreach service consultation that they had joined using their mobile phone, because the laptop and desktop were being used by other HCPs (Figure 9), and reflected:

> *The pictures are very small. So it just does not give you a realistic feeling of seeing a patient.* [HCP011]

XSL•FO
RenderX

Figure 9. Video consultation conducted on a mobile phone (HCP011).

XSL•FO
RenderX

In addition, participants generally agreed that periodic in-person consultations interspersed between their regular telehealth appointments were necessary to generate rapport between patients and HCPs. P015 had video telehealth oncology appointments every 6 - 8 weeks for over a year, despite which they said, "I've never met my oncologist," by which they meant that they had never met their oncologist in person. Even P012, who felt they were able to be more open through telehealth said:

> *the doctors should touch base with you specifically in person after a period of at least six months…. seeing them person to person sort of reconnects the relationship.* [P012]

In considering the benefits of in-person care, HCP010 said:

> *…we still want that relationship with the patient, we want to look them in the face and an important aspect of interpreting is body language. So even if you see them on the screen, [it] is not the same.* [HCP010]

HCP005 explained that some patients, "feel a bit suspicious or not completely trusting when you are not there [in person]."

Separately, HCP004 and HCP005 both also said that breaking bad news was more difficult through telehealth because of their inability to offer comfort through nonverbal communication like touch.

Care Quality Impacts of Telehealth

This final theme elucidates participants' perceptions about how telehealth impacts the quality of health care for patients.

Patient participants expressed mixed feelings regarding their satisfaction with the telehealth model of health care. While some participants perceived that the care they received through telehealth was satisfactory, others expressed concerns around issues such as lack of physical examination, impact on treatment timeliness, and communication.

Patients who described telehealth care positively viewed the crucial elements of care as unaffected. P014 explained that being able to share documents and show the HCP medications meant that:

> *[telehealth] doesn't stop the communication process in anyway…as [a] patient I'm not missing anything.* [P014]

Participant P014 was also able to monitor their blood pressure and oxygen saturation at home and share this information with their HCP. HCP004 saw telehealth as working well when there was another complementary team, for example, "hospital-in-the-home," which offered in-person care and provided clinical information to the palliative care patients. They also described the benefits of using telehealth to determine when an in-person visit was necessary:

> *it works best where there's opportunity for, or being able to identify that you can't rely on telehealth alone.* [HCP004]

Participants who believed that the lack of an in-person examination had compromised their care were more negative about telehealth. For example, P013 shared a photo of their arm in their lymphoedema sleeve (Figure 10) to describe the way telehealth had limited their care:

> *I was seeing her [my HCP] pretty much monthly on telehealth. As my arm would flare up, there was still not much she could do because we weren't allowed in … she finally got face to face with me, measured me up for the sleeve, so that was six months without proper diagnosis.* [P013]

Figure 10. Lymphoedema sleeve (P013).

XSL•FO
RenderX

This participant perceived that their symptoms had not been taken as seriously or treated as effectively because the HCPs involved had not been able to examine them.

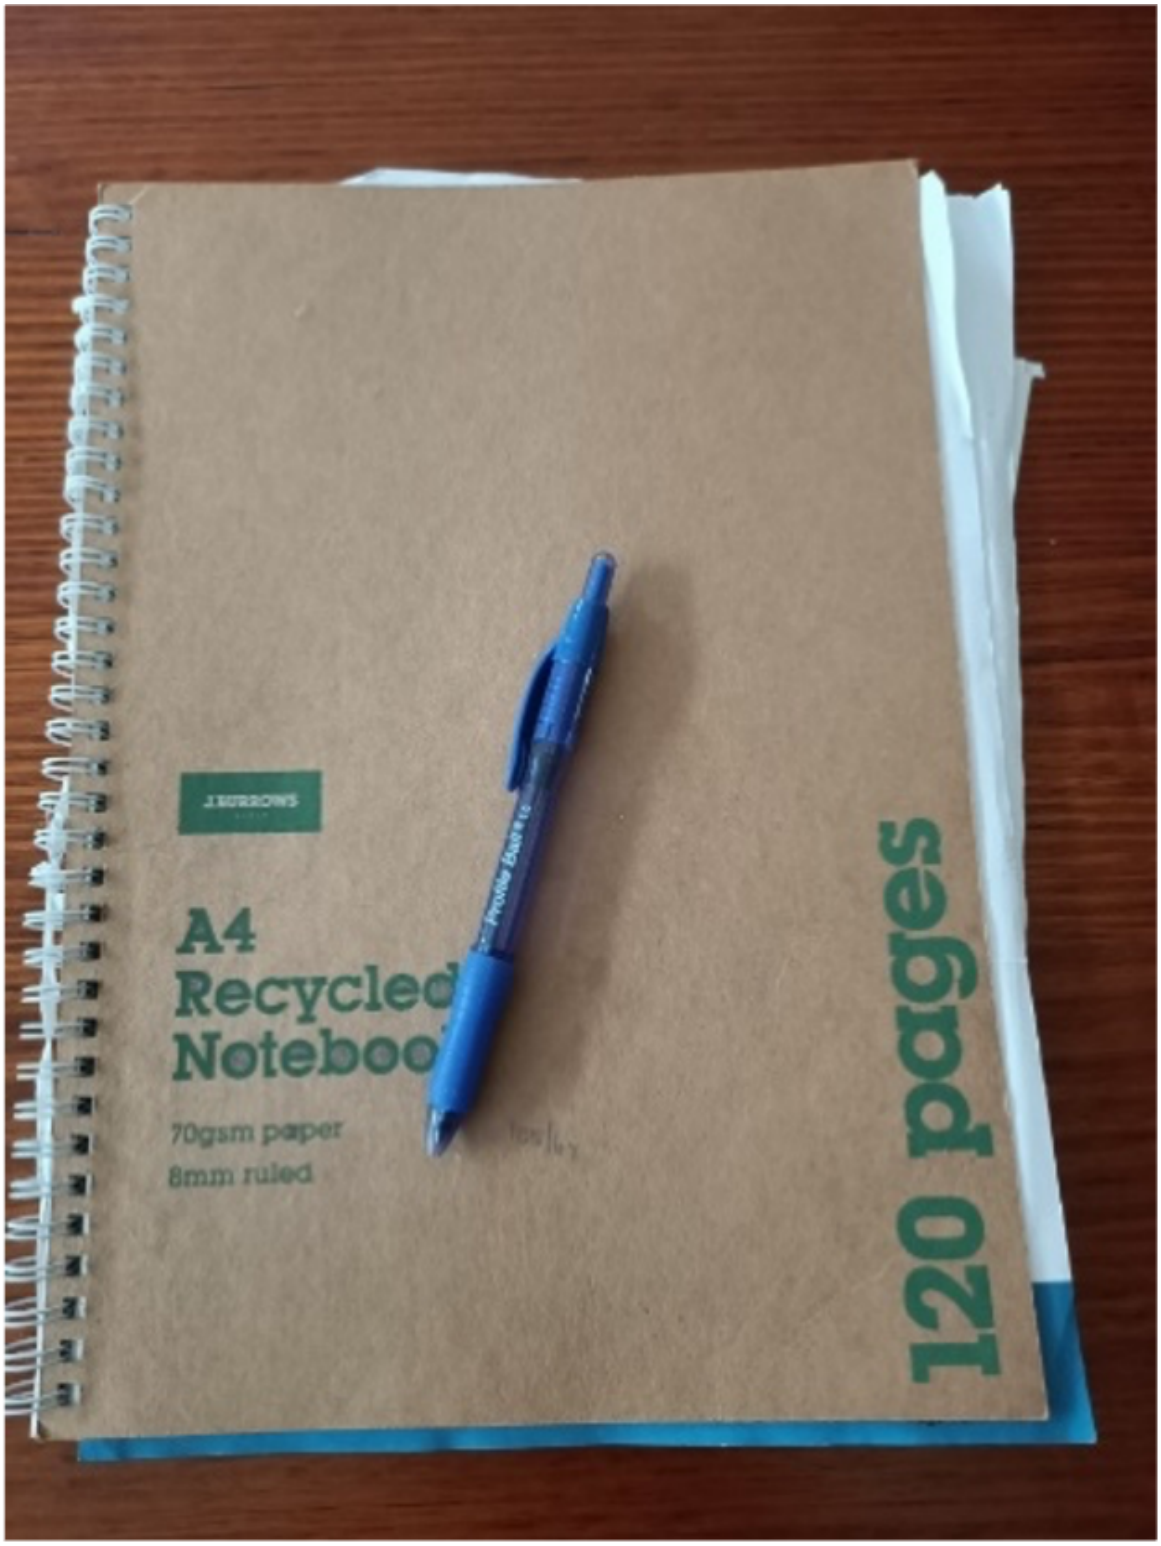
P016 used a photo of their skin (Figure 11) to discuss the implications of limited physical examination opportunities in telehealth:

> *I was trying to explain to the doctor what the problem was … he actually couldn't see me, what I was trying to explain he couldn't see … And we didn't really get to the bottom of what it was.* [P016]

Figure 11. Patient finding it difficult to show the health care professional (HCP) her skin redness concern (P016).

For this participant, in-person care was important not only in this specific instance, but also because:

> *the doctor would pick up from the last time he saw you or your oncologist who last saw you [on] sort of things that you don't notice in yourself … I just feel as I'm getting more unwell, that I need to have more face-to-face appointments than telehealth appointments, but they tend to push you towards telehealth.* [P016]



HCPs also stated that telehealth sometimes resulted in less thorough assessments. HCP001 explained that this may be the result of poor technical connection, whereas HCP005 described it as a problem when the assessment required a third party to facilitate the telehealth consultation, such as staff in an aged care facility, whose other duties meant they did not have the requisite time to devote to the consultation.

On the other hand, a positive aspect of the telehealth model of care for patients was their ability to feel more in control of their self-care and self-management during telehealth consultations. For example, patient P012 took a photo of their notebook (Figure 12) to illustrate that they felt more comfortable bringing prewritten notes for discussion and scribing notes during a telehealth consultation than they would in person:

> *Notebook [is] very important ... Leading up to all my appointments I have, I make notes. And then when my appointment comes up, I cross stuff off … that's really important. For me, it's my notes. That way, I know I'm not going to forget anything. And whatever they say to me that's relevant or important, something I had to do or whatever, I'll write it down … I probably wouldn't do that at the doctor's … But online I can just do it on the side while I'm talking to them.* [P012]

XSL•FO
RenderX

Figure 12. Patient feels more in control of their ability to take notes before and during telehealth consultations (P012).

Similarly, another patient P009 recounted a similar experience of feeling more comfortable about their ability to capture important information before and during a telehealth consultation by having family members present with them from the comfort of their homes:

> *Part of the brain tumors is that I can't remember stuff afterwards. So I have to have someone there who's like my virtual notepad … they can answer things that I may have forgotten especially to do with medication because it seems to be the main one or [one of the] side effects … So it works well as in, they've [husband and/or daughter] got an area where they can be comfortable … I have a pad and pen here. But of course I have sometimes husband and/or daughter not only remembering stuff like that's said but going back and reminding me of stuff I need to tell the oncologist that I may have forgotten about.* [P009]

XSL•FO
RenderX

Discussion

Principal Findings

Our intertextual analysis yielded 3 key themes: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. Participants' relationship to telehealth was nuanced. Generally, participants acknowledged the myriad of benefits that telehealth brings, such as greater psychological and physical comfort for patients, especially those based in rural areas. However, there was also a general sense that telehealth should be combined with in-person care for optimal patient-HCP therapeutic alliance and better patient outcomes. It should be noted that this study's data collection commenced during the pandemic, amid nation-wide efforts to rapidly scale telehealth models of care across Australia. Eastman et al [15] sought to understand patients' and HCPs' experiences of telehealth in community palliative care. Their findings were congruent with ours, suggesting that telehealth is being increasingly used in palliative care and generally patients and HCPs are supportive of using this model of health care, combined with regular in-person touchpoints.

A salient finding from our study was the notion of greater power symmetry between patients and HCPs in telehealth compared with in-person consultations. Patients alluded to feeling more empowered, in control, and psychologically comfortable during teleconsultations. This translated into them feeling more confident about "pouring out" information in front of their HCPs, than they would face-to-face. Furthermore, the safety of a device's screen afforded patients the space to take notes during consultations. Having teleconsultations from the comfort of their homes where family members could also be present where needed, meant that patients felt more at ease. In some cases, family members also served the important function of remembering what had been discussed during consultations, which enhanced patients' quality of care.

Our team conducted additional co-design activities with consumers which are outside the scope of this article. In those activities too, participants had reported the importance of taking notes before, during, and after their telehealth appointments. Participants described forgetting important details from their appointments and relying on their family to attend consultations to remember what had happened during the appointment.

Literature suggests that 40% - 80% of medical information and recommendations provided by HCPs during clinical consultations is forgotten by patients almost immediately. The poor information recall may have downstream impacts for treatment adherence [24]. Issues of memory recall may be exacerbated in palliative care patients who experience complex illness symptomatology. There is some evidence to suggest that patient-facing clinical consultation recordings can be helpful for patients in general. A scoping review conducted by Tsulukidze et al [25] in 2014 suggested that patients place a high value on audio recordings of clinical consultations and benefit from subsequently listening to the consultation recordings.

The participants of our study reported in this paper and subsequent co-design activities indicated that having a summary of the consultation at the end of telehealth session would mean that this information is kept secure and in one place for patients. Memory and cognitive deficits are often experienced by palliative care patients. Therefore, a mechanism to record salient information discussed during consultations would be particularly useful for this patient population.

The literature on patient-facing consultation summaries generated during telehealth is currently limited. A non-systematic literature scan in Google Scholar on this subject yielded no relevant papers. The closest relevant literature appears to be about artificial intelligence (AI) enabled digital scribes or documentation systems, which can help automate clinical documentation tasks ordinarily conducted by humans [26-28]. However, the literature on patient-facing clinical summaries in telehealth (whether generated manually by HCPs or through AI-enabled algorithms) is not yet developed.

The paucity of literature on this subject combined with the participants' unanimous views emergent in our investigations, emphasized the need for innovating in the area of patient-facing clinical consultation summaries. Since the conduct of the study presented in this paper, our team of software developers has created a telehealth-enhancement add-on feature which seeks to generate patient-facing summaries of clinical consultations during video telehealth sessions. The prototype was developed in an agile manner, involving think-aloud testing activities with end users. Subsequently, the minimum viable product (MVP) was subjected to a simulation study to generate early-stage evidence about end-users' perceptions of the add-on's potential clinical usefulness. The findings of our think-aloud and simulation studies will be reported in future papers. However, based on participants' accounts presented in this paper, we expect that the provision of a patient-facing document that summarizes the telehealth consultation and distills key actionable clinical advice for patient self-management, might enhance patient experience and self-management.

Limitations

The limitations of this project include the small number of participants interviewed. The small sample size was partly due to challenges in recruiting palliative care patients. Patients' complex symptomatology and in some cases, limited life expectancy, impacts their ability to participate in research studies. In addition, as the data collection was conducted during the pandemic, this posed additional challenges for HCP recruitment. Nevertheless, our multimodal data collection approach involving the use of photographs and interviews combined with dual perspectives of patients and HCPs meant that we had a rich dataset to generate an in-depth understanding of users' experiences of telehealth.

In this instance, we did not collect information about, or pose eligibility restrictions regarding participants' ethnic and racial background, socioeconomic status, and level of experience with telehealth. This decision was driven by the small number of palliative care participant population available to participate in the study. Future telehealth research may include

XSL•FO
RenderX

contextualisation of emergent findings through the lens of one or more of these socio-demographic characteristics.

Conclusion

This study explored patients' and HCPs' experiences of telehealth in a palliative care context. A total of 3 themes emerged: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. The findings presented in this article combined with other co-design activities, which are outside the scope of this paper, indicated the potential value of a telehealth enhancement add-on feature that generates patient-facing clinical consultation summaries. Our team has developed a video telehealth enhancement feature, which will enable clinicians to distill key actionable advice and self-management guidance discussed during teleconsultations in a take-home summary document for patients. The add-on prototype has been subjected to a preliminary simulation study which will be reported in a future publication.

Acknowledgments

We thank Ms Roxanne Kritharidis who conducted all of the interviews, cleaned transcripts, and prepared the data for analysis. We thank Dr Jennifer Bibb who obtained ethics approvals, supported data collection, and participated in data analysis and writing of the final co-design report on which this work is based. We thank Dr Elton Lobo who contributed to analysis discussions and started early paper drafts. Thank you to Dr Kate Robins-Browne who led data analysis and drafted first versions of this paper. We also thank Prof Victoria Palmer who designed the photo interviewing study as part of the co-design stage for the early parts of this project, oversaw data collection and analysis, and contributed to the early draft of the paper. This research is supported by the Digital Health Cooperative Research Centre Limited (DHCRC), Monash University, Healthdirect Australia, Monash Health, University of Melbourne, and Victorian Department of Health. DHCRC is funded under the Commonwealth Government Cooperative Research Centres (CRC) Program. Finally, we thank all the participants of this study who generously contributed their time towards this research.

Data Availability

The datasets generated during and analyzed during this study are not publicly available due to the sensitive nature of the data and vulnerable nature of the population.

Generative artificial intelligence was not used for any part of the study reported in this paper nor for manuscript development.

Authors' Contributions

MK contributed to formal analysis, writing–original draft, writing–review and editing, and project administration. TOB contributed to formal analysis, writing–original draft, writing–review and editing, and project administration. CP and MEF contributed to writing–review and editing. Abstract

Background: Irritable bowel syndrome (IBS) has a high worldwide prevalence and there are few effective treatment options. Patient education can influence patient behavior that subsequently may lead to changes in attitudes and skills necessary for maintenance or improvement in management of symptom severity and quality of life. However, as postdiagnostic patient education can be resource demanding, assessment of digital approaches and verification of their effectiveness is warranted.

Objective: This cohort study aimed to investigate the effects of a digital web-based multidisciplinary eHealth program on the domains of symptom severity (Irritable Bowel Syndrome Symptom Severity Scale [IBS-SSS]), quality of life (irritable bowel syndrome quality of life [IBS-QOL]), anxiety and depression (Hospital Anxiety and Depression Scale), and a measure of general client satisfaction (client satisfaction questionnaire), compared with an onsite multidisciplinary 2-day group-based education program ("IBS-school"), in 2 cohorts of 255 patients with IBS.

Methods: Patients diagnosed with IBS, aged 15-70 years, were enrolled after referral to the Section of Gastroenterology at Haukeland University Hospital, Norway. In total, 132 patients were recruited to the eHealth program and 123 to the IBS-school group for comparison. Data were self-reported and collected digitally at enrollment and after 3 months, between 2017 and 2019. Furthermore, 71 attending the eHealth program and 49 attending the IBS-school completed the questionnaires at 3 months. Intervention response was defined as a reduction of ≥50 points on the IBS-SSS.

Results: Patients attending the eHealth program reported a significant reduction in IBS symptom severity 3 months after treatment (n=71), compared with patients attending the IBS-school (n=50). Overall, patients categorized as intervention responders in both programs showed a significant reduction in symptom severity at 3 months. Here, 41% (29/71) of patients attending the eHealth program reported a mean IBS-SSS reduction of 103 (SD 72.0) points (P<.001). In addition, these patients reported reduced anxiety (P>.001) and depression (P=.002) and enhanced quality of life (P=.03), especially the degrees of dysphoria, body image, food avoidance, health worry, interference with activity, relations, and social relations. Patients responding to the IBS-school intervention (18/50, 36%) reported a mean IBS-SSS reduction of 119 (SD 86.2) points (P<.001), and reduced depression scores (P=.046), but no difference in overall quality of life. Both groups reported the respective interventions as "good" quality health care programs, scoring them 23.5 (SD 4)—the eHealth program 23.5 (SD 4), and the IBS-school 24.2 (SD 4)—on the client satisfaction questionnaire.

Conclusions: We conclude that the digital multidisciplinary eHealth program has a significant effect on IBS symptom severity in a portion of patients; it is useful as a tool in disease self-management and does not result in worse symptom scores than an onsite multidisciplinary 2-day group-based education program after 3 months. We believe these results indicate that a digital eHealth approach is preferable to an onsite multidisciplinary 2-day group-based education program covering the same topics.

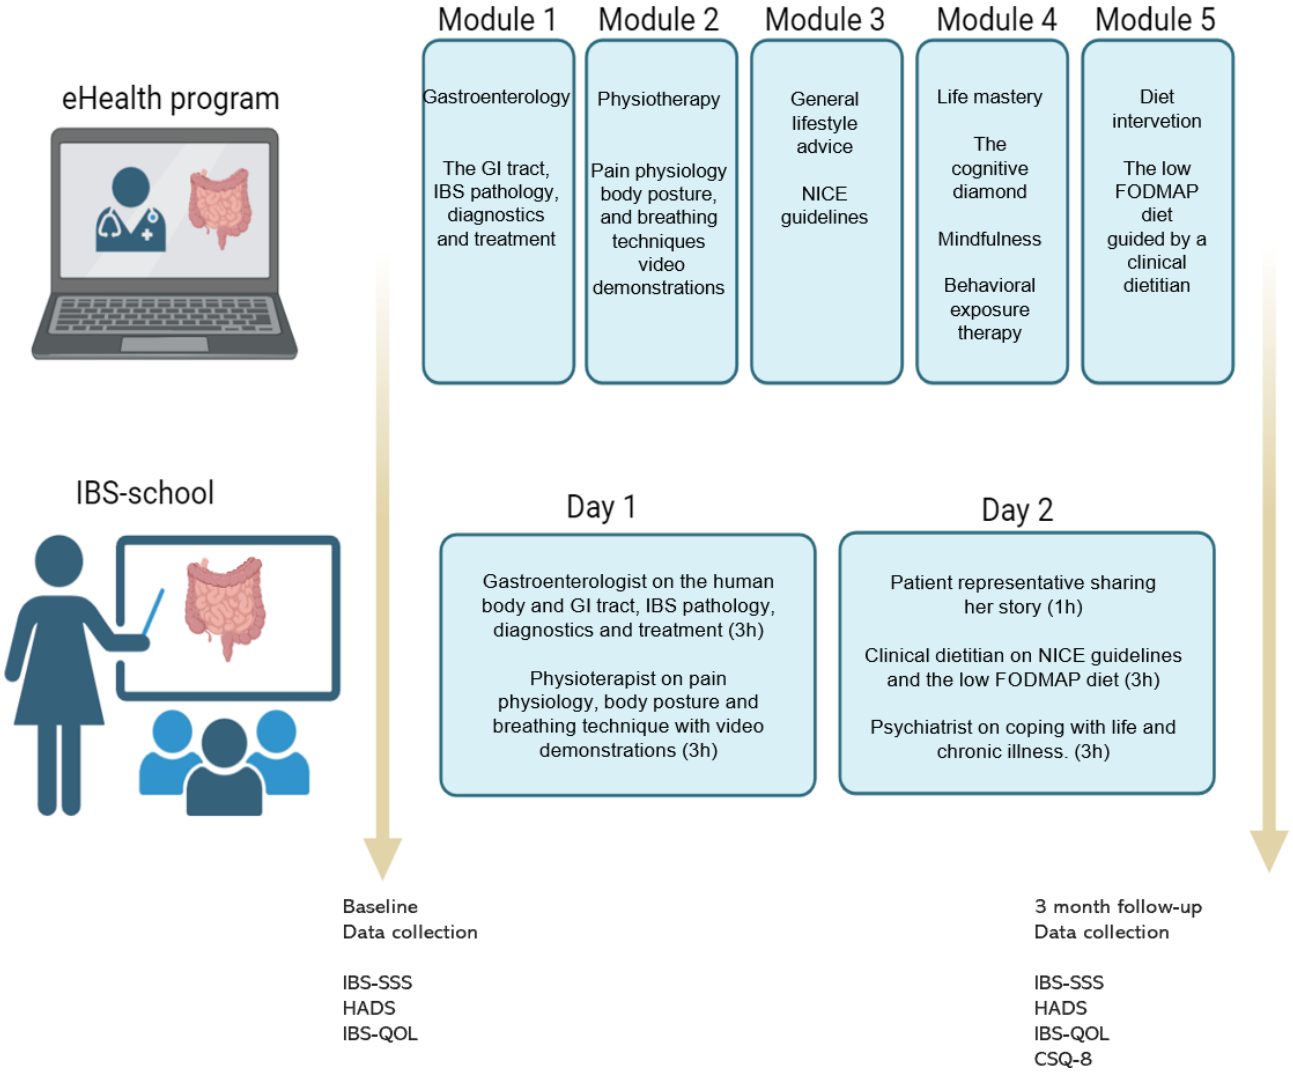
Introduction

Irritable bowel syndrome (IBS) is a chronic disorder manifested by recurrent abdominal pain and alterations in stool form or frequency [1,2]. The condition affects between 4% and 9.2% of the global population [3-5] and it is highly heterogenous. IBS' unclear etiology involves multifactorial disturbances of the bidirectional communication between the gut and the brain, including visceral hypersensitivity, low-grade inflammatory responses, intestinal motility disturbances, alterations of central nervous system processing, and alterations in gut microbiota composition [6]. However, no clear biomarker or therapeutic target for IBS has been identified. The condition lacks both a cure and medication that gives sufficient symptom relief, a fact that highlights the necessity of integrating nonpharmacological approaches including patient education in patient care [7]. Patients with IBS require personalized treatment for successful symptom relief. Approaches may include physical therapy, cognitive behavioral therapy (CBT), hypnotherapy, mindfulness and exposure therapy, and comprehensive dietary guidance by registered dietitians such as the low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet. However, access to these treatment options is often limited due to lack of trained professionals, travel distances, and cost. Thus, more accessible treatment options are warranted. Web-based interventions, patient education, and self-management has been demonstrated to be effective in patients suffering from chronic diseases, including IBS [8-10]. A systematic review from 2017 concluded with mixed results regarding the effectiveness of web-based mindfulness-based interventions compared with active control treatment conditions such as CBT. However, the study showed that treatment targeting symptoms of IBS had the largest effect size improvements [11]. A longitudinal qualitative study from 2020 showed that both telephone-based CBT and web-based CBT for IBS were positively received and had lasting positive impacts on participants' understanding of IBS symptoms, quality of life, and IBS-related behaviors [12]. A recent Japanese randomized controlled trial has shown that a multidisciplinary eHealth self-management program can reduce the severity of IBS-symptoms and improved the quality of life [13].

Indeed, limited health care resources, national priority guidelines, and sparse treatment options may restrict any long-term follow-up that patients with IBS may request from a secondary or tertiary care institution. Since 2012, Haukeland University Hospital has offered patients with IBS an onsite multidisciplinary 2-day group-based education program, a so-called "IBS-school." The multidisciplinary approach is designed to provide patients with evidence-based information and practical skills that may lead to improved IBS management, reduced IBS symptoms, and enhanced quality of life. Based on our clinical experience with group education, we have developed a novel internet-guided multidisciplinary self-care management program for patients with IBS, from now on referred to as the "eHealth program." The content in the eHealth program is based on topics covered in the IBS-school, but the patients also have access to digital clinical support during the program. Herein, we hypothesized that the eHealth program would have an equally good effect on symptom severity, quality of life, and patient satisfaction, compared with a cohort of patients attending IBS-school. Data from neither program have been published before. In this study, we aimed to investigate the effects of a digital web-based multidisciplinary eHealth program on the domains of symptom severity (Irritable Bowel Syndrome Symptom Severity Scale [IBS-SSS]), quality of life (irritable bowel syndrome quality of life [IBS-QOL]), anxiety and depression (Hospital Anxiety and Depression Scale [HADS]), and a measure of general client satisfaction (client satisfaction questionnaire [CSQ-8]), compared with an onsite multidisciplinary 2-day group-based education program, IBS-school, in 2 cohorts of 255 patients with IBS.



Methods

Patient Sample, Randomization, and Treatments

In this study**,** 255 patients between 15 and 70 years were recruited after being accepted for patient education at Haukeland University Hospital in Norway between 2017 and 2019. Random patients on the waiting list to the onsite multidisciplinary 2-day group-based education program, IBS-school, were contacted by phone by a study nurse and offered to attend the novel multidisciplinary digital 5-module eHealth program, from here on referred to as the "eHealth program." Patients attending the IBS-school were recruited on site when attending the 2-day group-based education program. Patients received oral and written information before giving written consent and sent it to the hospital by post. Furthermore, 123 patients that attended the IBS-school were used for comparison (N=255, 1:1). Here, patients were recruited by a study nurse on site. They received an oral and written information about the study before signing consent (Figure 1). Inclusion criteria included (1) being referred to receiving patient education on IBS by a gastroenterologist or general practitioner after the diagnosis of IBS had been determined (*International Classification of Primary Care, Second Editon* [*ICPC-2*] code D93; *International Statistical Classification of Diseases, Tenth Revision* [*ICD-10*] code K58), (2) being between 18 and 70 years, and (3) understanding written and oral Norwegian. There were no specific exclusion criteria.

XSL•FO
RenderX

Figure 1. Intervention overview. CSQ-8: client satisfaction questionnaire; FODMAP: fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; GI: gastrointestinal; HADS: Hospital Anxiety and Depression Scale; IBS: irritable bowel syndrome; IBS-QOL: irritable bowel syndrome quality of life; IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale; NICE: National Institute for Health and Care Excellence.

Ethical Considerations

Eligible patients gave informed written consent and participants were given the option to withdraw from the study at any time point without a specific reason. The data were deidentified and stored on a secure hospital server, and analysis was performed on anonymous data. None of the participants were compensated. The study was approved by the Regional Ethical Committee of Western Norway (REC-2016/1098).

Interventions

The Irritable Bowel Syndrome–School

Patients attended an onsite multidisciplinary 2-day group-based education program, IBS-school, at Haukeland University Hospital. The number of participants varied between 15 and 40 each month. The program involved lectures and question and answer sessions by 4 health care professionals. Refer to Figure 1 for the intervention outline. On day 1, a gastroenterologist talked about the human body and the gastrointestinal system, what IBS is, what causes it, diagnostics, and treatment options (3 hours). Second, a physiotherapist was giving a lecture on body posture and breathing techniques including demonstrations, introducing pain physiology, and the function of the human nervous system (3 hours). On day 2, a patient representative shared her personal experience with IBS (1 hour), and a clinical dietitian gave a lecture on National Institute for Health and Care Excellence (NICE) guidelines [14] that summarizes the most recent recommendations on IBS in adults in primary care, and the low FODMAP diet [15] (3 hours). Finally, a psychiatrist gave a lecture on coping with life including health worry, social relations, tiring thoughts and feelings, adaptations, and symptoms. A nurse with specialization in gastroenterology hosted the group education program to create a comfortable environment for exchange of personal experiences and participate in group assignments.

The eHealth Program

Patients who were enrolled in the digital eHealth program had access to a comprehensive, multidisciplinary web-based program that consisted of 5 modules (refer to Figure 1 for the outline). The modules consisted of instructive texts, videos, animations, and images over 150 web-pages on a digital treatment platform by CheckWare AS [16]. In addition, patients carried out “home assignments” based on principles of CBT, a protocol by Ljótsson et al [17] at the Swedish Karolinska Institute, followed by an

XSL•FO
RenderX

optional low FODMAP diet intervention guided by a clinical dietitian. The eHealth program allowed a secure login (eg, bank-ID) and digital communication between patient and a clinical dietitian throughout the process, at the patient's own request and need. The patients were expected to finish the program over a period of 3 - 12 weeks, at his or her own pace, all dependent on their motivation and work capacity. Module contents have been described further in this study. Module 1 describes the body and the gastrointestinal system. In this first module, the patient gets an introduction to what IBS is, how it is diagnosed, and what causes it. The patient learns about the function of our digestive system and how it is regulated, and how it can be disturbed in people with IBS. Module 2 describes the posture and breathing techniques. This module focuses on the connection between IBS and musculoskeletal disorders. Many people with IBS may have a "hyperactive" nervous system that can cause pain and physical maladjustments. In this module, a physiotherapist introduces the patient to pain physiology and how the nervous system works. There is a practical section with useful exercises for people with IBS. The module will give the patient an understanding of how long-term pain occurs, why it often persists, and how to influence it. Module 3 consists of diet and lifestyle advices. There is no miracle cure for IBS, but many people experience improvement by following some general advice. In this module, we look at lifestyle advice that has been shown by research to improve symptoms in people with IBS. It is recommended to try this before eliminating other foods or following strict diets. Module 4 focuses on coping with life. In this module, the patient learns techniques from cognitive therapy including "the cognitive diamond," mindfulness, and practice systematic exposure exercises has previously shown beneficial effects for patients with IBS. The protocol has been described in a study by Ljótsson et al [17]. Module 5 describes the dietary intervention with a low FODMAP diet. This is a dietary treatment that provides symptom relief in approximately 70% of patients with IBS [18]. In this module, the patient will be introduced to the low FODMAP diet in both theory and practice. The patient had access to digital guidance by a clinical dietitian during the entire course of the study.

Questionnaires

Overview

Patients completed questionnaires related to IBS symptom severity (IBS-SSS) [2], quality of life, (IBS-QOL) [19], and anxiety and depression (HADS) [20] upon enrollment at baseline and after 3 months.

The IBS-SSS is considered the gold standard measure of IBS symptoms and contains 5 questions that measure the frequency of abdominal pain, the severity of abdominal distention, dissatisfaction with bowel habits, and interference with quality of life, scored in the range of 0 - 500. A higher score indicating worse condition, scores <175 represent mild IBS symptoms, 175 - 300 represents moderate severity, scores >300 represent severe IBS [2].

The IBS-QOL is a condition-specific measure for assessing health-related quality of life in IBS. It consists of 34 items, each with a 5-point response scale in a range of 0 - 100, where the higher score indicates a better IBS specific quality of life. There are 8 subscale scores for the IBS-QOL: dysphoria, interference with activity, body image, health worry, food avoidance, social reaction, sexual, and relationships [21].

HADS is a scale of 14 items designed to measure anxiety and depression, 7 items for each subscale (ie, anxiety and depression). The total score is the sum of the 14 items, and for each subscale the score is the sum of the respective 7 items that range from 0 to 21 [20].

CSQ-8 [22] was completed at 3 months. The questionnaire is an 8-item measure with a total score ranging from 8 to 32, with the higher number indicating greater satisfaction with treatment.

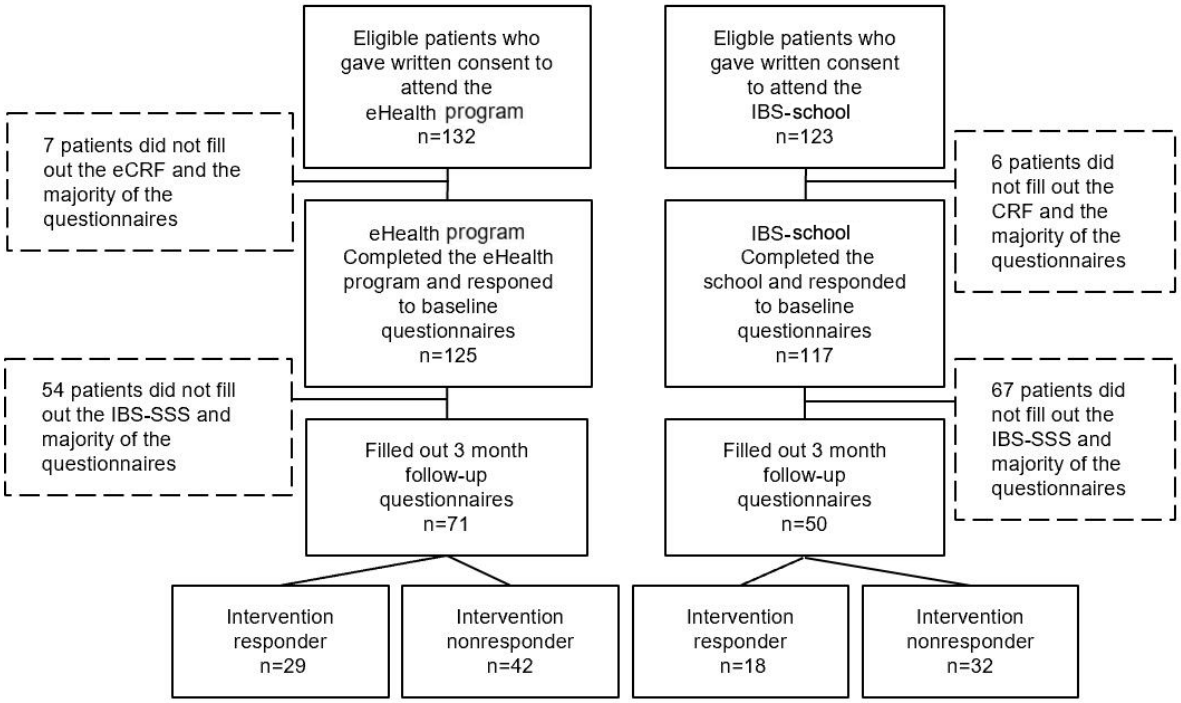
Primary Outcome Measure and Definition of Intervention Responders

In the field of IBS research, a change of 50 points in IBS-SSS score has shown to reliably indicate improvement in IBS symptom severity [2]. Our primary outcome measure was a >50-point reduction in IBS-SSS at 3 months, compared with baseline. Patients reporting a ≥50-point reduction in IBS-SSS at 3 months were categorized as "responders" to the intervention. Patients reporting <50-points on IBS-SSS were categorized as "nonresponders" to the intervention.

Statistical Analysis

Statistical analyses were performed using SPSS Statistics (version 26, IBM) for Microsoft Windows. Baseline patient characteristics and questionnaires were first presented according to intervention—eHealth group and IBS-school. At 3 months after intervention, patients were categorized as responders or nonresponders. For comparison between groups, unpaired *t* test were performed for parametric data and Mann-Whitney *U* for nonparametric data. For comparisons before and after interventions, paired *t* tests were performed for parametric data and Wilcoxon signed rank test for nonparametric data. A *P* value <.05 was considered statistically significant. The intervention responder or nonresponder analysis to the eHealth program or IBS-school was carried out performing a paired *t* test on data from patients who filled out the 3-month questionnaires (n=71 and n=50, respectively). A χ^2 test of independence was used to assess differences between intervention response.

Results



Patients and Characteristics

A flowchart of participating patients is illustrated in Figure 2. Of the 132 eligible patients who gave written consent to participate in the eHealth program group of the study, 7 did not fill out the minimum requirement including the electronic case report form and the IBS-SSS questionnaire. Of the 125 patients who completed the program, 54 patients did not respond to the IBS-SSS questionnaire at 3 months. Hence, the follow-up data from patients attending the eHealth program reduced to n=71 at 3 months. Of the 123 eligible patients who gave written consent to participate in the IBS-school group of the study, 5 did not fill out the minimum requirement including the electronic case report form and the IBS-SSS questionnaire. Thus, of the 118 patients who completed the program, 69 patients did not

XSL•FO
RenderX

respond to the IBS-SSS questionnaire at 3 months. Hence, the follow-up data from patients attending the eHealth program reduced to n=49 at 3 months.

Figure 2. Flow chart of participating patients with IBS. Patients reporting a ≥50-point reduction in the IBS-SSS at 3 months were categorized as "responders to the intervention". Patients reporting <50-points on the IBS-SSS were categorized as "nonresponders to the intervention". CRF: case report form; eCRF: electronic case report form; IBS: irritable bowel syndrome; IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale.

Participants were predominantly female (190/235, 81%) with a mean age of 38.3 (SD 12.4) years (Characteristics are summarized in Table 1). An unpaired *t* test showed that there was no difference in age between groups. A Mann-Whitney *U* test was performed to evaluate whether sex differed between groups, reveling no significant difference between patients attending the eHealth program and patients attending the IBS-school (Table S1 in Multimedia Appendix 1, U=6407.0, z=−1.394, P=.16). Furthermore, participants at the IBS-school and eHealth program displayed similar baseline characteristics upon enrollment, including moderate to severe IBS symptom severity.

There was no significant difference between most relevant features at baseline, except for anxiety and depression, as shown in Table 1. Here, patients attending the eHealth program scored an average of 11 (SD 5.2) which corresponds to mild to moderate anxiety, while patients attending the IBS-school scored 9.4 (SD 5.1), corresponding to a mild level of anxiety (2-tailed t_{232}=2.37, P=.02). Thus, both patient groups displayed an anxiety score typical of a clinical case of anxiety (HADS-anxiety ≥8 is considered a clinical case [20]), and patients attending the eHealth program presented a significantly higher baseline score than patients attending the IBS-school. Furthermore, patients attending the eHealth program reported significantly higher depression scores than patients attending the IBS-school (mean 7, SD 4.1 vs mean 5.9, SD 4, respectively; t_{232}=2.01, P=.045). However, both groups displayed an average depression score corresponding to nonclinical severity of depression (HADS-depression ≤8 is considered noncase [20]) which gives the difference little relevance on group level.

Symptom Relief and Enhanced Quality of Life

Overview

A paired *t* test revealed that patients attending the eHealth program reported a significant reduction in IBS symptom severity at 3 months, shown in Figure 3 (mean 279.3, SD 80 vs mean 242.7, SD 79.3; $t_{70}=4.91$, $P<.001$). Comparably, patients attending the IBS-school did not report a significant reduction in symptom severity (mean 248.6, SD 86.6 vs mean 235.4, SD 98.9; $t_{49}=0.85$, $P=.40$). Refer to Table S2 of Multimedia Appendix 1 for data. However, none of the groups achieved a clinically meaningful improvement of ≥50 points on IBS-SSS at 3 months. Patients in the eHealth program-group reported a 37-point reduction, whereas patients attending IBS-school reported a 13-point reduction in IBS-SSS total score (Table S2 of Multimedia Appendix 1). Thus, for further analysis we categorized participants as a “responder” or “non-responder” to the intervention, where the sample response threshold for responders was set as ≥50-point decrease in total IBS-SSS score, a threshold that has been demonstrated to correlate with improvements in clinical symptoms [2].

XSL•FO
RenderX

Figure 3. Overall change in IBS-SSS over time. On average, patients who completed the 3-month questionnaires at the IBS-school reported a 13 point reduction in IBS-SSS (n= 50), whereas eHealth program participants reported a 37-point reduction (n=71). A decrease of 50 points is defined as a clinical response to the intervention, categorizing the patient as a "responder to the intervention." The IBS-SSS eHealth program score at baseline was 279 (SD 80) and 243 (SD 79) at 3 months, *P*<.001; the IBS-SSS IBS-school score at baseline was 248 (SD 87) and 235 (SD 99) at 3 months (*P*=.40). Paired *t* test results are summarized in Table S2 in Multimedia Appendix 1. **P*<.001, indicating a significant difference in IBS-SSS scores before and after eHealth program intervention. Blue dot represents the eHealth program; orange dot represents the IBS-school. Paired *t* test was performed. Error bars present SD. Lower n indicate missing data. The reduced number from the total number of participants indicate missing data. IBS: irritable bowel syndrome. IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale.

Responders

Of the 71 patients, 29 (41%) attending the eHealth program responded to the intervention with a reduction in IBS-SSS score of ≥50 points, compared with 36% (18/50) who attended the IBS-school after 3 months (Figure 3). The results in this section are summarized in Tables 2 and 3. Patients categorized as responders to the eHealth program reported a significant mean reduction in IBS-SSS score of 103 (SD 72.0) points with a moderate effect size of 0.56 (t_{28}=7.62, Cohen *d*=1.33, *P*<.001). In addition, eHealth program–responding patients reported a significant reduction in anxiety, changing from a clinical case to a noncase classification (mean −4.7, SD 6.2; t_{28}=6.89, Cohen *d*=0.85, *P*<.001). Here, the effect size of 0.39 indicated a moderate effect. On average, these patients also reported an increase in overall quality of life, summarized in Tables 2 and 3 (mean 5.80, SD 19.1; t_{28}=−2.28, Cohen *d*=−0.30, *P*=.03). Here, features such as dysphoria (mean 18, SD 23.3; t_{28}=−2.1, Cohen *d*=−0.85, *P*<.001) and body image (mean 14.8, SD 18.6; t_{28}=−3.9, Cohen *d*=−0.72, *P*<.001) increased significantly with a moderate effect size. Features such as food avoidance (mean 6.3, SD 22.5; t_{28}=−2.10, Cohen *d*=−0.13, *P*=.045), health worry (mean 10.8, SD 23.5; t_{28}=−3.44, Cohen *d*=−0.43, *P*=.002), interference with activity (mean 13.4, SD 18.8; t_{28}=−4.03, Cohen *d*=−0.63, *P*<.001), relations (mean 9.5, SD 22.9; t_{28}=−2.72, Cohen *d*=−0.37, *P*=.01), and social relations (mean 10.7, SD 19.4; t_{28}=−3.62, Cohen *d*=−0.56, *P*=.001), all improved significantly, compared with baseline. The changes in sexual activity were not significantly different after 3 months (mean 5.4, SD 29.8; t_{28}=−1.52, Cohen *d*=−0.19, *P*=.14).

[a]IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale.

[b]Significant at the $P<.05$ level.

[c]HADS-A: Hospital Anxiety and Depression Scale – Anxiety.

[d]HADS-D: Hospital Anxiety and Depression Scale – Depression.

[e]IBS-QOL: irritable bowel syndrome quality of life.

Patients who responded to the IBS-school intervention reported an average reduction in IBS symptom severity score of 119 (SD 86.2) points (n=18; t_{17}=5.54), Cohen d=1.33, P<.001). In addition, patients reported a reduction in depression scores (mean −2.3, SD 4.4; t_{15}=2.17, Cohen d, P=.046). However, these patients did not report significant improvements in anxiety or overall quality of life (mean 2.5, SD 6.8; t_{15}=1.97, Cohen d=0.43, P=.07 and mean 2.4, SD 27.9; t_7=−0.57, Cohen d=−0.08, P=.64, respectively). Furthermore, the number of responding patients were too low for further in-depth statistical analysis of quality of life (n=8). Data for these analyses are presented in Table S3 of Multimedia Appendix 1.

Nonresponders

Patients who were nonresponders to the eHealth program reported no improvement in symptom severity or quality of life (mean 9.2, SD 70.4; t_{41}=−1.73, Cohen d=−0.13, P=.09) and a significant decrease in anxiety scores (mean −2.4, SD 4.8, t_{38}=3.65, Cohen d=0.52, P=.001), compared with baseline. However, both changes were of small effect (r=−0.27 and 0.25, respectively). Results are summarized in Tables 2 and 3. There were no significant changes in depression scores or overall quality of life or the respective sub-categories (P>.05). Nonresponding patients attending IBS-school reported significantly enhanced symptom scores (mean 46.5, SD 77.8; t_{31}=−4.08, Cohen d=−0.57, P<.001). However, it is worth noting that these enhanced symptoms scores were not above the 50-point threshold for clinical relevance. Furthermore, these

XSL•FO
RenderX

patients reported a significantly reduced overall quality of life (mean −11.4, SD 23.8; t_{23}=3.16, Cohen d=5.52, P=.004) and a significant increase in the domain of relationships (mean 18.7, SD 17; t_{23}=−2.11, Cohen d=−0.86, P=.046). Baseline characteristics for these analyses are presented in Table S3 of Multimedia Appendix 1.

Association Between Type of Intervention and Outcome

A χ^2 test of independence analysis was used to test whether the type of intervention was independent from the intervention outcome. Results showed that the proportion of patients who responded to the intervention in both groups (29/71 vs 18/50) were the same. Hence, there was no significant association between the type of intervention and response to the intervention (Pearson χ^2_1=0.2, Φ=0.041, P=.65). Thus, we conclude that there is no difference in treatment response between the eHealth program and IBS-school in affecting symptom severity scores. Data from this analysis is reported in Table S4 of Multimedia Appendix 1.

Patient Satisfaction

Patient satisfaction was investigated in both groups 3 months after enrollment (CSQ-8). Patients who attended the IBS-school reported a mean score of 24.2 (SD 3.7), compared with patients attending the eHealth program with a mean score of 23.5 (SD 4.0), which are both equivalent to “good” health care offers [22]. An unpaired t test revealed no significant difference between group scores (t_{115}=−1.032, P=.31; Table 4).

Table . Difference in client satisfaction scores (CSQ-8) between patients attending the eHealth program and irritable bowel syndrome (IBS)–school. A χ^2 test of independence was conducted. The reduced number from the total number of participants indicate missing data.

		n	mean (SD)	t test (df)	Cohen d	Effect size r	P value
Overall				−1.032 (115)	−0.193	−0.01	.31
	eHealth program	68	23.46 (4.0)				
	IBS-school	49	24.20 (3.67)				

Discussion

Principal Findings

In this study, we have shown that the novel digital multidisciplinary eHealth program has a significant reducing effect on IBS symptom severity and is useful as a tool in disease self-management. In total, 41% (29/71) of participants reported significant and clinically relevant symptom relief. Furthermore, we show that the eHealth program is safe, as patients not responding to the intervention reported unchanged symptoms and quality of life at 3 months. In addition, eHealth intervention–responding patients reported significant benefits on multiple domains of IBS-related quality of life such as body image, food avoidance, health worry, interference with activity, relations, and social relations. Levels of anxiety were significantly reduced, and levels of dysphoria were improved.

Comparably, 36% (18/50) of participants reported a clinically significant effect to the onsite multidisciplinary 2-day group-based education program, the so-called “IBS-school.” Thus, our results indicate that the digital multidisciplinary eHealth program may be equally effective to the IBS-school, which is often a standard treatment offer to newly diagnosed patients. Furthermore, patients responding to the IBS-school intervention did not report any significant improvements in quality of life or in anxiety, but a small not clinically meaningful decrease in depression scores. The number of IBS-school responders were too low for more in-depth statistical analysis on the domains of quality of life.

A χ^2 test of independence showed no difference between intervention outcome in the 2 groups; hence the eHealth program did not have a better intervention response than the IBS-school on the measures of symptom severity. However, the eHealth program had a significant effect on other aspects of IBS symptomatology, including anxiety and quality of life, whereas IBS-school did not.

Patients rated both the eHealth program and the IBS-school as good health care offers on measures of patient satisfaction of health care quality, scoring them 23.5 and 24.2 out of a maximum of 32 points, respectively.

We believe these results indicate that a digital eHealth approach, designed to provide patients with evidence-based information and practical skills, is preferable to an onsite multidisciplinary 2-day group-based education program covering the same topics.

Comparison With Previous Work

Initially at baseline in both groups, the greatest impairment in quality of life was observed for the subscale of food avoidance followed by body image, inactivity, and dysphoria. This order of impairment is similar to findings by Drossmann et al [21] in an international study from 2009 (n=1966). However, our findings show lower scores on all subscales except dysphoria and health worries, which are in the same magnitude. In comparison with a newer study on quality of life by Kopczyńska et al [23] (n=87), our baseline results show much lower scores on both overall and all subscales of quality of life. A recent Vietnamese study showed that patient education, lifestyle, and dietary intervention, administered by clinical pharmacists, improved IBS related quality of life compared with standard medical therapy over 8 weeks [10]. These study patients also showed a much higher baseline and postintervention quality of life-scores compared with our study. We speculate that our study participants represent a group with more severe IBS because they are referred to a tertiary health care institution that due to capacity issues has to prioritize those patients who need it the most. However, the low baseline scores on food avoidance in our study indicate that both our interventions with a key focus on diet was the right call. This core problem was targeted

XSL•FO
RenderX

because food is a known important trigger of IBS-symptoms [24]. On the domain of food avoidance, we observed an improvement in eHealth program-responders, compared with baseline (Tables 2 and 3). No such improvement was observed in patients attending the IBS-school. We speculate that this is due to the differences in comprehensiveness and durability. The eHealth program is designed to engage the patient interactively to learn how to make appropriate changes in diet. It offers a thorough guidance with videos and instructions on how to follow the low FODMAP diet, including the exclusion and reintroduction of foods. In addition, the patient has the option of digital question and answer sessions with a clinical dietitian throughout the program. The IBS-school is also designed for patients to learn how to self-help, but the program is much shorter with its 2 days of physical attendance. In the light of these results, we deduce that the eHealth program is not inferior to the established IBS-school as a health care offer. In fact, we show that an eHealth intervention program can provide the patient with self-help tools that can lead to reduced gastrointestinal symptoms and enhance quality of life for patients with IBS. This aligns with a recent randomized controlled study by Tayama et al [13] (n=40) showing that a multidisciplinary eHealth self-management program leads to an increased intake of FODMAP-groups and subsequently a more extensive diet. Severe food avoidance and dietary restriction is previously reported in 13% (829/955) of IBS-patients and this subgroup of IBS-patients reported more severe IBS-symptoms, reduced quality of life, and reduced intake of nutrients [24]. Thus, providing patients with evidence-based information, practical tools, and support by a clinical dietitian is important in clinical care of patients with IBS.

eHealth programs in the form of apps, internet-guided programs, or telehealth has recently accelerated as useful tools in clinical medicine. In an American study on satisfaction during COVID-19, most patients with IBS reported high satisfaction rates and ease of use with telehealth [25]. Here the authors reported on multiple benefits including the patient having to take less time off from work and improved access to the care team. Their most commonly reported challenges with telehealth included feeling impersonal and being unable to address all of their issues or concerns. A majority felt that telehealth was as good as or better than face-to-face visits and would use telehealth for future care. Only approximately 10% (130/1311) of the patients remained dissatisfied. In 2020, a Polish study showed that an educational program combined with elements of behavioral therapy, individualized for patients with IBS, is an important part of therapy [26]. In addition, as a part of a dietetic-led gastroenterology service in primary care, feasibility, acceptability, and cost-efficiency of using webinars to deliver first-line patient education for patients with IBS, has been shown to be successful [27]. A meta-analysis of chronic gastrointestinal illness interventions (19 studies conducted in 8 countries, n=3193) showed that eHealth gastrointestinal interventions improved patients' quality of life, psychological distress, medication adherence, and illness-related knowledge [28]. The meta-analysis also showed that eHealth gastrointestinal interventions significantly reduced the number of patient visits to the hospital. Taken together with our results, these findings support eHealth interventions holding decent promise in improving outcomes for patients with IBS.

Comparably on patient satisfaction, a randomized controlled trial by Lackner et al [29] showed that patients who received 4 gastroenterologist-led patient education sessions over 2 weeks reported 26.6 in patient satisfaction. Here, 43.5% (63/145) of patients reported improvement in addition to a higher satisfaction score than in our study. However, both these and our results reflect that subjective symptom relief may not be required for the patient to experience the treatment as useful. This is also highlighted by our patients attending the IBS-school who did not experience significant enhancement in quality of life nor reduction in symptom severity, but still reported a higher satisfaction than patients who objectively benefited more from the eHealth program.

Limitations

All 255 recruited patients completed the programs. However, there was a very high percentage that did not submit the 3-month questionnaires. In total, 41% (54/132) percent of patients attending the eHealth program, and 54% (67/123) of the patients who attended the IBS-school did not submit the 3-month follow-up questionnaires on IBS symptoms severity (Figure 1). Unfortunately, this occurred despite multiple efforts and reminders (phone calls, emails, and SMS text messages) from the research team encouraging the participants to respond. First, this high percentage of missing data are significant and may have affected the results of the study even though the rates appear similar across the groups. However, high dropout rates are a common issue in eHealth studies and known as "the law of attrition" [30]. This warrants the need for a larger study where an intention-to-treat analysis can be carried out without diminishing the power of the study. Second, eHealth literacy is defined by Norman and Skinner [31] as "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem". The individual patient's level of health literacy was not mapped during the study and variations in these abilities may have affected our results. Third, the patient population represents all subtypes of IBS and there are no analyses focusing on the differences in response between patients with predominant diarrhea, constipation, or a mix of the 2. Comorbidities or other additional diagnoses are common in IBS [32] but have not been excluded in this study and may have affected the results. Fourth, the use of drugs during the study period have not been reported. Hence, many drugs have side effects such as nausea, vomiting, diarrhea, constipation, flatulence, which are symptoms that the patient may confused with IBS symptoms. Fifth, a high placebo effect, which can be up to 40%, is a known challenge in clinical studies on IBS [20]. Although this study has not been designed with a control group, the placebo effect may have affected our results in either group and have not been adjusted for. However, we may speculate that the phenomenon has affected patients in both groups equally and importantly, the placebo effect may recede after 12 weeks, which was our end point [33]. Sixth, as both programs are broad and cover a variety of information, advice, and treatment including the low FODMAP diet and principles of CBT, another limitation of this study is the unknown specifics patients were

XSL•FO
RenderX

responding to in either program. Indeed, there are no measures on cognition verifying the direct effects of the principles of CBT or exposure therapy. This needs to be further investigated in a prospective study, and we acknowledge that an in-depth explanation for our observed benefits after attending the eHealth program remain to be clarified. Thus, these aspects are objectives in our currently ongoing randomized controlled trial [34]. In the light of limited primary and secondary health care resources, it will be useful to develop prediction tools to identify which patients may achieve improvement in both symptom severity and domains of quality of life. For these stratification analyses to be clinically meaningful, the number of participants need to be higher than reported in this study and performed in and randomized controlled trial.

Conclusions

We conclude that the digital multidisciplinary eHealth program has a significant effect on IBS symptom severity in a portion of patients, and is useful as a tool in disease self-management. In addition, it does not result in worse symptom scores than an onsite multidisciplinary 2-day group-based education program after 3 months. We believe these results indicate that a digital eHealth approach, that include benefits such as 3 months unlimited access to quality assured information and treatment with documented effect, is preferable to an onsite multidisciplinary 2-day group-based education program covering the same topics.

Acknowledgments

The authors wish to thank all patients who participated at the irritable bowel syndrom (IBS)–school and the eHealth program. In addition, we wish to thank Haukeland University Hospital's “Learning and Mastering Center” and their wonderful employees, the patient educators psychiatrist Tor Jacob Moe, physiotherapist Eirik Østhammer, psychosomatic psychiatrist Jørn Bødtker, patient representative Cecilie Ågotnes, IBS-school host nurse Per Førde Refsnes, clinical dietitians Cecilie Larsen and CT, CheckWare AS, and eHealth program developer Jan Gunnar Hesthammer, Section for eHealth, Haukeland University Hospital. We also wish to thank the Department of Medicine and Section for Gastroenterology at Haukeland University Hospital, Tine Nordgreen and Research Centre for Digital Mental Health Services, Centre for Research-Based Innovation, Haukeland University Hospital, and Bjrann Ljottson, Karolinska Institutet, and Pelle Lindfors, Sahlgrenska, Sweden. This work was supported by Helse Vest under grants HV1148 and R-10923.

Abstract

Background: Bangladesh and West Bengal, India, are 2 densely populated South Asian neighboring regions with many socioeconomic and cultural similarities. In dealing with breast cancer (BC)–related issues, statistics show that people from these regions are having similar problems and fates. According to the Global Cancer Statistics 2020 and 2012 reports, for BC (particularly female BC), the age-standardized incidence rate is approximately 22 to 25 per 100,000 people, and the age-standardized mortality rate is approximately 11 to 13 per 100,000 for these areas. In Bangladesh, approximately 90% of patients are at stages III or IV, compared with 60% in India. For the broader South Asian population, this figure is 16%, while it is 11% in the United States and the United Kingdom. These statistics highlight the need for an urgent investigation into the reasons behind these regions' late diagnoses and treatment.

Objective: Early detection is essential for managing BC and reducing its impact on individuals. However, raising awareness in diverse societies is challenging due to differing cultural norms and socioeconomic conditions. We aimed to interview residents to identify barriers to BC awareness in specific regions.

Methods: We conducted semistructured interviews with 17 participants from West Bengal and Bangladesh through Zoom (Zoom Video Communications). These were later transcribed and translated into English for qualitative data analysis. All our participants were older than 18 years, primarily identified as female, and most were married.

Results: We have identified 20 significant barriers to effective BC care across 5 levels—individual, family, local society, health care system, and country or region. Key obstacles include neglect of early symptoms, reluctance to communicate, societal stigma, financial fears, uncertainty about treatment costs, inadequate mental health support, and lack of comprehensive health insurance. To address these issues, we recommend context-specific solutions such as integrating BC education into middle and high-school curricula, providing updates through media channels like talk shows and podcasts, promoting family health budgeting, enhancing communication at cultural events and religious gatherings, offering installment payment plans from health care providers, encouraging regular self-examination, and organizing statewide awareness campaigns. In addition, social media can be a powerful tool for raising mass awareness while respecting cultural and socioeconomic norms.

Conclusions: Fighting BC or any fatal disease is challenging and requires support from various dimensions. However, studies show that raising mass awareness is crucial for the early detection of BC. By adopting a sensitive and well-informed approach, we aim to improve the early detection of BC and help reduce its impact on South Asian communities.

Introduction

According to the GLOBOCAN (Global Cancer Observatory) 2020 report on the estimates of cancer incidence and mortality among the people of 185 countries (produced by the International Agency for Research on Cancer), female breast cancer (BC) has been identified as the most commonly diagnosed cancer (11.7%) and is the fifth leading cause of cancer mortality worldwide [1]. The same report suggests that among women, BC accounts for 1 in 4 cancer cases and for 1 in 6 cancer deaths, ranking first for incidence in most of the countries (159 of 185 countries). Through numerous studies, researchers found that early detection can significantly reduce fatal outcomes, and awareness is one of the keys to early detection [2]. Spreading awareness is a challenge for different societies for various reasons, and researchers have been working on identifying those for a long time. In this work, we assess the barriers to mass awareness (and thus far early detection) of BC among people in 2 very densely populated but culturally similar and geographically neighboring areas—Bangladesh and West Bengal, India.

Bangladesh (area: 57,321 square miles) and West Bengal, India (area: 34,267 square miles) are 2 territories in South Asia. Bangladesh's official language is Bengali, and the mass people primarily use the Bengali language for daily conversation. In total, 8% (91,276,115/1,210,569,573) of the Indian population speaks Bengali and mainly resides east of the country, with a concentration in West Bengal [3]. The population density of Bangladesh is 1328.68 people per sq km (collected from the web), and in West Bengal, India is 1028 people per sq km (according to their 2021 census). The deep sociocultural linkages between the Bengali linguistic community in eastern India and Bangladesh remain stable even after India's partition and independence in 1947. The unemployment rate in Bangladesh is 5.23%, and in West Bengal, it is 5.2% (as of June 2022). A total of 70.54% (64,385,546/91,276,115) of people from West Bengal follow Hinduism, and 27.01% (24,654,825/91,276,115) follow Islam. In Bangladesh, 91.04% (150,360,405/169,828,921) are Muslims, and 7.95% (13,130,109/169,828,921) are Hindus. The life expectancy in West Bengal, India, is 71.2 years [4], and in Bangladesh, it is 73.57 years [5]. The approximate sex ratio (as of 2022) in Bangladesh is 102.12 males per 100 females, whereas in West Bengal, it is 105 males for every 100 females. The average literacy in Bangladesh is 74.91% [6], and in West Bengal is 76.26% [6]. The commonality in the history and sociocultural environment of eastern India and Bangladesh has created a pseudo-homogeneous society where language is one of the fundamental elements in this connectivity. Hence, our work focuses on understanding attitudes, perceptions, and behaviors around BC-related issues in these 2 densely populated areas.

Unfortunately, there are no available sources of comprehensive epidemiological, pathological, and outcomes data for patients with BC [7,8] for the chosen regions; so, we are using the closest information from the GLOBOCAN 2020 report [1] to estimate the incidence and mortality rate of BC in this part of the world (Table 1). The factors contributing to the rising incidence and mortality of BC in low-income countries such as Bangladesh and West Bengal, India, are multifaceted. It is important to acknowledge that the solutions required for addressing these challenges differ significantly from those implemented in high-income countries [9]. Therefore, adopting models or policies directly from high- or middle-income countries, which have demonstrated success in tackling BC, may not be applicable in this context.

Table 1. Age-standardized incidence rate and age-standardized mortality rate of breast cancer in India and Bangladesh (GLOBOCAN 2020 report) and some relevant sources like the World Health Organization.

Scope	Age-standardized incidence rate in 100,000	Age-standardized mortality rate in 100,000
World	47.8 [1]	13.6 [1]
South Central Asia (Bangladesh and India are geographically part of the area)	26.2 [1]	13.1 [1]
West Bengal, India	25.2 [8]	13.62 [10]
Bangladesh	21.4 [8]	10.69 [11]

Despite being classified as least developed countries, Bangladesh and West Bengal, India, are home to several highly equipped and specialized cancer hospitals, some for BC only; for example, the National Institute of Cancer Research and Hospital (Dhaka, Bangladesh) or Tata Medical Center (Kolkata, West Bengal, India). These institutions, staffed with highly skilled and experienced surgeons, oncologists, and gynecologists, offer mammograms, CT (computed tomography) scans, and other modern screening and medical facilities. However, advanced medical facilities are scarce in rural and suburban areas, and the capacity of existing institutions often falls short of meeting the demand. In addition, there are also significant uncertainties regarding the overall cost of treatment, the duration of care, mental health support, and gaps in preventative measures. Given this context, our goal is to identify key gaps in existing approaches to raising awareness about BC and addressing the barriers that prevent people from seeking preventative care and timely treatment. By targeting these blind spots, we aim to make meaningful changes that promote early detection and improve access to necessary medical services.

In this work, to understand the barriers to BC awareness, we conducted an open-ended interview with the residents from both regions about BC awareness (to assess their current state of knowledge, attitude and readiness, awareness, and so on) After carefully analyzing our interview data, we highlighted some common obstacles in both regions or societies, by grouping

XSL•FO
RenderX

them into different societal levels such as individual, family, local society, health care system, and state or country. In the upcoming sections, we discuss the study design (Methods), the highlighted barriers with some root causes, and suggested solutions (Results); then, we suggest how technology and social media can play a crucial role in resolving some of those effectively (Discussion).

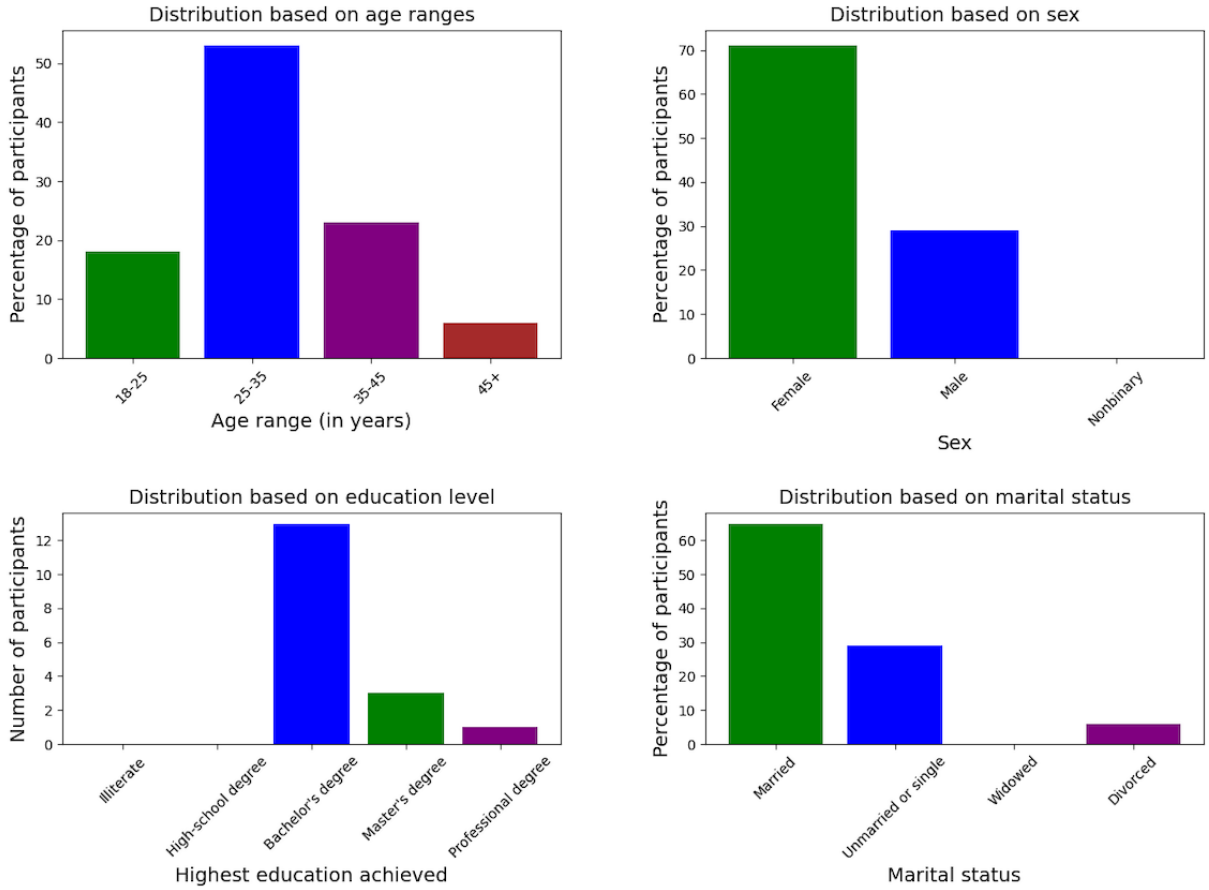
Methods

Study Design

The main objective was to evaluate the general knowledge and awareness of the participants regarding BC, identify sociocultural factors that could hinder mass awareness campaigns, and examine health care disparities and systemic issues. We conducted individual interviews with the participants using a semi structured questionnaire that included a variety of specific questions as well as 1 open-ended question (Table 2). The participants' responses included personal experiences and anecdotal stories.

Table 2. Our questionnaire.

Category	Questions
Awareness	• People of which age range do you think are at high risk of getting breast cancer? • What are the most common symptoms of Breast Cancer? • What are the common misconceptions about Breast Cancer? • Are there any media-related programs that have provided information regarding Breast Cancer or Breast Cancer diagnosis or progression of the disease? Example: Television talk shows, YouTube, WhatsApp, Facebook groups, or movie or television shows • Are you aware that breast cancer can affect anybody regardless of their sex and gender classification? If not, what gender and sex demographic do you think have the possibility of getting Breast Cancer?
Self-diagnosis	• Do you know and voluntarily do the Breast test yourself at home?
Post-diagnosis support	• What were the support mechanisms (nonpharma) provided to you? For example, mental health or NGO support, nutrition, or self-care. • Was the financial impact of the proposed treatment plan discussed with the doctor?
Open-ended	• Is there anything you would like to share about your journey or experience with Breast Cancer?



[a]NGO: nongovernmental organization.

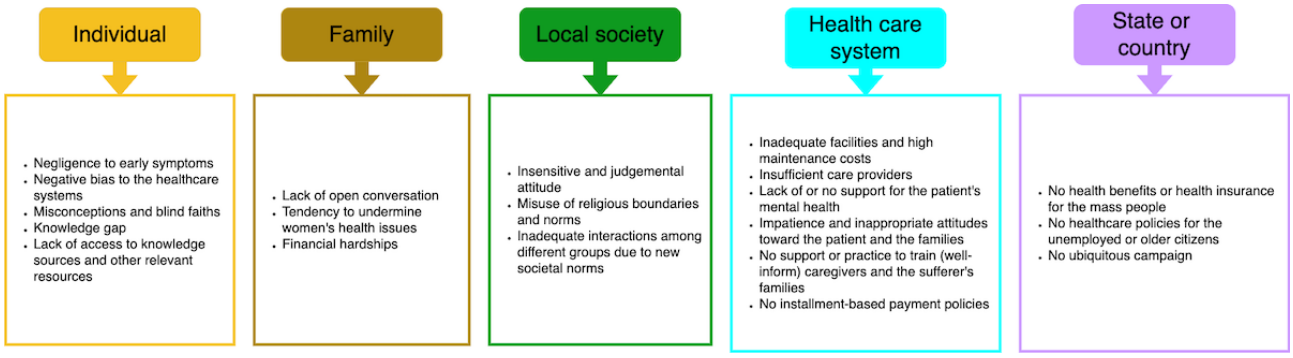
Participant Selection and Recruitment

We recruited participants through snowball sampling [12], using mutual connections and social media platforms such as Facebook (Meta). Semistructured interviews were conducted with 17 participants from West Bengal and Bangladesh. All our participants were above the age of 18 years, and recruitment was focused on participants who resided (at the time of study) in the 2 regions mentioned above. Our participants primarily identified as female, with an average age of 25-35 years, and most were married (Figure 1). The participants selected the language during the interview; most spoke Bengali. The researchers conducted the study through Zoom (Zoom Video Communications), and the audio recordings were transcribed and translated into English for data analysis.

XSL•FO
RenderX

Figure 1. Distribution of participants.

Demographics



We aimed to recruit a representative sample of participants from diverse educational and financial backgrounds from the region, as socioeconomic status and education play a huge role in the participants' access to health care in the region. Also, a cultural stereotype related to educational qualifications is widely propagated, relating educational accomplishments to open-mindedness, access to health care, and overall "success" in life [13]. Our participants self-declared their financial status as middle- and high-economic classes and were all in professions such as business, architecture, social development work, or education. Most of our participants had completed their undergraduate degrees (n=13), few had graduate degrees (n=3), and some were currently working toward a professional degree (n=1). The socioeconomic status of our participants is important in the larger context of interpreting the results and will be discussed further in the upcoming section.

Data Collection and Analysis

We transcribed the interview audio recordings, which were between 15 and 45 minutes long, and translated into English. Our qualitative data analysis follows a tiered approach and an inductive methodology [14,15] to generate themes. In tier 1, the initial coder examined the transcript identifying recurring themes, clustering them based on similarity, and using the descriptive coding methodology to label them. This clustering formed the foundation for subsequent analysis. Moving to tier 2, a second coder independently reviewed the clustered themes and descriptive terms associated with them, providing validation by either corroborating existing clusters or proposing new ones as necessary. Finally, tier 3 involved collaborative discussions between both coders to assess the relevance and significance of the clustered themes and descriptive terms associated with them. Through iterative deliberations and consensus-building, the final classification of themes was determined (Figure 2). As our interviews were semistructured (where the participants had the freedom to take the narrative and provide more information beyond a fixed set of questions), this method of generating themes bottom up and assigning descriptive terms to it allowed us the flexibility to show nuance and highlight subthemes. Both coders were familiar with the language spoken by the participants (Bengali) to parse through the linguistic, cultural, and social significance of the data generated during the interview sessions.

XSL•FO
RenderX

Figure 2. Outcome of our qualitative data analysis: major barriers to breast cancer awareness in the region.

The hierarchical representation of our themes and subsequent categories (Figure 2) is inspired by the presentation of the barrier tree [16] developed for a mobile-based BC monitoring study for the people in rural Bangladesh around 2012. Notably, several factors (such as feeling shy, fear, lack of familiarity, undermining women problems, religious belief, shared beliefs and practices, communication problems, scarcity of doctors, inconsistent patient data, long-term monitoring, and poverty) identified then are still highly relevant and came up during our analysis. The distinctions between both works are listed below.

First, most of our participants are city dwellers, but they shared stories and experiences from different parts (city, suburb, or rural) of the country or state during their interviews. Haque et al [16] studied in rural setups about 1.2 decades ago.

Second, we present the barriers by clustering them into 5 socioeconomic themes (individual, family, local society, health care system, and country or state). Haque et al [16] presented their findings into categories like identification and disclosure, achieving treatment, continuation of treatment, environmental issues, and user issues.

Third, while many research articles in the domain of BC primarily adopt a medical science perspective, such as the study by Haque et al [16], where the team visited a clinic or hospital to gather data and generate a barrier tree, our approach diverges by examining BC through a societal framework. By doing so, we aim to offer a comprehensive analysis that encompasses both the medical and societal impacts of BC. This approach allows us to explore the same problem from different lenses, shedding light on the multifaceted challenges and implications of BC beyond the purely medical aspect.

Finally, as a novel addition to the field, we delve into the mental health relevancy of patients with cancer and their caregivers, a crucial aspect that was not addressed in the other work.

We discuss the outcome of the qualitative analysis in the next section.

Ethical Considerations

The institutional review board of New College of Florida approved the study (Protocol #22-037), and we strictly followed all protocols to ensure data privacy and integrity, demonstrating our commitment to ethical standards. For the study, participation was voluntary; participants did not have to participate and could stop at any time. There were no penalties or loss of benefits or opportunities if the participant did not participate or decided to stop once started. Their decision to participate or not to participate did not affect their job status, employment record, employee evaluations, or advancement opportunities. The participants did not receive any benefit from the research team. There was no cost to participate. This research was considered minimal risk. Minimal risk means that the study risks are the same as those in daily life.

Results

The results of the data analysis are discussed in 2 phases; first, barrier identification and second, awareness raising.

Barrier Identification

The majority of our participants were aware of BC's symptoms, possible treatment mechanisms, costs, survival rate, and so on. During the interviews, they were able to list most of the significant symptoms of BC, like deformed breasts or nipples, lumps in the breast and armpit, discharge of pus or liquids, irritation, flaky breast skin, irregular breast pains, overall fatigue and weight loss, and so on. All but 3 participants knew of at least 1 person who has or had BC—either in their own or extended family, in the neighborhood, or in a friend's family—indicating how predominant this disease has become (Tables 3 and 4). A total of 14 participants "had heard of" self–breast-examinations, 13 participants "knew how to" perform self–breast-examinations, and 7 participants "had performed" self–breast-examinations (Figure 3). A greater than 50% decrease in the number of participants who had conducted self–breast examination is noteworthy.

The following sections share the barriers we highlighted from our data. Since the barriers often have cause-and-effect relationships and circular causality, we will not present them according to the identified societal levels like in Figure 2; instead, we would discuss them under the same section or title if they mostly appeared together during the interviews.

Tendency to Neglect Early Symptoms and Knowledge Gap

Our survey participants agreed that although BC is well-known, many people are unaware of the symptoms and often miss early signs. Specifically, when trying to identify symptoms in themselves, they either don't know what to look for or tend to disregard early signs of discomfort. For example, 1 participant stated:

> *One day, my mom had severe stomach pain. We took her to the doctor, who asked us to complete a USG of her abdomen as the doctor suspected that my mom had a tumor in her stomach. While doing the USG for the tumor, the doctor detected that she had gotten breast cancer, not a tumor…… it was already a late detection. It's at a deadly stage already. The treatment would have been much less painful if she had been diagnosed earlier.* [b007]

A similar story also stated the reluctance to pay heed to early symptoms or disclose them:

> *Though she (a neighbor) suspected it, she did not disclose it initially. When the pain became unbearable, then only she went to the doctor. She went to the doctors in the middle stage (not the early stage).* [b011]

XSL•FO
RenderX

> *One of my aunts (a family friend) had been diagnosed with breast cancer. However, it had already spread to the throat and jaw when she was diagnosed. So, the doctors could not remove/cure it, and she passed away.* [b008]

These responses reflect the results Amin et al [17] found in a survey that the research team conducted in Bangladesh in 2020; out of the 9 symptoms of BC, approximately 50% (N=500) of participants were unaware of 5 or more symptoms.

Misconceptions

Although none of our participants were medical professionals, our participant pool consisted of individuals who had all completed at least an undergraduate degree, were socioeconomically affluent, and were self-professed, open-minded individuals. Due to their educational backgrounds, we assumed that the number of misconceptions about BC would be lower than other groups. However, our participants had several deep-rooted misconceptions about BC, which are listed below.

First, it can only afflict females. Surprisingly, 10 out of 17 participants (59%) believed BC could only afflict females. The rest of the participants agreed BC occurred, irrespective of sex.

Second, it is more likely to afflict married women and those who have recently become mothers. Several participants stated that in married women, especially after giving birth to a child or during the breastfeeding period, it is highly likely to get inflicted with BC.

Third, it is more likely to afflict older women. Several participants responded that BC only affects older women; when probed further, they believed that the age range between 25 and 45 was not particularly susceptible to BC. Reports have suggested that Indian women in their early thirties till fifties are at considerable risk of developing BC, and the incidence risk increases till its peak when they reach 50-64 years of age. Furthermore, 1 in 28 Indian women are likely to develop BC during their lifetime [18-21]. It is more (1 in 22) for urban women than for the rural group (1 in 60). Amin et al [17] report similar statistics for Bangladesh (22.5 per 100,000 women and mean age being 41.8 years and 56% of the diagnoses were for reproductive-age women).

At the end of our interviews, we informed our participants that (1) BC is statistically more dominant among females but can afflict anyone, irrespective of gender and (2) there are various types (metastatic, inflammatory, and so on) of BCs that afflict people from various age ranges, so directly linking it to a particular age, marital status, or maternity may not be the best idea.

These factual misconceptions and knowledge gaps about BC are major factors related to the diagnosis of BC at an early stage. Our participant responses reinforced the need to disseminate accurate information to raise awareness.

Social Stigma and Lack of Open Conversation

First, beauty and breasts—judgmental attitudes. In addition to being an organ, breasts play a significant role in defining femininity and women's role in South Asian cultures. The fear of the disease attacks the fundamentals of female identity as a woman's breast conjures her sexuality and her capacity to nurture [22]. In patriarchal societies, such as Bengalis in West Bengal and Bangladesh, irrespective of educational or financial gains and social liberties through the years, women are perceived to have the roles of mothers, wives, or homemakers, whereas men are mostly seen as primary breadwinners of the family [23].

According to a report by a Pakistani Non-Governmental Organization, Aurat Foundation and USAID (United States Agency for International Development; 2016), in South Asian cultures, feminine traits include emotional, nurturing, passive, good homemakers, fair-skinned, without body or facial hair, long-haired, with a narrow waist, and sexually submissive. In contrast, masculine traits include being assertive, primary breadwinners, risk-taking, rational, and brave [24]. The ultimate danger of this notion to a Bengali (or maybe many people from other parts of the world) is that they feel one becomes "lesser feminine" if one has any breast health-related issue. On top of that, many people assume that BC's ultimate aftereffect is mastectomy, if not death, which adds a new level of stigma [25,26].

> *When I was very young, I learned that one of my friend's mom had breast cancer. At that time, my parents were very conservative; they would not open up in front of other family members/us. I learned later that doctors had to remove her breast. But the good thing is, she recovered totally, and it's been 20 years. She has an everyday life. I believe she received good treatment. Every treatment doesn't go wrong!* [b009]

> *Of the few breast-cancer and other cancer survivors I know of, I say it is common for breast cancer patients to feel humiliated or more mentally upset than other cancer patients. …… I don't notice any initiative in our society in this matter; neither is it commonly seen to provide some counseling for the patients for overcoming/fighting cancer.* [b005]

For several reasons, anyone with BC is reluctant to share their experiences. In many cases, patients with BC suffer from depression [17] due to a lack of a support system to debunk the body image and societal myths. The image of an ideal woman propagated in the media (television or social media) reinforces the narrative that is sometimes unhealthy to a person's body image [27]. Particularly the lack of influential media personalities sharing their stories of struggle and recovery or the absence of characters that represent the struggles of patients or survivors of cancer in television shows or media portrayals impacts the perception of the journey and struggles.

Our participants echoed these sentiments in their statements:

> *There is a taboo around breast cancer, regardless of class and status. People do not talk about it. We learn about it later, like once someone has recovered or died of breast cancer. Mostly, no one shares their journey with breast cancer.* [b014]

> *She (a breast cancer survivor) used to talk to me and hang out with our family. However, she and I never*

XSL•FO
RenderX

> *talked about it. Neither I asked, nor she opened up. If it is not very necessary, we will not share. That is the mindset.* [b012]

The term cancer comes with a connotation of impending doom and death; however, the significantly higher chances of patients surviving cancer because of early detection strategies and awareness are not emphasized at all [28]. When it comes to the 5-year overall survival, a study reported it to be 95% for stage I patients, 92% for stage II, 70% for stage III, and only 21% for stage IV patients [29]. It is important to highlight these statistics widely to encourage early detection and awareness. Survival rates of patients with BC are lower compared with Western countries, primarily attributed to early age onset, late-stage detection and delayed initiation of definitive management, and inadequate or fragmented treatment [28].

Second, cultural sensitivities. In addition to not expressing discomfort, awareness campaigns in India and Bangladesh must be wary of the strict cultural, religious, and moral censorship, which does not allow the posting of revealing images of breasts. People, in general, are brought up in an environment where they do not feel comfortable discussing sexual health or women's health concerns, including BC. The term "breast" is perceived through the lens of hypersexualization and hence comes under deep scrutiny from moral and religious sensitivities. As researchers embark on developing awareness campaigns, it becomes crucial to exercise cultural sensitivity, especially considering the conservative nature of the audience in these regions. Being mindful of cultural nuances is essential to ensure that the true essence of the campaign is not overshadowed by moral policing or societal restrictions. It is important to point out that women's health or sexual health and the term breast are not taboo; we cannot undo decades of cultural teaching and biases in a day. Hence respecting the norms and designing awareness campaigns around them would be a more sensitive approach.

> *She (my paternal aunt, who was a teacher) had lung infections and troubled breathing due to breast cancer, but the doctor tracked it back to breast cancer after doing several medical tests; she was never open about the symptoms (or discomforts with her breasts) upfront to the doctor.* [b001]

> *People are not comfortable talking about it. Since I am the son, my mom also never shared about her symptoms or sufferings.* [b007]

Third, women's health care is a necessity, not a luxury. Irrespective of South Asian patriarchal societies or more progressive Western societies, a woman's role in society, economy, and family cannot be ignored. The roles of caregiver, parent, and wife for a rural woman with added burdens of maintaining appearance and body image in the case of an urban woman all contribute to the issues that the contributions women make to the world are "nonproductive" or "nonessential." This perception sometimes from women themselves (in some cases, the family members) leads to the health concerns of women being ignored or underprioritized [23]. This includes a lack of attention to proper nutrition, timely intervention, care after diagnosis, and adequate mental health support. This practice or habit stood out as one of the major reasons why female patients often get a late detection of health-related problems.

> *We wait and hope that the discomforts will disappear automatically after a while – so we tend to linger. I have noticed this among my friends and family (especially females), including myself; we tend not to go to doctors so easily. I am not sure if it's a cultural thing! But it is less about financial conditions and more about awareness.* [b014]

Certainly, that mindset is changing gradually. Nonetheless, there is a need for increased awareness in this particular area:

> *A woman in the family will likely delay her treatment as she thinks it's the least important issue and is probably putting financial pressure on the family. But sometimes, they forget that delayed treatments may invite worse consequences.* [b003]

The Disconnect Between Health Care Models and People

Although none of the existing health care models worldwide are perfect, in the context of a deadly disease like BC and health-related supports, we noted the flaws, inconsistencies, and lack of patient-centered policies in the regions.

First, lack of a yearly health examination policy. Unlike in the United States or other parts of the world, Bengalis usually do not go for yearly health examinations, or it is not a common practice among doctors to prescribe yearly health checkups. The lack of adequate resources, such as available medical professionals, provider-centric consultations, and a symptom-based health care model, is partially responsible for this issue [30]. The region requires immediate advocacy for a robust primary health care system and the use of existing community care efforts to enhance awareness.

Second, out-of-pocket medical expenses. Health examinations are expensive, and it is unusual for the region to support health insurance employers [31]. There is no system of national health insurance in Bangladesh [31]. People whose employers cover health benefits also must pay to the facilities out of pocket first and then later ask for a reimbursement. This cost barrier leads to patients not seeking treatment early on.

Third, lack of integrated service and long-term plans. Those on tight budgets usually have to prioritize the price over reliability and integrated service available to few modern (and more expensive) health care facilities. Patients and their family members are often not fully aware of the overall costs (long-term plans alongside short-term plans) and risk factors so that they can make informed decisions.

> *Talking to the patient and their family about the situation and possibilities is crucial. Only then can we make an informed decision. But if the doctor dictates the options, the patient's family has to follow the order, no matter how expensive or if they have to lose their property in arranging the financial support.* [b009]

Fourth, open conversation between patients and the doctors. Due to various reasons, including high volume of patients,

XSL•FO
RenderX

doctors seem to spend much less time with the patients, which has been a consistent story we heard from our participants.

> *The more renowned the doctors are, the less interactive they are, or the less compassionate they are. There is much less scope and the chance of openly conversing with them.* [b014]

Fifth, insensitive and judgmental commenting. Medical professionals lack adequate training when addressing patients and their concerns. A dearth of empathy compounded by the enormous patient loads leads to negative interactions with the health care providers, and patients or family members do not feel comfortable asking essential questions. An insensitive comment may cause severe damage to the patient's (or their caregiver's) confidence and motivation. Effective doctor-patient communication is determined by the doctor's bedside manner, which patients judge as a major indicator of their doctor's general competence [32,33]. Doctor-patient communication skills are based on verbal and nonverbal communication, where 22% is transferred through voice tone, 55% through visual cues, and 7% verbally [34]. Lack of training to demonstrate effective behavior leads to scarring patient outcomes, one such is listed below:

> *I remember an oncologist's comment to his patient (lung cancer survivor, 65+ years of age) regarding the side effects of Chemo/radiotherapy: you don't have your natural hair anymore! So why worry about that?* [b003]

Sixth, the doctor's gender. BC disproportionately afflicts the female population, and since it concerns an intimate body part, it is common among the patients and their family members to withhold the treatment until they find a female specialist; in short, they prioritize the doctors' gender over professional expertise [32]. In a cross-sectional study conducted with 1257 female patients in Udaipur, India (August 2014), by Nagarajappa et al [32] found an overwhelming 85% (1069/1257) of the respondents said yes to the question: "I would always prefer being treated by a doctor of my gender." In some other similar studies conducted in 2019, researchers found that the most important attributes of maternal health care facility choice for Bangladeshi women were consistent access to a female doctor, the availability of branded drugs, respectful provider attitudes, and a continuum of maternal health care [35,36].

> *My aunt and uncle delayed the treatment as they were hesitant about choosing a doctor; they were looking for a female doctor, but there were not many female breast cancer specialists in Bangladesh during that period. My uncle (my mother's cousin) had hesitation. Had she been diagnosed earlier, she would have had a better chance of survival. She was a survivor, but her entire family suffered greatly due to the delay. My uncle later regretted his decision. I remember him expressing that to my mother (his sister).* [b003]

Although 61.1% (198/324) of medical students in India identify as female, a study by Bajpai et al [37] in 2020 found that men led 67.3% (218/324) of oncology teams in India. These numbers are similar to the numbers in the United States, where out of 667 female respondents, 442 identified as academic oncologists versus nonacademic ones [38]. This gender disbalance among physicians leads to patients not seeking timely medical care.

Seventh, lack of trust. Many people in the region believe that:

> *…an institute (hospital and caregiving center) that is capitalist in nature cannot have people's best interest at heart.* [b016]

This may play a significant role in people's hesitancy to seek health advice unless necessary.

Mental Health Support Infrastructure

All participants expressed concerns about lacking mental health support systems. Most reported that:

- family members and caregivers are never made aware of the patient's mental health, its relevance, and how to handle them [26].
- "I didn't know and never thought mental health could be impacted directly by these (or any) diseases." [b007]
- there is no infrastructure to support the mental health of patients suffering from terminal or deadly diseases.
- "Mental health is considered taboo, more significant of a taboo than breast cancer. People don't usually talk about it. Doctors also don't do a good job in this regard. Providing professional mental health support is not common in India/West Bengal to battle cancer." [b016]
- "Since cancer is associated with a lot of uncertainty, fear, and stress, the moment patients get diagnosed with cancer, they must get counseling. Mental support from proper channels can help patients gather the strength and courage to defeat it." [b010]

Role of Media

Media has always played a significant role in spreading awareness among the general population on various issues. We wanted to learn how our participants felt about the role of media around them in spreading BC awareness. A survey conducted by YouGov Global Media in India identified that in 2022, 59% of Indians under the age of 24 years depended on websites or web apps as their primary media source, whereas people above the age of 45 years depended on television (live or nonlive broadcast) as a primary media source [39]. In Bangladesh, USAID conducted a similar survey and found that 46.6% of respondents mentioned television, and then 33.1% said the internet was a primary source of information media [40]. Similarly, in India, 60% of the population in the age group of 45 years and above depend on television for news, whereas younger audiences tend to lean toward updates from social media instead of watching traditional television news (which broadcasts news at specific hours).

Social media and traditional media (television and newspapers) can substantially spread awareness among people. We wanted to understand whether the media's contribution to raising awareness was limited to a date or time (eg, Breast Cancer Awareness Month) or whether there is any consistent campaigning.

Our participants have reported seeing numerous posts, symbols (such as the pink ribbon or black screen), and talk shows on specific days, weeks, or months of the year (such as during

XSL•FO
RenderX

Breast Cancer Awareness Day). However, these efforts are transitory. They come and go; many posts are left unattended, unread, and unfollowed, and many programs and talk shows are left unwatched. The lack of consistent programming on any platform that regularly sends out relevant messages throughout the year leads to reduced engagement and interest.

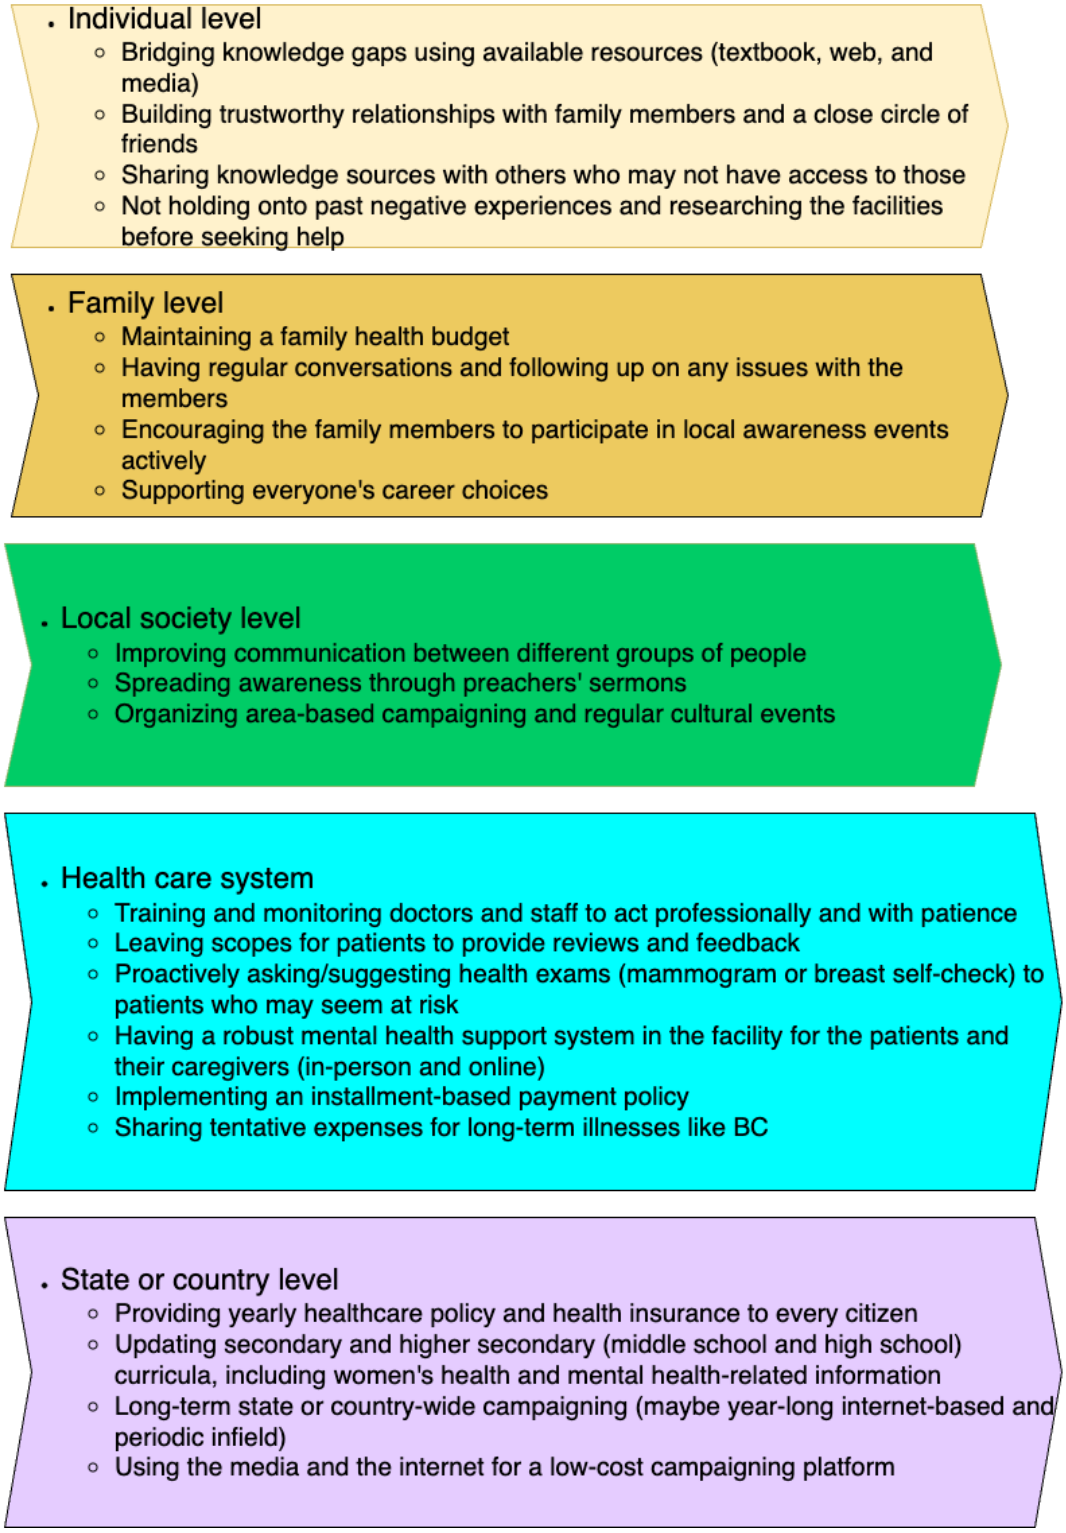
> *I have seen many programs aired on the national television of Bangladesh, but I believe that is not sufficient…. I haven't noticed any program regularly on this topic. If we talk about social media, I don't see enough posts relevant to this topic.* [b004]

> *People share (even if that's at a minimal level, especially on special occasions like Breast Cancer Month). But others may not have time to read it carefully due to their busy schedules. I sometimes see such posts but don't have time to read them thoroughly. I feel until it hits someone, they are likely to ignore (or blindside) it.* [b003]

Most BC-related posts (eg, Figure 4) on media platforms include either a pink bow [41,42] or wearing the color pink at campaign events [43,44]. To urban audiences' mammograms are widely promoted by health care professionals or organizations [41,45].

Figure 4. Media coverage, rallies, and campaigns.

The absence of relevant information about the disease, prognosis, and symptoms is stark and leaves the audience wondering how to perceive this awareness campaign. Often, momentum is lost, and true engagement is not achieved, leading to lackluster awareness numbers.



> *We see advertisements relating to breast cancer, sometimes on the television or elsewhere, or billboards, but then it is very short and crisp. And it just says that we should be aware of breast cancer, but then what to be aware of it is never mentioned anywhere.* [b017]

Awareness Raising

Many of the findings are codependent and mutually recursive. For example, lack of trust in health care systems in the area and financial hardships implicitly push people to neglect early symptoms of deadly diseases; lack of open conversation and social stigma block them from reaching out for mental health support, to name a few. Our discussions with the participants highlighted several means to help spread mass awareness in the regions. In this section, we present the summary of our suggestions to achieve mass awareness through Figure 5 and briefly discuss them right after.

XSL•FO
RenderX

Figure 5. Our recommendation to help raise awareness. BC: breast cancer.

Designing a Yearly Health Care Routine for Everyone

> *Society must believe that early diagnosis can help increase survival and reduce suffering. We need to build the practice of going through a yearly checkup.* [b008]

Given the population, unemployment, and other issues, achieving mass success in building this practice will require support and cooperation from international organizations (such as the World Health Organization) and local governments.

Spreading the Voice of Survivors

We often hear words from specialists (doctors and scientists) on mass media (eg, Shastho Kotha [46]). Aside from their knowledgeable notes, the programs will draw attention to the mass scale if BC survivors' interviews are included regularly. This will also reduce fear, hesitancy, and social stigma. When

XSL•FO
RenderX

people see interviews of BC survivors belonging to the same community (age, gender, social status, and so on), it will help everyone to open up about similar issues.

