This study presented the diverse attitudes and experiences related to technology use among Asian American and Pacific Islander adults during the COVID-19 pandemic. There were numerous benefits of using technology during a period of mandated physical and social isolation; however, there were many adverse experiences, including the detrimental effects of technology overuse on both mental and physical health. Important considerations for Asian American and Pacific Islander adults include awareness of how technology may exacerbate existing disparities, particularly among those with limited English proficiency. Further qualitative research would be beneficial in amplifying the perspectives of Asian American and Pacific Islander adults to uncover concerns and address health disparities.

Acknowledgments

The authors are grateful to all COVID-19 Effects on the Mental and Physical Health of Asian Americans and Pacific Islanders Survey Study (COMPASS) participants who completed the study. The authors would also like to acknowledge their community and academic partners in supporting the outreach and data collection. This study was conducted in collaboration with multiple academic institutions and community partners that serve diverse Asian American and Pacific Islander populations: the University of California San Francisco, University of California Davis, International Children Assistance Network, National Asian Pacific Center on Aging, Philip Jaisohn Memorial Foundation, Chinese Community Center, Hmong Community Center of Minnesota, Greater Boston Chinese Golden Age Center, United Sikhs, Memory and Aging Center at the University of California San Francisco, East Palo Alto Tennis and Tutoring, Yu-Ai Kai, India Community Center, and American Samoa Community Cancer Coalition. The authors sincerely thank Ms Hannah Jang for her administrative support on this manuscript. This research project is supported by the National Institute on Aging of the National Institutes of Health (R24AG063718 and R01AG083926). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Abstract

Background: Web-based mental health forums have the potential to play a significant role in providing accessible support for young people, supplementing in-person services and contributing positively to their mental well-being. However, limited engagement often constrains their impact and effectiveness in supporting young people.

Objective: Using the Behavior Change Wheel framework, this qualitative study explores the barriers and facilitators to young people's engagement with web-based mental health forums, focusing on the behaviors of creating new posts, responding to posts, and reading posts. Behavior change techniques (BCTs) are identified to address these barriers.

Methods: Semistructured interviews were conducted with 13 young people aged 17-25 years who use UK-based youth mental health forums. Three participants self-identified as men, 8 as women, 1 as nonbinary, and 1 chose not to disclose their gender. Transcripts were coded using the Theoretical Domains Framework (TDF), followed by inductive theme generation. TDF barriers were then mapped to BCTs to suggest intervention strategies.

Results: Thematic analysis revealed ten inductive themes across 5 TDF domains. Of these, 3 were enablers, 2 were barriers, and 5 functioned as both enablers and barriers. The findings indicated that skills, beliefs about consequences, emotions, and the social and physical environment are key influences on young people's engagement with web-based mental health forums. Positive emotions experienced after using the forums enabled posting, responding, and reading behaviors. Enablers of more active participation (ie, posting and responding) included anonymity and positive interactions with other users. The presence of moderators acted as an enabler for all 3 behaviors by providing a safe environment, but also as a barrier to posting, as moderation could restrict the content of users' posts. Similarly, mobile access facilitated posting, responding, and reading, whereas layouts not optimized for mobile use acted as barriers to typing and reading on the go.

Conclusions: This study contributes to the existing knowledge base by examining the different ways in which young people engage with youth mental health forums. Different strategies may be prioritized and adopted depending on whether forum providers aim to increase more active forms of engagement (eg, posting and responding, which can be encouraged by fostering positive interactions with other users) or overall engagement (eg, establishing clear rules of engagement and optimizing web page content for mobile access can benefit all forms of engagement). These insights can help improve the delivery of youth mental health forums and foster a positive ecosystem of support for young people.

Introduction

Young People's Mental Health and the Role of Web-Based Forums

Globally, young people are experiencing a significant decline in mental health, with rising levels of reported mental health problems [1,2]. The COVID-19 pandemic, in particular, accelerated the deterioration of young people's mental health [3]. In the United Kingdom, 1 in 3 young people aged 18-24 report symptoms of anxiety, depression, or both—an increase since 2000, when fewer than 1 in 4 (24%) reported these problems [4]. However, a recent report identified significant gaps in early mental health support for young people, with a rising number reaching crisis point [5]. From 2022 to 2023, the Children's Commissioner's annual report on children's mental health [6] found that 28% of children and young people referred to mental health services were still waiting for support, with some waiting up to 2 years.

Viable stopgaps for young people include web-based channels such as social media or mental health forums, which are typically available 24/7 and can potentially provide accessible mental health support at scale. As digital natives, young people are adept at using the internet to seek support and are often favorable toward this approach, as it offers greater convenience and anonymity [7]. While social media may have a wider reach [8], mental health forums can be seen as a more focused and structured channel for young people to obtain mental health support [9]. Engaging in youth mental health forums can offer benefits such as emotional support, alleviation of feelings of isolation and stress, and reductions in symptoms of depression and self-harm [10,11]. However, potential drawbacks include increases in mental distress and self-harm tendencies, particularly when safeguards are insufficient in forums addressing sensitive or distressing topics [9]. Thus, it is important to continually explore ways to increase the effectiveness of these forums while reducing their potential harmful impacts. In addition, young people's low engagement in web-based mental health forums remains a challenge, potentially limiting their effectiveness [12]. Research shows that mental health forums often fail to achieve their intended purpose because of low engagement rates [13], and users are unlikely to continue participating in inactive forums due to the limited support available [14]. Sustaining user activity in web-based forums helps to build a pool of knowledge and ensure that the forum remains relevant, facilitates the creation of online connections, and provides necessary support [14,15]. Therefore, there is a need to better understand the factors influencing engagement to maximize potential benefits.

Research shows that young people engage in web-based mental health forums in various ways. Many studies dichotomize them into *posters*, who are active participants contributing most of the content, and *lurkers*, who are passive participants and read posts without contributing [16,17]. Posters may create initial posts that introduce topics for discussion, often focusing on their own concerns, questions, thoughts, and lived experiences [18]. They may also respond to others' posts, providing emotional or informational support to the user who shared the original comment [19]. Lurkers, on the other hand, read posts either to find specific information or to browse more generally [20]. Young people's engagement in web-based mental health forums therefore encompasses multiple behaviors, including posting original content, responding to others, and reading posts.

While these behaviors should be treated as distinct, as they have different motivating and hindering factors [21], existing studies often examine youth mental health forum use more generally [22,23] or focus only on posters and lurkers [15,16]. However, this limits our understanding of the factors influencing young people's engagement across a range of different behaviors. Using the Behavior Change Wheel (BCW) approach [21], this qualitative study explores the barriers and enablers to young people's engagement in mental health forums, focusing on posting, responding, and reading behaviors, and identifies strategies for improvement. Such an examination can reveal both unique and shared influences and support the development of targeted interventions, offering a holistic view of young people's engagement with youth mental health forums.

Research Background

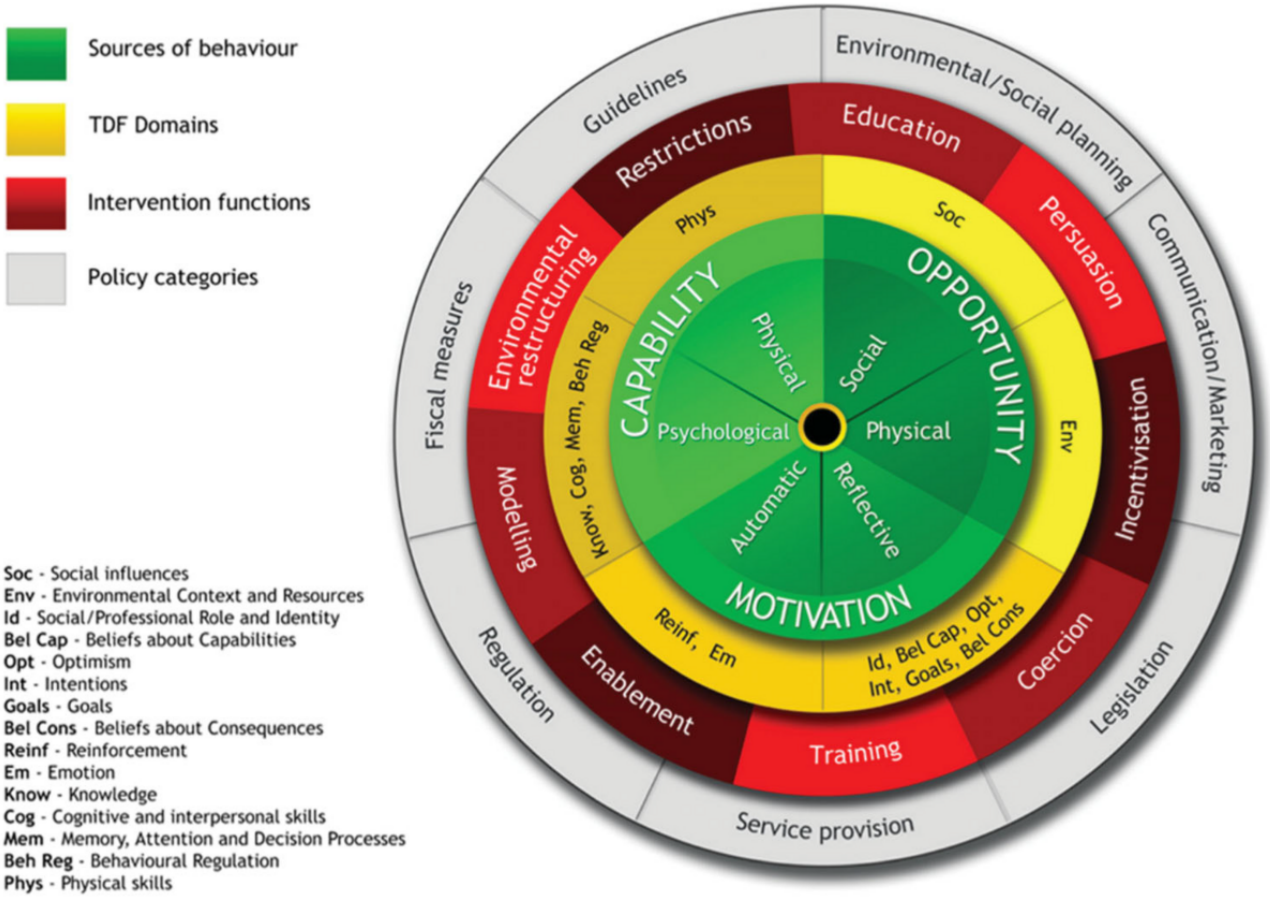
Current research has highlighted the benefits of mental health forums for young people. Web-based forums foster a sense of community and friendship, providing spaces where young people can receive practical advice on a variety of topics [18]. They not only offer informal support but also signpost young people to formal support services when necessary [24,25]. Thus, they can serve as important conduits, facilitating access to relevant professional services and encouraging help-seeking behavior among young people who need it. Furthermore, unlike professional or in-person services, web-based forums connect young people around the clock and therefore serve as valuable supplements to other mental health services within the broader ecosystem [19].

The characteristics of web-based mental health forums also enable different types of engagement among young people. As these forums contain a wealth of information and messages that are typically archived for long periods, young people can access relevant content at any time [9]. Reading the repository of existing discussion threads therefore provides immediate, personally relevant, and actionable information [14], such as personal experiences on managing specific situations and techniques for improving one's own mental health [26,27]. Reading posts also allows young people to reflect on their personal difficulties through the lens of others' experiences, for instance, by reframing common challenges as manageable [28].

In contrast to passively reading content, young people who actively use web-based forums—by initiating and replying to posts—can benefit from the therapeutic nature of writing and from providing support to other users in need [28]. The veil of anonymity offered by most web-based forums reduces users' feelings of threat and inhibition when posting or responding [29,30], creating vast potential to connect young people who share similar life experiences and emotions but may not be in close geographical or physical proximity [9]. Consequently, young people may feel more motivated to post on web-based forums because they can voice their opinions with greater confidence and less fear of judgment [14]. Posting also

XSL•FO
RenderX

contributes to the exchange of emotional and informational resources within the online space and encourages further engagement from users [31]. "Reply reciprocity," whereby users tend to receive more replies to their posts if they respond to others, further underscores the importance of encouraging participation, as this positive feedback loop promotes sustained user activity [31].



Several barriers to the use of web-based mental health forums have also been identified. Concerns about confidentiality and privacy can discourage posting on these forums, as can difficulties in accurately conveying emotions through writing [22]. In addition, reading about the challenges faced by other users may be triggering and induce negative moods [32]. Young people are also deterred from reading posts when forums lack high-quality resources or relevant topics [18,22]. Fears of causing harm to oneself (eg, worsening one's mental health condition) or to others (eg, making others feel worse) have likewise been identified as barriers to active participation [23]. Furthermore, some young people cite the lack of orientation for new users—making it harder to fit into a new online environment—as an additional barrier to active participation in mental health forums [32].

While existing studies have examined factors influencing engagement and proposed ways to enhance young people's experiences with mental health forums, such efforts are rarely guided by a comprehensive intervention framework like the BCW. Moreover, most studies on young people's use of web-based mental health forums take a one-dimensional view of engagement, without exploring the specific behaviors involved in interacting with these platforms. This limits researchers' and practitioners' ability to identify the distinct factors influencing different engagement behaviors and to develop effective, targeted solutions.

Behavior Change Wheel Framework

The BCW (Figure 1) is a comprehensive framework developed through the integration of 19 existing behavior change theories [21]. It offers a structured, evidence-based approach for diagnosing the barriers and enablers of behavior, which in turn informs the design and evaluation of interventions [33]. Central to the BCW is the COM-B model, which posits that capability (physical and psychological), opportunity (social and physical), and motivation (reflective and automatic) interact to produce behavior. The Theoretical Domains Framework (TDF) is often used alongside the COM-B model to provide greater granularity [34] and a more detailed understanding of different types of behavioral influences.

Figure 1. The Behavior Change Wheel and Theoretical Domains Framework (TDF).

Nine intervention types that enable behavior change form the layer surrounding the COM-B model, followed by an outer layer outlining 7 policy options for delivering these interventions [35]. The Theory and Techniques Tool [36] facilitates the mapping of TDF domains to behavior change techniques (BCTs) within the behavior change techniques taxonomy (BCTTv1). The taxonomy contains 93 evidence-based BCTs that are observable and replicable, facilitating behavior change [37].

XSL•FO
RenderX

This enables identified barriers to target behaviors to be linked to specific BCTs to achieve the desired change. The BCW approach has been successfully applied to enhance web-based mental health services for young people, including webchat counseling [38,39], helpline services [40], peer support groups [41], and self-harm content on a mental health forum [42].

Current Study

This study applies the BCW framework [20] to systematically explore the perceived barriers and facilitators of engagement in UK-based web-based youth mental health forums among young people aged 16-25 years. Through qualitative interviews, this study addresses the following research questions:

- Using the COM-B/TDF, what are the barriers and enablers to young people's engagement with youth mental health forums, specifically in relation to posting, responding, and reading?
- Using the BCTTv1, which BCTs can be applied to enhance young people's engagement with youth mental health forums, focusing on posting, responding, and reading?

This study can inform strategies to optimize the design and delivery of youth mental health forums, helping to better harness the potential of these web-based platforms in supporting young people's mental health and well-being.

Methods

Participants

The study targeted young people aged 16-25 years who had read, posted, or responded to posts in UK-based youth mental health forums. Participants were recruited via convenience sampling, with support from The Mix, powered by Mental Health Innovations—a UK-based charity that provides mental health support for young people, including crisis helplines, support groups, and web-based forums. The Mix helped publicize the study by sharing a recruitment poster and registration link via their web pages and social media channels. Additionally, the study was promoted on LinkedIn (LinkedIn Corporation) to broaden the pool of potential participants. Interested young people registered through an online form, which collected information such as age, gender, ethnicity, and frequency of youth mental health forum use.

Of the 32 young people who registered interest, 12 did not meet the eligibility criteria (eg, outside the target age range or not using youth mental health forums) and were excluded. Of the remaining 20 eligible participants, 6 did not provide consent after receiving the participant information sheet and consent form. Fourteen participants were interviewed; however, 1 interview was later excluded due to possible duplication.

The mean age of the 13 participants was 21 years, with a range of 17-25 years; 3 participants self-identified as male, 8 as female, 1 as nonbinary, and 1 did not wish to disclose their gender. Table 1 provides further details on participants' characteristics.

Table 1. Description of participants' characteristics.

Participant ID	Age (years)	Gender	Self-identified ethnicity	Experience with replying to posts on youth mental health forums	Mental health forums used
1	19	Woman	White British	Weekly	The Mix
2	25	Man	Indian	Weekly	The Mix
3	21	Woman	Iranian	Daily	The Mix
4	20	Man	Black African	Weekly	The Mix
5	23	Woman	Multiple ethnic groups	Never	The Mix
6	25	Woman	White British	Monthly or less	The Mix
7	18	Nonbinary	White British	Weekly	The Mix
8	23	Did not disclose	White British	Never	The Mix
9	23	Woman	Asian	Never	The Mix
10	23	Man	White British	Daily	The Mix and Kooth
11	24	Woman	Black African	Daily	Kooth
12	18	Woman	Black Caribbean	Monthly or less	The Mix
13	17	Woman	Multiple ethnic groups	Weekly	The Mix

Procedure

The researchers (ZL, SYL, and SL) conducted 1-on-1 semistructured interviews with participants from June to July 2024. These interviews were held online via Microsoft Teams. Participants could choose to respond using either audio conferencing or written chat, depending on their stated preference. All participants were asked the same set of questions based on an interview guide developed using COM-B and TDF domains, along with general questions that allowed for a broader

XSL•FO
RenderX

range of responses. The guide was developed by ZL, SYL, and SL in consultation with the senior author (LMG), and the questions were adapted from previous studies with a similar focus [38]. Sample questions were "What discourages you from responding to a post?" (general question), "What do you think are the benefits of using web-based mental health forums?" (reflective motivation: beliefs about consequences), and "Do others such as friends, family, or other users affect whether you use web-based mental health forums?" (social opportunity: social influences). The full interview schedule is provided in Multimedia Appendix 1.

Before recruitment began, the interview schedule was piloted with 4 young people from different demographic backgrounds (eg, gender, age range) to ensure that the questions were easily understood and that the interview could be completed within 30-45 minutes. Based on their feedback, the schedule was revised to use less technical language to enhance comprehension. The revised version also included additional prompts to encourage participants to provide more in-depth responses.

Publicity and participant recruitment began after the interview schedule was finalized. Interested individuals who met all eligibility criteria were provided with a consent form and a participant information sheet outlining the details of the study. After reviewing the information sheet and returning a signed consent form, participants were scheduled for 1-on-1 online interviews conducted by the research team. The interviews explored 3 types of behavioral engagement with web-based forums: reading forum content, creating new posts, and responding to existing posts. All interviews were recorded and transcribed. Participants received £25 (US $36) worth of vouchers as compensation for their participation.

Data Analysis

The behaviors of posting, responding to posts, and reading posts on youth mental health forums were coded separately by ZL, SYL, and SL. For each behavior, analysis followed a deductive approach guided by the Framework Analysis method, which included the stages of transcription, data familiarization, indexing, charting, and data interpretation [43]. Transcription and data familiarization involved repeatedly reviewing the interview content to develop a deeper understanding of the data. Indexing referred to applying an existing analytical framework to the dataset, while charting involved systematically organizing the data [44]. To support the indexing and charting process, a codebook was developed to define how each TDF domain applied to the specific engagement behaviors associated with youth mental health forum use (see Multimedia Appendix 2 for an example). The TDF served as a useful framework for coding and conducting a behavioral diagnosis to identify participants' perceived barriers and facilitators to forum use.

To enhance the reliability and consistency of coding, and to provide additional perspectives on the data, half of the total transcripts were second-coded by either ZL, SYL, or SL. Feedback from this process was used to refine the codebook applied throughout the deductive analysis phase. This was an iterative process in which the codebook was continually updated during transcript coding. The overall agreement rate exceeded 80% (122/146, 83.5%), and all coding discrepancies were discussed and resolved through mutual agreement.

After indexing and charting the data using the co-developed codebook, an inductive analysis approach was adopted to identify more specific and concrete themes. Candidate themes were examined to ensure internal consistency, and the data extracts within each theme were reviewed to confirm accurate representation, with further refinements made where necessary. Elements of Braun and Clarke's [45] reflexive thematic analysis were incorporated, emphasizing reflective and purposeful engagement with the data informed by the researchers' subjective experiences.

Following the deductive and inductive analyses, core inductive themes were shortlisted by ZL and LMG [46] based on their frequency and their importance and relevance to at least 2 of the 3 target behaviors. This criterion was used to identify key areas for improvement. Based on the identified TDF domains, associated BCTs with conclusive evidence-based links in the Theory and Techniques Tool were considered, while those with inconclusive or absent links were excluded. The final selection of BCTs and corresponding intervention strategies was informed by previous research on web-based forums and assessed for appropriateness and feasibility within this context by ZL, SYL, and SL. The selected strategies were further evaluated using the APEASE (Affordability, Practicability, Effectiveness, Acceptability, Side-effects, and Equity) criteria [21].

Ethical Information

This study was approved by the UCL Research Ethics Committee (reference number 16583/003; approval date: 27 July 2023). Informed consent was obtained, with researchers highlighting that participation was voluntary and that participants' sharing would be kept confidential.

Results

Overview

Ten core inductive themes were generated and mapped to the corresponding TDF domains (Table 2). These comprised 3 enablers, 2 barriers, and 5 that functioned as both enablers and barriers. Each theme is described in detail below, supported by participant quotes identified by their participant ID (Table 1). Themes specific to creating posts, responding to posts, and reading posts were also identified (see Multimedia Appendix 3).

XSL•FO
RenderX

Table 2. Description of core inductive themes.

Theme	Barrier/enabler	Description of theme	Relevant behaviors
Positive emotions	Enabler	Young people feel positive emotions (eg, relief, calmness) after using youth mental health forums.	Posting, responding, and reading
Beliefs about helpfulness of the reply	Barrier	Young people are discouraged from creating a new post or responding if they felt that the replies would not be helpful.	Posting and responding
Presence of moderators	Barrier/enabler	Presence of moderators on youth mental health forums makes the web space safer and reduces antisocial behavior, but may also limit the content of posts.	Posting, responding, and reading
Relevance of information	Barrier/enabler	Content that is not properly categorized or not personally relevant to young people discouraged reading and responding, but may encourage posting behavior.	Posting, responding, and reading
Accessing content on mobile phones	Barrier/enabler	The ability to access forum content on mobile phones facilitates usage, but when the layout is not optimized, it leads to difficulty in typing and reading on the go.	Posting, responding, and reading
Anonymity	Enabler	Anonymity reduces the sense of judgment from other users and encourages the sharing of thoughts.	Posting and responding
Time taken to obtain support	Barrier/enabler	Being able to quickly find the information needed can encourage young people to read posts, while the slow support and response prevent them from posting new content.	Posting and reading
Interactions with other users	Barrier/enabler	Positive experiences with other users facilitate posting and responding, while negative interactions discourage young people from doing so.	Posting and responding
Empathy	Enabler	Empathy helps young people relate to the original poster and provide more respectful and effective responses.	Responding and reading
Poor communication skills	Barrier	Poor communication skills hindered young people from creating and responding to posts in youth mental health forums. This barrier also had implications for reading, making it harder to understand posts.	Posting, responding, and reading

Automatic Motivation (TDF: Emotions)—Positive Emotions (Enabler)

Experiencing positive emotions was identified as an enabler for half of the young people using youth mental health forums across posting, responding, and reading behaviors. For those who actively engaged by posting or responding, these emotions often arose from the sense of connection with others. For example, P12 shared: “I feel relieved, I feel I'm able to interact (with) someone, I'm able to at least remedy a situation for someone, and I feel satisfied (with) myself.” P10 expressed similar sentiments, stating that they felt “a relief and calmness within that you've actually add(ed) value to someone’s life”. Even participants who only read forum posts reported experiencing positive emotions, often in the form of validation for their thoughts or behaviors. For example, P1 described: “it’s nice to read the posts and see that I’m not the only one feeling a certain way or experiencing a specific thing.”

Reflective Motivation (TDF: Beliefs About Consequences)—Beliefs About Helpfulness of the Reply (Barrier)

A barrier that discouraged a small number of young people from posting or responding was their belief about the helpfulness of replies. For example, P6 noted that responses are “not always helpful, depending on who responds.” P8 expressed a similar concern, highlighting that users may not “(get) the answers you wanted.” Specifically for the behavior of responding to posts, P1 reported sometimes withholding their response, explaining that they “might say the wrong thing to the person and end up making them feel worse or leave them feeling more confused.” Others expressed similar concerns, noting that they were cautious about responding to “avoid upsetting or triggering other users” [P1], or to ensure they did not “make things worse for anyone” [P6].

Physical Opportunity (TDF: Environmental Context and Resources)

Presence of Moderators (Barrier/Enabler)

For most young people, the presence of moderators in the forums could act as either a barrier or an enabler to posting, responding, and reading posts. Some participants noted that moderators helped make the online space safer, which in turn encouraged forum engagement. As P4 explained, “professional moderation on the online environment can ensure that the discussion boards remain (a) safe and respect(ful) space.” Participants also highlighted that moderators helped prevent exposure to content they preferred not to see, such as “seeing feeds that you think you don’t want to associate with or relate with, or even see” [P11], including “sexually explicit posts, political posts, terrorism, crimes” [P8]. Conversely, a small number of young

XSL•FO
RenderX

people felt that moderators could limit the content of posts and restrict self-expression. As P13 noted, "you're not able to adequately share what you're thinking about...the moderators put a lot of limitations that are making you not maybe express yourself the way you would have done if the moderator had no restrictions."

Relevance of Information (Barrier/Enabler)

A small group of young people noted that the relevance of information could act as either a barrier or an enabler for engagement, including posting, responding, and reading. For example, P6 explained, "there are a lot of subsections which...is needed but sometimes posts are in the wrong area or there are so many that things get lost" [P6]. Some young people also reported that the content they encountered on the forums was "not always relevant" and often focused on the "popular ones" [P3]. This perception that discussion board information might not be personally relevant or useful sometimes discouraged them from reading posts. As P3 explained, "whenever I read stuff about other people there, their situation isn't like mine." These participants therefore preferred creating posts on the forums rather than searching for information in existing posts, as posting could elicit responses that were more personally relevant and "felt more tailored to me and my current situation" [P6]. However, the inability to find relevant information also acted as a barrier, limiting young people's capacity to share knowledge and provide useful responses. P8 also noted that the presence of posts that were "repetitive or non-unique" discouraged her from responding and added that she "would respond to posts more (if) they were more varied."

Accessing Content on Mobile Phone (Barrier/Enabler)

For a small number of young people, accessing forum content on mobile phones could function as either an enabler or a barrier for posting, responding, and reading behaviors. One participant highlighted that the convenience of using her phone facilitated forum engagement: "the fact I can use it both on my phone and my laptop make me use it more because I can access it whenever I want" [P1]. However, others reported that the website's design and mobile experience were not optimized, which hindered their ability to use the forum on the go. As P5 elaborated, "If you're checking in via mobile phone, it can be a little awkward to navigate, some areas oversized or needing to be zoomed in upon, not always straightforward to type something in." Others shared similar challenges, with P9 stating that "using the website on cellphone is not convenient...It could be better if it launch apps," while P1 suggested that a mobile application could be helpful, allowing users to "access it easier" and "get notifications."

Anonymity (Enabler)

In the interviews, most young people highlighted anonymity as a key factor facilitating active engagement in forums, particularly for posting and responding. A secure, anonymous, and private environment was considered crucial for users to feel comfortable sharing their thoughts and concerns, thereby encouraging young people to create posts to seek help. For example, "I think the biggest contributor to me using it is the fact that it's anonymous so I don't have to worry about people I know seeing my posts" [P1] and "the sense of anonymity to most people so it's easier to open up about something and get the support" [P6]. When crafting responses, the sense of anonymity enabled young people to "freely talk about your situation or feelings without anyone judging you or questioning or invalidating you" [P1] and to "open up without the fear of people knowing who you are" [P11]. Anonymity facilitated engagement by allowing participants to share their thoughts with reduced concern about judgment from others.

Time Taken to Obtain Support (Barrier/Enabler)

For a small group of participants, the time required to obtain support could act as either an enabler or a barrier to posting and reading, depending on how quickly responses were received. Some participants preferred reading existing posts rather than creating new ones to seek information, as the immediacy of support available through reading was more appealing in the context of web-based forums. The wealth of information in the existing forum posts led some participants to view reading posts as a more desirable alternative to creating new posts. As P12 explained, "once I log in, I notice that most of the information that I needed to post, was already sometimes already there." This view was echoed by P8, who noted, "generally making posts means you can be waiting a couple of days for a response, whereas when you search and read information you get what you need immediately." The immediacy of support thus encouraged participants to read posts, while the potential for delayed responses discouraged them from posting.

Social Opportunity (TDF: Social Influences)—Interactions With Other Users (Barrier/Enabler)

For a small group of young people, interactions with other forum users specifically influenced active engagement (ie, posting and responding), acting as either an enabler or a barrier depending on the nature of these interactions. Participants who had positive experiences were more likely to increase their posting or responding behaviors, whereas those with negative experiences were less inclined to engage. For example, P6 described the role of reciprocity in deciding whether to reply, stating, "if someone has supported me before and they post I would be more likely to reply...It just feels like you are then helping someone who has helped you before." Conversely, negative experiences with other users discouraged young people from responding. As P11 explained, "usually if its someone that I know doesn't like me I will never reply to them...if there have been issues in the past with people it makes you want to avoid them." The impact of negative interactions extended beyond specific users to affect overall posting and responding behaviors. For example, "negative comments or replies by others" [P7] or instances where others "answer(ed) you rudely...really discourage(d)" [P13] deterred users from posting in general, whereas experiences of "peer support and empathy and understanding" [P4] encouraged engagement.

Psychological Capability (TDF: Skills)

Empathy (Enabler)

For most young people, empathy was identified as an important skill that helped them relate to the original poster when reading

XSL•FO
RenderX

posts and providing responses. Specifically, having empathy helped users "understand the situation...(and) how they're feeling" [P2], facilitating "emotional connection" and "driv(ing) you to offer support" [P4]. It also provided a foundation for young people to reply "respectfully and in an understanding way" [P6]. P11 elaborated that a lack of empathy could lead to negative outcomes: "they may tend to just reply without any emotions and for the person that has gone through this, it's hurtful and this discourages them from posting something that they feel like it's very personal or made them feel like that." P1 echoed these points, noting that empathy is necessary to "fully understand what that person is feeling before you begin to reply...otherwise the person may end up feeling more isolated or misunderstood."

Poor Communication Skills (Barrier)

Half of the participants reported that the poor communication skills of posters and responders discouraged them from engaging in posting and responding on youth mental health forums. For example, P3 stated, "I don't have great communication skills...that's why I don't always tend to write." P4 added that having good writing skills helped to "express your ideas and what you are going through." This barrier also affected the behavior of reading, representing a Physical Opportunity (TDF: Environmental Context and Resources) barrier, as young people were deterred from reading posts that were poorly communicated. This included posts that lacked clarity and coherence, such as those with incorrect grammar and punctuation, which made them more difficult for participants to read and understand. P13 explained, "if you're reading through a post that has grammatical mistakes...you can interpret it differently, but if it is clear, then you just get the information the way it is." In addition, some posts were described as "vague" [P9] or "confusing" [P10], with P9 adding that "some of the posts didn't make much sense...even after reading them."

BCTs

To address the identified barriers, the Theory and Techniques Tool was used to identify relevant BCTs. The most appropriate intervention components were then selected based on an APEASE assessment, as detailed in Table 3.

XSL•FO
RenderX

Table 3. Proposed intervention components and APEASE[a] evaluation.

Barrier (TDF[b] domain)	Suggested BCT[c]	Description	APEASE evaluation
Presence of moderators (Environmental Context and Resources)	• Adding objects to the environment • Restructuring the physical environment	• Clearly state rules and guidelines about content that is not permitted, and provide different interaction mechanisms for users	• Creating clear guidelines is an affordable, acceptable, and practicable way of setting the boundaries of what can be discussed in web-based forums. Having different interaction mechanisms can also be effective in providing the required social support for young people with different support needs [47].
Relevance of information (Environmental Context and Resources)	• Restructuring the physical environment	• Implement recommender engines (ie, tools which use machine learning to recommend relevant items to users) to improve the recommendation of relevant content	• While it may not be the most affordable option, it is the most effective, practicable, and acceptable in addressing stated barrier [48]. Thus, organizations are suggested to consider this option if resources permit.
Accessing content on a mobile phone (Environmental Context and Resources)	• Restructuring the physical environment	• Optimize website layout on mobile interface • Develop a mobile app	• An effective, practicable, and acceptable option to improve the readability and usability of forums on mobile devices. [49] • Effective and acceptable by young people, but may be less affordable than optimizing layout on the mobile interface [50]. Organizations may wish to consider this if resources permit.
Time taken to obtain support (Environmental Context and Resources)	• Restructuring the physical environment	• Leverage technology to facilitate quicker responses (eg, using automated triage systems; artificial intelligence as virtual assistants to help with replies) • Young people could be involved in developing the artificial intelligence tool to ensure it is acceptable, effective, and inclusive.	• Effective and acceptable, having the potential positive side effect of reducing the workload of moderators [51,52]. However, it is less affordable than having manual processes in place to prioritize replies, and organizations may wish to consider this if resources permit.
Interactions with other users (Social Influences)	• Social reward • Social support (unspecified)	• Moderators validate young people who create their first post or respond to posts; badges • Unmoderated forums to introduce moderators who can actively look out for negative interactions	• This is an affordable, practicable, and acceptable way to increase positive interactions on the forum, as such social interactions could improve mood and increase intrinsic motivation [53]. • For forums without moderators, this is an effective, practicable, and acceptable way to manage negative interactions between users [9,28].
Poor communication skills; self-understanding of emotions (Skills)	• Instruction on how to perform behavior	• Online self-administered training on ways to communicate effectively; self-paced learning tools/modules	• This option of using training to improve young people's communication skills is practicable [54]. An online self-administered training was assessed to be more effective than other methods of instruction, such as email (not suitable as it may be too wordy and hard for young people to absorb the information) or in-person training (more resource-intensive and difficult to accommodate available timeslots).
Beliefs about helpfulness of reply (Beliefs About Consequences)	• Information about social and environmental consequences	• Customized email outreach highlighting the positive consequences of posting and replying to forum posts	• This is an affordable and practicable option to convey succinct information. Using a personalized and persuasive tone in these types of communications has been shown to be effective in increasing participation in web-based communities [55].

Discussion

Principal Findings

This study addresses an existing gap by examining the factors influencing young people's engagement in youth mental health forums, including creating posts, responding to posts, and reading posts. Ten core inductive themes were identified across 5 TDF domains, including Skills, Beliefs About Consequences, Emotions, and the Social Influences and Environmental Context and Resources. Of these, 3 themes were enablers, 2 were barriers, and 5 functioned as both enablers and barriers. Some themes were relevant to all 3 behaviors, such as the presence of moderators, while others were specific to more active participation (ie, posting and responding), such as positive interactions with other users. While most themes were relevant to either active participation or overall engagement, some acted as a barrier for 1 behavior but an enabler for another, or were specific to responding and reading only. For example, the ability to quickly find the information needed encouraged reading posts, whereas slow support and responses acted as a barrier to posting new content. Empathic skills were important for both reading and responding. Most barriers were related to physical and social opportunity, suggesting that adjustments to the service structure could enhance young people's engagement. Below, the enablers of engagement are discussed first, followed by the barriers, along with the proposed contextualized BCTs to optimize engagement.

Enablers of Engagement With Youth Mental Health Forums

A range of capability, opportunity, and motivation factors influence young people's use of youth mental health forums. Regarding automatic motivation, this study found that both passive and active engagement with the forum can generate positive feelings, which serve as reinforcement to encourage similar behaviors in the future. This aligns with Smith-Merry et al's [28] findings, which reported that users of web-based mental health forums viewed responding as therapeutic and associated with positive emotions.

Regarding psychological capability, many young people in the study highlighted empathy as an important skill for responding to and reading others' posts. Empathy enables users to better understand others' situations and provide sensitive, thoughtful replies. Perowne and Gutman's [42] study found that empathy in communication was a key skill for moderators of self-harm content on young people's web-based forums, and this same skill is required by users to effectively understand and respond to others' posts.

Regarding physical opportunity, young people in this study reported that a platform allowing anonymity enabled them to express their opinions with less fear of judgment, thereby facilitating posting and responding behaviors. This finding aligns with research in other fields, such as education and physical health, which indicates that anonymity generally promotes self-disclosure and facilitates engagement with web-based forums [56-58].

Barriers to Engagement and Suggested BCTs

Presence of Moderators

Previous studies [9,59] have demonstrated that forum moderators play a crucial role in maintaining a safe online environment for participation. This was echoed in our study, where participants reported that the presence of moderators facilitated engagement by mitigating potential adverse effects of anonymity, such as bullying or disrespectful behavior resulting from disinhibition [14]. This study extends existing literature by highlighting a potential drawback of moderation: some young people may be reluctant to post for fear of negative consequences, such as being banned, if they freely express their thoughts or experiences. The BCTs of "adding objects to the environment" and "restructuring the physical environment" may help mitigate this issue. Specifically, forum providers can reduce ambiguity by offering clear rules or guidelines regarding content that should not be posted [60], giving young people greater certainty about what is acceptable on the forums. Additionally, alternative interaction mechanisms (eg, 1-on-1 chats, if available) can be offered for users to share personal anecdotes of a sensitive nature, ensuring they continue to feel supported for their mental health needs [47]. Providing such avenues allows young people to express their thoughts safely while reducing the likelihood of posting inappropriate content on web-based forums.

Relevance of Information

Consistent with past studies [29], another barrier to reading and responding to posts in youth mental health forums was the difficulty in finding relevant information. Most forums organize posts by recency (ie, the most recent posts appear at the top) rather than providing customized content tailored to users' interests. Furthermore, when forum content is not categorized intuitively or specifically enough (eg, a category is too generic and includes posts spanning a wide range of sub-topics), it hinders young people's ability to find personally relevant information. This, in turn, affects their ability to read or share knowledge and reduces their confidence in replying effectively. Interestingly, the inability to find relevant information may actually increase posting behavior, as users attempt to obtain content that is more personally relevant. However, when young people post solely because they cannot easily locate existing information, it can contribute to more repetitive content on the forums. Thus, it is important to optimize content relevance to reduce repetitive information and maintain the quality of interactions in the forums. To help young people find information that is relevant for reading and responding, forum providers could apply the BCT of "restructuring the physical environment," delivering more relevant or customized content based on users' previously indicated preferences. Implementing recommender engines based on participant preferences has been shown to enhance forum engagement, and this approach could be applied in the current context, as young people are more likely to read and respond to posts they find personally relevant [48].

XSL•FO
RenderX

Accessing Content on a Mobile Phone

Many young people value the convenience, immediacy, and ease of accessing services via their mobile phones [61]. Consequently, difficulties in using web-based forums on mobile devices—such as challenges with reading or typing—generally hindered posting, reading, and responding behaviors. By applying the BCT of "restructuring the physical environment," providers of youth mental health forums could optimize the layout of their websites for mobile interfaces. Additionally, forum providers might consider developing a mobile app to further facilitate ease of use on mobile devices. Converting websites into mobile apps offers several advantages, including the ability to provide instantaneous notifications (if users allow) and to sort content based on user preferences [50]. Providing more customized content through mobile apps could also help address the barrier of difficulty in finding relevant information on the forums. This, in turn, may lead to higher engagement and increased responding behavior.

Time Taken to Obtain Support

Efficiency is a key factor influencing user engagement in help-seeking and information-seeking via web-based forums [62]. Studies by Browne et al [63] and Lobban et al [12] found that forum users valued timely responses to their posts, as this helped them address their current difficulties. Similarly, users who read posts to seek help may be motivated by the desire for immediate support. To minimize the time required to obtain assistance on web-based forums, providers could apply the BCT of "restructuring the physical environment," leveraging technology to facilitate faster responses. For example, previous studies have highlighted the utility of automated triage systems to help moderators identify posts requiring immediate attention [51], as well as the use of artificial intelligence as virtual assistants to respond during off-peak hours [52]. These technological interventions can reduce reliance on manual post monitoring and increase the efficiency of responses.

Interactions With Other Users

Consistent with previous studies [14], some young people reported reservations about posting or responding due to prior negative interactions with other users. By contrast, others noted that they were more inclined to respond to users who had previously replied to them, supporting the concept of reply reciprocity [31,64]. This factor specifically affects active engagement (ie, posting and responding) and underscores the importance of fostering positive interactions on the forums to create a reinforcing feedback loop. To encourage greater posting and responding, forum providers could apply the "social reward" BCT, with moderators placing added emphasis on recognizing users who have made their first post or responded to others, thereby motivating continued engagement. Applying the BCT of "social support (unspecified)," it is important for unmoderated youth mental health forums to introduce moderators. These moderators should actively monitor the forums for negative interactions and work to diffuse and resolve conflicts efficiently [9,28]. By increasing positive interactions and reducing negative ones, overall active engagement with youth mental health forums can be facilitated.

Poor Communication Skills

Existing literature highlights communication skills as a key factor influencing forum engagement. Poor communication skills can act as a barrier, limiting young people's ability to post about their mental health issues or respond to others' posts. Consequently, young people had difficulty understanding poorly written posts, which hindered their reading. Previous research also indicates that longer posts can impede reading, as users are more likely to lose focus unintentionally [65]. Unclear or incoherent posts and replies can also affect users' ability to understand and act on the information provided [66,67]. To enhance communication skills, youth mental health forum providers could implement the "instruction on how to perform behavior" BCT. This might involve an online, self-administered training module that young people can access at their convenience. The training could include guidance on posting and replying effectively (eg, being clear and concise) and emphasize the importance of responding to other users' replies when they agree with the content. Although not in the same context, previous research has shown that online, self-administered social skills training can effectively reduce social fear and enhance social skills [54]. This highlights the potential of using online, self-administered training to enhance young people's skills and confidence in contributing positively to forums.

Beliefs About Helpfulness of Reply

A recent systematic review indicated that perceived effectiveness of professional help is a key factor influencing mental health help-seeking behavior. Adolescents' beliefs about the helpfulness of advice or interventions can significantly affect their likelihood of seeking support; for example, they may avoid seeking help if they have doubts about its effectiveness [68]. An empirical study of a web-based mental health community intervention also found that the quality and effectiveness of responses influenced young people's behavior in creating posts to seek help online [69]. To address the barrier of negative perceptions regarding the helpfulness of replies, forum providers could consider making the benefits of using web-based mental health forums more salient to users. The BCT "information about social and environmental consequences" could be used to emphasize the positive outcomes of posting or replying to forum posts. This could be paired with an active call to action, encouraging users to create posts or respond to existing ones. Implementation could include customized email outreach to new forum members or to existing members who have not yet posted or responded. The email could highlight the positive outcomes of posting or responding helpfully to other users, including validating those who have replied to the original post. It could also encourage recipients to complete the online, self-administered training mentioned above, helping to build their confidence in posting or replying. Directly reaching out to forum members with a persuasive message can effectively promote responding behavior. In similar contexts, studies have shown that actively inviting users to participate in discussions on web-based forums leads to increased engagement [55].

XSL•FO
RenderX

Limitations

The following limitations should be considered when interpreting the findings of this study. First, the use of convenience sampling may have introduced self-selection bias, meaning that individuals who consented to participate in the interviews could differ systematically from those who did not [70]. A similar study by Prescott et al [29] found that participants who volunteered for interviews were more likely to emphasize the advantages of web-based mental health forums rather than the disadvantages, possibly because individuals with more positive experiences were more inclined to share their opinions. To mitigate this, participants were assured of the anonymity of their responses and encouraged to provide honest feedback. Future research could also aim for a more representative sample, including a balanced mix of genders, as there may be gender differences in the use of online platforms for mental health support [8]. Additionally, most participants in this study used a single web-based mental health forum in the United Kingdom, which may limit the generalizability of the findings to other forums in different contexts. Future research could explore the barriers and enablers to posting, responding, and reading posts on other mental health forums targeting different age groups or populations. As the proposed intervention strategies were not evaluated in this study, future research could assess their effectiveness in optimizing young people's engagement with web-based mental health forums. Finally, as forums represent only a subset of the online mental health ecosystem, it may be valuable to explore how these strategies could be applied more broadly to other platforms, such as social media, to maximize their impact.

Conclusions

In today's digitally connected age, the internet serves as a valuable conduit for knowledge sharing and building connections. Youth mental health forums have the potential to provide accessible support, complement in-person services, and positively contribute to young people's mental well-being. However, a lack of engagement can limit the impact and effectiveness of these forums in supporting young people. This study contributes to the existing knowledge by examining the various ways in which young people engage with youth mental health forums. Different strategies may be prioritized depending on whether forum providers aim to increase active engagement (eg, encouraging posting and responding through positive interactions) or overall engagement (eg, implementing moderators and clear rules to support both active and passive participation).

Overall, these findings demonstrate the utility of the BCW approach in conducting behavioral diagnoses and developing behavior change interventions, contributing to the evidence supporting the application of behavior change frameworks in digital mental health interventions. This can help advance the emerging field of digital mental health intervention engagement, ultimately leading to higher-quality forum services that provide better support for young people.

Abstract

Background: Telerehabilitation is a promising solution to provide continuity of care. Most existing telerehabilitation platforms focus on rehabilitating upper limbs, balance, and cognitive training, but exercises improving cardiovascular fitness are often neglected.

Objective: The objective of this study is to evaluate the acceptability and feasibility of a telerehabilitation intervention combining cognitive and aerobic exercises.

Methods: A virtual reality–based dual-task exercise exploiting a cycle ergometer was designed, developed, and integrated with a commercially available telerehabilitation platform. Patients with different conditions were enrolled and administered subjective questionnaires investigating attitudes toward technology, usability, technology acceptance, and subjective workload. Their therapists were interviewed, and adherence and performance data were analyzed.

Results: In total, 26 patients with neurological or post-COVID symptoms were included. Their attitude toward technology (range: 0‐5) did not change after the training period (pre: 3.44 [IQR 0.63]; post: 3.50 [IQR 0.48]); the platform was rated usable and acceptable. Frustration and physical and mental workload were present, especially among younger participants. The adherence was moderate, but individual differences were present (0.59 [IQR 0.54]). The therapists highlighted the potential of remote rehabilitation programs but also identified some limitations.

Conclusions: This study proved the feasibility and acceptability of a customized virtual reality–based telerehabilitation program allowing for the safe implementation of aerobic cycling-based dual-task training. The solution was judged meaningful for dehospitalized patients, although some environmental and technical barriers should be overcome to implement telerehabilitation more effectively.

Introduction

Rehabilitation comprises a series of interventions aimed at optimizing the functioning of an individual; it can play an essential role in regaining or maintaining autonomy during activities of daily living and reduce the personal, social, and economic impact of several acute or chronic conditions. On the contrary, without regular rehabilitation care, individuals with neurological, rheumatological, musculoskeletal, or cognitive disorders may experience a worsening of their condition, reduced quality of life, and emotional distress [1].

XSL•FO
RenderX

In such a context, a possible solution for the sustainable implementation of continuity of care is telerehabilitation, i.e., the remote delivery of rehabilitation services using information and communication technologies [2-5]. Telerehabilitation increases accessibility to care services in remote areas and developing countries [6] and enables patients to engage in higher doses of therapy or repetition, thus improving their performance at impairment, activity, and participation levels [7,8]. Existing studies have proven that telerehabilitation can improve patients' adherence and satisfaction [9], allowing clinical personnel to assist patients who cannot travel or have mobility issues and leading to improved clinical outcomes similar to those obtained with standard therapy [10].

The importance of such remote care-related services has been further emphasized during the COVID-19 pandemic, which hit Italy severely in February 2020 [11]. The emergency that arose significantly overloaded hospitals and led to halting or limiting several clinical services [12]. Such an interruption caused detrimental effects on many patients who were in need of rehabilitation, raising the need to develop efficient, safe, and long-term remote rehabilitative programs [13].

Currently, telerehabilitation can be administered via video and phone calls from a therapist or through a platform that provides the patients with videos, messages, emails, and links to educational materials. Also, it can be supported by virtual reality (VR), a digital technology that allows the patient to train in a computer-generated scenario [14]. VR could generally offer many advantages to rehabilitation interventions [15]: it allows for the simulation of ecological and controlled environments in which patients can train safely and promotes the transferring of the acquired abilities to real life [16,17]. Also, VR has been proven to enhance performance and contribute to keeping patients' motivation at a high level [18,19]. Thus, it can play a key role in promoting adherence, especially for patients with chronic conditions and needing (life-)long treatments.

When COVID arose, several telerehabilitation services were commercially available on the market [2,4]. However, most of them provided only cognitive exercises; a few focused on upper and lower body muscle strength and mobility [20] but did not address lower limb coordination and cardiovascular fitness [21], which—instead—could be very helpful for patients with post-COVID syndrome and chronic conditions in general [22-24].

This work was conceived to respond to the lack of rehabilitation services during the second wave of the COVID pandemic (September to December 2020). In particular, it aimed to design and develop a novel VR-based exercise supporting lower body and cardiovascular training to complement the existing exercises dedicated to upper limbs and cognitive functions in a commercial telerehabilitation platform.

Afterward, the feasibility and acceptability of a customized telerehabilitation program, possibly including such an aerobic exercise, were assessed in different categories of patients.

The remainder of this paper is organized as follows. The Methods section describes the qualitative study performed; the Equipment subsection, besides technical aspects, presents the design choices and the rationale for developing the novel VR-supported exercise. The following sections contain, respectively, the study outcomes, their discussion, and the conclusions we drew with some recommendations for future work.

Methods

Study Design

The study presented in this work was a pilot, interventional, and multicentric study conducted between July 2022 and March 2023.

Ethical Considerations

The study was approved by the Ethics Committees of Ospedale Valduce – Villa Beretta Rehabilitation Center (VB) (Prot. N. 150/2022; date of approval: February 24, 2022), IRCCS E. Medea (MEDEA) (Prot. N. 23/22 – CE; date of approval: March 31, 2022), IRCCS INRCA Casatenovo (INRCA) (Prot. N. 14/22; date of approval: May 26, 2022). All the procedures were performed under the Declaration of Helsinki. All adult participants gave their written informed consent. In the case of participants below legal age, informed written consent was obtained from their parents or legal guardians. No compensation for participation was given.

Equipment

Requirements and Design

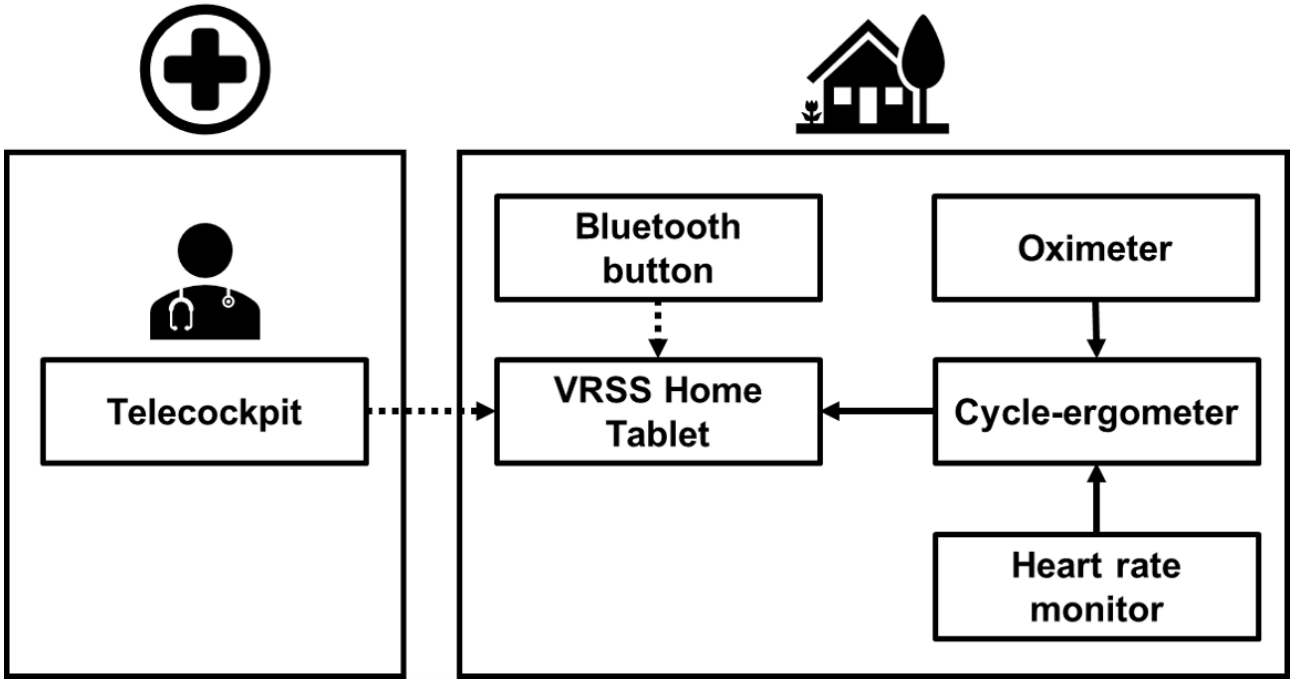
As this work was conceived to give an immediate response during the pandemic, the following three requirements were set: (1) the system must accommodate different conditions, including post-COVID patients, and include different exercises for motor, aerobic, and cognitive training; (2) it must be safe for home use; and (3) it had to be available in a short time.

The first two requirements were not easy to satisfy, as, in general, program interventions focusing on balance and gait were delivered in person due to the potential risks of falls [25]. Experiences reported in the literature either occurred while sitting or lying down or were dedicated to orthopedic patients with no other co-morbidities [20]. Furthermore, in most cases, the focus was on increasing muscle strength and mobility rather than promoting coordination and improving cardiovascular fitness [21].

We used a cycle ergometer to satisfy safety and controllability requirements and the need to support an aerobic training program for lower limbs. In this way, in fact, aerobic training could be carried out safely while seated and holding the cycle ergometer handlebars [26,27]. Moreover, using an ergometer allows for workload adjustment and, thus, the possibility of modifying the difficulty of the proposed task according to each patient's characteristics [28]. Finally, cycling and walking share common features: both movements are periodical, require alternative joints' flexion/extension, and require the contraction of agonist/antagonist muscles in a coordinated pattern [29]. To ensure safety related to the accomplishment of physical activity, additional physiological sensors were added to the system (i.e., heart rate (HR) and oxygen saturation) to interrupt the exercise when it was too exhausting.

XSL•FO
RenderX

To answer the third requirement, two elements were considered. First, we decided to use commercially available equipment already certified by Medical CE. Second, we investigated the availability of telerehabilitation companies to integrate a cycling-based task. These requirements were met by the cycle ergometer from COSMED (Rome, Italy) and the Virtual Reality Rehabilitation System (VRRS) produced by Khymeia Group (Padova, Italy). Both systems are further described in the following section, along with the developed virtual environment.



The Telerehabilitation System

The VRRS is a commercial telerehabilitation system composed of a tele-cockpit operated by the therapists in the clinics and a patient kit. The VRRS tele-cockpit allows for the creation of a daily rehabilitation plan and assessment of patients' compliance and performance. Through the tele-cockpit, the therapist can also video call the patients to assist her or him during the exercise execution. The patient kit comprises a Windows Surface laptop (VRRS Home Tablet), wearable sensors, and interaction devices (e.g., inertial measurement units). The VRRS system offers, per se, several modules dedicated to rehabilitating specific functions, e.g., cognitive, speech, neuromotor, and respiratory exercises [30].

For the sake of this study, the VRSS system was integrated with medical-certified cycle ergometers and a custom-built VR environment. In total, 3 different models of cycle ergometers were used: E100, E5, and E150 Pediatric. All were equipped with a chest band with a HR monitor; E5 models also integrated an oximeter to measure oxygen saturation (SpO_2).

The VR environment designed and developed with Unity (Unity Technologies) to support dual-task training was named ARTEDIA and made available, among other VRSS applications, on the Home Tablet. The technical connection details shown in Figure 1 are further described in [26].

Figure 1. A schema of the ARTEDIA application as integrated into the Virtual Reality Rehabilitation System (VRRS) from Khymeia [26].

The exercise occurs in a virtual park where the patient can travel along a predefined path; the forward velocity is synchronized according to the current ergometer's revolutions per minute (RPMs).

The cognitive exercise was based on the "go/no-go" paradigm, i.e., the participant has to respond when a "go" target appears; conversely, when a "no-go" target appears, participants should not react. During cycling, targets appear randomly at the edges of the path. The patient had to press the Bluetooth button mounted on the cycle-ergometer handlebar to kill the monsters ("go" targets), whereas animals ("no-go" targets) required no action (Figure 2). At each button press, the target disappeared, and visual feedback showed if the reaction was due or not. In case of a missed target, no feedback was provided.

XSL•FO
RenderX

Figure 2. A screenshot of the ARTEDIA application with a no-go target appearing along the route. On the right side, a patient doing the exercise is shown.

The therapist could customize the ARTEDIA exercise by selecting, for each session, the level of difficulty from 1 to 3 (targets frequency and highlight), the cycle ergometer workload (30-70 W), and the duration of the exercise (10, 15, or 20 minutes). Also, the therapist could define the maximum HR (range: 70 - 200 beats per minute) and minimum SpO_2 values (range: 85% - 100%). The exercise was automatically interrupted if the physiological measurement overcame these safety thresholds for more than 10 seconds. At the end of each session, correct answers, errors, missed targets, average RPMs, HR, and SpO_2 (if available) were saved.

Participants

The participants in this study were patients in diverse conditions but suitable to receive an unsupervised training program following their Individual Rehabilitation Project (IRP). Enrolled patients were adults with post-COVID syndrome (INRCA) and stroke (VB), children, adolescents, and young adults with neuromotor diseases (MEDEA).

Participants had to be older than 12. Participants above legal age (18 years) had to be able to provide informed written consent; for children and adolescents below 18, the consent was obtained by their parent or legal guardian. All patients were selected among the ones referring to the 3 involved clinical centers and were judged in need of an additional training period after discharge. All the participants had to live in Lombardy in a house with an available space of 1.5×1 meters (to accommodate the cycle ergometer easily), own a good internet connection, and be assisted by a caregiver who could support home-based training. Exclusion criteria were pain; tracheostomy; reduced trunk control; history of seizure; severe respiratory, renal, hepatic, or cardiological conditions; and the presence of motor, sensory, or cognitive deficits preventing the execution of the exercises. Patients taking part in other rehabilitative programs were also excluded.

Sample size estimation was made based on the *attitude toward technology* questionnaire developed by Huygelier et al. [31] (see paragraph Outcomes). Considering an effect size of 0.69 (as in the original work, i.e., [31]), α=0.05, and power =0.9, we obtained a sample size of 24 patients.

Study Protocol

Baseline

All patients were assessed for enrollment using the Trunk Control Test [32], the Visual Analog Scale for pain [33], and the Mini-Mental State Examination [34]. If considered eligible to participate in the study, each patient, depending on his or her condition, was administered a series of clinical measures to assess his or her baseline and define the IRP. These were the 6-minute walk test [35], the modified British Medical Research Council Questionnaire [36], the Quality of Upper Extremity Skills Test [37], the Gross Motor Function Measure [38], the Motricity Index [39], and the Berg Balance Scale [40].

Whenever possible, clinical scales were complemented with measures of cycling power to help the clinicians define ARTEDIA workload. Power measures were obtained using commercially available sensorized pedals (X-Power, SRM GmbH). This test saw 3 minutes of cycling on the cycle ergometer with a fixed workload set from 30 to 100 W. Data were analyzed to extract mean right and left power and the index of symmetry (*S*) [41]. The index of symmetry varies between 0 and 1, where 0 represents perfect symmetry, and 1 is the maximum power displacement (i.e., a leg has no or negative power).

Individual Rehabilitation Project

Depending on the baseline assessment, each patient was assigned to a complete telerehabilitation program, including lower limb aerobic and cognitive training with ARTEDIA, or an intervention foreseeing only Khymeia VRSS Home tablet exercises targeting cognitive and upper limb training.

The training was executed in unsupervised settings for all patients; most received the VRRS home tablet at their home. In total, 6 of them performed the rehabilitation program in a

XSL•FO
RenderX

room that one of the clinics (VB) set up to execute the training program. Such a room was near the clinic but only opened, closed, and sanitized by non-medical personnel; thus, patients were completely autonomous in following their IRP.

Each patient had access to the telerehabilitation system from 15 to 60 days; patients were instructed to train as defined by the therapist in their IPR and set in their VRSS Home Tablet profile.

Outcomes

Both subjective and objective outcomes were considered to achieve the objectives of the study.

The main outcome was attitude toward the technology; it was assessed before (T0) and after (T1) the intervention. This questionnaire, developed by Huygelier et al. [31], aimed at assessing the perceived ease of use, perceived usefulness, and anticipations about VR among older adults and was composed of 18 items to be assessed on a Likert scale from 1 (completely disagree) to 5 (completely agree).

Files stored on the VRSS home tablet were examined to extract objective data regarding patients' adherence. From these files, we extracted the total number of sessions, the total exercise time per day, and the total time spent using ARTEDIA; the following parameters were available for each ARTEDIA exercise: duration, mean RPMs, mean HR, mean SpO_2 (when present), number of correct answers, omissions, and errors.

As for subjective outcomes, the following dimensions were investigated at T1: perceived workload, usability, and technology acceptance. The questionnaires we used were the NASA Task Load Test (NASA-TLX) (considering raw scoring [42,43]), the System Usability Scale (SUS) [44], and the modified version of the Technology Acceptance Measure 3 (TAM3) [45] questionnaires, respectively.

NASA-TLX is a subjective method for measuring mental workload and includes 6 factors measured through a single question that has to be answered on a scale where 0 indicates no demand, and 20 maximum demand.

The TAM3 evaluates the acceptability of the system according to 13 dimensions. Responses to these questions were measured on a 5-point Likert scale, where 1 indicated strongly disagree and 5 strongly agree.

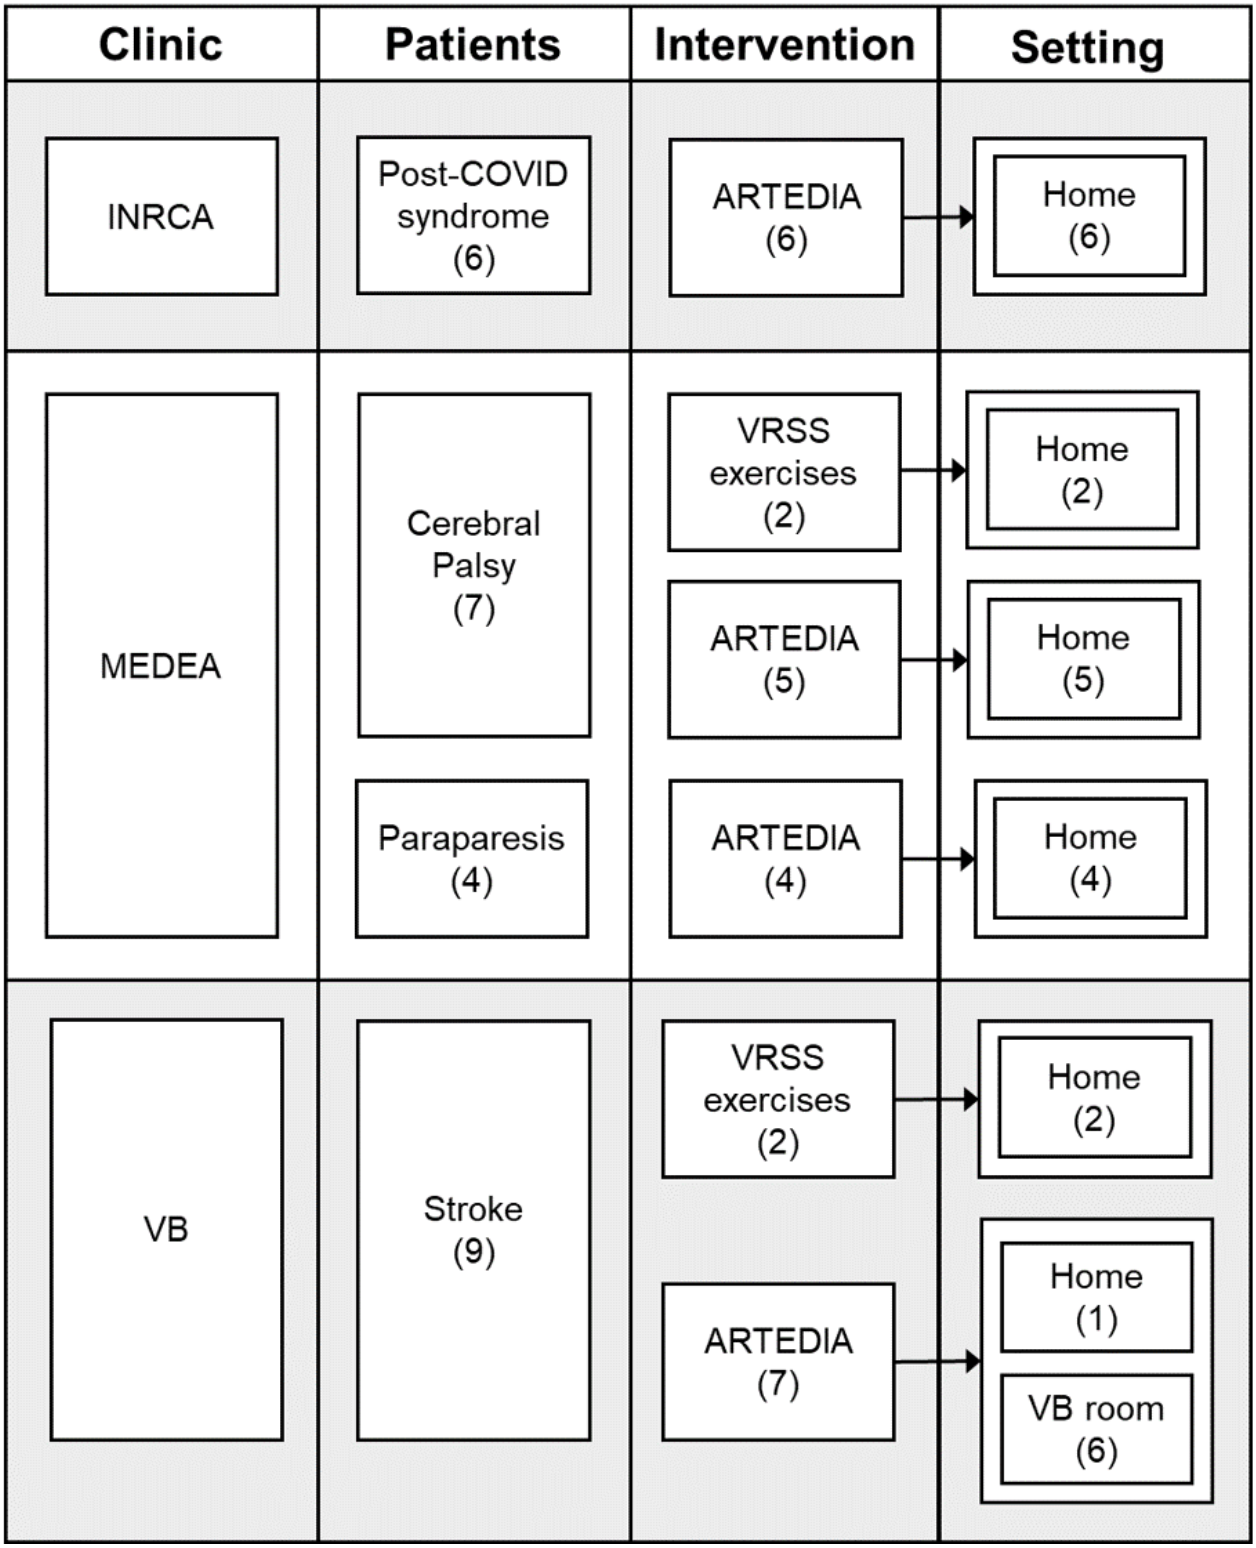
The SUS comprised 10 questions assessed on a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree). The scores are totaled and then multiplied by 2.5 to calculate the final score, which ranges from 0 to 100. Higher scores reflect superior usability.

At the end of the experimental campaign, all the therapists involved in the study in the 3 clinical centers (n=7) were interviewed to provide feedback about the system. The questions of the semi-structured interview are reported in the Supplementary Materials in Multimedia Appendix 1.

Statistical Analysis

Collected data are presented using medians and interquartile ranges; we report mean and standard deviations whenever needed for comparison with previous works. Pre- and post-intervention attitudes toward technology were compared using a paired Wilcoxon rank-sum test. Groups were compared using the Kruskal-Wallis test, and post hoc significance was investigated with Dunn's test. Correlations among subjective variables and between subjective and objective variables were calculated using Spearman's correlations. The reliability of TAM3 subscales was analyzed using Cronbach α. For all tests, the significance level was set at $P<.05$.

Results



Participant Characteristics

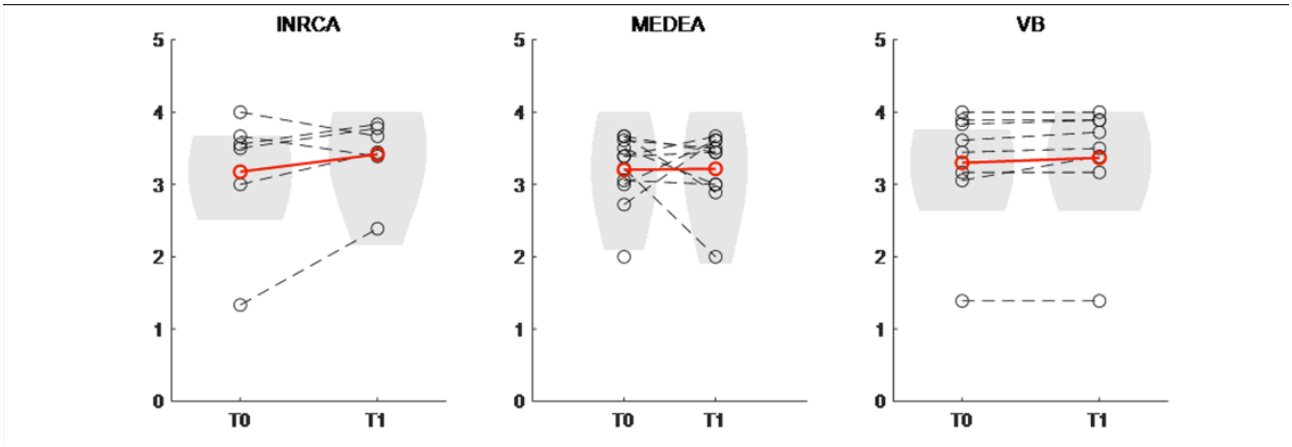
In total, 26 patients were enrolled in the 3 clinical centers. All participants had the maximum score in the Trunk Control Test and no pain, except for one (MEDEA2), who had a score of 2 due to foot pain. The patients' final allocation and their health conditions are shown in Figure 3. Baseline data for each participant is reported in Multimedia Appendices 2-4.

There were 3 dropouts. MEDEA8 (paraparesis) left the study because of the occurrence of pain, whereas VB008 was not able to cycle safely. One of the participants (VB006) had to leave the study after having performed 4 sessions of training due to a call for a surgical procedure, but questionnaire data were collected. All dropouts had the ARTEDIA exercise in their IRP.

XSL•FO
RenderX

Figure 3. Final study allocation and the number of patients involved divided for any of the 3 clinics (INRCA, MEDEA, VB). In between brackets, the number of patients is reported. VRRS exercises indicate the exercises available on the Khymeia Home tablet; ARTEDIA stands for programs containing our newly developed exercise.

Attitude Toward Technology



The median attitude toward technology considering all patients was 3.44 (IQR 0.63, mean: 3.23 (SD 0.71)) out of 5 at T0 and 3.5 (IQR 0.48, mean: 3.40 (SD 0.48)) at T1. Figure 4 shows the attitude toward technology in the 3 categories of patients.

The attitude toward technology was positive (above 3) at T0 for most patients; such a value was preserved at T1 in most cases, especially among adults. One patient in the post-COVID group rated their attitude at T1 over 1 point with respect to T0 (INRCA2), and 1 patient with cerebral palsy reached 0.9 (MEDEA2). One young patient (MEDEA7) showed a decrease greater than 1 point at T1. No significant differences were

XSL•FO
RenderX

recorded at the paired Wilcoxon test (P>.05), either considering the whole population of the patients enrolled by each clinic singularly.

Figure 4. Attitude toward technology (range: 0 - 5) in the 3 categories of patients as enrolled by the 3 clinics (INRCA, MEDEA, VB) measured pre- (**T0**) and post-intervention (**T1**). Each dashed gray line represents the observed scores of 1 participant, while the red solid line represents the group average. The gray area represents the density plots of the observed mean attitude scores.

Objective Data

Table 1 contains data regarding the IRP of each patient and his or her hours of actual exercise with the Home Kit, considering both ARTEDIA and VRSS Home Tablet exercises. The adherence, calculated according to the IRP each patient received, was 0.59 (IQR 0.54, min: 0.16, max: 1).

XSL•FO
RenderX

Table . Information about each patient Individual Rehabilitation Project and their adherence to the overall program the therapist prescribed. Data regarding upper limb and cognitive training are presented for the Virtual Reality Rehabilitation System (VRSS); more details are provided for the ARTEDIA exercise.

[a]PU: perceived usefulness.

[b]PEOU: perceived ease of use.

[c]SE: self-efficacy.

[d]PEC: perception of external control.

[e]PLAY: playfulness.

[f]ANX: anxiety.

[g]ENJ: enjoyment.

[h]SN: subjective norm.

[i]VOL: voluntariness.

[j]REL: relevance.

[k]OUT: output quality.

[l]RES: result demonstrability.

[m]BI: behavioral intention.

In terms of subjective outcomes, group differences emerged in terms of perceived cognitive workload, in particular in the subscales of physical demand (H(2)=8.00, *P*=.018) and frustration (H(2)=11.36, *P*=.035); MEDEA reached higher levels than VB for both variables (*P*=0.03and *P*=.002, respectively). Significant differences among groups were also present in the case of technology acceptance, in particular for the subscales of result demonstrability (H(2)=13.13, *P*=.001) and behavioral intention (H(2)=11.76, *P*=.003). Post-hoc tests showed that VB results were more positive than both MEDEA and INRCA (*P*<.007 in all cases). No other significant group differences were present.

Mean attitude toward technology at T1 was negatively correlated with physical demand (r_s=−0.48, *P*=.018), effort (r_s=−0.41, *P*=.049), and frustration (r_s=−0.52, *P*=.01) as measured by the NASA-TLX. Mean attitude at T0 was significantly correlated with frustration only (r_s=−0.51, *P*=.01).

Mean attitude (T1) and technology acceptance subscale correlations were significant (*P*<.05) in the case of perceived usefulness (r_s=0.52), perceived ease of use (r_s=0.55), playfulness (r_s=0.50), relevance (r_s=0.44), and behavioral intention (r_s=0.50); the correlation of attitude with usability was significant (r_s=0.68, *P*<.001).

None of the subjective variables was correlated to total hours of training or adherence ratio.

Considering those who did ARTEDIA, the difference between the HR threshold and the mean HR measured throughout the sessions was correlated only with frustration (r_s=0.55, *P*=.017). The correctness ratio (i.e., the number of targets identified correctly divided by the total targets) correlated significantly and negatively with mental demand and frustration (r_s=−0.62, *P*=.007 and r_s=−0.53, *P*=.023, respectively). No other correlation was significant.

Therapists' Feedback

The results of the semi-structured interview are presented in Table 4.

XSL•FO
RenderX

Table . The therapists' feedback grouped according to themes and positive and negative comments. When the comments were related to one participant in particular, their ID is reported between brackets.

	Pros	Cons
Perceived usefulness	• Implementation of continuity of care • Home-based treatment favored compliance • Possibility of lower limb training • Patients' monitoring throughout time	• Exercises are generic and not well-targeted • No easy assessment of the performance quality (i.e., if compensation was used) • Impossible to establish the reason behind pain occurrence (MEDEA7)
Accessibility	• Accessibility for chronic patients not receiving other care • Accessibility for patients living in remote areas	• Patients must fit precise conditions (high cognitive functioning, no spasticity) • Patients must be available to schedule calls with the therapist during working hours (MEDEA11) • The safety thresholds were not suitable for one patient (INRCA4) • Internet connection was not always stable enough • Architectural barriers impeded the installation of the setup (stairs, lack of space)
Usability	• Good autonomous management in most cases • Scheduling daily exercises promoted adherence • Engaging scenario promoting motivation	• Technical issues • Difficulty in providing support in case of malfunctioning

As per technical issues, we have tracked the following occurrences in patients from MEDEA: the sensors were not responding properly or were sending wrong input data (n=1; MEDEA7); server updates did not allow the therapist to update the IRP and the patient to access the daily training (n=2; MEDEA4, MEDEA5); generic malfunctioning of the system (n=1, MEDEA6). For one post-COVID patient (INRCA4), the minimum threshold set for oxygen saturation was still too high to proceed with the training. In this case, the patient replaced the sensor with another that was not linked to the system and monitored themselves according to the therapist's indications. Insufficient power of the internet connection and architectural barriers were mentioned in all the interviews.

Discussion

Principal Findings

The results of this study indicated the feasibility and acceptability of a customized VR-based telerehabilitation program that allowed for the safe implementation of lower limb and aerobic training. This result aligns with the outcomes in previous works studying telerehabilitation interventions, either with or without VR support. Furthermore, conducting this study allowed the provision of rehabilitation services to patients who had limited access to the clinic due to geographical distance or had ended their hospitalization.

The study was performed by enrolling a heterogeneous sample of patients, comprising post-COVID patients and adults, adolescents, and children with neuromotor impairments. It allowed us to demonstrate the feasibility of our proposed customizable telerehabilitation program to address diverse issues and needs. Although heterogeneity may constitute a limitation, it can be welcomed when scientific (e.g., pragmatic) studies are aimed to demonstrate the effectiveness in a population as similar as possible to the target population who may benefit from the intervention [47]. Moreover, it could help design the future delivery of targeted care, accounting for patients' diverse conditions [48].

Regarding the attitude toward technology, contrary to what was found in [31], in which Huygelier et al. recorded an increase from 3.4 to 3.9, we did not find any improvement after the treatment. This outcome may be explained by considering that the original work used immersive VR, whereas our system used more familiar technologies, such as laptops and smartphones. Therefore, it is possible that our participants did not change their minds due to the lack of a "wow" effect [49]; also, their anticipation and perception toward the use of digital technology were probably correct at the baseline and confirmed at the end of the experience [50]. Nonetheless, the patients' relationship and approach to technology did not change, and no technical factors affected technology adoption and caused participants to leave the program. This was also confirmed by usability and acceptance outcomes, which were both satisfactory (all technology acceptance subscale scores were >2.7, up to 5), and the positive correlations, found at T1, between attitude and usability, and attitude and perceived ease of use, playfulness, and intentions to reuse the system.

On the other hand, as mentioned by the therapists in their interview, our sample was selected to fit the requirements of mostly autonomous system use (i.e., cognitive level and presence of a caregiver), thus introducing a possible bias in this sense. Indeed, literature shows that the general acceptance of mHealth applications still encounters patients' resistance in more than half of the cases, resulting in minimal engagement and no clinical improvements [51,52].

XSL•FO
RenderX

Our patients' adherence to the proposed program was moderate-to-good (59%), in line with other works proposing unsupervised physical activity programs [53,54] or rehabilitation activities for patients [55]. Other interventions indeed recorded higher adherence, but they also accounted for a stricter sample selection: e.g., a tablet-guided exercise program for older adults obtained 85% adherence, but only 36% of patients accepted to participate in the program and completed it [56].

This issue has already been discussed in the literature, especially when dealing with programs promoting physical exercise: participants in scientific studies are volunteers and, therefore, inherently motivated to exercise or willing to be involved. This means that the results of trials engaging patients in exercise are mostly not generalizable to the general population.

Previous work tried to identify the factors that may influence adherence; a review conducted in 2021 identified 14 key factors affecting adherence in rehabilitation programs [57]; among the others, there was the involvement of professionals from several disciplines, exploration of patients' barriers and facilitators, participants' education, integration in daily living and social support, which we did not investigate. Among older adults, factors promoting an active lifestyle were also identified as personal factors: younger age, education, history of regular exercise, less depression, fewer impairments, and chronic conditions could all positively influence adherence to training programs [58,59].

This dependence upon personal factors was possibly present also in our case, as individual differences, not detected by our collected data, were present. Only in a few cases, analyzing all the information together, was it possible to formulate a hypothesis for higher or lower adherence. For instance, MEDEA7 encountered some problems with the sensors and experienced footache, and the therapist was not able to investigate the cause of the pain remotely. This has impacted their attitude toward technology (showing a decrease of over 1 point from T0 to T1) and possibly their adherence (49%). In the case of INRCA6, MEDEA6, MEDEA 10, and VB002, it is plausible that their initial condition—worse than other peers'—negatively impacted adherence, as they had to make more effort to participate in the program.

These considerations are to be considered cautiously: they are hypotheses, and in most cases, both the adherence and the total training hours were not directly attributable to any of the variables investigated. Because of this, we encourage future work to focus more on personal and anamnestic characteristics we have not explored.

Another element that could contribute to assessing the acceptability of an intervention and influencing patients' adherence is workload, i.e., the cost incurred by an individual while achieving a certain performance on a task with specific demands [60]. The concept of workload per se is hard to interpret, as it is impossible for many tasks to define a "redline" above which the performance degrades [61].

Indeed, in our case, it is plausible to think that some mental effort would be required to perform the proposed exercises per se, even without any influence of the technological system. Considering the performance data related to ARTEDIA dual-task exercise, it emerged that lower cognitive results were indeed linked to higher cognitive demands.

Instead, both cognitive and physical performances were negatively correlated with frustration. In the NASA-TLX questionnaire, the frustration item foresees the investigation of "how insecure, discouraged, irritated, and annoyed" one feels while accomplishing a task, i.e., it examines the unsuccessful fulfillment of objectives after repetitive attempts due to obstacles and negative feedback [62]. Also in this case, it is impossible to discriminate precisely if the frustration was due to the task itself (either cycling or go/no-go task) or the system management. However, some considerations could be made by examining the significant differences among groups: patients from MEDEA reported more frustration and physical effort and were also the group reporting the higher occurrence of problems, such as VRRS updates that caused temporary unavailability of the system, sensor malfunctioning, and the impossibility of the therapist to assess the cause of pain remotely. The relationship between frustration and technical issues has emerged before [63,64].

Another consideration that could be made is related to the absolute dose of therapy: the group of younger participants from MEDEA was also the one receiving a more intense training plan. Although no correlations were identified (possibly because of the small sample), this outcome was in agreement with previous studies, which highlighted that lower-dose interventions could fit better the patients' schedules and, therefore, be more accepted [65,66]. This was highlighted by the case of MEDEA11, who was mostly unavailable for the video calls with the therapists and had a low adherence rate, possibly because of other duties of daily living (21%). Given this, the topic of the appropriate dose to promote adherence in telerehabilitation deserves to be further explored in future works.

On the contrary, VB patients were less subjected to problems, possibly because the system was regularly checked and sanitized (as it was shared and close to the clinic, with one exception only), and—as mentioned before—they trained significantly less.

Despite the reduced adherence, due possibly to the need to travel to reach the room close to the clinic, the hybrid solution has been appreciated and, therefore, deserves further analysis, especially in the case of non-intensive training, e.g, for maintenance of muscle fitness and promotion of an active lifestyle among chronic patients.

In such a setting, sharing a single piece of equipment saves personnel time, money, and equipment management duties (e.g., handling transfers, installations, and conformity checks at the end of the training). Plus, environmental barriers such as lack of space and adequate internet connection are excluded, and prompt support can be provided in the case of technical or clinical issues. On the other hand, the accessibility to the service remains available only for those patients who can travel and reach the facility.

XSL•FO
RenderX

Limitations

This work has some limitations. First of all, the sample was heterogeneous, and although this choice allowed testing our telerehabilitation program with diverse conditions, this limited the generalization to the populations of adults and children with neuromuscular or post-COVID-related impairments. Second, the adherence to the intervention was very different, and we could not determine which factors influenced it either positively or negatively. Finally, rehabilitation sessions were carried out in two different scenarios (home and clinic-devoted room), and study participants were part of different age groups; this may have influenced the patients' subjective experiences. Although the in-depth evaluation of differences among subgroups goes beyond the scope of this work, it would have been interesting to investigate the effects of other factors, such as age or setting. Unfortunately, this was not possible due to the small sample. Nonetheless, the preliminary assessment of the feasibility of the proposed intervention paves the way for future trials in which more participants per group should be enrolled.

Conclusions

This work presents a feasibility study of a novel telerehabilitation system allowing cycling-based dual-task training. The system was preliminarily assessed with a sample of patients with different conditions and demonstrated usable, meaningful, and acceptable. Moderate acceptance was found by therapists who recognized several strengths but also a number of issues. For the effective implementation of a complete telerehabilitation program, including lower limbs, some improvements are still required to overcome environmental and technical barriers.

In the future, larger and more homogeneous populations should be engaged to extend the obtained results and increase their generalizability. A higher number of participants will also allow us to delve deeper into subgroup differences, highlighting which features are considered more relevant by each patient or age group to enhance personalization even more. Particular attention should be paid to the therapy dose and the rehabilitation setting to find the correct balance between treatment effectiveness and suitability with patients' daily life in order to promote optimal compliance.

Acknowledgments

The authors would like to acknowledge Khymeia Group for their support in carrying out this project and the integration of the cycle ergometer within their VRRS system. Moreover, the authors would like to acknowledge the support of Dr. Tito Dinon, who designed and realized the 3D-printed supports.

The work was supported by Fondazione Cariplo (ARTEDIA grant). It was partially supported by the Italian Ministry of Health (Ricerca Corrente 2024/2025 to EB).

Abstract

Background: Mental health during pregnancy is a critical factor influencing maternal and fetal outcomes. Anxiety and depression affect up to 30% of pregnant women, with significant consequences for maternal well-being and child development. Despite this, interventions during pregnancy remain limited, creating a need for innovative, accessible solutions.

Objective: This study aimed to evaluate the effectiveness of an immersive virtual reality (IVR) eHealth intervention in reducing anxiety and depression symptoms in women during pregnancy.

Methods: A 2-arm, randomized controlled trial was conducted across 5 primary care centers in Catalonia, Spain, between October 2021 and May 2024. The study included pregnant women (N=70) aged ≥18 years with moderate anxiety and depression symptoms (Edinburgh Postnatal Depression Scale [EPDS] scores: 9-12) at 12 to 14 weeks of gestation. They were randomly assigned (1:1) to an IVR intervention or standard care group. The intervention group engaged in daily 14-minute IVR mindfulness and relaxation sessions for 6 weeks. Mental health outcomes were assessed using the EPDS and State-Trait Anxiety Inventory.

Results: The intervention group demonstrated significant reductions in EPDS scores, with a mean decrease from 11.32 (SD 0.96) to 7.25 (SD 1.32; *P*<.001), compared to an increase in the control group from 11.32 (SD 0.94) to 16.23 (SD 1.25; *P*<.001). Similarly, State-Trait Anxiety Inventory scores improved markedly in the intervention group (mean decrease from 57.94, SD 5.23 to 35.03, SD 6.12; coefficient –30.47, 95% CI −45.23 to −15.72; *P*<.001), while the control group experienced a nonsignificant increase (from 66.10, SD 5.89 to 72.91, SD 6.34; *P*=.68). High adherence rates were observed, with 79% (26/33) of participants completing ≥30 sessions. Participant satisfaction was high, with 87% (29/33) reporting being "very satisfied" with the intervention.

XSL•FO
RenderX

Conclusions: The IVR eHealth intervention significantly reduced symptoms of anxiety and depression, demonstrating its potential as an accessible and effective tool for mental health support during pregnancy. High adherence and satisfaction levels underscore its feasibility and acceptability. Future research should explore the long-term effects and scalability of IVR interventions in diverse settings.

Introduction

Background

Mental health during pregnancy is a crucial aspect of women's overall well-being, influencing not only the mother but also the development of the fetus and the subsequent outcomes for the child [1,2]. Up to 30% of women may experience mental health disorders during pregnancy, including anxiety and depression [3-5]. These disorders, often interrelated, have a significant impact not only on the mother's health but also on the neurological development of the fetus, potentially leading to complications, such as preterm birth, low birth weight, and long-term emotional difficulties [6]. These adverse effects not only affect the immediate postpartum period but can also influence the child's long-term development, with possible repercussions on behavior, cognition, and mental health [7].

Despite their importance, interventions to address mental health disorders during pregnancy have been limited, with many focusing on the postpartum period, leaving a critical need for attention during pregnancy itself [8]. This deficit in intervention during pregnancy is concerning, as early detection and appropriate treatment of these disorders are essential to ensuring optimal health outcomes for both the mother and the baby [9]. Inadequate treatment or lack of interventions may increase the risk of obstetric complications, such as preterm birth or low birth weight, as well as long-term emotional and behavioral problems in the child [10,11].

Low-intensity interventions, as described by the National Institute for Health and Care Excellence, are particularly important for women experiencing mild to moderate symptoms of anxiety and depression. The National Institute for Health and Care Excellence recommends these interventions as a first step before considering more intensive treatments, as they can provide effective support with fewer adverse effects and are accessible to a wide population [12]. In this context, digital health technologies, known as eHealth, offer a promising new avenue for improving access to care and supporting the mental health of pregnant women [13].

The use of eHealth technologies is growing exponentially worldwide, supported by guidelines from international organizations, such as the World Health Organization, which promote the use of these technologies to improve public health [14]. According to World Health Organization, eHealth technologies can play a key role in expanding access to mental health services [15]. Their application in perinatal mental health has shown promising results in preliminary studies, especially in reducing symptoms of anxiety and depression [16]. These technologies offer the possibility of providing low-intensity interventions, such as mindfulness, relaxation, and other stress management techniques, in a way that is accessible and convenient for women [17]. In addition, mobile apps allow for closer and more personalized monitoring of women's mental health, offering continuous support and enabling quicker interventions in the event of concerning symptoms [18]. eHealth interventions can be a flexible alternative for those women who, for various reasons, cannot easily access traditional mental health services, offering solutions tailored to their individual needs and daily routines [19].

In this context, immersive virtual reality (IVR) is emerging as an innovative tool in the health field. IVR allows users to immerse themselves in simulated environments in a fully immersive manner, offering therapeutic experiences that can be highly effective in managing anxiety, depression, and other mental disorders [20]. Several studies have demonstrated that IVR can help reduce stress and improve emotional well-being in patients, providing cognitive and emotional distraction that facilitates relaxation and symptom reduction [21]. Moreover, its ability to recreate controlled environments makes it useful for exposure therapy and other psychological interventions [22]. This technology, combined with other eHealth tools, can offer personalized and highly effective solutions for pregnant women experiencing mental health issues, opening new possibilities for their management and treatment [23].

Furthermore, the integration of eHealth and mobile health technologies is gaining traction as an effective means of delivering mental health interventions. These technologies provide a direct, low-cost, and engaging manner to deliver care, making mental health support more accessible [24,25]. The global increase in the use of these technologies has led to a growing body of research supporting their efficacy, particularly in treating mood disorders during pregnancy [26,27]. Recent studies have also underscored the importance of mobile health interventions specifically designed for pregnant women, highlighting their effectiveness in reducing anxiety and depression symptoms during pregnancy [5,28].

Objectives

The objective of this study was to evaluate the effectiveness of an IVR eHealth intervention in improving mental health outcomes during pregnancy, specifically by comparing symptoms of anxiety and depression between pregnant women

XSL•FO
RenderX

in the intervention and control groups, assessing satisfaction with antenatal care between the 2 groups, and monitoring adherence to the intervention by tracking the number of completed IVR sessions.

Methods

Study Design

This study was a 2-arm, prospective, randomized controlled trial (RCT) designed to assess the efficacy of a low-intensity eHealth intervention in improving mental well-being among pregnant women. The CONSORT (Consolidated Standards of Reporting Trials) guidelines for RCTs were followed. Participants were randomly assigned (1:1) to the intervention or control group using a computer-generated randomization sequence. Specifically, the Epidat (version 4.2; Epidemiology Service of the Dirección Xeral de Saúde Pública, Xunta de Galicia) software was used to generate the randomization list, ensuring allocation concealment and minimizing selection bias. To maintain the integrity of the randomization process, the allocation sequence was generated independently by the principal investigator (MJ-B) before recruitment. Randomization was stratified by recruitment center to control potential site-specific variations. Allocation was concealed from participants and researchers responsible for data collection to reduce potential biases. Participants and health care providers were masked to group allocation to the extent possible in an intervention of this nature.

The study included pregnant women aged ≥18 years who attended primary care centers affiliated with the sexual and reproductive health care (*Atenció a la Salut Sexual i Reproductiva* [ASSIR; Sexual and Reproductive Health Care in English]). It was conducted across 5 primary care centers (ASSIR) in Catalonia, Spain, between October 2021 and May 2024. Between 12 and 14 weeks of gestation, participants who scored between 9 and 12 on the Edinburgh Postnatal Depression Scale (EPDS)—validated Spanish version [29]—were recruited and randomly allocated to either the intervention group, which received the eHealth intervention, or the control group, which received standard care. Participants were also screened for mental health conditions using the State-Trait Anxiety Inventory (STAI)—validated Spanish version [30]. Those with a diagnosis of severe psychiatric disorder, ongoing treatment by mental health specialists, and a history of gender-based violence were excluded.

Procedure

Participants who scored between 9 and 12 on the EPDS, indicating symptoms of moderate anxiety and depression, were considered for inclusion in the study. Participants were randomly assigned (1:1) to the intervention or control condition. The principal investigator generated a randomization list using the Epidat (version 4.2) software, and all study participants were masked ensuring the randomization process. Women assigned to the control group were informed that their follow-up would proceed as usual, while those in the intervention group received additional information about the eHealth intervention, including the use of IVR.

Intervention

The intervention group received an eHealth-based mental health program, which included the use of IVR technology to deliver mindfulness and relaxation exercises designed to reduce anxiety and depression during pregnancy. The IVR intervention lasted 14 minutes per session and was performed daily for 6 weeks. These sessions were based on mindfulness techniques, conscious breathing, and progressive muscle relaxation, with the aim of providing an immersive therapeutic environment that would promote stress reduction and improve the emotional well-being of the participants. The content of the intervention was developed by Delaguila Games [31], a company specializing in virtual reality applied to health care (Figure 1). The sessions were designed to be self-guided and accessible from home (Figure 2), using an Oculus Go (Meta Reality Labs) virtual reality headset. The program contained 3 main modules that could be selected individually or together, adapting to the needs and preferences of each participant. To ensure adherence and effectiveness of the intervention, the total number of sessions completed by each participant was recorded.

XSL•FO
RenderX

Figure 1. Screenshots of the virtual reality experience.

Figure 2. A pregnant woman using the immersive virtual reality application at home (with written patient permission).

Control

Participants in the control group received the usual antenatal care provided by the public health system. This refers to the pregnancy follow-up protocol established by the Department of Health of the Generalitat de Catalunya, which outlines standard guidelines for prenatal care and monitoring [32].

Sample

Pregnant women aged ≥18 years who were followed at the primary care centers of sexual and reproductive health care (ASSIR) of Mútua Terrassa in Barcelona, Spain, were invited to participate in the study.

In a previous published interventional work [33] using a mindfulness program to evaluate changes in the EPDS score in pregnant women, the authors reported a mean difference of −2.56 (SE 0.72) between the 2 groups of study (intervention and control) after the program. From that, the SD was calculated as SE=SD/Root(n), so SD=SE × Root(n). In this case, as the n was different in both groups (51 and 45), we used the minimum of both (n=45), obtaining a joint SD of 4.83. Assuming a power of 80% to detect differences in contrast of the null hypothesis H_0: $\mu_1=\mu_2$ using a bilateral Student *t* test for 2 independent samples, a significance level of 5%, and assuming a mean difference between both groups of −3.5 (SD 4.83 units), it was necessary to include 31 women in the nonintervention group

XSL•FO
RenderX

and 31 women in the intervention group, totaling 66 patients in the study. Considering that the expected drop-out rate is 5%, it was necessary to recruit 70 women (35 in each group).

Measures

Primary Outcome: Mental Health Status

The mental health status of the participants was measured using the EPDS and the STAI. The EPDS is a self-report scale comprising 10 items, where participants choose 1 of 4 responses that best describes how they felt during the past week. The EPDS has been validated in Spanish and shows good sensitivity (79%) and specificity (95.5%), with a Cronbach α of 0.87 [29]. Scores range from 0 to 30, with scores ≥13 indicating a positive screen for depression. The STAI assesses 2 dimensions of anxiety: state anxiety (a temporary condition in response to a specific situation) and trait anxiety (a general tendency to perceive situations as threatening) [30]. Both scales have demonstrated robust psychometric properties in various populations.

Secondary Outcomes

Satisfaction With Pregnancy Care

Satisfaction with pregnancy care was measured using a validated self-completed questionnaire [34], consisting of 28 items that assess different aspects of care, including equipment, accessibility, organization of the consultation, and the competence of the staff. The scale uses a 5-point Likert system, and scores are categorized as satisfied (scores >3) or very satisfied (scores >4). The reliability of this tool has been demonstrated with a Cronbach α of 0.92 [35].

Adherence to the Intervention Protocol

Adherence to the intervention protocol was monitored by tracking the number of sessions completed by each participant in the intervention group. In addition, participants in this group were asked to complete a questionnaire evaluating the usability and accessibility of the eHealth technology used during the study [36]. The number of sessions and time spent on each session were recorded to assess adherence and participant engagement with the intervention.

Pulse Measurements

Pulses were recorded before and after the intervention.

Participants were encouraged to report any adverse events, discomfort, or unexpected side effects experienced during or after the IVR sessions. If the participant experienced dizziness, nausea, or an increase in anxiety symptoms, she was instructed to stop the session and rest. If symptoms persisted, participants could contact the research team via an email address specially designed to resolve any problems. Participants had the right to withdraw from the study at any time, without having to justify their decision, and without this affecting their regular prenatal follow-up. In addition, the study team, made up of midwives and mental health professionals, was available to provide additional psychological support if necessary, ensuring that participants felt safe and supported throughout the intervention.

Data Collection and Management

Data were collected at 2 time points: baseline (12-14 weeks of gestation) and 6 weeks after the start of the intervention. All data were securely stored and anonymized, with access restricted to authorized personnel only. Participants' personal information was protected according to the ethical standards of Mútua Terrassa.

Statistical Analysis

Qualitative variables were described using absolute frequencies and percentages. Quantitative variables were summarized using the mean, SD, and median. The Kolmogorov-Smirnov test was used to assess the normality of distributions.

Sociodemographic and clinical characteristics were compared across groups. For quantitative variables, Mann-Whitney *U* tests were conducted. The chi-square test (or Fisher exact test for frequencies <5) was used to compare categorical variables. The effectiveness of the intervention was evaluated using mixed-effects models to assess changes in mental health outcomes over time by group. The interaction between time and intervention, as well as potential confounding factors such as age, previous admissions, current planned pregnancy, and personal history of anxiety, were also considered in these analyses.

In addition, the postintervention scores of the EPDS and STAI-E were transformed into binary variables. For EPDS, a cutoff score of 9 was selected based on bibliographic criteria [29], while for STAI-E, the third quartile value (>86 points) was used [30]. Finally, several logistic regression models were conducted for the primary outcomes with the study group included as an independent variable. These models were also adjusted for the previously mentioned confounding factors, including preintervention EPDS and STAI-E scores. Hosmer-Lemeshow goodness-of-fit tests were performed to assess the overall fit of the models [37]. Receiver operating characteristic curves were also calculated for this approach.

Statistical significance was set at $P<.05$, and all analyses were performed using R version 4.2.1 (R Foundation for Statistical Computing). For the mixed-effects models, we used the *nlme* package with the *lme* function and the *stats* package with the *glm* function in the logistic models.

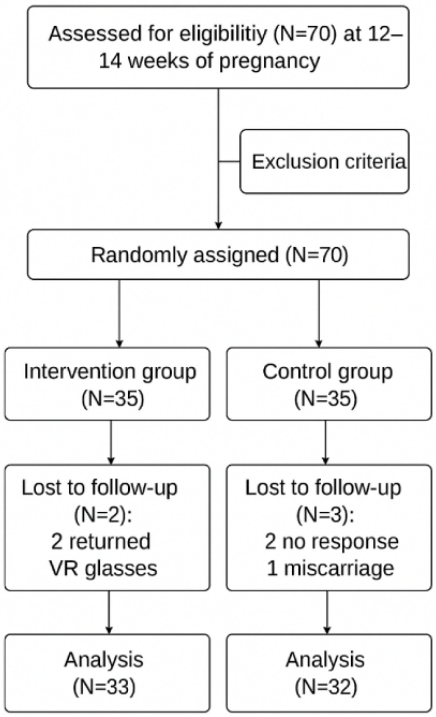
Ethical Considerations

The study protocol was approved by the Drug Research Ethics Committee of Mútua Terrassa (B1803). Informed consent was obtained from all participants before their inclusion in the study. The study was conducted in accordance with the Declaration of Helsinki and relevant European Union regulations on data protection. The informed consent process was conducted following strict ethical guidelines to ensure that all participants fully understood the nature of the study and its potential risks and benefits, and that their participation was voluntary. The steps taken for the informed consent process are provided in Textbox 1.

These measures were taken to guarantee that all participants provided truly informed and voluntary consent, minimizing any risk of coercion or undue influence.

XSL•FO
RenderX

Textbox 1. Informed consent process.



- A comprehensive explanation: before the enrollment, all participants received a detailed explanation of the study's objectives, procedures, potential benefits, and possible risks. This was done through both written and verbal communication by trained health care professionals.
- Time for reflection and questions: participants were given sufficient time to read the informed consent document and ask any questions. Researchers provided clarifications to ensure that participants had a clear understanding before signing the consent form.
- Assessment of understanding: to ensure comprehension, participants were asked to summarize key aspects of the study in their own words. If any misunderstandings were identified, additional explanations were provided.
- Voluntary participation and withdrawal rights: it was explicitly stated that participation was entirely voluntary, and that participants could withdraw at any time without any consequences for their health care or treatment.
- Safeguards against coercion: to prevent undue influence, recruitment was conducted by independent health care professionals who were not involved in participants' routine medical care. No financial or material incentives were provided to encourage participation.
- Ethics approval: the study protocol, including the informed consent procedures, was reviewed and approved by the Drug Research Ethics Committee of Mútua Terrassa (B1803), ensuring compliance with ethical and legal standards.

Results

Overview

The study included 70 participants with a mean age of 31.9 (SD 4.83) years, evenly distributed between the intervention group (n=35, 50%) and the control group (n=35, 50%; Figure 3). There were 2 losses to follow-up in the intervention group and 3 in the control group. All cases of loss to follow-up occurred in the period after the intervention.

Figure 3. CONSORT (Consolidated Standards of Reporting Trials) participant flowchart for the randomized controlled trial. VR: virtual reality.