> *I believe cancer changes our views and ways of life. We must break the practice of neglecting minor symptoms and not seeking medical advice. We need to improve trust and healthy communication between doctors and patients. Roughly 50% of the population is female. So, whichever cancer is more probabilistic to which population, they need to take it seriously. Financial hurdles should not be the first concern. It will be beneficial if there is a platform where people can talk about it and not treat it as something that cannot be discussed.* [b016]

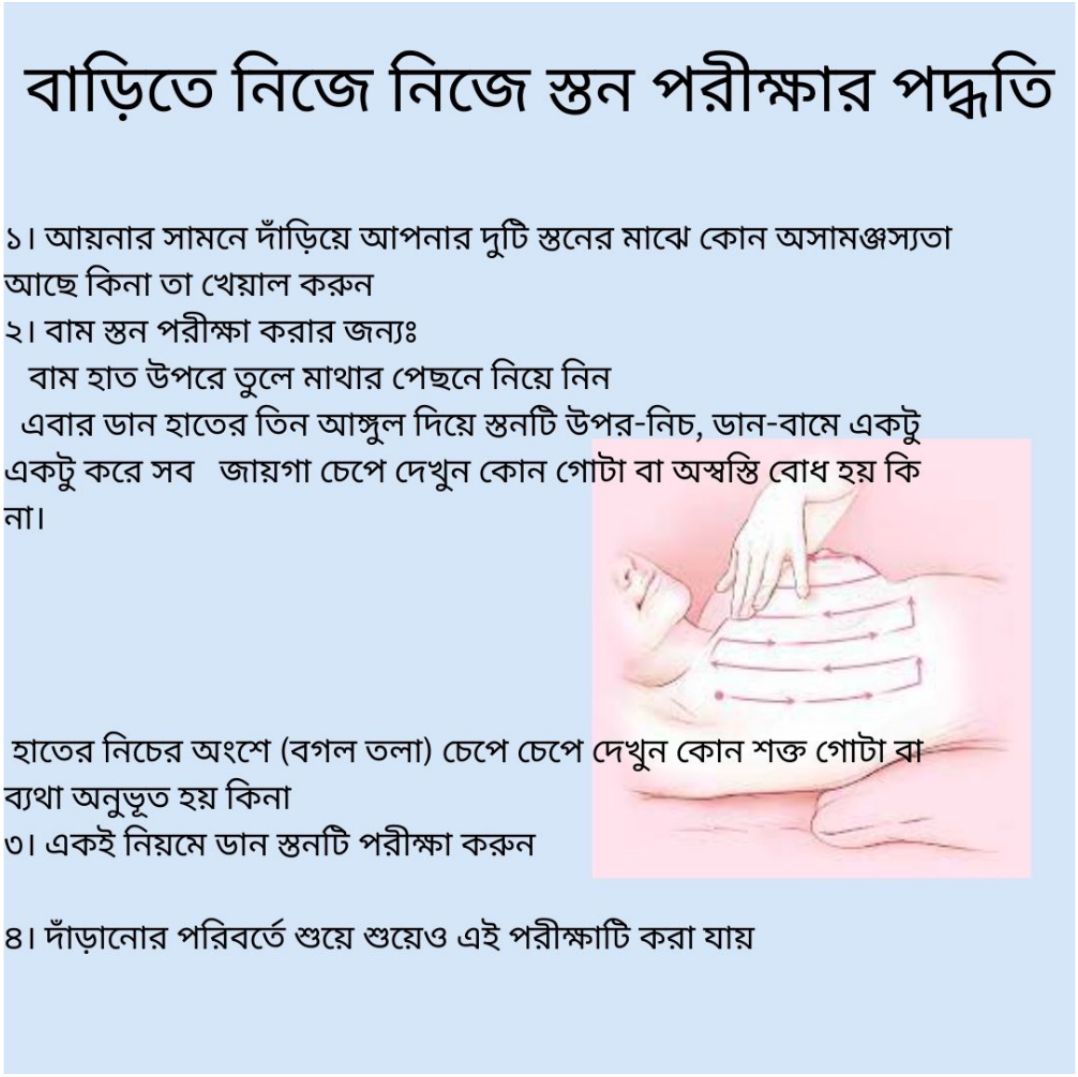
Sharing the experiences of BC survivors as they navigate treatment plans, manage financial burdens, and embark on their journey toward recovery can play a crucial role in dispelling fear, reducing anxiety, and challenging the taboos surrounding BC. Narratives that illuminate the resilience of these survivors, highlight the support of their families, and shed light on the obstacles they overcome contribute to humanizing this daunting illness.

Using the Grassroots Health Workers

> *NGOs like Surjer Hashi Clinic, Shobuj Chata Community Clinic, etc., wildly succeeded in child immunization and birth control in Bangladesh. So, if cancer awareness (like breast and cervical cancer) is taken as an agenda by such organizations, I am hopeful it will succeed.* [b003]

If the health workers spread a simple flyer about BC with some visuals and depictions in Bangla during their weekly visits, it will help raise awareness in rural areas quickly.

> *Bangladesh has successfully rolled out the idea of condoms and contraception, though we are considered a very conservative society. Major religions of our land directly oppose the idea of birth control. Yet the success came not because of the paid advertisements or programs in media but because of sending medical advice to the grassroots level. So, I believe we can succeed in growing awareness about breast cancer if the Government takes such programs into the hand.* [b005]



Establishing a Collaborative Effort on Social Media

Bangladesh's internet penetration rate stood at 31.5% (52.58 million/167.1 million) of the total population at the start of 2022 [47], and India's 47% (658 million/1.40 billion) of the population has internet access [48]. India and Bangladesh have both shown steady growth in mobile cell phone service, too. Instant messaging apps such as WhatsApp (Meta; 487 million users in India and 40 million users in Bangladesh) [49,50]. We strongly believe these platforms can be used to spread accurate awareness messages to users, particularly if government health organizations partner.

We suggest regularly preparing WhatsApp message broadcasts or mass forwards to groups, patients, or individuals from credible organizations such as local government branches (eg, zilla panchayat or district offices), medical associations (eg, Bangladesh Medical Association or Medical Council of India), or nonprofit organizations (eg, Sabuj Sathi). Sending these messages individually to users also avoids making anyone uncomfortable with the content, keeping in mind the social and religious sentiments or barriers in these regions. WhatsApp's ubiquitous presence in the digital communication ecosystem of both countries removes additional app downloads or installations. We propose using WhatsApp forwards (illustrated in Figure 6) as a cost-effective, easy-to-understand, and time-efficient method for dissemination. However, it is essential that these messages are reviewed by an expert before distribution to ensure accuracy and reliability.

XSL•FO
RenderX

Figure 6. Proposed self-breast examination instruction flyer.

Inclusive Texts in Secondary and Higher Secondary (Middle and High School) Curricula

Many people in both regions finish their education till middle- or high-school level. Some inclusive articles (written with appropriate languages and cultural values in mind) regarding women's health and the terminal and most predominant diseases in society will help spread awareness. The students and their families will gradually become aware; thus, many of the causes blocking the attention can be addressed thus far. Because textbooks can reach families where social media or entertainment media cannot.

> *I grew up in a village. I can talk to you from that context.… It isn't easy to spread awareness in the villages. For example, I grew up in a Muslim family where watching TV was not allowed, as it is anticipated that kids will be misguided by watching cartoons or inappropriate programs. So, getting this knowledge through TV was/is challenging for many kids like me.* [b006]

Per our research, no story, article, or novel about BC is included in the secondary and higher-secondary curricula of Bangladesh and West Bengal, India.

Educating the Caregivers and the Family Members

Besides building infrastructure for mental health support, doctors and other associates must educate the family members and caregivers about the patient's mental health and how to deal with it. We heard stories suggesting how a family can motivate a survivor to fight BC:

> *Someone very close to me has breast cancer. Initially, when it was diagnosed, the doctor prescribed her some medicine but barely communicated with her about her mental health. So, she melted down. After battling breast cancer for two years, she started self-motivating and regained her mental strength. She is a mother of two young kids, so that pushed her to keep going and not give up. She involved herself in activities like Yoga. Due to regaining mental strength, she started handling the treatment better (I am not suggesting that the cancer has disappeared, but she started driving it better).* [b002]

> *She (a relative) went into depression after the mastectomy. But since she has kids, she motivated herself. Her family also supported her very strongly. This support has helped her come out of the trauma. She is still following up with her breast cancer-related*

treatment. It is four years that she has been receiving treatments. [b011]

Discussion

In this research study, we aimed to understand the attitudes and perceptions of South Asian people, specifically people from Bangladesh and West Bengal, India, regarding BC. Our goal was to identify common barriers to raising mass awareness about BC in this population. In the results section, we discussed the significant barriers to BC awareness, which included a lack of knowledge and open conversation, negligence of early symptoms, negative bias toward health care systems, judgmental attitudes, and insensitive comments toward patients and their families, and financial hardship with limited options for financial support. We also provided suggestions to effectively raise mass awareness, including encouraging open conversations among family members and different groups, discussing relevant topics in social events and places of religious practices, integrating the topic into school curriculums, and disseminating accurate information through social and traditional media.

We present, in this work, the summaries of our findings in Figure 2 and Figure 5, where we clustered the critical points into 5 themes based on different societal levels—individual, family, local society, health care system, and state or country. Our findings highlighted the need for long-term planning and cooperation between people and the government, collaboration between national and international organizations, the use of media and education systems, and the importance of modern technologies and mass media in raising BC awareness.

Considering our dataset size (N=17) and the demographics of the participants, particularly their socioeconomic status and educational background, it is important to acknowledge that our findings are not fully representative of the entire population. Specifically, our dataset may not adequately capture the experiences of individuals living in rural areas, those below the poverty line, or those in the wealthiest brackets. These socioeconomic statuses certainly have disparate health care experiences and struggles. Our participant pool does offer valuable insights into the perspectives of the upper-middle-class segment of society and gives a general overview of barriers that should be further investigated.

For future work, it will be essential to extend this study to include participants from a wider range of economic and educational backgrounds. This broader approach will enable us to evaluate the generalizability of our findings and recommendations across diverse demographic groups and to uncover any critical issues that may have been overlooked in the current analysis. Such an expansion will contribute to a more comprehensive understanding of the nuances of this important issue and increase the applicability of our conclusions to a broader audience.

Abstract

Background: Patients with cerebrovascular accident (CVA) should be involved in setting their rehabilitation goals. A personalized prediction of CVA outcomes would allow care professionals to better inform patients and informal caregivers. Several accurate prediction models have been created, but acceptance and proper implementation of the models are prerequisites for model adoption.

Objective: This study aimed to assess the added value of a prediction model for long-term outcomes of rehabilitation after CVA and evaluate how it can best be displayed, implemented, and integrated into the care process.

Methods: We designed a mock-up version, including visualizations, based on our recently developed prediction model. We conducted focus groups with CVA patients and informal caregivers, and separate focus groups with health care professionals (HCPs). Their opinions on the current information management and the model were analyzed using a thematic analysis approach. Lastly, a Measurement Instrument for Determinants of Innovations (MIDI) questionnaire was used to collect insights into the prediction model and visualizations with HCPs.

Results: The analysis of 6 focus groups, with 9 patients, 4 informal caregivers, and 8 HCPs, resulted in 10 themes in 3 categories: evaluation of the current care process (information absorption, expectations of rehabilitation, prediction of outcomes, and decision aid), content of the prediction model (reliability, relevance, and influence on the care process), and accessibility of the model (ease of understanding, model type preference, and moment of use). We extracted recommendations for the prediction model and visualizations. The results of the questionnaire survey (9 responses, 56% response rate) underscored the themes of the focus groups.

Conclusions: There is a need for the use of a prediction model to assess CVA outcomes, as indicated by the general approval of participants in both the focus groups and the questionnaire survey. We recommend that the prediction model be geared toward HCPs, as they can provide the context necessary for patients and informal caregivers. Good reliability and relevance of the prediction model will be essential for its wide adoption.

KEYWORDS

cerebrovascular accident; machine learning; artificial intelligence; visualization; focus groups; questionnaire; informal caregivers; health care professionals

Introduction

Cerebrovascular accident (CVA), the collective name for ischemic stroke and intracerebral hemorrhagic stroke, affects 15 million people each year globally [1]. A CVA can have a range of symptoms that vary from patient to patient. Unilateral paralysis or weakness, numbness or loss of vision, speech difficulties and other cognitive dysfunctions, ataxia, diplopia, and nonorthostatic dizziness are some of these symptoms [2]. After the acute phase of treatment, patients often undergo a long rehabilitation process, although the length, intensity, and outcome can vary greatly between patients. In the Netherlands, 65% of CVA patients undergo rehabilitation at home after their hospitalization. The remaining 35% of CVA patients visit a rehabilitation center or geriatric rehabilitation center. Among patients in this group, 25% will not return to their homes and will go to nursing homes [3].

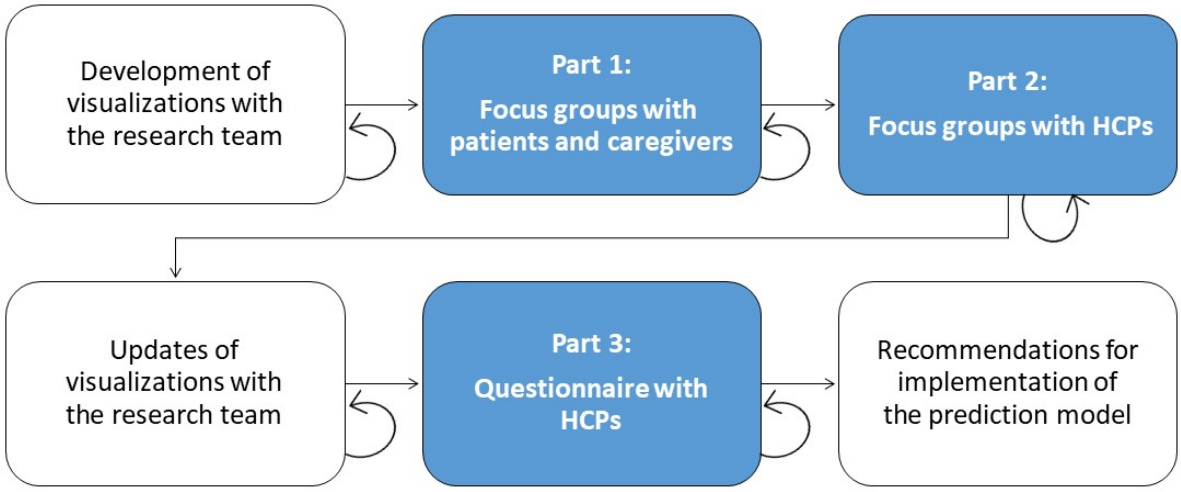
To provide the best care, health care professionals (HCPs) and patients should decide together which path to take in the care process [4]: shared decision-making. Efficient and practical goals can be determined when patients are involved in decision-making, leading to a more appropriate and suitable discharge location. Thus, CVA patients should be involved in decision-making regarding where rehabilitation will take place and setting rehabilitation goals [5]. A considerable number of CVA patients prefer active involvement in decision-making and consider themselves capable of doing so [6]. An important part of supporting active involvement in the decision-making process is to offer patients insights into expected outcomes.

Recovery is very heterogeneous for CVA patients in terms of speed, process, and outcomes, and is often considered too complex for HCPs to predict. As such, little information about expected medium- and long-term outcomes (3 months to >1 year) is provided to patients. Over the last few years, using artificial intelligence (AI) methods, several outcome prediction models have been developed. Some models on certain aspects of functional status have been developed, such as rehabilitation of motoric upper limb skills [7] or independent walking [8]. Others have reported testing at rehabilitation admission [9] or the use of wearable sensors [10] to provide useful data to predict postrehabilitation CVA outcomes. Most of these models use machine learning algorithms on structured clinical data, with varying accuracy [11,12]. Deep learning has offered the opportunity to combine more data and more different data types, such as imaging or free text, into a prediction model [13] and as such increase the accuracy of predictions. Several studies have investigated how deep learning can lead to better CVA outcome predictions [13,14] to reach clinically acceptable reliability. One of our previous studies [15] showed that combining structured clinical data and perfusion computed tomography (CT) scans can lead to an increase in performance.

While having accurate and reliable predictions is important, the explainability and clinical relevance of AI methods are essential for their adoption in medical practice [16,17], and many prediction model implementations currently fall short in these aspects [18]. Using a functional tool based on AI in a real-world setting would require both HCPs and patients to understand and trust the outcome prediction and see its relevance. Understanding a predicted outcome can be challenging for healthy people, but even more for CVA patients. These patients can have impaired cognition and often have a higher age [2]. Thus, information should be provided in an easy and clear manner for low cognitive effort. For example, when numerical data are presented, it is recommended to use simple visual forms such as flow or bar charts and circle diagrams [19].

The discharge interview usually addresses the duration and location of the rehabilitation. There are typically multiple possibilities after discharge, such as going home without or with home therapy, outpatient rehabilitation, geriatric rehabilitation, and clinical rehabilitation treatment [3]. A personalized prediction of CVA outcomes and the length of the rehabilitation process would allow HCPs to better inform patients and informal caregivers. This could form a basis for shared decision-making, as a more informed conversation about the preferences of the patient can be held. This research aims to assess the added value of a prediction model for long-term outcomes of rehabilitation after CVA, to investigate how its results can be best displayed, and to determine the best way to implement and integrate it into the care process.

Methods



Design

A qualitative study was designed with the goal of evaluating the added value of a prediction model for stroke outcomes in CVA care. More specifically, this study aims to investigate how to best display the outcomes of the model, and integrate and implement them in the care process in an appropriate manner. We based our study on a prediction model previously designed in our hospital [15]. Before the qualitative evaluation, the research team developed a mock-up of a display of the prediction model, together with several different visualizations of the model outcome and interpretability. The research team included a neurologist and an expert on medical AI. The mock-up design was iterative, allowing for an update after each part of the study.

The study consisted of 3 parts: focus group discussions with CVA patients and their informal caregivers, focus group discussions with HCPs, and a follow-up questionnaire to HCPs, as shown in Figure 1. In both sets of focus groups, the opinions of patients and HCPs on the current information management and their needs with regard to the prediction model were explored and analyzed using a thematic analysis approach. The questionnaire was used to evaluate the finalized prediction model and visualizations with the HCPs.

Focus Groups

Study Population

Patients who were admitted to St. Antonius Hospital between January 2020 and December 2021 for a CVA were selected using convenience sampling. Patients who had a CVA in the previous 3 months or who did not speak Dutch were excluded. We selected participants with a wide variation in age, gender, rehabilitation type (medical specialist, geriatric, home, or outpatient), and education level. An overview of the characteristics of the selected participants can be found in Table 1. Patients were approached by phone, and information letters were sent by email or postal address. Patients could bring their informal caregivers to the focus groups if this was of added value due to impaired cognition or higher age. The research team thought that an informal caregiver could assist in interpreting the model and could discuss patient preferences. Another advantage of including informal caregivers is that they are often involved in the entire hospitalization process of patients, and their opinions can therefore be valuable. Participants signed up by contacting the researcher and were asked to sign an informed consent form before the focus group started.

Table 1. Cerebrovascular accident participants in focus groups.

Participant	Age range (years)	Gender	Level of education	Rehabilitation
P1	71-75	Female	Vocational education	Geriatric rehabilitation center
P2	41-45	Male	Vocational education	Rehabilitation at home
P3	41-45	Female	Vocational education	Rehabilitation center
P4	71-75	Male	Applied university	Rehabilitation at home
P5	81-85	Female	High school	Rehabilitation at home
P6	66-70	Female	Applied university	Rehabilitation at home
P7	41-45	Male	High school	Rehabilitation at home
P8	76-80	Female	Vocational education	Geriatric rehabilitation center
P9	61-65	Female	Vocational education	Rehabilitation center

For HCPs, participants were recruited from a pool of HCPs involved in the discharge or rehabilitation process in the hospital. This included neurologists, rehabilitation doctors, junior doctors, nurses, and nurse specialists. All participants were approached via email or in person. The research team aimed to have 3 participants in each focus group, specifically a medical specialist, a general doctor, and a nurse.

Data Collection

The focus groups were led by 2 researchers (CGA and SvH). SvH moderated the focus groups with patients, and CGA moderated the focus groups with HCPs. We opted for the separation of patients and HCPs in different focus groups, such that the participants in both groups would be able to speak more freely about their experiences. We started with 3 focus groups for patients and their informal caregivers and 3 focus groups for HCPs, and we assessed whether saturation of data was reached or more focus groups were necessary. Each focus group had different participants.

The focus groups consisted of 2 phases. The first phase of the focus group was intended to explore the needs and expectations of the use of a prediction model during the discharge interview. This started with a reflection on the discharge interview and rehabilitation process, what expectations were created, what shared decisions were made, how the process went, and other

XSL•FO
RenderX

questions about topics and components that were addressed in the prediction model. The goal was also to determine how a prediction model could contribute to better expectations and improve the discharge interview.

In the second phase of the focus groups, different options for visualizations of the prediction model were discussed. We have elaborated on their design in the section on visualizations. Before the second phase of the focus group started, there was a short explanation of the visualizations. After this, the participants were asked to discuss several topics. First, whether the visualizations were clearly explained. Second, they were asked about relevance and what they think about the visualizations being used. During the focus groups with HCPs, this also included the predictors included in the model. Finally, they were asked to discuss which of the visualizations they preferred and why.

Focus Group Guide

Focus group guides were used, consisting of open and follow-up questions for the 2 phases of the focus groups (Multimedia Appendix 1 for patients and Multimedia Appendix 2 for HCPs). The focus group guides consisted of a few open questions, aimed at starting a discussion on information provision to patients in the current care process and the suitability of the prediction model and its visualizations. The focus groups followed an iterative design, which meant that after each focus group, the questions in the interview guide were adjusted if certain topics needed to be added or changed.

Data Analysis

Analysis of the focus groups was performed by researchers CGA and SvH in a thematic analysis approach using Atlas.ti [20]. CGA and SvH are early stage researchers with educational training and some research experience in focus group research. The thematic analysis was performed as follows. First, the researchers transcribed and anonymized the interviews. Then, both researchers separately open coded the transcripts. The data were coded axially by clustering codes by meaning, and the clusters were assigned themes. When all 6 transcripts were axially coded, the data were selectively coded to determine the relevance and consistency of the themes [21]. Finally, the themes were defined by noting the characteristics of the themes for consistent use. After analysis, the researchers held discussions about the data until a consensus was reached. We aimed for research triangulation by having 2 researchers independently analyze the data and iterate until agreement.

Questionnaire Survey

Study Population

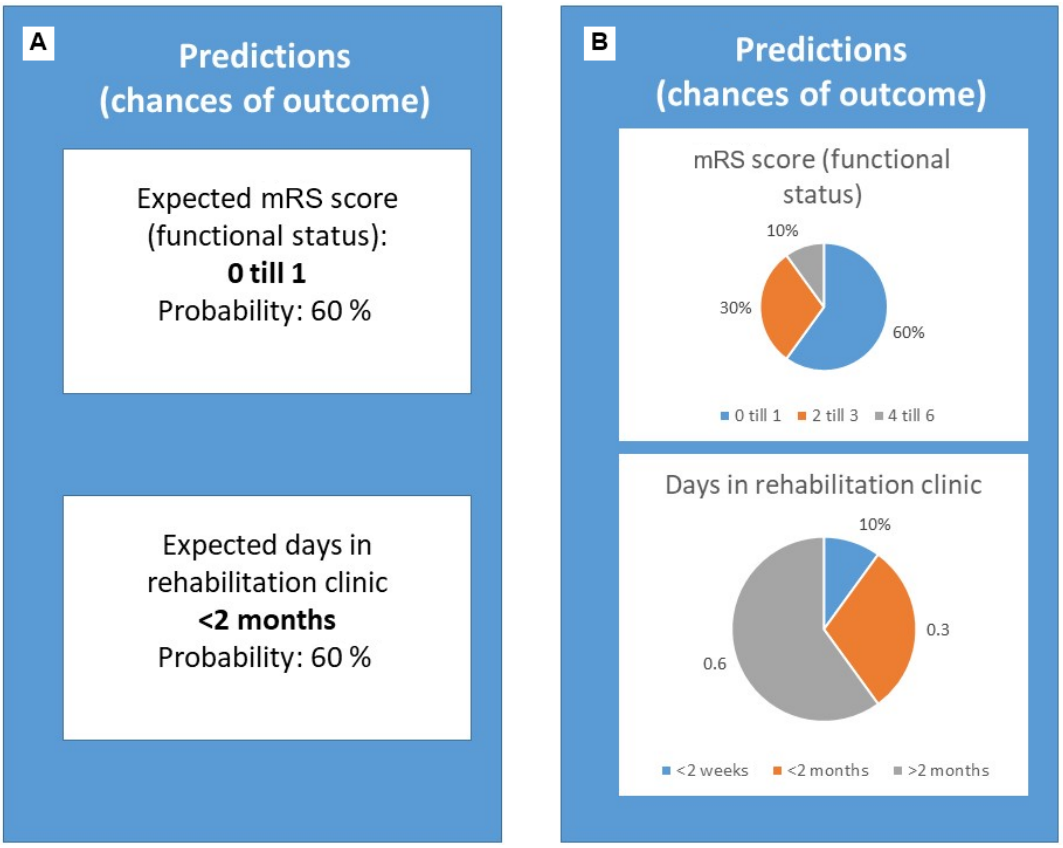
The study population of the questionnaire consisted of HCPs. Similar to the focus groups, the participants were recruited from the pool of HCPs involved in the discharge or rehabilitation process in the hospital. However, only HCPs who directly worked with the prediction mode, such as junior doctors and neurologists, were asked to fill out the questionnaire. They were contacted by email or phone, or in person.

Data Collection

The last part of this study consisted of a questionnaire for a final analysis of the visualizations by HCPs. A simulated visualization (updated after the focus groups; see section visualizations) was shown to the HCPs for different scenarios for possible situations of patients in a discharge interview. They were asked to answer a modified Measurement Instrument for Determinants of Innovations (MIDI) questionnaire [22], which is a tool for describing the helpfulness and possibilities of medical technological devices. We selected 2 relevant sections out of 4 in the questionnaire regarding the innovation itself and the end users. The other 2 sections regarding work environment and sociopolitical environment were out of scope and more suitable for a later implementation phase. The questionnaire was adapted to fit the setting of the prediction model and was distributed via RedCap [23]. The questions were divided into 5 sections: general opinions, advantages and disadvantages, effects on patients, effects on colleagues, and opinions on implementation. The questionnaire consisted of 21 questions on a Likert scale and 1 open question.

Data Analysis

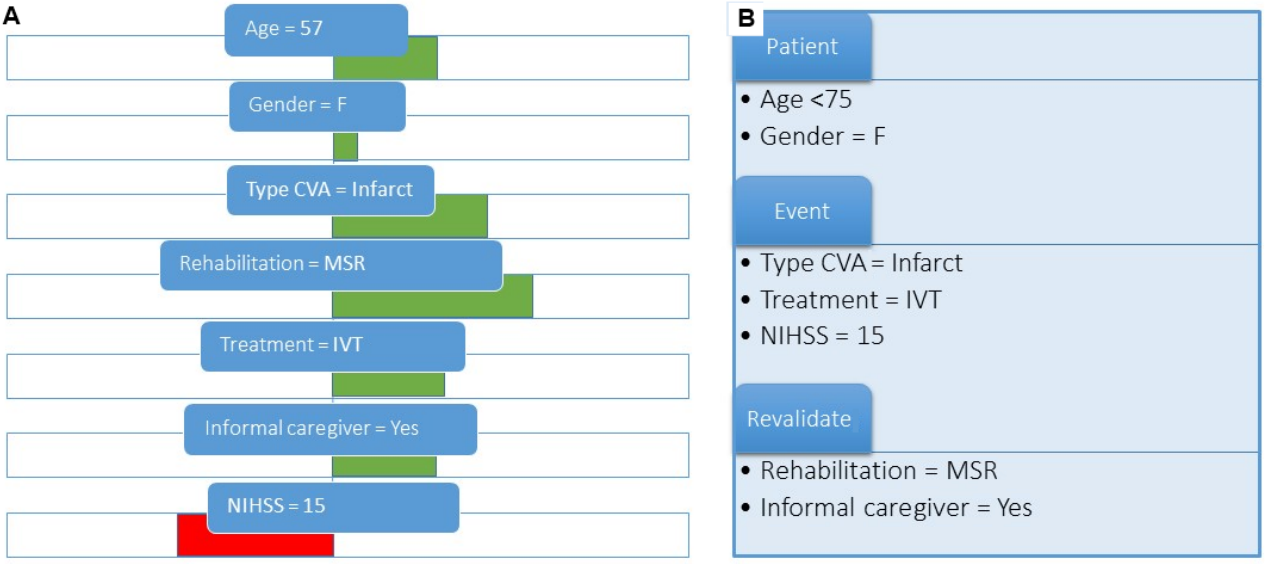
No statistical analyses were performed on the questionnaire, as the MIDI questionnaire is not a validated questionnaire and the sample size is small. Instead, the questions were meant to provide a formalized evaluation of the prediction model and its visualizations. Both the general score of the prediction model and the agreement have been reported.



Prediction Model and Visualizations

The model visualizations were based on the model described in a previous article [24]. This model aims to predict a 2-fold outcome: functional outcome (modified Rankin scale [mRS] score) after 3 months and length of stay in a rehabilitation center. Two feature sets were used as predictors: hospital data and data from geriatric rehabilitation clinics. The hospital data were based on registry data from the Dutch Acute Stroke Audit [25], such as medical history, treatment data, and admission data, and the other data included intake data, admission data, and discharge data.

The design of the visualizations followed an iterative setup with the research team. Before the focus groups, the research team created a mock-up, with outcomes and visualizations for 2 fictional patients, as a functional model with real patient data was not yet available. Based on examples and previous literature about explainable AI in health care [26,27], a choice of 2 different visualization styles was made. One with a more simplified textual approach having clear and limited information, and one with a more detailed visualized approach having more information in the form of diagrams. We chose circle and bar charts for this style, as they are considered the most “approachable style” of visualization of numbers [19]. The visualizations of the outcomes in both styles are shown in Figure 2.



XSL•FO
RenderX

Figure 2. Different visualizations of outcomes (translated from Dutch). (A) Textual limited information; (B) Visual detailed information. mRS: modified Rankin scale.

Next to outcome visualizations, we also included explanations of the predicted outcomes by the models, which have been shown to be important for the adoption of AI in medicine [14]. We opted to show the model explainability through feature importance, where for the predicted outcome of the model for each patient, the contribution of each feature is shown. This can also be described as local interpretability, which has been further explained previously [19,23]. For example, it can show that the age of that specific patient contributed 20% to the decision of their personal outcome. This can be both positive or negative feature importance, indicating whether it made the predicted outcome more or less likely. The detailed visualization (Figure 3A) shows this in red and green bars. For the simplified version (Figure 3B), only the most important features for the outcome were mentioned (not the extent of their contribution).

Figure 3. Different visualizations of influencing factors (translated from Dutch). (A) Visual detailed information. The color and length of the bars indicate the size of the effect on the outcome. (B) Textual limited information. CVA: cerebrovascular accident; IVT: intravenous thrombolysis; MSR: medical specialistic rehabilitation; NIHSS: National Institutes of Health Stroke Scale.

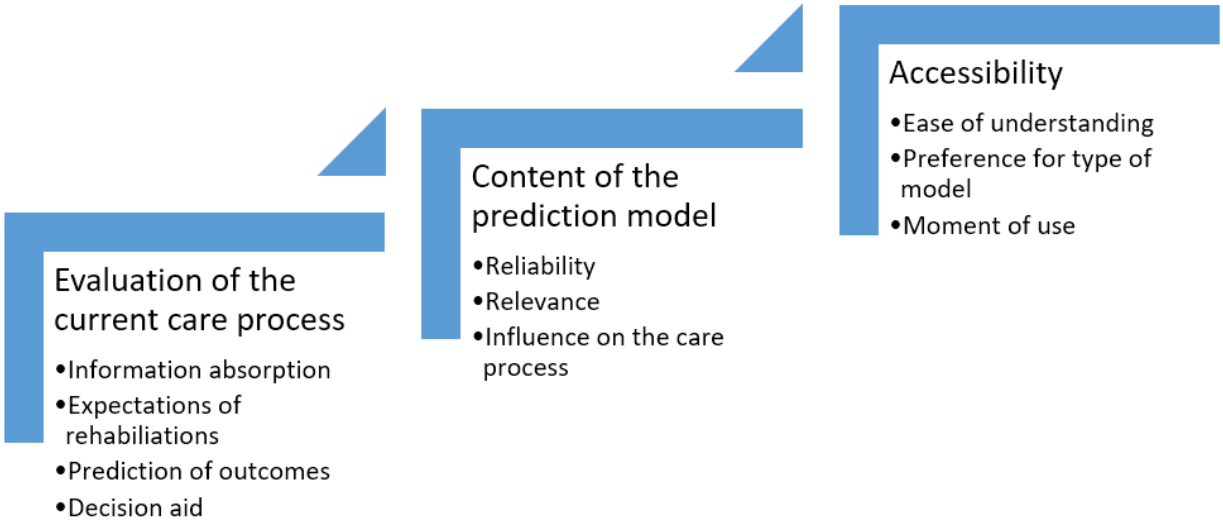
XSL•FO
RenderX

Visualizations were developed for 2 fictional patients in 2 different visualization styles, resulting in 4 examples. The complete translated visualizations can be found in Multimedia Appendix 3. Based on the feedback from the focus groups, 1 visualization style was selected, and the visualizations were modified in accordance with the focus group feedback. These final visualizations were used for the questionnaire.

Ethical Considerations

The Medical Ethics committee of Utrecht (MEC-U) declared that this study is not subject to the Dutch Medical Research Involving Human Subjects Act (WMO) and issued a non-WMO statement under number W22.007, and subsequently, the board of directors of St. Antonius Hospital issued a statement of no objection (permission to perform) under number Z22.009. All participants provided informed consent.

Results



Focus Groups

The focus groups took place in April and May 2022 and lasted for 60-90 minutes with patients and caregivers and for about an hour with HCPs. We conducted 3 focus groups of each type (total 9 patients, 4 informal caregivers, and 8 HCPs). After these sessions, further focus groups were not deemed necessary, as saturation was reached.

A few minor changes were made to the interview guide after the first focus group with patients. We put less focus on the discharge interview and more on the questions about the care process in general for patients and the family interview for HCPs. For the focus groups with patients and informal caregivers, the transcripts were sent to these participants for a member check. None of the participants had any remarks on the transcripts.

The results of the focus groups have been organized by theme in prediction model development in 3 sections: evaluation of the current care process, content of the prediction model, and accessibility of the model (Figure 4).

Figure 4. The 10 themes in the focus groups divided into 3 categories.

Evaluation of the Current Care Process

Information Absorption

Some of the patients said that they either could not remember or did not understand the information given at the discharge interview. This could be due to the symptoms of their CVA. For example, a patient developed aphasia because of the CVA. As a result, she did not know what questions to ask during the discharge interview and did not manage to do so. However, most patients said this was due to information overload caused by discharge taking place shortly after the CVA, and the impressions and emotions during admission. On the other hand, most of the informal caregivers said that they received the information provided during the discharge interview and helped the patients with the information when necessary.

The patients and informal caregivers who could remember said that they were positive about the information provision, calling it clear, open, and informative, with a lot of room for questions. HCPs mentioned that they often found it hard to estimate whether patients and caregivers truly understood the given information, saying that patients always say they understand, even if they do not. They also mentioned language barriers as a common issue. Moreover, they were not sure whether the extra resources given, such as websites or information flyers, were read and understood by patients, as they did not discuss these with them.

Expectations of Rehabilitation

Most patients and informal caregivers had little idea of what to expect from rehabilitation and expressed that they felt thrown in at the deep end. One patient described her lack of expectations as follows:

> *I just let everything wash over me. That was all I could do.*

Only 1 patient said he knew what he could expect in his personal situation, even if daily tasks proved more difficult. Informal

XSL•FO
RenderX

caregivers expressed wishes for more information from the hospital about rehabilitation, with 1 informal caregiver expressing that he would have wanted a rehabilitation plan from the hospital:

> *[...] my mom is not the first one with a CVA, so there is a certain expectation and based on that […] protocols are made. It's my first time, and then there's nothing […] that's hard. Something has to be done about that. That's what I missed.*

Eventually, most patients were happy with the rehabilitation, except for a few bad experiences with HCPs. HCPs' experiences matched with the views of the patients and caregivers, and they stated that they do not have a good overview of rehabilitation and therefore cannot give patients an expectation of what will happen during rehabilitation. Some HCPs believed that this information should be given in rehabilitation clinics. They also mentioned that there could be a disparity in the expectations between patients and informal caregivers. In those situations, patients often felt like they were ready to be discharged home, while caregivers would still be very worried and push for inpatient rehabilitation.

Predictions of Outcomes

Almost all HCPs mentioned the difficulty of making individual predictions. They explained that this was due to patients, even similar patients, having varying recovery paths and because they did not have oversight over recovery during rehabilitation. Only the 2 most experienced neurologists felt more comfortable giving general predictions using age and the severity of the event. One of the junior doctors mentioned that they did not feel like they had enough knowledge and data to make such predictions.

> *I also don't know the exact scientific evidence from the top of my head […] for someone with a hemiparesis after 3 months.*

These statements were in agreement with the experiences of the patients. In the perception of the patients, if the physician did predict outcomes, it was not very precise. For example, they mentioned that the physician predicted that they would recover gradually in the first 3 months. Moreover, they said that no data in the form of numbers or percentages were used.

We asked all participants what they considered the most important outcomes to have a prediction on. Three outcomes were mainly mentioned: functional status in the medium or long term (multiple months or years), time of rehabilitation, and the chance of a new CVA. A new event was something that many patients were very scared about. They wanted to know how high the chance of recurrence was and wanted reassurance that it was as low as possible. HCPs mentioned it was not necessary to have a prediction of recurrence, as medications will always be given to minimize those chances.

Decision Aid

Many patients and informal caregivers felt like the physician took their opinions into account. According to the participants, it varied for each patient whether they had a choice in discharge location. Most participants said they did not have a choice in this decision. However, most participants felt that they could not make a better decision than a physician could, and they accepted the physician's opinion and professionalism. According to the participants, physicians have more knowledge about a CVA than patients and therefore know what is better for them.

> *You have to imagine; it was all new to us. So […] how can your opinion be different from what they recommend to you? It's almost impossible because you're in a situation like that so you can't judge it.*

Physicians mentioned shared decision-making. There is often not really any discussion on where the patient should be discharged.

Content of the Prediction Model

Reliability

Many patients were initially skeptical about a model that would predict outcomes. This was based on the physician's statement that it is not possible to make personal predictions. Several patients and informal caregivers said they did not believe that a physician could make accurate predictions and that consequences could only be seen after rehabilitation. Furthermore, some caregivers also found the prediction too absolute and programmed.

> *If it's such a well-founded prediction but we asked the neurologist about the whole thing, and he couldn't really give us any answers about predictions […]. Won't we get the wrong expectations from an overview like this?*

HCPs were also skeptical of the reliability of the model. They similarly argued that they see a lot of variation between patients and wondered if it is possible to make accurate predictions. In general, they believed that all included predictors would be usable. However, the HCPs questioned the reliability of the model due to the absence of certain important predictors, such as pre-existent functioning (Barthel score), detailed comorbidity, and the character of the patient. They acknowledged that the last aspect would be hard to measure. Moreover, if it is just a tool for information, the doctors argued that it is not that bad if the prediction is not 100% accurate**.**

> *[perfect performance] would be preferable, but you can never predict that […] maybe the important part is how to translate model performance to the patient*

One of the informal caregivers felt that there should be a disclaimer with the model because the outcome could never be 100% right.

Relevance

While most HCPs were generally enthusiastic about the proposed model, another point of skepticism was regarding relevance, as they were hesitant about how to explain the predicted outcomes to patients, especially regarding percentages. Patients confirmed these concerns. One of the patients said he did not like percentages because one can never say what 90%, for example, truly quantifies. Patients agreed that it is better to have a conversation and explain the information instead of simply showing the model. HCPs mentioned that while a general model for outcome prediction would be good, a more useful option would be if there were more different outcomes. For

XSL•FO
RenderX

example, where it would be more useful if we could split it into several types of complaints or symptoms (like aphasia or paralysis).

There was disagreement among patients regarding whether they wanted predictions at all. Some stated that they would be curious to know their predictions. Another participant stated that the information he received from his physician was sufficient and that he did not need a more specific prediction. Some of the caregivers said they would find it convenient to use a prediction model during a discharge conversation and that a prediction could supplement the information given by HCPs. Most HCPs were slightly worried about the risk of giving too much information, as it is currently already too much. However, some physicians also thought that a prediction could help clarify the situation, making the other information more digestible.

Influence on the Care Process

There were several points discussed concerning the possible influence of a prediction model on the care process. There was agreement among HCPs that it would be good for the patient as guidance if it is understandable for the patient. Junior doctors especially thought it would be good for HCPs as well for guidance in conversations with patients, reaching a better ground to make prognoses and overcoming unconscious biases about patients.

While most patients and informal caregivers expressed the positive aspects of guidance similar to HCPs, some patients worried that if the prediction is negative, it could be scary or it could demotivate the rehabilitation process. The patients stated that a lot of motivation is necessary for the best recovery.

> *And if I were [example patient] and 82 [years old] I don't know if I would be up for knowing […] that bad outcome*

However, most patients and informal caregivers did not want HCPs to hold back negative results from them. Moreover, doctors mentioned they would not be worried about this, as they are used to delivering bad news.

The main importance for HCPs was a way to inform patients and to offer clearer information for expectation management in the further rehabilitation process. As such, using this prediction tool would not have a direct result on the treatment or outcome of patients. There was the question of why this would be useful, and it was expressed that the goal of the tool should be clear; otherwise, it might not be used.

Accessibility

Ease of Understanding

The HCPs in general found the prediction model and the visualizations quite clear, and most thought that with explanation the model should be understandable for patients. However, several patients and informal caregivers found it hard to understand. Even after another explanation, they struggled to fully comprehend the meaning. One patient mentioned this might be due to one of the complications of his CVA being a lack of concentration and thus not having enough concentration to read. They struggled with the medical terminology, even after explanation. One patient said that it might be convenient for a physician but it is too hard for a patient. Most patients and caregivers understood the visualizations if they looked at them for a little longer but concurred that an explanation is needed from someone with a medical background or a more detailed but simple explanation is needed in additional text.

Preference for a Model Style

There were differences among patients regarding the preferences for the style of visualizations. Most of the participants preferred the prediction model with more graphics and less text because it was more visual and easier to understand. One participant stated that when a patient has symptoms like trouble with reading or concentration, it is easier to see the graphs.

> *I also think that for people who have […] more symptoms, who understand it a […] less easily […] the pictures are a little bit more informative.*

A few patients said the bar charts for feature importance did not have their preferences, as they contained too much information and the features could not be changed.

All HCPs preferred the more detailed visualization, and they argued that they contained more information and made the prediction more "alive." Interestingly, they thought patients would not have the same preferences. The HCPs also argued for integration into the electronic health record (EHR), as this would help with ease of use and adoption in the care process. Some HCPs were afraid that due to the high workload and the model not having a direct impact on the care process, the model might not be used if it is not easily accessible.

Moment of Use

Whether to use the model during the discharge interview or during the family interview, which happens a few days into admission with informal caregivers, was a point of discussion among HCPs. It could be beneficial for both. The discharge interview can be very rushed, and during the family interview, there might be more time to go over the predictions. However, this would be earlier in the process, which means that less information might be included in the predictions. Moreover, they agreed that having some form of access afterward would be good. Different options were mentioned: at the rehabilitation center, with the general practitioner, or at the 3-month follow-up.

The patients generally agreed with this view. One patient stated that it would be good to see the prediction when you feel like it, but it would have been too much during the discharge interview.

> *It is useful but […] too extensive [for] a normal person […] does not understand a thing. [...] Then it is explained by someone with a medical background […] who can perhaps explain it better. […] Maybe after a few months go back and look at it again […]. What are the expectations now, what are the expectations later.*

Questionnaire Survey

Based on the results of the focus groups, we extracted a set of recommendations. These recommendations were either immediately included in the visualizations of the prediction

XSL•FO
RenderX

model or served as general recommendations for further development or for the context of the implementation in current care. The recommendations are summarized in Table 2.

Table 2. Recommendations from the focus groups.

Category	Theme	Recommendation	Incorporation
Evaluation of current care	Information absorption	Recognize that the information might not be understood at the discharge interview	Implementation
Evaluation of current care	Expectations of rehabilitation	Create a better overview of rehabilitation for patients, informal caregivers, and health care professionals	Context of care
Evaluation of current care	Prediction of outcomes	Highlight that the model meets the needs of patients, informal caregivers, and health care professionals regarding providing a prediction of the outcome	Immediately
Evaluation of current care	Decision aid	Make sure the patient's opinion is heard in the decision process, for example, through shared decision-making	Context of care
Accessibility	Ease of understanding	The target audience of visualizations should be health care professionals and not patients	Immediately
Accessibility	Moment of use	Do not limit the use of prediction to the discharge interview	Implementation
Accessibility	Model preference	Visualize outcome and feature importance (visualization version b)	Immediately
Content of the model	Reliability	Include the general predictive performance of the model, for example, according to the margin of error	Future research
Content of the model	Relevance	mRS[a] score in 3 categories, including the possible functional score, measured during hospital stay	Future research
Content of the model	Influence on the care process	Clarify the goal of the model (informing patients) to improve adherence	Immediately

[a]mRS: modified Rankin scale.

The visualizations were adapted according to the recommendations. We selected the more “visualized” versions (see Figures 2B and 3A). Moreover, we focused on HCPs as our target audience and therefore removed explanations of well-known abbreviations and concepts, such as the National Institutes of Health Stroke Scale (NIHSS) score. We also specified that the moment of use could be the discharge or family interview and that the goal of the prediction model was to inform patients. Moreover, we included more detailed information on feature importance, based on our underlying model. The adapted visualizations can be found in Multimedia Appendix 3.

The questionnaire was sent to 16 relevant HCPs in St. Antonius Hospital, and we received 9 responses. The answers to the closed questions are summarized in Table 3. For each question, we have reported scores. Moreover, we have presented the average score and SD for each section. Negatively phrased questions (questions 4, 8, and 9) were scored in reverse.

XSL•FO
RenderX

Table 3. Questionnaire results reported on a Likert scale (0-5).

Question[a]	Score, mean (SD)
General statements	
1. The prediction model matches well with my usual way of working.	4.0 (0.5)
2. The prediction model is based on factually correct information.	3.7 (0.5)
3. The prediction model offers all the information and materials necessary to work with it properly.	3.6 (0.5)
4. The prediction model is too complicated for me to use.	4.1 (0.8)
5. I expect that the effects of the use of the prediction model will be clearly visible.	2.9 (0.4)
6. I think the prediction model is suitable for my patients.	3.8 (1.0)
Advantages and disadvantages	
7. The use of the prediction model gives me the opportunity to inform my patients better.	3.8 (1.0)
8. The use of the prediction model during discharge or family interviews will cost me more time than usual.	3.2 (0.5)
9. I find it too complicated to use the prediction model during discharge or family interviews.	3.9 (0.8)
Prediction model and patients	
11. I expect that with the prediction model, my patients will be better informed about the expected functional status after 3 months and the duration of rehabilitation.	3.4 (0.5)
12. I think it is important to use the prediction model to better inform my patients about the expected outcomes: the functional status after 3 months, and the duration of rehabilitation.	4.0 (0.5)
13. I consider it part of my job to use the prediction model.	3.6 (0.7)
14. Patients will generally be satisfied if I use this prediction model.	3.8 (0.4)
15. Patients will generally be cooperative if I use this prediction model.	3.7 (0.5)
Prediction model and colleagues	
16. I can count on sufficient help from my colleagues when necessary while using the prediction model.	3.5 (0.5)
17. How many doctors who conduct discharge interviews will actually use this prediction model?	3.8 (0.7)
18. To what extent will (your fellow) neurologists expect you to use the prediction model?	3.2 (0.4)
19. When it comes to working with the prediction model, how much do you care about the opinion of (your fellow) neurologists?	3.7 (0.5)
Application of the prediction model	
20. If you wanted to, do you think you would be able to apply the prediction model during the discharge or family discussions?	3.9 (0.3)
21. I have sufficient knowledge to be able to use the prediction model.	3.8 (0.8)
22. To what extent are you aware of the content of the prediction model?	3.1 (1.1)

[a]Question 10 was an open question (What are the other advantages or disadvantages of this prediction model?) and is not included in the table.

We considered statements with a score of ≥3.5 and an SD of <1.0 to be sufficient to positive, with agreement among HCPs. Most statements were received as such, and we considered the general feedback to be moderately positive. Moreover, in all categories of statements, we noted that most statements were at least moderately positive with agreement, highlighting that there is no topic where the prediction model consistently underperforms. The high scores for "*The prediction model matches well with my usual way of working*" (score 4.0), "*I think it is important to use the prediction model to better inform my patients about the expected outcomes: the functional status after 3 months, and the duration of rehabilitation*" (score 4.0), and "*If you wanted to, do you think you would be able to apply the prediction model during the discharge or family discussions?*" (score 3.9) indicate a high willingness to implement the prediction model.

For some questions/statements, the HCPs were not positive on average (score of <3.5) or were not in agreement (SD ≥1.0). The statement "*I expect that with the prediction model, my patients will be better informed about the expected functional status after 3 months and the duration of rehabilitation*" had a score of 3.4. This was just under our set threshold. Interestingly, the statement "*I think it is important to use the prediction model to better inform my patients about the expected outcomes: the functional status after 3 months, and the duration of rehabilitation*" had a score of 4.0. It shows that the HCPs, even when not sure about the positive outcome of use, still found it important to use the prediction model. The same concern was highlighted in 2 statements that had high disagreement among the HCPs: "*I think the prediction model is suitable for my patients*" (score 3.8, SD 1.0) and "*The use of the prediction model gives me the opportunity to inform my patients better*" (score 3.8, SD 1.0). This shows consistency with the focus

XSL•FO
RenderX

groups indicating that there seems to be variety in the extent to which HCPs are positive about the effects of the prediction model.

In the other statements that were not positive on average or had high disagreement, we also noted similar findings that came up in the focus groups as well. The statement "*Iexpect that the effects of the use of the prediction model will be clearly visible*" had the lowest score of 2.9. This is not completely unexpected as the model's primary function is to inform and not provide decision support. Moreover, the issue of high workload was reflected in the statement "*The use of the prediction model during discharge or family interviews will cost me more time than usual*" (score 3.2). Lastly, the statement "*To what extent are you aware of the content of the prediction model?*" had both a low score and high disagreement (score 3.1, SD 1.1), indicating that more detailed explanation and training are necessary to understand the model.

The statement "*To what extent will (your fellow) neurologists expect you to use the prediction model?*" had a low score of 3.2. This shows that many HCPs would consider the use of such a prediction model to be more elective. Next to the scaled questions, we also asked 1 open question "*what are the other advantages or disadvantages of this prediction model?*" A big point of contention was whether the prediction model would be accurate enough, as certain factors like recovery during the time in the hospital and mental resilience were not included. A positive aspect mentioned a few times was that it could also be used to preinform the rehabilitation clinics for helping with planning.

Discussion

Principal Findings

This study shows the added value of a prediction model for long-term outcomes of rehabilitation after stroke in CVA care under certain conditions. The need for a prediction model was consistently shown in focus groups and a questionnaire survey, as evidenced by the general approval of participants. Several recommendations can be made, most importantly on the following 5 conditions: primary target, timing of discussing the predictions, different focuses of HCPs and patients, goal of the prediction model, and visualization of the model.

First, the primary target audience of the prediction model should be HCPs. While the information provided is of interest to both patients and informal caregivers, not all patients can fully understand the outcomes of the prediction model. This resembles the findings of other studies that investigated different digital health tools for stroke patients, which reported complaints of difficulty [28] or disinterest among some patients [29]. Our study specifically found that patients prefer HCPs to provide information and guide them through the visualizations of the model.

Second, the timing for using predictions should also be considered. As patients mentioned, it could be more useful when targeted toward patients at different points in the care process. Here, it is interesting to see if the model can be simplified, as was requested by interested patients, and how that should be offered. Another study on digital health tools for patients with brain injuries [30] highlighted the importance of user testing among these patients. This would be a good way to ensure that the simplified model fits the patient's needs and understanding.

Third, for HCPs, the reliability and relevance of the model are key. HCPs focus largely on the reliability and relevance of the model. It is essential to not only provide good reliability and relevance but also clearly communicate the aspects to HCPs. Reliability is essential to validate the performance of the model. Therefore, changes in outcome reporting were considered to be more in line with the current care [31]: divide the mRS score into 3 categories and include predictive factors. By including the general predictive performance of the model (eg, according to the margin of error), the reliability can be better communicated to HCPs. These 2 points of reliability and relevance are very much in agreement with the guidelines for the implementation of AI in health care [32,33]. While the performance and generalizability of the model were not the focus of this study, they should be properly validated before model implementation. We found that patients focused more on the impact on rehabilitation, the emotional aspects, and understandability.

Fourth, HCPs and patients should understand the goal of the prediction model. This understanding can improve adherence and the willingness of HCPs to cooperate, which are essential for the adoption of the model in practice [32]. This matched our results, as this was one of the main points of the HCPs in both focus groups and the questionnaire survey. We aimed to clarify the goal of the prediction model after the focus groups. However, the questionnaires showed that the goal of the prediction model was still unclear to some HCPs, even after a more detailed explanation in the introduction of the questionnaire. This could be mitigated by properly informing HCPs, for example, by providing in-person training or a detailed demonstration of the model. It is also essential to highlight the goal of the explainability aspect of the model. The visualizations showed to what extent certain factors contributed to the model's decision, but that did not mean changing those factors would necessarily lead to a different outcome for the patient. For example, while the model might assign high importance to a certain treatment in the prediction of negative outcomes, it does not mean that not performing this treatment would lead to a better outcome.

Finally, all participant groups showed a preference for a more visual model. This matches the general consensus in visualization science, which argues for presenting numerical data in simple visualizations, such as bar or pie charts [15]. Our results showed that this is even more relevant for patients who have experienced a stroke. However, the visualizations that we used relied on red and green bars to highlight the importance of features, which can be an issue for colorblind people [34]. While none of our participants reported issues related to colorblindness, it should be adapted to a more inclusive visualization.

Strengths and Limitations

One of the main strengths of this study was the involvement of different stakeholder groups, including patients, informal

XSL•FO
RenderX

caregivers, and HCPs, with different roles. Moreover, the double setup with separate focus groups and questionnaires allowed for a check of agreement between the results of the different methods. One limitation to consider is our use of convenience sampling, which could have skewed the results. People with very severe stroke or with trouble reading or understanding were not represented. For HCPs, we mainly included people who were already open to research and new developments. The interviews with patients and informal caregivers were performed several months after the CVA, so their actual responses at the time of discharge might have been different. Moreover, we used mock-ups for the visualizations and not "real" predictions based on actual patient data. Although the visualizations were based on our existing models and data as much as possible, this was not a personal prediction. This made the visualizations more difficult to understand than expected, and the focus groups might have been more efficient with a functional model based on the actual patient data.

For the questionnaires, we had a relatively small sample size, and therefore, we did not perform any statistical analyses. As there was high agreement among the HCPs and the majority (9/16) of invited HCPs responded, it is likely they are a representative sample of the HCP group in the hospital, but we cannot know this for sure. Moreover, this group did not include all HCPs involved in stroke care. It is possible that physical therapists or general practitioners would have a different outlook on the prediction models, as they might be more involved in the rehabilitation of patients or involved at a different point in rehabilitation care. Lastly, this study was limited to a single hospital in the Netherlands. Differences between hospitals and especially between medical practices among countries can impact the generalizability of our results. Combining these limitations, we would recommend a quantitative follow-up study based on our questionnaire. Preferably, this should be a multicenter and international study to confirm the generalizability of our results outside the confines of our hospital.

Implications and Future Directions

From this study, we can extract lessons to be considered when implementing AI in medicine in general. An important aspect is that the need for information provision is highly variable between groups as well as individuals. The results of the prediction model can be highly personal, and similarly, the needs of a patient and the setting and specific illness of the patient can be personal. It is essential to clearly define the purpose of the tool, as there are not only different levels of understanding but also different priorities. For example, patients do not always appreciate detailed information, especially if the information is not actionable but only informative. It is also essential to consider a model that can have multiple purposes. A model, such as ours, could also be used for advanced resource planning in rehabilitation clinics by estimating the future demand on the clinics and evaluating the effectiveness of the rehabilitation.

An important point is to investigate how to include patients who struggle with technology due to language, socioeconomic, or medical issues. For example, this study excluded non-Dutch speakers, but HCPs mentioned that language issues could further complicate explaining the expectations of recovery. This difficulty in communication should not be increased by a new technological tool or prediction model. Relying more on technology can lead to more inequality in care [35], especially for vulnerable patients, such as stroke patients [32]. One effort that can prevent such issues is the development of a comprehensive framework for AI implementation in health care and the creation of a roadmap for AI implementation. Such frameworks are being developed [31,33], but none of them are exhaustive, and having resources that detail considerations for AI application and evaluation are still necessary to develop AI with meaningful medical applications [33].

Conclusions

The findings of this study show that participants are generally positive toward a prediction model for long-term outcomes of rehabilitation after stroke in CVA care under certain conditions, with a general preference for a more visualized prediction model. The prediction model should be geared toward HCPs, as they can provide the context necessary for patients and their informal caregivers. For HCPs, good reliability and relevance of the prediction model are essential for its proper integration. We recommend a quantitative follow-up study to confirm these results in multicenter and international settings.

Abstract

Background: Problem gambling and gambling disorder cause severe social, psychiatric, and financial consequences, and voluntary self-exclusion is a common harm reduction tool used by individuals with gambling problems.

Objective: The aim of this study was to explore users' experience of a novel nationwide, multioperator gambling self-exclusion service, "Spelpaus," in Sweden and to inform stakeholders and policy makers in order to improve harm reduction tools against gambling problems.

Methods: Semistructured interviews were conducted with 15 individuals who reported self-perceived gambling problems and who had experience of having used the self-exclusion service Spelpaus in Sweden. Interviews were transcribed and analyzed through qualitative content analysis.

Results: We identified 3 categories and 8 subcategories. The categories were (1) reasons for the decision to self-exclude, (2) positive experiences, and (3) suggestions for improvement. The subcategories identified a number of reasons for self-exclusion, such as financial reasons and family reasons, and positive experiences described as a relief from gambling; in addition, important suggestions for improvement were cited, such as a more gradual return to gambling post–self-exclusion, better ways to address loopholes in the system, and transfer from self-exclusion to treatment.

Conclusions: Voluntary self-exclusion from gambling, using a nationwide multioperator service, remains an appreciated harm-reducing tool. However, transfer from self-exclusion to treatment should be facilitated by policy making, and loopholes allowing for breaching of the self-exclusion need to be counteracted.

(JMIR Hum Factors 2025;12:e66045) doi:10.2196/66045

gambling disorder; gambling addiction; behavioral addiction; harm reduction; self-exclusion; voluntary self-exclusion; Spelpaus; lived experience; human factors; usability; qualitative study

Introduction

Background

Gambling disorder is a behavioral addictive disorder known to cause severe financial, social, and mental health consequences to affected individuals [1-3]. Among the harm-reducing or harm-preventive strategies used against gambling-related harm, voluntary self-exclusion is a well-established responsible gambling measure aiming to prevent and reduce the damage that can be caused by gambling [4].

Through self-exclusion, gamblers can voluntarily suspend themselves from gambling. However, 1 well-known limitation of self-exclusion services may be the possibility to gamble with another operator than the one the gambler has been self-excluded

XSL•FO
RenderX

from [5]. Gamblers are therefore usually required to self-exclude from multiple different operators. Consequently, in recent years, to further prevent gamblers from breaching their self-exclusion, it has become more common to offer gamblers the possibility to self-exclude from multiple operators at the same time.

In January 2019, the legislation for the Swedish gambling market changed, and monopoly was replaced by a license-regulated market [6]. This regulation meant that gambling operators, including overseas operators, needed to apply for a Swedish gambling license to operate on the Swedish market. In connection to the new regulations, the nationwide self-exclusion service "Spelpaus" was launched. Gambling operators with a Swedish license must adhere to this self-exclusion service, along with a series of other measures for responsible gambling. Spelpaus offers the possibility to self-exclude from all gambling operators with a Swedish license for 1, 3, 6, or 12 months. Self-exclusion cannot be canceled prematurely, and if the 12-month option is chosen, the self-exclusion continues beyond the 12 months, unless the individual actively chooses to cancel it after that period. Self-exclusion via Spelpaus also prohibits gambling operators from sending direct advertisements to self-excluded customers.

Spelpaus is in many ways a unique harm-reducing tool since it is nationwide, covers all licensed gambling operators (both online and land based), and can be accessed separately from the gambling operators. Thus, it theoretically represents a novel harm reduction strategy over and above other responsible gambling measures. Indeed, theoretically, this system may have a larger coverage and fewer loopholes (ie, fewer practical possibilities to turn into other gambling modalities and gamble despite self-exclusion) compared to a self-exclusion system involving 1 or few gambling operators. Around 100 gambling companies have a Swedish gambling license, with most of them operating exclusively online.

The prevalence of gambling problems in the Swedish population is estimated to be approximately 0.5% on a diagnostic level and a total of 1%-2% with at least moderate-risk gambling according to the Problem Gambling Severity Index [7,8]. Formal treatment seeking, or treatment provision, is low; less than 1000 people annually receive a gambling disorder diagnosis in the whole of Sweden, and even when taking other care providers into considerations, it can be assumed that only a small minority of people with a gambling problem on a diagnostic level receive formal treatment [9]. In contrast, low formal treatment seeking is often described in gambling disorder; however, a more informal but still active help-seeking behavior appears to be common, and voluntary self-exclusion from gambling can be part of this [10].

In Sweden, around 110,000 inhabitants are enrolled in Spelpaus [11], a number that has steadily increased since the launch in 2019 [12]. Thus, we believe that an increasing number of people with problematic gambling are attempting to intervene against their problem through self-exclusion, although we must consider that people without gambling problems also choose to self-exclude.

The steady increase in registrations in Spelpaus indicates that it is perceived as a helpful tool for many people. However, there are also limitations in the self-exclusion service, making it possible to breach the self-exclusion. Such a limitation is that Spelpaus only covers operators with a Swedish license, therefore making it possible for gamblers to gamble with overseas operators outside the Swedish license gambling market. In a 2020 web survey among gamblers, 38% of gamblers stated that they had gambled with unlicensed operators, while being self-excluded through Spelpaus [13], and in a later survey in 2022, the corresponding figure was 49% [14]. In another survey, conducted by the Swedish Gambling Authority, 25% gamblers stated that they had gambled with unlicensed operators during their self-exclusion [15]. In addition, continued gambling despite self-exclusion remains part of the clinical picture in clinical gambling disorder treatment in this setting [16].

Previous international experience of responsible gambling tools has demonstrated not only the feasibility of self-exclusion services and their use by individuals with gambling problems [4,17,18] but also that users experience limitations of these services [10,18]. Altogether, previous research calls for more in-depth examinations of user experience with self-exclusion services and suggestions for improvement of their effectiveness. In particular, this is relevant for the present type of self-exclusion service, which theoretically has been designed to overcome well-known limitations of older self-excluson systems; this novel Swedish service (1) is government based and independent of gambling operators, such that an individual does not need to enter a gambling site in order to self-exclude; (2) covers all licensed operators in the country and therefore prevents the possibility to change between licensed operators during an ongoing self-exclusion period; and (3) involves both land-based and online-based operators.

Thus, altogether, the relatively recent introduction of a unique, large-scale, multioperator self-exclusion service in Sweden has attracted a large number of users, but it is hindered by the risk of breaching one's self-exclusion to an extent that is clearly of relevance in the treatment setting. Therefore, it is of great value to study which effects of the Spelpaus service are perceived as favorable and challenging by its users and to also study this in more detail than in previous quantitative survey studies.

Aim

Based on the aforementioned research gap, the aim of this study was to enhance comprehension of the user experience of the Spelpaus service within the gambling community and to acquire a more profound insight into the reasons for use of this harm reduction tool and its advantages and challenges. Thereby, the overarching goal of the study was to inform policy makers about potential drawbacks and the potential for improvement of the harm reduction tool.

Methods

Study Design

This research was exploratory in nature. A semistructured interview guide was developed to ensure the exploration of diverse perspectives and experiences related to Spelpaus. Notably, this study represents the first attempt to comprehensively examine user experiences of Spelpaus, thus

XSL•FO
RenderX

justifying the use of qualitative content analysis for its methodological flexibility. The protocol of this study has been published previously [19].

An initial interview guide was developed based on the study's aim and research questions. A test interview with a peer support worker who had experience with self-exclusion services was conducted, leading to refinements of some questions to be more open ended. Further details of the interview questions are provided in the study protocol [19].

Context

The study was conducted in Sweden, a country with approximately 10.4 million inhabitants, where gambling is prevalent, with around 56% of individuals aged from 16 to 84 years having engaged in gambling activities in the past year. Moreover, 18% gamble at least once per month. The prevalence of gambling is higher among men aged 45-84 years, and online gambling has increased markedly in popularity in Sweden over the past decade [20]. Problem gambling in the present setting is predominated by online casino gambling and sports betting, with online casino gambling representing a large majority of patients seeking treatment at a gambling disorder facility in Sweden [16].

Sweden has a license gambling market since 2019, where online and land-based gambling operators are allowed to operate, provided they adhere to a number of responsible gambling regulations, one of which is adherence to the nationwide Spelpaus service. The legal gambling age in Sweden is 18 years [6]. After being a more traditional, land-based gambling market, but with a large predominance of a government-owned gambling monopoly for many years [21], the Swedish gambling market was gradually increasingly affected by overseas online operators, which represented a large proportion of visible gambling advertising despite their unregulated status [22]. This led to the decision to liberalize the gambling market into a licensed, but controlled, market from 2019. Given the new license-based gambling market since 2019, and thereby the relative recency of a unique self-exclusion service, the present setting is of interest to assess the qualities and challenges of such a new harm reduction instrument.

Potential stakeholders and users of the study's findings may include policy makers, public health officials, mental health professionals, gambling addiction counselors, researchers in the field of addiction studies, advocacy groups, and individuals and families affected by problem gambling. The insights garnered from this research could inform the development of targeted interventions, public health campaigns, regulatory measures, and support services aimed at addressing and mitigating the adverse effects of gambling behavior within the Swedish population.

Recruitment Process

Criterion sampling was used in the recruitment process. Participants were selected based on 2 critera: (1) being 18 years old or older during the time of the interview and (2) having previous or ongoing experience of using Spelpaus (any experience was enough, and it was not a requirement that the self-exclusion be in close temporal association with the interview). Recruitment was conducted online through social media advertisements managed by Trialy, a company specializing in research recruitment. Potential participants received information about the study and registered their interest via the Trialy website, completing a short online survey regarding their age and experience with Spelpaus. Eligible individuals were contacted by the first author (JT) and provided with additional study information. They were then sent written information about the study and about participants' rights and asked to sign and return (by mail) an informed consent form. When written consent was obtained, an interview was scheduled. Individuals were recruited during spring-summer 2023.

Sample

In total, 13 men and 2 women, aged between 31 and 62 years, participated in the study, representing various regions of Sweden. All participants reported either a gambling problem or identified themselves as being at risk, with prior or current experience using the Spelpaus self-exclusion service. This gender distribution aligned with existing research findings on gambling demographics in Sweden, which indicate a higher prevalence of gambling-related issues among men [16]. The gambling types involved in each person's gambling pattern were reported. Although the study did not systematically record whether gambling occurred (and had occurred) in online-based or land-based settings, the distribution of gambling types reported by the participants was comparable with the gambling types typically seen in Swedish problem gambling treatment settings, where online casino and sports betting is predominant [16].

Interviews

All interviews were digital (both video and audio) and were carried out by the first author (JT) of the paper, who has experience in qualitative interviewing and psychiatric research, especially in psychiatric research, ensuring a sensitive and nuanced data collection approach. The interviews were audiorecorded but not videorecorded and lasted between 23 and 67 minutes. During the interview process, the authors continuously reviewed and assessed the interviews to discern recurring patterns. Following the completion of 12 interviews, the emergence of new categories began to decline. In the final 2 interviews, only categories closely aligned with those identified previously surfaced. Consequently, the authors made the decision to conclude recruitment for the study. All interviews were then transcribed verbatim by the first and second authors (JT and SH).

As compensation for their time and efforts in the study, all participants received 2 cinema tickets.

Researcher Characteristics and Reflexivity

Our research team included professionals in psychiatry and social work, with substantial experience in qualitative research and interviewing. Throughout the study, we reflected on our backgrounds and preconceptions, particularly regarding gambling disorders and harm reduction strategies, and their potential influence on data interpretation. This reflexivity was integrated into our coding and analysis discussions to include

XSL•FO
RenderX

multiple perspectives and thereby to expand our own perspectives.

To ensure trustworthiness, triangulation was used throughout the analysis process. Multiple researchers independently coded the data, followed by discussions to reach consensus, minimizing the influence of individual biases and ensuring comprehensive data representation.

Data Analysis

This study used qualitative content analysis as the primary method for data analysis, chosen for its flexibility in systematically describing textual data, aligning well with the exploratory nature of this research. The analysis focused on manifest content, which involves identifying clear, descriptive categories that summarize data without deeper interpretive meanings. As noted by Graneheim and Lundman [23], categories represent the descriptive level of content and express the manifest content of the text, consistent with this study's goals. We deliberately chose not to identify themes, aiming instead to capture the descriptive aspects of participants' experiences, a recommended approach when focusing on manifest content rather than latent content [24,25]. Although themes can provide interpretative layers, we chose not to use them in this analysis, maintaining a descriptive focus to capture clear, observable patterns in participants' experiences with Spelpaus. This approach reflects the strength of qualitative content analysis in emphasizing the descriptive aspect without requiring thematic depth when the aim is to focus on manifest content [23].

The qualitative content analysis followed Graneheim and Lundman's [23] approach, focusing on identifying categories that represented the manifest content of participants' responses. Key analysis steps included repeated readings of the transcripts by 3 authors (JT, SH, and HH), identifying meaning units, condensing those units, and labeling them with codes, which were then grouped into categories based on similarities. The transcribed interviews were read through repeatedly and independently, and then the material was discussed by all authors. The content of the interviews related to the aim of the study was divided into meaning units, which were then condensed and labeled with codes. Similarities and differences in the codes were identified before they were divided into different categories and subcategories (Table 1). All steps of the analysis process were carried out separately and then discussed within the group to reach consensus. Various meetings within the group were held during the analysis process to discuss the different findings before a consensus about the results was reached.

Table 1. Examples of the data analysis process.

Meaning unit	Condensed meaning units	Code	Category	Subcategory
"If you should have a gambling stop like this, it should really apply to everything, because the brain will always find a way otherwise. This is the good thing—that it is a stop. You can't make a phone call, you can't just change your mind, because now it is a stop. I think that is very important." [Male participant, 31 years old]	The gambling stop should really apply to everything. Because the brain will always find a way otherwise. The good thing is that it is a stop, you cannot just change your mind. I think that is important.	Satisfaction with Spelpaus	Positive experiences	Prevention of future gambling problems
"Well, the downside is that it gives a little bit of a false sense of security. At least when it comes to certain people...as if you gamble on other gambling sites...it doesn't help anything." [Female participant, 35 years old]	The downside is that it gives a little bit of a false sense of security. When it comes to certain people who gamble on other sites, it does not help anything.	Suggestion for improvement: to also stop overseas gambling sites	Suggestions for improvement	Addressing loopholes

Ethical Considerations

The study was conducted according to the principles of the Declaration of Helsinki and was approved by the Swedish Ethical Review Authority (approval number 2022/06933-01, amendment 2023/01684-02). All participants received oral and written information about the study and about participants' rights, prior to signing a consent form. Written informed consent was obtained from all participants.

Categories and Subcategories

As shown in Table 3, we identified 3 categories: motivations and reasons for self-exclusion (including triggers, such as financial strain and concern for close relationships), perceived positive experiences (eg, reduced gambling urges and improved quality of life), and challenges and suggestions for improvement (notably, breaches through unlicensed gambling sites and lack of integrated support).

XSL•FO

Suggestions for improvement	• Integrated support systems • Addressing loopholes • Practical enhancements

Reasons for the Decision to Self-Exclude

The motivations underlying the choice to use the self-exclusion service were multifaceted, often encompassing a combination of factors.

Precipitating Factors

Numerous participants reported specific events that precipitated heightened gambling activity, ultimately leading to the decision to self-exclude. Common triggers included winning a large amount of money and quickly gambling it away, traumatic family incidents, interpersonal conflicts, financial struggles, and the onset of the COVID-19 pandemic. For instance, 1 (7%) participant articulated:

> *I was facing unemployment without insurance, which exacerbated my gambling tendencies. Although I secured employment thereafter, the meager income did not deter my gambling. The resurgence of COVID-19 in September restarted my gambling habits, leading to a downward spiral.* [Male participant, 44 years old]

Additionally, some participants opted for self-exclusion to prevent the risk of others accessing their gambling accounts as part of gambling-related criminal behavior. An example of this was the following interviewee who had a gambling problem but who also had a family member with a severe gambling problem:

> *...At the same time, this has helped us a lot every time she has wished to gamble on our accounts.* [Female participant, 35 years old]

Another reason to self-exclude was because the individual wished to facilitate debt settlement, as self-exclusion was a prerequisite for debt relief applications.

> *I applied for a debt settlement, but since I did not take it [self-exclusion] for a year, I did not get it…I would like to make another attempt for a debt settlement application, but then I probably have to take a 12-month period [of self-exclusion] as well.*

Self-Awareness of Gambling Habits

A prevalent reason for self-exclusion was an enhanced awareness of one's gambling behavior. Participants acknowledged excessive gambling tendencies, albeit with varying perspectives on whether they had developed a full-fledged gambling problem or were teetering on the brink of one. Fueled by these insights, individuals opted for Spelpaus to forestall further progression into problem gambling or to address existing issues. As 1 (7%) participant reflected:

> *I have had a realization, particularly in recent months...I recognize that I need to address this behavior before it escalates.* [Female participant, 56 years old]

This introspective process often unfolded gradually, sometimes facilitated by professional guidance or peer support.

Concern for Close Ones

Many participants described the adverse impact of their gambling habits on loved ones, with 10 (67%) individuals mentioning that their loved ones had been negatively impacted to a great extent. Financial strain, deceit, and compromised relationships were common themes. Some participants lamented fractured relationships resulting from their gambling, while others acknowledged the toll gambling took on family bonds and quality time spent together. One participant expressed:

> *It is not just about the money lost—it is the betrayal, the lies...and the time squandered gambling instead of being with my family that truly stings.* [Male participant, 39 years old]

Although self-exclusion was often an independent decision, familial influence or shared deliberation with loved ones also played a role. The following 2 (13%) citations are examples of this:

> *The relationship with my parents is starting to get a little bit better; for many years, it was pretty bad. They have helped me out with money a lot of times. Every time I call them, they think I am going to ask them for money again, so it [gambling] has hurt our relationship a lot.* [Male participant, 44 years old]

> *If you fail in a game or something, you get kind of aggressive, depressed, and angry. You also get very affected emotionally. If you bet on 7 games and 1 of them fails, you get upset, angry, or sad. It has affected my close ones the most.* [Male participant, 40 years old]

Positive Experiences

Participants identified several benefits associated with using the Spelpaus self-exclusion service.

XSL•FO
RenderX

Prevention of Future Gambling Problems

Self-exclusion was perceived as a preemptive measure to safeguard against relapse into gambling behaviors. Even individuals who had not experienced gambling urges for an extended period recognized the potential for future vulnerability. By enacting self-exclusion, participants closed the door to impulsive gambling, thus mitigating the risk of relapse. Several participants credited the Spelpaus service for preventing immediate urges to gamble. A couple of the participants who began gambling again described how they after the end of the self-exclusion period managed to gamble in a more controlled way than before.

> *After the self-exclusion, it was much more under control. I gambled a lot less, bet smaller amounts…if I felt I need to limit it now or I have to stop now. When you feel it is starting to be too much or take too much time, you feel a little self-control. Then I take a free weekend or several days free from betting, and after that, I bet a little, and then it feels like everything is under control.* [Male participant, 40 years old]

Another participant described the partial effect on gambling, primarily on impulse-driven uncontrolled gambling:

> *A part of me does not really want to say goodbye and never gamble again, but I want it to be at a reasonable level. It is at ATG [Swedish horse-betting company]. I am staying there. I think I gamble for 96 (Swedish) kronor a week now, but it was still that break (self-exclusion) that forced me to deal with it somehow.* [Male participant, 55 years old]

Improved Quality of Life

Many participants reported enhanced well-being during the self-exclusion period. Freed from the grip of gambling, individuals experienced a newfound sense of calm, happiness, and control over their lives. Moreover, self-exclusion provided an opportunity for personal growth and self-improvement, allowing participants to redirect their focus toward constructive pursuits, such as physical exercise and social interactions. One individual reflected:

> *You can relax because you have given away the control to something else…once I have chosen to self-exclude, I cannot do anything about it…and I get so mentally relaxed, I do not have to think about it at all anymore.* [Male participant, 32 years old]

Financial stability and restored trust within familial relationships were also cited as positive outcomes, as 1 (7%) respondent expressed:

> *My family can tell that I feel better when I do not gamble. I am happier, more positive, and I do not call them and ask for help. Of course, they notice a big difference when I do not gamble.* [Male participant, 31 years old]

In addition, the self-exclusion period provided an opportunity for reflection within the motivational process:

> *When I had my Spelpaus, I became quite aware of the problem, so I had a lot of thoughts about the need to do something about this problem.* [Male participant, 40 years old]

Suggestions for Improvement

Participants identified several areas for enhancement within the Spelpaus self-exclusion service.

Integrated Support Systems

Acknowledging self-exclusion as 1 component of the multifaceted approach to gambling cessation, participants emphasized the need for additional support mechanisms. One participant expressed:

> *My fear is that when the self-exclusion disappears, I have not come so far that I will not get stuck in gambling again…I think it is important that you try to solve your problems when you are self-excluded.* [Male participant, 43 years old]

Peer support groups, counseling services, and psychotherapy were deemed vital complements to self-exclusion. However, participants expressed reluctance to seek out support independently, underscoring the importance of proactive outreach and integrated support systems from within Spelpaus. Some of the participants who considered themselves to be more at risk of developing a gambling problem expressed that Spelpaus alone was enough for them.

> *If you take a year, and you have the opportunity to end it, then there needs to be some kind of dialogue before, and some kind of amount limit.* [Male participant, 55 years old]

> *I think it should be combined with a guaranteed CBT [cognitive behavioural therapy] or diary where you write what you feel, what you can do and what you think you should be able to do. Then of course, in the best of worlds, group therapy is perhaps even better than being digital.* [Male participant, 55, years old]

Addressing Loopholes

Participants raised concerns regarding the efficacy of Spelpaus in preventing access to overseas gambling sites. The absence of coverage for nondomestic operators posed a significant loophole, enabling some individuals to circumvent self-exclusion measures. Suggestions for improvement included enhanced international cooperation and stricter regulations on gambling advertisements.

Practical Enhancements

Participants proposed various technical and logistical improvements to Spelpaus, including more flexible and expanded self-exclusion options, longer time intervals, and a more deliberative process for ending self-exclusion periods. Mainly, participants asked for time intervals longer than 12 months. Several participants saw it as problematic to be able to gamble immediately after the end of a self-exclusion period. Additionally, participants advocated for heightened demands on gambling operators to deter relapse and streamline the self-exclusion process.

> *The self-exclusion service should be able to be developed so you cannot access overseas sites…when*

XSL•FO
RenderX

> *you select it, it should be covering all sites within the EU [European Union] or something like that…that you have a self-exclusion service for all of Europe when you choose it.* [Male participant, 62 years old]
>
> *The best thing would have been if there was a self-exclusion site where you are self-excluded from all gambling…that you have some kind of cooperation with other countries and everything and that it will be a stop everywhere.* [Female participant, 35 years old]

Several respondents stated that the possibility of returning to gambling after the self-exclusion period should still be hindered or slowed down in order to prevent impulse-related relapses even after the predetermined self-exclusion period is over. Some examples of this was an "embargo" period during which gambling still could not be reopened. Some participants found themselves waiting to gamble immediately after the self-exclusion period ended, so they suggested there be some kind of deposit limit for all clients coming back from self-exclusion, a mandatory telephone call or other message to individuals for whom self-exckusion is ending, prohibition of direct advertising to individuals immediately after a self-exclusion period, or mechanisms making the risk of gambling during alcohol influence smaller (eg, through prohibition of gambling during the night).

One respondent described the need for an embargo period:

> *After 12 months, you should not be able to cancel it on the same day; it should be 1, 2, 3 months notice…otherwise, when 12 months have passed, you can just gamble without any restrictions.* [Male participant, 32 years old]

Other respondents described the need for other possible measures to apply in the policy of self-exclusion:

> *After the self-exclusion ended, the advertising started coming again. It becomes like a reminder. So one could simply get going and gamble again!* [Male participant, 31 years old]
>
> *There should be some time to think it over when a client has asked to come back to gambling again. Some time should elapse, and then the person should be asked again. After some time, you should be asked about whether you really want to gamble again. There are people who get a kick, but after some time, that feeling migh pass again.* [Male participant, 44 years old]

Discussion

Principal Findings

This study aimed to deepen the understanding of the user experience of a nationwide, multioperator self-exclusion service, beyond what is known from recent quantitative research studies with web panel members and clinical data from patients in treatment for a gambling disorder. The potential challenges of a multioperator self-exclusion service have been demonstrated in surveys, showing that primarily among individuals with highly intense gambling practices, self-exclusion is popular but often breached by its users [13,14]. However, advantages of being self-excluded, and a deeper understanding of how this is related to the challenges of the method, largely remain to be understood.

Here, this qualitative study resulted in the description of 3 overarching categories that provide a deeper understanding of the problem: the main reasons for the decision to self-exclude, the advantages perceived by the users of this method, and the users' suggestions for improvements.

The decision to self-exclude from gambling platforms is often prompted by a sudden realization of escalating gambling behavior and a subsequent desire to regain control. Although the development of a disordered gambling pattern or financial difficulties were reported to have contributed to the decision to self-exclude, it was also reported, less expectedly, that self-exclusion may also be triggered by a wish to prevent another person from gambling on one's account. This may be a less expected reason for self-exclusion and will merit further investigation, especially in relation to the role of gambling in criminal behavior. Gambling or conducting financial transactions using somebody else's identity may represent one of the features of a severe gambling problem and also constitutes a criminal act [26].

Importantly, the role of the gambler's concerned significant others emerged as one of the reasons for self-exclusion. This highlights the importance of further addressing the interplay between individuals with gambling problems and their close ones and may also facilitate treatment processes if families of the affected individual are actively involved. This finding is consistent with previous research indicating that concerned significant others can favor treatment seeking and a favorable treatment outcome in their near ones with gambling problems [27,28]. In addition, the active participation of partners in the treatment of patients with a gambling disorder can be beneficial, both to the outcome of the affected patients and to the well-being of patients and their partners [29]. Thus, altogether, concerned significant others appear to play an important role through different phases of help seeking in individuals with problem gambling, even in the earlier harm-reducing interventions that self-exclusion is meant to represent.

Furthermore, the data showed that one reason for self-exclusion may be the intention to demonstrate one's willingness to quit gambling when formally applying for a public service where this is either required or believed to have an effect favoring the application process. This type of instrumental decision to self-exclude in order to obtain specific services or to fulfill expectations of external decision makers rarely has been reported in this context before. Whether this happens as part of an individual motivational process or entirely based on the requirements from others remains to be studied.

When external factors are cited as a reason to self-exclude, whether it be the concern of family members or the requirements from a treatment setting or authority, it can be argued that the choice to self-exclude does not represent the same decisive step in a motivational process as it does when an individual self-excludes based on their own decision to stop gambling in order to prevent or alleviate symptoms of addiction. Thus, the

XSL•FO
RenderX

possibly different levels of personal commitment associated with self-excluding will be relevant to include in the theoretical framework of self-exclusion in the future.

Overall, many favorable effects from self-exclusion were cited, despite previous experience where research has highlighted some major limitations of this service. Previous studies have been conducted using quite different methodologies, relying on larger quantitative data sets from online surveys [13,14] and clinical documentation [16], and where the findings were primarily the high rates of breaching one's self-exclusion within this service. This paper, importantly, adds to the literature regarding the present type of multioperator, nationwide self-exclusion service; in previous publications from this setting, it has been highlighted that the rate of breaching of one's self-exclusion is high in people with a gambling disorder [16] or with intensive online gambling patterns [14]. Here, several respondents described a large favorable impact on life after having self-excluded. Therefore, the description of more favorable experiences from this study provides a valuable experience, which contributes to the overall picture of this model, and strongly deepens the understanding of how this service fairs in affected individuals, over and above previous analyses conducted with quantitative methodology.

Although self-exclusion offered a respite from gambling-related stressors, several suggestions for improvements of the system emerged from the interviews. Participants emphasized the importance of holistic support systems and regulatory measures to augment its efficacy as a harm reduction tool. Suggestions for improvement partly followed what could be expected from previous web survey studies on gamblers; as many individuals who self-exclude also struggle with the risk of relapsing on overseas and nonlicensed gambling sites, users desired further legislative efforts making it possible to also self-exclude from other services, including those that are registered outside the present jurisdiction. Gambling in unlicensed, overseas online casinos has been reported to be the most common means of breaching one's self-exclusion period, as reported in the online surveys previously conducted here in this setting [13,14]. Thus, one major implication of this is the political process of how to exclude unlicensed gambling operators from the gambling market or to prevent financial transactions to gambling companies operating abroad. The legal framework and technical boundaries of this go beyond the scope of this study, but these findings highlight the need for gambling regulations to stretch beyond the controlling of the land-based gambling opportunity within each geographical jurisdiction.

One important and relatively novel suggestion was the linking between a mere harm-reducing self-exclusion service and actual therapeutic efforts against the addictive disorder. Importantly, this would move the purpose of the self-exclusion service from being an anonymous electronic support tool to actually providing a conduit to treatment. Treatment seeking in gambling disorder is known to be low, with several barriers reported [18]. Importantly, it has been reported that despite perceived barriers against treatment seeking, individuals with gambling problems may use more informal ways to seek help and not necessarily formal enrolment into psychotherapeutic treatment. For example, this may involve access to online advice or other online tools to facilitate a behavioral change [10]. In that aspect, any degree of referral from self-exclusion to different degrees of online support, advice, or treatment may be a way forward to improve the outcome of a person with gambling problems, over and above the effect of self-exclusion per se.

Such a system of transferring self-excluding clients to addiction treatment has not, to the best of our knowledge, been described in previous literature, and this may suggest a new area of research. For example, in such a system, it would have to be considered whether there is a potential barrier against enrolling in a self-exclusion service if it may, under some conditions, trigger a personal contact from a gambling operator, from a public authority, or from a treatment provider. However, it has been demonstrated that unsolicited motivational telephone calls to people displaying hazardous gambling habits may be a way to lower wagering and increase harm-reducing measures [30,31] and that acceptability of such motivational efforts appears to be high [32]. Thus, if self-exclusion from gambling would trigger an outreach effort aiming to improve the individual's gambling, it could be argued that this would not require a formal therapist-guided treatment but possibly may involve a brief, personalized intervention but with the capacity to refer individuals to further treatment when needed. Such individualized, personalized normative feedback has been suggested to be effective in other treatment or harm reduction interventions in problem gambling [33,34] and can initiate or enhance an internal motivational process in affected individuals, over and above the effects from the sole self-exclusion.

Likewise, another expansion of the self-exclusion tool, as suggested by this study, would be to slow down the procedure of opening up gambling opportunities after the self-exclusion period is terminated. This would also be a novel strategy that would require further study, but potentially, given the loss of the control component in gambling disorder, a more gradual onset of gambling after the self-exclusion period may provide further possibility to consider one's choice to gamble and may reduce the harm potentially associated with a sudden onset of high-risk gambling. Likely, any tool that slows down access to online gambling may potentially have a harm-reducing and relapse-preventing effect [35].

Overall, including the considerations made by interviewees in this study and their suggestions for improvement, a self-exclusion service generally appears to be promising and possible to increase even further. However, the major obstacle to this method, the risk of breaching one's self-exclusion through the use of gambling sites outside of the system, may remain. Here, one also has to consider the fact that the choice to self-exclude may cause the gambling patterns upon a potential relapse to happen on an unlicensed market and thereby with a lower degree of control than inside a licensed market. Previous experience, however, has pointed out that in individuals with extremely intense gambling patterns, such gambling patterns may happen on many operators, and a limit set upon one's gambling in one setting may be followed by gambling on another site. Still, even when this happens, such as during a deposit limit imposed during the COVID-19 pandemic in Sweden, still many clients report such a limit to be favorable and to have decreased their gambling pattern, rather than the

XSL•FO
RenderX

opposite [36]. Thus, although a method such as self-exclusion cannot hinder all types of gambling, it may still have motivational effects that limit the money lost and limits some of the consequences even in a high-risk gambling behaviour.

Strengths and Limitations

This study has a number of potential limitations, but given the novelty of the research topic and the merits of an in-depth qualitative study design, it also has considerable strengths. Recruitment via social media advertisements and digital interviews can be considered as both a strength and a limitation. The recruitment method enabled recruitment without any geographical limitations, therefore enabling a wide sample of individuals with different backgrounds, gambling habits, and experiences. However, it is possible that advertisements in social media attract interviewees with slightly different views on and experiences of self-exclusion from gambling than help-seeking individuals or individuals currently attending some type of land-based or online-based gambling venue. In contrast, the capacity of a qualitative design to identify a range of different aspects of a behaviour may benefit from this type of broad recruitment.

Digital interviews may represent another limitation, as these cannot readily be compared with physical interviews. Small changes in tone and body language are easily overlooked when the interview is held online. Meanwhile, the use of digital interviews in this study substantially facilitated data collection, widened the possibility to participate from the whole country rather than only locally, and may have facilitated recruitment of affected individuals who may not readily disclose their personal suffering and show up in person in a mental health–and addicion-oriented research unit. Indeed, challenges, but also potential advantages, of online qualitative research interview have been discussed in the research literature in recent years [37], pointing to the fact that such online interviews can play an important role in qualitative research.

Another potential limitation is the time aspect; some of the participants had recent or even ongoing experiences of Spelpaus, while others had been using it further back in time. Although this may be seen as a limitation, their information about their Spelpaus-related experience still is of great value (ie, as their ongoing or previous experience).

Additionally, the absence of a diagnosis of gambling gisorder as an inclusion criterion means that assessments of participants' gambling problems relied solely on self-reported statements and estimations, which may not capture the full spectrum of gambling-related issues. This limitation underscores the possibility that experiences with Spelpaus may vary based on individuals' level of gambling problems.

However, this study addressed a novel research issue and has strengths in a number of aspects. This is, to the best of our knowledge, the first qualitative study centered around the users' experiences of the relatively novel and unique nationwide self-exclusion service. Consequently, it offers updated and in-depth insights into gamblers' experiences with Spelpaus, elucidating its advantages and challenges as a harm reduction tool.

Conclusion

This qualitative study aimed to deepen the knowledge about and understanding of a novel nationwide service for self-exclusion from gambling. This includes the experience of individuals who have a history of being self-excluded, including their reasons for self-exclusion and their experience of the system's merits and challenges. Based on the interviews, this study suggests that although breaching one's self-exclusion remains a challenge, users of this service also report major advantages from being self-excluded. Users suggest further improvements to the self-exclusion model, such as international collaboration in order to prevent overseas gambling operators offering gambling outside of the self-exclusion system and also structured links from self-exclusion to further help and support, possibly also involving formal treatment. The study provided new information about self-exclusion and about a broader ranges of reasons for self-excluding, over and above the reporting of severe gambling problems (eg, the role of self-exclusion in the relationship with concerned significant others or to prove willingness to quit gambling). Several favorable effects from self-excluding were reported, in addition to a need for clearer obstacles against going back to gambling once self-exclusion ends.

Conflicts of Interest

AH has research funding for other projects from AB Svenska Spel, which is the state-owned gambling operator of Sweden, and from Svenska Spel's independent research council, as well as from the research council of Systembolaget, the Swedish alcohol monopoly. None of these organizations had any role in, or influence on, this project. The project itself was carried out thanks to funding from the research council of Svenska Spel. The funder did not have any influence on the procedures of this research or on the interpretation and reporting of results.

Abstract

Background: Peer support groups or web-based chats for young people offer anonymous peer support in judgment-free spaces, where users may share their thoughts and feelings with others who may have experienced similar situations. User engagement is crucial for effective web-based peer support; however, levels of engagement vary. While moderation of peer support groups can have a positive impact on the engagement of young people, effective moderation can be challenging to implement.

Objective: This study aimed to identify barriers and facilitators to user engagement with, and moderation of, web-based peer support groups among young people aged 16 to 25 years and to provide recommendations for enhancing this service.

Methods: Drawing upon the Theoretical Domains Framework (TDF) and the Behavior Change Wheel (BCW), this study conducted qualitative interviews and gathered open-ended questionnaires from service users and moderators of The Mix, the United Kingdom's leading web-based mental health platform providing peer support groups for young people. Semistructured interviews were conducted with 2 service users and 8 moderators, and open-ended questionnaires were completed by 7 service users. Themes were coded using the Capability, Opportunity, Motivation, and Behavior (COM-B) model and the TDF. The BCW tools were then used to identify relevant behavior change techniques to improve user engagement in, and moderation of, the service.

Results: Thematic analysis revealed a total of 20 inductive themes within 10 TDF domains—9 (45%) for engagement and 11 (55%) for moderation. Of these 20 themes, 3 (15%) were facilitators of engagement, 7 (35%) were facilitators of moderation, 4 (20%) were barriers to moderation, and 6 (30%) barriers to engagement. Results suggest that skills, knowledge, beliefs about consequences, intentions, emotions, and the social and physical environment are important factors influencing service users and moderators of group chats. In particular, supporting the improvement of memory, attention, and decision-making skills of those involved; adapting the physical environment to facilitate effective interactions; and reducing negative emotions are suggested to optimize the value and effectiveness of peer support groups for young people's mental health for both the service users and moderators of these services.

Conclusions: The study demonstrates the effectiveness of the BCW approach and the use of the TDF and COM-B model to understand the influences on behavior in a systematic manner, especially for mental health and well-being interventions. The findings can be applied to design structured interventions to change behaviors related to the engagement with, and moderation of, web-based peer support groups and, in turn, improve mental health outcomes for young people.

Introduction

Background

Young people aged 16 to 25 years are particularly vulnerable to mental health difficulties [1]. Recent evidence shows an increase in reported mental health problems for young people aged 16 to 25 years, particularly following the COVID-19 pandemic [2,3]. For example, in young people aged 17 to 19 years in England, rates of probable mental disorders rose from 17.7% in 2020 [4] to 23.3% in 2023 [5]. Nevertheless, health care systems and support often overlook the needs of young people [6]. In the United Kingdom, 75% of young people experience delays in accessing mental health support, leading to a worsening of their condition [7].

Web-based mental health communities are a viable option to bridge the mental health service gap for young people. They offer anonymous peer support in judgment-free spaces, where users may share their thoughts and feelings with others who may have experienced similar situations [8]. Web-based peer support can be asynchronous or synchronous, providing online support in a group format, with or without moderation [9,10]. Synchronous or real-time support, such as web-based chats, provides users with in-the-moment assistance without the delays that can occur within asynchronous services [11,12]. Notably, studies have shown the efficacy of web-based peer support platforms compared to in-person talk therapies [13]. They offer clinical effectiveness [14] and scalability for public health impact, enabling outreach to a larger population [13]. Therefore, there is a strong argument for the use of web-based peer support platforms for young people as they address key barriers and hold the potential to enhance mental health treatment by providing a safe, accessible, and effective means of support.

Despite numerous benefits, studies have also highlighted challenges to web-based peer mental health support that limit its effectiveness [15], including varying engagement rates [14]. Low rates of engagement can lead to negative outcomes, such as perceived exclusion and isolation [16], whereas high rates have been found to improve young people's mental health [17]. Effective moderation of web-based, user-led mental health services has been found to improve user engagement [18]. However, there are few studies examining user engagement in, and moderation of, synchronous web-based peer support groups, especially capturing the perspectives of both service users and moderators [11,19]. Service users, with their lived experience of giving and receiving support, can offer valuable insights and suggestions for improving these platforms. Moderators, due to their proximity to users and responsibility for supporting positive interactions, safety, and engagement [14], may have practical insights to enhance platform effectiveness [20]. A systematic examination of these behaviors from different viewpoints would enable the identification of tailored intervention strategies to improve moderation of web-based peer support services and enhance user engagement. Using the Behavior Change Wheel (BCW) [21], this qualitative research study investigates the barriers and facilitators to user engagement and moderation for web-based peer support groups among young people aged between 16 and 25 years and then proposes tailored strategies for optimization.

User Engagement in Web-Based Peer Support

Digital health research has defined user engagement as the extent and subjective experience (characterized by attention, interest, and affect) of use [22]. Studies measure engagement in terms of use time, log-ins, or module completion [23,24], with approximately 60% of studies measuring attendance alone to assess engagement [25]. However, although passive involvement or observational participation in web-based peer support groups has recognized benefits [26], considering only attendance falls short as it omits active participation and interaction, which fosters the sense of community and support unique to this service. Therefore, this study considers engagement in the broader sense, incorporating any observable written contribution, such as comments expressing thoughts and feelings or support for others. This inclusive approach captures subjective experience, aids barrier and facilitator identification, and can inform interventions for enhanced meaningful engagement.

Previous research highlights key barriers and facilitators to young people's engagement with digital mental health interventions and services [27,28]. Barriers include interventions that are perceived as unappealing or unhelpful, technical issues, privacy concerns, and young people lacking time or remembering to use the intervention. Facilitators include the personalization and flexibility offered by digital interventions, along with effective design, usability, opportunities to build connections, and the potential for a rewarding user experience [27,28].

However, there is a gap in research examining influences on young people's engagement in synchronous web-based peer support groups for mental health. Barriers and facilitators are likely to differ from those in other digital mental health services, as peer-to-peer support is viewed as less stigmatizing and more relatable [29]. In addition, synchronous interactions have a different pace compared to other formats [11]. Recent research focusing on peer-to-peer chats has centered on moderators' roles without including service user voice [30].

Moderation of Web-Based Peer Support

Moderation involves managing content, safeguarding, and providing support to users when needed [18]. It can be carried out by health professionals or trained volunteers [19]. Effective moderation has been found to have a positive effect on user engagement and has also been helpful in preventing "toxic" web-based settings [18]. Negative effects of web-based platforms such as trolling and stalking may also be prevented by effective moderation [16]. In web-based chat groups and

XSL•FO
RenderX

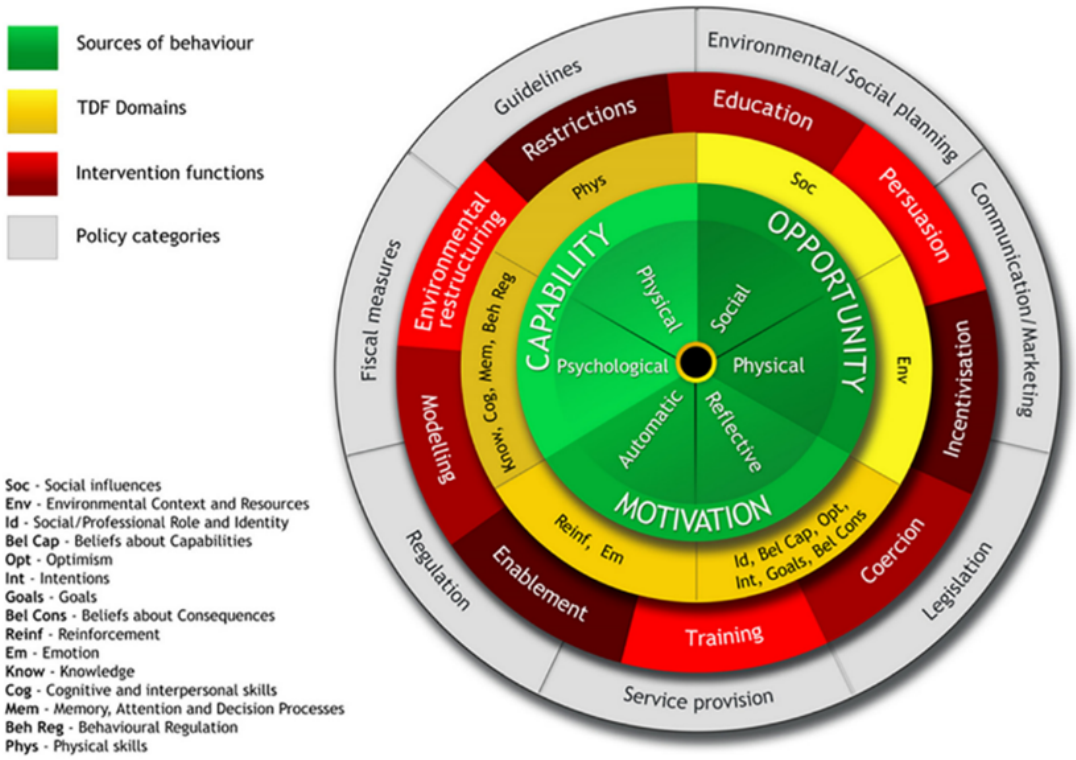
discussion forums, moderators ensure adherence to group guidelines to enhance user safety and prevent service users from becoming overly dependent on one another [31,32].

There has been limited research on the moderation of web-based mental health interventions [19]. Synchronous group settings pose distinct challenges as they require real-time monitoring of the chat and interaction between peers and moderators. In a recent study, Deng et al [30] explored moderation of peer support for a web-based mental health community. In this study, although moderators were qualified mental health professionals, they experienced challenges, such as dealing with emotionally triggering problems or hostile users. In a similar environment, Saha et al [33] highlighted challenges, such as a lack of concern for moderators' well-being and moderators' uncertainty about when to intervene. However, the services examined in these studies were not specifically designed for young people. Thus, there is a need to understand moderation and, importantly, how to enhance it, particularly in the context of real-time group chats for young people moderated by young volunteers, in a way that is structured and rooted in theory.

To address these research gaps, this study triangulates moderator and service user perspectives using a theoretically based behavior change approach, providing a comprehensive examination of user engagement and the moderation process in synchronous web-based mental health peer chats. The BCW provides a systematic and comprehensive framework to enhance understanding of behavior and support the identification of linked, relevant behavior change techniques (BCTs) to address the identified barriers and optimize group chat engagement [21].

BCW Framework

The BCW comprises interconnected tools to guide decision-making and facilitate the systematic development and evaluation of behavioral interventions [21]. At its center lies the capability, opportunity, motivation, and behavior (COM-B) model of behavior, which supports the identification of the barriers and facilitators to a behavior (Figure 1 [21]). Capability refers to an individual's physical as well as psychological capacity to perform a specific activity. Motivation is the cognitive processes that drive human behavior. Finally, opportunity refers to external factors that are outside the individual and may facilitate behavior.



The components of COM-B can be further elaborated into 14 domains using the Theoretical Domains Framework (TDF), providing a more granular understanding of the influences on behavior [34,35]. In the next layer of the BCW are intervention functions, which are the broad categories of means by which an intervention can change behavior. The outer layer consists of policy categories to support long-term, system-wide implementation.

The Behavior Change Techniques Taxonomy (BCTT) comprises 93 observable and replicable BCTs. The BCTT is a reliable method for specifying, interpreting, and implementing BCTs, which are considered "active ingredients" to facilitate behavior change either alone or in combination [36]. Expert consensus allows for mapping of the COM-B and TDF domains to intervention functions and corresponding BCTs, guiding appropriate strategies for change [37].

The BCW approach has been successfully applied in previous research to understand the barriers and facilitators to the use and delivery of digital mental health platforms for young people, including webchat counseling [28,38] and moderation of self-harm content in web-based discussion boards [39].

Figure 1. The Behavior Change Wheel and Theoretical Domains Framework (TDF) (adapted from Michie et al [21]).

This Study

Given the lack of research in this area, this qualitative study systematically explores the barriers and facilitators to the user engagement and moderation of synchronous web-based peer group chats for young people and proposes evidence-based strategies for improvement. Data were gathered from open-ended questionnaires and in-depth, semistructured interviews with young service users and moderators of The Mix, a web-based mental health support service for young people aged <25 years. Using the BCW [21], the following research questions were addressed:

1. Using the COM-B and TDF, what are the barriers and facilitators to young people's engagement in web-based peer support groups?
2. Using the COM-B and TDF, what are the barriers and facilitators to moderation of web-based peer support groups?
3. Using the BCTT, what strategies can be used to improve user engagement in, and moderation of, web-based peer support groups for young people's mental health?

Methods

Participants

This study collected data from service users and moderators of The Mix, the United Kingdom's leading digital mental health support service for young people aged <25 years. The Mix offers free mental health support, including a helpline, phone and webchat counseling, crisis support, discussion boards, and moderated live group chats. These synchronous group chats are freely available for young people aged 13 to 25 years. Table 1 summarizes the peer-to-peer mental health group chats of The Mix analyzed in this study.

The Mix circulated a poster to moderators (total population of 52) and service users to promote participation. Interested participants contacted the researcher through email, and their involvement was entirely voluntary. As shown in Table 2, a total of 2 service users were interviewed, and a further 7 service users completed an open-ended questionnaire about their engagement. A total of 8 moderators (n=5, 63% staff and n=3, 38% volunteers) participated in interviews about moderation. Of these 8 moderators, 4 (50%) staff members and 1 (13%) volunteer also completed a separate interview about user engagement. As this was a qualitative study, it aimed to gather rich and detailed data from participants, similar to previous studies in a similar context [38,39], rather than to achieve a representative sample.

All moderators were women, while most of the service users were either women or did not self-identify their gender, with the exception of 1 man and 1 nonbinary service user. Moderators were aged between 19 and 30 years, and service users were aged between 18 and 24 years (Table 2). Moderators were involved with The Mix ranging from 6 months to as long as 8 years and worked for 1 to 2 hours per week.

Semistructured interviews, based on the TDF, were conducted via the Microsoft Teams platform and transcribed for analysis. The interviews lasted between 30 to 60 minutes each and were designed to gain in-depth service user and moderator insights into experiences of group chats regarding peer interactions, structure of the chats, and feelings about contributing. Questions included, for example, "How long do you spend on The Mix's chat per week?" and "How do other people in the group chat

XSL•FO
RenderX

make it easier or more difficult for you to share your thoughts, feelings and experiences or support others with theirs?" Questions for moderators only included the following: "How do other people influence how you contribute to the moderation of posts on the group chats?"

For user engagement only, participants were offered the alternative option to complete an open-ended Microsoft Forms questionnaire to combat any difficulties young people felt in expressing themselves in an interview and may have hindered participation [28]. The questionnaire included 5 open-ended questions, exploring what made it easier or harder for users to share their experiences, what influenced their decision to participate or not, and what changes they would make to the chat if given the opportunity.

Table 1. The Mix's peer-to-peer mental health chat groups.

Group chat type	Description	Participants, n	Structure	Participation	Privacy	Moderation
Support chat	Peer support for mental health struggles	Variable	Open discussions	Active participation	No sign-up required, no password protection	Moderated by trained young volunteers and staff
Support circle	More intimate setting, where everyone takes turns to obtain support while the rest of the group listens	≤5	Rotating support and sharing	Sign up to receive support or as a "listener"	Password protected, full session attendance	Moderated by trained young volunteers and staff

Data Analysis

Data were thematically analyzed using the 6-phase process developed by Braun and Clarke [40]. NVivo (Lumivero) and Excel (Microsoft) were used as analytical tools. The initial stage involved gaining familiarity with the transcribed interviews. A deductive coding approach was adopted initially, which involved reviewing items of data from the transcripts and questionnaires and organizing them into the TDF domains, providing a "start list" [41,42] of themes to be categorized as barriers or facilitators. The process was repeated using an inductive analysis to generate specific subthemes within each TDF theme. These subthemes were then reviewed, defined, and included in the codebook [43]. A codebook was developed to facilitate coding and was iteratively updated. As new data were added to TDF domains, facilitators and barriers were modified, expanded, or recategorized using the constant comparison method to identify patterns and variations within the dataset [44]. Triangulation

XSL•FO
RenderX

was completed with data from both service users and moderators to explore consistencies and contradictions in influences on young people's engagement with group chats. Reflexivity was prioritized to ensure openness and challenge in interpretations [45]. To ensure coding reliability and validity, 2 researchers independently cross-coded 1 transcript; a reliability check was conducted, and agreement was reached on any discrepancies.

Following data analyses, the coded TDF barriers were mapped to corresponding intervention types, using the BCW, and then specific BCTs were selected using the links specified in Cane et al [46] as well as the more recently developed Theory and Techniques Tool [47,48]. The selection of the relevant and appropriate intervention types and BCTs was informed by an appraisal of the affordability, practicability, effectiveness and cost-effectiveness, acceptability, side effects, and equity criteria [21]. This approach has been used in a multitude of studies [49,50] to evaluate intervention strategies. The selection of policy options was out of scope because the study was focused on a single organization rather than system level. Finally, the BCTs were operationalized, and intervention strategies were proposed based on a review of previous literature.

Ethical Considerations

Low-risk ethics approval was obtained from the University College London Ethics Committee (Z6364106/2023/03/149 social research, 25069/001). Participant information and a consent form were provided to interested parties to sign digitally and confirm consent. Participants were advised that participation was completely voluntary and they could withdraw at any time, up to 4 weeks after their data were collected. As reimbursement for the interviews, participants were given a £10 (US $12.45) voucher. Questionnaire respondents could opt into a lottery prize draw to win 1 of 2 £10 (US $12.45) vouchers by providing their email address. To protect participant privacy and confidentiality, data were fully anonymized.

Results

Overview

Table 3 sets out the themes identified as both barriers and facilitators to user engagement and moderation. These are set out according to both COM-B and TDF frameworks.

Table 3. The COM-B[a] and TDF[b] themes and subthemes for user engagement and moderation.

COM-B and TDF themes	User engagement subthemes	Moderation subthemes
Psychological capability		
Cognitive and interpersonal skills	• Difficulty expressing feelings and needs (barrier) • Skills to listen and validate (facilitator)	• Developing skills (facilitator)
Knowledge	—[c]	• Understanding the guidelines (facilitator)
Memory, attention, and decision-making	• Memory recall of guidelines (barrier)	• Responding quickly in complex situations (barrier)
Behavioral regulation	—	• Holding back on advice (barrier)
Reflective motivation		
Beliefs about consequences	• Judgment and confidentiality concerns (barrier)	• Impact of moderation (facilitator)
Social and professional role and identity	—	• Congruence between social and professional identity (facilitator)
Intentions	• Wanting to support others (facilitator)	• Intending to shape young people's perceptions (facilitator)
Automatic motivation		
Emotions	• Fear and anxiety (barrier)	• Distressing subject matter (barrier)
Physical opportunity		
Environment, context, and resources	• Overload and lack of structure (barrier)	• Organizational resources (facilitator) • Lack of visual cues (barrier)
Social opportunity		
Social influences	• Similarity and familiarity (facilitator) • Integration of new users and gaps in support (barrier)	• Support offered (facilitator)

[a]COM-B: Capability, Opportunity, Motivation, and Behavior.

[b]TDF: Theoretical Domains Framework.

[c]Not applicable.

Young People's Engagement

As shown in Table 3, a total of 9 barriers and facilitators were identified as subthemes across 7 domains of the TDF. Themes were mainly consistent across support chat and support circle responses, but a small number of differences arose between the 2, and these are indicated, where relevant, in the following subsections.

Cognitive and Interpersonal Skills (Psychological Capability)

Difficulty Expressing Feelings and Needs

Several service users and moderators described the difficulty users face in expressing their emotions and thoughts, which can prevent them from opening up in the chat. Subthemes are described below, together with illustrative quotes. Service user quotes are indicated by "SUX," volunteer moderator quotes are indicated by "MVX," and staff moderator quotes are indicated by "MSX," where "X" is the participant number, to identify each participant as per Table 2. One user commented the following:

> *[What makes it more difficult to open up is] not being able to express myself about feelings.* [SU8]

Moderators also noted that vague statements about one's emotional state without specific requests for support may be a barrier to others' engagement, as they provide insufficient guidance for other users to offer relevant support. For example, one user stated the following:

> *I think it depends on how someone phrases the question...if they're sort of saying, "And I'm feeling really low today" or "And I can't do this anymore," like some of those trickier comments.* [MV5]

Skills to Listen and Validate

Both moderators and users identified that having skills to effectively validate and listen to others facilitated peer support and engagement. One moderator noted the following:

XSL•FO
RenderX

> *The people that tend to offer the most peer support are those that...know how to validate someone's experiences.* [MS1]

Users described how they did this, with one user stating the following:

> *Everyone listened and waited their turn...I listened to others, and they encourage people waiting their turn to help others.* [SU6]

Personal experiences that related to others' struggles made it easier to connect and offer support, but 1 user stated the following:

> *There are some situations where I can't exactly relate...so I stay quiet.* [SU5]

Memory, Attention, and Decision Processes (Psychological Capability): Memory Recall of Guidelines

Difficulties in absorbing, retaining, and applying guidelines posed a significant barrier to a couple of users. Users indicated that they struggled to remember guidelines due to content volume, distractions, and cognitive limitations, impacting their ability to engage. Even long-term users found it challenging, with 1 individual expressing the following:

> *I can't actually remember what [the guidelines are]. They're very basic from what I do remember.* [SU1]

Mental health crisis situations further exacerbated guideline oversight, leading some users to unintentionally deviate from the chat's intended mode of engagement in the moment. Moderators noted that this issue was worsened by some users, particularly regular ones, who found the guidelines unengaging and tended to ignore them.

Beliefs About Consequences (Reflective Motivation): Judgment and Confidentiality Concerns

This was a barrier revolving around young people's apprehensions about being judged, misunderstood, or facing negative reactions when sharing personal thoughts and experiences, particularly in the presence of new members. One participant stated the following:

> *Some people feel like a new person may judge more or less or may be offended more or be offended less. So [withdrawing] very much sort of safeguarding themselves, protecting themselves, and protecting others.* [SU1]

This could also lead users "to not give too much information" (SU7). Similarly, a moderator highlighted concerns about users fearing judgment, with 1 moderator stating the following:

> *...judging that person for talking about that cause I think that's probably what they worry about quite a lot.* [MV5]

Both moderators and users mentioned concerns about confidentiality, giving examples of where their privacy was violated by other members, leading to negative consequences. As a result, they became hesitant to share. One moderator stated the following:

> *Some members also worry confidentiality will be broken so they don't open up in fear of the police being called.* [MS2]

Intentions (Reflective Motivation): Wanting to Support Others

Overall, the intention to create a supportive environment was a facilitator, which motivated users to engage to support others. One user expressed the following:

> *Most of the time, I try my best to offer support and be there for the person too. I just want people to be able to open up to me, and when they do, I try to be a good friend.* [SU2]

However, moderators were concerned that some users may prioritize self-support, limiting their involvement in supporting others and welcoming newcomers. One moderator stated the following:

> *Often times, the young people are so busy sharing their own experiences that they don't make enough space to support others who may be going through a similar thing.* [MS1]

Emotions (Automatic Motivation): Fear and Anxiety

A frequently mentioned barrier by both users and moderators related to the user's fear of being perceived as a burden by sharing their thoughts, feelings, and experiences. One user expressed the following:

> *As for not opening up so much that's more when I feel like I'm a burden and not wanted, but that's me not The Mix.* [SU4]

Users identified that "Worrying what people think" (SU7) in terms of oversharing or repeating themselves caused them to hold back or stop sharing altogether. Another user shared similar sentiments, noting that opening up more "doesn't really make me feel better, it just makes me anxious and guilty" (SU2). These feelings of self-doubt and anxiety hindered users from fully opening up and receiving the support they needed.

Environmental Context and Resources (Physical Opportunity): Overload and Lack of Structure

A barrier identified by almost all participants was the lack of structure and organization within the support chat, especially during busy times. This could result in confusion, overwhelm, and a sense of disorganization. Users sometimes struggled to fully engage and provide or receive support effectively because, as 1 user said, "When you have a lot of people, you do get to a point where you do have like five, ten different conversations going on, all different levels of importance so it does get a bit confusing" (SU1) and "It can be hard to type that fast" (SU6). One moderator added the following:

> *It can be hard for someone to post, and their message may get missed.* [MV5]

Another user highlighted the following:

> *Support Chat needs to be more organized...The way it currently is...stresses me out, I find myself leaving midway most of the time.* [SU9]

XSL•FO
RenderX

Social Influences (Social Opportunity)

Similarity and Familiarity

The presence of individuals who had experienced similar situations or who were known to each other was highlighted by moderators and users as helping foster a sense of belonging and encouraging engagement. One user noted the following:

> *It helps that there are people who know what you've been through, so you don't feel alone. It makes you feel more comfortable to open up.* [SU1]

It was seen to be "Easier to have people with similar problems and get ideas surrounding mental health teams etc." (SU3). Several long-term users also highlighted that regular participation by both users and moderators builds trust and familiarity, facilitating engagement. One user stated the following:

> *Because we've been with [the moderators] for some time, they understand our situations a little bit more so it makes it easier for us to open up to them and...we can trust them.* [SU5]

Moderators shared similar insights, noting that regular users "feel quite attached to the moderators, so they'll leave support circle and join support chat for a bit and then come back" (MV5).

Integration of New Users and Gaps in Support

A frequently mentioned barrier by several members and most moderators related to how some regular users tended to chat among themselves or with the moderators, making it difficult for new users to integrate into the group. This could lead to new users feeling like outsiders and being less likely to engage. One user stated the following:

> *When I first started coming to circle, it was very awkward for me because the other people in there had been doing it a lot longer and I felt like a bit of an outsider.* [SU5]

New users described not receiving responses to messages, which seemed to have a notable impact on them. One of them stated the following:

> *What prompts me to withdraw is when some of my messages get ignored. I know it's not on purpose but it kind of makes me feel unwanted.* [SU4]

This was a theme that was also recognized by multiple moderators as a deficiency in social support.

Moderation

As shown in Table 3, a total of 11 barriers and facilitators were identified as subthemes across 10 domains of the TDF. The following paragraphs describe the themes in more detail, along with selected quotes.

Cognitive and Interpersonal Skills (Psychological Capability): Developing Skills

Most moderators discussed how they developed their skills over time through a continuous learning process, which helped them become more effective and refine abilities such as active listening and conflict management:

> *But it's like a continuous learning process, so I wouldn't say they give you kind of training at the beginning of you know, how to be an active listener and how to give that specific type of support.* [MS1]

Observing and practicing moderating also helped develop the necessary skills for moderation. One moderator expressed the following:

> *I think a lot of it is just sort of the exposure and just sort of the repeated attendance of chats and you sort of build, you work out sort of what things you've said have gone down well.* [MS7]

Knowledge (Psychological Capability): Understanding the Guidelines

Knowing and understanding the guidelines and procedures laid out by The Mix was a recurrent enabling theme of moderation, mentioned by all moderators, facilitating the identification of what is and is not deemed inappropriate. One moderator expressed the following:

> *And then the handbook also has things around the tech side of things, so using the platform how to use the moderator functions as well, so we're able to mute people. We're able to freeze them and then remove them from the room as well.* [MS3]

The guidelines were also particularly helpful for directing individuals at risk through appropriate safeguarding procedures. One moderator stated the following:

> *"It's got things from and sort of managing young people that come in who are in crisis. So many kinds of questions to ask safely within the room and the kind of signpost we can give.* [MS2]

Memory, Attention, and Decision Processes (Psychological Capability): Responding Quickly in Complex Situations

The complexity of group chats acted as a barrier for most moderators, presenting challenges by their fast-paced nature and situations that moderators may not have come across before. Attentively responding to the chats becomes challenging. One moderator expressed the following:

> *But there's only so fast you can type, and only so many conversations you can kind of have going on at once that you can't talk to everybody.* [MS8]

In addition, dealing with novel or gray situations caused confusion about what is acceptable in the chat and what is not, making decision-making difficult. One moderator stated the following:

> *There's still some situations that catch me off guard. You know, some people saying things that I've not come across before, experiencing things that I've not come across before.* [MV5]

XSL•FO
RenderX

Behavioral Regulation (Psychological Capability): Holding Back on Advice

Having a natural inclination to offer advice made it difficult for some moderators to self-monitor their responses. Going against instincts and refraining from giving advice when young people shared their problems required self-monitoring of behavior. One moderator expressed the following:

> *It is like to go against that nature and leave it open to the room to support each other and not give advice.* [MS1]

As moderators found it difficult to hold back, effective moderation became challenging. One moderator stated the following:

> *We can't give medical advice, it's tough...we shouldn't really be saying (giving advice) to someone.* [MV5]

Belief About Consequences (Reflective Motivation): Impact of Moderation

Overall, the perceived outcome of moderation for young people, as understood by moderators, facilitated their moderation. Moderators had different beliefs on the impact that moderation had on young people. Some believed that moderation helped create a safe space. One moderator expressed the following:

> *I think young people find it really reassuring to have, like, moderators there because there's a lot of online support spaces, but they're not always moderated or kept safe.* [MS2]

Some moderators felt that young people could feel left out and unsupported. One moderator stated the following:

> *And sometimes the young people can feel like the moderators are not responding to them.* [MS3]

The vast coverage of the impact of moderation was also highlighted by moderators. One moderator expressed the following:

> *I think you do notice the impact because it covers everything OK, like mental health is the main domain. But it's also like everything like education, careers, drugs and alcohol. Just like everything that someone could be going through. So I think you do notice a wider impact.* [MV4]

Social or Professional Role and Identity (Reflective Motivation): Congruence Between Social and Professional Identity

The alignment of personal values and social identity with the professional role of a moderator facilitated moderation for all moderators. One moderator expressed the following:

> *I love volunteering and I love working in a church in the voluntary sector and working with charities. So and I like working with young people. A lot of my work has been with young people. So and yeah, I think it does. It does fit in that respect personally.* [MS3]

The role of a moderator aligned with the identity that moderators had built for themselves. One moderator stated the following:

> *I also work in mental health in my 9 to five job, so that really helps and that's why I wanted to start it in the first place because I started the chat at university and I was trying to broaden my experience working with people with mental health conditions.* [MS7]

Intentions (Reflective Motivation): Intending to Shape Young People's Perceptions

Some moderators expressed a deliberate intention to shape and manage young people's perceptions and expectations of the chat. One moderator expressed the following:

> *I've tried over the years to change the young peoples' perception of what the chat should be used for, I think that in the spirit of trying to make it more of a group conversation like a group chat.* [MS1]

This intention served as a strong facilitator for moderators. One moderator stated the following:

> *So I guess how we manage those situations, yeah, we can warn community members like, we encourage them to take a step back and let the moderators manage the situation. And yeah, we always let them know like they might be removed from the room if they don't like, listen to us.* [MS2]

Emotion (Automatic Motivation): Distressing Subject Matter

Most moderators identified that topics discussed in group chats, such as self-harm and suicidal thoughts, could take an emotional toll on moderators and cause stress and exhaustion. One moderator stated the following:

> *The topics that are being discussed are quite distressing. Examples are feeling very, very low and sometimes it becomes a bit of an echo chamber of you know, they're all talking about feeling like they want to end their life or feeling like self-harming.* [MS1]

These topics also gave way to discussions about the larger mental health ecosystem and evoked concern among the moderators for the young people. One moderator expressed the following:

> *Hard when you see them struggling. And so yeah, I think when that happens, you like worry quite a lot and it does kind of be on your mind for like a few days.* [MS2]

These distressing thoughts and related feelings inevitably acted as a barrier for moderators.

Environmental Context and Resources (Physical Opportunity)

Organizational Resources

The multitude of resources provided by The Mix was appreciated by all moderators. These encompassed guidelines, debrief forms, newsletters, and more, helping them moderate effectively. One moderator stated the following:

XSL•FO
RenderX

> *It really helps to have that handbook there to walk you through those guidelines and how to respond.* [MS3]

Moderation was facilitated through the ready availability of these resources, providing moderators with content that could be used in the chat. One moderator expressed the following:

> *And we have our Mod handbook which is really helpful in terms of giving us like example messages to pop in the group chat and to manage certain situations.* [MS7]

Lack of Visual Cues

Working in a web-based environment meant that moderators had to work without any visual cues, such as facial expressions. One moderator stated the following:

> *I think moderating is quite a unique task...especially when it's online.[MS2]*

This absence made it difficult for moderators to gauge the intensity of young people's emotions and thus required extra effort and attention, which could be a barrier for some moderators. One moderator expressed the following:

> *I guess you have to put a bit of extra effort into that because you don't have the visual cues of like, nodding and all that stuff.* [MS1]

Social Influences (Social Opportunity): Support Offered

Support offered during and after moderation (eg, support from supervisors and emails checking up on moderators) acted as an enabling influence. All respondents had an overwhelmingly positive response toward the support that they received from their supervisors and believed that this support helped them moderate. A respondent stated the following:

> *[The Mix] never makes you feel unappreciated. Like we get quite regular emails of just a reminder that you're all doing really good things...and I think yeah, when you have had a difficult chat and sort of things, they're feeling a bit hard, just things like that really make a difference.* [MS7]

In addition, volunteers reported that the presence of a supervisor in the chats made moderation easier. One moderator stated the following:

> *The moderator would flag it to the supervisor on shift and just say you know ohh it looks like these two are having a bit of a disagreement. What should we do?* [MS1]

One moderator expressed the following:

> *They are really understanding about wanting someone else to step in with a conversation that hits too close to home or needing 5 mins to yourself during the session. There is also a debrief form and if I say anything I felt unhappy with, they always chase it up to check on me or ask if I want more training in the area.* [MV6]

BCTs to Address Barriers

To optimize user engagement, Table 4 presents the BCTs identified to address the core barriers and enhance the facilitators, along with examples.

Table 5 shows the potential intervention types along with the corresponding BCTs to overcome the identified barriers to moderation.

XSL•FO
RenderX

Table 4. Barriers to engagement and strategies for change.

TDF[a] domain	Barrier	Intervention types	Potential BCTs[b]	Operationalization of BCTs
Cognitive and interpersonal skills	Difficulty expressing feelings and needs	Training	Instruction on how to perform a behavior (4.1[c]); behavioral practice/rehearsal (8.1)	Self-reflection worksheets: provide optional worksheets with guidance on identifying emotions and the support needed before users' participation in the group chat.
Memory, attention, and decision processes	Memory recall of guidelines	Enablement	Commitment (1.9)	Group agreement (in the support chat): collectively agree to abide by principles and behaviors aligned with the guidelines at the start of the support chat.
Memory, attention, and decision processes	Memory recall of guidelines	Education	Prompts/cues (7.1)	Reminders: implement periodic reminders or prompts about the chat guidelines to reinforce their importance and improve memory recall.
Beliefs about consequences	Judgment and confidentiality concerns	Education	Information about emotional consequences (5.6)	Share success stories: highlight success stories or testimonials from other young individuals who have benefited from engaging in peer-to-peer group chats.
Emotions	Fear and anxiety	Enablement	Reduce negative emotions (11.2)	Clarify burden misconceptions: provide information and resources from peers about the value of sharing and supporting each other, and share examples of challenges discussed by previous service-users in groups chats to address misconceptions that sharing is a burden and facilitate engagement.
Environmental context and resources	Overload and lack of structure	Environmental restructuring	Restructuring the physical environment (12.1)	Group similar topics and establish topic rotation: encourage moderators and members to brainstorm and group similar topics together either during the support chat (eg, via a poll website such as Slido) or before the chat (eg, via a poll on the discussion boards), allowing for more focused and meaningful discussions instead of fragmented conversations (alternative: create more themed chat sessions).
Environmental context and resources	Overload and lack of structure	Environmental restructuring	Restructuring the social environment (12.2)	Limit chat size: implement a cap on the number of members allowed in the support chat at 1 time to maintain a manageable and supportive group size.
Environmental context and resources	Overload and lack of structure	Environmental restructuring	Adding objects to the environment (12.5)	Emoticons: consider moving to a new chat software that enables members to offer immediate reactions to others' messages via emoticons rather than messages.
Social influences	Integration of new users and gaps in support	Enablement	Social support (unspecified; 3.1) and social support (practical; 3.2)	Buddy system: assign new users a designated "welcoming buddy" (peer) whose role is to encourage or practically facilitate interactions during their initial sessions; grouping or pairing system: pairing or grouping members in the chat as each other's dedicated "supporters" for the session to enhance peer support and encourage more engagement.

[a]TDF: Theoretical Domains Framework.

RenderX

Table 5. Barriers to moderation and strategies for change.

TDF[a] domain	Barrier	Intervention types	Potential BCTs[b]	Operationalization of BCTs
Memory, attention, and decision processes	Responding quickly to complex situations	Training	Behavioral practice/rehearsal (8.1[c])	Practice sessions: create practice moderation sessions that simulate the quick nature of group chats, which could help moderators to enhance their attention and decision-making processes.
Behavioral regulation	Holding back on advice	Training	Self-monitoring of behavior (2.3)	Diaries: ask moderators to make a note of situations and monitor when they feel instinctively inclined to offer advice to avoid it in the future.
Emotion	Distressing subject matter	Enablement	Reduce negative emotions (11.2)	Positive messaging: providing information about the positive impact of moderation through regular updates (eg, weekly or biweekly emails such as "Here's the impact that you helped deliver!") to increase moderators' positive emotions and reduce concerns about young people.
Environmental context and resources	Lack of visual cues	Environmental restructuring	Prompts/cues (7.1)	Phrase book: prompts or cues may be provided to compensate for the lack of visual cues. A booklet of phrases or "words to look out for" may be provided such that moderators may look out for these words to gauge if an individual is at risk, which may otherwise be missed.

Discussion

Principal Findings

This study addresses a research gap by investigating the influences on engagement with, and moderation of, synchronous web-based peer support group chats to support young people's mental health. Using the BCW framework, thematic analysis revealed a total of 20 themes, 9 (45%) for engagement and 11 (55%) for moderation. Of the 20 themes, 3 (15%) were facilitators of engagement, 7 (35%) were facilitators of moderation, 4 (20%) were barriers to moderation, and 6 (30%) were barriers to engagement. The following discussion focuses on the COM-B and TDF themes that were prominent and common across both user engagement and moderation. The findings of this study are discussed in relation to previous research, and the potential BCTs to address the identified barriers to engagement and moderation are contextualized.

Facilitators Common to Moderation and Engagement

Cognitive and interpersonal skills and knowledge (psychological capability) enabled users to express their feelings and needs. Both moderators and users benefitted from having the skills to listen and respond to other users. Moderators developed these skills through practice and were supported by a strong knowledge and understanding of the chat guidelines. Similar themes have been found in other modes of web-based mental health support [39].

Intentions (reflective motivation) were also core themes for moderators and users—both were driven by their desire to help others and ensure that the chat was a valuable resource for users. This sentiment is echoed elsewhere in the literature on web-based support groups, where listeners aimed to create a "safe and warm" space for their clients [51]. Similarly, moderators in this study consciously resolved to provide a safe and nonjudgmental space for young people. This is a theme that can be seen elsewhere in the literature, relating to other web-based peer mental health communities [30].

Finally, for both engagement and moderation, social influences (social opportunity) was another facilitator, where other users, moderators, or supervisors were seen as understanding, supportive, and appreciative of others' needs. For users, this meant being able to share experiences in a safe environment, and moderators felt valued, appreciated, and encouraged in their moderation. Such support also promotes moderators' mental health. As has been previously suggested by Aldamman et al [52], perceived organizational support was positively related to mental well-being, reduced emotional exhaustion, and reduced stress among humanitarian volunteers. This aspect is also linked to the potential of moderators to contribute to the enhancement of the mental well-being of service users, as demonstrated by Perry et al [19].

Barriers Common to Moderation and Engagement

Group chats present a complex environment due to their dynamic and fast-paced nature, with multiple users. Users could find it difficult to remember and adhere to the guidelines, especially in pressurized situations (eg, crises). Although moderators were familiar with the guidelines, they found it challenging to make real-time decisions, particularly during busy chats when many users were interacting rapidly with one another. This inherent complexity can function as a barrier to effective moderation and engagement. With a continuous inflow of new messages in group chats, it becomes challenging to focus on messages and identify any specific theme, as noted by Li et al [53]. Moderators in this study also encountered difficulties in promptly and accurately assessing messages for potential at-risk situations, under time pressure, while simultaneously

XSL•FO
RenderX

ensuring that all the young people in the chat felt supported. The BCT of "Behavioral practice" can help equip moderators to handle novel situations quickly as they arise. This BCT has been successfully used to "positively influence" behavior in the context of user training [54] and in interventions supporting shared decision-making [55].

The challenges with rapid decision-making of how to respond partly resulted from the chat environment being unstructured and uncontrolled in terms of the volume and speed of message exchanges; this was a barrier for moderators and users. Implementing emoticons (BCT "adding objects to the environment") could offer an alternative and rapid way of engaging with messages, helping to express emotions while reducing message overload [56]. Previous studies have also highlighted participants of a Cognitive Behavioral Therapy-based peer support platform feeling overwhelmed and stressed due to message volume and unfamiliar dynamics [57]. This underscores the need for accessible and well-organized chat platforms. One promising BCT is "restructuring the physical environment." Similar topics could be grouped within the platform or support chat sessions could be themed to allow users to explore and self-organize into groups based on shared characteristics and pain points, as has been implemented elsewhere [58].

Another aspect of the environment that was highlighted in previous studies was the lack of visual clues to support decision-making. This was a particular barrier for moderators, impeding connection and relationship building [39,59]. The BCT "prompts/cues" has been previously suggested in a similar context to improve moderation [39]. These could be in the form of electronic prompts or suggested phrases that pop-up when a young person writes a phrase that may need to be flagged. Such prompts may support moderators to identify individuals at risk and compensate for the lack of visual cues. This BCT has been successfully used to prompt action by the user in various contexts [60] and can also be used to simultaneously address barriers related to memory difficulties.

Given the sensitive nature of the discussions within web-based peer support chats, it is perhaps unsurprising that emotions can constitute another barrier. The BCT of "reduce negative emotions" can help address this. For users, the fear and anxiety associated with disclosure can prevent them from sharing in the chats, hindering their access to the help they need. Previous interventions report participants finding it helpful to know that others were undergoing similar emotions, reducing feelings of isolation [61]. Therefore, providing information and resources from peers about the value of sharing and supporting each other, and sharing examples of challenges discussed in group chats by previous service users may facilitate engagement. This could further build a sense of a supportive and friendly community on the platform, which facilitates willingness to share feelings and difficulties in other contexts [57]. Dealing with distressing topics such as mental health issues, suicidal thoughts, and other issues that young people are dealing with often becomes emotionally exhausting for moderators. In this case, the BCT "reduce negative emotions" could involve providing moderators with information about the positive impact of their moderation, to counter any negative emotions. A scoping review highlighted that this BCT has frequently been used in the development of mental health interventions [62]. Resilience-building training may also be helpful in equipping moderators to deal with the "emotional cost" of content moderation [63].

Barriers Specific to User Engagement

The barrier of "difficulties expressing feelings and support needs" experienced by users aligns with a prior study on webchat counseling engagement among young people, which found users lacking self-expression skills [28]. "Constructive emotional sharing" is a skill that can be improved with practice [64]. Promising BCTs to address this barrier include "instruction on how to perform a behavior" and "behavioral practice/rehearsal." For example, self-reflection worksheets could encourage users to identify their feelings and practice written statements before participating in group chats [64]. Statements such as "I feel...when...because" could be shared, leading to more personalized responses [65]. These BCTs could prove particularly beneficial for newcomers or individuals less familiar with the dynamics of group chat interaction, also creating positive spillover to a further barrier "integration of new users and gaps in support." A barrier identified here aligns with a previous study, which found that receiving empathic comments initially has a significant cascading effect, motivating individuals to reciprocate and offer support to others [66]. To further encourage integration and support for new users, the BCT "social support" could be introduced by assigning a designated "welcoming buddy" whose role is to support new members during their initial sessions or pairing members in the chat as each other's "supporter" to enhance peer support and encourage more engagement. Prior research has shown that shared interests encouraged conversation between new pairs in a peer support intervention, who were strangers when they were initially paired [67].

Having judgment and confidentiality concerns constituted another barrier. Overcoming such concerns can contribute to more fluid communication in web-based peer support and are a core component of building trust [67]. The BCT "information about emotional consequences" may address this barrier through sharing success stories, statistics, or personal narratives. Within the recovery model, this increases a sense of acceptance, understanding, and authenticity, particularly for new service users who tend to experience these fears more than long-term users [68].

Barriers Specific to Moderation

Moderators found it difficult to hold back on offering advice. Rooted in the logic of care [69], moderation is contextualized and involves an empathetic dialogue or interaction between moderators and users [70]. In such an open-ended process, holding back, given the natural flow of an interaction, proved a challenge for moderators. "Self-monitoring of behavior" could be a potential BCT that may help moderators to keep their behavior in check and change it. This could be achieved by encouraging moderators to note when they instinctively offer advice or feel like they want to do so, allowing them to reflect and monitor their own behavior if such situations arise again. This technique has proved effective in many behavior change

XSL•FO
RenderX

interventions in different contexts [71,72], particularly for health behaviors [73,74].

Limitations

The findings of this study need to be considered in light of certain limitations. The sampling of this study was reliant on self-selection, which may have introduced bias and favored participation by more confident users and moderators, potentially influencing the barriers and facilitators identified [75]. Although the participants were assured that their responses would remain confidential and would not have any consequences with respect to their relationship with The Mix, they may nevertheless have given socially desirable responses, whether intentionally or subconsciously [76]. Furthermore, it is noteworthy that the study participants were predominately women, making the sample relatively homogeneous. However, the overall population of moderators and group chat users at The Mix is also mainly women (>70% of users and 95% of moderators). Finally, the study's findings are grounded in the data obtained from a single mental health group chat forum, which could limit the generalizability of the results to other chat contexts operating under different circumstances.

Conclusions

Group chats are an increasingly popular form of digital mental health intervention, and this study contributes to building the evidence base, which can help optimize them as a safe and timely form of mental health support for young people. It is particularly valuable as it examines synchronous group chats, which are characterized by in-the-moment empathic interactions and emotional connections. Through using the COM-B and TDF, the study found that skills and knowledge, beliefs about consequences and intentions, emotions, and the social and physical environment are important factors influencing both the users and moderators of group chats. In particular, supporting the improvement of memory, attention, and decision-making skills of those involved; adapting the physical environment to facilitate effective interactions; and reducing negative emotions are suggested to optimize the value and effectiveness of group chats for young people's mental health support for both the users and moderators of these services. The intervention types and BCTs proposed serve to emphasize the importance of training and support, particularly for moderators, in this important role. The study also further demonstrates the effectiveness of the BCW approach and the use of the TDF and COM-B to understand the influences on behavior in a systematic manner, especially for mental health and well-being interventions.

A natural progression of this work would be to implement and evaluate the interventions proposed in the study and gauge to what extent the suggested BCTs reduce the identified barriers. In addition, the fidelity of the BCTs could also be assessed to understand the nuances of intervention delivery [77] to facilitate contextualized tailoring of the intervention. In an environment where digital mental health interventions for young people continue to grow in significance, this study and future suggested studies can contribute toward ensuring that they are evidence based and consider the voices of young people themselves.

Abstract

Background: The literature around the safety of digital mental health interventions (DMHIs) is growing. However, the user/patient perspective is still absent from it. Understanding the user/patient perspective can ensure that professionals address issues that are significant to users/patients and help direct future research in the field.

Objective: This qualitative study aims to explore DMHI users' experiences, views, concerns, and suggestions regarding the safety of DMHIs.

Methods: We included individuals aged 18 years old or older, having experience in using a DMHI, and can speak and understand English without the need for a translator. Fifteen individual interviews were conducted. Deductive thematic analysis was used to analyze the data.

Results: The analysis of the interview transcripts yielded 3 main themes: Nonresponse: A Concern, a Risk, and How Users Mitigate It, Symptom Deterioration and Its Management, and Concerns Around Data Privacy and How to Mitigate Them.

Conclusions: The results of this study led to 7 recommendations on how the safety of DMHIs can be improved: provide "easy access" versions of key information, use "approved by..." badges, anticipate and support deterioration, provide real-time feedback, acknowledge the lack of personalization, responsibly manage access, and provide genuine crisis support. These recommendations arose from users' experiences and suggestions. If implemented, these recommendations can improve the safety of DMHIs and enhance users' experience.

digital mental health; safety; user perspective; patient perspective; qualitative; risks; risk mitigation; deterioration; nonresponse; data safety

Introduction

Digital mental health interventions (DMHIs) are mental health interventions that are delivered through digital platforms such as mobile apps, websites, or virtual reality [1]. Some of the added benefits of mental health interventions that are delivered digitally are improved accessibility, scalability, convenience, and the potential for anonymous engagement [2]. To realize these benefits, users need to trust that these interventions are effective and safe [2]. The evidence shows that DMHIs can be as effective as traditional face-to-face therapies, especially for common mental health disorders such as depression and anxiety

XSL•FO
RenderX

[3,4]. However, the safety of DMHIs is still an evolving field [1,2,5,6].

DMHI's users face similar risks to those in face-to-face therapy, such as deterioration in symptoms, novel symptoms (experiencing new mental health symptoms during treatment), and nonresponse [1]. Deterioration of symptoms, observed in approximately 3%-10% of psychotherapy cases [7,8], signifies a phenomenon where patients' conditions worsen during therapy. Deterioration is the most common side effect of mental health therapies (face to face and digital) [1]. There is a debate in the literature about whether deterioration is a normal and integral part of therapy or an unnecessary side effect [9,10]. A recent experts' consensus study concluded that short-term deterioration that occurs during therapy is part of therapy and should not be considered a safety concern; however, deterioration still needs to be monitored to ensure that it is not chronic, severe, and does not lead to an adverse event such as the patient dropping out of treatment [11]. Nonresponse occurs when the therapy is not effective in relieving the target symptoms [12]. It is considered a negative outcome as it hinders access to more effective treatments, spontaneous remission, and may prolong or even increase distress [12]. Additionally, the digital nature of DMHIs introduces additional risks to mental health therapies such as technical issues and privacy concerns [5,13].

The expanding body of literature addressing the safety of DMHIs is noteworthy [1,5,6]. While considerable attention has been devoted to exploring the safety of DMHIs (how it is assessed, analyzed, and reported), a notable gap exists in the qualitative understanding of individual perspectives on the topic. Existing qualitative studies in this field have either focused on the viewpoints of health professionals and medical students [14,15] or have sought user opinions on specific digital innovations usually as part of a wider program of development work. A few studies have sought service users' views on digital interventions more generally [16-18], but no work to our knowledge has investigated user/patient perspectives specifically about the safety of these technologies [19,20]. Understanding the user/patient perspective on safety can help direct future research in the field to ensure professionals focus on issues significant to users/patients; identifying users' concerns can help professionals address these issues, leading to higher rates of adherence and engagement. For that reason, this qualitative study aims to explore DMHIs users' experiences, views, concerns, and suggestions regarding the safety of DMHIs.

Methods

Design and Aim

This qualitative study utilized individual interviews to explore users' experiences, views, concerns, and suggestions about the safety of DMHIs. The Consolidated Criteria for Reporting Qualitative Research (COREQ) was used to report the results of this study [21].

Recruitment

The study included individuals aged 18 years or older, with previous experience using a DMHI, and speaking and understanding English without the need for a translator. The DMHI needed to be a mental health intervention that was provided via a tech-based medium (eg, app, website, virtual reality) and targeted a specific mental health condition. Participants were recruited using nonpurposive sampling by posting advertisements on authors' own professional social media platforms, such as X (formerly Twitter; X Corp.) and LinkedIn (Microsoft Corporation), an online participant recruiting platform (MQ; MQ Mental Health Research), the university's (King's College London) research volunteering circular email, and through DMHI trials whose participants consented for their details to be shared for future research. A total of 54 potential participants reached out; 15 (28%) were eligible and participated in the study, 7 (13%) did not complete the online eligibility form, and 32 (59%) were ineligible. Eligibility was determined through screening questions asked of potential participants to gather further details about the specific intervention used. The main reasons for ineligibility were that the intervention used was telehealth (eg, face-to-face therapy conducted via video call) or did not target a specific mental health condition (eg, mindfulness apps).

Participants

A total of 15 participants were recruited to participate in this study. Researchers initially estimated a sample size of 6-16 participants based on pragmatic recommendations from the literature, suggesting that 6-16 interviews provide sufficient information power [22]. Then the final sample size (15 participants) was determined based on the richness of the data and their ability to sufficiently answer the research question [23]. Of the 15 participants, 12 (80%) were females and 3 (20%) were males. All participants lived in the United Kingdom at the time of the interviews. Participants had an average age of 30 years (SD 6.43 years; range 19-42 years). On average, participants had used a DMHI for 8 months (SD 10.51 months; range 1-36 months). The DMHIs used by participants in this study were Beating the Blues, Calm Harm, FREED-M, Happify, Molehill Mountain, Moodkit, Silver Cloud, Sleepio, STOP app, Woebot, Youper, and an online intervention for Bulimia. See Table 1 for more information on the interventions used by participants in this study. Some participants used the DMHI for both anxiety and depression. Other than that, no other participants used the DMHI for more than 1 target symptom or condition.

[a]DMHI: digital mental health intervention.

[b]N/A: not applicable.

Materials

Individual interviews with participants were conducted and recorded online via Microsoft Teams (Microsoft Corporation). Interviews were semistructured. See Multimedia Appendix 1 for the topic guide. The interviewer (RT) used prompts to facilitate and guide the discussion. RT has experience conducting individual interviews for research purposes.

Procedure

Participants viewing the study advertisement were asked to email the researcher if they were interested. The researcher replied to introduce them to the study, share the participant information sheet (PIS), and request that they complete an online (Qualtrics) questionnaire to check eligibility. The same researcher contacted eligible participants to check that they had read the PIS, answered any questions that they had, and asked if they were interested in participating in the study. Those expressing a desire to participate were emailed an online form that includes a few questions (details below) and an e-consent form (using Qualtrics) to sign and a link to book a 1-hour slot for the interview. The online form asked for demographic details such as gender and age, details about the intervention (name and intended purpose), and how long they used the intervention for. All interviews were audio recorded. At the end of the interview, participants were sent a thank you email and a £20 (US $25) voucher as compensation for their time. Interviews lasted on average 40 minutes. Recordings were automatically transcribed by Microsoft Teams and were verified for accuracy by RT. Once transcription was complete all recordings were deleted.

Analysis

Thematic Analysis Process

The 15 transcripts were uploaded onto NVivo (Lumivero, LLC) for analysis [24]. We used deductive thematic analysis to analyze the data. Thematic analysis is a process used to identify

XSL•FO
RenderX

patterns or themes within qualitative data to answer or explore a research question [25,26]. The analysis was conducted collaboratively by 2 researchers (RT and JY), who followed Braun and Clarke's [25] step-by-step guide to conduct a thematic analysis by familiarizing themselves with the 15 transcripts and coding the data. They then organized the codes based on relatedness, reviewing them, and defining and naming them as subthemes and themes [25]. The thematic analysis acknowledges "the researcher's reflective and thoughtful engagement with their data, and their reflexive and thoughtful engagement with the analytic process is essential" [25]. It recognizes the potential benefits of using multiple coders, such as achieving richer interpretations, however, it does not view this as a requirement [26]. Researchers are discouraged from attempting to provide accounts of "accurate" or "reliable" coding or pursuing consensus among multiple coders [26].

Given the research question and acknowledging that participants' experiences and perspectives on safety may vary in this study, the analysis was used to reflect the range of experiences of participants and highlight how these might differ, rather than attempting to merge these experiences into a single, unified interpretation [25]. Once the results of the study were ready, they were shared with all 15 participants to review and ensure that they were representative of their experiences. Three participants responded and said that they agreed with the results and did not offer any additional insights or suggest any alterations.

Researcher Reflexivity

A critical realist epistemology was adopted for this study, where the researchers aimed to explore participants' subjective experiences, acknowledge them as "real," and recognize the researchers' inability to fully access that reality [25]. The researchers were aware of their reflexivity [27]; at the time of this study, they all worked on a separate clinical trial that aimed to assess the efficacy and safety of a specific DMHI. The first author (RT) was completing her PhD on the safety of DMHIs. This study was 1 of 4 separate pieces of work for the PhD (other work comprising a systematic review, a methodology paper, and an experts' consensus study). This study was not directly related to or in any way part of the clinical trial that researchers were working on. As a team, the researchers were invested in learning how users/patients experience risks, react to them, and what risks matter to them in order to contribute to the field and improve their approach to safety.

Ethical Approval

Ethical Clearance was provided for this study by the King's College London (reference number LRS/DP-22/23-35403).

Results

Overview

The analysis of the data using deductive thematic analysis led to 3 major themes:

- Nonresponse: A Concern, a Risk, and How Users Mitigate It
- Symptom Deterioration and Its Management
- Concerns Around Data Privacy and How to Mitigate Them

Theme 1: Nonresponse: A Concern, a Risk, and How Users Mitigate It

Assessing the Effectiveness of DMHIs

Under this theme, participants spoke about their concerns regarding the DMHI being ineffective, experiencing ineffectiveness/nonresponse as a risk, and the methods they used to assess whether a DMHI was safe and effective.

Concerns Around Nonresponse

Users of DMHIs were concerned about the potential ineffectiveness of these interventions. Will these interventions be able to help them? Are these interventions evidence-based? One important area of concern is illustrated as follows:

> *Umm, I was concerned with like how helpful it would actually be, being that it is an online thing and like I'm not actually talking to a person you know...I was even actually concerned when I started the first session, whether the program would have lasting effects on actually helping me or supporting my mental health.* [Participant 6, used a DMHI for depression for 2.5 months]

It is likely that participants were doubtful about their interventions' effectiveness because they were struggling and in such emotional pain that they were unsure how a technology with no human could alleviate their pain and improve their mood.

Nonresponse as a Risk

Participants also spoke about the risk of the DMHI being unhelpful and ineffective, and how that at times led to further frustration, deterioration, and self-blame, for example:

> *I found it ineffective, if I'm honest. I think it was the set of six or eight weeks...I remember that the second week I burst into tears. It just felt so pointless. I can't remember what set me off, but it just felt so pointless.* [Participant 9 used a DMHI for an eating disorder for 1.5 months]

Another participant explained how the ineffectiveness of the DMHI led to a deterioration in her symptoms and feelings of isolation and self-blame. She said:

> *So, it's sort of added to that frustration when it was making the situation worse...So now, I felt like it would lead me to do sort of negative coping strategies...I'd be like get angry and irritable with people, or I'd go and overeat....it definitely sort of furthered the thoughts that there was like no one to help me...It made low moments even worse...It almost triggered sort of thoughts of like, oh, something's wrong with me. Why can't the program help me?* [Participant 14 used a DMHI for post-natal depression for 24 months]

Users' Method for Assessing Safety and Effectiveness

Users used 2 main methods to assess whether they thought a DMHI was safe and effective: (1) social proofing, which refers

XSL•FO
RenderX

to the tendency to follow the behavior of others as a guide for one's own actions [28]; and (2) assessing the contribution of experts or a trusted body. Some participants opened up about finding it difficult to assess the safety of a DMHI, and not knowing how to do that.

Participants wanted to know that professionals were involved in the development of the DMHI and that scientific research has been conducted to assess it, saying:

> *I suppose I would want to know how it was developed and in partnership with mental health practitioners...so I think with credibility, I guess things like whether they have worked with the university or with kind of recognized academics and done any kind of scientific research and rather than just user testing.* [Participant 11 used a DMHI for insomnia for 1.5 months]

In this participant's case in particular, knowing that the intervention was evidence-based was very important because she had struggled with insomnia for more than a decade and had tried many things (face-to-face therapy and medication) that were not helpful for her. Users also relied on other users' experiences. They checked reviews, ratings, and social media groups to find out more about the DMHI. The following quote is an example of this:

> *Uh, I have this habit of looking up these things online, so I would look up reviews of the app online. Maybe even check out any details about how helpful it has been. If people have had good experiences, bad experiences, they've had negative experiences, what have they been about and how I could avoid them. I would maybe even like look at Facebook groups.* [Participant 6 used a DMHI for depression for 2.5 months]

Some participants were honest about not knowing how to check the safety of the DMHI, and needing the support of professionals to be able to do so, they said:

> *I mean, unless it was like referred by my GP or kind of, you know, promoted through kind of official channels like the NHS website or something, I don't know how I would even check that an app has all the right checks, and you know safeguarding approvals or whatever.* [Participant 13 used a DMHI for depression and anxiety for 2 months]

Other participants suggested that the DMHI needs to assess users' suitability, saying:

> *I guess before someone's able to access the app kind of going through, I don't know, some sort of risk assessment on like who would find it useful.* [Participant 7 used a DMHI for paranoia for 3 months]

Another participant thought that this could be achieved by the DMHI clearly stating its intended use and target population:

> *I think the app would need to be really explicit about the limitations and sort of say up front like this is not for severe mental health issues or this is for maintenance.* [Participant 14 used a DMHI for post-natal depression for 24 months]

Theme 2: Symptom Deterioration and Its Management

Addressing Symptom Deterioration in DMHIs

Under this theme, participants spoke about experiencing symptom deterioration. Participants also gave their feedback on one of the methods used to support them when experiencing or struggling to cope (referral to other services and crisis support) and their suggestions on how deterioration can be managed.

Deterioration of Symptoms

Participants talked about how using a DMHI and dealing with their mental health struggles at times led to a deterioration in their mental health symptoms because it made them think about things that were upsetting. One participant who was struggling with sleep said:

> *I did find thinking more closely about my trouble with sleep did initially make me more anxious about sleep and made it harder to sleep. So, like the kind of tracking and then realizing that actually that was a really bad night...sometimes makes it harder to sleep the next night, by bringing it to the forefront.* [Participant 11 used a DMHI for insomnia for 1.5 months]

It is important to note that this participant found her intervention effective in helping her manage her insomnia and improve her sleep quality. This aligns with recent findings from an expert consensus study, which concluded that symptom deterioration is not a safety concern of DMHIs but rather a normal part of therapy [11].

In some cases, the inflexibility of the predetermined content in the DMHI and its inability to cater specifically to each user's needs (ie, lack of personalization) meant that the DMHI was unable to relate to users' emotional state and could lead to a deterioration in symptoms, for example:

> *So sometimes the AI (chatbot) like would give me suggestions that didn't really fit my situation. So, I'm like, you know what? Forget it. I'm not even going to do it, and I would feel worse afterwards because I wanted to express it. And then I'm just sitting here typing things, and it's not helping. It wasn't really built to recognize that CBT isn't effective for certain situations.* [Participant 14 used a DMHI for post-natal depression for 24 months]

Managing Deterioration

As deterioration is the most common negative effect of DMHIs [1], the authors asked participants how they think DMHIs could support them through it. Some participants said that normalizing deterioration would be very helpful. Participant 1 explained how that could be done in a hybrid model:

> *I think one way to support...is to have a video call therapy session. With an agent for example to make me understand that these things are normal. So, at that I would be reassured that I'm getting back to*

XSL•FO
RenderX

> *normal.* [Participant 1 used a DMHI for depression for 36 months]

Another participant explained how that could be done in a nonhybrid model:

> *Uh, maybe you know if the app had a mood tracker. The algorithm could check if you're feeling low right after therapy. It might just send them a message "Hey, if you're feeling down, you just check, you just had therapy. This could be normal" and that would be like, uh, fair enough.* [Participant 5 used a DMHI for depression and anxiety for 1 month]

Another participant suggested using regular check-ins to detect deterioration and provide users with support accordingly, saying:

> *Umm, I think the biggest thing is regular check-ins. That's quite an important thing about how they're finding it and what particularly is so difficult, maybe even not slowing it down, but having a bit of flexibility around kind of OK, you found this section of the app pretty difficult.* [Participant 10 used a DMHI for self-harm for 1.5 months]

Signposting to Other Services for Support

Most participants (11/15, 73%) were provided with emergency numbers, within the DMHI, to call in case they felt that they could not cope and needed further support. Some participants shared that they found this support helpful:

> *They gave me the contact numbers of like mind and Samaritans in case I needed urgent help. I'm using an online service. If I did need help, I could contact these services, which is actually really helpful because once or twice when I really felt like I was troubled at night, this did come in handy.* [Participant 6 used a DMHI for depression for 2.5 months]

However, other participants felt that the signposting to crisis support within the DMHI was tokenistic, sharing:

> *It's hard to feel like it's a genuine thing. It feels almost like a boilerplate that they put in every conversation. It doesn't really feel like there's thought going into it like "Ohh I recognize that the program can't help you with this. This would be better for a psychiatrist.* [Participant 14 used a DMHI for post-natal depression for 24 months]

Further analysis of these data highlighted that the participants who had a positive experience with the DMHI (ie, found it helpful) experienced the referral to crisis support information positively. By contrast, participants who found the DMHI unhelpful and were frustrated with it found the crisis support information unhelpful and ingenuine. Thus, users' relationship with the DMHI and their feelings toward it informed how they felt about being referred to other services. Users who found the DMHI helpful were likely to view the information about other services as a helpful bonus, whereas those who found their DMHI unhelpful were likely to doubt its genuine concern for them and thus viewed such referrals as a mere box-ticking exercise.

Theme 3: Concerns Around Data Privacy and How to Mitigate Them

Participant Perspectives on Data Privacy

Under this theme, participants spoke about their concerns around data privacy and their suggestions on how to help ease these concerns.

Concerns Around Confidentiality and Data Privacy

Participants were concerned about their data. Was the DMHI confidential? If not, who is it sharing their data with? Participants talked about their concern that the data might be shared with their health care team without their consent:

> *I had concerns about the information that I was putting in, and the kind of data that might have been collected. It's kind of that worry that what you're writing isn't actually confidential or you know that it could go back to someone else. I think one of the biggest worries for me was that what I was inputting in the app might have been given to my psychologist or somehow, you know, connected with the NHS or something like that.* [Participant 10 used a DMHI for self-harm for 1.5 months]

It is worth noting that, given the sensitivity of participant 10's struggle with self-harm, it is understandable why they were particularly concerned about their data being shared—even with their health care provider.

A User-Friendly Data Policy

Participants expressed their frustration with the vagueness and complexity of how DMHIs present their data protection policy and had suggestions on how that can be improved. Some thought that DMHIs should make key data protection information available in a simpler and more readily accessible format:

> *Maybe just share more information...like make it clear what you do to protect users' data. I don't want to have to go through, you know, all of your Terms and conditions, privacy policies and things like that to find out what it is. I mean, nobody's actually going to do that. I would never actually do it, so it would be helpful if it was just clearly mentioned somewhere.* [Participant 6 used a DMHI for depression for 2.5 months]

Another participant said that all they wanted from a DMHI is to be honest about what data they are storing and why:

> *They could kind of like emphasize maybe that your data isn't stored under an identifiable name that leads to you. Or say we are storing the data, but it is confidential and we're doing it to help more people. That's all...just being open about it.* [Participant 8 used a DMHI for an eating disorder for 3 months]

It is worth noting that the data from this study did not show any association between duration of use and participants' experiences. Participants had mixed responses to the DMHI when they used it for a short period (1.5 months, eg, participants 10 and 11), and those who used the DMHI for a long period (24 months; eg, participant 14) did not necessarily have a good

XSL•FO
RenderX

experience. However, Table 1 does show that the DMHIs that were targeting low mood–related areas were used for the longest period, such as depression (on average 19.25 months), self-harm (on average 12.75 months), and postnatal depression (on average 24 months). It is also noted that self-administered interventions were used for longer periods compared with hybrid interventions (on average 9.33 months vs 1.66 months). This is expected given that self-administered interventions require fewer resources and clinician time.

Discussion

Advancing Knowledge on DMHI Safety

This research was successful in exploring and understanding users' experiences, views, concerns, and suggestions regarding the safety of DMHIs. Until now, such findings have been absent from the literature. These findings contribute to advancing the field of digital mental health safety by providing valuable evidence of the viewpoints and experiences of its target population.

Principal Findings

Overview

The main findings of this study are presented in Table 2 (also see Figure 1) using user-friendly language and in the form of recommendations.

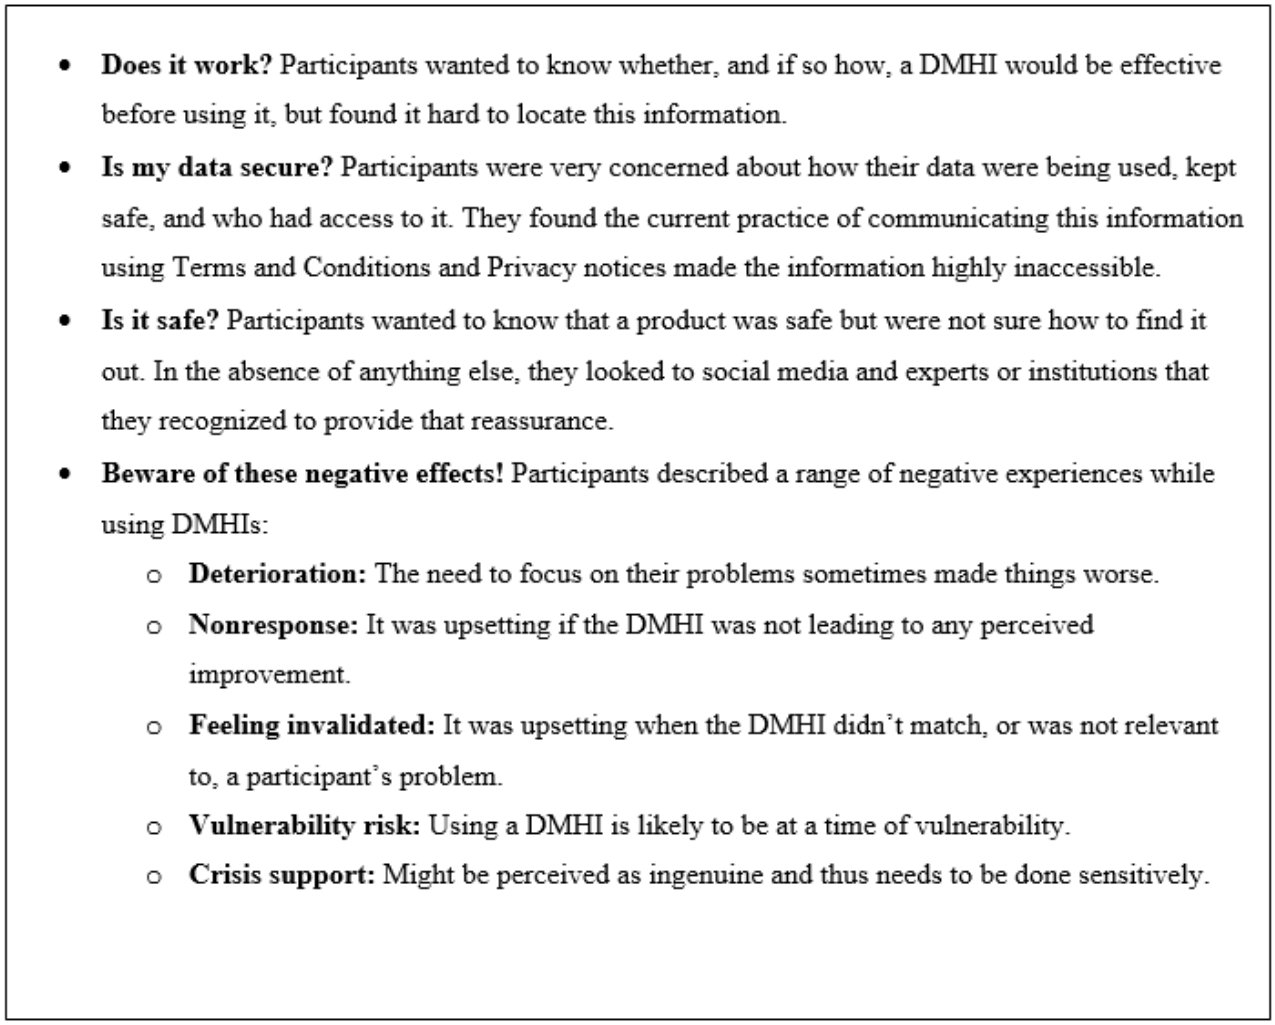

Table 2. User-informed recommendations to improve DMHI[a] safety.

Recommendations	Description
1. Provide 'easy access' versions of key information	Ensure that DMHI product manufacture and approval include a requirement to provide readily accessible, easy-to-read lay summaries of key information. At a minimum, these should cover (1) evidence of effectiveness; (2) data usage, security measures, and access (ie, who can access the data); and (3) potential negative effects.
2. Use 'Approved by...' badges	Introduce a sectorwide, widely recognized, branded badge to provide top-level reassurance of the quality and safety of any DMHIs bearing that badge.
3. Acknowledge the lack of personalization	DMHIs should flag to users their inability to be fully personalized and adaptable to an individual user's needs to mitigate feelings of invalidation and disappointment.
4. Anticipate and support deterioration	Before using a product, users should be alerted to possible mood or symptom deterioration, given normalizing information, and signposted to relevant support to help mitigate these effects should they occur.
5. Provide real-time feedback	DMHIs should internally track users' progress and provide feedback on whether they are benefiting as expected. Where there is no individual benefit, despite the appropriate use of the product, users should be automatically advised to seek alternative support.
6. Provide genuine crisis support	Content should include an acknowledgment of the DMHIs' limitations and a summary of each crisis service's support. It is recommended to consult the target population on wording to ensure genuine concern for users is communicated.
7. Responsibly manage access	DMHIs should incorporate an assessment of suitability focusing on risk levels and the appropriateness of the intervention for users' specific mental health conditions and severity. This could be done with a simple set of initial built-in questions which output a recommendation to use, or not use, the product based on the user's response.

[a]DMHI: digital mental health intervention.

XSL•FO
RenderX

Figure 1. Key findings (in lay language). DMHI: digital mental health intervention.

Users' Concerns Around the Safety of DMHIs

In this study, users expressed 2 primary concerns regarding the safety of DMHIs: (1) whether a product would be effective and (2) whether their data would be secure and confidential. Evidence around the effectiveness of DMHIs is usually disseminated in academic peer-reviewed articles. This poses an accessibility challenge for the typical users, which is only slightly tempered by recent initiatives toward making open-access publications the norm in academia. It has been documented that uncertainty around the effectiveness of a DMHI is a key barrier to its use [15]. To address users' concerns about effectiveness, it is crucial to translate scientific findings into lay language and publish them in user-friendly formats to improve accessibility (recommendation 1). This dovetails well with the increasing requirements placed upon academics to evidence the impact of their work.

Regarding users' second major concern, data safety and confidentiality, participants in this study suggested that DMHIs provide their users with clear and concise information on how their data are used, stored, and who has access to it. Recognizing that users often overlook traditional lengthy privacy policies and terms and conditions [29], DMHIs could supplement these by providing users with a layperson's summary of how their data are being used, kept safe, and who has access to them (recommendation 1). Clear and transparent communication about data and privacy would help build trust, a key component of the therapeutic relationship [30]. The evidence to date suggests that the digital therapeutic alliance is both relevant and important in DMHIs [19,20].

Assessing a DMHI's Safety From Users' Perspective

It is important to understand how users assess the safety of DMHIs, as this will inform professionals about where users look for safety information and so where and how best to provide it. Participants in this study described methods for assessing the safety of a DMHI that reflected social proof, a concept first attributed to Robert Cialdini [31,32]. Social proof refers to situations where people use opinions and information from others similar to themselves to influence personal choices, decisions, and behaviors, especially if uncertain [31,32]. In the present context, this involved reading online product reviews on websites and mobile app stores. Other participants expressed that they did not know how to assess the safety of a DMHI. In a different qualitative study, medical students shared a similar experience, expressing difficulty in identifying which DMHIs were evidence-based [15]. These students also criticized the lack of guidance available for users on how to find evidence-based DMHIs [15].

XSL•FO
RenderX

There are already regulatory bodies equipped and responsible for assessing the efficacy and safety of DMHIs and making recommendations for use. In the United Kingdom, this includes NICE (The National Institute for Health and Care Excellence) and the MHRA (Medicines and Healthcare Products Regulatory Agency). The NHS (National Health Service) previously had a health app store called the "NHS Health Apps Library," but it was decommissioned in 2021 due to the increasing complexity of maintaining the library and ensuring the safety and effectiveness of the listed apps. An alternative to this has emerged through the Health App Library provided by the Organization for the Review of Care and Health Apps (ORCHA), in collaboration with health providers such as NHS Trusts. This library offers a list of mobile apps that have been reviewed by ORCHA for effectiveness and safety. One effective way to demarcate a product's safety and efficacy status would be for regulators to introduce a branded, recognizable stamp or badge to be displayed by products achieving prespecified minimum safety and efficacy requirements (recommendation 2). What those requirements should be, however, would entail significant additional research to achieve a consensus across industry, regulatory bodies, academia, developers, and users. Nevertheless, this approach would capitalize on users' existing tendency to seek safety information via the product's mobile app page or website and is therefore likely to ultimately be an effective means of disseminating key information on which end users can base their decisions. A notable advancement in this direction is Google's revision of their app store's health policy, which mandates that starting from May 31, 2024, all health apps posted on their app store must prove compliance with relevant laws and regulations (privacy policy, ethics approval, and certification when required) [33].

Risks Experienced by DMHIs' Users and Their Suggestions on How to Mitigate Them

Participants in this study spoke about 3 risks they had experienced as a result of using a DMHI: feeling invalidated by the DMHI, deterioration in their symptoms, and nonresponse. Users noted that, unlike a human therapist, the DMHIs' inability to be fully responsive, personalized, and adaptable to each user's needs left them feeling invalidated and unheard. Such experiences undermine the therapeutic relationship. There is evidence that personalization in a DMHI fosters therapeutic alliance [20], and thus the lack of it is likely to undermine this alliance. The weaker the digital therapeutic relationship, the more this is likely to undermine the effectiveness of the DMHI [30]. In a qualitative study involving Australian psychologists and their experiences with DMHIs, the psychologists expressed the view that DMHIs are inferior to face-to-face therapy due to their limited capacity for personalization [14]. In another qualitative study, medical students made the same comparison between DMHIs' and health professionals' ability to provide personalized therapy [15]. This is a limitation of current technologies, which might change with the future advances of artificial intelligence. However, for now, it is important for DMHIs to acknowledge and communicate this limitation to users to mitigate feelings of invalidation (recommendation 3).

Participants suggested that DMHIs can support users experiencing deterioration by informing them about the possibility, normalizing it, and providing pathways to relevant support when it occurs (recommendation 4). These suggestions align with those made by digital mental health professionals in a recent consensus statement [11]. Other studies have suggested implementing an automated process within DMHIs to monitor and flag when participants' symptoms deteriorate beyond a predefined threshold [5]. Although that threshold would be subject to individual conditions and clinical opinion within any specific context, a useful starting point would be to adopt the clinical "rule of thumb" that considers a 20% change in symptoms as a meaningful variation [34].

"Nonresponse" is a documented potential side effect of DMHIs [1,12]. It was interesting to see how nonresponse from users' perspective was almost a compound negative effect that led to a cascade of unwanted effects including feelings of frustration, hopelessness, deterioration, isolation, and self-blame. One way to address this would be for DMHIs to track users' clinical outcomes, identify those experiencing nonresponse, and provide them with targeted pathways to further support as a way of mitigating these possible adverse consequences (recommendation 5).

The Risk Mitigation Methods Experienced by DMHIs' Users

When discussing how DMHIs mitigate risks and safeguard users, users highlighted the importance of signposting to other sources of support. The majority of users (11/15) were provided with details of emergency numbers and other mental health services; however, not all users found these helpful. Some users felt that this was a checkbox exercise that DMHIs needed to complete and that the crisis support provided was ingenuine. Users of DMHIs may feel this way because of their experiences with mental health services, and because most mental health services/interventions tend to provide crisis support information. Signposting to a different service needs to be done delicately to ensure that the user feels cared for. For that, DMHIs need to be careful about how they present crisis support details. Including an acknowledgment of the DMHI's limitations, a concern for the user, and a description of the support that each crisis service provides might help make users feel that the intention to provide support is more genuine (recommendation 6). Soliciting user input on how such information is phrased and presented would also be of benefit (recommendation 6).

Only 1 user among our sample of 15 was informed of the potential side effects of the DMHI that they were using. A recent systematic review on the safety of DMHIs found that only one-third of the interventions informed their users of their adverse events or possible side effects [1]. The even lower level of side effect awareness in our study might be due to the commonplace practice of embedding side effect information within inaccessible or often unread documentation (eg, terms and conditions or instructions for use) [6]. Indeed, as reported above, our participants told us that they found these documents particularly impenetrable, suggesting some may have missed out on important side effect information. To ensure user safety, it is important to improve the visibility and accessibility of side effect information by adopting new methods of communication (recommendation 1). This might include a digital equivalent of

XSL•FO
RenderX

listing possible side effects on medication labels. Existing regulations already require a digital product label to be displayed within the product itself and this label includes "Cautions" and "Warnings." It would be a relatively simple matter to add a section "Possible Side Effects" as a further requirement.

However, simply adding information is unlikely, on its own, to meet users' needs as identified by our study. In addition (and as already discussed earlier), serious consideration should be given to adopting the practice of requiring "easy read" or "lay summary" versions of key information which is provided alongside full and formal versions. This is now standard practice in domains such as academia, governmental, and other public sector organizations. Our study suggests that, as a minimum, this should apply to information on data security and side effects.

Finally, to minimize this risk, our sample of participants/users recommended that DMHIs should evaluate each user's suitability, with a focus on assessing risk levels and determining the appropriateness of the intervention for their specific mental health condition and severity. These assessments can be included as a standard procedure before onboarding a user onto a DMHI, similar to how patients are screened before they receive face-to-face therapy (recommendation 7).

Limitations

There are a few limitations to this study. The participants in this study were mostly female (12/15, 80%). The DMHIs used by participants were mostly self-administered (12/15, 80%), and thus results might be biased by their experiences. Additionally, recruiting for a study to explore users' perspectives on the safety of DMHIs might have attracted individuals who have experienced such issues. It is important to be aware of how the sample of participants in this study could have shaped the results. This is expected in qualitative studies, which aim to explore and understand the experiences and opinions of a sample of the population [35].

Conclusions

The results of this study led to 7 user-informed recommendations on how the safety of DMHIs can be improved. These recommendations arose from users' experiences and suggestions. The key findings (Figure 1) and recommendations of this paper could improve the safety of DMHIs, enhance users' experience, address some of their concerns, and foster a more trusting therapeutic relationship between the user and the DMHI.

Acknowledgments

We are grateful to all our participants for taking the time to participate in our study and share with us their valuable experiences and opinions. We also would like to express our gratitude to the National Institute for Health and Care Research (NIHR) Biomedical Research Centre hosted at South London and Maudsley NHS Foundation Trust in partnership with King's College London. The views expressed are those of the author(s) and not necessarily those of the NHS, the NIHR, the Department of Health and Social Care, the ESRC, or King's College London.

Abstract

Background: Many youth with significant mental health concerns face limited access to mental health services. Digital programs, such as mobile apps designed to address mental health issues, have the potential to expand access to strategies for managing these conditions. However, few mental health apps are specifically designed for youth experiencing severe concerns, such as suicidal ideation. BritePath is a new app developed to enhance communication and interaction between providers and youth at risk for suicidal behavior.

Objective: This study aims to explore health care providers' opinions and concerns regarding the use of mental health apps for youth at significant risk of suicidal behavior.

Methods: We conducted individual semistructured interviews with 17 providers across 7 states. Interviews were conducted via video, recorded, and transcribed. Codes were developed using a team-based approach, with discrepancies resolved through team discussions.

Results: Most providers were aware of mental health apps in general and expressed interest in trying the BritePath app with patients experiencing depression, suicidality, or both. Analyses identified 4 key themes related to mental health apps: (1) almost all providers viewed mental health apps as an adjunct to, rather than a replacement for, psychotherapy visits; (2) most providers were concerned about the cost of apps and youth access to them; (3) providers noted the challenge of maintaining patient engagement with apps over time; and (4) providers were concerned about patient privacy, in terms of both data shared with app developers and data privacy within families. Analyses of providers' opinions specifically about the BritePath app identified 4 additional themes: (1) providers believed that access to safety plans within BritePath could be beneficial for youth at risk for suicidal behavior; (2) providers reported that BritePath's interactive features could enhance communication between providers and youth; (3) providers appreciated BritePath's flexibility and the ability for both youth and providers to tailor its content to individual needs; and (4) providers expressed concerns about integrating BritePath into clinical workflows within health systems.

Conclusions: The use of mental health apps is expanding, yet there is limited understanding of how to effectively integrate these tools into mental health treatment. Providers are increasingly referring patients to mental health apps, and most expressed interest in trying the BritePath app for patients with depression, suicidality, or both. However, providers also identified several concerns, particularly regarding privacy and safety.

depression; adolescent; suicidality; safety plan; mental health; apps; suicide

Introduction

Background

Adolescent suicidal behavior, suicide ideation, and depression are major public health problems that have increased significantly over the past 20 years [1-3] and have been exacerbated by the COVID-19 pandemic and its sequelae [4-8]. For example, between 2019 and 2021, the number of female high school students reporting that they had seriously considered attempting suicide increased by 6% [3]. These increases in suicidal ideation, behavior, and depression have disproportionately affected youth from historically minoritized racial and ethnic groups [2-4]. Once youth are identified as having a significant risk of suicidal behavior, they are typically treated in emergency departments or urgent care settings or hospitalized for stabilization before beginning outpatient treatment [9]. However, many youth remain at high risk of suicidal behavior even after acute treatment or stabilization in intensive settings. Managing youth with high levels of suicidal risk requires close communication between patients and clinical providers, such as psychiatrists or mental health therapists (referred to collectively as providers hereafter). Evidence-based care for these youth includes regular monitoring of depression symptoms, suicidal ideation, and suicidal behavior [9-11]. However, most health systems fall short of maintaining this level of close communication due to barriers such as lack of time and resources, as well as difficulties in staying in touch with at-risk youth after they leave intensive settings or acute treatment.

To address these concerns, researchers are developing new mobile apps aimed at improving both the efficiency of communication with youth at risk for suicidal behavior and shared decision-making between providers and adolescent patients. These tools are increasingly promoted to address mental health concerns in general and depression in particular [12-16]. Empirically based apps for depression range from cognitive behavioral self-help programs [15,16] to screening [16,17] or mood-tracking apps [18]. Recent research indicates that these tools are generally acceptable to providers [13,17]. However, there are several limitations to their use in clinical practice. Much of the evidence comes from surveys asking providers about the acceptability of apps [19] or studies that have not focused on specific concerns about particular apps [13]. Few studies have examined the use of apps within the context of mental health treatment [15]; instead, most have focused on patients' use of apps independent of providers [13]. To date, no prior research has examined the acceptability of apps designed to support shared decision-making between providers and youth at high risk for suicidal behavior. While some experts have raised potential ethical and safety concerns about using digital interventions with high-risk populations [19,20], improving connections to treatment after nonfatal suicidal behavior has the potential to enhance the treatment trajectory and long-term outcomes for these youth.

Study Goal

The aims of this study were to characterize providers' (1) opinions on the barriers and benefits of using apps in mental health care in general, (2) perspectives on the use of apps with adolescents with depression or suicidal thoughts and young adult patients, (3) interest in and willingness to use a recently developed app (BritePath) intended for use with adolescents with suicidal thoughts or young adult patients, and (4) barriers to implementing the BritePath app in routine clinical practice.

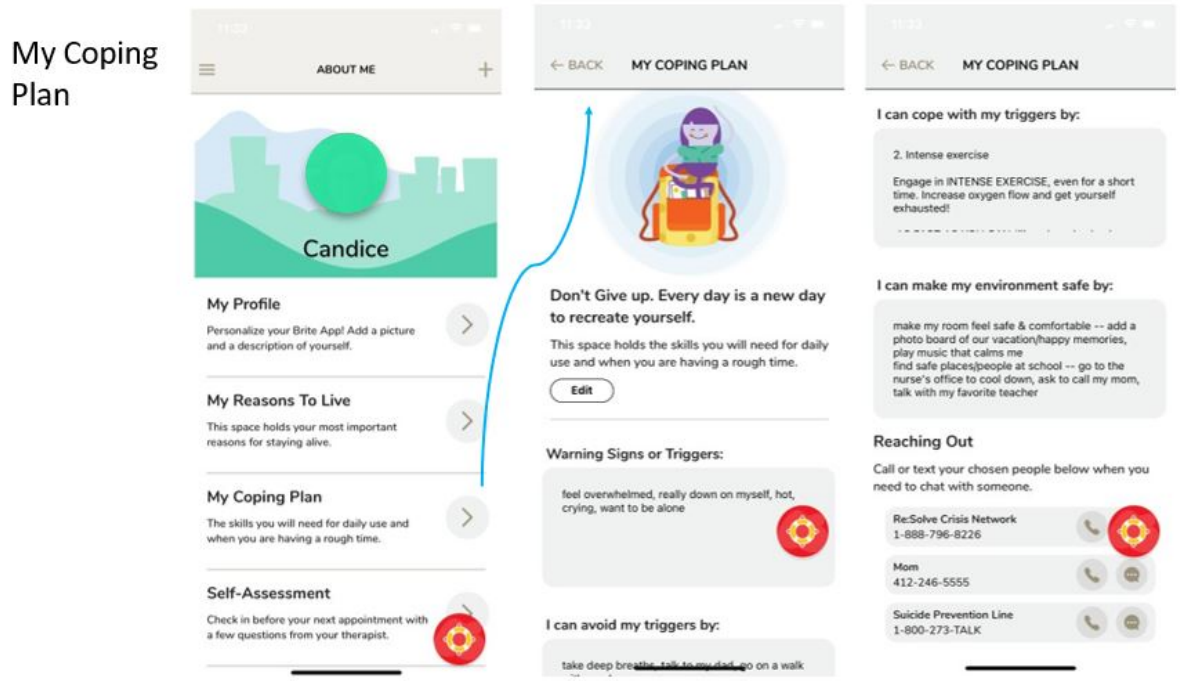
Methods

Implementation of BritePath: Benefits and Barriers

This qualitative study was conducted as part of the Center for Enhancing Treatment and Utilization for Depression and Emergent Suicidality (ETUDES Center), an ALACRITY Center funded by the National Institute of Mental Health (NIMH P50MH115838), aimed at helping providers better support youth experiencing severe depression, suicidality, or both. This study explores issues related to the use of mental health apps in general with this population and examines potential benefits and barriers to implementing an already developed app, BritePath, in health systems that have not participated in the research studies developing BritePath and are not affiliated with the ETUDES Center. To date, all information regarding the acceptability of the BritePath app has been gathered within the institutions that developed it.

The BritePath App

The BritePath app was developed to improve communication between providers and youth with depression or suicidal thoughts. It consists of 3 integrated components: (1) *Guide2BRITE*, an electronic guide for mental health providers that includes step-by-step instructions for onboarding a patient's safety plan into the app, as well as guidance on discussing key treatment components such as emotion regulation and distress tolerance skills; (2) the *BRITE app*, a personalized and interactive safety plan and self-monitoring tool for youth; and (3) the clinician dashboard, *BRITEBoard*, which allows providers to track youth's app use, distress levels, and treatment progress while facilitating communication and collaboration among mental health and primary care providers.



BritePath promotes self-monitoring and self-management through personalized strategies to avoid or cope with triggers for suicidal urges [21]. It is based on BRITE, a patient-facing safety planning app developed by researchers in psychiatry and psychology at the University of Pittsburgh and the University of Texas Southwestern Medical Center [21]. To our knowledge, BritePath is the first smartphone-based safety planning app to be tested in clinical trials involving adolescents with severe depression or suicidal thoughts. BritePath provides providers

XSL•FO
RenderX

with tools to onboard their adolescent and young adult patients to the app. This includes assisting youth in developing and personalizing a safety plan, incorporating distress tolerance and emotion regulation strategies, and monitoring symptomatic progress for at-risk youth in their care. Figure 1 provides a screenshot from the BritePath app for a mock patient.

BritePath was first tested for clinical effectiveness in a pilot randomized trial that evaluated BritePath in combination with a related intervention. The study found that the combined intervention reduced the rate of suicide attempts by 50% in the 6 months following hospital discharge [21]. This pilot study also suggested that more frequent use of BritePath increased reasons for living. However, the small sample size did not allow for comprehensive testing of BritePath alone. A more recent, larger randomized trial found that BritePath is as effective as usual care for youth hospitalized for suicidality. Additionally, youth who received BritePath were less likely to have a subsequent suicide attempt and had a longer time until a repeat attempt [22].

Figure 1. Example of the safety plan in the BritePath app.

Sampling and Recruitment

We identified a convenience sample of mental health and primary care providers who have cared for patients with mental health concerns. Providers were recruited through health systems participating in the Mental Health Research Network [23] and via snowball sampling [24,25], in which interviewed providers recommended additional potential participants. No specific level of digital experience or skills was required for participation in the study.

Ethical Approval

All study procedures were approved by the Institutional Review Board of the Kaiser Permanente Center for Health Research (KPCHR) at Kaiser Permanente Northwest (approval ID: MOD20050381-003), where the study was conducted. Interviews were conducted via KPCHR Teams, and digital recordings and transcripts were securely stored within the primary organization's firewall-protected file service.

Data Collection

Semistructured interviews were conducted remotely via Microsoft Teams. The interview guide (Multimedia Appendix 1) was developed by our medical anthropologist expert (NV) in coordination with the principal investigator (FL). Additionally, a qualitative investigator from the larger BritePath team reviewed the guide for content. The interviewer (FL) used a semistructured interview guide (Multimedia Appendix 1) to ensure consistency across interviews. The framework that guided the design of our qualitative interview guide focused on usability and concept testing. We examined whether providers from different backgrounds and training would consider using BritePath. The included questions aligned with several frameworks for adopting new technology, such as the Diffusion of Innovation theory [26,27]. The interviews assessed providers' opinions on using apps with patients and their impressions of the benefits and barriers of mental health apps in general. Participants were then shown a series of visuals (screenshots) depicting what a user would see while interacting with the BritePath app. These prompts ensured that participants had a clear and consistent understanding of the app's features and user interface. During this portion of the interview, participants were asked about their initial impressions of the BritePath app, as well as the barriers and potential benefits of using it in their practice. They were also given the opportunity to suggest features they would like to see in future app developments. Each interview lasted 30-40 minutes and was audio recorded and transcribed by an independent transcriptionist. Transcripts were entered into Atlas.ti [28], a qualitative analysis software program

XSL•FO
RenderX

used for coding and managing data. Atlas.ti was then used to generate reports for the analysis of interview transcripts.

Analysis

Thematic analysis, a method for analyzing patterns of meaning in a data set, was used to interpret the data by identifying themes and their interconnections [29-32]. Following established thematic analysis procedures [30], members of the research team (JC, LF, and NV) first familiarized themselves with the data and, together with FL, developed an initial code list consisting of a priori codes reflecting the interview questions. JC and LF coded the first interview using this initial code list and identified additional codes while reviewing the transcripts. The full team met to review coding consistency between reviewers and to evaluate the need for new, emergent codes. Modifications to the code list were made based on discussion and consensus. This process was repeated, with 2 team members coding 2 additional transcripts each. The full team met to discuss differences between coders for these additional transcripts and found minimal discrepancies in the codes applied. Upon confirming sufficient consistency in code usage and identifying no additional emerging codes, a master code list was finalized and used to code the remaining transcripts. After coding all transcripts, the full study team individually reviewed reports of coded interview segments to identify themes. The final themes were then derived through discussion and consensus. This formal, team-based analysis procedure was used to enhance the credibility and trustworthiness of the findings.

Results

Providers' Perspectives on Mental Health Apps and the BritePath App for Youth at Risk of Suicidal Behavior

We conducted semistructured interviews with a convenience sample of 17 providers from 7 states in the United States (Table 1). Our goal was to understand providers' opinions on the use of apps for youth with mental health concerns in general and the use of the BritePath app for youth at risk of suicidal behavior. First, we asked providers about their experiences using mental health apps with patients. Next, we gathered their opinions on a specific app, BritePath, designed to improve patient engagement and communication with providers for youth at risk of suicidal behavior. The interview guide is available in Multimedia Appendix 1.

Table 1. Provider demographics (N=17).

Characteristic	Values, n (%)
Age (years) group	
25-34	4 (23)
35-44	6 (35)
45 and over	7 (41)
Sex at birth	
Female	15 (88)
Male	2 (22)
Provider type	
Physician	2 (22)

Type of setting	
Large health system	10 (22)
Smaller group practice	4 (47)
Individual practice	3 (41)

Providers' Opinions About the Use of Apps for Mental Health Concerns in General

Overview

All providers reported familiarity with mental health apps, and most stated that they had referred at least one patient to a mental health–focused app—for example, to help patients learn a skill such as relaxation. However, none of the providers reported regularly using any mental health app during treatment visits or in an interactive manner with patients. Each theme is discussed in more detail below.

Theme 1: Mental Health Apps Have the Potential to Be Valuable as an Adjunct to Therapy Visits

Providers reported that they felt mental health apps could add value to the therapeutic relationship as an adjunct or complement to face-to-face or video-based psychotherapy sessions. However, most did not believe that mental health apps could serve as a substitute for psychotherapy visits. Several providers noted that these apps can offer access to exercises for learning new skills or encourage the use of tools discussed in therapy, making them a useful complement to treatment sessions.

XSL•FO
RenderX

> *I think they can be really great adjuncts if you have the time to utilize those as a clinician. I am always interested for my patients of course for them doing things in the many hours outside of therapy, so I see you from 1:00 to 2:00 and then there are all these other hours that in theory you're doing the things that we were practicing in that one hour. If there are apps that can promote, engage, and promote the use of those strategies, whether it's thought records or sleep diaries or mood meters, things like that. And then they can bring that back in and we can look at it together and that facilitates the conversation, I think that would be great.* [P5]

> *And this way as a clinician I am teaching a skill, but I want it to be reinforced by this tool that mainly my client really loves but eventually is a way to train the brain to think a new and different way.* [P4]

Providers also noted that this approach to learning skills may be particularly useful for teenagers, who frequently engage with their phones.

> *I think they're a great compliment to therapy. I think they're really useful as a tool. I am not a huge fan of the app-based therapies you know. Like text therapy and stuff like that, I think it's not a good fit for everybody of course. But I think the apps themselves as far as tools and teaching and reinforcing skills I think are really helpful. And I would imagine for teenagers, I am assuming most of them are on their phones quite a bit. So that might be kind of a really easy transition or way to incorporate into something they're already doing. I think it would be cool especially for teens if there was a way to have some sort of feedback or back and forth with their therapist so they could actually share what they're doing, that would be neat. I think there's a lot of potential there for younger people.* [P14]

Although providers generally expressed support for mental health apps, most also raised several concerns. They described issues from both the provider and patient perspectives.

Theme 2: Cost/Access to Tool

The cost of purchasing an app was noted as a potential barrier. Providers suggested that they would only consider recommending apps with relatively low fees or a 1-time payment rather than ongoing costs.

> *Obviously free is best. Especially for teens, even young adults that are trying to make ends meet. If not then maybe something that's a one-time fee. If it was a subscription that would be harder for that population. I think that's something that older adults could possibly swing, but unless the parents are paying for it, it doesn't seem like that would be a good match.* [P13]

> *On the patient side yeah I think it would depend on how expensive the app would be. If they've got to pay $50/month that certainly could be prohibitive for folks.* [P5]

In addition, providers expressed concern that some youth, particularly those from low-income backgrounds, might lose phone service or have limited minutes, which could hinder access to the app and reduce engagement with its tools. They also noted that youth might have only intermittent access to mental health apps for various reasons, such as an inability to consistently pay for phone service or depleting their data or minutes. This loss of access could be frustrating for youth trying to use mental health apps and could interfere with their engagement with the app's content.

> *Most of our patients do have smart phones so that's usually not a barrier. But sometimes getting their cell phones shut off has happened before. So whether or not they'll have continuous access I think has been a barrier in the past.* [P8]

Theme 3: Engagement

Many providers expressed concern that a common barrier to using mental health apps is a lack of patient engagement. Several participants shared experiences of patients downloading apps but never using them beyond the initial session. Others noted that apps often lose their appeal quickly, making sustained engagement a challenge.

> *Yeah, and I think the literature is pretty clear that if you send patients off to use some sort of behavioral health app, they'll use it once or twice. They'll check it out and then use drops of precipitously.* [P1]

> *I think patients often download and forget about them which is probably the biggest one is the engagement with some of these apps is low. After a short amount of time they might forget about it and then they don't really come back to it. So in the context of therapy that was less of an issue because I would be there and be encouraging that use. So that's one of the barriers if people were just using it out in the real world.* [P9]

Providers described challenges in getting youth to engage with an app at all. Several noted concerns that apps must be visually appealing and up-to-date to attract teens, who are often highly tech-savvy. Based on their experience, if an app was not engaging enough, usage would decline, similar to what they had observed with other patient-focused apps.

> *I think we all know that teens are very sophisticated with apps and tech so I think having it be interesting and up to date is I think if they're going to use it, it's got to be flashy in some way.* [P3]

Theme 4: Patient Privacy

Most providers expressed concern about patient privacy. Some noted that their patients had raised concerns about the privacy of data collected by apps, which could make them hesitant to use mental health apps. Providers also emphasized that health systems would need to ensure patient privacy before integrating an app into treatment.

> *I know so many patients just in general are very concerned about their privacy. So I think that would be at the top of my list is just knowing that I could have confidence in saying to this person this app has*

XSL•FO
RenderX

> *been vetted in these different ways. This is the security that it offers. Maybe it's even password protected when you sign in so that way if your mom picks up the phone and she can't get into that particular app. I feel like that's a deeply personal thing. And I would want to make sure that I am protecting my patient's confidentiality and I can speak to how this app does that.* [P2]

> *I think always a concern is privacy and making sure the data is secure and HIPAA compliant. Especially working in health systems we're always concerned about technology and the privacy of patient information.* [P9]

Some providers also discussed concerns about patient privacy at home. Before recommending an app, they wanted to be confident in their understanding of how patient data were being protected.

> *On the other hand, if their parents are checking their phone and they don't feel like they have privacy they might not be able to use it in the same way that they might have otherwise had they had more privacy.* [P8]

Providers' Opinions About the Use of the BritePath App

Overview

All of the themes providers discussed regarding mental health apps in general were also reported in relation to the BritePath app. For instance, providers expressed privacy concerns both broadly and specifically in the context of BritePath. After hearing a description of BritePath, all but one provider expressed interest in trying this type of app for patients with depression, suicidality, or both. In addition to the general themes identified for mental health apps, several additional themes emerged specific to BritePath.

Theme 1: May Make Visits More Efficient

Providers described several ways in which an app such as BritePath could make therapy visits more time-efficient. Some noted that BritePath could help patients gain insight into the relationship between their mood and the activities they engage in between visits.

> *I think such a common thing with younger teens is being able to reflect back on how their week went or how their time went. And often times having something that is kind of tracking in the moment gives so much more actual information of when there were any spikes in anxiety or in distress in some way to help be like oh I saw this happened on this day, what happened then. To help anchor them into being able to talk about some things. So I can see that being a real benefit.* [P15]

> *I think it's so important for people to be able to see visually what the distribution is of the moods throughout the week. And also to remember that they're not always in that low point. So having some check ins throughout and maybe not only on their really bad days, right, but check ins every day would be helpful probably so they could be able to track down only the downs but maybe the ups or the little bit better.* [P14]

BritePath was also seen as a tool for providers to gather information on patient moods and their use of techniques between in-person sessions. Providers noted that access to this information via the app could make sessions more focused and productive by reducing the need to collect it during visits and allowing for better session preparation. Additionally, real-time patient-reported data on the app were perceived as more complete and valid than recalled information shared during a visit.

> *If you had the time to review what someone did or didn't do since you last saw them before they even walked in the door...I've saved at least 10 minutes of the precious 45 that we have together. I can launch straight into hey your mood meter was great over the last week. Or I see you check in on your safety plan on Tuesday, tell me a little bit about that? I don't have to say so how did the last week go? Oh Tuesday was bad. Tell me more about Tuesday and then wait for them to bring up the fact that they had to use their safety plan on Tuesday. We can just get straight to it. And it helps...not only the time saver, but hopefully not having to deal with retrospective recall.* [P5]

> *I think too if we have a session with a patient and they're just in that moment trying to recall their week is not as impactful as if you can actually go back and see what they're feeling in any particular time and probably would really help with recall bias.* [P8]

Providers also discussed how the BritePath app could facilitate communication with youth and enhance their engagement in the treatment process.

> *I think...leveraging digital health tool...I think another place this can be helpful is if kids engage in it, it gives you more to talk about in the session. You know doing sessions with teenagers a lot of times it's pulling teeth to get them to say anything. At least this would provide them with one, another way to keep them engaged and two, more fodder for talking to someone that may not be interested in filling 45 minutes' worth of talking.* [P5]

Theme 2: Provides Access to Safety Plans

Most providers noted that a key benefit of BritePath was giving patients convenient and consistent access to their safety plans through the app. They believed that because most youth carry their phones, they would be more likely to have their safety plan readily available in a crisis—unlike a paper version, which could be easily misplaced.

> *I think the nice thing about it, is it's all in one place. It's easily accessible on our phone. If they're in distress at any given moment they can pull it out and it's all right there. That makes it much more likely that they're going to use their skills in the moment, versus us giving them a piece of paper or emailing*

XSL•FO
RenderX

> *them or whatever else technology that would be used in the past. So I think that's a huge advantage.* [P13]

> *So patients can have a safety plan in the EHR but if they can't access it. We print it out and who knows where they left it. This gives them something, most people are pretty good about not leaving without their phone. So, it's a way that's there, it's accessible.* [P1]

However, providers also had questions and concerns about the functionality of storing the safety plan on a youth's phone. Some wondered whether the safety plan could be easily integrated into the patient's electronic health record. Another concern was whether providers would be notified when a patient accessed or used their safety plan.

> *Would the provider be alerted if there was a change? For example, if someone were to use the program or use part of their safety plan would that then ping me as a provider? Or would I just need to go and check on the patient status every so often to know those sorts of things? Another thing I might be curious about is how it might communicate with my EHR, if there was a way to import the information or download, even the safety plan for example so that way I could then upload it into the patient's chart. I think that would be important for me too.* [P2]

Theme 3: Offers an Additional Way to Communicate With Patients

Providers noted that BritePath could serve as an alternative communication tool for patients. Some recounted experiences with teens who struggled to express themselves and suggested that BritePath could offer these youth another way to connect with their providers. One provider also noted that this feature could enhance engagement in treatment for some patients.

> *Obviously, someone who is busy, if they're actually busy or just having issues with talking with a clinician face to face, this is a way to avoid that stress of direct interpersonal interaction. So that's a positive. And adolescents have all sorts of reasons why they sometimes don't want to engage with care. This is a way for them to get some care even if they're not feeling like interacting with their clinician that week. That I see as a benefit. Asynchronous so it can be on their time rather than someone else's time.* [P12]

> *If you think about teenagers, they are much more comfortable with technology and sometimes that's a great place to start for therapy or treatment with them because they might not feel comfortable talking to a professional.* [P9]

Several providers valued BritePath's 2-way communication feature, noting that it could facilitate shared decision-making and provide real-time updates to the treatment plan.

> *I think there's a real value in that shared decision-making component that can go into an app like the one you're describing. And it also becomes an important way of sort of communicating.* [P1]

> *I think that two-way communication is what I think could be the most useful if it's going between the patient and the therapist and you're able to interact back and forth. So in terms of modifying treatment plan or knowing what is resonating with the person.* [P3]

Theme 4: Flexibility and Personalization of the BritePath App

A number of providers expressed enthusiasm for BritePath's flexibility and personalization features. Several noted that allowing youth to customize the app with photos, videos, motivational reminders, or prompts for coping strategies could help sustain engagement, increase usage frequency, and accommodate diverse patient needs.

> *I think that's definitely a bonus. Sometimes the out of the box app works just fine. But the more you can tailor it or personalize it to someone's specific needs, the more likely they are to use it, so I think that that could definitely be useful!* [P9]

> *I love that there can be general tools but also some really individualized personal things in there in too. I just love the idea of having names and photos of people, loved ones and pets and things like that.* [P14]

One provider highlighted BritePath's potential to empower youth by allowing them to personalize their treatment and safety plan.

> *The place a teen usually goes to for soothing support regulation is the phone. But it often feels like the phone is just riddled with pitfalls of things that could make things worse. Maybe don't go on Instagram and compare your life to other people. So the fact that there's something right next to it potentially on their phone for them to dive into instead of something that could be potentially more disregulating or harmful I think is fabulous. The more opportunity I think there is to customize what's happening in that app the more I'd be inclined to really empower my client to tap into a wise place, tap into wiser parts of themselves, have those places and parts load what's in the app. So then they have access to it in those harder moments. I could see that being a particularly empowering thing.* [P11]

The collaborative functionality of the app was also seen as a benefit, as it enables providers to modify the app's content in collaboration with patients over time as their needs change.

> *I think that two-way communication is what I think could be the most useful if it's going between the patient and the therapist and you're able to interact back and forth. So in terms of modifying treatment plan or knowing what is resonating with the person.* [P3]

Theme 5: Concerns About Integration of BritePath Into Clinical Workflow

Providers expressed additional concerns specific to BritePath, beyond those related to mental health apps in general. One

XSL•FO
RenderX

concern was its impact on clinical workflow. For instance, providers questioned how well the app would integrate with existing electronic medical record systems. They also expressed concerns about its ease of use for busy clinicians.

> *Another thing I might be curious about is how it might communicate with my EHR, if there was a way to import the information or download, even the safety plan for example so that way I could then upload it into the patient's chart. I think that would be important for me too.* [P2]

> *Do I have to have a certain log in? Do I see a list of patients that I have that are using it? How cumbersome is it to get into that? And what's the patient's understanding and expectations for me, either monitoring that data or accessing that data or is there even some sort of portal to do that? Or is it more that the patient brings in their phone with their smart phone app and sort of shows me what they've been up to?* [P1]

In some cases, these concerns amplified existing worries about mental health apps in general, such as what might happen if a patient experiences a crisis. Additionally, several providers raised concerns about managing patient expectations regarding 24/7 access to their provider and ensuring that patients understood how to handle crises when providers were unavailable.

> *The only thing that has come up before... as far as cell phone and texting technology is somebody trying to text you in crisis while you're off work. You're not checking, so if there's something that presents in the app that is alarming or suggests that this client is in danger of harming themselves and you haven't checked the app in whatever amount of time, that would be I guess the concern for me too.* [P13]

> *I would want to make sure that whatever the app is that it stays within the boundaries of how I am available to the client or not. And I'd want it to be clear, it's tricky because if I can get a report about where they're at conceivably I could get a report when they're having a moment of increased distress and does that require me to then reach out to them too? So, I'd want it set up to be like hey either this app only releases this data to me X amount of times, so if you put in that you're having a hard time I am not going to see it.* [P11]

Discussion

Principal Findings

The focus of this qualitative study was to gain a deeper understanding of provider opinions on the use of mental health apps in general and the BritePath app specifically for treating teen and young adult patients with depression, suicidality, or both. Providers in this study had no prior exposure to the BritePath app. Most were aware of mental health apps in general and expressed interest in trying the BritePath app with patients with depression, suicidality, or both. Nearly all providers viewed mental health apps as a complement to other mental health treatments rather than a replacement for psychotherapy visits.