Sociodemographic and Clinical Characteristics

Regarding sociodemographic and clinical characteristics, the intervention group had a higher mean age (in years) compared with the control group (33.77, SD 3.46 vs 30.03, SD 5.3; *P*=.003). Furthermore, a significantly higher proportion of participants in the intervention group reported having their own income (35/35, 100% vs 21/35, 60%; *P*<.001) and a university-level education (24/35, 69% vs 8/35, 23%; *P*<.001;Table 1).

[c]Not available.

Regarding prepregnancy mental health treatment history, participants who reported treatment history had received a variety of interventions, including individual or group psychotherapy, pharmacological treatment with antidepressants or anxiolytics, and follow-up by mental health professionals in primary or specialist health care. The length of treatment varied among participants, ranging from brief interventions <6 months to continued treatment >2 years. Disaggregated data about specific treatment adherence or the exact type of medication used by each participant were not available in this study.

Regarding obstetric characteristics, 86% (30/35) of pregnancies in the intervention group were planned, compared with 57% (20/35) in the control group (*P*=.02; Table 2). No significant differences were found between the groups regarding the history of cesarean sections, traumatic deliveries, or high-risk pregnancies (all *P*>.05).

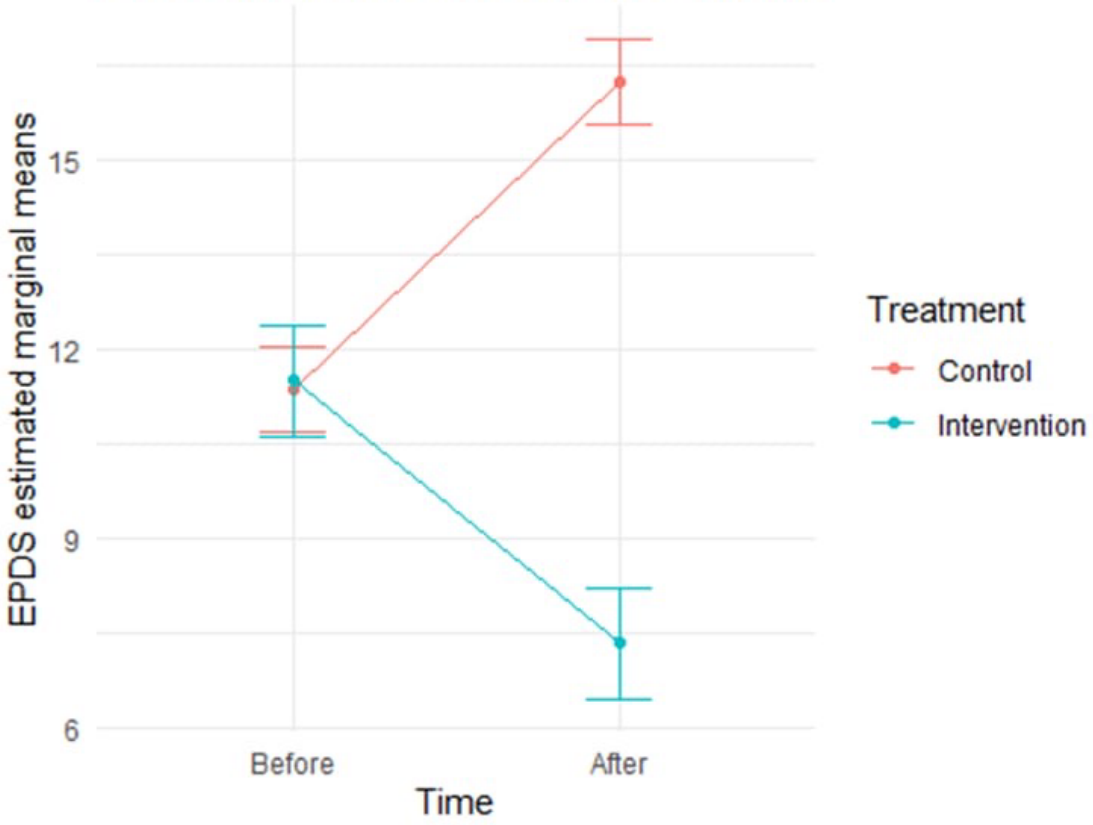
[b]Gestational week of all participants at enrollment was 12 to 14 weeks.



[c]IVF: in vitro fertilization.

Comparison of EPDS Scores Between Groups Before and After the Intervention

At baseline, the EPDS score was comparable between both groups (*P*=.56). Following the intervention, the mean EPDS score significantly decreased in the intervention group (from 11.32 to 7.25; *P*<.001), whereas it increased in the control group (from 11.32 to 16.23; *P*<.001). The adjusted mixed-effects model revealed a significant interaction between time and treatment (coefficient=−9.03, 95% CI −11.29 to −6.76; *P*<.001), indicating a substantial reduction in EPDS scores attributable to the intervention over time (Figure 4).

XSL•FO
RenderX

Figure 4. Interaction between time and treatment in the Edinburgh Postnatal Depression Scale (EPDS) score.

Furthermore, the adjusted logistic regression model demonstrated that participants in the intervention group had a significantly lower likelihood of exhibiting postintervention EPDS scores ≥9 points compared to the control group (odds ratio [OR] 0.03, 95% CI 0.01-0.8; *P*=.001; Table 3). In addition, a planned pregnancy was associated with a lower probability of achieving EPDS scores ≥9 points. In contrast, a higher preintervention EPDS score was associated with an increased likelihood of achieving EPDS scores ≥9 points (OR 3.32, 95% CI 1.52-9.58; *P*=.008). The model demonstrated good calibration, as evidenced by the Hosmer-Lemeshow goodness-of-fit test (*P*=.10) and the area under the receiver operating characteristic curve (area under curve=0.82).

Table 3. Multivariate logistic regression model for postintervention Edinburgh Postnatal Depression Scale (EPDS) score (>9 points).

Variable	Multivariate[a] odds ratio (95% CI)	*P* value[b]
Intervention group	0.03 (0-0.18)	.001[b]
Preintervention EPDS score	3.32 (1.52-9.58)	.008
Age (y)	0.99 (0.8-1.12)	.93
Personal income	2.2 (0.12-41.26)	.58

[b]*P* value is considered statistically significant when <.05.

Comparison of STAI-E Scores Before and After the Intervention

At baseline, the STAI-E score was similar in both groups (*P*=.12). Following the intervention, the intervention group experienced a significant reduction in mean scores (from 57.94 to 35.03; *P*<.001), whereas the control group showed an increase (from 66.10 to 72.91; *P*<.001). The adjusted mixed-effects model identified a significant interaction between time and treatment (coefficient=−30.47, 95% CI −45.23 to −15.72; *P*<.001; Figure 5), indicating a substantial improvement attributable to the intervention over time, similar to the effects observed with the EPDS. Conversely, the control group exhibited a nonsignificant change, with mean scores increasing slightly from 66.10 to 72.91 (*P*=.68).

XSL•FO
RenderX

Figure 5. Interaction between time and treatment in the State-Trait Anxiety Inventory (STAI)-E score.

Furthermore, the adjusted logistic regression model demonstrated that participants in the intervention group had a significantly lower likelihood of presenting postintervention STAI-E scores >86 points compared to the control group (OR 0.05, 95% CI 0.01-0.40; *P*=.01). In addition, a higher preintervention STAI-E score was associated with an increased probability of exceeding the threshold (OR 1.04, 95% CI 1.01-1.08; *P*=.02;Table 4).

Table 4. Multivariate logistic regression model for postintervention State-Trait Anxiety Inventory (STAI) scores (state; >86 points)

Variable	Multivariate[a] odds ratio (95% CI)	*P* value[b]
Intervention group	0.09 (0.00-0.73)	.05[b]
Preintervention STAI-E score	1.04 (1.01-1.08)	.02
Age (y)	0.83 (0.64-1.01)	.08
Personal income	0.40 (0.05-2.46)	.34
Current planned pregnancy	0.32 (0.05-1.75)	.20
Personal history of anxiety	0.95 (0.16-6.05)	.96

[a]Hosmer–Lemeshow goodness-of-fit test, *P*=.18. Area under the receiver operating characteristic curve=0.79 (95% CI 0.65-0.88).

[b]*P* value is considered statistically significant when <.05.

Pulse Measurements

Before intervention, the intervention group had a mean pulse of 85.91 (SD 5.47) beats per minute. After intervention, the mean pulse decreased to 76.94 (SD 6.62) beats per minute, indicating a significant improvement.

Intervention Adherence

Among the 33 participants in the intervention group, 32 (97%) provided valid data for adherence analysis. The average number of completed sessions was 37.84 (SD 9.83), with a median of 42 sessions. A total of 17 (51%) participants completed all 42 sessions, while 26 (79%) participants completed at least 30 sessions. Only 6 (18%) participants completed fewer than 30 sessions, and 1 (3%) participant had no adherence data available.

Participant Satisfaction

Participant satisfaction with the eHealth intervention was quantitatively assessed. Of the participants in the intervention group, 87% (29/35) reported being “very satisfied” with the intervention, while 9% (3/35) were “satisfied,” and 3% (1/35) expressed a neutral stance. No participants reported dissatisfaction.

XSL•FO
RenderX

In addition, 91% (32/35) of participants found the intervention "easy to use," and 86% (30/35) stated that it "helped them feel more supported during their pregnancy." These quantitative measures highlight the high level of acceptability and usability of the intervention.

No serious adverse events were reported. Only mild cases of dizziness (3/35, 9%) and temporary nausea (2/35, 6%) were recorded, all of which resolved spontaneously within a few minutes without requiring interruption of the intervention.

Discussion

Principal Findings

This study examined the efficacy of a low-intensity eHealth intervention supported by IVR technology in improving mental health outcomes during pregnancy. The results provide evidence that the intervention contributed to significant reductions in anxiety and depression scores among participants in the intervention group, compared to the control group. Specifically, participants in the intervention group experienced a decrease in EPDS scores from 11.32 to 7.25, while the control group showed an increase from 11.32 to 16.23. A mixed-effects model revealed a significant interaction between time and group (coefficient=−9.03; P<.001), emphasizing the intervention's effect on mitigating depressive symptoms. Similarly, for STAI-E, the intervention group's score decreased from 61.89 to 35.03, whereas the control group's score increased to 72.91. These findings underscore the intervention's capacity to address acute and persistent anxiety symptoms during pregnancy. The reduction in EPDS and STAI-E scores could be related to changes in cortisol levels, sleep quality, or social support [38].

The choice of IVR as an intervention tool is based on the growing scientific evidence supporting its efficacy in reducing anxiety and depression. Previous studies have shown that IVR can induce states of relaxation, facilitate emotional regulation, and reduce stress through immersion in controlled environments designed to promote psychological well-being [18,19]. Its ability to isolate the user from external stimuli and generate an immersive experience promotes greater adherence to, and engagement with, the intervention, which is particularly beneficial in pregnant populations. Furthermore, previous research has shown that IVR activates neurobiological mechanisms associated with the reduction of stress and anxiety [20], reinforcing its suitability as a low-risk, nonpharmacological strategy that is easy to implement in this context. Although the intervention was not specifically validated in women from various cultural contexts, it was designed to be accessible and applicable to a broad spectrum of users. The content of the intervention focused on mindfulness and relaxation exercises, techniques widely used and recommended in perinatal mental health care. To ensure that it was accepted and understood, a neutral and accessible language was used, without specific cultural references that could limit its applicability in different settings. In addition, priority was given to usability and ease of integration into the daily routine of the participants, which are the key aspects to maximize adherence to the intervention.

Our approach in this study is based on modern theories of emotional processing, which postulate that emotional responses are mediated by neural networks associated with memory and fear regulation [39]. IVR facilitates immersion in relaxing and controlled environments that induce a physiological relaxation response, promoting regulation of the autonomic nervous system and reducing activation of the amygdala, a key structure in the response to stress and anxiety [19]. Furthermore, the immersive experience in IVR promotes attentional focus and cognitive distraction, mechanisms that have been shown to be effective in reducing symptoms of anxiety and depression [18,20]. The intervention is based on mindfulness-based therapy, which has been widely validated in the treatment of anxiety and depression [16]. IVR enhances this practice by providing an immersive environment that facilitates the experience of presence and engagement with the activity, optimizing therapeutic benefits. Repeating sessions over 6 weeks favors the consolidation of emotional regulation patterns through neuroplasticity mechanisms, generating sustained changes in the perception of stress and anxiety [21]. Thus, the theoretical model that supports our intervention combines the physiological regulation of stress through modulation of the autonomic nervous system, cognitive distraction and attentional focus facilitated by immersion, and the progressive internalization of emotional coping strategies through the repeated practice of mindfulness in a safe and structured environment.

Although our study protocol did not include a specific assessment of sleep quality or anxiety sensitivity, some publications suggest that anxiety and depression during pregnancy are closely related to these factors. Previous studies have shown that mindfulness- and relaxation-based interventions, such as the one used in our study, can improve sleep quality and reduce stress levels [40,41]. Furthermore, it has been shown that anxiety sensitivity can act as a vulnerability factor for the development of anxiety and depressive symptoms, which reinforces the relevance of addressing these aspects in future research [42].

There are several mechanisms that may explain the observed benefits of IVR-based intervention on mental health. First, the cognitive and emotional distraction effect plays a key role in reducing symptoms of anxiety and depression. The immersive nature of virtual reality allows attention to be diverted from stressors, providing a controlled and immersive environment that promotes relaxation. This mechanism has been demonstrated in previous studies, in which exposure to virtual environments effectively reduced the perception of stress and pain in clinical contexts. Second, the induction of physiological relaxation may be a determining factor. The IVR intervention includes mindfulness and guided relaxation techniques, which have been associated with reduced autonomic activation, decreased heart rate, and better emotional regulation. These effects are consistent with our findings, in which a significant reduction in symptoms of anxiety and depression, as well as a decrease in heart rate, was observed in the intervention group. Third, the influence on neuroplasticity and emotional engagement could contribute to the positive effects of IVR. Immersive experiences can modulate neural circuits associated with stress and mood regulation, promoting adaptive cognitive

XSL•FO
RenderX

and emotional responses. Furthermore, the activation of reward-related brain areas during the virtual experience can improve mood and motivation, which would explain the high levels of adherence and satisfaction observed in our study. Finally, the increase in the perception of support and self-efficacy could mediate the effectiveness of the intervention. By providing a structured, engaging, and easily accessible tool for mental well-being, IVR allows users to take an active role in managing their symptoms. This sense of control has previously been linked to better outcomes in digital health care interventions. In any case, future studies should explore these mechanisms in greater depth by using neuroimaging techniques, physiological monitoring, and qualitative evaluations of the user's experience.

Regarding the generalizability of the findings, we acknowledge that the study was conducted in a specific region of Spain, which might limit its applicability to other populations. Nevertheless, to strengthen external validity, the following 2 strategies were implemented: (1) participants were recruited from 5 primary care centers (ASSIR), allowing for the inclusion of women with different sociodemographic profiles within the public health system; and (2) the virtual reality intervention used does not depend on specific cultural or contextual factors, facilitating its implementation in other prenatal care settings. Our findings are consistent with previous studies on eHealth and virtual reality for the management of anxiety and depression, suggesting that this technology may be effective in several pregnant populations.

With regard to the representativeness of the sample and the strategies to improve diversity, participants were selected in public primary care centers, ensuring equal access to the intervention and avoiding biases associated with the use of private services. Broad inclusion criteria were established, including women aged ≥18 years with moderate symptoms of anxiety and depression (EPDS scores: 9-12), which favored the heterogeneity of the sample. All participants had to speak and understand Spanish, ensuring understanding of the intervention and evaluation of the results without linguistic bias. Although differences were observed in the educational level of the participants, we performed adjusted analyses to control possible effects of these variables on the results.

In our study, no serious adverse events were reported. A pilot study in the United States analyzed the feasibility of IVR for distraction and pain management in women in labor and reported a high acceptance with no serious side effects [43]. While in the general population the use of IVR may be associated with effects such as dizziness, nausea, or disorientation—known as cybersickness—these effects appear to depend on the design of the intervention, the duration of exposure, and the individual characteristics of the users [44]. Although the evidence so far suggests that IVR is a safe and well-tolerated intervention in pregnant women, we encourage future research evaluating potential adverse effects in the long term and in more diverse populations.

Comparison With Previous Literature

Our findings align with previous literature emphasizing the potential of digital mental health interventions for perinatal populations. For example, Bell et al [45] demonstrated the effectiveness of virtual reality in managing anxiety and depression in diverse clinical settings. Similarly, studies such as Pallavicini et al [46] highlighted the ability of virtual reality games to elicit positive emotions and reduce state anxiety through immersive and interactive experiences. These findings suggest that IVR technology's immersive nature enhances user engagement and emotional regulation, supporting its use as a tool for mental health interventions during pregnancy.

In addition, Fuster-Casanovas et al [47] observed a significant rise in the adoption of eHealth tools for managing mental health in Catalonia, further highlighting the role of digital platforms in enhancing accessibility to psychological support. Their findings resonate with our study's results, as both suggest that digital tools, particularly IVR, can bridge gaps in care by offering scalable and engaging solutions for vulnerable populations. Moreover, Bell et al [48] reported that virtual reality interventions significantly reduced anxiety in adolescent patients in hospital settings when immersive, therapeutic applications were used, providing further evidence for the clinical utility of such technologies in diverse populations.

Satisfaction

Participant satisfaction with the IVR-based intervention was remarkably high, as evidenced by postintervention surveys. Participants reported that the immersive nature of the technology facilitated relaxation and emotional engagement, which contributed to the observed reductions in anxiety and depression symptoms. These findings are consistent with previous studies, such as Bell et al [48], which demonstrated that virtual reality interventions elicited positive emotional responses and were well-received by users. In addition, Pallavicini et al [46] noted that the interactive elements of virtual reality contributed to enhanced user experiences, making the intervention more enjoyable and effective. Further support comes from Al Kuwaiti et al [49], who highlighted that virtual reality's adaptability and immersive environments increase patient satisfaction in therapeutic applications. The positive feedback underscores the acceptability of IVR as a feasible mental health intervention, particularly in populations with limited access to traditional therapies.

Adherence

Adherence to the intervention protocol was high, with 97% (32/33) of participants providing valid data. Among them, 79% (26/33) completed at least 30 sessions. This is in line with findings from Fuster-Casanovas et al [47] who highlighted the ease of use and accessibility of eHealth tools as key factors in ensuring consistent engagement. High adherence rates were also observed in studies using similar virtual reality–based interventions, such as Bell et al [45], which attributed participant compliance to the engaging and user-friendly nature of the technology. In addition, findings by Garcia et al [50] suggested that virtual reality interventions designed with user-centric features significantly improved adherence by maintaining user motivation and interest. Furthermore, Indovina et al [51] demonstrated that adherence to virtual reality–based pain management programs was strongly associated with the level of interactivity and the ability to tailor content to user preferences. These findings suggest that the immersive and

XSL•FO
RenderX

interactive characteristics of IVR not only enhance satisfaction but also foster sustained participation, which is critical for achieving meaningful mental health outcomes.

We found that user-centered design and personalization of IVR is very important. As far as individual needs assessment is concerned, before implementing the IVR intervention, it is essential to conduct an initial assessment of each pregnant woman's needs, preferences, and expectations. This may include questionnaires about her anxiety and depression levels, as well as her preferences regarding types of exercises (eg, mindfulness, relaxation, and guided imagery) and virtual environments (eg, beaches, forests, and mountains) [23]. This assessment would allow for the creation of a personalized intervention plan that fits each woman's specific needs, thus increasing adherence to, and satisfaction with, the intervention [52]. As far as adaptation of virtual environments is concerned, they should be designed to be inclusive and culturally sensitive. For example, women from certain cultural backgrounds may feel more comfortable with environments that reflect their natural or cultural environment. This could involve adapting landscapes, sounds, and narratives to be culturally relevant [53]. Furthermore, environments should be adjustable in sensory intensity (eg, sounds, colors, and movement) to suit individual preferences and avoid overstimulation, especially in women who may be more sensitive during pregnancy [54]. Regarding flexibility of duration and frequency of the IVR session, they should be flexible to suit pregnant women's routines and energy levels. Some women may prefer shorter but more frequent sessions, while others may benefit from longer but less frequent sessions [55]. The ability to pause and resume sessions is also important, as pregnant women may need frequent breaks due to physical discomfort or fatigue [56]. The incorporation of real-time feedback systems can improve the personalization of the intervention. For example, heart rate sensors or short questionnaires during sessions can provide information about the woman's emotional state, allowing the IVR content to be adjusted based on her responses. This dynamic approach can help ensure that the intervention is always relevant and effective for each woman [56]. Finally, to ensure that the IVR intervention is truly user-centered, it is essential to involve pregnant women in the design and development process. This may include focus groups, pilot testing, and satisfaction surveys to gather direct feedback about the content and usability of the intervention [57]. Active user participation not only improves the acceptance of the intervention but also increases the likelihood that it will be effective and sustainable in the long term [58].

Strengths and Limitations

While our study contributes to the growing evidence base for IVR interventions, it is not without limitations. First, the relatively small sample size restricts the generalizability of the findings. Second, the reliance on self-reported adherence and satisfaction data introduces potential reporting biases. In addition, the absence of long-term follow-up limits our ability to evaluate the sustained impact of the intervention on postpartum mental health.

Another limitation to consider is related to the extrapolation of these results to women from disadvantaged socioeconomic backgrounds, or whose technological limitations could be restrictive, given that the availability of, and familiarity with, technologies such as IVR can differ significantly between socioeconomic groups. Also, the representativeness of the sample is limited because the participants generally had a high educational level and good access to health care and technological resources, which could bias the results toward greater effectiveness and adherence. Another potential limitation is related to possible biases derived from self-reporting of adherence to, and satisfaction with, the intervention, which may reflect a social desirability bias. Finally, it is worth noting that long-term follow-up was not conducted, which limits conclusions about the sustainability of the treatment's effect on postpartum mental health. Future research should therefore consider, including more diverse samples, including women from different socioeconomic and cultural backgrounds, as well as evaluating alternative methods of technological access that facilitate the equal participation of women in vulnerable situations. In addition, future studies should implement longer follow-ups to assess the sustainability of the observed impact on mental health and delve deeper into possible biases arising from self-reporting and the specific characteristics of the studied group.

Nonetheless, this study has several strengths. The use of IVR technology represents an innovative and accessible approach to perinatal mental health care. Rigorous adjustments for baseline differences strengthen the reliability of our findings, and the high adherence rates suggest feasibility for real-world implementation. Importantly, the results of this study provide a foundation for future research to build upon, particularly in exploring the long-term effects and cost-effectiveness of IVR interventions for pregnant women.

Clinical Implications and Future Directions

From a clinical perspective, the integration of IVR-based eHealth programs into prenatal care offers a promising avenue to address gaps in mental health support. These programs can serve as scalable and engaging solutions, particularly in contexts where traditional resources are limited. Future studies should explore how to customize IVR content to meet individual needs and preferences, potentially enhancing both engagement and outcomes. Fajnerova et al [59] emphasized the potential of multiuser virtual environments for facilitating group-based mental health interventions, which could be explored further in maternal care settings.

Our primary objective in this RCT was to assess the immediate efficacy of the IVR intervention on symptoms of anxiety and depression during pregnancy, using standardized instruments (EPDS and STAI). However, the evaluation of durability of these beneficial effects beyond the immediate intervention period is essential to confirm its clinical utility and inform maternal mental health policies. We therefore plan to conduct future longitudinal studies that include extended postpartum follow-up periods (eg, from 6 to 12 months after birth) to assess whether reductions in prenatal symptoms of anxiety and depression symptoms are maintained after delivery. These future studies will adopt longitudinal designs to analyze the persistence of improvements in maternal mental health outcomes, including

XSL•FO
RenderX

the potential prevention of postpartum depression (PPD) and anxiety. In addition, long-term secondary outcomes related to maternal and infant health will be studied, specifically assessing maternal psychological well-being, mother-child bonding, parenting stress, and infant development trajectory using validated tools. These assessments will help determine whether the benefits observed during pregnancy have significant long-term effects, contributing to improved mother-child interactions and improved infant development trajectories. In addition, to improve the robustness and generalizability of the findings, future studies will include larger and more diverse cohorts, multicenter trials, and economic analyses to assess the cost-effectiveness of IVR interventions and their long-term effects on postpartum mental health. We believe that this comprehensive approach will provide robust evidence about the clinical relevance, sustainability, and scalability of IVR interventions in perinatal care settings.

We are also aware that there are some limitations related to the implementation of IVR-based interventions and eHealth technologies in real-world clinical settings. Effective implementation will require rigorous compliance with data protection regulations (eg, General Data Protection Regulation), clear informed consent processes, and robust cybersecurity measures to protect confidentiality among users. Furthermore, it is critical to consider the question of equity. The sociodemographic characteristics observed in this study suggest a potential bias toward participants with higher educational levels and stable economic situations, which could limit the applicability of the intervention in socioeconomically disadvantaged populations. Addressing these equity concerns involves ensuring technological accessibility, affordability, and ease of use across diverse socioeconomic groups and geographic locations, while also considering differences in technological ability and internet connectivity. Financial constraints are also a barrier, particularly relevant in the context of national health care services, where resources are often limited and require careful budgeting. The implementation of these technologies may require considerable initial investments, as well as clear financial strategies to ensure long-term sustainability and cost-effectiveness. Finally, practical challenges, such as integration into existing health care services, obtaining acceptance by health care professionals, and devising sustainable financing models must also be considered. For all of these reasons, future research should focus on longitudinal analyses, assessing not only immediate efficacy but also sustained use and real-world feasibility, with the aim of developing scalable and inclusive solutions tailored to different clinical contexts and populations.

In relation to how to integrate IVR-based interventions into the health care system, we propose different key aspects as shown in Textbox 2.

Textbox 2. Proposed strategies to integrate immersive virtual reality (IVR)–based interventions into health care system.

Implementation within primary care and maternity services

- Midwives and health care professionals could incorporate IVR sessions into routine prenatal visits, offering guided relaxation and mindfulness exercises as a complementary mental health support tool.
- The intervention could be integrated into antenatal education programs, in which pregnant women receive structured sessions on stress management and emotional well-being using IVR technology.

Home-based digital health care support

- Pregnant women could be prescribed access to the IVR application for home use, with health care professionals monitoring adherence and outcomes through a digital platform.
- A mobile app could complement the IVR sessions by providing additional psychological support, reminders, and educational content tailored to individual needs.

Scalability within public health care system

- Collaboration with public health care providers could facilitate the incorporation of IVR technology into maternal mental health care programs, ensuring accessibility for a broad population.
- Future research should focus on cost-effectiveness analyses and feasibility studies to assess the sustainability of implementing IVR interventions on a larger scale.

Regarding to how to implement IVR in routine clinical practice, we consider the following recommendations for the integration of IVR into antenatal care protocols:

1. Early detection of anxiety and depression symptoms: through the implementation of IVR, routine screening for anxiety and depression symptoms could begin during antenatal visits, using validated tools, such as EPDS and STAI-E. Women presenting with moderate anxiety or depression symptoms (scores within the range established in our study) could be referred for the IVR intervention as part of a stepped care approach.
2. Training of professional health care staff, especially midwives and primary care nurses, in the use of IVR technology and in supervising sessions: this would include training in setting up the equipment, explaining relaxation and mindfulness exercises, and monitoring patients' progress. It would also be important to provide guidelines about how to address potential questions or concerns from patients regarding the use of technology.
3. Access to technology: primary care centers could have IVR equipment available at antenatal follow-up consultations. Alternatively, lending IVR devices to patients for use at

XSL•FO
RenderX

home could be considered if adequate follow-up is ensured. The intervention could be designed to be self-guided, with preprogrammed sessions that patients could complete independently, but with the possibility of contacting a health care professional in case of questions or need for additional support.

4. Integration into the individualized care plan, including the IVR intervention and tailoring to each patient's specific needs and the context of their pregnancy: this could include coordination with other mental health professionals, such as psychologists or psychiatrists, in cases where a more intensive approach is required. In addition, it could be combined with other low-cost interventions, such as prenatal exercise programs, mindfulness workshops, or support groups, to offer a holistic approach to mental well-being during pregnancy.
5. Continuous monitoring and evaluation: a continuous monitoring system should be established to evaluate the effectiveness of the intervention and adjust it as necessary. This could include collecting data about adherence, patient satisfaction, and changes in anxiety and depression symptoms over time. Health care professionals could use the data collected to identify patients who could benefit from additional or more intensive interventions.
6. Cultural and socioeconomic considerations: as accessibility and acceptance of technology may vary depending on the cultural and socioeconomic context, it is important to adapt the intervention to the specific needs of each population. This could include translating content into different languages or adapting IVR scenarios to make them culturally relevant.

We have also reflected on the potential long-term effects of the IVR intervention. In the effects on postpartum mental health, we should consider the following: first, anxiety and depression during pregnancy are known risk factors for the development of PPD [8]. Because our intervention demonstrated a significant reduction in anxiety and depression symptoms during pregnancy, it is plausible that it may also contribute to a decreased risk of PPD [60]. Previous studies have shown that interventions that improve mental health during pregnancy have a protective effect against PPD, suggesting that IVR could have a positive impact on women's emotional well-being after delivery [61]. Second, maternal mental health is closely related to the quality of the mother-child bond [62]. A reduction in anxiety and depression symptoms during pregnancy could facilitate a stronger and more positive bond between mother and infant, which in turn could have beneficial effects on the child's emotional and social development [6]. Future studies could assess the impact of the IVR intervention on the quality of the mother-child bond using validated scales, such as the Postpartum Bonding Questionnaire [63]. In addition, regarding the effects on child development, we can consider the following: first, maternal anxiety and depression during pregnancy have been associated with an increased risk of problems in the child's cognitive and emotional development, including learning difficulties, attention problems, and emotional disorders [64]. By reducing these symptoms during pregnancy, the IVR intervention could contribute to a healthier development of the child [16]. Longitudinal studies could evaluate the impact of the intervention on the cognitive and emotional development of children using tools such as the Bayley Scales of Infant and Toddler Development or the Child Behavior Checklist [65]. Second, some research suggests that maternal stress and anxiety during pregnancy may be associated with an increased risk of neurodevelopmental disorders, such as attention-deficit/hyperactivity disorder or autism spectrum disorder [66]. Although the relationship is not direct, it is possible that reducing stress and anxiety during pregnancy through the IVR intervention may have a protective effect in this regard [61]. Future studies could explore this hypothesis by long-term follow-up of children whose mothers participated in the intervention. Finally, regarding future research, we consider the following: first, to assess the long-term effects of the IVR intervention, longitudinal studies following women and their children for several years after delivery would be necessary. These studies could measure not only maternal mental health, but also children's cognitive, emotional, and social development [60]. Second, it is important to explore the underlying biological and psychological mechanisms that could explain how reducing anxiety and depression during pregnancy influences postpartum mental health and child development. For example, changes in cortisol levels or other biological markers associated with stress could be investigated [6]. Third, future research could explore the effect of combining IVR intervention with other postpartum interventions, such as parenting support programs or cognitive behavioral therapies, to maximize benefits on maternal mental health and child development [16].

We consider that feasibility, scalability, and costs are key aspects for the IVR interventions to be effectively implemented, especially in underserved populations where access to mental health care is limited. With regard to feasibility and scalability in real-world settings, we consider the following: first, the IVR intervention requires the use of virtual reality devices, which can vary in cost and complexity. In our study, we used midrange devices that are relatively affordable and easy to use. These devices could be purchased by primary care centers or maternal health clinics or even rented to reduce initial costs. IVR technology is becoming more accessible and device costs have decreased in recent years, making it easier to implement in resource-limited settings. Second, implementation of the IVR intervention would require basic training of health care personnel, such as midwives, nurses, or psychologists, in using the technology and supervising sessions. This training could be done in a short period and would not require advanced technical skills. Furthermore, the intervention could be designed to be self-guided, which would reduce the need for constant supervision by health care staff. Third, the IVR intervention is highly adaptable and could be tailored to meet the needs of various populations, including those with language or cultural barriers. For example, relaxation and mindfulness scenarios could be adapted to reflect culturally relevant environments, and content could be translated into different languages. Regarding cost and resource estimation, we consider the following:

1. Device cost: the cost of IVR devices can vary between €300 (US $327) and €600 (US $654) per unit, depending on the brand and features. For a primary care center with a

XSL•FO
RenderX

moderate workload, several devices could be purchased for rotational use.
2. Content development: the development of IVR content (eg, mindfulness exercises and relaxation) may involve an initial cost, but once developed, the content can be used repeatedly without significant additional expenses.
3. Maintenance: maintenance costs are relatively low, as modern IVR devices are long-lasting and require few upgrades.
4. Training: training of health care staff could be completed in a short period, such as a one- or two-day workshop, at an estimated cost of €500 (US $545) to €1000 (US $1090), depending on the number of participants. This training would not require advanced technical skills.
5. Implementation and long-term savings: the intervention could be designed to be self-guided, reducing the need for constant supervision by health care staff. In the long term, the IVR intervention could generate significant savings by reducing the need for more expensive interventions (eg, pharmacological or individual therapies), particularly for cases of mild to moderate anxiety and depression. Additionally, improved mental health in pregnant women could help reduce obstetric and neonatal complications related to stress and depression.
6. Adaptability: the IVR intervention is highly adaptable and could be tailored to meet the needs of various populations, including those with language or cultural barriers. For example, relaxation and mindfulness scenarios could be culturally adapted and translated into different languages.

All currency conversions from euros to US dollars were calculated using the average exchange rate at the time of the study (€1=US $1.09).

In addition, by improving the mental health of pregnant women, costs associated with obstetric and neonatal complications related to stress and depression could be reduced.

In relation to scalability in underserved populations, we consider the following: First, the IVR intervention could be particularly useful in rural or remote areas where access to mental health care professionals is limited. The devices could be transported between different health facilities or even used at home under remote supervision. In addition, the portable nature of IVR devices allows their use in communities with limited infrastructures if there is access to electricity and adequate space for sessions. Second, to facilitate implementation in underserved populations, collaborations could be established with nongovernmental organizations or public health agencies already working in these areas. These organizations could provide logistical and financial support for the acquisition and maintenance of the devices.

In this study, women with a history of diagnosed anxiety or depression were excluded because this clinical subgroup could present a different evolution compared to those with recent and moderate symptoms, which could affect the validity of the results. However, we consider that future studies could evaluate the effectiveness of this intervention in populations with a previous psychiatric history. We also consider that future studies could further explore the influence of pregnancy planning on the effectiveness of digital interventions for perinatal mental health.

It is worth remembering that IVR has been applied in other areas of mental health: first, IVR has been used for posttraumatic stress disorder, in which it has proved to be an effective treatment tool, particularly in the context of exposure therapy. The technology allows for the simulation of controlled and safe environments where patients can gradually confront the stimuli that trigger their symptoms, facilitating desensitization and emotional processing [67]. Studies have shown that IVR can be particularly useful in war veterans, accident survivors, or survivors of violence, in whom exposure to virtual environments can help reduce the symptoms of reexperiencing, avoidance, and hyperarousal associated with posttraumatic stress disorder [68]. Furthermore, IVR can be combined with evidence-based therapies, such as cognitive behavioral therapy, to improve treatment outcomes [69]. Second, IVR has also shown potential in the treatment of substance-use disorders, particularly in relapse prevention. Virtual environments can simulate high-risk situations (eg, bars or parties) where patients can practice coping strategies in a safe and controlled environment [70]. In addition, IVR can be used for aversion therapy, where patients are exposed to virtual stimuli associated with substance use, which can help reduce craving and dependence [71]. Recent studies have shown that IVR can be effective in treating alcohol, tobacco, and other drug addictions; improving treatment adherence; and reducing relapse rates [72]. Third, IVR has been widely used in the treatment of specific phobias, such as fear of flying, heights, or closed spaces. Gradual exposure to these stimuli in a virtual environment allows patients to confront their fears in a controlled manner, which reduces anxiety and improves functioning [73]. Furthermore, IVR can be useful in the treatment of generalized anxiety, by providing relaxing environments and mindfulness exercises that help reduce symptoms of excessive worry and muscle tension [46]. Fourth, IVR has also shown potential in supporting individuals with autism spectrum disorders, particularly in developing social skills and reducing anxiety in social situations. Virtual environments can simulate complex social interactions, allowing patients to practice and improve their communication skills in a safe environment [74]. Fifth, IVR has been used as a complementary tool in the management of chronic pain, which is often associated with mental health disorders, such as depression and anxiety. Virtual environments can distract patients from the pain and provide relaxation techniques that improve their emotional well-being [51].

Finally, we would like to mention the integration of artificial intelligence and machine learning into IVR interventions. We believe that these new tools have great potential to improve the personalization and effectiveness of IVR. Artificial intelligence–based algorithms could allow the individualization of IVR experiences based on, for example, emotional state or therapeutic response.

Conclusions

The findings of this study highlight the significant potential of IVR-based eHealth interventions in improving mental health outcomes during pregnancy. By reducing symptoms of anxiety

XSL•FO
RenderX

and depression, the intervention demonstrated its capacity to address critical mental health challenges faced by pregnant women, aligning with the growing emphasis on integrating digital health solutions into prenatal care. This intervention, grounded in immersive and interactive technology, not only achieved significant reductions in EPDS and STAI-E scores but also fostered high adherence and participant satisfaction. These results underscore the feasibility of implementing IVR-based programs as accessible, low-intensity, mental health interventions within broader health systems. Such programs hold promise for addressing disparities in access to care, particularly for vulnerable populations or those with limited availability of traditional mental health services.

Despite these, conclusions should be interpreted with caution given the relatively small sample size, the socioeconomic and educational homogeneity of the participants, and the possible presence of biases derived from self-reporting in the assessment of adherence and satisfaction. Furthermore, the lack of long-term follow-up limits the ability to determine the sustainability of the observed benefits. Therefore, although the findings support the potential efficacy of IVR-based interventions in specific contexts, additional studies with more diverse samples and longer follow-ups are required to confirm these results and explore their applicability in different socioeconomic and cultural contexts.

Future research should aim to address these limitations while exploring the scalability, cost-effectiveness, and cultural adaptability of IVR-based interventions. In addition, longitudinal studies are needed to evaluate the sustained impact of such interventions on postpartum mental health and their potential influence on maternal and child outcomes.

Acknowledgments

The authors would like to extend our gratitude to all the participants who generously contributed their time to this study. Special thanks to midwives in the primary care centers and professionals who supported the recruitment and facilitation of this research, including Centre d'Atenció Primària (CAP; Primary Care Center in English) Rambla, CAP Can Tries, CAP Rubí, CAP Can Mates, and CAP Can Parellada.

We also wish to thank Delaguila Games [31], the developers of the immersive virtual reality technology used in this study. Their innovation and technical expertise played a crucial role in creating a user-centered intervention tailored to the needs of pregnant individuals.

Finally, we are grateful to the research team, midwives, and health care professionals involved in the implementation and execution of the study.

This research was supported by funding from the Departament de Salut, Generalitat de Catalunya (PERIS Grant SLT006/17/249). This study was partially funded by the Official College of Nurses of Barcelona [75] as part of the Nurse Research Projects Grants (PR-642/2023). In addition, the study received the Mustela Scholarship for midwifery research projects awarded by the Mustela Foundation (FAME 2023).

Authors' Contributions

CE and GFP contributed equally to this work and should be considered senior authors.

Abstract

Background: Fostering innovative and more effective interventions to support active aging strategies from youth is crucial to help this population adopt healthier lifestyles using technologies they are already familiar with. Mobile health (mHealth), particularly apps and wearables, represents a promising approach due to its versatility, ease of use, and ability to monitor multiple health variables simultaneously. Moreover, these devices offer opportunities for personalization and support in health behavior change, making them valuable tools for shaping healthy habits from a young age.

Objective: This study aims to (1) investigate whether young adults (18 - 26 years old) use apps or wearables to monitor or improve their health variables (ie, physical activity, diet, and mental health); (2) examine how they use them; (3) identify the most commonly used apps and wearables and the most frequently monitored health variables across these domains; and (4) evaluate the importance of different characteristics and functions of apps and wearables for health purposes.

Methods: This cross-sectional study used a public involvement framework to enhance the research quality and was conducted through an anonymous web survey disseminated across Italy over a 3-month period. The survey consisted of 5 sections: (1) demographics, (2) mobile apps and wearable devices for physical activity and sports, (3) mobile apps and wearable devices for diet, (4) mobile apps and wearable devices for mental health, and (5) preferences regarding mobile apps and wearable devices. Participants were eligible if they were young adults who reported using at least one app or wearable device to monitor at least one health variable (eg, steps, training, sleep, calorie intake). No additional eligibility criteria were applied.

Results: A total of 693 questionnaires were analyzed for aims 1 and 4, with the sample showing an equal gender distribution (females: 363/693, 52.4%). For aims 2 and 3, a total of 317 questionnaires were included. Participants using an app or wearable for physical activity accounted for 320 (46.2%), while 60 (8.7%) and 156 (22.5%) reported use for diet and mental health, respectively. Moreover, the frequency of use was predominantly on a daily basis, particularly for wearables. The app and wearable characteristics identified as most important were user-friendliness, free access to content, loading speed, and icon clarity.

Conclusions: Findings suggest that Italian young adults, particularly women, predominantly use wearables over apps to track health data, with both being checked on a daily basis. Physical activity is the most frequently monitored domain, likely due to its ease of tracking, while diet and mental health receive less attention. Overall, these tools are used more for monitoring than for actively improving health-related variables. The most valued characteristics identified by young adults include ease of use, free access to all content, and fast loading speed. These insights should guide the design and refinement of digital health interventions targeting this population.

Introduction

Promoting healthy aging, or “active aging” [1], helps prevent excessive pressure on medical systems in the forthcoming years [2], while improving both individual and collective health [3]. This strategy combines theoretical and practical interventions to teach people, starting from youth, how to monitor and enhance health through a virtuous and sustainable lifestyle [4]. Reaching a large population in real time is crucial for the success

XSL•FO
RenderX

of this slow and consistent process. In the last decades, mobile health (mHealth) [5,6] interventions have provided general and personalized information to support decision-making and behavior change. In this context, mobile apps designed for smartphones are particularly popular among young people and adults [7], offering continuous data collection via built-in sensors and adaptability to different scenarios [8,9]. Given the rapid evolution of this technology, it is crucial to understand its use and effectiveness in creating sustainable and useful mHealth apps. To promote lasting behavioral changes for active aging, apps must specifically target young adults [10] and adapt to their needs. Educating young adults (18-26 years old) [11] about healthy lifestyles using familiar tools [12] encourages long-term adoption. Therefore, it is important to explore how apps and wearables for health purposes are used by this specific population to manage domains such as physical activity (PA), diet, and mental health. In particular, considering that health is defined as a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity [13], these domains might play a role in health promotion for early active aging strategies.

The Health Belief Model (HBM) is a useful framework for understanding health-related behaviors [14]. It suggests that individuals are more likely to engage in health-promoting actions, such as using apps or wearables, if they perceive susceptibility to health issues, recognize their severity, and believe the benefits outweigh the barriers. Cues to action, such as app notifications, and self-efficacy in performing healthy actions further drive behavior change. By incorporating these elements, apps and wearables can motivate young adults to adopt healthy habits, supporting early active aging strategies.

In 2023, Italy had 5.3 million young adults, with about 1 million overweight or obese, 2.3 million not practicing any sports, and 2.4 million with chronic diseases [15]. Hence, it is fundamental not only to monitor but also to help this population effectively manage and improve its health. Moreover, in 2023, students enrolled in secondary high schools in Italy were reported to be 2.7 million, while 1.8 million were enrolled in universities [15].

Additionally, identifying the most and least appreciated features of these apps and wearables, along with their functions, is crucial for creating preventive and educational interventions [16] that assist young people in monitoring and improving their health [17-19], well-being, and quality of life through familiar technology tailored to their needs and expectations.

Therefore, this study aims to (1) determine whether young adults use mobile apps and wearable devices to monitor and improve their health variables (ie, PA, diet, and mental health); (2) understand how young adults use mobile apps and wearable devices to monitor and improve these health variables; (3) assess the most used mobile apps and wearables in terms of brands, as well as the most monitored variables via both apps and wearables; (4) evaluate the most important functions and characteristics of mobile apps and wearable for health variables based on young adults' opinion.

Methods

Study Design

This work consists of a cross-sectional study performed via an anonymous web survey distributed across the Italian territory. The survey was created in accordance with the International Handbook of Survey Methodology [20] and the Declaration of Helsinki [21], and was distributed via Microsoft Forms (Office 365 Suite), which ensures secure and ease of data collection, as well as anonymity in compliance with General Data Protection Regulation [22] policies. Before accessing the survey, each participant was presented with an informative note about the study and data processing.

Participation was completely voluntary, and completion of the survey could be interrupted at any time and for any reason, without the need for explanation; in such cases, no data were saved. The reporting of this manuscript follows the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [23]. At each phase of the research, a habitual mobile app user was involved to ensure the "public involvement," as discussed below.

Ethical Considerations

Ethical approval for this study was granted by the University of Genoa's Ethical Committee for Research (CERA2023.24, approved on April 27, 2023). The study adhered to good clinical practice guidelines for the ethical conduct of research involving human participants. Participants were not compensated for their involvement, as clearly stated in the information sheet and informed consent form provided before their participation. All participants reviewed the study details and provided informed consent before taking part. Data were anonymized at the point of collection, as the use of Microsoft Fforms allowed participants to complete the survey without submitting personal information unless explicitly requested by the researchers. Data were collected and stored in accordance with current regulations, in a password-protected digital archive accessible only to the researchers directly involved in the study.

Web Survey

The web survey was created by a panel of 5 professionals from different fields, such as sports science and health, psychology, engineering, and physiotherapy, and a habitual mobile app user pursuing a master's degree in communication sciences. Existing questionnaires were reviewed to identify relevant questions, but none were deemed suitable for this specific research. Consequently, a preliminary draft of the survey was developed for evaluation and subsequent validation. The final web survey was divided into 5 sections: (1) demographics; (2) mobile apps and wearable devices for PA and sport; (3) mobile apps and wearable devices for food and diet; (4) mobile apps and wearable devices for mental health; and (5) preferences regarding mobile apps and wearable devices. Once imported into Microsoft Forms, the questions were organized with branching logic, allowing participants to skip sections on unused mobile apps or wearable devices, thereby enabling faster and more efficient completion. Following the demographics section, each subsequent section began with an initial yes-or-no question,

XSL•FO
RenderX

giving participants the option to either skip that section or proceed. The estimated total completion time was about 5 minutes. The full survey is available in Multimedia Appendix 1.

The web survey was assessed for face and content validity [24] by 10 potential participants who used mobile apps to monitor their PA, diet, or mental health. These individuals met the study's inclusion criteria and were asked to provide feedback on the survey before its adoption in the data collection process, to ensure data reliability and quality. Specifically, each participant had either a face-to-face meeting or a video call with the same professional, who explained the research aims, provided the informative note and informed consent documents, and, once consent was obtained, initiated the survey completion. Afterward, participants were asked questions about the survey's characteristics, and all notes and suggestions were recorded. The feedback received was subsequently discussed by the panel of experts to produce the final version of the web survey. Face and content validity assessments are crucial in survey creation to ensure that the main topic under investigation is correctly addressed and that the questions and answers are understandable to the target population. This ensures that the results can be accurately analyzed and compared with the research question. In particular, content validity is provided by the panel of experts in the field investigation, whereas face validity is assessed by potential participants. Additionally, to evaluate the internal consistency of the survey, a Cronbach α [25] analysis was performed. The results confirmed good internal consistency (Cronbach α=0.891), as values of 0.70 and above are generally considered acceptable. The scale ranges from 0 to 1, with 1 indicating the highest level of internal consistency. The higher the value obtained for the survey items, the better the internal consistency is considered to be. No other validation methods were applied to this survey.

Public Involvement

Our work employed the "study-focused" public-involvement framework [26], considering the point of view of the target population (ie, young adults aged 18 - 26 years using at least one app or wearable to monitor or improve PA, diet, or mental health) across all phases of the study [20]. The public representative was (1) a 23-year-old female student; (2) enrolled in the first year of a master's degree program in communication science; and (3) actively engaged with a mobile app for PA and possessing previous experience in using a mobile app for diet. Given the exploratory nature of this study, which aimed to investigate the prevalence of app and wearable use for health purposes among young adults as a whole, and not among specific subgroups (eg, by gender), a single representative, male or female, of the target population was deemed sufficient and was not expected to influence the results. The focus was on understanding general behaviors rather than subgroup-specific patterns, such as those based on gender.

The public representative volunteered to actively participate in formulating the research question and played a crucial role in creating, validating, and distributing the web survey. After the data collection period, she was also involved in the data analysis and the overall interpretation of the results, which was fundamental for better understanding the needs of the target population and maximizing the value of the collected data. Moreover, the public representative contributed to the writing and review of the final draft of this paper.

Participants

To answer the first and last aims (1 and 4) of the study, participants were considered eligible if they were young adults (ie, aged 18 - 26 years) and could read and understand the informative note and the web survey.

For aims 2 and 3, participants were eligible if they used at least one mobile app or wearable device for PA, diet, or mental health, and could read and understand the informative note and the web survey.

No other limitations were set for the population or for the type of app or wearable device used.

Setting and Modalities of Contact

The web survey was distributed via Microsoft Forms (Office 365 Suite) in July and from September to October 2023. Potential participants were reached through various modalities, including face-to-face, digital, and printed invitations (see Multimedia Appendix 2). Printed advertisements were placed in locations frequently visited by young adults, both education-related and not (eg, university campuses, local groups headquarters, libraries). Social media platforms (eg, Facebook, Instagram, WhatsApp), email, and high school and university mailing lists were also used to disseminate invitations to complete the survey. To maximize nationwide reach, all 73 universities in Italy were contacted. Of these, only 7 agreed to assist in distributing the survey. The list of universities was publicly available online, and each university's website was visited to obtain a contact email to explain the study rationale and request assistance with its promotion. The universities and high schools that agreed to collaborate were free to choose the dissemination method they considered most appropriate. To help balance the potential sample of participants, voluntary and social groups were also invited to share the study invitations. Concerning email, researchers used addresses that were publicly available in the "Contacts" section of relevant websites to reach potentially interested groups. Additionally, participants were encouraged to share the invitation with others who might be interested in participating. The recruitment process aimed to reach a diverse and broad audience, including individuals both engaged and not engaged in education, and from different regions of the country. Efforts were made to maintain a balance in region of origin, gender representation, and age distribution within the predefined age range. As the web survey was anonymous, and to prevent multiple responses, the option to submit more than 1 questionnaire was disabled directly in the platform settings. To further ensure data reliability, the dataset was checked for duplicates in Microsoft Excel after data collection. In cases of potential duplicates, variables such as age, gender, height, weight, and education were examined; no duplicates were found.

XSL•FO
RenderX

Statistical Analysis

Sociodemographic data were analyzed using descriptive statistics, with percentages reported where applicable, and continuous variables presented as mean (SD). Binomial logistic regression analyses were performed to assess the influence of gender and education level on the use of apps and wearables. The last section of the questionnaire was analyzed using different methods. The first method defined consensus as being reached for each statement when 2 conditions were met [27]: (1) at least 51% of participants responded with "quite important" or "very important," and (2) the median score exceeded 2.5. In our case, considering the IQRs, if the median was above 2.5, it could be assumed that at least 75% of the responses fell in the neutral or positive categories (ie, 2, 3, and 4). The second method involved the calculus of a ratio value between positive and negative answers collected. Moreover, a descriptive evaluation of results obtained from the Likert-type scale was adopted.

For evaluating the main variables monitored through mobile apps and wearables, the variables were divided into specific areas of interest (ie, PA, diet, and mental health) and aggregated into categories based on their similarities. PA-related variables were divided into "PA metrics" (ie, daily steps, distance covered, daily activity, training, number of weekly trainings, calorie consumption, elevation, and speed/step per kilometer) and "physiological parameters" (ie, heart rate, weight, oxygen saturation, sleep, stress, rest, body composition, menstrual cycle monitoring, and respiratory frequency). Diet parameters were grouped into "nutritional metrics" (ie, calorie consumption, macronutrient count, and water) and "body metrics" (ie, weight and body composition). Finally, mental health parameters were categorized as "sleep," "mental well-being" (ie, stress, mood, and emotions management), and "mindfulness and meditation practices" (ie, breathing, meditation, mindfulness). Additionally, the motivation behind the use of these mobile apps and wearables was presented, with results split between the 2 types of mHealth.

The last section of the questionnaire investigated mobile app and wearable preferences, and the results of each question were graphically reported. Participants were asked to indicate their level of agreement with each statement on a 5-point Likert-type scale. The possible answers were as follows: (0) "not important at all," (1) "unimportant," (2) "neutral," (3) "quite important," and (4) "very important". The results were then aggregated into 3 levels of agreement: negative (ie, 0 and 1), neutral (ie, 2), and positive (ie, 3 and 4). Moreover, an analysis of IQRs was performed, and medians and the distribution of responses were reported.

Bias

Young adults with different levels of education were contacted to reduce any possible selection bias. To better describe the target population, invitations were disseminated across the entire Italian territory without restrictions, with the aim of reaching participants with diverse characteristics such as age, gender, occupation, and education level. Other universities and several secondary high schools were also contacted to increase the number of responses. Detailed modalities of dissemination are reported in the "Setting and Modalities of Contact," and study limitations are discussed in the "Strengths and Limitations" section.

Results

A total of 821 responses were received, and after applying the inclusion and exclusion criteria, a final sample of 693 questionnaires was analyzed. Specifically, 42 questionnaires were excluded because participants did not consent to data treatment, 83 did not meet the study's age range (ie, 18 - 26), and 3 were excluded due to unusable data. Demographic data for the final sample are presented in Table 1.

XSL•FO
RenderX

Table . Demographic characteristics of the sample (n=693).

Characteristics	Values
Age (years), mean (SD)	21.2 (2.5)
Gender, n (%)	
Female	363 (52.4)
Male	329 (47.5)
Nonbinary	1 (0.1)
BMI (kg/m^2), mean (SD)	22.3 (3.03)
Last educational degree, n (%)	
Secondary school diploma	95 (13.7)
High school diploma	414 (59.7)
Higher education	184 (26.6)
Not using any mobile app or wearable, n (%)	317 (45.7)
Physical activity (n=144), n (%)	
1 app	106 (73.6)
2 or more apps	38 (26.4)
Diet (n=52), n (%)	
1 app	45 (86.5)
2 or more apps	7 (13.5)
Mental health (n=45), n (%)	
1 app	37 (82.2)
2 or more apps	8 (17.8)

Data regarding the use of mobile apps or wearables for PA, diet, or mental health variables are reported in Table 2 and include only those participants who reported using at least one app or wearable to monitor at least one health variable (n=376).

Table . Total number and percentage of participants using mobile apps or wearables for physical activity, diet, and mental health (n=693)..

[a]N/A: not applicable.

[b]A1: SweatCoin, Strava, Fitbit, iSkiTracker, Pedometer, MyWellness, My workout plan, Huawei health, Hevy, Relive, Pokemon Go, Fitdays, Adidas Running, Nike training, GloryFit, Nike Run, etc.

[c]A2: Oppo, Google, Real me, Redmi, Suunto, and Liujjo.

Furthermore, the frequency of use of both mobile apps and wearables was evaluated and is presented in Table 4.

XSL•FO
RenderX

Table . Frequency of use of mobile apps and wearables.

Variables	Physical activity		Diet		Mental health	
	Mobile app	Wearable	Mobile app	Wearable	Mobile app	Wearable
Total users, n	144	232	52	23	45	130
Every day, n (%)	53 (36.8)	148 (63.8)	31 (59.6)	16 (69.6)	16 (35.6)	91 (70.0)
5 or 6 times a week, n (%)	20 (13.9)	24 (10.3)	10 (19.2)	3 (13.0)	4 (8.9)	12 (9.2)
3 or 4 times a week, n (%)	31 (21.5)	27 (11.6)	2 (3.8)	2 (8.7)	8 (17.8)	10 (7.7)
1 or 2 times a week, n (%)	20 (13.9)	22 (9.5)	4 (7.7)	1 (4.3)	9 (20.0)	8 (6.2)
Less than once a week, n (%)	20 (13.9)	11 (4.7)	5 (9.6)	1 (4.3)	8 (17.8)	9 (6.9)

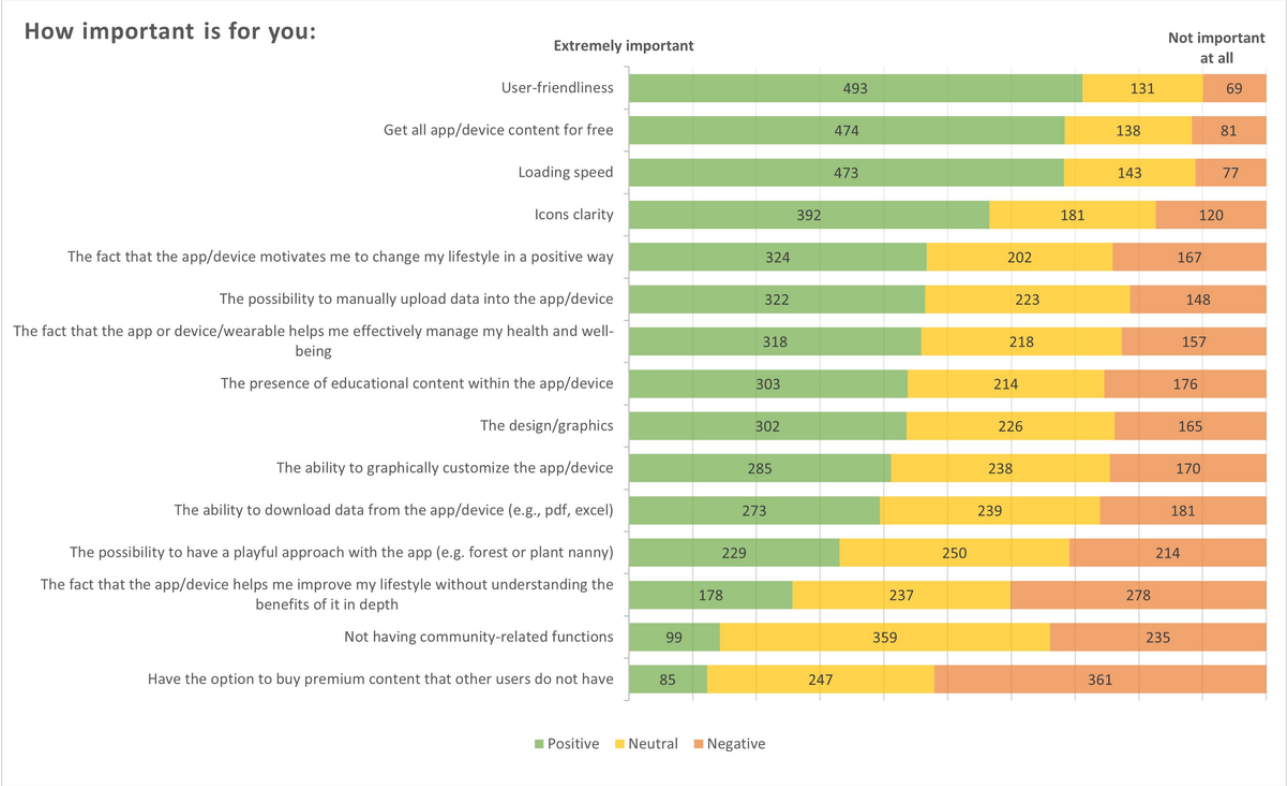
Moreover, motivation for the use of apps and wearables, as well as the health variables monitored via these devices, is reported in Multimedia Appendix 3. The vast majority of the sample did not report using premium or paid content (310/320, 96.9%, participants monitoring PA; 58/60, 96.7%, monitoring diet; 152/156, 97.4%, monitoring mental health). Those who did use these additional functionalities primarily sought more detailed information on specific aspects such as sleep, rest periods, training, macro- and micronutrients, or personalized advice based on their data. Similarly, community functions were not used by most participants (289/320, 90.3%, monitoring PA; 54/60, 90%, monitoring diet; 142/156, 91%, monitoring mental health; see Multimedia Appendix 4)

Additionally, an analysis of the frequency distribution of answers based on gender and level of education was conducted. Binomial logistic regressions were also performed on these parameters to explore possible associations between the use of apps and wearables and gender or education level. Regarding gender, the percentage of females monitoring PA is higher than that of males (216/693, 31.2% vs 138/693, 19.9%), while nonusers are 191 out of 693 (27.6%) for males and 147 out of 693 (21.2%) for females. A slight difference was also found in diet monitoring, with 325 out of 693 (46.9%) females and 297 out of 693 (42.9%) males reporting no monitoring. For mental health, gender differences were observed, with 105 out of 693 (15.2%) females and 64 out of 693 (9.2%) males reporting monitoring. Logistic regressions examining gender influence on the monitoring of PA, diet, and mental health revealed a slight positive correlation for males in each sphere. Specifically, the models account for 2.4% for PA, 1.0% for diet, and 1.1% for mental health. Full results of these binomial logistic regressions are reported in Multimedia Appendix 5. Regarding education level, the frequency distribution for females and males differed across categories: (1) secondary school diploma (females: 23/693, 3.3%; males: 72/693, 10.4%), (2) high school diploma (females: 228/693, 32.9%; males: 185/693, 26.7%), (3) bachelor (females: 100/693, 14.4%; males: 4/693, 0.6%), and (4) master's degree (females: 12/693, 1.7%; males: 4/693, 0.6%). Logistic regression models explained 5.0% of the variance for PA, 0.5% for diet, and 2.4% for mental health. For PA, having a bachelor's or master's degree showed a slight negative influence on the use of apps or wearables, and the same pattern was observed for mental health, while for diet, only a master's degree has a slight negative influence on use. Full results of these analyses are reported in Multimedia Appendix 5. Finally, none of the differences related to gender or education level were statistically significant (see Multimedia Appendix 5).

For the fifth and final part of the questionnaire, all 693 participants were included in the analysis. Considering the assessment of the most important characteristics of mobile apps and wearables, 4 elements emerged as particularly important for young adults: (1) user-friendliness, (2) free access to all content, (3) loading speed, and (4) icon clarity. Figure 1 presents the aggregated responses for each question according to the level of attributed importance.

XSL•FO
RenderX

Figure 1. Mobile apps and wearables' functions preferences (n=693).



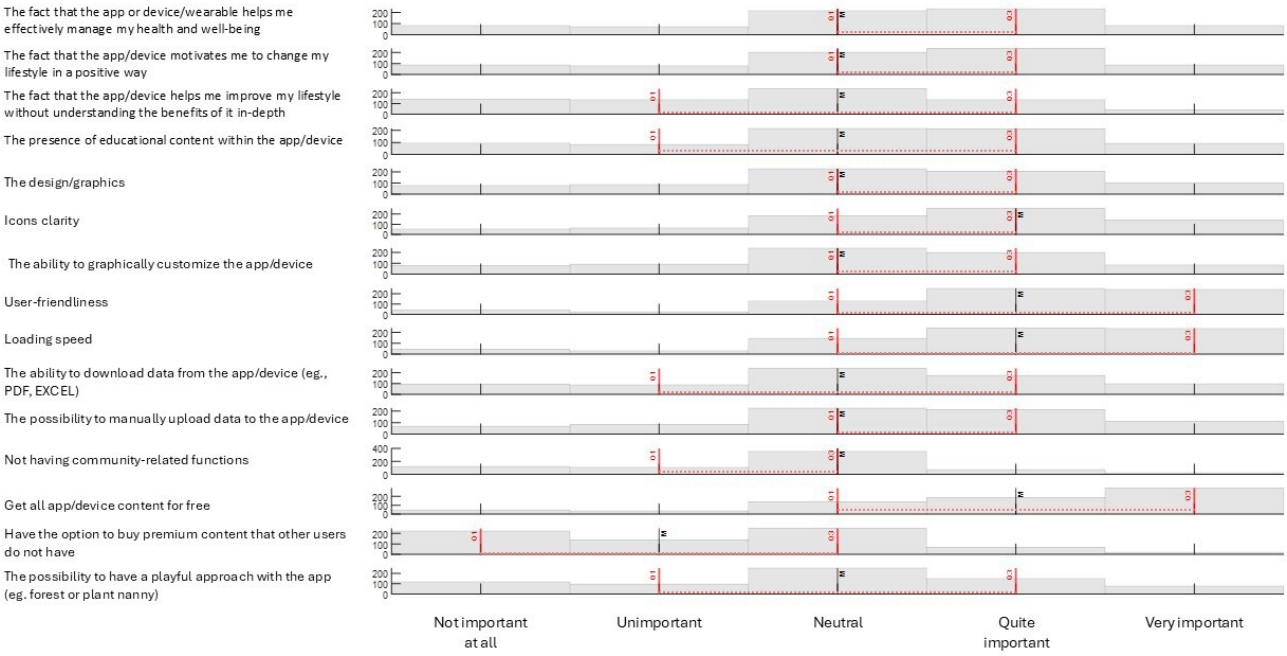


Figure 2 shows the distribution of responses, including IQRs and medians. Results are displayed for each of the original 5-point Likert scale options available to participants.

Figure 2. IQRs, medians, and distribution of responses for mobile apps and wearables' functions preferences.

A second method of analysis was applied to the last section of the questionnaire, particularly to the data regarding elements considered important. The analysis evaluated the ratio of positive to negative answers, both with and without including neutral responses, as reported in Table 5.

XSL•FO
RenderX

Table . Ratio values of responses for mobile apps and wearables' functions preferences.

Device's characteristics	Positives/negatives	positives+neutralsnegatives+neutrals
User-friendliness	7145	3120
Get all app/device content for free	5852	2800
Loading speed	6143	2795
Icons clarity	3267	1904
The fact that the app/device motivates me to change my lifestyle in a positive way	1940	1469
The possibility of manually uploading data into the app/device	2176	1429
The fact that the app or device/wearable helps me effectively manage my health and well-being	2025	1425
The presence of educational content within the app/device	1722	1350
The design/graphics	1830	1326
The ability to graphically customize the app/device	1676	1282
The ability to download data from the app/device (eg, PDF, Excel)	1508	1219
The possibility to have a playful approach with the app (eg, forest or plant nanny)	1070	1032
The fact that the app/device helps me improve my lifestyle without understanding the benefits of it in depth	0.640	0.806
Not having community-related functions	0.421	0.771
Have the option to buy premium content that other users do not have	0.235	0.546

From this analysis, it can be observed that user-friendliness, loading speed, free access to all content, and icon clarity were confirmed as the most important elements for our sample. Moreover, the possibility of manually uploading data and the efficiency of the app or device in helping individuals manage their health were also indicated as potentially important. When neutral responses are also considered, the elements with the highest ratio values remain user-friendliness, free access to all content, loading speed, and icon clarity. Other ratio values were lower and may not warrant further investigation.

Discussion

Principal Findings

This study comprehensively investigated the use of apps and wearables to track and improve health variables among young adults. The average BMI of the sample fell within the normal range, consistent with national trends. In 2023, the Italian National Institute of Statistics reported that the majority of young adults, approximately 2.8 million individuals, had a BMI within the normal range [15]. While nearly half of the participants reported using these tools to track PA, only a minority used them to monitor diet or mental health. Conversely, almost half of the sample reported not using any app or wearable for health purposes. This might be due to a low perceived relevance of health monitoring, negative aspects associated with using such tools (eg, distress or fixation), or a lack of understanding or trust in these devices and the results they provide [28,29]. Another main issue in using apps and wearables for health is the manual input required for certain data, which leads to lower adherence and reduced usage of these tools [30-32]. The findings regarding diet are consistent with those reported by Hahn et al [33] in a study conducted on a comparable population. Similarly, the reported percentage of use for mental health apps aligned with previous literature [34,35], except for Borghouts et al [35], who reported a higher usage rate. Viewed through the lens of the HBM, PA may be the most frequently monitored health domain due to the greater perceived benefits of tracking it and the immediate, tangible feedback provided by step count, distance covered, or calories burned. In line with this, the perceived severity and susceptibility of problems related to sedentary behavior (eg, weight gain) may also serve as motivating factors. By contrast, monitoring diet and mental health presents greater barriers, as it often requires manual data entry [30], thereby reducing engagement, self-efficacy, and both the frequency and quality of data collection [31,32]. In particular, diet variables cannot be automatically monitored, especially from wearables. For mental health, automated tracking of variables such as sleep or stress through heart rate variability [36] provides an exception, as it requires less user interaction, fostering higher self-efficacy by simplifying behavior monitoring. To increase diet and mental health monitoring, digital assistants (eg, vocal assistants), artificial intelligence, and machine learning could be

XSL•FO
RenderX

implemented into apps and wearables to automate tasks that are now manually required [37], lowering the need for users' interaction and broadening the adoption also to other populations with lower digital skills.

The higher prevalence of app and wearable use among females, particularly for PA and mental health, might also be viewed through the HBM lens. Women's greater focus on prevention could reflect a higher perceived susceptibility and severity of health risks, as well as stronger cues to action, such as societal expectations and health information targeting females [38]. In line with this, a previous study highlighted that females were more likely to use well-being apps to improve their health, whereas males were more interested in tracking their variables and tended to lose interest in these apps more quickly [39]. Moreover, factors influencing young adults' adoption and use of apps for health purposes are shaped by socioeconomic status and educational level, creating discrepancies and barriers for individuals with low socioeconomic status and lower educational levels, even when they are interested in using them [40].

In contrast with other studies [30,41,42], a very high frequency of use was found among the majority of our sample (148/232, 63.8%, users of wearables for PA), who reported using mobile apps and wearables to measure their health variables on an everyday basis. According to the HBM, this preference may be due to the immediate perceived benefits of short-term feedback, which reinforces behavior change. However, 38 out of 144 (26.4%) participants reported the need for multiple apps to track PA, highlighting a potential barrier: fragmented tools may lower perceived practicality and increase user burden. Integrating comprehensive solutions that address all necessary variables could enhance adoption and self-efficacy. Moreover, it can be argued that the wider adoption of apps for PA might be due to their greater market presence, supported by the widespread promotion of well-known brands such as Nike or Puma. The daily use of apps and wearables may indicate their potential in health interventions that require frequent monitoring over time, as well as the possibility of tracking small daily results to keep users motivated toward long-term goals.

Survey respondents demonstrated a clear preference for wearables over apps, especially for PA and mental health tracking. According to HBM's self-efficacy principle, the automatic data collection provided by wearables reduces the effort required for health monitoring. This ease of use increases confidence and adherence, as wearables simplify behavior tracking [43] while offering precise data [44]. Nonetheless, further analysis of the response ratios revealed a positive interest in the option of manually uploading data, which could represent an additional personalization feature of apps or wearables. Conversely, diet monitoring remains underutilized due to barriers such as manual input requirements, which reduce both perceived benefits and self-efficacy. Additionally, in our sample, wearables were also used to monitor sleep, mindfulness, and meditation practices. The latter is an interesting aspect, as another study [45] reported the use of a wearable to assess meditation practices, but only to identify abrupt movements during meditation rather than to monitor variables such as breathing or heartbeat. By contrast, participants in our sample reported using wearables to monitor actual meditation and mindfulness practices.

Comparison With Prior Studies

Regarding the motivations for use in our population, apps and wearables were mostly adopted for monitoring health variables and, additionally, for receiving personal advice based on individual data collected. These results align with previous literature [31] on young populations [43], which also reported a similar rationale behind the use of technological tools to support health. Considering these motivations and the HBM theory, the importance of cues to action and personal advice emerges. Hence, based on the results obtained, health interventions for young adults might benefit from the use of apps and wearables to monitor health variables while also providing personalized advice to support daily tasks aimed at improving health outcomes over time, particularly in the PA domain. A study conducted on university students showed that PA apps, in particular, are valued and considered useful; therefore, people are more likely not only to use them but also to promote their use [46], further supporting the hypothesis that apps may be beneficial in long-term health interventions beginning in youth.

Characteristics of mobile apps and wearables identified as important by the respondents were (1) user-friendliness, (2) free access to all content, and (3) fast loading speed of the app/wearable and its contents. These elements are key enablers of technology adoption and should therefore be carefully addressed by app and wearable developers [47]. User-friendliness, in particular, may increase self-efficacy, tool effectiveness [48], and young people's adoption of technology [49]. Previous evidence has already highlighted the importance of user-friendliness for young populations, especially in relation to fitness apps [50]. Moreover, free content may reduce financial barriers to access for people with low socioeconomic positions, thereby enabling the reach of broader populations [51,52], especially considering that app prices can vary depending on the specific app and market [53]. In line with this assumption, almost all participants were not interested in purchasing premium content. Interestingly, all the abovementioned aspects relate only to device characteristics and do not consider the specific types of content provided (ie, educational, motivational, informative) [38]. Regarding loading speed, this feature has been emphasized in previous literature [47,54,55] as a crucial element for technology acceptance, as users typically spend very little time deciding whether to use an app on their devices [56]. Hence, to ensure young adults' use of apps and wearables in health interventions, the choice should favor fast-loading tools that are inexpensive or free, to minimize reported barriers.

Interestingly, only half of the sample acknowledged the importance of including educational content within apps [57,58], as well as the importance of technology assisting users in understanding the benefits of improving health variables [47]. Similar results were observed for the motivational aspect: half of the users considered it important that apps or wearables support them in improving their health. This may be considered controversial, given the nature of the apps and wearables investigated and previous studies reporting a positive attitude

XSL•FO
RenderX

toward the technology's supportive role in improving health variables [40,59]. Nonetheless, this finding is consistent with responses on motivations for use, which highlighted that the primary function of apps and wearables was perceived as monitoring health variables. While the HBM emphasizes that understanding the benefits of healthy behaviors can motivate action, these results indicate a need to better communicate such benefits through engaging, user-centered app features.

Regarding the aesthetics of apps and wearable devices, the overall design and graphical aspects were not considered as significant as the clarity of the icons [52,53]. This particular element has been highlighted as a crucial factor in attracting users to the technology [60]. Additionally, the possibility of personalizing the app or wearable interface was deemed quite important, in line with existing evidence [61-63]. Such personalization may enhance users' perceived self-efficacy and reduce barriers to adoption, making the technology more adaptable to individual needs.

Despite evidence supporting gamification strategies for enhancing engagement and health outcomes [64], only one-third of our respondents expressed interest in playful features. This may suggest that young adults already feel sufficiently motivated to use these tools, reducing the perceived need for additional cues to action. A deeper analysis of the response ratios highlighted the significance of community functions. Previous literature has reported these features as a positive strategy for promoting challenging behaviors and motivation [65], serving as optional cues to action in health interventions. However, while participants in our study acknowledged community functions as important, they also reported not using them, raising questions about their actual role in motivating users to achieve their goals. In the literature, community features are often described as useful and appreciated in motivating individuals to improve their behaviors, particularly among young women [39], but mostly when they can view and compare results with people they personally know [50,66]. Nonetheless, a scoping review reported mixed results regarding their effectiveness in improving PA outcomes, largely due to the poor methodological quality of the studies evaluated [67]. Therefore, despite some positive results, further research is needed to strengthen the evidence on the use of community and social features in health programs targeting PA [68]. These features could be incorporated into health apps and wearables as optional tools, allowing users to decide whether to engage with them based on individual preferences. Thus, considering both the results obtained from our study and those of previous research, it would be useful for future studies to further investigate the effectiveness of community and social functions in young adult populations through both qualitative and quantitative approaches.

Given that mobile apps and wearables are frequently used by young adults for monitoring purposes, they could be integrated as valuable tools in strategies for early active aging [69,70]. These technologies may support the monitoring of health variables while also educating individuals about the importance of improving them. To further promote adoption and more efficient use of apps and wearables for health purposes, it is important to involve young adults in their design and development processes [63,71,72]. Finally, clear guidelines should be provided on how to develop effective health-related apps and wearables [73].

Strengths and Limitations

A strength of this study is the specific population investigated and the broad inclusion criteria adopted, which allowed for a more accurate description of the patterns of young adults who use apps and wearables for health purposes. Moreover, the broad inclusion criteria enabled heterogeneity in participants' characteristics, supporting the generalization of findings to the broader population. Another strength was the large number of questionnaires collected, which ensured sufficient statistical power to perform different types of analysis on the data and even examine subgroups (eg, gender). Despite this being the first study conducted in Italy on this population, some limitations should be acknowledged. First, the public representative who participated in the study was a student with prior professional experience in different roles (eg, social media manager, press officer). While her status as a student may have been an influencing factor, her communication skills and educational background provided a privileged perspective, making her contribution appropriate and constructive rather than biased. However, it cannot be excluded that her high level of education may limit the representativeness of individuals with lower educational backgrounds. Second, although this study investigated commercial mobile apps, the apps mentioned by participants were predominantly from renowned tech brands, with only a limited number of independent, nonprofit-oriented apps being reported. Future studies should aim to include a larger number of users of apps and wearables not linked to major brands to capture a broader range of opinions on different types of health tools. Third, data collection was conducted exclusively through digital procedures, which may have posed a barrier for individuals with poor digital literacy. However, given the young age of participants and the nature of the topic under investigation, such barriers were considered unlikely to represent a significant hindrance. Fourth, it cannot be excluded that, due to the digital nature of data collection, our sample may have been skewed toward individuals more comfortable with technology. Fifth, it is also possible that participants who completed the questionnaire were more interested in the topic investigated, which could have introduced distortion in the results. Sixth, the final sample included a high proportion of students, which may have influenced the findings; including more young adults who are not students might yield different results. Seventh, despite researchers' efforts to ensure the reliability of responses (as explained in the "Methods" section), the anonymous nature of the web survey could have introduced inaccuracies and self-reporting bias. In particular, participants may have overestimated their healthy behaviors (eg, social desirability bias). However, given the large number of responses and the nature of the topic, it is unlikely that responses were falsified. This likelihood is further supported by the study's aim, which focused on investigating the prevalence of app and wearable use rather than assessing their effectiveness. Eight, as it fell outside the study's aims, objective health outcomes were not directly assessed in relation to app or wearable usage; instead, only the outcomes reported and collected by apps and

XSL•FO
RenderX

wearables were considered, given that this was an exploratory study aimed at assessing the prevalence of use in young adults. Finally, socioeconomic status and geographic location data were not collected, making it impossible to examine their potential interactions with other variables. These aspects should be addressed in future research.

Future Directions

Further studies should assess the motivation, expectations, and user experience associated with apps and wearables for health variables, exploring other aspects that young adults might find helpful in improving their health. Barriers and facilitators to the use of these technologies in young adults should also be investigated to strengthen the evidence base and enhance their adoption. Moreover, future research should involve a larger proportion of individuals not engaged in educational programs and include those with weaker digital skills. Similar prevalence assessments should also be conducted in other age groups, such as adults and older adults. Finally, studies targeting health in young adults, particularly improvements in PA, should prioritize wearables over apps.

Conclusions

This study highlighted that young Italian adults track health-related variables more often via wearables than through apps, although both are consulted daily. Based on the results, young adults, particularly females, predominantly monitor PA-related variables, as these can be more easily tracked, while mental health and diet are monitored less. Moreover, apps and wearables are mainly adopted for monitoring rather than for improving health variables. Regarding the most important characteristics and features of these tools for young adults, user-friendliness, free access to all content, and the loading speed of the app/wearable software and content emerged as key. These characteristics should therefore be considered when developing or optimizing health interventions supported by apps and wearables in this population.

Acknowledgments

This work was carried out with the kind collaboration of the following institutions: Università degli Studi di Genova, Liceo Don Bosco Alassio, Liceo Statale Calasanzio, Istituto Ferraris Pancaldo Savona, Università degli Studi G. d'Annunzio Chieti, and Università di Parma, as well as Professors Fabrizio Sors and Cristiana Simonetti. Abstract

Background: A large amount of data are generated in health care facilities, yet it is rarely made available for secondary research use. The reasons are manifold. Most importantly, different stakeholders' needs must be balanced. However, there are currently hardly any feasible solutions for this.

Objective: This study aimed to develop a data trust model with supporting user interface applications to provide a legally and ethically sound framework for secondary use of medical data. The development was based on extensive surveys of various stakeholders.

Methods: Semistructured interviews were conducted with researchers (data users) and institutional representatives of the Medical Center–University of Freiburg, and online questionnaires were administered to patients (data subjects), data users, and institutional representatives. The questionnaire for data subjects covered the dimensions of trust (measured with a 5-point Likert scale), quality of interaction and involvement (measured with a 4-point Likert scale), subjective and objective understanding, and usability (measured with the user version of the Mobile Application Rating Scale). For all other stakeholder groups, the questionnaire focused on usability measured using the user version of the Mobile Application Rating Scale. The surveys comprised a requirement elicitation followed by two rounds of evaluation. Independent-samples Welch *t* tests were used to compare group means between the first and second evaluations.

Results: We devised SouveMed, a framework for secondary use of medical data, applied to the use case of sleep research data. The model includes secure onboarding of data subjects and using digital consent and a digital interface for data users for onboarding, defining research aims, querying the amount of available data, and, finally, either downloading data or having algorithms run on it. At its core is a data trust entity that matches descriptions, consents, and constraints of all stakeholders using digital representations and constraint-solving techniques. Fourteen participants took part in the requirements elicitation, 22 in the first evaluation, and 16 in the second evaluation. In both the first and the second evaluations, data subjects showed a high level of trust in the concept, with mean ratings on the trust scale of 4.23 (SD 0.46) in the first and 4.23 (SD 0.68) in the second evaluation ($t_{15.78}$=0.03, P=.97). Regarding usability, the mean functionality score of the data user system increased from 3.56 (SD 0.77) in the first to 4.58 (SD 0.38) out of 5 points in the second evaluation ($t_{10.69}$=−3.28, P=.008). The mean functionality score of the data subject system increased from 4.30 (SD 0.41) in the first to 4.50 (SD 0.74) in the second evaluation ($t_{13.99}$=−0.75, P=.46).

Conclusions: The SouveMed concept provides a comprehensive framework for the secondary use of medical data. The developed processes can be adapted to other areas of medical research.

Introduction

Digitalization in health care holds great potential for data-driven research and scientific progress for the benefit of patients and the general public. This includes, for example, automated systems for disease prediction [1-3], as well as innovative approaches that enhance data exchange between practitioners and enable better patient monitoring [4]. However, the use of data for purposes outside the specific treatment context (ie, secondary use) is hindered by several aspects. While an increasing amount of data is being digitally recorded during treatment, the common notion of *data silos*, where data is in principle readily accessible for research purposes, is too simplistic. This is because many processes in routine clinical care are not yet sufficiently digitized, and many analog, paper-based processes remain [5,6]. Furthermore, even digitized data is often not sufficiently preprocessed to be directly accessible for research purposes. They are documented using different software systems that lack interoperability and are stored in a variety of file formats [5-7]. In clinical practice, for example, questionnaires are still frequently handed out in paper form. Digitizing these questionnaires can simply mean that they are scanned and saved in PDF format. A major challenge in this context is the fact that electronic health records, while principally useful for research, are primarily intended to document treatment and reimbursement. Separate measures are necessary to render health record data *fit for purpose* regarding research and to check data quality [8,9].

Legal restrictions are another major obstacle. In the European Union, the introduction of the General Data Protection Regulation (GDPR) has been celebrated as a milestone for the protection of data subjects' rights but has also been criticized for creating obstacles to research [10-13]. For example, it has been criticized that the GDPR sets higher standards for anonymization than was previously the case in many European Union member states [12,14]. Recital 26 of the GDPR states that pseudonymized data "should be considered to be information on an identifiable natural person." This has been interpreted to mean that, in principle, all key-coded data must be considered and treated as identifiable personal data, even if the researcher holding the data is not in possession of the key to re-identify it [14]. Therefore, a legal basis is required for the processing of this data, which generally requires greater efforts from researchers and their infrastructure in terms of data protection.

Article 9 of the GDPR outright prohibits the processing of sensitive personal data, which includes health-related data. An exception is made in Article 9 (2) (a) if the patient (data subject) has given explicit consent to the processing of the personal data. Another exception refers directly to scientific research. Under Article 9 (2) (j), processing of sensitive data is allowed for research purposes if appropriate safeguards are in place and a lawful basis for the processing of data is given in the Union or the relevant member state in accordance with Article 6 [11,15].

With regard to consent, there are different consent models to choose from, ranging from broad consent (ie, consent for future studies whose exact research questions and specifications are unknown) to specific consent for a particular study. Hybrid models between broad and specific consent have been developed that allow participants to specify the terms of use without having to give consent for each individual study (tiered consent; for a general overview on different consent models, see [16]). However, in the area of secondary use of medical data, it may be impractical to obtain explicit consent (eg, due to the need to *reconsent* for data already generated), and it has been suggested that it would often be useful to consider other possible legal bases (eg, [11,14]).

The secondary use of health data must, however, also comply with other legal and ethical principles that are not fully taken into account in the GDPR [14]. While from the perspective of the GDPR, obtaining active consent might be replaced by referring to the special purpose of scientific research (if the required legal basis in the relevant member state exists, as mentioned above), consent is still a central ethical standard in medical research. Of particular interest in the field of medical research are the ethical principles formulated in the Declaration of Helsinki (DOH) [17] and Taipei (DOT) [18] of the World Medical Association. The DOH formulates general ethical principles for medical research involving human subjects, while the DOT focuses specifically on principles for databases containing health data. Both statements emphasize the importance of explicit consent for the secondary use of health data. The DOH states that "physicians or other qualified individuals must obtain free and informed consent from research participants for the collection, processing, storage, and foreseeable secondary use of biological material and identifiable or re-identifiable data" [17]. The DOT sets out further rules, such as the right to receive information about the use of the data and the right to change or withdraw consent at any time [18]. Indeed, these principles are in line with the spirit of the GDPR, which formulates and generally strengthens key data subject rights centered on purpose limitation, sovereignty, and transparency, including the right to be informed about processing and the rights to erasure and restriction of processing (see Articles 5 and 6) [10,15,19].

In addition to these basic requirements for the secondary use of research data, it should not be neglected that the secondary use of medical and research data affects many different interests, which must be carefully balanced in order to achieve the acceptance of all stakeholders. Besides the data subject and data users, these stakeholders crucially include the data-generating side, which is typically a clinic or practitioner who cannot waive their care obligations regarding the patient, including the use of sensitive data. With respect to the data subjects, it has been shown that patients are generally very willing to allow access to their health data for public research purposes [20-24]. Nevertheless, many patients are concerned about a lack of privacy, transparency, and data security [25,26]. To address

XSL•FO
RenderX

these concerns, a sufficient level of trust is required [27,28]. In this regard, appropriate patient involvement and communication appears to be crucial [25,26]. Adequate information about the secondary use of health data should be provided in an understandable and, at best, personalized form [26], including information about specific projects and findings related to data use [28]. Although there are large interindividual differences in the level of involvement favored by patients, many studies show that a large number of patients prefer a high level of control over their health data [28-32].

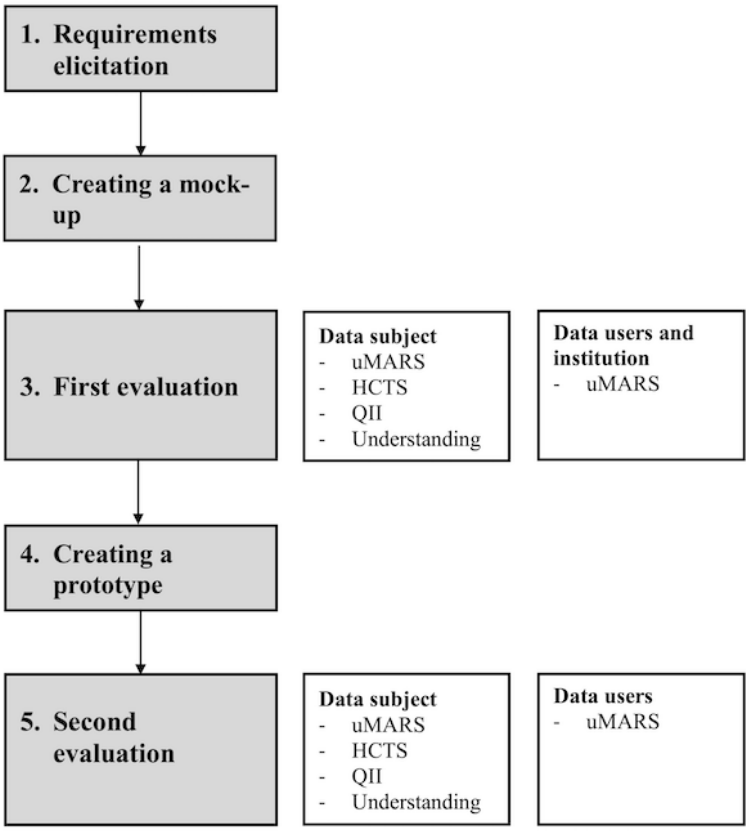
As noted above, data users are another important stakeholder group. There is a widespread view that considers health data to be the private property of patients. However, this approach falls short. Concepts of ownership cannot easily be applied to data, and health data can be considered as coconstructed, involving both the data subject and the clinicians and researchers with the generating institution, who contribute their efforts in collecting, classifying, interpreting, processing, and storing the data [33-35]. Because of this crucial contribution and the care obligations of the generating institutions noted above, the needs and constraints of institutions and researchers involved in the generation of health data must be equally considered. Correspondingly, the willingness of institutions and researchers to share health data without appropriate incentives, as well as trust and legal security, is often low [36,37]. At the same time, data users formulate their own requirements for the composition of data sets, utilization options, and acceptable expenditures.

The secondary use of health data, therefore, takes place in a complex environment: legal norms (relating to, but not limited to, data protection regulation), ethical standards, and the interests and needs of different stakeholder groups must be taken into account and balanced. At the same time, a progressive increase in the amount of data available can be expected, which necessitates time- and cost-efficient processes to make use of this data. While initiatives such as the envisaged European Health Data Space (EHDS), the centralized Finnish health data registries, and the German *Medizininformatikinitiative* (medical informatics initiative), among others, prove that the secondary use of health data is on the political and societal agenda, overall, the development is still in its infancy and the great potential that lies in the secondary use of data is currently not being realized. As a possible solution to the problems outlined above, the possibility of data trust models is being discussed (eg, [38-41]). In a report for the United Kingdom government by Hall and Pesenti [41] on the future use of artificial intelligence, data trusts are defined in an overarching manner as “a set of relationships underpinned by a repeatable framework, compliant with parties’ obligations, to share data in a fair, safe and equitable way” (p. 46). Nevertheless, as comprehensively summarized by Lauf et al [42], there is currently no universally accepted definition of a data trust. Instead, based on an analysis of applications across various domains, four *archetypes* of data trusts have been proposed, each with distinct characteristics: data brokerage trustees, data processing trustees, data aggregation trustees, and data custody trustees [42]. In view of the strict data protection requirements associated with the use of health data, existing studies in the medical domain have examined technical features designed to mitigate potential risks. For example, based on a security-by-design approach, the modular separation of demographic and medical data has been proposed to improve data protection within a data trust [43]. In the context of the German medical informatics initiative, the secondary use of medical data is being facilitated by the so-called data integration centers at several university hospitals. Access to the data is controlled by *use and access committees*, which manually review and evaluate data requests before granting access [44,45]. However, beyond these technical and organizational considerations, the successful implementation of a data trust model also depends on stakeholder acceptance and its effective integration into existing clinical workflows.

The aim of the present study was to design a comprehensive legally and ethically sound data trust model from the early conceptualization, through the technical implementation of a prototype system, to its evaluation from the perspectives of various stakeholders. In this study, a data trust model was conceptualized as a neutral entity that facilitates data use while accounting for the interests of all involved stakeholders. Importantly, the data trust—by our definition—does not make decisions on behalf of others. At its core, the system includes a matching service that automatically compares the rules and requirements specified by each stakeholder. When these align, access is granted, without the system itself exercising intentionality. Development prioritized preserving data subjects’ sovereignty while ensuring that system processes remain scalable.

The evaluation was preregistered in a clinical trials registry (German Clinical Trials Registry DRKS00031093). A particular focus was on the use case of sleep research. Sleep research seemed particularly suitable as it is a highly relevant field that warrants further intensified research efforts due to the high prevalence and disease burden of sleep disorders. For example, up to 10% of the general population experiences an insomnia disorder [46] and between 9% and 38% (dependent on age group and methodological approach used) from obstructive sleep apnea [47]. In addition, the field of sleep research is particularly suitable for data-based approaches, as investigating sleep generates a large amount of data, such as sensor data (from the conventionally used polysomnography to modern lifestyle devices such as smartwatches) and subjective data [48]. Besides that, this field is especially sensitive because of its links to psychiatry and is underrepresented in current data-sharing initiatives.

Methods



Overview of Study Design

The conceptualization of the data trust model was carried out in five steps (see Figure 1). First, a participatory approach was used to identify relevant needs regarding a data trust model from the perspective of different stakeholders and to define basic requirements for a data trust (requirement elicitation). This included a survey of data subjects, patient representatives, and sleep researchers (data users). An initial conceptual model was then developed, which included a refinement of the relevant procedures and first interactive mock-ups of user interfaces (UI). In a second step, these UIs and procedures were evaluated

XSL•FO
RenderX

from the perspective of data subjects, data users, and institutional representatives (including data protection and ethics experts; first evaluation). The feedback was used to further refine the system prototype that was developed in parallel. This prototype was then evaluated again in a second evaluation, which was similar to the process used in the first round of evaluation.

Figure 1. Overview of the study design. HCTS: Human-Computer Trust Scale; QII: Quality of Interaction and Involvement; uMARS: user version of the Mobile Application Rating Scale.

Requirements Elicitation

Separate questionnaires were developed for data subjects/patient representatives and data users. The questions were developed on the basis of a structured consensus process in the project group with the participation of IT experts and sleep researchers and included questions on general attitudes toward data sharing and preferred consent models as well as technical and organizational requirements, depending on the target group. The full questionnaire used for the requirements elicitation is available upon request.

Evaluation

Overview

The aim of the evaluation study was twofold. First, we wanted to gain some general insights into attitudes toward data sharing with a data trust model from the perspective of different stakeholder groups. These included data subjects from the sleep laboratory, Department of Psychiatry, Medical Center–University of Freiburg, as well as data users/representatives from data-generating institutions. We also aimed at evaluating our specific data sharing process and data trust model from both perspectives. To this end, we conducted a series of anonymous surveys using a semistructured interview and questionnaires (see below). The relevant constructs for the development of the questionnaires were identified in internal project workshops as well as on the basis of a systematic literature search and the needs analysis.

Semistructured Interviews

Semistructured interviews were conducted with data users and institutional representatives to gain a more comprehensive picture of the views on data sharing and the corresponding needs. This consisted of a total of 10 predefined questions (see Multimedia Appendix 1).

Questionnaire

In total, the questionnaire for data subjects comprised 51 items, which included 4 sociodemographic questions, 5 open questions, 33 Likert scale items, and 9 statement items. The questionnaire for data users/institutional representatives included a total of 30 items, which included 2 sociodemographic questions, 6 open questions, 16 Likert scale items, and 6 statement items.

Trust was assessed using the *human-computer trust scale* (HCTS) [49]. The HCTS is a 12-item questionnaire for assessing user trust based on the *human-computer trust model* [50]. The HCTS includes questions on three dimensions that have been shown to measure trust. These include benevolence (ie, the belief that a system acts in the interest of the user and provides sufficient help if necessary), competence (ie, whether the system

XSL•FO
RenderX

has all features and functions that are necessary to fulfill the intended tasks), and perceived risk (individual evaluation regarding the probability of adverse consequences when using the system). All questions were answered on a 5-point Likert scale from 1 ("strongly disagree") to 5 ("strongly agree").

Quality of interaction and involvement (QII) was assessed using 7 questions developed by Abdelhamid et al [51]. The questions were translated into German and adapted to relate specifically to the SouveMed process (eg, "Have your feelings and emotions been given the attention they deserve?"). Data subjects had to answer on a 4-point Likert scale ("yes, always" to "no, never").

The German version of the Mobile Application Rating Scale (MARS) [52] was used to assess usability. Three of four sections that are part of the user version of the MARS (uMARS) [53] were presented. These include the following sections: functionality (eg, "How easy is it to learn how to use the SouveMed app; how clear are the menu labels, icons and instructions?"), aesthetics (eg, "Visual appeal: How good does the SouveMed app look?"), and subjective quality (eg, "Would you recommend the SouveMed app to people who might benefit from it?"). We decided to use only a subset of the sections to avoid overlap with other elements of our comprehensive questionnaire and because some sections were not applicable to the objectives and content of our specific system. All questions were answered on a 5-point Likert scale, with responses reflecting judgments ranging from "inadequate" to "excellent." Higher scores, therefore, reflect higher quality ratings for the respective domain.

Sociodemographic information and understanding were assessed using 13 items of the questionnaire developed by Richter et al [21]. This included a self-assessment of understanding, subjective reasons for possible poor understanding, and questions to assess the content-related understanding objectively.

Participants

Current patients and participants of other studies in the sleep laboratory at the Department of Psychiatry, Medical Center–University of Freiburg, as well as data users, that is, sleep researchers and representatives of the Medical Center–University of Freiburg with special expertise in data protection or ethics, were approached and invited to participate voluntarily in the study. Participants who were 18 years or older were included and provided informed consent. We excluded pregnant participants and patients with severe mental or somatic disorders that would have made it unreasonable or impracticable to conduct the survey.

Ethical Considerations

Approval of the ethics committee of the University of Freiburg, Freiburg, Germany, was obtained (case number 23-1047-S2). The study was conducted in accordance with applicable German and EU data protection regulations as well as the DOH. Participation was voluntary and not compensated. All participants were informed about the aims, methods, risks, and potential benefits of the study and provided documented informed consent. No personally identifying information was collected, ensuring that all study data were fully anonymized.

Statistical Analysis

The results were averaged, and questionnaire scores are presented as mean (SD) values where possible. Analyses were performed using the statistics software R (version 4.5.0). In the case of missing data, subjects were excluded only from analyses involving the variables for which data were missing (pairwise deletion). Independent-samples Welch t tests were used to compare group means between the first and second evaluation, and Hedges g was calculated as a measure of effect size. P values ≤.05 were considered statistically significant.

Results

Requirements Elicitation and the SouveMed Data Trust

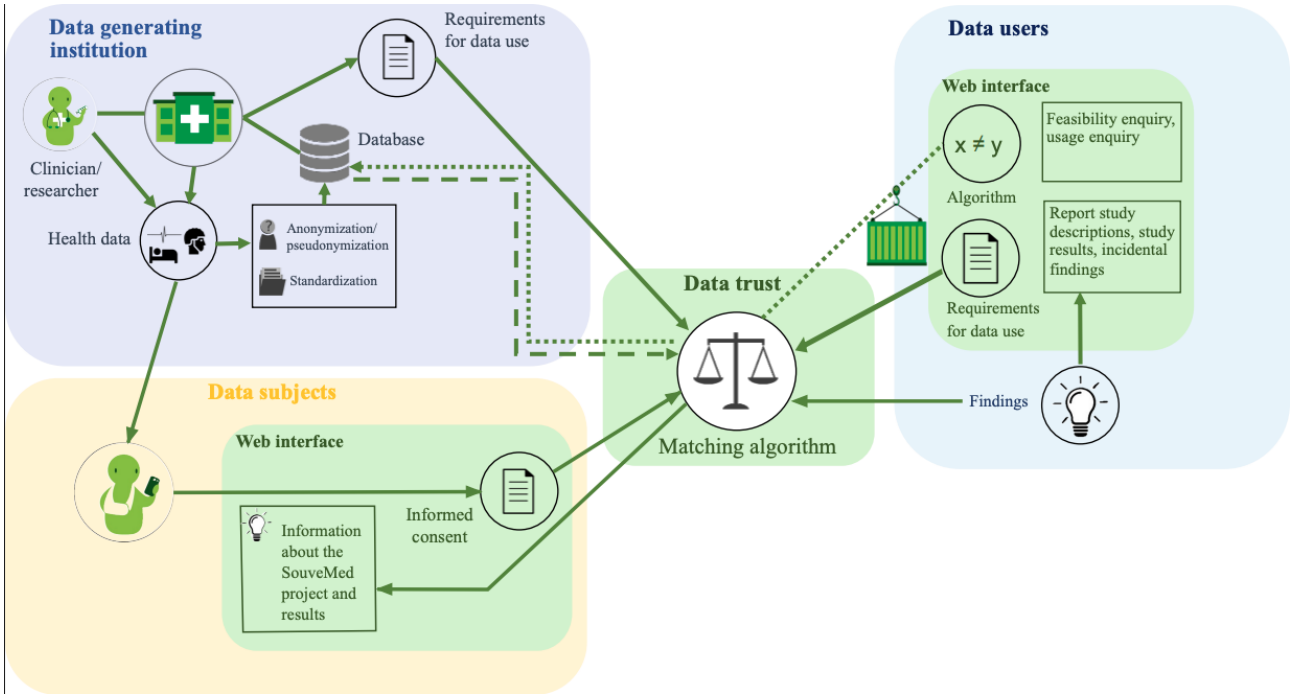
Requirements Elicitation

We received feedback from a total of 14 participants, including 10 data subjects/patient representatives and 4 data users. From the data subject's perspective, the survey revealed a clear preference for the possibility of personal contact as part of the informed consent process. There was also a preference for a consent model that allows for further refinement of the conditions under which data sharing is permitted. However, the majority of respondents were critical of giving separate consent for each individual data request. In addition, there was a high general willingness to provide data, although sufficient transparency and data security were often formulated as the most important conditions for this. Furthermore, 5 (50%) of the data subjects considered it "very important" or "important" to receive information about study results that were obtained using their own data. With 6 data subjects (60%), a majority considered it "very important" or "important" to receive a brief description of study projects, and 5 (50%) considered it "very important" or "important" to receive more detailed information about the status of these studies. A large proportion of the data subjects surveyed were therefore interested in comprehensive participation.

From the perspective of data users, there was a clear preference for the European Data Format for the raw polysomnography data. The availability of a range of relevant metadata (eg, number of people, age, diagnosis statistics, etc) was also seen as essential to the attractiveness of the system.

The SouveMed Data Trust

Based on the needs analysis and workshops by the project group, we developed the *SouveMed* concept, a comprehensive workflow for the secondary use of health data (see Figure 2) with the following key features from the perspective of different stakeholder groups. From the perspective of data subjects, the following functions exist:



- *Onboarding:* A key element of the SouveMed concept is the separation of the onboarding process, that is, the willingness to participate in SouveMed and manage consents with the SouveMed system, from the act of consenting to or disallowing the use of data. It is therefore envisaged that data subjects will only be approached during their visit to the clinical facility to obtain information about

XSL•FO
RenderX

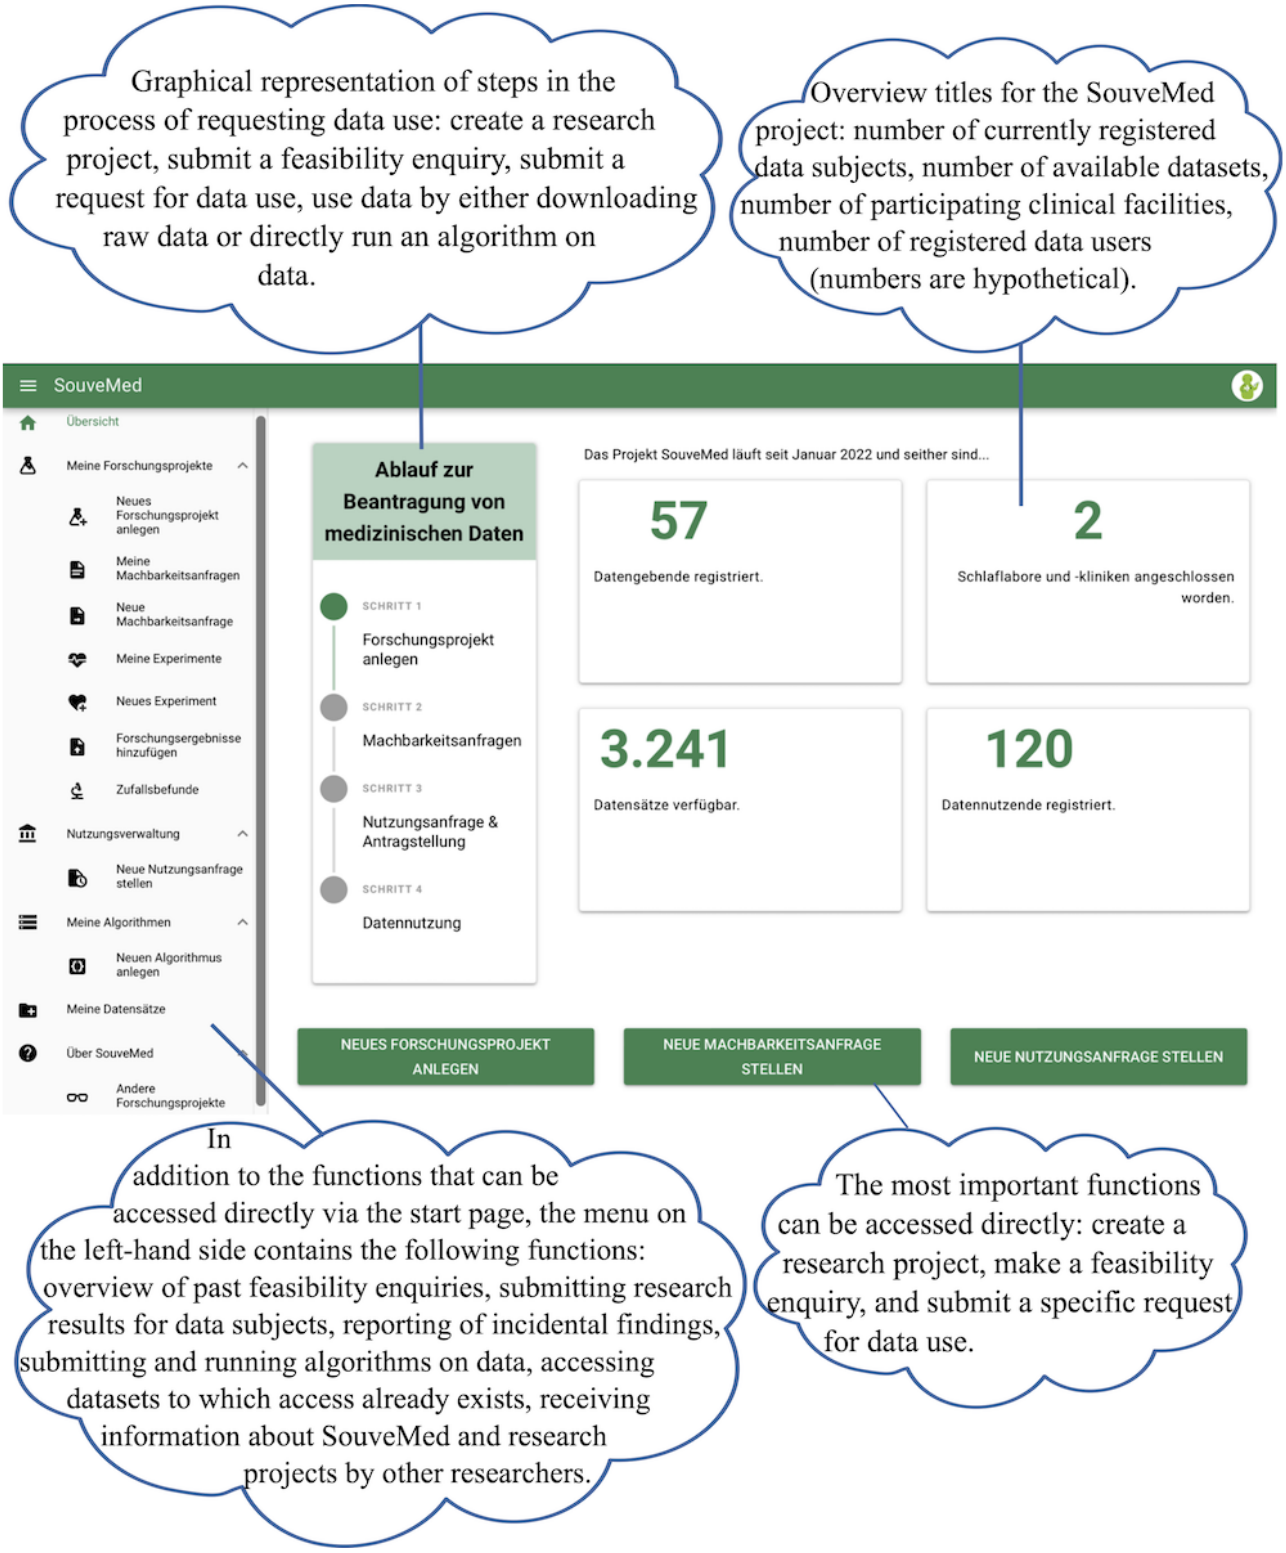
SouveMed and to register on the platform. This involves establishing the data subject's identity and generating a SouveMed ID, that is, a number that can be used together with a password to log in to the platform.

- *Providing consent:* In order to allow participants the necessary time for their decision as well as independence from the clinical setting, decisions are laid down digitally on the SouveMed platform. Consent is designed as a tiered consent (see Multimedia Appendix 2): It applies to a specific visit in the clinical facility and can be further specified, for example, regarding user groups (public or commercial research) and type of shared data (individual or aggregated). The currently valid consent can be viewed at any time on the digital platform, and consent can be withdrawn just as easily as given, amounting to a revocation of data use.
- *Participating in data usage:* The SouveMed platform enables participation in the use of data. Data subjects can obtain information about projects that have accessed their data (including a clear description of the main objectives and results of the studies) and have an overview of current and past consents via a consent archive. Should concerns about data protection or other questions arise, they can easily find the relevant contact information on the SouveMed platform.

Figure 2. The SouveMed concept.

From the perspective of data users, the following functions exist:

- *Feasibility inquiry:* Users can submit a feasibility inquiry for a defined research project (ie, specify the inclusion and exclusion criteria and receive the number of available matches with these criteria), as a low-threshold way to determine whether a research project with SouveMed data is realizable.
- *Usage inquiry:* If the result of the feasibility inquiry appears promising, data users can request data usage directly via the SouveMed platform. They can also obtain an overview of their former and current inquiries.
- *Data analysis on the platform.* Users can submit their own scripted algorithms and evaluate datasets in a controlled data trust environment using the curious container technique (for more details, see [54]). This allows for increased data protection, as only aggregated data are shared, including data from participants who only consented to the sharing of aggregated data.
- *Enabling participation of data subjects:* Users can use the SouveMed platform to report incidental findings, as well as provide study outlines and results to data subjects.



Finally, from the perspective of the data-generating institutions:

- Institutions can define requirements for data use, for example, embargos.
- Institutions can monitor the data flow decisions of the platform and ensure conformance with requirements.
- Technical prerequisites were established for this control functionality for data-generating institutions, but it was not implemented as a web interface; SouveMed is designed to be decentralized with a data access component that is under control of the generating institution.

In the SouveMed project, separate UIs were developed for data users (see Figure 3) and data subjects (see Figure 4). Conceptually, it is intended that data users must create their own user account, whereby a contract between the affiliated institution and SouveMed is a prerequisite for this. A key element of the SouveMed system is the *data trust component*, which automatically matches the descriptions, preferences, and requirements of all stakeholders (data subject, researcher, and institution) using digital contract representations. For details on the technical implementation of the described functions of the SouveMed concept, please refer to [54] and [55].

Evaluation

Sample Characteristics

A total of 22 participants (14 females and 8 males) were studied in the first evaluation. These included 11 patients with sleep disorders and 11 data users/institutional representatives. In the second evaluation, a total of 16 participants (9 females and 7 males) were examined. These included 10 patients with sleep disorders and 6 data users. Of the 22 participants in the first evaluation, 5 (23%) were between 18 and 30 years old, 10 (45%) between 31 and 45 years old, 4 (18%) between 46 and 60 years old, and 3 (14%) between 61 and 75 years old. Of the 16 participants in the second evaluation, 2 (13%) fell into the age range of 18 to 30 years, 7 (44%) into the age range of 31 to 45 years, 5 (31%) into the age range of 46 to 60 years, and 2 (13%) into the age range of 61 to 75 years.

The general willingness to make data available for secondary use was assessed in the data subject group with a mean value of 4.35 (SD 0.58) on a 5-point Likert scale (“very low”=1 point to “very high”=5 points; for the first and second evaluations combined). The need for a corresponding system was assessed in the group of data users/institutional representatives with a mean value of 4.29 (SD 0.77) on a 5-point Likert scale (“very low”=1 point to “very high”=5 points; for the first and second evaluations combined).

Semistructured Interview

Data users and institutional representatives described the system as clear and equipped with all the functions they required. It was pointed out that thorough explanations of the secondary use of research data are also important for this stakeholder group. Furthermore, it was uniformly emphasized that the need for a system that facilitates the secondary use of research data is very high.

Previous contact with the concept of data trust models was mentioned by only two participants. With regard to the required functionalities, it was emphasized that access to the system should be easy and that all legal requirements should be met. When the representatives of the institutions were asked whether they would agree to the use of SouveMed in their institution, all gave positive feedback. One person emphasized the importance of an integrated model for all areas of health care in order to avoid isolated solutions for different areas.

XSL•FO
RenderX

User Version of the MARS

In the first evaluation, 8 data users/institutional representatives and 10 data subjects provided complete data on the uMARS. In the second evaluation, 6 data users and 10 data subjects provided complete data on the uMARS.

Functionality

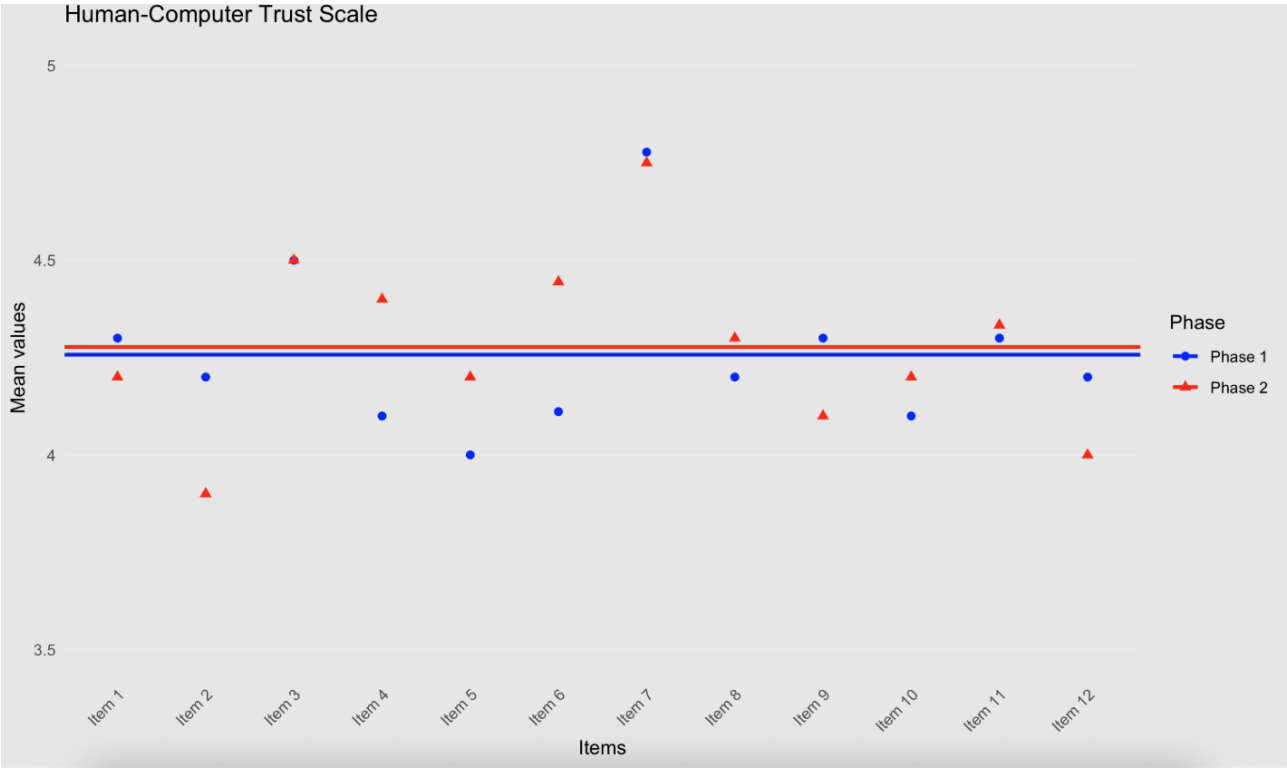
The mean functionality score of the data user system increased from 3.56 (SD 0.77) in the first evaluation to 4.58 (SD 0.38) in the second evaluation. This difference was statistically significant ($t_{10.69}$=−3.28, *P*=.008), with a large effect size (*g*=−1.51, 95% CI −2.76 to −0.26). The mean functionality score of the data subject system increased from 4.30 (SD 0.41) in the first evaluation to 4.50 (SD 0.74) in the second evaluation. This difference was not statistically significant ($t_{13.99}$=−0.75, *P*=.46; *g*=−0.32, 95% CI −1.23 to 0.58).

Aesthetics

The mean aesthetics score of the data user system increased from 4.08 (SD 0.68) in the first evaluation to 4.17 (SD 0.55) in the second evaluation. This difference was not statistically significant ($t_{11.91}$=−0.25, *P*=.80; *g*=−0.12, 95% CI −1.23 to 0.98). The mean aesthetics score of the data subject system increased from 3.93 (SD 0.44) in the first evaluation to 4.23 (SD 0.94) in the second evaluation. This difference was not statistically significant ($t_{12.72}$=−0.91, *P*=.38; *g*=−0.39, 95% CI −1.30 to 0.52).

Subjective Quality

In the first evaluation, the mean score for the recommendation item (“Would you recommend this app to people who might benefit from it?”) of the data user system was 4.63 (SD 0.52). In the second evaluation, the mean score increased to 4.83 (SD 0.41). This difference was not statistically significant ($t_{11.93}$=−0.84, *P*=.42; *g*=−0.42, 95% CI −1.52 to 0.70.



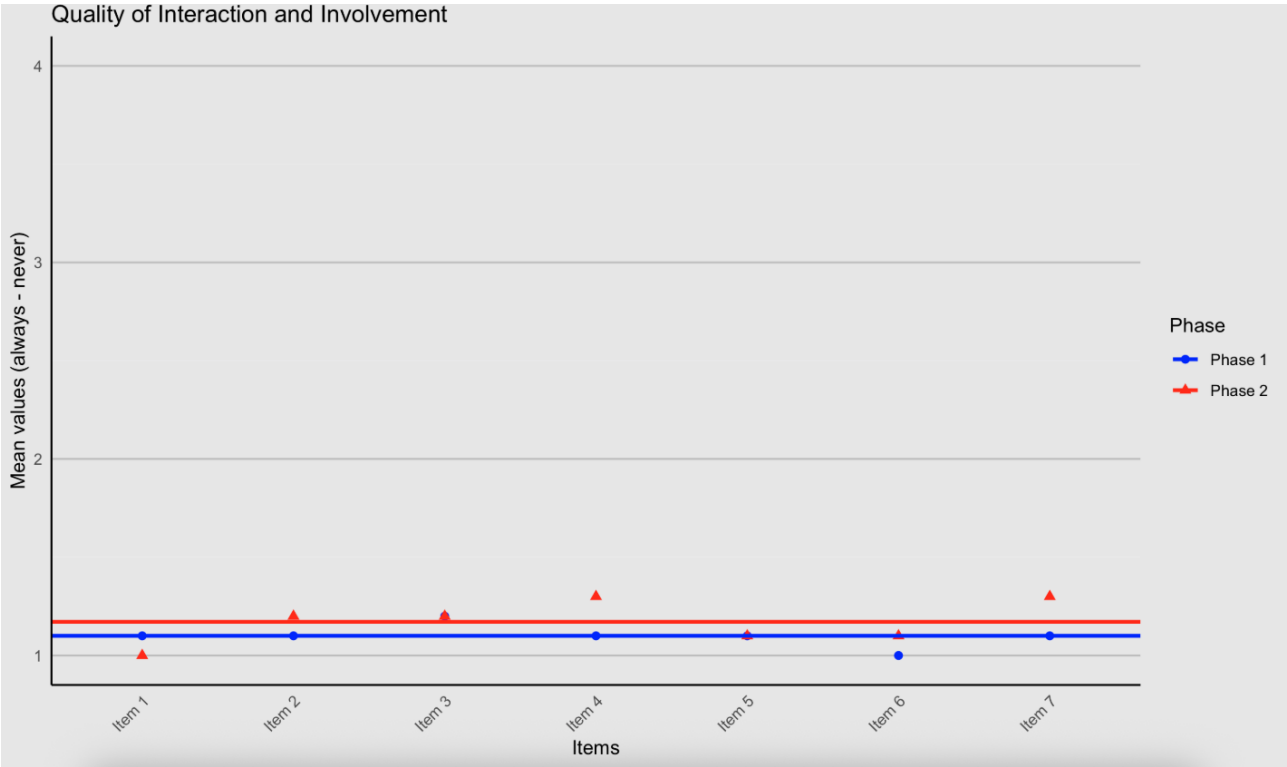
In the first evaluation, the mean score for the recommendation item of the data subject system was 3.90 (SD 0.74). In the second evaluation, the mean score increased to 4.20 (SD 0.79). This difference was not statistically significant ($t_{17.92}$=−0.88, *P*=.39; *g*=−0.38, 95% CI −1.28 to 0.53).

In the first evaluation, data users rated the system with an average of 3.75 out of 5 (SD 0.71) stars and in the second evaluation with 4.17 (SD 0.41) stars. This difference was not statistically significant ($t_{11.44}$=−1.39, *P*=.44; *g*=−0.65, 95% CI −1.78 to 0.48). Data subjects rated the system with an average of 3.90 (SD 0.57) stars in the first evaluation and 4.10 (SD 0.57) stars in the second evaluation. This difference was not statistically significant ($t_{18.00}$=−0.79, *P*=.44; *g*=−0.34, 95% CI −1.24 to 0.57).

Trust

In the first evaluation, the assessment of data subject trust resulted in a mean rating of 4.23 (SD 0.46) on the HCTS. One data subject did not respond to the trust scale and was excluded from the analysis. In the second evaluation, the mean rating was 4.23 (SD 0.68; see Figure 5 for item-level mean values). This difference was not statistically significant ($t_{15.78}$=0.03, *P*=.97; *g*=0.01, 95% CI −0.87 to 0.91).

Figure 5. Data subject trust.



XSL•FO
RenderX

Quality of Interaction and Involvement

In the first evaluation, the assessment of QII resulted in a mean rating of 1.10 (SD 0.19), with lower scores indicating higher perceived quality. In the second evaluation, the mean rating was 1.17 (SD 0.34; see Figure 6 for item-level mean values). This difference was not statistically significant ($t_{14.12}$=−0.58, P=.57; g=−0.26, 95% CI −1.15 to 0.66). In the first evaluation, 1 data subject did not respond to the QII scale and was excluded from the analysis.

Figure 6. Quality of interaction and involvement.

Subjective Understanding

When participants were asked whether they thought the information about their data use was understandable, the mean rating was 4.40 (SD 0.97) in the first evaluation and 4.30 (SD 0.95) in the second evaluation. This difference was not statistically significant ($t_{17.99}$=0.23, P=.82; g=0.10, 95% CI −0.80 to 1.00). The scope/length of the information was rated as “just right” by 8 of 11 (73%) data subjects in the first evaluation, “too long” by 3 of 11 (27%) data subjects, and “too short” by none. In the second evaluation, it was rated as “just right” by 8 of 10 (80%), “too long” by 2 of 10 (20%) data subjects, and “too short” by none. The results on objective understanding can be found in the supplementary material (see Multimedia Appendix 3).

Perceived Risk

Data users and institutional representatives were asked to rate the perceived risk to their institution of using SouveMed. Sixteen (94%) out of 17 responded that they perceived no risk (for the first and second evaluation combined), and 1 of 17 (6%) perceived a risk (for the first and second evaluation combined). Data protection concerns were mentioned as a potential risk.

Discussion

Principal Findings

Making health data accessible for secondary research use is a major challenge in the upcoming decades for both health care institutions and research organizations. In addition to the increasing opportunities created by digitalization and the high willingness of data subjects to make health data available, as the present study and other works show [20-23], the potential is not being realized for a number of reasons. These include changing legal norms, inadequate preprocessing of data, and the existence of a large number of different, sometimes conflicting interests of the various stakeholders.

The SouveMed Concept

Data trust models are a promising solution to address this complexity. However, apart from a few small, heterogeneous initiatives, there are hardly any fully developed approaches in this regard in the field of medical research. We have therefore developed an ethically sound framework for the secondary use of medical data that is applied to the use case of sleep research. The model includes secure onboarding of data subjects and digital use of information, consent, and feedback channels; a digital interface for data users for onboarding, defining research aims and categorization, querying available data set numbers, and, finally, either downloading data or having algorithms run on it; and, crucially, a digital data trust that matches the

XSL•FO
RenderX

descriptions and preconditions of all stakeholders (data subject, data user, and institution) using digital contract representations. Data access is granted in our model only when all requirements and conditions set forth by the various stakeholders are satisfied. The explicit focus of our data trust model is on data subject sovereignty and participation, as data subject involvement and appropriate communication are critical to build trust [25,26] and were central to many data subjects in our needs analysis. Accordingly, a majority of data subjects emphasized the importance of a personal contact person in the consent process to be able to ask individual questions. In addition, transparency about data use was mentioned as an important prerequisite for the willingness to provide data, and there was a clear preference for a consent model that allows for further refinement of the conditions under which data sharing is permitted. Based on these results, the SouveMed model provides the opportunity for data subjects to give *real* informed consent by presenting them with comprehensible information material and encouraging them to ask individualized questions in the information process. By separating information and consent in terms of time and space, the ethically questionable linking of health care and the provision of informed consent is avoided. Participants also have the opportunity to receive information about study projects that use their data. The combination of information in face-to-face contact and via a digital platform enables both personalized information for data subjects and patient sovereignty over the amount of involvement, both key requirements demanded of a system for secondary use of health data (eg, [23,26,31]).

SouveMed uses an opt-in solution where data subjects explicitly decide whether or not they wish to share data. This is in line with generally recognized ethical standards for medical research [18,56]. In addition, the present finding regarding the usefulness of tiered consent provided in an electronic format is in line with previous studies investigating different consent models and modes of patient involvement (eg, [30,57-59]). In our approach, the use of a digital interface for consent management also allows data subjects to easily withdraw their consent, which fulfills the requirement in Article 7 of the GDPR that withdrawal of consent must be as easy as giving consent [15].

Evaluation of the SouveMed Concept

The present evaluation study showed a high degree of trust in our concept in both the first and second evaluations, as measured by the HCTS. It also showed a high level of satisfaction with our communication process, also in the first and second evaluations. Thus, the SouveMed system has proven to be effective in meeting data subjects' main concerns related to the secondary use of health data. The results of the usability assessment using the uMARS showed very good usability for both evaluations, with a slight increase in usability in the second evaluation. Good usability is key to increasing and maintaining data subjects' motivation to actively participate in SouveMed and is probably also related to trust [60].

From the perspective of data users and institutions, they may benefit from easy access to raw data and the ability to run algorithms on data in a secure environment. Both our requirements analysis and our evaluation study have shown that there is an urgent need for systems that enable secondary use of research data. The data on uMARS from our evaluation study showed excellent usability in all three subscales (functionality, aesthetics, and subjective quality) from the perspective of data users and institutions, which improved even further in the second evaluation. In this evaluation, all data users surveyed stated that the SouveMed system offers all the functionalities they desire from such a system. Except for a significant increase in the perceived functionality of the data user system, no statistically significant differences were observed between the first and second evaluations. This result is likely due to the limited sample size and the already high ratings in the first evaluation, which constrained the potential for further measurable improvements.

Overall, these results indicate that the SouveMed data trust effectively realizes the needs and requirements identified during the needs analysis and literature review.

Future Perspectives

Various legislative initiatives in the European Union (eg, EHDS [61]) and in Germany (eg, *Forschungsdatengesetz* [62] and *Gesundheitsdatennutzungsgesetz* [63]) are currently aimed at simplifying the secondary use of health data. This is to be welcomed in principle, as it contributes to the development of a viable research landscape and addresses a major challenge in medical research. Nevertheless, the solutions must be preceded by an analysis of the underlying problems and address them precisely. The results of this and numerous other studies indicate that the secondary use of health data is not hindered by a lack of willingness on the part of data subjects to provide data. It therefore does not seem necessary to pass over data subjects by allowing the use of health data without consent. There is also no lack of infrastructure for centralized data storage, which entails far more risks but only minimal benefits [64]. What is notably absent is a clear workflow for the secondary use of health data that can be easily integrated into routine clinical care, that takes data subjects' needs into account and thereby gains their long-term acceptance, and that relieves researchers of complex legal considerations and negotiations.

In the European Union, a standardized legal framework has been established through the EHDS, which permits an opt-out mechanism for the secondary use of health data [61]. According to Article 54, this should be implemented via "…an easily understandable and accessible user-friendly mechanism to exercise that right to opt out…" Article 54 further emphasizes that it is "…imperative to provide natural persons with sufficient and complete information regarding their right to opt out…" Nevertheless, how this will be implemented in practice in the individual member states is still largely unclear. Although an opt-in solution is preferred in our project, the SouveMed concept could serve as a blueprint for a system that enables data subjects to receive information about the secondary use of their health data and to express their preferences, including a possible opt-out.

Sleep research was selected as a use case because large volumes of data are typically generated in this field (eg, through polysomnography). In this context, it is important to consider that the likelihood of reidentifying individuals grows with the amount of data collected, making true anonymization increasingly difficult. Similar challenges are expected in other

XSL•FO
RenderX

areas of research due to expanding data volumes. Therefore, we argue that the active involvement of data subjects and other stakeholders is becoming ever more critical.

A key advantage of SouveMed is also the algorithmic trust component. Future data exchange will increasingly have to rely on algorithmic decisions to manage large amounts of requests in a time- and cost-efficient manner. Data use and access committees would oversee the rules of data use rather than each single application.

Limitations

There are some limitations to this study. First, the sample size was small and therefore probably not sufficiently representative. Therefore, surveys of larger patient and other stakeholder groups that include other diagnostic entities are needed. In addition, no *real* implementation of the SouveMed system was carried out as there were insufficient resources to achieve this in the current project. Although we tried to keep the framework of the evaluation as natural as possible, everyone involved was aware that it was not about real data sharing, which could have influenced the results.

Many aspects of our model were developed not only conceptually but also technically (see [54,55]). Nevertheless, further studies focusing on the technical implementation of digital contract representations are needed, as this is a key element of an effectively functioning matching algorithm that was not fully elaborated technically in the SouveMed project.

Funding

This study was funded by the German Ministry of Education and Research (grant 16DTM115A). We acknowledge support by the Open Access Publication Fund of the University of Freiburg.

Abstract

Background: Digital health literacy is a key factor in enabling users to navigate in an increasingly digitalized health care system. Low levels of digital health literacy are associated with higher age, low education, and income, as well as low functional health literacy. Around 6.2 million adults living in Germany have low reading and writing skills. Due to their low literacy, this group is often underrepresented in research studies and therefore little is known about their digital health literacy and use of digital health tools.

Objective: The objectives of this study were to assess digital health literacy in adults with low reading and writing skills and to explore which digital health tools they use in daily life.

Methods: An interviewer-administered survey and focus groups were conducted with adult residents of Bremen, Germany, who were aged 18 - 64 years and had low reading and writing skills. In addition, a stakeholder workshop was held to derive recommendations on how digital health literacy could be improved. The survey questionnaire included 21 items addressing the use of digital health technologies and digital health literacy (eHealth Literacy Scale). Focus group participants completed several tasks on web-based health information and then discussed their experiences. Survey data were analyzed using descriptive statistics and linear regression. Qualitative content analysis was applied to analyze the focus group data and the written documentation of the stakeholder workshop.

Results: Survey participants (n=96) were on average 43 (SD 10.7) years old, 72% (69/96) were female, and 92% (88/96) were not born in Germany. Participants reported mainly using information-related digital health technologies such as health apps (40/96, 42%), health websites (30/96, 31%), or activity trackers (27/96, 28%). The mean digital health literacy score was 22 (SD 8) points, with 35% (34/96) of participants classified as having a low digital health literacy (score between 8-19/40 points). Digital health technology use was associated with higher digital health literacy. For participants in the 5 focus groups (total n=39; mean age 43, SD 12.6 years; n=34, 87% female), limited technical skills and language problems were the most important challenges. Furthermore, focus group participants reported that they favor videos when searching for web-based health information and prefer to seek support from family members or local organizations for health issues. Stakeholders (n=15) recommended that health websites should be available in multiple languages, contain simple and easy-to-read language, and use images, symbols, and videos.

Conclusions: While adults with low reading and writing skills use digital health technologies, many find it challenging to search for health information on the internet due to lacking technical skills and language problems. To ensure that adults with low reading and writing skills are not further left behind, future research should focus on developing tailored interventions to promote digital health literacy.

(JMIR Hum Factors 2025;12:e65345) doi:10.2196/65345

KEYWORDS

digital health literacy; digital health technologies; digital health; digital divide; mobile phone; adults; mixed methods study

Introduction

The digitalization of health care services, such as video consultations or prescribed digital health applications, is accompanied by a shift of prevention and health promotion activities and interventions to the digital environment (eg, wearables and online sport courses) [1,2]. Health information from the internet is easily and instantly available [3]. However,

XSL•FO
RenderX

the large amount of health information on the internet is often overwhelming for users, and it is particularly difficult to use the information found to make health decisions [4]. The level of digital health literacy is a key factor in enabling users to navigate in an increasingly digitalized health care system. According to one well-known definition, digital health literacy describes the ability to seek, find, understand, evaluate, and apply health information from digital sources to one's own health problem [5]. In addition, interaction with health apps (eg, for tracking physical activity) or interactions on social media platforms, including creating own content, are also included under current concepts of digital health literacy [6,7]. Hence, digital health literacy combines various subskills such as computer literacy (ie, use of computers and digital devices), information and media literacy (ie, critical use of information and media), science literacy (ie, knowledge and understanding of scientific principles, concepts, and processes), traditional literacy (ie, reading and writing skills), and health literacy [1]. Studies show that digital health literacy is unevenly distributed among population groups and influenced by sociodemographic factors such as age, education, income, and ethnicity. Older adults and persons with low levels of education and income have been found to have lower digital health literacy than their counterparts [6,8,9], whereas ethnicity was not linked with digital health literacy in the systematic review and meta-analysis by Estrela and colleagues [6]. One study found that being a Spanish-speaker in the United States was not associated with digital health literacy [10]. However, other studies found a lower level of digital health literacy among Arabic native speakers in Sweden [11] and non-English versus English-speaking parents of children with special health care needs in the United States [12]. The second Health Literacy Survey Germany did not find an association of digital health literacy with migration background per se, however, that survey showed an association of low functional health literacy, used as a proxy for general literacy (reading and writing skills and numeracy), with low digital health literacy [7,13]. This is important as an estimated 12% of the adult German population (ie, 6.2 million adults) have low reading and writing skills, meaning that they can only read and write simple sentences in German [14]. Around half of the participants with low reading and writing skills reported to have another native language than German. In addition, adults with low reading and writing skills are less likely to write emails or search for health-related information on the internet compared with adults with sufficient reading and writing skills [14]. Even though several studies have already investigated digital health literacy of the general population living in Germany [4,7,15] and various subgroups such as students [16], school children [17], teachers [18], physicians [19], or community inhabitants [20], very little is known about the digital health literacy of adults with low reading and writing skills and their use of digital tools for health purposes. Therefore, the main objectives of this study were (1) to assess the digital health literacy in adults with low reading and writing skills and (2) to explore which digital tools they use in daily life.

Methods

Study Design

This is an exploratory study using a mixed methods design consisting of a survey, focus group discussions, and a stakeholder workshop. The study report adheres to the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) [21] (Checklist 1) and Consolidated Criteria for Reporting Qualitative Research (COREQ) [22] (Checklist 2) guidelines.

Participants

Inclusion criteria for the survey and focus group discussions were (1) age between 18 and 64 years; (2) living in Bremen, Germany; and (3) low reading and writing skills in German (ie, able to read and write simple sentences in German only; alpha level <4). Eligible participants could be native German speakers, adults who could read and write in their native language but not in German, or adults who could not read and write either in their native language or German.

Procedure

We aimed to conduct 70 survey interviews and 5 focus groups with 6-8 participants each, striving for a balanced ratio of participants with different literacy levels (ie, native German speakers, good literacy in native language but not in German, and low literacy in either native language and German). Survey and focus group participants were recruited via a snowball system. Health mediators employed at the research institution for the project duration recruited participants via their local community networks (eg, mothers' centers and integration courses). Flyers were displayed in various locations (eg, mothers' centers and meeting centers for citizens) and distributed during events organized by our community office (ie, Leibniz Living Lab) or cooperating city district initiatives. In addition, the project was presented in German language courses and integration courses, and eligible participants were approached personally via the health mediators and their local networks. The health mediators had a native language other than German (eg, Russian or Turkish) but were fluent German speakers and, due to their main occupation, were well-connected in the community and with the people who had immigrated to Germany living there. Participants were also recruited from German language courses provided by adult education centers. The language courses aimed to teach reading and writing skills to native German speakers and people who have immigrated to Germany and could understand and speak German.

All participants recruited by the health mediators were asked to complete a 9-item test to determine their literacy level [23]. Participants recruited from adult education centers did not have to complete this test as their literacy level had already been assessed for their language course attendance.

Survey Questionnaire

The structured interviewer-administered survey took approximately 30 minutes to complete and included 21 items covering three topic areas: (1) use and acceptance of digital health technologies (5 items), (2) digital health literacy (8 items),

XSL•FO
RenderX

and (3) sociodemographic characteristics (8 items). The items were self-developed or adapted from existing surveys or instruments. The German version of the questionnaire can be found in Multimedia Appendix 1.

Use and acceptance of digital health technologies were assessed based on purposes of digital devices, use of digital devices in health context, use of digital health technologies (ie, list with 12 digital health technologies), perceived advantages, and disadvantages [24,25].

Digital health literacy was measured using the German version of the eHealth Literacy Scale (eHEALS) [26]. Each item was rated on a 5-point Likert scale ranging from strongly disagree to strongly agree.

Sociodemographic characteristics included age, sex, country of birth, spoken language at home, self-assessed speaking, reading, and writing skills in native language, highest educational degree, and employment status. Items for age, sex, country of birth, spoken language at home, highest educational degree, and employment status were adapted from the "German Health Update" 2019/2020 study [27]. The item for self-assessed reading and writing skills in native language was self-developed.

The interviewer-administered questionnaire was filled out by a health mediator or a member of the research team during a personal interview conducted in our community office (ie, Leibniz Living Lab), mother centers, or adult education centers. Based on the participant's preference, the interview was conducted in German, English, Russian, Arabic, Turkish, Macedonian, Twi, or Tamil.

Focus Group Protocol

The approximately 90-minute long focus groups were structured into four parts: (1) welcome and introduction, (2) task course, (3) overarching discussion, and (4) summary and farewell.

During the welcome and introduction, participants received the study information in verbal and written form, gave informed consent to participate, and filled out a short questionnaire on sociodemographic information (ie, age, sex, and employment status). During the focus group, participants were presented with 4 tasks which were developed on the basis of the Digital Health Literacy Instrument (DHLI) by van der Vaart and Drossaert [28]. For each of the 7 DHLI dimensions (ie, operational skills, navigation skills, information searching, evaluating reliability, determining relevance, adding content, and protecting privacy), a performance-based item was developed that included the application of a particular skill in a fictional situation [28]. We adapted the proposed items for our context and target group, focusing on the dimensions of operational skills, navigation skills, information searching, evaluating reliability, and determining relevance (Textbox 1). The tasks were not intended to measure participants' digital health literacy. All tasks were formulated in simple language and were read out to the participants. In addition, pictures and symbols were used to describe the content of the tasks. Participants solved tasks individually on their smartphones or using a laptop provided by the study team. If necessary, participants were supported by the study team while completing the tasks. After each task, a group discussion on encountered difficulties and strategies to overcome difficulties was held (ie, what experiences did you have while working on the task? What was difficult for you? What did you do if you did not make any progress in the search?). In addition, the study team described a possible solution for each task. In the overarching discussion, participants discussed which digital devices they use, which formats (eg, videos) they prefer, and how they use web-based services for health-related purposes. At the end of the focus group, the study team provided a summary and gave out a handout to the participants with solutions to the tasks. Focus group discussions were conducted in German at our community office (ie, Leibniz Living Lab), mother centers, or adult education centers, and were moderated by at least 3 members of the study team. Focus group discussions were audio-recorded and transcribed verbatim. The focus group protocol is available from the authors upon request.

Textbox 1. Tasks for focus group discussion.

- Please open the internet on your laptop or smartphone. Please close the internet. Please open the website www.bremen.de (website with information and facts about the city of Bremen). Please open a search engine such as Google search (Digital Health Literacy Instrument [DHLI] dimensions: operational skills, navigation skills).
- Please search the internet for a general physician in your neighborhood. Note the telephone number to make an appointment (DHLI dimensions: information searching).
- Please open the website www.gesundheitsinformation.de (website for independent and evidence-based health information). When does a child with fever need to see a physician? (DHLI dimensions: information searching, determining relevance)
- Please search the internet. When do you need to see a physician if you have severe back pain? (DHLI dimensions: information searching, evaluating reliability, determining relevance)

Stakeholder Workshop

The main project results were presented and discussed with local stakeholders in a workshop conducted in our community office (ie, Leibniz Living Lab) using the world café method [29]. Stakeholders were recruited via a snowball system. Thus, stakeholders from civil and public services, local public authorities, and community social service providers or groups that work with adults with low reading and writing skills and are located in Bremen were asked to participate in the workshop. After presenting project results (ie, survey and focus group discussions), the stakeholders split into three groups (approximately 5 stakeholders per group) and discussed the following questions at group tables for 15 minutes each: (1) which competencies are needed by adults with low reading and writing skills to use digital health technologies, (2) how should

XSL•FO
RenderX

digital health technologies be designed for adults with low reading and writing skills, and (3) which and how stakeholders should be involved in making digital health technologies for adults with low reading and writing skills accessible. After 15 minutes, the next group went to the table until all 3 groups had discussed all the questions. Each group table was moderated by 1 researcher (SM, RW, or TB) and 1 - 2 health mediators. The results of the world café were documented on meta-plan paper. In addition, discussion notes for each group and photo documentation were completed. All participants received a copy of the discussion notes and world café results.

Data Analysis

Filled-out survey questionnaires were entered independently into the software LimeSurvey by 2 members of the study team (SM and Finola Goepfert; refer to Acknowledgments). The data were then imported into IBM-SPSS 24 (IBM Corp), cleaned, and prepared for statistical analysis. The responses to all survey items were analyzed descriptively using absolute and relative frequencies or means and SDs. Linear ordinary least square regression models were computed to investigate the association between digital health literacy and participant characteristics including age, sex, formal education, language skills, and use of digital health technologies. Based on the distribution of scores, formal education was categorized into 3 groups (low: less than 9 years of schooling, no formal degree; medium: 9 - 10 years of schooling, lower secondary education; and high: 12 - 13 years of schooling, university entrance qualification), employment status into 5 groups (full-time employed, part-time employed, care work, language course, and other), and use of digital health technologies into 2 groups (no use vs use of at least 1 digital health technology). Participants were grouped into three categories of language skills based on language spoken at home and self-assessed reading and writing skills in native language: (1) native German speakers, (2) good literacy in native language but not in German, and (3) low literacy in both native language and German. For digital health literacy, two variables were computed: (1) total eHEALS score, ranging from 8 (lowest digital health literacy) to 40 points (highest digital health literacy) and (2) a 3-category variable based on the study by De Santis and colleagues [24] (low: 8 - 19 points, medium: 20 - 29 points, and high: 30 - 40 points).

Qualitative content analysis [30] following a deductive-inductive approach was applied to analyze the focus group data. First, focus group transcripts were imported into MAXQDA 2020 (VERBI–Software Consult Sozialforschung GmbH) and relevant text units were coded into overarching categories and subcategories. Categories and subcategories were derived from the focus group protocol (deductive coding). New categories and subcategories were created if text units did not fit into any of the pre-existing categories or subcategories (inductive coding). Second, data were grouped and summarized into themes using Microsoft Excel. Coding, grouping, and summarizing of the data was performed by one researcher (SM) and checked by a second researcher (Meret Lakeberg; refer to Acknowledgments). Any discrepancies in the coding or reduction process were discussed until a consensus between researchers was reached. Illustrative quotes were selected from the existing material as anchor examples and translated into English. All translations were checked by a native English speaker.

As this is an exploratory study, no sample size calculation was conducted.

Ethical Considerations

This study was approved by the Ethics Committee of the University of Bremen, Germany, on December 6, 2022 (reference 2022 - 29), in accordance with the ethical guidelines for human participant research and the Declaration of Helsinki. All participants received verbal and written information about the study and gave informed consent (Multimedia Appendix 2) for their data to be used. All data were anonymized to ensure privacy and were securely stored on a password-protected server at the research institution accessible only to the research team. Participation in the survey and focus group discussions was voluntary, could be terminated at any time, and was reimbursed with €15 (US $17). No identifiable participant information has been included in the manuscript or supplementary materials.

Results

Survey

A total of 108 interviews were conducted between December 2022 and March 2023. Mean interview duration was 29 (range 6-75) minutes. Of the total, 12 interviews were excluded based on the following reasons: participants aged 65 years and above (n=5) or not meeting criteria for low literacy (n=7). The remaining 96 interviews were included in the analysis. Of these, around half were conducted in German (n=47, 49%), 13 in Russian (14%), 12 in Twi (13%), 8 in Arabic (8%), 6 in English (6%), and 4 in Turkish (4%). None of the interviews was conducted either in Macedonian or Tamil, respectively. For 6 interviews, no information on the conducted language is available. Interview participants were on average 43 (SD 10.7) years old, 72% (69/96) were female, 92% (88/96) were not born in Germany, 38% (36/96) reported a medium level of formal education, and 30% (29/96) attended a language course (Table 1). In total, 11 participants (12%) were German native speakers, 32 participants (33%) reported good literacy in their native language but not in German, and 53 participants (55%) had low literacy in both German and their native language. Mean digital health literacy score was 22.2 (SD 8) points ranging from 8 to 40 points. Digital health literacy was classified as low in 35% (n=34), medium in 44% (n=42), and high in 19% (n=18) of participants. In addition, 59 participants (62%) were digital health technology users.

Regression analysis found no associations between age, sex, and digital health literacy (Table 2). Digital health literacy was approximately 6 scale points lower among participants with low language skills in both their native language and German as compared with native speakers. Participants with a medium level of formal education reported a higher digital health literacy compared with those with no formal degree. Furthermore, the average digital health literacy score was approximately 10 points higher among digital health technology users compared with nonusers.

XSL•FO
RenderX

The 5 most commonly used health-related digital technologies were health apps (40/96, 42%), health-related websites or forums (30/96, 31%), fitness trackers (27/96, 28%), web-based appointment scheduling (24/96, 25%), and email contact with doctor's surgery or pharmacy (20/96, 21%) (Figure 1). Health care–related digital technologies, such as prescribed digital health applications (3/96, 3%), electronic sick leave notice (3/96, 3%), or electronic prescription (1/96, 1%), were used by very few participants. None of the participants reported accessing their electronic health record or using video consultations. Participants with low digital health literacy used fewer digital health technologies than those with medium or high digital health literacy, and specifically none of the health care–related options (Figure 1). Results stratified by language skills showed higher usage of digital health technologies by native German speakers and adults with good native language literacy compared with participants with both native language and German literacy (Multimedia Appendix 3).

Most participants (n=74, 77%) used a smartphone or tablet to access health-related information (Table 3). The most common reasons for using digital health technologies were time savings (n=44, 46%), access at anytime from anywhere (n=42, 44%), motivation to stay healthy (n=39, 41%), and cost-effectiveness (n=38, 40%). Reasons for not using digital health technologies included preference for personal advice (n=41, 43%) or paper-based information (n=33, 34%), concerns about data security (n=20, 21%), mistrust in health information (n=19, 20%), technical problems (n=9, 9%) and lack of a suitable device (n=6, 6%).

Focus Groups

A total of 5 focus groups (total n=39 participants) were conducted between April and June 2023. Participants were on average 43 (SD 12.6) years old, 87% (34/39) participants were female, and 46% (18/39) attended a language course (Table 1).

Anchor examples for the reported difficulties and strategies to overcome difficulties can be found in Table 4. Due to technical difficulties in using digital devices (eg, computer) or the use of cookies on websites, searching for health information on the internet was difficult for participants. Most focus group participants reported language problems in comprehending technical and foreign words on health information websites and reading and writing German. The lack of translation options (eg, calling family members or friends with better German skills or unstable internet connection for using translation services) while filling out German-language forms in medical practices was also reported as a difficulty. In addition, participants reported difficulty in using search engines to find important and relevant information on the internet. Some participants mentioned that they were unsure on how to use or search on the internet because they were afraid of ordering something.

Most focus group participants stated that they seek advice from family members, friends, acquaintances, or local organizations when they encounter difficulties while searching for health information on the internet. Participants also tried to find a solution themselves by combining word and image searches or using translation tools. Some participants relied on their own experience (eg, if a child has fever) or on previous knowledge and thus did not consider searching for health-related information on the internet. In general, most focus group participants stated that they preferred personal or telephone contact with health care providers (eg, to arrange doctor's appointments or for acute medical concerns).

In the overarching discussion, focus group participants reported which digital devices, formats, languages, and digital health technologies they have used so far (Table 4). Participants used smartphones to search for information on the internet. Information was sought in German, in the native language, or in a combination of German and the native language.

XSL•FO
RenderX

Participants who could not or could barely read and write in their native language sought information in German, whereas participants who could read and write well in their native language sought information in their native language or a combination of German and their native language. Participants mainly used videos or a combination of different formats such as video and text. They also reported searching for images or using voice assistants.

XSL•FO

Table . Examples of difficulties in using digital health technologies and strategies to overcome difficulties reported in focus group discussions.

Difficulties and strategies		Anchor examples
Difficulties		
	Use of digital device	• *If you can [work] with the computer, it's not difficult. […] I can with a smartphone. But with a laptop or computer I can't.* [ID02, task 1]
	Cookies	• *For me, cookie[s] were always [difficult] to accept. It was very, very difficult for me.* [ID03, task 3]
	Reading, writing and understanding German	• *For me, sometimes I have problem. Not all doctor or doctors can speak English, and my German [is] not so good. So sometimes when I look on the internet and sometimes my idea is: This doctor speaks English, or a little English? Or not? So sometimes is a bit difficult for me when I take a doctor from the internet.* [ID05, task 2] • *Internet not difficult, but sometimes we don't understand German. That's why [it's] a bit difficult for me. [...]* [ID04, task 2]
	Translation	• *And one problem is when first visiting, they give all the papers [to fill out]. And all is in German. And if someone can't understand everything, yes, once I [asked] the nurse, because I can't understand everything, my German is not good. But I can't help you, you have to do it on your own. And they don't have internet to translate. [...]* [ID05, task 2]
	Technical terms and foreign words	• *It wasn't difficult for me, but I don't understand the words, [for example] physiotherapy. The words. I don't know [if they] mean this or that, and I don't understand all of them. There's a lot of information, that's the problem.* [ID05, task 4]
	Searching and finding health information	• *It was a bit difficult this time. So you have to search and read at the same time. I also got a bit of help. [Interviewer: But what was more difficult?] So writing down this information. And to find it. [...]* [ID03, task 3]
	Uncertainty	• *So I can open it, I can see everything. But I'm afraid to order something. [...] That's why I don't dare to do that. [...]* [ID02, task 1]
Strategies used to overcome difficulties		

XSL•FO
RenderX

Difficulties and strategies		Anchor examples
	Seek support from family, friends, acquaintances, or local organizations	• *It's easy with me, but I'm a bit of a problem. I ask my colleague or my children, or. But now it's not difficult for me.* [ID02, task 2] • *[...] We can also enter, we have done a lot, because now Bremen is full of people from Ukraine and then you can enter directly into Google: Ukrainian-speaking doctors. Or we have another possibility and each of us, not just people from Ukraine, from Syria, from Persia, from Iran. We stick together, we share experiences. It's an organization called Bras. And when you go [there], you get in touch. Give your own details, then at a doctor's appointment, you get an interpreter.* [ID03, task 2]
	Try again	• *We'll try next day [laughs]. If I don't make it today, I'll try next day.* [ID02, task 2]
	Draw on own experiences or previous knowledge	• *In our home country our mother has a picture of fever, for fever goes down. That is a warm, a little warm, a little not warm water [Interviewer: Poultice?] Yes, every parent from Africa, for example Ghana, knows that if the child has a fever and you have no medication then you do that.* [ID05, task 3]
	Combine word and image search	• *Some words I don't understand well. I write on Google with German and then I see photos. Because I can't write in my own language. I write German and then photo comes up and I see photo and understand what it means.* [ID02, task 1]
	Use translation function	• *For me [it] is a bit difficult because I know many words in German - I don't understand it. So, I have to copy and then translate in Google Translator and sometimes the rest of the words from German it gives me wrong in English or different idea.* [ID05, task 4]
	Arrange a doctor's appointment by phone or in-person	• *When I'm looking for a doctor, I prefer to call, also because sometimes they want to have it that way. Then I make an appointment and at home I have a calendar of when I can go and then I do it.* [ID02, task 2]
	Personal contact to medical practice	• *You just go there and you have back pain or something. You don't have to call or google it first. It's much easier than going anywhere else.* [ID01, task 4]
Overarching discussion

Difficulties and strategies		Anchor examples
	Use of digital device	• *It's faster and easier. Computers, some people don't know how to use computers, they can't cope, so it's easier with a smartphone.* [ID03, overarching discussion]
	Language	• *I do it in German. Because I speak Arabic and Kurdish, but I can't read and write because I didn't go to school in my country, only in Germany. I do everything in German.* [ID01, overarching discussion] • *And if there's something I don't understand, then I go to the dictionary or translation, so you can learn. If you always switch to your own language, you'll never learn German.* [ID03, overarching discussion] • *For health, I don't go to German. It's important and you have to understand everything. That's why I just go to English.* [ID05, overarching discussion]
	Format	• *Yes, video, because text is difficult for me a bit, because I don't read well and it's difficult to understand, but videos are easy and I always watch and have to understand (which teachings).* [ID04, overarching discussion] • *It depends on what you need […]. Sometimes text is enough, sometimes video, sometimes like this.* [ID05, overarching discussion] • *[...] If I don't feel like writing, I speak into the microphone. Then I do that, then it works well, yes.* [ID02, task 2]
	Use of digital health technologies	• *I usually go straight away. [Interviewer: And why directly to the doctor?] Yes, it's easier. I call for an appointment and then I go.* [ID03, overarching discussion] • *So I'll check the Internet first. If that gives me the right answer. If not, I sometimes call my mother and ask her. If she has any ideas. If that doesn't help, I go to the doctor.* [ID01, overarching discussion] • *So I just search the Internet when I need offers for health. It's much easier for me. [...] If I'm looking for a medicine, for example painkillers, ointment for back pain, they show it straight away and which pharmacies are close to me.* [ID03, overarching discussion]

Stakeholder Workshop

In total, 15 stakeholders (n=8 from civil and public services, n=1 from local public authorities, and n=6 from community social service providers or groups) and 8 members of the study team (n=3 researchers and n=5 health mediators) took part in the 150-minute stakeholder workshop at our community office (ie, Leibniz Living Lab) in October 2023. Discussions highlighted the following: First, to be able to use digital health technologies, adults with low reading and writing skills need to be curious and open to learning and trying out new things. They also need to be patient, have a high tolerance for frustration, and be willing to ask for support. Second, basic (German) language comprehension and interpretation of figures and symbols are as necessary as the financial resources to purchase digital devices. Third, health information websites should contain little, simple, and easy-to-read language, be available in multiple languages, barrier-free (eg, by integrating a read-aloud function), and compatible with smartphones. In addition, they should have easy navigation with few "clicks" to the searched content, no time limits, and use of images, symbols, and videos. Fourth, health programs should be named rather than using nondescriptive project acronyms. Fifth, web-based health services should refer to local contacts or organizations (eg, in the city district) and instead of a chat function, persons with low reading and writing skills may benefit

XSL•FO
RenderX

from a talking chatbot. Finally, stakeholders who should be involved are health professionals, health and educational institutions, physicians, health insurance companies, authorities, and stakeholders with ongoing health projects. To enable access to stakeholders not only digitally but also via analog channels, these should have fixed structures on site (eg, an office in the city district). Relevant stakeholders should be connected regularly, for instance, through the establishment of a working group. In addition, stakeholders should be educated and trained to pass on knowledge about web-based health services to adults with low reading and writing skills.

Discussion

Principal Results

This study assessed digital health literacy in adults with low reading and writing skills, explored which digital tools they use, and how digital health literacy can be improved from a stakeholder's perspective. Most participants had a low to medium digital health literacy. Digital health literacy was particularly low among those with low reading and writing skills both in their native language and in German and among those without a formal schooling degree. Participants reported using mainly information-related digital health technologies such as health apps, health websites, or activity trackers. Use of digital health technologies was associated with higher digital health literacy. Language problems and lack of technical skills made it difficult for participants to search for web-based health information, so support for health-related questions is mainly sought from family members, friends, or health care providers (eg, physicians).

Comparison With Previous Work

Adults with low reading and writing skills use digital health technologies, but less frequently compared with other population groups. For instance, compared with an online survey of adults insured at a statutory health insurance company in Germany [31], adults with low reading and writing skills reported lower usage of health websites (30/96, 31% vs 755/1678, 45%) and online appointment scheduling (24/96, 25% vs 1359/1678, 81%). In addition, similar to results reported by Schaeffer et al [7], use of digital health technologies in adults with low reading and writing skills is associated with higher levels of digital health literacy.

Compared with 2 cross-sectional telephone surveys of internet users living in Germany, the digital health literacy level was much lower in our study (mean eHEALS score of 22 points vs 31 points in survey 1 and 30 points in survey 2) [4,24]. This is also evident when comparing the eHEALS scores of the included studies in the systematic review by Estrela and colleagues [6] with our study. The included studies reported mean eHEALS scores ranging from 25 to 33 points. However, the authors stated that higher eHEALS scores were observed in studies targeting medical staff and that were conducted online or via phone. Furthermore, 2 more recently published systematic reviews and meta-analyses support these results [32,33]. In the reviews, mean eHEALS scores between 26 and 33 points [32] and between 20 and 29 points [33] were reported. Both reviews included studies with diverse population groups such as adolescents, university students, adults (ie, general adult population, army personnel, healthy adults, and adults with chronic diseases), or older adults. However, none of the included studies targeted adults with low reading and writing skills.

As several studies have shown, digital health literacy is unevenly distributed across populations with vulnerable groups such as older adults, persons with low levels of education and income reporting particularly low levels of digital health literacy [4,6-9,32]. More than one-third of our participants stated that they had no formal education. Low education and functional literacy appear to be cumulative resulting in a particularly low digital health literacy in adults with low reading and writing skills. Klinger and colleagues [13] come to similar conclusions; persons with low literacy skills and German proficiency have greater difficulties processing health information. This underlines the need for multilingual information in simple language and multimedia materials such as videos which was also supported by results from our focus group discussions and the stakeholder workshop. Best practices for researchers that should be considered when working with persons with limited literacy are, for instance, the use of graphics and visualizations, the consideration of cultural differences in the interpretation of graphics and phrases, the critical review of the wording of written materials, and the consideration of the digital (health) literacy of the target group [34]. However, even if reliable health information in various formats is available on the internet such as on the website for reliable and understandable information about health of the German Federal Ministry of Health [35], such information may not be accessible for persons with low and reading and writing skills due to lacking technical skills. Stakeholders responsible for community health projects and who are contacted for health purposes can improve (web-based) health information accessibility for adults with low reading and writing skills. However, to ensure that stakeholders can provide reliable information to adults with low reading and writing skills, they need sufficiently high levels of digital health literacy.

Our results are particularly important in the light of the ongoing shift of health and social services toward digital information exchange, contact provisions, and service inquiries. Given the lower digital competencies of persons with low reading and writing skills, more focus is needed on the risk of leaving less literate groups behind or reducing their options for interaction via their preferred, often nondigital pathways.

Strengths and Limitations

To our knowledge, this is the first study that assessed digital health literacy and digital technology use of adults with low reading and writing skills in Germany. The recruitment strategy via health mediators and adult education centers was successful and more participants than initially planned took part in the survey. However, this study has several limitations. First, selection bias occurred as we were not able to recruit a sufficient number of German native speakers. In addition, more females than males participated in the survey and focus group discussions. Second, some participants had difficulty answering the survey questions, in particular the eHEALS items. For the eHEALS items, differences between the individual items were hardly recognizable for participants, even if the interview was

XSL•FO
RenderX

conducted in their native language. Cutoff scores for the eHEALS sum score were built using the cutoffs proposed by De Santis and colleagues [24]. However, it should be noted that there are no uniformly used cutoff scores reported in the literature. Third, even though sufficient knowledge of German was required for participating in the focus groups, the discussions sometimes proceeded sluggishly due to language problems, and some participants may not have spoken as openly as they would have done if the focus group discussion had been done in their native language. Fourth, analysis of the qualitative data (ie, coding, grouping, and summarizing) was conducted by one researcher and checked by a second researcher. This ensures objectivity, but the gold standard would be to analyze the data or a part of the data by 2 researchers independently. However, this was not possible due to limited resources. Fifth, there are further methodological weaknesses (eg, no sample size calculation was conducted) inherent in the exploratory design of the study. This study aimed to gain first insights into the digital health technology use and digital health literacy of adults with low reading and writing skills in Germany. Based on the results, a methodologically more sophisticated study can be conducted in which, for instance, an intervention to promote digital health literacy in adults with low reading and writing skills is evaluated in a randomized controlled trial.

Future Directions

The results of this study indicate a need for studies that develop and evaluate interventions to promote digital health literacy for adults with low reading and writing skills. In total, 1 scoping review and 1 meta-analysis investigated interventions to enhance digital health literacy [8,33], but these reviews focused on study populations of children, adolescents, older adults, or adults with diabetes, cardiovascular diseases, or other health conditions, and not adults with low reading and writing skills. Most of the included interventions focused on educational training to improve health-related knowledge and skills and were delivered in-person, via the internet (eg, app, website, and online platform), or through a combination of in-person and web-based sessions [8,33]. Our findings also suggest that interventions to improve digital health literacy in adults with low reading and writing skills should focus on improving technical skills and how to search for web-based health information (eg, where and how to find reliable health information on the internet). In addition, practical sessions should be included similar to the tasks used in our focus group discussions. Based on learnings from our study, interventions to improve digital health literacy should be delivered using a combination of in-person and web-based modalities (eg, videos). Furthermore, our research underscores the importance of considering the low digital health literacy level of adults with low reading and writing skills. In addition, 2 previous literature reviews pointed out that digital technologies so far have not considered digital health literacy levels of the target group [36,37] and, in particular, persons with low reading skills who may have different reading and design requirements and needs [36].

An additional future research direction is to further develop the tasks used in the focus group discussions to create a more objective tool for assessing digital health literacy. There are several instruments for measuring digital health literacy available [38]. Existing instruments are based on self-reports, and some instruments, such as the widely used eHEALS scale, only relate to searching for health information on the internet (Web 1.0) and do not include interactions on social platforms (Web 2.0) [28,38]. For the focus group discussions, some of van der Vaart and Drossaert's performance-based items [28] were adapted to gain more in-depth knowledge on the challenges adults with low reading and writing skills face while searching for health-related information on the internet. The tasks gave valuable insights into the digital health literacy of our participants and can serve as a basis for further developing existing DHLI.

Conclusions

This mixed methods study showed that while adults with low reading and writing use digital health technologies, many have low to medium digital health literacy and find it challenging to search for health information on the internet due to lack of technical skills and language problems. Tailored interventions to promote digital health literacy are needed to ensure that adults with low reading and writing skills are not further left behind.

Acknowledgments

We gratefully acknowledge the support of Leibniz ScienceCampus Digital Public Health (LSC DiPH) Bremen [39], which is jointly funded by the Leibniz Association (W4/2018, W72/2022), the Federal State of Bremen, Germany, and the Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Germany. LSC DiPH funded this study and did not influence its results. We would like to thank the health mediators (Patience Bonsu, Isil Dönmez, Elena Junck, Sabine Krliu, and Mariam Taraf) for recruiting participants, conducting the interviews, and supporting the focus group discussions and stakeholder workshop. We thank Finola Goepfert, BA, for entering the filled-out survey questionnaires into the software LimeSurvey. In addition, we would like to thank Meret Lakeberg, BA, for checking the coding, grouping, and summarizing of the focus group data. No generative AI was used for this manuscript.

Data Availability

All data generated and analyzed during the study are included in the manuscript and its supplementary materials. The data are not deposited in a public repository due to the sensitive nature of participant information.

Abstract

Background: Digital health competence is increasingly recognized as a core competence for health care professionals. A comprehensive evaluation of knowledge, skills, performance, values, and attitudes necessary to adapt to evolving digital health technologies is essential. DigiHealthCom (Digital Health Competence) is a well-established instrument designed to assess digital health competence across diverse health care professionals.

Objective: This study aimed to translate and culturally adapt DigiHealthCom into simplified Chinese (Mandarin) and verify its reliability and validity in assessing digital health competence of Chinese health care professionals.

Methods: DigiHealthCom was translated into Chinese following the guideline proposed by its original developers. The cultural adaptation involved expert review and cognitive interviewing. Internal consistency, test-retest reliability, content validity, convergent validity, discriminant validity, and factor structure were examined. Item analysis tested item discrimination, item correlation, and item homogeneity. Internal consistency was assessed using Cronbach α, and test-retest reliability was measured using the intraclass correlation coefficient. Content validity was assessed through both item and scale content validity indices. Convergent validity was measured by the Average Variance Extracted and Composite Reliability, while discriminant validity was measured by the heterotrait-monotrait ratio. A five-dimension model of DigiHealthCom was confirmed using confirmatory factor analysis.

Results: The finalized Chinese version of the DigiHealthCom was completed after addressing differences between the back-translations and the original version. No discrepancies affecting item clarity were reported during cognitive interviewing. The validation process involved 398 eligible health care professionals from 36 cities across 15 provinces in China, with 43 participants undergoing a retest after a 2-week interval. Critical ratio values (range 16.05 - 23.77, P<.001), item-total correlation coefficients (range 0.69 - 0.89), and Cronbach α if the item deleted (range 0.91 - 0.96) indicated satisfactory item discrimination, item correlation, and item homogeneity. Cronbach α for dimensions and the scale ranged from 0.94 to 0.98, indicating good internal consistency. The intraclass correlation coefficient was 0.90 (95% CI 0.81 - 0.95), indicating good test-retest reliability. Item content validity index ranged from 0.82 to 1.00, and the scale content validity index was 0.97, indicating satisfactory content validity. Convergent validity (average variance extracted: 0.60 - 0.79; composite reliability: 0.94 - 0.95) and divergent validity (heterotrait-monotrait ratio: 0.72 - 0.89) were satisfactory. Confirmatory factor analysis confirmed a well-fit five-dimension model (robust chi-square to df ratio=3.10, comparative fit index=0.91, Tucker-Lewis index=0.90, incremental fit index=0.91, root-mean-square error of approximation=0.07, standardized root-mean-square residual=0.05), with each item having a factor loading exceeding 0.40.

Conclusions: The Chinese version of DigiHealthCom has been proved to be reliable and valid. It is now available for assessing digital health competence among Chinese health care professionals. This assessment can be used to guide health care policy makers and educators in designing comprehensive and implementable educational programs and interventions.

Introduction

The World Health Organization (WHO) defines digital health as the field that involves the development and use of digital technologies to improve health outcomes [1]. In 2019, the WHO released the world's first guidelines for digital health interventions, outlining 10 ways to use digital health technologies to enhance health and primary services [2]. This concept extends beyond eHealth to include a wide array of smart devices and connected equipment, encompassing digital technologies such as the Internet of Things, big data, artificial intelligence, and robotics [2]. The release of these guidelines was followed by the Global Strategy for Digital Health (2020 - 2025), which emphasizes prioritized digital health strategies for global health care development [1]. China has incorporated measures for the development of a digitally healthy nation in the 14th Five-Year Plan [3]. With the global market projected to grow from US $211 billion in 2022 to US $809.2 billion by 2030 [4], digital health care is recognized as a rapidly expanding sector. Digital health has emerged as a significant trend in the evolution of global health care services. The digital transformation that the health care sector is currently undergoing is redefining the roles and responsibilities of health care professionals [5,6], creating an urgent need for digital health competence among them.

Given increasing prominence of digital health in global health care landscape, it is critical for health care professionals to possess sufficient digital health competence. Digital health competence is increasingly recognized as one of the core competencies for health care professionals, which would enable them to design and evaluate the impact of digital solutions on patient care and determine the best way to implement digital solutions in their work [7,8]. Although patients are becoming more accepting of and motivated to use digital health care services and tools, health care professionals face a digital skills shortage that impedes the adoption of digital solutions [9-11]. Inadequate digital health competence may lead to negative experiences and frustration with technology adoption among these professionals [12]. There is a strong association between health care professionals' digital health competence and their willingness to use such tools [13,14]. Studies have highlighted that the acceptance of digital health technologies by health care professionals significantly influences the adoption of digital solutions and emphasizes the critical role of digital health competence in ensuring patient safety [12,14]. Therefore, assessing digital health competence is essential to effectively providing digital health care solutions to the public.

Previous studies have attempted to explore digital health competence among health care professionals but have struggled to define it comprehensively due to the evolving nature of digital technologies [15]. Existing assessment tools primarily focus on informatics competence, digital health literacy, or skills related to the application of digital technologies. Examples include the Digital Health Literacy Instrument (DHLI, 2017) [16], the eHealth literacy questionnaire (eHLQ, 2018) [17], and the Nursing Digital Application Skill Scale (NDASS, 2024) [3]. The eHLQ is designed for eHealth user, especially individuals with low digital health literacy and those with chronic conditions [17]. The NDASS targets nurses' digital application skills in clinical settings [3]. Digital health literacy reflects users' knowledge and skills within their cultural, social, and institutional context [17]. Competence entails an integrative understanding of the knowledge, skills, performance, values, and attitudes essential for the effective execution of a given task [18]. Therefore, it is crucial to comprehensively evaluate the knowledge, skills, performance, and attitudes required for various health care professionals to adapt to the evolving digital health technologies.

Developed and validated among Finnish health care professionals in 2022, the DigiHealthCom (Digital Health Competence) instrument offers a more comprehensive scope than existing tools and is applicable to a wide range of health care professionals. In addition to assessing competence in using digital solutions and information and communication technology (ICT), it also explores previously unaddressed domains that reflect future requirements, such as acceptance of digital solutions, human-centered remote counseling, and ethical competence concerning digital solutions [19]. Furthermore, the instrument has been used to explore digital health competence profiles and associated factors in 817 health care professionals from 9 organizations in Finland [20]. It has been translated into 15 languages, and a large-scale international cross-sectional study on the digital health competence of health care professionals is currently in progress. Our team is part of this collaborative research effort. This study aimed to culturally adapt and validate the Chinese version of DigiHealthCom for Chinese health care professionals.

Methods

Study Design

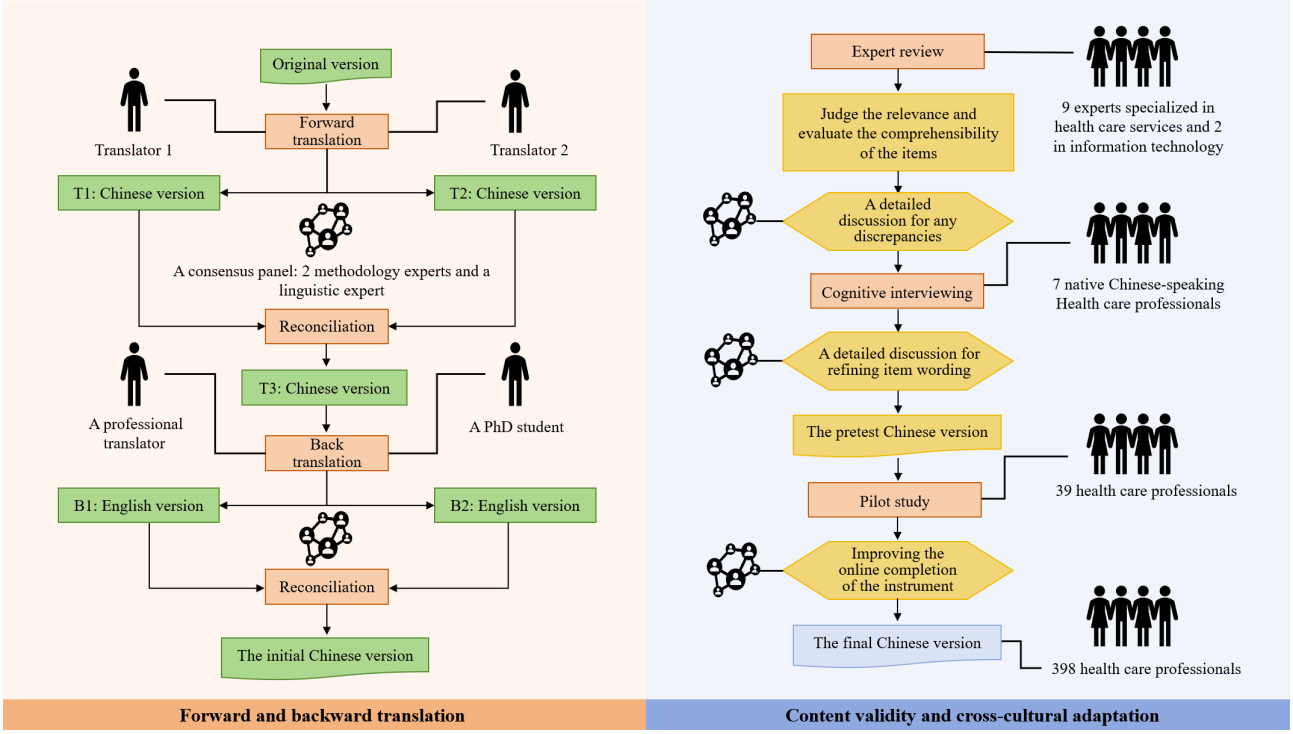
A cross-sectional study was conducted.

Participants

Participants were recruited between May 2023 and April 2024 via convenience sampling. Recruitment posters with QR codes were disseminated on social networks specific to health care professionals. In addition, health care professionals attending local academic conferences were invited to participate. The inclusion criteria for participants were (1) employment within a health care organization and (2) consent to participate. The exclusion criteria were (1) individuals who were retired or had less than 1 year of work experience; (2) health care students; (3) individuals who completed the questionnaire in less than 150 seconds, as this indicated random clicking; or (4) individuals who displayed erratic response patterns.

According to the thumb rule, the sample size should be 5 to 10 times the number of items. With an anticipated 10% rate of invalid responses, a minimum of 231 samples was necessary. Finally, a total of 398 cases were included in the study. To assess the test-retest reliability of the instrument, 43 participants who provided contact information completed the questionnaire again after a 2-week interval.

XSL•FO
RenderX



Instrument

The DigiHealthCom instrument comprises 5 domains, comprising a total of 42 items—competence in human-centered remote counseling (16 items), digital solutions as part of work (9 items), competence in ICT (5 items), competence in using and evaluating digital solutions (8 items), and ethical competence related to digital solutions (4 items). Each item was rated on a 4-point Likert scale (1=completely disagree, 2=partially disagree, 3=partially agree, and 4=completely agree). For each domain, a mean value of ≤2.49 indicated low competence, 2.50 - 3.49 indicated intermediate competence, and ≥3.50 indicated high competence [20]. DigiHealthCom has been validated among health care professionals across tertiary, primary, and private health care settings (n=817), demonstrating satisfactory internal consistency (Cronbach α=0.80 - 0.97) and content validity (item content validity index [I-CVI]: 0.77 - 1.00; S-CVI/Ave: 0.94) [19].

Translation and Cross-Cultural Adaptation

To ensure a high-quality Chinese translation of DigiHealthCom, a rigorous translation and cross-cultural adaptation process was followed [21]. Figure 1 illustrates the translation and cross-cultural adaptation process.

Figure 1. The translation and cross-cultural adaptation process of developing the Chinese version of the DigiHealthCom (Digital Health Competence) instrument.

Forward and Backward Translation

In total, 2 bilingual nursing professionals, who are native Chinese speakers (a nursing expert and a nursing graduate student), independently translated the English version of DigiHealthCom into Chinese, resulting in 2 forward translations (T1 and T2). A consensus panel reviewed these translations for conceptual equivalence, clarity, and comprehensibility, producing a reconciled version (T3). Subsequently, the T3 version was back-translated into English by a professional translator and a PhD student unfamiliar with the original version, both knowledgeable about Chinese and English-speaking cultures. The consensus panel reviewed and resolved discrepancies between the back-translations and the original version, finalizing the initial Chinese version. The consensus panel comprised 2 nursing researchers experienced in scale development and a linguistic expert.

Expert Review

To assess the content validity of the Chinese version of DigiHealthCom, 11 experts were invited to evaluate the relevance of its dimensions and items using a 4-point ordinal scale (1 [not relevant], 2 [weakly relevant], 3 [strongly relevant], and 4 [very relevant]). The expert panel consisted of 9 health care specialists and 2 IT experts. In addition, expert evaluated the comprehensibility of the items. The consensus panel, initially involved in the translation process, conducted a detailed discussion to resolve any potential discrepancies.

Cognitive Interviewing

Cognitive interviewing was used to evaluate the clarity and cultural suitability of the initial Chinese version. A total of 7 native Chinese speakers, including 2 doctors, 4 nurses, and 1 IT technician, were recruited. Participants were briefed on the study's objectives and methods before interviews, and their consent was obtained.

The first author, trained in qualitative research methods, conducted the interviews in a meeting room. Participants completed the Chinese version of DigiHealthCom independently and engaged in cognitive interviews. Interviewers evaluated whether participants found the items relevant to their condition and if they encountered any understanding difficulties. Field notes were taken. Modifications were deemed necessary if at

XSL•FO
RenderX

least 1 participant (1) found an item difficult to understand, (2) demonstrated mostly or completely inaccurate comprehension of an item, or (3) provided feedback indicating the need for improvements, especially regarding cultural relevance. The consensus panel determined whether to retain or alter item wording following expert review and cognitive interviewing. Discrepancies affecting item clarity were resolved to create the pretest version of the Chinese DigiHealthCom version. Specific item modifications were detailed in Table S1 in Multimedia Appendix 1.

Pilot Study

A pilot study was conducted with 39 health care professionals from a general hospital in Guangzhou, China. The pilot study confirmed that no further modifications were required. The final Chinese version of DigiHealthCom consists of 5 dimensions and 42 items.

Data Collection

Data were collected using the Wen Juan Xing (a Chinese web questionnaire platform) [22]. Respondents accessed the questionnaire by scanning a QR code or clicking a link, with 1 response allowed per IP address to prevent duplicates. The questionnaire platform performed completeness checks before submission. The Chinese version of DigiHealthCom was presented alongside a sociodemographic questionnaire. The questionnaire consisted of 2 pages and 73 items. Sex, age, education, service area, professional license, work experience, type of organization, and frequency of patient work were collected. Participants who voluntarily chose to provide contact information participated in a retest after a 2-week interval. An introduction outlined the study's purpose and provided questionnaire instructions.

Statistical Analysis

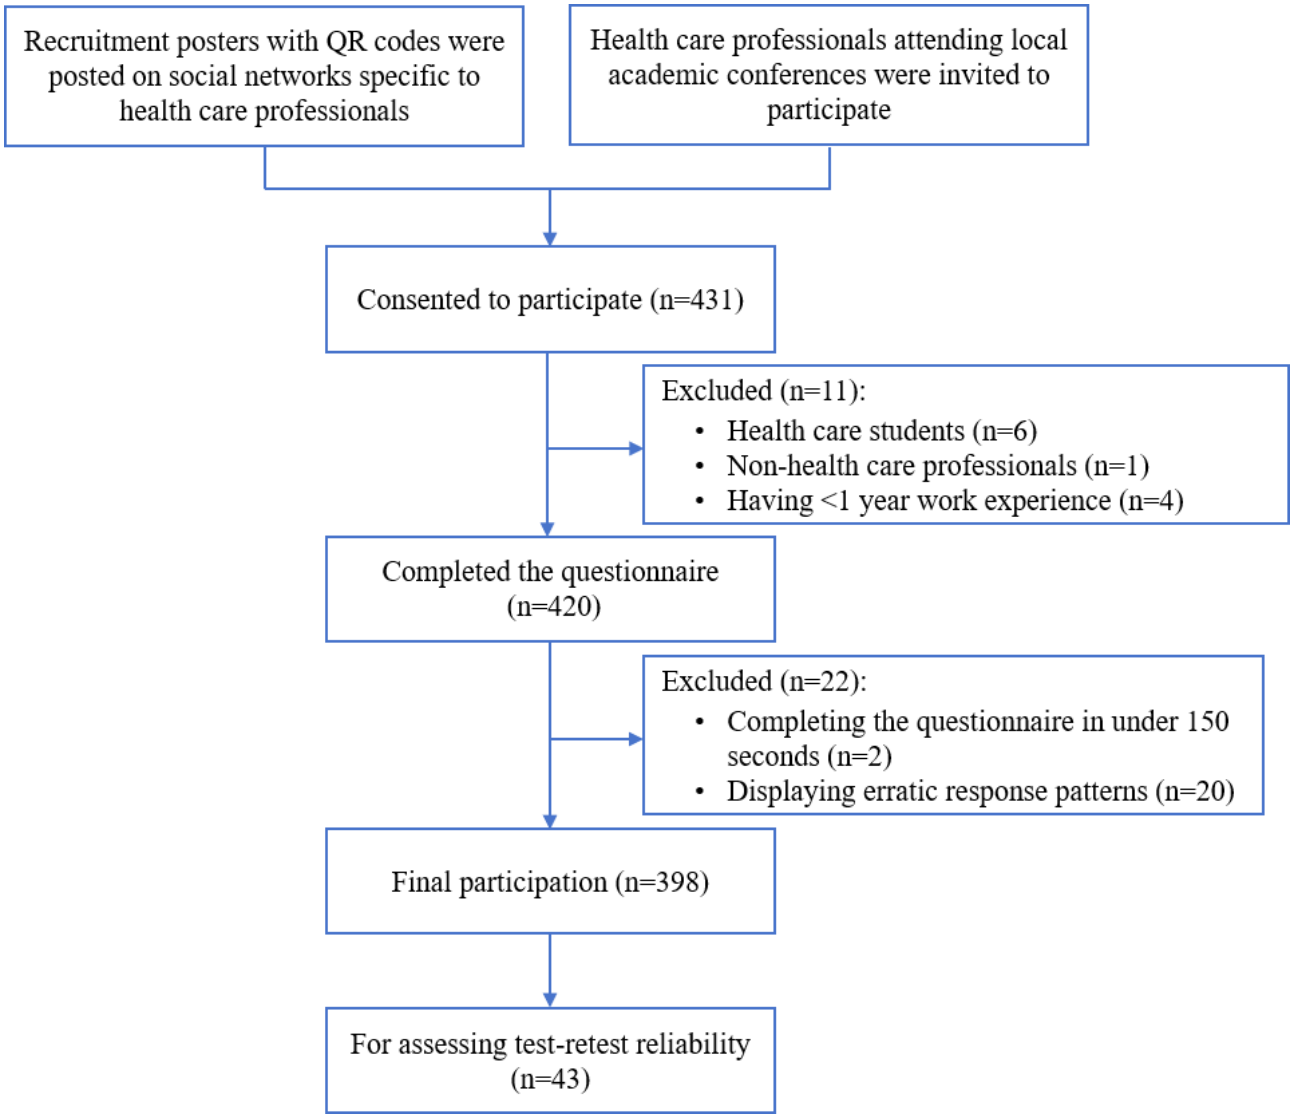
Item analysis was used to evaluate item discrimination, item correlation, and item homogeneity. For item discrimination, respondents were classified into high-score (top 27%) and low-score (bottom 27%) groups based on their total scores. An independent *t* test determined whether each item could significantly distinguish between these groups. Items with a critical ratio ($|t|$) less than 3.0 were considered for exclusion [23]. In addition, item homogeneity and item correlation were tested using Cronbach α if the item was deleted and corrected item-total correlation coefficient. Items with a corrected item-total correlation coefficient below 0.40 were considered for exclusion [23]. Cronbach α and Intraclass correlation coefficient (ICC) were used to assess the internal consistency and test-retest reliability of the instrument. A Cronbach α≥0.70 indicated good internal consistency, while ICC>0.70 indicated good time stability [23]. The I-CVI and the Scale CVI/Average (S-CVI/Ave) were used to evaluate content validity of the instrument. I-CVI≥0.78 and S-CVI/Ave≥0.90 indicate satisfactory content validity [24].

Construct validity was evaluated using confirmatory factor analysis (CFA) with a robust chi-square to df ratio (χ^2/df) less than 3, Tucker-Lewis Index (TLI), Incremental Fit Index (IFI), and Comparative Fit Index (CFI) greater than 0.90, and root-mean-square error of approximation (RMSEA) and standardized root-mean-square residual (SRMR) less than 0.08, indicating an acceptable data-model fit [25]. The average variance extracted (AVE) and composite reliability (CR) were used to assess convergent validity, with AVE greater than 0.50 and CR greater than 0.70 indicating good convergent validity [26]. Discriminant validity was performed using the heterotrait-monotrait ratio (HTMT), with a correlation matrix value <0.90 considered good [26].

Furthermore, participants were divided into 2 groups based on geographic location for the sensitivity analysis. The DigiHealthCom scores were compared to evaluate potential selection bias. The absence of a significant difference in digital health competence between the groups indicates that selection bias is unlikely in the study sample. Statistical analysis was conducted using IBM SPSS (version 27.0), IBM AMOS (version 29.0), and Smart PLS (Version 4.1.0.0; GmbH Corp). A *P* value of less than .05 was considered statistically significant.

Ethical Considerations

Ethical approval was obtained from the Ethical Committee at Nanfang Hospital, Southern Medical University, China (NFEC-2023 - 165). This research adhered to the principals of the Declaration of Helsinki. All participants provided informed consent and voluntarily completed the web questionnaire. Participants had the option to skip questions, review, and delete their responses. Participants had the right to withdraw from the survey at any time. Those who completed it received a random monetary reward ranging from CNY 2 to 5 (US $0.28 to 0.69). Participants' rights and researcher's contact information were provided on the first page of the web survey. Minimal sociodemographic was collected to maintain ethical standards. Participant information was kept confidential and anonymous. The CHERRIES (Checklist for Reporting Results of Internet E-Surveys; Checklist 1) was used to enhance the transparency of the study [27].



Results

Characteristics of the Participants

Initially, 431 participants were recruited for this study. Furthermore, 33 participants were subsequently excluded due to not meeting the inclusion criteria (n=7), having less than 1 year work experience (n=4), completing the questionnaire in under 150 seconds (n=2), and exhibiting erratic response patterns (n=20). Finally, 398 eligible health care professionals were included. Figure 2 illustrates the participant enrollment flowchart. The participants enrolled from 36 cities across 15 provinces, as identified by IP addresses. Among the participants, 249 (62.6%) were recruited from Guangzhou, a megacity in Guangdong province that contains 6125 registered medical facilities. As shown in Table 1, 364 (91.5%) participants were female, 386 (97%) worked in health care services, and 357 (89.7%) were nurses. The participants had an average of 13.7 (SD 9.4) years of work experience, with 281 (70.6%) working directly with patients for at least 5 days per week. Participant characteristics are summarized in Table 1.

[a]Including physiotherapist, paramedical technician, and pharmacist.

Results of Item Analysis

Item analysis showed a significant difference between high-score and low-score groups. The critical ratio values for all items were above 3.0 (range 16.05 - 23.77, P<.001; Table 2), indicating excellent item discrimination. All corrected item-total correlation coefficients exceeded 0.4 (Table 2). The Cronbach α if the item deleted (range 0.91 - 0.96) were acceptable (Table 2).

Item	Critical ratio	CITC[a]	CID[b]	I-CVI[c]
EC4	21.44	0.86	0.91	1

[a]CITC: corrected item-total correlation.

[b]CID: Cronbach α if item deleted.

[c]I-CVI: item content validity index.

[d]RC: human-centered remote counseling competence.

[e]DS: digital solutions as part of work.

[f]ICT: information and communication technology competence.

[g]UE: competence in using and evaluating digital solutions.

[h]EC: ethical competence related to digital solution.

Internal Consistency and Test-Retest Reliability

As shown in Table 3, internal consistency (Cronbach α=0.94 - 0.98) and test-retest reliability were good (ICC=0.90; 95% CI 0.81 - 0.95).

Table . Internal consistency and test-retest reliability of the Chinese version of the DigiHealthCom (Digital Health Competence).

Dimension	Cronbach α (N=398)	ICC[a] (N=43)	95% CI of ICC
RC[b]	0.96	0.80	0.63-0.89
DS[c]	0.96	0.90	0.81-0.95
ICT[d]	0.94	0.79	0.62-0.89
UE[e]	0.96	0.80	0.63-0.89
EC[f]	0.94	0.81	0.65-0.90
Total	0.98	0.90	0.81-0.95

[a]ICC: intraclass correlation coefficient.

[b]RC: human-centered remote counseling competence.

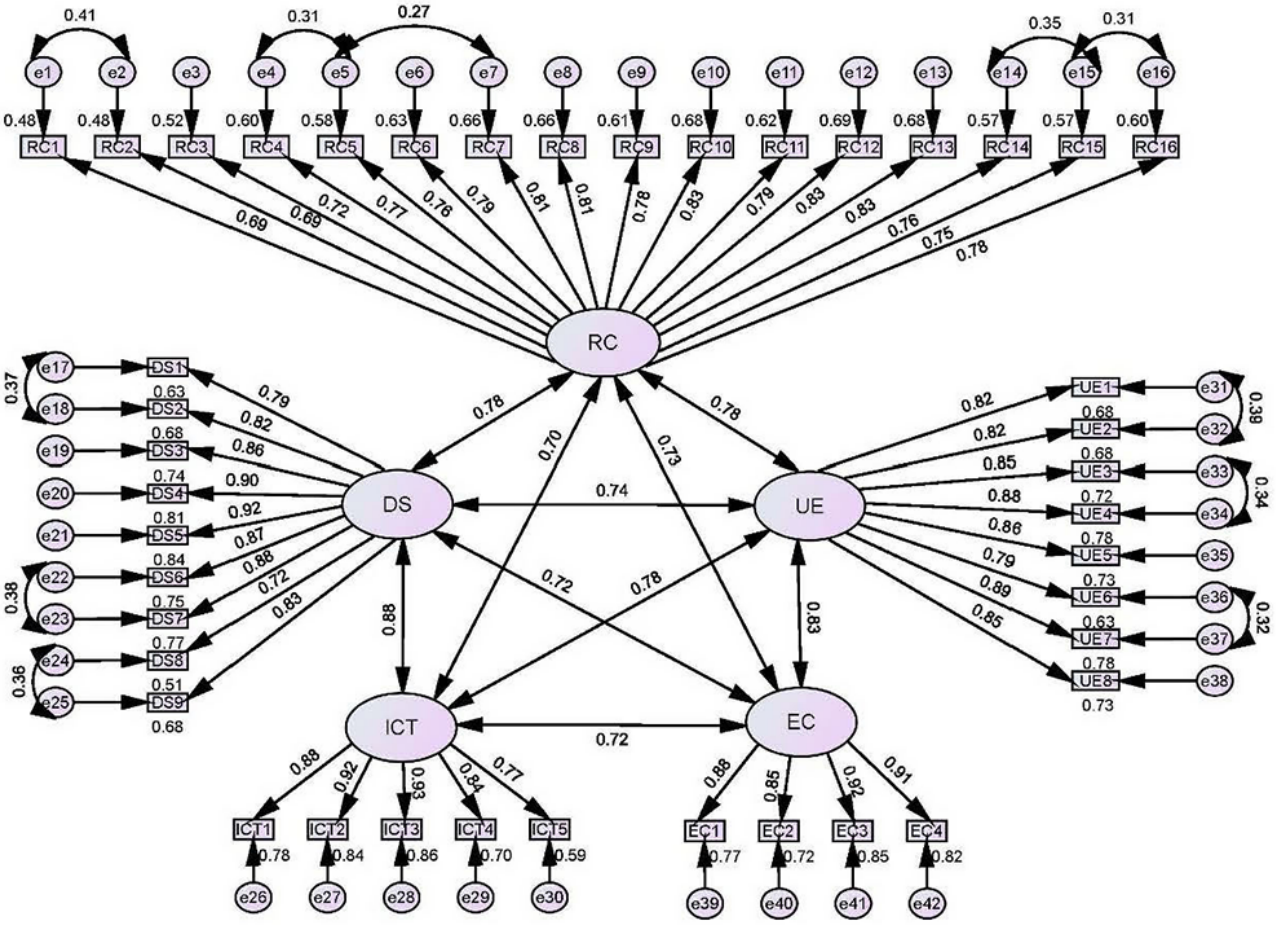
[c]DS: digital solutions as part of work.

[d]ICT: information and communication technology competence.

[e]UE: competence in using and evaluating digital solutions.

[f]EC: ethical competence related to digital solutions.

Content Validity



To test content validity, 11 experts evaluated the relevance of the items. The S-CVI/Ave for the instrument was 0.97, and the I-CVI ranged from 0.82 to 1.00 (Table 2), indicating satisfactory content validity.

Construct Validity

As illustrated in Figure 3, the results of CFA supported the 5-factors structure (digital solutions as part of work; ethical competence related to digital solutions; ICT competence; human-centered remote counselling competence; competence in using and evaluating digital solutions). The indices, including χ^2/df (3.10), CFI (0.91), TLI (0.90), IFI (0.91), RMSEA (0.07), and SRMR (0.05), indicated an acceptable model fit. The factor loadings of items ranged from 0.69 to 0.93 (Figure 3). The AVE values for each dimension exceeded 0.50 (range: 0.60 - 0.79), with the CR values >0.70 (range: 0.94 - 0.95), indicating excellent convergent validity. The HTMT values within the matrix were less than 0.90 (range: 0.72 - 0.89), indicating good divergent validity. These results collectively demonstrated satisfactory construct validity of the instrument.

XSL•FO
RenderX

Figure 3. The confirmatory factor model of the Chinese version of the DigiHealthCom (Digital Health Competence; N=398). DS: digital solutions as part of work; EC: ethical competence related to digital solutions; ICT: information and communication technology competence; RC: human-centered remote counselling competence; UE: competence in using and evaluating digital solutions.

Sensitivity Analysis

Participants were divided into 2 groups based on geographic location: Southern China and Northern and Western China. The DigiHealthCom scores were compared to evaluate potential selection bias. As illustrated in Table S3 in Multimedia Appendix 2, no significant difference was found in DigiHealthCom scores between the 2 groups (P>.05), indicating that selection bias is unlikely in the study sample.

Discussion

Principal Findings

In this study, we translated and culturally adapted the DigiHealthCom instrument into Chinese and assessed its reliability and validity among Chinese health care professionals. The Chinese version of DigiHealthCom demonstrated satisfactory internal consistency, test-retest reliability, content validity, and construct validity. To our knowledge, this study represents the first effort to validate a comprehensive Chinese tool for measuring digital health competence among health care professionals.

In this study, each item of the Chinese version of DigiHealthCom was translated and back-translated strictly following the dual direct-to-back translation model [21] to ensure alignment in semantic, conceptual, and content with the original English version. And then, we conducted expert review involving 11 experts in nursing and IT to examine content validity of the Chinese version. High content validity indices imply that the instrument provides a broad enough range of content to allow conclusions about the targeted construct. We also conducted cognitive interviewing and a pilot study to ensure its clarity and comprehensibility [28]. Issues related to semantic validation and understanding identified in the initial Chinese version were addressed after receiving feedback from the expert review and cognitive interviewing, leading to improvements such as clarifying complex terms and vague definitions. Item analysis revealed good differentiation and high correlations between the items in this study. Furthermore, this instrument underwent rigorous testing for internal consistency, test-retest reliability, and construct validity, exhibiting excellent internal consistency, time stability, and construct validity, resonating with the original study [19]. The types of reliability and validity assessed in this study represent essential psychometric properties for a measurement instrument.

Discrepancies between existing instruments largely stem from differing conceptual frameworks. The DHLI measures 7 individual skills: operation, navigation, information searching, evaluating reliability, determining relevance, adding self-generated content, and protecting privacy [16]. The eHLQ comprises 7 dimensions, addressing users' attributes, their interaction with technologies, and their experience with systems

XSL•FO
RenderX

[17]. Our CFA findings confirm a 5-factor structure, consistent with the exploratory factor analysis findings of the initial study [19]. Beyond competence in using and evaluating digital solutions and ICTs, the DigiHealthCom instrument addresses additional essential domains that were previously unaddressed, that is acceptance of digital solutions, human-centered remote counseling, digital interaction skills with patients and interprofessional teams, and ethical competence related to digital solutions [19]. Notably, acceptance of digital solutions significantly influences health care professionals' adoption of digital solutions [13,14]. Competence in person-centered remote consultations is crucial for fostering patient engagement and improving accessibility to equitable digital health services [8]. Furthermore, proficient digital interaction skills facilitate effective coordination in digital settings, thereby supporting decision-making and optimizing treatment plans [8]. As digital solutions become more prevalent, attention to data privacy and information security has intensified [29,30]. Ethical competence related to digital solutions ensures appropriate management of patient information, fostering trust in digital health technologies and enhancing the safety of digital health services [20,31]. These domains provide a unified theoretical framework for comprehensively measuring digital health competencies among various professionals [8,9,19], which are essential for delivering high-quality digital health services to meet future demands.

The Finnish health care system is renowned for its universality, robust public funding, and centralized digital infrastructure [32]. Regional variations exist in Finland; for example, northern districts have fewer professionals specializing in remote counseling and the integration of digital solutions compared with southern areas [20,33]. Strategies have been implemented to enhance health care professionals' digital health competence and improve education related to health care digitalization, including technology to support client engagement, digital services integrated into nursing work, and considerations of safety and ethics in the digital environment [20,34]. In contrast, China experiences regional disparities in digital health infrastructure and access to digital health services, especially in rural areas, despite the rapid growth of digital health services [35]. In addition, system compatibility across hospitals remains an unsolved issue [35]. These factors may influence the development of digital health competence among health care professionals. A cross-sectional study conducted in a central Chinese province reported that 49.9% (1690/3386) of clinical nurses demonstrate low telehealth readiness [36]. Consequently, evaluating, addressing, and reducing regional disparities in health care professionals' digital health competence is vital for promoting equity in health care service provision. Validating a comprehensive digital health competence measurement instrument for health care professionals is imperative to address challenges posed by diverse health care environments, such as China's. The Chinese version of DigiHealthCom is now ready for application in a wide range of settings and various health care professionals. Researchers, educators, health care providers, and policy makers can use it to evaluate digital health competence among diverse health care professionals, and develop digital health training curricula and policies based on the assessment.

Limitations

This study acknowledges several limitations. First, the primary participants were nurses. Future research should involve a broader spectrum of health care professionals. Second, although recruited from diverse health care institutions, the participants mainly came from southern China, which may introduce selection bias due to regional disparities in digital health infrastructure. To address this, participants were divided into 2 groups (Southern China versus Northern and Western China) for sensitivity analysis, and their DigiHealthCom scores were compared. We did not find significant differences in digital health competence between the 2 groups, indicating that selection bias is unlikely in the study sample. Future studies could benefit from employing a stratified sampling method. Third, the absence of a standardized method for assessing digital health competence among health care professionals hindered the evaluation of criterion validity. Assessments of digital health competence predominantly rely on subjective self-reports, which might be susceptible to response bias. However, relying exclusively on performance-based assessments or other objective measures to evaluate competence also presents challenges. Therefore, using a more holistic combination of methods could offer a viable solution. Future research should consider larger sample sizes and multicenter external evaluations to address these limitations.

Conclusions

In conclusion, we have successfully translated, culturally adapted, and validated DigiHealthCom for Chinese health care professionals. Our findings demonstrate that the Chinese version of DigiHealthCom is a reliable and valid instrument for assessing digital health competence among these health care professionals.

Acknowledgments

The authors would like to acknowledge all the participants who participated in this study; in particular, Dr Donglan Ling for help with the translation process. XL is supported by the National Natural Science Foundation of China (grant 82171202). The funding agents had no role in the study design; collection, analysis, and interpretation of the data; writing of the manuscript; or decision to submit the paper for publication.

Data Availability

The dataset collected in this study is available from the corresponding author on reasonable request.

Abstract

Background: The accuracy of the *ICD-10-CM* (*International Classification of Diseases, Tenth Revision, Clinical Modification*) procedure coding system (PCS) is crucial for generating correct Taiwan diagnosis-related groups (DRGs), as coding errors can lead to financial losses for hospitals.

Objective: The study aimed to determine the consistency between an artificial intelligence (AI)-assisted coding module and manual coding, as well as to identify clinical specialties suitable for implementing the developed AI-assisted coding module.

Methods: This study examined the AI-assisted coding module from the perspective of health care professionals. The research period started in February 2023. The study excluded cases outside of Taiwan DRGs, those with incomplete medical records, and cases with Taiwan DRG disposals *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision)* PCS. Data collection was conducted through retrospective medical record review. The AI-assisted module was constructed using a hierarchical attention network. The verification of the Taiwan DRGs results from the AI-assisted coding model focused on the major diagnostic categories (MDCs). Statistical computations were conducted using SPSS version 19. Research variables consisted of categorical variables represented by MDC, and continuous variables were represented by the relative weight of Taiwan DRGs.

Results: A total of 2632 discharge records meeting the research criteria were collected from February to April 2023. In terms of inferential statistics, κ statistics were used for MDC analysis. The infectious and parasitic diseases MDC, as well as the respiratory diseases MDC had κ values exceeding 0.8. Clinical inpatient specialties were statistically analyzed using the Wilcoxon signed rank test. There was not a difference in coding results between the 23 clinical departments, such as the Division of Cardiology, the Division of Nephrology, and the Department of Urology.

Conclusions: For human coders, with the assistance of the *ICD-10-CM* AI-assisted coding system, work time is reduced. Additionally, strengthening knowledge in clinical documentation enables human coders to maximize their role. This positions them to become clinical documentation experts, preparing them for further career development. Future research will apply the same method to validate the *ICD-10* AI-assisted coding module.

diagnosis-related group; artificial intelligence coding; International Classification of Diseases, Tenth Revision, Clinical Modification; ICD-10-CM; coding professionals

Introduction

The *International Statistical Classification of Diseases* (*ICD*) system was set up by the World Health Organization (WHO) for the purpose of tracking diseases globally. Over the past several decades, the WHO has made significant changes to both content and structure. It accompanies a new scientific understanding of diseases and new structures for organizing *ICD* codes to accommodate enhanced use and extensibility [1]. The WHO introduced the *ICD* in 1948, and it is a universal language used to categorize diseases or causes of death. The use of it is attributed to health care–related units in 194 countries and is generated by professional coders based on discharge records, with countries adjusting the *ICD* to their circumstances. In 2016, Taiwan adopted the international trend of switching from *ICD-9-CM* (*International Classification of Diseases, Ninth Revision, Clinical Modification*) to *ICD-10-CM* (*International Classification of Diseases, Tenth Revision, Clinical Modification*) procedure coding system (PCS) for coding hospital patient diagnoses, procedures, analysis and reimbursement. The National Health Insurance Administration (NHIA) under the Ministry of Health and Welfare has adopted the 2014 edition of *ICD-10-CM* PCS, with approximately 71,900 diagnosis codes and 78,500 procedure codes.

The use of the *ICD-10-CM* PCS involves coding and classifying morbidity data from health records, reimbursement claims, and administrative databases. Improving health care quality, monitoring public health, and conducting research are all benefits of the *ICD-10-CM* PCS in Taiwan and involves converting the physician's discharge diagnosis into *ICD-10-CM* codes by following the primary diagnosis selection principle announced by the NHIA. The diagnosis-related group (DRG) provides information such as health insurance reimbursement, relative weight, presence of comorbidities, and complications for the current hospitalization.

The accuracy of *ICD-10-CM* PCS coding is crucial for generating accurate Taiwan DRGs, as coding errors can lead to financial losses for hospitals [2,3]. According to the coding principles set forth by the NHIA and the Taiwan Society of Medical Records Management, coding is based on the inpatient and emergency room records of patients. In the past, this task was undertaken by trained and certified clinical coding professionals (referred to as coding professionals hereafter), but with the rapid advances of medical technology, the rules of disease classification have also evolved, and coding professionals must regularly accumulate relevant training hours to update their disease classification skills [4].

In recent years, artificial intelligence (AI) and natural language processing have shown exciting potential in the field of automatic clinical coding. In 2021, the disease coding scales in the United States were worth approximately 18 billion US dollars. Several technology companies in the United States have developed AI-assisted coding systems, and scholars believe that interdisciplinary collaboration and feedback from clinical coding professionals are essential to further refine the modules [5,6]. Research on AI-assisted coding consistently conclude that it improves quality and reduces error rates while saving costs [7,8]. AI-assisted *ICD-10-CM* PCS coding can be considered as a text classification task within the field of machine learning [9]. In recent years, studies in the machine learning text classification field have predominantly proposed using deep learning–based neural networks [10]. Many research papers have focused on AI assistance in *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision)* coding [11-14], but few have examined the results of coding implementation from the perspective of disease classification personnel. The development and validation process of the AI-assisted coding model requires the involvement and feedback of clinical coders to enhance accuracy and correctness, aligning with user needs [15].