Mental Health Apps in General

Most providers were supportive of mental health apps, recognizing their potential to provide access to information and skills that could improve youth mental health. Key benefits included their availability at any time—particularly when providers were not accessible, such as late at night—and their ability to reinforce skills such as stress reduction between sessions. However, providers differed in their level of comfort with these tools. Some frequently recommended resources such as online cognitive behavioral therapy programs or anxiety management apps, while others were less enthusiastic. Most providers noted that mental health apps might be particularly useful for younger individuals, as they frequently use phones and other digital devices. These findings align with existing research on provider and patient perspectives, which indicate broad support for digital mental health tools [13,17,33-35]. However, most providers emphasized that apps alone were not sufficient for youth with significant mental health concerns. Many explicitly stated that these tools should complement, rather than replace, psychotherapy.

All providers expressed concerns about patient privacy. They discussed potential risks related to data collection by apps, including unauthorized access by individuals other than the youth (eg, parents) and uncertainties about how app providers might use collected data. While privacy concerns are common with app usage in general [13], providers emphasized that data collected by mental health apps are particularly sensitive and require high standards of privacy and protection. Several providers noted that app usage has become so commonplace that privacy policies are often overlooked, which may be especially problematic for youth. One provider specifically highlighted the difficulty in determining how commercial apps safeguard data privacy, which they found concerning.

Many providers also raised concerns about maintaining youth engagement with apps. Difficulty in sustaining engagement with digital tools has been noted in prior studies [36,37]. Several providers pointed out that they currently have little to no insight into how engaged their patients are with mental health apps. This uncertainty tempered some providers' optimism about the potential of these tools as a strong aid in treatment.

Providers also identified several logistical barriers to the effective use of mental health apps. The cost was a common concern, particularly the potential inaccessibility of apps that require ongoing payments (eg, monthly fees). Additionally, several providers noted that youth often experience inconsistent access to phones due to service suspensions, late payments, or lack of internet access. While these concerns have been raised in studies on app use in general [13], they may be especially critical for youth with mental health concerns, as intermittent access could disrupt their ability to use these tools as a coping mechanism.

BritePath App

Each of the potential benefits and concerns providers expressed about mental health apps in general were also raised in relation

XSL•FO
RenderX

to BritePath, including data privacy, patient engagement, and cost-related concerns. In some cases, providers expressed stronger opinions—both positive and negative—specifically regarding BritePath. For example, concerns about patient privacy were heightened due to the app's inclusion of sensitive information on symptoms and suicidality. By contrast, providers strongly supported BritePath's potential to enhance psychotherapy visits by facilitating more in-depth collaboration between providers and patients on skill development.

Providers raised several additional themes regarding BritePath. Many highlighted the value of the app's personalization features, noting that these could enhance patient engagement. Most providers expressed enthusiasm for BritePath's ability to facilitate communication between sessions and help providers prepare more effectively for upcoming appointments.

Providers also raised concerns about ensuring that safety issues were thoroughly addressed if BritePath were to be used in practice. While they appreciated the idea of having a safety plan integrated into the app, they emphasized the need for built-in safeguards, such as pop-up messages directing patients to emergency services when necessary. Additionally, providers wanted to ensure that patients understood that communication through the app would not guarantee a 24/7 response from providers.

Practical Implications for Research and Clinical Practice

Providers suggested several ideas for future research on apps addressing suicidality in youth. Integrating ambient phone data, such as activity tracking, could enable more timely and accurate recording of safety plan activities, reducing reliance on self-reporting. Additionally, visually linking mood and activity data, along with incorporating pop-up mood assessments, could enhance patient awareness of the relationship between mood and behavior. Increasing personalization in mood tracking and allowing patients to annotate their mood data may further improve engagement with the app.

Although providers were enthusiastic about the potential benefits of a customizable, readily accessible safety plan on a patient's phone, many also raised concerns about ensuring the security of this information. From a clinical perspective, safeguarding safety plans on the device would be essential for successful implementation within health systems. Additionally, embedding a clear and transparent patient consent process into the app—one that explains who will have access to their data and why—would be crucial in helping patients understand the risks associated with using a tool such as BritePath. Furthermore, ensuring that BritePath is compatible with different phone operating systems and can integrate with various electronic health record systems would be key to facilitating widespread adoption in clinical practice.

Strengths and Limitations

This study provides new insights into providers' perspectives on the use of mental health apps for youth at risk of suicidal behavior. We acknowledge the potential for sampling bias. To address this, we aimed to recruit a diverse range of providers from different health systems affiliated with the NIMH Mental Health Research Network [23]. While this sample may not be fully representative of providers across all health systems, participants were drawn from health systems in 7 US states. Although the sample is not fully representative of all providers in the United States, it includes a variety of geographic areas, organizational arrangements, and provider types, ensuring a diverse range of perspectives. In designing our qualitative interview guide, we focused on usability and concept testing rather than adhering to a specific technology adoption theory, such as the Technology Acceptance Model [26] or the Diffusion of Innovation Model [27]. However, our interview questions covered many of the key domains included in these models. We invited providers who delivered mental health services within these health systems to participate, without requiring a specific level of experience with apps or other digital tools in their practice, as we aimed to capture a broad range of experience levels. It is possible that providers with a greater interest in app use were more likely to participate.

One goal of this study was to explore providers' opinions about the BritePath app, which was developed for use with youth at risk for suicide. Specifically, we sought feedback from providers with no prior clinical experience or knowledge of BritePath to assess its potential for future implementation in health systems. Our focus was on understanding the broader applicability of mental health apps, with a particular emphasis on BritePath. While we collected limited demographic data on providers, it is possible that unmeasured factors influenced their perspectives on the use of mental health apps. For example, although respondents represented a range of age groups, most were younger providers, who may have been more comfortable with apps in general than older providers. Despite these limitations, this study offers new insights into providers' perspectives on mental health apps, including the BritePath app, and highlights key concerns regarding their use with young patients at risk for suicide.

Conclusions

The use of mental health apps is expanding, yet more research is needed to determine how they can be most effectively integrated into mental health treatment. Most providers expressed interest in using the BritePath app for patients with depression, suicidality, or both; however, concerns about privacy and safety remain.

Abstract

Background: As technology is integrated into health care delivery, research on adoption and acceptance of health technologies leaves large gaps in practice and provides limited explanation of how and why certain technologies are adopted and others are not. In these discussions, the concept of legitimacy is omnipresent but often implicit and underdeveloped. There is no agreement about what legitimacy is or how it works across social science disciplines, despite a prolific volume of the literature centering legitimacy.

Objective: This study aims to explore the meaning of legitimacy in health and technology as conceptualized in the distinctive disciplines of organization and management studies, science and technology studies, and medical anthropology and sociology, including how legitimacy is produced and used. This allows us to critically combine insights across disciplines and generate new theory.

Methods: We conducted a critical interpretive synthesis literature review. Searches were conducted iteratively and were guided by preset eligibility criteria determined through thematic analysis, beginning with the selection of disciplines, followed by journals, and finally articles. We selected disciplines and journals in organization and management studies, science and technology studies, and medical anthropology and sociology using results from the Scopus and Web of Science databases and disciplinary expert–curated journal lists, focusing on the depth of legitimacy conceptualization. We selected 30 journals, yielding 796 abstracts.

Results: A total of 97 articles were included. The synthesis of the literature allowed us to produce a novel conceptualization of legitimacy as a form of social infrastructure, approaching legitimacy as a binding fabric of relationships, narratives, and materialities. We argue that the notion of legitimacy as social infrastructure is a flexible and adaptable framework for working with legitimacy both theoretically and practically.

Conclusions: The legitimacy as social infrastructure framework can aid both academics and decision makers by providing more coherent and holistic explanations for how and why new technologies are adopted or not in health care practice. For academics, our framework makes legitimacy and technology adoption empirically approachable from an ethnographic perspective; for decision makers, legitimacy as social infrastructure allows for a practical, action-oriented focus that can be assessed iteratively at any stage of the technology development and implementation process.

Introduction

Background

Technological innovations and health care delivery have become increasingly intertwined in recent decades [1,2]. With each promising innovation, new questions are raised about how to integrate the technology into health domains and the social implications of doing so [2-8]. This problem has given rise to evaluation processes such as health technology assessment [9] and a range of government institutions, such as the National Institute for Health and Care Excellence in the United Kingdom, to help make decisions about the appropriate use of technologies in various health care contexts [10].

Questions of legitimacy are implicit in debates about embedding technologies in health care, and these implicit questions about legitimacy permeate the literature about health and technology. While there is limited conceptual work on legitimacy in health and technology specifically, within the small body of work that exists, legitimacy is explored through a wide range of theoretical lenses and conceptualizations. However, there is no consensus about what legitimacy is or how it works nor is there much conversation among different branches of the literature. Across social science disciplines and medicine, legitimacy is affiliated with many concepts, including "acceptability" [11], "reasonableness" [12], and "transparency" [3,4]; these terms are sometimes conflated with legitimacy itself. Definitions of legitimacy range just as widely, especially among different disciplines: in organization and management studies (OMS), legitimacy is often defined as "normative appropriateness" [13,14], although science and technology studies (STS) and medical anthropology and sociology (MAS) include definitions such as "the acceptability of claims to authority" [15,16] and "accountability for reasonableness" [10] when the term is defined. Some disciplines, such as OMS, follow a strong tradition of explicit theorization of legitimacy, while others, such as medicine, usually do not explicitly problematize or define the word "legitimacy," although legitimacy and similar concepts may play a substantial role in discussions in the field. Within the same discipline, some authors use legitimacy interchangeably with other concepts [6], while others focus on a single subcategory of legitimacy developed from a narrow line of theoretical thought [17]. Given the breadth and depth of the literature on legitimacy in health and technology, it is clearly an important topic. A cross-disciplinary conceptualization of legitimacy that can be applied to questions about embedding technologies in health care would allow for a deeper understanding of these processes.

We chose to focus on legitimacy for several reasons. Legitimacy specifically is widely used but poorly defined within multiple fields studying health and technology and points toward social and organizational processes. Even though legitimacy is clearly important in studies of health and technology across many disciplines, it is abstract and there is very little cohesion both within and across social science disciplines around how it is produced and how it is used.

To understand the role of legitimacy in relation to the embedding and governance of technology in health care, we fleshed out the different ideas and underlying assumptions authors bring to the OMS, STS, and MAS literature. This paper explores three research questions: (1) What does legitimacy mean in the context of health and technology? (2) How is legitimacy produced? (3) How is legitimacy used to explain the challenges of embedding technologies in health care? On the basis of a synthesis of the literature, we developed a novel conceptualization of legitimacy as social infrastructure. This allowed us to focus on the aspects of legitimacy related to norms, materialities, semiotics, and specific relationships among stakeholders and larger systemic contexts.

Existing frameworks guiding policy intentions around technology adoption in health care often do not reflect the realities of everyday practice nor do they focus on the social processes of embedding technologies in health care [18]. Current models and frameworks for embedding technologies (in health care), such as the Unified Theory of Acceptance and Use of Technology [19] and the Technology Acceptance Model (TAM) [20,21], provide useful information about the judgments and perceptions of various actors in relation to a specific technology. While these models provide useful insights into actors' *intention* to adopt, as well as the ethical considerations they may perceive and institutional norms they may face, they do not often explain how and why certain technologies are or are not adopted or accepted *in practice* among particular groups and thus can provide only limited governance support [22]. Most technology adoption and acceptance models deal primarily with behavioral intention [20,21]. These models attempt to explain individual behavior intentions (as a proxy for actual behavior) through an analysis of a variety of factors, which can include beliefs, attitudes, perceived control, and perceived norms. This leaves substantial gaps, including the lack of attention to external factors impacting the embedding process [20] and any difference between behavioral intention and practice. Focusing on the impact of legitimacy within technology embedding processes can help fill these gaps by allowing for more comprehensive and nuanced conversations about technology adoption and acceptance.

A Cross-Disciplinary Legitimacy Conceptualization

The goal of this review is to produce a theoretical synthesis of how the legitimacy of health and technology is conceptualized. We aim to generate theoretical insights that will allow for a cross-disciplinary approach to legitimacy. To do this, we used the critical interpretive synthesis (CIS) review method to produce a cross-disciplinary understanding [23] of how legitimacy is produced and maintained without privileging one discipline's theoretical traditions over another's [24].

We used OMS, STS, and MAS as a disciplinary framework to understand the different strands of reasoning within legitimacy studies. OMS includes the most clearly developed theorization of legitimacy as a concept and several of the best-known review articles [14,25]. Legitimacy studies is a well-defined subarea of OMS research that explores legitimacy in the context of management, entrepreneurship, and institutional endeavors. OMS primarily focuses on how legitimacy works at the level of organizations and institutions, rather than among individual people or through technologies.

XSL•FO
RenderX

STS explores the social and cultural implications of science, technology, and technology development [26,27]. STS tends to focus on controversies, the unforeseen implications of technology development and adoption, and "black box" technologies [28] that inhibit full understanding. This contributes to a strong disciplinary interest in legitimacy, particularly of technology and medicine. STS centers interactions with technologies and technical change in legitimacy discussions, rather than separating the motivations of human actors from technologies and practices.

Although MAS developed from different traditions, they have partially converged in the study of medical cultures and interactions from a qualitative perspective [29], which is also the focus of legitimacy studies in MAS. MAS generally takes a skeptical view of taken-for-granted institutions. Many studies explore the impact of this taken-for-grantedness on people who are harmed by or left out of these institutions and systems. This leads to a natural questioning of legitimacy and deeper exploration of baseline assumptions, particularly in a health care context. Together, these disciplines explore health and health technologies with less focus on institutions and more focus on humans and connections among them. We hope that greater synthesis of different conceptualizations of legitimacy could provide a more holistic perspective about how and why technologies are or are not embedded in health care that integrates ideas from outside current frameworks based on adoption, acceptance, and implementation.

This review does not focus on ethics, although some articles that deal with ethics are included in this review. Within ethics, there is general consensus that legitimacy in health and technology is produced through ethical judgments and values-based reasoning [30-33]. While there is more cohesion in ethics than in other disciplines that deal with legitimacy, the scope of the literature is narrower and generally limited to moral or ethical legitimacy [3,34]. Legitimacy is often defined in ethical terms across several disciplines, including management, STS, and health policy. Articles with an ethical focus on health care technology adoption usually prioritize normative and moral dimensions of legitimacy, which may or may not be related to other aspects that contribute to overall legitimacy, such as utility or social acceptability [35]. While moral legitimacy is an important dimension of the subject, it has also already been studied and reviewed extensively and is far more clearly defined within the literature than other dimensions of legitimacy. Therefore, we chose to focus on other aspects of legitimacy to fill gaps in the existing social science literature. In addition, our review does not center legal approaches. Legal literature defines legitimacy according to principles of a participatory democracy [36]. Because the focus of this review is on social processes rather than democratic principles, we have chosen to center other means of legitimacy production and thus other branches of the literature, while acknowledging that democratic principles can play an important role [15,37].

Methods

Overview

In a research landscape that increasingly encourages and necessitates interdisciplinary collaboration, a CIS [24] allows us to develop a richer conceptual frame that can bring these different disciplines into conversation with one another [23,38]. The CIS method specifically addresses the limitations of conventional systematic reviews in cases where the objective is to generate a critical analysis of a body of the literature [24]. It draws on a tradition of qualitative inquiry: rather than summarizing the literature using preidentified key concepts, CIS uses an inductive, iterative process to interpret data, develop key concepts, and synthesize concepts with data through the process of the review itself [39]. Therefore, CIS produces a critical interpretation of the data reported in literature, which allows questioning of taken-for-granted assumptions [24].

We found CIS to be a particularly appropriate review style for an exploration of legitimacy in health and technology because, unlike traditional review styles, CIS is adept at dealing with "a large, amorphous, and complex body of literature" [24]. CIS synthesizes findings in a way that is both conceptually valuable to researchers and useful in informing policy. Furthermore, the CIS review style can manage the abstract nature of legitimacy across 3 disciplines without reducing the complexity of existing literature.

CIS is methodological and rigorously structured. However, it is also labor intensive compared to other review styles and deprioritizes transparency and full replicability available through systematic reviews. As in other kinds of interpretive research, different researchers using the same materials may have come to different conclusions, and full transparency of analysis cannot be expected at the same level as quantitative studies. We chose the CIS method in service of greater interpretive flexibility and conceptual depth and because it allowed us to account for the diversity of qualitative research without privileging a small range of studies that met specific and, here, less-relevant methodological standards.

Despite many empirical papers that address some aspects of legitimacy in relation to health and technology, there is a much more limited number of articles dealing with legitimacy in the domains of health and technology at a conceptual level. Therefore, we adopted broad definitions of both technology and health, including as many articles with strong legitimacy theorization as possible. "Health" in this paper refers to "human health and well-being"; "technology" includes "any devices, machinery, or equipment developed for the application of scientific knowledge that may impact human health." We acknowledge that there are potentially many other ways to operationalize these concepts that could be relevant to this review and health care in general [40]. Given the broad, conceptual focus of the review, as well as the wide range of distinctive technologies considered, we introduced 2 measures that allowed us to provide a clear focus. First, we zoomed in on conceptualizations of legitimacy; it was outside the scope to examine the specific empirical contexts and details of these conceptualizations (ie, the use of specific technologies within

XSL•FO
RenderX

specific health practices). Second, looking at specific disciplines proved helpful to demarcate boundaries around our topic. We used academic disciplines as the basis of our theoretical categories to give structure to a broad and abstract review, following in a strong disciplinary synthesis tradition established by other CIS researchers [23,38].

Our review was conducted in 4 cycles [38]. In the first cycle, we conducted an exploratory search in relevant journals with many articles on legitimacy in the context of health and technology. Using this search and subsequent iterations, we refined inclusion criteria (for instance, a threshold for legitimacy theorization) to determine a list of disciplines, journals within each discipline, and articles within these journals that would be a part of our review (see Multimedia Appendix 1 for details). In the second cycle, we read and coded included articles directly from the text, then grouped codes into thematic areas. Third, we analyzed legitimacy in health and technology within each discipline through interpretive disciplinary summaries. Finally, we developed a synthesizing argument across all 3 disciplines, based on these interpretive summaries.

Search Strategy

Journals within each discipline were selected for the review manually. Given the interdisciplinary nature of this review, we sought to include relevant journals within each discipline from a wide range to ensure diversity of perspectives.

The first author ran an initial search in Google Scholar and the Web of Science (WoS) database using the terms “legitimacy,” “health,” and “technology.” However, it became clear that regardless of how specific the search criteria became, most records returned through a database search would not include deep conceptualizations of the term “legitimacy.” This is because this term is commonly used across many disciplines as an unproblematic descriptor of technologies, legal processes, narrative choices, medical decisions, policies, and institutions. Therefore, we switched to a more iterative, manual strategy for discipline and subsequently journal selection (Textbox 1). The first author searched through a few of the major journals (based on impact factor or prior knowledge of the review team) in depth to understand whether studies addressing questions of legitimacy in a specific discipline generally included deeper conceptualization. This method allowed us to narrow down the disciplines to be included (see Multimedia Appendix 1 for details).

  (interdisciplinary journal: some articles included within science and technology studies)
- Sociology-The Journal of the British Sociological Association
- Sociological Theory

Upon the selection of disciplines, journals were first included based on impact factor: the top 10 journals in each discipline according to the WoS formed the base of the list. Then these journals were screened for topical relevance, and lower-ranked journals were excluded when the topic was not relevant. Finally, journals were added from library guides created by universities that are well-known in the field, especially if no definitive rankings were available from the WoS (STS) or there was too much disciplinary overlap in the rankings (MAS). This resulted in a list of approximately 20 journals per discipline. We then screened all journals for legitimacy, health, and technology results to produce the final list, prioritizing journals that contained significant theorization and conceptual work around legitimacy (see Multimedia Appendix 1 for details).

RenderX

Selection Process

Overview

A total of 791 abstracts were selected for initial review in April 2021 (Figure 1). Articles were sorted based on inclusion criteria: an article was included if there was evidence of explicit theorization or problematization of legitimacy in the abstract and the subject of the article was health or technology or both. A final search for more recent articles was run in August 2022, resulting in 1 additional inclusion. Multimedia Appendix 1 gives more information about the inclusion criteria.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of inclusions. WoS: Web of Science.

Triangulation

The first author (SH) read all 791 abstracts and categorized them according to the inclusion criteria as "include," "exclude," or "review." The last author (RW reviewed 79/791, 10% of the total articles' abstracts at random (every 10th article when arranged in alphabetical order by author name). The resulting inclusion list closely matched SH's selection. In the 7 disagreements, the 2 reviewers came to a joint decision about each contested article and edited the inclusion criteria. SH then reviewed the abstracts again. With no disagreements following this protocol, the literature list of 96 articles was finalized in March 2021, with an addition of 1 article in August 2022, bringing the total to 97, including, by discipline, 48 for STS, 29 for OMS, and 20 for MAS [4-8,10,12,13,15,16,37,41-126].

Synthesis Methods

The goal of our initial analysis was to develop "synthetizing constructs" for each discipline, which "build on the explanations and interpretations of the constituent studies and are simultaneously consistent with the original results while extending beyond them" [24]. To accomplish this, SH first coded themes across a random selection of 30 articles spread equally across the 3 disciplines in Atlas.ti (ATLAS.ti Scientific Software Development GmbH). Inductive coding began with words taken from the article text. We made an exception for deductive codes relating to assumptions made as part of our "critical and reflexive approach" to this review [24]; for instance, coding whether articles discussed legitimacy as a process, perception, or asset based on our background understanding of existing legitimacy theorization across multiple disciplines. SH grouped codes by theme within each discipline. This thematic analysis was performed with the help of tables of code co-occurrences, generated in Atlas.ti, which showed overlap of unique codes within each document; this allowed us to understand when codes could be combined into a theme. We also used network visualizations, which helped us understand how different aspects of legitimacy may relate to one another on a broader scale (see Multimedia Appendix 2 for an example of one of these visualizations). This process allowed reviewer SH to maintain a differentiated perspective on each discipline and acted as a memory aid for the reviewer given the volume of the literature. SH then wrote summaries of the approach to

XSL•FO
RenderX

legitimacy within each discipline, which were discussed with RW. SH coded the remaining articles using Excel (Microsoft Corporation) while editing the disciplinary summaries as necessary. Multimedia Appendix 1 provides an example.

SH developed a synthesizing argument that could connect constructs of legitimacy across all 3 disciplines. SH tested the fit of different conceptualizations with the disciplinary summaries and then explored the development of these metaphors with RW. After SH had read 90% (87/97) of the articles, no further edits or additions to the disciplinary summaries or synthesizing argument were necessary, likely indicating data saturation.

What Does Legitimacy Mean?

The basis of legitimacy epistemology in OMS can be traced to the highly influential paper by Suchman [14]. His definition of legitimacy still forms the basis of most subsequent theorizing in this field: "Legitimacy is a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions" [14].

This definition builds from and expands on Weber's [127] understanding of legitimate authority, among other conceptualizations [41], focusing on the application of Weberian legitimacy concepts such as "tradition, affectual attitudes, value, and legality" [127] within a "socially constructed system of norms, values, beliefs, and definitions" [14]. Bitektine and Haack [128] further expanded on the Weberian connection to Suchman [14] with a multilevel legitimacy theory that differentiates among legitimacy judgments at the individual and collective levels [42]. Because of strong theoretical cohesion in this discipline, authors draw generously from these theoretical traditions, and most legitimacy subtypes are variations of normative legitimacy. Normative legitimacy deals with the norms, systems, and underlying assumptions that result in an institution, technology, or system being considered legitimate, and is generated through systems and social processes that may not be made explicit until there is a legitimacy crisis [41].

This definition is notable for its understanding of legitimacy as a perception of actions based on socially constructed norms and implicit conceptualization of legitimacy as a taken-for-granted state. However, perhaps more important is what is left out: because legitimacy is "generalized," it is not dependent on materialities or physical space, nor does the definition of legitimacy change specific to relationships among institutions or individuals. Our critical interpretive analysis shows that these kinds of assumptions seem to help determine the lines of reasoning for most OMS legitimacy scholars included in this review.

Our analysis shows that OMS legitimacy studies constitute a cohesive body of literature in which theoretical contributions are made incrementally. For instance, most authors outline exactly how they are adding to the existing literature (usually based on the definition by Suchman [14]) in a specific way. For instance, articles often divide legitimacy into ever more granular categories such as "network legitimacy" [43] and "actional legitimacy" [44] or focus on a particular aspect of the definition by Suchman [14] to explore in more depth, such as "normative appropriateness" [129]. Therefore it is easy to trace the lineage of theory. However, because every article adheres to the same framework, there is less diversity of thought. In light of this, a division could be made between technology literature and health care literature. Technology literature, usually with an entrepreneurship bent, tends to focus on audience perception and innovation framing through discourse, by teaching entrepreneurs how to appeal through discourse to different kinds of funding audiences [45]. For example, entrepreneurs seeking crowd-based funding are advised to make "contribution claims" emphasizing identity and added value to the funding community, rather than institutional ties or the significance of potential scientific or social advancements that may legitimate the entrepreneur to other audiences [45]. Health care literature focuses mainly on institutional legitimacy, for instance, by examining the negotiations involved in academic health center mergers [46] or the role of physician executives in institutional contexts [47]. For example, Kitchener [46] emphasizes that even as new sources of legitimacy for an academic health center became necessary in the wake of both a merger and a changing environment, the aim was to create an "aura" of legitimacy within a new institutional logic; in other words, even though the source of legitimacy changed, it was still defined through institutions.

How Is Legitimacy Produced?

On the basis of the literature reviewed for this study, conceptualizations of legitimacy production in OMS fall into 3 categories. Legitimacy-as-process, or legitimation, is "an interactive process of social construction" [25], often with clearly delineated steps toward generating legitimacy [48,130]. Articles using this conceptualization tend to track change over time [13,49,50], for instance, by examining the legitimation journey of a single innovation over decades [50]. Legitimacy as perception or "a social judgment, an evaluation, a socio-cognitive construction" [25] is used most frequently in relation to audiences or the question "legitimate to whom?" usually when examining innovations within larger organizational contexts [45,51,52]. Finally, a legitimacy-as-property conceptualization, in which legitimacy is viewed as an asset to be gained, increased, or lost [25], emphasizes how an entity gains legitimacy rather than differences between legitimate or illegitimate entities; this conceptualization appears to play a smaller role in more recent work. Legitimacy as a process and legitimacy as a perception are often used simultaneously within the same paper; there is an acknowledgment that both perspectives can offer valuable insights. For instance, McKnight and Zietsma [53] describe the process through which new ventures can achieve "optimal distinctiveness" (a perception) through framing and collaboration strategies (a process). Similarly, Garud et al [54] discuss entrepreneurial storytelling as a legitimation process that relies on audience perceptions, thereby promoting an understanding of audience perceptions

XSL•FO
RenderX

as part of analyses of different narrative techniques, which are framed as processes of legitimation [53].

How Is Legitimacy Used?

Within the literature reviewed, we noted that legitimacy is often assumed in OMS to be necessary for resource acquisition and is mostly relevant in an institutional setting. Because resource acquisition is the *raison d'être* of business in capitalism, legitimacy is considered essential. All literature included in our review aims to explain legitimation journeys or to advise institutions and entrepreneurs on how to move toward legitimacy. The stated goal is often to advance legitimacy theory within OMS, rather than explore empirical evidence beyond specific case studies.

Our analysis shows that nearly all legitimacy problems in OMS are framed as problems of categorization: either an institution or innovation has been miscategorized by its intended audience, or it has not yet been categorized [51]. Because of this, there are several articles that deal with the paradox of legitimacy for disruptive innovations: the innovation must conform to a category to be seen as legitimate, but it will not be seen as necessary unless it also distinguishes itself within the category [45,53,54]. Articles often describe how entrepreneurs can strike this balance or analyze how an older innovation navigated the paradox. For instance, Ruef and Scott [41] produced a multidimensional model of legitimacy designed to help hospitals use knowledge of legitimacy norms and categorization to "attract managerial legitimacy." Other authors provide articles that, while academic, can also be interpreted as how-to guides for entrepreneurs attempting to formulate narratives for different audiences. Articles in this category posit that entrepreneurs must fit the narrative to the correct category of both the legitimacy problem [54] and the audience's perspective [45].

Articles discussing specific innovations often explore problems of categorization through "institutional logics" [45,46,55] or the forms normative legitimacy may take within a particular institution. These articles acknowledge that different institutions have different norms, and therefore, entrepreneurs and innovators must adapt their storytelling to "fit" with the institution. Our analysis of the OMS literature showed that institutions that are taken for granted have no narrative flexibility. This means that any changes made not only require buy-in from professionals but also immediate practical implementation of changes (such as shifting patient education responsibilities from physicians to nurses) to avoid becoming mired in default institutional processes [56]. However, an entrepreneurial venture wrestling with liability of newness [53] has nearly endless opportunities for narrative reframing and limited risk of stagnation in nonexistent institutional processes [45].

Summary

In short, OMS seems to heavily theorize granular definitions of legitimacy, derived mostly from normative legitimacy. Most articles describe how organizations can move from illegitimate to legitimate status. Legitimacy must be negotiated at multiple levels and can be conceptualized as a process, perception, and asset. On the basis of our initial analysis, legitimacy in OMS rests on taken-for-grantedness and categorization according to institutional logics; it is hampered by liability of newness [51] and difficulties fitting into an institutional logic or other category.

We now move on from the critical interpretation phase of CIS methodology and toward synthesis. We develop synthetic constructs to metaphorically unite major themes within each discipline. While the OMS line of reasoning is somewhat homogeneous, our interpretive analysis shows that there is acknowledgment that different institutions use different systems of thought, or institutional logics, to judge and negotiate legitimacy. Stakeholders must navigate these different systems by fitting themselves into clear categories. However, the system by which legitimacy is judged and negotiated is rarely fully navigable to any one stakeholder.

In this way, navigating legitimacy in OMS is like using a highway system. The roads themselves (in this case, pathways to legitimacy) are clear and concrete but can only be used by particular categories of vehicles in particular locations, in the same way that, for instance, entrepreneurs must use particular discourses (ie, roads) to legitimate their invention to certain audiences (locations) [45,50,54]. The metaphor of the highway system allows us to capture OMS' conceptualization of legitimacy as a rule-bound system of connections, driven by institutions. The highway system metaphor shows us that the OMS perspective on legitimacy is unusual for how fully theorized and comprehensive it is. However, in the same way that mapping a highway system alone does not describe everything that happens on the road, this metaphor also helps us articulate gaps in OMS theorization. OMS focuses on pathways to legitimacy, institutional involvement, and categorization; however, it can be difficult to explore the moments of legitimacy breakdown, unexpected contradictions within legitimacy journeys, and the influence of materialities on legitimacy within the concrete and bounded pathways that make up legitimacy conceptualization in OMS.

Science and Technology Studies

What Does Legitimacy Mean?

Within the legitimacy literature reviewed, nearly all STS articles dealt with health care or science practices on the edge of scientific validity or public acceptance, usually by focusing on controversial technologies. Authors seemed to pay significant attention to the audience for these controversies. Innovations explored within STS also include changes in health care and scientific systems or discourses, for instance, the process of creating new institutions within an academic environment [57].

In this way, it seems that legitimacy in STS can only be discussed easily when it is in question. This may be linked to STS's longstanding focus on controversies as strategic locations of research and the STS tendency to "stay with the trouble" [131]. Taken-for-grantedness may be considered such an integral part of legitimacy that it raises red flags in a discipline that is highly sensitive to unintended consequences.

However, in the STS literature reviewed, legitimacy itself is rarely the subject of an article. Our interpretive analysis shows that legitimacy is still undertheorized in STS, in that many

XSL•FO
RenderX

articles do not reference other legitimacy literature or define the term. When legitimacy is explored in depth, authors tend to deal with it as a type of knowledge coproduced at the site of controversy between human and nonhuman actors. For instance, 2 articles examine the demarcation of boundaries in discourse about future-facing technologies; in these articles, narratives about nanotechnology and forensic science both impact and are impacted by developments in the technology [16,58]. For instance, Selin [16] demonstrates that even if a single vision of the future of nanotechnology is accepted by scientists over all others, competing visions may still have an impact on the direction of technological development via other avenues, such as governance and funding. We interpret this as evidence that legitimacy is coproduced between the narrative around new scientific disciplines and concrete innovations within those disciplines.

A consequence of the focus on disputed boundaries that we observed in the STS literature seems to be that STS scholars treat legitimacy as mutable. Boundary work [59] articles conceptualize legitimacy as a process that happens through negotiation within relationships among people and institutions. Boundary work deals with how people and institutions negotiate changing roles, limits, and responsibilities, often in relation to knowledge practices [59]. Within our review, most authors seem to use boundary work only as an explanatory framework for discursive strategies, but some articles include writing and practices as instances of boundary work [60]. For instance, Granja and Machado [58] describe how forensic scientists clearly demarcate their expertise and the limits of their role in the justice system through both discursive strategies and practical performances of accountability such as fastidious record keeping as a strategy to maintain their legitimacy. While perception can play a role in this process, we found no STS boundary work articles within the literature reviewed that consider legitimacy to be merely an asset. We interpreted this as possible evidence of the STS disinclination to consider any relationship or object to be fixed and a general disciplinary focus on processes of knowledge production.

How Is Legitimacy Produced?

We found that processes of legitimacy coproduction of new technologies in health care are described in relationships among a variety of human and nonhuman actors [28]. STS seems to resist explanations that pin legitimacy's presence or absence on a single explanation or strategy. Instead, by examining the influence of nonhuman actors, STS encourages readers to embrace complexity in legitimacy relationships. For example, Barker [61] discusses how a drug marketing campaign legitimated a contested illness; McLevey [62] details how legitimacy goals for policy recommendations change how think tanks make knowledge; and Greco [63] uses the concept of "scientific ideology" to explore how the placebo effect threatens the legitimacy of scientific rationality in biomedicine. In these examples, the influence of unexpected nonhuman actors shapes legitimacy in a porous way; this influence adds complexity to legitimacy relationships. These examples thus turn the "expected" legitimacy relationship upside down. Barker shows that a treatment can make an illness legitimate (rather than an illness becoming legitimate and then treatment being developed). McLevey [62] demonstrates that knowledge may be made to legitimize policy recommendations (rather than knowledge first being created and then informing policy decisions). Finally, Greco [63] posits that a biomedical effect can threaten the legitimacy of biomedicine (rather than biomedicine creating biomedical effects that reinforce its legitimacy).

How Is Legitimacy Used?

Through our critical interpretive analysis, legitimacy in STS appears to be yet another "two-faced Janus" [28], in that it is coproduced by both taken-for-granted processes and unexpected assemblages, which may appear contradictory. For instance, Brown and Michael [64] note that the institutional mechanisms for validating scientific discovery play a part in legitimizing medical use of pig organs. However, the authors also find that these taken-for-granted institutional processes are not enough to legitimate transspecies transplantation. Rather, porcine donor organs are legitimated in their interpretation through an unexpected assemblage of institutional processes and scientific and cultural judgments about pigs. While anatomical similarities between humans' and pigs' organs exist from a scientific perspective, human-pig differences legitimate porcine donor organs (over, for instance, monkey organs) from a cultural perspective [64]. These apparent contradictions do not threaten the legitimacy of porcine donor organs; instead, the authors interpret these contradictions as necessary to establish legitimacy for a controversial innovation in medicine.

While most articles in the reviewed STS literature use the concept of legitimacy to explore complexity in relationships among technologies, ideas, people, and institutions, a small subset of the literature consists of discourse analyses focusing on language as the only vehicle of legitimation [4,62]. In these articles, there is no room for other means of legitimation, such as nondiscursive practices, language-free materialities, or physical space. In addition, policy-oriented articles about discourse-based legitimation strategies tend to view these strategies as mutually exclusive: "legitimacy can only be achieved if complexity is reduced via language" [65]. This appears to be a radical departure from the assembled view of legitimation present in most STS articles, in that legitimacy is produced by specific arguments designed to convince one party that another is legitimate, rather than *through* the complexity of negotiation among people, technologies, ideas, and institutions. However, both STS subgroups use legitimacy as a relational concept, whether relationships are implied through arguments or complex negotiations.

Summary

Our analysis demonstrates that STS approaches legitimacy through controversy and contestation. Because of its empirical orientation and wide variety, the way legitimacy is approached in STS cannot be viewed as theoretically cohesive. We found that STS explores legitimacy as an artifact of knowledge coproduction, centering nonhuman actors and complex legitimacy processes through discourse, practices, or both. In one conceptualization, legitimacy is viewed as a constant and complex negotiation among actors and their contexts. However, discourse analyses often view the complexity of these relationships as a problem for legitimacy rather than an integral

XSL•FO
RenderX

aspect of the concept. Despite this divergence, nearly all STS literature reviewed seems to assume that legitimacy is relational and includes nonhuman actors, contexts, and practices of knowledge production.

Moving toward our synthetic constructs, we posit that in STS, the coproduction of legitimacy through both taken-for-granted processes and unexpected assemblages functions such as the mutable infrastructure of a computer operating system. The hardware of the computer does not change (much), even though the overall capacity of the computer relies on constant updates of existing software. New operating systems build on what came before while adding something new to stay relevant. Similarly, the legitimacy of technologies in health care is viewed predominantly as being built on underlying infrastructures, such as evidence-based medicine (EBM) and laboratory protocols. However, it is also considered to be shaped by unexpected influences, such as the coexistence of traditional medicines with EBM standards [66] and popular conceptualizations of new technologies that do not align with the use of those technologies by experts [58]. Furthermore, legitimization of a technology may have unexpected consequences, such as a medicine legitimizing an illness [61]. Legitimacy, according to STS scholars, must be constantly negotiated among nonhuman actors through an iterative process that is most visible at the boundaries. Through the metaphor of computer operating systems, STS emphasizes a dualistic perspective of legitimacy. Legitimacy in STS depends on the mutability and unexpected creativity of practices, actors, and context (ie, software); simultaneously, this "software" of legitimacy must be built on top of preexisting systems that are much more rarely changed in substantial ways (ie, hardware). Without these preexisting systems, the knowledge production practices delineated by STS scholars have nowhere to operate.

Medical Anthropology and Sociology

What Is the Meaning of Legitimacy?

On the basis of our critical interpretation of the MAS literature under review, we found that MAS tends to center relationships among people within larger systems and physical spaces, rather than the nature of the systems or institutions themselves. Similar to STS, the MAS literature reviewed usually discusses controversies rather than strategies of legitimation.

Because few articles use concrete definitions of legitimacy or conceptualizations that reference any other body of literature, even if they discuss legitimacy issues in depth using empirical evidence, we found legitimacy to be undertheorized within MAS as a discipline. Several articles use terms such as "medical legitimacy" [6] or "narratives of legitimation" without definitions [67]. Some define legitimacy only in relation to another concept [12,68,69]. More than any other discipline, MAS seems to veer toward legitimacy definitions that are limited by subject and narrow [59] in scope: for instance, "being legitimately on sick leave requires both a certified illness and the inability to perform one's work as a result of that illness" [70]. In our interpretation, this appears to allow for more empirical grounding but prevents conversation with other literature about legitimacy as a larger concept. Within the MAS literature reviewed, legitimacy is always relative, in that there is no universal legitimacy that works across all contexts.

However, there is still some cohesion visible among a subset of articles in the discipline. Several authors frame legitimacy as a form of "symbolic capital" in the Bourdieuvian sense [69,71,132] that can be used for resource acquisition. These articles and others also use boundary work [59] to describe the legitimacy of professional roles as a negotiation of boundaries mostly through discourse [72]. In combination with the disciplinary tendency to focus on the disenfranchised, these framings paint legitimacy as a power issue [37].

The literature reviewed seems to prioritize nuanced accounts of both social processes in contested situations and the spaces and materialities that shape the contestation of a technology. For instance, in an exploration of medical quackery in South Africa, Hornberger [68] shows that even when using medically useless technologies, providers of these technologies can construct legitimacy for their patients because of contextual elements, such as lower education levels, local beliefs, and problems accessing proven medical treatments. Spaces, materialities, and relativity appear to be especially important in articles about disconnects between policy and practice in professional settings [73]. For example, Perrotta and Geampana [7] explore how in vitro fertilization (IVF) professionals navigate the disconnect between the standards of EBM and the enthusiasm of patients for the latest technologies. In another account of IVF, Barnreuther [84] notes that because the research took place in a physician private home in India, as opposed to an institutional setting in a Western country, the resulting technical success was deemed illegitimate and went unrecognized in both medicine and research for decades. We find that these kinds of nuanced accounts present a deeper and more empirically grounded understanding of the meaning of legitimacy in context, despite a lack of theorization.

How Is Legitimacy Produced?

Our critical interpretation of the MAS literature emphasizes the intertwined nature of practices, discourses, social processes, and materialities in the production of legitimacy. Authors often seem to assume these are impossible to separate from each other without losing meaning. For instance, in a study of the use of restraint in a hospital psychiatry ward, McKeown et al [74] examine how boundaries of space (ie, office or patient area), identity (ie, health care professional or patient), and diagnosis work together to legitimize or delegitimize the use of force in context. In this way, legitimacy is defined, not merely influenced, by the environment in which it is generated [75].

When legitimacy is conceptualized as a power problem, categorization seems to solidify the standing of already-legitimate actors. Meanwhile, power appears to become less accessible for the illegitimate when professional boundaries are unclear [69,76-78] or impermeable to outsiders [8,79,80]. Common MAS topics include contested illnesses and attempts of patients to receive treatment [70,80,81] and role negotiations of nonmedical practitioners within the medical establishment [69,79,82-84]. In both cases, power imbalance is usually framed as the primary obstacle to legitimacy, which is necessary for a more egalitarian redistribution of power. Although some authors

XSL•FO
RenderX

argue it is possible to have some power without legitimacy [72,82,84], the physical location of institutions, people, and technologies still defines flows of resources, manifesting in, for instance, differential treatment of patients at a rural hospital that would be unlikely at an urban hospital due to differences in hospital conditions rather than patient deservingness [85]. On the basis of these examples, our interpretation is that MAS and OMS have some overlap in this area in that both disciplines seem to approach legitimacy as an issue of access to resources.

How Is Legitimacy Used?

MAS literature reviewed often examines how legitimacy can flow through the taken-for-granted artifacts of professionalism. These artifacts include prescriptions [78] and complicated-looking fake medical machines [68]. Because the object itself is imbued with legitimacy through specific qualities in the professional context (eg, an appearance of being "official" or "high tech"), artifacts in these articles seem to reinforce the legitimacy of the pharmacist writing the prescription or the practitioner using the machine. Material artifacts may also include larger systems such as old IT infrastructures or preexisting contracts that impede desired change within institutions [73], implicitly reinforcing the legitimacy of institutional systems. While these materialities impact potential changes in legitimacy, they are usually not the subject of debate in the MAS literature. Therefore, it seems that the legitimacy of the prescription-writing pharmacist may be contested, but the prescription itself usually is not [78].

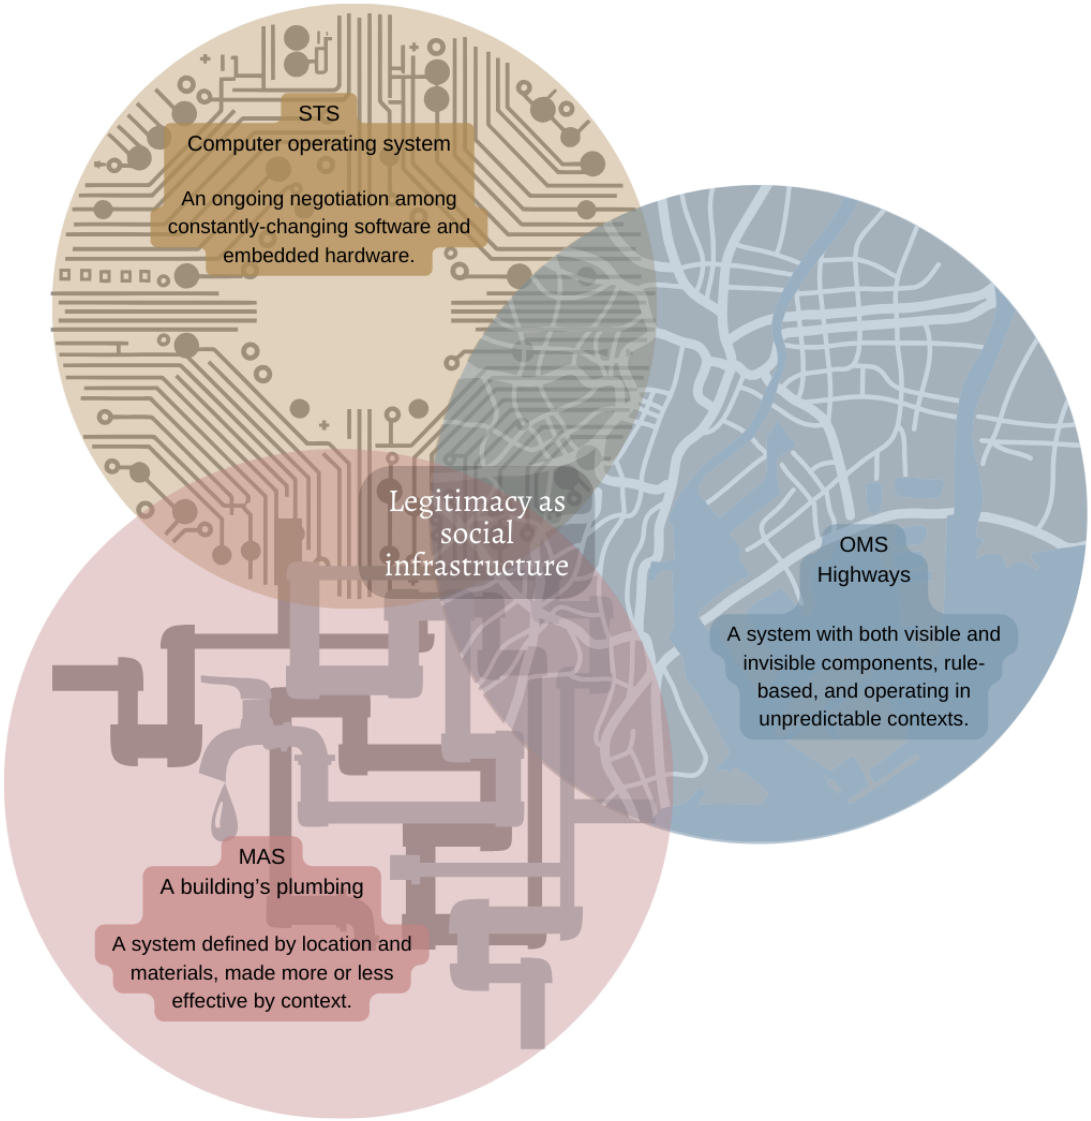
Summary

Our critical interpretation of the MAS literature is that legitimacy in this discipline is a relative and context-dependent concept. Legitimacy is often understood to be intertwined with power relations, but authors disagree about the nature of this connection and its implications. Finally, MAS articles center sites of controversy in which the subject has already been deemed illegitimate by focusing on space, materialities, and relationships. MAS authors appear to use these lenses to question "default" narratives of legitimacy in favor of exploring how and why a technology, system, group, or experience came to be viewed as illegitimate.

Here we develop our final disciplinary synthetic construct. Our interpretive analysis found that in MAS, legitimacy is physical, material, and always relative. Therefore, we employ the metaphor of a building's plumbing: each part of the system, from the pipes to the faucets, performs a different function, which defines both their physical form and location. No two buildings can have identical plumbing systems, because no two buildings, even if constructed similarly, are situated in exactly the same location—thus, they must connect to the local environment in different ways. In much the same way, the materialities of health and technology, and how these materialities interact with spaces and actors, are considered to define the legitimacy of health and technology in MAS. A "quack" technology reads as legitimate instead of "fake" because of both its physical form and the spatial context it inhabits [68]; an innovation such as IVF in the "wrong" space may never be recognized as innovation at all [84]. In both cases, if we understand legitimacy to be an infrastructure that is dependent on both space and materialities, we can better connect the different underlying systems and elements that comprise legitimacy for health technologies. A sink connected to a sewer line requires multiple specific parts, arranged in a particular way, running through a particular location, to function. In the cases noted earlier, materials, the spaces in which they are developed, and the spaces in which they are used must be arranged in particular ways for technologies to be considered legitimate, whether the audience is the international scientific establishment [84] or residents of a rural South African community [68]. The metaphor of a plumbing system emphasizes the categorical importance of context and physical materials in the construction of legitimacy: in MAS, legitimacy cannot exist without these. Therefore, this metaphor also helps us understand why MAS generally avoids comprehensive definitions or theorization of legitimacy; other than a few basic building blocks, systems of legitimacy for MAS are essentially viewed as nontransferrable between contexts.

Synthesizing Argument: Legitimacy as Social Infrastructure

Legitimacy is omnipresent and important within all 3 disciplines. However, it is often undertheorized and the subject of many implicit assumptions across MAS and STS literature. In OMS, conversely, increasingly detailed theorization results in the proliferation of "subtypes" of legitimacy with limited empirical support (see Table 1 for more details). Our synthesizing argument allows us to bring these different disciplinary traditions into conversation with each other through a new conceptual framework for legitimacy.



Using the 3 disciplinary metaphors we developed, we propose that legitimacy can be conceptualized as a social infrastructure, based on the criteria for an infrastructure by Star and Ruhleder [133]. If we combine the metaphors of a highway system (OMS), computer operating system (STS), and plumbing system (MAS), we begin to see the building blocks of an infrastructure that can support an entire city (Figure 2). Each metaphor shows a particular element of city infrastructure (ie, understanding of legitimacy) clearly. However, similar to a layered map of a city's interconnecting infrastructures, we gain a fuller picture of how legitimacy works in health and technology when we layer the metaphors to view their intersections and divergences. Knowing how computer systems monitor traffic and manage stoplights helps us better understand both computer systems and highways; similarly, an STS understanding of how unexpected assemblages may work with taken-for-granted processes can help us better understand how these unexpected assemblages may impact theory about taken-for-granted processes in practice within OMS. Therefore, such a layered map allows for a richer conceptualization in which there is room for different approaches to legitimacy without denying the validity of any single conceptualization.

Table 1. Disciplinary characteristics: legitimacy in organization and management studies (OMS), science and technology studies (STS), and medical anthropology and sociology (MAS).

	OMS	STS	MAS
Theoretical foundations	Major focus on theory, granular definitions of legitimacy common; normative legitimacy most prevalent	Some theoretical exploration but limited theoretical cohesion	Limited theoretical exploration, reliance on granular definitions based on empirical evidence
Conceptualized as	A process (of negotiation); perception; or asset, and sometimes as several of these at once.	A product of knowledge coproduction; a negotiation among human and nonhuman actors, contexts, and epistemic cultures	A relative and context-dependent concept intertwined with power relationships
Purpose of literature	Describe how organizations can move from illegitimate to legitimate status	Investigate instances of controversy and contestation	Explore how and why a subject came to be viewed as illegitimate
Most important related concepts	Taken-for-grantedness; categorization and standardization	Relationships, taken-for-grantedness, and unexpected assemblages	Materialities, relationships, and space

Figure 2. Disciplinary metaphors. MAS: medical anthropology and sociology; OMS: organization and management studies; STS: science and technology studies.

Similar to a physical infrastructure, legitimacy can be understood as a binding fabric that makes possible certain types of relationships among people, institutions, and technologies. In our conceptualization, legitimacy is an inherently relational concept: it can only exist between two or more entities, rather than within the perceptions of a single person or institution. The notion of social infrastructure makes space for legitimacy to exist outside of human judgments, without devaluing the importance of perception in the production of legitimacy. Just as infrastructures consist of both materialities and abstract systems (eg, roads are made of concrete, but their use is facilitated by traffic laws), social infrastructure melds semiotic,

XSL•FO
RenderX

material, and normative aspects of legitimacy and explores how they might work together. Infrastructure thus allows for the integration of disparate and seemingly contradictory aspects of making legitimacy. While Star [134] has emphasized that infrastructure is inherently a "relational property," we use the word "social" to focus on how legitimacy supports specific types of relationships among people, institutions, and technologies; in particular, how these relationships are shaped by implicit and intangible norms and values [135]. For instance, understanding the nuances and norms of pharmacists' relationships with both physicians and health care institutions reveals why a simple policy change allowing pharmacists to prescribe medication legally is not enough to legitimize the practice [78]. This moves us away from conversations about legitimacy as a conduit for resources and toward more clarity about how legitimacy acts as a binding fabric within social relationships.

Descriptions of legitimacy across all 3 disciplines fit the criteria for an infrastructure by Star and Ruhleder [133]. For instance, legitimacy is usually only visible "upon breakdown" [133]. Contestation and controversy are the only sites of legitimacy exploration in MAS and STS; in OMS, legitimacy is discussed in terms of desired change in legitimacy status (ie, moving from illegitimacy to legitimacy), and contestation is captured explicitly through concepts such as "liability of newness" [53,54]. In addition, maintenance of this social infrastructure happens through continued adherence to legitimizing protocols and norms within relationships; deviations can result in a crisis of legitimacy. In this sense, legitimacy is characterized by a strong fit with predefined categories and "standards" [133] in many articles [45,53,65,85], even when legitimacy itself is not defined. In our conceptualization of legitimacy, norms and values make up the "installed base" into which legitimacy is embedded [133] and are responsible for legitimacy's taken-for-granted nature.

Legitimacy also acts similar to infrastructure, in that it can be used to invisibly support the work of organizations, technologies, or people [55,86,133], often by allowing for acquisition of resources or power [69,87]. In fact, values and norms are often so deeply entrenched and invisible that even the infrastructure supporting them (ie, legitimacy) becomes taken-for-granted and invisible itself. This combination can make it extremely difficult for any contradictory experiences or knowledge to find expression within a society's taken-for-granted, unquestioned truths [85,88,89,132]. Therefore, it is understandable why the moments of crisis when legitimacy is "visible upon breakdown" usually occur when norms and values clash with each other. For example, in the exploration of IVF by Perotta and Geampana [7], new reproductive technologies are a site of legitimacy crisis because they are heavily desired by patients but cannot adhere to standards of EBM. In this situation, physicians must navigate among the medical value of providing patients with the care they seek, the medical value of providing evidence-based care, and the medical norm of adhering to preset medical standards that may not have kept up with available care options.

Finally, the origins of legitimacy parallel those of any other infrastructure. Legitimacy is built on existing social systems: it "wrestles with the inertia of the installed base" [133] and borrows both strengths and weaknesses from that base, resulting in legitimation by once-functional mechanisms that are now relics. For instance, Sheard et al [73] show how desired changes in practices in a hospital setting are stalled by existing social, technical, and bureaucratic systems and entrenched social practices, despite a lack of effectiveness of these entrenched systems and a desire for change among the people acting within them. Overcoming this systemic inertia requires the integration of new practices and systems into the installed base, regardless of the current utility of that base; attempts to completely overhaul entrenched institutional practices or technologies without attention to the installed base rarely succeed.

In all 3 metaphors, infrastructure serves as a system through which different elements that contribute to legitimacy can negotiate with one another. A social infrastructure conceptualization reflects the nature and parameters of these negotiations. Thus this lens allows us to see where different perspectives on legitimacy could provide a more holistic picture of how legitimacy works in practice, encouraging a collaborative approach to conflicting views on legitimacy.

We hope this conceptualization can provide a useful lens to better understand how legitimacy is produced and how it works among institutions, technologies, and people. We aim to move the conversation toward a more holistic perspective on embedding technologies in health care that goes beyond models based primarily on judgments and perceptions.

Discussion

Principal Findings

Our conceptualization of legitimacy as social infrastructure allows for deeper analysis and understanding of the meaning, production, and uses of legitimacy when embedding technologies in health care. Our review contributes to the OMS literature by bringing in outside perspectives. Cross-fertilization among the 3 disciplines reigns in the proliferation of legitimacy theory in OMS while providing a better connection with empirical research. STS and MAS literature benefit from grounding empirical exploration within a more cohesive theoretical framework. Our review also helps contextualize studies of legitimacy that are more limited in scope; for instance, while discourse analyses of legitimacy are useful, this review demonstrates that discourse comprises just one aspect of legitimacy production [67,90,91]. By allowing for many definitions of legitimacy, the notion of legitimacy as social infrastructure is adaptable enough to produce meaning across disciplines while providing ways to explore relational, material, and semiotic aspects. By providing a framework through which to explore many conceptualizations and understandings of legitimacy, we hope LSI can facilitate fruitful cross-disciplinary collaborations of legitimacy researchers. Specifically, LSI allows different conceptualizations to coexist without competing with one another, providing a framework in which researchers can build on the work of other disciplines without having to disregard the traditions of their own discipline. In addition, this framework provides value to acceptance, adoption, and implementation researchers and other stakeholders interested

XSL•FO
RenderX

in better explaining how technologies are embedded in health care. Through an interdisciplinary understanding of legitimacy and a focus on relationships and moments of breakdown, LSI provides a mechanism to study technology embedding both contextually and over time. In this way, LSI produces a more comprehensive understanding of how the interconnected social, medical, environmental, and institutional elements surrounding a technology may interact in ways that impact legitimacy for a given technology, and thus, whether a technology will become embedded in health care.

Embedding Beyond Current Frameworks

Legitimacy as social infrastructure provides an alternative to current models describing how technologies are embedded in health care. We can use this conceptualization to account for gaps between policy intentions and practices when embedding technologies. Social infrastructure produces a more comprehensive understanding of the issues underpinning technology adoption than frameworks that hinge on trust [136,137], transparency [4,137], and acceptability [19], especially when those frameworks are based on behavioral intention [20,21,138]. Articles included in this review have shown that the complexities of embedding technologies in health care often clash with the best-intentioned policy choices because these frameworks generally do not account for the full scope of legitimizing processes within health care delivery systems. This is particularly evident in articles that focus on contested illnesses [80,89,92] and professional boundary work negotiations in light of new policies or collaborations in health care [47,56,77,78,93,94]. For example, Weiss and Sutton [78] demonstrate that even though policy changes explicitly allow pharmacists to prescribe medication, actually doing so in practice involves a more complex negotiation of roles and hierarchies to legitimize pharmacist prescribing activities. The new prescribing policy, based on notions of trust and acceptability, is not enough. For patients whose contested illnesses do not meet EBM criteria [80], negotiations and individual relationships are essential to access any kind of medical care [95]. Here, EBM criteria designed to increase transparency and trust in medicine prevent patients with real symptoms from accessing necessary care.

The many technology acceptance and adoption frameworks available currently have difficulty explaining adequately how and why some technologies are embedded in health care but others are not; in other words, “the literature does not specify the conditions for full use to be achieved” [138]. Similar to legitimacy, these terms are not clearly defined across the literature [138]: “acceptance” and “acceptability” generally are defined in terms of perceptions of potential users [138,139] and separate from both “adoption” and “appropriation,” which deal with the processes and practices of using the technology [138]. Other models aim to identify factors contributing to acceptance of new technologies. TAM is the most well-known example; it has been adapted and added to by numerous authors since its inception [20,21,138,140]. However, similar to most adoption and acceptance frameworks, TAM is based on behavioral intention, which has limited utility in predicting actual behavior [141,142] and does not generally attempt to integrate other systemic or relational aspects of technology acceptance. Within this review, Reay et al [56] demonstrated that gaining discursive buy-in, the focus of behavioral intention models of technology adoption, “is not enough” to legitimize new practices in a clinical setting without action and interpersonal, structural support.

Other frameworks have attempted to integrate sociocultural aspects of technology acceptance, specifically in low- and middle-income countries, although acceptance still generally focuses on individual users rather than systemic or relational factors [143]. More unusually, the nonadoption, abandonment, scale-up, spread, and sustainability framework by Greenhalgh et al [22], which is explicitly directed at health technologies, attempts to fill gaps left by TAM and other models by focusing on nonadoption and abandonment of technology instead of acceptance. This framework incorporates norms and values to some extent but does not focus specifically on legitimacy and the impact of norms and values on technology development.

The legitimacy as social infrastructure framework (LSI framework) is different from these models: rather than starting with adoption and acceptance of technologies, our conceptualization focuses on the relationships and negotiations that result in adoption and acceptance or not. If we take legitimacy as a necessary element in technology adoption and acceptance, conceptualizing legitimacy as social infrastructure allows us to understand how adoption, acceptance, and implementation frameworks may work together to explain the process of embedding technologies in health care. For instance, rather than conducting acceptance, adoption, and implementation studies separately in a health technology development project, researchers could use the conceptualization of legitimacy as social infrastructure as a framework to iteratively explore the binding fabric of relationships and legitimacy narratives that make up the landscape in which a new technology is being developed and provide advice to decision makers based on these findings. This focus would also allow project stakeholders to contextualize the results of a traditional acceptability or adoption study to better support the end goal of successfully embedding a technology in health care. Doing so would move conversation beyond simple adoption and acceptance and toward a more holistic perspective about this embedding process based instead on an analysis of legitimacy.

Focus on Relationships and Narratives

Momentum for embedding technologies in health care often fades due to unforeseen complexities [144] when moving technologies from laboratories to real-world environments. Particularly for mobile health technologies in which social and relational elements play a heightened role, the LSI framework could prove extremely useful in both anticipating and navigating complexity in the real world by describing changing relationships and narratives. Legitimacy as social infrastructure could provide a better blueprint that takes contextual factors into account earlier and avoids some of the acceptance and adoption bottlenecks that develop in linear models.

The struggles and unintended consequences of embedding technology in practice have been well-documented in STS and OMS [58,61,93,96]. The LSI framework conceptualizes how these documented struggles impact legitimacy and, thus,

XSL•FO
RenderX

technology adoption and acceptance. STS understands new technologies (including those designed for health care) to be both directional and open-ended [23]. Technologies are embodied with certain scripts and ideas, produced both through the development process and purposely in the minds of developers and other stakeholders, impacting how they can be used and when. However, the scripts managing this directionality never completely determine how a technology is used in practice [23,145]. Integrating technologies into real-world environments necessarily involves tinkering [22,23,144] by users, developers, and other stakeholders, often contradicting a technology's directionality entirely. For instance, as Perrotta and Geampana [7] demonstrate, new medical technology may be used in ways that contradict its original EBM-derived script, given a particular set of circumstances generated by patients, economics, and the pace of technology development. What happens next is a negotiation that determines how real-world context, practices, and technology scripts interact to generate a legitimacy relationship. Conceptualizing legitimacy as social infrastructure allows us to both understand the nature of these interactions and how they may or may not lead to technology adoption and acceptance in a health care setting. For instance, Sheard et al [73] discuss the complex systems and legitimacy relationships that impact the ability of care providers in the United Kingdom to act on patient feedback; this feedback is solicited in the first place to increase trust in and acceptability of the medical system. If we view patient feedback frameworks as a form of health care technology, legitimacy as social infrastructure helps us better understand and anticipate the relative importance of backgrounded relational and structural systems [73] that determined whether patient feedback was incorporated successfully in the health care institutional systems under study. An infrastructural understanding reveals how the 3 issues identified (ie, normative legitimacy, structural legitimacy, and organizational readiness [14,73]) work together to support or deter change in a complex organizational setting. A binding fabric of relationships ties all of these issues together and clarifies why the quality of certain relationships is more important than others. This focus also adds to understanding of the phenomenon of "institutional entrepreneurs." Relationships likely play a role in how institutional entrepreneurs avoid being "confined by the status quo," allowing them to change organizations from within despite legitimacy challenges for others [73].

Future Research and Applications

Given the utility of this conceptualization in bringing together 3 very different disciplinary traditions around legitimacy, future research could expand on this work to incorporate perspectives from disciplines, such as ethics and law, that we could not include here. In addition, it is possible that legitimacy is usually not explicitly conceptualized in medicine and psychology due to an implicit discipline-wide understanding of the values that underpin the concept. In other words, norms and legitimacy in medicine and psychology may be so closely intertwined with the goal of providing care that legitimacy may not be contested or questioned from these disciplinary perspectives. These kinds of taken-for-granted assumptions make it important to explore the origins, production, and meanings of legitimacy more thoroughly in the psychology and medical fields. Our conceptualization could allow for such investigation in fields in which the language describing legitimacy is either absent or perceived to be self-evident.

Potential applications of legitimacy as social infrastructure in practice have a wide range thanks to the flexibility and adaptability of the conceptualization. For example, to manage risks appropriately, regulators and others must have knowledge and understanding of the subject of regulation, in this case, health care technologies. This includes not only technical knowledge, but epistemological understanding of what is seen to constitute valid forms of knowledge, what is being left out, and "system knowledge of the context regulation is operating in" [146]. By approaching the embedding of technologies in health care as a result of knowledge coproduction, the notion of legitimacy as social infrastructure can provide deeper understandings of the systems and context of health technologies. It can then help regulators differentiate valid from invalid forms of knowledge in context. Regulators also experience legitimacy concerns themselves, in that regulation must be legitimate to function [9,147]. An understanding of legitimacy as social infrastructure could provide regulators with clarity about the practices, decisions, and structures that may impact their own legitimacy. For instance, knowing more about how their relationships with various stakeholders contribute to their legitimacy could help regulators take stakeholders' viewpoints into account at the most impactful moments and more appropriately narrate their decisions for different audience needs.

Limitations

Given the broad focus of our topic "legitimacy in health and technology," we included a heterogenous collection of empirical topics within each discipline. While this allowed for a broad discussion of legitimacy in health and technology, we did not produce one overarching definition of legitimacy; rather, we developed a conceptualization that can be used as a framework with the diversity of definitions already available. Similarly, the disciplinary boundaries are somewhat "fuzzy" [24]: OMS is a subdiscipline of sociology, STS overlaps with both MAS and OMS, and MAS is a combination of 2 disciplines with similar approaches. We found these disciplinary constructs useful because, despite their overlap, they highlight substantial differences among social science approaches to legitimacy.

In addition to the legal and ethical boundaries previously described, in this review, we did not engage with several other topics related to the legitimacy of technologies in health care. While the word "legitimacy" is used frequently in medicine and health economics, very few articles in these fields define the concept or explore it in any depth. Rather, the vast majority use the word uncritically within a surface explanation of the importance of a problem, either by claiming without evidence that legitimacy is an asset held by organizations, technologies, or people [148-150] or by mentioning that the legitimacy of a technology is under threat but without fully discussing why or how [151,152]. When legitimacy is defined, it is often reduced to a series of related concepts, such as "expertise, reciprocity, and trustworthiness," without discussing how these interact to

XSL•FO
RenderX

create legitimacy [153], although there are a few exceptions [9]. Due to the general lack of critical exploration, medicine and health economics were excluded as disciplines. This is an area that would benefit from further research using the LSI framework.

For similar reasons, we focused our search strategy within journals known to provide deep conceptualization of legitimacy (see Multimedia Appendix 1 for further details). Given the abstract and conceptual nature of our subject, a database search proved inadequate for finding all relevant articles; however, searching only within specific journals, despite rigorous selection, may have biased study findings. We feel the benefits of closely adhering to CIS protocol in this manner outweighed this issue due to our study's interpretive goals and the abstract subject matter.

Conclusions

The notion of legitimacy as social infrastructure provides a deeper understanding of how and why technologies are or are not embedded in health care. Social infrastructure focuses on the aspects of legitimacy related to norms, semiotics, materialities, and specific relationships among stakeholders and institutional contexts without excluding or privileging one form of knowledge production over the other. Through this conceptualization, the production and use of legitimacy can be studied ethnographically by following the social infrastructural networks and relationships that constitute and maintain legitimacy. By moving beyond judgment- and perception-based frameworks, legitimacy as social infrastructure approaches the problem of embedding technologies in health care through the lens of knowledge coproduction. The LSI framework enables empirical data collection and analysis that transcends disciplinary boundaries without negating the discrete lines of theoretical thought of any one discipline.

Given the interdisciplinary nature of health care policy and practice and the wide range of stakeholders involved, clearer and deeper communication around legitimacy could have far-reaching impacts. This could include new frameworks explaining technology adoption and acceptance, greater consensus about what makes a health care technology or policy decision legitimate, and strategic direction for decision makers working with disruptive health care technologies within entrenched systems.

Abstract

Background: Digital health technologies, particularly mobile health (mHealth) apps and wearable devices, have emerged as crucial assets in the battle against hypertension. By enabling lifestyle modifications, facilitating home blood pressure monitoring, and promoting treatment adherence, these technologies have significantly enhanced hypertension treatment.

Objective: This study aims to explore the perspectives of health care professionals (HCPs) regarding the perceived benefits and barriers associated with the integration of mHealth apps into routine hypertension care. Additionally, strategies for overcoming these barriers will be identified.

Methods: Through qualitative analysis via semistructured interviews, general practitioners (n=10), cardiologists (n=14), and nurses (n=3) were purposefully selected between October 2022 and March 2023. Verbatim transcripts were analyzed using qualitative content analysis.

Results: The results unveiled 3 overarching themes highlighting the benefits of mHealth apps in hypertension care from the perspective of HCPs. First, these technologies possess the potential to enhance patient safety by facilitating continuous monitoring and early detection of abnormalities. Second, they can empower patients, fostering autonomy in managing their health conditions, thereby promoting active participation in their care. Lastly, mHealth apps may provide valuable support to medical care by offering real-time data that aids in decision-making and treatment adjustments. Despite these benefits, the study identified several barriers hindering the seamless integration of mHealth apps into hypertension care. Challenges predominantly revolved around data management, communication contexts, daily routines, and system handling. HCPs underscored the necessity for structural and procedural modifications in their daily practices to effectively address these challenges.

Conclusions: In conclusion, the effective usage of digital tools such as mHealth apps necessitates overcoming various obstacles. This entails meeting the information needs of both HCPs and patients, tackling interoperability issues to ensure seamless data exchange between different systems, clarifying uncertainties surrounding reimbursement policies, and establishing the specific clinical benefits of these technologies. Active engagement of users throughout the design and implementation phases is crucial for ensuring the usability and acceptance of mHealth apps. Moreover, enhancing knowledge accessibility through the provision of easily understandable information about mHealth apps is essential for eliminating barriers and fostering their widespread adoption in hypertension care.

Introduction

Hypertension is a significant health problem affecting millions of people worldwide [1]. In Germany, too, hypertension is one of the most common diseases affecting a large proportion of the population. Prevention and effective treatment of hypertension are therefore crucial to prevent associated serious complications such as ischemic heart disease, strokes, and renal disease, and to improve the quality of life of those affected [2-4].

In recent years, the development of digital health technologies has experienced a considerable upswing, opening up promising perspectives for the prevention and management of hypertension [5]. Mobile health (mHealth) apps, wearables, and other digital tools enable patients to monitor their blood pressure levels, track lifestyle changes, and set health goals. These technological advances also offer health care professionals (HCPs) new opportunities to improve patient care and promote healthier lifestyles [6]. mHealth apps in particular have been shown to improve the treatment of hypertension [7].

In Germany, the following professional groups are primarily involved in the treatment of people with hypertension. General practitioners play a central role in the diagnosis, treatment, and long-term care of patients with hypertension. They are often the first point of contact for patients with hypertension and coordinate further care. Cardiologists specialize in the diagnosis and treatment of heart disease, including hypertension. They can treat complex cases of hypertension and offer specialized diagnosis and treatment options. Internists can also play a role in the care of patients with hypertension, especially if there are comorbidities or complex medical problems. Nursing professionals (nurses, nursing assistants) play a crucial role in the care of patients with hypertension. They help implement blood pressure control measures, educate patients, and help monitor symptoms and side effects [8]. In October 2020, physicians in Germany were allowed to prescribe digital therapeutics (DiGA [Digitale Gesundheitsanwendungen]) in standard care for the first time [9]. DiGAs can be prescribed by physicians for a 3-month use period and is fully reimbursed by the statutory insurance companies. To obtain approval, mHealth providers must demonstrate the safety, functionality, quality, data security, and a fundamental benefit in a clinical study to obtain DiGA status. Patients receive a written prescription for a DiGA based on respective indications (eg, depression) and have to send it to their insurance company.. At the time this study was conducted, there was no DiGA that is specific for the prevention of hypertension. In perspective, however, it is expected that mHealth apps for the prevention of hypertension will obtain DiGA status and will be made available to patients. In their recent study, Dahlhausen et al [10] pointed out the significant role of HCPs, specifically physicians, in promoting mHealth use among patients. In order to understand the implementation of mHealth into hypertension care, it is necessary to understand the perspectives of physicians, nurses, and medical assistants and their perception of benefits and challenges, as well as their information needs, in order to best integrate mHealth into hypertension care.

Nevertheless, a certain frustration is noticeable among physicians in Germany. Not least because there have been repeated technical problems in the past with the connection to the German telematics infrastructure (TI). The TI comprises a range of technical components that are relevant for operation in medical practices. These include the practice management system (Praxis Verwaltungssystem), which supports the organization and documentation of practice tasks, and the connector, a piece of hardware that enables access to the TI and communicates with the eHealth card terminal and the Praxis Verwaltungssystem via a secure network. The eHealth card terminal is used to use the electronic health card and to check practice ID cards. Other components include mobile card terminals, practice or institution ID cards, a virtual private network access service, and the electronic health professional card, which is required for various applications such as the electronic doctor's letter and prescriptions [11]. However, half of the physicians have to struggle with technical problems at least once a week, compared to 36% in 2020. Overall, frustration with the digitization process has increased [12].

While there is a wealth of research focusing on the patient perspective regarding digital health tools [13-15], there remains a lack of comprehensive evidence on how physicians perceive and integrate these technologies into their clinical practice. Despite the promising potential of digital health tools, the potential obstacles and barriers to widespread adoption of these technologies in the clinical setting have not been thoroughly explored. A deeper understanding of the structural and individual factors that influence the implementation and adoption of digital prevention approaches is imperative. Integrating digital prevention approaches into the health care system requires a clear delineation of the role and positioning of these technologies within the broader health care landscape. A thorough investigation of how digital health tools can be effectively integrated into the existing health care infrastructure and how they are perceived by the various stakeholders in the health care sector is crucial.

Addressing these research gaps can contribute significantly to a more nuanced understanding of how digital health and specifically mHealth apps can be optimally used for hypertension prevention. It can also identify potential barriers and pave the way for strategies to improve clinical adoption and seamless integration of these technologies. In this study, we explore the following research questions: Which benefits

XSL•FO
RenderX

do HCPs see in mHealth apps for prevention? What are possible structural and individual barriers to the use of mHealth apps? How can the challenges be met?

Methods

Study Design

This paper reports on our exploration of the HCPs' perspectives regarding mHealth apps in hypertension prevention. We conducted in-depth interviews with general practitioners, cardiologists, and nurses. This study is part of the DiPaH project [16], which examines structural and individual factors in different stakeholders that influence the use of digital preventive measures in patients with arterial hypertension in Germany.

Ethical Considerations

This study was approved by the Ethics Committee of the Brandenburg Medical School Theodor Fontane (E-02-20220620). All experimental protocols were approved by a named institutional or licensing committee. All methods were carried out in accordance with relevant guidelines and regulations. Participants were informed verbally and in writing about the purpose, the procedure, the significance of the study, and the benefits and risks that may be associated with it and had the opportunity to ask questions. They were also informed that they had the right to withdraw their consent to participate in the study at any time, either verbally or in writing, without giving reasons. They were also informed that personal data would be recorded and stored, whereby the data would be pseudonymized, but that no data would be published that could be used to identify the person. For security reasons, the data received from the participants were always stored in a password-protected folder on a secure desktop computer. Written consent was obtained after participants were given the opportunity to ask questions. Patients were not involved in designing this study. Participants were offered €75.00 (approximately US $77.89) as an incentive for their participation in the study.

Recruitment

Participants were selected using purposive sampling [17]. We included HCPs who were currently actively involved in the treatment of people with hypertension, such as general practitioners, cardiologists, and nurses. The participants were selected according to defined categories, aiming to generate a heterogeneous sample with the broadest variety of different perspectives [18]. The following categories were included: region of practice (rural vs urban), main area of practice (outpatient vs inpatient), and gender (male vs female). A further inclusion criterion was interest and willingness in participating in an interview. Participants were recruited both by systematic invitation and by snowball sampling. The following sources were used for recruitment (Textbox 1).

Textbox 1. Sources used for recruitment.

- Social media accounts of the university (Brandenburg Medical School Theodor Fontane), such as Facebook, Instagram, and Twitter
- Association of Statutory Health Insurance Physicians Brandenburg (KVBB): newsletter
- General practitioners' association Brandenburg: information study participation at events
- Personal contacts among colleagues (snowball sampling)
- Interested persons contacted the study team by telephone or e-mail, and it was checked in advance whether they could be included before an interview was conducted

Data Collection

A preliminary semi-structured interview guide was drafted by a multiprofessional team (SM, FM, DB, and SSp). The semistructured interview guide consisted of open-ended questions that explored how the participants are attuned to digital applications and mHealth apps, what benefits and barriers they see in digital technologies for prevention, what information needs they have, and how these can be met. The focus was on hypertension apps with the following functions: educating about hypertension, monitoring blood pressure, and promoting adherence, although no specific apps were offered or recommended to participants. Sample interview questions included: Which mHealth apps in the context of hypertension treatment are used in your practice, or what experiences have you had with it? What benefits do you see in the use of mHealth apps? What barriers do you see in the use of mHealth apps? How well informed are you about mHealth apps, and where are knowledge deficits? In addition, sociodemographic data were collected, including profession, gender, age, number of inhabitants of the place of practice, duration of professional activity, and setting. To ensure clarity and relevance of the questions, we did a pilot test of the interview guide with 5 eligible participants recruited from clinics and outpatient physicians in the study's catchment area (refer to Multimedia Appendix 1).

All interviews were conducted via telephone during October 2022 to March 2023. The interviews were recorded and transcribed verbatim in accordance with data protection guidelines. Data collection continued until no substantially new findings emerged and saturation of content was reached. Saturation of content is defined as code saturation, when no additional issues are identified, and meaning saturation, when no further dimensions, nuances, or insights of issues can be found [19]. We chose to conduct 27 interviews, as this number has proven to be adequate in previous studies to reach theoretical saturation in the exploration of digital approaches [20,21]. Field notes (a short summary of the interview) were taken following each interview to ensure better comprehensibility of the interview situation. The field notes themselves were not included in the analysis.

XSL•FO
RenderX

Data Analysis

Qualitative analysis of the interviews was performed iteratively by the study team (SM and FM) based on Kuckartz's structured qualitative content analysis [22] using MAXQDA Analytics Pro 2022, Release (version 22.1.0; Verbi GmbH). After transcription of the audio material, the analysis began with a screening of the interview texts, whereupon the interviews were coded. Relevant text passages from the interview material were coded according to a deductive-inductive procedure. Main categories and subcategories were formed inductively from the codes. Until a common understanding of all the emerging categories was achieved, consensus discussions were held continuously in the research group. Other categories were developed deductively based on the research questions and merged into the coding tree. By then, the process of gathering data had already concluded. Two researchers (SM and FM) separately applied the established category system to analyze the complete data set, ensuring that the process could be traced and replicated. The data was analyzed in German. To present the findings, significant excerpts from the transcriptions were chosen as representative quotes. These quotes were translated into English by native speakers and incorporated into the manuscript. The manuscript has been compiled in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research; refer to Multimedia Appendix 2) [23].

Results

In total, 27 interviews were conducted and analyzed until theoretical saturation was reached. The mean duration of the interviews was 42 (range 33-56) minutes. The mean age of the participants (N=27) was 50 (range 35-74) years. Most participants were female (14 female/13 male). A total of 14 cardiologists, 3 nurses, and 10 general practitioners participated. In total, 9 persons worked in the inpatient setting and 17 persons worked in the outpatient setting. One person worked in both settings. Four of the HCPs had already had experience with digital applications in daily practice or were also working with them. Detailed characteristics of study participants are shown in Table 1.

Table 1. Detailed characteristics of study participants.

Characteristics	Participants (N=27), n (%)
Professional group	
General practitioner	10 (37)
Cardiologist	14 (52)
Nurse	3 (11)
Duration of professional activity	
>10	9 (33)

Themes

The analysis explored 7 key themes, categorized into benefits and barriers. Themes identified as benefits included (1) patient safety, (2) patient autonomy and support, and (3) support in medical care. Themes identified as barriers were organized by the following context: (4) handling of data, (5) in the context of communication, (6) in daily routines, and (7) in dealing with the systems.

Benefits

Although few of the HCPs use or have used mHealth apps in their daily practice, they were able to mention benefits they expected to gain from using mHealth apps. In the context of benefits, 3 overarching themes could be identified: potential to increase patient safety, patient autonomy, and support in medical care (Figure 1 and Multimedia Appendix 3).

Figure 1. Coding tree of the benefits regarding mHealth apps in hypertension prevention. mHealth: mobile health.

A different number of subcategories could be assigned to the 3 main categories. The following 3 subcategories were assigned to the “Patient safety” category: preventing secondary illnesses, improving patient adherence in medication, and circumventing the white coat effect. The following 3 subcategories were assigned to the category “Patient autonomy and support”: motivating factor, supporting patients, and reflectivity. The following 5 subcategories were categorized under the category “Support in medical care”: clear presentation of blood pressure levels, constant access to health data. Results can be evaluated quickly, better data quality compared to analog methods, and improved physician-patient communication.

Patient Safety

Respondents see the potential of mHealth apps primarily in the prevention of secondary diseases. In addition, participants see the potential of mHealth apps to improve patient adherence to treatment in terms of medication adherence, which in turn has an impact on patient safety.

The respondents attribute a better representation to the blood pressure levels measured at home and subsequently documented. The interviewees hope that through the use of mHealth apps, patients will consistently document their blood pressure and thus always have an overview of their blood pressure levels. This is because, in contrast to the blood pressure levels measured in the practice, they seem to correspond more closely to the reality of life. The “white coat effect” is thus circumvented.

Patient Autonomy and Support

An mHealth app can offer a variety of features that serve as a motivating factor for patients from the perspective of health care providers. Gamified elements, progress tracking, and reward systems can provide incentives for developing and maintaining health-promoting behaviors, strengthening patients' self-motivation, and fostering engagement in their health.

From the HCP’s perspective, an mHealth app can be a valuable addition to medical care by providing support to patients in several ways. First, the mHealth app can provide personalized advice based on the patient's individual needs and health goals. This can include dietary recommendations, lifestyle changes, or stress management tips. Second, mHealth apps can act as reminders, reminding patients to take their medication, which could improve adherence to therapy.

An mHealth app can also include reflectivity and help patients comprehend information about their blood pressure to their behaviors, which can support them reduce or avoid unfavorable behaviors.

Support in Medical Care

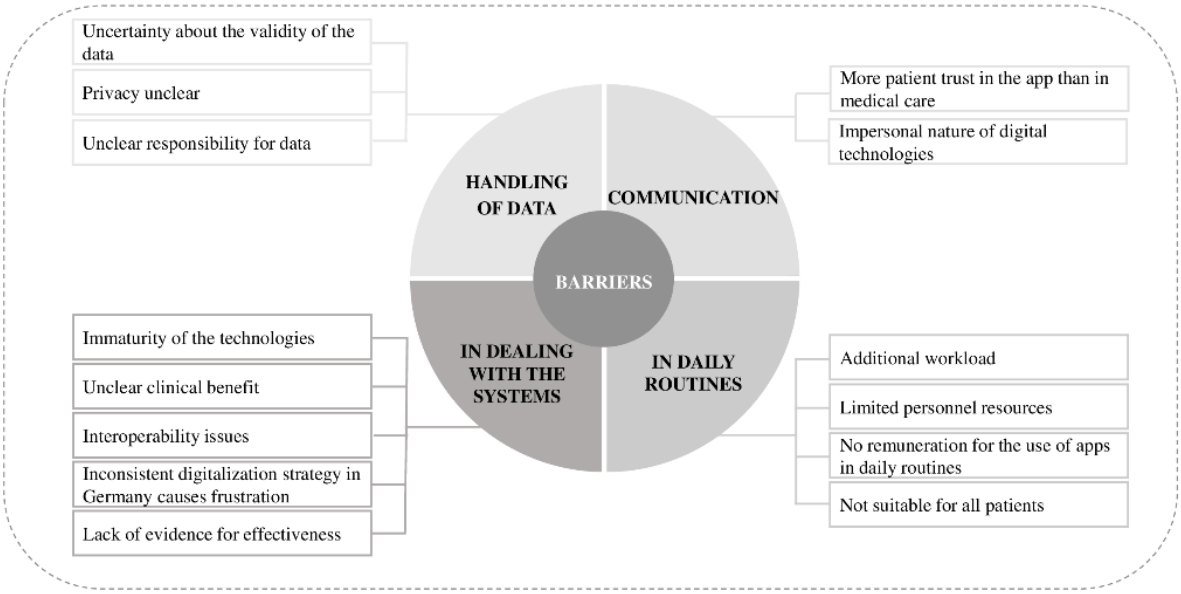
By using mHealth apps, the HCPs assume that blood pressure levels can be presented in a clear and understandable way. mHealth apps allow patients to access their levels on their smartphones or other digital devices. Patients can track the development of their blood pressure over time and identify possible trends or abnormalities so that they can seek medical help timely if necessary.

Patients have constant access to their current health data. This enables real-time tracking of their health status, even if they are not undergoing immediate medical treatment.

XSL•FO
RenderX

mHealth apps provide quick results that can be evaluated immediately. Physicians can thus make timely decisions about the treatment and care of their patients.

HCPs attribute better data quality to mHealth apps compared to analog methods.



Using mHealth apps, patients can send the data they collect in their daily environment directly to the medical facility before visiting the physician. This allows the physician to check the blood pressure levels in advance and prepare specifically for the conversation with the patient. The time saved helps to make the physician-patient conversation more efficient and targeted so that relevant questions and concerns of the patient can be better addressed.

The benefits initially included constant access to health data, which was particularly mentioned by participants in the outpatient sector. This group also appreciated the motivating factor that the apps could provide to support them in their health routines. Participants in large cities also preferred the app's clear display of their blood pressure readings, which helped them to better understand their health data. The time saved in doctor-patient communication was also mentioned as a benefit by the outpatient participants.

Barriers

We identified barriers in 4 different aspects of the HCPs work life: handling of data, in the context of communication, in daily routines, and in dealing with the systems (Figure 2 and Multimedia Appendix 4). A different number of subcategories could be assigned to the 4 main categories. The following 3 subcategories were assigned to the category “Handling of data”: uncertainty about the validity of the data, privacy unclear, and unclear responsibility for data. The following two subcategories were assigned to the category “in the context of communication”: more patient trust in the app than in medical care and the impersonal nature of digital approaches. The following 4 categories were assigned to the category “in daily routines”: additional workload, limited personnel resources, no remuneration for the use of apps in daily routines, and not suitable for all patients. The following 5 subcategories were assigned to the category “in dealing with the systems”: immaturity of the technologies, unclear clinical benefit, interoperability issues, and inconsistent digitalization strategy in Germany, which causes frustration and lack of evidence for effectiveness.

Figure 2. Coding tree of the barriers regarding mHealth apps in hypertension prevention. mHealth: mobile health.

Handling of Data

One of the main barriers to the use of apps for blood pressure monitoring is uncertainty about the validity of the data collected. Concerns about the accuracy of data documented by patients can undermine HCPs’ confidence in the data and willingness to use such tools.

Another important concern related to the use of mHealth apps in the treatment of hypertension is privacy. Fear of data breaches or unauthorized access to patient information may limit the use of such tools.

Unclear responsibility for data presents another hurdle. Physicians and nurses feel uncertain about who is responsible for managing and interpreting the data they collect. The wealth of data generated by mHealth apps can be overwhelming, and the lack of clear structures and policies for appropriate use of the data can be challenging.

In the Context of Communication

The HCPs expect that a potential barrier to communication when using mHealth apps is the tendency of some patients to trust the mHealth app more than their medical care. This misconception could lead to patients relying solely on the mHealth app for solutions or seeing its advice as better than that of their physician. This could hinder communication with HCPs and lead to a lack of collaboration between patients and physicians.

XSL•FO
RenderX

Another barrier perceived by HCPs is the impersonal nature of mHealth apps. In contrast to direct interaction, the use of mHealth apps could lead to a lower intensity of exchange between patients and HCPs. In addition, mHealth apps may be perceived as less empathetic and less tailored to the individual needs of patients.

In Daily Routines

The HCPs apprehend that introducing mHealth apps in medical practice can initially lead to an additional workload for them. The introduction of new technologies requires training, the adaptation of workflows, and integration into existing IT systems, which can initially lead to time and resource constraints.

In many health care settings, resources are lacking in order to engage HCPs in the active use of mHealth apps in practice. Adoption and integration of new technologies requires time, training, and technical support, which can be challenging in an already strained health care system. Limited capacity impedes readiness to use mHealth apps for hypertension care.

At present, the use of mHealth apps is not sufficiently reimbursed in everyday health care in Germany. HCPs do not receive additional compensation or incentives for the use and deployment of digital tools in the care of hypertensive patients. This lack of compensation may cause some HCPs to be hesitant to use digital tools, as it may entail additional tasks without financial compensation.

Although mHealth apps offer many benefits, they may not be suitable for all patients. Older people or those with limited digital capabilities may have difficulty using digital applications. In addition, some patients, especially those with hypertension, may overmeasure their blood pressure, which can negatively impact their blood pressure levels. According to HCPs, digital tools for monitoring blood pressure may be less appropriate for such patients.

In Dealing With the Systems

A major barrier to the use of mHealth apps in hypertension care is the immaturity of the technologies. HCPs suspect that mHealth apps do not work reliably, have bugs, or do not have all the necessary features to meet the demands of medical practice. As a result, they may be reluctant to recommend digital technologies for fear that the systems will not exist at a later date.

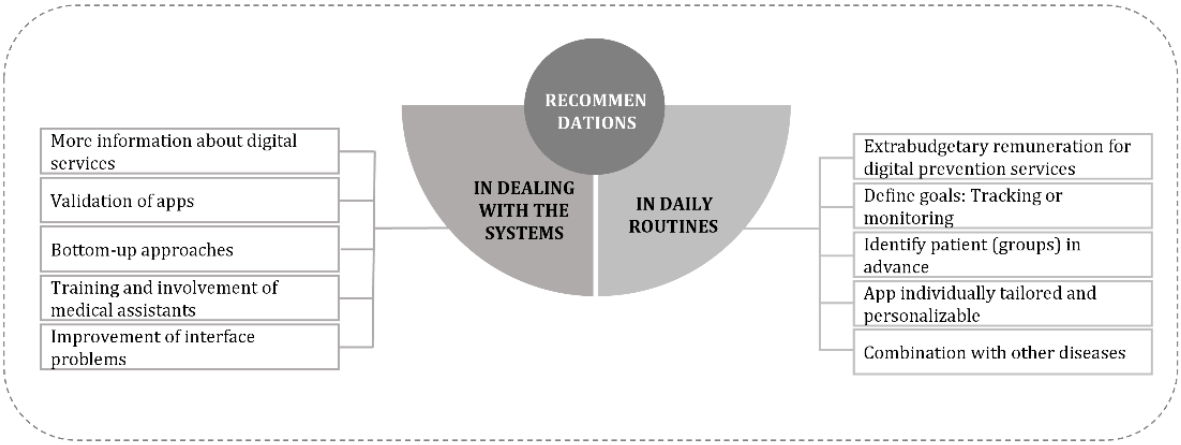
Another barrier to the use of mHealth apps in hypertension care is the unclear actual utility and clinical effectiveness of such tools from the perspective of HCPs.

The diversity of mHealth apps and their interfaces is another barrier for HCPs. The incompatibility or lack of interoperability between systems can hinder smooth data exchange and integration.

The insufficient as well as inconsistent digitalization strategy in Germany is a source of frustration for HCPs. There is often a lack of a clear, long-term vision and of a structured approach to drive the integration of digital technologies in health care. The development and implementation of digital health solutions is often fragmented and inconsistent, leading to confusion, ineffective solutions, and a return to analog methods. These negative experiences are a significant barrier to the adoption of digital tools.

The actual effectiveness and long-term impact of mHealth apps in treating hypertension are poorly researched or demonstrated from the perspective of HCPs. The lack of evidence on the clinical effectiveness of such tools raises doubts and influences their willingness to use them.

Specific Aspects in Various Subgroups



Participants from the outpatient sector in particular pointed out interoperability problems that could hinder the smooth exchange of data. In addition, the unclear clinical benefits of the apps were not recognized by everyone, especially not by the participants from the outpatient sector. It was also noted from the outpatient sector that not all apps are suitable for every patient. Concerns about data protection were also expressed by participants in the outpatient sector, who were worried about the security of their personal health data. Finally, the lack of reimbursement for the use of health apps from the outpatient sector was cited as a further barrier. Women expressed concerns about the validity of the data collected by the apps.

Recommendations for Successful Integration of mHealth Apps Into the Health Care Landscape From HCPs' Perspective

In the context of recommendations, 2 themes could be identified: in daily routines and in dealing with the systems (Figure 3 and Multimedia Appendix 5). A different number of subcategories could be assigned to the 2 main categories. The following 5 categories were assigned to the category "in daily routines": extrabudgetary remuneration for digital prevention services, defining goals: tracking or monitoring, identifying patient (groups) in advance, app individually tailored and personalizable, and combination with other diseases. The following 5 subcategories were assigned to the category "in dealing with the systems": more information about digital services, validation of apps, bottom-up approaches, training and involvement of medical assistants, and improvement of interface problems.

XSL•FO
RenderX

Figure 3. Coding tree of the recommendations for successful integration of mHealth apps into the health care landscape. mHealth: mobile health.

In Daily Routines

One of the fundamental challenges in integrating hypertension mHealth apps into routine medical practice is that the time spent using and counseling patients is not adequately compensated. To address this problem and increase HCPs' motivation to use digital prevention services, extrabudgetary reimbursement for the implementation and support of these apps in HCPs' practices should be considered. According to the participants, such remuneration would ensure that HCPs are appropriately compensated and thus create an incentive to increasingly integrate mHealth apps into their daily work.

It is crucial to define clear goals for the use of mHealth apps in hypertension prevention. HCPs should work with patients to determine which parameters or data should be collected by the mHealth app and which specific health goals are being pursued. The HCPs assume that a distinction can be made between tracking and monitoring approaches. While tracking helps patients to collect data on their blood pressure, lifestyle, and other relevant parameters themselves, monitoring enables the physician to regularly monitor and analyze the collected data. The clear definition of goals facilitates the use of the mHealth apps and ensures that the collected data can be used meaningfully and effectively.

The HCPs mentioned that not all patients benefit equally from mHealth apps. It is important to identify in advance which patients or patient groups could benefit most from a hypertension prevention mHealth app. Some patients may already be well informed and motivated to use digital health technologies on their own, while others may need more support and guidance. By identifying those patients who could best benefit from mHealth app use, clinicians can target their mHealth services more effectively and efficiently.

Another important improvement is that hypertension apps should be customized and personalizable. Each patient is unique, and the mHealth app should therefore be customizable to each individual's specific needs, health goals, and preferences. Personalization options could include selection of relevant health goals, medication reminders, or customization of the app interface to the user's personal preferences. By tailoring the app to each patient's individual needs, the user experience is likely to be enhanced and the likelihood of long-term use increased.

Hypertension often occurs in combination with other conditions, such as diabetes or obesity. To improve the care of multimorbid patients, mHealth apps for hypertension could be combined with other health applications to provide comprehensive and integrated care.

In Dealing With the Systems

It is important that HCPs have access to comprehensive and reliable information about the functionalities, efficacy, safety, and privacy policies of the various hypertension apps. A transparent and evidence-based presentation of this information can help to address concerns about the quality and reliability of the apps and stimulate physicians' interest in using these digital tools.

Careful validation of mHealth apps is essential to ensure that hypertension management apps actually deliver the promised benefits and provide medically robust data. HCPs need reliable information about the scientific evidence and clinical validity of the apps in order to effectively integrate them into their clinical practice.

To improve the adoption and integration of apps for hypertension, it is crucial to promote bottom-up approaches. This means including the user perspective, including physicians and medical staff, in the development and implementation of mHealth apps from the very beginning. Involving users in the development process makes it possible to adapt mHealth apps to the specific needs and requirements of physicians and ensure high usability.

Successful integration of hypertension apps requires not only training of physicians but also the involvement of other HCPs, especially medical assistants. Medical assistants play an important role in helping physicians use mHealth apps and interact with patients. Extensive training of medical assistants on how the mHealth apps work and are useful, as well as how to effectively use the data collected, can help ensure that the integration of the apps is seamless in the practice workflow.

Interoperability and compatibility between different mHealth apps and existing practice IT systems are critical. Often,

XSL•FO
RenderX

physicians and medical assistants face the challenge that the interfaces between the mHealth apps and existing IT systems are not sufficiently optimized, which can lead to technical difficulties and data inconsistencies. Targeted improvement of the interface issues enables physicians to work smoothly with the mHealth apps and seamlessly integrate the captured data into their practice workflows.

Discussion

Principal Results

This qualitative study is the first to explore the factors that enable or hinder the use of mHealth apps for the prevention of hypertension from the perspective of general practitioners, cardiologists, and nurses in Germany. Until now, mHealth apps for the prevention of hypertension are only fragmentarily used in the care of hypertensive patients. From the perspective of the caregivers, the main potentials of mHealth apps lie in increasing patient safety, patient autonomy, and support in medical care. However, the presented results point to major challenges in data handling, patient-HCP communication, integration into standard care, and interoperability. Measures such as extra-budgetary remuneration for digital preventive services, setting targets through tracking or monitoring, identifying patient groups in advance, adapting and personalizing mHealth apps, and combining them with other diseases could, in the view of the HCPs, help to overcome the barriers. In dealing with the systems, the HCPs mention aspects such as more information about digital services, validation of mHealth apps, bottom-up approaches, training and involvement of medical assistants, and improvement of interface problems.

Comparison With Prior Work

Our results are in line with earlier research in mHealth and beyond: physicians and nurses recognize the added values and positive potential of mHealth apps in supporting patients, fostering patient autonomy, and improving medication adherence [24,25]. The attributed benefits are supported by evidence: for instance, Li et al [26] report improvements in self-management behavior and medication adherence in adults using mHealth. Furthermore, self-monitoring of hypertension-related behaviors via smartphone apps combined with tailored advice has a modest but potentially clinically significant effect on blood pressure reduction [27].

Despite the advantages of mHealth, as of yet the barriers hinder their integration into the medical routine. One of the main concerns is the handling of data. Physicians frequently doubt the validity of data collected by patients and have concerns regarding data privacy and security. This can impede trust in the data and willingness to use such mHealth apps.

The mode of communication between physicians and patients can also be influenced by the use of mHealth apps. Some patients may tend to place more trust in the instructions provided by the mHealth app than in the recommendations of their medical caregivers. This could hinder communication with HCPs and impede collaboration between patients and physicians. However, studies have already demonstrated that there are contrary findings to the presumed concerns: findings of a systematic, narrative review show a generally positive influence of mHealth apps on physician-patient communication and relationships, which at times was correlated with better health outcomes [28]. And perhaps the use of apps can make visits more efficient, because blood pressure levels can be transmitted to the practice in advance, and conversations can be focused on essential aspects.

In the interviews, it is stated that mHealth consumes more resources and deteriorates patient communication. In rheumatology, digital health and especially mHealth are considered resource-saving. Digitization creates more time for patient interaction, which enhances the quality of care. If questions have already been answered beforehand, there may be extra time in the conversation with the patient to focus on essential aspects, which can positively impact the perceived quality of care [29]. Furthermore, it is emphasized in rheumatology care that this would allow more time for patient consultations. This is a contradiction. However, rheumatology is more digitized compared to hypertension care because of the greater shortage of personnel and disease burden.

Furthermore, apps can initially mean additional workload for HCPs. The introduction of new technologies requires training, adaptation of workflows, and integration into existing IT systems, which can lead to time and resource constraints. In addition, due to limited resources, many medical facilities may not be adequately prepared to actively integrate digital technologies into their practice. To be able to use digital technologies in their daily routine, physicians also need the appropriate digital skills [30]. In a recent measurement of physicians' professional digital health literacy, they scored 53.1 out of a possible 100 points [31]. For nurses, this figure is only slightly higher at 54.5 points. The most difficult task for physicians and nurses is “helping patients assess the trustworthiness of the digital health information they find,” followed by “helping patients find the digital health information that is relevant to them.” In the future, physicians and nurses will need support especially in this area so that the digital transformation in health care can be driven forward.

A lack of integration of digital tools into the reimbursement structure of the health care system in Germany is also a barrier to the use of such applications. Currently, physicians only receive remuneration for prescribing DiGAs, which does not translate to monitoring apps that have not obtained the DiGA status. There are ongoing discussions about which remuneration model is suitable for mHealth. Labinsky et al [32] reported that only 13% of patients that were prescribed a DiGA completed the whole program. This may also be due to a lack of incentives for physicians to ask if the apps are being used. Considering the low adherence with DiGA, performance-based compensation appears to be appropriate.

Implications

Several recommendations for the integration of mHealth apps into medical practice can be derived from the results. It is important to provide HCPs with low-threshold access to comprehensive and reliable information about available mHealth apps to address their concerns about quality and privacy. Validation of mHealth apps for effectiveness and clinical

XSL•FO
RenderX

validity is critical to convince physicians that these apps provide real value [33]. Bottom-up approaches or participatory study designs that include the user perspective, including physicians and medical assistants in the development process, can help ensure that apps are better tailored to the needs and requirements of medical practice and have a higher usability.

Involving HCPs, especially medical assistants, is also important as they play a key role in helping physicians use mHealth apps and interact with patients. Extensive training of medical staff on how the apps work and their benefits can help ensure that the integration of the apps is seamless in the practice workflow.

Our results underline the importance of staggered use of the mHealth app for effective blood pressure control in patients with hypertension. A high frequency of use at the beginning of treatment helps both patients and health care providers to quickly identify and implement individualized strategies to lower blood pressure. Once the target values have been stably achieved, the frequency of use can be gradually reduced so that the mHealth app can serve as a monitoring tool without unnecessarily increasing the time required by medical staff. This flexible handling could allow the mHealth app to be optimally integrated into everyday clinical practice while minimizing the burden on health care providers in terms of data management.