In Taiwan, several hospitals have also ventured into the development of AI-assisted coding for disease classification. However, due to variations in physicians' documentation of medical records across different hospitals, the AI-assisted coding systems developed are not universally applicable [11], necessitating the development and validation of customized AI-assisted coding systems. Medical coding personnel must review the discharge records meticulously and then translate the discharge diagnoses and procedures (interventions) recorded in the medical records into *ICD-10* codes. In the past, the most significant factor contributing to coding errors was handwritten medical records by physicians, which were difficult to decipher or included abbreviations, leading to mistakes [16]. In recent years, most medical centers in Taiwan have adopted electronic health records, resulting in a significant reduction in coding errors caused by handwritten records. Clinical coding personnel also encounter various pressures, including the need to accomplish all inpatient coding tasks within specified deadlines, optimize Taiwan DRGs assignment coding, enhance and maintain coding reliability and validity, and engage in discussions with clinical physicians regarding the content of medical record writing.

Recently, the global trend in AI coding has been on the rise [11,13,17-19]. In this study, we have developed an exclusive *ICD-10-CM* AI-assisted coding module. Coding professionals took part in the research and offered suggestions to improve the efficiency of coding operations. Consequently, this study focuses primarily on the following two research aims: (1) to verify the consistency between the AI-assistant coding module and a coding professional in encoding, based on the MDC results in Taiwan DRGs and (2) to find the clinical departments within the medical center that can benefit from using the developed AI-assisted coding module.

Methods

Data Description

This study used a total of 136,841 unstructured discharge summaries of patients who were hospitalized, recorded in Kaohsiung Medical University Chung-Ho Memorial Hospital from April 1, 2019, to December 31, 2020, as the primary data source. Textbox 1 displays an example of a discharge summary from the Kaohsiung Medical University Chung-Ho Memorial Hospital.

Textbox 1. Example discharge summary.

Chief complaint:

Abdominal pain for 1 day

Impression on admission:

Sepsis, focus on retroperitoneal abscess

Discharge diagnosis:

Sepsis, focus on retroperitoneal abscess due to surgical site infection

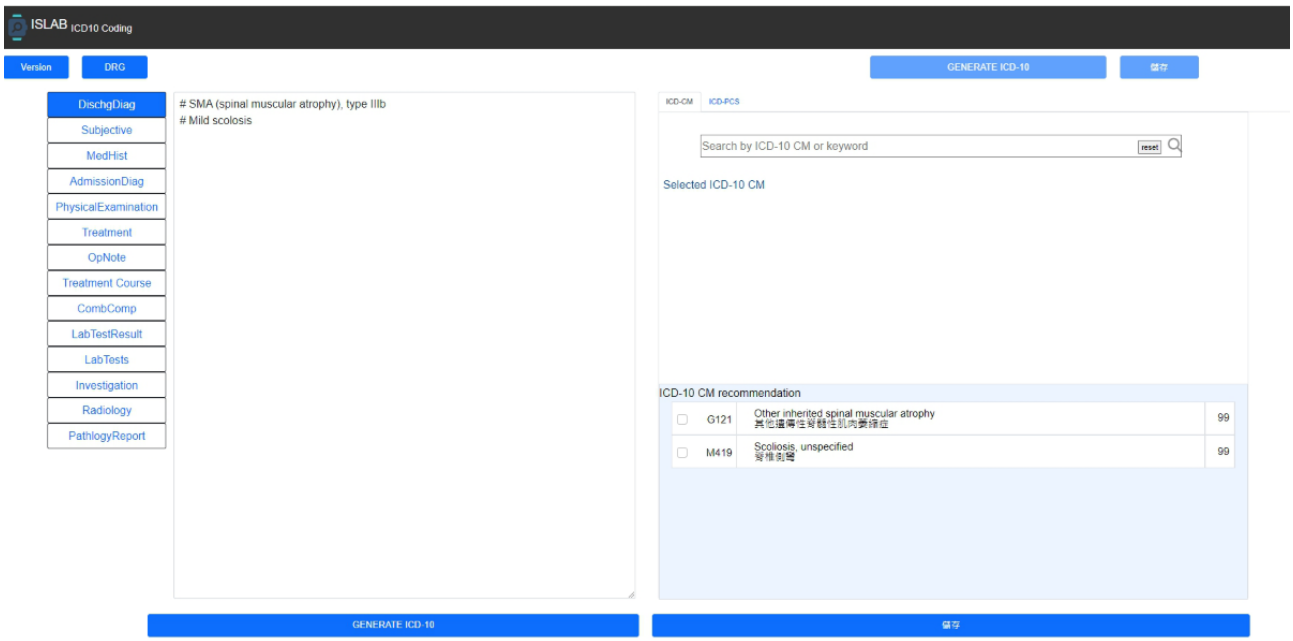
History on admission:

This time, according to the patient's statement, he suffered from recurrent abdominal dull pain after discharge. The pain was serious by jejunostomy feeding, and there was no relieving factor. The pain suddenly progressed...

This study verified the AI-assisted coding from the perspective of coding professionals. Since the AI-assisted coding system was introduced in the medical center in February 2023, the study period began in February 2023. The subjects of this study were selected based on the following exclusion criteria: non–Taiwan DRGs cases, cases with procedures (*ICD-10* PCS) in Taiwan DRGs, and cases with incomplete medical records. According to the study conditions, there were approximately 700 to 1000 cases per month. The coding by both the AI-assisted coding module and coding professionals were based on the electronic discharge summaries of a certain medical center each month.

Research Design

After each data entry was encoded by the AI-assisted coding module and verified by a coding professional, it was transmitted to a certain university's database. The results of both the AI-assisted coding and coding professional were compared using an Excel (Microsoft) file. Following the linkage to the NHIA's DRG calculation software, separate datasets for Taiwan DRGs were obtained for both the AI-assisted coding and coding personnel, with the consistency of the primary diagnosis coding between these two groups being examined. In cases of discrepancies, the medical records were scrutinized again by the coding professional to determine if the AI-assisted coding results met the criteria for primary coding as per the coding professional; the consistency results of the Taiwan DRGs data for both the AI-assisted coding and coding professional were adjusted accordingly.



AI-Assisted Coding Construction Process

The AI-assisted *ICD-10-CM* coding system was developed by CSL, CHL, and BTS, based on approximately 110,000 discharge summaries collected from April 1, 2019 to December 31, 2020, in a medical center. The deidentified summary data were processed by segmenting sentences and filtering out meaningless delimiters and prefix symbols (eg, # or "") by using a clinical natural language processing tool [20]. The data were categorized into 21 groups based on the first 3 codes of the *ICD-10-CM*, and models were built using bidirectional encoder representations from transformers (BERTs) [21] and hierarchical attention networks (HANs) [22]. The results favored HANs, leading to the decision to adopt the HAN module. The precision, recall, and F1 scores of the developed HAN model were 0.55, 0.82, and 0.66, respectively. For the top 50 most frequent codes, the F1 score of the developed HAN model was 0.818.

Aside from module modeling, another time-consuming task was the design of the user interface for the coding professionals, as it needed to present discharge summaries, laboratory data, and imaging reports, as well as the *ICD-10-CM* codes predicted by the AI-assisted coding module. Coding professionals were actively involved in providing feedback during the interface design process. Figure 1 provides an illustration of the designed user interface, which provided suggestions automatic *ICD-10-CM* recommendation and fields for coding professionals to input the final codes. The developed AI-coding system was integrated into a medical center's hospital information systems in November 2022 and operated in February 2023.

Ethical Considerations

This study was approved by Kaohsiung Medical University Ching-Ho Memorial Hospital (institutional review boards number: KMUHIRB-E(II)-20230214). The institutional review board approval covered secondary analysis without additional consent. Data was anonymized or deidentified. There was not any compensation provided to participants.

Statistical Analysis

The study involved an analysis incorporating descriptive statistics for exploration, as well as inferential statistics for investigating MDCs and relative weight. Statistical computations were conducted using SPSS version 19. Research variables consisted of categorical variables represented by MDC, and continuous variables were represented by the relative weight of Taiwan DRGs.

Results

Distribution of *ICD-10* Codes

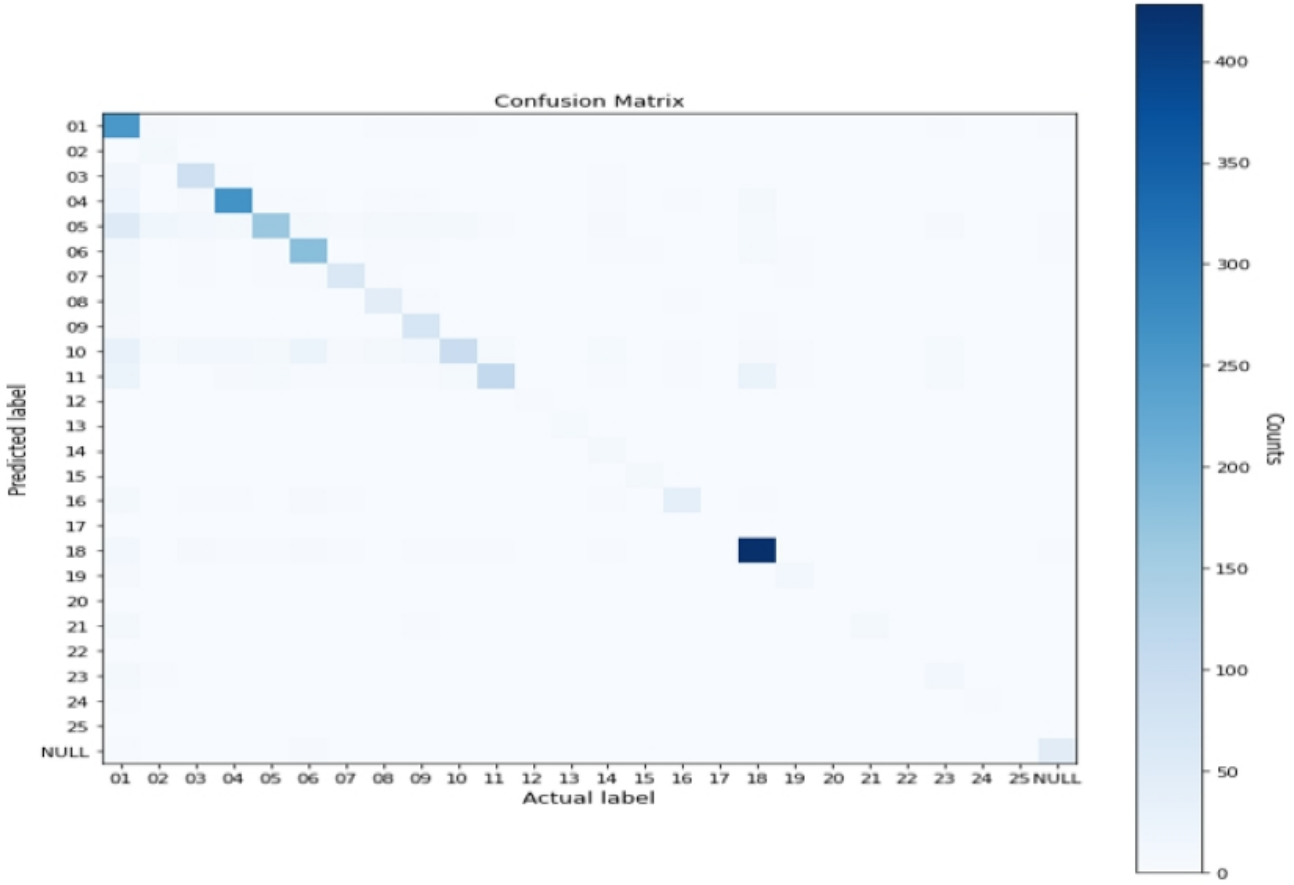
The distribution of the *ICD-10* codes seen in the collected training dataset is shown in Multimedia Appendix 1. The first digit of the *ICD-10-CM* code consisted of English letters, so the alphabetical characters on the horizontal axis of the log data were the first digit of the *ICD-10-CM* code, showing diseases pertaining to different systems. According to Multimedia Appendix 1, data starting with codes C, E, and I in *ICD-10-CM* had the highest volume, with C representing neoplastic diseases; E for endocrinal, nutritional, and metabolic diseases; and I for diseases of the circulatory system. These were the body systems with the highest learning volumes for the AI-assisted coding module.

Descriptive Statistics

In the period from February to April 2023, a total of 15,756 discharges were recorded. Excluding cases with interventions, non–Taiwan DRG cases, and cases with incomplete medical records, there was a total of 2632 cases. The primary diagnosis was the key factor in deciding the main disease category, while secondary diagnoses only affected the distribution of Taiwan DRGs within the same primary disease category. According to disease classification rules, the primary diagnosis was based on the reason for the patient's admission, but only one disease could be selected as the primary diagnosis. If multiple diseases were treated during admission, selecting any one of them as the primary diagnosis was not considered an error. Therefore, the coding professional (author ATL) manually examined the discharged cases' notes to categorize the output of the AI-assisted system into one of the following categories. The results are shown in Table 1.

Table . Frequency distribution and percentage analysis of primary diagnoses.

Variable	Month of case, n (%)		
	February (n=748)	March (n=991)	April (n=893)
No primary diagnosis	181 (24.2)	277 (28)	285 (31.9)
Incorrect secondary diagnosis with a primary diagnosis	462 (61.8)	477 (48.1)	369 (41.3)
All correct	79 (10.6)	181 (18.3)	177 (19.8)
All incorrect	26 (3.5)	56 (5.7)	62 (7)



XSL•FO
RenderX

Operational definitions were as follows:

- No primary diagnosis: in comparison to the coding professional, a single hospitalization's predicted diagnosis codes did not include a primary diagnosis.
- Incorrect secondary diagnosis with a primary diagnosis: in comparison to the coding professional, a single hospitalization's predicted diagnosis codes included a primary diagnosis, but there was at least 1 error in the secondary diagnoses.
- All correct: all predicted diagnosis codes for a single hospitalization perfectly aligned with those given by the coding professional.
- All incorrect: in comparison to the disease classification personnel, none of the predicted diagnosis codes in a single hospitalization were the same.

In Figure 2, we analyzed the agreement of MDC classification between the AI-assisted coding module and the coding professional through a heat map analysis. The vertical and horizontal axes in Figure 2 represent MDCs coded by the AI-assisted coding module and MDCs coded by coding professionals, respectively. The intensity of color in the figure indicated a higher number of agreed MDCs between the AI-assisted coding module and professionals. As shown in Figure 2, MDC 1 (diseases and disorders of the nervous system), MDC 4 (diseases and disorders of the respiratory system), and MDC 18 (infectious and parasitic diseases and disorders) had the highest agreements.

Figure 2. MDC heat map analysis between AI-coding module and professionals.

The κ Coefficient Test

Furthermore, we assessed the MDC agreement between the AI coding module and coding professionals using the κ coefficient test. The κ values were broadly categorized into 5 groups based on various levels of agreement: extremely low agreement (0.00-0.20), fair agreement (0.21-0.40), moderate agreement (0.41-0.60), high agreement (0.61-0.80), and almost perfect agreement (0.81-1.0).

When analyzing the cumulative data for February to April 2023 (Table 2), the MDCs with the highest consistency were MDC 4 (diseases and disorders of the respiratory system) and MDC 18 (infectious and parasitic diseases and disorders), followed by MDC 1 (diseases and disorders of the nervous system), MDC 3 (diseases and disorders of the ear, nose, mouth and throat), MDC 6 (diseases and disorders of the digestive system), MDC 7 (diseases and disorders of the hepatobiliary system and pancreas), MDC 9 (diseases and disorders of the skin, subcutaneous tissue and breast), MDC 11 (diseases and disorders of the kidney and urinary tract), MDC 13 (diseases and disorders of the female reproductive system), MDC 15 (newborn and other neonates), and MDC 16 (diseases and disorders of the blood and blood forming organs and immunological disorders).

Inferential Statistical Analysis: Wilcoxon Signed Rank Test

The κ coefficient test was used for a broad-scale analysis of MDCs. However, under the same MDC, it was possible to further classify the data into numerous Taiwan DRGs, with each having its own code and relative weight. Even within the same MDC, this might result in different Taiwan DRGs. Furthermore, some diseases could be treated across departments. Therefore, for the statistical analysis of relative weight, we first conducted a normality analysis of the relative weights obtained from both AI-assisted coding and coding professionals. The statistical results based on the Kolmogorov-Smirnov analysis yielded a significance level of less than .05, showing a nonnormal distribution. Given that the research sample consisted of paired data, the nonparametric Wilcoxon signed rank test was used to analyze whether there were differences in relative weight between AI-assisted coding and coder-assigned coding; the null hypothesis assumed that there was no difference in relative weight between AI-assisted coding and coder-assigned coding.

The Wilcoxon signed rank test, with clinical departments as the unit of analysis, identified differences in relative weight in the following 12 departments: Division of Endocrinology and Metabolism, Division of Hematology and Oncology, Division of General Internal Medicine, Division of Geriatrics and Gerontology, Division of Trauma, Division of Neurosurgery, Division of Cardiovascular Surgery, Division of General and Digestive Surgery, Division of Pediatric Neurology, Department of Otorhinolaryngology, Department of Neurology, and Department of Rehabilitation Medicine. As shown in Table 3, the overall statistical result with a *P* value of <.001 showed that there were still differences between AI-assisted coding and coder-assigned coding in this study.

[a]AI: artificial intelligence.

Discussion

Principal Results

For clinical coders, it is clear from the MDCs that AI-assisted coding can serve as a reference for disease systems. However, hospital administrators may require detailed statistical results from clinical departments to make judgments. In the individual clinical department analysis based on the Wilcoxon signed rank test, the Division of General Internal Medicine, the Department of Neurology, and the Division of Neurosurgery had the highest number of cases studied, but the statistical results were inconsistent with coder-assigned coding. However, in the κ coefficient test, the statistical results for the nervous system MDC were highly consistent. This is because patients admitted to the Department of Neurology and Neurosurgery do not exclusively have neurological conditions. According to further analysis shown in Table 4, the AI model's predictions for neurological system diseases were still highly consistent with those of the disease classification staff in the neurology department. However, respiratory and urinary system conditions have affected the AI model's coding performance for neurology and account for the discrepancies seen in both the Wilcoxon signed rank test and the κ coefficient test.

XSL•FO
RenderX

In the circulatory system, the statistical results for the Division of Cardiology and Division of Cardiovascular Surgery in the Wilcoxon signed rank test were also markedly different. Upon closer examination of the data from the exploratory study, it was discovered that in the Division of Cardiovascular Surgery, half of the cases helped by AI-coding modules did not have the main diagnosis coded, which could be attributed to differences in how physicians document medical records. For example, after carefully reviewing the 24 cases of data collected by the Cardiac Surgery Department, it was found that 12 Taiwan DRGs were inconsistent. All of these did not follow the disease classification coding rules and did not include the main diagnosis (Table 5).

Table . Discussion on writing medical records in the Division of Cardiovascular Surgery.

Number	Excerpt of discharge diagnosis	Cause analysis
Case 1	"Chest tightness for a week Acute heart failure with reduced ejection fraction * 2023/04/24 Thallium 201 (Stress SPECT (single-photon emission computed tomography) imaging): mild myocardial ischemia in inferolateral wall of LV (left ventricle)"	The examination results were attached to the discharge diagnosis, leading to coding confusion.
Case 2	"Type A aortic dissection - post TEVAR (Thoracic endovascular aneurysm repair)+ stenting grafts in the ascending to descending aorta, left common carotid and subcalvian arteries on 2023/02/07 # Suspect gastroparesis related to relative gastric malperfusion"	The discharge diagnosis showed coding confusion with previously treated conditions.
Case 3	"Type B dissection, intramural hemorrhage - 2023/03/10 Chest CT (computed tomography) angiography:1) Suspect intramural hematoma in the descending aorta.2) Suspect thrombus formation in the bilateral femoral arteries.3) Suspect a thrombosed aneurysm in the right internal iliac artery"	The anatomical location was not clearly documented, making correct coding impossible.

Furthermore, in MDC 14 (pregnancy, childbirth, and puerperium) and MDC 21 (injuries, poisonings, and toxic effects of drugs), there are specific coding rules. Clinical coders need to synthesize the entire medical record information and apply the coding rules, which could result in diagnoses different from those presented in the discharge summary.

Limitations

The AI-coding module was trained on inpatient data from April 2019 to December 2020. Advancements in medical care might lead to variations in the diseases of admitted patients. Taken together, these show situations where the AI-coding assistance module might not capture the main diagnosis, as observed in the Dermatology Department.

Conclusions

With the rapid advancements in global medical technology and the evolving challenges of diseases, the development of DRG-based hospital payment systems in various countries is also meeting significant challenges. Key areas for future research include determining the flexibility of DRG payments, balancing payment structures, and aligning with disease management goals [23]. The Taiwan DRGs system, like those in other countries, aims to prevent medical institutions from delivering excessive services and causing unnecessary waste, all while safeguarding patient rights. It looks to strengthen management mechanisms to improve the quality and efficiency of care and ensure fair payments among peers.

In this context, AI-assisted coding emerges as a powerful tool [24]. A recent study used cross-random control methods to prove that AI-assisted coding reduces the coding workload [25]. The focuses of our research were the practical applications of AI models, with two main goals. The first was to investigate the consistency between the AI-assisted coding module and coding professionals and the second was to find the departments suitable for using the AI-assisted coding module. The research results showed that the highest consistency in MDC classification was seen in diseases of the respiratory system, as well as infectious and parasitic diseases. In the analysis of various inpatient specialties, departments such as the Division of Cardiology, Division of Nephrology, and Department of Urology showed no significant difference from coder-assigned coding results; accordingly, consideration could be given to integrating the AI-assisted coding module into the hospital information system, allowing physicians to reference Taiwan DRGs assignments for hospitalized patients, thus effectively controlling medical expenses.

However, upon analyzing the entire hospital department, discrepancies were observed in alignment with disease categorizations and personnel coding, so the research team is actively working on continuous improvements. Nevertheless, AI-assisted coding indeed served as a valuable reference by reducing human errors, as during the research period, it was found that the error rate detected by human coders (number of coding errors by human coders/total cases) was 1.9% (50/2632). Given the regular updates to the tool book by the Department of Health and the revisions in coding rules, the coding assistance module undoubtedly proves to be a powerful tool.

XSL•FO
RenderX

The development of AI-assisted coding for the *ICD-10-CM* PCS is just the beginning for intelligent health care in disease classification. Many operational aspects of hospitals are closely related to the *ICD-10-CM* PCS, including inpatient coding monitoring, discharge preparation services, and infectious disease surveillance, among others. For hospital administrators, the goal of AI-assisted coding is to achieve best operational revenue. For human coders with the assistance of an *ICD-10-CM* AI coding system, work time is reduced. Additionally, strengthening knowledge in clinical documentation improvement enables human coders to maximize their role, positioning them to become documentation experts [15] and preparing them for further career development.

Abstract

Background: Language acquisition is a critical developmental milestone, with notable variability during the first 4 years of life. Developmental language disorder (DLD) often overlaps with other neurodevelopmental disorders or simple language delay (SLD), making early detection challenging, especially for primary caregivers.

Objective: We aimed to evaluate the effectiveness of the Gades platform, an adaptive screening tool that enables preschool teachers to identify potential language disorders without direct support from nursery school language therapists (NSLTs).

Methods: The study took place in a nursery school and an early childhood educational and psychopedagogical center in Madrid, Spain, involving 218 children aged 6 to 36 months, 24 preschool teachers, and 2 NSLTs. Initially, NSLTs conducted informational sessions to familiarize teachers with DLDs and how to identify them. Following this, the teachers used the Gades platform to conduct language screenings independently, without ongoing support from NSLTs. The Gades platform was enhanced to collect detailed profiles of each child and implemented an adaptive screening model tailored to account for variability in language development. This setup allowed preschool teachers, who are not language experts, to observe and assess language development effectively in natural, unsupervised educational environments. The study assessed the platform's utility in guiding teachers through these observations and its effectiveness in such settings.

Results: Gades identified language difficulties in 19.7% (43/218) of the children, with a higher prevalence in boys (29/218, 13.3%) than in girls (14/218, 6.4%). These challenges were most frequently observed in children aged 15 to 27 months. The platform demonstrated a high accuracy rate of 97.41%, with evaluators largely agreeing with its recommendations. Teachers also found Gades to be user friendly and a valuable tool for supporting language development observations in everyday educational settings.

Conclusions: Gades demonstrates potential as a reliable and accessible tool for early detection of language disorders, empowering educators to identify DLD and SLD in the absence of NSLTs. However, further refinement of the platform is required to effectively differentiate between DLD and SLD. By integrating Gades into routine preschool assessments, educators can facilitate timely interventions, bridging gaps in early childhood education and therapy.

Introduction

Screening and Prevalence of Developmental Language Disorder

Communication plays a fundamental role in children's cognitive development. Through communication, children acquire knowledge, express their thoughts and emotions, develop their cognitive ability, and establish relationships with others. Adequate communication development enables them to learn and participate in various social contexts. Therefore, language acquisition during childhood is one of the most critical developmental milestones but with the most substantial interindividual variability in the first 4 years of life. Children start consolidating their language learning process from the age of 4 to 6 years [1-7].

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*), published by the American Psychiatric Association, introduced a new category known as neurodevelopmental disorders (NDDs) that groups different conditions that emerge early in child development before starting elementary school. These conditions eventually persist throughout adulthood [8-12].

The NDDs include communication disorders related to language, speech, and communication impairments. Developmental language disorder (DLD) is classified as a communication disorder. Children with DLD experience challenges in the acquisition and use of language. Language proficiency depends on receptive and expressive abilities. Therefore, children diagnosed with DLD encounter difficulties in both domains [12]. Thus, vocabulary is more limited than expected, and sentences are shorter and less complex with grammatical errors or with speech alterations in narration and comprehension or production of sentences. In addition, they may appear shy or prefer to communicate only with their family members. Children with DLD not only have symptomatology in communication skills but also have difficulties in cognitive and sociocultural processes [5,13-16].

Moreover, a family history of language disorders is often present, and DLD occurs with other disorders, such as autism spectrum disorder and attention-deficit/hyperactivity disorder (ADHD), in 30% of cases [5,17,18]. This makes early detection of DLD in these children more challenging for primary care pediatricians due to the significant comorbidity and similar symptoms with other NDDs [19].

On the other hand, early detection of DLD can be masked by misidentifying it as simple language delay (SLD). DLD is a persistent disorder with a slow rate of improvement and significant variability. This differentiates it from SLD [1,5,20]. However, this indicator does not allow for early detection of DLD, as we cannot identify whether the child has a one-off delay or is showing symptoms of DLD. To differentiate among them, difficulties must be identified in other areas, such as semantics, pragmatics, morphosyntax, and phonology [3]. Therefore, language difficulties manifest through the aforementioned skills that are measurably below what is expected for age, significantly impacting academic achievement, work performance, communication, and socialization [8-11].

DLD is diagnosed at the age of 4 years and is usually stable over time, as interindividual differences in language ability are reduced [1]. However, there may be warning signs that manifest themselves earlier. A study carried out by Vall d'Hebron Hospital Universitari in Barcelona, Spain, highlights a significant portion of children aged 5 to 17 years who exhibit clear symptoms of NDDs but have not been previously diagnosed with DLD [21]. Moreover, communication disorders are one of the significant NDDs with more prevalence in Spanish schools (1.05%-3.42%), along with ADHD and learning disorders [21,22]. Other studies estimated that the population prevalence of language disorders, without any relation to other intellectual disabilities, is 7.58% for children aged 4 to 5 years [17] and 6.4% at the age of 10 years [23]. To summarize, within a preschool setting of 30 children, it can be anticipated that about 2 children may exhibit DLD manifestations [17]. In total, 10% of preschool children present difficulties in language acquisition, of whom 5% to 7% end up being diagnosed with DLD, and the rest are diagnosed with SLD [5].

Before the detection and diagnosis of DLD, there is a prevention phase. Here, the nursery school plays a key role, as it is within this environment that the child spends most of their time and is involved in different interactions [1]. These interactions contribute to developing their communicative skills (communicative intention, nonverbal communication, imitation, waiting, etc) with peers of a similar age and teachers. Research has demonstrated a correlation between children with DLD and their academic performance. In fact, 88% of these children fail to meet the necessary curricular standards during their first year of school [14,17]. Hence, there is a pressing need to support education professionals with enough training and knowledge to identify early indicators of potential language disorders [1,24-27].

In the detection phase, the aim is to identify early whether a child is suspected of having some NDDs. To achieve adequate detection, tools such as screening forms and questionnaires allow information to be compared with previously defined risk indicators [20,28-32]. Some regions, such as Madrid (Spain), have early childhood educational and psychopedagogical guidance teams supporting nursery schools' detection phase. These teams engage in preventive actions and collaborate to detect developmental issues during the initial years of a child's life. If an educational case is identified, it is referred to the early intervention centers responsible for the assessment and intervention phase [33].

The assessment and intervention cover different aspects. During the assessment phase, it is necessary to analyze the family environment through interviews with relatives. In addition, hearing tests should be administered to eliminate potential associated psychological disorders. Evaluation of communication, playing with peers, comprehension, language production, and psychomotor skills are also essential. Finally, this information is correlated with medical history [6,14,15,20]. The intervention phase for DLD should be multidisciplinary, involving teachers, occupational therapists, speech therapists,

XSL•FO
RenderX

and psychologists skilled in children's language development techniques [7,24,27,34].

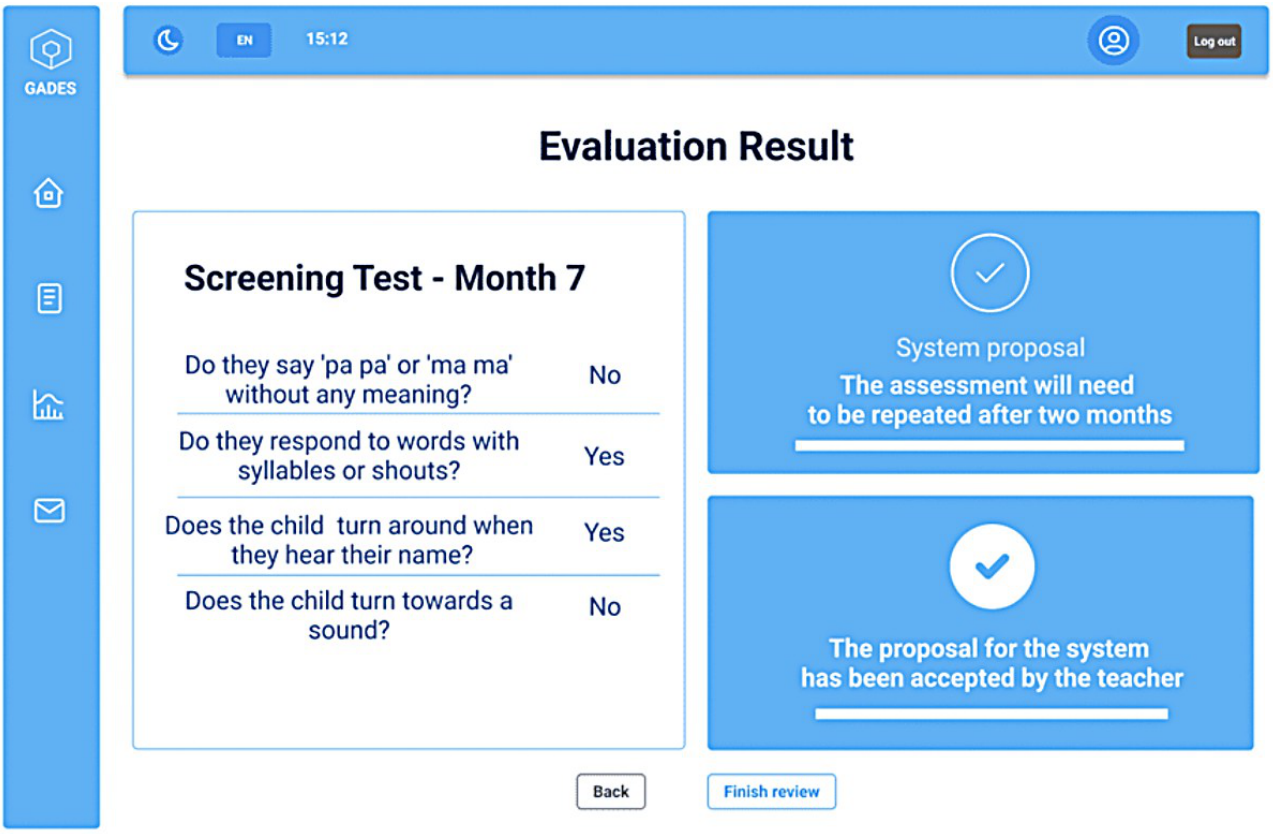
Gades: A Screening Tool for DLD

Gades functions as a clinical decision support system designed to grant expert knowledge regarding language disorders to preschool teachers. It offers a screening form to assess the language acquisition process during the early stages of a child's development. Gades allows the implementation of screening systems in natural environments for the child, thereby embracing the principles of pervasive therapy [35].

Pervasive or ubiquitous therapy is a therapeutic approach supervised by professionals that aims to promote engagement in activities focused on improving the individual's life within their natural environment through the support of information and communication technologies. It aims to be person centered instead of focusing on a specific clinical pathology. It especially seeks to identify how a problem impacts and manifests across various contexts [18,36]. This approach has the same phases of prevention, detection, assessment, and intervention as normative therapy. Moreover, using information and communication technologies ensures consistency and continuity of the therapeutic process within the person's natural setting [32,37-39].

For children's pervasive therapy, its application extends beyond the clinical center to environments like the child's school or home. Nursery schools are included in these settings. Being places where children spend much of their time, they are crucial for the early detection of DLD [24]. During this educational phase, teachers or educators and specialists in therapeutic pedagogy, such as nursery school language therapists (NSLTs), are typically involved. However, many nursery schools lack NSLTs, and even when they are available, fewer than half of the children suspected of having a language disorder are referred to or receive support from these specialists [1,7,17,23,27].

Martín Ruiz et al [35] developed and evaluated a previous version of Gades. The platform's cornerstone is a knowledge base (KB) that includes 106 milestones related to children's language acquisition based on age, defined and agreed upon by language experts. The previous version of this KB covered children aged 1 month to 72 months [35]. Building upon the findings of the previous experiment, increased instances of suspected DLD were identified in children aged 0 to 3 years. Consequently, in the current experiment, we focus on prioritizing the implementation of Gades during this developmental period. To extend this goal, Gades has undergone modifications and enhancements to its functionalities to gather additional pertinent information concerning language acquisition in children. These adaptations include integrating inquiries specific to the bilingual context of the children and their family backgrounds and evaluating results from the Gades across different language areas.



When using Gades, the corresponding milestones, tailored to the child's condition, are incorporated into a screening form through questions that education professionals use to assess a child's language development level. The milestones are categorized into 2 main types: "warning milestones," which prompt a reevaluation, and "alarm milestones," indicating the need for direct referral to health professionals. Gades' KB assesses 4 areas of speech and language development: sensory reception, speech perception, production, and pragmatic.

After the form adapted to the child is completed, Gades generates an evaluation result, including a suggestion for action if deviations from typical child development stages are detected. Therefore, it provides education professionals with expert knowledge on language acquisition, enhancing the early detection of DLD. Furthermore, this screening form acts as a psychopedagogical report for early intervention health professionals. Gades can aid in identifying the language development profile of a child suspected of having DLD through the assessment of processing-oriented and performance-based tasks.

Figure 1 depicts the graphical user interface of Gades, showcasing the evaluation results of consultation for a child aged 7 months. The platform displays the outcomes of the screening form, including the posed questions and the teacher's responses. Response options include "yes" if the child performs the specified action, "no" if not, and "do not know/no answer" for unknown answers. This form is completed based on the preschool teacher's observations of the child without direct interaction. After review, the system recommends that the assessment be repeated in 2 months, a suggestion that the overseeing teacher has validated. Gades also features additional tools for child registration, language evaluation, and user profile management.

XSL•FO
RenderX

Figure 1. Gades' evaluation result page for a child aged 7 months. In total, 4 questions were asked based on the child's age, and the system suggested repeating the evaluation in 2 months. The preschool teacher concurred with the system's recommendation.

Goal of This Study

For effective early detection and intervention of DLD, it is essential to offer sufficient services to these children to minimize the impact on their social, emotional, and educational development. Thus, language disorders often require a multidisciplinary approach among professionals from diverse fields such as education, speech-language therapy, and medicine to extend their reach into various settings [17,18,24]. Supporting training programs and systems for health and education professionals fosters collaboration. This collaboration facilitates the creation of adequate evaluation and intervention plans that meet the diverse needs of individuals with language difficulties, enhancing the quality of care and inclusivity [22,26,30,31,38,40].

Within this collaboration, the early detection of warning signs, which are potential indicators of language disorders in children, should be an integral part of the daily work of those interacting with children [1,7]. Supporting early childhood education professionals is crucial to ensure that they possess adequate knowledge and tools for preventing and detecting early language development issues in children aged 0 to 3 years because behaviors and warning signs related to language disorders can be identified from the age of 2 years onward [1,3,4,24]. It facilitates appropriate early diagnosis of DLD or SLD through subsequent assessment at early intervention centers. Moreover, given the absence of an NSLT in some schools, preschool teachers must have access to these resources.

Considering the higher incidence of suspected DLD observed in children aged 0 to 36 months in the previous experiment [17,23], this paper aims to emphasize the use of Gades during this period, targeting kindergarteners aged 6 to 36 months in a nursery school and an early childhood educational and psychopedagogical center. Gades has been adapted and expanded to gather more relevant information on language acquisition, including questions tailored to bilingual contexts and family backgrounds. Therefore, our primary goal is to evaluate Gades' ability to differentiate between typical and atypical language development for the target ages with these minor adjustments.

As the previous experiment consisted of a controlled environment, this paper also presents the relationship between preschool teachers and the Gades platform. Specifically, how Gades serves as a valuable tool for guiding nonexperts, such as preschool teachers, in conducting language observations. Therefore, it evaluates Gades' effectiveness in a real setting and its adherence to clinical criteria without direct supervision or intervention of language experts or technical staff. A potential challenge is also associated with integrating these technological tools into unsupervised educational settings to support therapeutic interventions [41].

Moreover, this screening process aims to identify the patterns indicative of a child with problems in language development, including SLD or DLD. Considering the updated *DSM-5* criteria, language development in children occurs within heterogeneous and dynamic contexts. Hence, it is imperative to use screening tools to identify significant patterns and milestones in the language development of a child with DLD, facilitating early detection and intervention. To accomplish this, the screening

XSL•FO
RenderX

tools must be intersectional, considering influential parameters, such as clinical conditions and the sociocultural and linguistic environment surrounding the child. Consequently, the final goal is to outline the framework for an adaptive screening model for language disorders that reflects the child's current developmental and social context. This approach ensures a comprehensive and nuanced understanding of each child's unique situation, enhancing the accuracy and effectiveness of early detection methods. Therefore, this study hypothesizes that the Gades platform can effectively support preschool teachers in the early detection of language development difficulties, including DLD and SLD, within natural educational settings, achieving high accuracy rates and providing actionable insights without requiring direct supervision from language disorder specialists.

Methods

Overview

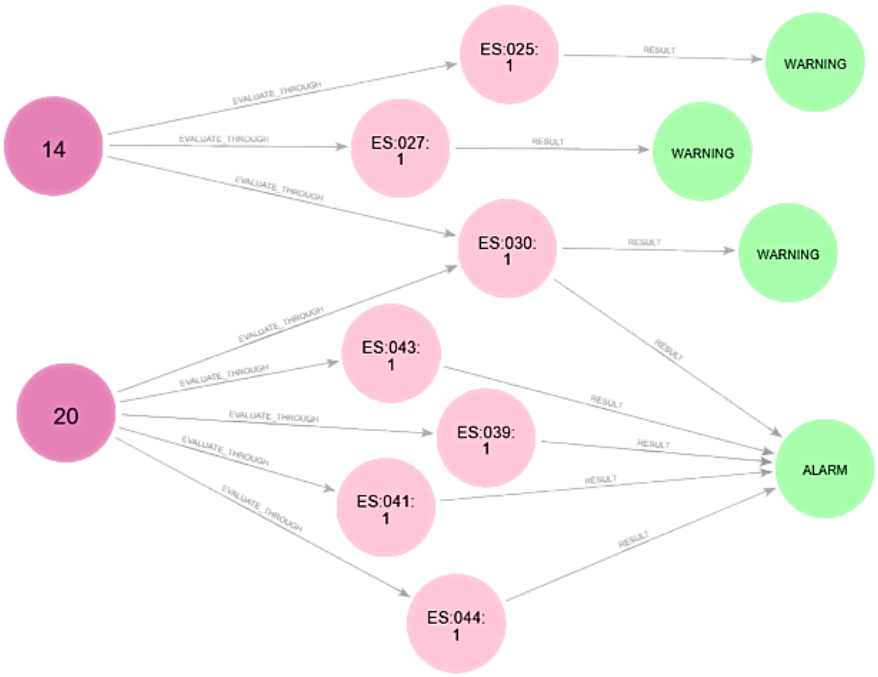
This study used a prospective observational design to evaluate the updated Gades platform in real-world educational settings. The design involved monitoring children aged 6 to 36 months and their evaluators—preschool teachers and early childhood educators—over a defined period, collecting data as they naturally occurred during regular classroom activities. This approach was selected to ensure that the platform's performance could be assessed in authentic, uncontrolled conditions, reflecting its practical application. By focusing on how educators integrated Gades into their daily routines, the study aimed to capture unbiased insights into its usability and effectiveness in identifying early signs of language development difficulties.

Requirement Analysis

Individuals encounter varied communicative situations involving diverse entities and methods in everyday life. Current diagnoses and treatments for various disorders frequently overlook key characteristics, such as diversity, heterogeneity, and the role of socialization. The *DSM-5* and numerous studies highlight the necessity to consider interindividual differences in language acquisition early on. These sources suggest that assessments of language, speech, and communication should consider sociocultural aspects, linguistic context (including dialects), and socioeconomic status, as these aspects directly influence language development [1,12,16,17,19,21,31,32,42-44].

Bosch et al [21] demonstrated that 1.05% of the participants had communication disorders, with the most significant factors being foreign origin, genre, socioeconomic status, and age. Consequently, the diagnosis of language impairment should consider the individual's background, bilingual context, direct clinical observations in settings such as home or school, and results of standardized tests to assess the severity of the disorder.

The New Gades Platform



Building on the previous experiment with the Gades platform [35], we updated it with new technologies and features. These enhancements enable the collection of additional information from children to conduct more accurate and suitable assessments of a child's language development. This includes gathering details about the child's family background, linguistic environment, and medical history, all of which contribute to a more comprehensive understanding of each child's unique developmental context. Therefore, incorporating these minor adjustments delineates the structure of an adaptable screening model that considers the variability in language development. This methodology guarantees a thorough and nuanced comprehension of each child's individual circumstances, enhancing the precision and efficacy of techniques for identifying potential issues in language development.

Implementing Neo4j (Neo4j Inc), a graph database technology, is crucial in optimizing our Gades platform, specifically in enhancing the accuracy of language disorder detection. Neo4j allows for a more natural and flexible representation of complex data and interconnected relationships between them, which is essential for modeling the intricate interactions and dependencies observed in child language development [45]. In the context of Gades, Neo4j facilitates the dynamic integration and analysis of large volumes of data related to language development milestones, assessment responses, and individual characteristics of children. For example, the graph structure enables us to directly link children's responses to specific questions with language development patterns and automatically flag connections that indicate potential delays or deviations from typical development.

Therefore, the KB has also been migrated to Neo4j graph databases. As illustrated in Figure 2, each milestone is represented through a month (dark pink node) with several questions (pale pink nodes) and a final suggestion (green nodes). Thus, in the figure, a dark pink node is represented each month, corresponding to different questions designed to evaluate the child's language proficiency, depicted by pale pink nodes. Notably, some questions are linked to multiple months, reflecting the dynamic nature of language development assessment. Different action suggestions can be generated based on the answers to these questions, such as confirming typical development, recommending reassessment, or advising referral to early childhood care services (green nodes represent these). This graph-based approach facilitates a nuanced analysis of the child's language development, allowing for tailored interventions sensitive to each child's unique progression.

XSL•FO
RenderX

Figure 2. Gades' knowledge base in Neo4j: milestone months (dark pink node), questions identifiers (pale pink nodes), and suggestions (green nodes). Each month has various questions to evaluate language acquisition (for a child aged 14 months or 20 months) with suggestions such as typical development, repeat evaluation, or advising referral to early childhood care services.

With the updates to Gades, the system has addressed feedback from educators seeking more information on DLD. Previously, questions were categorized by language development areas and were only accessible to the system's technical staff. However, with the recent improvements, information about various skills is now accessible to the evaluation staff. This improvement means that by using Gades, preschool teachers and other professionals can gain deeper insights into the specific language development areas being assessed. Such transparency not only empowers educators with a better understanding of language development but also enables them to contribute more effectively to detecting warning signs.

Table 1 illustrates the classification and number of questions across different categories. The sensory reception category is administered in the earliest months of life, primarily to assess for hearing issues, and gradually transitions into language perception. This aspect entails the capacity to receive, process, and comprehend linguistic information through sensory channels, whether auditory or visual. Pragmatics includes conversational skills, coherence, cohesion within discourse, and the functional and social use of the language. Finally, language production encompasses phonology, morphosyntax, semantics, and nonverbal communication. This structured approach allows for a comprehensive assessment of a child's language development, targeting specific areas crucial for early detection and intervention of language disorders.

Table 1. Classification of questions according to language category [35].

Language development domains	Number of questions
Sensory reception	3
Language perception	32
Production	48
Pragmatics	25

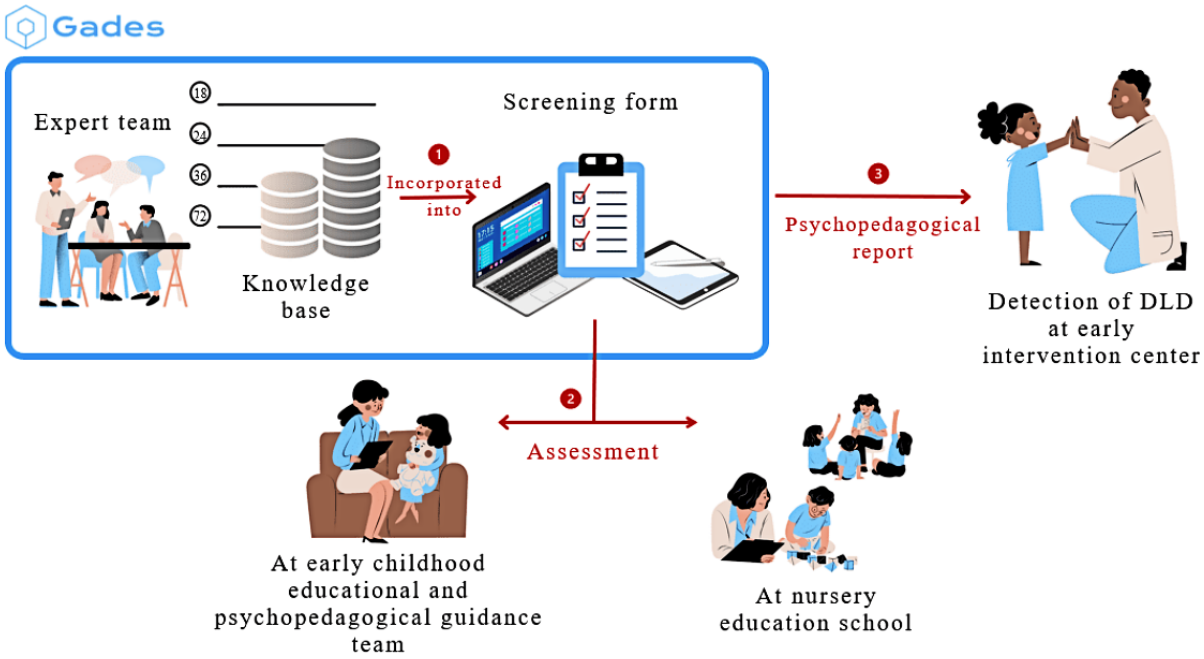
Hypothesis and Experiment

We aimed to validate the reliability and effectiveness of the new Gades platform in a real setting without the direct supervision or intervention of language experts or technical staff. We explored the interaction between preschool teachers and the Gades platform, highlighting how Gades functions as a valuable tool for facilitating language observations to detect warning signs of language difficulties by nonexperts. The Gades platform is specifically designed to assist in detecting early language difficulties that may signal potential DLD. By focusing on these early warning signs, Gades supports the early detection and monitoring of language development challenges in real-world educational settings.

The Gades KB was established in a previous study [35] and is grounded in standardized tests commonly used to assess DLD. This ensures that Gades relies on validated methodologies to identify and interpret potential language difficulties.

The study's population sample consisted of 218 children aged 6 to 36 months from 2 educational centers in the city of Madrid: a preschool center and an early childhood educational and

XSL•FO
RenderX



psychopedagogical center. All children enrolled in the first cycle of early childhood education, which aligns with this age range, participated in the study. This selection was based on recent evidence highlighting the critical importance of identifying language difficulties during this developmental period [1,3,4,24]. The screening data were collected from March to June 2023, providing an initial assessment of Gades' effectiveness in a real-world educational setting. Notably, access was limited to Spanish-speaking and some bilingual children.

The screening assessments for DLD involved the active participation of 24 nursery school educators and preschool teachers and a clinical professional from the early childhood center. Throughout this study, we will refer to them as evaluators. Hence, 2 categories of evaluators were involved in the experiment. The initial cohort consisted of professionals from early childhood centers, who, while not specialized in DLD, possessed adequate knowledge of NDDs. The second group comprised nursery school educators and preschool teachers, who may lack specialized language expertise but possess valuable insights into the children's competencies under their care. Before starting the experiment, the evaluators received training from qualified professionals affiliated with the Specific Language Disorder Association of Madrid. This training aimed to deepen their understanding and expertise regarding DLD and its identification with children aged 6 to 36 months. The training, delivered in a concise 2-hour format, was designed to ensure efficiency while providing comprehensive insights. By the session's conclusion, it was anticipated that the educators would have developed a more nuanced understanding of typical language milestones and a heightened capacity to discern early indications of language difficulties in children under their care.

During the evaluations, they operated without direct assistance from the training professionals or the Gades technical support team. Consequently, the experiment was conducted in an uncontrolled setting, relying exclusively on the evaluators' direct observation of the children's behavior for further evaluation through Gades. The evaluations were conducted following the guidelines recommended by Gades, aiming to ensure that the process was as effective and informative as possible within the constraints of the study's design.

Figure 3 outlines the Gades' framework, starting with an initial phase where a series of meetings were conducted to review and validate the KB established in the previous experiment. This phase involved experts in language disorders and the technical personnel from Gades to ensure the KB's relevance and accuracy. The panel of experts, who were also involved in constructing the KB as part of a previous study [35], recommended that including 3 to 6 questions per month would constitute an adequate measure for detecting language development issues. In the context of this study, the same experts conducted a review and confirmed the continued validity and applicability of the content of the KB. Once the KB was validated, the second phase, the screening process, began.

Figure 3. Gades' detailed framework. The process starts with expert validation of the knowledge base, integrated into a screening form with control and language questions. Evaluators assessed the children, and Gades provided recommendations, such as reassessment or referral, forming the basis of a psychopedagogical report. DLD: developmental language disorder.

The assessments were carried out by experienced female educators and professionals proficient in using digital platforms and information technologies. They used mobile devices and workplace computers to conduct evaluations, strategically scheduling them during the children's nap time around midday to minimize distractions. This approach involved each evaluator conducting assessments of the children under her care, which consisted of 2 parts. The first part included control questions related to the child's medical history and linguistic context, serving as a baseline for understanding each child's unique background. The second part consisted of the language difficulties screening questions. These questions were

XSL•FO
RenderX

meticulously developed in collaboration with experts to cover risk parameters for the early detection of DLD.

After the screening form was completed, the Gades system generated a recommendation to the evaluator, such as suggesting a repeat assessment in the upcoming months or indicating the need for a referral to an early intervention center. If a referral was recommended, nursery schools in Madrid forwarded the result to the expert through a psychopedagogical report. The designated expert, a language professional, was responsible for conducting a standardized evaluation tailored to the child's needs. Meanwhile, the educator played a supportive role by closely observing the child's progress in class and paying particular attention to areas of difficulty. Regular communication between schools and the expert was maintained with biweekly visits to ensure follow-up and support.

The application of the Gades platform was deliberately structured to be as nonintrusive as possible, allowing evaluators to focus on their primary duties while still contributing to the study. On average, each child underwent 1.24 (SD 0.49) assessments, indicating a consistent approach to the number of evaluations. The average duration of an assessment was 70 (SD 41.8) seconds per child, demonstrating the platform's efficiency in collecting data within a brief timeframe. To validate the Gades platform, both quantitative and qualitative analyses were conducted.

Quantitative validation focused on assessing the platform's accuracy and reliability. Descriptive statistics were used to summarize the duration and frequency of assessments. Agreement between the system's recommendations and evaluators' decisions was measured using concordance rates, calculated as the proportion of evaluations where the evaluators accepted Gades' recommendations. Statistical significance was set at $P<.05$. In addition, the platform's accuracy rate (97.41%) was determined by dividing the number of accepted suggestions (n=263) by the total number of evaluations (N=270). Instances of disagreement were analyzed qualitatively to identify patterns or recurring issues.

Qualitative validation focused on the integration of Gades into educational settings and its usability as perceived by preschool teachers. Evaluators were asked to provide feedback via a standardized questionnaire, following a validated system usability scale [41]. Responses were anonymized and collected outside the Gades platform to reduce potential bias. Evaluators also provided open-ended feedback to capture their experiences and insights, highlighting the platform's strengths and areas for improvement. The qualitative data were analyzed thematically to identify trends and recurring themes.

This combination of statistical and thematic analyses ensured a comprehensive validation of Gades. By comparing the platform's outcomes against educator feedback and established clinical criteria, the study aimed to validate Gades' ability to aid in the early detection of language development issues, such as SLD or DLD. Furthermore, comparisons between the initial version of Gades (2014) [35] and the current version highlighted improvements in adherence to clinical standards and system usability.

Ethical Considerations

This study, including the validation of the Gades platform and the experiment conducted through it, received ethics approval from the Ethics Committee of the Polytechnic University of Madrid in October 2023 GYGSDAALTD-MLMR-DATOS-20231010 and GYGSDAALTD-MLMR-HUMANOS-20231010). This approval ensures that both the use of the Gades platform and the specific experimental protocol comply with ethical standards, including data protection, participant rights, and research transparency.

For this study, an opt-out consent model was implemented. Participants were informed in advance about the study's objectives, the nature of the data collection, and the measures taken to ensure anonymity. They were given the opportunity to decline participation or withdraw their data at any point without providing a justification. Consent was implied by the participants' choice to continue with the evaluations, as no identifiable personal data were collected. Anonymized data were securely provided to the research team.

The professionals overseeing the evaluations maintained confidentiality in accordance with professional secrecy standards. Only the principal investigator had access to the evaluation results, which were securely stored in an encrypted database, accessible solely through authorized credentials.

Results

Sample Summary

The sample size for this study was calculated using a finite population correction formula to ensure adequate representation and statistical power. On the basis of demographic data from Madrid, the estimated population of children aged 6 to 36 months was approximately 150,000 [46]. With an assumed prevalence of DLD of 7%—a conservative estimate derived from epidemiological studies [17]—a 95% CI (Z=1.96), and a margin of error of 5%, the required sample size was calculated. The formula incorporates the finite population adjustment to account for the limited size of the target population, yielding a minimum required sample size of approximately 100 participants. This calculation also considered the variability in language development within the population.

The study's population sample comprised 218 Spanish-speaking children aged 6 to 36 months, more than double the calculated minimum sample size, ensuring robust statistical power and enhancing the reliability of the results. It featured a control group of 134 children from the nursery school (center 1) without any previous diagnosis or visible language difficulties and an experimental group of 84 children from the early childhood educational and psychopedagogical center (center 2), suspected of NDDs. Both groups were matched by gender to maintain homogeneity. Each child was assigned a random identifier for data anonymization and to facilitate subsequent analysis by the research team.

In Madrid's nursery schools, for each child, the evaluations were conducted by 2 assigned preschool teachers, also called an "educational pair." The concept of an "educational pair"

XSL•FO
RenderX

refers to 2 professionals sharing responsibilities and collaborating for the children's development and well-being, enabling the distribution of evaluation tasks between them. Therefore, in classrooms with children aged <12 months, each teacher evaluated an average of 4 (SD 0) children. For groups with children aged from 13 to 24 months, the responsibility increased to an average of 6.75 (SD 0.577) children per teacher. For those aged >24 months in the classroom, the average was 5.9 (SD 6.610) children per preschool teacher. Evaluations at the early childhood educational and psychopedagogical center were conducted by the teacher specializing in therapeutic pedagogy (NSLT).

Table 2 presents an overview of the study's sample, detailing the distribution of the children by age and gender: 45.4% (99/218) of the girls and 54.6% (119/218) of the boys participated. Within this group, 36% (36/99) of the girls and 40.3% (48/119) of the boys came from the early childhood center, initially identified with potential NDD concerns. Specifically, for participants aged >3 years, the study included 4 boys and 2 girls, all aged 37 months, except for 1 girl who was aged 38 months. The second year of the initial preschool cycle had the highest representation, with the largest number of children aged between 18 and 28 months, averaging 10 (SD 3.045) children per month. The average age in months per grade was distributed as follows: up to 12 months, the average age was 10.020 (SD 1.136) months; from 13 to 24 months, the average age was 20.331 (SD 1.108) months; and from 25 to 36 months, the average age was 31.578 (SD 1.094) months.

Table 2. Distribution of children by center, gender, and age range[a].

Grade	Up to 12 mo (n=26), n (%)	13-24 mo (n=102), n (%)	25-36 mo (n=84), n (%)
Children from center 1			
Female	10 (38.4)	22 (21.6)	31 (36.9)
Male	8 (30.7)	24 (23.5)	39 (46.4)
Children from center 2			
Female	5 (19.2)	22 (21.6)	9 (10.7)
Male	3 (11.5)	34 (33.3)	11 (13.1)

[a]Center 1 is the nursery school, and center 2 is a psychopedagogical center. The age ranges align with the preschool grades. The second year of the initial preschool cycle had the highest representation (102 children).

The screening form's initial section included questions regarding the child's medical history and linguistic context. Birth complication cases were more prevalent in center 1, particularly among male participants. Results indicated that 8.2% (11/134) of the children with no previous diagnosis of NDD experienced birth complications, including prenatal, perinatal, and preterm risks. 2.9% (4/134) were reported among females while among males, 5.2% (7/134) were observed. In center 2, only 2% (2/84) cases were reported in males and no cases in females. Notably, 3 children faced more than 2 of these risks, such as family history combined with perinatal risk. The mean gestational weeks remained relatively consistent across both centers and genders, with slightly more variation among girls. The average gestational age was 39.518 (SD 5.363) weeks, female children had an average of 38.984 (SD 2.36) weeks in center 1 and 40 (SD 0) weeks in center 2, while males had 39.563 (SD 1.29) weeks in center 1 and 39.791 weeks (SD 1.44) in center 2. A baby is considered premature if born before the 37th week of pregnancy. According to the study, only 3.7% (8/218) of the children were born preterm, highlighting specific early life factors that could influence developmental outcomes. Instances with a family history or bilingual cases were limited. Among the 218 cases studied, only 2 reported a family history of other NDDs such as autism spectrum disorder. Information regarding the bilingual context was exclusively available for children from center 1 (N=134). 7 (5.2%) cases were found among females, and 3 (2.2%) cases were recorded in males. It suggests that the language development impact of being raised in a bilingual environment could not be thoroughly assessed across the entire sample.

Overview of the Obtained Health Results

This section presents the results obtained from the evaluations that were conducted. A total of 270 assessments were completed, accounting for instances where children underwent multiple assessments. Retaining only the latest assessment conducted for each child (218 evaluations), there were 19.7% (43/218) children, which resulted in a suggestion to refer them to an early intervention center for a specific assessment by a professional. These types of suggestions were classified as alarms. That was the most severe system decision. Table 3 shows the results of the final assessments. The system has recommended repeating the remaining assessments in subsequent months to further evaluate and discard language issues. Suggestions that indicate repeat evaluation are classified as warning type.

XSL•FO
RenderX

Table 3. Distribution of Gades' final suggestionsa (N=218).

Description	Distribution, n (%)
Typical developmental	117 (53.7)
Refer to early childhood care	43 (19.7)
Repeat assessment (within 3 mo)	28 (12.8)
Repeat assessment (within 2 mo)	19 (8.7)
Repeat assessment (within 1 mo)	11 (5)

[a]More than half of the sample (n=117, 53.7%) were identified as typical language development. However, 19.7% (43/218) of assessments identified language difficulties as indicative of possible simple language delay or developmental language disorder.

Table 4 displays the distribution of assessment types by gender. It reveals that more alarm cases were identified in boys (29/218, 13.3%) compared to girls (14/218, 6.4%). In addition, both genders had a similar frequency of warning assessments and neurotypical results.

Table 4. Distribution of evaluations by suggestion type and gender. More alarm cases were identified in boys (29/218, 13.3%) compared with girls (14/218, 6.4%). Both genders had a similar rate of warning assessments and neurotypical results (N=218).

Gender and evaluation	Evaluations, n (%)
Female	
Alarm	14 (6.4)
Warning	29 (13.3)
No findings	56 (25.9)
Male	
Alarm	29 (13.3)
Warning	29 (13.3)
No findings	61 (27.9)

Gades identified more cases of alarm and warning in children already undergoing evaluation by specialists than from the center (alarm: 29.7%; warning: 32.1%), but we do not know whether these children had language disorders. Hence, among children already experiencing some difficulties, it identified that there may be some indication of language difficulties (ie, DLD or SLD).

Table 5 shows the distribution of evaluations that were classified as an alarm because it was detected that the assessed child did not meet the language acquisition milestones expected for their age. The incidence of language impairment from center 2 was comparable between boys and girls (15:10) and 30% (25/84) of the cases were detected as alarms. Meanwhile, for children without a suspicion of NDD coming from nursery school (center 1), difficulties in language and communication were detected in 13.4% (18/134) of the cases. However, a notable discrepancy was observed between boys and girls (14:4).

Table 5. Distributions of alarm evaluations by gender, month, and center[a].

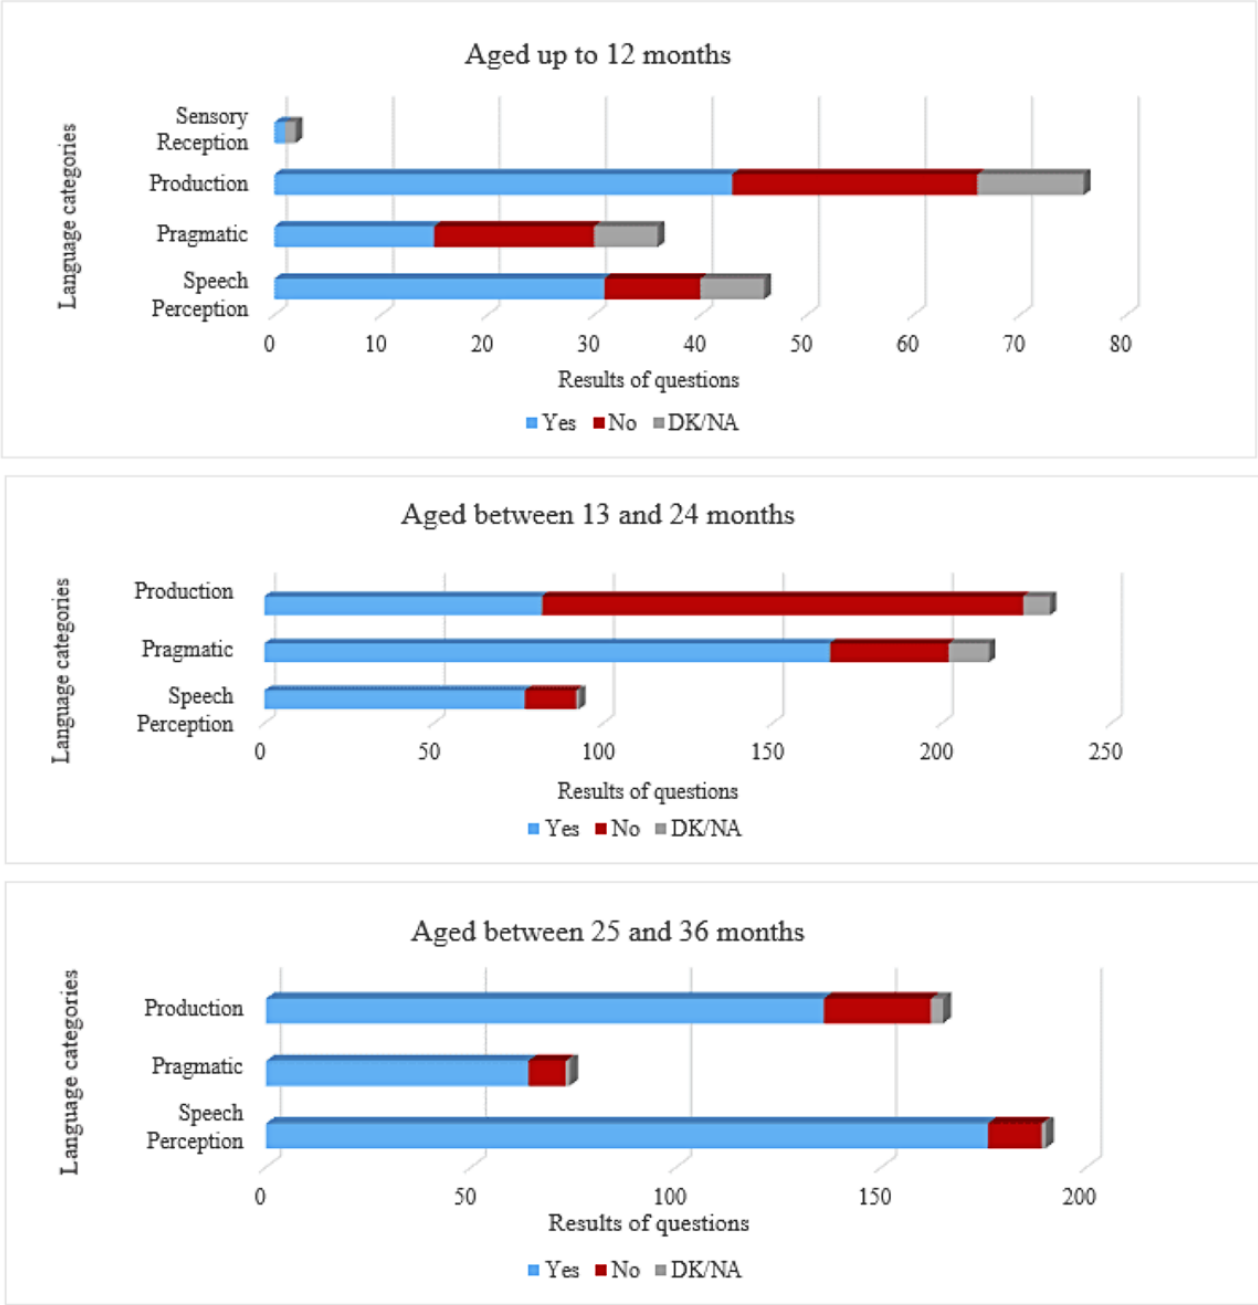
Month	9	10	11	14	15	16	18	19	20	24	25	26	27	28	30	32	37	Total
Children center 1																		
Female	0	1	1	0	0	0	0	0	1	1	0	0	0	0	0	0	0	4
Male	0	1	0	1	0	0	4	0	0	1	1	2	1	0	1	1	1	14
Total	0	2	1	1	0	0	4	0	1	2	1	2	1	0	1	1	1	18
Children center 2																		
Female	1	0	0	0	2	0	1	3	0	0	0	1	1	1	0	0	0	10
Male	0	0	0	0	3	1	4	2	2	2	1	0	0	0	0	0	0	15
Total	1	0	0	0	5	1	5	5	2	2	1	1	1	1	0	0	0	25

[a]For children coming from center 1, language issues were detected in 13.4% (18/134) of the cases. The incidence of language issues from center 2 was comparable between male and female participants (15:10), with alarms detected in 30% (25/84) of the cases.

Notably, most of the suspected cases were detected in months 15, 18, 19 and 24. All these months correspond to the second year, encompassing children aged between 1 and 2 years. Upon thorough analysis of the evaluations during these months,

XSL•FO
RenderX

difficulties were discerned in the language production category for month 15. Half (23/40, 50%) of the children resulted in alarms. When compared to assessments from previous months, several observations emerged. First, most questions in this category were not been asked in previous months, as the child's age renders them too young to possess these competencies. Second, only 1 question, "first disyllables (one word in addition to dada and mama)?" was repeated in months 12 and 14, with half (8/14, 57%) of the assessed children answering negatively in both months. For month 15, all respondents answered negatively.



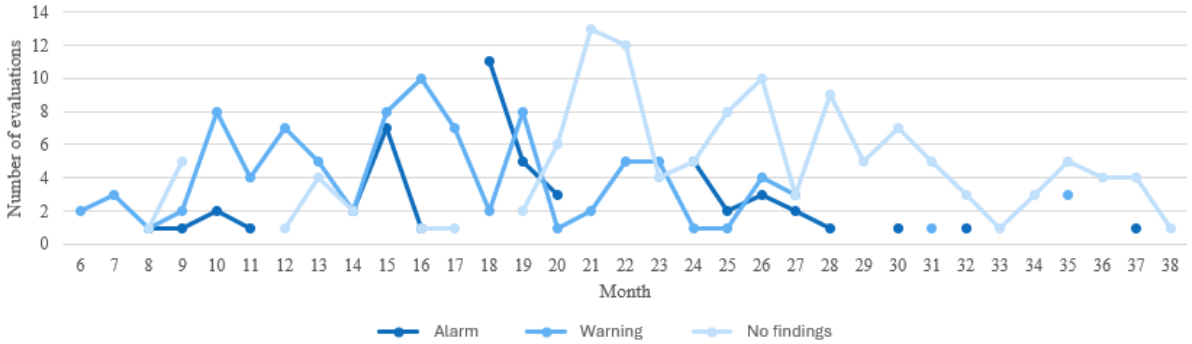
Month 18 had the highest number of detected suspected cases (9/11, 82%). During one of the meetings, educators expressed that they had observed more issues in language production, citing example, such as the child's inability to articulate certain words. In addition, similar questions asked in previous months also resulted in alarms. For instance, the one with the most error answers was "first bisyllables (two words in addition to dada and mama)?" In subsequent months, specifically month 19, identical pragmatics and language production questions were asked, and negative responses were received.

In month 24, 40% (4/10) of the evaluations raised alarms. Upon analyzing the questions, 3 were related to pragmatics and language comprehension, which were previously asked in earlier months. Most children satisfactorily answered these questions, indicating alignment with their current developmental stage. Therefore, the cases prompting alarms may signify potential instances of children with SLD or DLD.

Figure 4 depicts the results of questions categorized by language development areas. The sensory reception category was evaluated only for children aged up to 12 months to discard hearing issues. Children aged <12 months encountered more challenges in the production and pragmatics categories. Furthermore, there were no cases of hearing problems. The pragmatics category showed an equal balance between successes and failures. Conversely, children in the second year demonstrated notable difficulty in answering questions within the language production category, with a higher-than-average rate of incorrect responses. Other categories showed satisfactory performance.

XSL•FO
RenderX

Figure 4. Distribution of results based on language-category questions. Each question is categorized according to language category (refer to Table 1 for more information) and can be answered with a yes, no, or do not know/no answer (DK/NA). Children aged from 13 to 24 months demonstrated notable difficulty in production questions. Children aged >24 months exhibited positive responses across most categories.



Finally, children aged >24 months exhibited predominantly positive responses across most categories. Hence, it becomes evident that children aged <24 months exhibit a higher frequency of errors, attributable to the inherent variability in language acquisition during this developmental stage. Consequently, there is a pressing need for greater flexibility in language milestones and extending their coverage across months.

As illustrated in Figure 5, this distribution reveals that instances of children with difficulty in language development are prevalent between months 15 and 27, gradually decreasing in the final months until 3 years of age.

XSL•FO
RenderX

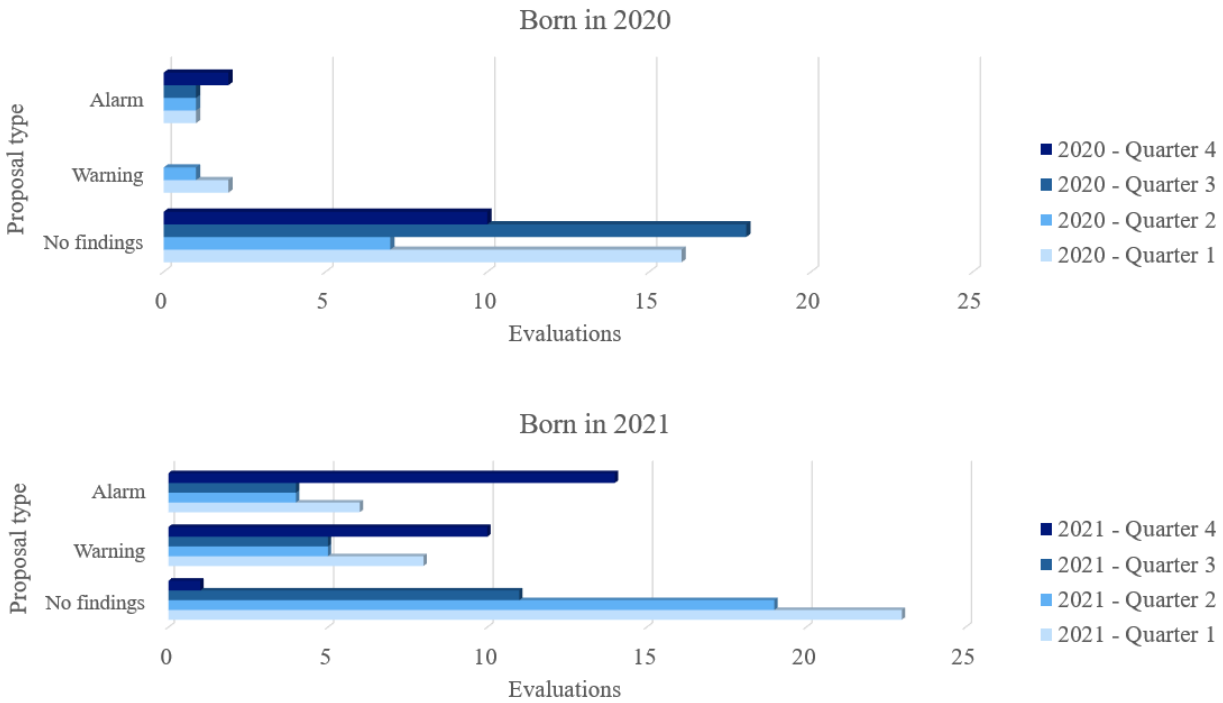


Figure 5. Distribution of suggestion type per month. Cases of children with language development issues were prevalent between months 15 and 27 (dark blue). The graphic reveals a gradual decline during the final months, with more typical development cases (pale blue).

In contrast, the evaluations were analyzed considering the control questions asked and the correlation between language development and the child's date of birth. In Madrid's nursery school classes, children were grouped based on their birth year. Consequently, at the beginning of the school year in September, a significant age gap existed between children born in the first quarter and those born in the last months. The latter group comprised the youngest in the class, resulting in a notable developmental difference between them.

The assessment outcomes for the youngest children in each class are presented in Figure 6. The youngest children were defined as those born from October to December 2020 for the age range of 25 to 36 months and from October to December 2021 for the age range of 13 to 24 months. This categorization was not applicable for children aged <12 months, as we did not have children from the last trimester. Hence, upon comparing the alarm for children born in 2020 and those born in 2021, it consistently appeared higher for those in the previous quarter. The youngest children tend to yield poorer results using Gades, as language development differs.

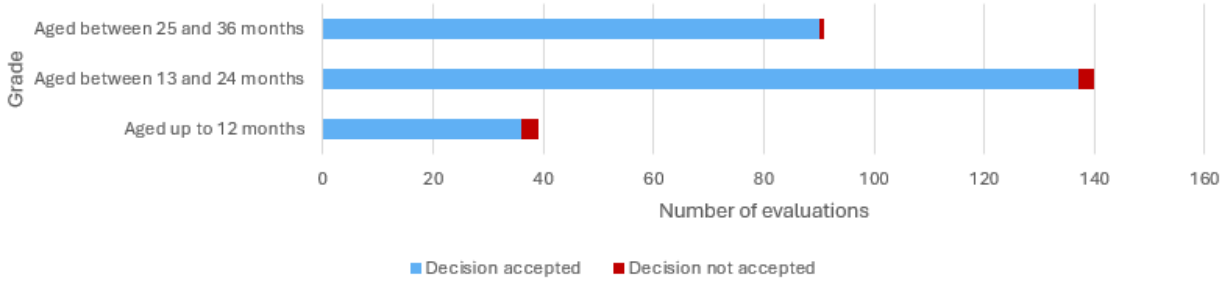
Figure 6. Assessment results by school quarter and suggestion type. For children born in 2020 (age between 25 and 36 months) alarm cases were more prevalent among children from quarter 4. However, these results are tempered by many more typical development cases at the same age. By contrast, for children born in 2021, the youngest children (quarter 4) tended to have alarm suggestions using the Gades platform.

The results of the assessment outcomes in relation to the control questions can be observed in Table 6. It is noteworthy that the 2 children who disclosed a family history of other NDD in the control questions were identified as cases with difficulties in language development (ie, SLD or DLD cases). Among cases with reported issues during pregnancy (ie, perinatal, prenatal, or premature), a notable percentage resulted in difficulties in language development (9/13, 69% including warnings). In the case of preterm children, only 8 (3.7%) of the 218 cases were identified as cases with difficulties in language development. Only one of these preterm cases, a girl, was assessed as an alarm. The 3 cases of preterm boys without previous NDD

XSL•FO
RenderX

demonstrated typical development. The remaining alarms in boys corresponded to cases of prenatal (3/218, 1.4%) and perinatal (4/218, 1.8%) risks. A similar scenario extended to bilingual cases, where only 1 child exhibited an alarm of language development difficulties.

Table 6. The child's evaluations were distributed by control information, gender, and suggestion typea (N=218).



Gender and evaluation	Birth complications, n (%)		Family history, n (%)		Bilingual cases, n (%)	
	Center 1	Center 2	Center 1	Center 2	Center 1	Center 2
Female						
Alarm	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Warning	3 (1.4)	0 (0)	0 (0)	0 (0)	3 (1.4)	0 (0)
Typical development	1 (0.5)	0 (0)	0 (0)	0 (0)	4 (1.8)	0 (0)
Male						
Alarm	4 (1.8)	2 (0.9)	1 (0.5)	1 (0.5)	1 (0.5)	0 (0)
Warning	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Typical development	3 (1.4)	0 (0)	0 (0)	0 (0)	2 (0.9)	0 (0)

[a]Among children with birth complications, 69% (9/13) of them showed language development difficulties. Those with a family history of neurodevelopmental disorder also faced challenges, while only 1 bilingual child showed an alarm.

Gades' Performance

Gades' performance is assessed by the extent to which the system's decisions align with the perspectives of evaluators who support its recommendations. If there was disagreement with a recommendation, evaluators were prompted to justify dissent. Evaluators based their agreement or disagreement with the system's decision on their understanding of the child, considering factors such as age, family environment, and communicative intent. According to the results, Gades exhibited an accuracy rate of 97.4% (263/270). Out of 270 evaluations, only 7 (2.6%) suggestions were declined by evaluators. Figure 7 shows a higher disagreement rate with the system's decisions in children aged <24 months. Specifically, the accuracy rate was 92.3% up to 12 months, compared to 97.8% in the second grade (aged between 13 and 24 months) and 98.9% in the third grade (aged between 25 and 36 months).

Figure 7. Gades acceptance per grade. Out of 270 evaluations, only 7 proposals were declined (ie, 3 for evaluations of the first and second grades and 1 for evaluations in children aged >24 months). Even so, the acceptance of Gades remains above 90% in all courses.

Considering the total of 270 assessments conducted, including those where children were evaluated twice, the accuracy of Gades' decisions is depicted in Table 7. Among the suggestions provided by the Gades system, where evaluators disagreed (7/270, 2.6%), some suggested referring the child to early intervention for a specialized assessment (5/270, 1.9%).

Table 7. Gades' accuracy by the suggestion typea.

Suggestion description	Accepted suggestion, n (%)	
	No (n=7)	Yes (n=263)
Refer to early childhood care	5 (1.9)	45 (16.7)
Typical development	0 (0)	125 (46.3)
Repeat assessment (within 2 mo)	2 (0.74)	29 (10.7)
Repeat assessment (within 3 mo)	0 (0)	44 (16.3)
Repeat assessment (within 1 mo)	0 (0)	20 (7.4)

[a]Evaluators did not agree with Gades' suggestion in 2.6% (7/270) of evaluations. Most of these unaccepted suggestions were for the most severe cases identified by Gades ("refer to early childhood care"). Gades exhibit an accuracy rate of 97.41%.

XSL•FO
RenderX

When the evaluator disagreed with the Gades' decision, they were required to provide a comment stating the reason for nonacceptance. Thus, several reasons explain why the evaluators did not accept Gades' decision (Table 8). In 4 instances (ie, for months 10, 12, 15, and 18), they noted that the questions were not tailored to the child's developmental stage. In 2 cases from 18 months, the evaluator rejected the suggestion. Moreover, in case "The questions do not align with the child's developmental stage," the assessor disagreed with the suggestion and conducted an immediate reassessment. This subsequent assessment issued a warning (ie, to repeat the evaluation in the next months). In addition, in 2 cases involving 2 boys, the evaluators intended to continue observing the child's progress as they had identified other communicative skills. Finally, there was no disagreement for typical development cases.

Table 8. Evaluator's reasons for rejecting the final suggestion from Gadesa.

Reason	Children's gender	Evaluation month
Refer to early childhood care		
"We will monitor the situation closely. If necessary, we will consult the Early Assessment Team for guidance."	Male	26
"There are alternative forms of communication besides verbal language, and he demonstrates proficiency in them. We will observe his development and see how it progresses."	Male	18
"The questions do not align with the child's developmental stage."	Female	10
"The questions do not align with the child's developmental stage."	Male	10
"The questions do not align with the child's developmental stage."	Female	15
Repeat assessment (within 2 mo)		
"The questions do not align with the child's developmental stage."	Female	12
"We consider that it is not necessary at this stage."	Male	18

[a]The suggestions that were not accepted relate to "refer to early childhood care and repeat assessment (within 2 months)". Most of the reasons were that the assessment conducted by Gades was not aligned with the child's developmental stage.

Overview of the Obtained Functional Results

Numerous interviews were conducted with the evaluation staff, and they completed a web-based form assessing the usefulness and practicality of the Gades tool in uncontrolled educational settings, following the guidelines outlined in the referenced study [41]. None of the evaluators had previous experience using this specific platform. It was noted that preschool educators and professionals in early childhood educational and psychopedagogical centers found Gades highly acceptable. Most (18/24, 75%) of the evaluators found the system easy to use, although it required dedicated time. They experienced occasional technological issues such as student search processes or time sessions. A quarter felt previous technological knowledge was necessary.

The educators used an observational methodology during the school day to respond to the form's questions, considering it noninvasive and conducive to respectful support within an appropriate environment for the child. They suggested that implementing the Gades assessment during the first term of the school year, particularly during the adaptation period, could be challenging due to their limited familiarity with the child. In addition, they proposed conducting evaluations every 3 months for cases initially indicating "typical development" to ensure ongoing progress.

While control questions were valuable for accurate results from the Gades system, access to certain information, particularly related to birth difficulties, was limited for many children. Regarding the comprehension and appropriateness of the KB questions, educators encountered comprehension difficulties in only 2 out of the 108 questions, which they resolved by consulting the Gades' technical staff. They noted that some questions were unsuitable for the child's developmental stage. They highlighted the absence of questions about family context, communication dynamics, and disruptive behaviors in the second and third years.

Regarding recommendations, 75% (18/24) of the evaluators reported that they would suggest Gades to other nursery schools, emphasizing the need for previous DLD training to observe children effectively. They reported high knowledge acquisition and insight into their students' language development. For instance, they had observed that girls aged <12 months initiated communication earlier and more fluently.

Discussion

Principal Findings

This study's core findings underscore the Gades platform's effectiveness as a robust tool for screening language disorders in preschool environments, successfully identifying language difficulties in 19.7% (43/218) of the children assessed. This rate, with a notable prevalence in boys (29/218, 13.3%) compared to girls (14/218, 6.4%), is significantly higher than the traditional prevalence estimates of 2% to 7% for DLDs [8,17,21,23,43]. This discrepancy suggests that Gades may be particularly sensitive to early signs of language difficulties or may also capture cases of SLD. As a screening tool rather than a diagnostic system, Gades aims to identify children at higher risk for DLD or SLD, which might lead to elevated detection rates compared to studies focused strictly on diagnosis. Comprehensive assessments by specialists at early intervention

XSL•FO
RenderX

centers are required for a definitive diagnosis, highlighting the necessity of further evaluation following initial screening outcomes.

The study validated Gades' technical and functional capabilities in uncontrolled educational settings without direct intervention by an NSLT. The platform's utility in guiding nonexpert users, such as preschool teachers, through the screening process was particularly noteworthy. Teachers could use Gades effectively to observe and assess language development, reflecting its potential to empower educators with limited specialized training in language disorders.

Moreover, Gades demonstrated a high accuracy rate (97.41%) in aligning with the educators' assessments, underscoring its reliability and the robustness of its underlying algorithms and KB. The discrepancies between the system's recommendations and the educators' judgments were minimal, indicating a high level of agreement and trust in the platform's diagnostic suggestions.

The findings also illuminated specific age ranges (between 15 and 27 months) where language difficulties are most prevalent, reinforcing the importance of targeted early intervention during this critical developmental period. The ability of Gades to adapt its screening approach based on the child's age and specific educational context was a key factor in its effectiveness.

These promising results suggest that integrating Gades into regular preschool assessments could significantly enhance the early detection of language disorders, potentially leading to more timely and effective interventions.

Extending Detection to Natural Environments

This study highlights the importance of checking for developmental disorders similar to DLD in natural settings, such as preschools, where children naturally spend much time. DLD, similar to autism and ADHD, is among the most common developmental challenges but often goes unrecognized because its symptoms may resemble simple speech delays or overlap with other developmental disorders, leading to delayed diagnoses. Equipping educators, teachers, and school professionals with the right knowledge and support is crucial because they can spot early signs of these disorders. Early detection, significantly enhanced through collaboration with a multidisciplinary team, is key to improving a child's prospects for developing language skills effectively.

Applicability and Scalability

The Gades platform is designed to be versatile and scalable, making it a valuable tool for educators worldwide, especially in regions with limited access to specialized language disorder services. This flexibility is crucial for adapting to diverse linguistic and cultural environments across global educational systems. To effectively implement Gades in these diverse settings, developing training programs sensitive to local languages and educational standards is essential. These programs should equip educators with the skills to use the platform effectively and to recognize early signs of language disorders, even without specialized training.

Considering the technological limitations in different regions, Gades should be designed to operate in low-bandwidth environments and comply with local data protection regulations. This will make the platform accessible and trustworthy. Enhancing the platform's database to support multiple languages and reflect cultural specifics can make Gades a more inclusive tool that accurately reflects diverse child development patterns.

Practical implementation strategies include collaborating with local educational authorities to incorporate Gades into routine screening processes. This might involve tailoring the platform to meet local developmental benchmarks and language nuances. Partnering with local educational institutions can provide continuous support and feedback, helping to refine the platform.

Gades could offer versions that range from sophisticated, high-tech applications to more basic, web-accessible formats to accommodate varying technological capabilities. Establishing a community of practice among Gades users would encourage sharing best practices and provide essential peer support, enhancing the platform's overall effectiveness and user experience.

Limitations

One significant limitation of the Gades system is its reliance on the accuracy of the input provided by educators, who may not have specialized training in identifying language disorders. This dependency can introduce biases or inaccuracies in the screening process, as nonexpert interpretations of language development may vary widely, affecting the reliability of the outcomes. To mitigate these potential biases, it is essential to implement comprehensive training programs for educators using the platform. These programs should focus on familiarizing them with common language development milestones and the specific signs of language disorders. In addition, incorporating automated prompts and guidelines within the Gades system can help standardize recorded observations, reducing subjective interpretation errors.

Further refining the interface and feedback mechanisms of Gades can also enhance the accuracy of the data collected. For instance, the platform could include illustrative examples or short training videos on typical versus atypical language behaviors to guide educators' assessments before they input data. Regular updates and calibrations based on user feedback and new research in language development could further improve the system's precision and adaptability to real-world educational environments.

The study's limitations extend beyond the technical aspects of the Gades platform to include concerns about the sample size and the uncontrolled implementation settings. The small sample size may not adequately represent the broader population of preschool children, limiting the generalizability of the findings. In addition, while providing real-world insights into the use of Gades, the uncontrolled setting might introduce variability in how the platform is used across different environments, potentially influencing the consistency and applicability of the results. These factors could lead to higher variability in outcomes, which might not fully indicate the platform's efficacy under different or more controlled conditions.

RenderX

Future Directions

Future research should include larger and more diverse populations to address the limitations mentioned to ensure that findings are robust and widely applicable. Controlled trials, where variables can be more tightly managed, would also help understand the platform's effectiveness across varied educational settings and populations. This would allow for more reliable validation of the platform's capabilities and identify specific conditions under which it performs best, guiding more targeted improvements.

To enhance Gades' effectiveness and reliability, it is imperative to refine the tool by expanding the KB to better differentiate between DLD and SLD at earlier stages. Adapting the system to align more closely with the actual ages of children rather than their academic year will provide more accurate assessments. Implementing educator training modules will equip them to effectively recognize early signs of language difficulties. Future versions of Gades should include a nuanced approach for assessing the youngest children in the class, considering their specific developmental stages and potential delays without prematurely recommending specialist evaluations. These improvements will ensure that Gades supports early detection and integrates smoothly into regular preschool assessments, potentially enhancing the effectiveness of interventions for language disorders.

Conclusions

This study confirms that DLD remains a commonly overlooked condition with significant variability and potential overlaps with other developmental disorders. Importantly, our findings reinforce the critical nature of age-specific screenings, with the most alarms for language difficulties arising in second-year grades, supporting the hypothesis that this period is crucial for detecting DLD risk factors. Despite the conservative and generic screening process, which identified language difficulties in 19% of cases—higher than the 7% prevalence typically noted in other studies—some of these instances may represent SLD. This suggests a need for refining language milestones within the Gades system to more effectively distinguish between DLD and SLD.

The qualitative outcomes from the Gades platform demonstrate its value in designing tailored educational programs and therapeutic interventions. By integrating such tools without the need for direct support from NSLT, Gades facilitates a deeper understanding of individual language development patterns. This insight enables educators, particularly those without specialized training in language disorders, to identify and address developmental challenges more effectively and earlier. The platform has been well-received in terms of usability and practicality, enhancing educators' ability to actively monitor and support language development.

Moreover, implementing Gades has provided substantial learning opportunities for preschool teachers. Educators with no previous expertise in DLD have gained significant knowledge and skills in informal screening processes, which has had a transformative impact on their ability to recognize and respond to language development issues. This empowerment of teachers underscores the potential of Gades to serve as a foundational tool in early education settings, enhancing early detection and intervention strategies.

To extend the utility of Gades beyond this study context, it is crucial to provide practical recommendations for its implementation in various educational settings. Tailoring the platform to accommodate different regional educational standards and linguistic backgrounds can maximize its effectiveness and reach. In addition, the successful deployment of Gades is contingent upon comprehensive training programs for educators. These programs should focus on enhancing understanding of language milestones, screening techniques, and the specific functionalities of the Gades platform. Effective training could be implemented through web-based modules, workshops, and ongoing support systems to ensure educators can proficiently use the tool.

In conclusion, the Gades platform represents a significant advancement in the field of educational technology for screening language disorders. By facilitating detailed observation and reporting of language development, Gades supports educators in their daily interactions with children and contributes to a broader strategy for addressing DLDs in early childhood education. The adoption of such tools, accompanied by adequate training and tailored implementation strategies, holds the promise of significantly improving outcomes for children at risk of DLD and SLD across diverse educational landscapes.

Acknowledgments

The authors would like to thank the team of educators and preschool teachers from Escuela Infantil Sabina and Patricia Calcerrada Muñoz from Equipo de Orientación Educativa y Psicopedagógica de Atención Temprana de Parla (Madrid, Spain) for their collaboration in performing the experiment presented here. In addition, the authors give special thanks to Esther González Dávila and Elena Jambrina Prieto from the Asociación del Trastorno Específico del Lenguaje de Madrid for their support in this study.

Abstract

Background: Young sexual minority men (YSMM) are disproportionately impacted by HIV in the United States. HIV or sexually transmitted infection (STI) testing rates and pre-exposure prophylaxis (PrEP) uptake are low in this priority population. Novel strategies are needed to increase access to HIV and STI prevention services among YSMM.

Objective: This study aims to describe the development and assess the feasibility and acceptability of LYNX, a mobile app to increase HIV testing and PrEP uptake among YSMM.

Methods: Informed by the Information-Motivation-Behavioral Skills model, the LYNX app was refined through 4 iterative focus groups in 2 US cities among YSMM aged 15 to 24 years. The LYNX app includes SexPro, an innovative tool that provides a personalized sexual health protection score, a sex diary to track sexual partners, HIV and STI testing information and reminders, access to home HIV and STI test kits, and geospatial-based testing and PrEP clinic site information. The refined app was then tested for feasibility and acceptability in a 2-month technical pilot. Baseline and 2-month follow-up assessments and exit interviews were completed. Self-reported app acceptability and use based on paradata were reported.

Results: In iterative focus groups among 30 participants (age: mean 20, SD 3 years; Black: 12/30, 40%; Hispanic or Latinx: 13/30, 43%), the app's design was well-received. Participants recommended providing information on how the SexPro score was calculated and how they could improve their score, changes to the language in the sex diary tailored for YSMM, providing a chat feature to facilitate communication between staff and app users, and gamification features to increase overall youth engagement with the app. These recommendations were incorporated into the app. In the technical pilot among 17 participants (age: mean 22.4, SD 1.6 years; Black: 4/17, 24%; Hispanic or Latinx: 8/17, 47%), the mean system usability score was 70 out of 100, falling

XSL•FO
RenderX

in the “good” range. Use of the app was high over the 2-month pilot (app opened an average of 8.5, SD 8.0 times with an average duration of 3.8, SD 3.2 min/session), indicating good feasibility. The most commonly used features included the testing feature (n=15, 100%), activity calendar (n=14, 93%), and diary (n=13, 86%). Overall, 11 (79%) participants were likely to continue using LYNX, and 10 (71%) participants were likely to recommend it to a friend. In exit interviews, there was a high level of acceptability of the content, interface, and features of the LYNX app.

Conclusions: Following a user-centered design approach, we tailored the LYNX app to increase HIV and STI testing and PrEP uptake among YSMM in the United States. Our positive findings support further testing of this mobile health tool in an upcoming effectiveness trial in broader youth populations.

HIV testing; sexually transmitted infection testing; pre-exposure prophylaxis; youth; men who have sex with men; sexual minority men; mobile health; HIV prevention; STI

Introduction

Background

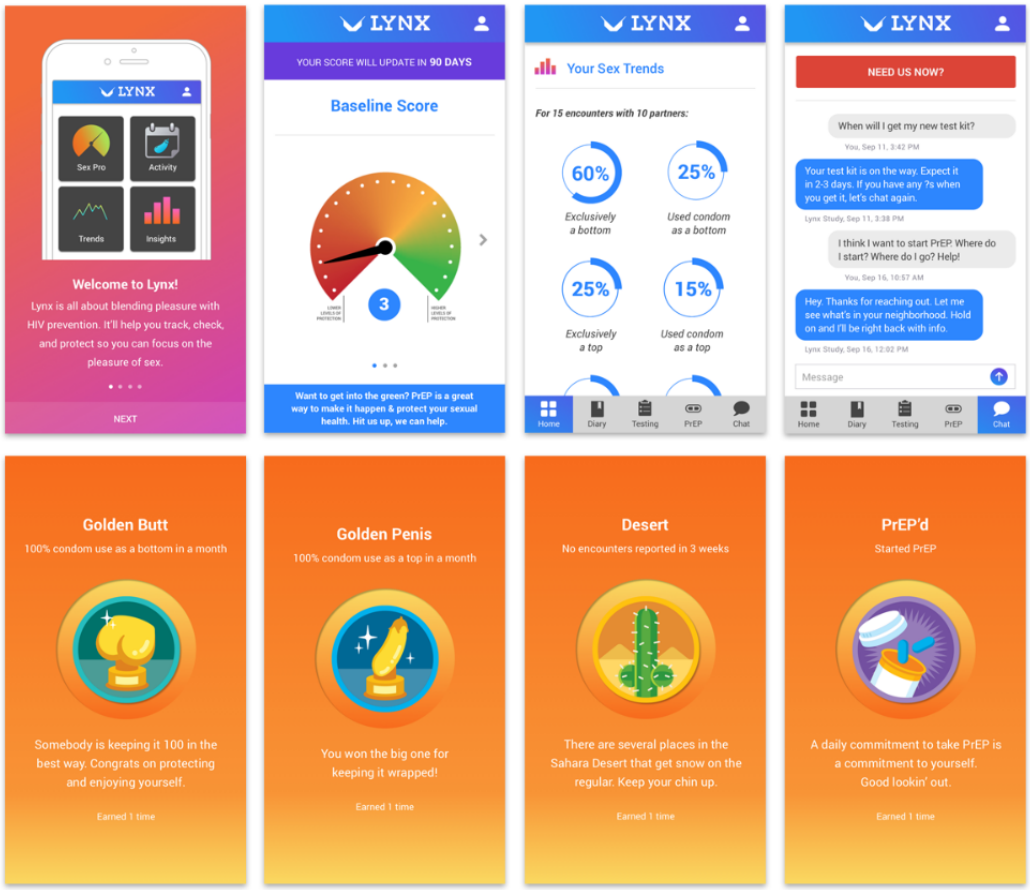
Young sexual minority men (YSMM) are disproportionately impacted by HIV in the United States. In 2021, 19% of the estimated 32,100 new HIV cases in the United States were among young people aged 13-24 years, with YSMM accounting for 82% of new HIV diagnoses in this age group [1]. YSMM of color are particularly impacted by HIV, with Black and Latino sexual minority men (SMM) accounting for 53% and 28% of infections among YSMM, respectively, in 2021 [1]. There is an urgent need to expand access to effective HIV prevention strategies in this priority population.

HIV Testing and Pre-Exposure Prophylaxis Use Among YSMM

HIV testing is the gateway to the HIV treatment and prevention continua, and it affords an important opportunity to offer timely treatment for YSMM living with HIV and for linkage to effective preventive strategies for those who test HIV negative. Although the Centers for Disease Control and Prevention recommends at least yearly HIV testing for SMM, in a recent national web-based survey, only 40% of YSMM reported testing in the past year, and 45% had never tested in their lifetime [2]. Young people are the least likely to be aware of their HIV status, with only 56% of US youth living with HIV aware of their diagnosis in 2022 [3]. Despite YSMM having among the highest annual sexually transmitted infection (STI) rate among any age group [4], STI testing rates are also low [5], with only a third of YSMM reporting STI testing in the last year [6]. Low perceived risk, lack of symptoms, limited knowledge of STIs, and lower access to health care providers have been identified as barriers to HIV and STI testing [7-9].

Numerous studies have demonstrated the effectiveness of pre-exposure prophylaxis (PrEP) for HIV prevention [10-12], now one of the pillars of the Ending the HIV Epidemic Initiative in the United States; however, uptake of PrEP has been low among YSMM. According to national prescription data, youth aged 15 to 24 years had the greatest unmet need for PrEP among all age groups, with a PrEP-to-need ratio of 9, indicating that for every person in this age group diagnosed with HIV, there were only 9 people using PrEP, compared to a PrEP-to-need ratio of 17 for people aged 35 to 44 years [13]. Demonstration projects also highlight challenges with PrEP uptake. In the Adolescent Medicine Trials Network for HIV Interventions (ATN), 110 study of YSMM aged 18 to 22 years, PrEP uptake was only 16%, and PrEP adherence was lower among Black YSMM and declined overall during follow-up, particularly with less frequent visits [14]. A number of factors contribute to low PrEP uptake, including low awareness and knowledge about PrEP, limited access to PrEP providers and clinics, deficits in self-perceived risk, HIV- and PrEP-related stigma, and medical mistrust, especially among YSMM of color, and highlight the importance of innovative strategies to increase testing and PrEP uptake tailored for YSMM [15-17].

Potential of Mobile Health Technologies



Mobile technologies have enormous potential to reach and engage YSMM in HIV prevention [18-22]. Mobile phone use is nearly ubiquitous among youth, and youth are more likely to use their mobile devices for more activities, such as downloading mobile apps, internet access, social media, and accessing health information, compared to people in older age groups [23,24]. The expansion of smartphones has increased the possibilities of dynamic, mobile phone–based HIV prevention interventions. Particularly, a mobile phone app designed to increase HIV testing and PrEP uptake could be highly scalable and has great potential to expand access to and uptake of prevention services among youth.

Using the Information-Motivation-Behavioral Skills (IMB) model [25], we previously developed the LYNX app, a highly interactive mobile app to promote accurate risk perception and increase HIV and STI testing and linkage to care, which has been previously described [26]. Components of the app are shown in Figure 1 and include (1) SexPro (Sexual Health Promotion), an innovative tool that provides a personalized HIV risk score displayed on a “speedometer” (1-20), with a higher score representing higher levels of protection [27]; (2) a sex diary to help users track their sexual partners and encounters, which are then displayed in a calendar; (3) HIV and STI testing information and reminders; and (4) ability to order home HIV

XSL•FO
RenderX

point-of-care self-test kits (Oraquick) and home STI testing collection kits (self-collected specimens mailed to a central laboratory for testing) through the app and access the geospatial-based testing site and linkage to HIV care information. To protect participant privacy, the app is accessed through a secure password-protected log-in, and information collected through the app is encrypted and stored in a secure environment that supports Health Insurance Portability and Accountability Act (HIPAA) compliance.

Figure 1. LYNX app screenshots. PrEP: pre-exposure prophylaxis.

In this study, we describe the results of a 2-phase study to develop and refine the LYNX app tailored for YSMM through iterative focus groups and an open technical pilot. This study was conducted within the National Institutes of Health's ATN as part of the University of North Carolina and Emory Center for innovative technology (iTech), which had the overall goal to develop technology-focused interventions addressing the HIV prevention and care continuum for youth [28].

Methods

Study Population

Eligible participants included cisgender men who were aged 15 to 24 years, self-reported being HIV negative or HIV status unknown at screening (technical pilot only), not currently taking PrEP (technical pilot, as participants are testing an app, which assists with PrEP uptake), fluent in English, owned an iOS or Android mobile phone, and had self-reported evidence of being at risk for HIV acquisition (detailed risk criteria are described in the study by Liu et al [26]). Focus group participants were able to participate in the technical pilot if they remained eligible.