In addition, it is important to improve the interface issues between digital health apps and existing IT systems. Interoperability and compatibility between different digital apps and medical practice software systems are critical to ensure smooth integration and use of the apps. Targeted improvement of the interfaces can enable physicians to work smoothly with the apps and seamlessly integrate the collected data into their practice workflows.

The use of digital care services could be beneficial if the goal of use were addressed in advance in physician-patient communication. For example, use in the sense of self-tracking would not necessarily require medical intervention. Whereas the use in the sense of monitoring is associated with a control function, and physicians are actively involved in the process. Further studies are also needed to analyze the benefits and effectiveness of digital care services.

Based on the current findings and recommendations made by the HCPs, various stakeholders (eg, policy makers, health insurance companies, physicians' associations, associations of the scientific medical societies, patient organizations, health care researchers, or app developers) in different fields of the health care system should take action to push the integration of mHealth app in daily practice (Textbox 2).

Textbox 2. Recommendations for the integration of mobile health (mHealth) apps into medical practice.

Structural conditions

- Extrabudgetary remuneration for digital prevention services
- Improvement of interface problems
- Training and involvement of medical assistants
- More information about digital offers

App development

- Bottom-up approaches and user experience design
- App individually tailored and personalizable
- Combination with other diseases
- Validation of mHealth apps

Use in patient care

- Assessment of patients' eligibility to use mHealth
- Identify patient (groups) in advance
- Define goals: tracking or monitoring

Strength and Limitations

Our study is the first to investigate the benefits and barriers of using mHealth apps in preventing hypertension in Germany. We drew closely on the reality of care and the perspectives of the physicians and nurses. The qualitative interviews allowed for obtaining an in-depth understanding of the experiences with or without apps in preventing hypertension and expected advantages and disadvantages. However, there are certain limitations to our study. The results might be subject to a selection bias because perhaps people who were more interested in the topic took part in the study. Due to the sampling strategy, we may not have been able to reach everyone and did not record important aspects. A generalization of the results is therefore impossible. In addition, patients were not interviewed at this time.

The authors are aware that this general exploration can only be a first step given the breadth and diversity of the topic "hypertension mHealth apps." Further studies must be conducted in the context of specific health care situations to build upon these findings. These limitations directly translate into opportunities for further research: We are planning to extend

XSL•FO
RenderX

the study to a larger sample in Germany [16] and to validate the qualitative results with a questionnaire survey.

Further research should also focus on how to identify patients who may or may not be eligible for mHealth apps in hypertension care; how HCPs can be effectively informed about mHealth and digital health in general, as well as what reimbursement strategy will reinforce the effective use of mHealth in the care of chronic conditions.

Conclusions

HCPs recognize the benefits of mHealth apps for patient safety or to support disease management. However, at present, best practices for implementing mHealth apps in preventing hypertension do not exist. In order to be able to use digital tools such as mHealth apps efficiently, the barriers, such as information needs, interoperability issues, uncertain remuneration, and vague clinical effectiveness, need to be overcome. Above all, users need to be involved in design and implementation processes. Furthermore, low knowledge needs to be eliminated by offering access to low-threshold information on mHealth apps.

Acknowledgments

The authors would like to thank all interview partners and participants for their valuable contributions and time. We would like to express our special thanks to the Association of Statutory Health Insurance Physicians Brandenburg (KVBB) and the General Practitioners' Association Brandenburg for their support during the recruitment process. This work was supported by the Innovation Committee at the Federal Joint Committee (Innovation Fund, grant number 01VSF18014).

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files). For further questions regarding the reuse of data, please contact the corresponding author (susann.may@mhb-fontane.de).

Authors' Contributions

SM made substantial contributions to the design of the work, the data acquisition and analysis, and the interpretation of the data; drafted the manuscript and had full access to all the data in the study; and takes responsibility for the integrity of the data and the accuracy of the data analysis. FM made substantial contributions to the design of the work, the data acquisition and analysis, and the interpretation of the data; drafted the manuscript and had full access to all the data in the study; and takes responsibility for the integrity of the data and the accuracy of the data analysis. EW made substantial contributions to the design of the work and the data acquisition and analysis and substantively revised the manuscript. FS made substantial contributions to the data analysis and substantively revised the manuscript. MH made substantial contributions to the data acquisition and analysis and substantively revised the manuscript. DB made substantial contributions to the design of the work, obtaining funding, and data acquisition and analysis, and substantively revised the manuscript. SSp made substantial contributions to the design of the work, obtaining funding, and data acquisition and analysis, and substantively revised the manuscript. All authors have approved the submitted manuscript. In addition, the authors have agreed both to be personally accountable for the author's own contributions and to ensure that questions related to the accuracy or integrity of any part of the work, even ones in which the author was not personally involved, are appropriately investigated, resolved, and the resolution documented in the literature. SM and FM contributed equally to this work (shared first authorship). DB and SSp contributed equally to this work (shared last authorship).

Abstract

Background: Telehealth is a recognized and rapidly evolving domain in the delivery of emergency medicine. Research suggests a positive impact of telehealth in patients presenting for emergency care; however, the regional challenges of acute telemedicine delivery have not been studied. The WA Country Health Service (WACHS) established the Emergency Telehealth Service (ETS) in 2012 to provide telehealth and other technology-enabled services to regional Western Australian hospitals and clinics. The WACHS ETS supports 87 rural and remote WACHS-operated hospitals as well as 10 non-WACHS health clinics via high-definition audio-visual equipment installed in the resuscitation bay of the emergency department (ED) at each site. This 12-year practical application of emergency telemedicine offers a unique opportunity to explore the experiences and perceptions of clinicians delivering virtual care to rural and remote communities.

Objective: This study explores the perceptions of ETS clinicians regarding acceptability, appropriateness, and clinical decision-making when delivering emergency telemedicine in rural and remote settings.

Methods: This qualitative study used semistructured interviews to explore the perspectives of ETS clinicians regarding the factors influencing their clinical decision-making. It explored how ETS clinicians determine and modify clinical risks associated with using audio-visual equipment to deliver care. Emerging themes were compared with the concepts arising from the interim guidance of the Medical Board of Australia, and both the Australian and New Zealand, and American Colleges of Emergency Medicine.

Results: Overall, 16 doctors, 4 clinical nurse coordinators, and a nurse educator from WACHS ETS provided their experiences and perspectives. Accurate clinical decisions, especially regarding patient disposition, were crucial to virtual care. Timeliness and accuracy were enhanced through a mutual learning model grounded in the local context. Mitigation strategies such as improvisation and flexible technology use compensated for technological barriers. Nonmodifiable risk factors included patients' presenting complaints, clinical urgency of presentation, ED capability, clinician scope of practice, and, if a transfer was required, the distance between the ED of original presentation and the hospital of definitive care.

Conclusions: Telehealth can enhance clinical decision-making in rural and remote EDs, and ETS clinicians can prioritize patient safety through a lens incorporating both local hospital capabilities and community contexts. Even for the most experienced

XSL•FO
RenderX

clinicians, telehealth was not comparable to face-to-face communication in all circumstances. The impact of the ETS on the scope of the regional emergency medicine practice and on the building of clinical skills warrants further study in relation to its overall effectiveness and cost-effectiveness in rural and remote EDs. These findings identify areas for further qualitative research while providing a rich contextual background for rigorous quantitative analysis of the effectiveness of the ETS.

Introduction

Background

Telehealth has rapidly emerged as a means of providing health advice and care to people at sites where health providers at the hospitals of initial presentation (presenting hospitals) may lack capability or require assistance with the diagnosis and treatment of presenting clinical conditions. In recognition of the rapidly evolving domains of telehealth in the delivery of emergency medicine (EM) in the United States [1] and Australia and Aotearoa (New Zealand) [2], the Australasian College of Emergency Medicine (ACEM) [2], American College of Emergency Physicians [1], and Medical Board of Australia [3] deliberated on interim principles, considerations, and minimum standards to guide emergency telemedicine ("the interim guiding principles from the Colleges of Emergency Medicine"). Telehealth in the emergency department (ED) aspires to improve the quality of health care for patients in remote and other settings by increasing access to specialists and optimizing health service utilization and disposition coordination, including timely access to definitive care [2].

Guiding Principles on Emergency Telemedicine Implementation

These interim principles provide minimum standards for telehealth practice in the ED. As the Colleges of Emergency Medicine have identified, the use of telehealth in EM is in the formative stage and currently lacks a strong evidence base for clinical practice in the context of emergency care.

The ACEM and Australian New Zealand Fellow of ACEM (FACEM) Telemedicine Community of Practice (ANZFTCOP), superseded by a formal ACEM Emergency Telehealth Network, raised the importance of local context and the unplanned and exigent nature of emergency care [3]. The ANZFTCOP distinguished the nature of emergency medical practice from the broader telehealth discussion as it involves the provision of acute care without an ongoing clinical relationship either in-person or virtually [3]. The Community of Practice also pointed to circumstances where it may not be possible to access emergency physician expertise without recourse to telemedicine [3]. This is common for many rural and remote Australian EDs. The ANZFTCOP suggested that the decision regarding the appropriateness of conducting a telemedicine session instead of an in-person consultation should be based on individual clinical circumstances and expert clinician judgment [3]. Table 1 provides an amalgamated summary of the key guiding principles from these position statements and guidance documents.

XSL•FO
RenderX

Table 1. Amalgamated summary of the interim guidance on emergency telemedicine implementation.

Key themes	What is emergency telehealth and what should it do?	What is not emergency telehealth and what should it not do?
Locally grounded	• Should be an important complement for locally and regionally provided comprehensive health care. • Should be part of regional models of emergency care delivery validated by all relevant stakeholders across the public health system. • Should have regard for the local context and be grounded in the relationship with local clinicians including but not limited to knowledge of the local population, service availability, and patient pathways. • Should have appropriate escalation procedures in place to activate emergency services.	• Should not replace local care. • Should not be considered as a substitute for face-to-face consultations. • Should not involve low-value care that would not have otherwise been provided. • Should not be a stand-alone solution to address health workforce capacity and maldistribution.
Of similar quality and standard to ordinary care	• Assessments and consultations: (1) should be thorough within the limitations of telehealth and virtual consultations, (2) should replicate the components of an emergency medicine consultation, and (3) should be cognizant of the peculiarities or distinctive requirements of specific conditions. • Should implement quality assurance programs to monitor clinical performance, patient outcomes, and integrated ongoing care.	—[a]
Timely care	• Should ensure that definitive care is not delayed.	• Should not create additional barriers to accessing emergency medical care.
Appropriateness of care	• Should ensure that the patient's presenting problem is suitable to be assessed and managed remotely.	• Not appropriate for all clinical consultations.

[a]Not applicable.

Study Setting

The WA Country Health Service (WACHS) is one of the largest country health services in the world in terms of geographical coverage (2.55 million square kilometers, 96% of the land mass of Western Australia), with a population of 531,934 (18% of the Western Australian population; population density of 0.21 per square kilometer). It is organized into 7 distinct and diverse regions with 118 health facilities, accounting for 41% of the total number of emergency presentations across Western Australia (over 40,000 presentations per year) [4]. Most hospitals outside the large regional centers are staffed mainly by nursing staff supported by a resident general practitioner (GP) credentialed to provide medical services at the hospital. There are variable numbers of consultant specialists providing services at the larger regional resource centers. The majority of WACHS hospitals do not have on-site access to emergency medicine physicians (FACEMs).

The WACHS established the Emergency Telehealth Service (ETS) in 2012 to provide telehealth and other technology-enabled services to regional Western Australian hospitals and clinics. The ETS is the earliest and most established service stream of the WACHS Command Centre, which supports 87 WACHS hospitals and 10 additional non-WACHS facilities through high-definition videoconferencing services [5]. The Command Centre is a 24/7 virtual clinical and operational hub including services for general medical inpatients, mental health, midwifery, after-hours palliative care, and transfer coordination. It supports clinicians in regional hospitals and nursing posts by providing ready access to specialist clinicians who use technology, videoconferencing, and real-time data to assist in delivering quality patient care [6].

In addition to over 38,000 clinical consultations per year, the ETS supports rural and remote clinicians to maintain skills and knowledge through an education program and opportunities for professional development [5]. The consulting clinicians are located across multiple geographical areas (Perth, across regional Western Australia, other Australian jurisdictions, and internationally). Most medical practitioners are FACEMs complemented by EM-credentialed GPs and emergency nurse practitioners. The central hub of the Command Centre is based in Perth, and referrals are coordinated by a team of clinical nurses and clinical nurse consultants.

Referrals to the ETS vary across hospital types but are mainly from small hospitals (81.5%), nursing posts (9.7%), and integrated district health services (8.2%), and the ETS is least used by regional resource centers (0.7%) [4,7]. The proportions of ED presentations involving the ETS also vary across hospital types, with nursing posts and small hospitals involving the ETS in 21.3% and 23% of all ED presentations, respectively. Between July 2018 and April 2023, the uptake for nursing posts ranged from 2.8% for nonurgent presentations to 62.1% for emergency presentations that must be attended within 10 minutes. For small hospitals, the uptake ranged from 5.3% for nonurgent presentations to 47.9% for presentations requiring resuscitation. The more remotely located EDs appear to have greater reliance on the ETS especially for the management of more urgent cases [4,7].

Evidence on Telehealth Implementation in Rural and Remote EDs

Studies have identified factors that negatively influence the experiences of regional clinicians in rural and remote EM practices. These include [8,9] the lack or absence of medical backup or resources, the geographical and social isolation of

XSL•FO
RenderX

rural communities, poor health system coordination, the loneliness experienced by regional clinicians, and the challenges of health care provision in geographically isolated locations [10-12].

The challenges these conditions pose are community specific [8], and studies found that rural and remote EM physicians drew on the strength of professional relationships to improvise, solve problems, and create systems of support to meet local needs in order to survive and thrive in the middle of rural and remote challenges [8,9].

Published studies on the use of telehealth in EM suggested positive impacts on patient care, including benefits such as cost reduction, improved quality of care, reduced mortality rate, reduced patient treatment time, and reduced time between first contact and treatment [13]. Moreover, in the rural and remote context, studies have reported reduced patient transfers from rural facilities to major centers [10-12,14-16] and improved capability of rural centers [10,17,18]. However, studies have not discussed the complexities of rural and remote EM practices in depth or taken them into account in their analyses.

The use of telehealth in rural and remote EDs to help alleviate these regional EM practice challenges has not been studied. Whether or how emergency telemedicine in rural and remote settings improves patient health outcomes and the factors influencing the clinical decisions of emergency telehealth clinicians remain uncertain. There is a need for quality evidence to better understand these factors to help identify the gap in the effectiveness of emergency telehealth [12,14,15,17,19-27].

Studies have, however, identified challenges in the implementation of virtual care, and emergency telehealth is one of the practice areas considered [14,22,23]. These include technical difficulties [11,12,23,25-27], factors impeding the process of care [10,14,16,19-21,24-26], and factors impacting patient privacy, confidentiality, and data security [24-26].

It has been proposed that to understand the factors influencing job satisfaction, the complex environments around rural and remote EM practices must be considered [8]. However, the impact of environmental factors on clinical decision-making in rural ED practice has not been considered.

The clinicians' perceived clinical risks have been identified as a challenge in rural and remote EM practices [8,9]; however, how individuals perceive the risks in rural and remote emergency telehealth practices and the impacts on their clinical practices have not been explored previously. In rural and remote EDs, it is possible to assume that when the perceived clinical risk is high, the approach to diagnosis and treatment may change, leading to increased rates of transfer. The distinctions between these perceived clinical risks when delivering face-to-face versus virtual EM services warrant investigation.

To the best of our knowledge, specific links between the challenges of clinical reasoning and decision-making in virtual emergency care and the rural and remote context have not been identified. However, these factors are critical for understanding the effectiveness of implementing telehealth in rural and remote EDs.

Study Aims

From the perspective of WACHS clinicians delivering the ETS, this study explored the perceptions of emergency telehealth clinicians regarding the acceptability, appropriateness, and determinants in clinical decision-making when delivering emergency telehealth in rural and remote settings. This study aims to understand the following: (1) the factors influencing clinical decisions during an emergency telehealth consultation; (2) the impact of involving emergency telehealth clinicians in rural and remote ED consultations on the health workforce and the safety of clinical service delivery; and (3) how the clinical risks associated with emergency telehealth consultation can be modified, including whether improving the status of factors that are amenable to change can positively influence the safe and effective delivery of the ETS.

Methods

Overview

This qualitative study used semistructured interviews to explore the perspectives of ETS clinicians regarding the factors influencing their clinical decision-making. It explored how ETS clinicians determine and modify associated clinical risks. Emerging themes were compared with the concepts arising from the interim guidance of the Medical Board of Australia and both the Australian and New Zealand, and American Colleges of Emergency Medicine. The WACHS ETS was used to examine contextual factors influencing the quality and perceived effectiveness of emergency telehealth in rural and remote areas.

Sampling Techniques and Study Participants

A combination of convenience, snowball, and purposive sampling was used to obtain a diverse perspective on the ETS model of care. Convenience sampling was required given the nature of ED work and participant availability to recruit FACEMs, GPs, ETS nurse coordinators, and clinical nurses. A purposive sampling of WACHS ETS physicians who were interstates or overseas occurred toward the end of the participant recruitment.

On December 17, 2020, an invitation email was sent to all ETS doctors and nurses by one of the FACEM members of the research team. This was followed by individual follow-up emails on January 22, 2021, to ETS doctors, as well as emails and in-person follow-ups by one of the ETS clinical nurse consultants in the research team.

Interview Guide Development

The interview protocol (guide) was developed in collaboration with the clinical researchers at the Command Centre. This interview guide was then distributed to the full research team for review.

After piloting the interview protocol with a select leadership group, the protocol was updated to include probes on whether an electronic stethoscope would help provide confidence in clinical decision-making, as well as adding questions related to the clinical governance, service legitimacy, and legality of the ETS practice. Minor changes were also made to the wording and ordering of the content areas and probes within each content

XSL•FO
RenderX

area. The final version of the interview protocol is presented in Multimedia Appendix 1.

Simultaneous Data Collection and Analysis

Semistructured in-depth interviews explored the experiences and opinions of the clinicians involved in ETS implementation and the factors considered in clinical decision-making.

Participants were given the option to participate in an interview via MS Teams (Microsoft Corp) or phone, from a place and at a time of their choosing. Interviews were audio recorded, automatically transcribed, and repeatedly played back in the open-coding phase of the analysis to validate the accuracy of the transcription. Due to the nature of emergency work, the recruitment and conduct of the interview occurred opportunistically to catch moments when the clinicians were available. This meant that interviews sometimes occurred outside rostered work times, with some conversations interrupted by work-related demands.

Data analysis proceeded simultaneously with data collection and issues arising from information [28]. The early phase of the analysis included open and axial coding [29], identifying the emerging themes with open coding from clinician interviews. The emerging themes were then compared with the guiding principles identified from the interim guidance documents of the Colleges of Emergency Medicine and Medical Board of Australia. The key guiding principles were introduced as axial codes to place the open codes within the context of EM practice. In the final phase of the analysis, risk factors considered by clinicians in their clinical decision-making during an emergency telehealth consultation were extracted and classified into technology related, presenting hospital/location related, or EM related. The modifiability of each of the factors was assigned by the lead author and confirmed by co-authors based on author experience, the rural and remote context of Western Australia, the public health service landscape, and the resources available to the WACHS. The factual findings reported in this paper were discussed with and confirmed by the WACHS Command Centre.

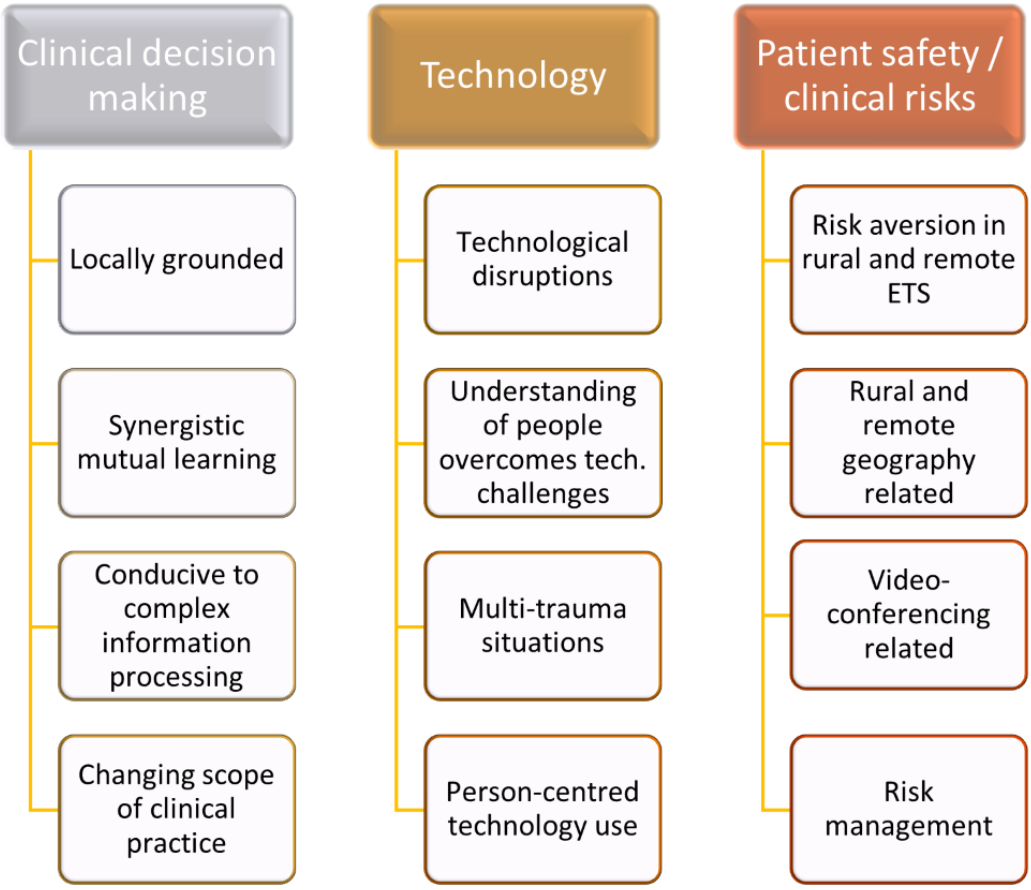
Ethics Approval

This research obtained ethics approval from the WACHS Human Research Ethics Committee (approval number: RGS0000003076) and reciprocal ethics approval from the Curtin University Human Research Ethics Committee (approval number: HRE2019-0740-09). Site access was governed by the WACHS research governance policy and procedures. A participant information and consent form was attached to individual email invitations to the participants to review, sign, and return before the scheduled interview. For participants who attended the interview but were unable to sign the consent form, verbal consent was obtained before the commencement of the interview. Interview recordings were transcribed verbatim by the first author. The transcripts and recordings were allocated a participant code and stored in a password-protected electronic folder that is separated from the folder where the participant register is stored.

Results

Interviews and Participants

Most interviews were conducted via MS Teams (17/21, 81%), and the remaining were conducted by phone (4/21, 19%). Participants were in their private homes, a dedicated home office space, or Western Australian health facilities.



Sixteen WACHS ETS doctors and 5 ETS nurses participated in the interviews. There were 9 FACEMs, 5 GPs, 2 ED registrars, 4 clinical nurse coordinators, and 1 nurse educator. All participating ETS nurses were based at the Command Centre in Perth, while 5 of the ETS medical practitioner participants were based in Perth, 6 were based in regional Western Australia, 4 were overseas, and 1 was interstate. Two senior rural GPs provided their perspectives from both the receiving and provisioning ends of the ETS (as GPs working in regional locations). Around a quarter of ETS doctors and 16% of ETS nurses in the Command Centre participated in the interviews. All ETS nurses, except 1, were recruited by the same clinical researcher through face-to-face invitations, while 83% (15/18) of the ETS doctors who participated in the interviews responded to the initial invitation to participate. The purposive recruitment yielded 2 additional ETS participants to add weight to the perspectives of overseas or interstate doctors. Multimedia Appendix 2 lists the details of the participants, including home base, professional designation, gender, ETS role, and perspectives they contributed to this study.

Domains That Emerged From the Simultaneous Data Collection and Analysis

The major thematic domains identified in this analysis were clinical decision-making, technology, and patient safety or clinical risk. The themes and subthemes have been outlined below. Figure 1 provides a representation of the domains and themes.

XSL•FO
RenderX

Figure 1. Thematic domains and subthemes that emerged in this study. ETS: Emergency Telehealth Service; Tech.: technology.

Clinical Decision-Making: Benefits of Involving the ETS to Support Clinical Decisions

Participants identified 3 key benefits of ETS involvement in rural and remote clinical services. Hospital clinicians reported that having the ETS improved the willingness and confidence of regional clinicians to practice in remote locations. The ETS enabled synergistic mutual learning through the collaborative patient management of site-based and ETS clinicians. Further, ETS FACEMs experienced the benefit of ETS practice over site-based practice as it allowed them to be more cognitively focused when processing complex information. Participants touched on the changing scope of clinical practice as part of their discourse on clinical decision support.

Locally Grounded Clinical Decisions

Participants described timely and appropriate disposition (admission, discharge, or transfer) of patients as the most significant clinical decision for rural and remote EDs. Disposition of ED patients, especially from less-resourced remote EDs, has significant patient safety and clinical risk implications. Clinical decisions pertaining to patients presenting to small and remote EDs differed from those of better-resourced urban or regional center EDs as site-related factors needed to be considered.

All participants commented that multiple interacting factors were at play when deciding to transfer a patient for ongoing management. Table 2 lists the factors they considered in their clinical reasoning, and only 1 was related to technology. The predominant consideration was the resources available locally within the presenting hospital and in the local community. The next consideration was the distance to a destination site of definitive treatment if a patient's condition deteriorated. The final consideration was the timing of transfer and its appropriateness according to an individual patient's health condition.

XSL•FO
RenderX

Table 2. Thought processes in clinical decisions including patient disposition considerations via rural and remote emergency telehealth.

Thought processes of decision-making clinicians	Technology related	Hospital/location related	Patient related	Emergency medicine related
Normal diagnostic decision-making: what is wrong with the patient?	No	No	No	Yes
Can the patient be adequately assessed for all relevant possibilities at the site? What [differential diagnosis] am I potentially missing and is that putting the patient at risk?	Yes	Yes	No	No
Is this patient safe to go home medically and socially?	No	Yes	Yes	No
Is there a local GP[a] in town to care for the patient the next day?	No	Yes	No	No
Am I happy for the patient to wait till the next day for follow-up in a community?	No	Yes	Yes	Yes
Considering the patient's location, the weather conditions, and the local resources available, is the patient safe to stay at this site and/or be admitted locally for observation?	No	Yes	No	No
Does the patient need to be retrieved earlier [compared to the standard of a tertiary center or regional center ED[b]]?	No	Yes	No	No
Where and how do I transfer them? Is this patient safe to go somewhere with private transport or road ambulance, or do they require aeromedical transfer?	No	Yes	Yes	No
What does the patient want? (some patients do not want to leave their community)	No	No	Yes	No

[a]GP: general practitioner.

[b]ED: emergency department.

Synergistic Mutual Learning With Joint Clinical Decision-Making

ETS physicians were reliant on the local knowledge of hospital clinicians at the site of patient presentation to facilitate and consider community, social, and resource factors in clinical decisions for regional patients. Rural-based hospital clinicians reported benefits from the assistance of ETS clinicians in making clinical decisions, especially their support in connecting to appropriate and available resources.

Regional-based participants reported that the involvement of ETS colleagues supported them in answering the questions listed in Table 2, with increased speed and confidence. An ETS physician who also worked at a site based on a WACHS ED stated:

> *It makes certain that we make the best decisions for our patients. ETS does make the decision-making process much easier in the region. I've got somebody else online who can call me if I'm looking after somebody who's critically ill. They can help organize transfers and ICU admission, they can help me with drug doses, so I can…crack on and do what I need to do. And I know that I'm working in a safe environment.* [ETS Doctor #3]

Participants also stated that they acquired a different skill set working in a supportive role to clinicians in remote facilities, including ways of communicating instructions to presenting hospital clinicians (mainly nursing staff), gathering medical history, prescribing medications, and efficiently analyzing and synthesizing presenting complaints.

For ETS clinicians who were FACEMs mainly based in metropolitan hospitals, participation in ETS consultations provided a new and unfiltered experience in the rural and remote clinical practice. Many reported that this changed the way they practiced in their substantive role on the floor of tertiary EDs:

> *I think [the learning has been] in both directions, one, it makes me realize how resource rich we are in a tertiary hospital. Two, it makes me realize that the nurses and other staff out there [in regional WA] are often just as competent, just as knowledgeable, and just as skillful and often braver than we are in tertiary hospitals. It certainly helps me stay grounded when I'm accepting referrals. [Tertiary hospital] has a big catchment, we receive a lot of these people from peripheral hospitals and nurse run clinics. And one that certainly helped me know where all these places are, when I'm on the receiving end of the phone…I'm able to explain to other staff exactly how resource limited, a lot of these clinics are. And there is a reason they haven't had blood tests and haven't had imaging. And in fact, there's no doctor there. So they have just been seen by nurses must come to be seen by us, we don't have to be difficult about accepting them. I think that's been quite useful.* [ETS Doctor #43]

Conducive to Complex Clinical Information Processing

Participants reported that their ability to control and prioritize their consultations in the virtual environment assisted their efficiency in processing complex information and enabled more objective assessment than working in person on the ED floor, given their distance from the patient. Participants reported the

XSL•FO
RenderX

benefits of providing virtual care compared to working on an ED floor:

> *If you're on an ED floor you are interrupted constantly because you're physically there…one of the most frustrating things is you're constantly distracted, and you can't finish a task from A to B, I think that adds hugely to burnout. …But you are focused here [at ETS], …we can only see one camera…one patient at a time. …And the chaos is more manageable… you can choose to not be interrupted. So I feel that it's very satisfying, because you're so cognitively focused. And I think that can potentially lead to better quality care… because you can just make better decisions.* [ETS Doctor #6]

With the ability to control the environment they practice in, ETS FACEMs found the virtual environment conducive to them being more cognitively focused.

Changed Scope of Clinical Practice

The impacts on the scope of practice of regionally based clinicians, especially nurses, were dichotomously reported. Most participants reported an increasing scope of site-based clinical practice with ETS doctors guiding local nurses to perform procedures that they otherwise would not have the confidence to do on their own. A contrary perspective was the engagement of ETS clinicians in treatment and procedures or clinical decisions, which local clinicians would have performed independently through a local process in place prior to ETS implementation. For example, regarding giving a tetanus booster, 1 participant commented:

> *…we'll get consults of patients who need a tetanus booster, they've had a small wound a few days ago, …I don't know what they would have done before, I think they would have done it and had a process in place to do it.* [ETS Doctor #2]

The changing scope of practice was noted by the participants. This reflected policy changes to increase medical practitioner involvement in ED consultations and was an emerging theme that warrants further in-depth exploration.

Technology

The second thematic domain was technology, which included technological (digital) disruption and mitigation strategies in emergency telehealth consultations.

Participants were of the view that the WACHS ETS had already made most of the technological and process improvements and considered that any further changes on the technological front would have incremental benefits in effectiveness for improving patient health outcomes. One FACEM participant stated:

> *A lot of the system problems are the fact that we have a hundred places that are tiny and it's hard to get [for example] a pathologist, or experienced nurses for long stays. A lot of it is system problems that are difficult to modify.* [ETS Doctor #43]

> *We probably made the easy gains and the incremental changes you can make to improve things from here are big and costly, and difficult. For example, attracting and keeping people in remote communities and providing enough staffing to let GPs take holidays and do professional development and be replaced by someone, rather than leaving the community to rely on telehealth because there is no one else to cover.* [ETS Doctor #43]

Participants described the ways in which they modify how they use the telehealth technology or adjust the process of care to improve the quality of ETS consultations.

Technological (Digital) Disruptions

A commonly expressed view among ETS physician participants was that during videoconferencing, one is expected to lose nonvisual cues and some verbal cues due to technological (digital) disruptions. Clinicians reflecting on the videoconference consultation experience suggested that the amount and quality of information a clinician could gather through video came down to their level of understanding of people as individuals. They referred to the nuances of patients' expressions observable during videoconferencing and being able to relate to the regional context of the patients. Table 3 provides a summary of the circumstances around the technological barriers during an ETS consultation and the mitigation strategies participants used to overcome these technological disruptions.

XSL•FO
RenderX

ETS[a] technology-related issues	Technology barrier			Mitigation strategy		
	Barrier	Circumstances	Participants	Strategy	Incompatibility	Participants
Positioning of the monitor where the image of the ETS physician appears (ie, at the foot of the ED[b] stretcher)	• Sending the wrong message that the doctor is looking down on the patient. • Abrupt appearance does not allow ETS to ease into the scene as in the case of an in-person ED floor.	When people on the floor are not adequately prepared and people are unaware why the ETS clinician is appearing on the screen, there can be disruptions in the actions already taking place in the ETS bay.	ETSD[c] #1, 4, 6, 7, 10, and 13; ETSN[d] #3	• Prepare patients before the VC[e] link is up; explain the process before and after VC consultation, including the steps leading up to transfer when interhospital transfer is indicated • ETS physician is identified as not from Perth and thus does not appear as "someone from Perth talking down on us"	• In a critical encounter, there is no time and space to prepare patients and people in the room. • Only available to regional-based ETS clinicians.	ETSN #3; ETSD #7
Talking into an open space; broadcasting of sound from the VC setup into the ETS bay	• Impersonal, with privacy and confidentiality potentially compromised; concurrent private conversations can occur from adjacent ED bays, which can create distracting noise during the consultation process.	Especially when multiple parties are involved in the conversation	ETSD #1, 4, 7, 10, and 13; ETSN #3	• Mute VC sound and use a telephone directly with site-based clinicians or patients for audio to ensure private conversations. • Transition to telephone only after an initial meet and greet with VC. • Clinicians on the floor are encouraged to wear headphones to enable switching voice channels between different target audiences.	• If children are involved, communicate with parents or carers	ETSN #3 and 4
The ETS clinician's visual field of the ETS bay is restricted by the camera's visual field	• ETS clinicians are not aware of others in the room.	Consulting before realizing a family member or another patient is in the room; knowing who is in the room and their relationship with the patient can change the dialogue and alter the instructions given regarding the next steps.	ETSD #1 and 6	• Use a telephone before screen appearance, find out who is present, and clarify the purpose of involvement. • Self-introduction, role of ETS consultation, and a name shown at the base of the screen.	—[f]	ETSD #2, 4, 8, 9, 12, 13, 15, and 43
Zoom in or out function adjusted locally without the ETS clinician's awareness	• Unable to zoom in to see what needs to be seen.	Significant (disastrous) impact in critical situations.	ETSD #5	• Having a reliable camera that the ETS doctor can control.	—	ETSD #4 and 14

[a]ETS: Emergency Telehealth Service.

[b]ED: emergency department.

[c]ETSD: ETS doctor.

[d]ETSN: ETS nurse.

[e]VC: videoconferencing.

[f]Not applicable.

The videoconferencing equipment setup and the restriction of the camera's visual field created technological barriers affecting the quality of ETS consultation. Physical distance was the perceived distance between either side of the high-definition audio-visual equipment installed in the resuscitation bay of the ED at each site.

XSL•FO
RenderX

Participants experienced constraints of the camera setup made consultations impersonal and visual cues easily missed or distorted, and they shared how they adapted in their ETS practice to ensure effective visualization. One doctor said the technical issues and logistics of commencing a consultation with sudden appearance on a screen and sound broadcasting as key differences to working on the floor:

> *…, you got to spend time to dial in, and, then suddenly just appear on the screen in front of the patient… sometimes they're a bit shocked because you're big and loud on the screen… especially if they're drunk, confused that can exacerbate that [shock]. And sometimes I don't know what the volume is, sometimes I'm absolutely booming. And then everybody can hear me in the ED… they got to find the mute button, unmute me and decrease the volume…* [ETS Doctor #6]

A few participants suggested that adding a reliable remote-control pan or zoom would considerably improve the quality of the ETS physical assessment:

> *…great history and reading the cues if someone is lying very still, are they squirming around, are they making reasonable eye contact, are they coherent when they talk, all of that sort of stuff... you know looking for facial droop, obvious distal neurological deficit can be done really well [with reliable and high resolution camera].* [ETS Doctor #14]

Understanding of People Can Overcome Technological Challenges

Through reflective practice, participants redefined and modified their practice over the ETS to mitigate the shortcomings of the videoconference equipment setup. There were varied responses to technological (digital) disruptions in interpersonal communications. ETS doctors gave examples of how they used visual and imperfect auditory cues to assist with formulating their working diagnosis when direct eye contact was not possible via videoconferencing. Visual cues, such as closing hands and fidgeting, were used to the clinician's advantage to help with diagnosis. Humor and a nonjudgmental approach were helpful in getting patients to reveal their alcohol issues and to work collaboratively with patients over videoconferencing to reach the best outcome for them. These human approaches made a notable difference in the virtual physical assessment process.

Multitrauma Situations With One Videoconference Bay

In a multitrauma situation when only 1 doctor was available on site, teamwork was required. For example, when the site-based doctor was busy with hands-on procedures in collaboration with an ETS FACEM, a local nurse stepped up to perform the team leader tasks under the guidance of ETS clinical nurses. When there were multiple casualties, all casualties would need to rotate to be in front of the cameras (typically 2 perpendicular pan/tilt/zoom cameras), and by using headphone channel switching, ETS clinicians could converse with each of the site clinicians individually. When there was a requirement to "shuffle" beds in and out of the camera visual field, adequate explanation ahead of the action was noted as an indispensable component of patient-clinician communication.

Person-Centered Technology Use

Facing variations in the quality of the internet connection, fixed positioning of cameras, and the broadcasting of sound into an open space of the ETS bay at regional EDs, ETS clinicians developed approaches to work with and via the presenting hospital clinicians to improve the quality of videoconference consultation while also protecting the privacy and confidentiality of patients. Overcoming technological limitations required users to troubleshoot and adapt to circumstances, requiring flexibility to ensure the effectiveness of virtual care. This finding pertains more to the exigent nature of EM and less to the rural and remote context of ETS delivery.

Patient Safety and Clinical Risk Considerations

The final thematic domain was related to the perceived risks of virtual care identified by the study participants (Table 4). The central aim was to ensure patient safety when using telehealth. If the ETS team perceived that patient safety was compromised by remaining at the local facility (particularly if there was no on-site medical practitioner), they would strongly consider transferring patients to an appropriate hospital for ongoing management. ETS clinicians who had higher levels of perceived clinical risk had a lower threshold to transferring their patients. Participants were confident that with experience (both at the site and virtually), some transfers could be avoided. The modifiability of risks as assessed in this study identified areas for potential improvement and the factors to consider in the effectiveness dialogue.

XSL•FO
RenderX

Table 4. Factors that make emergency telemedicine clinicians risk averse in rural and remote areas in Western Australia.

Clinical risks and sources of risks in the Emergency Telehealth Service practice	Technology related	Hospital/location related	Emergency medicine related	Is it modifiable?
Insufficient or lack of local resources				
Nature of ED[a] cases: sudden deterioration not always predictable	No	No	Yes	Not modifiable
Distance/time required to transfer to a location with more resources against the risk of deterioration	No	Yes	No	Not modifiable
No short-stay unit: cannot keep the patient after hours	No	Yes	No	Potentially
Local workforce capacity and capability				
Clinicians on the ED floor are unable to perform the required physical assessment	No	Yes	No	Limited
Procedural (IV[b] access and treatment procedures)	No	Yes	No	Potentially
No doctor or insufficient nurses onsite to admit the patient	No	Yes	No	Potentially
No GP[c] in town to follow-up on the next day	No	Yes	No	Limited
Unable to secure a clear diagnosis				
Unable to access required testing or imaging	No	Yes	No	Not modifiable
Unable to fully examine: chances of missing a clinical cue are greater	Yes	No	No	Limited
Not 100% confident with the clinical picture despite full complement of clinical information	No	No	Yes	Not modifiable
Variable internet quality: disrupts physical assessment	Yes	No	No	Limited
Camera is not always reliable	Yes	No	No	Modifiable
Individual factors				
Physician personality and approaches to risk	No	No	Yes	Not modifiable
Physicians are less comfortable with the reliability of their own physical assessment over VC[d] compared to face-to-face evaluation	Yes	No	No	Potentially
Patient preference (to stay closer to home)	No	No	Yes	Not modifiable
Patients and family members are risk averse to telehealth consultation	Yes	No	No	Potentially

[c]GP: general practitioner.

[d]VC: videoconferencing.

Concept of Risk Aversion in the WACHS ETS

Risk aversion impacts transfer rates from the site of presentation. The level of risk ETS clinicians were willing to take in keeping patients locally depended on 4 broad categories risk considerations. The first and second considerations of risks were related to the presenting hospital capacity and capability (ie, the health service resources and workforce). Risk aversion was associated with increasing remoteness of the presenting hospital. The third category of risk was unanimously reported by all the ETS physician participants. They reported that they were not able to examine the patient adequately or be completely confident with the clinical information relayed by site-based clinicians. This concern reflected how well ETS clinicians felt they could apply strategies to mitigate technological (digital) disruptions. The final category reflected individual clinician factors, such as their personality and their own tendency to be risk averse, and was present in EM generally, irrespective of whether it was place based or virtual. Factors related to the nature of EM and patients presenting to EDs would not have changed this risk even if managing clinicians were able to be "teleported" to the scene in person, and these aspects have not been discussed further in this paper.

Risk Aversion Associated With the Hospital of Presentation and the Rural and Remote Geography

Of 17 risks, 8 emerged from the ETS risk-aversion discussion related to the hospital of presentation and the rural and remote geography. These were less readily modifiable than the videoconference-related risks. The least modifiable risk was related to the inability to access the required tests or imaging, and this was reported by multiple clinicians. If point-of-care testing and the pathological approach available locally were not adequate to reach a clear diagnosis, the patient would be

XSL•FO
RenderX

transferred for further investigation. The extent to which this was considered an issue varied, with 1 participant (ETS doctor #3) having a view that point-of-care tests, routine pathology, and x-ray imaging available locally were generally satisfactory and sufficient for many of the presentations, and this view differed from that of many other participants.

Another factor associated with the presenting health facility was related to the regional workforce capacity and capability to perform the required physical assessment or procedure, or to keep patients locally for observation onsite or in the community. This mainly applied to sites where there were no medical practitioners. These factors had limited modifiability at the time of the consultation but were potentially adaptable. When the ETS clinician was unable to work with the clinician onsite to overcome the limitations of physical assessment over videoconferencing, the workforce capacity at the presenting hospital impacted the ability to secure a clear diagnosis and manage the patient adequately. Workforce capability was also related to the inability to perform required procedures ranging from establishing vascular access, inserting an intraosseous needle, and simple suturing to performing more complicated procedures, which could have avoided transfer. Generally, this is related to nursing-only facilities staffed by clinicians with limited scope of practice. Even when a diagnosis was made and the required procedures are performed, a patient might still be transferred if there was no doctor or insufficient nursing capacity to keep the patient on site for further observation, including if there was no GP in town the next day to follow-up in the community.

The final factor adding to the risk aversion of ETS clinicians was related to resources available at the hospital of presentation. The key issue raised here was the absence of a short stay–type inpatient unit to keep patients in the hospital for overnight observation. The distance and time required to transfer patients to a location with higher levels of capacity and capability were considered against the risk of deterioration of the patient's condition and the assessment of clinical risk. These factors were not modifiable and subject to the treating clinician's judgment of the patient's health condition.

Videoconference-Related Risk Aversion

Of the 4 categories of ETS clinical risk, 2 included factors that were related to the inability to secure a clear diagnosis and were related to videoconferencing. Many participants discussed the need to transfer patients because they were not confident with the clinical assessment via video. These included their perception of missing significant clinical signs, due to being unable to directly palpate or examine the patient, which impeded reaching a clear diagnosis. For example, 1 FACEM participant commented as follows:

> *…spending a lot more time thinking about exactly what I'm going to do and why… you don't have any of the nice reassurance normal investigations you would normally have. You are putting yourself more at risk by doing telemedicine because the chances of missing something are greater because you don't have access to all the little things that would make you much more comfortable.* [ETS Doctor #14]

ETS physician participants also reported issues with internet connectivity and speed, and many made comments on issues associated with the reliability of the camera affecting their ability to formulate a clear diagnosis. As discussed above, issues related to the camera were associated with the way it was physically positioned in the allocated treatment bay; operational limitations with pan, tilt, or zoom; and the camera technology itself. The internet speed and connectivity were more challenging as they were impacted by the internet provision where both the patients and ETS clinicians were physically based (nationally and internationally).

Finally, user acceptance of videoconference consultation differed among participants. Not seeing patients face-to-face made some clinicians more cautious and risk averse, with treating clinicians also reporting that some patients or family members were risk averse to telehealth consultations due to a lack of experience or understanding of this alternative modality of clinical service delivery. Several ETS clinicians reported that they spent more time second-guessing their observations and decisions, suspecting that they are less reliable over videoconferencing compared to a face-to-face meeting.

Risk Management for Patient Safety Instead of Risk Aversion

Complementing the higher level of potential and perceived risk associated with videoconference consultations, participants shared a range of perspectives on the perception of clinical risk:

> *…am I risk averse? I am probably less. It's not my personality. My personality is not risk averse. And I think most emergency physicians are not risk averse. That's not the nature of our business. There's risk everywhere we are risk managers.* [ETS Doctor #2]

Despite observing the potential risks associated with videoconference consultations, participants believed that those who were overly risk averse would not participate in telehealth, and it was a matter of finding a balance between the perceived benefits of ETS and the expected risks associated. A pragmatic view was that ETS physicians were no more cautious on camera compared to being on the ED floor; however, due to incomplete data points to inform an evidence-based clinical decision, interhospital transfer may be suggested for the required investigations. In terms of confidence in their decisions, some participants reported that they felt comfortable with their clinical decision-making as FACEM training helped balance relatively scant information in undifferentiated patients, and this was no different from the decision they would make in a face-to-face meeting:

> *Well, that's my job. It's not so much about being confident. Well, you've got to be confident in your decision because otherwise you can't afford to be in the [emergency medicine] business. I mean, you know, if you if you're worried about the patient, then you do something to alleviate that worry… Occasionally, there are times when it is difficult… for example, if a patient has a communication problem in either they are deaf, or they can't speak properly, and so my interaction is sufficiently degraded but otherwise, for*

XSL•FO
RenderX

> *[most] times, I don't think it does make a particular difference to be honest. The difference between me not being there and being there is far more evident in the skills that are brought face-to-face. And those are nearly all procedurals.* [ETS Doctor #5]

Discussion

Overview

The experiences and perspectives of WACHS ETS clinicians contributed to an in-depth understanding of the factors influencing clinical decision-making during an emergency telehealth consultation in rural and remote settings. The study progressed the understanding of the mutual learning opportunities presented during the joint decision-making process, the perceived clinical risks of emergency telehealth practice in the rural and remote context, and the technological barriers imposed on clinical decisions and the modifiability of these perceived risks.

Principal Results: Meeting the Principles of the ETS Practice

This research described the mutually beneficial effects of ETS consultation recognized by the participants in their clinical practice. These were in line with the principles and interim standards stipulated by the Colleges of Emergency Medicine that telehealth should complement and be part of the regional model of emergency care delivery validated by all stakeholders [1-3]. This finding also aligns with previous research, which highlights how rural and remote ED clinicians rely on the support and expertise of their colleagues to navigate and succeed in the unique challenges of rural and remote settings [8-10,17,18]. It further explored how this dynamic operated when colleagues provided support through a virtual presence. This research provides additional insights into how collegiality during emergency telehealth consultations supports various aspects of practice. These include enhancing confidence in rural and remote clinical practices, advancing the practice of virtual EM, and incorporating the rural and remote context into collaborative clinical decision-making involving stakeholders on both sides of the technology.

Clinical Decision-Making

The participants described clinical decision-making mediated by a complement of ordinary technologies. Considerable regard was given to the context of the hospital of initial ED presentation, the community where the patient is from, and the regional Western Australia health service delivery landscape. ETS clinicians were reliant on the local knowledge of presenting hospital clinicians, the patients, and their family members to incorporate these local contexts into collaborative decision-making. The capacity building was mutually beneficial for regionally based clinicians and ETS clinicians. Their complementary skills and synergies in what they were able to contribute to patient care became apparent during ETS consultations. In this paper, we have referred to this phenomenon as “synergistically mutual learning.”

Many participants described their experience of improved efficiency in processing complex clinical information through better focus. This reflected the time-sensitive nature of the ED, especially when the hospital of definitive treatment was hours away, and the organized chaos in multitrauma situations. This finding represents a novel contribution from the perspective of emergency physicians conducting virtual ED consultations. The quality of clinical reasoning was reported to be superior in ETS practice where there was greater reliance on synthesizing medical history, reviewing clinical records, and carrying out focused processing of multiple sources of information. In situations where there was a heavy reliance on physical examinations and complex laboratory or imaging investigations, clinicians were cognizant of the peculiarities and distinctive requirements of the specific conditions and replicated, as much as possible, the components of an EM consultation. This was in line with the guiding principles stipulated by the Colleges of Emergency Medicine to deliver a service of similar quality and standards as ordinary care [1,2].

The perspectives of ETS clinicians highlight a critical aspect of improvement in the overall efficiency of emergency care delivery not previously reported in studies of the efficiency of emergency telemedicine within receiving hospitals [10-12,14-16].

Clinical Use of Technology

At the forefront of technological change is how humans personalize technologies. The way technologies are used is a significant part of the innovation in the EM practice in rural and remote settings. This study extended past findings of technological difficulties impeding care processes [10,14,16,19-21,24-26], patient privacy, confidentiality, and data security [24-26] by explaining how emergency telehealth practitioners introduced human factors to the innovative use of emergency telehealth through their understanding of people and tailoring the use of the same technology to the needs of patients on the other side of the camera as described in Table 3. To the best of our knowledge, this is the first description of how human users innovate to close the distance across technological barriers in an emergency telehealth scenario.

Modifiability of Patient Safety and Clinical Risks Identified

Risk factors related to ETS technology were modified through upgraded camera resolution, fixed camera positioning, increased user experience, improvisation, and consumer preparation. The quality of physical examinations was generally considered unlikely to match the quality of face-to-face examinations, especially when examinations of hard-to-visualize areas of the body or procedural interventions were indicated. However, emergency telemedicine using videoconference facilities has been considered to have reached a plateau and might be sufficient to cover a great majority of presentations. Additional investment in other examination equipment will need to be carefully evaluated as the benefits of further equipment upgrades are likely to be incremental against the costs of purchasing the equipment.

To meet the standard of replicating components of an EM consultation stipulated in the interim guidance [1,2], the need for an appropriately skilled and competent local workforce

XSL•FO
RenderX

cannot be overlooked. Workforce capabilities were potentially modifiable through education, including pre- and postvocational training opportunities; however, modifiability was offset by the ongoing issue of the turnover of clinical staff in rural and remote hospitals. This said, participants provided examples of how inter- and intraregional movement of clinical staff helped to retain the necessary skill sets within Western Australia. The extent to which clinical skills acquired through ETS involvement in ED consultations benefited the overall capability of the regional clinical workforce in WA fell outside the scope of this paper; however, this is an area of significant importance and relevance to the effectiveness of the ETS.

The pivotal but nonmodifiable consideration in clinical decision-making was the physical distance from definitive treatment locations and presenting hospitals. Local hospital resources, capacity and capability were beyond the scope of this study, but it was acknowledged that these had limited modifiability, at least in the short term.

This paper did not explore the impact of the ETS on the quality and standard of care in larger regional EDs, and the dominant view that EM specialists are risk managers is of significance. Any manifested risk aversion is likely related to patient safety considerations given that rural and remote contextual factors are nonmodifiable or have limited modifiability. Despite the dominant view that the ETS added value to presenting hospital clinical decisions, there were also concerns that pre-existing processes and capacity had been disrupted by the care processes now available through the ETS. The change in the scope of practice in presenting hospitals, particularly regarding nursing staff, because of ETS involvement is a subject for further detailed exploration to reach an optimal balance.

Novel Contributions of This Study

Prior work has paid considerable attention to advocating for telehealth policy reform [30] and identifying the barriers and enablers of telehealth implementation in rural and remote EDs. This is the first study to systematically detail the complex interrelationships between technological and human interfaces. The barriers to quality and safety of emergency telehealth consultations and mitigation strategies used by the WACHS ETS clinicians when collaborating with rural and remote EDs were detailed. These perceived clinical risks and risk mitigation strategies added new insights into the contextual factors influencing the effective implementation of rural and remote ETS.

Findings around technological challenges were consistent with the findings of previous studies that pointed to variations in usability, depending on the setting and situation. Unlike previous studies that compared the approach of different types or combinations of telehealth technologies (eg, videoconferencing, store and forward, and telemonitoring) [21], this study embraced the use of available technology as a norm in rural and remote ETS practices in Western Australia. The focus on the strategies used in WACHS ETS delivery to overcome technological barriers in this study makes a novel contribution to advancing our knowledge on the modifiability of the risks associated with rural and remote virtual care and helps to inform future quantitative analysis and interpretation of findings on the effectiveness of rural and remote ETS.

Limitations and Future Research

The findings reported in this paper are subject to several limitations. Clinical nurse coordinators are the first contact points for accessing the ETS, and this triaging (referred to as ETS prioritization to distinguish from the Australasian Triage Scoring system) plays a pivotal role in case review order and selection. The ETS prioritization process ensured that the presenting hospital and community context were incorporated into timely and appropriate care from the first point of ETS contact. This paper focused on regional context considerations influencing clinical decisions around the disposition of ED patients during a virtual consultation and did not examine regional context factors already incorporated during the process of ETS prioritization. Future reports on ETS prioritization would be an essential addition to the body of knowledge on emergency telehealth implementation in the rural and remote context.

Telehealth, especially emergency telehealth, is a relatively new area in clinical practice with evolving clinical governance standards. Medical indemnity issues were discussed during the interviews but did not emerge as a dominant theme in the data analysis. WACHS ETS physicians are particularly focused on patient safety. However, based on available data, it is difficult to conclude the extent to which medicolegal considerations are at play in the response to the risks associated with the ETS practice.

The financial viability or cost-effectiveness of virtual care is best explored quantitatively. It is worth noting that participants were value conscious in evaluating disposition options. However, they were not able to comment on the financial viability of the service as it was not within the role of most of these clinician participants. The implementation factors identified inevitably influence the effectiveness of telehealth in rural and remote EDs but are insufficient to determine the effectiveness of the ETS. This study represents a step toward determining the effectiveness of ETS delivery and is an area for future research.

The recruitment of participants may have been subject to social desirability bias, and some nonresponders may have had an alternative opinion about the service, which they felt did not align with the health service's official position. The presenting health condition is one of the central tenets in this research, although the data collection did not focus on specific health conditions. Our intention in this paper was to capture the overarching themes of clinical decision-making and how they affect the safe and effective delivery of rural and remote ETS to improve patient health outcomes. There were no comparisons between the treatments of urgent and nonurgent presentations because formative analysis showed the tendency of using the ETS for more urgent cases. This focus was due to the higher proportion of FACEMs among the study participants, who were more likely to encounter urgent cases.

Conclusion

Telehealth has the potential to improve the processes of clinical decision-making in rural and remote EDs. The participants, all

XSL•FO
RenderX

of whom participated in delivering the ETS, perceived improved accuracy, confidence, and speed of clinical decisions. The reach and effectiveness of the ETS in addressing the identified health needs remain to be tested.

Patient safety was central to all clinical decisions, which were grounded in the capability of presenting hospitals and the local community context. The risks of delay in definitive care for those patients requiring transfer for ongoing management associated with the geographical distance to the hospital for definitive treatment and the presenting hospital capability were not amenable to change. The importance of social and geographical contexts for appropriate telehealth delivery was highlighted in this study.

Technological barriers to the safe and effective delivery of the ETS were amenable to improvisation and improvements to infrastructure, but overall, participants were aware that they could not reach the same reliability as that in face-to-face consultation for all presenting conditions. Although the ETS was an acceptable and feasible option for ED consultation, the maintenance and sustainability of the ETS as part of routine practice and policy are dependent on presenting conditions.

Investment into rural and remote telehealth has the potential to support regionally based clinicians both directly in patient care and indirectly by promoting their (health workforce) longevity in regional areas through the ongoing development of the virtual care network. The effect of the ETS on the scope of the regional ED practice and the building of clinical skills within the region warrants further in-depth exploration including its potential implications for the overall effectiveness and cost-effectiveness of telehealth services in rural and remote EDs.

Acknowledgments

This research was initiated by the WA Country Health Services (WACHS) and Curtin University, and received financial support from both institutions as well as the Digital Health Collaborative Research Centre (DHCRC) in the form of PhD scholarships. The WACHS also contributed in-kind support in the form of clinician time, industry supervision, and administrative and research infrastructure support. This research received further in-kind contributions from the School of Population Health at Curtin University, WA Centre for Rural Health at the University of Western Australia, WACHS Command Centre, and WACHS Country Health Innovation Project Support Office in the form of academic supervision, industry mentorship, and knowledge exchange.

Abstract

Background: Commercial wearable and mobile wellness apps and devices have become increasingly affordable and ubiquitous. One of their aims is to assist the individual wearing them in adopting a healthier lifestyle through tracking and visualizing their data. Some of these devices and apps have a wheelchair mode that indicates that they are designed for different types of bodies (eg, wheelchair users with spinal cord injury [SCI]). However, research focuses mainly on designing and developing new condition-specific self-tracking technology, whereas the experiences of wheelchair users with SCI using self-tracking technology remain underexplored.

Objective: The objectives of this study were to (1) provide a comprehensive overview of the literature in the field of self-tracking technology and wheelchair users (as a basis for the study), (2) present the self-tracking needs of wheelchair users with SCI, and (3) present their experiences and use of commercial self-tracking technology.

Methods: We conducted semistructured interviews with wheelchair users with SCI to understand their experiences with self-tracking and self-tracking technologies, their self-tracking needs, and how they changed before and after the injury. The interviews were thematically analyzed using an inductive approach.

Results: Our findings comprised three themes: (1) being a wheelchair user with SCI, (2) reasons for self-tracking, and (3) experiences with self-tracking technologies and tools. The last theme comprised 3 subthemes: self-tracking technology use, trust in self-tracking technology, and calorie tracking.

Conclusions: In the Discussion section, we present how our findings relate to the literature and discuss the lack of trust in commercial self-tracking technologies regarding calorie tracking, as well as the role of wheelchair users with SCI in the design of commercial self-tracking technology.

Introduction

Background

Every year, up to 500,000 people experience spinal cord injury (SCI) and, as a result, become wheelchair users [1]. This population must adjust to their new body, learn to use a wheelchair, and sustain an active lifestyle. An active lifestyle is vital for their independent living and quality of life. If they are not active, their shoulders can be injured because they are overused in their daily life without being trained for specific activities (eg, getting in and out of the wheelchair). Another risk is that they can gain weight, which requires them to change to a wider wheelchair, thus rendering more places inaccessible.

As commercial self-tracking technology (eg, smartwatches) becomes increasingly common, wheelchair users can access and benefit from its advancements. Some of this technology (eg, Apple Watch and Runkeeper) has already implemented accessibility settings for wheelchair users. Up to now, research on self-tracking technology has focused on (1) chair-ables, artifacts placed on or in the wheelchair to promote a healthier lifestyle [2-4]; and (2) studies on wheelchair users' experiences with self-tracking technology that was provided or introduced to them [5-7]. However, the everyday lived experience of self-tracking and related technology (ie, self-tracking technology) of wheelchair users with SCI is underresearched. This can result in the exclusion and underrepresentation of this specific group in the research and development of commercial wearables. Excluding part of the population as "special users" is an ethical and social issue [8,9]. In addition, more commercial technologies are anticipated to become accessible to a broader audience once the European Accessibility Act (EAA) is applied. This act focuses on digital products and services, underlining the importance of mainstream technology being accessible to people with disabilities and older adults [10].

The objective of this study is to build on previous research on self-tracking and self-tracking technology among wheelchair users with SCI [5-7,11] to include lived experience of self-tracking and self-tracking technology. Through an interview study, we aimed to answer the following question: How do wheelchair users with SCI experience self-tracking and commercial self-tracking technology in their everyday lives?

This section first provides an overview of SCI and the impact of the injury on people's lives. This is followed by a short overview of existing research on wheelchair users and self-tracking technology for health and well-being. Finally, we position our research in the context of contemporary society and technological research focusing on the role of wheelchair users with SCI.

SCI Overview

Worldwide, approximately 90 million people live with SCI, many of whom are either underage or part of the working population [1,12]. Each year, between 250,000 and 500,000 people sustain an injury to their spinal cord [1]. The average lifetime costs of an SCI starting at the age of 25 years range from €0.45 million to €2.1 million (US $0.49 million-$2.3 million), which exceeds those related to dementia, multiple sclerosis, and cerebral palsy [1]. Poor quality of life for people with SCI, their families, and caregivers—in combination with the socioeconomic burdens caused by the injuries—make it imperative to find solutions for this condition.

A motor-complete SCI leads to complete muscle mass loss in the legs and, thus, life as a wheelchair user. For a walking person, the muscles in the legs are the main consumers of energy both in an active state (eg, when the person exercises or moves) and in a rest state (eg, sleeping or sitting) [13,14]. In addition, an injury above thoracic level 6 provokes an altered (physiological) autonomic response during both rest and activity [15]. This results in an altered metabolic response, leading to reduced energy burn in both states [13-15]. Body weight balance is partly explained as caloric balance based on calorie intake and output [16-18]. After an SCI, the total energy burn (ie, calorie burn) is much lower than before. Generally, after the initial acute phase, people with SCI lose weight due to the loss of muscle mass and the healing process. During rehabilitation, most people get used to their light body weight and narrow wheelchair, facilitating an active and independent daily life. Throughout the rehabilitation phase, body weight tends to increase (approximately ≥2 kg during the first year) [19]. This relates to the lack of compensatory caloric intake due to the lower metabolic demands (total daily energy burn), which leads to energy imbalance with higher calorie intake than energy burn [19]. Increased body weight can have many consequences, such as higher stress on shoulder muscles due to extra weight being carried each time the person transfers to and from their wheelchair [20]. Moreover, it becomes more difficult to manage daily activities such as self-care. The resulting shoulder pain and reduced independence are often devastating [20]. Thus, calories are extremely important for people with SCI. Maintaining an appropriate calorie balance becomes much more achievable when energy burn and calorie intake can be monitored.

Wheelchair Users With SCI and Self-Tracking Technology for Health and Well-Being

Overview

Self-tracking is a voluntary, reflexive practice in which people collect data about themselves to enhance self-awareness and understanding by observing, noting, and interpreting various aspects of their lives [21]. Self-tracking technology is any technology that supports people in self-tracking practice. This technology can include apps—where the user registers information about their health and well-being—smartwatches or other wearable technology (wearables), or sensors embedded in assistive technology such as a wheelchair (chair-ables). Self-tracking technology is not assistive technology as it does not aim to improve the functional ability of people with disabilities or enable and enhance their participation and inclusion in different domains of life [22]. However, self-tracking technologies can offer inclusivity through adjusting functionality to include people with disabilities.

In this study, we focused on the experiences of people with SCI with mainstream technology as we aimed to contribute to an inclusive design. However, we recognize the importance of

XSL•FO
RenderX

understanding and learning from assistive technology for our target demographic. This understanding could direct inclusive design research and practice as it provides insights into adjusting or expanding the mainstream technology to be more inclusive.

Assistive Technology

Chair-ables have been researched in terms of tracking specific behaviors and self-care–related injuries. Let us take the case of pressure releases, which are vital for wheelchair users in avoiding pressure ulcers potentially contributing to premature death [23]. A chair-able can support wheelchair users with pressure release exercises. Sensors can be placed on the wheelchair to measure in-seat movement, classify the activity from the sensors into weight shifts, and inform the user with their data as well as sending push notifications upon achieving goals related to pressure releases [2]. In 2021, Ahad et al [4] developed and evaluated the reliability of an algorithm and a chair-able that could support people on wheelchairs in doing their pressure release exercises. The year after, design considerations for supporting electric wheelchair users with SCI on their pressure releases were published [24]. The authors [24] implemented context-aware and unobtrusive reminders delivered by the wheelchair for incomplete or incorrect pressure release exercises. The interaction with the wheelchair in this context [24] was preferable to an interaction with an app. Similarly, but in the context of self-tracking apps, Amann et al [25,26] used participatory design to design, develop, and evaluate an evidence-based app that uses a smart camera to prevent pressure injuries.

As for self-care, Büyüktür et al [3] presented requirements for semiautomated tracking to support people with SCI in their self-care by interviewing patients and health care professionals. Their main findings were that the patients' routines change from the clinic to the home environment and each patient decides to focus on what they value the most (eg, sleeping instead of waking up to change position during their sleep). Each patient and their informal caregivers try different routines in the home environment until they find one through which they can track the behavior and with which they can comply. Thus, Büyüktür et al [3] recommended a highly tailored and flexible system that can follow the patient's routines as they change and give them feedback. In general, a systematic literature review [11] showed that there is research on self-management of SCI in the home environment and clinic as well as the promotion of physical activity and a healthy lifestyle (eg, wellness and fitness). For example, one of the articles reviewed [27] presented that an intervention that tracked the activity of wheelchair users with SCI and motivated them through just-in-time messaging had the potential to improve physical activity for wheelchair users with SCI. Similarly, an interview study [28] explored the barriers that people with SCI face to staying physically active: (1) lack of tailored physical activity forums with wheelchair users with SCI and (2) lack of personalized fitness-tracking technology tailored to wheelchair-based activities.

Mo et al [29] explored the information needs of wheelchair users, and they identified a lack of tailored, accurate, and affordable tracking for wheelchair users both commercially and academically. Even though they argued for inclusive technology, the start of filling this gap could be in the assistive technology literature. Li et al [30] introduced WheelPoser, a system that tracks and identifies wheelchair users' on-the-move activity. They argued that they could do that by using 4 small sensors. Their dataset, code, and models are available for everyone to use, which allows mainstream technology to become more inclusive by using the same system as an add-on to their trackers or only the dataset to train their own systems. Huang et al [31], recognizing the lack of data on wheelchair users for training artificial intelligence algorithms on pose estimation, developed and evaluated a dataset to fill that gap. Their dataset is publicly available as well. Another article published in a disability forum explored the relationship between the successful completion of activity guidelines for people with SCI and the fitness or health status of the person with SCI [32]. This paper referred to activity guidelines [33,34] for people with SCI and an understanding of how mainstream technology can tailor its features (eg, daily goals) to a specific SCI group.

Inclusive Technology

Research underlines the need for inclusive and accurate commercial technology for wheelchair users through studies [35] and literature reviews [36,37]. The participants in the study by Li et al [35] showed interest in tracking their activity, but they did not trust the accuracy of contemporary commercial technology, understanding that those using powered wheelchairs could track some data on their activity that were relevant to them, such as distance. A literature review explored how academic publications in the personal informatics field address the information needs of wheelchair users [36]; it consolidated recommendations to tackle the design challenges that researchers and practitioners may face when attempting to design for including wheelchair users' activity tracking and information needs. In 2019, Moon et al [37] conducted a literature review of studies on the inclusivity of contemporary digital technology. They advocated for inclusive and universal design to become an integral part of commercial digital technology's development process and consolidated methods that can support the process.

Another systematic literature review [11] published in 2023 examined the use of mobile health in supporting people with SCI to maintain or improve their health. It showed that research lacked results regarding the role of commercial self-tracking technology for health and wellness to support people with SCI. The authors [11] attributed this gap in research to the fact that commercial self-tracking devices are inaccurate in their calculations for wheelchair users. However, in 2021, a study [38] evaluated the accuracy of the Apple Watch Series 1, showing that the watch was accurate for high-frequency strokes on a wheelchair (eg, a treadmill) but not for low-frequency strokes (eg, walking). Even though the research was published recently, the results of this research may not correspond to the current version of the Apple Watch (Series 7).

Related to commercial trackers and their use by of wheelchair users with SCI or their preferences, there is research limited to commercial technology given to them for a specific amount of time. For example, Ungurean and Vatavu [7] published a study in 2022 exploring the needs of wheelchair users related to activity trackers regarding different self-tracking technologies

XSL•FO
RenderX

(eg, rings, watches, armbands, and chair-ables). The researchers [7] interviewed participants after letting them watch videos of 2 different self-tracking technologies (eg, ring and armband) to understand their perceptions, preferences, and willingness to use wearables. Some of their participants were already wearable technology users, and the researchers mentioned that this could have supported them in answering the interview questions [7]. However, the study's results focused on the videos that the participants watched.

Malu and Findlater [5] based their research on the work by Carrington et al [6]. Carrington et al [6] tracked variables of wheelchair basketball players and presented the variables to the athletes to understand their needs and potential data use. In addition, Malu and Findlater [5] included wheelchair users who were not necessarily athletes. Their participants were interviewed, participated in design workshops, and tried 2 commercial technologies. Specifically, they used 3 fitness trackers for 30 minutes before they compared them and participated in a design session for designing a fitness tracker. Finally, both studies agreed that the values that people in wheelchairs may want to see are energy burned (calories), distance, GPS data, and pulse. The participants in the study by Malu and Findlater [5] added that calorie intake is equally important to energy burned. Finally, Malu and Findlater [5], unlike Carrington et al [6], showed that commercial self-tracking devices using GPS and comparing mobility in steps between different dates were acceptable and of value to their participants.

In 2019, Helle and Rosenbeck Gøegb [39] conducted a focus group interview study with 7 wheelchair users who were members of a basketball team. The study aimed to explore wheelchair users' experiences with current self-tracking devices and future requirements. Their key results showed that their participants only found the distance and time parameters useful and perceived calorie consumption, pulse, steps, and training intensity as inaccurate [39]. Their study participants commented that "some activity trackers provide reminders that assume that the user can walk" [39]. The authors concluded that accurate activity trackers designed for wheelchair users are needed. It is not obvious from this publication whether the participants were daily users of the technology or whether the technology was given to them for study purposes, and we do not know whether they were professional athletes.

To summarize, research on self-tracking and self-tracking technology and its use by wheelchair users with SCI is primarily focused on either building technology for them or gathering requirements and their opinions on contemporary commercial self-tracking technology, with which they may have limited experience [5-7,11,25,39]. Our research enriches this body of knowledge [5-7,11,25,39] with lived experience of people who track or tracked their activity or use or used commercial self-tracking technology. This study also increases the body of knowledge of everyday lived experiences with self-tracking devices and self-tracking for an often underrepresented community in technological research—wheelchair users with SCI [40].

More Reasons for Inclusion in the Design of Commercial Technology

People with disabilities are often considered users of "special" products designed explicitly for them instead of active participants in the mainstream market [41]. "Special" targeted products would have a smaller share in the market, and they may be more expensive and, therefore, inaccessible for many people with disabilities as people with disabilities—at least in the European Union (EU) [42]—tend to be at a higher risk of financial challenges. According to Eskyte [41], dividing the market into "average" and "vulnerable" users is an obstacle to incorporating accessibility requirements into general consumer product development. In 2025, all digital services and products in the EU market need to be accessible according to the EAA [10], which will urge practitioners to design digital products and services with a diverse audience in mind.

Publications in technological fields support that building things for people with disabilities often means building better things for everyone [9], and a systematic literature review [11] shows that research on technology for people with SCI tends toward user-centered design. Even though user-centered design focuses on the user by collecting information about them, building empathy—often by simulating their health conditions [43]—and potentially involving them in key stages of the design and development process, it does not seem to be enough. Bennett and Rosner [44] argued for a more participatory way of designing; instead of designing for the person who is different from the designers (eg, wheelchair users), we should design *with* them as part of the design team. Their research indicates that, by trying to simulate their life experiences, we do not treat them as equals but as something different from us, different from the norm [44]. While the solution to the limitations of current empathy-building methods seems to be the participation of the specific user group in the design process, participation does not guarantee technology acceptance [26] and may be hard to achieve [40]. For example, in the case of SCI, Kabir et al [40] support that, due to the impact of the condition on the user, for example, speaking or fatigue issues may have been excluded from the research because the collection methods of the designers and researchers are inaccessible. Kabir et al [40] describe that the methods need to be adjusted based on each participant's abilities, something that some publication forums and reviewers may consider a methodological weakness of a study.

This paper does not argue about replacing the involvement of people with SCI in research or user research. However, it gives an idea of how current people with SCI experience commercial self-tracking technology and describes some of their needs. Even though researchers and practitioners will need to involve people with SCI when designing accessible products, this study can act as a starting point to understand some people's experiences with SCI, their self-tracking habits, and their use of self-tracking technology.

Methods

We will first present the research context and then how the data collection and analysis were conducted.

XSL•FO
RenderX

Context of the Study

This research was conducted as part of a long-lasting cooperation among researchers in the human-computer interaction field; a researcher in physiotherapy focusing on wheelchair users with SCI; and a center for SCI in Gothenburg, Sweden. This cooperation aims to explore the use of affordable commercial wearables and build an application that uses the wearables' data to accurately calculate the collected variables specifically for wheelchair users with SCI. The project is based on research exploring the energy outtake for wheelchair users with SCI on specific exercises [21-24]. Within the scope of this project, we conducted interviews to understand *how wheelchair users with SCI experience self-tracking and the use of commercial self-tracking technology in their everyday lives*.

Ethical Considerations

At the start of the cooperation, the planned research was reviewed and evaluated for its ethical integrity following the process of the Department of Applied IT at the University of Gothenburg, Sweden. This qualitative study interviewed people with SCI on their tracking habits and use of commercial self-tracking technology. This type of research does not fall under any of the categories described by the Riksdag (the supreme decision-making body of the Kingdom of Sweden) as research requiring ethical clearance as no sensitive personal data or other personal data were collected or published [45]. The study did not have access to or collect interviewees' personal information prior to, during, or after interviews. The participants were informed about the study through an informed consent form and could ask questions before taking part. The information sheet also included details on how they could withdraw. The data of the participants were handled according to the Swedish implementation of the European General Data Protection Regulation. Participants received no compensation.

Recruitment, Data Collection, and Data Analysis

We conducted 9 semistructured interviews [46,47] with wheelchair users with SCI. Knowing from the literature [40] that we may face challenges in recruiting participants for interviews, we used nonprobability convenience sampling using the network of the SCI center in Gothenburg, Sweden, and personal connections. Eligible for participation were people aged >18 years who had SCI for more than a year and who used a wheelchair to move. If participants did not fulfill all the aforementioned criteria, they were excluded. The aim was to have a deep understanding of the experiences of the people who contacted us rather than having a certain quantity of data.

Due to the geographical distribution of the participants and to accommodate the interviews at any time the participants wanted (even if it was on short notice), we conducted the interviews and recorded them over Zoom video call (Zoom Video Communications). In that way, the participants could also show us how they tracked themselves if needed. The interview guide had three groups of questions: (1) introductory and background questions, aiming to get to know the interviewees and their habits concerning daily life and exercise activity, including mobility; (2) questions about experiences of self-tracking and self-tracking technologies before and after their injury, aiming to understand the relationship of the interviewee with self-tracking and self-tracking technologies before and after their injury; and (3) closure of the interview questions, aiming to allow the interviewees to add anything they wanted us to know and understand their interest in the results of the study. We did not collect any actual measurements of their physical activity, nor did we try to evaluate their physical activity based on any tool as the focus of this study was to understand their experiences with self-tracking and self-tracking technologies.

The average duration of the interviews was 45 (SD 12.9) minutes, with the shortest being 30 minutes long and the longest being 69 minutes long (390 min; 6.5 h of video recordings in total). All participants were Swedish; 89% (8/9) of the interviews were conducted in English, and 11% (1/9) were conducted in Swedish. The participants interviewed in English could communicate clearly and fluently in English. The interviews were transcribed, and the first author analyzed them through inductive thematic analysis [48] following the steps by Braun and Clarke [49]. The first author familiarized themselves with the data and found codes and initial themes (steps 1-3). All authors reviewed, defined, and named the themes (steps 4-5). In our qualitative and explorative study, we focused on providing a rich description of our participants' experiences with self-tracking and self-tracking technology rather than the frequency with which they talked about each theme. The quotes used were modified to remove repetitions and for grammatical correctness. The quotes taken from the Swedish-language interview were translated into English.

Methodological Limitations

To invite the participants, we used the connections mentioned previously. In the invitation, we informed participants that it would be an online interview; thus, participants who had difficulty speaking due to their injury or other reasons may have been excluded [40]. We expected a small sample who would have the time and energy to participate. To counteract this, we invited people with SCI to participate regardless of whether they were current or past users of self-tracking technology as long as they had tracked something related to their injury or physical activity at some point. We focused on analyzing and obtaining a deeper understanding of the experiences of the 9 people rather than on collecting more data.

Results

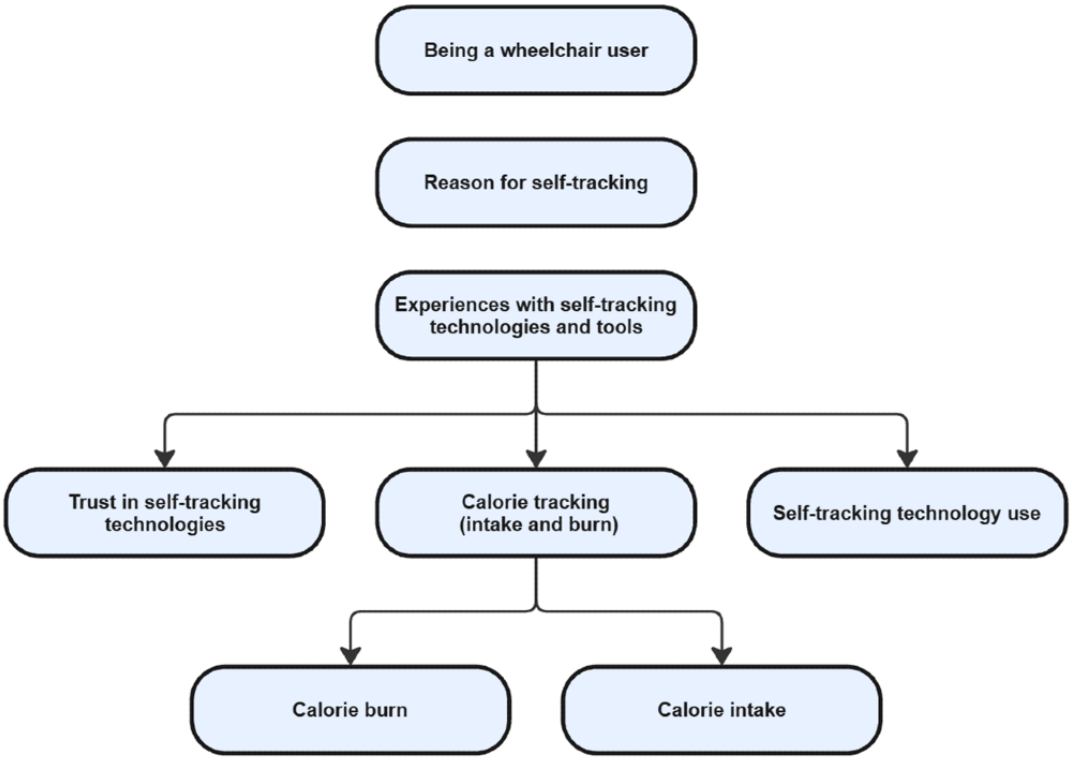
Overview

A total of 22% (2/9) of the participants were female, reflecting the gender ratio of SCI at 20% female [50]. In total, 22% (2/9) of the participants had never used self-tracking technology, but they had all tracked some variables. Apart from participant P5, no one was currently an athlete. All the participants (9/9, 100%) were well past their first year of living with SCI, characterized as phase 3 or the chronic phase [40]. No participant had any serious issues with breathing or speaking during the interview regardless of their level of injury. More details about each participant's sex, age, years with SCI, and use of self-tracking technology, as well as the code used to refer to them in the following sections, can be found in Table 1.

XSL•FO
RenderX

Table 1. Demographics of the participants, including their use of self-tracking technology.

Participant code	Sex	Age group (y)	Years with SCI[a]	Use of self-tracking technology
P1	Male	50s	35	Yes
P2	Female	40s	31	Yes
P3	Male	30s	5	Yes
P4	Male	≥65	29	No
P5	Male	30s	12	Yes
P6	Male	40s	13	Yes
P7	Female	≥65	40	No
P8	Male	60s	6	Yes
P9	Male	50s	—[b]	Yes



[a]SCI: spinal cord injury.

[b]Not applicable.

In total, 78% (7/9) of the participants had extensively experienced self-tracking technology; however, this high level of engagement with technology should be considered within the context of the study. People living in Sweden use IT daily for mundane things (eg, mobile payment is common; 92% of the population) [51]. In addition, Sweden is among the 7 countries in the EU with the lowest gap in employment between people with and without disabilities, which may have allowed our participants to have enough income [52] to purchase self-tracking technologies.

The thematic analysis resulted in 3 themes, one of which had 3 subthemes. The first theme, *being a wheelchair user with SCI*, included codes relevant to the participants' descriptions of their activity levels, themselves, and their lives. The second theme, *reasons for self-tracking*, included codes related to the participants' self-tracking habits. The third theme, *experiences with self-tracking technologies and tools*, included subthemes related to self-tracking technology use, calorie tracking (intake and burn), and trust in self-tracking technologies. Figure 1 provides a more illustrative understanding of how the themes are structured. The figure is designed to be read from top to bottom and left to right. A tabular form of the figure can be found in Multimedia Appendix 1.

Figure 1. The final themes that resulted from the thematic analysis in a diagrammatic representation. Multimedia Appendix 1 shows the representation of the themes in a tabular form with a summary of the main findings.

Being a Wheelchair User With SCI

This presentation of the participants aims to increase our empathy and understanding of how they experience their lives as wheelchair users and as former walking persons. Wheelchair users with SCI experience life first as walking people and then as wheelchair users. This means that they must adjust to their new body and develop new skills and often see themselves and their life divided into 2 periods—before and after the injury. For example, P8, who had a physical job and changed to a desk job after becoming a wheelchair user, mentioned that "before the injury, I did not track [my activity]. You could see I was physically in a good place. I was very masculine. After the injury, it is another story...you need to train, of course, a lot of rehabilitation." The various SCIs can influence people's bodies and lives differently, widening the diversity of their bodies.

Our participants dealt with the change in their skills in five ways: (1) adjusting their previous knowledge to the new situation, (2) giving up old habits, (3) being challenged to keep old habits, (4) reflecting on the behavior of their body, and (5) acquiring new skills. For example, regarding item 1, P3 adjusted his previous knowledge to the new situation in the following way:

> *I knew what because of my experience before the injury. I knew how to train, [but] I had to adapt to the situation I got into. I could not do everything in the same way, but I got some tips from the rehabilitation clinic, and I tested them myself.*

Others had advanced skills as non–wheelchair users that they lost when they became wheelchair users. For example, regarding item 2, P9 preferred to give up old habits "since I know that I have been playing badminton at a certain [high] level, it is frustrating to find myself being bad at it in the wheelchair. So maybe I would rather play tennis or basketball," whereas others saw their new life as a challenge to keep doing what they used to do. For example, regarding item 3, P1, who used to ski before his injury, felt that sit skiing would not be a challenge. When he tried it and realized how difficult it was for him, he was challenged to keep skiing:

> *I tried [sit ski], then it was so super hard.... So somewhere, it triggered me that I need to practice to get better at it.*

Regarding item 4, P9 reflected that his body did not react the same while running. As now he was not using his legs but his arms to move the wheelchair, it was harder for him to raise his pulse and feel the effects of exercise before his arms got tired. All of them had to learn to use a wheelchair, and the learning experience differed from person to person (item 5). For example, P4, one of the main organizers of a wheelchair community, mentioned that, when he started using a wheelchair, there was not much support but, in his community, they support others with basic wheelchair skills:

> *[W]e [practice] with balancing the wheelchair [on the back wheels] without dropping it back. [It] is very useful and hard skill.... It is very dangerous [as] you can hit your head.*

Everyday activities take more time based on the level of the injury and how it has influenced the body. For example, P7 mentioned that "I have to take care of myself and then work...it takes a lot of time," so she did not have much time to dedicate to exercising. P6, who worked at a rehabilitation center where people stayed for several weeks, said the following:

> *[R]ehabilitation is a lot about...you come here for 4, 6, 8, 10 weeks and you lay a foundation, but to get to be autonomous/independent. You need to continue when you get home because that's where you really need to put in the effort. And I tried to be clear with patients that this is the beginning. When you come home, that's where the struggle or the real-life starts.*

P6 underlined that, when one is in the rehabilitation clinic, they are free from daily responsibilities that may increase when they return to their daily life and take time from the exercise levels they need to sustain. Finally, P4 and P8 pointed out that, in addition to SCI, one develops more chronic conditions due to aging (eg, P8 kept track of his diet due to type 2 diabetes, and P4 tracked his blood pressure and related medication because he had a myocardial infarction).

To summarize, wheelchair users with SCI need to learn to know and adjust to their new bodies—bodies that are diverse by nature combined with the type of injury. When they learn basic wheelchair skills, they must deal with everyday life, which of course takes time for everyone, but for them, it can take time from their exercise. Exercise is a vital part of the high level of activity they need to sustain to be independent and healthy.

Reasons for Self-Tracking

Habitually, inpatients in rehabilitation clinics are told to document their activities or have them tracked during any type of rehabilitation or training related to their injury. However, few of our participants described this as tracking. For example, P9 mentioned the following:

> *If one is in rehab, one should keep track so they can see that the exercise is working...*

P7 remembered tracking during her injury-related training:

> *[Y]ou get a mentor that you can check up to after a couple of weeks, then you must make a new measure and see how you are doing. That was very useful.*

P8 reflected on the lack of technology and feedback during rehabilitation:

> *I think I get the idea [of tracking] from having to fill out all those forms when I was in the rehab center. Every week I have to write on paper, my weight, how much I lost when I went to the toilet, how much I ate on a particular day...and then the doctor concluded...[what I should change]...with the technology we have today just putting that on paper was not doing anything to me...I was just waiting for the outcome from the doctor.*

Our participants had different motivations for tracking. A total of 44% (4/9) of them (P1, P2, P5, and P9) mentioned that they had started tracking as they were practicing a sport. They tracked because their coach had told them to, or their coach did the

XSL•FO
RenderX

tracking for them. However, all of them kept tracking their behavior even after stopping exercising. P2 tracked variables related to swimming (eg, swimming style, time, and meters) as she was training for the Paralympics; nowadays, she tracks the activities she does through her Apple Watch as "it's so simple...the watch does it for me" and also uses it as a motivation to move—"it kind of reminds me to move" and "it keeps track, and it tells me you did a good [job] today." P1 mentioned his reaction the first time he was asked to track variables related to skiing (eg, weather conditions, exercise type, and timing) and how he came to keep tracking his activities:

> *Well, it was the trainer who said, you need to keep track on what you do. Why I've already done it. That was my answer. But then I started to do it. And then I realized that let's say after one season, I looked in the diary [and thought] oh, I need a lot of those things and [those things] didn't pay off. Maybe I should do less of those things since they don't pay off so much and maybe I should increase the things that pay off.*

P9 continued reflecting on his motivation for tracking his activities using his Apple Watch:

> *[I]t is not so much that I want to be in a national team or anything, it is more important that I can stay healthy and be a part of family activities and continue to do that. That is the most important thing to me.*

P3 mentioned keeping track of his training, especially when making changes to his training activities:

> *When you gonna train intensively for a month or something, I think it's interesting to keep track of your training. If you have a goal or race as well, which I don't right now.*

He reflected the following:

> *Yeah, I think most parts of tracking is for motivation for me at least, and then also, it's just interesting to see some data.*

P2 and P3 mentioned that they used tracking to increase motivation, as did P6:

> *[I]t's mostly motivation to see that to give myself a pat on the shoulder.*

Some participants (P1, P5, P6, and P9) tracked their activity before their injury as they were practicing different sports or participating in competitions. On the other hand, P4, P7, and P8 were not interested in tracking or were motivated to track only after their injury. P4 tracked his activity only as part of a game his colleague created—a point system that considered activities one did (eg, walking) and measurements of weight, waist, and chest. The person with the most points won. The point system was adjusted for P4 as he was in a wheelchair. P4 mentioned this game:

> *It was like, a challenge, you know...we challenge ourselves and even checked together "now I'm up to 2000 points" or whatever.*

P7, who had a higher level of injury, mentioned that she was never interested in tracking but that she kept track of her weight and the time it took her to move between places in her house:

> *[I]f you go to the bathroom, I got to make it in 10 minutes, [to] compete with myself to do with it as quickly as possible.... The only thing I track is my weight. My heart rate is no use because I can't get [much variation]*

P8 mentioned that he started feeling the need to track after his injury; before, he could simply see that he was muscular.

Summarizing, our participants performed a lot of tracking during their rehabilitation period to support the health care professionals following them, but the tracking was done on paper. Those training before their injury had a habit of tracking different variables and found value in tracking, but not everyone felt the need to track. In any case, the injury changed the way in which our participants tracked, either from not needing to track to needing to track or by changing the reasons for tracking and the variables they tracked.

Experiences With Self-Tracking Technologies and Tools

In this section, we will present the experiences of our participants with self-tracking technologies and tools through three subthemes: (1) use of self-tracking technologies, (2) tracking calories, and (3) trust in self-tracking technologies.

Self-Tracking Technology Use

The participants had experience using the Apple Watch, Runkeeper, Polar Beat, Pulse Polar Watch, and Nike+. While these technologies automate tracking and keep score of data, the participants also used manual means of tracking data about themselves. They mentioned using Microsoft Excel, a stopwatch, Lifesum, and paper as examples of manual means of self-tracking. One participant (P5) also mentioned that they "track in my mind." However, the most recurrent technologies in the responses were Apple Watch and Runkeeper.

Before their injury, only P6 and P9 used technology (Nike+ Running App) to track their activity. P1 kept a logbook with ski-related variables (he continued after the injury until he bought his Apple Watch), and P5's coach tracked his activity and gave him a schedule or advice accordingly. After their injury, participants P3, P5, P6, and P9 started using the Runkeeper app, which includes a wheelchair user mode. P3 and P5 used it to measure their speed and the distance they ran, and P6 and P9 used it to train for marathons or similar events. However, P9 mentioned that he had given up on Runkeeper because it did not work well with his Apple Watch:

> *Nike, that's actually what I used when [training for the] world run because it's, it's pre-installed in my Apple watch. So, when I got the Apple Watch, the first thing I did was download RunKeeper on my Apple watch. But I noticed that it wasn't attached to it with all its [features]. But there was also already a running up called Nike.*

P1, P2, and P9 were using Apple Watch to track their activities. Apple Watch includes an option for wheelchair users. In the

XSL•FO
RenderX

default mode, the Apple Watch tracks many activities (eg, biking, swimming, and skiing). However, if one sets it to the wheelchair user mode, only 4 activities become available: wheeling in- or outdoors and walking or running speed. P2 preferred to track her activities separately and used the default mode:

> *So most of the time I use the activities that are in the watch. I'm aware that they [calories] are not adapted for me and my muscle mass. That is not the important thing to me. For me, the important thing is that kind of keeps track and tells me that—okay, you did a good job.*

For P2, it was more important to track her activities and obtain positive feedback than to have access to accurate measurements of some of her activities.

The Apple Watch also displays 3 concentric rings: the inner blue ring shows how many times in the day one has moved (ie, changed position), the middle green circle shows how many minutes of brisk activity one has had, and the outer red circle indicates the active calories burned throughout the day. When P2 referred to the positive feedback she received, she meant how full these rings were. P1 and P9—who used the wheelchair mode on their watches—also looked at those rings for a quick daily overview. P9 mentioned the following:

> *[I] look at it but I don't pay too much attention to it.... I can see that I have done my full day's work and that's kind of the analysis I do, not so much else.*

Some of our participants used other apps and devices. For example, P8 had tried the Samsung Health app, but the measurements provided were not relevant to him. P1, one of the Apple Watch users, used a digital food diary (Lifesum) compatible with his watch to track his diet. P5, who was using Runkeeper, also used Polar Beat when training to measure his heart rate; however, he also considered the limitations of the technology. Specifically, he said the following:

> *I don't know if it's correct, but they mean that if you're a tetraplegic [injury level], your heart rate can't go over 120 Mm. And you can push as hard as you can. And you can't get over 120 But on the Polar-Beat that I [wear around the arm], I have been up to 136, I don't trust the one you put around [the chest] like this.*

This section shows that our participants were familiar with self-tracking tools. Many used or tried digital self-tracking technology after their injury, and some had done it even before. They tracked variables that could influence their sports performance or support them in understanding their body (eg, pulse and diet). They also tracked in less quantifiable ways, for example, what activities they did (eg, skiing or swimming) or the completion of goals set on their Apple Watch, which provided motivation. However, all participants mentioned calories and their measurement and consumption. Some expressed the need for a "lifestyle app" supporting them in healthy living as a whole—both in activity and diet tracking.

Tracking the Calories

Overview

When our participants talked about their experiences with self-tracking technology, the discussion always turned to calorie tracking or similar variables (such as weight and diet). Keeping a healthy lifestyle and not gaining weight is an issue for wheelchair users, and the impact of gaining weight on their life quality is tremendous. P9 was the most descriptive on how gaining weight could influence his life quality:

> *I just want one thing; I don't want to have to change my wheelchair into a wider one. If I get fatter, for example, it would be harder to make all these movements that I have to do in and out of the car every day, in and out of my bed every day in and out of the shower every day, or maybe every other day. Also, if because I'm getting fatter, if I have to get a wider wheelchair, I wouldn't get into certain doors, for example, in hotel rooms because my wheels are wider apart...I don't want that to happen and I'm ready to try any mechanical device to help me from not having to do that.*

This quote illustrates the potentially more serious consequences of gaining weight for wheelchair users and the need to track the calorie burn and, if possible, intake. P5 mentioned that "in our world, calories are very important," and P1 commented on weight gain and aging:

> *[W]eight is a problem all the time, especially now when I am getting a bit older, and it is easier to gain weight than losing it.*

Even P7, who seemed uninterested in tracking her activities and did not use any self-tracking technology, mentioned that "tracking it's not so important for me" but "I track weight because it is important for us." When our participants discussed tracking their calories, they mostly talked about calorie burn (P1, P2, P3, P5, P6, P8, and P9). Only 44% (4/9) of the participants (P1, P3, P4, and P5) mentioned calorie intake or diet, and only 11% (1/9; P7) mentioned weight (which can be perceived as a balance between calorie intake and burn).

Calorie Burn

As wheelchair users with SCI have less muscle mass than a walking person, they consume calories differently. P1 mentioned the following:

> *It is really hard for a paraplegic [injury level] to burn calories. It takes so much more time to burn the same amount as you [a full-muscle ability person]. If you're out jogging for one hour, I must wheel maybe for three.*

Therefore, to burn enough calories, they need to spend more time exercising.

Few commercial self-tracking technologies have their features adjusted to wheelchair users. Runkeeper and Apple Watch were 2 technologies mentioned by our participants that consider wheelchair users in some of their features. Our participants did not trust the self-tracking technology they used regarding calories and, instead, used other variables as a proxy for calorie

XSL•FO
RenderX

burn. Consequently, they managed their calories by staying active or using self-tracking technology as a motivation to stay active. P6 used self-tracking technology (FitNotes and Runkeeper) to keep a high level of activity in addition to motivating himself:

> *[One session] wasn't good enough, next week, I'm doing two sessions. And I'm taking the time [for an extra session] by putting something else out of my schedule. Or if, last week, I trained five times. I tell myself I did something good. Continue!*

P5, who used the Runkeeper app, underlined that he checked the distance and speed provided by the app but not the calories despite mentioning that calories were very important to him. He also discarded the calories that his wearable showed (Polar Beat, which measures heartbeat and calories), saying that "I don't care about the calories because I know...the calories are all wrong." P3 also mentioned heartbeat as an indicator for understanding that his training had an impact:

> *[H]eartbeat is always good because if your heartbeat races, you're doing something.*

He also reflected on a noncommercial smartwatch he had tried as part of another study that measured steps, finding steps not to be a good indicator or proxy for understanding his activity levels:

> *I do not know if I am moving a lot, I have more steps on my watch, but I do not know how it works and I do not know what it reduces it and what it does not.*

Similarly, P8 reflected that the visualization of steps in commercial self-tracking technology as an activity proxy was irrelevant to him:

> *Samsung health (smartphone) counts my steps which is not connected with the reality...Like FitBit.*

Apple Watch is one of the self-tracking technologies that has adjusted some of its features for wheelchair users (eg, wheeling in- or outdoors and walking or running pace); however, only P1 trusted and followed their calorie burn. In contrast, P9 pointed out the following:

> *I have my Apple Watch on when I do [strength exercises]. I guess it's not smart...it tracks some of the movements I make as a push in my wheelchair. It was the same with that would that pole pooling...it doesn't track it as something else than kind of push with the wheelchair.*

Thus, the watch counted his calories based on the strokes he did to move his wheelchair, and he argued that, regardless of what exercise he did, the watch would always measure only wheeling in- or outdoors and walking or running pace but not the actual exercise. Therefore, the calories could not be estimated based on a different activity but only on the strokes he did, so he did not pay attention to them but used the watch mainly for motivation. P2, another Apple Watch user, said the following:

> *[A]ll other activities are in there, but they are not adapted for people with no full muscle ability. With that said, I had kind of decided that it doesn't really matter if I spent 300 calories or 500 calories.*

She added that she used the watch to motivate herself to move. Thus, she preferred to use the Apple Watch in the default mode rather than in the wheelchair mode, favoring the ability to track different activities over a more accurate calorie estimation.

Some participants also used nontechnological means to measure their calories manually. For example, P1, who was part of a medical research project on SCI, became aware of the connection between his energy consumption and his pulse and took action based on that:

> *[B]efore being part of the project about energy consumption for a disabled person, I had no way to determine how much energy I consume during the day but after that, I made charts because I have a really strong correlation between pulse and how much energy I consume.*

To summarize, a person with SCI consumes calories at a slower pace than a full-muscle, able-bodied person and needs to be more active to burn the same amount of calories. Most commercial technology currently in the market does not account for this difference, which leads to apps incorporating the wheelchair symbol without adjusting the calorie burn for this type of user or apps calculating the calorie burn correctly but only for limited activities. Thus, our participants estimated their calorie burn based on how many exercise sessions they did or their heart rate increase. Self-tracking technology was used mainly for motivation, and steps were not perceived as a good proxy for activity tracking or calorie burn.

Calorie Intake

Weight is impacted not only by calorie expenditure but also by calorie intake. For example, P4 said that "Exercises are good but if you don't stop eating too much, you will never lose weight." Just like P3 adjusted his exercise knowledge to the new situation, P5 needed to adjust what he knew about diet. Before the injury, P5 had a personal trainer who planned his weekly exercise and diet, for example, to gain muscle. However, P5 mentioned that he found that he could no longer follow what he had learned from his trainer after the injury:

> *When I ended up in a wheelchair, I was used to having the [diet and exercise] paper in the back of my head. But every other person in a wheelchair said you can't eat as much as you did before. So today I'm eating small portions but more often. I don't do breakfast, lunch, dinner.*

P5 had to adapt his weight management after becoming a wheelchair user by avoiding the traditional food distribution throughout the day.

Even though participants were interested in counting their calorie intake, only P1 used a dietary app, called Lifesum. He mentioned that the intake of calories was also important and that it would be interesting to have a daily calorie goal and take note of the type of diet one follows, if applicable. P1 said the following:

XSL•FO
RenderX

> *An app that could measure what I eat, and I can put in parameters like, [amount of] calories [that] are ok for the day, and any kind of diet I follow.*

Another participant, P7, felt that she had control over her diet owing to a course organized for people with SCI that she took after her injury:

> *[In this course] you start tracking everything, they check your weight and height, how you train and exercise, how you feel—everything. And then you get a plan and learn a lot [about] bad calories, and you know exactly how much you are going to eat and how to change...you get a mentor that you can check in with after a couple of weeks, then you [must] make a new measure or everything and see how you are doing. That was very useful.*

Here, instead of using a tracking tool, the user learned how to manage their calorie intake in an educational setting, when episodic measurements were made, and then made sense of them with the support of their mentor.

The participants expressed that calorie intake was as important as calorie burn. They described that they had to adjust their eating habits after the injury to fit their new bodies. Even though only P1 used self-tracking technology to track their diet, other participants mentioned that they had to undergo training or go through an adjustment period to learn how much they could eat by tracking their diet.