Through the National Institutes of Health's ATN iTech U19, participants were recruited across 2 sites—Chicago, Illinois (study site: CORE Center), and Tampa, Florida (study site: University of South Florida). Participants for focus groups and the technical pilot were recruited through a variety of strategies, including web-based and social media postings (eg, Craigslist, Grindr, and Facebook advertisements); distributing posters, flyers, and palm cards about the study; direct outreach at local venues frequented by YSMM (eg, community-based organizations, schools, social clubs, health fairs, and balls); clinic-based recruitment; and participants in prior studies. To ensure inclusion of youth most impacted by HIV, we oversampled YSMM of color, with a goal of enrolling two-thirds of the cohort as YSMM of color and at least one-quarter as Black YSMM. Oversampling was accomplished by focusing recruitment efforts on venues more likely to be frequented by YSMM of color.

Iterative Focus Groups for App Refinement

After an initial prototype of the LYNX app was developed by the study team, we conducted 2 rounds of formative work through a series of 4 focus groups and individual interviews with 30 YSMM across our 2 iTech sites, which informed iterative development of the LYNX app. YSMM participated in 1 of the 4 groups, which each met 2 times. Participants unable to be scheduled for a focus group were offered an individual

XSL•FO
RenderX

interview, with the same content covered in both focus groups and interviews. Groups were divided by age strata (15-18 years, 19-24 years, etc), and focus groups were conducted in a private room at each site by a research staff member trained in qualitative methods and group facilitation. All participants completed a written consent or assent process before initiation of the focus group. During the focus group discussion, participants were shown how to download and install the app and were given a demonstration of key features of the LYNX app. The home HIV and STI testing process was also explained, and participants were shown a test kit. New app components were developed to increase PrEP uptake and included a PrEP Facts page with information about PrEP, a map showing local PrEP clinics in an area, PrEP video testimonials of youth sharing their experiences about taking PrEP, and a feature of SexPro showing how PrEP can improve one's score. Participants were asked to give feedback on each component of the app and suggestions for improvement. At the end of the focus group, participants completed a brief web-based survey to assess demographic characteristics and use of technology to help contextualize the focus group discussion.

Members of the iTech Analytic Core reviewed transcripts and identified emergent themes. We conducted thematic analysis using a deductive approach to code data for app acceptability overall and for each component, with a focus on functionality, appearance, usability, and privacy and confidentiality. Key findings are described in the text using representative quotes and were used to refine the LYNX app before initiation of the technical pilot.

Changes to the LYNX App

On the basis of feedback from the focus groups and interviews, we made a list of recommended changes to the app. The study team then prioritized changes based on the perceived impact of the changes on the usability and acceptability of LYNX, the likelihood of increasing HIV and STI testing and PrEP uptake, and the technical feasibility of the modifications. We then worked with our app developer to implement these revisions to the LYNX app.

Technical Pilot to Assess Feasibility and Acceptability of the LYNX App

After refining the LYNX app based on our formative work, we conducted a 2-month technical pilot among 17 participants to assess the feasibility and acceptability of the LYNX app and to elicit additional feedback for app improvement. Eligible participants who enrolled in the study completed a web-based survey on sociodemographics, risk behaviors, and use of technology. Study staff assisted participants in downloading the LYNX app and were shown how to use key features of the app using an onboarding guide. Participants were encouraged to use all components of the app over the next 2 months, including ordering and using the HIV and STI test kit.

Upon completion of the technical pilot at month 2, participants were asked to complete a brief web-based survey to assess preliminary usability and acceptability of the app using the System Usability Scale (SUS), a validated tool assessing various domains of the app with demonstrated high internal consistency across several studies [29]. The SUS is a 10-item scale that measures a system's usability on a scale of 0 to 100. Feasibility was assessed using app analytics to determine whether the app was used, how many times it was used, and which components were used most and least frequently. Feasibility was a priori defined as having at least 60% of individuals open the LYNX app at least once after introduction to the app by research staff.

Each participant also completed an exit interview to provide feedback on functionality, technical performance, errors and bugs encountered, overall experiences using the app, feasibility and acceptability of methods to confirm HIV testing results, and feedback for further refinement. Exit interviews were conducted remotely with qualitative-trained study staff from the iTech Analytic Core using a HIPAA-compliant videoconferencing technology. Debriefing reports capturing the quality and key findings were completed after each interview. Interviews were also transcribed and analyzed using the same approach outlined earlier.

Ethical Considerations

The study procedures were reviewed and approved by the University of North Carolina Institutional Review Board (IRB) as a single IRB-of-Record (approval number: 17-0170). IRB authorization agreements with all participating research entities were enacted. Written informed consent was obtained before conducting any study activities. All study data were identified by a coded number only to maintain participant confidentiality. The LYNX protocol is registered at ClinicalTrials.gov (NCT03177512). For iterative focus groups, participants received US $50-$60 for completing each focus group or interview, depending on local site standards. For the technical pilot, participants received US $50-$60 for completing the baseline visit, US $25-$30 for completing the 2-month survey, and US $50-$60 for completing the final exit interview. Additionally, at one site, a $30 gas card for round trip transportation was provided. Incentive amounts varied by site and were based on local site standards.

Results

Iterative Focus Groups for App Refinement

Characteristics of the 30 focus group participants, 18 (60%) in Chicago and 12 (40%) in Tampa, are shown in Table 1. Mean age was 20 (SD 3.0) years; 13 (43%) self-identified as Hispanic or Latinx, 18 (60%) completed high school or lower, and 13 (43%) were currently in school. A substantial proportion reported having health insurance (n=21, 70%), ever tested for HIV (n=26, 87%), tested for other STIs in the past year (n=22, 73%), and ever taken PrEP (n=16, 53%). Most participants reported using iOS (n=20, 67%), receiving health information through a website or an app on a mobile phone (n=23, 77%), and that they thought receiving health information through a mobile app would be of interest to YSMM (n=27, 90%).

[a]STI: sexually transmitted infection.

[b]PrEP: pre-exposure prophylaxis.

[c]Among all participants.

[d]MSM: men who have sex with men.

Overall, the app was well-received by participants, and the design was thought to be aesthetically pleasing and intuitive. Participants saw the app's utility and thought that it would be a helpful tool for people to engage in their sexual health. A participant in Tampa stated the following:

> *I see this as a fitness health app, but for sexual health. So that does seem useful.*

Participants suggested that the goal of the app be made clear as part of the onboarding process, which was added after the first round of focus groups.

Regarding SexPro, participants felt the numeric score and the color coding (red for low score indicating low protection from HIV, yellow or orange for intermediate score indicating moderate protection, and green for a high score indicating high protection) were important to provide a more robust understanding of what their score meant. One participant in Chicago described it as follows:

> *The higher the number the better, even 12 versus 9 just sounds and feels better. Like if I have a 12, I feel like I'm getting there, I can start to get better. If I see a 7, I just think "fuck!" I'm screwed. Especially versus if you just showed me that scale with no numbers, I would be worried, I would think I'm not protected. I would think crap, I'm screwed.*

Another participant in Chicago stated the following:

> *Yeah, if it's orange I wanna do something to get it to go up (to green). But if it's red you might think you are going to have to make drastic lifestyle changes to get out of the red zone.*

Participants thought that seeing the score could help motivate a change in behavior, as a participant from Tampa stated the following:

> *Seeing the score would be good to motivate you to maybe change your life, or your habits, so you can increase your score.*

Several participants suggested adding a summary to help users understand what went into their score, as well as suggestions for how to improve their score. A participant in Tampa said the following:

> *I think it would be useful to see, rather than a number, but like why I got a number. If I compared my score to a friend's, and they had a different number—we could compare, like, this is what I did, this is what you did, that's why a summary page would be more useful.*

Participants also liked the sexual diary component of the app. A participant in Chicago said the following:

> *I do think that's kind of useful, so you can keep track of what you're doing, or you know, if you need to "slow your ho down"—I feel like you can be able to hide it, so people don't see it, or call your 5-star person up.*

Another participant in Chicago commented the following:

> *The diary makes it fun, and not just a health app. I would look forward to looking back at it because of all the fun comments I made in it. It makes being safe fun to me.*

One participant liked having a separate place to track their sexual partners without having the information living in their phone's contact list, saying the following:

> *Let's just say I was raped, or I had lost my phone or whatever, I could download the app on my new phone where I had backed it up and I would still have that person's information in the app, because I don't*

XSL•FO
RenderX

> *usually add people in my phone contact list. It's good information to have and keeps it all private.*

Participants also liked the notes section of the diary, as it made the diary seem less like a tool of objectification, with a participant in Tampa saying the following:

> *People judge people anyway, but having like the notes makes it more personal... you can go back and look at the things you said to remember, or things about that person you want to recall later, even if it's like, you know, their apartment was dirty.*

Participants did recommend changing the terminology for describing partner types in the diary. For example, they found "no strings attached" to be confusing and suggested changing this to "one night stand."

Most participants felt comfortable using the home HIV and STI self-collection kits and saw value in this service, although YSMM aged 15 to 18 years expressed some concerns regarding potential errors with using the STI test kits and felt the shipping process was cumbersome and may be a deterrent for youth. Participants remarked that testing services were limited in their area (particularly Tampa). They reported that the few places that offered services had limited hours that conflicted with work and school schedules. A participant in Chicago said the following:

> *This option is a lot better especially if you are scared to go to a doctor. That's reassuring.*

They highlighted the importance of confidentiality. A participant in Tampa said the following:

> *As long as the packaging is confidential that came to my home. I'm totally fine to do a care kit like that. Especially since it's free to request and ship.*

However, some participants felt that testing at home would mean they would miss out on the opportunity to build rapport with their medical provider. In addition, some participants reported concerns with collecting the specimens and preparing the kits for shipment, as a participant in Chicago said the following:

> *For me it's easier to go to the doctor's office, then I don't have to worry about messing something up or anything like that.*

If someone were to receive a positive HIV test result, participants wanted immediate access to a provider who could offer supportive counseling. They also suggested adding a chat function to communicate with the clinic.

Participants appreciated the PrEP components of LYNX, including the ability to find local PrEP clinics in their area; however, they recommended that the goal of increasing PrEP uptake be made clearer in the onboarding section of the app. One focus group participant in Tampa said the following:

> *As far as like the HIV and like the prep, thing when I first downloaded it, I didn't really see it as that being like the focus. I thought like the focus was more of tracking your partners.*

While some participants liked showing how one's SexPro score increases on PrEP, they recommended including information about other non-PrEP–related factors that could influence their SexPro score, as described by another participant in Tampa:

> *Yeah like if swiping right included other things like let's see what your score would look like if you used like more condoms, or you know decreased your number of partners as well. Like different factors not always just, well if you were on PrEP this is what would like... obviously PrEP is not the only thing that's going to bring up your level and increase your protection.*

Participants were also interested in gamification and receiving feedback from the app based on the data they entered into the app. When shown examples of badges in the focus groups, one participant said the following:

> *It's a pat on the back. It's cute! You are being rewarded for being a ho! (followed by laughter)*

They liked the golden penis badge and suggested having a "gold butt" badge as a complement (Figure 1). They also recommended creating badges to keep track of PrEP pill taking and having a "desert badge" when they are not having sex. They also liked the idea of having a trends and insights page, which would provide additional feedback on their trends in sexual behaviors.

Changes to the LYNX App

On the basis of the feedback from the focus groups, we made several revisions and additions to the LYNX app, guided by the IMB model. Regarding "information," several welcome screens were added to the onboarding process to clarify the goals of the app, including the message "to marry pleasure with prevention," which was a theme that emerged from the focus groups, as well as clarifying the goal of increasing PrEP uptake. To provide more information about PrEP, a PrEP Facts page was added that included answers to frequently asked questions about PrEP. Regarding SexPro, we added information on behaviors contributing to the calculation of their SexPro score, with an option to click on "Learn why these matter," which provides a more detailed description of how different behaviors change one's risk for HIV acquisition. We also added information about how participants could improve their score and how their score would be impacted by taking PrEP. To provide additional feedback to participants on the data they entered into LYNX, we also created a trends page that summarized different sexual behaviors and encounters (eg, you were exclusively a bottom 50% of the time) and an insights page that summarized characteristics of their sexual partners (gender identity, partner type, partner HIV status, and number of repeat partners). Regarding "motivation," we added video testimonials of YSMM on their experience taking PrEP to help motivate YSMM to consider taking PrEP. We also added several gamification features to the app, including the ability to earn different types of badges (Figure 1), and a "top 5" feature for the 5 most highly rated partners and 5 most highly rated sexual encounters. In addition, the language in the sex diary was modified based on input from the focus groups (eg, changing "no strings attached" to "one night stand") and the notes section was included in the

XSL•FO
RenderX

final design to allow participants to enter free text to capture anything they would like to remember about the partner. Regarding Behavioral skills, we added the PrEP locator function to allow participants to find a local PrEP clinic that served youth. We also added a chat function to allow participants and study staff to send and receive in-app messages for additional guidance and support, as well as a "need us now" button in red at the top of the chat screen, which would allow participants to call an on-call provider available at all times. This chat function was real time and monitored by study staff (including study clinicians), who responded to participants within 24 business hours. Finally, we engaged a copywriter who simplified the language, using fewer words, and made the language in the app more appealing for youth. There were a few suggestions that were not incorporated into the app due to feasibility considerations but noted for future iterations of the app, including log-in via touch ID or social media log-in (instead of passcode), adding a group sex option in the sex diary, and adding dosing reminders for people who started taking PrEP.

Technical Pilot to Assess Feasibility and Acceptability of the LYNX App

From April to June 2018, a total of 17 participants were enrolled in the pilot study: 8 (47%) in Chicago and 9 (53%) in Tampa. Table 2 describes baseline characteristics of participants included in the technical pilot study. Overall, the mean age was 22.4 (SD 1.6) years; 8 (47%) self-identified as Hispanic or Latinx, and 5 (29%) completed high school or lower. The majority were currently employed (15/17, 88%), reported low income (12/17, 71%), lived with another person (14/17, 82%), currently had health insurance (10/17, 59%), and did not have a primary health care provider (12/17, 71%). The mean number of partners was 3.1 (SD 2.5) in the past 3 months, and 11 (65%) participants reported condomless sex. A total of 5 (29%) participants never tested for HIV, and only 1 (6%) tested in the past 3 months. For other STIs, 9 (53%) participants had never tested before and 8 (47%) tested >3 months ago. Regarding prevention technologies, 11 (65%) and 15 (88%) heard about HIV self-testing and PrEP before the study, respectively. Most participants (n=10, 59%) reported using the iOS mobile phone operating system, had a phone contract billed monthly (n=9, 53%), and used apps more than once per week (n=14, 82%).

A total of 15 (N=17, 88%) participants completed the follow-up visit. The mean SUS score was 70.4 (SD 17.2), corresponding to a rating in the good range (Table 3) [30]. The highest score was on item "I thought the system was easy to use" (mean 4.3, SD 0.9), and the lowest score was on item "I needed to learn a lot of things before I could get going with LYNX" (mean 2.2, SD 1.4). Most reported using the LYNX app at least once a week (8/14, 57%); that they would be somewhat likely, likely, or very likely to continue using the app (11/14, 79%); and would definitely recommend it to a friend in need of similar help with getting tested for HIV and STIs and accessing PrEP (10/14, 71%). A total of 43% (6/14) of participants ordered an HIV test kit, and 36% (5/14) ordered an STI test kit.

Most participants rated all components of LYNX as not at all difficult or a little difficult to use (Figure 2). Almost 86% (12/14) of participants reported the components "Taking SexPro Quiz" and "Entering information as part of the onboarding process" as not at all difficult. More than half of the participants considered all components at least somewhat helpful (Figure 3). "Ordering test kits and safer sex supplies" was considered extremely helpful for 64% (9/14) of respondents. More than half of the participants strongly agreed or agreed with statements related to IMB model impact (Figure 4). More than 90% (13/14) strongly agreed or agreed that "the LYNX app helped me keep track of my sexual partners and the types of sex I have" (13/14, 93%). More than 70% (10/14) strongly agreed or agreed that "The LYNX app helped me understand my risk for getting HIV" (10/14, 72%) and "The LYNX app helped me understand whether PrEP would be a good fit for me" (11/14, 79%) and half strongly agreed or agreed that the app helped them in starting PrEP (7/14, 50%).

Participants opened the app, on average, 8.5 (SD 8.0, range 1-31) times during the 2-month pilot intervention period, with an average duration of 3.8 (SD 3.2, range 0.2-11.8) minutes per session. Across all participants, the cumulative time spent in the app ranged from 0.6 to 183.7 minutes, with a median of 16.5 (IQR 5.45-40.8) minutes. The mean time between enrollment and first app log-in was 5.7 (SD 17.2, range 0-67) days. The mean number of features accessed was 9.5 (SD 4.8, range 0-14) out of 16 features. The "testing" feature was used by all participants (15/100, 15%), followed by "Activity Calendar" (14/15, 93%) and "Diary" (13/15, 87%; Table 4). The most visited features were "Home Screen" (240 visits), "Diary" (189 visits), and "Testing" (174 visits).

Table 3. System Usability Scale (SUS) and app use among technical pilot participants in Tampa and Chicago (N=14).

SUS[a]	Values
Items, mean (SD)	
1: I think that I would like to use LYNX on a regular basis.	3.5 (1.3)
2: I found LYNX unnecessarily complex.	2.4 (1.3)
3: I thought the system was easy to use.	4.3 (0.9)
4: I think that I would need the support of a technical person to be able to use LYNX.	2.3 (1.4)
5: I found the various functions in LYNX were well integrated.	4.0 (1.4)
6: I thought there was too much inconsistency between different parts of LYNX.	2.6 (1.2)
7: I would imagine that most people would learn to use LYNX very quickly.	4.2 (1.1)
8: I found LYNX very cumbersome to use.	2.5 (1.2)
9: I felt very confident using LYNX.	3.9 (1.1)
10: I needed to learn a lot of things before I could get going with LYNX.	2.2 (1.4)
SUS total score, standardized (0-100), mean (SD)	70.4 (17.2)
In the past 2 months, on average, how often did you use the LYNX app?, n (%)	
Once a month or less	1 (7)
A few times a month	5 (36)
Once a week	5 (36)
A few times a week	2 (14)
Once a day	1 (7)
How likely would you be to continue using the LYNX app if it were available?, n (%)	
Very unlikely	2 (14)
Unlikely	1 (7)
Somewhat unlikely	0 (0)
Neutral	0 (0)
Somewhat likely	4 (29)
Likely	4 (29)
Very likely	3 (21)
If a friend were in need of similar help with getting tested for HIV or STIs[b] and accessing PrEP[c], would you recommend the LYNX app to him?, n (%)	
No, definitely not	0 (0)
No, I do not think so	0 (0)
Yes, I think so	4 (29)
Yes, definitely	10 (71)

[a]Scores range from 1 (strongly disagree) to 5 (strongly agree).

[a]STI: sexually transmitted infection.

[b]PrEP: pre-exposure prophylaxis.

[c]YSMM: young sexual minority men.

Among the 15 participants enrolled in the technical pilot, 9 (60%) participants completed an HIV test during the pilot, including 4 (27%) who tested at home. In addition, 4 (27%) participants started PrEP during the pilot.

Among 17 pilot study participants, 14 (82%) completed follow-up exit interviews. Overall, there was a high level of acceptability of content, interface, and features of the LYNX app, although some participants reported that they did not use all the app features (eg, sex diary) due to being in a monogamous relationship. One participant in Tampa noted the following:

> *I think that this app is so beneficial for like young gay men...they are scared and not confident in talking about this stuff and they don't have anyone to talk to...I think that's one thing that's really like important*

XSL•FO
RenderX

> *for this app because it has the answers, it has where to go, it has everything you need to know when you don't have the answers.*

Most participants liked the SexPro feature and thought that it accurately reflected their risk; however, most did not look back at the score during the pilot and did not believe that the SexPro score changed their level of interest in PrEP. Most participants liked the diary, trends, and insights features, as they helped them keep track of their partners and encounters and reflect on their sexual behaviors. One participant in Tampa said the following:

> *Yeah. I actually really thought the app is great. I lost tracking, my—like just my encounters and thought that was really beneficial especially like going back in time to kind of look at it because I don't know, it just keeps your eyes open about what you're doing.*

However, one participant felt that the diary was judgmental and objectifying of partners and was concerned that it would hurt a partner's feelings if they somehow saw it. Participants felt the diary was more helpful in tracking one-time encounters with casual partners, and this feature was less helpful for those in monogamous relationships. One participant suggested being able to look at data from a specific time frame (rather than cumulative partners and encounters), and several participants wanted the ability to edit previously entered entries. While most participants did not use the chat function, they liked that the feature was available, especially the "need us now" button. Many participants did not recall receiving notifications and reminders for HIV and STI testing, and would have preferred either weekly or monthly reminders. A few participants reported technical issues, such as receiving notifications at unscheduled times, and noted some bugs with the chat feature. Several participants who used the test kit reported being fearful of collecting the blood sample, and one participant had trouble with sending the kit back as they had lost the instruction sheet. Several participants suggested having video tutorials to help with the specimen collection and shipping process. One Chicago participant suggested adding resources for mental health, healthy relationships, and connections to the community. When asked whether they would use the app in the future, one participant in Chicago said the following:

> *Yes, 100%... It's really—it's good. I would–like yeah, I would advocate for it.*

Discussion

Principal Findings

Sexual minority youth face numerous barriers to accessing HIV and STI prevention services, including stigma and lack of access to prevention clinics, and have expressed high levels of interest in mobile health (mHealth) interventions to support HIV and STI prevention, which may help address some of these barriers [31,32]. While a growing number of mobile apps are now being designed and tested to support HIV and STI testing, linkage to care, and PrEP uptake [33], few have been tailored specifically for youth. This study describes findings from 2 phases of formative research to develop and tailor the LYNX app to increase HIV and STI testing and PrEP uptake among YSMM in the United States and demonstrated high initial acceptability and feasibility of the app.

To increase user engagement with mobile apps, it has been suggested that developers use an iterative data collection process to obtain input from the target audience about app preferences [34]. Similar to other studies that used focus groups or theater testing as part of formative development [35-38], we conducted iterative focus groups with a cohort of YSMM to efficiently elicit feedback and inform the development of updated prototypes of the LYNX app. Overall, the app's design was well-received by YSMM, and we received feedback to improve key components of the LYNX app, including the SexPro score and sexual diary, as well as recommendations for additional features to facilitate timely communication between users and staff and increase overall engagement and use of LYNX. In a 2-month technical pilot of the app, the revised LYNX app demonstrated feasibility based on use of the app as assessed via paradata and good acceptability as assessed via self-report.

Sanabria et al [39] used a multimethod, user-centered design approach, including input from a youth advisory board, a think-aloud protocol, and use case scenarios, to evaluate the usability of a mobile app to increase HIV testing among sexual and gender minority youth. This app, featuring HIV prevention information and an imaging algorithm for interpreting home-based HIV tests, demonstrated high user satisfaction and perceived usability that was independent of education and health literacy levels [40,41].

Several HIV risk scores have been developed and tested to assist in identifying individuals who may benefit from PrEP [42-45]; however, these have primarily been designed to be administered by providers and can be problematic, because clients may not be comfortable disclosing behaviors that put them at increased risk for HIV [46], and because identifying people at risk can be stigmatizing [47]. In this study, we tailored a patient-facing sexual health score (using a positive frame, with a higher score indicating higher sexual protection) specifically for use in youth. YSMM in our focus groups liked having both a color and numerical representation of protection from HIV; however, they wanted additional information on how the SexPro score was calculated and how they could improve their score. On the basis of these findings, key adaptations included adding information on the factors contributing to their score and how they could increase their score by changing behaviors or initiating PrEP.

Prior HIV research studies have also used sex diaries to capture detailed event-level sexual encounter data and to understand different profiles of HIV risk [48,49]; however, few have incorporated diaries into mobile apps as part of an mHealth intervention. A mobile app designed to collect sexual behavior in the Amsterdam PrEP Project was frequently used by SMM, with sexual behavior data collected by the app consistent with questionnaire data among those who used the app consistently [50]. In addition, in a study by Glick et al [51], completing sexual diaries was associated with reduced frequencies of reported anal sex, acquisition of new partners, and lower incident HIV and STI diagnoses. In our study, the sexual diary was included as part of the LYNX app as a strategy to help YSMM better understand and track their sexual behaviors, as well as

XSL•FO
RenderX

increase engagement with the use of the app. In focus groups and the technical pilot, participants liked the diary feature; however, they made recommendations to tailor the language used in the sexual diary for YSMM and recommended an open-text section so the youth could customize their diary entries. The diary also appeared to be more useful for YSMM with a greater number of casual sexual partners. It will be important in future studies to characterize the types of partners YSMM enter into the app, for whom the diary is most useful, and whether diary use is sustained over time.

A key finding in our study was the importance of incorporating gamification features to increase engagement with the LYNX app by the youth. In a recent systematic review on the impact of mHealth-based gamification on the HIV prevention and care continuum in SMM by Luo et al [52], gamification interventions were shown to reduce condomless anal sex acts and were associated with an increase in PrEP adherence. Across the 26 studies included in the review, the most frequently used game components were points, followed by challenge, discussion forums, and mentorship or character narrative. In the LYNX app, we incorporated several gamification features based on feedback from YSMM in focus groups, including the ability to earn different badges, a "top 5 feature" for the most highly rated partners and sexual encounters, and a trends and insights page to synthesize the partner data they entered into the app into useful summaries. In other studies, the youth have also suggested that tangible versus virtual rewards (eg, a gift card) may be more likely to increase engagement [53], which should be explored in future studies.

Similar to other studies, most LYNX participants expressed interest in home HIV and STI self-collection kits, which could help overcome barriers to HIV testing among YSMM [31]. Convenience, privacy, and rapid result delivery have been cited by YSMM as principal motivators for using HIV self-tests [54]. In our study, YSMM expressed some concerns with collecting and preparing the specimens for shipment. The youth may benefit from videos demonstrating the specimen collection process and check-ins from staff on whether they need assistance with completing the test kits. On the basis of feedback in focus groups, we added a chat feature to facilitate communication between YSMM and staff and a button to call a clinician (eg, in the event of a positive HIV test), app features which have also been recommended in other studies of youth [55,56].

Limitations and Strengths

This study had several limitations. First, the technical pilot was small and not designed to evaluate the efficacy of the intervention. In addition, due to the short duration of the pilot, we were unable to evaluate long-term feasibility and acceptability. Nonetheless, formative work through focus groups and optimizing usability in a technical pilot are critical steps in developing and tailoring interventions before testing efficacy in large randomized controlled trials. Social desirability may have impacted YSMM responses in the focus groups and technical pilot; however, we used a self-administered web-based survey to assess usability and acceptability and paradata metrics from the LYNX app to objectively assess feasibility. In addition, participants in focus groups and exit interviews were reminded that there were no right or wrong answers and were encouraged to provide honest feedback that would help us best improve the app. For both phases of this study, participants were enrolled in Chicago and Tampa, potentially limiting the generalizability of the findings, although both regions are in high-priority "ending the HIV epidemic" jurisdictions, and 1 site is located in the South, the region accounting for over half of new HIV diagnoses nationally. Despite these limitations, our study had several strengths, including enrolling a diverse cohort of YSMM across both sites; the user-centered approach, incorporating input from our participants into the final design of our intervention; and the mixed methods approach to evaluate feasibility and acceptability in our technical pilot.

Conclusions

Using a user-centered design approach via iterative focus groups, we tailored the LYNX app to support HIV and STI testing and PrEP uptake among YSMM in the United States. Preliminary testing in a technical pilot demonstrated high acceptability and feasibility of the refined version of the LYNX app and supports further evaluation in an upcoming effectiveness trial.

Acknowledgments

We would like to thank Amayvis Garcia for assistance with recruiting participants and collecting study data. This study was funded by the National Institutes of Health Adolescent Medicine Trials Network for HIV Interventions (grant U01HD068040; principal investigators: LHW and PS). The authors thank all the participants for their helpful insights and feedback in this study. TST was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior—Brasil—Finance Code 001, Conselho Nacional de Desenvolvimento Científico e Tecnológico, and Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro.

Conflicts of Interest

AYL has received funding for investigator-sponsored research studies from Gilead Sciences and Viiv Healthcare and has led studies in which the study drug has been donated by Gilead Sciences. SPB has received funding for research studies from GSK, Gilead Sciences, and Merck. TST received consulting fees from Gilead. TO is a full time employee of AstraZeneca.

Abstract

Background: Digital health interventions (DHIs) are widely used to manage users' health in everyday life through digital devices. The use of DHIs generates various data, such as records of intervention use and the status of target symptoms, providing researchers with data-driven insights for improving these interventions even after deployment. Although DHI researchers have investigated these data, existing analysis practices have been fragmented, limiting a comprehensive understanding of the data.

Objective: We proposed an analysis task model to help DHI researchers analyze observational data from a holistic perspective. This model was then used to prototype an interactive visual analytics tool. We aimed to evaluate the suitability of the model for DHI data analysis and explore task support using a visual analytics tool.

Methods: We constructed a data analysis task model using 3 key components (ie, user grouping criteria) for DHI data analysis: user characteristics, user engagement with DHIs, and the effectiveness of DHIs on target symptoms based on comparisons before and after the intervention. On the basis of this model, we designed Maum Health Analytics, a medium-fidelity prototype of an interactive visual analytics tool. Each feature of the prototype was mapped one-to-one to the analysis task described in the model. To investigate whether the proposed model adequately reflects real-world DHI analysis needs, we conducted a preliminary user study with 5 groups of researchers (N=15). Participants explored the tool through scenario-based analysis tasks using in-the-wild data collected from a mobile DHI service targeting depressive symptoms. Following the session, we conducted interviews to assess the appropriateness of the defined tasks and the usability and practical utility of the visual analytics tool.

Results: DHI researchers responded positively to both the analysis task model and the visual analytics tool. In the interviews, participants noted that the tool supported the identification of users who needed additional care, informed content recommendations, and helped analyze intervention effectiveness in relation to user characteristics and engagement levels. They also appreciated the tool's role in simplifying analytic tasks and supporting communication across multidisciplinary teams. Additional suggestions included improvements for continuity across tasks and more detailed engagement metrics.

Conclusions: We proposed an analysis task model and designed an interactive visual analytics tool to support DHI researchers. Our user study showed that the model allows a holistic investigation of DHI data by integrating key analysis components and that the prototype tool simplifies analytic tasks and enhances communication among researchers. As DHIs grow, the proposed model and tool can effectively meet the data analysis requirements of researchers and improve efficiency.

Introduction

Background

Digital devices, such as smartphones and wearables, are extensively used in health care to deliver interventions beyond traditional medical settings [1]. These interventions, known as digital health interventions (DHIs), are designed to address various health issues and promote healthy behaviors, such as physical activity and smoking cessation, or to manage chronic conditions, such as depression and diabetes, in daily life [2,3].

DHIs use various intervention strategies, including behavior change techniques, which have proven to be effective in altering health behaviors [4-6]. These techniques include monitoring user behavior, setting goals, providing social support, and incorporating gamification. Furthermore, DHIs can be classified into different categories, such as digital health, medicine, and therapeutics, based on clinical evidence and real-world outcomes [7]. Previous studies [8-11] have investigated the delivery procedures of DHIs, identified barriers in their delivery paths, and determined the opportune moments for providing DHIs. All these studies share the common objective of effectively improving user behavior or symptoms targeted by DHIs.

DHIs are commonly designed as mobile apps, such as those in mobile health, which enable individuals to install and use them on smart devices. When users engage with the features and content offered by DHIs, various data are collected. For instance, several types of log data are passively gathered during user interactions with DHIs. Most of these log data consist of detailed records of user activities, including the frequency of DHI app use; individual DHI content accessed; and user interactions, such as taps, swipes, and text entries, within particular intervention content [12]. In addition, some data are actively provided by users through manual inputs, which are essential for capturing information that may be challenging to track using passive log data alone. These data often include basic user information, such as sociodemographic details, and periodic self-reports on their physical or mental health status.

Previous studies have performed various analyses to better understand the data collected from DHIs and assess either user engagement with the intervention content or the effectiveness of the interventions in supporting target users. Researchers studying DHIs have explored user engagement with interventions, assessing either subjective experiences about how immersed users are or objective behaviors, such as use frequency [11]. When quantitatively assessing engagement, researchers can analyze macroindicators, such as the number of log-ins to the DHI, frequency of content access, time spent, sequence of content use, as well as microindicators, such as the number of clicks and swipes [13-16]. A recent study [17] suggested similar metrics for measuring engagement, categorizing them into individual-level metrics, such as launch counts, use durations, and long-term use patterns, and population-level metrics, including the ratio of users who open the app at least once and the number of completers.

In addition, researchers have evaluated the effectiveness of DHIs on target symptoms by comparing health status before and after the use of DHIs in natural settings. The evaluation of DHIs typically progresses from measuring efficacy with a small group of users in controlled environments (eg, randomized controlled trials) to assessing effectiveness with a large group of users in uncontrolled environments [1]. By evaluating effectiveness without predefined treatment and control groups, researchers can investigate whether DHIs can yield the intended health changes or real-world evidence by analyzing real-world data (RWD), although numerous confounding factors exist [18,19]. Several metrics, such as user engagement and DHI effectiveness, can indicate how actively users have used DHIs and whether they have experienced improved health conditions, thus providing reasonable criteria for evaluating DHIs. A relevant example is the SilverCloud platform proposed by Doherty et al [20], which explores ways to encourage users to engage more actively in online mental health interventions. Using this platform, researchers have proposed approaches for visualizing log data to understand the engagement levels of individuals or groups of users [21] and predict the clinical outcomes of interventions using machine learning techniques [22].

Nevertheless, existing analyses of DHI data have often been performed separately based on individual researchers' interests, which limits their ability to understand data from various perspectives. Consequently, researchers may miss meaningful relationships among various indicators that can be extracted from DHI data. Moreover, the lack of a comprehensive analysis of DHI use patterns and changes in health status makes it challenging to determine how to improve DHIs according to the needs and preferences of specific user groups. Given that data analyses are repeated throughout the development and evaluation life cycle of DHIs [23], it is necessary to integrate the diverse analytical approaches that researchers can use with DHI data.

Objectives

Therefore, we proposed an analysis task model to help DHI researchers analyze data from a holistic perspective, enabling them to uncover interactions and patterns that are not visible when these factors are analyzed independently. We constructed this model based on common analysis practices observed in previous DHI research, particularly those identified in a meta-analytic review by Moshe et al [24].

To achieve this goal, we developed an analysis task model to help researchers explore DHI data from multiple perspectives. This model guided us to implement a prototype for an interactive visual analytics tool named Maum Health Analytics, which was designed to support the practical application of the model. The tool was evaluated using RWD collected from Maum Health,

XSL•FO
RenderX

a mobile DHI service for individuals experiencing depressive symptoms.

This study aimed to evaluate whether the proposed analysis task model is suitable for DHI data analysis and explore how visual analytics can support such tasks. Our preliminary user study identified several benefits of the Maum Health Analytics tool from the human-computer interaction perspective. We found that the proposed tool helped DHI research teams investigate user engagement and the effectiveness of the Maum Health DHI service from various angles, gain insights for recommending intervention content, and better understand users who may need additional care. Furthermore, Maum Health Analytics facilitated communication among various stakeholders, streamlined repetitive analysis tasks, and exhibited potential for integration with existing analytic systems.

Overall, our contribution can be summarized as follows:

1. We proposed an analysis task model for DHIs, aimed at assisting researchers in understanding DHI data from diverse perspectives.
2. We designed an interactive visual analytics tool based on the proposed model and explored its feasibility and design implications to better support researchers in analyzing DHI data.

Methods

This section describes the development of the analysis task model, the visual analytics tool, as well as the procedure of the preliminary user study conducted with the prototype. The subsequent sections present the quantitative and qualitative study results and discuss their implications for future research and the design of DHI analytics.

Analysis Task Model

Overview

As part of our previous work on DHIs [25], we conducted an in-depth analysis of RWD collected from a mobile DHI service named Maum Health, which supports individuals with depression. Through this process, we identified recurring analytical needs among DHI researchers, motivating us to design a dedicated visual analytics tool for this study. Within this service, users could assess their depression symptoms using the 10-item Center of Epidemiologic Studies Depression Scale (CES-D-10) questionnaire [26] and access intervention content, such as art therapy (named Mandala), physical activity promotion (named Geunsimtapa), and cognitive-emotional games (named Finding Blue) to alleviate symptoms. Following a 3-month deployment of the DHI, we analyzed depression states and content use logs stored on the server to extract data-driven insights to enhance the intervention service.

As a multidisciplinary DHI research team comprising intervention content designers, clinicians, and system developers, our analysis addressed several research questions, including differences in depression changes based on user characteristics (eg, initial depression level) and the association between DHI use and changes in depression. During the DHI data analysis, we made 3 key observations regarding the analysis tasks.

First, DHI researchers primarily focused on exploring user engagement with DHIs and the effectiveness of these interventions when evaluating existing DHI services. They determined that the DHI service can be considered as well designed if it is used more actively and if it leads to improvements in target symptom levels compared with before its use. In addition, given that the DHI was deployed to assess whether it supports the achievement of the intended outcome (ie, improving the depressive state) in the real world, researchers usually measure the effectiveness of a DHI instead of its efficacy. Unlike efficacy, which is typically measured in clinical trials involving random user assignments to control and treatment groups (controlled research setting), effectiveness is evaluated using data from observational studies, allowing researchers to observe how interventions are performed in natural settings (uncontrolled nonresearch setting) [1]. This measurement is relevant to RWD in health care and medical domains [18], where data are collected without randomly assigning participants to specific treatment conditions, and researchers conduct observational studies [27,28].

Second, researchers have attempted to investigate whether certain groups of users would exhibit higher (or lower) levels of the aforementioned metrics, aiming to examine the relationships between user groups and the metrics. They analyzed the engagement and effectiveness of user groups specified based on certain criteria and compared them across different groups [8]. Although these analyses are valuable, they are often conducted separately, limiting a comprehensive understanding of how different factors, such as user characteristics, engagement levels, and effectiveness, interact. This fragmented approach can result in missing critical insights from a holistic perspective.

To address this gap, we constructed an analysis task model that aimed to integrate these typical analysis task components and facilitate a more thorough understanding of DHI data. Specifically, this model was constructed based on a meta-analytic review by Moshe et al [24], which assessed multiple studies on DHIs developed to address depressive symptoms. The review outlined four factors that previous studies analyzed regarding their association with the effectiveness of DHIs: (1) the characteristics of participants, (2) the presence of guidance in using DHIs, (3) engagement with DHIs, and (4) study design and quality. Because several existing studies have performed similar analyses [24], we determined that these analysis tasks were common and should be integrated into the proposed model. However, we excluded two factors from the proposed model: the presence of guidance in using DHIs and study design and quality. This decision was made because our DHI service did not involve any human expert support, and we did not aim to demonstrate the efficacy of DHIs through clinical trials.

Consequently, we constructed our analysis task model with three key components: (1) user characteristics, (2) user engagement with DHIs, and (3) the effectiveness of DHIs on target symptoms. On the basis of these key components, we

XSL•FO
RenderX

identified a set of exploratory analysis tasks by referring to the practices of existing studies, as explained in subsequent sections. These tasks are intended to examine each component and explore how they relate to segmented user groups. For instance, the model supports not only the analysis of overall effectiveness across all users but also comparisons across user subgroups segmented by user characteristics or engagement levels. In this model, effectiveness is treated as an outcome variable to be examined within specific segments instead of as a factor used to define those segments. Although the model enables the exploration of the relationships among components within specific user segments, it does not assume causal or recursive dependencies. Instead, it provides a structured framework for performing an in-depth analysis of specific user segments.

The overall structure of the proposed model is illustrated in Figure 1, and further details of each component and the associated analysis tasks are described in the subsequent subsections and Table 1.

Figure 1. Overview of the proposed analysis task model for digital health intervention (DHI) data.

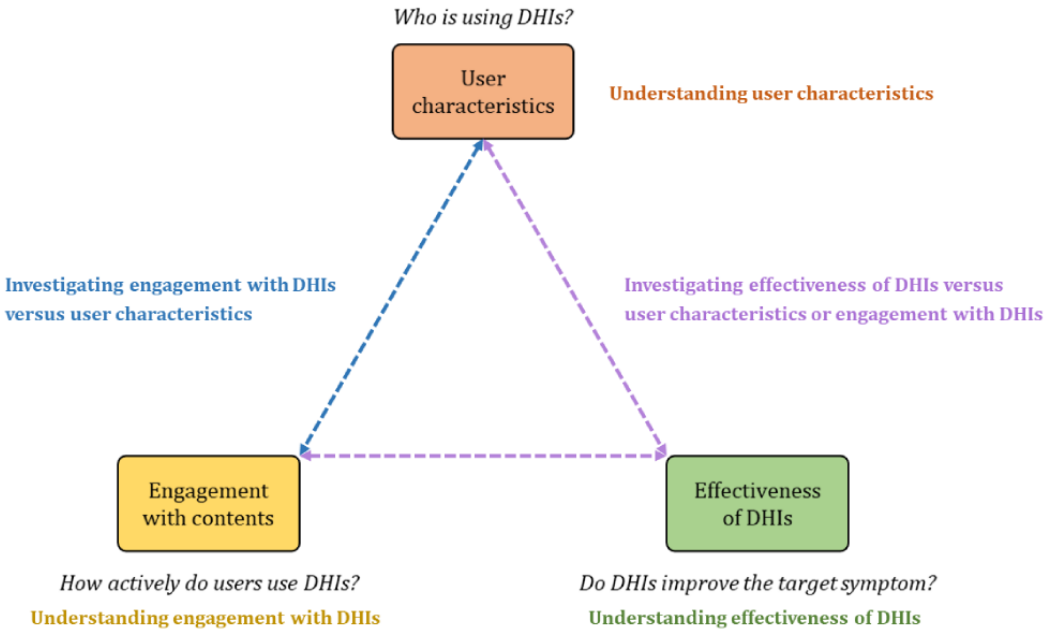

Table 1. Mapping of model-defined analysis tasks to interface, visualizations, and interactions in the Maum Health Analytics tool.

Model components, interface, and task IDs	Task description	Visualization and interactions
User characteristics (interface: User page)		
T1.1	Track the number of users over time	Line chart
T1.2	View user distribution by characteristics	Bar chart
T1.3	Explore individual user records	Table; filtering (by user characteristics)
User engagement with DHIs[a] (interface: Engagement page)		
T2.1	View engagement level across all users	Histogram
T2.2	View engagement level across user subgroups	Histogram; filtering (by user characteristics)
T2.3	Compare the engagement level among user subgroups	Histogram; group selection (by user characteristics)
T2.4	View user characteristics across engagement subgroups	Bar chart; filtering (by user engagement)
Effectiveness of DHIs (interface: Effectiveness page)		
T3.1	View effectiveness across all users	Histogram
T3.2	View effectiveness across user and engagement subgroups	Histogram; filtering (by user characteristics and engagement)
T3.3	Compare effectiveness across user and engagement subgroups	Histogram; group selection (by user characteristics and engagement)
T3.4	View user or engagement across effectiveness subgroups	Bar chart; filtering (by effectiveness)

User Characteristics

Understanding the characteristics of DHI users is crucial because different user groups may lead to differences in DHI use behaviors and changes in target symptoms. As demonstrated in a large-scale cross-study evaluation by Pratap et al [29], user characteristics, such as gender, age, and geographic or racial or ethnic diversity, may influence the sustained use of DHIs. Similarly, other studies have shown that these characteristics could impact dropout rates from DHIs and changes in outcomes [30,31].

User characteristics for DHI data analysis can vary, including demographics (eg, age, gender, and ethnicity), physical states (eg, height and weight), and psychological states (eg, mood, depression, stress, and motivation) [11]. In addition, factors such as personality traits, digital health literacy, and the availability of time and space for using DHIs can be considered important constructs of user characteristics [9].

Regarding user characteristics, the proposed model comprises 3 analysis tasks, identified based on a review of existing DHI research and the authors' deployment experiences (as illustrated in the Methods section). First, researchers track the changes in the number of DHI users over time (task T1.1). This task is essential to understanding the overall adoption and sustained use of DHI services. Researchers can assess whether the DHI services are effectively used by monitoring the number of enrolled and active users. Next, researchers examine the distribution of DHI users based on their characteristics (eg, gender, age, and baseline symptom levels), as suggested in previous studies (task T1.2). This task involves sorting and filtering users based on various characteristics to explore the composition of the user population. It helps to identify trends and patterns in user engagement and the demographic reach of the DHI service. Finally, researchers review the detailed records of individual DHI users belonging to specific groups determined by user characteristics (task T1.3). This task allows for a more granular analysis, providing insights into the behavior and engagement levels of users within specific segments of the population. By following these tasks, researchers can gain comprehensive insights into who uses their DHI services through diverse visualizations, ranging from a broad overview to detailed individual records.

User Engagement With DHIs

User engagement is an essential metric in DHI research, as highlighted in previous studies. This component is crucial not only for understanding the current activeness of users interacting with DHIs but also for exploring strategies to maintain and enhance their sustained use [32,33]. Low engagement levels in DHIs are analogous to situations in which patients do not properly take medications. Therefore, this metric should be closely monitored to assist DHI users in maintaining their use until desired health outcomes are achieved.

As reviewed by Pham et al [34], previous studies have used various indicators to measure engagement levels, including the frequency of log-ins, accessed DHI features and modules, and duration of DHI use. Among these metrics, we included the frequency (ie, launch counts) and duration (ie, use time) of DHI content use in the proposed analysis task model, as they were commonly used in existing studies [11,35-37]. Furthermore, if a structured activity exists within each intervention, its completion level can be measured and evaluated as a detailed user engagement metric [38].

For user engagement with DHIs, we included 4 analysis tasks in the model. First, researchers assess the engagement level of each DHI content item across all users (task T2.1). This task involves evaluating various engagement metrics for each DHI content item, such as launch counts, use time, and completion levels, as highlighted in previous studies [11]. This provides an overview of how each content item is used.

However, considering that user characteristics may influence engagement with DHIs, researchers assess the engagement level of each DHI content item for user groups specified by user characteristics (task T2.2). This task allows for a segmented analysis based on attributes, such as age, gender, or baseline symptom levels, which helps understand how different user groups interact with DHI content. Furthermore, they compare the engagement level of each DHI content item across different user groups (task T2.3). For instance, to determine whether age affects engagement levels, researchers can compare the distribution of engagement metrics among DHI users of different age groups. This comparative analysis helps identify patterns and variations in engagement across user characteristics.

This group-level analysis can also be performed in reverse; researchers assess the user characteristics distribution for a user group where they attain a certain level of engagement (task T2.4). By performing these analytical tasks, DHI researchers can evaluate the extent to which DHI content is actively used, identify differences in engagement levels among various user groups, and understand the distribution of user characteristics at certain engagement levels.

Effectiveness of DHIs

As the primary objective of DHIs is to improve target symptoms, evaluating their effectiveness is necessary. To evaluate the effectiveness of DHIs in real-world settings, researchers analyze the changes in depression symptoms by comparing self-reported symptom levels before and after DHI use. This pre-post comparison allows us to determine whether the intervention has led to a statistically significant improvement in target symptoms, thus estimating the effectiveness of DHIs. As explained in the previous section, effectiveness is measured in an uncontrolled setting to observe how the DHI influences the target symptoms in natural environments. For depression assessment, the following instruments are widely used [39,40]: the 9-item Patient Health Questionnaire [41], the CES-D [42], the Beck Depression Inventory—II [43], and the Patient-Reported Outcomes Measurement Information System [44]. These assess depressive symptoms through items targeting self-reported negative emotions, self-perception, social interaction, and diminished positive affect.

Similar to the analysis of user engagement with DHIs, the analysis task model included 4 tasks for evaluating the effectiveness of the DHIs. The first task is to assess the changes in depression levels across all users based on their self-reported

XSL•FO
RenderX

depression states (task T3.1). This task provides an overall measure of the impact of the DHI on target symptoms.

The next task is to assess the changes in depression levels for the user groups (task T3.2) and compare these changes across different user groups (task T3.3). As illustrated previously, user characteristics and engagement levels can influence the effectiveness of DHIs. Hence, the user groups in tasks T3.2 and T3.3 can be specified based on user characteristics or the engagement level of each DHI content item. For instance, effectiveness can be evaluated for a user group comprising women who use a specific DHI content for more than an hour, or it can be compared among user groups divided by age. This segmented and comparative analysis helps to identify how the effectiveness of DHIs varies across user characteristics and engagement levels.

Group-level analysis can be performed in reverse, such as task T2.4; researchers assess user characteristics and engagement level distribution for a user group where they attain a certain change in depression levels (task T3.4). This task is crucial for understanding user characteristics and engagement behaviors associated with significant changes in depression levels. These tasks assist researchers in exploring the effectiveness of DHIs from multiple perspectives. They allow for the analysis of effectiveness while considering moderating factors, thereby enabling a nuanced understanding of how various user characteristics and engagement levels influence outcomes. Moreover, they provide methods to tailor DHIs to different users based on the observed effectiveness across diverse user groups.

Interactive Visual Analytics

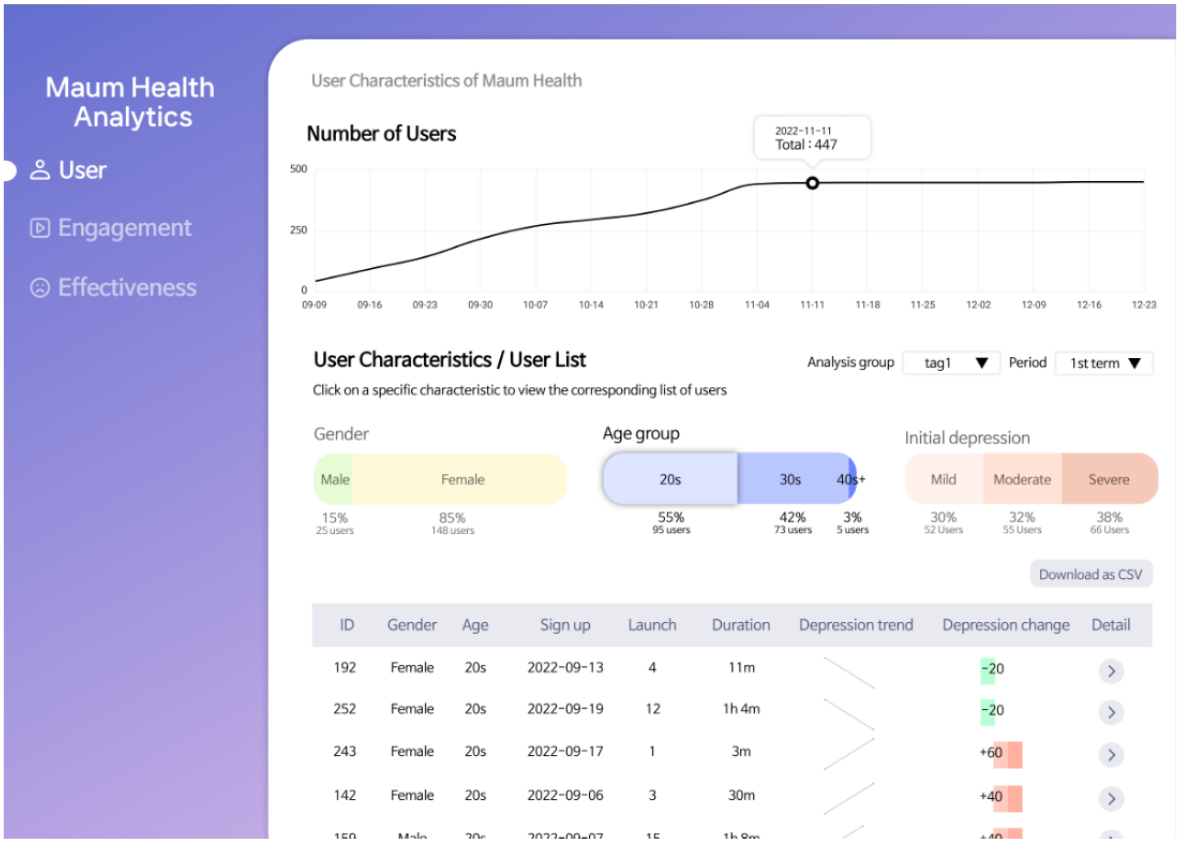
We designed Maum Health Analytics, a prototype of an interactive visual analytics tool, to facilitate researchers in conducting DHI data analysis tasks from multiple perspectives. This prototype was developed based on the analysis task model proposed in the previous section, with each feature directly mapped to a specific analytical task defined in the model.

The primary goal of this prototype was to evaluate whether the proposed model adequately supported the typical analysis workflow used by DHI researchers. To achieve this, we developed a medium-fidelity prototype that implemented the tasks defined in the model. Rather than building a complete system, we focused on creating a functional prototype suitable for the initial evaluation.

The prototype was created using Figma and designed to enable users to explore DHI data through task-specific features embedded in predefined analysis scenarios. The development followed an iterative design process. We created an initial version that mapped model-defined tasks to concrete interface features and functionalities. This prototype was thereafter refined through multiple feedback sessions with 2 domain experts who were clinicians with experience in developing their own DHIs and analyzing real-world DHI data. They participated in expert heuristic evaluations and provided feedback on the clarity of the task flow, adequacy of the visual representations, and interpretability of the analytic results. On the basis of their input, we made several adjustments to the prototype to improve its usability and relevance. In the final version, we incorporated the actual analysis results derived from the RWD collected through our previously deployed DHI, Maum Health. This addition provided users with a realistic context during the preliminary user study and allowed us to better evaluate the usability of the tool.

Each analysis task defined in the model was mapped to a corresponding interface component and visualized in the prototype. Table 1 summarizes the mapping, including the key visual elements and interaction types used to support each task.

Consequently, Maum Health Analytics features 3 main pages. Each page corresponds to 1 of the 3 key analysis components: user characteristics, user engagement with DHIs, and the effectiveness of DHIs. On each page, researchers can select the specific user group conditions that they wish to investigate, and the tool displays the analyzed results interactively. These results are primarily presented through visual elements, such as bar charts, line charts, tables, and histograms, aiding researchers in quickly grasping the overall trends or differences. Moreover, detailed analysis results, such as statistical testing, are provided together to assist researchers in interpreting these findings.



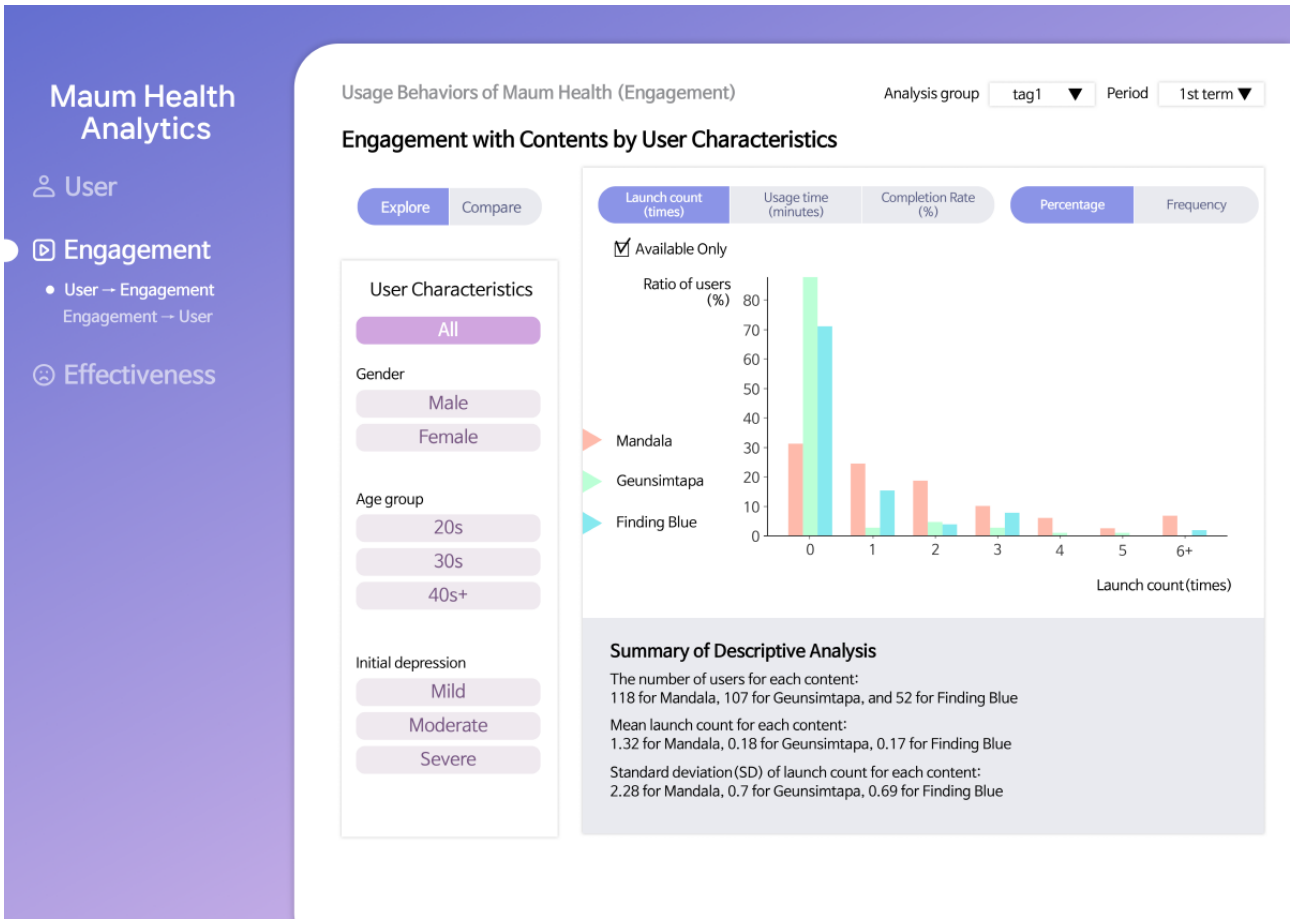
To enhance usability, we included a tag feature throughout the visual analytics tool. Tagging allows the development of researcher-defined groups. For instance, a researcher can create a tag for a user group characterized by high engagement levels and severe initial depression. Once saved, these tags enable quick and easy access to researcher-defined user groups and function as custom favorite lists. This allows researchers to efficiently revisit and analyze the same user groups without having to redefine the conditions, streamlining the data analysis process with Maum Health Analytics.

In the subsequent section, we provide brief explanations for each page of the Maum Health Analytics tool.

The User page (Figure 2) supports tasks associated with user characteristics, presenting visualizations of the number of DHI users over time (task T1.1) and the distribution of users by characteristics (task T1.2). Researchers can select specific user characteristics from the horizontal bar chart in the middle; users matching these criteria are displayed in the table that appears under User Characteristics and User List. Furthermore, they can select a specific user from the table to review detailed records (task T1.3), including the user's basic information, engagement levels with DHIs, changes in depression levels, and individual DHI content use records.

XSL•FO
RenderX

Figure 2. The User page of the Maum Health Analytics tool that supports tasks associated with user characteristics.

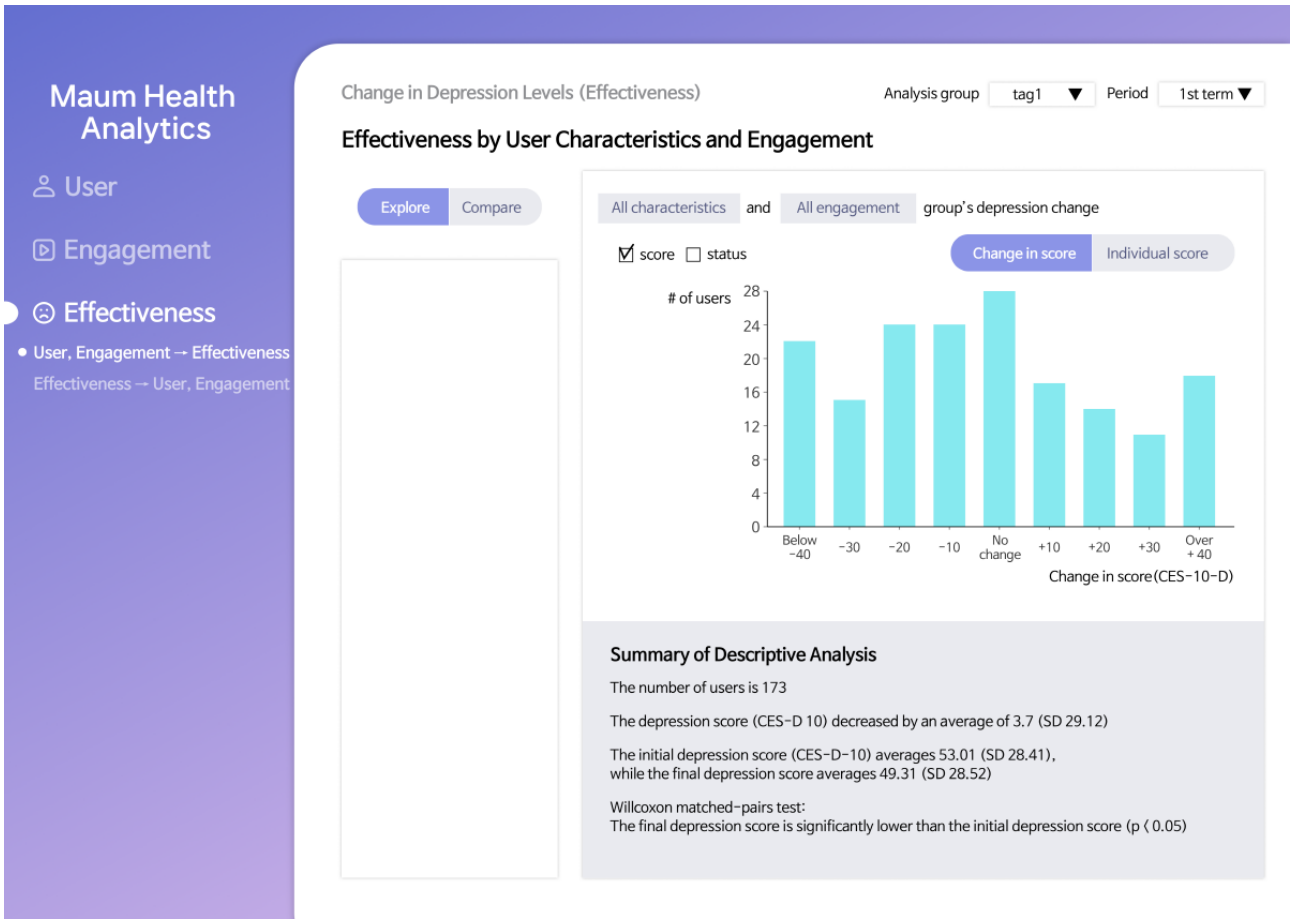


Line charts were selected to effectively show temporal trends in user participation (task T1.1), whereas bar charts allowed for a clear comparison of categorical variables, such as age or gender (task T1.2). The use of a table enables detailed record-level exploration for individual users (task T1.3), thereby supporting granular analysis.

On the Engagement page (Figure 3), researchers can explore the engagement level of each DHI content item across all users (task T2.1) or within selected user groups (task T2.2) specified by user characteristics. As shown in the figure, the histogram illustrates the distribution of engagement levels within the selected user group, providing insights into the overall use behavior for each DHI content item. In addition, researchers are allowed to compare the engagement level across different user groups (task T2.3) to identify the users who are more engaged with each DHI content item. Furthermore, user groups can be formed based on specific engagement levels to examine the user characteristic distribution within these groups (task T2.4).

XSL•FO
RenderX

Figure 3. The Engagement page of the Maum Health Analytics tool that supports tasks associated with user engagement with digital health interventions (DHIs).



Histograms were used to visualize engagement distributions across user groups (tasks T2.1 to T2.3) as they effectively represented frequency patterns and enabled quick comparisons among subgroups. Bar charts were selected for task T2.4 to show how demographic characteristics vary by engagement level, thereby supporting the group-based analysis.

Finally, researchers can explore the changes in depression levels on the Effectiveness page (Figure 4) either across all users (task T3.1) or within selected user groups (task T3.2). When specifying user groups for investigation, researchers are allowed to select user characteristics or user engagement with the DHI content, and the results are shown in a histogram. Similar to the Engagement page, researchers can compare changes in depression levels across different user groups (task T3.3). In addition, they can create user groups based on depression changes to understand the distribution of user characteristics and engagement levels within these groups (task T3.4).

XSL•FO
RenderX

Figure 4. The Effectiveness page of the Maum Health Analytics tool that supports tasks associated with the effectiveness of digital health interventions (DHIs) on the target symptom.

Histograms were used to visualize changes in depressive symptoms before and after the intervention (task T3.1) as they are well suited for showing the distribution of continuous outcome variables and identifying general patterns of improvement or decline. For tasks T3.2 and T3.3, histograms were used to view or compare symptom change distributions across subgroups according to user characteristics or engagement, allowing for an intuitive visual comparison of group-level outcome variations. For task T3.4, bar charts were selected to summarize user characteristics and engagement within the effectiveness-based subgroups, thus supporting the identification of traits associated with greater or lesser effectiveness.

Further details about the Maum Health Analytics tool are provided in Multimedia Appendix 1.

Preliminary User Study

Maum Health Dataset

As previously mentioned, we decided to provide the analysis results derived from the data collected through our DHI service, Maum Health, when evaluating the interactive visual analytics. Here, we provide a brief description of Maum Health and the data it collected.

Maum Health

Maum Health is a DHI service developed to improve depressive symptoms and is offered as a mobile app. Similar to typical mental health mobile apps, Maum Health provides various intervention content beneficial for depressive symptoms, including art therapy (Mandala), physical activity (Geunsimtapa), and a cognitive-emotional screening game (Finding Blue). Each intervention content item consists of sessions comprising activities that users can perform on their own. For instance, users can make color drawings, perform walking and stretching exercises, and play interactive games when engaging with each content item. Moreover, it assesses users' depression levels every 2 weeks using the CES-D-10, a well-established and validated instrument for assessing depressive symptoms in mental health research. The results are converted to a 100-point scale, where a higher score indicates more severe depression.

Dataset

The Maum Health DHI service was distributed through a public counseling center located in Seoul, South Korea, which operates under the Seoul Metropolitan Government. The center is situated in an urban residential area with high accessibility via public transportation and provides mental health counseling services specifically for young adults, supported by licensed psychiatric professionals. As part of the counseling process, the center recommended Maum Health as a supplementary digital tool for managing mental health. Consequently, this DHI was used by 529 people over approximately 3 months, starting in September 2022. During this period, self-reported data entered by the users

XSL•FO
RenderX

and log data automatically recorded based on the use of the intervention content were collected.

The self-reported data in Maum Health consisted of one-time basic user information and periodically recorded levels of depressive symptoms. When users first registered for Maum Health, they provided demographic information, such as gender and age, along with information that might be related to depressive symptoms (eg, marital status and alcohol or smoking experience). Moreover, while using Maum Health, users reported their depressive symptom levels biweekly through the CES-D-10 survey.

As users engaged with the 3 different types of intervention content available on Maum Health, log data were recorded automatically. Whenever a user finished a session with specific content, the time stamps for the start and end points of the session were recorded. Furthermore, for each session, the completion rate was recorded to indicate how well the user performed the given activity. We used features from both self-reported and log data in the design of the Maum Health Analytics tool, as summarized in Table 2.

Table 2. Features of the Maum Health DHI service data used in the design and evaluation of the Maum Health Analytics tool.

Analysis components and categories	Features
User characteristics	
Basic information	Gender, age group, and initial depression level
Additional information	Marital status, cohabitant, occupation, education, economic status, drinking, smoking, army experiences, and handedness
Medical history	Depression history, medication, and physical illness
User engagement with DHIs[a]	
Mandala (art therapy)	Total launch counts, total use time, and average completion rate
Geunsimtapa (physical activity promotion)	Total launch counts, total use time, and average completion rate
Finding Blue (cognitive-emotional games)	Total launch counts, total use time, and average completion rate
Effectiveness of DHIs	
Depression level	CES-D-10[b] score

[a]DHI: digital health intervention.

[b]CES-D-10: 10-item Center of Epidemiologic Studies Depression Scale.

Considering the potential quality issues with RWD, we established inclusion and exclusion criteria for the data to be used when evaluating the Maum Health Analytics tool. We selected users who had at least 2 depression score records, which allowed us to observe changes in depression levels. Among them, we included users with a gap of 2 to 4 weeks between evaluations, as they were considered to maintain their DHI use sufficiently well. Consequently, we used data from 173 (32.7%) of the 529 users. Recognizing that the initial use time of the Maum Health DHI service could vary among users, we considered the relative use period starting with each user's first day of use. As a result, the final dataset used to evaluate the Maum Health Analytics tool included 3470 data points, comprising user-provided demographic information, preprocessed log records of DHI content use, and periodic self-reports of depressive symptoms.

Study Procedure

Participants

To evaluate the Maum Health Analytics tool, we recruited 5 groups of experts with experience in analyzing DHI data. Each group comprised 3 to 5 experts, including clinicians, intervention content designers, and system developers, who collaborated as a team. In total, 15 DHI researchers participated in the study (woman researchers: n=6, 40% and man researchers: n=9, 60%), who were aged between 26 and 44 years (mean 34.1, SD 6.4 years). All participants had previous experience in developing DHIs and analyzing real-world DHI data. Although they had not used the Maum Health DHI service as end users, they became familiar with its structure and features through their involvement in related research and evaluation activities. The details of these expert groups are listed in Table 3, and we will refer to these experts as "DHI researchers" hereinafter.

Table 3. Composition of participants by digital health intervention research teams.

Group IDs	Participant IDs	Expertise of the group
A	A1, A2, and A3	Clinicians and intervention content designers
B	B1 and B2	Clinicians and intervention content designers
C	C1, C2, C3, C4, and C5	Intervention content designers
D	D1, D2, and D3	Clinicians, intervention content designers, and system developers
E	E1 and E2	System developers

XSL•FO
RenderX

Evaluation

Textbox 1 provides an overview of the evaluation procedure, comprising the research introduction, scenario-based use session, qualitative interviews, and quantitative usability assessment. During the user study, we first briefly introduced our research and explained the Maum Health Analytics tool, along with the dataset used for the evaluation, to the participants. Then, we asked them to explore the various features of our tool. Given that our tool was a medium-fidelity prototype, the participants were only able to navigate predefined functions, interactions, and corresponding analysis results.

Textbox 1. Overview of the study procedure for evaluating the Maum Health Analytics tool.

Research introduction

- The authors introduced the study and provided an overview of the Maum Health Analytics tool.

Scenario-based use session

- Participants explored the Maum Health Analytics tool for 30 min.
- Realistic data analysis scenarios were provided to support system evaluation during this session.

Qualitative evaluation

- Semistructured interviews were conducted for 60 to 90 min.
- Participants evaluated the analysis tasks and discussed their applicability in real-world settings.

Quantitative evaluation

- The Post-Study System Usability Questionnaire was administered to assess the system's usability.

In the evaluation session, we presented participants with specific DHI data analysis scenarios, enabling them to test all the tasks supported by Maum Health Analytics. For instance, if the scenario was "The expert investigates the distribution of user characteristics among those who frequently used Mandala above average," the participants would follow several steps within the tool to analyze the data. Considering the limited functionality of the prototype, these scenarios were selected based on cases with sufficient Maum Health data to showcase the results completely. We visualized the analysis results from real-world DHI data to make the evaluation realistic, ensuring that the participants could interact with and assess the prototype in a meaningful context.

After the participants used the Maum Health Analytics tool, we conducted an interview session and asked key questions from the perspective of analyzing the Maum Health DHI service data: (1) Were the analysis tasks defined in our tool appropriate? (2) How could the information provided be used in practice? Each session lasted approximately 60 to 90 minutes, depending on the participant group's pace and discussion depth. All interview sessions were recorded with the participants' consent and transcribed to thoroughly examine their responses. Thereafter, we performed inductive analysis [45] while repeatedly reading the interview transcripts to identify key phrases, ideas, and themes. Next, we conducted affinity diagramming to group similar themes derived from the transcripts and reviewed the themes iteratively until all researchers agreed on the final themes.

We also used the Post-Study System Usability Questionnaire (PSSUQ) [46], which is based on a 7-point Likert scale, to evaluate the overall usability. The PSSUQ is specifically designed for scenario-based usability studies and includes a subscale for information quality, allowing us to quantitatively assess whether the defined analysis tasks are suitable. According to Lewis [47], the PSSUQ scores for real-world systems commonly ranged between 2.5 and 3.0 across subscales, with lower scores indicating better usability. Although no absolute benchmark has been proposed, scores within this range have been interpreted as indicating acceptable usability in practical settings. We used the Korean-translated version of the PSSUQ previously developed and validated by Jeon and Park [48]. The participants in our study did not report any difficulties in interpreting or responding to the translated version during the usability evaluation.

We analyzed the responses using descriptive statistics and computed the mean and SD for each of the 3 PSSUQ subscales: system usefulness, information quality, and interface quality. Two items related to error recovery (items 7 and 8) were excluded because the user scenarios used in this study did not involve any error-handling tasks.

Ethical Considerations

This study was approved by the Institutional Review Board of the KAIST university (KH2022-098), and written informed consent was obtained from all participants.

Results

Overview

The previous section introduced the analysis task model and visual analytics tool developed for DHI research. On the basis of them, we conducted a preliminary user study to evaluate the usability of the system. This section presents the results of this evaluation, including both quantitative and qualitative findings.

Quantitative Evaluation

The PSSUQ comprises 16 items across 3 subscales (ie, system usefulness, information quality, and interface quality) rated on

XSL•FO
RenderX

a 7-point Likert scale (1=strongly agree, 4=neutral, 7=strongly disagree), with lower scores indicating better usability.

For the Maum Health Analytics tool, the mean score of the PSSUQ was 2.89 (SD 1.02), and that of the overall usability was 2.80 (SD 1.57). Each subscale had similar mean scores: system usefulness 2.94 (SD 1.01), information quality 2.87 (SD 1.21), and interface quality 2.84 (SD 1.31). These scores fell within the range commonly observed in previous usability studies (2.5-3.0) and are generally interpreted to reflect acceptable usability levels [47].

Qualitative Evaluation

Analysis Task Model

Our interviews revealed participants' opinions on the analysis task model and its components proposed in this study.

User Characteristics

Participants found that tasks related to user characteristics helped enhance their understanding of user groups, particularly those sharing specific characteristics. They were interested in examining individual use records as concrete examples of the findings identified at the group level. By reviewing representative users within a group, they can understand broader trends and verify their interpretations:

> *When I discovered that females used Mandala more, I became curious about each female user's usage patterns. Reviewing their specific usage logs could help me identify common characteristics of this user group.* [A1]

The participants further noted that such an in-depth exploration was challenging in their previous practice, particularly when user interactions were recorded only on personal devices and were not easily accessible:

> *We could analyze DHI usage statistics by group, but it was challenging to check detailed usage logs since we had to take their phones for analysis.* [A3]

These comments highlighted that visualizing individual-level use data supported a deeper and more nuanced understanding of group-level patterns.

In addition, the participants reported that tasks in this category were useful for identifying DHI users (or user groups) who may require additional attention. They emphasized the importance of evaluating whether users met a minimum level of engagement (in launch counts or use time) within a given period and examining specific users who fell short of these thresholds:

> *For instance, if there is a weekly recommended use, I'd like to see how many users in the group meet that goal.* [B1]

The participants reviewed group-level engagement metrics and paid particular attention to individuals with low engagement within those groups. Among the participants, clinicians focused on improving users' target symptoms and discussed how such insights could inform intervention decisions:

> *I was wondering why this user didn't use Maum Health contents that much, and why her status got worse even while using intervention contents.* [A1]

They planned to intervene with users with low engagement to increase their engagement:

> *Perhaps I need to decide how to manage the low engagement users, for instance, send a text message, make a call, and so on.* [B1]

Some participants also mentioned that tagging could help monitor users who required closer attention:

> *In our study, there are individuals whom doctors have to care for more intensively. Previously, we had to find such users whenever we analyzed them. But here, I think it would be easier and more convenient because we can mark them with tags and monitor them accordingly.* [C2]

E1 viewed tags as customizable user characteristics and noted that using them as favorites made it easier to track certain users. Together, these findings suggested that being able to review individual user records within user characteristic tasks helped to identify users at both the group and individual levels who might require further intervention to improve their symptoms.

The participants also mentioned that tasks supported by Maum Health Analytics could help track new incoming users and monitor the retention of existing ones. They noted that understanding the characteristics of both groups was essential for delivering appropriate intervention content:

> *There is a difference between user groups by their retention rate. Based on that information, we could determine the frequency of exposing specific content for each user group, which might be available here, too.* [D1]

However, participants emphasized the need to distinguish "active users" from merely registered ones, identifying this as a potential area for improvement. For intervention content designers, knowing who actively engaged with the system was considered more important than simply tracking overall registrations:

> *I'd like to see how many users are actively using DHI, not just registered. For designers, it is important to see whether they are using DHIs well enough.* [C1]

To better determine active use, the participants suggested including session-level dropout information on individual user pages:

> *I think the quitting ratio while using content is also important. The intervention content may be interesting at the beginning, but it gets boring as time goes* [C3]

These findings implied that supporting both retention tracking and active user identification contributed to a comprehensive understanding of DHI users and facilitated effective user management planning.

User Engagement With DHIs

Participants reported that Maum Health Analytics could help them identify user groups that exhibited high engagement with

XSL•FO
RenderX

specific DHI content, serving as useful information for making more effective content recommendations. Tasks related to user engagement, such as task T2.4, provided a distribution of user characteristics among highly engaged users. For instance, when extracting users who used Mandala above the average level, participants observed an increased proportion of woman users, which they found helpful in decision-making:

> *After examining the characteristics of users who use a particular content often, we can recommend it to similar users, such as those in the same age group. Maybe we can promote the DHI service by targeting similar groups of people through social media.* [A1]

The participants assumed that users with similar characteristics would demonstrate similar engagement levels. They considered this assumption valuable for improving recommendation strategies for specific groups of users, particularly because DHI content is typically recommended based solely on target symptom severity (eg, depression scores) without considering user preferences or engagement patterns:

> *I think this tool can be used to make feedback more customized while monitoring the changes in DHI engagement.* [A2]

Conversely, some participants indicated that users with low engagement should be further examined to design new content tailored to them. For instance, a participant noted the following:

> *If the proportion of females in users with high engagement is significant, we should create another content targeting men. Otherwise, the male user group may not be supported well and might leave the Maum Health app.* [A3]

However, B1 noted that recommendations based solely on engagement should be used cautiously and that the actual improvement in depressive symptoms should also be considered. These findings demonstrated that examining engagement patterns in conjunction with user characteristics can support more personalized and effective content recommendations while also highlighting the importance of considering intervention effectiveness alongside DHI use behavior.

Some participants mentioned that presenting the overall distribution of engagement with the intervention content was useful, as it could help establish guidelines for DHI use. They noted that interventions such as traditional cognitive behavioral therapy can be easily evaluated in terms of engagement because the number of sessions is predefined. However, setting evaluation criteria is challenging when users use the content independently without specific guidelines.

After exploring the overall engagement levels and those of specific user groups through the Maum Health Analytics tool, participants expected to establish engagement guidelines using this tool as more DHI data accumulated over time:

> *If the data becomes sufficient, values such as average or top 25% could be more meaningful. Observing the overall engagement level with this tool, we can provide engagement guidelines for each step or set a recommended use.* [B1]

This indicated the potential for establishing optimal use guidelines by analyzing long-term DHI engagement patterns, which currently lack established benchmarks.

In addition, the participants mentioned the need to evaluate user engagement more rigorously. In particular, the system developer group emphasized the importance of selecting appropriate use metrics, such as launch counts and use time, when measuring engagement. Compared with other groups, they primarily focused on improving usability and maintaining overall engagement levels rather than evaluating the effectiveness of DHIs. Consequently, they prioritized analyzing detailed content use logs and identifying metrics that more accurately reflected the actual user behavior:

> *For example, there are cases when users stop using content when getting a call or eating. In those cases, they stayed in the content but there was no interaction recorded in the usage log.* [E1]

The participants also highlighted the importance of distinguishing what constitutes "effective" engagement, thereby emphasizing the need to focus on use behaviors that indicate meaningful interactions with content:

> *It is necessary to analyze how much users actively participated in the content before investigating its effectiveness. Then, we have to further examine what was behind if DHI turned out to be ineffective.* [E2]

This implied that measuring engagement in DHIs should go beyond basic metrics, such as launch counts or use time, and instead incorporate indicators that more accurately capture users' actual interaction behaviors.

Effectiveness of DHIs

Participants responded that the Maum Health Analytics tool was helpful in systematically evaluating the effectiveness of DHIs by examining changes in target symptoms. Because DHIs are intended to support users' mental health, the participants found it meaningful to analyze symptom improvement in relation to engagement with each type of intervention content:

> *Of course, showing individual indicators can be a meaningful analysis for almost all apps. However, for DHIs, we should investigate which intervention features interact with each other and how they improve symptoms, requiring a relational analysis of multiple factors.* [D1]

> *For example, for game apps, the longer the usage time, the better. But in the case of DHIs, we need to see not only how long it has been used, but also how effective it is. I think this tool supports this process well enough.* [E1]

The participants compared Google Analytics with our tool, highlighting a key difference in their purposes. They explained that the key distinction of the proposed analytics tool was the inclusion of health-related indicators, making it more suitable for analyzing DHI services:

> *Unlike Google Analytics, which mainly focuses on usage behavior and user retention, we can analyze*

XSL•FO
RenderX

> *DHI including the users' health indicators in this tool. This is critical for health-related services.* [D1]

This suggested that evaluating the effectiveness of DHIs required integrating health outcomes with use metrics and that Maum Health Analytics enabled such multidimensional analysis more effectively than existing analysis practices.

We observed that evaluating content effectiveness from multiple perspectives using Maum Health Analytics was considered beneficial by participants, particularly in the context of designing or studying the intervention content. They explained that the tool simplified comparisons that would otherwise require repeated statistical analyses and manual setup under each condition:

> *Previously, it was inconvenient to repeatedly perform statistical analysis for each condition, so we sometimes skipped examining some questions in detail. Perhaps, we lost opportunities to find something new.* [C1]

By supporting comparisons based on user characteristics and engagement levels, the tool enabled users to explore effectiveness across different subgroups more efficiently:

> *Like the analysis in research, I was able to create control groups and experimental groups based on several criteria and easily compare the difference in depression change between the groups. I could see the relationship between engagement and effectiveness through this process.* [C2]

The participants also highlighted the tag feature as a practical way to track and compare user-defined groups. This allowed them to monitor symptom changes in relation to factors such as the app version or intervention updates:

> *I like the tag because we can immediately see how much DHI has improved after updates if we label tags based on the version of DHI.* [C1]

C1 added that using tags to compare groups could help the research team formulate and evaluate new hypotheses, similar to A/B testing.

In addition, participants found it useful to evaluate other indicators based on the change in depression levels. As DHI services are still in their early stages, no clear evidence exists that increased use leads to better outcomes. Therefore, B1 suggested that it might be more insightful to investigate other indicators based on the effectiveness of the DHI. These findings suggested that enabling flexible group comparisons and supporting exploratory evaluations of DHI effectiveness can help researchers uncover new patterns, generate hypotheses, and refine intervention strategies based on subgroup insights.

Interactive Visual Analytics

We also explored participants' experiences with the interactive visual analytics tool during the interview sessions.

Simplifying the Analysis Tasks of DHI

Participants mentioned that using the Maum Health Analytics tool helped simplify several of the manual and repetitive tasks they typically faced in DHI data analysis. In particular, they appreciated not having to download the entire dataset each time, recognizing this as one of the most practical features:

> *Our lab is developing a similar DHI app, but we have to download and analyze the entire dataset since there's no analytics tool like this. But here, we can check what happened to the user right away without such tasks.* [A3]

Because most existing dashboards were built for experiment management instead of analysis, participants found it helpful that our tool efficiently supported basic analytical tasks.

Participants also appreciated the ability to view analysis results in real time:

> *I have experience in developing chatbot-based interventions, and I wanted to know in real-time whether users are using them well or how they respond. I was satisfied to see that information on this tool.* [A3]

> *Real-time information may be meaningful to those who provide counseling services based on analyzed results, those who manage certain groups of users, and those who monitor the entire service.* [B1]

The participants also appreciated that the tool allowed them to extract and export user groups for further analysis. In particular, A2 and A3 highlighted the usefulness of isolating specific subgroups, such as outliers with unusual engagement or symptom patterns, and downloading their data to examine them in more detail using external analytical tools. These findings highlighted how Maum Health Analytics can reduce the burden of manual data handling and facilitate a more efficient and targeted analysis workflow.

Supporting Communication Among Various Experts

The participants assessed that the Maum Health Analytics tool would facilitate communication among stakeholders during the DHI improvement process, particularly when experts from different domains collaborate. They emphasized that the tool could bridge the gaps between those with differing levels of expertise in data analysis and interpretation.

Previously, content designers had to create separate documents to explain analysis results to other domain experts, which they found to be inefficient:

> *As a content designer, I always had to prepare additional materials about the analysis results to explain it to mental health counselors. However, with these visual explanations, I think they can understand the results easily without any further documents.* [A3]

They added that even stakeholders unfamiliar with data analysis could interpret the visual results and answer relevant questions using Maum Health Analytics:

> *Since this tool showed the results visually, I thought it would be suitable for those who are not familiar with how to analyze data well. With this visual analytics tool, they would be able to answer various questions related to DHI usage.* [A2]

XSL•FO
RenderX

Participants also noted that in cases where data analysis and user recruitment were handled by separate individuals or teams, the tool could help track and understand the user base:

> *If someone else is recruiting DHI users, there will be difficulties in the analysis since we have to examine the data without understanding the participants. This tool displays that information right away, making it easy to track DHI users' information even if we don't recruit the participants by ourselves.* [C1]

These findings suggested that Maum Health Analytics could serve as a shared platform to enhance communication and understanding among DHI stakeholders with diverse roles and technical backgrounds.

Providing Statistical Analysis and Interpretation of Results

The participants reported that the Maum Health Analytics tool was useful in providing statistical analysis results when evaluating engagement and effectiveness. They emphasized that statistical testing added an objective basis for interpreting and presenting findings:

> *There must be people who think statistics are important. For example, in the public domain of managing these studies, it is important to leave a numerical rationale.* [B1]

> *If we say that this result is statistically significant, I think we can clearly communicate it to experts in other fields.* [C3]

The statistical analysis was meaningful, particularly because most of the results were presented visually in graphs. However, the participants suggested that these results should be accompanied by more insightful explanations to better support DHI improvement. Although descriptive statistics, such as means and SDs, can be roughly interpreted from visualizations, some participants noted that providing statistical testing results along with practical interpretations would be more beneficial:

> *When considering people who are not familiar with statistics may see statistical analysis, it would be nice to provide interpretations related to decision-making, such as what this result means and how to utilize it in updating DHIs.* [C1]

These findings indicated that providing statistical results together with clear, practical interpretations could improve the usability of analytical tools and help stakeholders better understand and apply insights.

Enhancing Continuity Across Analysis Tasks

Participants commented that the transition between different analysis tasks could be improved by allowing the currently selected user groups to be pinned. They expressed the need to fix a group of interests and view all subsequent analysis results for that group:

> *For example, if I went to another page after checking the engagement distribution of Mandala, I wanted to view the analysis results of the same user group first.* [B1]

One participant specifically emphasized the need for a feature that allowed saving filtered user groups:

> *We first narrowed the user group down by adding more filters, but we had to find and select the conditions again if we moved to other pages. As a result, the analysis tasks seemed somewhat disconnected.* [E1]

They suggested that the ability to save and pin a specified user group could serve as a bridge between analysis tasks, enabling a more seamless experience when working with DHI data. They expected this feature to help researchers maintain continuity across tasks and pages by preserving their focus on the same user group. This implies that ensuring continuity between the analysis steps is a critical design consideration for supporting exploratory workflows in DHI data analysis.

Discussion

Principal Findings

Overview

We proposed an analysis task model for practitioners to explore and analyze RWD generated by DHIs. Building on previous studies related to DHIs, we developed a task model comprising key components, including user characteristics, user engagement with DHIs, and the effectiveness of DHIs. The model comprised data analysis tasks that explored not only each component individually but also their interrelationships. In addition, we designed an interactive visual analytics tool based on the proposed model to investigate how the model and tool could support diverse DHI data analysis practices. To make the evaluation more realistic, we visualized the analysis results from RWD collected from Maum Health, a currently operational DHI service, via the prototype and examined the DHI researchers' user experience while using it.

Overall, the participants responded positively to the proposed model and the visual analytics tool. They noted that this supported analyses that were previously difficult or time consuming. Features such as reviewing individual user records, examining engagement and effectiveness from multiple perspectives, and comparing user-defined subgroups were helpful in improving the design and evaluation of DHIs. This evaluation also revealed several areas for improvement. The participants suggested including more detailed engagement metrics that reflected actual user interactions, adding functionality to retain selected user groups across views, and providing clearer interpretations of statistical results to support collaboration among researchers with different levels of data literacy.

In subsequent sections, we provide several insights into the analysis task model and the interactive visual analytics tool and suggest design implications for supporting researchers when analyzing DHI data.

Analysis Task Model

The analysis task model allowed the DHI research team to analyze the data holistically, addressing the limitations of existing studies that analyzed each key component separately.

XSL•FO
RenderX

The proposed model supported the analysis of the relationships between key components by specifying user groups based on certain conditions (eg, gender) and comparing target outcomes (eg, changes in depression). During this process, the research team identified meaningful insights for improving DHIs, such as suggesting content to potential target users, setting criteria for DHI use, and determining better interventions. This aligns with recent studies investigating which DHI use behaviors (ie, engagement with DHIs) affect target outcomes [8,49], highlighting the importance of further analyses of these relationships.

In real-world settings, DHIs can be distributed through app stores to individuals with varying characteristics, contexts of use, and engagement levels [50]. Therefore, as suggested by our model, evaluating the DHI use behaviors and changes in target symptoms for each group of similar users is critical. Group-level analysis has been widely used in previous studies on large-scale health data [13,24,51]. These studies explored the overall trends or patterns at the user group level and derived insights to address common issues within the group. Given that DHI data can be collected from several users, DHI researchers may follow similar analytical practices.

In addition, the records of individual users can be provided as sample cases to complement the understanding of a specific user group. Because it is challenging to review all records, the analysis task model can be improved to suggest the representative users of that group. For instance, they could be users showing mean or median engagement levels or those with the most frequently reported user characteristics. This approach helps researchers gain a more nuanced understanding of user behavior and outcomes, allowing for more tailored and effective interventions.

Considering the researchers' feedback regarding our prototype that they would set guidelines after exploring the engagement levels for each user group, group-level analysis could also be used to determine the optimal dosage. In practice, determining the dosage of typical DHIs is difficult because of various behavioral and contextual factors influencing dose-response relationships [14,16]. The proposed model could support researchers in investigating how much DHI use is required to achieve a certain level of improvement in the target symptoms. On the basis of this insight, they can further improve existing DHIs by adjusting the dosage or revising the difficulty of tasks to be performed in the intervention content while monitoring how these changes affect the effectiveness of DHIs.

Interactive Visual Analytics

The interactive visual analytics for DHIs proposed in our study demonstrated the potential of allowing researchers to perform analysis tasks efficiently. The findings of this study revealed that researchers often conducted similar DHI data analyses; however, there is a lack of research on visual analytics tools to streamline this process. The Maum Health Analytics tool has enabled researchers to analyze DHI data from diverse perspectives in real time through simple interactions.

The proposed analytics can be used at various stages of the development and evaluation life cycle of DHI services, which typically follow an agile software development process [23]. This process involves several stages of design and testing, with results from each testing fed back into the previous cycle to continuously improve DHIs. Therefore, researchers need to monitor and evaluate DHI data, and our tool can make this iterative process more efficient.

We also discovered that interactive visual analytics can be useful for DHI research teams comprising experts from diverse domains and backgrounds, such as clinicians, intervention designers, and system developers. As shown in this study, the purpose of data analysis may vary owing to background differences. For instance, clinicians value whether target symptoms have improved, whereas system developers focus more on the interaction log generated from DHI.

In such situations, the analyses provided by our analytics tool allow researchers to explore unfamiliar aspects of DHI data and extend their knowledge of the data. This facilitates communication among researchers from different fields, generating diverse approaches to better support users and improve existing intervention components. Furthermore, the analytical tool can be used to quickly share results with stakeholders outside the research team, such as funding bodies or external project managers, thus aiding the decision-making process.

Design Implications

Our findings offer further ways to quantify DHI use behaviors and diversify the metrics used to represent user engagement with interventions. As reported in this study, some DHI users may simply run the intervention content without actively engaging with it. This implies that relying solely on traditional high-level engagement metrics, such as launch counts or use time, may not distinguish this type of passive use, which could negatively affect the analysis quality.

Therefore, we propose incorporating fine-grained engagement metrics to better understand how active users interact with DHIs. For instance, rather than simply measuring how often a DHI is launched or how long it is used, we could track specific actions, such as touches, swipes, or clicks, within the app to obtain a clearer picture of user engagement [12]. Moreover, if the DHI includes activities that users are supposed to perform, the system could track their adherence to these activities and incorporate these data into the engagement metrics. By doing so, we can identify more meaningful (or effective) engagement and analyze its impact on improving target symptoms. This approach provides a more nuanced understanding of user behavior and the effectiveness of interventions.

In addition, we suggest design implications of interactive visual analytics tools for DHI researchers. Given that multiple user groups can be formed from data, determining the groups that should be investigated is challenging. Therefore, this tool can be designed to proactively identify the important user groups that should be examined by researchers. For instance, an analytics tool can recommend user groups with very high engagement or very low effectiveness, as these may provide critical insights. Leveraging the data analysis history stored in the analytics tool can provide analysis results that researchers

XSL•FO
RenderX

are interested in or guide them to discover other important user groups.

Furthermore, we can support user group selection using natural language, making it easier for researchers to locate the groups they want to explore. This could be a practical alternative, particularly if numerous metrics are available for analyzing user engagement with DHIs and their effectiveness. In addition, enabling researchers to explore various factors based on a specified user group (ie, the tag function in this study) would enhance the user experience of visual analytics by allowing for seamless DHI data analysis.

When designing a visual analytics tool, both the exploratory and explanatory aspects should be carefully considered. Members of a multidisciplinary research team may have varying levels of knowledge and experience in data analysis. Therefore, interpreting the results is crucial for applying data-driven insights in practice. For instance, our tool can be further improved by explaining the statistical results and offering practical guidelines based on them.

With recent advances in large language models, visual analytics can generate reports based on data analysis histories thus enhancing researchers' understanding of DHI data [52]. As suggested in a recent study [53], the data presented in visual elements can also be accompanied by a data-driven narrative generated by large language models, which effectively aids data communication. By integrating these features, the visual analytics tool can become a powerful and user-friendly resource for multidisciplinary research teams, facilitating deeper insights and more effective decision-making in the development and evaluation of DHIs.

Limitations and Future Works

We conducted a preliminary user study on the interactive visual analytics tool designed based on the findings from our research experience and previous studies. The analytics tool presented in this study was a preliminary medium-fidelity prototype, with limited interaction capabilities intended for exploratory evaluation. In future studies, it will be necessary to develop a fully functional system based on this prototype and compare it with existing analytical tools. During this process, it is important to include DHI data collected over extended periods to allow users to evaluate how engagement and effectiveness evolve over time, as frequently observed in real-world DHI implementation.

Investigating how this analytics tool and the underlying analysis task model are applied in real-world settings is another important direction for future research, particularly for supporting DHI research teams more effectively. By addressing these aspects, we aim to create comprehensive and robust analytics that contribute to the field of DHIs.

In addition, the analytic task model and visual analytics tool proposed in this study were developed based on data from a mobile DHI service focused on mental health, specifically targeting depressive symptoms. Thus, the scope and tasks of the model may be influenced by characteristics unique to this domain. When applying the model to DHIs in other health domains, it is necessary to adapt the analytical components to reflect domain-specific requirements. For instance, physical and metabolic health interventions may rely on objective indicators, such as step count, blood glucose levels, or sleep duration, which require different approaches for modeling and evaluation. Similarly, engagement in these domains may involve different types of intervention activities and their corresponding completion metrics. In such cases, an analytical framework is needed to accommodate more nuanced metrics that better reflect user engagement and health outcomes. Furthermore, interventions involving real-time tracking or context-aware features may produce logs that require different forms of temporal or event-based analyses. Expanding the model to support such flexible representations and metrics is critical to enhance its applicability across diverse types of DHIs.

Conclusions

We proposed an analysis task model to support DHI researchers by incorporating analysis practices from existing DHI research. On the basis of this model, we designed a prototype of an interactive visual analytics tool to explore how the proposed task model and tool can aid in DHI data analysis tasks. A preliminary user study demonstrated that the proposed model enabled a holistic investigation of DHI data by integrating the 3 key components and examining their relationships. Moreover, the analytics tool demonstrated the potential to simplify repetitive tasks and facilitate communication among researchers from diverse backgrounds and interests.

As the use of DHIs continues to grow, research on enhancing data analysis and supporting decision-making for improving existing DHIs has become increasingly important. In this context, we expect that the model and tool proposed in our study will effectively meet the data analysis needs of DHI researchers and make the process more efficient.

Authors' Contributions

All authors participated in the conception of the study. GJ, HL, and UL developed the task analysis model and designed the interactive visual analytics, with contributions from KH and HK. KH and HK collected the Maum Health data, while GJ, HL, and UL analyzed and prepared it. The preliminary user study was conducted by GJ and HJ, with feedback from UL, KH, and HK. GJ prepared the manuscript, and all authors read, commented on, and contributed to the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Socially assistive robots (SARs) hold promise for supporting older adults (OAs) in hospital settings by promoting social engagement, reducing loneliness, and enhancing emotional well-being. They may also assist health care professionals by delivering information, managing routines, and alleviating workload. However, their acceptability and usability remain major challenges, particularly in dynamic real-world care environments.

Objective: This study aimed to evaluate the acceptability and usability of a SAR in a geriatric day care hospital (DCH) and to identify key factors influencing its adoption by OAs and their informal caregivers.

Methods: Over the course of 1 year, 97 participants (n=65, 67%, OA patients and n=32, 33%, informal caregivers) took part in a mixed methods evaluation of ARI, a socially assistive humanoid robot developed by PAL Robotics. ARI was deployed in the waiting area of a geriatric day care robot in Paris (France), where it interacted with users through voice-based dialogue. After each session, participants completed 2 standardized assessments, the Acceptability E-scale (AES) and the System Usability Scale (SUS), administered orally to ensure accessibility. Open-ended qualitative feedback was also collected to capture subjective experiences and contextual perceptions.

XSL•FO
RenderX

Results: Acceptability scores significantly increased across waves (wave 1: mean 15.4/30, SD 5.81; wave 2: mean 20.9/30, SD 5.25; wave 3: mean 22.5/30, SD 4.23; *P*<.001). Usability scores also improved (wave 1: mean 47.9/100, SD 24.18; wave 2: mean 57.4/100, SD 22.46; wave 3: mean 69.3/100, SD 16.03; *P*<.001). A strong positive correlation was observed between acceptability and usability scores (r=0.664, *P*<.001). Qualitative findings indicated improved ease of use, clarity, and user satisfaction over time, particularly following the integration of a large language model (LLM) in wave 2, leading to more coherent, natural, and context-aware interactions.

Conclusions: Successive system enhancements, most notably the integration of an LLM, led to measurable gains in usability and acceptability among patients and informal caregivers. These findings underscore the importance of iterative, user-centered design in deploying SARs in geriatric care environments.

Trial Registration: Approved by the French national ethics committee (CPP Ouest II, IRB: 2021/20) as it did not involve randomization or clinical intervention

Introduction

The rapid aging of the population worldwide is one of the major demographic challenges of the 21st century. According to United Nations projections, the number of people aged 65 years and over worldwide is expected to increase from 727 million in 2020 to over 1.5 billion by 2050 [1]. This demographic evolution is accompanied by a growing need for long-term care and increased use of specialized services, particularly in geriatric institutions [2]. Consequently, geriatric institutions will face significant challenges in managing a rising number of residents, many of whom present multiple chronic conditions that require comprehensive and personalized care [3]. In response to this societal challenge, the adoption of innovative technologies and, in particular, socially assistive robots (SARs), is increasingly considered a complementary solution to improve the well-being and autonomy of older adults (OAs) [4,5]. SARs are robotic entities designed to interact with humans in socially and emotionally engaging ways. According to Dautenhahn [6], a SAR is "a robot that can interact with humans in a social context, while possessing communication and learning capabilities that mimic, to some extent, human behaviors." These robots integrate artificial intelligence (AI) and natural language processing to a certain extent, enabling them to interact more naturally with users, leading to enhanced engagement and adaptation to different social contexts [7]. Within geriatric institutions, SARs have the potential to alleviate caregiver workloads, provide cognitive and social stimulation for patients, and assist with daily tasks [8]. However, for these innovations to be successfully implemented and fully beneficial, 2 critical ergonomic dimensions must be addressed: their acceptability and their usability in human-robot interaction (HRI).

The effectiveness of SARs in geriatric institutions largely depends on the quality of HRI [5,9]. Acceptability refers to how willing users—including patients, their informal caregivers, and health care professionals—are to adopt these new tools. This willingness is shaped by their beliefs, needs, and trust in the system [10,11]. Usability, in this context, refers to the extent to which a system supports users in accomplishing their tasks effectively, efficiently, and with satisfaction, within a defined environment. Beyond the system's ergonomic characteristics, such as interface layout, feedback modalities, and physical interaction, it also encompasses aspects such as learnability, error tolerance, and cognitive demand, which are particularly critical when designing for OA populations. [12-14].

Despite their potential, SARs still face significant limitations regarding the quality of HRI and user engagement with the technology. Studies highlight that SARs often struggle to convey emotions effectively, understand the context, and predict users' behaviors accurately [15-17]. These shortcomings can lead to rigid and unnatural communication, hindering the robot's ability to interpret human intentions and emotions [18]. Additionally, SARs often lack adaptability to individual preferences, which can result in a gradual decline in the user's interest and engagement [19]. These challenges highlight the importance of designing HRIs that are intuitive, customizable and aligned with the expectations of OAs to enhance both acceptability and successful integration into geriatric institutions. For example, OAs expect robots to use clear, slow speech; maintain a polite, emotionally supportive tone; minimize technical vocabulary; and favor voice-based over touchscreen-based interaction, all of which have been repeatedly identified as essential for promoting acceptance and usability among OAs [5,19-23].

To overcome these limitations, recent research has explored the integration of large language models (LLMs) into SARs to enhance their communication and interaction capabilities [24-26]. LLMs allow for greater conversational flexibility, improved comprehension of complex requests, and enhanced contextual coherence in responses [27,28]. However, these advancements also introduce new challenges, including biases in generated responses, lack of transparency in robot decision-making, and difficulties in real-time interaction management [29,30].

Given the cognitive and physical limitations often present in OAs, SARs must feature intuitive and user-centered HRIs to maximize their effectiveness [20]. SAR acceptability encompasses not only perceived ease of use but also alignment with user needs, including preferences related to the communication style, autonomy, affective support, and

XSL•FO
RenderX

interaction dynamics [10,31-35]. Among OAs, factors such as low digital literacy, distrust of technology, and sensory or cognitive impairments can influence acceptance [21,36]. Barriers to adoption may include reluctance regarding the robot's appearance, the communication style, or ethical concerns about reduced human interaction [11].