Trust in Self-Tracking Technology

P1, P2, P3, P5, P6, and P9 used self-tracking technology to track their activities but did not trust this technology, especially regarding the calories. P1 trusted his Apple Watch because "Apple bought a survey conducted in the US that was about paraplegics, working [out], and how much calories [they burn] with which workload. And they put that algorithm in the watch. For example, let's say a paraplegic person has a 30% slower or lower metabolism compared to able-bodied, that is in consideration in this app." He compared his watch to Runkeeper:

> *I'm out wheeling with 100 pulses; I get depressed because it's like 210 calories. But if you go to RunKeeper, and you have been jogging for one hour, you have 700 calories. So, if you use that app, you will be so fooled and tricked by it. Because it is hard for a paraplegic to burn calories.*

P1 made a comment on commercial apps using the wheelchair symbol deceptively:

> *[Y]ou have apps on the market RunKeeper, or whatever, you download it because it has a wheelchair symbol [thinking] Oh, yeah, this is a cool company, they even bother to [consider] wheelchair [users]. Yeah, but people don't understand. That's a chart with calories from an able-bodied person. They just replace the running person symbol with the wheelchair symbol.*

P2 was dissatisfied that, as a wheelchair user, she could only track 4 activities on the Apple Watch. Therefore, she preferred to use the watch without the wheelchair user setting to keep track of the different activities rather than accurately tracking the calories—as the quote in the previous theme shows. Despite this, P2 stated that they were an "Apple family" and that she trusted Apple because "it's people I know that are interested in technology that buy all the gear and try all the gear out that's Apple Watch is good I'm buying kind of trusted them Yeah. And my husband recommended and said that it would be worth it [now] that I had already started to add more exercise into my life, and I thought that could be a good fun thing to try." In this case, what made the technology more trustworthy was not the actual technological features but the social context. On the other hand, P9 did not trust his Apple Watch to accurately calculate the calories because it tracked everything as strokes on a wheelchair regardless of the type of activity—as his quote in the previous theme showed. However, he mentioned that he trusted his Apple Watch more than an app on his phone as he could not see how an app could track accurately:

> *[T]here was a wheelchair feature that I can put [in the RunKeeper], instead of running or cycling, I put it on the chair. But for example, it didn't track my pushes, because it can't track my pushes, it seems it's only on the phone. So, I think it helps that it's on my Apple watch on my hand to be able to keep track of [the pushes]. So, if I only have the phone in my, pouch that I have on my sitting pillow, or I have it on my arm higher, it doesn't track my movement in the same way.*

P9 expressed his distrust of Runkeeper because it did not provide the user with an explanation of how the app measures the calories of a wheelchair user.

Similarly, P3 and P5 mentioned that they did not trust the technology they used (Runkeeper and Polar Beat) regarding the calories it presented them with. Specifically, P5 mentioned the following:

> *Now it's like, if I go for a walk, it shows how far and the pace and even it [RunKeeper] shows the calories. But I do not think the calories are exact, so I don't care so much about the calories.*

He explained that, apart from calories, "I trust just the RunKeeper because it's like a map, a GPS. You have walked three kilometers. You got the pace for each kilometer." This quote illustrates that, despite P5 distrusting some features of the app (calories), he trusted others that were more easily understandable. He added the following:

> *So for now, I'm pretty happy with the Polar-Beat it is just the calories are not...and it's not reliable.*

Although the user considered himself satisfied with the Polar Beat use, he chose not to rely on the calorie measurement.

Summarizing, trust in self-tracking technology (or the lack of it) is influenced by the perception of the participants regarding how the technology works and how the development company accounts for different bodies related to calorie burn.

XSL•FO
RenderX

Discussion

Principal Findings

This section recaps our contribution followed by a short discussion on trust and transparency related to self-tracking technology. Then follows a section with the implications of commercial self-tracking technology, which concludes with directions for future research.

To address the question of how wheelchair users with SCI experience self-tracking and commercial self-tracking technology in their everyday lives, we interviewed 9 wheelchair users with SCI who had experience with self-tracking or self-tracking technology. The last theme, *experiences with self-tracking technology and tools* in Figure 1 divided into 3 subthemes, shows that current self-tracking technology fails to accommodate wheelchair users' needs concerning calorie management in 2 ways. First, the current commercial technology calorie calculation is based on a body with full muscle ability and, therefore, is inaccurate for people with SCI (subtheme: *calorie tracking*), and second, the users do not trust the calories in the self-tracking technology (subtheme: *trust in self-tracking technology*). Nevertheless, the wheelchair users we studied continue to use self-tracking technology to motivate them to stay active and to monitor variables such as heartbeat, speed, and activity schedule as proxies for their energy consumption (subtheme: *self-tracking technology use*).

This research has limitations due to the small number of interviews and the positioning of the research in a technologically advanced country (Sweden), which also has 1 of the 7 lowest gaps in unemployment between people with and without disabilities in the EU. If the study had been conducted in a different context with, for example, lower technological literacy and use or lower employability of people with disabilities, the results may have differed, particularly on the number of people who have used self-tracking technology. Finally, all of our participants (9/9, 100%) were White. If our participants had had a darker skin tone, the results may have differed, particularly in relation to the *trust in self-tracking technology* theme as self-tracking technology is even less accurate on darker skin [53]. Nevertheless, this study adds to the body of knowledge by validating previous studies on the different variables that wheelchair users want to see. It expands the current body of knowledge by focusing on long-lived experiences of self-tracking and contemporary commercial self-tracking technology, especially on calorie management—the most important factor influencing the life quality of wheelchair users with SCI.

Our research contributes to the scientific community as follows. It extends the work by Malu and Findlater [5] on fitness trackers on wheelchairs by interviewing wheelchair users with SCI who had lived, daily experience with tracking their activity or self-tracking technologies. In line with the work by Malu and Findlater [5], our findings in the *calorie tracking* subtheme indicate that one of the most important values to be measured is calories (intake and burn), followed by distances, GPS data, and pulse, as indicated by the *self-tracking technology use* subtheme. However, our findings in the *calorie burn* subtheme indicate that steps are not a good variable to measure for wheelchair users, which contradicts the study by Malu and Findlater [5] but is in line with the work by Carrington et al [6] and Helle and Rosenbeck Gøegb [39].

Our research, specifically the *self-tracking technology use* subtheme, is in line with the work by Helle Rosenbeck Gøegb[39] regarding the tracking of distance and time. In addition, the *trust in self-tracking technologies* subtheme is partially in line with the results of Helle and Rosenbeck Gøegb [39] showing a lack of trust in technology related to some variables (calorie burn and training intensity). Our participants, similarly to those in the study by Helle and Rosenbeck Gøegb [39], trusted the self-tracking technology regarding their speed measurements and were interested in these measurements; however, neither the participants in the aforementioned study nor our participants trusted calorie burn tracking (see the *trust in self-tracking technology* subtheme). Some of our participants showed a lack of trust in training intensity as well (similarly to those in the study by Helle and Rosenbeck Gøegb [39]); for example, smartwatches counted every activity as a stroke on a chair without distinguishing it from upper-body strength training (see the *trust in self-tracking technology* subtheme). Finally, our findings in the *reasons for self-tracking* theme suggest that being able to track different activities and calorie burn and keep track of exercise schedules, as well as seeing activity goals being reached, was motivational for our participants to keep the active lifestyle they needed, which is in line with the findings of past research [27,28,54].

Trust and Transparency

Participants' trust in self-tracking technologies was heavily influenced by their understanding and perception of how these devices worked. For example, Apple Watch users often trusted the device more than phone apps, believing that the watch's ability to track arm movements made it inherently more accurate than a phone carried in a pocket. However, this trust was conditional and limited; participants expressed confidence in the calorie estimates only for the 4 wheelchair-specific activities provided by the device. Regarding other activities in which calorie expenditure was approximated using these predefined categories, they expressed skepticism about accuracy. This led to varying strategies—some participants attempted to fit all their activities into 1 of the 4 wheelchair-specific categories to achieve more reliable calorie estimates, whereas others discarded calorie tracking entirely and used the watch in nonwheelchair mode to access a broader range of features.

Previous work on trust in self-tracking technology has revealed that users often have a *mental model* of how apps or devices work and calculate data [55]. Trust in self-tracking technologies, particularly in the context of wheelchair users with SCI, hinges significantly on the transparency of how data are collected, processed, and presented. Participants in our study exhibited a nuanced understanding of their devices, often forming mental models to rationalize the data's validity. However, the perceived "black box" nature of calorie calculations—whether on the Apple Watch or Runkeeper—fostered skepticism. This reinforces previous findings that transparency regarding algorithms and data processing is critical for trust [56]. On the

XSL•FO
RenderX

basis of this, we suggest that designers prioritize user education by including detailed explanations of their algorithms, especially when adapting generic metrics such as calorie burn for niche user groups, such as wheelchair users. This aligns with broader calls [57,58] for designing technologies that foster informed trust.

Furthermore, trust in technology is not isolated from social factors [59]. Apple Watch users' trust was partially rooted in social recommendations and previous brand experiences. This suggests that trust may extend beyond technical accuracy to include the brand's perceived reliability and commitment to inclusion. Investigating the interplay between social networks, brand trust, and technology adoption among wheelchair users could provide further insights into how collective validation influences individual trust decisions.

Distrust in calorie tracking was not merely technical but also emotional, linked to fears of inaccuracy impacting critical life decisions (eg, managing weight to maintain mobility). This illustrates that trust is not just a cognitive process but a deeply affective one. Incorporating participatory design with wheelchair users at every stage of the design and development process—testing, iteration, and after launch—can mitigate such emotional concerns. By co-designing solutions, developers can address both the technical and psychological dimensions of trust.

We observed how distrust often led participants to bypass calorie metrics altogether, choosing instead to focus on other variables or manual methods. This self-empowerment reflects resilience but also signals a failure of the technology to deliver on its promise. Therefore, tools must enhance user agency by aligning design goals with real-world constraints and expectations.

Finally, we observed a mismatch between representation and actual design. Runkeeper users appreciated the app's reliance on GPS and speed data, which they found straightforward and comprehensible. However, despite this, they distrusted the app's calorie calculations even when using its wheelchair mode and described feeling misled by its implied inclusivity. The use of wheelchair symbols created an initial perception of inclusivity but, ultimately, resulted in feelings of deception among participants due to inaccurate calorie calculations. This reflects a broader issue in which symbols and icons signaling accessibility and inclusiveness are in fact merely superficial. Misrepresentations such as these can diminish trust but also risk alienating the very communities that the technologies claim to support. Implications such as these are discussed further in the next section.

Implications for Commercial Self-Tracking Technology for Wheelchair Users With SCI

The most important need and valuable variable for our participants (subtheme: calorie tracking), and of the participants of previous research with wheelchair users, was the accuracy of calorie consumption [6,39,60]. Previous research [6,39,60] and our participants indicated that commercial fitness and wellness technology that uses the wheelchair symbol does not necessarily calculate accurately the calories burned by wheelchair users (subtheme: *trust in self-tracking technologies*). Research [6,39,60] also indicates that specific technology for wheelchair users needs to be developed, personalized, and tailored to their needs, which underlines the importance of tailoring mainstream self-tracking technology to the user group that it intends to include [61]. Furthermore, there is extensive research on wheelchair user–specific technology for self-tracking health and well-being [27,28,54], as well as exploring current technology with wheelchair users to inspire designs of wheelchair user–specific fitness and wellness technology [5]. Even though a big part of the aforementioned literature focuses on assistive technology or technology specifically for wheelchair users, mainstream self-tracking technology that aims to be inclusive toward wheelchair users can take advantage of what assistive technology research can offer (eg, databases and artificial intelligence models) [30,31], as well as what the medical field offers, which already has some physical activity guidelines for wheelchair users [14,32,34,62].

On the other hand, the production of new wheelchair-specific self-tracking technology (which is not assistive technology) divides the market into wheelchair users and non–wheelchair users. Recent research [41] indicates that, by excluding specific populations from the development of commercial products, the incorporation of accessibility requirements into general consumer products comes to a halt. In addition, special technology could cost more as it targets a specific population. Regarding wheelchair users, special technology may not be a financially viable solution as they have a higher risk of financial issues [42]. Working with affordable materials to create new technology for a specific population can also lead to them not using it because it could be stigmatizing [63]. From 2025 onward, digital services and products in the EU market should be accessible according to the EAA [10,49]. Our findings show that the self-tracking technology currently in the market is not prepared to be accessible to wheelchair users with SCI. This technology is not trusted when it comes to calorie calculation. Our participants described how they used proxy variables to estimate their calorie consumption and activity level. They expressed the need for a self-tracking technology that accurately calculates their calorie intake and burn during a variety of activities. Many of the issues with self-tracking technology that uses the wheelchair symbol can be solved by involving wheelchair users in the design and development phase. This involvement will make the technology more relevant to the people it aims to include (ie, wheelchair users) and open the market to broader audiences [64-66].

On the basis of the literature presented in this paper and our findings, we see a need for future research and development regarding inclusive self-tracking technology for wheelchair users with SCI supported and inspired by assistive technology literature.

First, there is a need to explore ways to make affordable technology already used by wheelchair users closer to their needs and make it more accurate regarding calorie burn (ie, track a variety of activities and calorie intake). Our study can be seen as a starting point for this exploration of commercial fitness self-tracking technology and its use by wheelchair users with SCI, complementing previous literature on similar subjects [5-7,11].

XSL•FO
RenderX

Second, we argue that there is a need to confront and acknowledge the limitations of the methods used to conduct similar research and alternate them for the research and practice to be more inclusive. According to Kabir et al [40], data collection and design methods may be inaccessible to some populations, leading researchers to exclude them as they perceive them as "difficult to reach and research." Instead, they suggest having a palette of methods and adjusting them based on the participants' abilities [40]. Similarly, Moon et al [37] provide a comprehensive toolbox for more inclusive user research when designing with wheelchair users in mind. In addition, Li et al [30] and Huang et al [31] provide freely available concrete tools (ie, databases and code) for developing an inclusive self-tracking technology to be used by anyone wanting to make self-tracking technology more inclusive.

Third, regardless of all the support that this paper and the literature provide, the inclusion of wheelchair users as an integral part of the design process of the self-tracking technology targeting this demographic should be seen as mandatory for the product to be relevant to the new audience (ie, wheelchair users) [65,66].

Future Research

Our next steps are a series of participatory workshops in which we—together with people with SCI and the support of the SCI center we partnered with—identify further tracking needs and co-design a first version of an app that could support them in learning about their new body in different stages of their postinjury phase. In the workshops, we plan to include the physiotherapist who cooperates with us to include the health care perspective without compromising the power balance. His participation will also create an environment in which the participants can learn more about SCI and how the health care system perceives SCI and them as patients. To create a link for the communication between health care professionals and people with SCI, we will use the connections of our partner at Karolinska Institute to investigate the needs of health care professionals (ie, which of the data tracked by people with SCI are relevant to the health care professionals and in what form to fit their practice when consulting with their patients).

Acknowledgments

The authors thank all the people who dedicated their time to participate in the interviews. Without their contribution and their rich experiences, this study would have been impossible. The authors thank their collaborators from the spinal cord injury center that supported this research and helped them find participants for this study.

Authors' Contributions

VM led the research and the writing process of the paper. VM designed and conducted the interviews and the initial thematic analysis with support from KC. AW and MR participated in the later stages of the thematic analysis and contributed to the overall writing of the paper. TH contributed to the writing of the paper and was responsible for the medical accuracy of the paper regarding spinal cord injury.

Conflicts of Interest

None declared.

Multimedia Appendix 1
The final themes resulting from the thematic analysis in a tabular form.

Abstract

Background: Guided mobile-based interventions may mitigate symptoms of anxiety disorders such as panic disorder, agoraphobia, or social anxiety disorder. With exposure therapy being efficacious in traditional treatments for these disorders, recent advancements have introduced 360° videos to deliver virtual reality exposure therapy (VRET) within mobile-based interventions.

Objective: Despite ongoing trials evaluating the treatment's efficacy, research examining patient perceptions of this innovative approach is still scarce. Therefore, this study aimed to explore patient opinions on specific treatment aspects of mobile-based interventions using mobile VRET and psychotherapeutic guidance for anxiety disorders.

Methods: A total of 11 patients diagnosed with panic disorder, agoraphobia, or social anxiety disorder who had previously taken part in the experimental conditions of 2 randomized controlled trials for a mobile intervention including mobile VRET participated in cross-sectional, retrospective interviews. Using a semistructured interview format, patients were asked to reflect on their treatment experiences; personal changes; helpful and hindering aspects; their motivation levels; and their encounters with the mobile-based intervention, manualized treatment sessions, and the mobile VRET.

Results: Thematic analysis led to the formation of 14 themes in four superordinate categories: (1) perceived treatment outcomes, (2) aspects of the mobile intervention, (3) experiences with mobile VRET, and (4) contextual considerations. Patients offered their insights into factors contributing to treatment success or failure, delineated perceived treatment outcomes, and highlighted favorable aspects of the treatment while pointing out shortcomings and suggesting potential enhancements. Most strikingly, while using a blended app-based intervention, patients highlighted the role of psychotherapeutic guidance as a central contributing factor to their symptom improvement.

Conclusions: The findings of the thematic analysis and its diverse patient perspectives hold the potential to guide future research to improve mobile-based treatment options for anxiety disorders. Insights from these patient experiences can contribute to refining mobile-based interventions and optimizing the integration of VRET in accordance with patients' preferences, needs, and expectations.

Introduction

Background

Anxiety disorders such as social anxiety disorder (SAD), panic disorder (PD), or agoraphobia (AG) are a pervasive public health issue with 12-month prevalence rates between 0.9% and 1.2%, causing severe impairment for those affected [1-3]. SAD, PD, and AG are characterized by intense fear reactions toward specific situations or bodily sensations that are normally perceived as harmless or nonthreatening [4]. In SAD, typical anxiety-provoking situations include social interactions (eg, being at the center of attention and meeting new people) as the fear is linked to negative evaluation, criticism, or embarrassment and rejection [5]. In PD, panic attacks are triggered by an overinterpretation of occasional bodily arousal (eg, elevated heartbeat) as life-threatening (eg, having a myocardial infarction) [6]. The catastrophic misinterpretation of such sensations can then lead individuals to be afraid of losing control or experience fear of death. In contrast, AG entails paniclike fear in situations in which escape is difficult (shopping queues, the subway, or car rides) as patients often describe their main concern revolving around losing control, having a medical emergency, being trapped, or not receiving help [7]. Affected individuals often describe anticipatory anxiety as especially troublesome, which may explain why all 3 disorders are often associated with avoidance and safety behavior [8,9].

Cognitive behavioral therapy (CBT) has been found highly effective in treating PD and AG. [10]. Typical methods used in CBT for these disorders are psychoeducation, behavioral experiments, and exposure therapy [11]. However, despite compelling evidence supporting the treatment's efficacy [12], most affected individuals fail to receive treatment (ie, according to Stein et al [13], less than a quarter of patients are admitted for treatment). One reason that keeps individuals in need from receiving treatment is the increasingly exhausted supply capabilities in mental health care, leading to prolonged waiting periods and large pretreatment attrition rates [14]. This is further aggravated by the fact that treatment recommendations such as exposure therapy often remain unfollowed due to time constraints, high costs, and resource demands [15,16].

Exposure therapy, one of the most effective treatments for anxiety disorders, involves the systematic confrontation with feared stimuli or situations to reduce avoidance behavior and facilitate fear extinction. There are several underlying mechanisms that may explain the effect of exposure therapy. First, early theories emphasize that repeated confrontation with anxiety-inducing stimuli promotes habituation [17], leading to a reduction in fear responses and supporting a learning process whereby patients experience that anxiety can diminish without avoidance. Second, confrontation also addresses general therapeutic factors such as problem activation and problem-solving, which have been repeatedly shown to be key mechanisms in psychotherapy [18]. Current theories suggest that the central mechanism in exposure therapy is inhibitory learning, which is induced by expectancy violations. In this framework, to optimize exposure success, it is key to challenge patients' predictions about feared outcomes [19,20]. Despite the documented efficacy and repeated validation of exposure therapy, it remains underused in clinical practice. A contributing factor is the underdiagnosis of anxiety disorders, which reduces access to appropriate treatment [21,22]. However, even when correctly diagnosed, the implementation of exposure therapy is not guaranteed. Reasons for this vary, including logistical challenges, a lack of resources, concerns about patient distress, or insufficient training [16]. In addition, patients might be reluctant to confront feared stimuli or discontinue treatment, which poses additional considerable barriers.

A recent approach to bridge the shortage of treatment capabilities in mental health care is using internet- and mobile-based interventions (IMIs) [23], which include smartphone apps that are tailored for specific psychological disorders such as SAD, PD, and AG. Most of these apps incorporate basic CBT interventions and have been shown to be effective in reducing symptoms, for example, through (a combination of) psychoeducation, cognitive restructuring, mindfulness, and relaxation techniques [24-26]. IMIs can follow a stand-alone approach or may also include varying degrees of psychotherapeutic guidance. Regarding the latter, guided treatment programs have been shown to be superior to stand-alone approaches in reducing clinical symptoms, as indicated by larger acceptability, engagement, and adherence [23,26]. These factors are crucial as they have been linked to improved treatment outcomes and sustained recovery [26]. Possible advantages of IMIs include flexible use at almost any time and place and relieving the psychotherapists' time burden [27]. While the use of IMIs could constitute an option to bridge scarce treatment capabilities, little is known about the potential of IMIs with exposure components to overcome these boundaries and provide less resource-intensive and more accessible exposure therapy as the first-line treatment option for anxiety disorders [28]. Therefore, the question arises of how exposure therapy can be integrated within IMIs.

One way to reduce barriers in the delivery of exposure therapy is the transfer of anxiety-eliciting situations to a virtual reality (VR) environment. VR exposure therapy (VRET) allows for the creation of specific scenarios that may be challenging or impractical to replicate in real life (in vivo) and that are tailored to elicit fear responses [29-31]. These simulations can be adjusted according to each patient's unique needs (ie, massive or gradual approach) and specific concerns while therapists maintain full control during such sessions [32,33]. For instance, therapists can pause, repeat, or pick scenarios based on the patients' progress, feedback, or observed reactions, whereas no unforeseeable events can appear as in in vivo therapy. Even if a certain level of risk is necessary for successful exposure therapy, which cannot be guaranteed by the artificial nature of VRET, the so-called immersion (ie, the feeling of realism created in VR atmospheres) helps uphold the patients' apprehension of imminent danger. This, in turn, can activate central fears and allow for their correction. Moreover, aversive risks such as physical harm can mostly be ruled out in VRET, rendering it to a certain degree safer than in vivo exposure therapy. So far, VRET has been used in the treatment of multiple anxiety disorders, such as SAD or AG, to reduce symptoms and improve quality of life successfully [34,35]. For instance,

XSL•FO
RenderX

patients with SAD have experienced significant reductions in fear of public speaking or social interactions [36-39]. Patients with AG have had less anxiety and shown less avoidance when traveling or enduring crowded places [40]. The quantity and duration of VRET sessions varies in the literature, typically lasting between 30 and 60 minutes and being conducted 8 to 12 times. Compared to exposure in vivo, increased acceptance and lower refusal rates have been reported in the past, making VRET a low-cost treatment option with a high success rate [30,41].

VRET has been used in mainly 2 ways in the existing literature. The first involves a computer-based system, allowing patients to engage with avatars, affect their surroundings, or receive immediate feedback during exposure [42]. Advantages of this approach include a high degree of immersion, the ability to tailor scenarios to individual needs, and the option to simulate dynamic (eg, social) interactions. The second approach uses 360° video systems, which present prerecorded scenarios without the possibility of affecting these through interaction. Notable advantages of this method are low costs, effortless scalability, and integrability with other mental health approaches such as IMIs as it requires considerably less technical equipment than interactive VR systems [43]. However, theoretical models of SAD [5] suggest that approaches with higher degrees of interaction might be more beneficial as fear is linked to interpersonal feedback or interaction [44]. Interestingly, both approaches have been found efficacious in reducing symptoms of SAD, PD, and AG [45]. However, research that directly compares interactive VRET systems and VRET via 360° video systems for the treatment of the aforementioned disorders is still scarce.

Taken together, the use of an IMI might reduce waiting times, whereas VRET might help implement exposure without high costs and resources [30]. To benefit from and provide additional advantages from the combined use, new approaches most recently have tried to integrate mobile VRET into IMIs [46-48]. Instead of using expensive VR equipment, patients use a head-mounted construction in which they can insert their smartphone as a screen and display 360° videos. By doing so, it has been demonstrated that treating acrophobia via self-guided VRET is possible [46,49]. Currently, randomized controlled trials (RCTs) are ongoing to investigate the efficacy of improving symptoms of SAD, PD, and AG using this innovative treatment approach [47,48,50].

To date, compared to a robust body of quantitative research, there are considerably less qualitative studies that have examined VRET. Research investigating the patient perspective has found that immersion and engagement are critical factors for its success, with patients highly valuing the ability to confront fears in a controlled and virtual environment [51,52]. However, perceived challenges are limited interactivity in prerecorded scenarios and technical difficulties, which may decrease the immersive experience and, therefore, the perceived effectiveness of the intervention [51,52]. Regarding the use of IMIs, qualitative research on patients' opinions has highlighted high accessibility and flexibility as major strengths while raising concerns about the lack of relational and emotional support inherent to the oftentimes self-guided nature of IMIs [53,54]. Although the cited literature provides valuable insights into the perspective of patients using VRET and IMIs separately, qualitative research regarding the integration of mobile VRET within guided IMIs is scarce. This research gap is addressed in this study.

Objectives

This study aimed to investigate patients' perspectives on integrating mobile VRET into guided IMIs for SAD, PD, and AG. Specifically, the goal was to identify key aspects that patients perceive as relevant to improvement or deterioration, including factors associated with the treatment's limitations, benefits, and outcomes [55,56]. This study also attempted to explore how patients navigate through the different treatment components, what their subjective reasons were for experiencing change or not, and their views on the combination of app-based treatment with psychotherapeutic guidance. On this basis, ideas can be formed on how to improve further similar approaches by facilitating patient adherence.

Methods

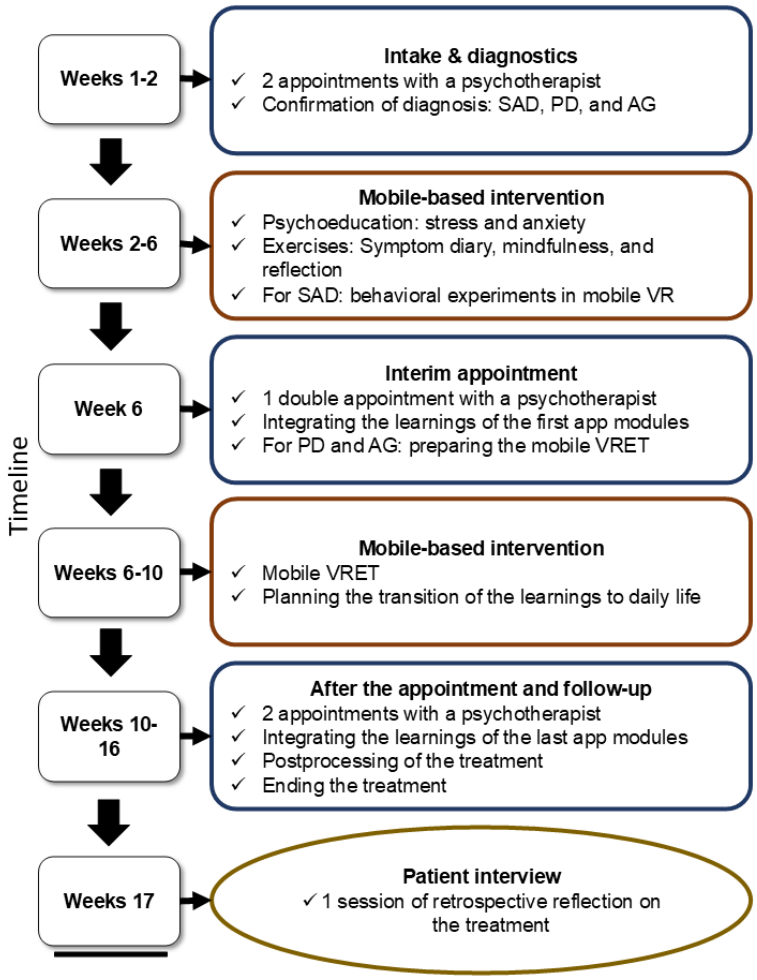
Participants

Patients were recruited from 2 RCTs that used a blended treatment approach comprising an IMI with in-app mobile VRET and appointments with a licensed psychotherapist. The work by Planert et al [47] and Hildebrand et al [48] provides further details concerning the trials.

Inclusion criteria were (1) fulfilling the *International Classification of Diseases, 10th Revision*, diagnostic criteria for one of the following psychological disorders: *agoraphobia, unspecified* (F40.00), *agoraphobia with panic disorder* (F40.01), *agoraphobia without panic disorder* (F40.02), *social phobia* (F40.1), or *panic disorder* (F41.0); (2) being aged ≥18 years; and (3) having completed the treatment in one of the RCTs [47,48]. Exclusion criteria for participation in the trials included a history of cardiovascular conditions (eg, stroke or myocardial infarction), respiratory disorders (eg, asthma or chronic obstructive pulmonary disease), epilepsy, pregnancy, impaired vision, schizophrenia, severe depression, acute suicidality, or substance use disorders. None of the patients received outpatient psychotherapy during the treatment period apart from the therapy provided as part of the study. Only participants from the treatment group in either of the 2 trials were invited upon completion of the RCT. A total of 11 patients (n=5, 45% patients with SAD; n=6, 55% patients with PD or AG) agreed to partake in the interviews.

Mobile-Based Intervention

The IMI in this blended treatment was an app for mobile phones incorporating 3 distinct treatment programs specifically developed for SAD, PD, and AG (Invirto [57]), of which patients completed 1. The app is based on a CBT treatment and consists of structured modules targeting different treatment aspects: goal setting, motivation, psychoeducation, tension regulation, cognitive techniques, exposure therapy, behavioral experiments, emotion regulation, exposure, reflection, and relapse prevention. For example, tension regulation was provided via breathing exercises, incorporating mindfulness-based techniques to help



XSL•FO
RenderX

patients manage physiological arousal. Unlike classic behavioral therapy methods, which rely heavily on face-to-face interactions, the app enabled patients to work autonomously through the modules. While the psychotherapists provided some guidance during scheduled appointments, the intervention allowed patients to progress within the structured program at their own pace. Modules incorporated a mix of prerecorded video sequences of psychotherapists, interactive experiments, self-assessments, exercises, and a wide range of potentially fear-evoking situations in a controlled VR environment. Using 360° videos, patients were able to choose scenarios such as giving a public speech, undergoing a job interview, or being in a crowded space or public transport that were thought to provoke or aimed at provoking symptoms of their specific anxiety disorder.

Procedure

Throughout the blended treatment, 5 psychotherapeutic appointments were conducted (for details, see the work by Planert et al [47] and Hildebrand et al [48]). As the mobile-based app offers 3 different treatment programs depending on the anxiety disorder, a joint recruitment process took place. Figure 1 provides an overview of the treatment procedure and study schedule.

Figure 1. Procedure of the treatment process and study schedule. On the left, the boxes indicate the corresponding week of the trial. Blue boxes indicate psychotherapeutic sessions, whereas the red boxes indicate periods in which the patients worked independently with the treatment app. The yellow box marks the time point at which the patient interviews took place. AG: agoraphobia; PD: panic disorder; SAD: social anxiety disorder; VR: virtual reality; VRET: virtual reality exposure therapy.

At study entry, patients received 2 diagnostic appointments in which they were assessed for eligibility. During these appointments, the diagnosis was checked, and an anamnesis took place. Those diagnosed with PD, AG, or SAD received access to the app (ie, 1 of the 3 treatment programs), which was available for 90 days after prescription. They were instructed to complete the first modules (self-guided phase I), including psychoeducation on the corresponding disorder and exercises (eg, identifying and visualizing triggers of fear and exercising diaphragmatic breathing for PD to reduce hyperventilation and promote relaxation [58]). To check on the completion of the self-guided phase I, patients were called to check up on their progress and whether they were ready for the next appointment. The self-guided phase I was set to 6 weeks; however, progressing to the next appointment was only possible after completing all modules from phase I.

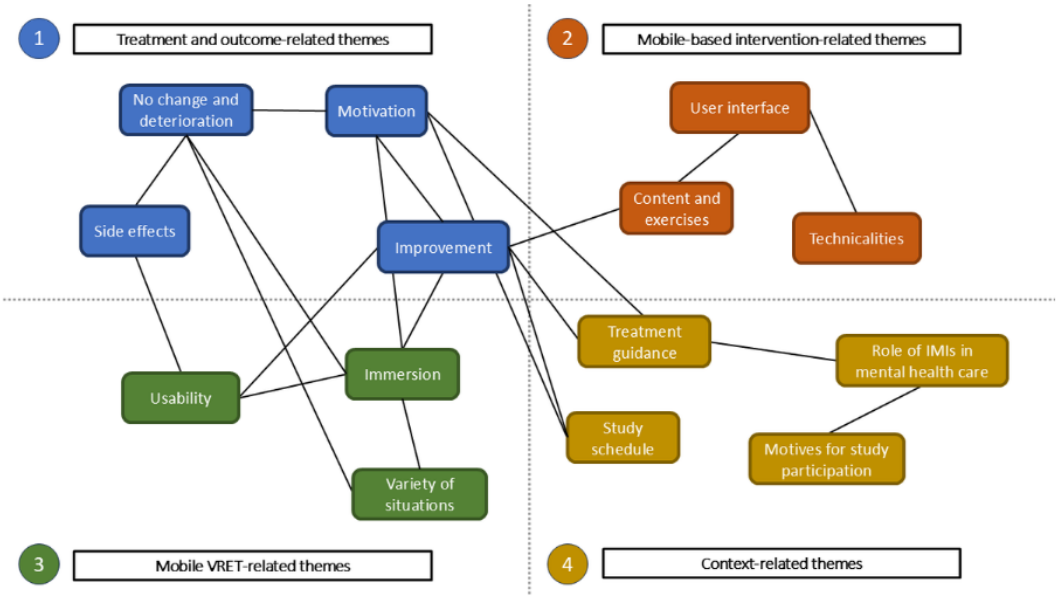
After completing the self-guided phase I, there was a third appointment to evaluate what patients had learned in the last modules and prepare for the next phase. As the treatment programs slightly differed with respect to the specific diagnosis, the content of the third appointment differed as well. For patients with SAD, the third appointment included evaluating the previous psychoeducation, exercises, and the behavioral

XSL•FO
RenderX

experiments in mobile VR. In addition, the patients were prepared for the transfer of those behavioral experiments into everyday life. For patients with PD or AG, the evaluation included the previous psychoeducation and exercises without VR. The patients were prepared for behavioral exercises (eg, running upstairs) and exposure to mobile VR (eg, sitting in a car or train) via 360° videos without the possibility of interacting (eg, by provoking reactions from objects or persons nearby). Patients received additional guidance to apply previously learned breathing techniques and integrate these during exposure tasks, ensuring that patients were able to handle physiological symptoms of panic that would arise. After the third appointment, all patients had 4 weeks to complete the remaining modules (self-guided phase II). This included exposure in vivo, emotion regulation, and relapse prevention in all treatment programs. For patients with PD and AG, this also included exposure in VR in multiple scenarios (eg, a car or plane ride or a supermarket). Afterward, patients and psychotherapists evaluated the complete intervention in a fourth appointment. After 6 weeks, patients had a follow-up appointment to assess long-term changes in symptoms and were asked to participate in a half-standardized interview. The obtained data were retrospective insights from patients who completed the whole treatment and were able to extensively use the app in their daily routine.

Half-Standardized Interview Procedure

All interviews were held in German and took, on average, 30 minutes and 40 seconds (SD 6 min). The interviews were conducted by author JP, a clinical psychologist. After describing the interview's purpose and how data protection was ensured, each interview began with an open-ended question, providing interviewees with an initial opportunity to freely discuss the aspects of the treatment they found most notable. This was done by asking the following: "How did you experience the treatment you were taking part in?" Afterward, the interviewer followed a semistructured manual based on the Client Change Interview [59]. The Client Change Interview establishes aspects that are potentially associated with a client's change in psychotherapy, such as helpful and hindering aspects, personal or psychological changes they made, or attributions for these changes. In this study, the interview manual was expanded through specific questions about the app included in the study, along with the mobile VRET, the study design of the RCT, and the expected role of the specific treatment in mental health care. The interview was semistructured, and for every point that the interviewee brought up, the interviewer was instructed to ask follow-up questions to ensure an in-depth understanding. All the interviews were semantically transcribed by student assistants. The interview procedure was conducted under the supervision of researchers AM and TK to ensure consistency and adherence to ethical guidelines.



Data Analysis

To analyze the interview data, a thematic content analysis was conducted according to Braun and Clarke [55,56]. The analysis was carried out by authors JP (first coder) and ASH (second coder), both clinical psychologists, who independently from one another reviewed the data. An inductive approach was chosen to generate codes directly from the transcripts of the interviews.

The qualitative data analysis was conducted using MAXQDA 2022 (version 22.7.0; VERBI GmbH) [60]. As a first step, both coders intuitively went over a part of the interviews in a summarizing manner. This was done to establish codes representing the content of the interviews. At this point, codes were not structured. Afterward, the established codes were reviewed by both coders collaboratively to ensure accuracy and check on errors or parts and messages that the other coder might have missed. The generated codes were then interpreted and grouped into overarching categories (eg, VR-related content and IMI-related content) by 1 coder. The second coder then checked the categories and the assigned codes. Afterward, the codes in 1 overarching category were grouped into multiple themes by the second coder and checked by the first coder. Both coders then reflected on and interpreted the categories and themes with their corresponding codes and depicted them in a thematic map (Figure 2) to visually illustrate the findings.

XSL•FO
RenderX

Figure 2. Thematic map of the established themes within their respective categories. Themes are divided by category. Links between the themes indicate thematic relatedness depending on the statements of the interviewed patients. IMI: internet- and mobile-based intervention; VRET: virtual reality exposure therapy.

Ethical Considerations

The interview procedure after the follow-up appointment was approved by the Research Ethics Committee of the University of Siegen through an amendment to the corresponding ethics statement (ER_48_2021, amendment AZ_56/2023) All participants provided informed consent before participation, which could be withdrawn at any time without giving any reason. All collected data were pseudonymized to protect participants' confidentiality. No monetary compensation was issued.

Results

Overview

As the interviews were conducted in German, extracted quotes were translated from German into English literally. The extracted quotes appear indented and in italics in the sections corresponding to each theme. Table 1 shows the demographic characteristics of the 11 interviewees.

Table 1. Demographic information of the study sample.

Patient code	Age range (y[a])	Gender	Primary diagnosis (*ICD-10*[b])	Symptom change[c]
P01	20-39	Woman	Social anxiety disorder	–8.5%
P02	20-39	Woman	Panic disorder	–50%
P03	20-39	Woman	Social anxiety disorder	–28.4%
P04	>40	Woman	Agoraphobia	–92.3%
P05	>40	Woman	Social anxiety disorder	–20.2%
P06	>40	Woman	Panic disorder	–73.2%
P07	>40	Woman	Panic disorder	–27.6%
P08	20-39	Woman	Agoraphobia	–70.1%
P09	>40	Man	Agoraphobia with panic disorder	–19.4%
P10	20-39	Woman	Social anxiety disorder	+10%
P11	20-39	Man	Social anxiety disorder	–3.8%

[a]Information on age is given as ranges to protect the anonymity of the interviewed patients.

[b] *ICD-10: International Classification of Diseases, 10th Revision.*

[c]Symptom change indications refer to either of 2 disorder-specific questionnaires: the Questionnaire for Social Anxiety and Social Competence Deficits or the Panic and Agoraphobia Scale.

The themes of the various interview segments were divided into 4 overarching categories: "treatment and outcome–related themes," "mobile-based intervention–related themes," "VRET-related themes," and "context-related themes" (Figure 2).

XSL•FO
RenderX

Category 1: Treatment and Outcome–Related Themes

The first category covered themes that were related to patient-perceived aspects of the blended treatment or its outcomes. In total, this category consisted of 4 themes: symptom improvement, no change and symptom deterioration, side effects, and motivation throughout treatment.

Theme 1: Symptom Improvement

Throughout the treatment, many of the interviewed patients experienced symptom improvement. Indications as to how and why their symptoms might have improved are covered by this category's first theme. While some patients reported a perceived symptom remission, others indicated that, while the treatment helped, they felt not fully recovered:

> *I was able to learn a lot and made big advancements. By now, I oftentimes go by car alone and I feel like I make progress every day, I also stopped thinking about my anxiety.* [P04; position 8]

> *Well, I still have anxiety. Partly, it got better.* [P03; position 18]

Various reasons were given for the perceived improvement. While some patients stressed the superior role of one component of the therapy (eg, therapeutic appointments, VRET, or psychoeducation), some pointed out that the comprehensive approach with a treatment app, mobile VRET, and psychotherapeutic appointments was helpful:

> *Yea, I'd say the therapist rather helped me, coming from an interpersonal understanding.* [P02; position 29]

> *It was an interplay. There was the app, in which I learned about anxiety and its causes. And then I had a person that accompanied or led me. The appointments helped me to keep going and push through.* [P06; position 50]

While sometimes the mobile VRET was highlighted as an especially helpful ingredient, others claimed that everything but the mobile VRET was beneficial:

> *And these experiments with the VR-headset. They really helped me, because in these situations, I really had anxiety, but I knew it was not real and it doesn't matter how I behave.* [P03; position 51]

> *I think the video took an hour, I was on the highway and I was in the passenger seat. But being the passenger was no problem for me. That's the same as if I was in somebody's car, that doesn't bother me either.* [P09; position 54]

In addition to the treatment components, symptom insight, learning to reflect on these symptoms, and receiving access to treatment after a long search were mentioned as crucial factors. Reflecting on their treatment progress, participants illuminated different protective factors that facilitated their symptom improvement, such as engaging modules, social support, hope, optimism, and motivation to use the app.

Theme 2: No Change and (Short-Term) Symptom Deterioration

Some patients reported retrospectively no change or even deterioration of their initial symptomatology. They brought up that the treatment was not able to address all aspects of their anxiety due to the manualization and the one-size-fits-all approach. In addition, they reported a lack of individualization and personalization:

> *It's not possible as it is a pretty general format. For example, symptoms I don't have are described or you are put in a state that does not cause anxiety. That is something I suspected to happen in the beginning.* [P11; position 108]

One patient brought up that, through psychoeducation, symptoms worsened by shifting the focus toward them:

> *I always watched the first few modules at night. This was usually the time when I got my panic attacks and listening to the modules was kind of a trigger for me. For example, it's about what happens in your brain and what symptoms it can have. After hearing about the symptoms, I started to notice them and that is how my panic was caused. Very unpleasant, nausea and shortness of breath. When the person in the app talked about it, it sometimes made it even worse for me.* [P02; position 48-49]

Theme 3: Side Effects

The theme of side effects covered codes addressing unwanted changes associated with the treatment but not related to the patients' anxiety disorders. Side effects included simulation sickness (eg, "I got a little headache" [P02; position 36]) and the surfacing of other problems (eg, trauma), which were not addressed by the app:

> *I think there still is something. For now, I'd use the app, but through the treatment, other areas arose that were problematic, which were kind of hidden before. In that sense, you could say that it had a negative effect.* [P10; position 44]

Theme 4: Motivation Throughout the Treatment

Motivation was oftentimes addressed by the interviewed patients, depicting it as a dynamic process throughout the treatment. Many mentioned it as a crucial factor to the success or failure of their treatment. Different factors were given as reasons for an increase or decrease in motivation. Patients described the motivation to reduce symptoms to be able to master feared situations and increase well-being:

> *I was totally motivated, I wanted it, no matter what. For me it was so important, as from day to day, my life completely shifted and I couldn't deal with it. Before, I was a happy and funny person and suddenly, I was afraid of everything.* [P07; position 64]

During the interviews, patients emphasized the necessity of being motivated for the, in large part, self-reliant treatment. Therefore, a lack of motivation was brought up as a potential risk factor for treatment success:

XSL•FO
RenderX

> *In the beginning [I was] very motivated, but at some point, that faded a little. And then I had a few weeks doing nothing. Then I realized I should do something and did a few exercises. But sometimes, I lack the motivation to sit down at home and engage [with the app]. I think it lacks the person that in some way "kicks your butt."* [P03; position 74]

However, a high initial motivation was no guarantee for long-term engagement with the treatment app. For example, a patient reported a reduction in motivation to engage with the app due to a quick initial symptom reduction and overall improvement. Eventually, this made it harder to find the required time for the treatment or resulted in difficulties facing their anxiety in the frame of the treatment and a lack of translation into their everyday life:

> *In the beginning, it was fairly easy [to work with the app] because I knew it had to happen. The weeks before that weren't really worth living. Once I got a grip on my anxiety, also because of the app and the therapy, it got harder, as it is quite time-consuming and I couldn't estimate how long the next module would take.* [P02; position 62]

Category 2: Mobile-Based Intervention–Related Themes

The second category covered 3 themes regarding the mobile-based app used in the intervention evaluated in this study: app content and exercises (theme 1), user interface (theme 2), and technicalities (theme 3). The displayed codes do not concern the mobile VRET, which is covered in another category (category 3: VRET-related themes).

Theme 1: Content and Exercises

The first theme covered patients' opinions concerning the content and exercises of the app. Patients viewed the modules covering psychoeducation, the in-app push notifications, and the option to repeat contents as especially helpful:

> *I was surprised, how well the content was specialized to my panic disorder. I guess there is different content available that is shown to you, depending on what you have.* [P02; position 62]

> *Also, it was nice that I received notifications.* [P04; position 33]

Patients had mixed opinions on the relaxation exercises. Some described them as "extremely helpful" (P08; position 16-17), whereas others perceived them as rather misleading and distressing:

> *These breathing or mindfulness exercises partly worsened my panic. Well, definitely the breathing exercises, as I tried it a lot in the beginning. As soon as I gave room to my panic and tried to breathe against it, it became worse and made it take longer.* [P02; position 34]

Some patients expressed a desire for in-app contact with other patients or their psychotherapist to share progress or solve issues with peers:

> *It could be that for social anxiety, this isn't realizable, but I could well imagine that it works like group therapy. So you could talk about it. "How was the situation for you?" "What was your take-home message?"* [P11; position 144]

Theme 2: User Interface

Overall, the app was perceived as well built regarding quality and user interface:

> *And I found [the app] qualitatively well-made. And it was good to listen to it and to read through it.* [P11; position 96]

The option to choose the in-app psychotherapist was brought up as an advantage. However, the importance of an option to speed up videos in the modules was highlighted. To further facilitate usability, a function to consume the content while being absent from the screen was desired:

> *Not being able to lock the screen, not being able to close the app. These are mechanisms that in some way make sense, but most of the time I used the app while cleaning, doing my laundry, or doing my homework. And then your cellphone is in another room and you have to click to proceed. That wasn't severe, but also not comfortable.* [P10; position 86]

Theme 3: Technicalities

The sign-up process was marked as a problem source, and a transparent guide on how to obtain access to the treatment app and a function to download content were deemed helpful. However, it was also pointed out that technical difficulties, if they occurred, were quickly solved by the app support:

> *One time a situation didn't load, so I contacted the support and they solved it fairly quickly, on the same day. It worked directly.* [P11; position 88]

Category 3: VRET-Related Themes

The third category consisted of 3 themes covering opinions that were related to the mobile VRET modules of the treatment app. Participants discussed their experiences in the VRET, including the degree of immersion, the usability, and the variety of situations displayed on the treatment app.

Theme 1: Immersion

The first theme covered the perceived degree of immersion. Regarding this theme, several patients emphasized the feeling of immersion as helpful for their improvement and the ability of the app to create immersion and elicit fear:

> *And then I had anxiety, even though it was not real. It was quite surprising that I was able to do that. It was quite interesting and for some part even fun. Overall, I think it was mostly interesting to get to know more about [the anxiety].* [P03; position 34]

> *I think that is especially because I am conscious about being in a virtual situation. Other aspects, such as noises from the outside felt different. It is so advanced that you can completely exchange certain things,*

XSL•FO
RenderX

> *which somehow felt very real, without the real consequences, however.* [P11; position 79]

On the other hand, other patients found the prerecorded situations unrealistic, which could have negatively affected the degree of immersion. In that sense, it was addressed as a shortcoming that the mobile VRET consisted of 360° videos without possible interaction. This was perceived as especially problematic by patients with SAD as the prerecorded audience did not react to them:

> *You wear the VR-headset and you are sat in front of an audience, which is obviously filmed and the VR doesn't really matter, because no matter what I do, they will always react the same. And that is not what causes my fear, it rather is the direct contact with others.* [P01; position 26]

> *So sometimes, when I misspoke, I had the feeling that it usually would've been a situation that would have caused a reaction. That took a bit of the immersion away. But I cannot estimate how much.* [P11; position 82]

In addition, some patients with PD or AG described a lack of anxiety when confronted with situations in mobile VR:

> *What I didn't like, was the virtual [reality], yes, that didn't match. I have to be honest, I sat on an airplane with weird people that did not look real and made repetitive movements. The airplane didn't even shake or do anything that would have caused something in me. Or being alone in the basement. You would imagine this being creepy, yes? But nothing happened, not even a mouse hushed by or anything. I tried a lot, but that wasn't for me. Or a shopping queue, nothing happened. Unrealistic. But for the rest, the app was great.* [P07; position 28]

Theme 2: Usability

The second theme was the usability of the VRET. While some patients did like facing feared situations at home, others felt discomfort when using mobile VRET:

> *My parents were home for the whole day so I could only train in situations when no one was at home. At some time in the evening, when I was sure that no one could hear me.* [P05; position 66]

Some patients described problems with the compatibility of the VR app and their smartphone despite their device meeting the manufacturer's specified minimum technical requirements. For example, they mentioned lags in the 360° videos:

> *It should have worked with my phone, but it lagged so much, for five seconds it worked and then it stood still for another five.* [P09; position 52]

Regarding the VR headset, patients had problems with adequate fit and the glasses fogging up on the inside:

> *The VR headset did not really fit well and I got a bit of a headache because I wasn't able to correctly adjust the resolution.* [P02; position 36]

Another patient brought up that the weight of the head-mounted construction with the smartphone inside made it difficult to wear the equipment for an extended period:

> *I found the headset very heavy. At some point, I had to put my elbows on my knees and by that point, it did not feel like not being at home on the couch.* [P10; position 107-108]

Finally, it was suggested that, as the app was only available for 90 days, the VR equipment should be only distributed temporarily as, when the license ends, the patient has no further use for the equipment that is tailored to the treatment app.

Theme 3: Variety of VR Content

A third theme covered the situations available in VR within the treatment app. Patients described the situations presented on the app as aligning well with fear-evoking situations in real life. They also liked the variety of agoraphobic situations they were able to experience without having to face these situations in real life:

> *So first of all, being able to identify the anxiety and then being able to directly test it. It was nice to directly go into the specific situations. So, thinking back, I would have never gone into the situation [in reality]. It was practical, I did not need to go somewhere to go through the fear.* [P06; position 100]

However, the situations were criticized for the lack of eventfulness. Patients did expect options to further increase fear and adjust situations:

> *I thought that the situations would increase in intensity. I thought that eventually, I would stand on a huge stage and give a speech. And I thought that something VR-related would happen with the people. Not being in a prerecorded situation, but something like a chat.* [P11; position 100]

While the app did implement situations for SAD (eg, giving a talk in front of an audience) and AG (eg, a bus ride), one patient criticized the lack of available situations for eliciting bodily arousal PD–related symptoms:

> *In the end, some modules did not fit my panic disorder anymore but fitted more to other anxiety disorders.... But I think that also was because I wasn't able to pick a location that would cause my panic. For me, it is rather a personal, bodily thing. I tried one exercise on the airplane but after two minutes it was boring as it did not elicit panic.* [P02; position 34-36 and position 62]

Category 4: Context-Related Themes

The fourth category comprised themes that addressed the framework in which the patients received the treatment.

Theme 1: Significance of Treatment Guidance

The treatment consisted of an app with mandatory psychotherapeutic sessions for the preparation and postprocessing of certain modules. Many of the patients addressed this guidance in their interviews. For most, this was a crucial ingredient for symptom improvement or a protective

XSL•FO
RenderX

factor against deterioration. In addition, patients who did not particularly like the treatment app or the mobile VRET components still regarded the psychotherapeutic sessions as helpful:

> *The therapist definitely helped. Just being able to talk and also for my understanding. So, the empathy and to accept it as normal and not be upset about it.* [P02; position 27-28]

Despite the guidance, it was criticized that patients could not share the completed modules with their psychotherapist. However, the combination of the treatment app and the psychotherapeutic sessions was brought up as a well-rounded mix by most patients. One of the reasons given was that the appointments facilitated the integration of the content learned on the app:

> *After I held the speech [in VR] I had an appointment and the therapist was able to improve my anxiety a little, which I would have never achieved on my own. That's why it was very good that I still had the appointments. Completely on my own, it wouldn't have been possible.* [P03; position 38]

Some patients addressed the desire for more appointments accompanying the app-based treatment:

> *I would've appreciated it if the time between the appointments was shorter and that we would've met more often and spoken more.* [P07; position 82]

Theme 2: Study Schedule

Patients attended psychotherapeutic appointments at prearranged intervals as part of the RCTs. Most patients indicated not feeling like "being part of a research scenario" (P01; position 54) but being glad to contribute to research findings. However, to enable the manualized appointments in the experimental condition, the patients were asked to engage with the treatment app between the scheduled sessions. While this was perceived as helpful for staying motivated by most patients, some patients perceived it as stressful. The schedule was linked to treatment outcomes and limited the flexibility of the treatment:

> *First I felt relieved because usually, you have to wait a long time for a therapy spot. I was happy about any help, after all. It went quickly and I felt relieved, but also obligated to do this and that module between the appointments.... A downside was that time-wise, you are independent, but also in this study combination. If you have this time frame in which you have to finish certain modules before coming to the next appointment, it is a downside for me, as it limits my flexibility.* [P02; position 13-14 and 56-57]

Theme 3: Motives for Study Participation

In their interviews, patients expressed their motives for participating in this study. For example, one patient was motivated to improve the supply situation for women in mental health care:

> *It is super important to generate new findings, therefore I find [participating in research] always positive. Especially, I think for many diseases, women are underrepresented, and when I can contribute to improving this and technology.* [P02; position 69-70]

Another motive was receiving access to therapy as this is often hindered by long waiting times. Patients hoped to be prioritized by contributing to research:

> *I find the first step very hard and also exhausting when you are looking for a therapist. And when through [the study], you can quickly talk to someone, I consider this helpful, as you are rewarded for your first step and you don't need to call another 20 [psychotherapists] and receive 19 rejections.* [P01; position 62]

Theme 4: Role of Mobile-Based Interventions in Mental Health Care

The fourth theme consisted of different opinions regarding the role of app treatment in mental health care. As such, IMIs were considered as an add-on to conventional therapy (eg, as an alternative to traditional homework or to bridge the waiting period before beginning psychotherapy):

> *Sometimes I think [waiting times] take way too long. The anxiety or the problems get more severe the longer it takes until they finally receive treatment. With this, you can at least work a bit on your own.* [P07; position 198]

In addition, IMIs were considered as having fewer barriers. This way, they could be a well-suited first step for patients searching for help:

> *I think many people are afraid to attend therapy in the first place or to completely trust another person. So I think it is easier to start the treatment with an app. For example, writing down things in the app without the therapist noticing. So I can imagine that this could lessen the barrier to starting a treatment.* [P11; position 67]

However, while IMIs were perceived as suitable for complementing therapy or bridging waiting times, some patients also described limitations in their applicability. They thought that IMIs might only be suited for certain aspects of treatment or patients. For example, some people might prefer books over using their smartphones to inform themselves about their disorders. P05 mentioned that she perceived the app treatment as helpful as she already knew what her problem was:

> *If you have problems in many areas of your life and the app asks you to name your problems and then you type down an eternally long text, in that case, a real conversation is more practical. However, if you know your problem and just want to work on it.... For me, that was very helpful and I think that could also be helpful for others.* [P05; position 82]

Patients consistently made clear that, from their experience, IMIs could be a complementary tool but should not replace psychotherapy:

XSL•FO
RenderX

> *Difficult. I think that depends on the person. But I cannot imagine [IMIs replacing therapy]. Not in the current state.* [P03; position 96]

Discussion

Principal Findings

Overview

The goal of this study was to systematically analyze patients' perspectives concerning the integration of mobile VRET into guided IMIs for treating anxiety disorders. This was done to inform how patients perceive this innovative treatment approach and where chances and challenges might lie. This way, in 4 overarching categories, 14 themes were identified: symptom improvement, no change and deterioration, side effects, motivation, content and structure, user interface, technicalities, immersion, usability, variety of situations, treatment guidance, study schedule, motives for study participation, and role of IMIs in mental health care.

Perspectives on Treatment Outcomes

The first category of themes captured patients' experiences with symptom alleviation throughout the treatment. Most striking about the themes in this category was that patients articulated a variety of reasons for their change or no change in symptoms and linked these to different aspects of the treatment. Improvement was explained by oftentimes highlighting the helpful interactions with the guiding psychotherapist but also by pointing out especially helpful treatment components such as psychoeducation, which was easy to follow as well as informational. Mobile VRET was also frequently brought up as allowing for the controlled encounter of feared and previously avoided situations [30]. Thus, fear responses can be elicited in a controlled virtual setting, enabling a confrontation of fears in line with the principles of in vivo exposure therapy, leveraging gradual exposure and habituation while maintaining the control of a simulated environment. By reducing logistical barriers, mobile VRET highlights the potential it holds in mental health care [35], which is further supported by meta-analytic findings yielding no inferiority of VRET compared to in vivo exposure therapy concerning primary treatment outcomes [61-63]. No change was explained by the treatment components not meeting the individual symptomatology, showing that the superficial modality of an app-based treatment might not fit every patient. The results give rise to the argument that treatment apps alone may not provide the depth of therapeutic interaction needed for comprehensive mental health care. Regarding the theme of side effects, how to deal with adverse events related to the treatment needs to be reflected on [23], as it happened to one patient, who learned through the treatment that there were other issues they needed to deal with for which there was no room in the manualized short-term treatment. Without the frame of the study context, this occurrence could have gone unnoticed, and the patient would most likely not have received further treatment.

Bringing together these findings with the results of previous quantitative studies, it can be stated that there are very few but promising studies on the efficacy of mobile VRET in IMIs. These emphasize clinical improvements and provide initial evidence of treatment benefits, particularly for components such as mobile VRET [46,64]. While additional quantitative studies have yet to profoundly support the treatment's efficacy, the current qualitative studies can expand the findings by showing that the patient-perceived treatment outcomes are often tied to specific treatment components, such as psychoeducation, VRET, or tension regulation. These components have also been found efficacious in quantitative research [42,65], whereas other qualitative studies have determined motivation, symptom insight, and social support as crucial factors in treatments incorporating IMIs [52,53]. In comparison, the qualitative approach used in this study highlighted that the personally perceived commitment, motivation, and outcome expectancy were intertwined with personal impairments (anticipatory anxiety limiting daily routine and reinforcing the circle of avoidance and increase in fear over time) and treatment goals (building confidence for certain scenarios and gaining tools to manage physiological symptoms), which cannot be taken into account in many quantitative approaches.

Patients pointed out motivation as a central construct when addressing treatment outcomes. While motivation has also been found to be a key factor in traditional psychotherapy [66], it appears to play an even bigger role when the patient is self-reliant in working through most of the treatment content [67]. In particular, motivation was described as a dynamic process that is highest in the beginning, when the psychological strain is highest, and decreases throughout the treatment. After its decrease, it is then associated with no change or even deterioration, resembling previous findings on motivation in traditional psychotherapy [68]. For this treatment approach, this finding highlights the need for additional motivators as the treatment progresses to protect the patient from demotivation and losing benefits from the treatment.

Perspectives on the Treatment App

The second category of themes covered patient opinions regarding the treatment app. Most strikingly, psychoeducation was brought up as an overwhelmingly positive treatment component that can be delivered well via an app, which is in line with previous research on patient perspectives on digital treatment modalities [69]. In addition, a high degree of individualization (eg, choosing the voice of the in-app psychotherapist) and an adjustable user interface were stressed as preferable. An aspect that faced repeated criticism was the in-app relaxation. While mindfulness interventions have been found efficacious in mental health care [70], this sample encompassed patients with anxiety disorders. It might be that, for such disorders, in particular regarding PD, relaxation is better delivered via psychotherapeutic interaction than through an app considering the possibility of relaxation-induced panic attacks [71]. It is also known that confrontation with situations and contexts that have previously been avoided contributes to an initial increase in fear or discomfort, which is positively associated with treatment success [72]. However, in the framework of self-guided or blended treatment, patients might be more inclined to discontinue treatment as they perceive the initial negative emotional states as threatening, thereby reinforcing avoidance behavior and, ultimately, intensifying the risk of unwanted events. For patients, it was also important to

XSL•FO
RenderX

have quick access to the treatment app and be able to use it without barriers. One of these barriers was long informational sections, which patients could not speed up or listen to while being active (eg, walking or cleaning) as the app would require the user to click to move along. These findings are comparable to those of other qualitative studies on opinions on app treatment as, in general, a desire for a high degree of personalization stood out in this study as well [69]. However, while implementing the patients' suggestions might lead to more treatment acceptance, whether these suggestions could raise other issues has to be carefully considered for each suggestion on its own. For example, allowing for the locking of the screen or opening of other apps while using the treatment app could lead to less focus on the treatment and, eventually, a decline in motivation or less treatment success.

Perspectives on Mobile VRET

In the third category, themes were listed that were related to the mobile VRET of the treatment app. The most discussed aspect was the degree to which the head-mounted construction with the patient's smartphone serving as a display was able to create an immersive experience for VRET [43]. While it was welcomed by some patients, who described being pleased with the high immersion, others criticized a lack of interaction given the fact that the mobile VRET consisted of prerecorded 360° videos. As previously outlined, different systems are used in VRET that are either equipped with dynamic interaction options or, as in this study, based on 360° videos that do not offer the chance to affect the scenarios or characters in them. Patients addressed this by pointing out a lack of interpersonal interaction during VRET, which made the experience less immersive. This aligns with the clinical presentation of SAD, where interpersonal interaction plays a central role [5,44], and suggests that the degree of the immersive interaction required might vary depending on the disorder. Nonetheless, many participants across all 3 anxiety disorders found the 360° videos personally beneficial for treating their anxiety, appreciating the practical benefits of accessibility and ease of use, supporting their engagement during the exposure tasks. It is important to note that these evaluations were conducted without directly comparing 360° videos to interactive VRET systems, which could be addressed in future research. In this study, the hardware was identified as a problem source in the theme of usability. These findings suggest that mobile VRET still needs time to overcome these particular challenges but, overall, can be useful in treating SAD, PD, and AG.

Although numerous studies have drawn out the possibilities of VRET in mental health care [35], it is yet to be seen how the intriguing treatment approach of using mobile VRET can be further improved to be well received by patients. One way could be to integrate desired elements such as the possibility to choose from a large pool of fear-evoking situations with optional adjustments, such as the crowdedness of certain places or the pace of car, bus, or tram rides, as brought up by the interviewed patients.

Perspectives on the Study's Context

Themes in the fourth category, which were context related, showed that, for the patients, the psychotherapeutic supervision was very important, the study schedule may have had an influence on symptom change, and most patients could well imagine using (guided) treatment apps but could not imagine them as a substitute for psychotherapy. Overall, the interviewed patients highly valued the psychotherapeutic sessions as part of the guided treatment approach. Despite the app being the main ingredient of their treatment, the psychotherapeutic guidance was mentioned in all interviews and was always brought up positively or with the request to have more psychotherapeutic sessions. This finding is in line with those of previous literature that found guided IMIs to be superior to unguided ones [26], indicating that alliance as a mechanism of change also holds up for digitally delivered interventions [73]. While the general modality of using IMIs is partly aimed at reducing psychotherapeutic involvement [23], how far this reduction is taken should be carefully considered for each treatment approach. In this study, many interviewed patients distinguished the psychotherapeutic appointment as the most remarkable factor in their treatment, whereas conceptually, one could argue that it was only intended as a supporting element, with the main focus laying on the treatment app with mobile VRET [47,48].

The thematic connection between the theme of study schedule and the theme of symptom improvement originated in patients giving aspects of the study schedule as reasons for their improvement. For example, it was mentioned that the psychotherapeutic appointments and calls from the study team served as deadlines and reminders to finish the modules in the treatment app, which then led to a more holistic understanding of etiological and maintaining factors underlying their anxiety disorder. Here, it is important to note that these checkups would not have occurred in a real clinical setting. Despite making sure that the RCTs from which the interviewed patients were recruited accurately reflected real-world clinical settings, it is essential to acknowledge that the patients still engaged in a structured intervention within a controlled environment [47,48]. Therefore, these minimal but necessary alterations could have influenced the quantitative results. Beyond trials investigating the treatment efficacy, it is important to also further identify characteristics in patients (eg, demographic and clinical variables, personality traits, and coping mechanisms), as well as process (eg, fear reduction during exposure) and context variables that may predict the treatment outcomes of these interventions and develop clear indications as to who should gain access to these treatment options [72,74,75]. In addition, for this reason, future interventions could increasingly incorporate deadlines and checkups to increase the patients' commitment to engage with the otherwise self-reliant treatment contents.

While treatment acceptance is a crucial factor in mostly self-delivered treatments, in their interviews, patients also reflected on the role of IMIs in the mental health care system. Due to the scarcity of treatment capabilities, they could imagine IMIs as a way to bridge waiting times. However, they could not imagine the tested treatment substituting psychotherapy as a whole, which is comparable to other qualitative research on patient attitudes toward IMIs [54]. This finding is also in line with those of research on the perspective of psychotherapists

XSL•FO
RenderX

on IMIs, who welcomed the digital treatment option as an aid for certain aspects but also could not imagine it as a substitute for psychotherapy [76].

Relating this study's results to the current situation of outpatient psychotherapy, several advantages and challenges of the investigated treatment modality can be highlighted. As accessibility and a low threshold for engaging with IMIs were appreciated, they might be advantageous in bridging waiting times or reducing stigma or hesitancy associated with seeking psychotherapeutic treatment [26]. This might be especially beneficial in countries with long waiting times, such as Germany [77]. Another advantage was that the treatment functioned as digital homework, contributing to problem activation outside the treatment, which has been associated with treatment success in the past [18]. Patients also listed the cost and scalability of the treatment as potential advantages over outpatient psychotherapy. However, oftentimes, the importance of psychotherapeutic guidance was emphasized, which is why a challenge might lie in the self-guided nature of mobile VRET. Namely, the procedure partly opposes current treatment guidelines [10], indicating that initial exposure attempts are best psychotherapeutically accompanied to prevent adverse effects or misapplication (ie, premature termination). In addition, a lack of individualized support remains a challenge, which was criticized by patients in direct comparison to regular outpatient psychotherapy.

Limitations and Future Research

While this study was capable of drawing a multifaceted picture of patients' opinions, some limitations need to be addressed when interpreting the findings. First, the findings of this study are derived from a blended IMI with integrated mobile VRET, indicating that the observed benefits or challenges may not directly translate to other treatment modalities. For instance, experiences with unguided IMIs or stationary VRET may differ from those with blended IMIs with mobile VRET. In addition, while the reliance on a qualitative method of data analysis to interpret the obtained interview transcripts offers rich insights, it also inherently requires caution when interpreting causality. Such an approach captures patient perspectives but does not allow for claims regarding the treatment's efficacy, which would require further exploration through controlled, comparative, and quantitative research designs. Future trials of a confirmatory nature are needed to further investigate the exploratory findings of this study.

Another point worth noting is that the interviews were conducted as part of a larger RCT. From the patients' perspective, it was interpreted that the study schedule, despite being incorporated into an outpatient clinical setting, might be linked to the obtained results. Differences between the study and treatment as usual include, for example, a high degree of standardization, required comparability of therapeutic settings, frequency and duration of therapy, and a reliance on treatment manuals. Therefore, for future research, it could be beneficial to conduct studies in a more naturalistic setting. This could include investigating treatment adherence and feasibility in less structured clinical settings such as standard outpatient care. Another relevant option for future research could be investigating challenges to the treatment's accessibility in contexts with different resources and infrastructure (eg, rural vs urban regions) as IMIs and mobile VRET in particular are theorized to possibly address disparities in the supply of mental health care by reducing geographical barriers and providing scalable solutions in underserved areas.

Conclusions

This study explored patients' perspectives on IMIs embedding mobile VRET for SAD, PD, and AG. As such, various components such as the psychoeducational content were listed as beneficial in the intervention, and motivation was continuously perceived as a crucial factor for treatment engagement. The mobile VRET was welcomed as an innovative add-on to overcome anxiety but, for some patients, lacked immersion and personal fit due to the reliance on prerecorded 360° videos without interaction. Finally, the psychotherapeutic guidance of the intervention was appreciated as especially beneficial and stood out as a central aspect in most of the interviews as it helped the patients integrate their learning from the IMI and served as a deadline to engage with the IMI before the next treatment session. This study has shown that, in the further development of IMIs and other associated interventions such as VRET, it is important not only to empirically test the efficacy of such procedures or their acceptance among psychotherapists but also not to ignore the perspectives of patients and those affected as these are highly valuable to further improve existing procedures as well as ensure their applicability. For future research, it is suggested to explore patients' perspectives on other treatment modalities or investigate the findings of this study using confirmatory research designs.

Acknowledgments

The authors thank the patients who participated in this study and the subsequent interview procedure. JP and ASH are funded by the German Research Foundation, Research Training Group 2493 (DFG project number: 398510439). No monetary (or any other type of) remuneration has been received by the developing team of the treatment app used in this trial.

Conflicts of Interest

None declared.

Abstract

Background: Surgical lighting systems (SLSs) provide optimal lighting conditions for operating room personnel. Current systems are mainly adjusted by hand; surgeons either accommodate the light themselves or communicate their requirements to an assistant to ensure optimal surgical conditions. This poses challenges to maintaining sterility, proper accessibility, and illumination and can lead to potential collision problems. Furthermore, the personnel operating the light may not have deep medical knowledge or equipment expertise.

Objective: This paper introduces a touch-free interaction concept for controlling an SLS using speech and gestures.

Methods: We used an iterative, user-centered design approach with participatory design sessions. This process involved conducting a literature review, several observations of actual surgical sites, and engaging stakeholders through interviews and focus groups. In addition, we carried out 2 user studies: one in a virtual reality setup and another in a living laboratory environment.

Results: Our findings indicate that our interaction concept is a viable alternative for controlling an SLS. Despite some technical limitations, surgical experts found the system intuitive and useful, recognizing the significant potential for touch-free lighting adjustments in the operating room. The combination of speech and gesture modalities was seen as helpful and even necessary, with some interactions better suited to one modality over the other. Offering both modalities for each interaction provided greater flexibility.

Conclusions: Our findings suggest that our proposed touch-free interaction concept can enhance surgical conditions and has the potential to replace traditional adjustment.

Introduction

Background

The illumination of the operating room (OR) is critical to ensuring optimal surgical conditions. Surgical lighting systems (SLSs) are designed to provide optimal lighting for the surgical staff in the OR. They provide settings for adjusting the intensity of the light, its color temperature, and the size of the illuminated field, which are mainly controlled with control panels situated on the lamp's body. Such adjustments to the SLS are necessary for various reasons, such as differentiating between only

XSL•FO
RenderX

marginally different-looking tissues [1]. Making modifications to the lighting conditions requires the surgeon or an assistant to operate the control panel with their hands, which is often located in an ergonomically unfavorable position, such as above the surgeon's head [2].

Generally, an OR is required to have two sets of distinctive lighting types: (1) general room lights (ambient lights) and (2) focused and precise procedural surgical lights to illuminate areas of incision (surgical lights) [3]. Optimal surgical illumination combines sufficient ambient light with the ability to apply focused light at specific positions and angles throughout different stages of an operation [4]. Current SLSs are primarily controlled and adjusted by hand, and surgeons are eager to operate the SLSs themselves while keeping sterility. It is essential to look for an ergonomic solution for the SLS adjustments to maintain the surgical staff's focus on their primary task and keep distractions to a minimum. Hence, controlling the SLS should be intuitive and straightforward to keep the mental load to a minimum and increase interaction safety [1]. Moreover, during an operation, the surgical staff must reposition the SLS several times to ensure optimal surgical illumination. Research shows that every 7.5 minutes, a change in the lighting position takes place [2]. Such position changes are also commonly performed by hand. However, performing such adjustments by hand can lead to collisions and other mechanical problems. In addition, this raises concerns regarding sterility and increases potential safety risks [5]. Even though it is required to sterilize all equipment the surgical staff comes in contact with during an operation, this still might not be done sufficiently due to the lack of information and attention of the OR personnel, use of the wrong sterilization product, or insufficient and ineffective work of sterilization [5]. During an operation, surgeons often need to interact with the OR equipment, such as radiological images and lights [6]. Due to sterility concerns, surgeons may be unable to interact with such equipment and depend on their assistants. Communicating this need with the personnel might be complex and lead to further errors if the assistant and the surgeon cannot communicate properly. Consequently, there is a possibility of interruptions in the workflow.

In this work, we propose the use of natural user interfaces (NUIs) [7,8] to provide surgeons with an intuitive interface for adjusting the SLS. NUIs have the potential to enable clinicians to have freehand control of the OR equipment while maintaining sterility. Data from several studies highlight the potential and advantages of using NUIs in ORs [1,6,9-13]. This paper presents an interaction concept that combines voice and gesture to control the SLS. We used a touch-free approach to protect sterility in the OR and ultimately increase patient safety. To develop this interaction concept, we used an iterative user-centered design approach with participatory design sessions. First, we conducted a literature review and had several observations of actual surgical sites to develop the initial list of interactions. Using this list, through co-design, we discussed individual interactions for both modalities of speech and hand gestures with 7 experts using interviews and developed an initial interaction concept. Subsequently, we conducted 2 focus groups to discuss the concept with the OR personnel. The revised interaction concept based on the focus groups' feedback was then used in a virtual reality (VR) prototype and evaluated by 6 experts. Considering the results of the VR evaluation, we developed a prototype in a living laboratory and conducted a laboratory study with 12 surgeons and surgical assistants. Our findings suggest that our interaction concept is a valid alternative for controlling the SLS. Even though certain technical limitations were experienced, surgical experts found the system highly useful and intuitive and saw great potential for touch-free approaches to lighting adjustments in the OR. This paper contributes the following: (1) the design and implementation of a touch-free interaction system for controlling the SLS informed by domain experts and (2) 2 user studies providing an exploratory evaluation of how this system can support surgical personnel. The implications of our work can support researchers and medical companies when adapting touch-free approaches for adjusting SLS. It further gives an understanding of the potential and challenges of such approaches. The broader insights of this research can also be valuable for the general use of NUIs in the OR to enhance surgical conditions and increase patient safety.

All figures used in the manuscript can be viewed in Multimedia Appendix 1.

Related Work

Many OR personnel believe that lighting is a major inconvenience [14]. Previous literature identified the following types of problems with SLS: *mechanical*, *collision*, *accessibility*, and *illumination* problems [2,15,16]. *Mechanical* problems include the requirement of excessive force to move the SLS, which can make a 1-hand light adjustment difficult and occasionally cause the SLS to get jammed. In such cases, surgeons usually ask for the help of other OR personnel. This can delay the completion of the adjustment and could lead to possible errors because the personnel responsible might not have the necessary medical knowledge or familiarity with the equipment [2]. *Collision* problems refer to the times when the SLS collides with other OR equipment or against the heads of the personnel [2]. *Accessibility* problems occur when surgeons have to stand up or move to perform an adjustment because the SLS is out of reach [2]. *Illumination* problems refer to the issues that the surgeons or the surgical staff experience regarding the SLS lighting conditions, such as wound illumination, refocusing the light beam, and increasing illumination levels [15].

In the following sections, we provide an overview of the previous literature on smart surgical light control and touch-free techniques for an OR, including voice and gesture interaction in the OR.

Smart Light Control in the OR

Appropriate lighting during surgery is critical for patient safety [17]. Researchers have looked into various methods to enhance the lighting conditions in the OR and the interaction with the SLS. Teuber et al [18] presented a method for autonomous positioning of surgical lamps during open surgeries using a depth camera and robotic arms. The authors tested their algorithm in a VR simulation and found that their method was robust and could ensure close-to-optimal lighting conditions in real-world surgeries. Burger [15] developed a technique for

XSL•FO
RenderX

autonomous, real-time adjustment of an SLS by identifying the wound based on heat sources to achieve complete automation of an SLS in the OR. The findings suggested that the combination of optical and thermal cameras with stereo image-processing techniques could be used to identify and track a heat source. Moreover, predefined scene lighting has been commonly examined and used for medical environments, such as angiography rooms [3]. This is accomplished by defining specific lighting features, such as the light position, intensity, angle, and color. Mühlenbrock et al [19,20] introduced a novel lighting system consisting of numerous small lighting modules permanently mounted on the ceiling. This system actively avoids casting shadows using depth sensors. Through simulations and a subsequently constructed prototype, which was evaluated with surgeons, it was demonstrated that in open abdominal surgeries, this system can illuminate a surgical wound more effectively than conventional surgical lights and was deemed more suitable for use in the operating theater by surgeons. In addition, point cloud recordings were used to investigate how the positioning and optimization of these light modules affect the achievable brightness at the surgical site [21]. Other studies have shown the potential of freehand control for operating the OR lights. Hartmann and Schlaefer [9] used an RGBD (red, green, and blue, plus depth) camera for gesture tracking to study gesture-based control of OR lights. Their results showed that gesture control could be quickly learned and effectively used to operate OR lights. Similarly, to offer the surgeons a sterile and ergonomically comfortable operation, Dietz et al [1] developed a freehand gesture control using a Kinect (Microsoft Corporation) system for the SLS. Participants reported high usability scores for the system and rated it ergonomically more comfortable than the conventional control panels and less likely to distract them from their tasks. In this work, we build on the lighting modules introduced by Mühlenbrock et al [20] in our living laboratory study, implementing a freehand control method to adjust the lighting conditions in the OR.

Touch-Free Techniques in the OR

An extensive body of literature has previously looked into touch-free methods for controlling OR equipment. As input modalities, gaze [22-24], gestures [12,22,25-33], or voice [11,34-36], for example, were researched. Hatscher et al [22] used gaze tracking and foot gestures on an interactive floor as input modalities for hands-free interaction to interact with medical image data. Their results show that selection is accomplished faster via gaze than with a foot-only approach, but gaze and foot easily interfere when used simultaneously. To minimize the dependency on OR personnel, Zaman et al [35] investigated voice- and foot-based interactions for the surgeon to interact with 2D images in VR. Their findings suggest that both modalities have acceptable usability. While the voice command system was perceived as more comfortable, foot-based interaction was more efficient.

The use of voice technology in health care is growing. Research has shown that voice-based commands could lower the cognitive and physical cost of accessing specific features or performing certain actions [37]. Feedback from experts revealed that surgeons have previously requested more voice-controlled features in ORs, including voice commands for adjusting lamp positions [14]. Often, in critical situations during an operation, the surgeon and the assistants must use both hands to ascertain the patient's health [38]. In this context, the advantage of voice interaction is that the surgeons can concentrate on the operation while simultaneously controlling other components using their voice [38,39]. The most crucial point is that the surgeon's hands are always unencumbered. Previous research has looked into the use of voice interaction in an OR [36,40-43]. El-Shallaly et al [40] evaluated a voice interface regarding the use of time and surgical staff during laparoscopic cholecystectomy. Their results showed that the voice interface significantly optimized the operating time and the use of surgical staff. In a comparison study, Alapetite et al [39] compared a voice interaction system with the traditional touchscreen and keyboard interface to update anesthesia records during crisis situations. Their results showed an accurate speech-based registration performance even during emergencies and time-critical scenarios. Punt et al [44] compared the efficiency, reliability, and user satisfaction of controlling an endoscope's zoom and light intensity using voice control, a touch panel, or manual control by an assistant. Most participants experienced voice control as the quickest interface, although in reality, it was slower than the other 2 conditions. Recent advances in natural language processing and artificial intelligence have extensively enhanced the efficacy of such systems, addressing some of the most prominent concerns with these systems, such as speech recognition. These advances provide new opportunities to explore the use of voice in various domains, including health care [45]. The emergence of large language models and generative artificial intelligence technologies such as ChatGPT (OpenAI) has ushered in notable improvements in this regard [46]. Another commonly proposed modality for hand-free interaction is gesture control. Gesture-based systems have been considered a novel application to adjust medical equipment [32,33]. Previous research has looked into navigating magnetic resonance imaging and computer tomography images using arm gestures during surgery [6,13,31]. Nestorov et al [30] designed a touch-free medical image control system using Leap Motion (Leap Motion, Inc) and Kinect. Their results showed an average acceptability rate for both systems. Nonetheless, surgeons and radiologists found Kinect to have better utility and be more beneficial for most clinicians. Overall, each of these modalities has demonstrated potential in ORs, improving the working conditions for surgeons. Researchers have also investigated the combination of different interaction modalities. Data from several studies suggest that incorporating voice and gesture inputs can be helpful in the OR [10,29,42]. To operate a system without the risk of equipment contamination, Ebert et al [10] developed a system prototype that allows for touch-free control of medical images using a depth camera and voice recognition software. The authors found that the touch-free system performs favorably and removes a potential vector for infection, protecting both patients and staff. Similarly, Hötker et al [42] demonstrated the feasibility and utility of using speech and gesture for reviewing images in interventional radiology to navigate through image data in a sterile environment. Their results showed high-command recognition rates and stability under different lighting conditions. In a study investigating the uses of voice control versus gestural control in the OR, Mentis et al [11]

XSL•FO
RenderX

designed a system that allows for both modalities at the user's choice.

Authors suggest that the benefits of each technology are circumstantial and recommend enabling functionalities to be achieved using both modalities to have a more flexible combination of their benefits as the context of the procedure requires [11]. Previous studies have highlighted that voice interaction is better fitted for trigger functions or functionality switches, whereas hand or body gestures are more suitable for continuous manipulation of parameters [11,38]. Although alternative methods for controlling the OR equipment have been largely investigated, to our knowledge, using speech and gesture to operate the SLS has yet to be evaluated in this context. Moreover, previous literature still lacks an understanding of the experts' expectations and perceptions of such systems. Building on the previous work, in this paper, we engage with OR personnel to design a touch-free interaction concept for controlling the SLS in an iterative user-centered approach.

Methods 1: Initial Concept

Overview

In this work, we sought to develop and evaluate a touch-free interaction concept for controlling an SLS. For this, we used an iterative, user-centered approach to address the needs and requirements of the OR personnel. We could not directly translate existing touch-free practices to controlling an SLS, as the use case in the OR is unique due to its constraints (eg, patient safety or sterility aspects) and requires extra attention. Therefore, we chose a human-centered approach to best integrate and fulfill the needs of the OR personnel. The iterative process allowed us to enhance the concept by reevaluating it several times. This approach also helped us identify possible weaknesses and issues at the early stages. Furthermore, it enabled us to fill the gap between our intended design and how the experts interpret it [47,48]. We first sat in on an actual surgery to observe how surgical personnel interact with the SLS; on the basis of the observations and related work, we curated a list of required SLS interactions, which were discussed with experts and further refined using a focus group.

Assessing OR Light Adjustments

To come up with our initial concept, we first reviewed the existing literature to explore previous work on contactless approaches for controlling surgical equipment [1,10,29,38,42]. A short summary of our review is mentioned in the Related Work section of this paper. Furthermore, to better understand how the OR personnel, especially the lead surgeon, interact with the current surgical lights, we attended an open liver surgery. The main goal was to identify what type of interactions occur with the lights, which personnel modify the SLS, how often it is adjusted, and how the adjustments are made throughout different phases of an operation. In total, 7 surgical personnel were involved in this surgery. The operation took around 81 minutes. For this surgery, 2 satellite lamps were used as focused lights to illuminate the wound. During this time, 21 light adjustments were made (6 major and 15 minor), that is, approximately 1 adjustment for every 4 minutes. Major light adjustments involve significant changes to overall illumination or focus to accommodate procedural needs, while minor adjustments are precise tweaks to optimize visibility without altering the general lighting setup. We observed that all the light adjustments were made using a single hand during the surgery. The reasons for light adjustments were mainly due to the lead surgeon or assistants changing poses, using other OR equipment, such as the ultrasound device, or changing the light's focus. Only around 35% of adjustments took the shortest route to get to the next position. The lead surgeon only adjusted the SLS 20% of the time. Three other assistant surgeons made the remaining adjustments. We observed that light adjustments led to interruptions and interference with the personnel's task at hand. For instance, the lead surgeon had to stop what they were doing to adjust the light and then continue with the work. Considering our literature research and observation of the surgery, we developed a list of possible interactions to perform with the SLS, which includes the *light switch*, *light beam position*, *size of the illuminated field*, *light intensity*, and *predefined lights*. On the basis of the recommendations from the previous research, we chose the 2 modalities of *speech* and *gesture* to use for our touchless interaction concept.

Expert Interviews

After developing a list of possible interactions with the light, we conducted 7 interview sessions with the OR personnel to better match our concept to their needs and discuss our modalities and individual interactions, with the aim of designing an initial interaction concept.

Procedure

All interview sessions were held remotely via video calls while the experimenter recorded verbal statements and observations. The participants were asked to give informed consent and fill in the demographics questionnaire before the session. Participants were briefed about the interview procedure at the beginning of each session. We explained our concept and research goals, including our intention to use voice and hand gestures to control the SLS. We first asked about the experts' impression of the concept when the interview started. After that, they provided feedback about each interaction and its positive or negative aspects. We then asked for their suggestions to enhance the current concept. For further qualitative analysis, we audio-recorded the sessions. The interview sessions took between 35 and 45 minutes. The interview recordings were summarized, then analyzed and coded based on domain summaries [49,50], where the themes are structured around a shared topic rather than shared meaning, with the goal of capturing the diversity of meaning in relation to a specific subject or area of focus [51]. The transcripts of the interviews were coded by a researcher using inductive coding [52,53], where a single quote could be assigned to multiple codes. In addition, we collected insightful and unique statements.

Participants

We recruited 7 senior physicians (1 female and 6 male) who were aged between 41 and 58 (mean 47, SD 6.16) years, all with at least 17 (mean 22, SD 5.12) years of medical experience and active roles in surgeries. Moreover, 4 were general and

XSL•FO
RenderX

visceral surgery specialists, 1 was a neurosurgeon, 1 was a urological surgeon, and 1 was an ear-nose-throat specialist.

Ethical Considerations

Ethics approval was received for every step of our evaluation from the University of Oldenburg ethics board. For each step, participants gave informed consent before participation. All data collected during the study were anonymized following the sessions to ensure participant confidentiality and privacy. No personally identifiable information was stored or retained. Participation in the study was entirely voluntary, and no compensation was provided.

Results 1

Overview

The experts generally liked the idea of using voice and gesture to control the SLS. They found it beneficial to have more control over the lights and avoid having additional personnel to make such changes. One expert said, “It is exhausting to ask an assistant to control the light. It takes extra effort” (P1). Another mentioned, “Everything you have to ask somebody else to do for you should have smart control” (P4). Furthermore, one expert pointed out that using such a concept can reduce unnecessary movement in the OR, for example, moving around for activities such as regulating or switching the lights. All participants agreed that multiple personnel should be able to adjust the SLS. This includes the anesthesiologist, the instrument nurse, and the assistant surgeons. One participant suggested that restricting access to certain personnel in special cases could be helpful. One participant suggested designing the interactions based on what is commonly used in ORs, such as similar sentences or phrases that are now used as an assistance request, “Easiest way is always to follow what you have done before” (P3). Two other experts recommended designing familiar gestures based on real-world interactions. For our experts, minor position changes were the most critical interactions often used during surgeries. Four participants mentioned that major position adjustments are less often performed in surgeries than fine adjustments, which matches our observations. Regarding the light intensity, 4 found it helpful to adjust the light intensity intraoperatively. On the other hand, 3 found it unnecessary to adjust the brightness of the SLS. In addition, 6 out of the 7 participants agreed that using predefined lights is beneficial. Participants found it helpful to record specific light characteristics to be able to reload them again afterward. One expert said, “It is an absolutely useful feature to save specific light positions and go back to it later” (P2). Another participant mentioned, “It would be beneficial if we could define certain positions based on the positions of the organs and just load them” (P3). One expert judged predefined lighting conditions to be an unnecessary feature. Furthermore, 3 participants suggested changing the light color to be helpful during the surgery. One surgeon highlighted that using the color green during laparoscopic surgery is quite beneficial, and it would be helpful to make this change with the new concept. Participants also pointed out possible concerns regarding each modality. Although all participants gave highly positive feedback on the concept, some were uncertain about the efficiency of the technology. Five participants were concerned about the noise level in the OR and whether voice input could be used in such an environment. Participants were worried about the recognition of the gestures and speech commands. Two mentioned that the unrecognized commands could frustrate the personnel and add more stress. Four participants were worried about misrecognition and false positives where the OR personnel give input, but the system does something otherwise. Moreover, participants raised concerns about having multiple hands near the wound, which might be problematic for gesture recognition. In addition, 6 out of the 7 participants suggested using a wake word for the voice input to minimize false recognition by the system. Four experts emphasized the importance of choosing a suitable wake word, suggesting using words or phrases not commonly used in the OR. A similar initiation step was also recommended for the gesture interaction to avoid false recognition. Moreover, 2 participants pointed out the importance of considering lighting scenarios that different surgical disciplines can use. Experts mentioned that designing smart lighting systems may not suit every type of surgery. For instance, the positions are typically predefined in spinal surgeries, and there is little variation. Moreover, in some instances, the surgeons use different lighting sources, such as headlights.

Initial Concept

Overview

On the basis of the discussions and findings from the expert interviews, previous literature, and technical considerations, we developed an initial interaction concept (Table 1).

Table 1. Interactions in the initial concept with their respective modality and action to perform the interaction.

Interaction	Modality	Action
System activation	Speech	“Activate”
Light switch	Speech	“Surgical lights on”
Light beam position (minor)	Gesture	Move hand for positioning
Light beam position (major)	Speech	“Position three”
Light intensity	Speech	“Intensity 75 percent”
Size of the illuminated field	Gesture	Distance between the two hands
Predefined positions	Speech	“Standard mode”
Previous position	Speech	“Previous position”

XSL•FO
RenderX

System Activation

To interact with the system, the system first needs to be activated using a wake word. This activation is done via speech using the command "activate." After using the wake word, there is a 5-second window to interact with the system. The system returns to standby mode when an action is performed, awaiting the next wake word. If no action happens, the system returns to standby mode after 5 seconds.

Light Switch

Switching the lights on and off is done using speech. Users can turn the SLS on by saying, "surgical lights on!" and, similarly, switch it off by saying, "surgical lights off!"

Light Position

The major position changes are done using speech interaction. The possibility is to either use numbers for each major position (eg, "position two") or specific names (eg, "position stomach"). The surgical team can add custom positions with their desired names for that position. Fine (ie, minor) adjustments are performed with a combination of speech and gestures. After the wake word, users must use the command "edit position!" The system will then follow the personnel's hand. After finding the right spot, the position can be set by saying "save position!" The position is saved afterward, and the hands are no longer tracked as the system returns to standby mode. The personnel can always command the system to return to the previous position by saying, "previous position."

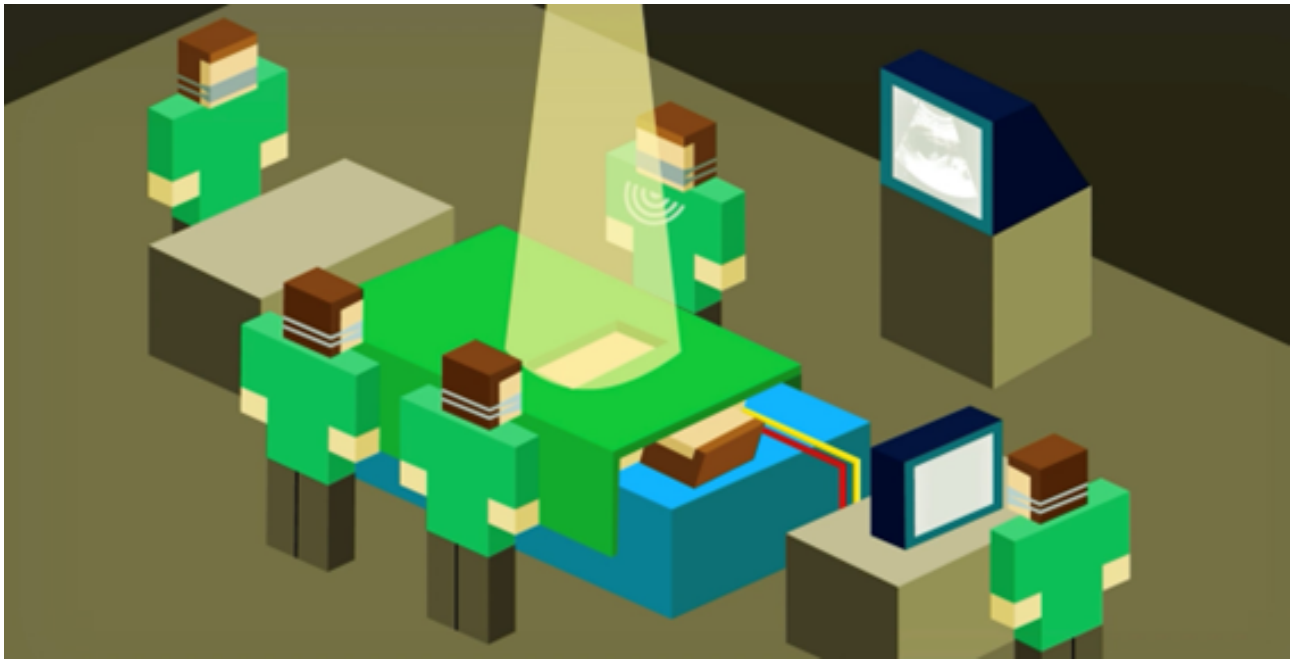
Light Intensity

The intensity of light is also adjusted by speech. Users can use percentages to modify the intensity, for example, "intensity 75 percent."

Predefined Settings and Modes

Different predefined illumination modes can be set where specific lighting conditions are saved for multiuse purposes. For instance, in dark mode, the lights are off, and the personnel can better focus on the information from the monitors (eg, the ultrasound device). The modes are set using speech, where users can give commands such as "standard mode," "dark mode," or "laparoscopic mode" (which turns the light green).

Field of Illumination



To adjust the size of the illuminated field, we chose a combination of hand gestures and speech. After system activation, users must use the command "edit angle." The system would then track the surgeon's hands and calculate the distance between them. The more distant they are, the wider the angle, and vice versa. After finding the right size, the position can be set by saying "save." The position is saved afterward, and the system returns to standby mode.

Methods 2: Focus Groups

Overview

We conducted 2 focus groups with the surgical personnel to evaluate and discuss our initial interaction concept. We used an approach similar to scenario-based design methods [54] and vignette experiments [55]. We developed animated videos demonstrating the interactions based on the concept (Figure 1). In these videos, we visualized how each interaction could be done in the OR using the previously defined and described input modalities. This allowed us to investigate the interaction and technologies without worrying about technological concerns. The main goal for the focus group sessions was to design the input format for each interaction, including individual voice commands and different hand gestures. Furthermore, we wanted to discuss the appropriate modality for individual interaction.

Figure 1. A frame from the concept animation that was used in the focus group sessions to help visualize the interactions for the experts.

XSL•FO
RenderX

Procedure

We conducted 2 focus groups, inviting different target groups. Both sessions were conducted in a hybrid format. The first focus group (FG1) consisted of 6 surgeons (2 female surgeons and 4 male surgeons), all present in a hospital meeting room, with 2 researchers assisting them in person (Figure 2). Two other researchers joined in via video call. The second focus group (FG2) was conducted with 4 surgical assistants (one female surgical assistant and 3 male surgical assistants). Similar to the first session, all participants and 3 researchers were present in a hospital meeting room, and 1 researcher joined via video call. We grouped surgical assistants separately from surgeons to allow for a comfortable reflection without the potential influence of the hierarchical structure within surgical teams. Both sessions were video recorded for further analysis. Participants gave informed consent and filled in a demographics questionnaire at the beginning of each session, which was followed by a brief overview of the session's procedure. Our interaction method was then presented along with the chosen modalities as well as the primary research goals. Next, individual interactions and possible input forms for each were discussed. The participants then acted on these suggestions in Wizard-of-Oz style, where they would make hand gestures or say the speech commands and the researchers would modify the lamp to simulate the interactions so that the participants could experience their suggested interactions better. Afterward, we demonstrated our animated concept video and collected the participants' feedback. We discussed the animated videos after the initial discussion about the interactions to avoid biasing participants with our chosen interaction set and modalities. In the end, we left the floor open for further comments or suggestions from the experts. The first session took approximately 90 minutes (FG1), and the second took approximately 80 minutes (FG2). On top of the video recordings in each session, 2 researchers noted verbal statements and their own observations. The researchers reviewed, analyzed, and summarized the session recordings of both focus groups.

Figure 2. A surgeon acting out the interactions in the first focus group session.

Results 2

Overview

The focus group results generally mirrored those obtained from interviewing experts. The focus groups led to further insights regarding participants' concerns with the system and how such systems should be designed. Participants again pointed out that the interactions should be familiar to the personnel: "It would be nice to have a similar approach like the current way of moving the lamps" (P2 in FG1). All participants agreed that multiple personnel should be able to access the system. One participant mentioned, "When both surgeon's hands are occupied, an assistant should be able to control the light" (P5 in FG2). In both focus groups, experts agreed that the interactions should be kept as simple and short as possible. Participants believed it would be valuable if the new interaction concept could help shorten the operating time.

Appropriate Modality

Three participants agreed that speech would be more practical than gestures overall, as they believed gestures could be more distracting and lead to collisions. Participants agreed that speech would be more suitable for switching the lights on or off. All

XSL•FO
RenderX

recommended that hand gestures should be used to perform fine adjustments. Regarding brightness and field of illumination, there were mixed feelings. Two participants believed speech would be more appropriate, while others suggested using gestures. The feedback about adjusting the size of the illuminated field varied among participants. Some believed this was best performed by speech using some sort of a scale, such as percentages, while others thought it would be more accurate using hand gestures. Two participants highlighted that the hand gestures should all be made using 1 hand. They believed that occupying both hands to adjust the SLS could delay the operation. The participants of both focus groups mainly agreed that position changes should be done with hand gestures, as they seem more precise. It was difficult for the participants to imagine speech commands that could accurately and quickly adjust the position of the light's focus.

The general agreement in the sessions regarding the voice commands was that they needed to be as short as possible. Experts believed that more extended commands would be harder to remember. More importantly, brief commands would save time, a critical aspect of surgeries. Using phrases not commonly used in the OR was recommended to avoid false recognition. There was uncertainty about the language used for the speech commands. Three participants believed the commands should be given in the local language (German), as it is easier to learn, remember, and correctly pronounce them. Others suggested using a language different from the local one, such as English, because it is not commonly spoken in the OR. It was recommended that the system should be flexible and able to handle multiple phrases per action, meaning multiple commands should be able to perform the same interaction.

Individual Interactions

We received multiple suggestions for a wake word, including "sun," "sunlight," "OP light," and "light." Among these, "light" was favored by most as it is short and easy to remember. Moreover, it was recommended that an activation step be used for hand gestures to avoid false positives. One participant suggested holding a gesture for a specific amount of time before giving the actual gesture. One participant recommended simulating pressing a light switch with hand gestures to switch the lights on and off. Another suggested opening and closing a fist to switch the lights. Participants mainly agreed that "lights on" or "lights off" are appropriate commands for speech regarding the light switch. For positioning the light beam, 2 participants tried to grab the beam of light and move it to a different position. Others in the group also found this form of interaction natural. Participants had difficulty imagining an appropriate speech command for positioning. One participant suggested using distance and a direction (eg, "20 centimeters left"), but others found this complex and time-consuming. Participants mainly agreed that having the possibility to go back to the previous position could be beneficial during operations. Regarding light intensity, one of the participants recommended using percentages. Another suggested using numbers from 1 to 10. For gesture interaction, a participant suggested moving a fist up and down to adjust the light intensity, similar to dragging a slider. Similar to the light intensity, numeric commands were recommended for speech input to adjust the illumination field. For gestures, 1 participant suggested using both hands in an L-shaped form (fully opened thumb and index finger, while other fingers are closed) and moving them closer or further away to make adjustments. The group also favored this, although it did not follow the one-hand-in-use recommendation. Predefined light settings were highly favored by the participants. All participants agreed that such a feature could be valuable for the OR and could help save time. One participant said, "We can use a specific setup and call it 'scenario 1', and then just say 'scenario 1' if we want to use this setting" (P3 in FG1).

Feedback on Animated Videos

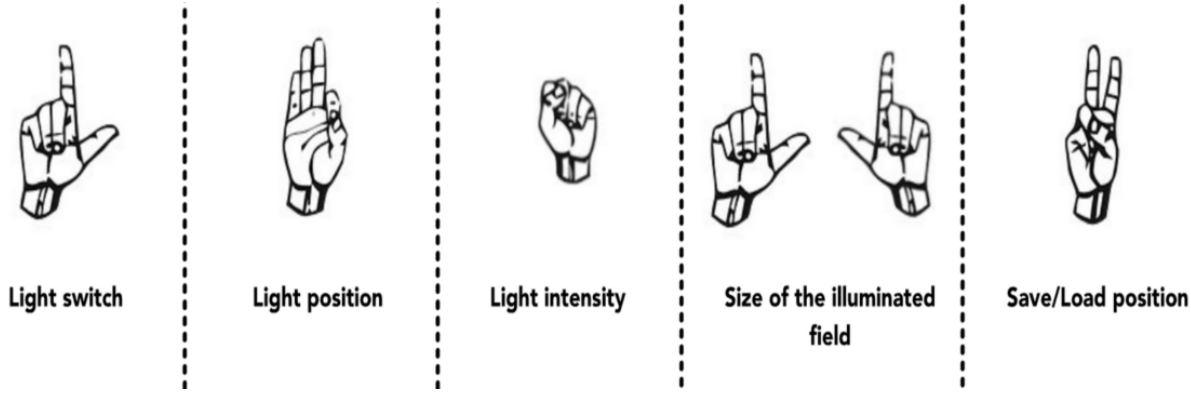
Participants commented on the initial interaction concept based on the animated video. They generally liked the interactions and found them intuitive. Experts found some speech commands long and highlighted that they must be quick and short. Participants found the wake word sufficient but suggested using their recommended phrases instead. They found it appropriate to switch the lights with speech. Similarly, participants believed that modifying the light's position with hand gestures is intuitive and would be challenging with speech. Nevertheless, they found it helpful to use speech for predefined positions, including the previous position. It was mentioned that hand gestures used for the concept are easy to remember. Two participants recommended adjusting the system with both modalities to give the personnel more options and to allow them to choose the best based on circumstances.