Simultaneously, usability focuses on how efficiently, effectively, and satisfactorily a system can be used to perform expected tasks [13,14]. In geriatric institutions, usability considerations extend to physical ergonomics (eg, size, weight, tactile interfaces, voice interaction), user safety, and emotional comfort [37]. Evaluating SAR usability through standardized methods, such as the System Usability Scale (SUS), helps obtain insights into adoption barriers, assess the ease of operation, and guide iterative technological improvements [12,38]. These aspects emphasize the necessity of a user-centered approach tailored to the specific needs of elderly users [20].

Several studies have investigated the acceptability and usability of SARs by OAs in real-world contexts, including institutional settings, such as nursing homes and hospitals [19,37,39]. However, many of these evaluations rely on scripted interactions or exclude contextual constraints found in routine care environments. Although increasing attention has been paid to the perceptions of professional caregivers, relatively few studies have examined the opinions of informal caregivers (family or friends), despite their role in health care decision-making and daily care activities [21,36]. These gaps highlight the need for in situ evaluations that incorporate the perspectives of both patients and informal caregivers, while considering institutional realities.

To tackle these challenges, empirical research is essential to assess the acceptability and usability of SARs in real-world conditions. This study aimed to evaluate the performance, acceptability, and usability of a SAR among patients and their informal caregivers in a geriatric day care hospital (DCH) in Paris (France). It also aimed to identify the factors that facilitate or hinder SAR adoption in geriatric institutions. The findings will provide deeper insights into the expectations and concerns of OAs and their informal caregivers regarding the use of SAR in health care, while offering a set of recommendations to guide future technological and ergonomic advancements in this field.

Methods

Participants

This study involved 2 populations: OA patients attending consultations at a geriatric DCH and their informal caregivers.

Inclusion criteria for patients were (1) being ≥60 years old, (2) having a Mini-Mental State Examination (MMSE) score above 10 (indicating the absence of severe cognitive impairment; based on standard thresholds, scores of 25-30 are considered normal, 21-24 as mild, 10-20 as moderate, and below 10 as severe) [40], and (3) not exhibiting symptoms of altered reality and understanding and speaking French fluently. Informal caregivers were family members or friends (primarily spouses or children) aged ≥18 years, accompanying the patient and speaking French fluently.

No *exclusion criteria* were applied based on gender, socioprofessional backgrounds, or ethnicity.

Recruitment

Recruitment was carried out using the DCH database, and participants were prescreened prior to enrollment, contacted over the phone, and invited to participate in the study the day of their next consultation. An information letter was sent by post and informed consent was collected onsite.

Setting

The study was conducted between May 2023 and July 2024 in the geriatric DCH of the French Memory Clinic of a geriatric hospital in Paris (France). The DCH provides specialized outpatient care for OAs with physical or cognitive impairments, offering a wide range of consultations, including neurology, oncology, cardiology, psychiatry, and memory assessments. Three waves of data collection were carried out during this period, with a different sample of participants included in each iteration.

Study Design

A mixed methods design was used, combining qualitative and quantitative methods to provide an in-depth understanding of the acceptability and usability of a SAR in a geriatric institution. Mixed methods are particularly suited to exploring complex phenomena in the health and social sciences, as they enable the integration of complementary perspectives and strengthen the validity of results [41,42]. By combining quantitative rating scales with semistructured interviews, this approach identifies both general trends and nuances specific to users' perceptions [43,44]. Mixed methods also enable data triangulation, essential for understanding factors that influence SAR adoption in real-world contexts [45]. This approach, widely recognized in health service evaluation, guarantees a richer, contextualized analysis of the dynamics at play [46,47].

Materials

ARI Robot

The SAR used in this study was ARI, developed by PAL Robotics (Spain) [48]. The robot is 1.65 m (5 ft 5 in) tall and weighs 50 kg (Figure 1). The robot moves by rolling and is equipped with articulated arms that are not designed for load bearing. Its interface includes a touchscreen located on the torso for dialogue transcription, animated eyes with a gaze-tracking module, luminous ears, and an emergency stop button on the back of the robot. ARI supports autonomous operation for 8-12 hours prior to recharging. It is equipped with wired and wireless connectivity capabilities for flexible integration into a variety of environments. For visualization, ARI is equipped with 3 wide-angle cameras positioned on the head, chest, and back, giving it a wide and versatile view of its surroundings. In terms of audio, the robot features 4 microphones, facilitating voice recognition and the efficient capture of ambient sounds.

XSL•FO
RenderX

Figure 1. Photos of the ARI robot: front and side (photo credit: PAL Robotics).

For this study, the ARI robot was programmed with a set of modules explicitly developed as part of the European H2020 SPRING (Socially Pertinent Robots in Gerontological Healthcare) project described by Alameda-Pineda et al [49]. Among these modules, the conversational system was initially developed before recent LLM advances (eg, ChatGPT), relying on a "traditional" modular architecture that combines retrieval-based responses, rule-based intent handling, and open-domain generation (wave 1) [50]. To take advantage of LLMs' abilities for solving complex language-related tasks, the conversational system was redeveloped (wave 2) and refined (wave 3) with an LLM-based architecture, based on the Vicuna model with 13 billion parameters (Vicuna-13b-v1.5 [51]). For deployment in hospital settings, it was adapted to function offline and integrated with a custom prompt targeting health care–related scenarios in French. This design ensured safe use without requiring an internet connection, while enabling more coherent and context-sensitive interactions with patients and informal caregivers.

At the time of the study, ARI had not yet been commercially deployed in hospitals or long-term care institutions beyond the scope of research projects. Its use in this evaluation should therefore be considered as part of an exploratory, precommercial experimentation phase within controlled health care settings.

Introduction of ARI's Capabilities

The SAR was deployed in the waiting area of a geriatric DCH to welcome and assist patients and their informal caregivers. Although participants were free to interact spontaneously with the robot, the researcher introduced 5 illustrative use cases at the beginning of the session to showcase the robot's potential functionalities: (1) greeting and welcoming the user, (2) recalling hygiene and infection prevention procedures, (3) providing information about the consultation procedure, (4) offering orientation and guidance about hospital services, and (5) providing entertainment activities. These examples were intended to guide participants' understanding of the robot's capabilities without restricting the content of their interactions.

Ethical Considerations

The study was approved by the French National Ethics Committee Comité de Protection des Personnes, CPP Ouest II, Maison de la Recherche Clinique-CHU Angers (Institutional Review Board [IRB]: 2021/20) and complied with the General Data Protection Regulation (GDPR; DPO: 20210114153645, AP-HP register). It did not involve randomization or clinical intervention. Informed consent was obtained from all participants onsite. Participants were informed that they could stop their participation at any time. The original consent covered the secondary analysis without further consent. Participant data were anonymized. No compensation was provided to the participants.

XSL•FO
RenderX

Assessment Scales

To assess the acceptability and usability of the ARI robot in a DCH, we used 2 standardized scales:

- The Acceptability E-scale (AES): Acceptability was assessed using the AES, French version [52]. Acceptability is defined as the psychological determinants that shape an individual's intention to use a technology prior to any direct experience with the system. The AES scale comprises 6 items rated on a 5-point Likert scale, yielding a total score ranging from 6 to 30. For marketable products, the AES's acceptability threshold is set at 25.81/30.
- The System Usability Scale (SUS): Usability was assessed using the SUS [53,54]. Usability refers to the degree to which a system can be used by specified users to achieve specific goals with effectiveness, efficiency, and satisfaction in a specified context of use. Ease of use influences user performance and satisfaction, while acceptability determines actual usage [55]. The SUS consists of a 10-item scale designed to assess the overall usability of a system, generating an overall score out of 100, where a higher score reflects better usability. For this scale, experimenters are asked to respond to statements on a 5-point Likert scale, with ratings ranging from "strongly disagree" to "strongly agree." The usability threshold for marketable products is 72/100 for this scale.

The adapted versions of both scales used in this study are provided in Multimedia Appendix 1. For each scale, participants were invited to comment on their choices in a discussion with the researcher.

Assessment Procedure

Each session (~45 minutes) took place in a dedicated room. After free interaction with the robot, participants completed 2 validated instruments: the AES and the SUS. Both were administered orally and supported by open-ended discussions to elicit qualitative data. Finally, participants were accompanied back to the waiting area.

Data Analysis

To ensure a comprehensive understanding of the research topic, both qualitative and quantitative data were collected. Each session was audio-recorded and subsequently transcribed for analysis.

Descriptive statistics (means, SDs, and percentages) were used to describe the sample characteristics and the scores obtained on the AES and SUS.

To assess statistical differences between waves and between groups, several statistical tests were performed. First, Kruskal-Wallis tests were used to compare multiple groups, and Mann-Whitney tests were used to compare 2 scores or 2 groups. Shapiro-Wilk tests were used for normality assumption. When significant differences were found, Tukey post hoc tests were conducted to further explore the data. $P<.05$ was considered statistically significant in all analyses.

Qualitative data were analyzed using inductive thematic analysis [56], allowing themes to emerge from the transcripts of the interviews with the researcher.

System Evolution for Each Experimental Wave

To evaluate the evolution of the ARI robotic system with the help of feedback from participants, we carried out system updates. Over the evaluation period, the ARI robot received 2 updates, resulting in 3 waves of experimentation (Figure 2). Table 1 shows the overall differences in system performance over the 3 test waves, and the full list is described in SPRING Deliverable D1.6 [57].

Results

Participants' Sociodemographic Data

Descriptive Statistics

Over the 3 experimental waves, 110 participants agreed to take part in the study. Of these, only ninety-seven (88.2%) completed the experiment. Incomplete robot assessment sessions occurred when participants were called away for their scheduled medical appointments. The results presented reflect the feedback from these 97 participants across the 3 experimental waves (wave 1: n=14, 14.4%; wave 2: n=43, 44.3%; wave 3: n=40, 41.3%). Table 2 shows the sociodemographic data for the participants in each wave. Participants were categorized as patients (P) or informal caregivers (IC).

Table 2. Sociodemographic data for each experimental wave.

Profile and characteristics	Wave 1 (n=14)	Wave 2 (n=43)	Wave 3 (n=40)	Total (N=97)
P[a]				
Participants, n/N (%)	11/14 (78.6)	30/43 (69.8)	24/40 (60.0)	65/97 (67.0)
Males, n/N (%)	2/11 (18.2)	9/30 (30.0)	6/40 (25.0)	17/65 (26.2)
Females, n/N (%)	9/11 (82%)	21/30 (70.0)	18/40 (75.0)	48/65 (73.8)
Age (years), mean (SD)	78.4 (7.1)	78.3 (6.6)	81.2 (6.4)	79.4 (6.7)
Education (years), mean (SD)	13.6 (2.1)	12.9 (3.5)	11.4 (3.6)	12.5 (3.4)
MMSE[b] score, mean (SD)	27.8 (1.9)	25.2 (4.5)	25.5 (3.9)	25.7 (4.1)
IC[c]				
Participants, n/N (%)	3/14 (21.4)	13/43 (30.2)	16/40 (40.0)	32/97 (33.0)
Males, n/N (%)	1/3 (33.3)	5/13 (38.5)	9/16 (56.3)	15/32 (46.9)
Females, n/N (%)	2/3 (66.7)	8/13 (61.5)	7/16 (43.7)	17/32 (53.1)
Age (years), mean (SD)	75.3 (11.6)	63.9 (19.4)	67.9 (12.9)	67 (15.7)
Education (years), mean (SD)	12.0 (3.0)	15.0 (0)	13.2 (4.1)	13.8 (3.2)
MMSE score, mean (SD)	N/A[d]	N/A	N/A	N/A

[a]P: patients.

[b]MMSE: Mini-Mental State Examination.

[c]IC: informal caregivers.

[d]N/A: not applicable.

Sociodemographic data analysis using nonparametric tests (justified by significant Shapiro-Wilk tests indicating nonnormal distributions: $P<.001$ for socioeducational level, $P=.008$ for MMSE score, and $P\leq.003$ for age across waves 2 and 3) revealed no significant difference in terms of age across the 3 waves ($\chi^2_2=0.388$, $P=.82$) and no significant difference in the socioeducational level ($\chi^2_2=3.330$, $P=.19$), suggesting a relatively homogeneous distribution of these characteristics among the groups. Furthermore, no significant difference was observed regarding the MMSE scores of patients across waves ($\chi^2_2=4.064$, $P=.13$).

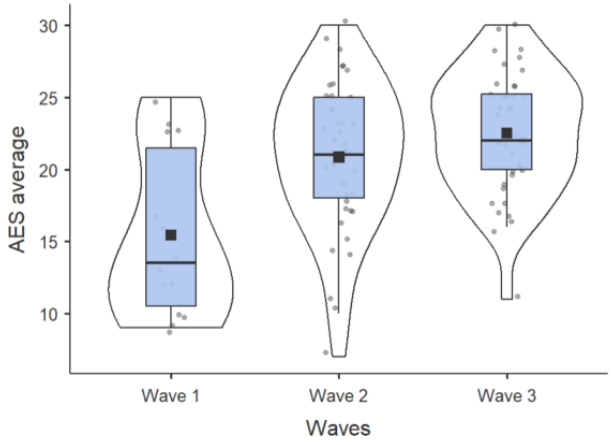
A correlation analysis was carried out between AES and SUS scores in order to explore the consistency of participants' responses across the 2 scales. The results revealed a strong positive correlation between the 2 variables (r=0.664, $P<.001$), indicating that higher acceptability scores are associated with higher usability scores.

Acceptability E-Scale

The mean AES scores over the 3 waves of observation showed a positive progression between waves (Figure 3): 15.4/30 (SD 5.81) for wave 1, 20.9/30 (SD 5.25) for wave 2, and 22.5/30 (SD 4.23) for wave 3; this indicated a steady increase over time. Using the Kruskal-Wallis test, the mean AES scores showed a significant increase between waves ($\chi^2_2=13.4$, $P<.001$). The Mann-Whitney test revealed no significant differences in AES scores between male and female participants (U=960, $P=.71$) and between patients and informal caregivers (U=905, $P=.57$).

XSL•FO
RenderX

Figure 3. AES scores across the 3 experimental waves. AES: Acceptability E-scale.



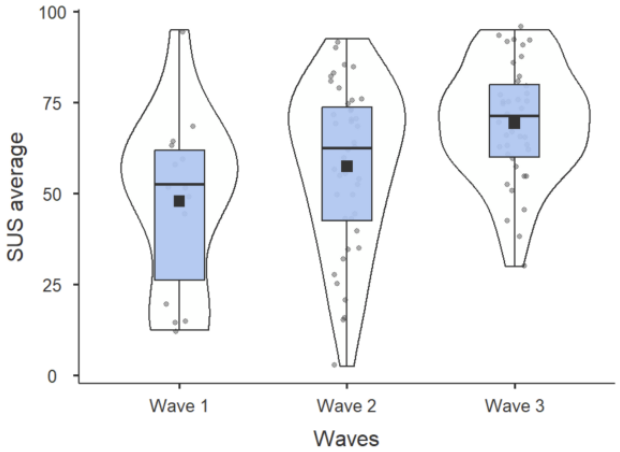


Figure 4. SUS scores across the 3 experimental waves. SUS: System Usability Scale.

Analysis of AES scores across the 3 experimental waves showed a significant difference between waves 1 and 2 (P<.01), as well as between waves 1 and 3 (P<.001). Additionally, no significant difference was observed between waves 2 and 3.

Based on these findings, an item-by-item analysis was conducted to identify specific differences across themes related to system acceptability. Tukey post hoc tests revealed significant differences in 4 of the 6 items: robot's usability, robot's perceived usefulness in the hospital setting, robot's response time, and overall satisfaction with the robot.

Regarding satisfaction with the robot, a significant mean difference of –0.956 was observed between waves 1 and 2 (P=.02) and a difference of –1.336 between waves 1 and 3 (P<.001). With respect to the robot's perceived usefulness in the hospital, a significant mean difference of –1.289 was found between waves 1 and 3 (P=.004). The robot's response time showed a significant difference of –1.86 between waves 1 and 2 and a significant difference of –2.079 between waves 1 and 3 (P<.001). Finally, on overall robot satisfaction, a mean difference of –0.815 was observed between waves 1 and 2 (P=.042), as well as a mean difference of –1.246 between waves 1 and 3 (P<.001).

System Usability Scale

The mean SUS scores over the 3 waves of observation showed a positive progression between waves: 47.9/100 (SD 24.18) for wave 1, 57.4/100 (SD 22.46) for wave 2, and 69.3/100 (SD 16.03) for wave 3; this indicated a steady increase over time. Using the Kruskal-Wallis test, the mean SUS scores showed a significant increase between waves (χ^2_2=11.4, P<.001). The Mann-Whitney test revealed no significant differences in SUS scores between men and women (U=848, P=.14) and between patients and informal caregivers (U=855, P=.19).

Analysis of SUS scores across the 3 experimental waves revealed significant differences between waves 1 and 3 (P<.01) and between waves 2 and 3 (P<.05). No significant difference was found between waves 1 and 2 (P>.05).

Based on these findings, an item-by-item analysis was conducted to examine specific differences in responses related to system usability. Tukey post hoc tests revealed significant differences in 5 of the 10 items: conversation complexity, assistance, inconsistency, ease of use, and user confidence.

Regarding the complexity of conversations, a significant difference of –1.089 was observed between waves 1 and 3 (P=.01). Regarding the assistance required to interact with the robot, a significant difference of –1.182 was observed between waves 1 and 3 (P=.02). Regarding the design of the robot's

XSL•FO
RenderX

functionality, a significant difference of –1.039 was observed between waves 1 and 3 (P=.005), as well as a mean difference of –0.569 between waves 2 and 3 (P=.04). Robot inconsistencies showed a significant difference of –1.28 between waves 1 and 2 (P=.003) and –1.632 between waves 1 and 3 (P<.001). Finally, regarding confidence using the robot, a significant difference –1.050 was observed between waves 1 and 3 (P=.01).

Qualitative Data

Thematic Qualitative Analysis

A thematic qualitative analysis of participants' feedback was conducted to explore perceptions of the ARI robot's acceptability and usability. Verbatim responses from patients and informal caregivers were reviewed and categorized into 5 themes representing key aspects of user experience: (1) ease of use, (2) comprehension of the robot's responses, (3) perceived usefulness of the robot in a hospital setting, (4) quality of interaction, and (5) overall system satisfaction. These themes correspond to established dimensions of acceptability (eg, perceived usefulness, satisfaction) and usability (eg, ease of use, comprehension, efficiency). Each theme is illustrated next with representative quotes translated from French to English.

Ease of Use

The robot's ease of use, an essential component of acceptability, was progressively enhanced throughout the study. Although its physical ergonomics remained constant, updates to the dialogue system facilitated more fluid and coherent interactions. These improvements contributed to participants' perceptions of the robot as simpler and more intuitive to operate. Several participants pointed out that the novelty of the robot could, at first, generate a certain amount of reluctance, suggesting that perceived ease of use also depended on experience acquired through interaction. For example, in wave 1, some found the voice interface practical:

> *The voice is helpful because I can't see well [referring to the transcript on the robot's screen]. You just have to ask it a question.* [Informal caregiver, wave 1]

Others found it unintuitive:

> *Not at all [easy to use]!* [Patient, wave 1]

However, some participants pointed out the limit of novelty when faced with a robot:

> *I mean, we're not used to it. When you're used to it, it's easy, but not the first time. It's a bit confusing. You have to get used to it.* [Patient, wave 1]

This need for an adaptation period was most prominent in wave 1, when the system was less refined, but it also emerged in a few cases in waves 2 and 3. This suggests that although improved usability facilitated smoother interactions, user familiarity remained a factor influencing initial comfort in engaging with the robot.

As waves progressed, more participants acknowledged the simplicity of interacting with the robot:

> *It's easy...you just need to ask questions, and if the question is relevant, it answers.* [Patient, wave 2]

However, some participants reported challenges in formulating their questions appropriately:

> *I had to force myself to phrase my questions differently from how I would naturally say them.* [Informal caregiver, wave 3]

Understanding the Robot's Responses

Although voice synthesis remained consistent, updates to the dialogue system, particularly the integration of an LLM facilitated clearer and more coherent exchanges. Participants generally found the language comprehensible; however, some reported mismatches between their questions and the robot's responses, suggesting that perceived comprehension remained sensitive to the contextual specificity of the interactions. In wave 1, participants' opinions ranged from finding the robot's speech fully understandable ("They were completely understandable and easy" [patient, wave 1]) to reporting inconsistencies in comprehension. In wave 2, many agreed that the robot spoke clearly:

> *It was perfectly understandable.* [Patient, wave 2]

However, some responses were found to be off-topic:

> *Its explanations are clear, but some responses were off the mark.* [Informal caregiver, wave 2]

In wave 3, participants generally found the language clear:

> *I found it very clear and precise.* [Patient, wave 3]

However, some noted occasional mismatches between their questions and the robot's responses:

> *Not entirely understandable, because it made me ask the same question multiple times.* [Patient, wave 3]

Perceived Usefulness of the Robot in a Hospital Setting

Perceptions of the robot's usefulness evolved over the 3 waves. Although some participants found it useful for providing basic information, others expected a more interactive experience. Over time, the focus shifted to the accuracy of the robot's responses, with some seeing it as a "glimpse into the future," while others emphasized its current limitations. In wave 1, some found it practical for basic information:

> *Just telling me [the location needed] it's next door was enough for me.* [Informal caregiver, wave 1]

However, others expected a more interactive experience:

> *If it [the robot] had come with me [to show me the path], it would have been better.* [Patient, wave 1]

In wave 2, usefulness was conditional on the accuracy of responses:

> *Plenty useful, but only if it understood the question and answered it correctly.* [Informal caregiver, wave 2]
>
> *It did the job, but a good signpost could do it too.* [Informal caregiver, wave 2]

By wave 3, opinions remained divided, with some participants perceiving the robot as indicative of future technological developments:

XSL•FO
RenderX

> *It's an opening into something futuristic. So, it's useful to me.* [Informal caregiver, wave 3]

However, for others, opinions remained mixed with respect to the robot:

> *Well, it annoyed me quite a bit [...] Every time I ask it a question, it tells me to go to the reception.* [Informal caregiver, wave 3]

Some participants highlighted its efficiency and consistency compared to human interactions:

> *It answered all those questions 100%. [Informal caregiver, wave 3)*
>
> *Even if some people might find a human more pleasant, humans can get tired or irritated—whereas ARI [the robot] never does.* [Informal caregiver, wave 3]

Quality of Interaction

Throughout the study, updates to the robot enhanced the fluidity of interactions and the quality of user feedback—2 factors critical to its acceptability. These improvements, particularly in the response speed, interruption management, and response richness, were reflected in participants' feedback. During wave 1, the robot demonstrated inconsistent response patterns, as reported by participants:

> *I asked a question, but it [the robot] responded with something completely unrelated—it was totally incoherent.* [Patient, wave 1]

Some participants also perceived that the robot had a limited range of programmed responses:

> *I have the impression that it is programmed only to answer certain questions.* [Patient, wave 1]

Additionally, participants noted that the robot often repeated suggestions unrelated to their queries:

> *But it does offer to go to lunch a lot.* [Patient, wave 1]

In wave 3, some participants noted that the robot responded promptly:

> *You ask the question, and it answers almost immediately.* [Informal caregiver, wave 3]

However, others reported challenges in interrupting the robot while it was delivering a response:

> *You can't interrupt it, and that bothered me a bit.* [Informal caregiver, wave 3]

Furthermore, some participants expressed a preference for the robot's responses over those provided by human receptionists:

> *I prefer your robot's answers to those of the ladies at the reception.* [Patient, wave 3]
>
> *There are humans who aren't as direct and precise [...] I'm surprised.* [Patient, wave 3]

General Satisfaction

Overall satisfaction with the experimentation of the robot reflected growing acceptance in terms of both functional effectiveness and ease of use, with clear progression observed from the first to the final wave. In wave 1, some participants appreciated the robot's novelty:

> *I think it is really nice. I think it's fun and funny.* [Informal caregiver, wave 1]
>
> *I like it—it's nice. Really nice. It's great to see a robot. But a human is still nicer.* [Informal caregiver, wave 1]

Conversely, some participants expressed dissatisfaction:

> *I'm sorry if I sound upset, but I didn't feel any satisfaction.* [Patient, wave 1]
>
> *I didn't get any satisfaction—the robot didn't help me at all. It's actually a bit scary.* [Patient, wave 1]

In wave 2, reactions remained mixed; some participants found the robot engaging and entertaining:

> *I find it amazing, it's super.* [Patient, wave 2]
>
> *It's impressive, it's the first time it's happened to me, I didn't know robots at all before today, and it's impressive to see a machine that you ask questions to, that answers you.* [Patient, wave 2]

However, others highlighted its limitations:

> *I'm sure the robot has potential, but at the moment, it's not performing well.* [Informal caregiver, wave 2]

In wave 3, participant feedback was generally more favorable. Participants described the robot as "very interesting, very instructive because it's very knowledgeable. It answered me perfectly well" (patient, wave 3) and declared that "it's funny because you don't expect to find something like this, and it does have quite a lot of answers" (informal caregiver, wave 3). Others expressed an overall appreciation:

> *Oh, I like it a lot. I think it's nice, it has beautiful eyes.* [Patient, wave 3]
>
> *I like this thing.* [Patient, wave 3]

Discussion

Principal Findings

This study provides one of the first in situ evaluations of a SAR equipped with an LLM in a geriatric hospital setting. Quantitative data showed a significant increase in both acceptability and usability of the ARI robot, corroborating the qualitative findings. Participants reported improved ease of use, comprehension, and perceived usefulness across experimental waves, as reflected in the significant increases in AES and SUS scores. Acceptability scores increased from 15.4/30 in wave 1 to 22.5/30 in wave 3 (P<.001), while usability scores rose from 47.9/100 to 69.3/100 (P=.003). Verbatim feedback reflected a growing appreciation for the robot's functionality and ease of interaction, aligning with observed improvements in satisfaction and perceived usefulness. These improvements are largely attributable to technical upgrades, most notably the integration of an LLM, which enhanced the naturalness, contextual relevance, and consistency of interactions. The experimental conversational system, developed collaboratively within the

XSL•FO
RenderX

European H2020 SPRING project [58], consists of an audiovisual perception pipeline that captures speech and behavioral cues, processed by a dialogue system powered by an LLM to synthesize responses into sound. Collectively, these developments contributed to a more fluid, engaging, and user-centered experience with the robot.

Although the ARI robot is commercially available, the conversational system developed in this study remains experimental. The final scores did not meet established thresholds for acceptability (AES score>25.81) and usability (SUS score>72), underscoring the need for further refinement prior to large-scale hospital implementation, such as transitioning to full-duplex communication, adding multilingual support, and incorporating nonverbal feedback. Nonetheless, the upward trajectory of these scores is encouraging, suggesting strong potential for future clinical deployment as performance approaches benchmark criteria.

Limitations

This study presents several limitations related to both the experimental design and the technical capabilities of the robotic system.

From a methodological perspective, the study was conducted at a single site within an innovation-friendly clinical environment. Although this facilitated implementation, it may limit the generalizability of the findings to institutions with different organizational structures or cultural contexts. Moreover, the recruitment strategy relied on voluntary participation, introducing a potential self-selection bias.

Another limitation concerns the ecological validity of the experimental conditions. Although the ARI robot was deployed in a hospital setting, the interactions took place in a quiet, controlled room rather than in a dynamic waiting area. This may have minimized external distractions and reduced communication challenges typically present in real-world hospital contexts. In addition, the interaction occurred only once per participant. As a result, the findings largely reflect first impressions and do not capture how user perceptions evolve with repeated exposures or long-term use. Longitudinal studies are needed to assess the durability of engagement and trust over time.

On a technical dimension, although the integration of an LLM improved conversational coherence, the system remained prone to occasional misinterpretations or generic responses, especially when confronted with vague or ambiguous input. This limitation is consistent with known issues in LLM-based dialogue systems, which often struggle with generating contextually appropriate and nongeneric responses when input is vague or underspecified [59]. Furthermore, the robot's speech recognition system showed sensitivity to user-specific features, such as accent, the speech rate, and background noise. Finally, the absence of multilingual support reduced inclusiveness for non–French-speaking users, an important consideration in multicultural health care environments.

Comparison With Prior Work

Our findings align with the existing literature showing that AI-powered SARs can significantly enhance user engagement when interactions are intuitive and socially appropriate [5,19,26]. The integration of an LLM between waves 1 and 2 notably improved the ARI robot's conversational fluency and contextual relevance, features widely recognized as essential for effective HRI [1,2]. Although natural language processing has long been identified as a key component of user engagement, few studies have directly captured the impact of integrating an LLM into SARs in a health care context. Most prior evaluations were either conducted before the emergence of transformer-based language models (pre-2019) or focused on single-instance deployments with fixed systems. Moreover, although most existing studies on SARs have been conducted in controlled environments, such as laboratories or nursing homes [3,4], few have examined how real-time system refinements affect user perceptions over successive implementation phases. This study addressed this gap by documenting how progressive improvements to the LLM-based dialogue system influence usability and acceptability in situ over 3 successive waves.

Future systems should integrate multimodal strategies (eg, gesture recognition, facial expression analysis, affective cues) to support more natural and empathetic communication in health care environments [16,49].

Our results also align with previous research advocating for voice-based interaction as particularly suitable for OAs, especially in contexts where digital literacy may vary [22,23]. Participants consistently favored spoken communication over touchscreen input. Furthermore, the inclusion of real-time transcription improved accessibility, confirming prior findings on the value of combining auditory and visual cues for inclusive design [60].

Confidence in using the system was closely linked to interaction quality as although wave 3 participants, who received consistent and context-aware responses, gained confidence, those in earlier waves, confronted with erratic outputs, voiced concerns about the robot's reliability. Interestingly, some participants also blamed themselves, reflecting a well-documented phenomenon in HRI literature, automation bias, where users tend to overestimate the capabilities of intelligent systems and assume personal responsibility for communication failures [39,61]. These findings underscore the critical role of transparency and predictability in AI-driven behaviors as key determinants of user confidence, reinforcing prior research in HRI [16,62,63].

Finally, our results reaffirm the need for user familiarization with voice-based robotic interaction in health care contexts. For the majority of participants, this study marked their first direct interaction with a SAR, and many indicated the need for a period of adjustment. Initial hesitation often gave way to positive engagement, echoing previous research showing that structured onboarding and repeated exposure are key to long-term acceptability [11].

XSL•FO
RenderX

Recommendations

Drawing on the empirical findings of this study, the following recommendations are intended to inform the design and implementation of SARs tailored to the specific interactional needs of OAs in geriatric care settings. These evidence-based insights aim to guide researchers and industry stakeholders in developing socially assistive technologies that are both user centered and contextually appropriate within health care environments.

Improve Natural Language Processing, Speech Recognition, and Multilingual Support

To enhance the quality of HRI in geriatric care, it is recommended that future SARs integrate more advanced natural language processing capabilities than those available in current open models to ensure greater coherence and contextual relevance in responses. Speech recognition systems should be optimized to account for prosodic variation, regional accents, and articulation differences (eg, slower speech rate, reduced vocal intensity, hesitations, or imprecise consonant production) commonly observed among OAs due to age-related changes in respiratory and orofacial motor control [64]. In addition, the incorporation of multilingual functionality is essential to accommodate the linguistic diversity of users in health care settings and to promote equitable access to robotic services.

Develop Clear Onboarding Protocols and Autonomous Robot Self-Presentation

To facilitate user engagement and support initial interaction, it is recommended that future deployments of SARs include a structured onboarding protocol. This may involve brief demonstrations or the distribution of printed materials (eg, leaflets with example questions) to familiarize users with the robot's capabilities. However, recognizing that real-world hospital settings may not consistently offer human assistance at the point of interaction, SARs should also be equipped with a robust self-introduction feature. This feature should autonomously guide users through the robot's purpose, functionalities, and appropriate use cases, clarifying when and how to engage and what types of questions it can address. Such improvements are essential for promoting user autonomy, reducing uncertainty, and improving the perceived usefulness of SARs in health care environments.

Such improvements are essential for OAs, who often face reduced digital literacy, cognitive decline or impairments, or heightened anxiety when interacting with unfamiliar technologies. Research has shown that guided introductions, whether verbal or visual, enhance initial confidence, reduce hesitation, and support sustained engagement [65,66].

Ensure Compliance With Privacy, Ethical, and Regulatory Standards

It is essential that the development and deployment of SARs in health care settings align with existing ethical guidelines and data protection regulations. Particular attention must be given to the collection, processing, and storage of sensitive health-related information. Developers and implementers should establish clear protocols for obtaining informed consent, ensuring transparency regarding data usage, and enabling users to understand the scope and limitations of data handling. Additionally, SARs should be designed to support confidential interactions, especially when used with vulnerable populations, such as OAs, by incorporating features that safeguard user privacy and uphold professional standards of care. Early integration of ethical and legal considerations will be critical to building trust and ensuring responsible implementation.

Enhance Interruption Management and Conversational Fluidity

Participants highlighted the difficulty of interrupting the ARI robot while it was speaking, a limitation that disrupted the natural flow of dialogue. To address this issue, future iterations of SARs should improve turn-taking mechanisms and enable responsive interruption handling, especially in multiparty or fast-paced care environments. These refinements are essential for supporting user-led interaction, minimizing frustration, and improving conversational naturalness.

Enable Autonomous Navigation and Spatial Guidance

Several participants expressed the desire for the ARI robot to not only provide verbal instructions but also physically accompany them to their destination. Incorporating autonomous navigation capabilities would expand the robot's role from an informational assistant to an active guide, offering greater support to users with mobility or orientation difficulties in complex care environments, such as hospitals. To ensure safe and effective guidance, particular attention should be paid to obstacle detection and navigation in dynamic environments, as well as to adapting the robot's speed to the walking pace of OAs.

Conclusion

This study showed that SARs, when iteratively enhanced and evaluated in real-world conditions, can reach growing levels of acceptability and usability among OAs and their informal caregivers. The integration of an LLM was a turning point in improving the ARI robot's ability to engage in meaningful, coherent interactions. These findings suggest that SARs, when designed with user needs in mind, hold strong potential for supporting care delivery in geriatric hospital settings.

Future work should focus on further leveraging the capabilities of LLMs to enable adaptive, personalized interactions that respond to individual users' communication styles, memory, and emotional cues. Additionally, the integration of multimodal communication features, such as gaze tracking, gesture and facial expression recognition, and targeted dialogue strategies, will be essential to enhancing the ARI robot's relevance, trustworthiness, and effectiveness in complex health care environments.

Abstract

Background: Mass displacement is a grand public health challenge. Refugees and immigrants experience a disparate hypertension burden and disparities in self-management. Successful hypertension self-management is key for improving outcomes, but research on its feasibility in refugee and immigrant health care settings is limited.

Objective: This study aimed to identify clinic staff–perceived barriers to and facilitators of implementing a digital intervention for hypertension self-management among refugee and immigrant patients and to identify its feasibility and usability.

Methods: Primary care physicians and medical assistants who care for refugees and immigrants in San Diego were interviewed using human-centered semistructured methods (n=18). Interviews were analyzed using an inductive approach. Usability testing for the software (Med Pro Care) was conducted with participants (n=15) to test the feasibility of real-time tracking of blood pressure (BP) home readings for hypertension self-management. Clinical staff rated their satisfaction on the System Usability Scale and the NASA Task Load Index, which measured mental workload.

Results: For refugee and immigrant patients self-managing hypertension, clinical staff identified barriers and facilitators in the following areas: (1) social determinants of health increase hypertension burden among refugee and immigrant patients, (2) clinical staff face challenges to effective hypertension care for refugee and immigrant patients, (3) perceived benefits of potential intervention for self-management, and (4) perceived barriers to potential intervention for self-management. Primary care physicians completed 90% of the tasks, and medical assistants completed 83% of the tasks successfully. Most clinic staff found the software system for monitoring BP to be easy to use with an average score for usability of 4.1 of 5.0 (SD 0.4).

Conclusions: Addressing identified barriers to and facilitators of self-management of hypertension is crucial to designing effective interventions in real-world refugee and immigrant health care settings. Telemonitoring interventions using software that transfers BP readings to clinical staff in real time may be feasible from the perspective of clinic staff and can address hypertension disparities in marginalized populations, such as immigrants and refugees. Addressing identified barriers to and facilitators of self-management is crucial to designing effective interventions in real-world refugee and immigrant health care settings. Our findings suggest that clinic staff view digital telemonitoring as both feasible and supportive of patient empowerment, health literacy, and improved communication—factors essential to addressing hypertension disparities in marginalized populations.

Introduction

Background

Hypertension holds global significance as one of the most important modifiable risk factors for cardiovascular disease. Almost one-third of the global population is diagnosed with hypertension [1], which causes 7.5 million deaths annually, and its increasing prevalence has led to greater morbidity for the global population from its sequelae, such as heart disease [2,3]. Notably, forcibly displaced populations, whose numbers are at all-time highs, including immigrants and refugees, experience a heightened burden of hypertension [4,5]. The challenges of fleeing conflict, interrupted health care access, adapting to new environments, and enduring persecution and trauma amplify the stress experienced by refugees and contribute to a higher hypertension risk [6-8]. In addition, in host societies, immigrants and refugees confront multifaceted barriers to engaging in health care, encompassing language and cultural barriers, economic barriers, and acculturation difficulties [9]. These factors contribute to this minoritized group's poor control of hypertension [10-14]. This is reflected in empirical evidence consistently pointing to elevated hypertension rates and almost double the cardiovascular disease risk in refugees compared to other immigrants or the hosting population, irrespective of their country of origin, compared to host country citizens [5,8].

Self-management of hypertension, including both self-monitoring of blood pressure (BP) and self-titration of medication, is an evidence-based, cost-effective method for improving BP control [15,16]. Patients who self-monitor are more likely to lower their BP [17,18], have fewer BP-related office visits [19,20], improve communication with their providers regarding lifestyle factors [21], and incur significant health care cost savings compared to usual care groups [22], regardless of the number of other comorbidities [23]. In addition to the reported accuracy of self-monitoring, many providers share positive perspectives on self-titration, emphasizing its potential benefits, including improved patient-provider relationships and enhanced self-efficacy [24-26]. Given the ongoing self-management demanded by chronic conditions such as hypertension, self-titration could provide crucial support for clinics in efficiently caring for their patients and decreasing clinic visits [7,21,27].

Objective

Providers are often responsible for health education, telemonitoring, and regular follow-up with patients for hypertension self-management, but acceptability and efficacy of digital health technologies, integration with existing electronic health records, usability, and technology support have emerged as key concerns [15,17,24,28]. Our study examined the feasibility of using technology for BP monitoring when caring for refugee and immigrant patients, and the barriers to and facilitators of this model of care. We also assessed the usability of a specific software (Med Pro Care; Withings) attached to connected BP monitors (Withings) that can help clinic staff implement telemonitoring in their clinics while receiving real-time BP readings from their patients at home [29].

Methods

Design

This study was part of a larger investigation into refugee and immigrant patients' barriers to hypertension care and opportunities to improve self-management. Patient participants in that study were provided a free and validated Withings BP monitor, a Food and Drug Administration–approved, cellular-connected home BP monitor [29], and were instructed to maintain a BP diary. The data from the BP monitor were transmitted to a web-based dashboard called Med Pro Care [29]. Our part of the study examined the clinic staff's perspective and experience with the Med Pro Care software using the data recorded from the patients in the larger study. Clinic staff participants in our study were previously trained by our staff on the use of the Med Pro Care dashboard, where they could view the charts for the patients in the larger study and where to find their BP readings in the software. The study was designed to determine the feasibility and usability of the Med Pro Care software for future research on longitudinal telemonitoring.

Our study used a human-centered design, mixed methods approach to gathering data concerning the perspectives of clinic staff on self-management of hypertension for refugee and immigrant patients and the usability of Med Pro Care for use in the clinic to help clinical staff telemonitor patients' home BP readings. We administered semistructured interviews, a demonstration of the Med Pro Care software for reviewing patient charts, and a usability test of Withing's Med Pro Care software, all to both medical assistants (MAs) and primary care providers (PCPs). Qualitative interviews aimed to identify clinic staff's experiences with treating refugee and immigrant patients with hypertension to better understand the social aspect of their health care (Multimedia Appendix 1), whereas the quantitative data collected from the usability test demonstrates the effectiveness of a possible solution addressing identified social factors (Multimedia Appendices 2-4). This study was conducted at federally qualified health centers, university clinics, and private clinics across southern San Diego County, California, where most refugees and immigrants in the region have resettled [30].

Participants

Participants included the following clinic staff: (1) MAs and (2) PCPs in San Diego County who regularly provided care for refugee and immigrant patients. We chose to ask both the same questions and combine their responses for data analysis because of growing evidence showing that multilevel interventions that involved integrated multidisciplinary care and promotion of self-management behaviors, which is done by diverse clinic staff, including providers, nurses, pharmacists, and MAs, were associated with the largest BP reductions [31,32]. Clinical staff were included if they self-reported regularly seeing refugee or immigrant patients in the San Diego region. Individuals were excluded if they did not care for patients with hypertension or self-reported not regularly caring for refugee or immigrant patients. While some participants self-identified as immigrants themselves, our study did not include a formal inquiry about previous or current citizenship or legal status.

XSL•FO
RenderX

Recruitment took place between August 2021 and November 2022 through 4 sites: (1) the Family Health Centers of San Diego (FHCSD), a federally qualified health center system that provides care for a large portion of refugees in San Diego County; (2) University of California San Diego Health System; and (3) 2 private practices in San Diego County. Study staff received contact information for potential participants through hospital directories and contacted clinic staff via email or phone. MAs were recruited via mass email to all MAs at the federally qualified health center, to which 13 MAs responded, and 2 were excluded for not working with patients with hypertension. Eleven MAs consented and participated, with 1 MA not completing the usability assessment. PCPs were referred by senior study staff who were aware of their practice. All 7 PCPs referred consented and participated, with 2 not completing the usability assessment.

Data Collection

Study staff created standardized operating procedures to ensure all interviews were conducted the same, regardless of the study staff who conducted the interview. In this process, the study team reviewed available literature about barriers to the implementation of self-management of hypertension for refugee and immigrant patients and created questions that could illuminate the clinic staff's perspective. The principal investigator then reviewed and approved these questions (Multimedia Appendix 1). The study coordinator (CG) then trained incoming study staff by reviewing the procedures and having new study staff shadow an interview.

Interviews were conducted in the participant's clinic (n=15), except for 1 PCP who participated in an office belonging to research staff and 2 PCPs who participated in the qualitative interview portion of the study over Zoom and did not complete the usability testing. Interviews typically lasted about 60 minutes in total and were audio recorded and later transcribed for qualitative analysis. Demographic information was collected from participants. Interview questions were the same for both MAs and PCPs and asked about their understanding of barriers to and facilitators of health care for refugee and immigrant patients, patient–clinic staff relationships, and the clinic staff's opinions of self-management of hypertension, including both self-monitoring and self-titration of antihypertensive medication. Although self-titration was not tested in the larger study, thus data were not available for our usability tests, participants were asked about their opinions on whether this was something that could help their refugee and immigrant patients because it has been previously shown to help self-management efficacy, such as in the TASMIN (Targets and Self-Management for the Control of Blood Pressure) trial where self-monitoring BP and an individualized self-titration algorithm improved systolic BP for patients in the United Kingdom [15,16]. Interview questions were the same for both MAs and PCPs because of their similar exposure to the social factors that were examined by the questions. While the focus was on refugee patients, question wording was modified to include immigrants for clinic staff who expressed more experience with immigrant patients rather than specifically refugees. Study staff then demonstrated the Med Pro Care software, which included administrative and monitoring tasks. Participants were then asked to complete a usability test of the software, where MAs were tested on more administrative tasks, such as registering patients and leaving notes on accounts, and PCPs were tested on more in-depth review of BP readings. Both MAs and PCPs were asked to complete 5 tasks. The usability test was screen and audio recorded using the TURF 4.0 software (McWilliams School of Biomedical Informatics) [33]. Participants then completed the System Usability Scale [34] and the NASA Task Load Index [35] for self-reported satisfaction and usability. Study staff then asked participants if they had any additional feedback on how the software could be used in their own clinics.

Data Analysis

Qualitative and quantitative data were analyzed separately. The semistructured interviews were analyzed using an inductive thematic approach to capture participants' experiences as comprehensively and accurately as possible [36]. To improve the credibility of the analysis, investigator triangulation was implemented as follows [37]: (1) 2 study staff (CG and MR) independently coded a set of transcripts (n=3), (2) then had multiple meetings to define a codebook and established intercoder agreements through the subjective assessment method [36]. The codebook was then reviewed by the principal investigator, finalized, and distributed to other researchers (NA and RA) who coded the remaining transcripts. Two study staff (CG and LB) analyzed the codes for recurrent themes following Crabtree and Miller's 5-step interpretive process [38]. Qualitative data were analyzed using Atlas. Using Microsoft Excel, 1 research team member (CG) performed basic descriptive statistical analysis on the demographic data, task completion, total clicks (collected from TURF software), and satisfaction questionnaires. For task completion, participants were given 1 point for successfully completing a task and half a point for partially completing a task. A final score was given as a percentage of tasks completed. Averages were then taken of all MAs scores and all PCPs scores separately. For the items that were negatively worded in the System Usability Scale, responses were reverse coded so that all items were aligned in the same direction, with higher scores being more favorable.

Ethical Considerations

The University of California San Diego Human Research Protection Program (#200063) granted institutional review board approval. All participants consented before participation and were compensated with a US $35 Visa gift card for their time. All participant data were fully deidentified prior to analysis to protect individual privacy and confidentiality. As part of our study, participants examined BP measurements from a larger investigation into refugee and immigrant patients' hypertension self-management (IRB#200063).

Results

Participant Characteristics

Data on participant demographics are listed in Table 1. MAs made up 61.1% (n= 11) of the 18 participants. Most participants were female (n=15, 83.3%). The 3 male participants were all PCPs. One PCP was a nurse practitioner, whereas all others were physicians. All MAs were associated with FHCSD,

XSL•FO
RenderX

whereas 42.9% (3/7) of PCPs were associated with FHCSD. The average age of participants was 38.9 (SD 11.9) years. Most participants self-identified as White (n=6, 33.3%), Hispanic (n=4, 22.2%), or Middle Eastern/North African (n=3, 16.7%). Besides English, the most commonly spoken languages were Spanish (n=9, 50%) and Arabic (n=6, 33.3%).

Barriers and Facilitators Identified From Interviews

The interviews from this study, both MAs and PCPs, yielded 4 themes for barriers and facilitators: (1) social determinants of health increase hypertension burden among refugee and immigrant patients, (2) clinical staff face challenges to effective hypertension care for refugee and immigrant patients, (3) perceived benefits of potential intervention for self-management, and (4) perceived barriers of potential intervention for self-management.

Social Determinants of Health Influence Hypertension Burden Among Refugee and Immigrant Patients

All participants, including both MAs and PCPs, described hypertension as a burden among many of their refugee patients and described various factors unique to these patients influencing its management. Some described how patients' attitudes toward the disease limit care, including how patients may lack self-efficacy or motivation to make necessary changes to their care regimen. For example, when asked if refugee patients often followed the advice or directions given by the physician, an MA stated:

> *some [patients] are stuck in their ways. And they don't feel like changing is gonna help them either way, so they just continue to do whatever they're doing.* [MA]

Participants also acknowledged how the experience of forced displacement along with its associated stress and trauma can exacerbate hypertension:

> *Especially in a refugee population, we do see stress causing high blood pressure pretty directly. And so, to talk about any traumas they may have experienced, and have a way to treat those, [is important]... just really create an open conversation about that because I think it's not often talked about.* [PCP]

They described the health care barriers refugee and immigrant patients face such as language and cultural barriers:

> *...oftentimes they come untreated. I feel like it's similar to other patient populations, but the difference is that the language barrier and education has hindered treatment in the past, or they stop treatment for periods of time.* [PCP]

Participants also noted that poor health literacy and low socioeconomic status can contribute to difficulty with managing hypertension:

> *Patients don't have the supplies to take a proper blood pressure or they don't have the correct information [to self-manage hypertension].* [PCP]

Clinical Staff Face Challenges to Effective Hypertension Care for Refugee and Immigrant Patients

Common barriers faced by clinical staff when treating refugees and immigrants included effective communication, health literacy, adherence, and monitoring. Participants noted physician-patient communication was a critical variable in delivering effective care. For example, when a PCP was asked to mention a specific worry regarding their patients and the care they receive, they noted:

> *Yeah, the language barrier, them not understanding the education part of it, taking medication incorrectly...* [PCP]

Furthermore, both MAs and PCPs expressed concern that not all their refugee and immigrant patients completely understand the instructions that are given, or clinical staff do not have enough time to explain everything. This leads to miscommunication and confusion for patients, which can lead to uncontrolled and untreated hypertension, worsening patient health. Even with assistance from interpreters, participants highlighted that patients would often struggle to understand the concept and how to conduct BP checks. This miscommunication was emphasized when an MA stated that:

> *...even with the interpreters they do struggle to check the BP. I know some people receive the machine but they don't know how to use the machine and they don't let us know they don't know how to use it so there is always miscommunication between patient and provider or medical staff.* [MA]

Clinical staff were also concerned that their refugee and immigrant patients are nonadherent to treatment for a multitude of reasons, including access to monitoring technology, ability and willingness to take medication, and willingness to make lifestyle changes. Indeed, participants discussed how some patients would veer off the established plan and take medications in a manner that was not agreed on with the physician. When discussing the burden of hypertension within refugee patients, a PCP mentioned:

> *I actually have a lot of patients that they just go off the plan on their own because they think like they know it and they stop medications randomly. They take extra from others without like running it by me and they don't even admit it until I try to get it out of an individual.* [PCP]

Another significant variable that may exacerbate the prevalence of hypertension among refugee patients was concerns over patient adherence to treatment. Many refugee patients had fears regarding the consequences of undergoing medical intervention from clinic staff and thus were noted as being less compliant. This was highlighted when an MA was asked about concerns over medical treatments toward refugees and stated that:

> *...not wanting to take the medication because they are scared, or I know some patients get scared of taking medications and think it might affect the organs.* [MA]

Perceived Benefits of Potential Intervention for Self-Management

When asked about participation in a hypertension self-management intervention, participants largely endorsed potential benefits for their patients, with 15 participants expressing interest in this type of intervention. Interviewed participants often expressed the desire to not only educate their patients but also encourage active participation in treatment

XSL•FO
RenderX

planning and self-management of their condition. To facilitate patient adherence and hypertension self-management, participants would often try to educate refugee and immigrant patients on the significance of checking BP consistently at home and the concept of following trends. Physicians would also explain how hypertension does not always present with noticeable symptoms and can eventually lead to severe consequences if not managed on time. When discussing methods that help patients adhere to their medications, a physician stated the following:

> *Explaining to them the rationale behind checking the blood pressure at home and the trend and also educating the patient about hypertension being a silent killer. And that most people with high blood pressure have no symptoms initially.* [PCP]

With regard to the Med Pro Care device, most of the participants interviewed accepted self-management for hypertension to include both self-monitoring and self-titration. They believed that it more actively involves and empowers patients to be more in control of their health. In addition, self-management would reduce clinic burden, as patients would not have to come to the clinic as much because they would be monitored more consistently. For example, after trying out the Med Pro Care device, a physician was asked whether the device would be beneficial in the clinic and the physician responded with:

> *I think, overall, that is a really beneficial way to empower patients, and to not have to have them come back to the clinic as frequently when access is already pretty hard. And then, just to feel like they are in more control of their medications.* [PCP]

As both self-monitoring and self-titration have been successful for the management of other diseases, such as diabetes, most participants believed that with standardized protocols, it can also be successful for self-management of hypertension. Furthermore, self-management through Med Pro Care was overall noted as being a safe method to monitor and manage hypertension with the possibility of a reduction in adverse outcomes in the long term. This sentiment was explicitly noted by a physician when questioned about the potential benefits of the implementation of the Med Pro Care device:

> *I think that'll make for quicker, I guess, management of their high blood pressure. Minimize, you know, the adverse effects of like, you know, strokes, kidney damage, other things like that... I think it's very safe, this method of blood pressure monitoring by the patient themselves. It's safe and natural, and I think if we can implement more of that make that more available overall it's going to improve patient care and lessen adverse outcomes.* [PCP]

Despite acknowledging factors that lead to poor BP control, participants noted how family support and caregivers of refugee and immigrant patients play a significant role in their care. For example, families often attend appointments with patients and assist with BP monitoring, facilitating self-management and improved BP control:

> *I think immigrant patients tend to have a lot of family support and their kids often just help them and so they can pretty much take care of like downloading the app and checking their BP every day.* [MA]

Perceived Barriers to Potential Intervention for Self-Management

Two participants expressed concerns about implementing both self-monitoring and self-titration, mainly noting lack of success in patients self-titrating their hypertension medication. In addition, there was some concern over a possible increased workload because of monitoring an increased number of available readings. One participant was specifically concerned about legal liability if the clinic missed concerning BP readings and the patient did not reach out to the clinic or go to the hospital:

> *My concern is that... Let's say you did not see that alert. I mean, I have patients every day. I'm going to be honest. I don't know if I have time to check this every day... I don't want extra liability.* [PCP]

There was also a concern that patients would not be motivated enough to commit to their treatment plans without coming into the doctor's office regularly and would not remain adherent to medication and monitoring enough to maintain control over their BP. Although these concerns were raised, most participants remained optimistic that self-management of hypertension was feasible with protocols and training.

Results of Task Study

MAs were able to complete approximately 69% of the 5 tasks given to them, which included more administrative tasks such as how to register patients in the system and filtering through patients. Technical errors occurred with patient registration during many of the usability tests, resulting in all but 2 MAs being unable to complete the registration task, which could have influenced MA ratings of usability. Excluding this task, MAs were able to complete approximately 83% of tasks, with the next lowest score being in finding specific BP readings. PCPs completed approximately 90% of the 5 tasks, which were more focused on monitoring patients' readings over time. MAs completed all tasks with an average of 90.75 (SD 41.82) clicks, and PCPs completed all tasks with an average of 129.20 (SD 85.86) clicks. The average time to complete tasks for MAs was 6 minutes and 5 seconds (SD 2 min and 28 s), whereas the average time for PCPs was 4 minutes and 35 seconds (SD 48 s). With an average usability score of 4.1 of 5.0 (SD 0.4), participants believed the system was usable, as presented in Table 2, with the highest ratings in being able to quickly learn the software and it being easy to use. Results from the Task Load Index (Table 3) also indicate that participants believed that the tasks were not burdensome or stressful. MAs and PCPs had similar ratings of usability and satisfaction, apart from 1 MA who rated the physical demand and how hard they had to work as higher than others.

Table . System Usability Scale results.

System Usability Scale[a]	MA[b], mean (SD)	PCP[c], mean (SD)	All participants, mean (SD)
I think that I would like to use Med Pro Care frequently.	4.4 (1.2)	4.0 (1.0)	4.3 (1.0)
I found Med Pro Care unnecessarily complex.[d]	4.2 (1.4)	3.0 (0.3)	3.8 (0.9)
I thought Med Pro Care was easy to use.	4.4 (1.4)	4.4 (1.2)	4.4 (1.3)
I think that I would need the support of a technical person to be able to use Med Pro Care.[d]	4.3 (1.2)	3.6 (0.8)	4.1 (1.0)
I found the various functions in Med Pro Care were well integrated.	4.3 (1.1)	4.2 (1.4)	4.3 (1.1)
I thought there was too much inconsistency in Med Pro Care.[d]	4.2 (1.0)	4.2 (1.4)	4.2 (1.1)
I would imagine that most people would learn to use Med Pro Care very quickly.	4.6 (1.3)	4.4 (1.2)	4.5 (1.2)
I found Med Pro Care very cumbersome to use.[d]	3.1 (0.4)	4.0 (0.9)	3.4 (0.5)
I felt very confident using Med Pro Care.	4.4 (1.2)	3.4 (1.4)	4.1 (1.2)
I needed to learn a lot of things before I could get going with Med Pro Care.[d]	4.0 (1.0)	4.2 (1.3)	4.1 (1.0)

[a]All questions on a scale from 1 to 5, 1=strongly disagree, 2=disagree, 3=neither disagree nor agree, 4=agree, and 5=strongly agree.

[b]MA: medical assistant.

[c]PCP: primary care provider.

[d]Negatively worded items were reverse coded so that higher scores indicate more positive responses.

Table . NASA Task Load Index.

NASA Task Load Index[a]	MA[b], mean (SD)	PCP[c], mean (SD)	All participants, mean (SD)
How mentally demanding were the tasks?	0.0 (0.0)	6.8 (7.8)	5.4 (7.4)
How physically demanding were the tasks?	9.5 (13.4)	3.5 (4.7)	5.5 (7.7)
How hurried or rushed was the pace of the tasks?	2.7 (2.5)	5.3 (6.7)	4.1 (5.1)
How successful were you in accomplishing what you were	6.2 (7.4)	5.3 (8.5)	5.8 (7.4)
How hard did you have to work to accomplish your level of performance?	9.0 (12.7)	4.8 (6.1)	6.0 (7.5)
How insecure, discouraged, irritated, stressed, and annoyed were you?	0.7 (0.6)	1.3 (2.5)	1.0 (1.8)

[a]All items were measured on a scale from 0 to 20, with 0 being the least amount of demand or effort and 20 being the greatest amount of demand or effort, except the performance item where perfect is 0 and failure is 20.

[b]MA: medical assistant.

[c]PCP: primary care provider.

On the basis of the follow-up questions following the usability testing, participants were generally satisfied with the software, especially in areas such as ease of use and being able to learn the system easily. Participants expressed concern over logistical issues such as how well this would integrate with currently existing electronic health records, who was responsible for

keeping up with the increased number of measurements, and legal liability.

Discussion

Principal Findings

There was a general understanding by local clinic staff that refugees and immigrants experience pre- and postmigration stressors that negatively impact health, including increasing the risk of uncontrolled hypertension, and complicating treatment. Our study showed that addressing these unique barriers is essential for effective hypertension management. The Med Pro Care software was generally accepted by our sample and can be used in the clinic to facilitate self-monitoring of BP. Digital self-monitoring can enhance patient-clinic communication and support chronic disease self-management. Our study adds to existing literature by examining the clinic staff's perspective in treating refugee and immigrant patients and what can be done in the clinic to better address their specific needs.

Participants emphasized cultural and linguistic barriers, access, and patient empowerment as key priorities. Consistent with prior research, an approach that is sensitive to the cultural context and acknowledges the unique experiences of refugee and immigrant patients is pivotal in establishing effective communication and fostering patient engagement [39]. For refugees and immigrants, who must navigate unfamiliar health care systems in new countries, strategies that improve communication and enhance patient self-efficacy are crucial to long-term chronic disease self-management [40].

Clinic staff generally believed that self-management of hypertension can help empower patients by improving communication, self-efficacy, and health literacy, thereby potentially enhancing hypertension management. This aligns with other studies, which show self-management enhances health awareness and literacy, although few have focused on refugee and immigrant populations [41,42]. Our results, therefore, provide a unique perspective because the clinic staff interviewed have first-hand accounts of the barriers and facilitators toward health management in refugee and immigrant populations. Further research should directly examine the perspective of refugee and immigrant patients to inform clinical implementation.

Self-management has shown great potential in controlling hypertension; however, scarce resources and logistical concerns have slowed its adoption into many clinics [26]. Clinic staff noted that relying on self-management could reduce clinic burden by reducing the need for patients to come into the clinic as frequently. The usability of the Withing's Med Pro Care software was overall well received and considered easy to use and requiring minimal training, which could support efficient integration into clinical practice.

Perceived challenges of self-management included the clinic's ability to handle an increased load of information and safety concerns over self-titration of medications. Participants noted that Med Pro Care's ability to flag concerning readings and display trends could address some of these concerns. Liability concerns may be mitigated by patient education and standardized protocols. In addition, clinical trials have shown self-titration to be feasible and safe for patients with hypertension [28,40,43]. Med Pro Care can facilitate communication between patients and clinics through regular BP readings and can increase the safety of self-titration of antihypertensive medications.

Our study recruited participants from 3 different types of clinics: a federally qualified health center, a university clinic, and 2 private practices. Despite differences in electronic medical records and resources, clinic staff across settings shared similar perspectives, showing shared experience and suggesting broad applicability of Med Pro Care.

Recent studies from China have supported multimodel digital interventions for the management of hypertension [44,45]. A similar intervention in Pakistan based on the Health Belief Model included reminders, education, and 24/7 individual support, which improved medication adherence and systolic BP [46]. These studies share similarities in addressing social factors by addressing individual needs for care and support but lack a focus on the unique needs of refugee and immigrant patients. Our study highlights this gap and supports future testing of digital hypertension self-management platforms tailored to refugee and immigrant populations.

Limitations

Despite being among the few in the field who researched refugee and immigrant population providers, our study had notable limitations. First, our sample was limited to 1 county and may not reflect clinics elsewhere. Second, clinic staff with heavier patient loads may have been underrepresented due to the lengthy interview process. Nonetheless, San Diego's large refugee and immigrant population provides valuable insights, and future studies should evaluate digital self-management interventions in broader settings to avoid exacerbating disparities.

Conclusions

While self-management interventions have been shown to be effective in managing hypertension, it is essential to incorporate input from clinic staff that care for refugee and immigrant populations to understand the real-world implications of eHealth interventions. Clinic staff generally found the Med Pro Care software easy to use and feasible for integration into care, supporting the role of digital tools in addressing hypertension management among refugees and immigrants. Our study demonstrated that the refugee and immigrant communities have unique needs in hypertension management related to access, language, and clinic support. The implementation of self-management is supported by clinic staff because of its potential to empower patients by facilitating autonomy and a more active role in patient engagement in health care. Hypertension self-management interventions should focus on increasing health literacy, self-efficacy, improving access to health care, and leveraging digital health to streamline workflows for clinics and enhance communication with patients. Future studies should focus on the development and evaluation of contextually tailored hypertension self-management interventions that are responsive to the unique needs of the heterogeneous US refugee and immigrant population.

Acknowledgments

First and foremost, the authors would like to thank our participants for their time, trust, and perspectives. The authors are grateful to the various staff members and administrative leadership at Family Health Centers of San Diego and the Majdal Community Center in El Cajon, San Diego, for providing in-kind support for the development of study procedures, onboarding of study staff, participant recruitment, and participant interface. The authors are also grateful to Withing's RPM for Solutions and the San Diego division of the American Heart Association for their donation of blood pressure monitors used in our research. Finally, the authors would like to thank the Al-Rousan laboratory members for their assistance with data collection, interview transcription, and feedback throughout the research process and manuscript preparation.

This project was made possible by funding from the National Health Institute (National Heart, Lung, and Blood Institute [NHLBI] grant K23HL148530). NM is funded by NHLBI grant R00-HL148511, National Institute on Minority Health and Health Disparities grants P50MD017341 (subproject 8126) and 3P50MD017341-03S2.

Abstract

Background: The global increase in the Internet of Things (IoT) adoption has sparked interest in its application within the educational sector, particularly in colleges and universities. Previous studies have often focused on individual attitudes toward IoT without considering a multiperspective approach and have overlooked the impact of IoT on the technology acceptance model outside the educational domain.

Objective: This study aims to bridge the research gap by investigating the factors influencing IoT adoption in educational settings, thereby enhancing the understanding of collaborative learning through technology. It seeks to elucidate how IoT can facilitate learning processes and technology acceptance among college and university students in the United Arab Emirates.

Methods: A questionnaire was distributed to students across various colleges and universities in the United Arab Emirates, garnering 463 participants. The data collected were analyzed using a hybrid approach that integrates structural equation modeling (SEM) and artificial neural network (ANN), along with importance-performance map analysis to evaluate the significance and performance of each factor affecting IoT adoption.

Results: The study, involving 463 participants, identifies 2 primary levels at which factors influence the intention to adopt IoT technologies. Initial influences include technology optimism (TOP), innovation, and learning motivation, crucial for application engagement. Advanced influences stem from technology acceptance model constructs, particularly perceived ease of use (PE) and perceived usefulness (PU), which directly enhance adoption intentions. Detailed statistical analysis using partial least squares–SEM reveals significant relationships: TOP and innovativeness impact PE (β=.412, *P*=.04; β=.608, *P*=.002, respectively), and PU significantly influences TOP (β=.381, *P*=.04), innovativeness (β=.557, *P*=.003), and learning motivation (β=.752, *P*<.001). These results support our hypotheses (H1, H2, H3, H4, and H5). Further, the intention to use IoT is significantly affected by PE and usefulness (β=.619, *P*<.001; β=.598, *P*<.001, respectively). ANN modeling enhances these findings, showing superior predictive power (R^2=89.7%) compared to partial least squares–SEM (R^2=86.3%), indicating a more effective identification of nonlinear associations. Importance-performance map analysis corroborates these results, demonstrating the importance and performance of PU as most critical, followed by technology innovativeness and optimism, in shaping behavioral intentions to use IoT.

Conclusions: This research contributes methodologically by leveraging deep ANN architecture to explore nonlinear relationships among factors influencing IoT adoption in education. The study underscores the importance of both intrinsic motivational factors and perceived technological attributes in fostering IoT adoption, offering insights for educational institutions considering IoT integration into their learning environments.

Introduction

Background

The use of Internet of Things (IoT) applications has been implemented in medical education projects [1]. IoT has the ability to completely transform the educational landscape by offering a more adaptable and quantifiable educational system that unites teachers and students under a single technological roof [2]. IoT innovation plays a significant role in transforming training at all levels, from school and college to university education [3]. Everyone, including students, instructors, and college campuses, can benefit from this innovation. Educators and administrators can leverage the power of IoT to connect people with devices and data, enabling them to gain valuable insights that have not been previously used in education. The traditional human-centered educational system has been transformed into an IoT-based one [4-6] using IoT. IoT has been leveraged to change the conventional personalized schooling system to an IoT-based system [4-6]. Figure 1 illustrates a cohort of university students actively engaging with IoT technology within an academic context. These individuals are adorned with sophisticated wearable devices, including smart glasses and smartwatches, which project information into their visual field, indicative of a digital and augmented educational milieu. The students are depicted with a palpable focus, using a portable electronic apparatus, likely for the manipulation of or interaction with the data overlay provided by their IoT devices.

The IoT has the potential to transform institutional practices and enhance learning capabilities across various levels and domains. University lecturers, students, and support staff can leverage large IoT platforms successfully. However, there is room for improvement in the utilization of IoT technology across different educational institutions. Researchers, scholars, and students can collaborate to develop IoT systems, devices, applications, and services, leading to the evolution of the educational environment as an increasingly dynamic and globally relevant subject. Better IoT deployments in colleges and universities have significantly improved positively to the creation of efficient and useful educational resources [7,8].

XSL•FO
RenderX

This research aims to explore how IoT technology is adopted and used by educators and students in universities across the Middle East. By integrating the technology acceptance model (TAM) and additional external factors, the study seeks to evaluate the effectiveness of IoT as an educational tool from the perspectives of both students and educators. Using the TAM as a metric, along with external variables, the research intends to identify and analyze the factors that influence the acceptance and use of IoT in medical education. The analysis uses a hybrid framework that combines structural equation modeling (SEM) and artificial neural networks (ANN) to examine how intrinsic motivational factors and perceived technological attributes affect IoT adoption. The SEM-ANN approach was specifically chosen to leverage the strengths of both methodologies [9,10]. SEM is highly effective in assessing the relationships between observed and latent variables, providing clarity on both the direct and indirect effects within the hypothesized model [11]. This method allows for robust statistical analysis capabilities, making it ideal for hypothesis testing and understanding the structural relationships among the theoretical constructs [12]. Conversely, ANN is used for its superior ability to model complex nonlinear relationships between variables, which are often not adequately captured by traditional linear models like SEM. ANN's data-driven nature allows it to directly learn and adapt to these relationships from the data, thereby enhancing the model's predictive accuracy and robustness. By integrating SEM with ANN, the study not only validates the theoretical framework through SEM's rigorous statistical analysis but also enhances the predictive power and generalization capabilities of the model with ANN's computational intelligence. This hybrid approach is particularly effective in exploring deeper, nonlinear interactions within the data, offering a more comprehensive understanding of the factors influencing IoT adoption. Given the complexities of modern datasets, which often exhibit nonlinear and digital behaviors among variables, this methodological integration is well-suited to achieving the research objectives and provides a justified, robust approach for the study.

The proposed hypotheses are: (1) intrinsic motivational factors like technology optimism (TOP), innovation, and learning motivation (LMT) significantly impact students' intention to adopt IoT; (2) perceived ease of use (PE) and perceived usefulness (PU), fundamental components of the TAM, strongly predict IoT adoption intentions among students in the United Arab Emirates.

This paper is organized as follows: "Literature Review" section delves into the existing research related to the adoption of IoT technologies, highlighting key theories and previous findings that set the groundwork for this study. Section "Methodology" details the research design, sampling methods, data collection procedures, and analytical techniques used to investigate the hypotheses. Section "Findings" presents the results of the data analysis, offering quantitative insights into the factors influencing IoT adoption. Section "Discussion" interprets the findings in the context of the existing literature, discussing the implications for theory and practice. Finally, the section "Conclusions" summarizes the study's main contributions, outlines its limitations, and suggests directions for future research. This structure is designed to provide a clear and logical progression through the topics covered, facilitating a comprehensive understanding of the study's scope and conclusions.

Related Work

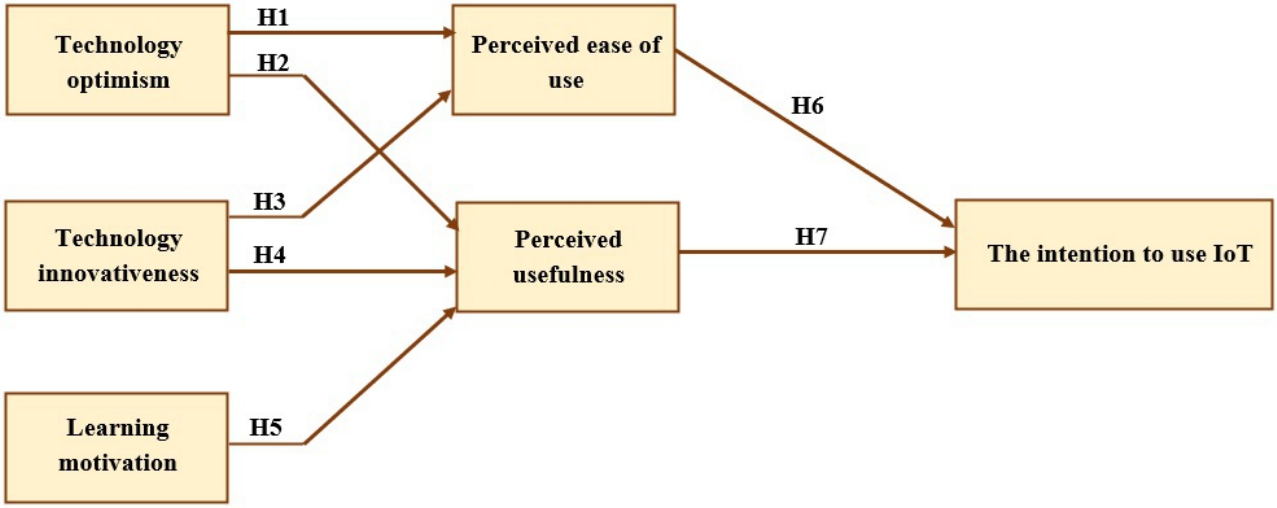
The review of existing literature on the topic of IoT has explored both practical and theoretical aspects, suggesting a correlation between IoT and other factors such as self-efficacy, technology utilization, motivation, security, privacy, training, and more [13-19], indicating a relationship between the IoT and other elements including self-reliance, technological use, inspiration, safety, privacy, schooling, and beyond [13-19]. Likewise, research has examined the impact of IoT in conjunction with TAM and other external factors, and IoT with the help of TAM and external factors [20,21].

As IoT applications become more intricate, they can significantly impact learning. The difficulty is the IoT technology's quick development, which requires diverse skills ranging from developing IoT applications to incorporating devices into management systems that analyze device-generated data [14,22]. Previous research has highlighted the significance of IoT in addressing challenges students encounter when using modern IoT apps and gadgets. Potential solutions include focusing on computational thinking education, assisting students in solving challenges, and providing clear instructions and training to facilitate the integration of new students with IoT devices and encourage training in it.

A different approach was taken in another study, where a workshop was offered to address the importance of IoT. The results showed that students found the workshop highly satisfactory for learning about IoT, improving problem-solving skills, and enhancing problem-solving capabilities, while also finding it enjoyable [13-15].

Several outside variables, including drive, contentment, ease of use, effectiveness, involvement, and interest, have been investigated to explore the relationship between IoT and students' attitudes. The most significant factors are motivation and enjoyment regarding IoT technology, which are essential for its acceptance among students. While satisfaction and performance indirectly affect the application of IoT, greater contentment levels are not proportional to higher interactions [18,19]. Recent studies have used qualitative and quantitative methods to examine the uptake of IoT and have identified favorable attitudes, ease of use, contentment, affordability, basic knowledge, security, and privacy as crucial factors that influence its adoption. Apart from motivation and enjoyment, training and experience are also crucial in uptaking IoT devices, and educational training workshops can significantly improve the learning curve, digital learning, real-life applications, and problem-solving skills [16,17,23].

Previous research has explored the various benefits of implementing IoT technologies in educational settings, including the ability for teachers to gain insight into students' performance and knowledge levels, as well as the potential for improved teaching quality. As a result, the use of IoT has the potential to greatly impact learning environments, leading to a more



XSL•FO
RenderX

advanced educational landscape. This could also lead to changes in how we interact and collaborate as a society, as IoT technology continues to connect us in new ways [24,25]. While previous studies have investigated students' attitudes toward IoT from different angles [14,22,26], there has been limited research on the importance of IoT technology from the perspective of teachers' knowledge of the significance of IoT innovation from the educational viewpoint of instructors and how it impacts pedagogy in the classroom. Therefore, this study aims to address this gap by developing a model that combines both students' and teachers' attitudes to examine the effectiveness and efficiency of IoT in educational environments. By creating a framework that incorporates the viewpoints of learners and educators, this research intends to close this imbalance by analyzing the usefulness and efficacy of IoT in classrooms.

Developing Hypotheses and Theoretical Framework

The study paradigm shown in Figure 2 describes how the inspiration for learning, technological exuberance, and technological advancements influence learners' perceptions of the PU and ease of use (PE) of IoT devices. Such concepts have not yet been looked into in relation to IoT devices and applicability. Although earlier research has examined how these factors may affect IoT adoption plans [27], their individual effects on students' attitudes toward this technology have not been analyzed before.

Figure 2. Research model. IoT: Internet of Things.

LMT is a crucial factor impacting students' behavior in conventional and digital educational settings. It is an outside variable of the suggested approach and can be influenced by multiple factors, including the learning environment, expectations, and social values. Research has shown that LMT significantly impacts students' academic achievements [28]. Students must therefore be driven to acquire knowledge in order to achieve the suggested intended goals [29,30]. Highly motivated learners can achieve their learning goals spontaneously and willingly. Social cognitivism emphasizes the significance of requirements, conducts, and ideologies in education.

Researchers are investigating the influence of TOP and innovation on students' adoption of IoT in the education sector. The study aims to understand students' attitudes and behavior toward technology by using 3 theoretical concepts: inventiveness, technological exuberance, and learning incentive. The researchers have combined the (TAM) constructs with the aforementioned variables to accomplish their study's objectives. Several researchers have used the TAM model to evaluate the effectiveness of IoT technology and its applications [31,32]. The model explains why people accept technology based on their attitudes and beliefs and how these beliefs impact their behavioral intention toward technology use [33,34]. It is an established concept that supports embracing technology in various settings and strongly links it to technological progress [35-37]. The TAM model can forecast variables like technology elation and inventiveness that influence how well a certain technology is received [38,39]. TOP refers to users' favorable perception of technology, while technology innovativeness (TIN) refers to users' willingness to adopt technology early and lead to its use.

The PE and PU constructs of TAM are closely related to TOP and TIN. In the academic setting, students' perceptions of technology can be influenced by their peers and instructors. If the student's immediate academic circle has a positive view of a particular technology, the student will likely also develop a favorable opinion. Similarly, tech-savvy students tend to have a positive self-perception. Early on in the acceptance of technology, students are usually eager to pioneer using advanced technologies [40-44].

Furthermore, a student's optimism about technology is linked to their level of involvement in guiding its use. Similarly, technological optimism can significantly impact a student's attitude. IoT acceptance is greater for learners who are enthusiastic about experimenting with novel innovations. Technological innovators infrequently perceive new innovations as being challenging or outside their comprehension. Individuals are more inclined to regret not having the freedom to play around with novel technologies [45]. As a result, a number of hypotheses are put forth:

XSL•FO
RenderX

- H1: TOP affects positively the PE.
- H2: TOP affects positively the PU.
- H3: TIN affects positively the PE.
- H4: TIN affects positively the PU.
- H5: LMT affects positively the PU.
- H6: PE affects positively the intention to use Internet of Things (INT).
- H7: PU affects positively the INT.

By evaluating the association between TAM and its connected factors, this research seeks to add to a collection of current work. It has been said that it is important to measure these variables and analyze their relationship to TAM to assess the efficiency of IoT in classrooms. Past research and literature have mostly focused on preservice teachers, and there is a need to conduct more studies involving in-service teachers to enhance the practicality of the TAM model [46,47]. Thus, this study investigates the correlation between teachers' levels of TAM and their attitudes toward IoT acceptance when working with teachers from different fields.

Methods

Data Collection

The data collection for this study was carried out between January 20 and March 20, 2023, throughout the academic year 2023 - 2024's winter semester, at educational institutions in the United Arab Emirates. The research team used web-based surveys to collect data, with 500 questionnaires randomly distributed. Of these, 463 surveys were answered, resulting in a response rate of 93%. Some questionnaires were rejected due to missing values. Since a few surveys had no responses, they were discarded, leaving 769 usable questionnaires, which is considered an appropriate acceptable sample size according to Krejcie and Morgan [48]. Although the sample size exceeded the minimum requirements, the research team used SEM SmartPLS (version 3.2.7; SmartPLS GmbH) and SPSS Statistics (version 23; IBM Corp) to evaluate the hypotheses and confirm the relationship between variables. It is important to note that the hypotheses were based on previous theories related to IoT, which formed the foundation of this study.

Ethical Considerations

Ethical considerations were meticulously adhered to throughout the research process. All procedures involving human participants were approved by the institutional review board of the host universities in the United Arab Emirates (#RAREC00065), ensuring compliance with ethical standards. Informed consent was obtained from all participants before data collection, and they were informed of their rights to withdraw from the study at any time. Privacy and confidentiality were strictly maintained, with all data being anonymized and securely stored to prevent unauthorized access. Participants were not compensated for their participation, as the study involved minimal risk and was conducted as part of educational activities within the institutions involved.

Student's Personal Information

The demographic data of the respondents (N=463) are presented in Table 1. The data showed that 70% (n=325) of participants were female and 30% (n=138) were male. In terms of age, 42% (n=193) of participants were between 18 and 29 years, 35% (n=163) were between 30 and 39 years, 21% (n=99) were between 40 and 49 years, and 2% (n=8) were between 50 and 59 years. Regarding education, 80% (n=372) of participants held a bachelor's degree, 14% (n=62) held a master's degree, and 6% (n=29) held a doctoral degree. To obtain participants' willingness to participate, the research team used a purposive sampling approach. The participants came from various universities, academic levels, and programs relevant to this research. SPSS Statistics was used to analyze the demographic data.

Table . Demographic data of the respondents (N=463).

Category	Value, n (%)
Sex	
Female	325 (70)
Male	138 (30)
Age (years)	
Between 18 and 29	193 (42)
Between 30 and 39	163 (35)
Between 40 and 49	99 (21)
Between 50 and 59	8 (2)
Educational qualification	
Bachelor's degree	372 (80)
Master's degree	62 (14)
Doctorate	29 (6)

Study Instrument

This research proposed a survey instrument for validating the hypotheses. To assess the 6 constructs of the questionnaire, an additional 18 questions were included in the survey. The origins and histories of these constructs are presented in Table 2. To make the research more relevant, the researchers modified the questions from previous studies.

XSL•FO
RenderX

Table . Measurement items.

Constructs	Items	Definition	Instrument	Sources
TIN[a]	• TIN1 • TIN2 • TIN3	The term "technology innovativeness" describes a user's perception that they are at the forefront of technology use. Users who are pioneers in adopting new technologies typically do not view them as complicated or difficult to comprehend. Such users may feel a sense of regret if they miss the chance to experiment with new technologies.	• I accept IoT[b] technology to be used in my daily classes. • I am the only one. There is only me prepared to use IoT technology among my fellow students. • I am ready to use. I am prepared to use and experiment with the latest information technologies.	[45]
TOP[c]	• TOP1 • TOP2 • TOP3	A person's readiness to use technology is known as technological optimism.	• I am ready to test. Prepared to take the test IoT technology. • To complete my assignments to finish my homework, I will be using IoT. • I will learn more with the help of my preparedness to use IoT.	[2,49]
LMT[d]	• LMT1 • LMT2 • LMT3	The concept of learning motivation is used to measure the behavioral intention to use technology. Motivation learning is composed of 4 key components, which are attention, relevance, confidence, and satisfaction. These components have been identified in previous studies [50,51].	• I can improve my focus by using IoT for my daily classes. • Using IoT makes me feel more confident. • Using IoT for study purposes satisfies me.	[50,51]
PE[e]	• PE1 • PE2 • PE3	The TAM[f] was introduced by Davis [52] as a means of assessing the effectiveness and acceptance of technology. The model includes the concept of PE, which refers to the user's perception of how effortless it is to use the technology.	• IoT technology being simple will polish my skills. • I can improve my learning achievements by using IoT technology. • IoT is simple and easy to use.	[52]
PU[g]	• PU1 • PU2 • PU3	Usefulness refers to PU that the users of technology may see.	• IoT technology will hugely benefit me. • IoT will make my abilities and skills better. • Using IoT for my daily classes is beneficial.	[52]
INT[h]	• INT1 • INT2 • INT3	An individual's view of what others think about a certain behavior is known as a behavioral intention to use.	• IoT will be my go-to for daily tasks. • In the future, I will be using IoT. • IoT technology will be my recommendation to every student.	[53]

[a]TIN: technology innovativeness.

[b]IoT: Internet of Things.

XSL•FO
RenderX

[c]TOP: technology optimism.
[d]LMT: learning motivation.
[e]PE: perceived ease of use.
[f]TAM: technology acceptance model.
[g]PU: perceived usefulness.
[h]INT: intention to use Internet of Things.

Survey Structure

The questionnaire survey given to the students has 3 sections. Three components make up the survey that is provided to learners: (1) personal data is the focus of the first section, (2) the general question related to the "Intention to Use IoT" is the second section, and (3) 15 items that deal with TIN, TOP, LMT, PE, and PU is present in the third section.

A 5-point Likert scale was used to assess the 18 items, with response options ranging from 1=strongly disagree to 2=disagree, 3=neutral, 4=agree, and 5=strongly agree.

Results

Data Analysis

In this study, the gathered data were analyzed using SmartPLS (version 3.2.7) software through the partial least squares–structural equation modeling (PLS-SEM) technique [54-56]. The evaluation consisted of 2 stages: the measurement model and the structural model [57,58]. PLS-SEM was selected for this research after considering several factors.

The selection of PLS-SEM for this study was based on several reasons. First, PLS-SEM is preferred when the study aims to build on an existing theory [59]. Second, PLS-SEM is effective in handling complex models in exploratory research. Third, PLS-SEM analyzes the entire model as a single entity rather than dividing it into components [60]. Finally, PLS-SEM allows for the simultaneous analysis of structural and measurement models, leading to more accurate results [61].

Convergent Validity

Hair et al [57] suggested that to assess the measurement model, it is important to examine the construct reliability (including Cronbach ɑ and composite reliability) and validity (including convergent and discriminant validity). Table 3 shows that the Cronbach ɑ readings are greater than the suggested criterion of 0.7, and vary from 0.797 to 0.858 [62], indicating good construct reliability. Similarly, the proposed criterion is also greater than the composite reliability numbers, which vary from 0.735 to 0.858 [63]. Factor loading and average-variance extracted (AVE) analysis are required to evaluate convergent validity [57]. The factor loading values in Table 3 are higher than the recommended threshold of 0.7, and the AVE readings are greater than the suggested limit of 0.5, spanning from 0.556 to 0.712. These results suggest that there is convergent validity.

Discriminant Validity

To assess discriminant validity, 2 criteria were recommended: the Heterotrait-Monotrait ratio and the Fornell-Larcker criterion [57]. According to Table 4, the Fornell-Larcker criterion is met, as the AVE and its square root for each construct exceed its correlation with other constructs [64]. Table 5 displays the Heterotrait-Monotrait ratio results, which demonstrate that each construct's value is below the threshold value of 0.85 [65]. This suggests that discriminant validity exists, and the measurement model's reliability and validity were confirmed without any issues. As a result, the collected data can be used for analyzing the structural model.

Hypotheses Testing Using PLS-SEM

To assess whether the theoretical constructs of the structural model are interconnected, the study used Smart PLS with maximum likelihood estimation to create a structural equation model [66]. The proposed hypotheses were then analyzed using this model. The results indicated a high level of predictive power for the model, with 86.3% of the variance in INT being accounted for, as shown in Figure 3 and Table 6.

Table 7 provides information on the β values, *t* values, and *P* values of all developed hypotheses based on the findings produced using the PLS-SEM technique. The researchers have confirmed each hypothesis. The empirical data supported H1, H2, H3, H4, H5, H6, and H7 following the data analysis hypotheses. This study demonstrates that TOP and TIN have a noteworthy influence on PE with respective regression coefficients (β=.412, *P*=.04), and (β=.608, *P*=.002), supporting H1 and H3. Moreover, the results indicate that PU is significantly impacted by TOP (β=.381, *P*=.04), TIN (β=.557, *P*=.003), and LMT (β=.752, *P*<.001), supporting hypotheses H2, H4, and H5, respectively. Finally, the study reveals that the relationship between PE and PU significantly affects INT with respective regression coefficients (β=.619, *P*<.001) and (β=.598, *P*<.001), supporting H6 and H7.

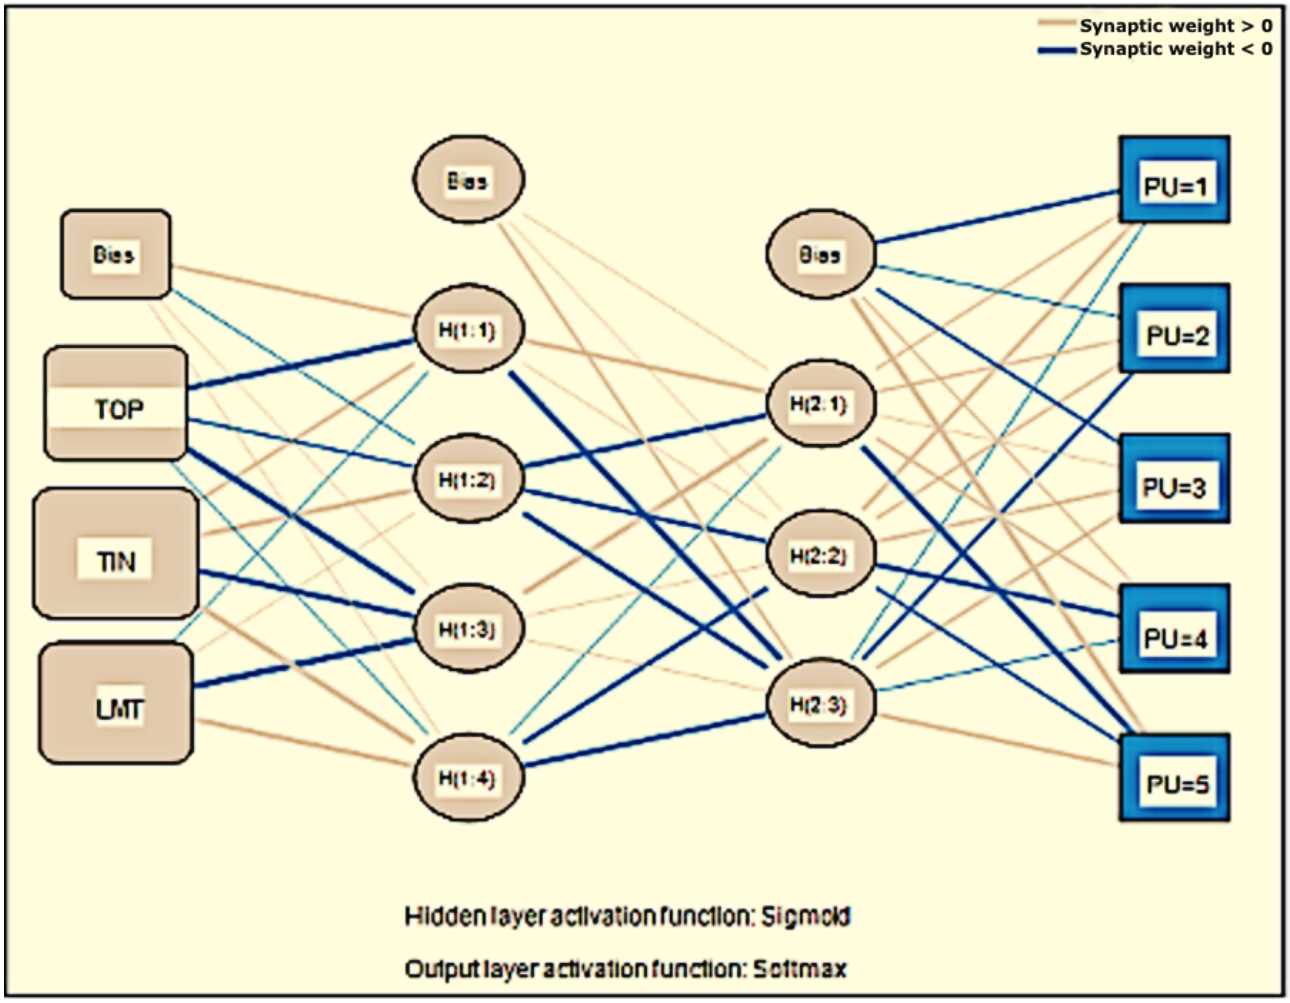
ANN Results

The predictors identified during the PLS-SEM analysis are further investigated through ANN analysis using SPSS software. The PLS-SEM analysis identified TIN, TOP, LMT, PE, and PU as critical factors; therefore, ANN analysis also considers these 3 factors only. The structure of the ANN model is based on behavioral intention as an output neuron and TIN, TOP, LMT, PE, and PU as input neurons (Figures 4-6). ANN model supported deep learning in all the output neuron modes through its 2-hidden layer deep structure [67,68]. The researcher applied the activation function of the sigmoid function to hidden neurons, as well as output neurons, keeping the values of input and output neurons between [0, 1]; this allowed the researcher to obtain better performance from the research model [69,70]. He also applied the 10-fold cross-validation method to training

XSL•FO
RenderX



and testing data in the ratio of 80:20 to ensure that there is no overfitting in the ANN model [71]. The researcher evaluated the root mean square of error (RMSE) to test the neural network model for accuracy. The training data showed an RMSE value of 0.1388 for the ANN model while the testing data showed an RMSE value of 0.1439. The training and testing data showed only slight variance in the RMSE values and SD values (ie, 0.0043 and 0.0096). Hence, we can infer that using the ANN model enhances the accuracy of the research model.

Sensitivity Analysis

The researcher estimated the value of normalized importance by comparing each predictor's average value with the maximum mean value depicted among all predictors stated in percentage form. The values of normalized importance and mean importance computed for the predictors involved in ANN modeling are recorded in Table 8. This table also depicts the outcomes of the sensitivity analysis which identifies the predictor of PU to have the most significant impact on behavioral intention; the second most significant impact was imposed by TOP while the least impact was imposed by PE. ANN application was additionally assessed for its accuracy and performance by computing the goodness-of-fit for authentication and validation of the application. The ANN application uses goodness-of-fit just as PLS-SEM analysis uses R^2 [72,73]. The predictive powers of both the applications are compared where ANN analysis outperforms the other one with a predictive power of (R^2=89.7%) against the PLS-SEM predictive power of (R^2=86.3%). Hence, ANN analysis can explain endogenous constructs more effectively than PLS-SEM. Moreover, ANN analysis is based on deep learning and has the potential to better identify nonlinear associations among constructs which results in variances in the predictive powers of the ANN and PLS-SEM methods.

[e]PU: perceived usefulness.

Importance-Performance Map Analysis

This study has used importance-performance map analysis (IPMA) as an advanced approach in PLS-SEM, which used behavioral intention as the main variable. As suggested by Ringle and Sarstedt [74], a better interpretation of the results of PLS-SEM is possible by using IPMA. A substitute way to only test the path coefficients (ie, importance measure), the average value of the latent constructs, and their indicators (ie, performance measure) are also included in the IPMA [74]. According to IPMA, the total effects reflect the predecessor factors' importance in developing the target factor (ie, behavioral intention), while the average of latent constructs' values is a reflection of their performance. The IPMA findings are reported in Figure 7. The estimation of the importance and performance of the 5 factors (ie, TIN, TOP, LMT, PE, and PU) has been shown in this table. According to the findings, the PU has been reported to have the largest values in terms of both importance and performance measures. Furthermore, it can be clearly seen that TIN has the second largest values in terms of both importance and performance measures. The third largest value was reported in the case of TOP in terms of the importance measure; however, it has the smallest value on the performance measure. Relatively, the opposite scenario was reported in the case of PE, as it had the lowest value on the importance measure.

Figure 7. Importance-performance map analysis results. INT: intention to use Internet of Things; LMT: learning motivation; PE: perceived ease of use; PU: perceived usefulness; TIN: technology innovativeness; TOP: technology optimism.

Discussion

Principal Findings

The main findings of this study indicate that the intention to adopt IoT technologies is positively influenced by both intrinsic motivational factors and TAM constructs. Specifically, TOP, innovation, and LMT play crucial roles at the initial level of influencing IoT adoption. At a secondary level, the perceived ease of use and PU, core elements of the TAM, directly enhance the INT technologies. Further analysis using ANNs and IPMA highlighted PU as a particularly significant predictor of IoT use intentions.

Based on these results, it is evident that technology features are critical in shaping users' PE and PU toward IoT applications and tools. The positive influence of TOP, innovation, and LMT is reflected across all model variables, suggesting that well-designed technology features can significantly boost IoT acceptance. The TAM framework effectively provides a user-friendly experience that meets users' value expectations and fosters positive emotional responses, which in turn, positively impacts their INT. Additionally, the significant positive impact of technology features on TOP boosts users' trust in the system's quality, further influencing their willingness to engage with IoT systems. The social aspect of technology use, where familiarity influences adoption, also plays a pivotal role in the INT features. Technology innovation contributes

XSL•FO
RenderX

significantly to perceived ease and usefulness, enhancing trust and satisfaction during the user experience, thus fostering a conducive environment for IoT adoption.

The confirmation of hypotheses H1-H5 supports the proposed conceptual model and the proposed hypotheses [75-77]. Previous research has also produced results that are consistent with these findings. However, other studies have shown that the lack of sufficient security and privacy are major challenges that may hinder the deployment of IoT in education [63,64], and to reduce these obstacles, future efforts to implement IoT in education must consider these factors. Although IoT has not been widely adopted in resource-limited countries, scholars need to examine the factors affecting its adoption to enable effective deployment. Therefore, scholars need to investigate the use and adoption of these technologies in other domains.

Managerial Implications

The adoption of IoT in educational settings demands that administrators and educational leaders ensure their faculty is proficient in using IoT technologies effectively in the classroom. This includes competencies in handling relevant technology tools, understanding pedagogical integration, and applying these technologies within various teaching scenarios. To support this, institutions should offer targeted professional development that focuses on both the technical and educational aspects of IoT. Additionally, management should consider the infrastructure upgrades necessary to support IoT technologies, such as improved wireless networks and enhanced security measures to protect student data [78,79].

Practical Implications

The practical applications of this study highlight the necessity for educational curricula to evolve alongside technological advancements. Institutions offering programs in computer science and engineering should integrate IoT courses to prepare students for the demands of the workforce, which increasingly relies on IoT technologies. Moreover, schools should align their IoT strategies with real-world applications, providing students with hands-on opportunities to work with IoT in context. This could include partnerships with IoT companies or practical projects that allow students to solve real problems using IoT solutions [80,81].

Theoretical Implications

This study contributes to the academic understanding of technology adoption by confirming the significant role of intrinsic motivational factors and TAM constructs in the adoption of IoT technologies. By highlighting the dual influence of personal motivation and perceived technological attributes, this research extends existing models of technology acceptance. Furthermore, the use of advanced analytical methods such as ANN and IPMA provides a deeper insight into the nonlinear relationships among the constructs, offering a nuanced perspective that can inform future research in technology adoption theories. This could encourage scholars to explore how different educational contexts or cultural backgrounds influence the adoption and effective use of emerging technologies like IoT [82,83].

Conclusions

IoT technology has fundamentally altered the tech and business industries, laying the groundwork for the creation of intelligent societies and advancing social and economic development. The IoT has advanced quickly and significantly. The research team developed the PE and PU frameworks for Arab customers using path estimation and modeling of structural equations depending on their responses to analyze individuals' acceptance of IoT. In addition to additional factors including technology exuberance, advancements in technology, and academic drive, the research additionally looked at the effects of TAM components on these factors. These factors and TAM components were found to be directly related to the study. According to the research, the incentive to learn, technological advancement, and technological positiveness all had a substantial influence on PE and PU. While earlier research has demonstrated that TAM components affect the motivation to use IoT, this research has investigated how other external factors, including social factors like LMT, can affect these constructs. The study used a conceptual model to examine users' attitudes toward IoT adoption, with 2 levels of analysis. The first level focused on social attitudes, particularly the impact of the incentive to learn as a standalone factor. The second stage looked at how personal traits influenced technological positivism and inventiveness, influencing customer needs and IoT interactions. Subsequent research could look at how individual characteristics affect incentives to learn and look at extra technological aspects that affect IoT uptake. Subsequent research could improve the assessment and give more insight into the value of IoT by including mediating factors between personal characteristics and technological attributes. The theoretical framework could also be used with cutting-edge technology like metaverse systems and artificial intelligence.

The Impact of Trust and the Role of the Opt-Out Mechanism in Willingness to Share Health Data via Electronic Health Records in Germany: Telephone Survey Study

Felix Wilke, Prof Dr

Department of Social Work, University of Applied Sciences Jena, Carl-Zeiss-Promenade 2, Jena, Germany

Abstract

Background: Electronic health records (EHRs) offer a valuable resource for research and health care improvement. However, public acceptance of sharing personal health data is critical to the success of such initiatives. In Germany, automatic data sharing via EHRs will be implemented unless people opt out.

Objective: This study aims to assess the willingness of the German population to share health data via EHRs and to explore the role of trust in influencing these attitudes.

Methods: A computer-assisted telephone interview study was conducted in December 2023, with 1004 respondents aged 18 years and older, representative of the German population. Descriptive statistics and multivariate linear regression models were used to analyze the data.

Results: The survey shows that 43.4% (n=432) of respondents would be willing to share their health data via EHR, and a significant 34% (n=338) remain undecided. While the population is open to adoption of the EHR for personal health issues (n=483, 53% show interest in using it), the opt-out model for data sharing is viewed critically, with 44.7% (n=438) of respondents rejecting it. Socioeconomic status significantly influences the willingness to share data, with higher income, education, and digital literacy being associated with greater openness to data sharing. However, trust emerged as the most significant factor. Additionally, experiences with digital technologies increase the willingness to share personal health data.

Conclusions: The German population shows general openness toward EHRs and data sharing. Trust plays a critical role in promoting willingness to share health data. The findings highlight challenges in Germany's transition to an opt-out system.

Introduction

Legislative Context and Research Questions

Health data stored in electronic health records (EHRs) are considered an extremely valuable source for advancing medical science and health care. EHRs have the potential to provide high-quality longitudinal data from a broad spectrum of the population. It is therefore not surprising that many countries are implementing data-sharing options to make use of these data. In Germany, the EHR ("elektronische Patientenakte") was introduced on January 1, 2021, and is available to all legally insured persons through their health insurance company. It can be used to store and manage medical diagnoses and treatment data. The use of the EHR also allows control over who can view and access data. However, by 2024, only 1% - 2% of the eligible population have an EHR. To increase the prevalence and benefits of the EHR, the German Bundestag passed the Digital Act ("Digital-Gesetz") and the Health Data Use Act ("Gesundheitsdatennutzungsgesetz") on December 14, 2023. This means that starting in 2025, for all people with statutory health insurance in Germany, an EHR will be automatically created unless they opt out. The Health Data Use Act further allows for the use of pseudonymized health data for research purposes by public and private institutions by amending §303e SGB V. That means data stored in the EHR will be available for research purposes including commercial purposes unless people opt out. The data will be made available through the German Health Research Data Center ("Forschungsdatenzentrum"). The legislative changes mark a paradigm shift in the way health data are handled: the creation of electronic patient records and the sharing of health data will be automatic unless people actively opt out. The German federal minister of health, Karl Lauterbach, stated that the paradigm shift will be a "gamechanger" for the development of health [1]. The new legal framework marks a step toward digitization

XSL•FO
RenderX

that many experts have been calling for for a long time [2]. At the same time, the extensive and passive sharing of health data has been criticized by various stakeholders.

This paradigm shift raises some serious questions about the social implications. There are a number of challenges to the "data is gold" perspective [3]. Some social scientists criticize that digitization in health bears potential for "panoptic surveillance" [4]. Other critics [5] have highlighted data security issues that can harm citizens in many ways. Furthermore, the risks, but also the opportunities to benefit from digital health, are unevenly distributed across society. There is ample empirical evidence of a so-called "digital divide," meaning that people with lower socioeconomic status have lower chances of using digital (health) services and face higher risks [4,6,7]. The digitization of health therefore needs to be critically monitored. Citizens should be aware of the potential benefits as well as the potential dangers of sharing personal health data. This becomes even more urgent with the implementation of an opt-out mechanism. Opt-out is an instrument of nudging [8]. It aims to increase the use of EHRs and the acceptance of data sharing by "choice architecture" [9]. Citizens retain their freedom of choice but are nudged toward using the EHR. However, an opt-out mechanism relies on informed citizens to take deliberative action, especially when data sharing can be harmful. The policy of choice architecture and the use of EHR data for health research make clear that health data sharing cannot be reduced to an individual action but must be analyzed in its social context. It raises questions of legitimacy, social inequality, and the diffusion of knowledge among citizens.

This paper focuses on public opinion on EHR data sharing in Germany. It answers three research questions: (1) Is there sufficient willingness in society to share health data that justifies the introduction of an opt-out scheme? (2) Does the willingness to share data differs with socioeconomic status? (3) How can individual willingness to share EHR data be explained?

State of the Art

This section summarizes the research on data sharing and evidence on EHR adoption. International research finds widespread support for the idea of EHRs among citizens and institutions in the health care sector [10-12]. However, "evidence indicates that consumers who have been offered access to PEHRs have not widely used them and the number of active users has remained low" [12]. For example, a recent study shows that in the United States, the number of active users of the EHR is about 26% (2019), despite its increasing integration in medical practice [13]. In Germany, until 2024, according to data from public health insurance, less than 2% of the insured actively requested an EHR [14]. At the same time, only about half of the population is even aware of the EHR [15]. Several studies have shown that interest and use of the EHR show a digital divide. Younger and more digital literate people show a higher probability of using EHRs, while older and low-income groups have less often access [12,16,17]. Regarding socioeconomic factors, lower educational and employment status, as well as belonging to an ethnic minority, have a negative impact on individuals' desire to access and use EHRs [12,18].

Several studies have examined citizens' motivations for using EHRs. The perceived advantages and disadvantages strongly influence the intention to use and the actual use. Key factors here are concerns about data protection and the fear of being discriminated by health insurers or employers on the one hand, and the benefits of better information and experience with the portals or providers on the other [12,19,20]. Data protection concerns are a key factor because health issues are relevant in many areas of daily life [10,12,19]. This can be seen directly when respondents report fears of stigmatization as a result of digitally disseminated health information from the EHR [21,22]. For people with chronic diseases, the balance of advantages and disadvantages seems to be clearly in favor of the advantages. Several studies have reported higher levels of interest in providing data due to the hope of treatment progress [23,24]. For people with chronic diseases, there are already care programs in place that people can benefit from, such as disease management programs [25].

While the research literature stresses that EHRs are potentially an important tool to transform "passive recipients of treatment to empowered consumers" [12], the empirical findings are rather disappointing. Several international studies have shown that the overall use of EHRs by patients remains low [12]. Furthermore, there is little evidence of empowerment effects [12]. Even people who have an EHR often do not know which data are stored in the health record and how to interpret the information [12,26]. When users experience that they do not understand the EHR or the information stored in it, their willingness to use it decreases significantly [23]. Thus, we can expect a significant gap between interest in EHRs and actual use. This gap is likely to be even more pronounced in Germany, with its high standards for data security and complicated routines for accessing the EHR.

Data sharing is an essential part of EHRs. Many EHR systems allow anonymized health data to be used for scientific research. While this can lead to progress in the health system, there is no clear-cut advantage for an individual sharing its data, since anonymization makes individual feedback regarding new health insights hard. That might be the reason, why in public discourse, data sharing is often labeled as "data donation" [27]. Research regarding data sharing has shown that a considerable part of the population (often exceeding 50%) is willing to share its health data [27-30]. There are considerable differences between different countries. For example, the Scandinavian countries show the highest willingness to share health data, while people in Southern Europe are rather skeptical about it [31]. For Germany, recent research suggests that 8 of 10 citizens are willing to share their health data for scientific purposes [15,32,33]. Notably, this high approval rate also seems to hold true for the planned opt-out regulation [33]. However, these high approval rates have to be interpreted with caution, since limited knowledge about health data sharing is widespread and some studies have methodological limitations. Like many other surveys in this area, the high approval rates rely on web-based surveys that have proven to be of less quality regarding the research results compared to face-to-face or telephone interviews [34]. One reason is that they show a higher tendency to produce biased results [35]. Since there is an empirical correlation

XSL•FO
RenderX

between digital literacy and the willingness to share health data, the results are likely to be too optimistic. Furthermore, some questionnaires tend to highlight the positive impacts of data sharing and thereby inflating the approval rate (The question of the survey conducted in Germany was [15,32]: “Assuming that in the future your personal health data, such as your medical history, examination results, X-ray images, etc. can be stored online in a digital health record. Would you agree that your personal health data is used anonymously and free of charge for the purpose of medical research so that in the future diseases can be better recognized and new treatments developed?” And “At present, the use of patient data for medical research requires the consent of patients. However, it is often difficult or even impossible to obtain such consent. Therefore, there are considerations in Germany to legally allow medical research without consent on encrypted patient data after an independent review of the research project. In return, it should be possible for every citizen to simply object to this so-called ‘data donation’ How would you find such a legal regulation ... for publicly funded research?”).

Empirical studies have revealed that the willingness to share data differs among different groups. The findings are comparable to the overall use of EHR: among those with higher age, educational level, and income, a higher willingness to share data can be observed [30,36-39]. Some studies investigate potential individual causes for the willingness to share health data for scientific purposes. These studies find that concerns about confidentiality breaches and data misuse are important factors that prevent data sharing [28,29]. Unsurprisingly, privacy protection, anonymization, and transparency have proven to be key factors for data sharing [29,40]. Furthermore, people are motivated by potential benefits, including more altruistic ones, like advancements in science and public health [29,40]. Another key factor is the use of health data. While international research has shown relatively high public support for the secondary use of health data, this support decreases significantly when shared data can be used by the private sector [41-43].

Another source of insight comes from studies that focus on the social contexts in which data are shared. They have identified 2 other relevant aspects: digital literacy and trust. Health data sharing relies on digital tools. Therefore, people who are more familiar with digital tools may be less reluctant to share data. In addition, technology companies such as Google and Apple have created many services that make use of data sharing in everyday life. Hence, digitally literate people are more involved in data sharing in general. In line with this argument, empirical studies show a higher propensity to share health data among the more digitally savvy people [36,37,40,44,45]. On a more abstract level, it can be argued that trust plays an essential role in health in general [46] and in data sharing in particular. Since the sharing of data is a socially highly indeterminate constellation for social action, trust is a crucial resource. The risks taken by data donors as well as the potential benefits depend strongly on other actors and can hardly be known in advance. For example, the question of anonymizing health data can only be answered in relation to existing knowledge and techniques. The benefits of data sharing are particularly uncertain because there is no guarantee of medical progress, and even if progress does occur, it is unclear whether data donors themselves benefit. Given these theoretical arguments, it is not surprising that empirical studies show an important influence of trust. They can show that trust in the institutions involved in data sharing is relevant, as is general trust in science [15,29,36,37,40,44,45].

Methods

Ethical Considerations

Ethics approval was obtained from the ethics department of the German Aerospace Center (21/23) before the interviews were conducted. Participants gave verbal informed consent to participate in the study. Anonymized interview data were provided to the author by the survey institute. No compensation was given to the interviewees.

Survey Design and Sample

The analysis is based on a dedicated telephone survey (computer-assisted telephone interview [CATI]) about health data conducted between December 7 and 21, 2023. The sampling was carried out by the survey institute drei.fakt (Erfurt) on behalf of the Ernst Abbe University of Applied Sciences Jena. For the study, a representative randomized stratified random sample was drawn based on randomized landline and cell phone numbers (30/70) [47]. Random landline numbers were called based on regional quotas. The mobile phone numbers were sampled and stratified by telephone provider. A total of 11,451 residential numbers were called. In total, 1004 respondents aged 18 years and older participated in an interview. In contrast to many web-based surveys in this area, CATI allows people without internet access to be able to take part in the survey. To ensure the quality of the sample, it was compared with the population for age, gender, and region during the field period. Statistics from the 2019 German microcensus served as a data basis for comparing the distribution of the sample with the distribution of the characteristics in the population. Compared to population statistics, the unweighted sample underrepresents immigrants and slightly overrepresents people with higher education. This selection bias of telephone interviews is well-known from survey research. Therefore, all analyses use a weighting variable in order to adequately represent the population in terms of demographic and socioeconomic characteristics.

Questionnaire

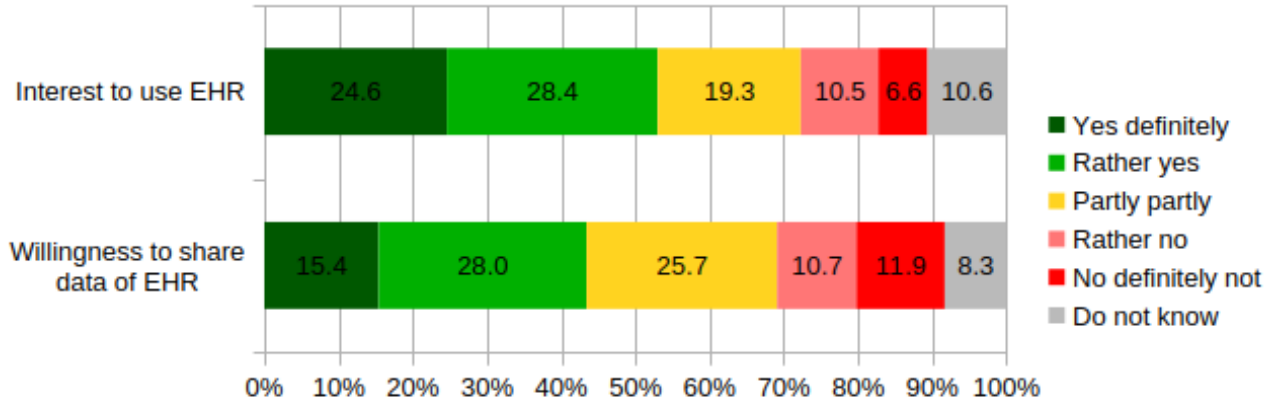
The questionnaire comprised 32 questions regarding various topics about health data sharing. The questionnaire included information on digital skills, the willingness to share personal health data in general, motives for and against data sharing, questions regarding trust and data protection, as well as attitudes toward the EHR and socioeconomic characteristics. The CATI lasted approximately 20 minutes. Most questions were based on a 5-point Likert scale or binary response options and included multiple response categories. The final questionnaire included feedback from 2 separate pretests. In this pretest, the survey instrument was tested for its practical suitability in the field and potential misunderstandings. The full questionnaire and survey data are available in German via the GESIS repository [47].

XSL•FO
RenderX

Data Analysis

Descriptive statistics and multivariate linear regression models are used for analysis. The dependent variable in the multivariate regression models is the attitude toward sharing health data via EHR. People were asked on a 5-point scale (1=yes, definitely and 5=no, definitely not): "Would you be willing to share your health data from your EHR anonymized for medical research purposes?" To minimize potential misunderstandings about the EHR, the question was preceded by a brief explanation of EHRs ("Since January 1, 2021, all people with statutory health insurance can use the EHR via an app of the insurance provider. The EHR contains medical findings and information from previous treatments."). It is important to note that this question is hypothetical, as only a small fraction of people actually had an electronic personal health record at the time of the fieldwork (see Introduction section). However, in order to measure the willingness to share personal health information and to take into account the new legal framework, the question was phrased in a hypothetical manner. This makes it possible to measure the willingness to share extensive and potentially sensitive personal health information rather than actual planned behavior. Therefore, the question is also analyzed for respondents without an EHR in order to reflect overall opinions about the new legislative approach.

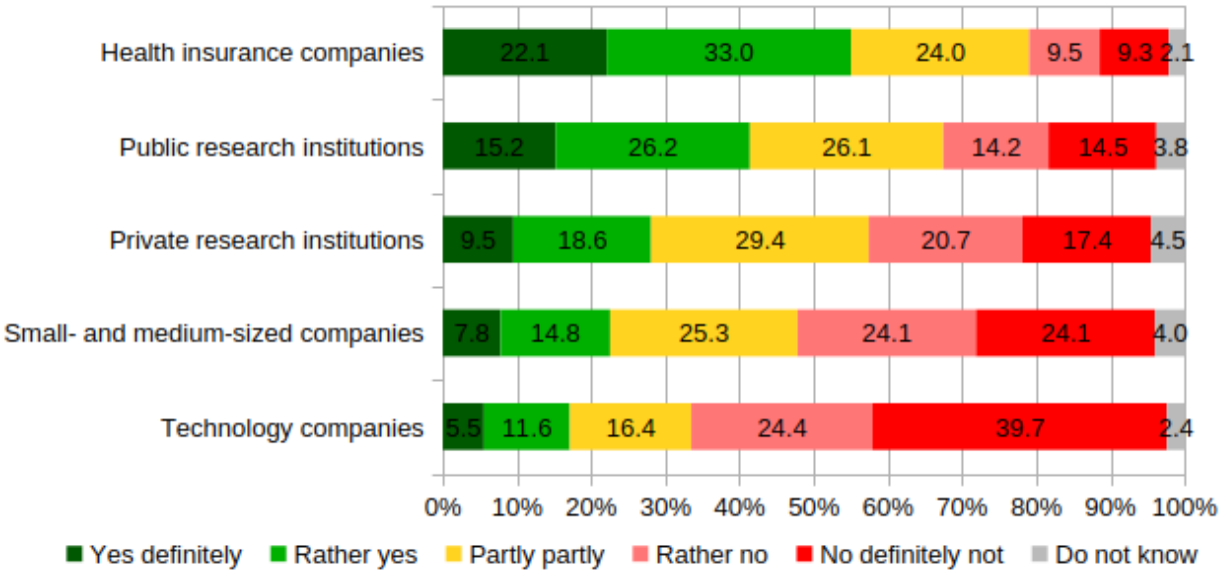
Results



The first step is to analyze the approval rates for the use of the German EHR. In general, the population is very open to the EHR. In total, 53% (n=483) of the population who claim to have no EHR yet show interest in using it. At the same time, 8.9% (n=89) of the sample state that they already have an EHR, in comparison to the 1% reported in official statistics. Therefore, it has to be assumed that some people lack a proper understanding of the EHR (see Limitations and Further Research Questions section). Only a minority of 17.1% (n=156) refuse to use it. The proportion of people with no clear opinion (partly partly or do not know) is significantly higher (n=272, 29.9%).

The legislative proposals also introduce the sharing of health data from the EHR for research purposes, as long as individuals do not actively object. Figure 1 summarizes whether respondents would be willing to share their personal health data stored in an EHR. The figure summarizes the attitudes of respondents with and without EHR. Respondents are more cautious about data sharing compared to the interest in using the EHR. In total, 43.4% (n=432) of respondents are willing to share their health data (yes, definitely or rather yes). Nearly 1 in 4 (n=225, 22.6%) respondents oppose data sharing. In addition, a large proportion of respondents are undecided (partly or not at all or do not know). A high interest in using the EHR corresponds empirically with a high willingness to share health data via EHR (no figure). The bivariate correlation is considerably large with 0.56 (Spearman).

The attitude toward health data sharing varies considerably with the data user respondents have in mind (Figure 2). The survey included a question regarding health data sharing with different institutions. It has to be noted that this question did not mention the EHR directly but addressed the willingness to share health data more generally. While 28.7% (n=285) and 18.8% (n=186) do not want to share data with public research institutions or public health insurances, about 38% (n=377) object to share their personal health data with private research institutions.



In the next step, the interest to use the EHR and the willingness to share health data for research purposes are measured for different socioeconomic groups. Table 1 shows the percentage of respondents in each group who intend to use the EHR and how many would agree with data sharing (yes and rather yes). In addition, respondents were asked for their opinions on different consent mechanisms. Figure 1 shows the proportion of people who explicitly reject the opt-out procedure as it will be introduced by law in 2025—compared to those who agree or are undecided (do not know).

University degree	118 (57.7)	116 (50.8)	131 (58.1)
Total sample	483 (53)	432 (43.4)	438 (44.7)
Total respondents, n	911	995	980

[a]Own calculations, weighted percentages for columns 1 and 2 (share of a sample with statement yes definitely and rather yes) and column 3 (share of a sample who disagrees opt-out) in response to the question: “The German government is planning to use data from the electronic health records for medical research, eg, for research on new diseases and therapeutic approaches. Which of the following consents do you agree with? ... My data will be shared until I object.” Options to answer: agree or disagree or do not know or nonresponse; nonresponse excluded; do not know is interpreted as no interest to use EHR, not in favor of data sharing and agree with opt-out.

There are clear socioeconomic differences in interest in using the EHR and willingness to share health data, which are similar for both variables. The higher a person’s socioeconomic position (like income or education), the more open respondents are to using the EHR and sharing their personal health data for research purposes. Older people and men also tend to be more open. There are pronounced differences by migration status. The final column summarizes attitudes toward the opt-out process. First of all, it is striking that the procedure implemented by the legislator is explicitly rejected by a significant part of the population. In the entire sample, 44.7% (n=438) say that they are against an opt-out. Additional analyses not presented here show that the remaining respondents either agree (n=400, 40.8%) or have no opinion (n=142, 14.5%). Interestingly, the opt-out model is mainly rejected by people in a higher socioeconomic position. There are hardly any differences with regard to the other socioeconomic variables, except for a lower level of rejection in the eastern part of Germany. Overall, the descriptive statistics suggest that citizens are open to EHR and data sharing but want a high degree of autonomy in dealing with their health data. Additional analyses not shown here indicate that active consent is supported by over 80% (n=788) of respondents.

In the next step, the willingness to share data via the EHR is examined in a multivariate linear regression model (Table 2). The dependent variable is the willingness to share personal health data expressed on a 5-point scale (Figure 1). To prevent an excessive reduction in the sample, people who answered “do not know” were assigned to the “partly partly” category. The findings presented here remain stable even with a smaller sample. The determinants identified in the State of the Art section are added as independent variables to the model. Special

XSL•FO
RenderX

attention is given to the role of trust. The first model includes socioeconomic parameters. As shown in Table 1, the multivariate model confirms socioeconomic differences. However, some more differentiated statements can be made. Controlling for other parameters, there is a curvilinear relationship between age and willingness to share. The positive squared age term indicates that the willingness to share is highest among the very young and the very old. The willingness to share is lowest among people in their 50s. On a 5-point scale, their willingness is about 0.5 points lower than that of 20-year-old people. Income has a positive significant influence on willingness to share, which confirms the descriptive findings. The level of education also has an influence. However, when controlling for income, medium levels of education are associated with the highest willingness to share. Women and people born abroad show no different opinion regarding health data sharing after controlling for income and education. The model also includes a dummy variable indicating the presence of chronic diseases. On the one hand, people with chronic diseases may be at a higher risk of data misuse, but on the other hand, they may be more likely to benefit from digitally supported medical progress. In fact, interest in sharing data appears to be 0.2 points higher for people with chronic physical diseases.

The second model adds comfort with digital technologies. As in comparable studies from other countries, there are significant effects. People who find it easy to use digital technology are more open to sharing their health data. However, the effect disappears when the trust variables are included (model 3). Trust turns out to be a very strong influencing factor. Trust in science has the strongest influence. This is particularly noteworthy because the trust indicator does not specifically address the EHR or the institutions behind it but science as a whole. Controlling for socioeconomic parameters, a person who mistrusts the scientific system has a willingness to share that is more than 2 points lower on a scale of 5 than a person who fully trusts the scientific system. In addition, trust in the big technology firms also has a highly significant influence on the hypothesized direction. The strong influence of trust can be seen directly in the sharp increase in the fit of the model (R^2). The model also includes a proxy for altruistic tendencies in the form of a general willingness to donate (eg, money). The dummy for people who donate on a regular basis is significant. In the last model, motivations and concerns that may be associated with data sharing were included. However, the last model should be interpreted with caution. Because the wording of the questions in the independent variables refers to data sharing, the coefficients may be biased by self-reference (eg, if you care about doing good for society by sharing your data, you will more be willing to share). Nevertheless, the coefficients provide important clues about the motives that drive data sharing. The multivariate results show an interplay between altruistic motives (doing good for society) and cost-benefit considerations (potential benefits for personal and fear of data breaches that expose personal health data to the public).

Discussion

Principal Findings

The results of this study shed light on attitudes toward the use and sharing of EHRs for research purposes in Germany, particularly in the context of the new legislation based on the opt-out mechanism. Overall, the study reveals a nuanced picture of the German population's attitudes. The empirical results show an openness to EHRs (about half of the nonusers express a desire to use their EHR, signaling significant potential for increased adoption). At the same time, a significant share of the population remains skeptical or undecided. The overall openness is in line with international research regarding interest in EHR [12]. Given these high levels of interest, the introduction of an opt-out model does not seem unjustified. However, especially a large fraction of undecided people need to be properly informed about the consequences of having their health data stored electronically. While there is general support for sharing health data, with 43.4% (n=432) of respondents indicating a willingness to do so, a significant portion (n=225, 22.6%) remain opposed, and a large number are undecided. The results indicate a significantly lower willingness to share health data than has been measured in comparable studies in Germany [15,33]. Possible explanations for these differences are (1) different timing: other studies collected their data at a time when there was no legal framework for health data sharing and therefore risks, etc, had not yet been widely discussed in public. (2) Methodological: this study is based upon a telephone survey rather than web-based and explicitly allows people to have no specific attitude by including categories like refuse to answer, do not know, and neither nor. Last but not least, the comparatively low willingness to share health data in this study compared to international research [27,28] may be due to the emphasis on the personal character of the data potentially shared. The ambivalent results highlight the need for careful consideration of how the opt-out mechanism is implemented and communicated. Although there is openness in principle, "soft paternalism" must be viewed critically precisely because of the high proportion of undecided citizens. In contrast to the principle of informed consent, in which the processes and risks of data sharing have to be explained before citizens allow data sharing, an opt-out solution presupposes that the population is sufficiently informed in other ways. This becomes even more clear after considering attitudes toward the opt-out mechanism, which 44.7% (n=438) disapprove. Especially people who are positive about EHRs and the sharing of their health data reject the opt-out mechanism proposed by the legislator more often. Presumably, "choice architecture" is seen as too much interference in their own decisions.

The study also confirms a digital divide, as socioeconomic factors significantly influence both the willingness to use EHRs and the willingness to share personal health data. The results are in line with international research findings [16,30]. Higher income, education, and digital literacy are associated with greater openness, while those with lower socioeconomic status are more reluctant. However, socioeconomic factors are not the most important in explaining openness to data sharing. Trust plays a critical role in determining the willingness to share health information. While other studies have pointed to the role of trust as a significant factor [15,40,44,45], this study shows that institutional trust has a decisive influence compared to other factors. The influence of socioeconomic variables, as well as other factors such as digital literacy, diminishes when trust variables are taken into account, highlighting trust as a fundamental element in the acceptance of digital health initiatives. The observed socioeconomic disparities reinforce the need for targeted interventions and information to ensure equitable access and participation in digital health.

Policy Implications

The paradigm shift to an opt-out system is expected to increase participation rates because it relies on passive inclusion rather than active consent. However, this comes at the cost of potentially creating a population of uninformed and passive citizens who are enrolled in the system without fully understanding the implications. This raises critical concerns about consumer autonomy and challenges the notion of the autonomous consumer who actively engages with—and consents to—data-sharing practices. With a large portion of the population still undecided about EHR adoption and data sharing, the need for population-wide education becomes even more apparent. Ideally, all citizens, regardless of their socioeconomic background, should be able to make informed and autonomous decisions about their participation. The study also shows the complex mechanisms of the digital divide, with those in higher socioeconomic positions being more open to the adoption of EHRs but also more likely to oppose the opt-out system. This suggests that the paradigm shift is perceived as a restriction of autonomy. Those with greater resources and digital literacy want to make informed choices and therefore resist mechanisms that limit their freedom of choice. While those with greater resources are likely to be able to opt out if they perceive the risks of data sharing to be too high, they could trigger serious political resistance to the opt-out mechanism. In contrast, individuals with lower socioeconomic status may be less able to navigate these systems and therefore are more vulnerable to passive inclusion.

The transition to an opt-out system for EHRs in Germany marks a significant policy shift with the potential to transform the health sector. However, for this shift to be successful, it is essential to address the underlying concerns of the population, particularly around data security, autonomy, and the digital divide. Continuous monitoring of the implementation of the opt-out system will be crucial to keep and build trust within the population.

Limitations and Further Research Questions

In contrast to web-based surveys, which are often used in EHR research, the CATI method used here avoids many problems of self-reporting, sample bias, and inference [48,49]. However, the quality of data collected through telephone interviews also experiences low response rates. It seems highly plausible that nonresponse is not random. People with lower levels of trust and willingness are supposedly less likely to participate in the survey. Thus, despite the weighting procedure applied, the sample may be biased toward more trusting people. This problem is common to other data used in comparable research.

Another limitation concerns the correct understanding of the EHR in Germany. During the field phase, little more than 1% of the insured population opted for the EHR. It is possible that many respondents do not have a proper understanding of the EHR or have no knowledge at all. The survey provides some evidence in this direction. A question about knowledge of the EHR reveals that 13.9% (n=139) have never heard of it. For this group, the evaluation of data sharing is probably less substantiated. However, at the same time, a large fraction says that they have heard of the EHR (n=720, 71.7%) or even use it (n=89, 8.9%). On the one hand, these results support the assertion that a large proportion of the sample has a basic understanding of the EHR. During the field phase, there was also an extensive media discourse about the EHR, as the Gesundheitsdatennutzungsgesetz was being discussed in parliament in December 2023. On the other hand, the self-reported use of the EHR does not match the official statistics. Some respondents probably confused the EHR with other apps provided by their health insurance. This problem of overreporting has also been observed in other studies [15].

The study focuses on the interest in using the EHR and the willingness to share health data. At the time of the field phase, EHR adoption was very low, and a legal framework for health information exchange was in its formative stages. Research has already shown that there is a gap between attitudes and actual behavior [12,42]. So the results have to be interpreted with some caution. In addition, the high proportion of undecided respondents indicates that reported attitudes are not very salient and therefore susceptible to survey effects. However, other studies share this disadvantage. Moreover, the consequences of limited interest in EHR do not only affect surveys but also have far-reaching practical implications, especially when using opt-out regulations.

Future research should focus on the gap between interest in using the EHR and actual behavior. With a focus on Germany, the potential burdens of adoption should be analyzed in more detail. With regard to trust, the potential ways to build trust within the health care system without relying too much on general institutional trust also point to new research directions. Furthermore, there are interesting research questions regarding self-responsibility in a system that becomes largely based on passive consent (opt-out).

Acknowledgments

This work was supported by the German Federal Ministry of Education and Research and the European Union—Next Generation (grant 16KISA015). The funded project is called AVATAR ("Anonymisierung persönlicher Gesundheitsdaten durch Erzeugung digitaler Avatare") and consists of several research institutions that aim to develop new methods for anonymizing patient data for research. The funding agency had no role in the design, conduct, analysis, interpretation, or approval of the study. The content is the sole responsibility of the author. The author would like to thank Elias Kühnel, Julia Berghäuser, Sven Bock, and Anna Weber for their thorough work on the questionnaire.

Abstract

Background: The use of individual wearable devices or internet-based applications to collect biometric data from research participants is popular, but several devices may be needed to replace a full set of research measurements.

Objective: In this study, we assessed the feasibility of a "Virtual Home Clinic" within the context of long-term epidemiologic studies.

Methods: Participants from 3 study cohorts were recruited. Devices were sent to the home to measure anthropometrics, resting metabolic rate, blood pressure (BP), heart rate (HR), heart rhythm, oxygen saturation, glucose, total cholesterol, physical activity, diet, sleep duration or quality, and arterial stiffness over the course of 1 week. Stool and saliva were also self-collected for microbiome, DNA, and cotinine. Feasibility and acceptability of collecting measurements using home devices were assessed.

Results: A total of 134 participants were enrolled (87% female, 31% Black; mean age 54.2, SD 8.4 years). Furthermore, 91% (N=122) performed at least one of the home tests. At least two-thirds of participants were able to complete all of the requested readings for glucose, electrocardiogram, BP, diet record, and resting metabolic rate. The scale that measured weight, body composition, and pulse wave velocity (PWV) was more difficult to use (113/134, 84% participants recorded at least one weight and 84/134, 63% recorded a PWV). The device to measure total cholesterol was least successful (32/134, 24% participants completed all readings, 72/134, 54% provided at least one result). Return of biospecimens was highly successful (115/134, 86% returned saliva and 113/134, 84% returned stool). Of 95 who responded to the user acceptability survey, 38 (40%) participants preferred home assessment, 36 (38%) preferred clinic, and 21 (22%) did not have a preference. The mean user acceptability score across devices for ease of use was 4.3 (SD 1.0), for instructions was 4.5 (SD 0.7), and for time to use was 3.9 (SD 1.1; scale of 1 - 5, with higher scores indicating greater acceptability). The study team documented several regulatory or IT, connectivity or account, data retrieval, and logistical issues encountered during the study.

Conclusions: Despite several complications involved with managing multiple devices and applications, most of the components of the virtual home clinic were reasonably feasible and acceptable to participants.

KEYWORDS

mHealth; cardiovascular risk factors; epidemiology; wearable devices; feasibility; acceptability; biometric

Introduction

Early life factors play an important role in successful aging [1,2]. However, prospectively collected data is needed to construct accurate trajectories of health status (eg, BMI, blood pressure, and cholesterol levels) and lifestyle factors (eg, diet, physical activity, alcohol, and tobacco use) across the lifespan to determine their association with cognitive and physical function later in life. Many barriers exist in collecting longitudinal data across the lifespan [3]. Importantly, as adolescents age into adulthood, many move away from their initial recruitment site which may reduce generalizability of findings of the remaining cohort from adult follow-up visits. Mobile health (mHealth) approaches have been proposed as a means to overcome some of these barriers [4], but the feasibility of collecting a broad range of measurements using at-home devices has not been sufficiently evaluated in this setting. Therefore, we conducted a study to evaluate the feasibility of a "Virtual Home Clinic" by sending biometric measurement devices to participants' homes. We also sought to determine

XSL•FO
RenderX

the acceptability of the virtual home clinic approach compared with a research clinic visit. Separately, we will seek to correlate measures obtained in the virtual home clinic to those in the research clinic. Our goal is to establish the feasibility and acceptability of using a suite of wearable technology and online applications to conduct "remote" study visits in epidemiologic studies to improve the sustainability of longitudinal studies whose study population has dispersed over time.

Methods

Population

Three cohorts that are members of the International Childhood Cardiovascular Cohort Consortium (i3C) [5] participated in this study: the Bogalusa Heart Study (BHS), the National Heart, Lung, and Blood Institute (NHLBI) Growth and Health Study (NGHS), and the Princeton Lipid Research Study (PLRS). The most recent phone follow-up of these cohorts this project was completed in 2019 [6].

The BHS which began in 1973 conducted 9 cross-sectional cardiovascular risk factor screenings of children aged 3 to 18 years between 1973 and 1992 in a community of Black and White men and women of Bogalusa, LA, with participation rates of 80% to 93%. In addition, 10 cross-sectional screenings of young adults aged 19 - 52 years who had previously been examined as children have been conducted to date, with participation rates of 72% to 93%. Cardiovascular risk factors (adiposity, BP, and cholesterol levels) and noninvasive measures of cardiac and vascular health (carotid intima media thickness and arterial stiffness) [7].

The NGHS was initiated in 1987 as a study of racial (Black-White) differences in the development of cardiovascular risk factors in girls in Cincinnati, Ohio [7]. All participants were between the ages of 9 and 10 years at baseline and followed annually or biannually to age 28 years. Cardiovascular risk factors, echocardiography and dual-energy x-ray absorptiometry (DXA) and abdominal magnetic resonance imaging (MRI) for adiposity were collected.

The PLRS was initiated in 1973 as part of the NHLBI Lipid Research Clinics Study [8]. The study enrolled children in first to 12th grades in the Princeton City School District of Cincinnati, Ohio, plus a 50% random sample of the students' parents (by household). Three study visits were conducted between 1973 and 1978 to collect a variety of cardiovascular risk factors. Between 1998 and 2003, 911 former school children participated in another in-person visit at mean age 36.

For the current feasibility study of the virtual home clinic, 50 participants from each cohort living near the study sites, with access to Wi-Fi at home, and who were willing to attend an in-person visit at the study sites were invited to participate. Procedures were explained, and informed consent was obtained electronically. These 50 per cohort were invited from a subset of 150 per cohort who had previously enrolled in a pilot study testing the feasibility of phone administration of neurocognitive evaluations. Enrollment into this virtual home clinic study thus represents a convenience sample of contactable and willing participants. The study protocol was approved by the institutional review boards of the participating institutions.

Data Collection

Participants were asked to complete the virtual home clinic and an in-person research clinic visit for the validation portion of the study. The virtual home clinic study kit was either mailed to a participant (if they conducted the virtual home clinic C first) or given to the participant at the end of their in-person visit. The virtual home clinic kit included detailed instructions, staff contact information, an iPad (Apple Inc) with device apps and instructional videos preloaded, a color-coded schedule of activities, and shipping materials for returning the kit. The virtual home clinic study protocol included 6 devices, 1 iPad app and 3 sample collections (Table 1).

DNA Genotek OMNIgene GUT OMR-200 stool collection		
	Microbiome (16s): % collected	Sample collection status recorded in spreadsheet.
Abbott Quantisal saliva collection		
	Cotinine	Samples sent to LabCorp for processing. Retrieve results from study's LabCorp portal and enter results in study database.
DNA Genotek Oragene OG-500 saliva collection		
	DNA: % collected	Sample collection status recorded in spreadsheet.

[a]CSV: comma separated values.

[b]PWV: pulse wave velocity.

[c]ECG: electrocardiogram.

[d]BP: blood pressure.

[e]REM: rapid eye movement

XSL•FO
RenderX

Together, the devices were selected to measure key cardiovascular parameters that would be included in a standard in-person follow-up visit. Requested measurements included 3 glucose and total cholesterol readings with the AimStrip Tandem (AimStrip), 3 electrocardiogram tracings with the Alivecor KardiaMobile 6L (Kardia), 7 weight or body composition and 3 pulse wave velocity (PWV) readings with the Withings Body Cardio scale (Withings), and 3 resting metabolic rate measurements with the Breezing Pro device (Breezing; Cincinnati cohorts only). One week of daily diet tracking was requested using the GB HealthWatch 360 app (HealthWatch 360), and participants were asked to wear a Garmin Vivosmart 4 fitness tracker watch (Garmin) for the entire week to measure activity (steps, minutes with elevated heart rate), oxygen saturation during sleep, and sleep duration and quality. In addition, 3 sets of 3 BP and HR measurements (total of 9) were requested using the QardioArm Home BP monitor (Qardio). Three biologic samples were requested: Abbott Quantisal saliva collection (Quantisal), DNA Genotek Oragene OG-500 saliva collection (Oragene) and DNA Genotek OMNIgene GUT OMR-200 stool collection (OMNIgene). Subjects were asked to return the kit and samples after 1 week. Once device data was retrieved, a full reset was performed on all hardware to ensure privacy between participants. For additional security, new iPad app accounts were created for each participant using only their unique study identifier and the demographics required by the app (eg date of birth, sex, height, and weight). Reset procedures were rigorously tested to confirm effective deletion of all data, and were documented in detail in study manuals. All kit components were thoroughly cleaned using hospital protocols before and after each virtual home clinic.

A questionnaire to assess acceptability, ease of use, and functionality of each device was sent to all participants electronically after completion of the virtual home clinic. User acceptability was assessed with the questions “Was this device or app easy to use?” (1=Very difficult to use; 2=Somewhat difficult; 3=Neither difficult nor easy; 4=Somewhat easy; and 5=Very easy); “Were the instructions easy to follow?” (same scoring); “How do you feel about the time it took to use the device or app?” (1=Took much longer than I would have liked; 2=Took somewhat longer; 3=Took about as long as I expected; 4=Took somewhat less time than I expected; and 5=Took very little time).

Statistical Analyses

Feasibility was assessed as proportion of requested in-home tests completed, and percent of requested saliva and stool samples returned. Mean scores by device and overall were calculated. Due to small sample size, differences by cohort, sex and race were not assessed.

Ethical Considerations

Each center obtained approval from their local institutional review board (IRB) and all participants signed an informed consent. All data was identified with only a participant ID number (deidentified). Participants were compensated $200 for completion of all arms of the study.

Results

Population

A total of 134 participants consented to participate (Table 2).

XSL•FO

HR[h] (beats/min)	73.0 (14.6)	75.3 (11.0)	67.7 (10.2)	72.3 (12.3)

[a]BHS: Bogalusa Heart Study.

[b]NGHS: National Heart, Lung, and Blood Institute Growth and Health Study.

[c]PLRS: Princeton Lipid Research Study.

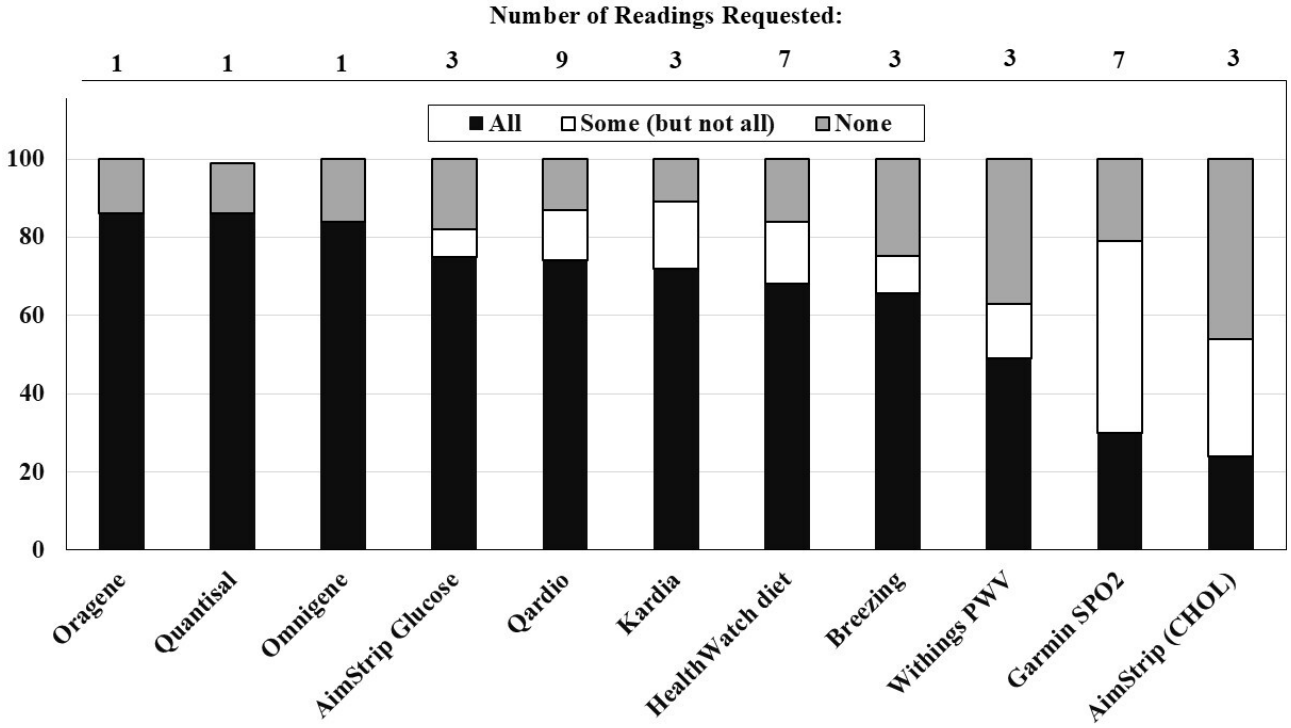
[d]LDL-C:

[e]HDL-C:high-density lipoprotein cholesterol.

[f]SBP: systolic blood pressure.

[g]DBP: diastolic blood pressure.

[h]HR: heart rate.



The mean age of the participants was 54.2 (SD 8.4) years, which differed somewhat by cohort. Males (13%) were less likely to participate than females (87%), partially due to the NGHS cohort consisting entirely of women. White individuals comprised 69% (93/134) of the participants and Black individuals were 31% (41/134). In-clinic measurements showed a mean BMI in the obese range (31.6, SD 8.3 kg/m^2), slightly elevated LDL (105.2, SD 33.5 mg/dL), glucose (106.5, SD 34.3 mg/dL), and systolic blood pressure (120.8, SD 16.6 mm Hg), and normal diastolic blood pressure (78.4, SD 10.6 mm Hg), total cholesterol (184.6, SD 41.0 mg/dL), and triglycerides (108.1, SD 79.6 mg/dL).

Data Collected

Table S1 in Multimedia Appendix 1 lists issues related to device or iPad application set up. General issues encountered included institutional firewalls requiring permission to load apps on an iPad; apps requiring Wi-Fi or a unique email address; complicated instructions for participants; different processes for account setup, data retrieval, cleaning or disinfection by device; need to delete old data or resetting for each device and participant; and differing exported data file formats by device (eg, CSV, PDF requiring data entry, or data entry directly from the device) requiring extensive programming to import into statistical software. Issues encountered during execution of the study (Table S2 in Multimedia Appendix 1) included IRB issues, changes in devices or apps during the study by the manufacturer, issues with batteries, and issues with passwords for apps. Success of completion of the virtual home clinic protocol by device or app type are displayed in Figure 1.

XSL•FO
RenderX

Figure 1. Completion success by device (N=134). PWV: pulse wave velocity, SpO_2: peripheral capillary oxygen saturation.

Overall, 122 out of 134 participants (91%) performed at least one of the home tests. Return of biospecimens was highly successful (115/134, 86% returned saliva and 113/134, 84% returned stool). At least 91 of the 134 (68%) participants were able to complete all of the requested readings for glucose, electrocardiogram, BP, and diet record. All requested resting metabolic rate measurements were obtained by 61 of the 93 (66%) NGHS and PLRS participants. The Withings scale that provided weight, body composition, and PWV was more difficult to use but 113 out of 134 (84%) participants provided at least one reading of weight, 109 (81%) provided at least one body composition reading, and 84 (63%) recorded a PWV. Physical activity (steps) and sleep quality and quantity were assessed in 113 out of 134 (84%) participants and oxygen saturation in 106 (79%) participants using the Garmin watch. The AimStrip device to measure total cholesterol resulted in the most calls to the research team and only 32 out of 134 (24%) participants completed all readings. At least one cholesterol result was provided by 72 out of 134 (54%)participants.

Participants were asked whether they preferred home or in-clinic assessment. Of the 95 who responded to this question, 38 (40%) preferred home assessment, 36 (38%) clinic and 21 (22%) did not have a preference. The mean user acceptability score (Table 3) across devices for ease of use was 4.3 (SD 1.0), for instructions was 4.5 (SD 0.7) and for time to use was 3.9 (SD 1.1). The Garmin, Qardio, and Kardia had the highest overall scores (4.7, SD 0.6; 4.6, SD 0.6; and 4.6, SD 0.7) followed by the Withings (4.2, SD 0.9), Breezing and HealthWatch 360 app (4.0, SD 0.7, and 3.9, SD 0.9), with the AimStrip achieving the lowest overall acceptability (3.6, SD 1.2). Greater success with a device was generally not correlated with higher acceptability ratings. This analysis was limited by the fact that participants completing few or no readings were less likely to complete the acceptability survey.

XSL•FO
RenderX

Table . Mean user acceptability score stratified by device.

Responses (n=100)	Withings	Breezing	Kardia	Qardio	Aim strip	HealthWatch 360	Garmin
Was this device or app easy to use?	4.1 (1.1)	4.1 (0.9)	4.6 (0.9)	4.7 (0.6)	3.6 (1.4)	4.0 (1.1)	4.7 (0.7)
Were the instructions for this device easy to follow?	4.4 (0.8)	4.5 (0.6)	4.8 (0.5)	4.8 (0.5)	4.1 (1.2)	4.5 (0.9)	4.8 (0.6)
How do you feel about the time it took to use the device/app?	3.9 (1.3)	3.4 (1.0)	4.4 (1.1)	4.3 (1.0)	3.2 (1.3)	3.4 (1.3)	4.6 (0.9)
Overall Acceptability Score (mean rating for the 3 factors assessed)	4.2 (0.9)	4.0 (0.7)	4.6 (0.7)	4.6 (0.6)	3.6 (1.2)	3.9 (0.9)	4.7 (0.6)

Discussion

Principal Findings

Our study demonstrated that, with careful implementation, collecting at-home biometric measures is feasible and generally acceptable to participants in a longitudinal study. Recently, attention has focused on the use of wearable technology and internet-based applications to capture data that otherwise could only be captured in the clinic. Although some technology, such as accelerometers, have been in use for years [9], there is increasing opportunity to use commercially-available wearable technology and other send-out or mail-back methods to collect epidemiologic data and biospecimens in lieu of clinic visits, even for measurements that have historically been exclusively conducted by medical personnel. However, there remains a considerable gap in knowledge about whether such devices are simple enough to facilitate the collection of valid research-quality data at home and whether these devices are acceptable in terms of ease of use and time commitment for participants participating in mHealth research studies. If these commercially available devices are feasible to use and acceptable to participants, the use of such technologies in extending the reach of epidemiologic studies to widely dispersed populations could revolutionize the field, reduce place-based follow-up bias, and improve the extent of measured data available in follow-up studies.

Our study found 122 out of our 134 (91%) participants performed at least one of the home tests thus demonstrating feasibility. Furthermore, return of biospecimens was highly successful. Home data collection was also highly acceptable with a mean user acceptability score across devices for ease of use of 4.3 out of 5. Interestingly, only 38 out of 95 (40%) participants assessed preferred a home assessment and 36 (38%) preferred in-clinic testing.

There were multiple general implementation issues identified, the majority of which arose because the devices or apps were developed for a single person's use, while this study required devices to be set up for multiple participants serially over the course of the study. The requirement for a unique email address for many devices, for example, quickly became an issue in this context, as individual participant data needed to be kept separate, but creation of an email address for each participant was not feasible. Device- or app-specific rules about creation or deletion of accounts required detailed protocols for study management. Similarly, data from many of the devices was primarily developed to be viewed in an app or portal by the individual using the device, rather than being exported and used in analyses. Thus, the processes for retrieving the data, and the formats available for the data exports, differed not only across but also within devices, creating complicated data management workflows. While work-arounds were developed to overcome nearly all of the issues, the burden on the study team was higher than for standard clinic measurements.

In terms of the specific devices we tested, our study is the first to date to demonstrate the feasibility and acceptability of the Withings scale to measure body composition in the home. This study also evaluated use of the Breezing in the home setting. All participants repeated the Breezing testing multiple times, and none reported complaints or issues; however, the sample size was small (n=20) and many did occasionally forget to perform the test in the fasting state. The present study did not ask whether participants were fasting for all tests, which would be a modification of study protocol in future studies. Another study evaluated the Breezing in the home in pregnant women [10]. They found 68% of participants performed all the requested readings, although 44% had technical issues [10]. User acceptability was modest with 56% reported they felt the device was enjoyable or had neutral feelings about it, while 44% reported it was not enjoyable [10]. We had higher completion rates and user acceptability but our population was not experiencing any pregnancy-related issues.

There are many studies validating apps to detect arrythmias such as the Kardia [11-14]; however, none of these studies provided user acceptability data. In a study using a different device to detect atrial fibrillation [15], adherence to the study

XSL•FO
RenderX

protocol (daily use for a year) was only 44%. Age, severity of symptoms, and BMI influenced adherence but no user acceptability data was provided [15].

There has been a rapid increase in commercially available direct-to-consumer home BP devices of which many, including the Qardio monitor used in this study, have undergone validation studies [16]. No data on acceptability has been published previously. The situation with home oxygen saturation measurements is similar. The Garmin Vivosmart had excellent agreement with a pulse oximeter at rest and 30 seconds after a sit-to-stand and 6-minute walk test [17], but no user acceptability data was provided and the device was not tested in the home. For more complicated hemodynamic measures such as PWV, there are no other commercially available devices for the home besides the Withings [18], and no user-acceptability data has been previously collected.

There are also a variety of commercially available products to measure lifestyle habits such as sleep, physical activity, and diet. The device we used (Garmin Vivosmart 4) has limited published validation data [19], but no studies on user-acceptability data. A study that used a Fitbit for activity monitoring found that 80% of participants provided at least some data during the 3-week study [20]. A few studies have evaluated smartphone apps to track dietary consumption [21], but none have published user acceptability data.

A few studies have examined general participant acceptability of mHealth apps in general. Harmon et al [22] summarized many of the barriers to implementation. For instance, older participants may not have a smartphone or experience in mobile apps. Waning participation over time is also noted when much of the data collection requires active participation from study subjects. Similar to our study, one group found that more than one-third of participants did not wear the device during the study period [23]. Push notifications can assist in reducing this issue but if the device app does not have this feature, sending reminders can be labor intensive. Also, reporting abnormal results requires specific infrastructure and supervision [22]. One study specifically measured acceptability based on a design where a single or multiple devices were used [24]. Although the use of multiple devices gave participants greater interest in the study and more perceived benefit, they had lower confidence in completing the measurements [24]. However, that study was a survey about attitudes toward mHealth studies and did not actually evaluate any specific devices.

Although our sample size is smaller than most epidemiologic studies, it is still larger than many of the mHealth papers that include user acceptability data published to date. We also had a predominance of females, few minorities and the requirement for Wi-Fi access for the participant to complete the at home visit. Although digital literacy was not directly assessed, our sample likely represents a reasonable cross-section of technological proficiency. The most willing and engaged participants likely self-selected themselves for participation as this was a subset of the full cohort. Participants were given some familiarity with the Breezing device during their in-clinic visit, so participants may have felt more comfortable with this device at home than would be the case in a truly remote visit where the participants would only have the study materials provided.

Conclusion

Our study demonstrated that a virtual home clinic is reasonably feasible and acceptable for remote assessments in longitudinal studies. Challenges for mHealth projects include manufacturer changes to the user interface or data extraction protocols over time, research-specific concerns such as maintaining unique profiles and emails for device apps without requiring the participant to use their personal information, and IRB and institutional concerns about device and participant safety. In addition, over the course of a longer study, the devices themselves might become obsolete and/or no longer supported by the manufacturer. Despite encountered challenges, successful data collection and positive user feedback suggest the potential for revolutionizing epidemiologic studies, especially for widely dispersed populations, and reducing geographic follow-up bias.

Abstract

Background: Patient-reported outcome measures (PROMs) are tools for assessing symptoms and the quality of care. Despite their growing use, conventional data collection methods limit widespread PROM implementation. In orthopedics, pain is a frequent patient complaint and a common PROM, especially following total knee arthroplasty (TKA). Although TKA is generally successful, some patients still report postoperative pain, potentially due to tourniquet use. Using an improved PROM data-gathering technique may help to address tourniquet use during a TKA procedure and its impact on postoperative pain. The PainPad, an automated self-logging device, was developed to capture patient pain levels accurately.

Objective: The aim of the study is to assess the feasibility and effectiveness of the PainPad device in quantifying in-hospital postoperative pain following TKA with or without tourniquet use.

Methods: A retrospective study with 234 patients who underwent TKA from 2018 to 2021 at Milton Keynes University Hospital was conducted. Patients were categorized as receiving TKA with an intraoperative tourniquet (tourniquet group) or TKA without a tourniquet (nontourniquet group). Postoperative pain during the first 24 hours was self-reported every 2 hours using the PainPad device. From both groups, data on hospital length of stay, total tourniquet time, and the presence of postoperative deep vein thrombosis were also collected.

Results: There were 115 TKAs with tourniquets (72/115, 62.6% female patients; mean age 69.26, SD 9.93 years) and 119 TKAs without tourniquets (91/119, 76.4% female patients; mean age 70.97, SD 9.01 years). When assessing 24-hour mean postoperative pain scores, the PainPad device data indicated no significant difference (P=.53; 95% CI −0.76 to 0.39) between the tourniquet (mean pain score 3.31, SD 2.34) and nontourniquet groups (mean pain score 3.12, SD 2.15). There was no correlation between tourniquet times and the pain scores retrieved from the PainPad device. A subgroup analysis comparing longer (>90 minutes) versus shorter (<90 minutes) tourniquet times showed no significant difference in terms of pain and length of stay.

Conclusions: The PainPad device is a feasible and effective method for collecting and evaluating in-hospital postoperative pain following TKA, allowing for the quantification of individual pain levels. This study aligns with the current health care trend toward leveraging innovative technologies and personalized data to enhance patient-centered care.

Introduction

Patient-reported outcome measures (PROMs) are tools that have become increasingly used to systematically assess symptom progression, satisfaction, and the overall quality of care provided from the patient's perspective [1,2]. Originally designed for research purposes, incorporating PROMs into clinical care represents a transition toward a more evidence-based and patient-centered health care system [3]. Implementing PROMs enables patients to quantify their subjective experience and allows physicians to monitor symptoms and make informed treatment decisions when combined with other objective measures.

Among surgical specialties, PROMs have been most extensively administered in orthopedics [4]. Since April 2009, the National Health Service (NHS) mandated all publicly funded health care providers of inpatient departments to collect PROMs for certain elective procedures, including hip and knee arthroplasties [5]. Despite the increasing use and evidence supporting PROMs, widespread implementation still faces several challenges among orthopedic practices. The additional time, cost, and administrative burden along with the risks of low patient participation, data errors, and incorrect interpretation have been frequently cited as limitations in integrating PROMs into surgical practices [3,5,6]. These limitations may be attributed to the current inefficiencies of conventional paper-based data collection methods. As initiatives strive to sustain PROM use, innovative data collection technologies tailored to the complexities of surgical workflows will be needed to alleviate these logistic and administrative constraints.

Within orthopedic practices, in-hospital postoperative pain is a regularly assessed PROM following surgical interventions, as it is a frequently cited patient complaint [7,8]. While some PROMs can be objectively measured, pain is inherently subjective and difficult to accurately capture. Current methods, such as patient pain diaries, are often prone to inaccuracies due to illegible handwriting, incomplete data, and recall bias [9-11]. Additionally, distributing, collecting, and processing paper-based PROM methods require significant administrative efforts and costs [12]. The manual data handling and entry further increase the risk of transcription errors, compromising the reliability of the collected data. The physical forms of paper-based methods also require substantial storage space, which can limit the timely retrieval of patient data [12]. The emergence of electronic devices and platforms presents an alternative approach to collecting pain-related data. Evidence suggests that electronic data collection methods may be more accurate, provide greater compliance, and yield fewer errors compared to conventional methods [13,14].

Even with total knee arthroplasty (TKA) being one of the most successful orthopedic procedures, 20% of patients were unsatisfied due to their postoperative pain levels [15]. A potential cause for this pain may be due to tourniquet use during a TKA procedure; however, this topic remains controversial among orthopedic surgeons. However, by using an improved PROM data-gathering technique, it may help to address the conflicting topic of tourniquet use during a TKA procedure and its impact on postoperative pain.

The PainPad is a handheld automated self-logging device that was developed to capture patient pain levels [11]. While other electronic pain collection methods have focused on remote monitoring in outpatient settings, the PainPad device was designed for inpatient hospital use to provide instantaneous postsurgical pain evaluation [11]. Thus, to showcase the clinical utility and effectiveness of assessing postoperative pain, the purpose of this study was to use the PainPad device to determine if tourniquet use during TKA has a detrimental effect on postoperative pain levels in the context of a modern multimodal pain pathway and early mobilization.

Methods

Ethical Considerations

This research was approved under Integrated Research Application System (229503) and the Open University Human Research Ethics Committee (17/LO/1404). Informed consent was provided by participants, and data were deidentified.

Study Design and Patients

This retrospective cohort study was conducted at Milton Keynes University Hospital (MKUH), United Kingdom, and reviewed 234 patients who underwent TKA. Patients undergoing a primary unilateral TKA between 2018 and 2021 at MKUH were included in the study. Any patients undergoing revision TKA were excluded.

Surgical Procedure and Postoperative Care

All cases were performed by 7 arthroplasty consultants at MKUH, and all patients underwent the multimodal analgesia program protocol for their inpatient rehabilitation. This modern multimodal analgesia protocol was specifically designed to enhance the recovery process, decrease the amount and frequency of opioid use, and reduce the length of stay (LOS) [16]. All patients were assessed preoperatively by the physiotherapy team to collect PROMs and range of movement.

Patients were categorized as receiving TKA with an intraoperative tourniquet (tourniquet group) or TKA without a tourniquet (nontourniquet group). For patients receiving the tourniquet, a conical tourniquet (85 cm long×8.5 cm wide) was inflated to 300 mm Hg and kept inflated from the beginning of the operation to the end of the procedure. This duration was considered the tourniquet time. Aside from tourniquet use, all TKAs were performed through the same standard surgical approach, and all patients received the same postoperative rehabilitation protocol.

The PainPad Device

Patients reported their postoperative pain levels using an automated self-logging device named "PainPad" (Figure 1). A previous study has outlined PainPad's design process and user testing with patients and hospital staff [11]. The handheld PainPad device (9.5×6.5×3 cm) consists of a large keypad allowing patients to rate their pain on a scale of 0 - 10 (0=no pain and 10=worst pain imaginable), mimicking the visual

XSL•FO
RenderX

analog scale (VAS). Patients were shown how to enter their pain level using the PainPad device. The physical box-like design of the PainPad allowed for easy and quick disinfectant and sanitary practices by hospital personnel. The PainPad device consists of 2 LEDs and a beeper to notify patients to enter their pain score every 2 hours to ensure compliance with pain logging [11]. These pain scores were then linked to the patient via their unique identifier. The combination of PainPad's pain database and the nurse's entered pain scores on the electronic patient record was combined to gain a maximal number of pain scores for each inpatient episode for analysis.

Figure 1. The PainPad device (9.5×6.5×3 cm) is a 3D-printed rectilinear box made of acrylonitrile butadiene styrene (ABS) plastic. It features a red and green surface-mounted LED light on the internal circuit board, which projects through light tubes on the surface, and a 3×4 membrane keypad recessed into the front face. Beneath the ABS shell is a 70-dB speaker that emits sounds prompting the user to self-report their pain level by pressing a button (0 - 10), which beeps when pressed. The device also plays distinct sounds to signal success or failure when clinicians assign it to a patient.

Outcome Measures

The primary outcome of this study was the self-reported 24-hour postoperative pain scores (mean, maximum, and minimum) on the PainPad device in both tourniquet and nontourniquet groups. Secondary outcomes included measuring hospital LOS, total tourniquet time, and the presence of postoperative deep vein

XSL•FO
RenderX

thrombosis (DVT) between both tourniquet and nontourniquet groups.

Statistical Analysis

Descriptive statistics were used to analyze patient demographics and general trends in outcome measures. Two-tailed *t* tests were used to determine the differences in patient demographics, 24-hour postoperative pain scores from the PainPad device, and hospital LOS between tourniquet and nontourniquet patients. Additionally, 2-tailed *t* tests were used to assess PainPad pain data and hospital LOS between a subgroup of patients with longer (>90 minutes) or shorter (<90 minutes) tourniquet times. The Spearman rank correlation was used to compare the tourniquet time with PainPad pain scores and hospital LOS. For our statistical analysis, the 2-tailed *t* test was suitable in comparing 2 groups of patients (ie, with and without tourniquet), with a Spearman rank determining a correlation between tourniquet use and pain scores. Our data met the criteria for both the 2-tailed *t* test (independence of observations, approaching normal distribution, and homogeneity of variances assessed through the Levene test) and Spearman rank (monotonic, paired, and interval data). All statistical testing was conducted using the SPSS software (version 21; IBM Corp).

Results

A total of 234 consecutive patients who underwent TKA (n=163, 70% female patients) were included (mean age 69.26, SD 9.93 years) and 119 underwent TKA without a tourniquet (91/119, 76.4% female patients; mean age 70.97, SD 9.01 years). Regarding patient demographics, there was a significant difference in female sex (*P*=.02) favoring the nontourniquet group (Table 1). The median hospital LOS was 2 (IQR 1 - 18) days, and there was no significant difference in hospital LOS between the 2 groups (*P*=.22; 95% CI −0.24 to 1.04). From the cohort, only 1 of 234 patients experienced a DVT event, which was from the nontourniquet group.

Table . Characteristics of included patients who underwent total knee arthroplasty using the PainPad device in the nontourniquet group and tourniquet groups.

Patient characteristics	Nontourniquet (n=119)	Tourniquet (n=115)	*P* value
Sex, n (%)			.02
Male	28 (23.5)	43 (37.3)	
Female	91 (76.4)	72 (62.6)	
Age (years), mean (SD)	70.97 (9.01)	69.26 (9.93)	.17

The PainPad device was used to assess patient-reported postoperative pain between the 2 groups. When assessing 24-hour mean postoperative pain scores, the PainPad device data indicated that there was no significant difference between the tourniquet (mean pain score 3.31, SD 2.34) and nontourniquet group (mean pain score 3.12, SD 2.15; *P*=.53; 95% CI −0.76 to 0.39). The PainPad device data further suggested no significant difference in the maximum pain score 24 hours postoperatively between the tourniquet (mean maximum pain score 6.34, SD 2.81) and nontourniquet group (mean maximum pain score 6.12, SD 2.87; *P*=.55; 95% CI −0.95 to 0.51). There was also no significant difference in the minimum pain score 24 hours postoperatively between the tourniquet (mean minimum pain score 0.66, SD 1.72) and nontourniquet (mean minimum pain score 1.03, SD 2.22; *P*=.15; 95% CI −0.89 to 0.13).

Tourniquet time was recorded from 110 of 115 patients with a median time of 73 (IQR 19 - 120) minutes. There was no correlation between tourniquet time and hospital LOS (Spearman ρ=−0.09; *P*=.38). When correlating tourniquet time with 24-hour postoperative pain scores retrieved from the PainPad device, there were no correlations for the mean (Spearman ρ=−0.01; *P*=.90), maximum (Spearman ρ=−0.18; *P*=.07), and minimum pain scores (Spearman ρ=0.12; *P*=.20). In correlating the VAS with 24-hour postoperative mean pain scores, there was a very low correlation (*r*=0.139) and an extremely low correlation with maximum pain score 24 hours postoperatively (*r*=0.078). This indicates that preoperative and postoperative pain were not correlated. A subgroup analysis of patients with longer tourniquet times (>90 minutes) and shorter tourniquet times (<90 minutes) was also evaluated. From this, there were no significant differences between longer and shorter tourniquet times in terms of hospital LOS and self-reported pain data as collected from the PainPad device (Table 2).

Table . Comparison of recorded PainPad postoperative pain levels and hospital length of stay (LOS) between long duration (>90 minutes) and short duration (<90 minutes) tourniquet groups.

Outcomes	Long duration tourniquet (n=91), mean (SD)	Short duration tourniquet (n=19), mean (SD)	*P* value	95% CI
Minimum pain	0.86 (2.01)	2.16 (3.04)	.09	−2.81 to 0.21
Maximum pain	6.29 (2.87)	6.37 (2.79)	.91	−1.54 to 1.37
Mean pain	3.14 (2.23)	4.00 (2.86)	.23	−2.30 to 0.58
Hospital LOS (days)	2.74 (2.49)	2.53 (1.81)	.67	−0.49 to 1.21

Discussion

Principal Findings

PROMs represent a standardized method for monitoring patient symptoms. The value of monitoring patients' self-reported pain levels during the first hours in the postoperative period is essential to ensure optimal analgesia and patient satisfaction [17,18]. This study provides evidence that the PainPad, an automated self-logging PROM device, is feasible in collecting pain levels after a major orthopedic surgical intervention. Since our institution uses a modern multimodal analgesia protocol to enhance the recovery process and limit the use of postoperative opioids, the PainPad device provided surgeons with real-time pain analytics within the 24-hour postoperative period to ensure that appropriate analgesia and prompt intervention were administered.

PROMs have become increasingly important in the context of orthopedics, as many surgical interventions aim to improve subjective patient outcomes such as pain. Incorporating PROMs, such as pain logging, into routine care can harness critical patient information to improve clinical decision-making and overall support patient-centered care. Generally, self-reported pain logging in an outpatient clinic setting is completed by paper-based methods in the form of questionnaires, forms, or patient diaries [10]. In contrast, during an inpatient hospital stay, nursing staff typically collect pain levels at regular intervals through monitoring or by having patients complete a numerical pain rating scale [19-21]. However, these methods are often time-consuming and impose additional burdens on clinical staff [11]. In some instances, staffing limitations can sometimes prevent sufficiently frequent pain log entries [11]. Additionally, studies have indicated that pain levels recorded by nursing staff are often incomplete and potentially inaccurate, as patients may feel reluctant to fully express their pain [20,22]. Orthopedic surgeons have also expressed various logistical and technical challenges in collecting pain levels and other PROMs. For instance, surgeons indicated that the additional administrative tasks involved in data collection and the prevalence of missing data along with poor visual display and the complexity of completing PROMs hindered their ability to administer PROMs to their patients [6]. Collectively, these limitations of conventional paper-based methods coupled with the earlier-mentioned barriers further emphasize the need for innovative technologies to seamlessly integrate self-logging of pain and PROMs.

Currently, the NHS PROM program administers paper-based collection methods, incurring an annual cost of US $1.1 million [23]. However, as the NHS transitions toward a paperless system and the PROM program expands, innovative technologies will be required to reduce costs and streamline data administration [24]. Studies have shown that electronic patient-reported outcome measure (ePROM) tools and devices are equivalent to their original paper-based counterpart [25,26]. With regard to paper-based methods, poor response rate is a limiting factor in assessing PROMs [27,28]. Yet, administrating ePROM tools has been shown to circumvent poor response rates, as automation permits outcomes to be collected at the scheduled intervals. Gurland et al [29] showed that administering ePROMs on a tablet to 103 patients who are undergoing surgery resulted in a 96% response rate in comparison to 25% with a paper-based collection method. Furthermore, ePROMs have the potential to enhance patient-physician communication by offering real-time pain tracking and avoiding possible recall bias [30]. The practicality of ePROM modalities, along with their advantages of automated data capture, lower long-term costs, faster completion times, and reduced administrative errors [12], demonstrates the potential role of ePROM tools within the NHS to ensure widespread data capturing.

Most self-logging pain and ePROM technologies are designed for remote or at-home monitoring. In contrast, the PainPad was developed as an automated device to enable patients to provide their pain ratings during their hospital stay. Previous research with the PainPad showed that it improved the frequency and compliance of self-reported pain logging among inpatients recovering from ambulatory orthopedic surgery compared to pain scores reported by nursing staff [11]. The PainPad offers a convenient user experience for both patients and staff. It was designed with patient feedback, ensuring an easy-to-use interface. In one study, authors noted that 29% of patients had difficulties completing the paper-based VAS form due to visual impairment and physical restriction [31].

The PainPad device has several advantages over other pain assessment methods in a hospital setting. Paper-based or verbal pain assessments can be limited by patient fatigue, cognitive impairment, and verbal communication difficulties and often require manual transcription that could lead to errors [32,33]. Mobile apps and tablets often require patients to navigate various user interfaces and provide typed or touched responses on a touchscreen that may be difficult for older patients, those with dexterity issues, or those experiencing severe postsurgical pain [34]. Other mobile apps such as the PainChek app use facial expressions for pain assessment; however, these tend to be used in long-term care settings for patients with moderate to severe dementia. Unlike other ePROM methods, the lightweight PainPad features larger buttons that make it accessible for those with mobility or vision issues, and the visual cues it provides minimize response errors and ensure accurate data capture. Additionally, the physical device allows patients who are unable to verbalize their pain to report it accurately. Incorporating tactile, auditory, and visual senses into the device is believed to minimize typical patient errors associated with paper-based or single-dimensional methods, thereby providing a more standardized assessment of individualized pain levels. This user-friendly interface minimizes the risk of noncompliance while ensuring immediate, real-time accurate pain logging, making it more suitable for hospital settings where rapid pain assessment is critical. Given the importance of hospital infection control, the device was designed for easy disinfection within the hospital environment and to seamlessly integrate into clinical workflows [11]. However, a drawback of the PainPad is that it has not been assessed in postsurgical pediatric patients, where adaptations may be required.

In our study, most were female participants, and research has shown that pain perception differs between sexes. Female participants often experience higher pain sensitivity and report

XSL•FO
RenderX

higher postoperative pain scores compared to male participants following TKA [35]. Additionally, patient age may also influence pain perception, as aging reduces pain sensitivity for lower pain intensities [36]. These sex and age-based differences in pain perception may influence how patients interact with and report pain using the PainPad device. Given these differences in pain perception, it is ideal for patients to self-report their pain at its most intense moments using accessible and patient-friendly tools. Prior research suggests that older patients might prefer alternative methods for self-logging their PROMs or struggle with handheld technologies [12,37,38]. Research has shown that younger patients have a greater preference for ePROM methods [12,38-40]. However, the mean age in our study was 69.2 years, indicating that older patients can effectively use this device. When comparing the PainPad interface to 2 tablet-based alternatives, older adults preferred the tangible PainPad interface for reporting their pain in the hospital setting [11].

In this study, we compared tourniquet use in TKA to showcase the clinical utility and feasibility of the PainPad device in collecting pain levels. Using tourniquets in TKA remains a topic of considerable debate. Some orthopedic surgeons advocate for their use, citing advantages such as improved surgical field visualization, enhanced cementation through increased interdigitation, reduced intraoperative blood loss, and shorter operative times [41]. On the other hand, studies have indicated a slightly elevated risk of DVT, quadriceps weakness, nerve injury, decreased range of movement, higher transfusion rate, longer LOS, and increased postoperative pain [42-49].

Our results suggest that the use of a tourniquet during TKA procedures has no impact on the postoperative VAS score in the context of a modern multimodal pain pathway with early mobilization. Furthermore, there was no significant difference between patients with a tourniquet for <90 minutes and those with a tourniquet for >90 minutes with regard to postoperative pain and hospital LOS. These findings contrast previous reports that demonstrated increased pain among patients who underwent TKA with a tourniquet [50,51]. However, this can be attributed to the predate use of modern multimodal analgesia protocols and early mobilization pathways, which aim to reduce postoperative pain levels and hospital LOS, increase patient mobility, and limit opioid analgesia use [52]. Moreover, the absence of precise PROM data collection methods may have impeded and further exacerbated the true efficacy of this technique. By providing patients with the self-logging PainPad device, we were able to gather sufficient data to demonstrate that tourniquet use is associated with positive patient outcomes, including effective pain management. By making a digital self-logging of PROMs more accessible, we suggest that better evidence will be available to improve other surgical and clinical procedures.

Limitations

There are limitations to this study that need to be considered. First, this was a retrospective study in a single academic center with 234 patients who underwent TKA, which limits the generalizability of our findings. The retrospective nature of our study may have also potentially introduced inherent selection, recall, and ascertainment biases, as the patient inclusion was based on available data from our institution's database. However, since the PainPad device collects pain scores in an instantaneous manner, this would ideally limit recall bias. Furthermore, our statistical analysis indicated no significant differences in major baseline confounding variables between groups.

Second, patient comorbidities and preoperative pain data were not collected, which may influence postoperative pain levels. Third, TKA procedures were completed by 7 orthopedic consultants, which may contribute to discrepancies in operative technique. However, all surgeons followed the same postoperative pain management protocol. Finally, this study only assessed 24-hour postoperative pain; however, within the 24 hours, there were multiple self-reported pain entries from patients (ie, completed bihourly) using the PainPad device. Further, large-scale studies that include various acute and chronic patient populations with diverse demographics (ie, pediatric patients) along with appropriate control groups will help ensure the generalizability of the results. Additionally, it will be important to directly evaluate the cost-effectiveness of using the PainPad device in a clinical setting.

Conclusions

The PainPad device is a feasible and effective method for collecting and evaluating in-hospital postoperative pain following TKA, allowing for precise quantification of individual pain levels. This study aligns with the current health care trend toward leveraging innovative technologies and personalized data to enhance patient-centered care.

Conflicts of Interest

OP and BP hold a patent on the PainPad device used for data collection. Neither OP nor BP have received compensation in any form for the use of the device in this study or any other setting. DG is an associate editor for *JMIR Human Factors* at the time of this publication.

Abstract

Background: A guideline-based clinical decision support system (CDSS) is a knowledge-based system designed to collect crucial data from electronic medical records to generate decision-making based on system data requirements and inputs from standard guidelines. Despite the potential to enhance health care delivery, the adoption rate of CDSSs in clinical practice remains suboptimal.

Objective: This study aimed to evaluate the determinants influencing the intention to use a new CDSS in preventive care within clinical practice.

Methods: A single-center, questionnaire-based, cross-sectional study was conducted among physicians and medical students responsible for providing comprehensive preventive services at the Continuity of Care Clinic, Siriraj Hospital, Thailand.

Results: In total, 89 participants were enrolled. Relationships between factors impacting the adoption of CDSSs were analyzed using correlation and regression analysis. We found that physicians' intentions to adopt the CDSS for preventive care were high, with 79% (70/89) of participants expressing their intention to use the system. According to the study's conceptual framework, modified from the original unified theory of acceptance and use of technology model, physicians' positive attitudes toward CDSS use in preventive services and a high level of effort expectancy emerged as crucial factors influencing the intention to use the new CDSS. The odds ratios for these factors were 5.44 (95% CI 1.62 - 18.34, *P*=.006) and 7.60 (95% CI 1.55 - 31.37, *P*=.01), respectively. Similar results were observed for medical students and for physicians who had graduated. The most prevalent barriers to CDSS implementation were related to physicians' attitudes, followed by issues such as the accuracy and burden of data input, time constraints for clinicians, and the risk of workflow disruption.

Conclusions: There was a high intention to adopt the CDSS in preventive care. Positive physician attitudes toward CDSS use in preventive services and effort expectancy were found to be critical factors influencing the intention to use the new CDSS.

KEYWORDS

clinical decision support systems; preventive health services; medical informatics; technology acceptance; continuity of patient care

Introduction

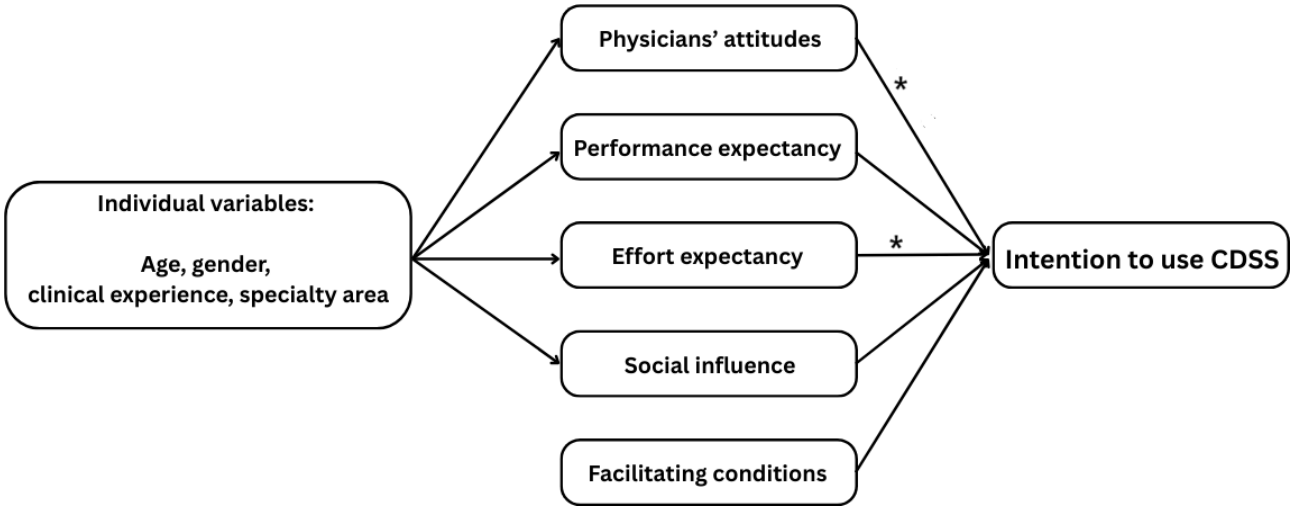
Background

In contemporary medical practice, evidence-based guidelines play a crucial role in integrating the best available evidence from various studies. These guidelines serve to support and guide physicians in making informed decisions regarding further investigation and treatment, ultimately improving the quality of care. Preventive care, among other areas, has numerous guidelines from various professional societies, recommending vaccinations and screening for diseases such as cardiometabolic diseases, cancer, and dementia. However, previous studies have revealed that clinical practice guidelines are not made full use

XSL•FO
RenderX

of in real-world clinical settings [1,2]. Barriers to implementing these guidelines include a lack of a comprehensible structure and local applicability, complexity in recommended clinical actions, a lack of awareness among physicians, insufficient time for recommended preventive services, a lack of awareness among patients, and financial constraints [2-5]. To improve the implementation of standard guidelines, clinicians value a user-friendly format, clear and valid evidence, details about competency and training requirements, and guidance on how to integrate experience with evidence when tailoring recommendations to individual patients.

The advent of information technology (IT) has had a major impact on the health care sector, with 1 notable advance in clinical practice being clinical decision support systems (CDSSs). CDSSs have been defined as systems "designed to aid directly in clinical decision making, in which characteristics of individual patients are used to generate patient-specific assessments or recommendations that are then presented to clinicians for consideration" [6]. CDSSs can range in complexity, from simple alerts and reminders to diagnostic assistance, therapy planning, and prescription decision support. A guideline-based CDSS is a knowledge-based system that collects crucial data from electronic medical records (EMRs), matches these data with the system's data requirements, and generates reasoning and decision-making based on input from established guidelines. This type of CDSS is considered a mid-level CDSS. Using a guideline-based CDSS can help to overcome obstacles associated with using traditional paper-based guidelines and enhance physicians' adherence to recommendations [6-8].



Literature Review

Despite increasing evidence for the benefits of guideline-based CDSSs, their adoption among outpatient physicians remains limited [9-11]. The challenges encountered during CDSS implementation stem from human factors related to system use, information quality, availability of EMR implementation, system quality, and system maintenance [11,12]. The main barriers to the implementation of mid-level CDSSs in low- and middle-income countries are inefficient CDSS-EMR system design, perception of use by physicians, and the cost of CDSS acquisition and maintenance. Additional barriers include negative beliefs about the impact of CDSSs on the clinician-patient relationship and physicians' reluctance to adopt these systems [13-15]. To investigate the successful adoption and acceptance of CDSSs, a comprehensive understanding of the interactions between human, technological, and organizational factors is crucial. Although numerous models exist for evaluating IT acceptance and use, in this study, we used the Unified Theory of Acceptance and Use of Technology (UTAUT). The UTAUT is formulated based on 4 core determinants of intentions and usage—performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC). It also includes 4 moderators of key relationships with technology—gender, age, experience, and voluntariness of use. The UTAUT model distills the critical factors and contingencies related to predicting behavioral intention to use technology, particularly technology used primarily in organizational contexts. There are a lot of theories that underlie the UTAUT model, including the diffusion of innovation theory, the theory of reasoned action, the theory of planned behavior, the motivation theory, the technology acceptance model, the personal computer utilization model, and the social cognitive theory [16].

A meta-analysis found that the 4 primary constructs of the UTAUT model exhibit varying degrees of predictive power, with PE emerging as the strongest predictor of intention to use a new technology [17]. Previous studies have confirmed the validity of the UTAUT model in health care settings and for CDSSs, with 1 study conducted in Thailand [18-21]. Furthermore, weak positive associations have been observed between the intention to use IT and reported IT use in low- and middle-income countries, while a negative relationship has been noted between the perception of a threat to professional autonomy and the intention to adopt CDSSs [14,15]. In this study, we developed a conceptual framework based on the UTAUT model, aiming to provide a comprehensive understanding of the adoption of guideline-based CDSSs in preventive care within the health care system of an upper middle-income country. The conceptual framework encompassed two key components: (1) physicians' attitudes toward CDSS usage, which are positively influenced by the perceived importance of preventive services, the belief that CDSSs will enhance the quality of care by improving adherence to clinical practice guidelines, and physician involvement in the CDSS development process, but negatively affected by perceived threats to professional autonomy; and (2) factors associated with CDSS PE, EE, SI, and FC, that is, the 4 factors that arise from the UTAUT model. The conceptual framework is illustrated in Figure 1.

XSL•FO
RenderX

Figure 1. Conceptual framework used in this study * indicates a significant association at the 95% level of intention to use the CDSS. CDSS: clinical decision support system.

The objective of this study was to assess user acceptance of guideline-based CDSSs in preventive care within clinical practice using the expanded UTAUT model and evaluate the readiness of medical staff and students to use this system in the Continuity of Care Clinic at Siriraj Hospital, Thailand.

Methods

Study Design and Participants

This study had a single-center, questionnaire-based, cross-sectional design. The participants comprised physicians and medical students who provided comprehensive preventive services at the Continuity of Care Clinic, Department of Medicine, Siriraj Hospital, between 2018 and 2021. The clinic primarily focuses on delivering ongoing care to adult patients with chronic noncommunicable diseases, aligning with the most up-to-date guidelines while promoting preventive measures such as screening for newly developed cardiometabolic diseases, cancer screening, counseling for individuals who engage in risky health behaviors, and appropriate vaccinations.

The sample size was determined based on an appropriate percentage of the finite population. The target population comprised 16 experts, 200 in-training physicians, and 300 medical students. Our primary aim was to survey a minimum of 15% of the target population, which would require a total of 75 participants to provide a sufficiently representative sample. To ensure the inclusion of individuals with valuable expertise, we planned to recruit all ambulatory medicine experts who served as permanent physicians at the Continuity of Care Clinic. This approach was intended to maximize the breadth of knowledge represented in our study, recognizing the importance of these experts' contributions within the broader target population.

Data Collection

Data collection was conducted using a newly developed online questionnaire, created in Google Forms, to assess user acceptance and examine the factors influencing the adoption into clinical practice of guideline-based CDSSs in preventive care. The questionnaire was pretested among a small group of physicians to ensure clarity and technical functionality. Minor revisions were made based on their feedback.

The first page of the Google Form presented participants with detailed information about the study, including its purpose, modes of contact, and data confidentiality, as well as the fact that participation was voluntary. Participants were recruited via institutional email, targeted LINE (LY Corporation; messaging app) groups, and in-person invitations. The inclusion criteria were medical students and physicians who had experience working in the Continuity of Care Clinic between 2018 and 2021 and who were currently working at Siriraj Hospital. Each participant could only respond once, and submission was allowed only after all mandatory fields had been completed. No IP addresses, email addresses, or other identifying information were collected.

Ethical Considerations

The research protocol received approval from the Mahidol University Multi-faculty Cooperative Institutional Review Board (protocol TMEC21-052, MU-MOU CoA 608/2021). Informed consent to participate was obtained electronically by requiring participants to click "Next" before they proceeded to the questionnaire. All responses were stored securely in a password-protected institutional Google Drive account, accessible only by the research team.

Routine Workflow for Preventive Services in the Continuity of Care Clinic at Siriraj Hospital

Outpatient services at Siriraj Hospital operate using a hybrid EMR system, in which medical records and prescriptions are initially handwritten on paper and subsequently scanned into an EMR for archival and review purposes. Laboratory results, radiological study reports, and medication prescription data are managed through separate electronic systems within the laboratory, radiology, and pharmacy departments, respectively, and are made viewable through EMR-integrated plug-ins. This system includes a basic-level CDSS, which provides pop-up reminders for drug allergies, renal function, and high-alert medications such as warfarin. A CDSS that retrieves data directly from the EMR is not applicable in this system.

XSL•FO
RenderX

At the Continuity of Care Clinic, the primary focus is on maintaining continuity of care for patients with chronic noncommunicable diseases, while simultaneously promoting preventive services. Due to the limitations of the EMR system, paper-based guidance for preventive care is incorporated into clinical workflows. This approach aims to ensure the consistent delivery of preventive services to each patient, despite the rotation of different physicians.

Online Questionnaire

The questionnaire consisted of 22 items, including questions regarding demographic details and items related to physicians' attitudes, EE, PE, SI, and FC, formulated in accordance with the structured questions of the UTAUT model [16]. Questions pertaining to physicians' attitudes were derived from factors identified in previous studies as being influential on usage intentions [14,15,22]. Responses were recorded on a 5-point Likert scale ranging from "strongly agree" to "strongly disagree." Among these constructs, physicians' attitudes and EE had 1 item that was negatively worded. The questionnaire was initially developed in English and subsequently translated into Thai using the translation-back-translation method. Before completing the questionnaire, participants were asked to view a demonstration video outlining the functionality and use of the proposed CDSS.

Introductory Video for the Proposed CDSS

The study participants were introduced to the proposed CDSS through an informative online video. The video was expertly created by an ambulatory medicine specialist who possessed extensive expertise in integrating preventive care into clinical practice and was also highly familiar with the EMR system employed at the study site. This video provided participants with invaluable insights into the prevailing challenges within the workflow and offered a firsthand experience of the system's performance. The demonstration included a comprehensive overview of data entry methods, advanced data visualization capabilities, and personalized recommendations for preventive services. In addition, the video covered essential information concerning support services and regular maintenance of the clinical rules associated with these systems. A summary of the video narration and selected snapshots from the demonstration video are provided in Multimedia Appendix 1.

Statistical Analysis

Data were analyzed using the R programming language (R Core Team). The descriptive statistics are presented as mean, median, SD, minimum, and maximum. Logistic regression analysis was used to identify factors associated with the acceptance of guideline-based CDSSs in preventive care. The final model was selected through the application of forward and backward selection methods in multiple logistic regression analysis. The statistical significance of the final model was evaluated using the Wald test.

Results

Demographic Data

A total of 89 participants took part in this study. Their baseline characteristics are presented in Table 1. Among the participants, 45 (51%) were male. The median age of participants was 25 (range 22-64) years. The majority of participants (49/89, 55%) were medical students, with 28 participants (32%) in their fifth year and 21 participants (24%) in their sixth year. Furthermore, 40 participants (45%) were medical graduates with varying levels of experience; 4 (5%) were general practitioners, 11 (12%) had undergone training in an internal medicine residency program, and 25 (28%) were internal medicine specialists, including 16 individuals (18%) who specialized in ambulatory medicine. The medical graduate participants had clinical experience ranging from 2 to 40 (median 8) years.

Table . Demographic data of study participants.

Characteristic	Statistical value (N=89)
Age (years), median (range)	25 (22 - 64)
Sex (male), n (%)	45 (51)
Clinical experience, n (%)	
Medical student	49 (55)
Fifth year	28 (32)
Sixth year	21 (24)
Graduated physician	40 (45)
General practitioner	4 (5)
Internal medicine resident	11 (12)
Internal medicine specialist	9 (10)
Ambulatory medicine expert	16 (18)
Duration of medical doctors' professional practice (years), median (range)	8 (2-40)

XSL•FO
RenderX

User Acceptance Measures

After viewing the demonstration video of the proposed system, 70 participants (79%) expressed a definitive intention to use the system if it were available. However, 18 participants expressed reasonable concerns about its usage, while 1 participant refused outright to use the new system. Notably, there were no differences in the intention to use the proposed system based on the participants' baseline characteristics. Nevertheless, within the medical student group, it was observed that sixth-year medical students exhibited a higher comfort level with adopting the new system compared with their fifth-year counterparts, with acceptance rates of 95% and 68%, respectively.

The mean (SD) and median (range) scores for each question are presented in Table 2. The scoring system for each question had a maximum value of 5. For negative questions, appropriate score conversions were implemented before calculating the total score for each construct.

[g]Not applicable.

Factors Associated With Intention to Use the CDSS

The outcome from the logistic regression analysis is presented in Table 4. Physicians' positive attitudes toward preventive medicine and the integration of new technology into clinical practices were found to be significant factors associated with the adoption and use of the new CDSS, with adjusted odds ratios (OR) of 8.41 (95% CI 2.54 - 27.82). The EE was also associated with the intention to adopt the CDSS (adjusted OR 11.71, 95% CI 2.45 - 55.95). However, PE, SI, and FC did not reach statistical significance in their association with the adoption of the proposed system. In addition, individual factors, such as age, sex, clinical experience, and duration of clinical practice, did not appear to influence the likelihood of adopting the proposed CDSS.

[a]OR: odds ratio.

[b]Adjusted by age and clinical experience group because the result from the univariable analysis showed a *P* value <.20.

[c]Where values lower than the mean of the total score were treated as baseline, that is, odds ratio=1.

[d]*P*<.001.

[e]*P*<.05.

[f]Not applicable.

[g]Where being male was treated as the baseline, that is, odds ratio=1.

[h]IM: internal medicine.

The final model consensus was established through the implementation of the forward selection and backward selection methods, using the Wald test. The integrated final model encompassed all determinants associated with the intention to adopt the CDSS, along with the demographic variables indicated in Table 4. The factors influencing the adoption and use of the proposed CDSS were identified as the physicians' attitudes (odds ratio 5.44, 95% CI 1.62 - 18.34, *P*=.006) and EE (OR 7.60, 95% CI 1.55 - 31.37, *P*=.01), visualized in the study's conceptual framework in Figure 1.

Subgroup analysis demonstrated that there were no significant differences in the logistic regression results between medical students and graduated physicians, as indicated in Multimedia Appendix 2. Nevertheless, it is important to highlight the notable factors associated with the intention to adopt the CDSS, which were identified as being physicians' attitudes and EE.

Benefits of and Barriers to CDSS Adoption in Clinical Practice

All study participants agreed that the proposed CDSS would bring benefits to their clinical practice. Specifically, 84 participants believed that the proposed system encompassed multiple components that would prove advantageous in their clinical practices. A summary of the participants' preferences and barriers to their adopting the CDSS is provided in Table 5.

XSL•FO
RenderX

Table . The benefits and barriers of the proposed clinical decision support system.

Benefits and barriers	Frequency, n (%)
Benefits of CDSS[a]	
Data gathering and data visualization	79 (89)
Provides supplementary information for recommended disease screening	70 (79)
Provides additional information regarding recommended vaccines	68 (76)
Individualized suggestions for further preventive services	61 (69)
Integration with the doctor's order sheet	50 (56)
Information to improve clinical decision-making	49 (55)
Provides flexibility in use, not mandatory for every patient	37 (42)
Barriers to CDSS adoption	
Other physicians usually take care of prevention services	6 (7)
The use of the CDSS would require them to allocate more time to each patient	5 (6)
Potential disruption of the current workflow with the implementation of the CDSS	4 (5)

[a]CDSS: clinical decision support system.

The majority of participants (70/89, 79%) reported having no concerns about implementing the new system in their clinical practice, while 19 participants raised concerns regarding the proposed CDSS. Among them, 4 participants had multiple concerns, while the rest expressed a single specific concern about the new system. The most prevalent barrier identified for the adoption of the new system was the participants' perception that they do not play a primary role in preventive services, which subsequently led to their decision not to use it.

Discussion

Principal Results and Comparison With Previous Work

This study suggests that a majority of medical professionals, including students and graduates, have a favorable attitude toward and intention to use a CDSS in their clinical practice. Factors, such as physicians' attitudes toward the use of CDSSs in preventive services and its perceived ease of use, play an important role in the adoption and use of the proposed system. The primary barrier to CDSS adoption arises from physician-related factors. If physicians are not actively involved in preventive services or do not prioritize them, they would be less likely to employ the proposed CDSS.

This study was undertaken to evaluate the acceptance of a new CDSS in preventive services. It was postulated that physicians differ from other users of IT due to the impact on their professional work of implementing an automated system that influences the comprehensiveness of their clinical management and adherence to clinical practice guidelines. However, physicians may perceive this disruption as a threat to their professionalism [23].

Our model indicates that a physician's attitude was one of the most influential factors determining their intention to use the new system. From the mean scores of each question included in this construct, we found that the highest score was for physicians recognizing the importance of disease prevention, which aligns with the primary function of the CDSS. The perception that the system can enhance the quality of health care delivery by promoting adherence to clinical practice guidelines ranked second. This finding is consistent with previous research emphasizing that physicians' decision to use IT relies on the usefulness and compatibility of any new technology with their clinical practice [24]. Physicians are more inclined to accept a system that they think will improve their performance. However, the perceived threat to professional autonomy, which has been identified as a significant deterrent to CDSS adoption among physicians [15,23], received the lowest mean score and exhibited the widest range of scores in this

XSL•FO
RenderX

construct. This suggests that participants had different concerns regarding the threat to their professional autonomy posed by the proposed CDSS. Nonetheless, most participants paid little attention to this factor, as evidenced by the median score of 4 out of 5. The level of clinical decision support provided by the CDSS can explain this discrepancy. In our study, the CDSS is intended to serve as a supportive tool for physicians' decision-making according to well-established clinical practice guidelines. The function of the proposed CDSS primarily involves clinical data gathering from EMR, data visualization, and recommendations for routine preventive services such as cancer screening and age-appropriate vaccination. These tasks do not rely heavily on individual clinical expertise, and the system allows physicians to make their own choices based on their experience and doctor-patient discussions. The low-to-medium level of clinical decision support provided by the CDSS may account for the limited concern expressed regarding the threat to professional autonomy in this study.

EE emerged as another influential factor determining the intention to use the new system. This finding is consistent with previous studies [15,20,21] and aligns with measures in the DeLone and McLean [25] information system success model that suggest ease of use is related to user satisfaction and adoption. The end user interface arrangement, which should be simple, user-friendly, and matched with a physician's thinking process, also constitutes a crucial factor contributing to system adoption [26].

The highest positive response on PE (mean score of 13.87 out of 15; 93%) reflected that participants expressed a strong belief in the system's potential usefulness. This is likely influenced by the demonstration video about the function and use of the proposed CDSS, which was made by an experienced clinician involved in preventive services at the study site to highlight how the system could address existing workflow gaps. Furthermore, the proposed CDSS has the potential to enhance physicians' performance, improve their effectiveness, and reduce the time spent on preventive services during patient encounters. The observed marginal positive relationship between PE and the intention to use the system (P=.05) was consistent with the expectation that perceived usefulness is a key determinant of adoption intention.

SI was not found to significantly affect the intention to use the CDSS in our study. This finding is consistent with previous literature suggesting that physicians differ from other groups of IT users, as they tend to prioritize a system's perceived usefulness over ease of use or peer influence within their organization [23]. However, this result may be attributable to the preimplementation context of our study, in which participants had no previous experience using the system and limited exposure to peer usage or established institutional norms surrounding its adoption.

Previous studies have indicated that SI may exert a greater effect, particularly among medical students, once a system has been actively implemented and its use becomes more visible within the learning or clinical environment [27]. Although our study was conducted during medical students' clinical clerkship phase, when decisions are likely shaped by clinical supervisors and perceived task relevance, peer and faculty endorsement may become increasingly influential as the CDSS becomes embedded in routine clinical workflows. Further research following system implementation is warranted to better understand the evolving role of social dynamics in CDSS adoption.

Subgroup analysis revealed that the factors influencing the intention to adopt the new CDSS did not differ significantly between medical students and physicians who had graduated. Correlation analysis indicated a significant positive correlation between physician's attitude, PE, EE, and intention to use the CDSS, consistent with several previous studies [15,20,21,28].

The rate of intention to adopt the proposed CDSS in this study was remarkably high (79%). No statistically significant differences were observed in the baseline characteristics of physicians related to the intention to adopt. However, there was a disparity in intention to adopt rates within the medical student group. Sixth-year medical students exhibited a higher comfort level with the new system compared with fifth-year medical students, with acceptance rates of 95% versus 68% (P=.04). These findings warrant further discussion. During medical education in Thailand, fifth-year medical students have had limited clinical exposure (less than 2 years) and are under the continuous supervision of medical staff. Consequently, they may not consider clinical judgment to be an integral part of their responsibilities. In contrast, sixth-year medical students engage in clinical clerkship, which distinguishes them from fifth-year medical students. Their mindset may differ, resulting in contrasting attitudes toward the benefits and usefulness of technology in their job, which could in turn influence their adoption rates. Furthermore, greater clinical exposure enables sixth-year medical students to recognize the substantial cognitive burden of being a general practitioner. They may perceive the system as being more valuable in alleviating their cognitive load than fifth-year medical students.

Qualitative analysis of free-text comments revealed that physicians regarded the system's ability to gather data from various sources in EMR and present these data in a recognizable and comprehensible format as the most beneficial aspect of the proposed CDSS. In addition, the system provides patient counseling information on preventive services, which was highly valued. These results align with those of previous studies, in that physicians perceive the benefit of CDSSs mainly in terms of accessibility to standardized information and the facilitation of patient discussion [19,21]. Automatic data gathering and visualization have also frequently been cited as favorable aspects of a CDSS [29]. These findings suggest that preventive services have relatively low priority in current clinical practice, primarily due to challenges in acquiring individual patient data and obtaining comprehensive information for patient counseling. A CDSS can effectively bridge this gap.

Regarding system performance, the results indicated that more than half of the study participants would prefer a single integrated system that incorporates a patient's history, laboratory results, vaccination records, and a linked appointment system. However, some physicians favored the use of the CDSS as an optional tool for each patient visit. This finding should be taken

XSL•FO
RenderX

into account during system design. An “add-on” system is perceived as being advantageous as it allows physicians to exercise their own choice. Nonetheless, this feature should be considered carefully, as it could pose a threat to system implementation due to low system usage [30].

Most study participants reported that they would use the proposed CDSS without any concerns. However, some participants expressed apprehension about adopting the CDSS. Regarding physician-related factors, physicians’ attitudes emerged as the primary barrier. As preventive services are not obligatory for all physicians, those who are not involved in such tasks or do not prioritize health promotion may be reluctant to use the proposed CDSS, as it could increase the time required for each patient visit and disrupt their routine workflow.

Regarding patient-related factors, the respondents expressed concerns about the accuracy of data input, as the system allows manual input of health maintenance data obtained elsewhere. Consequently, unverified data may lead to incorrect data being entered, which could subsequently impact the recommendations made during the use of the CDSS. This concern has been identified in previous studies with regard to information quality [31,32].

Finally, system-related factors were also identified as barriers to adoption. The burden of data input was the primary concern from this perspective. In addition, time constraints for clinicians and the potential disruption to workflow were considered important system design factors. These findings align with previous qualitative studies suggesting that a failure to balance the data input burden, the presentation of clinically relevant information, and integration into the workflow can negatively impact the adoption of CDSSs [29,30,33].

Study Implications

This study suggests that a carefully designed CDSS, featuring a simple, user-friendly interface, would be readily adopted by physicians. A potential application of this study is the development and implementation of the proposed CDSS described in the demonstration video. For successful implementation, several key factors should be considered, such as ensuring interoperability with existing EMR systems, developing a user-friendly interface, and integrating standardized security protocols. Streamlining data input and involving patients, while allowing physicians to verify and adjust data, may reduce the documentation burden.

Beyond system design, physician attitudes play a critical role in the adoption and use of a CDSS in the long term. Therefore, it is imperative to emphasize the incorporation of preventive services into the holistic care model during medical education, particularly in the context of chronic disease follow-up in ambulatory settings. In addition, long-term use of a CDSS requires institutional support, including ongoing training and effective change management strategies to facilitate integration into clinical practice.

Future Work

While this study demonstrates there would be a high rate of adoption of the proposed CDSS, some concerns remain among physicians, particularly regarding potential disruptions to clinical workflow, increased time spent per patient, and the burden of data input. Future qualitative studies will be important to guide the development of an improved system and to inform strategies for effective organizational implementation. In addition, addressing concerns regarding autonomy and emphasizing the role of CDSSs in supporting clinical decision-making may further encourage adoption. Long-term multicenter studies evaluating the system’s impact on clinical outcomes, as well as the perceptions of physicians and patients during clinical visits, would be valuable. In particular, these studies should explore how the use of a CDSS to guide clinical decision-making affects physician attitudes, patient trust, and the overall quality of the clinical encounter.

Strengths and Limitations

This study had several strengths. It represents the first evaluation of the intention of physicians to adopt a guideline-based CDSS in Thailand. A questionnaire was administered, incorporating determinants from the UTAUT model and factors identified to be salient in Southeast Asia, including physician attitudes toward new technology. Furthermore, a unique video was used to introduce the proposed system, featuring an experienced clinician demonstrating preventive services and addressing current workflow challenges. The video showcased the end user interface, data entry methods, CDSS performance, and integration with the existing EMR system, providing participants with an experience to aid their decision-making process.

However, the study also had some limitations. First, it was conducted at a single center, Thailand’s largest medical school hospital, potentially limiting the generalizability of our findings to other types of hospitals with differing EMR systems and limited IT support. Second, the inclusion of participants familiar with the continuity of care model incorporating preventive services resulted in a skewed-left distribution and wide CIs in the conceptual framework and logistic regression analysis.

Furthermore, this cross-sectional study examined preadopters of the CDSS, with self-reported constructs based on the demonstration video, impeding the determination of causal relationships. It is crucial to acknowledge potential differences in attitudes between preadopters and postadopters, limiting the generalizability of the study’s results to the early stages of CDSS implementation.

Challenges During the Research

This study was conducted during the COVID-19 pandemic, which posed several challenges. Hospital services for nonemergency cases were reduced by approximately 50%, and medical students transitioned to online learning. As a result, it was difficult to recruit study participants, particularly medical students, as they were not physically present at the clinic and were dispersed across various off-campus locations. Similarly, many graduated physicians were reassigned from the Continuity of Care Clinic to COVID-19 patient care duties. Furthermore, the closure of outpatient services greatly limited clinical exposure for medical students. Consequently, only approximately half of the fifth-year medical students had the opportunity to gain experience in providing comprehensive

XSL•FO
RenderX

preventive services at the Continuity of Care Clinic during the study period.

Conclusions

The use of CDSS in clinical management has the potential to enhance the quality of health care delivery. This study reveals a noteworthy inclination among physicians to embrace a guideline-based CDSS specifically tailored for preventive care. Furthermore, there were no significant differences in the intention to adopt the system based on diverse baseline characteristics of physicians.

Drawing upon the study's comprehensive conceptual framework, it was evident that positive physician attitudes toward incorporating CDSSs in preventive services, along with their perceived ease of use, emerged as the most pivotal determinants influencing the intention to use the novel CDSS. Conversely, factors such as PE, SI, and FC had minimal influence over the intention to adopt the proposed system. This study identified a range of common obstacles to the adoption of a CDSS, including physicians' attitudes, data input accuracy and burden, physicians' time constraints, and the potential disruption to existing workflow patterns.

Acknowledgments

The authors gratefully acknowledge all study participants who contributed their helpful and informative suggestions for the use of clinical decision support systems in preventive services. This research project was supported by the Master's Program in Biomedical and Health Informatics, Faculty of Tropical Medicine, Mahidol University, Thailand. WP is funded by Wellcome (grant 220211). Abstract

Background: Primary care providers (PCPs) face significant burnout due to increasing administrative and documentation demands, contributing to job dissatisfaction and impacting care quality. Artificial intelligence (AI) scribes have emerged as potential solutions to reduce administrative burden by automating clinical documentation of patient encounters. Although AI scribes are gaining popularity in primary care, there is limited information on their usability, effectiveness, and accuracy.

Objective: This study aimed to develop and apply an evaluation framework to systematically assess the usability, technical performance, and accuracy of various AI scribes used in primary care settings across Canada and the United States.

Methods: We conducted a systematic comparison of a suite of AI scribes using competitive analysis methods. An evaluation framework was developed using expert usability approaches and human factors engineering principles and comprises 3 domains: usability, effectiveness and technical performance, and accuracy and quality. Audio files from 4 standardized patient encounters were used to generate transcripts and SOAP (Subjective, Objective, Assessment, and Plan)–format medical notes from each AI scribe. A verbatim transcript, detailed case notes, and physician-written medical notes for each audio file served as a benchmark for comparison against the AI-generated outputs. Applicable items were rated on a 3-point Likert scale (1=poor, 2=good, 3=excellent). Additional insights were gathered from clinical experts, vendor questionnaires, and public resources to support usability, effectiveness, and quality findings.

Results: In total, 6 AI scribes were evaluated, with notable performance differences. Most AI scribes could be accessed via various platforms (n=4) and launched within common electronic medical records, though data exchange capabilities were limited. Nearly all AI scribes generated SOAP-format notes in approximately 1 minute for a 15-minute standardized encounter (n=5), though documentation time increased with encounter length and topic complexity. While all AI scribes produced good to excellent quality medical notes, none were consistently error-free. Common errors included deletion, omission, and SOAP structure errors. Factors such as extraneous conversations and multiple speakers impacted the accuracy of both the transcript and medical note, with some AI scribes producing excellent notes despite minor transcript issues and vice versa. Limitations in usability, technical performance, and accuracy suggest areas for improvement to fully realize AI scribes' potential in reducing administrative burden for PCPs.