Concerns

Similar to the interviews, experts had concerns regarding the reliability of the technology. They were skeptical about the accuracy of recognition of both speech and gesture. One expert mentioned, "It is critical to lower the stress level in the OR. At the moment, with this technology, I feel a bit stressed." (P1 in FG1). Participants were worried about the use of speech in the OR due to the high noise level. They repeatedly noted that surgeons may be unable to adjust the lamps as accurately as the current lights. Furthermore, 2 participants were concerned about the additional cognitive load on the surgical personnel caused by complicated interactions. They were worried that the surgical personnel might not remember the commands quickly enough in a stressful situation. Three participants suggested having a backup control for such situations. Regarding speech, 1 participant was skeptical about recognizing commands with different dialects.

Adjustments to the Interaction List

Considering the insights of the interviews and focus groups, we refined the interaction concept. Regarding speech commands, we shortened some of the commands and changed the wake word based on the expert recommendations to "Hey, light!" Because "light" was the favorite suggestion during focus groups, we adjusted it based on the technical recommendation by adding "hey" in the beginning to enhance the recognition and prevent false activation of the system. We also modified the predefined lights into saving and loading positions, where users could save specific lighting conditions and load them later on. To activate the gesture system, in line with recommendations from Dietz et al [1], the user could hold the gesture they will use to edit the



XSL•FO
RenderX

light settings for a certain period to perform an action. In this way, the probability of false positives will also be lowered, as it is less likely that surgical personnel will hold a specific gesture for a specific period. For instance, if the user wants to adjust the position of the light beam, they must hold the gesture for positioning the light first for a specific period. Once the system has been activated, the user is notified with auditory feedback that the gesture has been recognized, allowing the command (while maintaining the gesture) to be executed. We empirically set this time to 1.5 seconds after our initial testing sessions. The gesture system is deactivated when the command is executed until the next activation. Unlike Dietz et al [1], the user must only hold 1 gesture to activate and execute the command. In their approach, the activation gesture differed from the interaction gesture. To switch the lights on or off with hand gestures, users must hold an "L-shaped" hand gesture (Table 2) and move their hands in front, resembling the act of switching the lights on or off in the real world. Users must hold an "OK" gesture to position the light beam. The light would then follow the tip of their thumb and stop tracking once the hand is opened (Figure 3).

Table 2. Interactions in the virtual reality prototype for speech.

Interaction	Speech
System activation	"Hey, light!"
Light switch	"Lights on/off"
Light position	"20 centimeters left"
Light intensity	"Intensity 75"
Size of the illuminated field	"Angle 15"
Save or load positions	"Save/load position two"

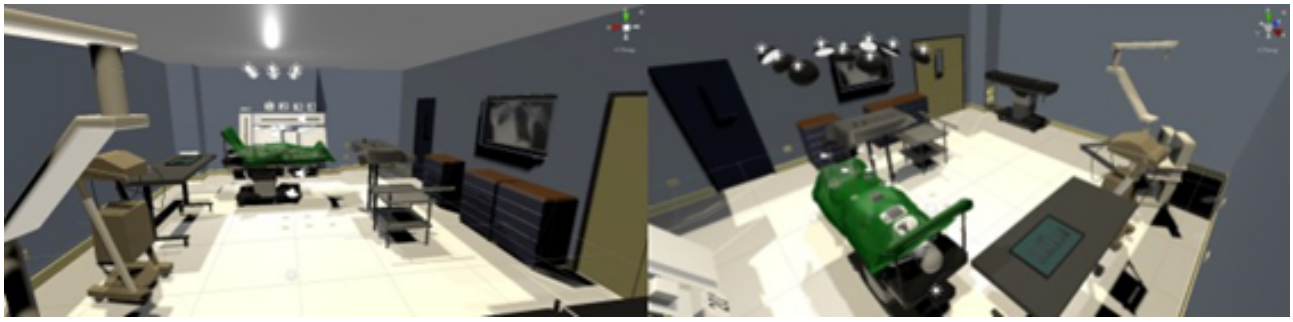
Figure 3. Interactions in the virtual reality prototype for gestures.

This gesture was chosen as it would resemble grabbing the beam of light and moving it around. To modify light intensity, we implemented the "fist" gesture. Users have to move their fists up or down to increase or decrease the light intensity. We chose the "peace" gesture to save and load the positions. To save, the user has to move the hand forward and backward for loading. To choose a specific number to save or load, the hand has to be moved left to choose slot number 1 or right to choose slot number 2. For instance, if a user wants to save a specific position as position 2, they first have to move the hand forward and then to the right. This hand gesture was inspired by changing gears in a car. To change the size of the illuminated field, both hands have to be held as "L-shaped." The closer the hands would get, the smaller the size, and vice versa. The complete list of interactions can be found in Table 2.

Methods 3: VR User Study

Overview

After adjusting the interaction concept, we implemented it in a VR prototype. In this prototype, one could adjust the SLS in a virtual OR using gesture and speech interaction. Both modalities were supported for every individual interaction. We designed the interactions based on the experts' recommendations, technical considerations, and suggestions from the aforementioned literature. After developing the VR prototype, we consulted 2 surgeons and discussed the interactions that had been implemented with them before conducting the study. On the basis of their feedback, we made final adjustments to the prototype. We then tested the prototype with 2 novice users to identify and resolve further issues. For this study, we did not implement the functionality to return to the previous position to reduce study time and prioritize more essential interactions, as this was considered a minor feature.



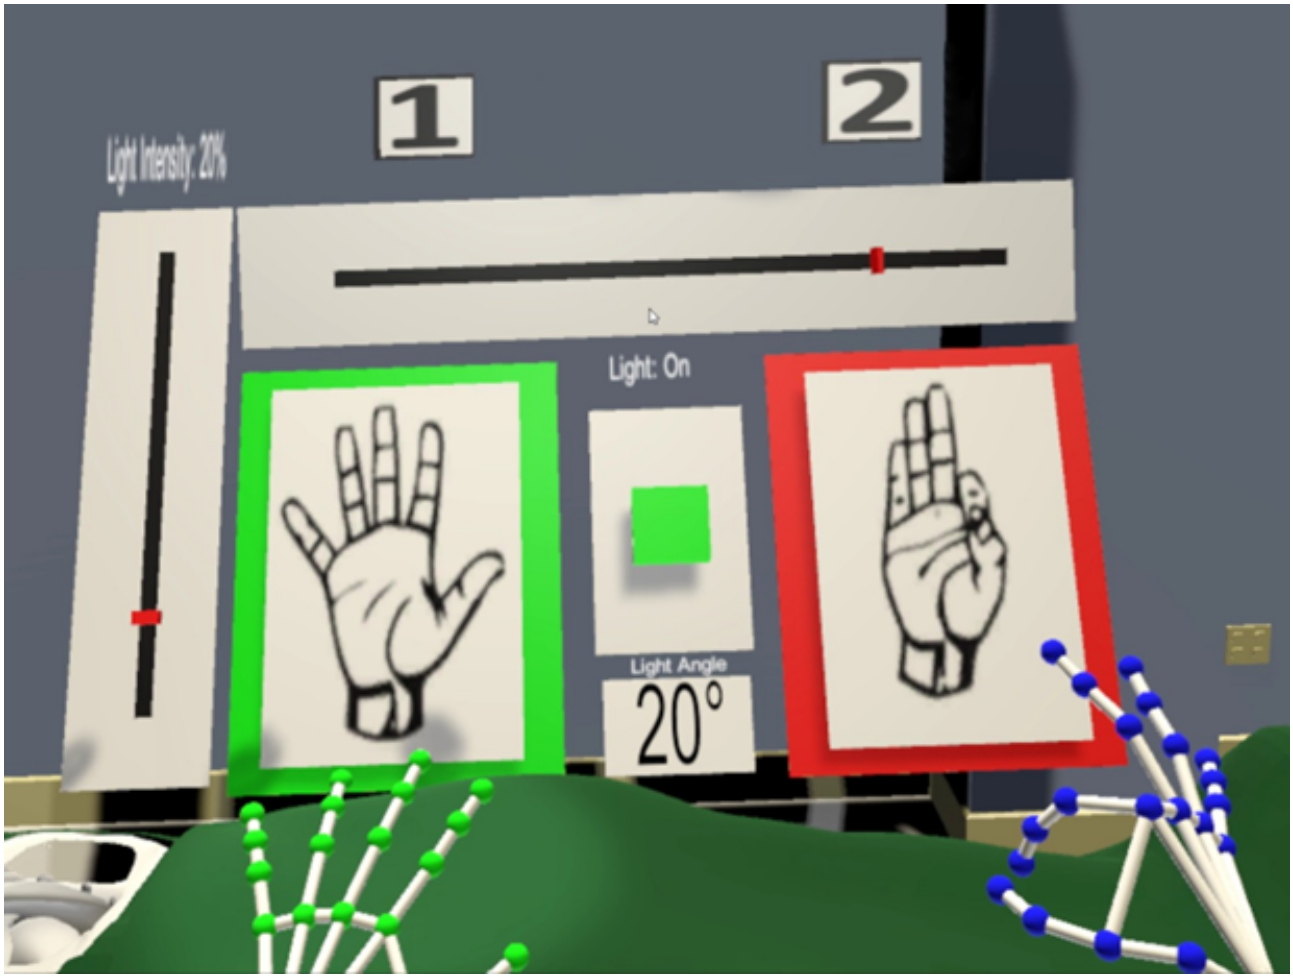
Implementation

The prototype was implemented in Unity 3D [56]. We used Valve Index [57] VR glasses to conduct the study. A virtual OR was designed to simulate a natural environment (Figure 4). We used the Picovoice Speech-to-Text library [58] for speech recognition and the Valve Index's 2 built-in cameras for gesture recognition using the hand-tracking SDK by HTC Vive [59].

XSL•FO
RenderX

A neural network classified the detected hands after matching features had been computed.

Figure 4. The virtual operating room used for the virtual reality study.



Feedback System

Both auditory and visual feedback were developed for the prototype based on recommendations from previous research [1]. Brief auditory feedback was played after the system was activated and commands were executed. The audio clips were short and subtle to not annoy or overload users with auditory feedback.

The visual feedback system was aimed at providing supplementary information regarding the hand gestures so the participants could understand the interactions better. This feedback system would show participants their current recognized hand gestures for both left and right hands using 2 separate boxes (Figure 5). The border of the boxes representing hand gestures could be either red or green. The border would turn green when a gesture was held for 1.5 seconds. This meant that activation occurred, and the designated interaction could be done. The border is red if activation has not yet taken place. A green button in the center represents the light switch. The button would be pressed when users hold the designated gesture for the light switch (“L-shaped”) and move forward. Below this button, a number shows the size of the illuminated field. For this, we used degrees rather than the diameter or the radius of the light, as the diameter could change with repositioning on uneven surfaces. Furthermore, a slider on the left side showed the degree of light intensity. Another slider at the top showed the save and load slots.

Figure 5. Visual feedback implemented in the virtual reality prototype.

XSL•FO
RenderX

Participants

Six experts took part in our study. The information about the participants' demographics can be found in Table 3. The participants included a chief physician, 2 senior physicians, and 3 assistant physicians. All were from the general and visceral surgery discipline. All surgeons regularly take part in operations (at least 2 times a week), besides one of the assistant surgeons, who takes part in operations once every 2 weeks. Only 2 surgeons had previous experience with VR, and 1 surgeon had experience with voice-based systems.

Table 3. Demographic information of the participants in the virtual reality study.

Participants	Sex	Age group (y)	Experience (y)
1	Male	56-60	26-30
2	Male	31-35	6-10
3	Male	31-35	1-5
4	Female	36-40	11-15
5	Female	36-40	6-10
6	Female	31-35	1-5

Procedure

In the beginning, the participants were informed about the procedure and risks of the study. After giving informed consent, the experts were given a detailed explanation of how the gesture and speech systems work and how the feedback system functions. They then spent 15 to 20 minutes familiarizing themselves with the VR environment. Furthermore, during this time, the participants were also asked to complete all the interactions at least once using both modalities to familiarize themselves with both speech and gesture systems. Subsequently, the experimenters explained the tasks for the study. Each participant had to perform the task in 3 rounds: once only using speech; once only using gesture; and in the last iteration, participants were free to choose the modality for each interaction. For the first 2 iterations, we changed the order of the modality for each participant to avoid order effects. In each iteration, the participants had to start by switching on the lights. They then had to position the light and adjust the illumination field, so it was positioned between the 2 drawn white rings (Figure 6). Then, they adjusted the light intensity by making it as bright as possible while not so bright that the gray tones could no longer be distinguished (Figure 7). Finally, they had to save the light settings and turn off the lights. After each iteration, participants answered a series of interview questions. The questions addressed aspects such as learnability, memorability, familiarization, audio and visual feedback systems, suggestions for improvement, and opinions on individual commands. Each session took approximately 40 to 50 minutes.

Results 3

Overview

Our results showed that participants found the concept compelling and helpful. All experts stated that they could imagine using the system regularly in the OR as a new system or as an add-on to the conventional lights. We witnessed that the experts often prioritized one modality over the other. Three participants suggested that gestures were generally more intuitive and easier to use, while others believed that speech was more convenient and faster to learn. One reason mentioned for this prioritization was that it was easier to master 1 than the 2 modalities. Two participants pointed out that the touch-free aspect of the interactions was a great advantage and very beneficial in the OR. They mentioned that such a system helps keep sterility and avoids asking other staff members to perform specific actions. On the other hand, 2 experts believed that the system is still not ready to fully replace a conventional SLS due to error rates and the time it takes to execute the commands, as it would be a potential risk in time-critical or emergency situations such as stopping heavy bleeding. They pointed out that the precision needs to be extremely high and the interactions even quicker.

Feedback Systems

All participants agreed that the audio feedback was helpful. Four experts mentioned that such feedback is necessary, especially for triggering the commands. Two participants noted that the auditory feedback could be turned off after a training phase for visible interactions such as positioning the light. However, 2 others mentioned that they could not imagine the system working well without auditory feedback. Participants found the activation tone of the speech system more helpful than the confirmation tone because the successful execution of the command is mainly confirmed by the visible changes in the light (with the exception of the save and load command). Regarding the visual feedback interface, 5 participants found it to be helpful, especially in the beginning. Four experts mentioned that they could use the system without visual feedback after a short training. However, 1 participant found the visual feedback disruptive and suggested only using auditory feedback.

Interactions

All but one participant found the gesture system intuitive and easy to learn. All agreed that with a short familiarization phase, one could understand and learn to interact with the system. However, 2 participants indicated that our familiarization phase was too short for the gesture interactions, and they recommended prolonging that to 30 to 60 minutes. Two participants found the execution of gestures to be ergonomic and quick. Three participants highlighted that knowing the commands from similar activities helped them to learn the interactions faster and the execution of the commands easier. Five experts believed that gesture interaction was more appropriate for positioning the light, as it was more precise. One participant found the load and save gesture command rather tricky and unintuitive. Another participant noted that it was unclear how to stop the hand tracking after performing the command. One participant found the gesture recognition not precise enough. The error rate for this user was higher than that of all other participants. Similar to the gesture system, all participants perceived speech commands as intuitive, fitting, and easy to remember. Two participants added that they particularly liked that the commands were short, which can be advantageous when used in the OR. One participant highlighted the high accuracy of the speech system. Two participants specifically praised the wake word “Hey, light!” and found it appropriate and fitting. One participant remarked that the trigger functions or functionality switches [11,38] are very suitable with voice commands because performing them requires little cognitive and physical effort (eg, light switch). A major criticism that was pointed out by 3 participants was about setting continuous parameters with speech, such as positioning the light beam. They found such interactions overly complex and confusing. One expert noted that estimating the numbers as measurements needed for the voice command is difficult. All participants wore medical masks during the study. We did not observe any negative impacts caused by wearing the mask. One of the participants believed that using the German language would be more convenient for the speech system. Others found English to be appropriate and sufficient. One participant experienced difficulties with the speech commands due to their accent.

Modality Preferences

Participants’ reasons for choosing a modality over another were based on the number of commands needed for execution, the

XSL•FO
RenderX

speed of the interaction, the cognitive and physical effort, and the precision of the commands. All but one participant used a mixture of both speech and gestures to go through the tasks in the last iteration. Table 4 shows the chosen modality of all participants for individual interactions in the third iteration. Among the 5 subtasks were 2 trigger functions and 3 continuous parameter settings. We observed that parameters were preferred to be set by gesture, as the dynamic feedback would help to interact more precisely. For such interactions, multiple speech commands were often needed to set the parameters accordingly. In the subsequent interview, we asked the participants why they chose a particular modality for each command in the last iteration. During these interviews, we found that, although participants might have preferred one modality over the other, 2 participants chose the less favored one to give it another chance. One participant who experienced problems using the speech system due to unclear English pronunciation performed all the tasks in the last iteration with the gesture. One participant indicated that they mainly worked with speech, as the familiarization phase was too short for them, and they forgot how to carry out the command with the other modality. All participants stated they could use the system entirely without further help after a short training period. Two participants stated that having both modalities simultaneously during surgeries is beneficial. One said that they would be able to use voice commands when their hands are busy or gesture when the noise level in the room is very loud. No participant expressed a negative characteristic of using both modalities simultaneously. Participants particularly emphasized the advantage of dynamic feedback and fine motor skills when setting continuous parameters with gestures, as well as speed and the low cognitive and physical effort in trigger functions when using speech.

Table 4. The selected modalities for each interaction in the third iteration of the virtual reality study.

Interaction type	Speech	Gesture
Light switch	5	1
Position	1	5
Intensity	3	3
Field of illumination	0	6
Save or load	4	2

Methods 4: Living Laboratory Study

Overview

The interaction concept was implemented in a prototype to be tested in a living laboratory. Similar to the VR study, participants could adjust the SLS in a living laboratory using gestures and speech, where every interaction could be made with both modalities. In this study, we used smart lighting modules introduced by Mühlenbrock et al [20] to test our interaction concept. This novel lighting system is specifically designed for the OR, which uses an array of small lighting modules mounted on the ceiling [20].

Smart Ceiling Lights

Each module is equipped with 2 motors for directional adjustment. The modules are arranged in a 7×8 grid with distances of 0.36×0.35 m and are controlled by a central computer that adjusts their intensity and orientation (Figure 8). To minimize shadows, the system uses geometry recognition of objects and personnel within the surgical area via 3 Kinect (version 2) [60] sensors, which are registered with each other and with the room. However, the automatic shadow prevention feature was disabled during the study. The lighting system provides an application programming interface that accepts commands for the absolute target position of the light in 3D space, relative adjustments to this position, and changes in lighting intensity. It then adjusts the motors and intensity of the lights accordingly. While individual modules are capable of providing up to 50 klx, compliance with medical standards limits the system to a maximum of 160 klx. The paper by Mühlenbrock et al [20] provides further details on the ceiling lights.

XSL•FO
RenderX

Figure 8. Smart ceiling lights used for the living laboratory study, consisting of an array of small lighting modules.

Interaction Concept Integration

We integrated our interaction software with the lighting system application programming interface to be able to interact with the lights using our touch-free concept. The prototype was implemented in Python (Python Software Foundation). We used Kinect Azure [61] for tracking hand gestures and used the Picovoice Speech-to-Text library [58] for speech recognition. A neural network classified the detected hands after matching features had been computed.

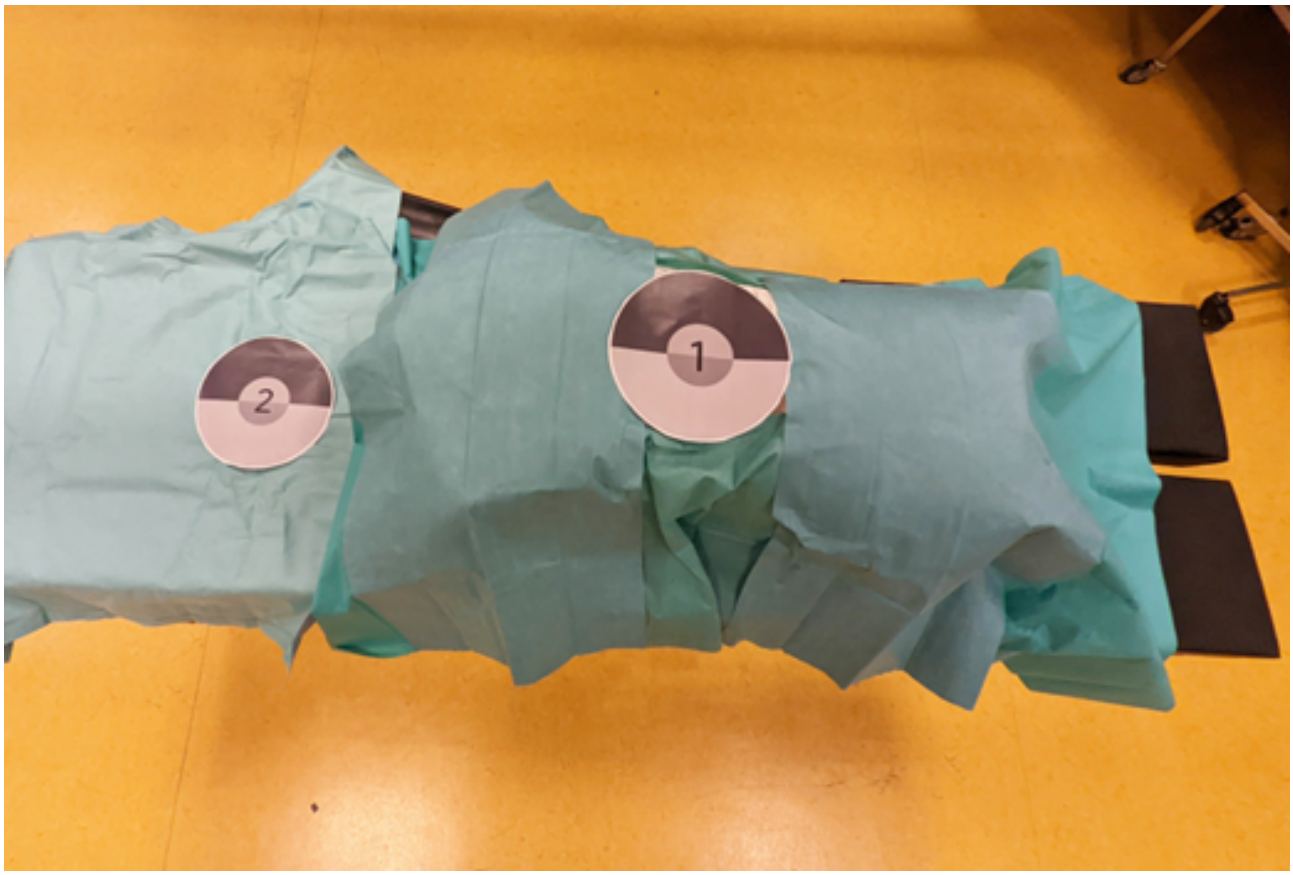
Due to the limitations regarding the motors in individual light modules, we were not able to change the field of illumination adequately. Therefore, we excluded this interaction from this study. The rest of the interactions were identical to the ones in the VR study (Table 2).

Moreover, in a realistic surgical environment, multiple hands may appear within the camera's field of view, complicating accurate hand recognition. To address this, we used the Kinect RGB camera and trained the system to track hands wearing a specific color of gloves—in this case, blue. This way, we could ensure that the system only tracks the designated surgeon's hands to adjust lights. Testing confirmed that only hands with blue gloves were detected. A notable advantage of this method is its ability to restrict access to authorized users based on glove color. However, a limitation arises when gloves become bloodstained, as red-tinted areas may hinder recognition. To mitigate this issue, the algorithm could be adapted to reassign red pixels to a skin-like color space to ensure consistent recognition.

Participants

For this study, we recruited 12 experts. Other than 1 medical student, all other participants were surgeons or assistant surgeons, and they regularly took part in operations (at least 2 times a week). The information about the demographics of the participants can be found in Table 5. All participants were from the general and visceral surgery disciplines.

Table 5. Demographic information of the participants in the living laboratory study.



Participants	Sex	Age group (y)	Experience (y)
P1	Female	21-25	1-5
P2	Male	41-45	16-20
P3	Male	46-50	21-25
P4	Female	26-30	1-5
P5	Male	31-35	6-10

P12	Female	26-30	1-5

XSL•FO
RenderX

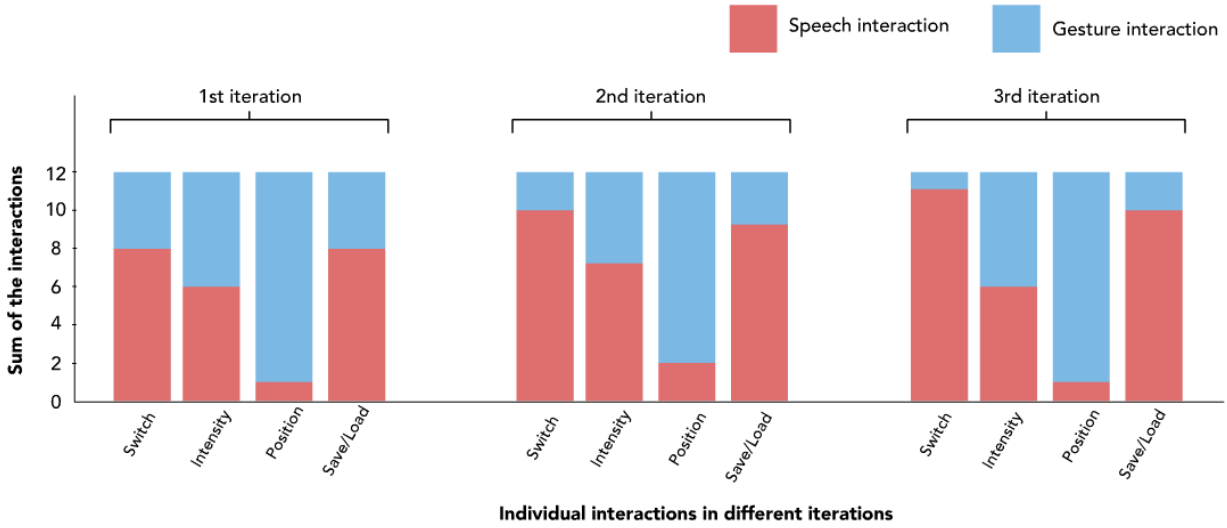
Procedure

After a short welcoming conversation, participants were briefed about the study procedure and gave informed consent. All participants were given a detailed explanation of how the interaction with the system works and how to use both modalities of gesture and speech. Participants then spent around 10 minutes familiarizing themselves with the system by performing all the supported interactions at least once using both modalities. Afterward, the experimenter explained the tasks to perform for the study. Similar to our VR experiment, each participant had to perform the task in 3 rounds. However, this time they could choose which modality to use for individual interactions in every iteration. For each iteration, we used 2 circular position marks, numbered mark 1 and mark 2 (Figure 9). Participants had to position the light on each ring, save that position with the mark's associated number, and switch between the 2 positions by loading the previously defined positions. The light intensity had to be set differently for each mark. One had to have a higher intensity and one, a lower intensity. Adjusting the size of the illuminated field was not considered in this study due to technical limitations with the physical lights in the living laboratory. The participants chose the order of the tasks to perform, and the experimenters suggested no strict order. At the end of each iteration, participants took a short break and continued with the next one. Once the last iteration was through, a semistructured interview was conducted where experts answered a series of questions about the overall system, learnability, memorability, familiarization, audio feedback, suggestions for improvement, and opinions on individual commands. Sessions took approximately 30 (mean 31.91, SD 4.85) minutes.

Figure 9. Setup of the user study in the living laboratory.

Results 4

Interaction Ratings



Our results indicated that most participants (11/12, 92%) found both speech and gesture interactions appropriate for their intended actions. Most participants (9/12, 75%) envisioned using such a system in the OR regularly. All participants agreed that, with a brief training period, they could use the system without needing ongoing technical support. While 2 participants suggested that the training might take up to a week, the remaining participants believed it could be completed in under an hour. They described the interactions as "fast and easy" (P3). We witnessed that the experts' performance improved over time. We saw that they worked easier with the system in the second and third iterations compared to their initial attempts. This trend suggests a positive learning effect with increased exposure to the system. Initially, during the first 2 iterations, participants were open to using both speech and gesture modalities for various interactions. However, by the final iteration, clear preferences for specific modalities had emerged depending on the task (Figure 10). For certain interactions, distinct modality preferences became apparent. Participants found speech more suitable for trigger functions, such as switching lights or saving and loading lighting conditions. Conversely, gestures were preferred for continuous parameters, such as positioning the light. Opinions on controlling light intensity were divided: half of the participants found gesture

XSL•FO
RenderX

interactions more intuitive, while the other half preferred using speech. All participants considered audio feedback as highly crucial for their interactions. A few participants (3/12, 25%) suggested using distinct sounds for different actions to help differentiate them more clearly. Participants found audio feedback particularly beneficial for specific tasks, such as positioning, as it provided essential information about the system's current state and alerted them when an action was not recognized.

Despite general satisfaction with individual interactions, participants provided several recommendations for adjustments and suggested new interaction features. Two participants recommended using shorter speech commands for adjusting light intensity. They proposed a simplified system where intensity is set on a scale of 1 to 10 rather than using percentage values. One participant (P5) suggested adding a feature to disable gesture tracking via speech commands to prevent misrecognition and unintended hand tracking. Participants also recommended the ability to revert to a previous light configuration. There were suggestions to combine modalities for specific interactions. For instance, 1 expert proposed a mixed approach for the save and load function: initiating the action with a gesture and then using speech to assign it to a specific slot (eg, "Save two"). However, 4 participants found the gesture-based save or load interaction unintuitive and overly complex. Two participants noted that this interaction was cognitively demanding because it required memorizing which position corresponded to each number. One participant suggested using specific names for save slots (eg, "save stomach") instead of numerical labels. In addition, 5 participants explicitly mentioned that using speech commands for positioning was inappropriate. They found it required excessive effort and approximation, making it less effective compared to the gesture.

Figure 10. Bar chart showing the experts' selected modality for each interaction on all 3 iterations.

Experimenter Observations

We observed that the field of view of the depth camera used to track hand movements positioned above the surgical bed was limited. Experts noted the desire to move the surgical light into zones that fell outside this camera's range. This limitation could be addressed by integrating multiple cameras, which would expand the tracking area and potentially enhance gesture recognition accuracy. Despite the system's capabilities, we still encountered several recognition errors for both speech and gesture modalities. To ensure reliability, these systems require better training and increased accuracy, especially in a high-stakes environment like an OR where patient safety is critical. The current system's precision needs to be enhanced to meet the strict demands of surgical settings. We found that participants' proficiency with the system improved over time with increased use. This suggests that future implementations should include longer and more comprehensive training sessions to help users become adept at operating the system efficiently. Four participants reported that the gesture-based positioning of the surgical light was slow. This issue stemmed from the limitations of the motors used in the light modules, which caused a noticeable delay in moving the light. Addressing these mechanical limitations could improve the system's responsiveness and enhance the user experience.

Discussion

Principal Findings

In this work, we examined a hands-free solution for controlling an SLS in the OR. In an iterative design process, we developed a system that uses speech and gestures as interaction modalities to control the SLS. We observed that surgeons and practitioners found such a system highly valuable and practical. They believed that this system could certainly support sterility and give them more direct control over the SLS.

Our results highlighted that the combination of modalities was a quite helpful approach, supporting the previous literature [10,29,42]. We witnessed certain interactions (specifically, triggers) that were much better suited to be performed by speech and others better suited with gesture (continuous parameters), in line with previous work [11,38]. In line with the recommendation from Mentis et al [11], our participants also suggested having the opportunity to be able to use both modalities for each interaction to have higher flexibility. We

XSL•FO
RenderX

witnessed that experts often preferred one modality over the other, largely based on perceived cognitive load and familiarity with the modality. Participants' opinions differed on which modality they found less cognitively demanding; some considered speech interaction easier due to its directness and hands-free nature, while others preferred gestures for visual immediacy. These findings highlight the potential of multimodal systems to enhance interaction effectiveness. The clear observation that certain tasks are better suited to one modality over another highlights the advantages of leveraging the strengths of both speech- and gesture-based interactions. Although mastering both interaction methods might initially pose a cognitive challenge for users, we believe this can be mitigated through brief technical training and the design of intuitive interactions and significantly reduce cognitive demands over time. Moreover, multimodal systems also serve as a critical redundancy layer—ensuring functionality even if one modality fails. In addition, providing users with the flexibility to choose their preferred modality fosters greater satisfaction and increases the likelihood of broader adoption.

The list of functions we planned for the adjustment of the lights was consistently found to be practical and useful by participants. Notably, participants highly favored predefined light settings, aligning with findings from previous research [3], as these settings simplify operations and save time for the personnel. The individual interactions were mainly found to be intuitive and usable. However, certain interactions that were not matched well with their modality were criticized, for example, saving and loading light settings with gesture. As this is considered a trigger function, speech seems to be the more intuitive modality to use. Participants found the freehand control aspect of using speech quite helpful. This meant the surgeons could use both hands at all times and focus on their primary tasks, as pointed out by previous work [38,39]. Furthermore, it is common that during surgeries, multiple hands are actively working on the patient, making it challenging to identify the correct hand for gesture control. Another concern with gestures is that they can cause collisions, a problem that does not occur with speech. On the other hand, speech is less appropriate for fine adjustments and more exact changes, as seen in our evaluations. In addition, a loud OR environment and problems with speech recognition, such as the accuracy for nonnative speakers or people with accents or certain dialects, could also be raised. These issues further emphasize the benefits of a multimodal system, where challenges with one modality can be mitigated by leveraging the strengths of the other.

A key advantage of our proposed system was the enhanced agency it could offer to the main surgeon. This was particularly appreciated when the surgeons' hands were occupied, as they could still control the lights, providing them with higher control and efficiency. Experts highlighted the benefit of eliminating the need to rely on additional personnel for adjustments, potentially reducing errors and saving time [2].

Throughout our examination, we observed that the biggest concern raised by the experts was the technological limitations, such as accuracy and functionality problems with the systems. In different stages of our evaluation, participants faced certain challenges with inaccuracies where the developed system did not behave as the experts intended it to do. The experts repeatedly highlighted that in such a sensitive context where patients' safety could be impacted, there is no room for error. Hence, the system ideally has to function error-free with perfect efficacy. As previous work highlighted, events that require unnecessary actions from the surgeons could hinder their performance [2]. It comes as no surprise that systems deployed in sensitive environments, such as health care, must prioritize reliability and error mitigation. Experts' emphasis on error-free operation highlights the unique stakes in surgical contexts, where minor inaccuracies could risk patient safety. In such high-stakes applications, designers must aim for the highest technical accuracy and consider appropriate backup methods and error recovery means to safeguard against unanticipated failures. Several technical concerns were highlighted, including the high noise levels in the OR and worries about their potential impact on speech command accuracy, as well as the challenges of achieving the high precision required for fine adjustments. Addressing these challenges is essential, and future research should focus on developing solutions that specifically mitigate these issues to ensure reliable system performance. Moreover, we observed that few participants did not trust the technology to work seamlessly due to old experiences or unfamiliarity with the technology (eg, "speech will not work well!"). Our participants highlighted that the lack of trust in the technology could raise the stress levels of the surgeons. Skepticism stemming from users' past experiences or unfamiliarity with the technology underscores the importance of fostering trust through transparency, education, and hands-on training with novel systems. Bridging the gap between perceived and actual system reliability through effective communication and usability testing is essential for promoting user trust and ensuring successful integration. A gradual adoption in low-risk contexts (such as VR simulation) can build confidence before full integration in critical tasks.

Limitations and Future Work

Our results offer valuable insights into using a touch-free interaction approach for controlling the SLS in the OR. Nevertheless, our work has certain limitations that require acknowledgment.

In our iterative evaluation, we mainly relied on qualitative approaches to assess our concept and interaction system. This provided us with in-depth insights into user perceptions, behaviors, and subjective experiences, enabling us to refine and improve the system based on detailed feedback and observations. However, for future work, incorporating quantitative approaches will be crucial to measuring usability, cognitive load, and user experience more objectively. By using metrics such as task completion times, error rates, physiological measurements, and standardized questionnaires, we can obtain a comprehensive understanding of the system's performance and its impact on users, ensuring a more robust and reliable evaluation. Moreover, our designed system was still a prototype, and participants encountered technical challenges at various stages. Future work should also focus on better training the systems to improve recognition rates, providing a more reliable foundation for such interaction methods.

XSL•FO
RenderX

Our studies primarily consisted of laboratory experiments and interviews. As an initial approach, this selection of methods is reasonable, providing controlled conditions to refine the system and gather preliminary insights. Nevertheless, testing the system in more complex environments and realistic situations—such as in noisy environments, with multiple hand-in scenarios, and across various surgical disciplines—would be beneficial. This would help us observe and address potential challenges and limitations, ensuring the system's robustness, adaptability, and effectiveness in real-world applications.

Finally, in our experiments, we observed that longer training sessions with the system could have led to better performance from the experts. Therefore, we recommend extended familiarization phases to allow users to become more acquainted with the system, enhancing their proficiency and effectiveness. Future work could also explore the optimal duration and structure of these training sessions.

Conclusions

This work sought to develop an intelligent interaction concept for controlling an SLS. We designed a touch-free interaction concept using speech and hand gestures to control the SLS. In an iterative process, using a user-centered design approach, we used a 5-step design process including a literature review and OR visits, interviews with surgeons and assistant surgeons, focus groups with the OR personnel, a VR evaluation, and a living laboratory study. Our findings suggest that experts find our interaction concept highly useful and beneficial for the OR. Despite facing technical challenges, surgeons saw great potential for such a touch-free approach and could imagine using it regularly in the OR. Moving forward, further refinement and validation of such a multimodal system will be essential to fully realize its potential in real-world surgical settings.

Acknowledgments

Abstract

Background: Chronic pain is prevalent among adults with sickle cell disease (SCD) and can be worsened by psychosocial factors such as depression and inadequate social support. Effective behavioral interventions (eg, cognitive behavioral therapy [CBT]) exist for chronic pain in various populations; however, few have been developed to address chronic pain in SCD. Several barriers have restricted the development and dissemination of CBT pain interventions in SCD, such as limited accessibility and time constraints. Digital interventions provide accessible and cost-effective pain management tools, offering self-management strategies, real-time monitoring, and personalized treatment options. Yet, there are limited data regarding patients' experiences with such interventions within the SCD population. The Cognitive Behavioral Therapy and Real-Time Pain Management Intervention for Sickle Cell Via Mobile Applications (CaRISMA) trial evaluated the effectiveness of a digital CBT intervention compared with a digital educational intervention for pain management in SCD. Evaluating participants' experiences can guide refinement of digital pain interventions in SCD.

Objective: This study aimed to gain a deeper understanding of the lived experiences of participants in the CaRISMA trial and to determine how to better adapt this intervention to the SCD population. The study examined individuals' overall experience with the trial and their perspectives of the trial components: a health coach, a chatbot-delivered digital CBT program, and an electronic pain diary.

Methods: Respondents were randomly selected to participate in semistructured interviews at (1) baseline, (2) the end of the intervention period at 3 months, and (3) the postintervention time point at 6 months or beyond. Interviews were audiotaped, transcribed verbatim, and analyzed using conventional content analysis.

Results: A total of 48 participants (women: 33/48, 69%) completed the interviews, with 24 and 19 completing midpoint and postintervention interviews, respectively. Participants generally had a positive experience in the trial. Many found value in learning about the connection between pain and mental health, considering it an important aspect of their well-being. The health coach played a key role in offering personalized support and guidance. Although the chatbot reinforced pain management strategies, its usefulness and engagement varied based on participants' prior knowledge of SCD. The pain diary helped increase self-awareness of pain patterns but was perceived as tedious and irrelevant by those without current pain episodes.

Conclusions: This qualitative substudy of the CaRISMA trial showed that participants valued the personalized support of the health coach, education about the connection between stress and pain, and the self-reflection fostered by the pain diary. These findings highlight the potential of digital, patient-centered approaches to address the multifaceted needs of SCD care. For digital

XSL•FO
RenderX

interventions, the inclusion of personalized support with ongoing communication appears to be a critical component that can influence treatment adherence and effectiveness.

behavioral; digital intervention; sickle cell disease; chronic pain; pain

Introduction

Sickle Cell Disease

Sickle cell disease (SCD) is a genetic disorder characterized by recurrent acute episodes of severe pain, commonly referred to as "pain crises," and chronic pain that can persist between these episodes. The unpredictable nature of SCD-related pain, combined with the physical and emotional burden of living with a chronic illness, leads to high rates of depression, stress, and reduced social support [1,2]. Additionally, stress and depression can further exacerbate pain, creating a cycle in which physical and emotional distress reinforce each other. Historically, pain interventions in SCD have focused on pharmacologic treatments, yet comprehensive biopsychosocial approaches that address both the physical and emotional aspects of SCD pain management remain limited. The 2019 American Society of Hematology guidelines for the management of SCD recommend a comprehensive approach to pain management, including pharmacologic treatments alongside behavioral health interventions that address psychological and social contributors to pain [1]. Despite these recommendations, access to integrated biopsychosocial care remains limited, leaving many individuals with unmet behavioral health and psychosocial coping support needs [3].

Cognitive Behavioral Therapy for Chronic Pain

Cognitive behavioral therapy (CBT) is a first-line, evidence-based treatment for chronic pain endorsed by the American College of Physicians and the United States Centers for Disease Control and Prevention [4,5]. CBT effectively improves pain outcomes in several chronic conditions, including SCD [6-8], by addressing psychosocial contributors to pain such as maladaptive thought patterns, promoting behavioral activation, and equipping individuals with coping strategies. CBT has also been linked to improved emotional regulation, self-efficacy, and health-related quality of life in patients with chronic pain.

Digital Interventions for SCD

Despite its effectiveness, access to CBT has been limited by barriers such as lack of transportation, costs, provider shortages, and scheduling conflicts. Digital behavioral interventions offer a promising avenue to expand access to behavioral health support, especially for individuals with chronic illnesses like SCD who face barriers to in-person care; however, the use of digital interventions in SCD has been limited. Digital CBT programs have demonstrated effectiveness for improving pain-related outcomes, coping skills, and mental health across chronic pain populations. Furthermore, when compared with non-CBT mobile apps, CBT-based apps demonstrated greater efficacy for behavior change than non-CBT apps, likely due to structured use of CBT techniques, engagement in cognitive reframing tasks, and empowerment of users [9]. However, there is limited evidence on the effectiveness and user experiences with digital behavioral health programs specifically designed for individuals with SCD [6,10-13], a population with unique medical, cultural, and psychosocial needs. Individuals with SCD report mixed experiences with available digital health interventions: Some found these tools helpful for learning coping strategies and tracking symptoms, while others noted limitations such as insufficient personalization or a lack of cultural relevance to the unique challenges of SCD [14]. In the context of SCD, where pain is deeply intertwined with stress, mood, and self-efficacy, digital CBT offers a targeted and scalable tool for helping individuals manage pain both psychologically and behaviorally, but more high-quality clinical trials of digital CBT interventions are needed.

Initial Development of a Digital CBT Intervention: Beginning With Addressing the Challenges in SCD Clinical Trials

Clinical trials in SCD face significant recruitment and retention challenges. Insufficient patient participation is a major impediment to the advancement of SCD research, with many studies terminating due to low enrollment [15,16]. A systematic review of 174 SCD clinical trials found that 14% were terminated specifically for failure to enroll participants, with only 35% of completed studies resulting in published manuscripts [17]. These challenges can be particularly pronounced for behavioral interventions, which require consistent engagement and are time-intensive for the participants. Our early research aimed to simultaneously address enrollment challenges and develop an accessible intervention by prioritizing people with lived experience. In collaboration with the SCD community, our group developed a digital CBT app adapted for adults with SCD. To explore the feasibility and preliminary impact of digital behavioral health tools in SCD, our group previously conducted a pilot randomized controlled trial with adolescents and young adults evaluating an earlier version of our CBT app compared with a CBT app for the general population [18]. The study demonstrated improvements in pain, self-efficacy, and depressive symptoms, highlighting the potential for digital interventions to address the biopsychosocial needs of this population. However, about 40% of participants did not engage with the digital interventions, revealing significant barriers to sustained participation.

Prior Work Refinement and Expansion of the Digital CBT Intervention: Further Addressing Engagement Challenges

To better understand the determinants of digital intervention engagement, we previously conducted a qualitative study using focus groups of adolescents and adults with SCD [18]. Participants identified 5 key engagement factors, including the importance of peer connection, personalized content and coaching, preferences regarding the coach's background (eg, a coach with lived SCD experience), the value of journaling and symptom tracking, and flexible engagement options [13]. These insights, along with data from our pilot randomized controlled trial, helped inform the design of the Cognitive Behavioral Therapy and Real-Time Pain Management Intervention for Sickle Cell via Mobile Applications (CaRISMA) trial. We randomized participants to 1 of 2 health coach-supported interventions: digital CBT versus digital patient education [19]. Participants also completed pain diaries during the study period. All components were designed to align with the preferences and barriers identified in our prior work, with the goal of creating a flexible, patient-centered digital platform for SCD pain management. Peer support delivered by health coaches was a core component of the intervention, as research suggests that peer-delivered models can build trust, improve engagement, and address barriers to mental health care in historically underserved populations [20-24]. In the primary outcomes study, we found that both the CBT and education interventions led to an improvement in pain interference; however, there was no significant difference between the arms [19].

This study focuses on participants' experiences in the CaRISMA trial and with the various components of the digital CBT program. Most of the previously published studies on digital interventions focus on single-component interventions [25]. Multicomponent, app-based interventions are less common but emerging [26]. The CaRISMA trial incorporated a multicomponent, culturally tailored platform that included peer-supported digital CBT, symptom tracking, and personalized chatbot engagement. Although there was no difference between groups, we found that digital CBT leads to improved pain-related outcomes [19]. Therefore, a critical next step is to better understand participants' experiences with the intervention components to in order to refine future approaches and enhance the likelihood of successful implementation in real-world settings.

Objective of This Study

This qualitative study aimed to gain a deeper understanding of participants' experiences with the CaRISMA trial, focusing on their perceptions of the health coach, chatbot, and pain diary components. By identifying key factors influencing engagement and satisfaction, we sought to better understand barriers to trial enrollment and retention in the SCD population, evaluate the potential for digital behavioral interventions to address this population's unique needs, and inform the implementation of culturally appropriate, patient-centered digital health interventions for individuals living with SCD.

Methods

Study Design and Setting

The protocol for CaRISMA has been previously published [27]. The CaRISMA trial enrolled adults with SCD who reported chronic pain (ie, pain at least 4 days a week over the past 3 months or longer). Participants of the CaRISMA trial were recruited from 7 comprehensive sickle cell centers and from 4 community-based organizations, either virtually or in person. Participants were randomized 1:1 to either the digital CBT or Education arm. Both arms had access to a health coach and a chat system via a chatbot. All participants were asked to complete daily pain assessments via an electronic pain diary app.

For this qualitative study, we aimed to recruit a diverse group of trial participants, stratifying our sample by depression severity assessed using the 9-item Patient Health Questionnaire (PHQ-9; PHQ-9≥10 vs PHQ-9<10) and trial arm (CBT vs Education). Trial participants were randomly selected for 1-to-1 semistructured interviews at baseline. We sought 24 interview participants from each study arm (CBT or Education), and within each of those 2 sets of 24 participants, we sought 12 participants with high depression severity (PHQ-9≥10) and 12 participants with low depression severity (PHQ-9<10). If a randomly selected participant declined to participate in the baseline interview, another participant was randomly selected until we had achieved a total of 48 interviews. This target was chosen based on a strong likelihood of achieving thematic saturation, the point at which additional interviews are unlikely to provide new insights [28,29]. Participants who completed baseline interviews were invited to participate in follow-up interviews at midtrial (3 months, end of intervention) and post-trial (between 6 months and 12 months) time points.

Intervention Components

Digital CBT

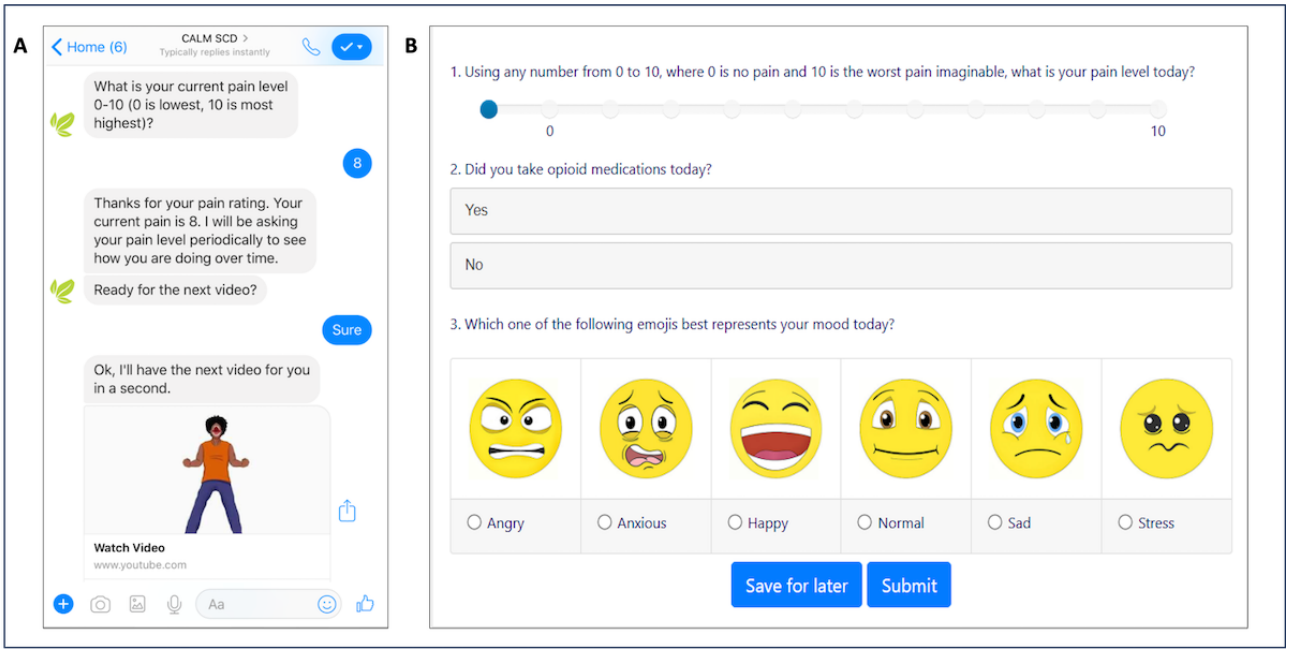
The digital CBT arm included a 12-week, tailored program designed for adults with SCD. It taught participants how to identify negative thoughts and emotions, use cognitive skills and problem-solving techniques, and apply effective coping strategies. The program focused on skill development through practice, homework assignments, and regular check-ins with a health coach.

Digital Education

The digital Education arm included comprehensive information about SCD and pain management through an interactive digital platform. Participants learned about chronic pain, lifestyle modifications, and SCD fundamentals while reinforcing their knowledge through interactive assessments. The program encouraged active learning by enabling users to discuss concepts with their health coach.

Health Coach

Health coaches—many of whom had personal connections as SCD patients, caregivers, or advocates—offered weekly support through phone calls or text messages, depending on participant preferences. Their primary role was to provide emotional support



XSL•FO
RenderX

and encourage active engagement with the digital platform. Each coach underwent comprehensive training and attended weekly group supervision sessions facilitated by a mental health professional and research lead.

Chatbot

The CaRISMA interventions were delivered by a scripted chatbot (Figure 1), which was developed in collaboration with patients, families, and community partners. The chatbot was accessed through the Facebook Messenger app and offered tailored responses, educational materials, and motivational content in various formats including videos, GIFs, and images, all adapted to participants' inputs. It also provided round-the-clock conversational support, adapting responses to each participant's unique circumstances and needs. Users were able to monitor their progress through the program, revisit materials they had completed, and view their accomplishments via progress metrics and achievement rewards.

Figure 1. Cognitive Behavioral Therapy and Real-Time Pain Management Intervention for Sickle Cell via Mobile Applications (CaRISMA) components including (A) chatbot interaction and (B) pain diary tracking.

Pain Diary

Patients were asked to track pain levels daily through a mobile web app, as illustrated in Figure 1. They received text reminders during 2-week assessment windows at the start of the study and at 3 months, 6 months, and 12 months. Between these formal tracking periods, they were encouraged to keep logging their pain scores in the app.

Qualitative Analysis

Analytic Approach

We used a qualitative descriptive approach for data collection and analysis, aiming to directly capture and summarize participants' experiences, thoughts, and feelings related to the interview topics. This approach is frequently used in health and medical research to provide clear and practical insights [28,30]. Here, we sought a holistic understanding of SCD patients' prior experiences with pain, depression, and treatment for either or both conditions.

Our interview guides for baseline, midpoint, and final interviews (Multimedia Appendix 1) were designed to explore participants' experiences throughout the trial. Baseline interviews focused on participants' previous experiences with SCD pain management and their initial impressions of the study. Midpoint interviews gathered feedback on their experiences partway through the trial and any changes they had noticed. The final time point interviews sought information on durable effects and knowledge gained from their trial experiences.

Data Collection and Coding Procedures

Data collection and analysis were conducted by skilled qualitative researchers at the Center for Biostatistics and Qualitative Methodology's Qualitative Core, under the supervision of a qualitative methodologist. Once a randomly selected CaRISMA participant agreed to be interviewed, the interview was scheduled at a time that was convenient for them. To accommodate CaRISMA participants who were located across multiple geographic locations, interviews were conducted telephonically or via teleconferencing software according to the interviewee's preference. Interviews were audio-recorded and transcribed verbatim, with identifying details redacted. Although we hoped to have one consistent interviewer across the time points, the duration of the study and the logistics resulted in interviews being conducted by 3 interviewers, all of whom received the same training.

Concurrent with data collection, interviewers completed a summary template after each interview to document key topics discussed and capture emerging themes. These summaries allowed the team to assess thematic saturation, which was achieved. A trained qualitative analyst inductively developed an initial codebook based on the content of the interviews. This draft codebook, complete with detailed code definitions, was

XSL•FO
RenderX

circulated to the study team to ensure that it reflected relevant topical and theoretical themes important to the study team, as well as the content of the interviews. The codebook was slightly revised to incorporate new codes specific to themes emerging in the midpoint and final interviews. Once codebooks were finalized, qualitative coding was completed with the assistance of MAXQDA 2022 software. For each data set, 10 transcripts were co-coded and then reviewed by 2 independent, trained qualitative coders from the Center for Biostatistics and Qualitative Methodology to ensure quality and consistency in coding. Any coding discrepancies identified were adjudicated by the coders to full agreement. The primary coder completed the coding of the remaining transcripts following the standards established in the codebook and refined through the adjudication process. This coding served as the basis of a conventional content analysis [18], in which the primary coder prepared summaries describing participants' responses related to each interview guide domain at each time point. These summaries were reviewed by the qualitative methodologist and other study team members to identify the most relevant findings for reporting. Additional manuscripts are planned to present findings related to pain management and depression. This manuscript focuses specifically on participants' experiences with and perceptions of the CaRISMA trial.

Ethical Considerations

This study was approved by the University of Pittsburgh Institutional Review Board (STUDY20110346). Informed consent for this study was included in the original consent process for participation in the CaRISMA trial. No compensation was provided for this portion of the study. Participants were compensated for their broader participation in the CaRISMA trial. All study data were stored on secure University of Pittsburgh servers, accessible only to authorized members of the study team. Specifically, access was limited to members of the Qualitative Core who conducted the analysis. Audio files and interview transcripts were labeled with unique study identifiers and did not include participant names or other direct identifiers. All transcripts were de-identified, with personally identifying information redacted during the transcription process

Results

Participant Characteristics

A total of 48 participants completed baseline interviews. Of those 48 participants, 24 completed a midpoint interview, and 19 completed a final time point interview following the conclusion of their interactions with CaRISMA. At baseline, the mean age of participants was 36 (SD 9.7) years, and the majority were women (33/48, 69%). Most participants were recruited through clinic visits (38/48, 79%). About two-thirds (33/48, 69%) had attended some college or higher education, while 31% (15/48) had some high school education or a high school diploma or equivalent. One-third of participants (16/48, 33%) were employed, and about one-half of participants (25/48, 52%) reported being on disability. The demographic and clinical characteristics of participants at the baseline, midpoint, and final interview time points are summarized in (Table 1).

Here, we focus on participants' experiences in the trial, focusing on the unique aspects of the CaRISMA program, including the health coach, chatbot, and pain diary.

Overall Trial Experience

Most participants reported a positive overall experience with the CaRISMA study, emphasizing that it provided a "safe space" to learn and express themselves without fear of judgment. One participant noted:

> *I enjoy doing it. I really enjoyed—like I said, I learned a lot. And I like the fact that I can say how I feel in a safe, safe space. [...] the thing I think I appreciated the most about the study was, no matter what I say, good, bad, or indifferent, it is appreciated, and I felt safe. I can say it exactly how I feel.* [P31]

Others appreciated the study's focus on the connection between chronic illness and mental health, noting that such an approach was rare but much needed. One participant noted:

> *I feel like the study went well. [...] The fact that you guys thought of doing something like this to think on mental health and just treating symptoms differently, I felt like was great for the community because a lot of us did not know anything about CBT.* [P68]

Additionally, several participants found the exploration of the link between pain and depression particularly valuable, highlighting the need for greater awareness of this relationship within the sickle cell community. One participant noted:

> *Yeah, it was good overall. I think that I was quite impressed that there's something being studied about, you know, like taking care of the relationship between chronic illness and mental health. I hadn't seen that before so that was a good one for me. Yeah, so it was good generally.* [P107]

Despite these positive aspects, participants also expressed a desire for more follow-up and reminders throughout the study. Many felt that regular check-ins and clearer communication could have improved their engagement and overall experience:

> *Yeah, I feel like that's, that's, that would help the study be so much more successful or everybody's feeling on the same page, just because — I mean, not saying that it's not successful now, but I feel like, you know, if you have people checking me in frequently and letting you know, hey, you know, you had this option, this option, this option, you maybe should try it out, see if this helps, whatever. It was just it was a lack of communication.* [P104]

Participants expressed mixed preferences regarding in-person versus social media–based engagement, with some valuing the sense of community and real-time connection that in-person meetings offer, while others appreciated the convenience and accessibility of digital platforms. One participant emphasized the benefits of in-person interactions, stating "It would be nice to be in-person, you know, we all get together now" (P110). Another noted the challenges of an in-person engagement:

> *Oh, I like in-person. Um, the only thing is, you know, distance, transportation, things like that, schedules of people that are working, you know. But in-person is always a good one, because you, for me, the most important thing about any person is a sense of community, um, and connection to someone else in real-time, right. But other than that, I think on, like, a walk through a study, because, you know, scheduling conflict, and time and transport and all those things might make in-person maybe a bit more difficult.* [P107]

Participants also had mixed opinions on the most effective social media platform for engagement, with some favoring Snapchat due to its artificial intelligence chatbot feature, which they believed could enhance interactions and provide a more conversational experience. Others preferred Instagram, citing its widespread use and strong messaging capabilities, suggesting that a more active presence with regular updates and resources could increase engagement. Another participant recommended a separate app for the study. If a separate app is not feasible, then Instagram is the next best option:

> *Yeah, I, I think, I think the app will be the best route. But if, if you couldn't, if, if it was added on other social media platform, I feel like Instagram will be a real, a real good one, because I think Instagram is probably more widely used, especially when it comes to, like, messaging. Um, so I, I think it will be, yeah, I think you'll get more of a reach on Instagram. Because I've been on CaRISMA Instagram page, and, I mean, it's, it's okay, but it don't, it don't really have [...] life on it. You know, that, that will be the only thing that they will have to do is just bring more life to the page.* [P68]

Others saw value in leveraging existing platforms to reach a broader audience. Overall, participants highlighted the importance of selecting a platform that aligns with user preferences while ensuring consistent engagement and accessibility.

Health Coach Interactions

Participants appreciated that the health coach had SCD *or* knew someone (eg, a family member) who has SCD. Participants thus felt understood by the health coach. For instance, one participant said, "I just like to be able to talk to my coach, because she's going through what I'm going through. So, it's, it's good to be able to talk to somebody" (P30). Another participant similarly said, "I loved it [the health coach]. It was like, you know, talking to somebody that I can, you know, relate to. Um, that was, that was a great thing. You know? Easy to communicate. You know" (P40).

Talking to someone who was knowledgeable proved to be very helpful. This led to enduring effects beyond the health coach interactions, with participants noting that they learned the importance of talking and reaching out to someone when they are upset or in pain. In at least one case, a participant sought counseling after completion of the CaRISMA program, as a result of learning how helpful it could be to talk to someone:

> *There is one thing that we did choose to implement, which was, you know, just kind of self-care and mental health check-ins, and that's something that on the side of after speaking with my CaRISMA coach about that, that's something that I decided to sign myself*

XSL•FO
RenderX

> *up for. So, I signed up for counseling through my church and we have little weekly check-ins; so that's been very helpful. [...] So yes, I, I would, I would think that, that was definitely was something that, that's helpful in the event that there is a depression or anxiety episode that rises.* [P53]

Participants also appreciated that the health coach was willing to be flexible when scheduling meetings, as the health coach understood the unpredictability of SCD. For instance, one participant said,

> *I feel like she's [...] very helpful. She's, uh, very, like, mindful of my time and my, my situation, like she understands that there are some days where I could just really just be ready to collab and have a long conversation. And then there are other days where I may not feel well and I'm not interested in really just talking on the phone, especially if I'm in the hospital or at home trying to relax. So, that's why I like; she comes in and texts and if, if we scheduled an appointment and that's not good day, she's very flexible. So, uh, I kinda like how everything is going with, with the coach that I have.* [P53]

Some participants lamented limited interactions with their health coach, wishing that they had more time to get to know them. For example, one participant said, "I kinda wish I had the, more time to talk to her more, so we could kinda get like a better understanding of each other" (P67). The participant added that, ideally, they would like to speak to the health coach "every week because with sickle cell stuff can change so quickly, so you never know what I could be doing this week or what could happen next week. So, I would say, like, every week but I know, like, schedules and work and school and different stuff puts a burden on me trying to check in with her every week. So, I mean, text messages is fine, but conversation is different than texting, so, that's what I mean" (P67).

Chatbot Use and Feedback

Most participants found the chatbot to be helpful, barring technical difficulties. Participants primarily enjoyed the chatbot if they gained new insights from it. Some participants said that the information they learned helped to reframe the way they think about their SCD. One participant found this to be an enlightening experience:

> *I actually learned something new. I didn't think I was going to learn anything. [...] So we know that the sickle cells are crescent shaped. [...] Well, I learned that different types of, you know, genotypes sometimes the sickle cells are shaped differently. Because I have [inaudible] mine are more shaped like crystals instead of crescents. So that was new. I was like what! And I love crystals [laugh]. You know, they kind of made me like the sickle cell a little bit. Like okay, girl, we're twins! [...] I really did not know that. I was like oh my God I've had sickle cell for 34 years and I did not know that.* [P82]

Some participants found the chatbot helpful for reinforcing pain management strategies, while others felt it provided limited new information for those already knowledgeable about their condition. For participants who gained new insights, the chatbot was a valuable learning tool.

Some participants also noted that the insight they gained challenged certain "preconceived notions" they held about SCD:

> *Um, yeah, there's been...um, information that I...probably didn't think about...before. On that. And, that you had, um — you know, it's just like you think this is logically, this is certain information you had in your head about stuff, and you find out that, oh, my god, that they makes sense, this, this — do you understand what I mean? [...] Okay. So, if I had a preconceived notion on a particular aspect of sickle cell; I don't know, if for any reason like…it could be like an old wives' tale. And then, on looking, going through that I get a different information and I'm like, oh, that makes sense; why did I ever think this is what it was? Yeah, that's what I mean.* [P69]

In contrast, participants who did not find the chatbot to be helpful reported that it did not teach them anything new. The participant explained that the chatbot was more useful for "people who [...] don't know much about their own disease":

> *To be honest, I think it was more unhelpful to me, because the questions that it asked are, are questions that I already know the answer to. Does that make sense? Like, um, some people don't know what kind of sickle cell they have, or they don't know their triggers or, or things like that. And my mom taught us growing up, like, to be able to speak for yourself when you went to the doctor, so I know what kind of sickle cell I have. I know — you know what I'm saying — my triggers, I know, um, my medications and the dosages and stuff like that. So, it would be helpful for some people who aren't really, I guess who don't know much about their own disease. Does that make sense? But I...I think I know my disease and my body pretty well to where that was, it wasn't helpful to me.* [P80]

Frequently, participants who did not use the chatbot suggested that it should take a more proactive role in encouraging participants to interact with it, rather than relying on users to engage on their own. For example, when asked what would improve their use of the chatbot, one participant asked for a reminder: "Train the bot to just kind of reach out and be, like, 'Hey, you haven't answered the question or asked a question in a couple days; is everything good or would you like to resume'-type thing" (P39). The need for reminders was particularly salient for anyone who did not regularly interact with Facebook Messenger outside of the study and might therefore not see it in the course of their day.

Use of the Pain Diary

One participant added that filling out the pain diary—and being able to show the pain diary to their health care providers—was very helpful:

> *And also, to see that part in the, in the study where they was asking, like, how you feel, like that was, that's something I wish was everywhere, honestly; I*

XSL•FO
RenderX

> *wish I had that everywhere. I wish you could, like, show the doctors how you feel and whatnot, because even if they did put it everywhere, I feel like if it was standardized, they probably would know how to deal with different pain levels, you know, and, and that would probably be able to help them structure, um, medication doses. Like I feel like that would be so helpful cuz they can see it, and it's not more of you trying to struggle and explain it to them; they already see it; they know exactly how this is affecting you. This is, this is what works for them, many other warriors on this level; let's give them the same — and I'm telling you, I feel like it would be so helpful. I feel like that needs to be implemented in every hospital for every, every person just — or not anybody. Um, but yeah, I, I, I think that was probably the, the biggest thing for me.* [P68]

Some participants found completing the pain diary daily redundant or tedious, particularly on pain-free days, leading them to develop their own strategies to manage this task. One noted:

> *To me personally because it would come every day. I would get the email for it every day. And at a certain point it felt redundant if I wasn't in pain for a few days or weeks at a time. Having to fill it out every day. So it got to the point where if I had pain I would say okay yeah I'll go fill it out now. Instead of every day putting no pain.* [P115]

Some participants appreciated completing the pain diary daily, even on pain-free days, as it allowed them to track their symptoms and emotions. It also helped them reframe their experience, reminding them that not all days are "bad" and that pain episodes eventually subside. For example, one participant stated:

> *I mean, I like the pain diary because then it shows me, like, you know, what I write. Pretty much write down everything on my own. To do it every day just to know okay I'm feeling bad this day but this day I was okay. So that kind of helps.* [P104]

Participants also appreciated having a record of their pain and pain medication usage. As one participant described it:

> *Not that I enjoy, but I do look forward to the daily pain diary; it just, it does make me stop and think about, you know, what pain I'm in and have I taken meds and do I, you know, what can I do to not decrease but to minimize the pain and, in turn, minimize, I guess, the amount of medication. So that is helpful.* [P58]

Thus, participants felt that the pain diary helped to increase their awareness of their pain and feelings, helping them make more informed decisions about their pain management strategies.

Representative quotes are summarized by intervention component in Table S1 in Multimedia Appendix 2.

Discussion

Principal Findings

Digital health interventions have emerged as a promising tool to enhance chronic pain management and coping. Based on feedback from people with lived experience, we designed the CaRISMA trial to equip adults with SCD with the tools, resources, and support systems necessary to improve long-term chronic pain outcomes. In the primary CaRISMA trial, we found that both digital interventions (CBT and Education) resulted in improvements in the primary pain outcome, pain interference, at 6 months [19]. Additionally, greater engagement with health coaches was associated with greater improvements in pain interference. The qualitative study reported here enhances our understanding of the first peer-supported digital CBT intervention for adults with SCD by examining participant experiences with its key components: the health coach, chatbot, and pain diary.

Overall Experience

Overall, participants reported a positive experience with the CaRISMA trial, appreciating the safe space provided for open discussions and the opportunity to learn about the connection between pain and mental health. Although some participants preferred face-to-face interactions, logistical barriers such as transportation and health limitations reinforced the value of flexible digital formats, consistent with findings in other chronic disease populations [31,32]. Regarding the delivery platform, some participants valued engagement via social media (eg, Facebook, Instagram), appreciating its convenience, accessibility, and ability to provide on-demand support. Participants also had varying opinions on which social media platform would be most effective, with some favoring Snapchat due to its chatbot feature, while others preferred Instagram for its broad user base and messaging capabilities. Given the evolving nature of social media, leveraging multiple digital platforms may enhance engagement by catering to diverse communication preferences. Alternatively, considering the shifting landscape of social media usage, consolidating resources into a single, dedicated app, separate from social media, could provide a centralized and streamlined user experience. These findings also highlight the importance of offering flexible, accessible digital health interventions that accommodate the unique needs, preferences, and logistical challenges faced by individuals living with chronic conditions like SCD.

Health Coach Experience

Participants strongly valued their health coach's lived experience with SCD, highlighting the need for culturally concordant and condition-specific health coaching. In other chronic disease populations, tailored peer support has contributed to enhanced trust, self-efficacy, satisfaction, engagement, and adherence by offering emotional support, shared experiences, and practical guidance [20,21,33]. In the CaRISMA trial, many participants appreciated that their health coach had SCD or personal connections to someone with SCD, which contributed to feeling understood and supported. Some participants also reported that interactions with their health coach motivated them to seek mental health counseling, demonstrating the intervention's

XSL•FO
RenderX

potential for long-lasting impact that possibly extends beyond pain management.

Participants found the health coach relationship so valuable that many expressed a desire for more frequent contact. We designed the CaRISMA program to consist of weekly check-ins; however, the unpredictability of pain episodes for both participants and health coaches interfered with check-ins. Our findings are aligned with those of previous studies demonstrating that more frequent, flexible check-ins improve engagement and adherence in chronic disease populations [34,35]. To optimize future interventions, health coach check-ins should be frequent and adaptable, incorporating scheduled and on-demand support. A multimodal approach, incorporating text messages, phone calls, and video check-ins, could help meet individual needs.

Chatbot Experience

The chatbot received mixed responses; some participants found it helpful for reinforcing pain management strategies, while others felt it provided limited new information. These differences may reflect variation in prior knowledge, learning preferences, higher health literacy, or the degree to which participants engaged with other components of the intervention. Digital interventions incorporating chatbots have been recognized as an effective way to deliver behavioral coaching, track symptoms, and strengthen patient engagement [36]. Although some participants had a positive or eye-opening experience with the feature, others suggested that the chatbot should be more proactive, initiating conversations and providing reminders rather than waiting for users to engage. Previous research highlights that adaptive, artificial intelligence–driven chatbots that tailor responses based on user engagement and knowledge levels improve overall effectiveness in digital health interventions [37]. This approach could be incorporated into future digital interventions for adults with SCD.

Pain Diary Experience

The pain diary helped some participants track pain trends, but others found it redundant and unnecessary on pain-free days. Daily pain diaries are widely used in both SCD and broader chronic pain populations to monitor pain patterns and inform treatment strategies. In previous studies, patient experiences with these diaries have varied, reflecting both benefits and challenges. For instance, in the Pain in Sickle Cell Epidemiology Study (PiSCES), 60% of participants submitted fewer than 5 months of the expected 6 months of pain diaries, indicating challenges in sustained daily reporting [38]. In the CaRISMA trial, some participants mentioned that tracking their pain helped them gain perspective on their condition, allowing them to recognize that not every day was a “bad” day. This is a sentiment echoed in prior research on digital self-monitoring tools for chronic pain [14,39]. However, others recommended the use of the pain diary only when participants are experiencing pain. Research has shown that user fatigue is a common barrier to adherence in digital health interventions, particularly when data entry is required daily without immediate benefits [14,40,41]. To enhance usability, customizable pain tracking options allowing participants to self-select tracking frequency might be helpful. Additionally, integrating mood tracking and other symptom assessments alongside the pain diary may provide a more holistic view of well-being.

Comparison With Prior Work and Future Directions

The CaRISMA trial offered a novel approach to pain management in SCD by integrating a culturally adapted, multicomponent digital intervention within a historically marginalized and medically underserved population. Our focus on a historically marginalized group with specific cultural needs contributes new evidence on tailoring digital behavioral interventions for high-need populations. Unlike previous digital health trials that often focus on single-component interventions, the CaRISMA trial evaluated a comprehensive model combining digital CBT, peer support via health coaches, symptom monitoring, and chatbot technology. This study also highlights the importance of tailoring digital behavioral health interventions to the unique needs of individuals with SCD. The findings suggest that a multicomponent approach can enhance engagement and effectiveness. Future trials should consider the following recommendations: (1) enhanced health coaching that involves frequent and flexible coach check-ins, including on-demand support, to improve participant engagement; (2) an adaptive and interactive chatbot that offers personalized education based on an individuals’ knowledge, needs, and preferences (eg, chatbot with adjusted tone and content based on patient-reported depression and pain severity or providing layered content depending on the user’s baseline familiarity with SCD education and management); and (3) flexible and customizable self-monitoring tools, such as pain diaries that allow users to adjust tracking frequency, skip entries on low-pain days, or annotate with additional symptoms and reflections, as well as view visual summaries of pain trends to support provider communication and self-awareness. Future research should also develop and test digital interventions that incorporate other therapeutic approaches, such as acceptance and commitment therapy [42,43] and mindfulness-based stress reduction [44,45]. Digital interventions may also offer a form of cognitive escapism, a concept referring to psychological relief and distraction from distressing symptoms. For instance, Anto et al [46] found that digital tools can help users disengage from pain and emotional burdens through structured, engaging content. Within the context of SCD, a digital CBT program may provide both therapeutic and escapist benefits, helping individuals better manage their symptoms while finding temporary relief from the psychological weight of chronic illness, which may be relevant to coping and engagement. These processes should be further investigated in adults with SCD.

Strengths and Limitations

This study has several strengths. First, to our knowledge, this is the first qualitative study to explore patient experiences with a peer-supported digital CBT intervention tailored for chronic pain in adults with SCD. Second, it fills a gap in understanding SCD patients’ perspectives on digital pain tools by examining multiple intervention components (health coach, chatbot, and mobile pain diary) and how each contributed to engagement and self-management. Third, by evaluating participants’ willingness and ability to use a mobile pain-tracking platform in a real-world setting, the study provides valuable insights for

XSL•FO
RenderX

the design and implementation of future digital health interventions. Finally, this study captured real-world barriers and facilitators to digital health engagement in a medically underserved, high-burden population with specific, actionable feedback regarding reminder frequency, chatbot utility, and diary fatigue that can inform digital health optimization.

However, the study also has limitations. First, this study does not account for participants' underlying mental health conditions, which may have influenced their responses to the interventions. Second, although participants were randomly selected for interviews, selection bias remains possible, as only 48 of the 115 individuals contacted agreed to participate. Third, attrition across interview time points may have introduced bias, as participants who remained engaged may differ systematically from those who dropped out. Although no clear patterns were observed among nonresponders, those who disengaged may differ in unmeasured ways from those who completed all interviews. This may reflect health issues, competing demands, limited perceived benefit, logistical barriers, or stronger motivation to remain involved. It is also possible that retention was skewed toward individuals with particularly strong feelings about the intervention or more positive experiences with the interventions who were more motivated to remain engaged. Although much of our feedback was positive, it is possible that more critical voices did not engage, although we have no data to support this speculation. Last, most participants had at least some college education, which may limit generalizability to individuals with lower educational attainment. As participants were also recruited from specialty centers and community-based organizations, findings may not reflect the broader SCD population

Conclusions

Overall, participants found the CaRISMA program to be a supportive space for learning, self-reflection, and symptom management. Digital interventions offer a scalable and accessible approach to addressing pain care disparities within the underserved SCD population. Regular, proactive communication emerged as essential for participant engagement, with inconsistent interaction likely contributing to dropout rates in this and similar studies. Future digital interventions should prioritize regular communication among participants, health coaches, and research teams to enhance retention and overall effectiveness. Additional research should focus on developing culturally appropriate, patient-centered, and adaptable interventions that address the diverse needs within the SCD population.

Acknowledgments

This study would not have been possible without participation and support of the individuals living with sickle cell disease who participated in the Cognitive Behavioral Therapy and Real-Time Pain Management Intervention for Sickle Cell via Mobile Applications (CaRISMA) trial. We are also grateful to Andrea Ball for her assistance with manuscript editing. This research reported in this publication was funded through a Patient-Centered Outcomes Research Institute (PCORI) Award (CER-2018C2-13320; principal investigators: CJ and KZA).

Data Availability

Due to the sensitive nature of the data, the data sets generated and analyzed during this study are not publicly available. However, de-identified numeric data are available from the corresponding author upon reasonable request.

Authors' Contributions

This qualitative study was conceptualized by MH and CJ. MH contributed to the methodology, investigation, data collection, and formal analysis of the study. OBO, MH, LM, and KG reviewed the transcripts and emergent themes to develop the thematic framework and manuscript outline. OBO and MH led the drafting of the original manuscript with contributions from LM. All authors were involved in writing, reviewing, and editing of the final version.

Conflicts of Interest

CJ has ownership in the company that develops the Painimation app, one of the exploratory outcome measures for the trial. The remaining authors have no conflicts of interest to declare.

Abstract

Background: Bring your own device (BYOD) adoption in health care improves clinician productivity, but introduces cybersecurity risks due to weak security controls, human error, and policy circumvention. Existing security frameworks and models are technocentric, while overlooking sociotechnical factors such as clinician behavior, workflow integration, and organizational culture. This misalignment reduces their effectiveness in health care settings. In addition, hospitals vary in structure, resources, and BYOD use, necessitating a flexible yet structured approach to assess security maturity and prioritize improvements, which is lacking in existing models.

Objective: This study aims to develop and pilot a hospital BYOD security maturity model that integrates technical, policy, and human factors for a structured assessment and improvement of BYOD security in health care.

Methods: This study used mixed methods action research to design and pilot a hospital BYOD security maturity model. Surveys and interviews with IT managers and clinicians shaped the model, which was trialed at a public metropolitan hospital in Victoria, Australia. Participants completed a maturity assessment and joined a 90-minute co-design workshop that prioritized 6 key domains and proposed improvements. Descriptive statistics and thematic analysis guided refinements to improve clarity and usability.

Results: The model was initially developed with 22 domains across 3 key dimensions: technology, policy, and people, each structured across 5 maturity levels to support systematic progression in hospital BYOD security. On the basis of participant feedback during the refinement process, 2 training-related domains were merged, resulting in a final model with 21 domains. The technology dimension includes domains such as identity, access, and authentication management; device security; and clinical communication, ensuring technical controls align with hospital policies and workflows. The policy dimension focuses on governance, covering areas such as BYOD strategy, regulatory compliance, and incident response, to establish clear security guidelines and enforcement mechanisms. The people dimension addresses human factors, including security awareness training, stakeholder involvement, and security culture, fostering staff engagement and adherence to security protocols. A maturity assessment survey conducted at a public metropolitan hospital in Victoria, Australia, revealed an overall maturity level of 2.04. Key areas for improvement included identity and access management, clinical communication security, and governance transparency. A 90-minute co-design workshop identified challenges and proposed solutions for the top 6 priority domains. Recommendations included implementing single sign-on, defining a formal BYOD strategy, enhancing secure communication tools, and improving stakeholder engagement.

Conclusions: The model can serve as a valuable tool for hospitals and policy makers, offering actionable recommendations to strengthen BYOD security. The pilot implementation demonstrated its practical applicability, helping the hospital identify security

gaps and develop a road map for structured enhancements. Further validation across diverse health care settings will enhance its adaptability and long-term impact.

Introduction

Background

Bring your own device (BYOD) is the practice of using personal devices, including laptops, smartphones, and tablets, for professional purposes. This practice has witnessed a significant increase in adoption across various sectors, especially within the health care domain [1]. A survey conducted in 2021 among hospital clinicians in Australia revealed that 87% of respondents engaged in BYOD for tasks related to their hospital responsibilities [2]. The ubiquitous and multifunctional nature of contemporary mobile devices attracts clinicians, who use BYOD for activities such as clinical documentation, accessing electronic medical records (EMRs), diagnostic decision support, and clinical communication [3-6]. For health care professionals, BYOD allows enhanced flexibility and convenience, thereby enhancing their mobility and productivity. Nevertheless, despite its benefits, BYOD is recognized as a contributor to increased cybersecurity vulnerabilities, which presents a significant concern for health care institutions [7,8]. A critical dimension of BYOD implementation is the insufficient security measures associated with clinicians' personal devices, rendering them more susceptible to security breaches, particularly due to human error and misuse. These elements are acknowledged as key contributors to data breaches within the health care sector [7,9,10]. In certain situations, clinicians may sometimes prioritize immediate patient care over adhering to IT security protocols, further exacerbating risks [11,12]. The risk escalates within a BYOD environment, wherein users exert greater control over hospital data residing on their personal devices, thus increasing the likelihood of security oversights. For instance, the proliferation of EMR use on mobile devices intensifies the difficulty of integrating security measures into routine workflows [13,14]. Moreover, adherence to health care privacy regulations further complicates the adoption of BYOD, as hospitals strive to reconcile security requirements with clinical operational efficiency [9].

Multiple academic studies have explored security issues associated with BYOD use, addressing challenges such as device theft, network vulnerabilities, malware, unencrypted data, and improper employee behavior [15-17]. However, research in the health care sector is comparatively limited. Several researchers emphasize the need for targeted academic investigations to offer a comprehensive and objective understanding of this field. They have highlighted that a one-size-fits-all approach to BYOD security is insufficient, and existing best practices and recommendations lack the nuanced approaches needed for specialized sectors such as health care, where security solutions must balance operational efficiency with strict regulatory requirements [18,19]. The intricate nature and multifaceted dynamics of technology implementation within health care calls for focused research on BYOD security in hospital environments. On the contrary, previous research has highlighted the limitations of existing BYOD security frameworks in health care, noting a predominant focus on technical solutions without adequately addressing the sociotechnical dimensions critical in clinical environments [15,16]. Existing frameworks emphasize technical controls such as access management and encryption (the process of converting data into a coded format to prevent unauthorized access, ensuring data security both in transit and at rest) but often overlook the importance of user behavior, organizational culture, and workflow integration [17,20]. This technocentric approach has been associated with increased vulnerability to cyberattacks due to neglected social aspects of security [21,22].

Recognizing these gaps, previous work involved developing a preliminary hospital BYOD security framework that integrated sociotechnical considerations, encompassing technical controls, policies, and human factors [10]. This framework outlined a 7-stage process—plan, identify, protect, detect, respond, recover, and assess and monitor—with recommendations tailored to the unique challenges of BYOD security management in hospitals. Subsequent empirical studies involving hospital IT managers and clinicians provided practical insights, further informing and refining the framework [2,23-25].

However, translating this comprehensive framework into actionable and practical sociotechnical security controls presents challenges. Hospitals vary significantly in their organizational structures, workflows, and available resources, making it impractical to implement all recommendations uniformly. There is a need for a flexible tool that allows hospitals to assess their current BYOD security posture and prioritize improvements in a manner that aligns with their specific contexts.

Maturity models have been used in information systems as instruments for assessment and systematic enhancement of organizational practices [26,27]. In information security, maturity models aid organizations in identifying cybersecurity gaps and developing tailored countermeasures that are feasible and aligned with organizational goals [28]. Nonetheless, existing maturity models in cybersecurity are predominantly technocentric and compliance-oriented, lacking in sociotechnical considerations and specific applicability to the health care sector [26,28-32]. A 2025 systematic review of cybersecurity maturity models identified several persistent gaps, including the absence of sector-specific frameworks and the limited integration of behavioral and organizational dimensions [33]. Similarly, other contemporary studies tend to focus on national cybersecurity capabilities, broad information security themes, or narrowly

XSL•FO
RenderX

defined applications, such as incident response, and hence do not address the full range of health care–specific challenges, nor do they provide comprehensive sociotechnical maturity frameworks [34-36]. The complexity of health care systems, characterized by intricate interactions between technology, clinical workflows, communication, and regulatory requirements, necessitates a maturity model that encompasses both technical and sociotechnical dimensions [37-39].

Objectives

Given the absence of a tailored maturity model addressing hospital BYOD security and its unique challenges, this study aims to bridge this gap by developing a comprehensive and holistic hospital BYOD security maturity model. Therefore, the aim of our research is to propose and present a comprehensive hospital BYOD security maturity model. Furthermore, we describe a pilot implementation that demonstrates the model's practical application to BYOD security in a specific hospital organizational context. In addition, the model presented aims to advance maturity model theory by offering a granular, domain-based structure that enables targeted progression mapping. This overcomes the abstraction of traditional models by operationalizing maturity in specific, interrelated hospital functions.

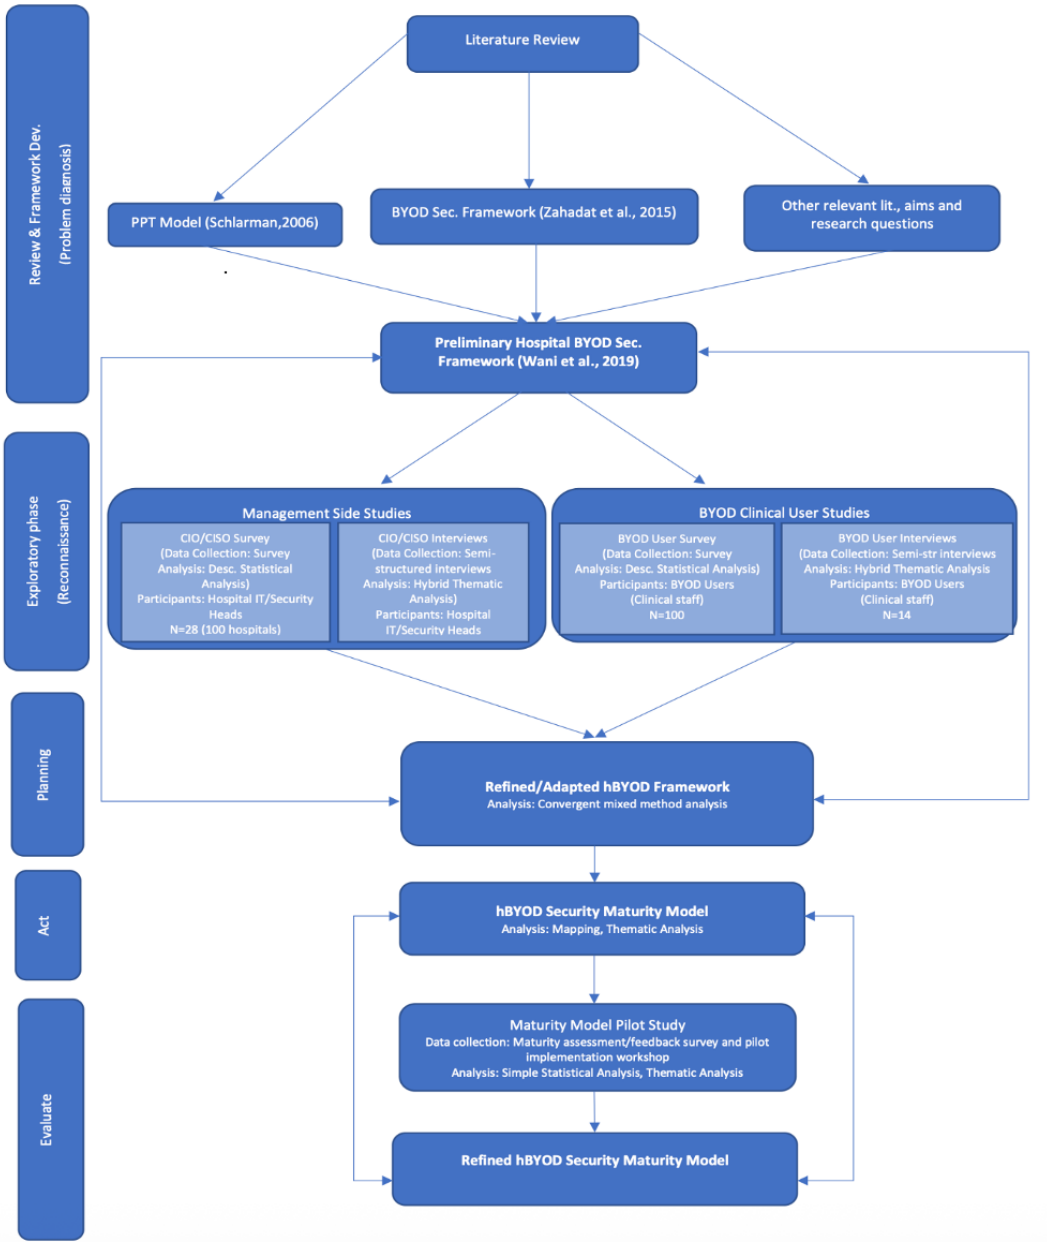
By bridging the gap between theoretical frameworks and practical implementation, this study aims to provide hospitals with a practical tool to enhance their BYOD security posture in a manner that is adaptable to their unique organizational contexts. The resulting maturity model is intended to facilitate a systematic approach to improving BYOD security, integrating both technical controls and sociotechnical factors, such as clinician behavior and organizational culture.

Methods

The method section comprises 2 subsections. First, we describe the method used to develop and refine the proposed hospital BYOD security maturity model. Then, we outline the method used to pilot its implementation.

Development and Application of the Proposed Hospital BYOD Security Maturity Model

Maturity Model Development



Before the maturity model, the authors developed a hospital BYOD security framework providing a comprehensive set of sociotechnical guidelines for BYOD security in hospitals across the BYOD life cycle. This framework was developed using a mixed methods action research (MMAR) approach, providing a robust foundation for the creation of the hospital BYOD (hBYOD) maturity model. The MMAR methodology enabled the integration of both qualitative and quantitative data (collected through empirical studies), ensuring that the framework addressed sociotechnical factors, including technical controls, policies, and human behaviors, to balance security with clinical productivity [40-42]. The quantitative studies involved surveys of IT management staff across hospitals to assess existing security practices and BYOD users, such as clinicians, to evaluate their security behaviors and compliance. The qualitative component included semistructured interviews with IT management staff to explore contextual factors influencing BYOD security decisions and with clinicians to understand how security measures impact their workflows and productivity. This comprehensive approach ensured that both the management and user perspectives were incorporated into the framework's development.

For the purposes of the maturity model, recommendations were mapped from the hospital BYOD security framework to the 5 maturity levels across all domains of the model. These descriptions and levels were triangulated among the 3 researchers to ensure consistency, accuracy, and alignment with the framework. By aligning the framework's recommendations with the maturity levels, elementary guidelines correspond to the lower levels, while more complex and advanced guidelines align with the higher levels, in accordance with the defined criteria for each level. This mapping ensures structured progression from basic to optimized practices within each domain.

Figure 1 illustrates the comprehensive process involved in developing the hBYOD maturity model, from initial problem analysis to the finalization of the model [10,19,43].

XSL•FO
RenderX

Figure 1. Hospital bring-your-own-device (hBYOD) security maturity model—Development process overview. BYOD: bring your own device; CIO: chief information officer; CISO: chief information security officer; PPT; people, policy, technology.

The proposed maturity model was initially developed with 22 domains across the 3 dimensions of people, process, and technology (PPT; 7 domains for technology, 7 for policy, and 8 for people), selected for their relevance to hospital BYOD security, following extensive research that included literature reviews and a series of empirical studies [2,23-25]. On the basis of participant feedback during the refinement process, 2 training-related domains were merged, resulting in a final model with 21 domains. Each domain represents a specific aspect of hospital BYOD security.

Each domain represents a specific aspect of hospital BYOD security. Incorporating the PPT dimensions ensured a holistic sociotechnical approach when assessing BYOD security maturity [43]. Every domain is defined across 5 maturity levels, ranging from level 1 to level 5, with unique definitions for each level in all 21 domains. These levels are aligned with prominent academic and industry-based maturity models [31,44-46]. An analysis of these models reveals the following definitions corresponding to each maturity level:

1. Nonexistent or very limited and elementary implementation, unreliable, completely reliant on manual effort, and major changes required.
2. Ad hoc or informal implementation, reactive, significant room for improvement, and mostly reliant on manual effort.
3. Well-defined but with gaps in management and enforcement, minimal automation, a high degree of manual effort, compliant, and moderate room for improvement.
4. Well-managed and enforced, structured practices, moderate level of automation, proactive, moderately agile, best practice, and low room for improvement.
5. Continually improving and highly agile and real-time, high levels of automation, complete integration, enterprise-wide practices, innovative, and up to date with little or no room for improvement.

XSL•FO
RenderX

The 5 maturity levels across all domains were derived from the hospital BYOD security framework (Multimedia Appendix 1), ensuring each level has a distinct and well-defined definition and characterization. Detailed mappings of the hospital BYOD security framework's recommendations to the maturity levels are provided in Multimedia Appendix 2.

Assessment Process Using the Maturity Model

The maturity model can be used to assess a hospital's BYOD security maturity through a straightforward process. For each of the 22 domains, a brief description of cybersecurity controls or practices is provided for each of the 5 maturity levels. Assessors rate their hospital from level 1 to level 5 in each domain, based on how closely their practices align with the provided descriptions. Assessors are expected to possess substantial knowledge of the described activities and have tangible evidence of the specified security controls.

When multiple assessors evaluate the same hospital, an average rating can be calculated for each domain to determine the overall maturity level. In addition, average ratings can be computed for each of the 3 PPT dimensions, as well as an overall average, providing cumulative ratings. This approach allows the model to identify specific areas for improvement and to represent the general capability of the hospital, based on individual domain maturity ratings and the cumulative mean maturity rating, respectively.

Prioritization and Roadmap for Improvement

It is important to note that areas for improvement can be prioritized or ranked based on the hospital's needs, future mission, capabilities, and feasibility considerations. Hospitals can plan a road map for enhancement by referring to the higher maturity levels in specific domains as guidance. For example, if a hospital's maturity rating in a particular domain is level 2, the descriptions of the progressive levels (levels 3, 4, and 5) can provide actionable insights on how stepwise improvements can be achieved. Depending on the hospital's capabilities and resources, it may aim for the level that is feasible to attain within a given time frame.

Pilot Implementation Study

This section outlines the methodology used for the pilot implementation study.

Ethical Considerations

Ethics approval was obtained from the hospital's ethics committee and the University of Melbourne, where the study was conducted (Ethics approval project no. 556/21). Informed consent was obtained from all participants through an information statement, and participation was voluntary, with an option to withdraw at any time. Survey responses were collected anonymously, and workshop data were pseudonymised and deidentified to ensure privacy and confidentiality. No patient data were collected. All data were securely stored on password-protected university systems. No compensation was offered to participants.

Study Site

The maturity assessment and improvement study were conducted at a major public tertiary metropolitan hospital in Victoria, Australia.

Study Participants and Recruitment

Overview

Two key groups of BYOD security stakeholders from the participating hospital were involved in this study. Participants were selected based on their involvement and understanding of BYOD security management, decision-making, or use within the hospital. The selection process was facilitated through nominations from the hospital's chief privacy officer to ensure the inclusion of individuals with relevant expertise and diverse perspectives. The criteria for participant selection included the following.

Technology Managers

IT professionals, cybersecurity managers, and policy makers responsible for BYOD decision-making, such as developing or implementing BYOD security strategies. They were chosen for their expertise in technical security controls, policy formulation, and compliance measures.

Clinical Stakeholders (Device Users)

Clinicians who understood BYOD use and clinical needs, such as those with IT and informatics roles. They were selected to provide insights into the impact of BYOD security controls on aspects such as clinical efficiency, usability, and compliance with hospital policies.

Nominated individuals were provided with a plain language statement and were included in the study upon giving informed consent. A total of 10 participants from the hospital took part in the study.

Study Design

The study was conducted in 2 stages.

Maturity Assessment and Model Feedback Survey (Before the Workshop)

A BYOD security maturity assessment and feedback survey was developed using Qualtrics (Qualtrics International Inc; Multimedia Appendix 3). Participants received a survey link and had 1 week to complete it independently before the workshop. Both technology managers and clinical stakeholders assessed BYOD security maturity by selecting the most appropriate level for each domain based on their knowledge and available tangible evidence. They also provided feedback on the accuracy, applicability, and clarity of the model, with an option to suggest improvements or indicate if they lacked sufficient knowledge to assess a domain.

Following the maturity assessment, participants were asked for their reflective comments on the structure of the model. This included (1) identifying any missing domains that should be included, (2) suggesting the removal of any domains deemed unnecessary, and (3) proposing reclassification of domains from one dimension to another.

XSL•FO
RenderX

At the end of the survey, participants were asked to prioritize and rank the domains within each PPT dimension based on their perceived importance for improving the BYOD security maturity of the hospital.

Maturity Improvement Discussion Workshop

Following the maturity assessment, a 90-minute Zoom (Zoom Communications, Inc) workshop was held with the same survey participants, including IT and clinical representatives providing management and user perspectives on BYOD use.

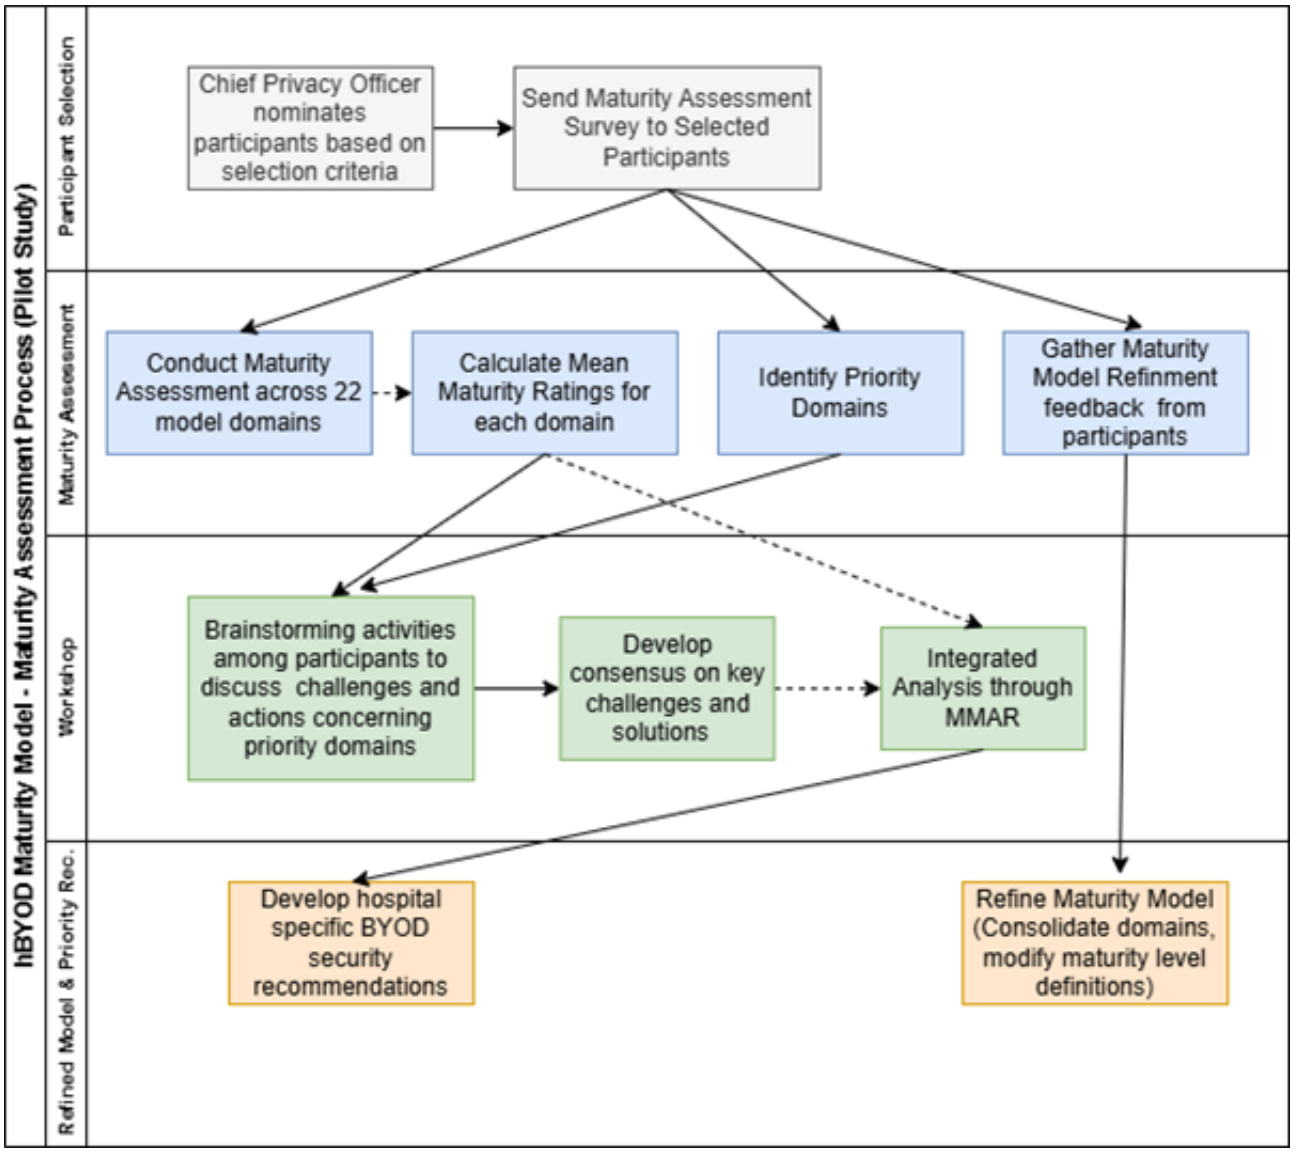
A participatory co-design approach was used during the workshop, enabling these stakeholder groups to collaboratively discuss challenges and propose recommendations related to the prioritized domains of BYOD security identified from the initial survey [47,48]. To maximize the effectiveness of the workshop, design and evaluation guidelines by Thoring et al [49] were followed.

The web-based workshop tool MURAL was used to document participant responses. Each group had 2 facilitators who managed time, addressed queries, and recorded key discussions. The full workshop session was recorded, transcribed, and deidentified.

Analysis

The maturity assessment data underwent descriptive statistical analysis to determine mean maturity ratings across the hospital's BYOD security domains. The top 6 priority domains (two from each of the technology, policy, and people dimensions) were identified based on participant responses.

For qualitative analysis, data from the maturity assessment, model improvement feedback, and workshop sessions were analyzed using thematic analysis [50]. A deductive approach was applied to assess how participant feedback aligned with predefined BYOD security maturity domains, followed by an inductive review to identify emerging challenges, contextual insights, and proposed solutions. This combined approach ensured that both structured evaluation and exploratory findings contributed to the refinement of the model and the formulation of consolidated, prioritized security recommendations for the hospital.



Participant Characteristics

A total of 10 participants from the model hospital, representing both participant groups—7 technology managers and 3 clinical stakeholder representatives—participated in the maturity assessment survey and the following discussion workshop.

Figure 2 provides an overview of the maturity assessment and model refinement process.

XSL•FO
RenderX

Figure 2. Maturity assessment and model refinement process overview. BYOD: bring your own device; hBYOD: hospital bring your own device; MMAR: mixed methods action research.

Results

This section is organized into three parts: (1) maturity model description, (2) feedback and refinements, and (3) hospital maturity assessment and workshop recommendations. The first part provides an overview of the maturity model domains, the second summarizes participant feedback and resulting revisions, and the third presents the findings from the maturity assessment survey and subsequent workshop conducted at the model hospital.

Maturity Model Description

Overview

The proposed maturity model was initially developed with 22 domains across 3 dimensions—technology (7 domains), policy (7 domains), and people (8 domains). Following participant feedback, 2 training-related domains under the people dimension were merged, resulting in a final model comprising 21 domains. This revision is detailed in the Feedback and Refinements subsection.

While this section provides only a brief overview of the 3 dimensions and their respective domains, the complete model, including detailed definitions for each of the 5 maturity levels per domain, along with clearly defined, measurable criteria, is presented in Multimedia Appendix 2. To aid interpretation, the operational indicators for each level have been bolded in the revised version of the appendix. These indicators are designed to support objective evaluation and guide structured improvement efforts.

Technology

Overview

The technology dimension demonstrates a clear progression from basic security practices to an advanced, integrated sociotechnical approach, where technology aligns with organizational policies and user needs. Each maturity level builds on the previous, addressing specific security and usability challenges relevant to BYOD use in hospitals. Table 1 presents a concise summary of the technology domains, offering a high-level overview of their structure and key focus areas.

XSL•FO
RenderX

Table 1. Technology dimension domain definition and descriptions (7 domains).

Technology dimension	Definition and description	Levels summary
Identity, access, and authentication management	Technologies and processes for verifying user identity and controlling access to hospital systems and data in a BYOD[a] environment	• Level 1: basic password-only authentication without additional protections for BYOD access. • Level 2: complex passwords with enforced policies, providing minimal improvement for personal device security. • Level 3: dual-factor authentication (eg, OTP or token) to enhance security for BYOD users. • Level 4: RBAC[b] tailored to BYOD device use, restricting access based on job roles. • Level 5: federated SSO[c] for seamless and secure access across multiple hospital systems from BYOD devices.
Storage and backup	Tools and controls for securely storing and backing up hospital data accessed or stored on BYOD devices, ensuring separation from personal data	• Level 1: no controls for securing or backing up data accessed via BYOD devices. • Level 2: minimal separation between personal and hospital data, with limited backup options for BYOD users. • Level 3: virtualizationd ensures BYOD users access data in secure, isolated environments without local storage. • Level 4: containerizatione fully separates hospital data on BYOD devices, with secure backup options. • Level 5: private cloud infrastructure with automated, encrypted backups for data accessed through BYOD devices.
Device security	Security measures to protect BYOD devices, including encryption[f], antivirus, and compliance monitoring	• Level 1: no restrictions or security requirements for BYOD devices. • Level 2: manual security controls, such as user-installed antivirus and basic settings. • Level 3: blacklist and white list capabilities to restrict unauthorized apps and ensure BYOD compliance. • Level 4: end point protectiong with real-time threat detection and device monitoring for BYOD devices. • Level 5: UEMh for centralized, automated security management of all BYOD devices.
Network security	Security protocols to protect hospital networks from threats introduced by BYOD use, including firewalls and segmentation	• Level 1: basic firewalls providing limited protection against BYOD-related threats. • Level 2: network segmentation separates hospital systems from BYOD devices to minimize risk. • Level 3: firewalls integrated with IDSi and IPSj) to identify and mitigate BYOD-originated threats. • Level 4: secure web gatewaysk filter internet traffic from BYOD devices, ensuring safe access. • Level 5: real-time threat detection using AIl and analytics to proactively secure hospital networks from BYOD threats.
Application security	Safeguards to secure applications in a BYOD environment, preventing unauthorized access and data breaches	• Level 1: no restrictions, allowing any applications on BYOD devices without security oversight. • Level 2: limited to basic applications with minimal security checks for BYOD use. • Level 3: vulnerable silos where hospital apps on BYOD gadgets lack integration or adequate oversight. • Level 4: approved white-listed applications with robust security policies for BYOD use. • Level 5: virtualized applications providing isolated and secure environments for BYOD users.
BYOD management and automation	Systems and tools to manage, monitor, and automate security measures for BYOD devices within the hospital	• Level 1: manual BYOD management with no centralized tools. • Level 2: ad hoc controls implemented reactively for BYOD issues. • Level 3: MDMm solutions enforce basic policies for BYOD compliance. • Level 4: MAMn tools control apps and permissions on BYOD gadgets. • Level 5: UEM provides comprehensive, automated security and operational management for BYOD gadgets.

XSL•FO
RenderX

Technology dimension	Definition and description	Levels summary
Clinical communication, photography, and file sharing	Secure platforms and protocols for communication, photography, file sharing, and data transfer using BYOD devices in clinical settings	• Level 1: undefined systems, with personal apps frequently used on BYOD devices for communication. • Level 2: generic communication platforms with limited security features for BYOD users. • Level 3: limited secure platforms partially integrated into hospital workflows for BYOD communication. • Level 4: fully integrated platforms with strong encryption and compliance features tailored for BYOD devices. • Level 5: dedicated systems specifically designed for secure clinical communication and file sharing on BYOD devices.

[a]BYOD: bring your own device.

[b]RBAC: role-based access control. A method of restricting system access based on an individual's job role to enforce security and limit exposure to sensitive data.

[c]SSO: single sign-on. An advanced form of SSO that allows users to access multiple apps and systems across different organizations or domains using a single authentication mechanism.

[d]A technology that allows hospital apps and data to be accessed in a controlled, virtual environment rather than being stored directly on BYOD devices, reducing security risks and enhancing centralized management.

[e]A security method that isolates hospital data and apps within a secure, controlled environment on a BYOD device, preventing unauthorized access to sensitive information while maintaining separation from personal apps.

[f]The process of converting data into a coded format to prevent unauthorized access, ensuring data security both in transit and at rest.

[g]End point protection: protection measures applied to end-user devices (eg, mobile phones, laptops) to prevent privacy or security breaches.

[h]UEM: unified end point management. A comprehensive security solution to managing and securing all devices (eg, desktops, mobiles, and tablets) from a single platform.

[i]IDS: intrusion detection system. Security tools are designed to detect, alert, and prevent potential cyberattacks by monitoring network traffic and system activities.

[j]IPS: intrusion prevention system.

[k]A security solution that monitors and filters internet traffic from devices to enforce hospital security policies, block malicious websites, prevent data leaks, and protect against web-based threats.

[l]AI: artificial intelligence.

[m]MDM: mobile device management. A security solution that allows organizations to control, monitor, and enforce policies on personal and organization-owned mobile devices.

[n]MAM: mobile application management. A security solution that focuses on controlling and securing hospital-approved apps on BYOD devices without managing the entire device, enabling secure access to clinical apps while maintaining user privacy.

The following sections provide a brief description of the 5 maturity levels across the 7 technology domains, illustrating the progression from minimal to advanced security capabilities and their application in BYOD contexts within hospitals.

Level 1: Minimal Security Controls

This foundational level exhibits basic security with limited controls. Authentication is password-based, without advanced access restrictions or separation between hospital and personal data on devices. Device security is minimal, allowing unrestricted personal device use, and network protection relies on basic firewall configurations. Application security is nonexistent, with employees using personal, unsecured applications. There are no centralized controls over BYOD use, and clinical communication occurs through personal apps, such as WhatsApp (Meta Platforms, Inc), posing significant data privacy and security risks.

Level 2: High Complexity and Minimal Automation

Security capabilities improve slightly, introducing single-factor authentication with complex passwords and limited device-level restrictions, mainly for high-risk devices. Network segmentation and guest network access are applied to separate personal and hospital data minimally, but data security largely depends on manual user management. BYOD management remains largely manual, and clinical communication continues through generic applications, offering little dedicated security.

Level 3: Basic Access Controls

At this level, more structured controls emerge, including basic identity and access management (IAM; a framework of policies and technologies ensuring that only authorized individuals can access specific hospital resources and systems) solutions with application-level virtualization (a technology that allows hospital applications and data to be accessed in a controlled, virtual environment rather than being stored directly on BYOD, reducing security risks and enhancing centralized management) for limited access control. Device security uses blacklist and white list capabilities to enforce some restrictions, while network security is strengthened with advanced firewalls and intrusion detection systems (security tools designed to detect, alert, and prevent potential cyberattacks by monitoring network traffic and system activities) and intrusion prevention systems. Although personal cloud options are permitted for backup, there is some degree of logical separation between personal and hospital data. Basic mobile device management (MDM; a security solution that allows organizations to control, monitor, and enforce policies on personal and organization-owned mobile

XSL•FO
RenderX

devices) tools are used for BYOD control and secure clinical communication platforms are available, although uptake remains minimal due to limited usability and integration.

Level 4: Role Based and Partially Integrated

This level introduces advanced IAM solutions with role-based access control, supporting more sophisticated, role-specific permissions. Data storage is managed through sanctioned cloud platforms with access restrictions based on user roles, enhancing data protection. End point protection (protection measures applied to end-user devices [eg, mobile phones and laptops] to prevent privacy or security breaches) incorporates network visualization and secure web gateways (a security solution that monitors and filters internet traffic from devices to enforce hospital security policies, block malicious websites, prevent data leaks, and protect against web-based threats), providing greater oversight of device security. Hospital-approved applications are made accessible through a secure app store, and mobile application management (MAM; a security solution that focuses on controlling and securing hospital-approved applications on BYOD devices without managing the entire device, enabling secure access to clinical apps while maintaining user privacy) tools enable more consistent BYOD management. Dedicated platforms for clinical communication offer basic integration with hospital systems, supporting more secure and streamlined workflows.

Level 5: Advanced, Integrated Security

The highest maturity level reflects an enterprise-level approach with fully integrated, automated security practices. IAM solutions use artificial intelligence for enhanced authentication management, including federated single sign-on (SSO; an advanced form of SSO that allows users to access multiple apps and systems across different organizations or domains using a single authentication mechanism) across all hospital applications, significantly improving user experience and security. Storage and backup solutions are handled via a private cloud with complete data isolation, ensuring data security. Comprehensive end point protection and real-time network monitoring provide robust defense against cybersecurity threats. Application security includes sophisticated isolation and restriction features, protecting sensitive data. Unified end point management (a comprehensive security solution to managing and securing all devices [eg, desktops, mobiles, and tablets] from a single platform) enables centralized, automated control over all BYOD devices, and dedicated clinical communication platforms integrate seamlessly with hospital systems, supporting efficient and secure communication workflows.

Policy

Overview

The policy dimension outlines a structured progression in BYOD policy development and governance within health care organizations. This dimension emphasizes the progression from a lack of structure in BYOD policy and security management to a comprehensive, proactive governance framework that aligns legal, technical, and operational elements of BYOD security within health care environments. Table 2 provides a brief overview of the policy domains.

XSL•FO
RenderX

Table 2. Policy dimension: domain definition and descriptions (7 domains).

Policy dimension	Definition and description	Levels summary
BYOD[a] strategy	The overarching plan for integrating BYOD into hospital workflows while ensuring security and compliance	• Level 1: no defined strategy for BYOD use. • Level 2: BYOD addressed informally as part of general IT strategy. • Level 3: a dedicated BYOD strategy focusing on security and compliance. • Level 4: comprehensive strategy covering clinical and nonclinical workflows related to BYOD use. • Level 5: proactively updated strategy aligned with evolving threats and hospital needs.
Policy components	Key elements of policies that define acceptable use, privacy, and security requirements for BYOD use	• Level 1: no specific BYOD policy components defined. • Level 2: basic acceptable use guidelines included in broader IT policies. • Level 3: dedicated BYOD policy components addressing security and privacy. • Level 4: comprehensive policies tailored for BYOD workflows and compliance requirements. • Level 5: regularly reviewed and updated policies integrating feedback and regulatory changes.
Regulatory compliance	Ensuring BYOD use adheres to health care regulatory standards and data security requirements	• Level 1: no understanding or monitoring of regulatory requirements for BYOD. • Level 2: minimal awareness of applicable regulations for BYOD use, with inconsistent adherence. • Level 3: regulatory requirements are clearly defined and communicated. • Level 4: compliance is routinely monitored and documented. • Level 5: automated systems ensure real-time adherence to regulatory standards for BYOD devices.
Policy enforcement	Mechanisms to monitor and ensure compliance with BYOD policies, including audits and corrective actions	• Level 1: no enforcement mechanisms for BYOD policies. • Level 2: limited BYOD monitoring with occasional audits. • Level 3: formal processes for BYOD monitoring and periodic reviews. • Level 4: balanced enforcement system integrating penalties and incentives. • Level 5: automated, real-time monitoring and enforcement of BYOD policies.
Incident response	Procedures for managing and resolving security incidents involving BYOD devices	• Level 1: no formal incident response processes for BYOD • Level 2: general IT incident management applies inconsistently to BYOD • Level 3: defined BYOD-specific incident response plans • Level 4: formalized processes with clear roles and rapid response capabilities • Level 5: automated, proactive incident response systems for BYOD threats
Lost device policy	Guidelines for handling lost or stolen BYOD devices, including data recovery and remote wiping	• Level 1: no procedures for lost or stolen BYOD devices • Level 2: staff follow ad hoc guidance for reporting and recovery • Level 3: defined policy for data wiping and device recovery • Level 4: selective data wiping to protect sensitive information • Level 5: real-time device tracking and automated data wiping capabilities
Accountability and governance	Defined structures and roles for overseeing and ensuring accountability for BYOD security	• Level 1: no defined roles or governance for BYOD security • Level 2: informal BYOD governance with limited oversight • Level 3: BYOD governance exists but is included in general IT management • Level 4: formal structures with clear roles and responsibilities for BYOD oversight • Level 5: agile BYOD governance processes integrated into organizational leadership and IT strategy

[a]BYOD: bring your own device.

The following subsections outline the progression of maturity levels within the policy dimension.

Level 1: Undefined BYOD Policy

At this foundational level, there is no formal BYOD strategy or dedicated policy for IT security concerning BYOD. Legal risks are not identified, and there are no established processes for enforcement, measurement, or compliance verification. Incident management is ad hoc and slow, with no defined roles or responsibilities for BYOD governance, making the organization highly vulnerable to security incidents.

Level 2: Basic, Informal Policy

BYOD policy is incorporated into the general IT strategy, with only loosely defined BYOD security aspects and references to legislation. Legal risks are vaguely defined, and compliance verification is minimal, with a general incident management process lacking specific standard operating procedures for BYOD incidents. Lost or stolen devices are not addressed, and governance is informal, lacking a clear structure and authority.

XSL•FO
RenderX

Level 3: Defined Policy With Basic Governance

A dedicated BYOD policy is established, offering high-level guidance. Legal risks are identified, but they remain complex and difficult for the staff to understand. There is basic enforcement, with a high-level compliance verification process. A BYOD incident management process is defined, but response times are slow, and devices are only wiped out when it is lost or stolen. Governance is somewhat integrated, with BYOD security part of the general IT and security governance framework.

Level 4: Comprehensive Policy With Formal Governance

At this level, a comprehensive BYOD strategy covers both clinical and nonclinical aspects, with well-defined legal risks that are regularly monitored. Compliance is measured through a balanced system, and a defined BYOD incident management process is in place, supported by a dedicated security team. The policy allows for selective data wiping on lost devices, and a formal BYOD governance structure is established to ensure accountability and clarity in roles.

Level 5: Advanced, Proactive Policy

The highest maturity level features a fully developed and continually updated BYOD strategy that is aligned with the latest threat, business, and legal landscapes. Compliance verification is automated with real-time measurement. The incident management process is highly automated and proactive, with swift responses and advanced capabilities. Governance is robust, ensuring that all aspects of BYOD policy are tightly managed within a well-defined structure, allowing for adaptability and scalability in response to evolving security needs.

People

Overview

The people dimension emphasizes the evolution from minimal awareness and isolated efforts to a fully integrated, proactive security culture. As maturity increases, the organization's workforce becomes more knowledgeable, engaged, and adept at managing BYOD security, aligned with the organization's overarching goals for patient safety and data protection in health care environments. Table 3 provides a brief overview of the people domains:

The following subsections outline the progression of maturity levels within the people dimension.

XSL•FO
RenderX

Table 3. People dimension: domain definitions and descriptions (8 domains).

People dimension	Definition and description	Levels summary
BYOD[a] security awareness and training	Programs to educate staff on the risks and security best practices specific to BYOD device use	• Level 1: no awareness programs or training for staff • Level 2: generic training offered occasionally, with minimal focus on BYOD security • Level 3: dedicated BYOD training programs addressing basic security risks • Level 4: comprehensive, role-specific training with practical scenarios for BYOD security • Level 5: regularly updated, workflow-integrated training emphasizing BYOD best practices
Training dissemination	Methods and channels for delivering BYOD-specific security training to staff effectively	• Level 1: no structured BYOD training dissemination • Level 2: periodic reminders or basic presentations • Level 3: online modules accessible to staff, covering BYOD security • Level 4: multichannel training, including workshops and hands-on sessions tailored to staff roles • Level 5: integrated dissemination through various media, including just-in-time training tools
Training importance	Emphasizing the role of training in maintaining security when using BYOD devices in the hospital environment	• Level 1: BYOD training not prioritized or mandatory • Level 2: training is optional and provided only to interested staff • Level 3: training viewed as important and made available to all staff • Level 4: training made mandatory with management oversight • Level 5: training incentivized and fully embedded in hospital practices, with performance linked to adherence
Management support	Leadership commitment and staff support to prioritizing and funding for BYOD security	• Level 1: no visible support from leadership for BYOD security initiatives • Level 2: limited acknowledgment of BYOD security risks • Level 3: moderate support, with funding allocated for basic BYOD security measures • Level 4: high-level support with strategic investments in BYOD security • Level 5: unrestricted commitment, with BYOD security as a priority in organizational strategy
Stakeholder involvement	Engagement of key stakeholders, including clinical staff and IT teams, in shaping BYOD security strategy, practices, and procedures	• Level 1: no involvement of stakeholders in BYOD decisions • Level 2: minimal IT department involvement without clinical input • Level 3: limited leadership and stakeholder input in shaping BYOD policies • Level 4: regular feedback and participation from clinical and IT teams • Level 5: continuous collaborative engagement of stakeholders in all BYOD-related strategies and practices
Security culture	Promoting a proactive organizational approach to securing hospital and personal data in a BYOD environment, fostering awareness and collaboration	• Level 1: no emphasis on security culture; reactive approach to incidents • Level 2: awareness limited to certain departments • Level 3: general staff awareness of security risks but minimal collaboration • Level 4: proactive initiatives to promote a security-conscious culture across the organization • Level 5: continuous improvement and organization-wide security commitment embedded into the culture
Usability and productivity	Balancing security measures for BYOD devices with ease of use to enhance clinical workflows and staff efficiency	• Level 1: BYOD security measures such as extensive restrictions and complex passwords, impede usability, leading to workarounds • Level 2: basic usability improvements, such as reduced sign-on, implemented without significant productivity gains • Level 3: improved usability through simplified processes such as basic sign-on • Level 4: workflow-optimized BYOD security measures, such as single sign-on and enterprise productivity BYOD apps • Level 5: fully integrated, seamless user experience enhancing both security and productivity through an optimized, secured, and unrestrictive BYOD environment
Expertise and skills improvement	Building and maintaining technical skills to manage and secure BYOD devices effectively	• Level 1: no focus on BYOD-related technical skills • Level 2: limited skill-building through ad hoc initiatives • Level 3: dedicated IT staff receive basic BYOD security training • Level 4: regular training and certifications provided for key staff • Level 5: advanced, ongoing skill development programs to maintain high levels of BYOD expertise

[a]BYOD: bring your own device.

Level 1: Limited Awareness and Reactive Approach

At this initial stage, there is no formal IT security training for staff regarding BYOD. Employees rely solely on personal knowledge and awareness, without any structured support or guidance from management on cybersecurity issues. There is a lack of stakeholder involvement in the BYOD strategy, leading

XSL•FO
RenderX

to a restrictive environment with low expertise and inadequate capacity to handle BYOD-related security issues.

Level 2: Basic Guidance With Minimal Organizational Support

This level introduces optional, generic IT security training, with basic guidelines and reminders sent to staff. Management provides limited support for cybersecurity initiatives, with only IT or executive groups involved in BYOD strategy development. The organization operates within a reactive security culture, where employees create workarounds due to limited resources. Individual staff members handle BYOD security issues independently, rather than through coordinated departmental efforts.

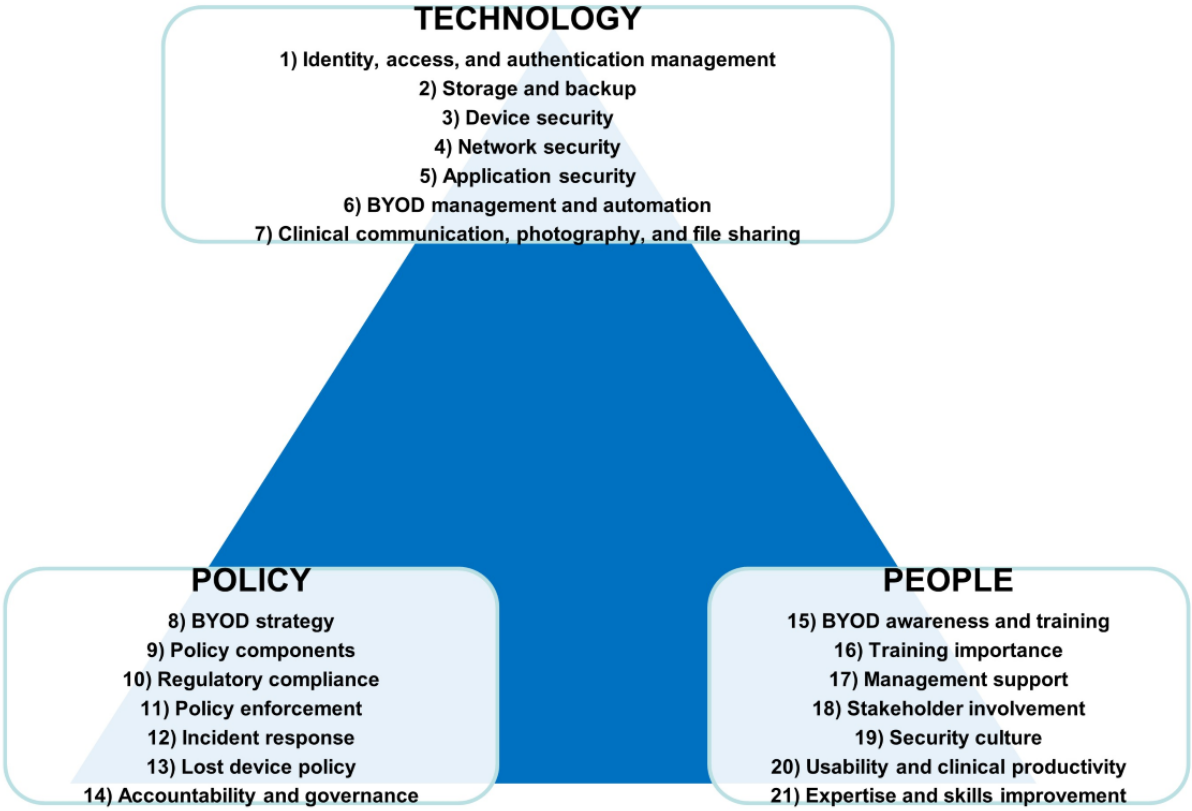
Level 3: Structured Training With Moderate Stakeholder Engagement

A dedicated BYOD security training program is in place, prioritizing cybersecurity with moderate management support. Clinical leaders play a minimal role in BYOD security decision-making, and there is general awareness among staff about the importance of patient data protection. However, resistance to change exists within some groups. Basic features, such as SSO, are introduced to simplify workflows, and dedicated IT personnel manage BYOD security.

Level 4: Integrated Security Culture With High Stakeholder Involvement

BYOD security training becomes a mandatory, strategic, and practical component of the organization's cybersecurity approach, with a high level of commitment and active management support. Clinical stakeholders, including BYOD users, are consulted in strategy development and changes, fostering a proactive security culture. The organization demonstrates strong capabilities to manage BYOD-related sociotechnical issues and leverages enterprise productivity features to enhance security and efficiency.

Level 5: Tailored Support and Proactive, Adaptive Security Culture



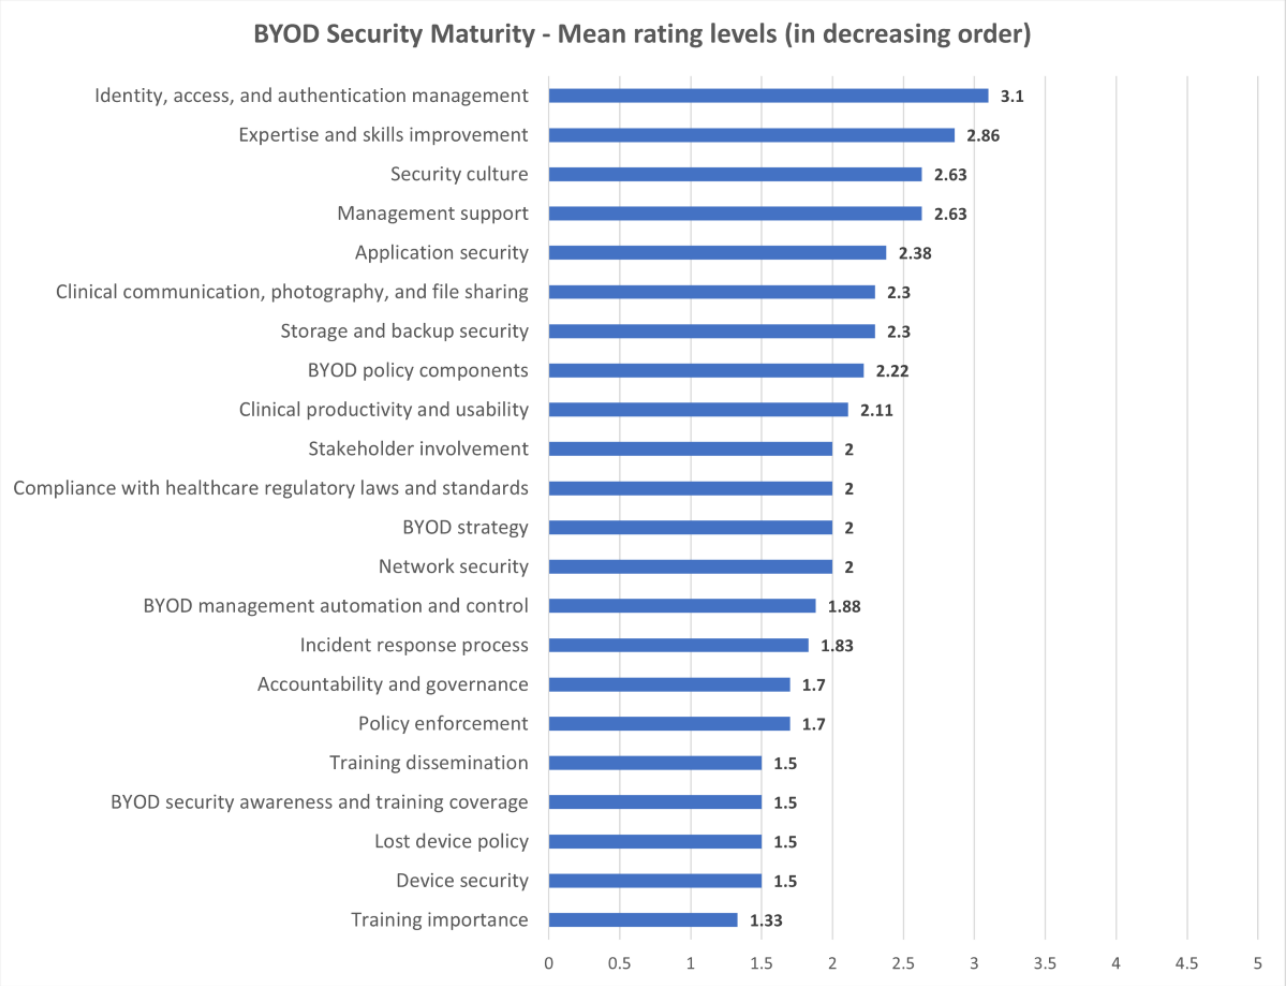
At the highest maturity level, BYOD security training is regularly updated and tailored to align with specific workflows, making cybersecurity a top priority. There is ongoing, unrestricted support from management, along with a collaborative process involving all stakeholders in BYOD strategy development. The organization promotes a proactive and continually improving security culture, where security concerns are autonomously managed through skilled improvement programs. This level represents a mature, integrated approach where the workforce is fully engaged and prepared to handle BYOD security challenges effectively.

Feedback and Refinements

Participant feedback led to both content and structural refinements of the maturity model. Content changes included clarifying technical terms, enhancing policy definitions, and tailoring guidance to BYOD use scenarios. Structurally, overlapping domains were consolidated for clarity and coherence. Detailed revisions, including before-and-after descriptions, are provided in Multimedia Appendix 4. Figure 3 illustrates the revised 21 domains across the 3 dimensions of the hBYOD security maturity model.

XSL•FO
RenderX

Figure 3. Hospital bring-your-own-device (hBYOD) security maturity model—dimensions and domains. BYOD: bring your own device.



Pilot Study: BYOD Security Maturity Assessment and Recommendations for Model Hospital

Maturity Assessment Survey Results

The hospital BYOD maturity assessment evaluated security practices for the model hospital across the initially envisaged 22 domains, categorized into technology, policy, and people dimensions. The overall mean maturity level was 2.04, indicating foundational security practices. Technology scored an average of 2.21, policy scored an average of 1.85, and people scored an average of 2.07. Figure 4 provides a summary of the assessment results.

XSL•FO
RenderX

Figure 4. Bring-your-own-device (BYOD) security maturity assessment results for the model hospital.

Workshop Findings and Recommendations

Overview

In the maturity assessment survey, participants ranked domains to identify priority areas. Given time constraints, only the top 2 ranked domains from each PPT dimension were discussed in the workshop. The following summarizes key challenges and solutions mapped to the maturity model recommendations:

Priority Domain 1 (Technology): Identity, Access, and Authentication Management

Challenge 1: Cumbersome Authentication Requirements

Clinicians faced productivity challenges due to complex authentication processes, such as logging into multiple hospital applications, setting up 2-factor authentication, and managing regular BYOD updates. The varying levels of technology expertise among clinicians further exacerbated the issue, increasing dependency on IT support staff.

Recommendations

The first recommendation was BYOD workflow analysis. Tailor authentication processes to align with clinical workflows, minimizing disruption (usability and clinical productivity: level 4). Define access levels based on roles and analyze data flows to ensure security without impacting productivity (IAM: level 4). The second recommendation was advanced IAM solutions. Invest in role-based access control, multifactor authentication, and SSO services to streamline IAM across device types and locations, enhancing efficiency and reducing IT overhead (IAM: level 4).

Challenge 2: Managing BYOD Device Identities Across Multiple Health Services

Clinicians working across multiple health services encounter conflicts in BYOD requirements, making it impractical to implement device management solutions such as MDM.

Recommendations

The first recommendation was *hospital-owned devices or device segregation*. Encourage using separate BYOD devices for different health services to simplify management. Alternatively, provide hospital-owned devices to staff working at multiple health services after following an approval process. Allow full administrative control over devices for IT administrators (device security: level 3). The second recommendation was centralized identity management**.** Implement state-level centralized identity systems to provide a unified authentication experience across multiple health services, ensuring compatibility and reducing complexity (IAM: level 4; BYOD management automation and control: level 4).

XSL•FO
RenderX

Priority Domain 2 (Technology): Clinical Communication, Photography, and File Sharing

Challenge 1: Lack of a Sanctioned Platform for Clinical Communication

The absence of a formal strategy led to the use of multiple platforms for clinical communication, photography, and file sharing, with no consistency. Hospitals relied on tools such as Microsoft Teams, SharePoint, and OneDrive, while clinicians often used personal apps such as WhatsApp and Messenger for communication.

Recommendations

The first recommendation was strategy and policy development. Define and formalize a comprehensive strategy outlining approved platforms, processes for obtaining patient consent, and guidelines on information sharing and separation of personal and hospital data on BYOD devices (clinical communication, photography, and file sharing: level 3). The second recommendation was stakeholder engagement. Ensure buy-in from clinicians and other stakeholders to promote adherence to the strategy, minimizing policy circumvention (stakeholder engagement: level 4).

Challenge 2: Use of Unsecure Platforms

Unsecure platforms for communication and file-sharing posed risks, such as data leakage and unauthorized access, especially when patient data or photographs were stored on personal devices or cloud storage.

Recommendations

The first recommendation was to formalize generic platforms. Restrict the use of unsecure personal apps and formalize hospital-approved platforms such as Teams, SharePoint, and OneDrive, leveraging their encryption and secure storage capabilities to reduce risks (clinical communication, photography, and file sharing: level 2). The second recommendation was to invest in dedicated platforms. Opt for secure clinical communication and file-sharing platforms tailored for hospital use. These platforms should integrate with clinical systems, support electronic patient consent for photography and data sharing, and improve usability, thereby enhancing clinical workflows (clinical communication, photography, and file sharing: level 4).

Priority Domain 3: BYOD Strategy

Challenge 1: Lack of Strategic Direction

Workshop participants highlighted the absence of a clear strategic framework for BYOD security. Sociotechnical controls were implemented on an ad hoc basis, with critical aspects such as approved applications, device definitions, information exchange, and policy enforcement measures left undefined. Inconsistencies in related policies further compounded the issue, creating confusion among staff.

Recommendations

The first recommendation was to develop a comprehensive strategy. Establish a formal BYOD strategy addressing both clinical and nonclinical aspects, with a strong focus on patient and staff data privacy and security (BYOD strategy: level 3). The second recommendation was to consolidate existing controls. Streamline and formalize existing sociotechnical controls to eliminate inconsistencies and conflicts in related policies (BYOD strategy: level 3). The third recommendation was effective communication. Disseminate the strategy through various channels to ensure staff understand and comply with BYOD security guidelines, fostering clarity, direction, and user buy-in (stakeholder involvement: level 3).

Priority Domain 4: Accountability and Governance

Challenge 1: Undefined Roles and Responsibilities

Workshop participants highlighted a lack of clarity regarding BYOD-related roles and responsibilities, leading to confusion among staff. Clinicians were unsure about boundaries for BYOD use, such as when and where devices could be used (eg, within the hospital or after work hours) and for what purposes. In addition, there was insufficient guidance on actions required to ensure patient data privacy, responsible BYOD use, and compliance with legal and hospital policies.

Recommendations

The first recommendation was to define and communicate roles: Clearly outline BYOD-related roles and responsibilities through user agreements or employment contracts (accountability and governance: level 3). The second recommendation was a BYOD governance framework. Implement a governance structure that specifies reporting lines and promotes accountability (accountability and governance: level 4). The third recommendation was policy alignment. Ensure these expectations are integrated into the hospital's BYOD strategy to enhance compliance and improve user behavior (BYOD strategy: level 3).

Challenge 2: Lack of Transparency

Staff expressed concerns about the rationale behind certain security measures, such as MDM, which they perceived as intrusive to personal privacy. This lack of transparency created mistrust, with staff uncertain about the implications of security requirements such as dual-factor authentication and device restrictions.

Recommendations

The first recommendation was to enhance transparency. Clearly explain the rationale behind BYOD security measures, addressing staff concerns about personal privacy and productivity (security culture: level 3). The second recommendation was effective communication. Use the BYOD policy, user agreements, and training sessions to inform staff about privacy protections and hospital efforts to maintain productivity (BYOD awareness and training: level 3; stakeholder involvement: level 3). The third recommendation was to build trust. Foster confidence by demonstrating how personal data are safeguarded and ensuring staff understand the benefits of implemented security measures (accountability and governance: level 4; security culture: level 4).

XSL•FO
RenderX

Priority Domain 5: Stakeholder Involvement

Challenge 1: Minimal Input From Clinical Stakeholders

Both clinical and IT management groups identified the lack of clinician input in BYOD policy and strategy development as a key issue. This gap often led to policies misaligned with clinicians' workflow and productivity needs, resulting in limited buy-in. The compliance-driven focus of IT management, aimed at meeting state regulatory requirements, was seen as a contributing factor. Clinicians also raised concerns about meeting device requirements and the additional costs of using personal mobile data. On the IT side, engaging busy clinicians in strategy discussions was challenging, as cybersecurity often took a lower priority compared to their clinical responsibilities.

Recommendations

The first recommendation was to involve senior clinical stakeholders. Engage senior informatics officers, such as chief medical informatics officers or chief nursing informatics officers, in BYOD policy development and decision-making. These leaders can act as bridges between clinicians and IT management (stakeholder involvement: level 3). The second recommendation was to facilitate regular engagement. Establish regular forums, such as monthly meetings, to discuss BYOD security issues, raise awareness, and gather clinician feedback (stakeholder involvement: level 4). The third recommendation was to promote cybersecurity awareness. Use informatics officers to educate clinicians on the importance of cybersecurity, integrating it into their roles to encourage active participation in related activities (stakeholder involvement: level 5).

Priority Domain 6: Security Culture

Challenge 1: Convenience-First Environment

Participants noted that in a hospital setting, patient care often takes precedence, leading to a preference for convenience over data security. Clinicians frequently circumvent policies by using unsanctioned platforms, such as WhatsApp, for tasks such as sharing patient photos or clinical information.

Recommendations

The first recommendation was user-friendly policies and tools. Minimize workflow disruption by ensuring BYOD tools and processes are intuitive and easy to use (usability and clinical productivity: level 4; security culture: level 3). The second recommendation was comprehensive training programs. Enhance staff awareness of BYOD security risks through interactive and tailored training methods, such as phishing simulations and role-specific modules (BYOD security awareness and training: level 4). The third recommendation was strategic awareness campaigns. Educate clinicians on the impact of policy circumvention to foster compliance and reduce reliance on insecure platforms (security culture: level 4).

Challenge 2: Resistance to Change

Clinicians may resist BYOD security measures, citing fears of personal privacy intrusion or productivity losses. For example, concerns about device monitoring or objections to multifactor authentication and mandatory updates are common.

Recommendations

The first recommendation was to change management programs. Develop systematic approaches to address resistance, incorporating strategies to reduce disruption and alleviate concerns (security culture: level 4). The second recommendation was the hospital's commitment to cybersecurity. Ensure visible management support to emphasize the importance of cybersecurity (management support: level 4). The third recommendation was to engage change champions. Use influential clinicians to advocate for security measures, explain their rationale, and address concerns about privacy and workflow impacts within their departments (security culture: level 5).

The workshop structure and screenshots of brainstorming notes from the MURAL worksheets used by the clinical and IT management groups are provided in Multimedia Appendix 5.

Discussion

Principal Findings

This study introduces a sociotechnical maturity model that offers a holistic approach to addressing hospital BYOD security risks. By combining technical controls with organizational policies and human factors, the model fills existing gaps in the literature by integrating technical controls with organizational policies and human factors. It uniquely defines maturity levels across 21 specific domains, making it modular and providing detailed guidance throughout all areas of BYOD security. In addition, encompassing the key dimensions of PPT, it offers a comprehensive framework that spans the entire BYOD life cycle within hospitals. This aligns with the recommendations of several researchers who highlighted the importance of integrating sociotechnical elements into information security management [22,51-53]. Furthermore, a prominent feature of the maturity model is its accommodation of unique health care sociotechnical factors. Domains, such as clinical communication and collaboration, clinical productivity and usability, and compliance with health care regulatory laws and standards, better represent the complexity of cybersecurity in health care settings, especially concerning BYOD environments. This focus is supported by McLeod and Dolezel [54], who emphasized the critical role of regulatory compliance and user behavior in health care cybersecurity. The model also contributes theoretically by operationalizing abstract socio-organizational factors, such as security culture, into discrete, assessable maturity levels. This allows hospitals to systematically measure and improve human-centered dimensions of security previously overlooked in dominant frameworks.

This model also directly responds to several limitations identified in cybersecurity maturity literature. For instance, Büyüközkan and Güler [33] noted the lack of industry-specific models and insufficient emphasis on human and organizational factors. While their model is broad and literature based, it does not include detailed, structured maturity levels or any health care–specific focus. Bitzer et al [35] present a sociotechnical maturity model with tangible evaluation metrics, but it is limited to incident response and does not extend across the broader health care cybersecurity landscape. Similarly, Smyrlis et al [36] offer a health care cybersecurity risk assessment model

XSL•FO
RenderX

that is entirely technical and lacks both maturity level structuring and attention to human or organizational dimensions. AlDaajeh and Alrabaee [34] center their work on national-level cybersecurity capabilities rather than institutional or clinical implementation. In contrast, our model provides a modular, multidimensional, and health care–specific approach that can be practically applied within hospitals, offering clearly defined maturity levels across technology, policy, and people dimensions to guide structured, real-world improvement in BYOD security. In addition, the structured and modular design of the model facilitates alignment with internationally recognized cybersecurity frameworks, such as ISO/IEC 27001 and the National Institute of Standards and Technology Cybersecurity Framework [55]. By covering key areas, including governance, access control, incident response, and compliance monitoring, the model enables translation of these high-level standards into context-specific, actionable practices. It supports hospitals in operationalizing global best practices through enforceable policies, measurable progress indicators, and a commitment to continuous improvement, all while addressing the distinctive sociotechnical challenges posed by BYOD in health care environments.

The model was developed through MMAR, which synergistically integrated perspectives from both IT management and clinical users. MMAR facilitated the consolidation and critical analysis of findings from multiple empirical studies, enabling the refinement of the preliminary framework and the mapping of recommendations to formulate a comprehensive maturity model that ultimately provides a structured road map for enhancing BYOD security capabilities within hospitals. Being incremental and iterative in nature, MMAR can allow successive refinements to the maturity model based on evolving insights by incorporating emerging cybersecurity threats, advancements in technology, and evolving hospital security needs. As demonstrated in this study, stakeholder engagement through IT and clinical representatives played a crucial role in refining the maturity model. Therefore, methodologically, this study contributes to cybersecurity maturity model development by applying MMAR, enabling co-creation with end users. This iterative, participatory process grounds the model in real-world hospital contexts and contributes to theory by demonstrating the value of embedded stakeholder engagement in model formulation.

In terms of model updating, a cyclical evaluation process can be applied for future updates to the model through a structured step-by-step approach. First, periodic reassessments should be conducted through a regular review of industry best practices, emerging security frameworks, and hospital-wide BYOD security evaluations, including surveys and compliance audits, to identify gaps and risks. Second, real-world case studies can be integrated by analyzing security incidents, policy effectiveness, and user compliance trends, ensuring the model reflects actual BYOD security challenges in hospitals. Third, expert consultations with cybersecurity professionals, health care IT leaders, and policy makers can help incorporate regulatory updates, advancements in security technologies, and evolving best practices. Fourth, refining domain definitions and maturity levels based on the best practices review, stakeholder feedback, and empirical findings will ensure that the model accurately represents new threats, technologies, and governance strategies. Finally, validation and implementation should occur through structured feedback loops, pilot testing across diverse health care settings, and continuous monitoring, enabling iterative refinements that enhance the model's adaptability and long-term applicability in hospital environments. This stepwise approach, enabled by the incremental nature of MMAR, ensures that the BYOD security maturity model remains dynamic, evidence based, and responsive to the evolving cybersecurity landscape in health care.

The technology dimension covers various BYOD security technical controls and practices across domains such as IAM, storage and backup security, device security, network security, application security, and clinical communication, photography, and file sharing. The lower levels reflect basic practices, such as single-factor authentication systems, mixing of hospital and personal data on BYOD devices, use of basic firewalls, no restriction or control over BYOD use, and use of personal and unsecure apps for clinical communication and collaboration. Such practices may lead to a higher risk of BYOD-related data breaches, as they suggest a complete dependence of BYOD security on user action due to a lack of control over BYOD-related user activities. As we move to higher levels, advanced technical controls, such as enterprise IAM solutions, federated and unified SSO, private cloud for hospital data storage and backup, unified end point protection to manage BYOD devices, network segmentation and visualization, software-defined networking, and a dedicated secure platform for clinical communication integrated with hospital clinical systems, are stipulated. These features minimize the risk of hospital data leakage, restrict unsecure behavior, improve clinical workflow, and also enable better management and control over hospital BYOD use. Such practices align with the topmost or "optimized" level of prominent information security maturity models [28].

The policy dimension focuses on hospital BYOD security strategy, governance, and compliance factors. Lower levels specify policy practices such as a lack of a formal BYOD governance structure, ad hoc and inconsistent policies on BYOD security, a slow incident management process, no or unchecked policy enforcement, and poor compliance to relevant regulations or standards. These practices indicate a lack of direction and guidance on BYOD security, which can result in poor management of BYOD security incidents and greater chances of breach of relevant legislation or regulations. Higher or more advanced levels are characterized by a well-defined, formalized, and comprehensive BYOD strategy and related policies, which are regularly updated in view of changes to the threat, business, and legal landscape. Real-time, automated, and advanced compliance measurement and incident management processes are also key features of higher BYOD policy maturity levels. Therefore, hospitals at higher BYOD security maturity levels are better guided and equipped to prevent, detect, and respond to BYOD security incidents. Such a proactive approach, incorporating technology-enabled solutions for real-time compliance monitoring, aligns with prominent adaptive security management frameworks emphasizing the importance of

XSL•FO
RenderX

continuously enhancing security practices by leveraging real-time data to promptly detect security incidents, monitor compliance, and adapt policies as needed [56,57].

Finally, the people dimension addresses the "human" element of hospital BYOD security and therefore consists of domains such as BYOD security awareness and training, stakeholder involvement, security culture, and clinical productivity and usability. The lower maturity levels of the "people" dimension indicate a reactive security culture where there is no or low commitment from hospital IT management and clinicians alike to improve BYOD security practices. It is characterized by minimal stakeholder input on BYOD security management, a restrictive BYOD environment, a lack of BYOD security training, and minimal skills or low expertise to manage BYOD security issues. Such measures may lead to unsafe security behavior among hospital staff, circumvention of policies, and a tension between clinical and IT departments, ultimately increasing chances of BYOD security breaches. As far as higher maturity levels are concerned, they indicate a proactive security culture, where cybersecurity is seen as a top priority by management and staff alike. Therefore, hospitals at an advanced state of BYOD security handle cybersecurity affairs autonomously and may implement measures such as dedicated BYOD security training tailor-made to clinical specialty, ongoing management support, and a regular stakeholder consultative process for BYOD security strategy or policy development. Eventually, these practices can improve staff commitment and knowledge of BYOD security while also ensuring that BYOD use is made productive, in addition to being secure. A balanced approach that effectively balances productivity with security can lead to a positive security culture, thereby improving compliance and reducing risks [58-60].

The pilot implementation demonstrated how the hospital BYOD security framework can be applied to assess current practices and codevelop tailored recommendations. The maturity survey identified key gaps, while the workshop enabled stakeholder-driven discussions to guide progress from the "as-is" to the "to-be" state. This participatory approach proved valuable in addressing BYOD security challenges that are particularly important in complex and dynamic environments such as hospitals [61].

Change Management Considerations

While the maturity model provides a structured approach to hospital BYOD security, its implementation presents several challenges that hospitals must consider. Resource requirements vary depending on the hospital's current BYOD security posture, as advancing to higher maturity levels may require investment in MDM solutions, end point security tools, secure authentication systems, staff training programs, and dedicated cybersecurity personnel. Change management strategies are essential to ensure smooth adoption, particularly when introducing stricter BYOD policies, access controls, or security monitoring tools that may impact clinical workflows. Engaging stakeholders, including IT teams, clinicians, and hospital administrators, through structured communication, tailored training, and phased rollouts can minimize disruption and improve adherence. Potential resistance from stakeholders, especially clinical staff, must be addressed by demonstrating that security measures do not hinder usability or productivity. Establishing leadership buy-in and appointing clinical and IT champions can further support organizational alignment and reduce friction during implementation. Furthermore, hospitals should ensure that BYOD security policies are clinically feasible, providing secure yet user-friendly alternatives (eg, approved hospital communication apps instead of WhatsApp) to prevent the circumvention of policies through shadow IT. Integration with existing systems is another key consideration, as BYOD security measures must be compatible with EMRs, secure messaging platforms, hospital networks, and cloud-based collaboration tools without disrupting access to critical clinical information.

Significance

The maturity model serves as a valuable tool for assessing the current state of BYOD security management within a hospital, leading to a better understanding of strengths, weaknesses, and gaps in the existing security posture. It facilitates structured improvement toward a higher maturity level. Both internal and external technology or security auditors can use the model. Internal auditors, such as the hospital's IT or cybersecurity practitioners, can periodically assess BYOD security to set new improvement goals. Hospitals can also engage specialized auditors to carry out the assessment process.

Hospitals can follow a systematic approach to improve their BYOD security posture using the maturity model (Textbox 1).

In addition, government agencies, such as health departments, can use the maturity model as an audit tool to assess whether a hospital's BYOD security aligns with established standards.

XSL•FO
RenderX

Textbox 1. Improving bring your own device (BYOD) security posture using the hospital BYOD security maturity model.

1. Understanding the current maturity state: conduct a BYOD security assessment across the 21 domains. This step establishes the baseline or "as-is" state, crucial for understanding the current BYOD security position.
2. Identifying priority domains: determine critical areas or domains of BYOD security that require attention. Prioritization is essential because hospitals have finite resources and may not be able to improve all domains simultaneously. Improvement should be carried out step by step, addressing priority areas first. Involving all relevant stakeholders, especially technical and clinical personnel, ensures that user requirements are considered.
3. Setting improvement goals: develop achievable and measurable improvement goals based on the progressive maturity levels specified by the model. Identify which maturity level to aim for in each priority domain, considering hospitals' unique needs, constraints, and regulatory requirements. Improvement goals should be clearly defined using quantifiable benchmarks or key performance indicators, such as increasing SSO adoption rates, training completion percentages, or MDM enrollment levels, to track meaningful progress. Goals should be feasible, with a well-thought-out plan that gains consensus among all relevant stakeholders within the hospital.
4. Measuring progress: continuously monitor the progress of set goals against measurable, time-bound metrics set in stage 3 to systematically measure progress and ensure structured, data-driven maturity advancement. Verify that all actions required to advance to the next maturity level have been completed, providing concrete evidence of progress.
5. Revisiting maturity improvement: recognize that BYOD security management is an ongoing process requiring regular cycles of improvement. Establish a reasonable time frame to revisit and enhance controls and processes to counter evolving and complex BYOD security threats.

Limitations

The utility of the proposed hospital BYOD security maturity model has not been extensively tested across diverse hospital environments. Although significant effort was invested to enhance the model's accuracy by mapping maturity levels to recommendations derived from empirical studies and aligning them with industry standards, the model's practical effectiveness remains to be fully validated. Feedback from study participants was incorporated to refine the model further; however, additional validation and evaluation studies are required in various hospital contexts to improve its accuracy and efficacy. In addition, the rapidly changing nature of cybersecurity threats and technologies means that the model may require continuous updates to remain relevant. New types of security risks, emerging technologies, and changes in legal requirements could necessitate revisions to the model's domains and maturity levels. Another consideration is the approach to maturity assessment; while averaging assessors' ratings provides an overview, it can obscure key issues in the maturity assessment process. A structured consensus-building method, such as the Delphi approach used in the development of the Essentials of Cybersecurity in Healthcare Organizations framework [62], could enhance assessment reliability by integrating expert opinions systematically. Future research should focus on implementing such consensus-driven assessment methods alongside extensive validation studies in diverse hospital settings to refine the model, enhance its generalizability, and ensure it remains a practical tool for improving BYOD security in the ever-evolving landscape of health care cybersecurity. In addition, future validation studies may provide further insights into refining behavioral assessment methodologies, potentially incorporating more direct behavioral metrics where needed to better evaluate how security behaviors are enacted in practice.

Equal representation of both clinical and technical stakeholders was initially planned; however, due to limited availability, only 3 clinical representatives were able to participate in the workshop. Nonetheless, these clinicians had consulted with their broader teams beforehand and conveyed shared concerns and perspectives during the assessment. This imbalance in representation may have introduced a bias toward technical perspectives in the model's pilot results. Future research should aim for a more balanced stakeholder composition and a larger, more diverse sample to ensure broader applicability and validation.

Conclusions

This study developed a sociotechnical BYOD security maturity model tailored for hospitals, addressing gaps in existing cybersecurity models. By integrating technical controls, policies, and human factors, the model provides a holistic approach to managing BYOD security risks. The pilot implementation demonstrated how hospitals can use the model to create a structured, modular road map for enhancing security while balancing the unique sociotechnical complexities of health care.

Acknowledgments

The authors extend their sincere appreciation to the University of Melbourne for its support through the Melbourne Research PhD Scholarship. They are also deeply grateful to all study participants and the participating organization for their valuable contributions to the research. The authors further acknowledge and thank everyone who played a role in the successful completion of the study. Special thanks are extended to Adj Professor Frank Smolenaers for his ongoing support and guidance throughout the project.

Abstract

Background: The COVID-19 pandemic forced the world to quarantine to slow the rate of transmission, causing communities to transition into virtual spaces. Asian American and Pacific Islander communities faced the additional challenge of discrimination that stemmed from racist and xenophobic rhetoric in the media. Limited data exist on technology use among Asian American and Pacific Islander adults during the height of the COVID-19 shelter-in-place period and its effect on their physical and mental health.

Objective: This study aims to examine Asian American and Pacific Islander adults' attitudes, perspectives, and experiences regarding their use of technology during the COVID-19 pandemic.

Methods: We collaborated with community partners and used social media to distribute the COVID-19 Effects on the Mental and Physical Health of Asian Americans and Pacific Islanders Survey Study, a nationwide multilingual survey available in English, Chinese, Korean, Samoan, and Vietnamese. The survey was administered from October 2020 to February 2021, and participants rated their level of agreement (1=*not at all* to 5=*extremely*) on 6 items assessing their attitudes toward technology use. Thematic analysis was conducted on responses to the open-ended question "Is there anything else you want to tell us about your use of technology during COVID-19?" The qualitative responses were reviewed, analyzed, coded, and organized into corresponding themes.

Results: The mean age of respondents was 45.9 (SD 16.3; range 18-98) years, with 5398 participants completing the quantitative survey and 1115 (20.66%) providing unique responses to the open-ended question. In the quantitative survey, 68% (3671/5398) of the respondents reported being comfortable using technology; the majority indicated that it helped them keep up with the news (4318/5398, 79.99%), maintain social connections (4102/5398, 75.99%), and provide care for others (2537/5398, 46.99%). However, responses were mixed regarding the usefulness of technology for health: 39.99% (2159/5398) agreed that it was helpful for mental health but disagreed regarding physical health. Four main themes emerged from the qualitative analysis: (1) technology was critical for functioning across many aspects of life and maintaining physical, mental, and emotional well-being; (2) technology was often the only means of interpersonal social connections; (3) overuse led to negative physical and mental health outcomes; and (4) technology use was associated with multiple challenges and barriers.

XSL•FO
RenderX

Conclusions: Our findings revealed diverse perspectives and experiences related to technology use by Asian American and Pacific Islander adults during the height of the COVID-19 pandemic. Dependence on technology may have exacerbated social inequities, particularly for those with lack of access to devices and Wi-Fi and limited English proficiency, affecting their ability to work, apply for jobs, and communicate virtually. Further qualitative research would be beneficial in amplifying the perspectives of Asian American and Pacific Islander adults to uncover concerns and address health disparities.

Introduction

Background

The impact of technology on society in the realm of health care access and delivery has been profound and multifaceted. The dependence on technology was magnified during the COVID-19 pandemic, underscoring the critical role that technology plays in nearly every form of communication. The pandemic caused widespread loss of life, a myriad of health consequences, and unprecedented physical and social isolation [1]. During this period, technology served as a vital tool for accessing health care, continuing remote work and education, and operating businesses. To protect older adults and others considered vulnerable, shelter-in-place policies were implemented to varying degrees across the world. As a result, many were forced to rely on virtual forms of communication, such as videoconferencing and online chat. In most cases, virtual communication became the only means of social interaction.

The pandemic also brought the digital divide to the forefront. Disparities related to COVID-19 and health care access were exacerbated for rural communities, racial and ethnic minority groups, individuals with low income, and other populations considered vulnerable. These groups were disproportionately burdened by the digital divide, compounding existing structural disadvantages [2]. These inequities may have been particularly acute for individuals with limited English proficiency in virtual workspaces and job interviews, where reliance on verbal communication can heighten communication challenges [3]. Research has also revealed that the widening of the digital divide intensified challenges, especially for rural residents [4]. However, to our knowledge, limited research exists on the use of digital technology among Asian American and Pacific Islander populations in the United States during the pandemic, particularly among older adults (aged ≥60 y) and adults with limited English proficiency. Asian American and Pacific Islander populations were especially vulnerable during the pandemic, as xenophobic attitudes became more prevalent due to racist statements linking China to COVID-19 [5]. As a result, many individuals from these communities experienced racism, discrimination, and hate crimes, which contributed to fear, loneliness, and social isolation [6,7].

A Pew Research Center survey of American adults conducted in April 2021 revealed that the internet served as a "lifeline" for many during the pandemic, but respondents also reported "struggles" associated with the increased use of and reliance on the internet [8]. Such surveys provide insights into general patterns of digital technology use, purposes, and associated challenges among the general American adult population. However, limited data exist on digital technology use patterns, perceived health-related support, and attitudes toward digital technology use among Asian American and Pacific Islander adults. Examining these gaps may assist in culturally and linguistically tailoring appropriate digital technology programs for these diverse populations. In addition, a better understanding of the impact of digital technology use is needed to inform clinical recommendations for physical and mental health.

Our prior work with the COVID-19 Effects on the Mental and Physical Health of Asian Americans and Pacific Islanders Survey Study (COMPASS) revealed that increased technology use during the pandemic was associated with poorer mental and physical health outcomes among participants [9]. Specifically, those who reported increasing their technology use by ≥7 hours per day experienced higher levels of depressive symptoms and worse physical health, regardless of age or ethnic background [9]. These findings suggest that even with high levels of digital access, increased technology use does not necessarily equate to positive health outcomes. Still, little is known about digital technology use among Asian American and Pacific Islander adults. In the COMPASS study, the majority of Asian American and Pacific Islander participants reported owning a smartphone (96.2%), home internet access (90%), a desktop or laptop computer (83.4%), a tablet (61.1%), cable television (43.5%), and a streaming device (45.7%).

Objectives

Building on previous findings, we aimed to address gaps in knowledge regarding technology use among Asian American and Pacific Islander populations by analyzing data from COMPASS, which examined mental and physical health implications associated with technology use during the height of the COVID-19 shelter-in-place period among Asian American and Pacific Islander adults in the United States. In this study, we quantitatively describe COMPASS participants' attitudes toward technology use and qualitatively explore their perspectives and experiences of technology use during the COVID-19 pandemic.

RenderX

Methods

Recruitment

A total of 5411 individuals participated in the study from October 2020 to February 2021. The survey was offered on the COMPASS website [10] in English, simplified Chinese, traditional Chinese, Korean, Vietnamese, and Samoan or by telephone with assistance from COMPASS staff and community partners (Multimedia Appendix 1). The survey was also offered by telephone in Cantonese, Mandarin, Vietnamese, Korean, and Samoan by multilingual COMPASS staff. The survey was shared through personal and professional networks via social media, email, telephone, health promotion webinars, flyers, and ethnic media across the United States. The 26 COMPASS community advisory board members and 15 community partners that serve Asian American and Pacific Islander populations supported recruitment efforts by promoting the survey among their networks. In addition, recruitment leveraged the Collaborative Approach for Asian Americans and Pacific Islanders Research and Education (CARE) registry [11,12], contacting eligible participants interested in participating in health research via email and telephone. The goal of the CARE registry was to increase the participation of Asian American and Pacific Islander individuals in research related to aging, Alzheimer disease and related dementias, and caregiving.

Ethical Considerations

The COMPASS research project was approved by the institutional review board of the University of California San Francisco (UCSF; 20-31925). Informed consent was provided by participants before survey completion. Participants had the option to receive a US $10 gift card upon completing the survey.

Eligibility and Procedures

Eligible participants were required to be aged ≥18 years; reside in the United States; and identify as Asian, Asian American, Native Hawaiian, Pacific Islander, or any combination of these with other racial or ethnic identities. Participants were also required to be able to read in English, Chinese (simplified or traditional), Korean, Samoan, or Vietnamese. We used the World Health Organization's instrument adaptation process [13], including backward and forward translation, to guide the multilanguage survey's scale and material development. All translated instruments were reviewed by multiple research team members for accuracy and cultural relevance. Non-English survey responses were translated into English through online translation services before analysis.

Methodology, Data Collection, and Measures

We applied a cross-sectional study design that included COMPASS quantitative survey data and qualitative data from an open-ended question asking, "Is there anything else you want to tell us about your use of technology during COVID-19?" Free-text responses of any length were accepted. The data were stored in REDCap (Research Electronic Data Capture; Vanderbilt University) tools hosted at UCSF [14,15]. For sociodemographic information, participants were queried about their age, sex, ethnic or cultural background, marital status, country of birth, education, employment status, annual household income, and English proficiency.

The technology use survey was developed by the COMPASS research team to explore patterns of technology use during the COVID-19 pandemic. Participants were queried about the number of hours they used technology per day and whether their technology use increased during the COVID-19 crisis. Responses were categorized into five groups: (1) "did not increase," (2) "increased by 1 to 2 hours per day," (3) "increased by 3 to 4 hours per day," (4) "increased by 5 to 6 hours per day," and (5) "increased by ≥7 hours per day." In addition, participants were asked about their comfort level with using technology and their engagement in various technology-mediated activities during the COVID-19 pandemic. These activities included video chatting with friends or family, video meetings for work-related activities, telephone or video visits with health care providers, exercise or physical fitness activities, mental health activities, keeping in touch with friends and family through social media, leisure activities or hobbies, and accessing news. Moreover, participants were asked to evaluate the helpfulness of technology. The survey encompassed statements concerning the use of technology for keeping up with the news, maintaining social connections, caregiving, supporting mental health, and enhancing physical health. Respondents indicated their level of agreement with each statement on a 5-point Likert scale ranging from 1=*not at all* to 5=*extremely*.

Analysis

Descriptive statistics were used to report the sociodemographic characteristics and technology use patterns of the sample. Qualitative analysis was conducted using content analysis. Two trained independent reviewers initially organized the raw participant responses and analyzed the data to identify subthemes and categorize significant statements. Using an iterative process and a constant comparative method, the research team refined the coding scheme, finalized the themes, and identified patterns and relationships across the qualitative data.

Coding and organization of interview data were conducted using Microsoft Word and Microsoft Excel. A third coder independently cross-checked the transcripts to ensure the consistency of the interpretation and summarized the coded content within thematic categories. After this initial round of analysis, the coders collaboratively reviewed subthemes and worked together to consolidate them under broader thematic umbrellas. Through continued discussion, 5 major themes were identified. Codes were developed to support each theme, with refined subthemes providing additional structure. Participant responses were then organized according to these codes to illustrate and support the thematic findings.

The first coder (ML) is a board-certified registered nurse and research analyst at UCSF, with extensive experience in public health, clinical nursing, and Asian American and Pacific Islander health promotion initiatives. Their professional background spans diverse health care settings, with a focus on community health; health equity; and holistic, family-centered care. The second coder (NP) is a project policy analyst at UCSF with a strong background in qualitative research and experience

XSL•FO
RenderX

engaging with research participants in both English and languages across several Asian American and Pacific Islander communities. Their expertise includes community-based participatory research, coordinating outreach initiatives, and developing volunteer programs for Asian American and Pacific Islander students. A third team member (LGP), also experienced in qualitative methods, served as an adjudicator to resolve discrepancies in data interpretation and assist in finalizing the thematic structure. The diverse backgrounds of all three coders informed their analytical lens, particularly in identifying sociocultural influences and health disparities within participants' narratives. Their lived experiences and cultural identities contributed to a reflexive and culturally responsive approach to qualitative analysis.

Results

Participant Characteristics

Only individuals who provided responses to the open-ended question (n=1115) were included in the analysis. The mean age of the participants was 45.9 (SD 16.3; range 18-98) years. The majority identified as Vietnamese (399/1115, 35.78%) and ethnic Chinese (336/1115, 30.13%), followed by those who identified as Korean (161/1115, 14.44%) and Filipino (69/1115, 6.19%). Most of the participants completed the qualitative question in the survey in English (665/1115, 59.64%), identified as female (731/1115, 65.56%), were either married or living with a partner (723/1115, 64.84%), and were born in a foreign country (776/1115, 69.6%). In addition, a significant portion of participants reported limited English proficiency (322/1115, 28.88%). Table 1 provides an overview of the demographic characteristics of the participants.

[a]Ethnic Chinese includes individuals who identified as mainland Chinese, Hong Kongers, Taiwanese, or Huaren.

The participants' technology use characteristics are presented in Table 2. The majority (644/1115, 57.8%) reported using technology for 1 to 8 hours per day. A notable portion (803/1115, 72%) reported increased technology use due to the COVID-19 pandemic. More than half of the respondents (627/1115, 56.23%) said that they were very or extremely comfortable using technology. During the pandemic, the most common activity was video chatting with friends or family, with 902 (81%) of the 1115 participants using platforms such as Zoom, WhatsApp, or FaceTime for communication. In addition, 614 (55.07%) participants engaged in video meetings for work-related activities, while 575 (51.57%) used technology for telephone or video visits with health care providers. Exercise or physical fitness activities were performed by 420 (37.67%) of the 1115 participants, while 187 (16.77%) reported engaging in mental health activities through technology. Social media served as a means of keeping in touch with friends and family for 866 (77.67%) of the 1115 participants, and 517 (46.37%) used technology for leisure activities or hobbies. Furthermore, 850 (76.23%) participants accessed news through technology platforms.

XSL•FO
RenderX

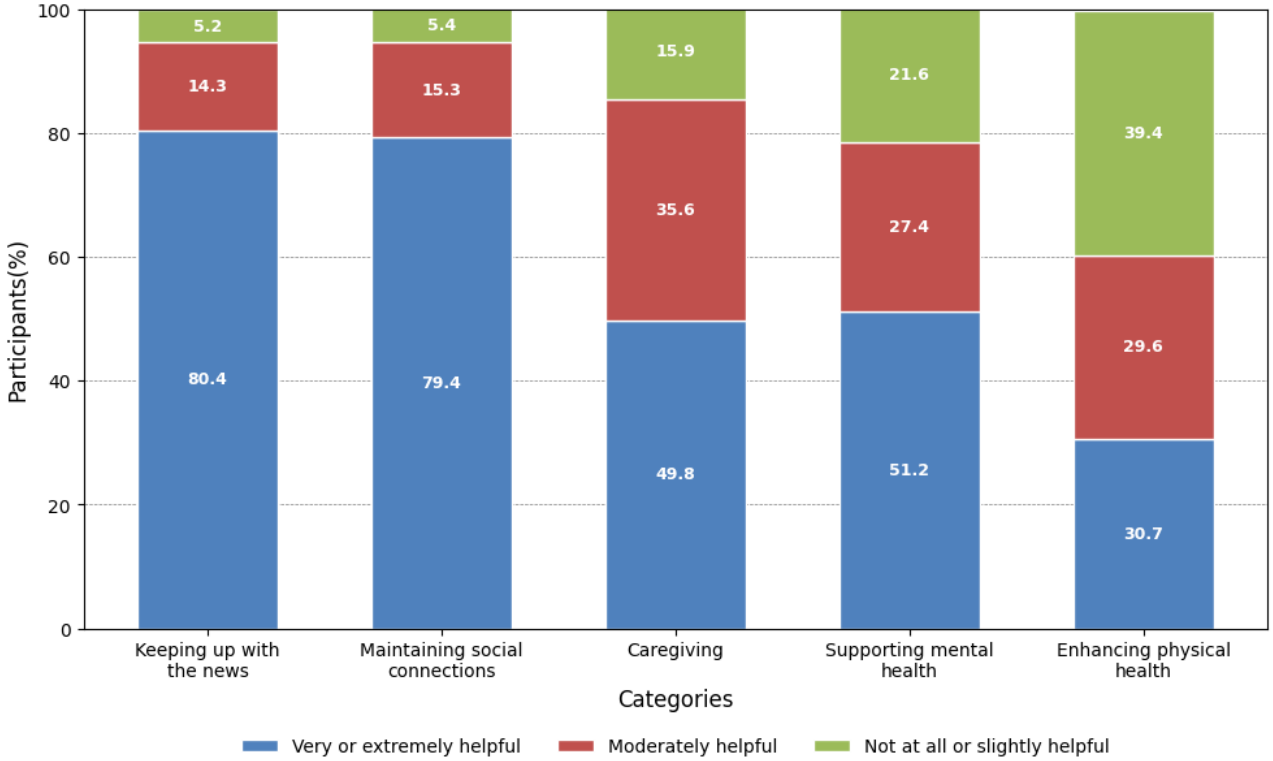

Table 2. Self-reported technology use of participants (n=1115).

Characteristics	Participants, n (%)
Total technology use (h/d)	
<1	66 (5.9)
1-4	321 (28.8)
5-8	323 (29)
9-12	238 (21.4)
13-16	120 (10.8)
≥17	46 (4.1)
Change in technology use due to the COVID-19 pandemic	
Decreased or stayed the same	292 (26.2)
Increased by 1-2 h/d	275 (24.7)
Increased by 3-4 h/d	311 (28)
Increased by 5-6 h/d	128 (11.5)
Increased by ≥7 h/d	89 (8)
Comfortable using technology	
Not at all	204 (18.4)
Slightly	91 (8.2)
Moderately	187 (16.9)
Very	301 (27.1)
Extremely	326 (29.4)
Types of technology used during the COVID-19 pandemic	
Video chatting with friends or family (eg, Zoom, WhatsApp, and FaceTime)	902 (80.9)
Video meetings for work-related activities	614 (55.1)
Telephone or video visit with health care provider	575 (51.6)
Exercise or activities for physical fitness	420 (37.7)
Mental health activities	187 (16.8)
Keeping in touch with friends and family through social media	866 (77.7)
Leisure activities or hobbies	517 (46.4)
Accessing news	850 (76.2)
None	20 (1.8)
Other (please specify)	20 (1.8)

The findings (Figure 1) indicate that the majority of participants (896/1115, 80.35%) found staying informed by accessing news through technology very or extremely helpful. In terms of keeping in touch with social connections, a significant majority (885/1115, 79.37%) perceived technology as very or extremely helpful, with only a small proportion (60/1115, 5.38%) reporting slightly or not at all helpful. Similarly, in the context of caregiving, a substantial portion of participants (938/1115, 84.12%) viewed technology as moderately or extremely helpful. However, perceptions regarding mental health support through technology varied, with a notable portion of participants (874/1115, 78.38%) finding it moderately or extremely helpful, while others (241/1115, 21.61%) indicated that technology was slightly or not helpful. Finally, participants' perceptions of technology's helpfulness for physical health varied, with a considerable proportion (565/1115, 50.67%) reporting technology being moderately or very helpful, while others (439/1115, 39.37%) expressed that technology was slightly or not helpful.

XSL•FO
RenderX

Figure 1. Survey responses to whether using technology was helpful in different aspects of life during the COVID-19 pandemic (n=1115).

Technology use among participants revealed a spectrum of use patterns (Table 2). Notably, 36.23% (404/1115) of the participants reported using technology for ≥9 hours per day. Specifically, 5.91% (66/1115) of the participants used technology for <1 hour per day, while 28.78% (321/1115) used it for 1 to 4 hours per day, 21.34% (238/1115) for 5 to 8 hours per day, 21.34% (238/1115) for 9 to 12 hours per day, 10.76% (120/1115) for 13 to 16 hours per day, and 4.12% (46/1115) for ≥17 hours per day.

Themes Related to Technology Use

Of the 5411 participants who completed the quantitative survey, 1115 (20.66%) provided responses to the open-ended question "Is there anything else you want to tell us about your use of technology during COVID-19?" A thematic analysis revealed four main themes related to digital technology use during the COVID-19 pandemic: (1) technology was critical for functioning across many aspects of life and maintaining physical, mental, and emotional well-being; (2) technology was often the only means of interpersonal social connections; (3) overuse led to negative physical and mental health outcomes; and (4) technology use was associated with multiple challenges and barriers.

Technology Was Critical for Functioning Across Many Aspects of Life and Maintaining Physical, Mental, and Emotional Well-Being

Overview

Technology use was found to be critical in maintaining daily activities related to skills and hobbies, work, and fitness during the pandemic. All these functions were reported to be vital for maintaining mental health, given the limited access to physical connection and ability to socialize outside of their homes. Participants reported feeling very isolated and believed that they would not have coped as well as they did without technology:

> *Without technology (internet, social networks, video streaming, online shopping), I'm not sure how I could survive this shelter-in-place.* [Ethnic Chinese participant, male, aged 44 y]

This reflects a common theme of isolation and disconnection experienced during the lockdown and shelter-in-place period. Many individuals were forced to physically distance from their community networks, resulting in increased reliance on technology to connect with others. In addition, many were unable to carry out routine errands, such as shopping, making delivery services their only option. One participant similarly emphasized her dependence on technology:

> *I would have gone absolutely insane without the internet during this quarantine.* [Filipino participant, female, aged 40 y]

During the lockdown, for many Asian American and Pacific Islander individuals, online access was the only means of connection to others. The internet was the safest way to follow public health guidelines, protect themselves and their loved ones from COVID-19 infection, and maintain their mental and emotional well-being. In terms of helpful aspects of technology, a participant described using social media to spread information and raise awareness on social issues relevant to Asian American and Pacific Islander individuals:

> *I used social media to spread information about anti-Asian discrimination and Black Lives Matter.* [Vietnamese participant, female, aged 49 y]

XSL•FO
RenderX

This statement reflects the broader context of the time, including the emotional unrest associated with the lockdown and the concurrent political movements and cultural propaganda directed toward the Asian American and Pacific Islander community. It highlights how these challenges were experienced by many individuals in this community and how they used social media as a tool for connection and raising awareness.

Skills and Hobbies

Many participants found technology to be beneficial for learning new skills and hobbies to pass time and for entertainment during the lockdown. These activities helped alleviate boredom and loneliness and created opportunities to explore new interests, for example, learning to cook, acquiring linguistic skills, and learning to play musical instruments. Such engagement was reported to help ease stress and remain occupied during the lockdown:

> *In my personal experience, the use of technology allowed me to learn and be exposed to people and places that may not have been possible. Also, I've become more knowledgeable with technology.* [Filipino participant, female, aged 62 y]

This quote illustrates how participants used technology to adapt and find new ways to connect with others as well as engage in new activities to promote positive habits and increase knowledge during the lockdown.

Another participant described how technology supported the continuation of daily activities and helped ease pandemic-related stress:

> *I have become better at the interplay between technology & non-technology- using technology to enhance aspects of my non-technology life like learning instruments or exercise.* [Chinese participant, female, aged 47 y]

This comment reinforces the theme of participants using technology to master new skills and hobbies to improve their quality of life during the shelter-in-place period.

Work

Learning new skills also included improving technology skills, such as adapting to online platforms for work and school. This included learning to navigate various tools and interfaces such as Zoom, Google Classroom, Google Workspace, Microsoft Office, and others:

> *I have had to learn to use a lot of technology tools for work within a very short period of time - Google classroom, Google slides, Google docs, Google drive, Ladibug document camera, Screencastify, Boom cards, interactive pdf, and of course, Zoom.* [Chinese (Huaren) participant, female, aged 51 y]

This quote reflects the transition to online forums and the use of new technological tools and how participants were required to quickly adapt to maintain productivity for work and school tasks during the lockdown.

Other benefits related to work included reduced commuting time and costs, which participants associated with increased efficiency and more time to focus on work-related tasks:

> *Good for my work I don't have to commute everyday no Bart [train]/bus fares don't have to wake up early to prepare going to work.* [Filipino participant, female, aged 68 y]

This supports the finding that new advances in technology and the incorporation of digital tools into work and school routines enabled participants to save time on commuting and increase productivity.

Fitness

Technology was reported to be especially helpful for monitoring and tracking fitness goals, particularly through devices such as Fitbit and Apple Watch:

> *I rely heavily on Fitbit to monitor and achieve physical fitness goals. This in turn has helped lower my blood pressure after these months of working out consistently.* [Korean participant, female, aged 66 y]

A Chinese participant (female, aged 60 y) shared that she was "doing virtual exercise classes daily," and another participant highlighted the role of activity tracking:

> *Apple Watch (and other activity trackers) have been helpful to keep me moving.* [Native Hawaiian participant, male, aged 25 y]

These quotes reflect the usefulness of technology for achieving consistent physical activity and monitoring daily progress for many participants. Thus, technology helped participants meet their fitness goals and was a tool to support positive health outcomes.

Technology Was Often the Only Means of Interpersonal Social Connections

Overview

Technology helped address participants' feelings of boredom and isolation by allowing access to streaming services, online shopping, and social media, as well as enabling them to feel connected to others. Staying connected through technology was also vital for work and health-related reasons, for example, when checking in on loved ones who were immunocompromised:

> *It's been very important in keeping me sane and connected to others.* [Vietnamese participant, female, aged 35 y]

This quote supports the finding that technology was essential in maintaining social interaction during the pandemic.

Connections for Social Interactions

During the COVID-19–related lockdown, many participants were unable to physically check in with friends and family and had to rely on alternative methods to maintain social connection. Technology use was reported to ease negative feelings by allowing quick and effective communication. Many participants with family members and friends residing out of the country used platforms such as Facebook Messenger, WeChat,

XSL•FO
RenderX

KakaoTalk, LINE, or WhatsApp for daily interactions and updates. Social media, Zoom, and Skype were also heavily used by participants to connect with loved ones and meet new people during this period of isolation. These tools were reported to be very useful for addressing communication challenges and easing worries of not being physically present:

> *Would have been much harder to cope without technology! Being able to video conference or text friends has helped maintain a sense of social connection while also being safe.* [Chinese participant, female, aged 51 y]

This quote further showcases technology's ability to bridge gaps in social connection, enabling participants to use tools to interact with members of their communities and support one another while maintaining safe distancing practices.

Technology was also reported to help participants meet new people and find online groups centered around similar interests and hobbies:

> *I have been involved in decisions about moving my community chorus to the virtual platform, a less than satisfactory replacement to singing together. But we have been able to reach out to singers from far and wide, something we would not have been able to do before!* [Chinese participant, female, aged 66 y]

This quote illustrates how technology enabled participants to meet others with common interests and hobbies, further expanding their communities and social interactions. Another participant shared a similar experience:

> *It's been an eye-opener to realize the capacity of the internet to connect people from all over the world through events, etc. I volunteer with our Girl Scout council and create virtual events for girls, who have attended from across the country!* [Japanese participant, female, aged 67 y]

This quote reflects the theme of technology facilitating the formation of new online communities, allowing participants to build relationships across geographic boundaries through common interests.

A participant expressed the importance of social connection with other Asian American and Pacific Islander individuals in the face of the racism and xenophobia that some experienced:

> *We Asians face a lot of discrimination. We can only communicate with friends online because it's risky to go out, and technology supports this.* [Chinese participant, female, aged 36 y]

This quote reflects participant concerns regarding the hate directed at Asian American and Pacific Islander communities during the lockdown and illustrates how technology enabled safe social interaction and communication.

Connections to Help Others

Technology was also reported to assist in the care of others, such as ordering groceries and essential supplies through online platforms:

> *It was helpful that I could order groceries for myself and my elderly parents on Instacart and also I am able to Zoom with them a few times a week so that we can "see" each other make sure everything is ok.* [Asian Indian participant, female, aged 53 y]

The availability of no-contact services provided a practical alternative to in-person errands, helping participants reduce their risk of exposure to COVID-19 infection while continuing to care for loved ones.

Connections for Work

Participants reported benefits associated with the shift to remote work. One noted advantage was the ability to expand business contacts across geographic regions and use platforms such as Zoom to widen professional networks and communicate with people in different time zones.

Connections for Health Reasons

Participants reported that technology use also facilitated access to wellness resources and communication with health care professionals. This included using technology to connect with meditation groups, community meetings, workshops, online physical activity classes, and telehealth services. Technology also enabled video calls with loved ones in hospital when in-person visits were not allowed:

> *Use of technology in the hospital provides an effective source of communication between the patient and his/her family members. I witnessed how helpful and meaningful to keep in touch with our patients' family by using smart phones or tablets, to see their loved one who is in the hospital in the screen really brought them a true happiness and brought positive effects to patients' wellbeing.* [Filipino participant, female, aged 52 y]

This comment illustrates how technology was used to care for others and protect individuals considered vulnerable by maintaining safe distancing. It also reflects concern regarding disconnecting from loved ones during the lockdown and how using technology allowed participants to continue to provide care and support to their communities.

Overuse Led to Negative Physical and Mental Health Outcomes

A common theme among participants was that increased technology use during the lockdown led to overuse, contributing to negative mental and physical health outcomes, including burnout. Participants described how increased reliance on technology use led to the feeling that they needed a break from technology and having no outlets away from technology use, feelings of increased reliance, and addiction to technology and social media.

Negative Mental Health

Participants also described needing mental health breaks due to feeling overwhelmed by constant COVID-19 updates from news outlets and social media. Some reported feeling addicted to social media and finding it difficult to step away due to loneliness or fear of "missing out," which resulted in increased anxiety and mental stress:

XSL•FO
RenderX

> *Technology, specifically social media has been incredibly stressful but addictive for me. I find myself much more anxious and unhappy when scrolling through other peoples profiles. But I feel this need to know otherwise I will miss out.* [Vietnamese participant, female, aged 24 y]

This quote reflects the broader theme of technology's impact on mental health during the pandemic, highlighting how constant access to social media and news updates made it difficult to disconnect for fear of missing essential information.

Technology also enabled participants to stay informed about the pandemic by providing access to news updates from outside of their immediate communities, including other cities, states, and countries. However, this constant exposure to negative news was also associated with increased anxiety and stress:

> *It's a double-edged sword—on one hand it has provided access to news and connection to family and friends, but it still feels isolating, lonely, and awkward to try and convey emotions and connections through the use of social media only.* [Asian Indian participant, female, aged 24 y]

This quote supports the finding that participants struggled to use technology effectively to maintain connection. Technology use helped participants stay connected with loved ones, but it also contributed at times to feelings of isolation and loneliness.

Discrimination Experienced by Asian American and Pacific Islander Individuals

Some participants reported negative experiences related to discrimination and racism during the pandemic, particularly on social media. Others expressed concerns about language barriers, xenophobia, and racism throughout this period:

> *I have been more sensitive to racially related news and posts on socially media.* [Chinese participant, female, aged 56 y]

> *[I] found that social media can be a bit more toxic during this period. Especially with all the negative news surrounding social justice, racism, the election, etc.* [Chinese participant, male, aged 28 y]

These quotes express the emotional and mental impact of frequent exposure to news and social media during a period marked by political unrest, social justice movements, and the pandemic, which resulted in participants feeling overwhelmed.

Burnout

Participants described feeling fatigued from constant technology use throughout the day but unable to disconnect due to the need to use technology for school and work:

> *I noticed that my technology usage has significantly increased during the COVID-19 pandemic. In doing so, I realized that I need to take screentime breaks so that I don't get exhausted from it.* [Filipino participant, female, aged 23 y]

Participants reported exhaustion from prolonged use of digital devices and limited opportunities to disconnect, given the lack of in-person alternatives for connection with others during the pandemic. This led to participants incorporating breaks from technology to maintain their mental health.

Some individuals reported being busier during the pandemic due to increased work hours and workload. A participant shared her experience as a frontline worker:

> *During the pandemic I have never been busier. Following my shifts at the hospital, I attend nightly community, task force, and organizing meetings learning about resources and responses to the COVID-19 pandemic that is disproportionately affecting our community of immigrant front-line workers with high levels of high-risk exposure. Technology has made it easier to connect local and national Filipino organizations, but Zoom fatigue coupled with clinical burnout is a real hazard.* [Filipino participant, female, aged 30 y]

This quote illustrates how frontline workers experienced long shifts and overwhelming workloads to protect their patients.

Participants also reported experiencing Zoom fatigue and feeling exhausted from daily online meetings. Some also reported struggling to separate work from home after transitioning to fully remote work, leaving little downtime to destress:

> *I was working from home 4 days per week before the pandemic, so I was just on my computer all day every day already. Now I'm on it more because I can't go out on weekends or in the evenings.* [Chinese participant, female, aged 35 y]

The combination of seemingly nonstop screen time from both work and personal activities contributed to mental and emotional exhaustion and resulted in feelings of burnout.

Negative Physical Health

Technology use during the pandemic was also found to be associated with negative physical health outcomes. Participants reported increased screen time and reduced physical activity, which contributed to symptoms such as fatigue, eyestrain, dry eyes, headaches, back and neck pain, wrist and hand pain, loss of sleep, dizziness, and weight gain:

> *Using electronic devices for long hours makes my shoulders, neck and back pains. However, I don't feel safe to see a doctor or physical therapist.* [Taiwanese participant, female, aged 37 y]

> *Too much screen time, more sitting for work related issues, common illnesses experienced, like headache and back pain.* [Asian Indian participant, female, aged 47 y]

These narratives reflect the physical toll of sustained technology use that compounded over time during the pandemic. Notably, the hesitation to seek care due to safety concerns highlights how the pandemic exacerbated both physical strain and barriers to accessing care for technology-related health issues.

Technology Use Was Associated With Multiple Challenges and Barriers

Many participants shared concerns regarding increased technology use, including language-related communication

XSL•FO
RenderX

challenges in virtual settings; increased costs; poor connectivity; and difficulty adapting to technology, particularly among older adults. These barriers may have been more pronounced for individuals who were underresourced or living in areas with limited internet access.

Challenges of Being a Nonnative English Speaker

Virtual work environments introduced new barriers for some Asian American and Pacific Islander individuals, as described by a participant:

> *As a nonnative English speaker/immigrant, I felt that I couldn't perform as well during a Zoom job interview as I became very self-conscious about my accent or mistakes that I make when I speak English. I think the Zoom interview environment has negatively impacted my chance of landing a job because it encourages interviewers to rely more on interviewee's speech as there are limited nonverbal cues that contributes to effective communication.* [Korean participant, male, aged 33 y]

This quote highlights the participant's perceived disadvantages when navigating a virtual job interview, with interviewers unable to meet interviewees and assess them as a whole. With first impressions limited to screen interactions, the complete dependence on technology was a barrier to connection and, in this participant's case, their success. Furthermore, relying primarily on speech disadvantaged the participant, a nonnative English speaker, heightening their fear of judgment and perceived risk of discrimination.

Increased Costs

Participants reported experiencing increased or additional expenses related to their increased technology use. These included upgrading internet service, paying higher data fees, and incurring increased electricity costs to support working or studying from home:

> *I had to upgrade my internet to be able to service people for work and during my internship for graduate school and it cost more to upgrade. Also, my electricity bill has gone up since I'm working and interning at home.* [Japanese participant, female, aged 41 y]

Increased costs posed additional challenges for individuals and families and was an added stressor, especially for those who were already facing financial strain.

Connectivity

Increased technology use at home also led to connectivity challenges related to school and work. Many participants reported that increasingly busy networks and limited bandwidth in certain areas led to decreased connectivity efficiency, which caused disruptions in work and school tasks. This often led to meeting disruptions, resulting in additional stress and loss of time to address connectivity issues:

> *With remote schooling and working remote, even in the suburbs, there are challenges with connectivity as everyone is online and using the internet for school and work. If the wireless networks and bandwidth are not strong, this often negatively impacts accessing internet for school and work.* [Filipino participant, female, aged 47 y]

This quote underscores that the usefulness of technology depends on reliable infrastructure. These challenges were especially pronounced for individuals in rural areas and for older adults who already faced barriers such as unfamiliarity with technology, financial constraints, and lack of support.

Technology Use Among Older Adults

Several participants reported difficulty navigating technology, with only 8.2% (91/1115) indicating that they felt slightly comfortable using technology and 18.4% (204/1115) reporting that they were not at all comfortable. The transition to increased technology use during the pandemic disproportionately affected older Asian American and Pacific Islander adults who struggled to adapt and often lacked the support necessary to learn how to operate technological tools. A participant expressed difficulty understanding how to use technology, stating that she would benefit from someone teaching her:

> *Please teach low tech adult/senior citizens like me how to use our iPhones, MacBook etc. We are dependent on our 7-12 year old grandchildren for tutorials (if we are lucky to have them nearby). Apple stores don't teach us anymore.* [Filipino participant, female, aged 77 y]

This quote reflects the generational gap in technology familiarity and the desire of older adults to improve their technology literacy and decrease their dependence on younger family members in this regard. It also highlights the frustration that some older adults felt due to limited opportunities for formal instruction and underscores the need for structured, age-inclusive technology education tailored to older adults.

Some participants expressed concern that their older adult loved ones did not know how to use technology to contact resources or reach out to family members for assistance during the pandemic:

> *I am grateful that I am comfortable and experienced in all aspects of technology. However, my mother (who does not live with me) is not, and it always worries me that she wouldn't be able to contact me if she has a pressing need, or that I am not around to help her immediately troubleshoot technological difficulties.* [Taiwanese participant, female, aged 31 y]

This participant's sentiment underscores the stress that families experienced when older adults lacked the skills to use technology independently. Limited technology access can create safety and communication barriers, especially during emergencies and periods of physical separation.

Another participant similarly reported worries regarding an older loved one:

> *Using technology is difficult with my elderly mom as she does not understand how to use it. As she is in an assisted living home, I cannot show her and the staff*

XSL•FO
RenderX

> *has limited time to help. For the hearing impaired or for those who are not familiar with screen interactions, technology is limited in its usefulness for meeting social needs.* [Chinese participant, female, aged 50 y]

This quote encapsulates the compounded challenges that older adults face when navigating technology, even in assisted living settings, and highlights how barriers such as impairments or unfamiliarity with digital interfaces can significantly hinder social connectivity and access to essential support.

Discussion

Principal Findings

This study describes the use of technology and its impact on the well-being and experiences of Asian American and Pacific Islander adults during the COVID-19 pandemic. While other studies have investigated the broad implications of technology on mental and physical health, the use of technology and its application to the culturally specific experiences of Asian American and Pacific Islander adults during the pandemic was largely unknown. The quantitative survey data revealed significant changes in lifestyle and communication behaviors that occurred during the pandemic. Nearly half of the respondents (528/1115, 47.5%) reported increasing their technology use by ≥3 hours per day during the pandemic, with up to 7.98% (89/1115) indicating an increase of ≥7 hours per day compared to before the pandemic. The 4 themes identified in this study highlight the mixed sentiment toward technology and social media use among Asian American and Pacific Islander adults, alongside notable challenges and barriers.

In the periods of social isolation during the pandemic, technology was a central force in facilitating individual well-being and fostering connections within the community [16]. Virtual platforms enhanced both the professional and hobby-related skills of participants, while connecting individuals with common interests. In addition to supporting mental and emotional health, technology benefited the physical health of participants through the use of fitness trackers and virtual interactions with health care professionals. Moreover, for the Asian American and Pacific Islander community, technology assumed a special significance by providing a sense of security amid rising anti-Asian discrimination. Virtual platforms and networks helped individuals stay informed about relevant social issues and incidents affecting their communities. Fearing for their safety, Asian American and Pacific Islander adults relied on technology, such as video chats and telephone calls, to maintain social connections without leaving home. Older adults were also better supported by family members who used mobile delivery services to order food and other essentials.

However, alongside the benefits of using technology, the detrimental effects of overuse on both mental and physical health were also revealed by this study. Participants reported concerns such as addiction to social media, burnout, and videoconferencing fatigue, which exacerbated feelings of loneliness and mental strain. For Asian American and Pacific Islander adults in particular, the increased exposure to negative news and discrimination on social media contributed to heightened awareness of discrimination, which in turn led to psychological distress. In addition to these negative impacts on mental health, technology overuse was associated with physical symptoms such as fatigue, eyestrain, back pain, headaches, and weight gain.

Our analysis of technology-related barriers for Asian American and Pacific Islander adults underscored how technology may exacerbate existing disparities within the community. Notably, technology may amplify inequities in employment opportunities, particularly evident in the challenges faced by nonnative English speakers during job interviews conducted over platforms such as Zoom. The shift to virtual interviews accentuated concerns about linguistic proficiency. Asian American and Pacific Islander participants expressed concern that interviewers may prioritize verbal communication over nonverbal cues, placing nonnative English speakers at a disadvantage. Moreover, increased reliance on technology also imposed financial burdens, potentially compounding economic disparities within the community. In addition, the growing global reliance on technology presented a significant barrier for older adults in the Asian American and Pacific Islander community who struggle to learn new technology. This challenge had a ripple effect on family members of these older adults, as they faced increased distress fearing an inability to contact older adult members in emergent situations or in times of social isolation.

While the themes of our study reveal a spectrum of positive and negative impacts of technology on Asian American and Pacific Islander adults, such mixed results regarding technology use are congruent with current literature sampling the general population. Our finding that technology was critical in maintaining individual mental and emotional well-being during the pandemic is supported by both studies concluding that the use of technology and digital tools was beneficial for young adults during the COVID-19 pandemic [17] and studies involving older adults [18,19]. In alignment with our findings, these studies reported reduced feelings of loneliness, better self-rated health, fewer chronic illnesses, higher subjective well-being, and fewer depressive symptoms. The use of technology as a facilitator for the feeling of community connection has also been well reported. A qualitative study involving older adults and their relatives highlighted how the use of technology-mediated communication by older adults during the pandemic afforded meaningful interconnections in their social lives and promoted cross-generational connections among family members [20].

Our finding that technology overuse can lead to detrimental effects on the mental and physical health of Asian American and Pacific Islander adults is also congruent with prior literature. Prior research has shown that moderate or severe depression levels were associated with greater time spent watching television and using computers (>6 h/d) for American adults [21]. In addition, our parent study of Asian American and Pacific Islander individuals found that those whose technology use during the pandemic increased by ≥7 hours per day had a 1.32-point (95% CI 1.00-1.64; *P* value for the trend <.001) higher Patient Health Questionnaire-4 score [9]. Negative impacts on physical health in the Asian American and Pacific Islander population are also congruent with our previous study

XSL•FO
RenderX

results, which detected significant changes in self-reported physical health scores with ≥3 hours per day of technology use [9], as well as independent studies reporting that technology use negatively affects physical activity and sleep routines, leading to headaches, neck pain, myopia, digital eye syndrome, and cardiovascular risk factors [22,23].

Finally, and perhaps most notably, our fourth theme, which discusses the multiple challenges and barriers to technology use for Asian American and Pacific Islander adults, contributes to the highly necessary investigation of racial disparities in an increasingly digitized world. Nonnative English speakers in this study described feeling disadvantaged in virtual workspaces, an experience recognized by a growing number of studies. In a case study of a multinational corporation after a shift to remote work triggered by the COVID-19 pandemic, researchers found that language-based discrimination in virtual spaces was primarily organizational and more subtle than in physical settings [3]. Virtual spaces also seemed to expedite the process of excluding migrant professionals, in part due to the emergence of separate meetings and parallel virtual channels for informal conversation [3]. Other barriers observed in our study, such as increased costs, connectivity challenges, and the lack of technological support for older adults, add to the growing body of evidence that technology may be exacerbating, rather than eliminating, socioeconomic and health disparities through the digital divide. This divide has significant clinical implications for the Asian American and Pacific Islander community.

This study illustrates ways in which Asian American and Pacific Islander adults found technology to be beneficial for mental and physical health. These results contradict our prior study results, which indicated that an increase in technology use during the pandemic correlated with negative mental health outcomes in the form of higher Patient Health Questionnaire-4 scores and lower physical health scores [6]. This discrepancy may be due to the variance in the framing of questions between the two studies. Our prior study (COMPASS) analyzed numeric responses from a structured set of questions, while this study analyzed responses to the open-ended question “Is there anything else you want to tell us about your use of technology during COVID-19?” This may have permitted respondents to consider alternative, positive applications of technology, such as its use as a tool to safeguard against an anti–Asian American and Pacific Islander social environment.

As revealed by our findings, while the COVID-19 pandemic accelerated the use of technology and telehealth, it also exacerbated existing challenges and barriers to accessing and using needed health care, evident in the growing digital divide and lack of digital literacy, as discussed in prior literature [24-26]. Asian American and Pacific Islander adults, particularly those with limited English proficiency, older adults, individuals with low income, and those living in rural areas or neighborhoods experiencing internet connectivity issues or lacking necessary digital literacy skills to effectively use telehealth platforms, face more challenges in adopting and using telehealth [27,28]. This leads to increased health disparities due to inequitable access to necessary health care. The barriers observed in our study, such as poor digital literacy, internet access issues, and lack of technology assistance, have been proven to be key drivers of the digital divide [29]. As such, identifying and resolving these barriers within the Asian American and Pacific Islander population is vital for the advancement of equitable health care and for appropriately addressing technology use as a social determinant of health. While many members of Asian American and Pacific Islander communities have become significantly more aware of the need to use such technologies, it is both crucial and timely to provide culturally and linguistically appropriate services, as well as training and resources to improve digital literacy, to address the identified disparities.

Consistent with previous research [30], our findings have revealed that dependence on technology, such as increased screen time, was associated with negative mental health. Conversely, avoidance of technology due to anxiety or lack of familiarity can prevent individuals from accessing telehealth services, potentially leading to delayed treatment or untreated health issues. Clinicians should be aware of these potential issues and integrate assessments of technology use and its impact on mental health into their care plans. Using a patient-centered approach to provide the needed support and resources to manage technology use in a helpful manner and offering alternative care options for patients who prefer not to use technology are important strategies in addressing these concerns.

The digital divide—highlighted during the COVID-19 pandemic as a disparity between the “haves” and “have-nots”—has been well documented [31]; however, more research is required to better understand the needs of diverse populations, not only by race and ethnicity, but also by English proficiency and age. This study contributes important knowledge in this area and may be helpful for developing social and educational programs to serve such diverse populations (eg, Asian American and Pacific Islander adults with low socioeconomic status and limited English proficiency).

Limitations

This study has several limitations. We used convenience sampling through community networks, social media, and the CARE registry, which may not fully capture the diversity of the broader Asian American and Pacific Islander population. There may be selection bias, with underrepresentation of individuals with limited internet access or those not engaged with community organizations. In addition, only 20.66% (1115/5398) of the respondents to the quantitative survey provided open-ended responses, which formed the basis for the qualitative themes presented in this study. In terms of generalizability, although the age range of participants was 18 to 98 years, the mean age was 45.9 (SD 16.3) years, which may reflect a generally more technology-savvy group. Furthermore, the majority of the respondents (665/1115, 59.64%) completed the open-ended question in English, likely reflecting a sample with a higher level of acculturation to the United States. Finally, we reported aggregated data across numerous Asian American and Pacific Islander groups, which may not represent the unique experiences of specific backgrounds within these communities.