Conclusions: This study offers one of the first systematic evaluations of the usability, effectiveness, and accuracy of a suite of AI scribes currently used in primary care, providing benchmark data for further research, policy, and practice. While AI scribes show promise in reducing documentation burdens, improvements and ongoing evaluations are essential to ensure safe and effective use. Future studies should assess AI scribe performance in real-world settings across diverse populations to support equitable and reliable applications.

KEYWORDS

artificial intelligence; AI; AI scribes; clinical documentation; administrative burden; primary care; competitive analysis; evaluation

Introduction

Overview

The majority of primary care providers (PCPs) in Canada and the United States report feelings of burnout, largely attributable to an increase in clinical documentation and administrative tasks [1,2], changes in practice patterns, and workforce shortages [3-5]. Since the widespread implementation of electronic medical records (EMRs) and evolving regulations and policies on medical documentation, PCPs, including family physicians and nurse practitioners, spend nearly half of their workday and an additional 40 hours per month completing administrative tasks after hours, such as clinical documentation of patient encounters and inbox management [6-10]. This increase in administrative burden has decreased provider satisfaction [2,10,11], impacted access to care as some providers have reduced clinical hours to manage administrative workload, and affected the patient-provider relationship [11,12]. Patient experience and satisfaction have also been impacted as PCPs have increasingly spent more time working in their EMR than on direct patient-facing care [12].

Advancements in artificial intelligence (AI) and machine learning have sparked interest in how automated processes can streamline and standardize clinical documentation in primary care. Several perspectives [13,14] and reviews [15,16] have described the need for AI scribes (also known as ambient scribes or digital scribes) to reduce administrative burden in primary care as well as other health care sectors. AI scribes use automatic speech recognition (ASR) and natural language processing (NLP) to record, transcribe, and automate clinical documentation. These tools are generally accessible via web browsers, mobile apps, or desktop applications, with some being integrated into EMRs while others function independently. The workflow typically involves clinicians activating the AI scribe during a patient encounter, where it listens and transcribes conversations and then generates a medical note thereafter. Some AI scribes also have capabilities to fill in billing codes or extract information to support diagnostic decision-making [17].

Several companies have developed AI scribes for use in primary care, promising to streamline workflows and reduce documentation time. However, there remain several concerns, including (1) the impact that AI scribes may have on the workflow of PCPs; (2) the effectiveness of these tools; and (3) the accuracy and quality of their outputs. To date, there are no evaluations that systematically compare the effectiveness of multiple AI scribes currently being used in primary care while also considering factors related to usability, technical performance, and accuracy [18-20]. In addition, given the risks primary care professionals and organizations may assume when adopting new technologies that potentially access, store, and retain personal health information (PHI), a thorough investigation of AI scribes currently being used in primary care is essential to ensure their safety and effectiveness.

Objective

The study aimed to develop and apply an evaluation framework to systematically compare the usability, effectiveness, technical performance, and accuracy and quality of various AI scribes used in primary care settings in Canada and the United States.

Methods

Study Design

We conducted a systematic comparison of AI scribes using competitive analysis methods in the Virtual Care Lab at Women's College Hospital (WCH) in Toronto, Ontario, Canada [21]. Competitive analysis methods are used to evaluate and compare the strengths, weaknesses, opportunities, and threats of competing products within a specific market to provide insights into market dynamics, identify gaps, and inform strategic decisions [22]. The analysis also incorporated expert usability approaches (eg, heuristic evaluation) and principles of human factors engineering [23-26]. Expert usability approaches enable the identification and examination of the current capabilities across several digital health tools to identify areas for improvement or features that are beneficial but may be missing [26]. Human factors engineering examines the interaction between systems, products, and their environment to enhance human performance, safety, and well-being [27]. Combining these methods enabled a comprehensive assessment and comparison of a suite of AI scribes while ensuring that the unique workflows of PCPs, their scope of work, and how they may be interacting with AI scribes within their clinical environments were considered.

The AI scribes included in this study were part of the Clinical Evaluation of Artificial Intelligence and Automation Technology to Reduce Administrative Burden in Primary Care project funded by the Ontario Ministry of Health through a Transfer Payment Agreement between Ontario Health and OntarioMD [28]. Only vendors who were compliant with Ontario's Personal Health Information Protection Act (PHIPA) and adhered to best practices in data privacy and security were selected for participation in the clinical evaluation. These practices included supporting PCPs in ensuring that PHI was collected, used, and disclosed for authorized purposes only; supporting PCPs in securing valid consent for using PHI; implementing stringent safeguards against unauthorized access of PHI; and managing PHI retention and disposal appropriately. Vendors were also required to store and process data within Canada or, if stored outside, to provide adequate notice to health information custodians to support regulatory compliance and notification obligations.

Evaluation Framework

Overview

Although there are instruments to assess physician note quality [29,30], a valid and reliable instrument that evaluates the usability, effectiveness, technical performance, and quality of

XSL•FO
RenderX

the medical notes generated by AI does not exist. We developed an evaluation framework that adapted existing tools related to the usability (eg, user control, flexibility and efficiency of use, aesthetic and design, and help and documentation) [24] and provider documentation quality (eg, comprehensiveness, organization, conciseness, and usefulness) [29-31]. The framework was also informed by medical documentation policies and guidelines developed by governing and regulatory bodies in Canada, including the College of Physicians and Surgeons of Ontario (CPSO) [32] and the Canadian Medical Protective Association (CMPA) [33].

The evaluation framework has 12 items grouped into 3 domains: usability, effectiveness and technical performance, and accuracy and quality (Multimedia Appendix 1). The framework includes both quantitative and qualitative measures to capture various features and functions of AI scribes. For applicable items, a 3-point Likert scale (1=poor, 2=good, 3=excellent) was used to streamline the evaluation process. Definitions for each measure and level of the Likert scale were predefined to ensure consistent application of the evaluation framework.

Usability

Usability refers to the efficiency and satisfaction with which users can complete tasks on a given interface or platform [34]. Key usability factors for health care technologies in health care literature include user-software interaction, task alignment, and navigation [35]. Incorporating these factors, the usability domain in our evaluation framework assessed user interface, EMR compatibility and integration, and process flow of the AI scribes. Compatibility and integration measured the level of integration with common EMR systems in primary care in Ontario, focusing on efficient data exchange, interoperability, and standardized format adherence. User interface refers to the accessibility of each AI scribe across platforms and the graphical and interactive features users interact with. Process flow measured the steps (ie, mouse clicks and keystrokes) and time needed to sign in and launch the AI scribe. All measurements of time were conducted by team members in the same location with a consistent internet connection. Timing was averaged over 3 trials for each AI scribe to account for minor variability and excluded time spent entering credentials or textual information. Both user interface and EMR compatibility were evaluated using the 3-point Likert scale (with 1 representing poor usability or EMR compatibility and 3 representing excellent usability and EMR compatibility).

Effectiveness and Technical Performance

To assess effectiveness, average documentation time was measured as the time required to generate a complete medical note following a standardized 15-minute clinical encounter. This was calculated as the amount of time elapsed from the moment the recording stopped to the time in which a finalized medical note was generated by the AI scribe, excluding any additional edits or review by a PCP. For each AI scribe, documentation time was averaged across 12 appointments (4 standardized encounters, each repeated in 3 trials).

Technical performance refers to the ability of an AI scribe to generate reliable transcripts and medical notes when challenged with complicating factors, such as interruptions, loud background noise, or multiple speakers. Secondary audio files were used to introduce these elements during standardized patient-PCP interactions. Background noises included nonverbal sounds such as typing, paper shuffling, and ambient office sounds, as well as conversational noises from nearby voices. Interruptions and third-party speakers included brief interjections or conversations from other voices, mimicking real-world scenarios where individuals may briefly speak or disrupt the main patient-PCP interaction or if a caregiver is present. Both the transcripts and medical notes generated by each of the AI scribes were evaluated against the 3-point Likert scale (1=poor performance, 2=good performance, 3=excellent performance). “Excellent” performance was defined as accurately attributing statements to the correct speaker, maintaining the logical flow of conversation, and minimizing omissions or distortions. “Good” performance allowed for minor attribution errors or brief lapses that did not meaningfully impact the clinical content. “Poor” performance was characterized by major attribution errors, significant omissions, disorganized conversation flow, or outputs that impaired the clinical utility of the transcript or note.

Accuracy and Quality in Documentation

The accuracy and quality of the medical notes generated by the AI scribes were assessed across 7 items: accuracy, comprehensiveness, care plan, organization, comprehension, conciseness, and usefulness (Textbox 1). These items were informed by medical documentation policies and guidelines developed by the CPSO [32] and the CMPA [33], validated quality frameworks that assessed the accuracy and quality of medical notes written by physicians and medical scribes [30,36], and early evaluations on the accuracy of AI scribes in other health care settings [31]. Each item was measured against a 3-point Likert scale and scores were averaged to determine a single performance score (with 1 representing poor accuracy and quality and 3 representing excellent accuracy and quality). The transcript was also assessed for overall accuracy and quality.

XSL•FO
RenderX

Textbox 1. Description of items to evaluate the accuracy and quality of medical notes generated by an artificial intelligence (AI) scribe.

Accuracy

The medical note contains information that is true and free from errors or hallucinations.

Comprehensiveness

The medical note includes complete documentation of all relevant patient information, including medical history, examination findings, diagnostic results, and treatment plans without omissions.

Care Plan

The medical note provides a holistic understanding of the patient's health status. The medical note allows health care professionals to readily interpret the patient's health status and develop a plan of care.

Organization

The medical note is well-structured, adhering to the SOAP (Subjective, Objective, Assessment, and Plan) format.

Comprehension

The medical note is accessible and devoid of ambiguity or difficult-to-understand terms, phrases, or sections. The medical note allows health care professionals to readily interpret the patient's clinical status and make informed decisions.

Conciseness

The medical note succinctly and effectively conveys all essential information, avoiding unnecessary elaboration or redundancy.

Usefulness

The medical note presents pertinent clinical information in a clear, concise, and actionable manner, facilitating effective communication, decision-making, and continuity of care among health care professionals involved in the patient's care.

We also conducted an error analysis to identify the types of mistakes made by the AI scribes when generating transcripts and medical notes using error classification schemes developed for ASR systems [37-39]. Error types included deletion or omission errors and errors in names, proper nouns, numbers, punctuation, medication names, medical terminology, homonyms, and the Subjective, Objective, Assessment, and Plan (SOAP) format.

Applying the Evaluation Framework

To conduct the competitive analysis, 4 research team members (EH, IC-K-Y, LM, and SL) had an "unlimited" or "premium" license for each AI scribe. Each team member played the audio files from 4 different simulated clinical encounters between a PCP and a standardized patient to generate transcripts and medical notes in the SOAP format from each AI scribe. The audio files were obtained from the College of Family Physicians of Canada Certification Examination in Family Medicine website and were selected because they portrayed common clinical encounters and patient populations observed in primary care. Each audio file also had a verbatim transcript, detailed case notes, and SOAP-format notes written by PCPs, all of which served as a rubric for comparing to the AI scribe-generated outputs. The use of audio files helped minimize discrepancies and challenges related to variations in clinical presentations; thus, providing uniform encounters to each AI scribe and allowing researchers to verify results against the original source for more accurate assessments. The SOAP format was selected for documentation as it was a universally available template across all AI scribe products and is one of the most recommended and widely used methods for documenting a patient encounter in primary care [32].

Team members individually evaluated items in the framework, collaborating weekly to resolve any rating discrepancies through discussion and consensus. If an agreement could not be reached, a fifth team member adjudicated. Clinical experts and family physicians also reviewed each measure, adding insights on usability, effectiveness, technical performance, and output accuracy and quality for each AI scribe. Their feedback was incorporated through a second round of review and consensus meetings among the core evaluation team. In addition, data from a questionnaire completed by the AI scribe vendors about their products' capabilities was analyzed, and publicly available resources, including company websites, product documentation, user manuals, whitepapers, case studies, and user testimonials were reviewed.

Ethical Considerations

The study was formally reviewed by institutional authorities at WCH and received research ethics approval from the WCH Assessment Process for Quality Improvement Projects pathway (APQIP #2023 - 0059). The study was conducted within a controlled simulation environment using audio recordings of standardized clinical encounters between a PCP and a standardized patient. The audio recordings are publicly available to use for educational and research purposes. Results generated as part of this study were based solely on these standardized patient encounters and did not include human participants or the collection of any PHI. All research data were securely stored on password-protected internal servers with access restricted to authorized study personnel.

Results

Overview

A total of 6 AI scribes were selected for evaluation based on their market availability and compliance with data privacy and security regulations in Ontario (ie, PHIPA). To highlight the general capabilities of AI scribes, specific product names are

XSL•FO
RenderX

not used; however, when referring to a particular AI scribe product, they are labeled as AI scribes #1 through #6. Table 1 provides an overview of the health care sectors and users for each of the AI scribes. While 2 AI scribes were exclusively used in primary care (AI scribes #1 and #4), the remaining 4 were also deployed in other health care sectors, including acute care, home care, palliative care, and community services. Of these 4 AI scribes, 3 were used by a broader range of health care professionals, including nurses, pharmacists, dentists, veterinarians, and administrative staff, in addition to physicians. The number of active, paid subscribers for each AI scribe varied significantly, from 20 for AI scribe #4 to over 21,000 users for AI scribe #6. Half of the AI scribes supported languages other than English (AI scribes #2, #3, and #5), while the remaining 3 only supported English but reported that they were developing additional language options (eg, French and Spanish). The performance of these AI scribes in non-English languages was not evaluated in this analysis.

Table . Overview of supported health care settings and users across different artificial intelligence (AI) scribe products.

Context	AI scribes					
	AI scribe #1	AI scribe #2	AI scribe #3	AI scribe #4	AI scribe #5	AI scribe #6
Care settings[a]	Primary care	Primary care, acute and ambulatory care, social and community services, home care, palliative care, mental health and psychiatry, pediatrics, rehabilitation services, dental care, optometry, surgery, and veterinary medicine	Primary care, acute and ambulatory care, palliative care, and home care	Primary care	Primary care, acute and ambulatory care, community services, and mental health and psychiatry	Primary care and acute and ambulatory care
Main users[b]	Physicians	Physicians, nurses, other regulated health care professionals[c], and administrative staff	Physicians, nurses, other regulated health care professionals[c], and administrative staff	Physicians	Physicians, nurses, and other regulated health care professionals[c]	Physicians
Number of users[d]	100	13,000	360	20	4000	21,000
Supported languages	English	English, French, and 50 other languages	English, French, and 20 other languages	English	English and French	English

[a]All health care sectors that the AI scribe was used in.

[b]Types of clinicians and health care professionals that the AI scribe was marketed to, and who had an active, paid subscription to use the AI scribe (ie, users).

[c]Regulated health professionals include pharmacists, dentists, occupational therapists, physiotherapists, social workers, psychologists, and therapists.

[d]Approximate number of current users with an active, paid subscription for the AI scribe.

Usability

Table 2 presents the results of the usability assessment. Of the 6 AI scribes evaluated, 4 were accessible on multiple platforms (desktop or laptop and mobile or tablet devices); thus, receiving an excellent form factor rating. In contrast, AI scribes #4 and #6 could only be accessed on a single platform, potentially limiting accessibility in diverse clinical settings. Four of the AI scribes also demonstrated some level of EMR integration. AI scribes #1 and #3 exhibited the highest degree of integration as they were compatible with multiple EMRs used in primary care in Canada and could exchange metadata (eg, schedules, visit details, previous notes, and summaries) and patient information (eg, name, date of birth, and health card number) when launched from within the EMR. AI scribe #5 could be launched within a single EMR, but no data exchange was available. AI scribe #6 did not connect directly to common EMRs in primary care but allowed users to transfer notes through a separate application. To add the medical note to the EMR, only AI scribe #5 offered a seamless drag-and-drop note transfer into the EMR with a single mouse click. For AI scribes #1 - #4, users would have to toggle between the AI scribe and EMR interfaces to manually copy-paste notes, adding to the number of mouse clicks or keystrokes required to use the AI scribe. AI scribe #6 used a separate program to transfer the transcript and medical note from the mobile app to the EMR.

XSL•FO
RenderX

Table . Comparison of usability features across different artificial intelligence (AI) scribe products.

Usability measures	AI scribes					
	AI scribe #1	AI scribe #2	AI scribe #3	AI scribe #4	AI scribe #5	AI scribe #6
User interface						
Main platforms used to access the AI scribe[a]	Supported on Google Chrome, Mozilla Firefox, Apple Safari, and Microsoft Edge	Supported on all web browsers	Supported on Google Chrome, Mozilla Firefox, and Microsoft Edge	Desktop application	Google Chrome extension but also available on other Web browsers, although not formally supported	Mobile app
Supported mobile and tablet devices	Mobile-friendly via phone's web browser	Mobile-friendly via phone's web browser	Mobile-friendly via phone's web browser	N/A	Native application for iOS and Android devices	Native application available for iOS and Android devices
Form factor[b]	Excellent	Excellent	Excellent	Poor	Excellent	Poor
EMR integration						
EMR integration	Excellent	Poor	Excellent	Poor	Excellent	Good
Ability to transfer medical note	Good	Good	Good	Good	Excellent	Poor
Process flow						
Steps to sign-in and launch the AI scribe	5	7	6	6	4	4
Average time to sign-in and launch the AI scribe[c]	10.01 sec[d]	13.58 sec	26.36 sec	14.59 sec	11.63 sec	7.21 sec
Factor authentication (FA)	1FA[e]	1FA	2FA[f]	1FA	2FA	1FA
Ease of Restarting	Good	Good	Good	Good	Good	Good

[a]Medium or technology through which users can access and interact with the AI scribe, considering the various types of interfaces and devices that enable user access.

[b]Design and accessibility of platforms required to use the AI scribe, particularly in relation to its ease of access in primary care settings.

[c]Approximate amount of time needed to sign in and launch the AI scribe for use during a patient encounter. This measure was averaged across 3 runs and did not include time spent typing when entering credentials or textual information.

[d]sec: seconds.

[e]1FA: single-factor authentication.

[f]2FA: 2-factor authentication.

Other processes affecting usability, such as sign-in and launch, varied across products. All AI scribes required user authentication for sign-in, with 4 AI scribes using single-factor authentication and 2 implementing 2-factor authentication. There did not appear to be a link between the number of steps and the amount of time it took to sign in and launch the AI scribe. The encounter initiation processes also varied across AI scribes; some required preloading appointment data (eg, patient name and appointment time), while others could start recording immediately. Each AI scribe featured a visible "start encounter" button, and all except AI scribe #4 provided live transcription. Transitioning between patient encounters required users to save the medical note before moving on to the next patient.

Effectiveness and Technical Performance

On average, for a 15-minute clinical encounter between a patient and PCP, nearly all AI scribes generated a SOAP-format medical note within 1 minute of pressing the stop recording button, with AI scribe #4 taking almost twice as long (Table 3). Documentation time for all AI scribes was affected by the encounter length and the complexity of the topics discussed. Encounters involving multiple or complex topics, or extended, nonlinear conversations—including rapport-building exchanges not directly related to medical care—generally increased the documentation time of the AI scribes.

XSL•FO
RenderX

Table . Effectiveness and technical performance across different artificial intelligence (AI) scribe products.

Performance measures	AI scribes					
	AI scribe #1	AI scribe #2	AI scribe #3	AI scribe #4	AI scribe #5	AI scribe #6
Effectiveness						
Average documentation time	41.87 sec[a]	53.54 sec	42.8 sec	1:40 min[b]	32.4 sec	20.66 sec
Technical performance						
Background noise	Excellent	Excellent	Excellent	Excellent	Excellent	Excellent
Interruptions	Excellent	Good	Excellent	Good	Good	Poor
Multiple speakers	Good	Poor	Good	Good	Poor	Good

[a]sec: seconds.

[b]min: minutes.

The performance of the AI scribes also varied when faced with complicating factors. All AI scribes successfully omitted nonconversational background noises. In contrast, only AI scribe #1 effectively filtered out interruptions and extraneous conversations, ensuring only the patient-PCP dialogue appeared in the transcript and medical note. AI scribes #2 - #5 included brief phrases from interruptions or extraneous conversations in the transcript but excluded them from the medical note. AI scribe #6, however, mistakenly incorporated information from the interruption into both the transcript and the medical note.

The ability of the AI scribes to manage conversations among 3 or more speakers also varied. AI scribes #1, #3, #4, and #6 received a “good” rating, effectively distinguishing between speakers and accurately assigning dialogue to speakers in the transcripts. In contrast, AI scribes #2 and #5 received a “poor” rating, often failing to differentiate between more than 2 speakers when generating the transcript. These errors led to inaccuracies in the medical note, where statements made by a third speaker were incorrectly attributed to the patient.

Accuracy and Quality in Documentation

Table 4 summarizes the evaluation findings on documentation accuracy and quality. None of the AI scribes consistently produced fully accurate and error-free transcripts or medical notes, although the types of errors varied. While most patient-PCP conversations were transcribed accurately, frequent grammatical and syntactical errors, such as repeated or omitted words, were observed, particularly among AI scribes #1 and #3 - #5. These AI scribes received an overall rating of “good” for transcript accuracy and quality, as these issues could affect the transcripts’ usefulness, making it harder for users to reference them quickly during later reviews, although it did not affect overall content.

XSL•FO
RenderX

Table . Evaluation of the accuracy and quality of the transcript and medical note generated by the artificial intelligence (AI) scribe.

Accuracy measures	AI scribe					
	AI scribe #1	AI scribe #2	AI scribe #3	AI scribe #4	AI scribe #5	AI scribe #6
Accuracy and quality						
Transcript	Good	Excellent	Good	Good	Good	Excellent
Medical note	Excellent	Excellent	Excellent	Good	Good	Good
Error analysis[a,b]						
Deleted words or omissions[c]	✓	✓	✓	✓	✓	✓
Generalizations[d]				✓	✓	✓
SOAP[e] structure[f]		✓	✓	✓		

[a]Checkmarks indicate that at least one occurrence of the error was observed.

[b]Error types not observed include errors in names, proper nouns, numbers, punctuation, medication names, or homonyms.

[c]Error where essential information is left out or not included, which can lead to incomplete understanding or documentation of the intended content or context.

[d]Error where specific information is simplified or replaced with a broader, less precise term, potentially leading to a loss of detail or nuance that could affect the accuracy or clarity of the information.

[e]SOAP: Subjective, Objective, Assessment, or Plan.

[f]Documentation error where information is incorrectly categorized within the SOAP sections of a medical note, potentially leading to confusion or misinterpretation of the clinical details.

For medical note accuracy and quality, 3 AI scribes (#4 - #6) produced notes rated as "good" quality, while the remaining 3 (AI scribes #1 - #3) produced "excellent" quality notes. An "excellent" rating indicated strong relative performance among the evaluated AI scribes rather than complete accuracy. The "excellent" notes were comprehensive, well-organized, and free from hallucinations or contradictory information, providing sufficient detail to accurately reflect the patient's clinical status and support informed decision-making. Interestingly, AI scribes that generated good-quality transcripts were still capable of producing excellent-quality medical notes (AI scribes #1 and #3), and the reverse was also true (AI scribe #6).

In the error analysis, errors involving names, proper nouns, numbers, punctuation, medication names, or homonyms were not observed. However, deletion or omission errors were observed across all AI scribes. The most frequent omissions involved details about the history of the presenting illness, social history, or lifestyle factors, with the extent of omissions varying across AI scribes. For example, in one clinical scenario, AI scribes #2, #3, and #4 omitted dietary information relevant to the encounter but still received a good rating, as this information could have been documented elsewhere in the patient's chart. Conversely, AI scribe #6 consistently omitted new social history details directly relevant to the presenting illness. AI scribes #4 - #6 also made generalization errors, simplifying medical terms in ways that lost specificity or nuance, such as reducing "Colles fracture" to "fracture" or even "dog fracture." In addition, AI scribes #2 - #4 displayed SOAP structure errors, such as misclassifying information in the Objective section despite the absence of a physical examination.

Discussion

Principal Findings

We conducted one of the first studies, to our knowledge, that systematically evaluated the usability, effectiveness, technical performance, and accuracy of 6 AI scribes developed for or used in primary care settings in Canada, including some tools that are also used in the United States. By leveraging competitive analysis methods, expert usability approaches, and human factors engineering, we developed a comprehensive evaluation framework that revealed a rapidly evolving AI scribe market and notable differences in performance across AI scribes.

Of the AI scribes included in this evaluation, most were accessible across multiple platforms, including desktops, laptops, mobile devices, and tablets, and could be launched directly within the EMR for easier access, although data exchange was minimal. In general, nearly all AI scribes generated a SOAP-format medical note in approximately 1 minute for a standardized 15-minute encounter, although documentation length increased based on the length of the encounter and complexity of topics discussed. While all AI scribes produced good to excellent quality medical notes, persistent deletion and omission errors highlighted the continued need for review and editing by PCPs. In addition, several factors were found to affect the quality and accuracy of both transcripts and medical notes, including extraneous conversations, encounters with multiple speakers, and the complexity of conditions discussed. Interestingly, AI scribes that produced good-quality transcripts could generate excellent-quality medical notes, and conversely, transcripts of excellent quality did not always result in equally high-quality medical notes. Despite these promising capabilities, limitations related to usability, technical performance, and

XSL•FO
RenderX

accuracy remain that must be addressed to ensure AI scribes continue to reduce administrative burdens effectively.

Comparison With Other Work

While studies on the usability of AI scribes in primary care remain limited, our findings are consistent with broader research on the usability of digital health technologies. For example, inadequate access, poor usability of platforms, and lack of workflow integration are known factors that contribute to PCP burnout, whereas enhanced accessibility and robust EMR integration are associated with improved PCP well-being and productivity [40,41]. As demonstrated in this study, flexible access to AI scribes across multiple platforms—such as mobile devices, tablets, and desktops—may enhance their usability by aligning better with PCPs' varied workflows and preferences. In addition, as highlighted in several commentaries, AI scribes remain an unregulated digital health tool [42,43]. While the current level of EMR integration may be sufficient in the absence of regulation, data privacy and security laws, like those in Ontario, Canada, place the responsibility on PCPs and institutions to understand privacy implications, assess risks, and ensure that AI scribe software functions as expected [42,43]. These considerations underscore the need for regulatory guidance and transparency in the development of AI scribe technology to support usability, enhance EMR integration, and maintain patient safety in primary care settings.

Studies on the accuracy and quality of transcripts and medical notes produced by AI scribes are emerging. For instance, Tierney et al [31] used a modified 9-item Physician Documentation Quality Instrument (PDQI-9) to evaluate the quality of notes produced by an AI scribe used in primary care, pediatric, hospital, mental health, surgical, and emergency care settings. Their regional pilot demonstrated that while the AI scribe produced high-quality notes, minor hallucinations and omission errors were common—similar to the error types observed in our study. In addition, a study on a commercially available Dutch AI scribe found that fully automated notes, without clinician editing, had poorer PDQI-9 scores, higher word counts, and reduced lexical diversity compared to those reviewed by clinicians [44]. Our evaluation of 6 AI scribes expanded upon this work and demonstrated that various AI scribes can produce good to excellent quality notes, though none were entirely error-free and likely require some editing by users. Compared with the PDQI-9 and other tools used to evaluate note quality, our framework consists of 7 items that focus on characteristics unique to AI-generated outputs, such as hallucinations, redundancy, and bias. Our framework also considers the ability of AI-generated notes to capture relevant patient information in a concise and actionable manner, with a particular emphasis on attributes like the Care Plan. It is designed to be suitable for SOAP-format medical notes, though it can be adapted to other formats, highlighting both similarities and differences in focus and scope.

Despite the promise of AI scribes, recent evaluations of large language models (LLMs), such as GPT-3.5 and Open AI's ChatGPT-4, urge caution before integrating AI-powered tools into clinical documentation workflows. In these studies, LLMs were fed medical evidence or transcripts of audio-recorded patient-provider conversations to generate summaries [45,46]. Findings revealed that LLMs frequently produce factually inconsistent summaries, with error types varying across replicates of the same case [45]. Performance also differed significantly across different LLMs [46]. In contrast to general purpose LLMs, such as ChatGPT, the AI scribes evaluated in our study primarily relied on conventional pipelines combining ASR systems and NLP models that were specifically fine-tuned for clinical documentation tasks. While some AI scribe vendors may be beginning to integrate LLM-based approaches, most tools included in this evaluation were optimized separately for ASR and NLP functions. Notably, the distinct functions of ASR systems and NLP within AI scribes likely explain why 'excellent' transcripts may sometimes accompany 'good' medical notes, or vice versa, as observed in our study. ASR systems are optimized to capture spoken words accurately, while NLP focuses on summarizing, organizing, and emphasizing clinically relevant information [14]. Consequently, some AI scribes may excel in extracting key details for notes despite minor transcript inaccuracies, while others may produce precise transcripts but lack effective summarization. A key takeaway is that the performance of AI scribes is expected to vary depending on the specific ASR and NLP systems used, and performance will likely change over time as these models are retrained on new data. The variability in performance within and across AI scribes underscores the need for ongoing evaluation and oversight to ensure that these tools continue to meet clinical documentation needs reliably [47]. Collectively, these findings highlight the importance of PCPs reviewing and editing AI-generated medical notes to ensure documentation accuracy and quality.

Overall, our study has important implications for research, policy, and practice. For research, the findings highlight the need for further large-scale studies to evaluate the usability, accuracy, and long-term impact of AI scribes, especially in real-world clinical environments. This research also raises important equity considerations, as the performance of various AI scribes may differ across PCP and patient populations or when used to support languages other than English [46,48]. For policy and practice, our findings provide benchmark data on the current performance of 6 AI scribes used in primary care settings, guiding users, institutions, and other stakeholders on both the strengths and areas needing improvement. This work can also set the foundation for broader implementation strategies that balance innovation with safety, equity, and accountability in digital health technology. Furthermore, there is a critical need for the ongoing evaluation of AI scribes and other AI tools in a manner that is both timely and rigorous. With the rapid evolution of AI technology, continuous assessment is necessary to ensure that these tools remain relevant, effective, and safe for diverse clinical contexts. Evaluations must be methodologically robust to address potential biases, assess long-term impacts, and ensure that the tools meet the needs of all patient and provider populations equitably to build trust, maintain accountability, and maximize the transformative potential of AI in health care.

XSL•FO
RenderX

Limitations

There are limitations to consider when interpreting findings. First, the evaluation was conducted in a controlled laboratory setting, which may not fully capture the nuances and complexities of real-world clinical environments. While we used standardized audio files representing typical primary care encounters, these simulations cannot entirely replicate live, unscripted interactions. It is also possible that some AI scribes were partially trained or fine-tuned using publicly available clinical audio datasets, which could introduce overlap with the types of audio files used in our evaluation. Although we cannot confirm the specific training sources used by each vendor (as this information was often proprietary), we acknowledge this as a limitation and recognize that model performance may differ when evaluated using de novo, real-world clinical encounter data. Second, we evaluated 6 AI scribes, although there are a countless number of AI scribes available globally. While the selected vendors reflect those used in primary care settings in Canada and the United States, the results may not capture the full range of features offered by all AI scribes. In addition, AI scribes and automation technologies are rapidly evolving. Although the evaluation framework may be applied to continuously evaluate AI scribes, as the underlying ASR and NLP models are retrained, findings represent the relative performance of each AI scribe at a single point in time and may not reflect any subsequent versions released since the time of the study. Finally, we assessed documentation quality using the SOAP format to ensure consistent evaluation of outputs across all AI scribes that were evaluated. While this may not represent the variety of templates or the specialized expertise required to select the most appropriate template for different clinical scenarios, the SOAP format remains the most widely recommended method for documenting clinical encounters in primary care, and its use in this study provided a consistent basis for comparison.

Conclusion

In conclusion, our findings demonstrate that developing a comprehensive framework to evaluate AI scribes is feasible, and findings from the competitive analysis underscore the value of AI scribes as a promising tool to alleviate administrative burden in primary care. However, findings also emphasize the need for ongoing enhancements to improve the usability, technical performance, and accuracy of AI scribes. Although AI scribes can generate good to excellent quality medical notes, user editing and review remain essential. Greater EMR integration and personalized customization are also needed to align with the varied documentation practices of PCPs. Overall, ongoing evaluation is crucial to ensure these technologies effectively support PCPs while enhancing safety, accuracy, and efficiency for both providers and patients. Future research should also explore AI scribe performance in dynamic, real-world settings.

Acknowledgments

The authors would like to thank the Ontario Ministry of Health for funding this study and OntarioMD and Amplify Care (formerly eHealth Centre of Excellence) for supporting this study and facilitating access to the artificial intelligence (AI) scribes. The funders had no role in study design, data collection, and analysis. PA is a recipient of the 2023 AMS Healthcare Fellowship in Compassion and AI.

Data Availability

The data generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

EH, EM, OB, and PA contributed to the conceptualization of the study. EH, IC-K-Y, LM, and SL were responsible for data curation and formal analysis. Funding acquisition was handled by OB and PA. EH, IC-K-Y, LM, and SL carried out the investigation. EH, LM, EM, OB, and PA contributed to the development of the methodology. EH managed the project administration. OB and PA provided the necessary resources. Software development was carried out by EH, IC-K-Y, LM, and SL. Supervision and validation were conducted by EM, OB, and PA. EH, IC-K-Y, LM, and SL contributed to data visualization. EH prepared the original draft of the manuscript. All authors contributed to the review and editing of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Accurate monitoring of tumor progression is crucial for optimizing outcomes in neurofibromatosis type 2–related schwannomatosis. Standard 2D linear analysis on magnetic resonance imaging is less accurate than 3D volumetric analysis, but since 3D volumetric analysis is time-consuming, it is not widely used. To shorten the time required for 3D volumetric analysis, our lab has been developing an automated artificial intelligence–driven 3D volumetric tool.

Objective: The objective of the study was to survey and interview clinicians treating neurofibromatosis type 2–related schwannomatosis to understand their views on current 2D analysis and to gather insights for the design of an artificial intelligence–driven 3D volumetric analysis tool.

Methods: Interviews examined for the following themes: (1) shortcomings of the currently used linear analysis, (2) utility of 3D visualizations, (3) features of an interactive 3D modeling software, and (4) lack of a gold standard to assess the accuracy of 3D volumetric analysis. A Likert scale questionnaire was used to survey clinicians' levels of agreement with 25 statements related to 2D and 3D tumor analyses.

Results: A total of 14 clinicians completed a survey, and 12 clinicians were interviewed. Specialties ranged across neurosurgery, neuroradiology, neurology, oncology, and pediatrics. Overall, clinicians expressed concerns with current linear techniques, with clinicians agreeing that linear measurements can be variable with the possibility of two different clinicians calculating 2 different tumor sizes (mean 4.64, SD 0.49) and that volumetric measurements would be more helpful for determining clearer thresholds of tumor growth (mean 4.50, SD 0.52). For statements discussing the capabilities of a 3D volumetric analysis and visualization software, clinicians expressed strong interest in being able to visualize tumors with respect to critical brain structures (mean 4.36, SD 0.74) and in forecasting tumor growth (mean 4.77, SD 0.44).

Conclusions: Clinicians were overall in favor of the adoption of 3D volumetric analysis techniques for measuring vestibular schwannoma tumors but expressed concerns regarding the novelty and inexperience surrounding these techniques. However, clinicians felt that the ability to visualize tumors with reference to critical structures, to overlay structures, to interact with 3D models, and to visualize areas of slow versus rapid growth in 3D would be valuable contributions to clinical practice. Overall, clinicians provided valuable insights for designing a 3D volumetric analysis tool for vestibular schwannoma tumor growth. These findings may also apply to other central nervous system tumors, offering broader utility in tumor growth assessments.

KEYWORDS

neurofibromatosis type 2; vestibular schwannoma; 3D volumetric analysis; magnetic resonance imaging

Introduction

Neurofibromatosis type 2 (NF2) is an autosomal dominant disorder caused by mutations in the NF2 gene on chromosome 22q12 [1,2]. This disorder is primarily characterized by the growth of vestibular schwannomas (VS), noncancerous brain tumors that arise from Schwann cells along the vestibulocochlear nerve [3]. Depending on the location of VS tumor growth, NF2 patients may develop a range of symptoms, including hearing loss, tinnitus [4], loss of balance, and dizziness [5]. As these tumors progress, they can become life-threatening if they

XSL•FO
RenderX

impinge on critical brain structures, such as cranial nerves and the brainstem [6].

Treatment for these tumors typically involves stereotactic radiosurgery, resection surgery [7], or, more recently, Brigatnib, an oral drug showing promising outcomes in those with neurofibromatosis type 2–related schwannomatosis (NF2-SWN) [8]. The decision to pursue these treatments depends on factors such as tumor size, growth, location, and mass, underscoring the importance of accurately monitoring and visualizing tumor progression over time [9]. T1-weighted cranial magnetic resonance imaging (MRI) with intravenous gadolinium has proven effective in visualizing VS tumors in cerebral space [10]. This imaging technique also helps distinguish VS tumors from other anomalies, including cysts, meningiomas, aneurysms, and facial nerve schwannomas, supporting more informed clinical decision-making [11].

Tumor progression can be monitored using various metrics, with the change in tumor size being the most common. In current standard clinical practice, linear analysis involves measuring the largest tumor diameter in two dimensions, usually in an axial or coronal view. Although linear measurements are derived from a patient's MRI planar slices, the complex geometry of VS tumors can introduce uncertainty in these measurements [7,9]. Larger VS tumors develop characteristic features that may not be fully captured in linear measurements, such as the round body and tail (the "ice cream cone" geometry) [12].

Approximate volumetric analysis addresses some of the limitations of linear analysis by incorporating an extra dimension from 2D to 3D. By approximating the tumor as an ellipsoid in each MR scan slice, the volume of the tumor can be approximated by summing the total areas derived from each slice. While this measure has been shown to be more sensitive to tumor growth than 2D measurements, it has also been found to overestimate tumor growth. As VS tumors continue to develop into the cerebellopontine angle, their shape in each MR slice begins to deviate from that of an ellipsoid [13].

The 3D volumetric analysis addresses the limitations of 2D linear and approximate volumetric methods by calculating tumor volume through the summation of tumor areas from each MR slice. Unlike approximating the tumor as an ellipsoid in each slice, this technique involves directly segmenting the tumor borders, which improves the specificity of the tumor's boundaries [14]. Although 3D volumetric analysis yields accurate tumor size measurements, it requires manual segmentation, a time-consuming process that can take hours per tumor, necessitating the use of automated volumetric analysis tools [15]. Furthermore, for 3D volumetric analysis to have utility in clinical practice, the 3D visualization resulting from this analysis, which describes the digital 3D model of the segmented tumor in 3D space, must be easily interpretable for clinicians to understand where the tumor exists with reference to the 3D mapping of the patient's brain.

The 3D modeling technologies such as OsiriX Lite (version 7.0.3; Pixmeo SARL), ITK-Snap (version 2.4.0; ITK-Snap), and BrainLab iPlan (version 4.5; BrainLab) have been described in the literature as performing semiautomated 3D volumetric analysis of VS tumors [16]. While these technologies show promising results with low coefficients of variability, they fail to provide adequate visualization of the segmented tumors in 3D space, limiting their clinical utility. Specifically, these technologies do not have the capabilities to overlay 2D planes on the 3D segmented tumor to demonstrate where different sections of the tumor are located within the patient's brain scan. Additionally, these technologies do not have features that allow for the overlaying of segmented tumors between chronological scans to investigate areas of tumor growth. We envision that the incorporation of visualization features like these has the potential to broaden the clinical utility of 3D volumetric analysis and visualization software and reduce the need for advanced 3D reconstruction when viewing 3D segmented tumors.

To make 3D volumetric analysis adopted more widely in clinical settings, a thorough understanding of clinical needs related to the analysis methodology (volumetric vs linear) and the 3D visualization must exist. Therefore, the aim of this study was to gain a deeper understanding of clinicians' current methods for measuring tumor growth, their recommendations for key features in a potential 3D volumetric analysis tool (to be developed), and their concerns regarding how the tool would be clinically integrated. To achieve this, we conducted surveys and interviews with clinicians who treat NF2. We hypothesized that insights from these experienced clinicians would guide the development of a US Food and Drug Administration–regulated auto-segmentation and visualization software to improve the diagnosis and measurement of VS tumors.

Methods

Study Sample

This study involved surveys and interviews with clinicians specializing in the treatment and diagnosis of NF2-related schwannomatosis. To be eligible for inclusion, participants had to be clinicians directly involved in the care of NF2-SWN patients and willing to complete a survey or participate in an interview. NF2-SWN patients were not included, as the software is intended primarily as a clinical tool rather than a visualization tool for patients. Clinicians with direct experience in diagnosing and treating NF2-SWN across various specialties, including neurology, neuro-oncology, neurosurgery, neuroradiology, and pediatrics, whose names were found on the Children's Tumor Foundation website were recruited for this study. Upon identifying clinicians' names and contact information, emails were subsequently sent to these clinicians, outlining the proposed 3D segmentation software and inviting them to participate in a survey and an interview.

Ethical Considerations

Ethics approval was obtained from the Yale University Institutional Review Board (approval number: 2000034426) through an exempt review. Verbal informed consent was obtained from all interviewed and surveyed participants before the collection of data, and the institutional review board waived the need for written consent. The clinicians providing the data were deidentified but were not anonymous. No vulnerable populations were included in the data collection of this study. Additional consent was not necessary for any secondary analyses

XSL•FO
RenderX

of the collected data. No compensation was provided for participation in this study.

Survey Data Collection and Analysis

Surveys were conducted via Qualtrics and included 25 statements organized into eight categories as follows: (1) linear/volumetric analysis, (2) markers of VS tumor progression, (3) surgical planning for 2D MRI scans of VS tumors, (4) 3D volumetric analysis, (5) 3D visualization of VS tumors, (6) surgical planning using 3D models of VS tumors, (7) postintervention monitoring, and (8) general questions (Textbox 1). The survey questions were structured as a Likert scale questionnaire, where clinicians indicated their level of agreement with each statement on a scale of 1 to 5, ranging from "completely disagree" to "completely agree." Additionally, clinicians were asked demographic questions about their clinical specialties, years of experience, and the number of VS cases they had treated.

XSL•FO
RenderX

Textbox 1. A total of 25 total statements were addressed in both the interviews and in the questionnaire. In the surveys, all clinicians selected 1 out of 5 choices based on how much they agreed with each statement. In the interviews, clinicians had the opportunity to share open-ended responses to the statements.

Category 1: 2D linear/volumetric analysis

1. Linear analysis of vestibular schwannoma (VS) tumors reflects tumor size

2. Volumetric analysis of tumors reflects tumor size

3. Linear measurements are sensitive to small changes in tumor diameter

4. Two different clinicians can review the same magnetic resonance imaging (MRI) but calculate two different tumor sizes.

5. The orientations of bi- and uni-dimensional linear measurements can change from one MRI to the next for a single patient.

6. Patient position in MRI machines influences the orientations of MRI scans, affecting linear measurements.

7. It can be difficult to make a decision about tumor growth from a series of linear measurements due to the lack of clear progression thresholds.

Category 2: markers of VS tumor progression

8. Change in tumor size is the most important marker of VS tumor progression

9. Edema and mass effects on surrounding critical structures are good markers of VS tumor progression.

Category 3: surgical planning with 2D MRI scans of VS tumors

10. It is simple to determine the best approach to tumor resection before operation (location or angle of entry, how to best maximize extent of resection while avoiding functional areas) from 2D MRI scans.

11. The cranial nerves and blood vessels that need to be avoided during intervention can easily be determined through analysis of MRI scans.

Category 4: 3D volumetric analysis

12. 3D volumetric measurements would be more helpful in determining clearer thresholds of tumor growth than linear measurements.

13. 3D volumetric analysis would standardize measurements by reducing variation in measurements of tumor size taken by different clinicians.

14. 3D volumetric analysis would lead to more informed clinical decision-making.

Category 5: 3D visualization of VS tumors

15. 3D volumetric measurements must be combined with 3D visualization of the VS tumor to be clinically meaningful.

16. The ability to interact with 3D models of VS tumors in the cerebral space (rotate, zoom, adding or removing structures from view) would provide information helpful for surgical planning.

17. Growth in tumor boundaries observed by overlaying 3D models of VS tumors from MRI scans collected over time is easier to interpret than comparing the same MRI scans in 2D.

18. 3D visualization of VS tumors and their location relative to critical brain structures (cranial nerves, brainstem, etc.) would be helpful in patient care.

19. Knowing regions of rapid versus slow tumor growth on VS tumors would be helpful in treatment planning.

Category 6: surgical planning with 3D models of VS tumors

20. 3D visualization of VS tumors in the surrounding cerebral space (relative to critical brain structures) would aid in surgical planning.

21. 3D models of VS tumors would lead to more informed decisions of the type of intervention to perform (eg, different approaches of tumor resection and gamma knife)

Category 7: postintervention monitoring

22. Being able to distinguish between post-op changes and residual tumor progression would significantly improve clinical decision-making (ex. After gamma knife).

23. Automatic diagnosis of tumor progress, regression/response, or stability according to changes in size over time would aid treatment planning.

Category 8: general

24. Having the ability to forecast tumor growth will significantly improve clinical decision-making.

25. 3D visualizations of VS tumors would significantly improve patient education by allowing patients to see their tumors in 3D space.

In the end, individual survey statement responses were statistically analyzed and means and SD were reported. Higher means indicated that clinicians agreed more with the statement. Following statistical analysis, survey statements relating to tangible features or capabilities of the software were grouped together, and the top four features that clinicians favored based on mean agreement levels were determined.

Interview Data Collection and Analysis

Two members of the research team (AH and DW) with prior training in conducting semistructured interviews and focus

XSL•FO
RenderX

groups jointly facilitated each focus group discussion (FGD) session; the senior author (FB) conducted all the individual interviews. The topics discussed within these discussions mirrored the 25 survey statements reframed as open-ended questions (Textbox 1). The FGD sessions lasted approximately one hour, and the individual interviews lasted approximately 30 minutes. Audio recordings from the FGDs and individual interviews were then transcribed verbatim by Zoom's transcription feature and returned to the research team for proofreading and subsequent analysis.

The data analysis team (AH, DW, and FB) met regularly to develop the codebook and note potential emergent themes. Interview sessions and data analysis continued simultaneously and iteratively until the team determined that data saturation had been reached [17]. Beginning with an initial set of codes derived from the domains included in the Interview Guide, the coding team members independently coded each transcript to identify potential additional codes. The team then discussed the merits of each existing or new code and created definitions for each for inclusion in the final version of the codebook. The codes were inductively developed, grounded in the data, iteratively reviewed, and revised based on the team's discussion of additional independently coded transcripts. The total interobserver agreement of the reviewers was assessed over the course of the reviews. The overall total interobserver agreement was 92% across the study.

The codes assigned to each quote were then reviewed for a final time by the first author as part of entering the coded transcripts using Dedoose. Using thematic analysis, the team identified patterns across the entire data set to arrive at a final, parsimonious set of themes. The analysis also examined the data for any "negative" instances where the data did not fit the domains or themes or where no information on specific topics queried was obtained. In addition to the qualitative analysis, descriptive statistics were generated to describe the study sample.

Results

Study Sample

A total of 14 clinicians were surveyed from the neurosurgery (n=5), neurology (n=7), oncology (n=1), and general pediatrics (n=1) departments. Clinicians came from 4 different medical institutions and had a range of general clinical experience ranging from 3 to 41 years (mean 21.9, SD 12.1). The average number of VS cases that clinicians treated each year ranged from 0 to 100 (mean 24.6, SD 28.9). The clinicians who did not directly treat VS cases still possessed considerable knowledge about VS treatment through their experience working with NF2-SWN patients.

12 additional clinicians from the neurosurgery (4) neuroradiology (4), neurology (2), and neuro-oncology (2) departments were interviewed to provide open-ended responses to the survey statements. This number was determined based on the amount of interviews needed to reach saturation [17].

Survey Data Collection and Analysis

The results for all survey statements are reported in Table 1.

XSL•FO
RenderX

Table . From the Likert questionnaire, clinicians voted with how much they agreed with each statement by choosing (1) “Completely disagree”, (2) “Mostly disagree”, (3) “Neither agree nor disagree”, (4) “Mostly agree”, or (5) “Completely agree”. For the statistical analysis, these metrics of agreement were given numerical values 1 through 5, with 1 aligning with “Completely disagree” and 5 aligning with “Completely agree.”

Statements	Values, mean (SD)
Category 1: 2D linear/volumetric analysis	
Linear analysis of vestibular schwannoma (VS) tumors reflects tumor size.	3.50 (0.94)
Volumetric analysis of tumors reflects tumor size.	4.43 (0.51)
Linear measurements are sensitive to small changes in tumor diameter.	2.43 (1.22)
Two different clinicians can review the same MRI[a] but calculate two different tumor sizes.	4.64 (0.49)
The orientations of bi- and uni-dimensional linear measurements can change from one MRI to the next for a single patient.	4.21 (0.97)
Patient position in MRI machines influences the orientations of MRI scans, affecting linear measurements.	4.71 (0.47)
It can be difficult to make a decision about tumor growth from a series of linear measurements due to the lack of clear progression thresholds.	3.79 (1.25)
Category 2: markers of VS tumor progression	
Change in tumor size is the most important marker of VS tumor progression	3.50 (0.94)

[a]MRI: magnetic resonance imaging.

Category 1: 2D Linear/Volumetric Analysis

Statistical analyses of statement responses revealed that clinicians felt that 3D volumetric analyses (mean 4.43, SD 0.51) offered a slightly greater reflection of tumor size than 2D linear analyses (mean 3.50, SD 0.94). Clinicians' responses additionally revealed that 2D analyses were generally not sensitive to small changes in tumor growth (mean 2.43, SD 1.22). Statements addressing variability in linear measurements highlighted a consensus around the potential for inconsistency due to factors like clinician interpretation (mean 4.64, SD 0.49), MRI orientation (mean 4.21, SD 0.97), and patient orientation (mean 4.71, SD 0.47), with high agreement that these factors impact linear measurements. Additionally, there was moderate agreement (mean 3.79, SD 1.25) surrounding the statement that linear measurements were difficult to interpret.

Category 2: Markers of VS Tumor Progression

Clinicians generally agreed that secondary effects, such as edema and impact on surrounding structures, serve as valuable markers for tracking VS tumor progression (mean 4.0, SD 0.78) and demonstrated a moderate agreement that tumor size is the most important marker above these secondary effects (mean 3.5, SD 0.94). This demonstrated the opinion that all metrics, including tumor size and secondary effects, may hold relatively equal importance to clinicians.

Category 3: Surgical Planning With 2D MRI Scans of VS Tumors

Responses indicated skepticism about the utility of 2D MRI scans in preoperative planning, with clinicians leaning towards neither disagreeing nor agreeing that these scans alone allow clear determination of surgical approach (mean 3.25, SD 1.16) and that critical structures can easily be determined through 2D MRI analyses (mean 3.13, SD 0.99).

Category 4: 3D Volumetric Analysis

Clinicians supported the use of 3D volumetric analysis over linear measurements, suggesting it would enhance consistency across clinicians (mean 4.21, SD 0.58), help establish clearer growth thresholds (mean 4.50, SD 0.52), and improve clinical decision-making (mean 4.14, SD 0.66).

Category 5: 3D Visualization of VS Tumors

In terms of features important for a 3D visualization software, most clinicians somewhat agreed that interactions with 3D models (rotating, zooming, or hiding structures) (mean 3.86, SD 1.17) and knowing areas of rapid versus slow growth (mean 3.71, SD 0.91) would be important for treatment planning. Clinicians were overall in agreement that overlaying chronological tumors to visualize growth (mean 4.00, SD 0.68) and viewing tumors relative to critical brain structures (mean 4.36, SD 0.74) were important for understanding tumor growth and improving patient care. However, clinicians generally neither agreed nor disagreed that visualizations were necessary for 3D analyses to be clinically useful (as opposed to volumes alone) (mean 3.07, SD 0.92).

Category 6: 3D Visualization of VS Tumors

In general, clinicians did not strongly agree or disagree regarding statements that claimed that 3D visualization would be a helpful aid for surgical planning (mean 3.20, SD 1.30) and would help make more informed clinical decisions (mean 3.00, SD 1.41).

Category 7: Postintervention Monitoring

Clinicians somewhat agreed that automatic diagnosis of tumor changes (regression/response or stability) according to changes in size would aid in treatment planning (mean 3.86. SD 0.66).

There was a greater agreement that the ability to distinguish between postoperative changes and residual tumor progression through chronological tumor overlaying would improve clinical decision-making (mean 4.29, SD 0.73)

Category 8: General

Clinicians strongly agreed that the ability to forecast tumor growth would be a significant improvement in clinical decision-making (mean 4.77, SD 0.44). In addition, clinicians somewhat agreed that 3D visualizations would be helpful for patient education (mean 3.92, SD 0.76).

XSL•FO
RenderX

The top four features that clinicians felt would be most beneficial in a 3D analysis and visualization software are listed in Textbox 2. These four features are listed in the order of priority based on the mean agreement levels in Table 1.

Textbox 2. List of 4 main features, ranked in order of clinician's priority, for 3D tumor visualization interface.

1. Forecast tumor growth based on previous 3D growth trends
2. Visualization of tumors with reference to other critical brain structures
3. Overlaying chronological 3D tumor models from the same patient to visualize growth
4. Interacting with 3D models, including rotating, zooming, and adding or removing tumors from view.

Interview Data Collection and Analysis

Interview findings were analyzed and sorted into four corresponding themes as follows: (1) shortcomings of the currently used linear analysis, (2) utility of 3D visualizations, (3) features of an interactive 3D modeling software, and (4) lack of a gold standard to assess the accuracy of 3D volumetric analysis.

Theme 1: Shortcomings of the Currently Used Linear Analysis

Clinicians observed that most medical professionals tracking the size or growth of VS tumors rely on linear analysis, primarily using uni- or bi-dimensional measurements. As such, linear analysis is considered the current "gold standard."

In general, discussions on the limitations of current linear analysis methods generally focused on the variability in measurements when conducted at different times or by different individuals. They highlighted several factors contributing to variability in these measurements. First, there is a lack of standardization in the linear analysis procedure, leading to variability in how clinicians perform measurements. Additionally, many clinicians will perform linear analysis by first determining the longest tumor diameter slice, a process that is subjective. Clinicians also noted that variations in patient orientation during MRI scans can result in inconsistent tumor presentations in axial and coronal views across different scans. Consequently, comparing linear measurements from one scan to the corresponding slice in another may be inaccurate. Finally, they emphasized that due to the subjectivity and potential inaccuracies in these measurements, tumor growth is more easily detected in scans taken over longer intervals, while frequent scans make it harder to discern changes.

Theme 2: Utility of 3D Visualizations

The clinicians interviewed agreed that visualizing VS tumors in relation to critical brain structures would significantly improve diagnosis and treatment planning. Currently, 2D MRI images must be mentally reconstructed by clinicians to understand how tumors interact with these critical structures in a 3D space. This mental reconstruction requires an abstract and advanced understanding of 3D cerebral anatomy, which typically comes with experience.

Clinicians further suggested that creating 3D models of tumors, along with color gradients to represent tumor growth over time, could enhance the visualization of tumor progression and help bridge the knowledge gap between experienced and less experienced clinicians. They also noted that additional markers—such as edema, necrotic core growth, and mass effects like compression on surrounding brain structures—are important in assessing tumor progression. Several clinicians emphasized that segmenting and visualizing these markers in 3D, alongside the tumor itself, could provide critical information for optimizing tumor management.

Theme 3: Features of an Interactive 3D Modeling Software

The clinicians agreed that adding interactive features to 3D modeling software would enable a more comprehensive understanding of each patient's case compared with simply viewing static 3D models on a screen. They suggested several interactive capabilities, including (1) adjusting the transparency of tumor models, (2) zooming in and out, and (3) rotating the models. These interactive functions were seen as providing significantly more information than traditional static 2D imaging. Clinicians also proposed incorporating animations of tumor growth over time, with newer tumors overlaid on older ones, to improve clinical understanding of disease progression. Additionally, they recommended incorporating a coordinate grid within the 3D tumor model to aid in tumor localization within the cerebral space, which could assist in guiding stereotactic interventions.

Theme 4: Lack of a Gold Standard to Assess the Accuracy of 3D Volumetric Analysis

In addition to providing suggestions regarding features that should be included in 3D visualization software, clinicians shared concerns regarding the incorporation of this type of software into clinical practice. These concerns primarily surrounded the novelty of this approach and the difficulty of validating measurements.

The clinicians interviewed noted that because linear measurements are currently the most common metric of tumor size, most experienced clinicians are adept at interpreting linear measurements to determine tumor management and treatment. By combining these linear measurements with the Response Evaluation Criteria in Solid Tumors (RECIST), clinicians can evaluate tumor growth. Thus, in the interviews, the clinicians expressed the concern that due to the novelty of using volume as a metric of tumor size, they may be unfamiliar with the clinical implication of these measurements and thus may be unable to take advantage of the additional information this 3D tool provides. Furthermore, clinicians expressed concerns regarding the lack of a gold standard by which to assess the accuracy of volumetric measurements. While no gold standard exists to determine the accuracy of linear measurements, the

XSL•FO
RenderX

novelty of volumetric analysis necessitates an additional metric of accuracy.

Discussion

Principal Findings

In this study, surveys and clinical interviews were conducted to evaluate the efficacy of current 2D tumor analysis protocols and to assess the clinical interest, recommendations, and concerns regarding the incorporation of 3D volumetric analysis for the treatment of NF2-related schwannomatosis. In summary, the consensus among clinicians was that a 3D volumetric analysis and visualization tool could greatly benefit the treatment of NF2-related schwannomatosis, but it must be implemented with caution. We believe that these clinician perspectives are extremely important as 3D volumetric analyses are increasingly being discussed within the literature, and for these technologies to have clinical relevance, the perspectives of clinicians must be at the forefront.

Clinicians were enthusiastic about the prospect of using 3D volumetric analysis in lieu of traditionally used linear analysis. This was largely due to several shortcomings of linear analysis that were highlighted through both survey results and interviews, with the two main concerns being varying patient orientations during MR imaging procedures causing variability in 2D image presentation and the subjectivity of defining the maximum tumor diameter in linear assessments. Despite efforts to collect linear measurements across scans as uniformly as possible by locating anatomical landmarks for individual patients, it can be challenging to ensure the measurement is collected in the same location. These limitations described by the interviewed clinicians align with those described by the Response Evaluation in Neurofibromatosis and Schwannomatosis consortium, something that led to their recommendation of using 3D volumetric analysis to assess tumor size initially [18].

From the interview and survey findings, there were several features of 3D analysis and visualization software that were believed to have the potential to benefit clinical practice. From interviews, the main consensus was that the ability to visualize the relationship between critical brain structures and tumors in 3D space would be the largest benefit of a 3D analysis and visualization tool as it would reduce the need for 3D mental reconstruction of where the tumor exists within 3D space. This feature was largely supported by the survey results as well, with "visualizing tumors with respect to critical brain structures" being the second highest feature that clinicians believed would be beneficial (Textbox 2).

Other features highlighted in both surveys and interviews demonstrated that the software should be interactable by incorporating zoom and rotation, allow for the adding/removing of the tumor from view, and have transparency adjustment features. These features are even more important when paired with the capability to view multiple chronological tumors at once, one of the other main features identified by both interviewed and surveyed clinicians as being important. Specifically, clinicians expressed enthusiasm for the prospect that these chronological tumor overlays could eventually lead to the capability of forecasting tumor growth. In Textbox 2 this "forecasting feature" ranked as the highest priority feature for clinicians demonstrating a belief that this could have a major positive impact on clinical treatment. Overall, the clinical opinions regarding important features demonstrate that current 3D modeling technologies such as OsiriX Lite, ITK-Snap, and BrainLab iPlan may not be heavily integrated into clinical practice due to shortcomings in their visualization capabilities, specifically their inability to overlay chronological tumors. Jester et al [19] provide a visualization of this chronological tumor overlay, demonstrating how it can give clinicians an interpretable vision of tumor growth over time.

Some statements regarding the benefits or potential use of 3D volumetric analysis or 3D visualizations were met with hesitancy, with average agreement levels nearing 3.0 (neither disagree nor agree). These statements claimed that 3D volumetric measurements must be combined with visualization to be clinically meaningful (mean 3.07, SD 0.92), that 3D models of VS tumors would lead to more informed decisions about the type of intervention needed (mean 3.00, SD 1.41) and that 3D visualization of VS tumors in the surrounding cerebral space would aid in surgical planning (mean 3.20, SD 1.30). This hesitancy demonstrates that while visualizations are important to clinicians, more precise volumes to compare between chronological scans may still be more important. Additionally, the hesitancy surrounding the use of 3D visualization to better define treatment approaches could also be attributed to a lack of understanding of how these visualizations may be used in this setting, something that could be better demonstrated to clinicians with a more detailed overview of the software's design.

Despite recommendations to move towards volumetric analyses, the interviewed clinicians also expressed concerns about how they would determine the clinical implications of volume measurements. These clinicians felt that they could comfortably determine the clinical implications of linear measurements by assessing the trends of uni- and bi-dimensional linear measurements of tumor size, but they lacked a similar knowledge of trends for volumetric measurements. As a future step to increase clinical confidence in the interpretation of tumor volumes, correlation studies can be conducted to determine the approximate relationship between linear and volumetric measurements. Additionally, future development of this diagnostic software can integrate linear analysis measurements as well, automating assessments of uni- and bi-dimensional diameters. Through such studies, clinicians can gain exposure to using segmentation software to perform volumetric analysis and interpret volume measurements while collecting familiar linear measurements. Pairing these correlation studies with currently used RECIST criteria can encourage the adoption of 3D volumetric analysis in the clinical space.

For full adoption and validation of 3D volumetric analysis in the clinical space, multi-center validation studies must take place with clinicians from multiple institutions performing 3D volumetric analysis on a diverse array of MRIs. DICE scores can be used as a metric to evaluate the differences in voxel selection within each scan between clinicians. To generate RECIST-compatible standards, current RECIST protocols

XSL•FO
RenderX

should be used as a basis to form corresponding 3D-specific protocols. This will require collaboration from multi-institutional research and clinical communities interested in the full adoption of 3D volumetric analysis.

Limitations

Clinical interviews incorporated in this study were conducted with a limited group of clinicians from just four institutions. Incorporating clinical feedback from a larger and broader group of clinicians experienced in the diagnosis and treatment of NF may more clearly elucidate the strengths and limitations of a novel segmentation and visualization software. Specifically, including perspectives from clinicians from institutions with varying levels of expertise, resources, and knowledge in treating NF and understanding how these varied departmental structures impact perspectives was not done in this study, but could aid in generating a tool more applicable to all clinicians, not just those from high-resource medical institutions. Additionally, though the sole user of this software is intended to be clinicians, other users, such as researchers, may use this software. However, within this study, interviews were limited to just clinicians, potentially limiting the information gathered.

Conclusions

Clinicians were overall in favor of the adoption of 3D volumetric analysis techniques for measuring VS tumors but expressed concerns regarding the novelty and inexperience surrounding these techniques. However, clinicians felt that the ability to visualize tumors with reference to critical structures, to overlay structures, to interact with 3D models, and to visualize areas of slow versus rapid growth in 3D would be valuable contributions to clinical practice. Overall, clinicians provided valuable insights for designing a 3D volumetric analysis tool for VS tumor growth. These findings may also apply to other central nervous system tumors, offering broader utility in tumor growth assessments.

Abstract

Background: Patients with traumatic brain injury are at an increased risk of developing venous thromboembolism. Clinical decision support systems (CDSSs) may improve the use of venous thromboembolism prophylaxis protocols, yet suffer from poor compliance among end users due to a lack of user-centered design.

Objective: The objective of this work was to improve the content, design, and workflow integration of a traumatic brain injury–CDSS based on feedback from experts and end users.

Methods: The CDSS was evaluated leveraging a dual usability approach. A set of usability experts (n=3) and trauma providers (n=5) performed heuristic evaluations and usability testing by end users. Data was collected through a triangulation of methods and analyzed using qualitative (thematic) and quantitative (descriptive) analyses.

Results: Among the 145 total issues identified across both methods, 66 issues were found to be unique. Of the 66, a total of 17 issues were found by heuristic evaluations, 43 by usability testing by end users, and 6 were found across both methods. Thematic analysis was conducted on the 66 unique issues, which were further assigned to themes and subsequent subthemes. We identified 13 unique themes. The 3 most prevalent themes of 66 issues were lack of supporting evidence (n=17, 26%), operational barriers arising from the test environment (n=11, 17%), formatting inconsistencies, and lack of following standards (n=8, 12%). The system's usability scale survey score was 77.5 (SD 16, 95% CI 57.6-97.4), interpreted as an acceptable or good usability range. The mean response score for Single Ease Questions for all tasks was 5.9 (SD 0.53).

Conclusions: Combining expert and end user–driven usability evaluation methods identified a more comprehensive list of issues. This can facilitate the optimization of the traumatic brain injury–CDSS, resulting in improved usability and care management.

KEYWORDS

traumatic brain injury; venous thromboembolism; clinical decision support system (CDSS); heuristic evaluations; end user–based usability testing; decision support system

Introduction

Traumatic brain injury is one of the leading causes of mortality and disability worldwide. In the United States alone, over 69,000 traumatic brain injury–related deaths occurred in 2021 [1]. Patients with traumatic brain injury are at an increased risk of developing complications secondary to venous thromboembolism [2]. Fifty-four percent of patients with a traumatic brain injury will develop a venous thromboembolism in the absence of appropriate anticoagulation intervention [3]. Despite the significance of timely venous thromboembolism prophylaxis administration, there has been a reluctance to

XSL•FO
RenderX

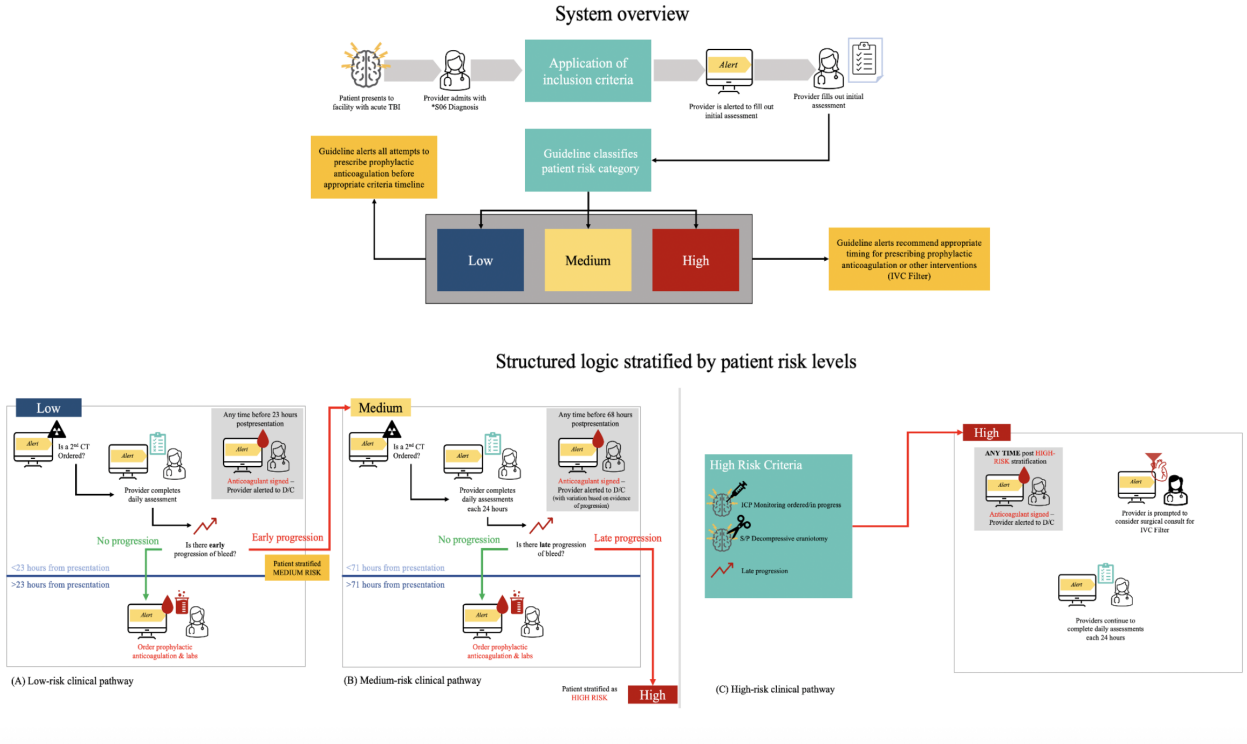
implement anticoagulation in such patients, thus resulting in delays in timely intervention [4-7].

Optimal use of venous thromboembolism prophylaxis protocols manages the risk of thromboembolism with the competing risk of progression of intracranial bleeding in patients following trauma [7]. However, there is variability in venous thromboembolism prophylaxis protocols across trauma centers [2,7,8]. In an attempt to optimize thromboembolism prophylaxis for the patient, institutional implementation of anticoagulation protocols has been shown to improve clinical outcomes [2,7,8]. To improve prophylactic anticoagulation of patients with traumatic brain injury without adversely affecting outcomes, integrating a clinical decision support system (CDSS) has emerged as an indispensable solution to supplement providers with evidence-based venous thromboembolism prevention guidelines [9]. Existing literature cites improved patient outcomes when evidence-based practices are followed, along with improved compliance with these practices through the use of CDSSs [10-12].

CDSSs, whether stand-alone or integrated with an electronic health records system, are considered a monumental step forward in health care delivery as they serve as reliable and readily available aids to decision makers. CDSSs serve as a platform for clinicians by comparing individual patient data and integrating evidence-based recommendations into their daily workflow [13,14]. When adhered to, these tools serve as an effective means of changing clinician behavior [15-17]. The use of CDSSs varies by purpose and context. However, the resultant benefits of CDSSs are found to consistently positively impact various elements of health care delivery for both patients and clinicians. For providers, it facilitates overall disease management by aiding complex decision-making that is mandated for accurate diagnosis, effective treatment, and efficient monitoring [18]. For patients, the use of CDSSs leads to fewer errors, improved patient safety, improved care quality, and enhanced health outcomes [19].

Despite these benefits, there are some risks and resistance to using CDSS [19]. This includes but is not limited to cost-related challenges, alert fatigue, physicians' autonomy and trust, liability issues, workflow disruptions, and usability challenges. The negative consequences of a tool to be developed and implemented could be mitigated if iterative evaluations are carried out earlier rather than in the later phase of the system development life cycle [20]. Often, due to the additional resources required (both time and money), iterative evaluations are not prioritized before deployment in clinical practice. However, predeployment usability evaluation could potentially save time and money by preventing the need for critical changes after system implementation [21]. This study highlights the criticality of early testing and engaging end users during the system development life cycle. Identifying and addressing users' concerns around tool optimization and workflow integration should be considered an integral component when building, implementing, and maintaining a CDSS.

Lack of user-centered design, interoperability, and implementation barriers hinder the widespread adoption of a CDSS [22-24]. There is a need for robust usability studies to address existing barriers and optimize the functionality of the CDSS according to users' needs. The objective of this study was to evaluate and optimize the usability of a traumatic brain injury CDSS integrated into a US Midwest American College of Surgeons–verified trauma center. Usability issues in a traumatic brain injury-venous thromboembolism-CDSS were identified by leveraging a dual usability evaluation approach. We hypothesized that combining expert and end user–driven methods of usability evaluation would help identify a wide range of unique issues specific to each method, along with common findings shared between the 2 methods.



Methods

Overview of Traumatic Brain Injury–Venous Thromboembolism Prevention Guidelines

The traumatic brain injury–CDSS delivers a patient-centered outcomes research guideline for venous thromboembolism prevention in patients with traumatic brain injury [2,25], which was centered around the modified Berne-Norwood criteria [8]. Patients are categorized as being at low, moderate, or high risk for spontaneous progression of hemorrhage, with prophylactic treatment regimens tailored for each group, respectively. The traumatic brain injury–CDSS is a modification of an original, natively developed COVID-19 CDSS logic model, which is currently translated to interoperable standards [16] (Figure 1). We chose this model for two major reasons: (1) we have previous experience implementing the traumatic brain injury venous thromboembolism prevention guideline with success [2], and (2) many of the data elements and artifacts (~80%) overlap with minimal additional mappings and technology build. The final CPG-FHIR (clinical practice guidelines on Fast Healthcare Interoperability Resources) COVID-19 CDSS included 108 data elements. The traumatic brain injury clinical practice guideline added 21 data elements specifically related to traumatic brain injury (eg, intracranial pressure monitoring, neurosurgical consultation, craniotomy, head computed tomography imaging, subdural hematoma, contusion, and Glasgow Coma Scale).

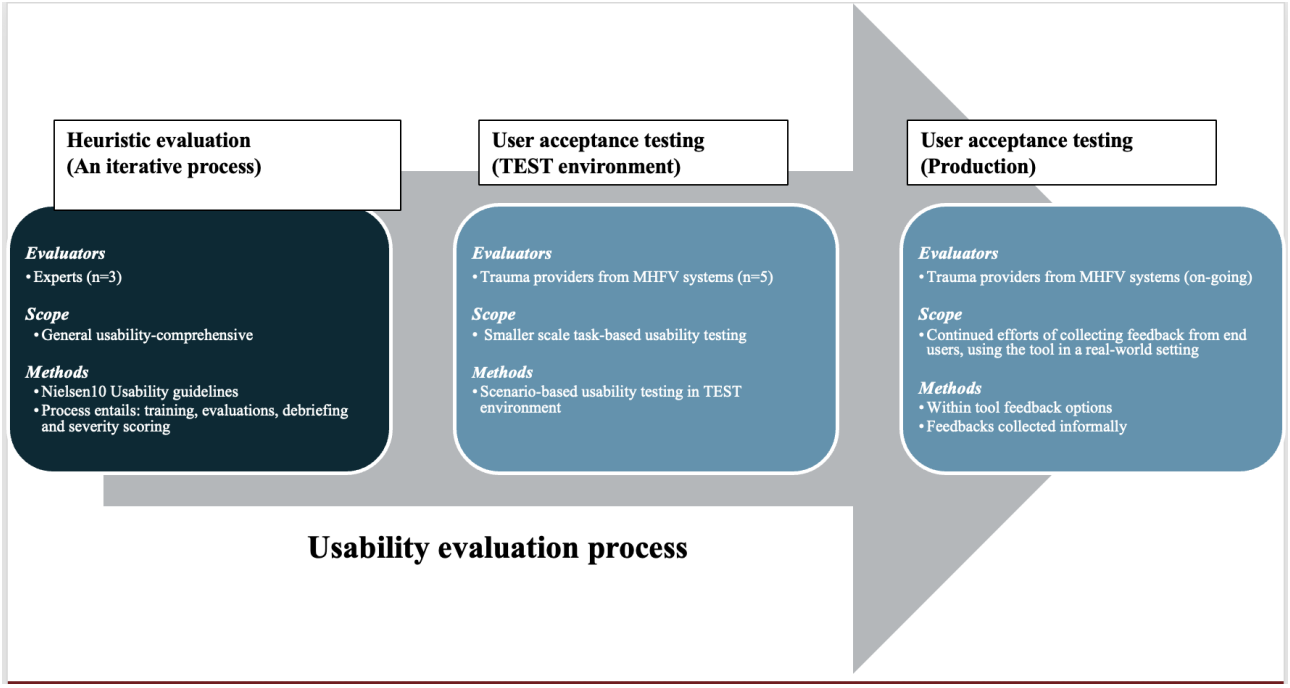
XSL•FO
RenderX

Figure 1. Clinical decision support system logic model for venous thromboembolism prevention among patients with traumatic brain injury. *S06: 2024 *ICD-10-CM* Diagnosis Code S06. CT: computed tomography; D/C: discontinue anticoagulation order; *ICD-10-CM*: *International Statistical Classification of Diseases, Tenth Revision, Clinical Modification*; ICP: intracranial pressure; IVC: inferior vena cava; S/P: status post; TBI: traumatic brain injury.

Given the logic model, patients will enter the system by admission under predetermined diagnoses, generally falling under the traumatic brain injury category. Our target population is adult patients admitted with an acute traumatic brain injury, as defined by *ICD-10-CM* (*International Statistical Classification of Diseases, Tenth Revision, Clinical Modification*): S06.1-S06.9 or S06.A. Patients who died within 24 hours of hospital admission and patients documented as "comfort cares" during the first 72 hours of hospitalization will be excluded. Additionally, patients with a pre-existing venous thromboembolism or inferior vena cava filter at the time of admission and patients with a mechanical heart valve or ventricular assist device will be excluded from the final analysis.

The CDSS is provided in the subsequent 72 hours (dependent on risk stratification) and administered in the form of seven alerts (Textbox 1). Textbox 1 provides descriptions of the seven alerts deployed at various points in time, stratified by level of risk.

Textbox 1. Description of seven alerts in traumatic brain injury–clinical decision support system (CDSS).



- **Initial assessment:** provides initial risk stratification.
- **Follow-up computed tomography (CT) scan alert:** Guide proper timing of a follow-up CT head scan based on stratification
- **Daily assessments:** Track patient course and modify stratification in the event of critical conditions; that is, progression of bleed, placement of intracranial pressure (ICP) monitor, decompressive craniotomy, etc.
- **Anticoagulation alert:** Guides the health care provider to prescribe the correct dose of anticoagulation medication at the appropriate time, and not too soon.
- **Discontinue anticoagulation order alert:** Any attempt to prescribe anticoagulation before the appropriate clinical decision support system calculated time triggers an alert to discontinue the medication.
- **Laboratory order alert:** Prompts order of appropriate laboratories to monitor side effects of the anticoagulation medications, that is, Anti-Xa, platelets, etc.
- **Laboratory level alerts:** Additional prompts to monitor laboratory levels for appropriateness.

Study Settings

Our foundational usability evaluation-related research work was conducted by a team of researchers from the University of Minnesota (UMN) and associated health systems, such as the M (Minnesota) Health Fairview and affiliated hospitals, which consisted of 9 state-verified trauma centers, including the flagship UMN as an American College of Surgeons–verified level 2 trauma center. The usability evaluation methodology is reported in Figure 2.

XSL•FO
RenderX

Figure 2. A process diagram of the methodology. MHFV: M (Minnesota) Health Fairview; TEST: test environment.

Data Collection

Expert-Based Usability Evaluations

Heuristic evaluations leveraging Nielsen 10 Usability Heuristics for User Interface Design were used iteratively during the whole development cycle, where issues identified were addressed sequentially [26]. The initial round of heuristic evaluations was conducted on screenshots of the user interface that researchers independently evaluated.

Three experts with varied backgrounds, that is, a physician informatics or usability expert (RFR); a hospitalist with content and CDSS-related expertise (SS); and an undergraduate in neuroscience (SF) conducted the evaluation independently. We then had a debriefing session to walk through findings from individual users, removing any duplicates. Once we had a final, consolidated, clean list of unique issues, each evaluator did the severity ranking of each issue. A 0 to 4 rating scale was used to rate the severity of usability problems (0=I do not agree that this is a usability problem at all; 1=cosmetic problem only: need not be fixed unless extra time is available on project; 2=minor usability problem: fixing this should be given low priority; 3=major usability problem: important to fix, so should be given high priority; 4=usability catastrophe: imperative to fix this before product can be released) [27]. While assigning the severity score to usability problems, 3 factors were considered: the frequency with which the problem occurs, the impact of the problem, and the persistence of the problem. The team reconvened in a severity scoring session where a scoring consensus was reached for each problem after mutual deliberations.

End Users' Based Usability Testing

End users' based usability testing was conducted with actual end users, that is, trauma providers from M Health Fairview and affiliated hospital systems. Purposive sampling was used for recruitment purposes by sharing information about the traumatic brain injury–CDSS usability study through emails, discussions during meetings, word of mouth, etc. Scenario–based usability testing was done with individual end users along with our usability team comprised of up to 5 team members, including a moderator (n=1), facilitators–information technology (IT) experts both from the MHVF and the vendors who helped with building (n=2 - 3); and a note taker (n=1). Each session was conducted on Zoom (Zoom Inc.) and lasted up to 90 minutes.

In the scenario-based guided usability testing, we asked users to perform certain tasks on 3 unique test patients corresponding to 3 risk groups: low, medium, and high. Two to four scenarios were associated with each test patient for a total of 9 scenarios, which required each user to perform a few predefined, sequential tasks. Participants were asked to think out loud as they interacted with the traumatic brain injury–CDSS in the Epic testing environment (Epic Inc). Once each scenario and relevant task were completed, participants were asked a few questions to elaborate on their experience and complete a single ease survey questionnaire (REDCap [Research Electronic Data Capture] Consortium; Vanderbilt University). At the end of the session, participants completed a System Usability Scale survey (SUS) [28] and Single Ease Question (SEQ) [29] and were asked to share their overall experience with the tool.

Building Test Patients and Testing in Epic Test Environment

Our team of experts was comprised of builders or IT specialists (SB, PM, and MS) and clinicians (SS, RFR, and CJT), who helped with building the 3 master test patients stratified by risk level (Textbox 2). Scenarios were generated by a team of clinicians having diverse sets of experiences (ie, CJT, a trauma surgeon, and project principal investigator, SS, a hospitalist, and RFR, a physician informaticist with user acceptance testing experiences) and builders or IT specialists (SB, PM, and MS)

XSL•FO
RenderX

after in-depth discussions. The goal was to have scenarios that are commonly encountered and require trauma providers to perform certain high-priority tasks. Copies of the master patients were created to be used by each study participant..

Textbox 2. Patient risk stratification modified the Berne-Norwood criteria.

Test patient # 1: low risk

- Subdural hematoma 2 mm.
- No moderate or high-risk criteria.

Recommendation: initiate pharmacologic prophylaxis if repeat head computed tomography (CT) was stable at 24 hours.

Test patient # 2: moderate risk

- Subdural or epidural hematoma >8 mm.
- Contusion or intraventricular hemorrhage >2 cm.
- Multiple contusions per lobe.
- Subarachnoid hemorrhage with abnormal CT.
- Evidence of progression at 24 hours.

Recommendation: initiate pharmacologic prophylaxis if the head CT was stable at 72 hours.

Test patient # 3: high risk

- Placement of an intracranial pressure monitor, craniotomy, or both.
- Evidence of progression at 72 hours.

Recommendation: consider placement of an inferior vena cava filter.

The purpose of the testing was to receive user feedback effectively and efficiently, ensuring that the testing context matches as much as possible with the user interactions in the real world. Leveraging the Epic test environment to create a simulated environment came with a few constraints described under limitations.

Data Analysis

Overview

The respective data was analyzed both qualitatively and quantitatively as described.

Qualitative-Thematic Analysis

We compiled all the issues identified by each method into 1 consolidated list. This included data collected through heuristic evaluations and usability testing by end users. First, a subset of the issue was coded independently by 2 individuals (RFR and SF) at a more granular level, and a codebook was generated after mutual agreement between both coders and applied to the full list of issues. Each analyst coded the rest of the transcripts for various usability problems, using the codebook generated earlier. We cataloged the lowest-level codes into higher-level subthemes and themes to gain a more holistic understanding of traumatic brain injury–CDSS.

Quantitative Analysis

The primary focus was on data collected from the SEQ survey and SUS. SEQ is an effective and efficient tool comprised of a single question asked immediately after task completion. SUS is the most widely used and accepted standardized tool to measure subjective usability. We performed descriptive analysis, reporting means and SDs.

Ethical Considerations

This component of the project is not a clinical trial. This study protocol (STUDY00017107) was submitted to the UMN Institutional Review Board and given the determination of “exempt” as secondary research for which consent is not required. The mixed methods investigation was determined as a “not human research” as a quality improvement activity. Signed and written informed consent was obtained to screen and audio record the session, with the speech-to-text transcription feature turned on. Each recording was saved on a secured and encrypted UMN device. Each participant later received a US $50 gift card for their participation.

Results

End Users’ Characteristics

Five trauma providers participated in the individual usability testing session. The detailed characteristics are described in Table 1.

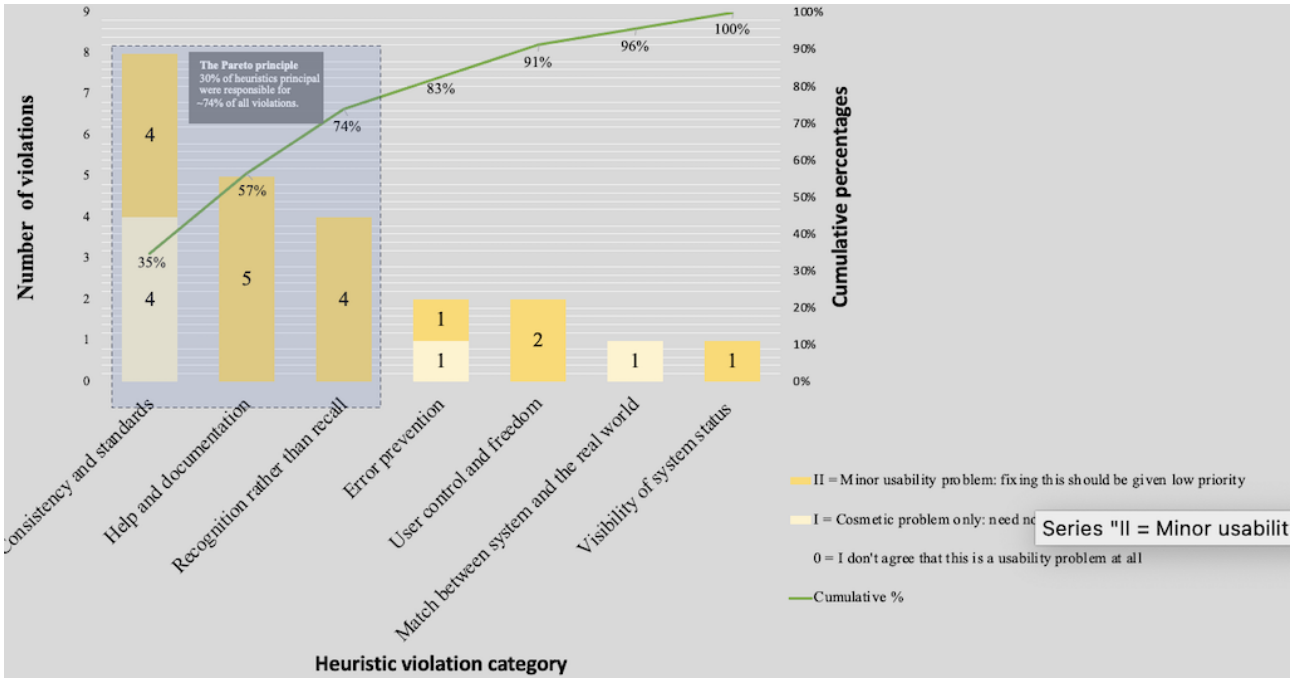
Intermediate	1 (20)

[a]MD: medical doctor.

[b]APP: advanced practice provider.



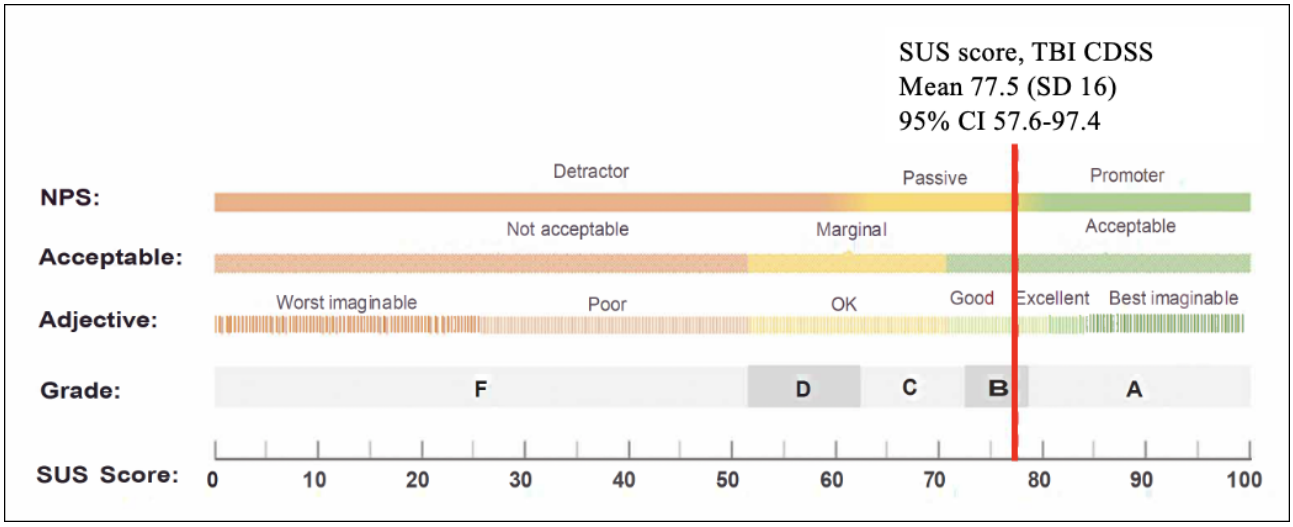
Usability-Related Findings From the 2 Methods

We identified a set of both common and unique issues using 2 methods: heuristic evaluation with experts (domain experts, ie, physicians, usability experts, or both) and usability testing with end users (the actual users).

Findings From Heuristics Evaluation

Thirty-seven heuristic violations (23 unique and 14 duplicates) were identified by 3 experts. The results showed that 30% of possible heuristics were responsible for ~74% of all violations, the Pareto principle (Figure 3). Three heuristics that represented the most violations were (1) consistency and standards (n=8, 35%), (2) help and documentation (n=5, 22%), and (3) recognition rather than recall (n=4, 17%). Of 23 unique, we found cosmetic (n=6) and minor (n=17) issues only.

Figure 3. The Pareto chart of heuristics principles violation and the severity ranking.



XSL•FO
RenderX

Findings From Usability Testing

We identified 108 issues (49 unique and 59 duplicates). Of 49 issues, we found cosmetic (n=6), minor (n=20), major (n=10), and catastrophic (n=2) issues. The remaining 11 were considered operational and not ranked. The mean responses to SEQ for all tasks were 5.9 (SD 0.53), ranked from 1 (very difficult) to 7 (very easy). The mean SUS score was 77.5 (SD 16) interpreted as an acceptable or good usability range (Figure 4). The 95% CI for the mean SUS score is 77.5 (95% CI 57.6 - 97.4).

Figure 4. The mean Systems Usability Scale score is interpreted as being within acceptable or good usability range (adapted from Lewis and Sauro [30], with permission from Jim Lewis). CDSS: clinical decision support system; NPS: net promoter score; SUS: Systems Usability Scale survey

Between the 2 methods, we identified a total of 145 issues, 66 of which were unique: 17 from heuristic evaluations, 43 from end users, and 6 common issues shared between both methods. Thematic analysis was performed on all unique issues, eliminating those arising from the constraints of thfsuye Epic test environment (66 - 11=55).

Ranking of Usability Issues

We ranked 55 unique usability issues on a severity scale from 0 - 4, where 20% (n=11) were marked as cosmetic; 58% (n=32) were identified as minor; 18% (n=10) as major, and 4% (n=2) as catastrophic issues. We identified both cosmetic and minor issues through heuristic evaluations and usability testing with end users. However, severe and catastrophic issues were solely identified during the usability sessions with end users.

Thematic Analysis

Thematic analysis was conducted on 66 unique issues identified through heuristic evaluations and usability testing. Eleven issues arising from Epic test environment constraints were eliminated. We identified 13 unique themes, including lack of supporting evidence, operational barriers arising from the test environment, formatting inconsistencies and lack of following standards, suboptimal data retrieval and display, lack of user control, lacking language clarity, order set-related suboptimal usability, language inconsistencies, best practice alert lacking patient-specific details, clinicians missing critical information or action, unfamiliarity with the full clinical context, infinite ordering loop leading to error, and having redundant options. The 3 most identified themes were lack of supporting evidence (n=17, 26%), operational barriers arising from the test environment (n=11, 17%), formatting inconsistencies, and lack of following standards (n=8, 12 %; Table 2).

XSL•FO
RenderX

Table . Thematic analysis distribution.

Theme	Unique issues (n=66)
Lack of supporting evidence	17
Operational barriers arising from the test environment	11
Formatting inconsistencies and lack of following standards	8
Suboptimal data retrieval and display	6
Lack of user control	5
Lacking language clarity	4
Order-set related suboptimal usability	4
Language inconsistencies	3
Best Practice Advisory lacking patient-specific details	2
Clinicians missing critical information, action, or both	2
Unfamiliarity with the full clinical context	2
Infinite ordering loop leading to error	1
Redundant options	1

Lack of supporting evidence refers to the end users' request to integrate and access evidence-based citations throughout the CDSS. Of the 17 usability issues about evidence-based medicine, 14 were identified by end users and 3 were identified by experts. Examples include users disagreeing with threshold values and requesting evidence-based medicine citations, and users requesting the ability of the CDSS tool to be explained.

Formatting consistency and a lack of following standards refer to the system's ability to present information clearly and concisely, with a consistent interface to ensure easy readability for the user. Of the 8 usability issues about formatting consistency and standards, 2 were identified by end users, and 6 were identified by experts. Examples include inconsistent and difficult-to-read text usage, style, color, and sizes.

Suboptimal data retrieval and display refer to the system's ability to present information in a manner that reduces user cognitive burden by increasing smooth and efficient navigation by auto-populating data (such as laboratory results). Of the 6 usability issues about easy retrieval and optimal display, all were identified by end users. Examples include users requesting that laboratory or imaging values and administration time be incorporated into the CDSS.

Lack of user control refers to the flexible design of the system to ensure smooth interaction with the user. Of the 5 usability issues about user control, 2 were identified by end users and 3 were identified by experts. Examples include users requesting the ability to navigate away from the tool and forgiveness when using the CDSS.

Lacking language clarity refers to specifying verbiage to omit any confusion the user may have. Of the 4 usability issues about language clarity, 3 were identified by end users and 1 was identified by experts. Examples include specifying verbiage used throughout the tool and using specific phrases (ie, the use of "active bleed" vs "new bleed" may imply 2 different ideas).

Order set-related suboptimal usability refers to any suboptimal interactions the user may encounter when interacting with the order set. Of the 4 usability issues related to order set-related suboptimal usability, all were identified by end users. Examples include users requesting the tool display prompts regarding its functionality on a case-by-case basis and easy access to the admission order set.

Language inconsistencies refer to the consistent use of verbiage throughout the system. Of the 3 usability issues about language consistency, they were all identified by experts. Examples include discrepancies between verbiage used in the storyboard or title and the consistent use of terms implying the same definition (ie, either "snooze" or "lockout time" should be used, not both).

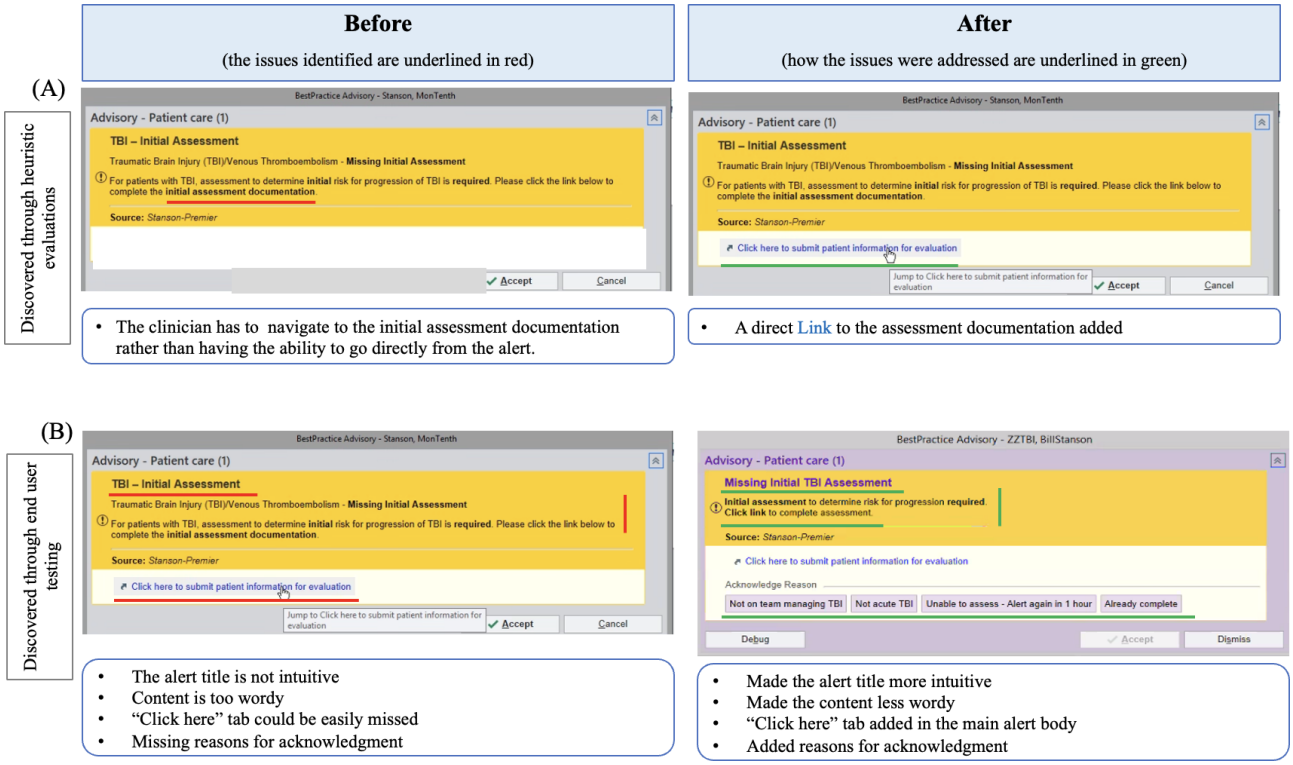
Best Practice Advisory (BPA) lacking patient-specific details refers to information that the system does not include, which users would prefer to be included. Of the 2 usability issues about BPA lacking patient-specific details, both were identified by end users. Examples include adding patient risk stratification to the BPA (ie, changing the tool to be more diagnostic) and including crucial patient-specific laboratory values.

Clinicians missing critical information refers to ensuring a system design that ensures easy readability for the clinician. Of the 2 usability issues about eliminating the chance of clinicians missing critical information, 1 was identified by end users and 1 was identified by experts. Examples include bolding information and making information more accessible to improve readability.

Unfamiliarity with the context refers to additional guidance presented to the clinician on the system. Of the 2 usability issues about unfamiliarity with context, both were identified by end users. Examples include ensuring proper education and introduction of the tool to clinicians to ensure it does not interrupt their workflow.

A redundant option refers to options already included as part of the system. Of the 1 usability issue about redundant options, it was identified by end users. Examples include omitting the "already ordered complete" button.

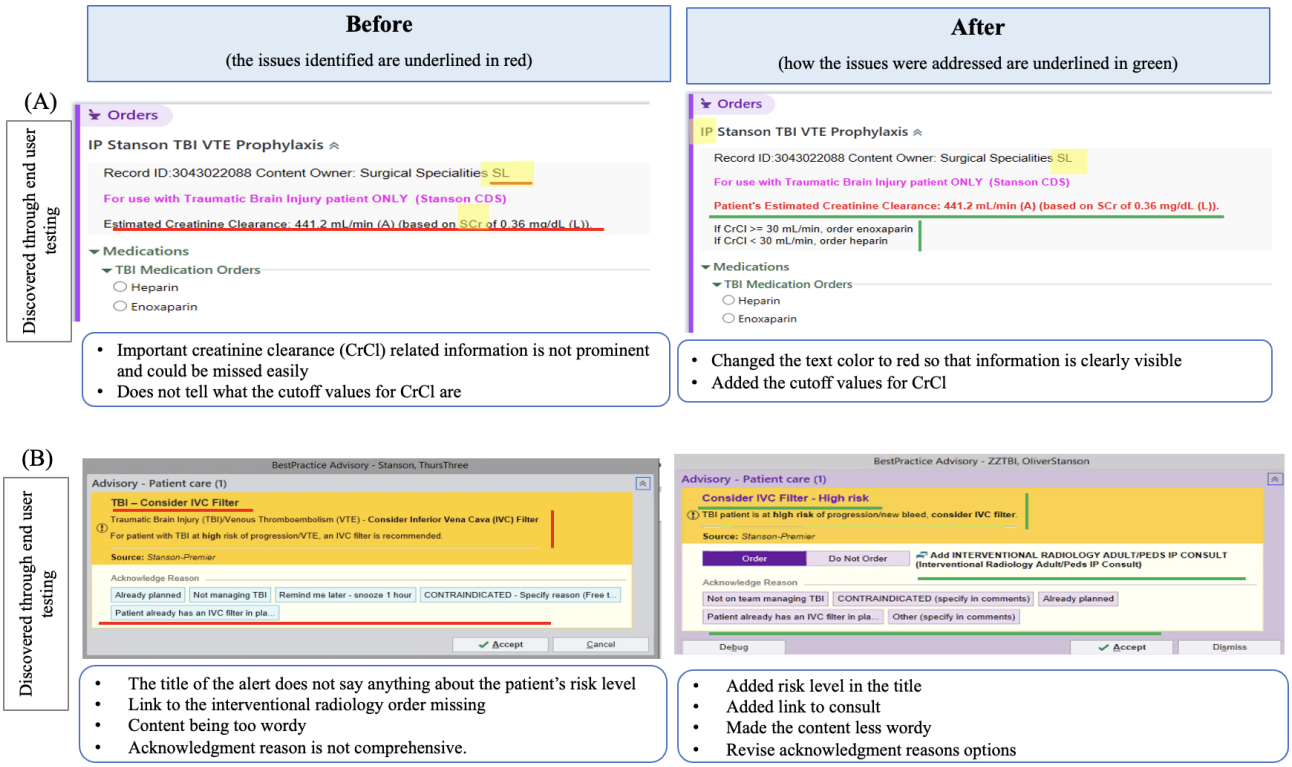
XSL•FO
RenderX



An infinite ordering loop leading to error refers to an infinite loop that occurs when using the system, during the beginning of its launch. It has since been resolved as of May 16, 2023. The 1 usability issue about the infinite ordering loop was identified by end users. Examples include users noting their warranted frustration with the ordering process.

Clinicians most often identified issues relating to the readily apparent integration of evidence-based medicine into the CDSS, recognizing a need for the use of citations and principles. Clinicians frequently noted how the CDSS might disrupt their workflow. For practical feasibility, request the integration of critical laboratory or imaging values and consistency in formatting throughout the tool to reduce user cognitive burden and ensure an efficient workflow. A compilation of unique usability issues categorized by theme is included in Multimedia Appendix 1.

Examples of Usability Modifications



Figures 5 and 6 present a few examples of modifications made based on insights from heuristic evaluations and usability testing by end users. The full list of identified usability issues is provided as a supplementary table.

Discussion

Summary and Interpretation of Findings

Using a dual usability evaluation approach, namely expert-driven heuristic evaluation and end user–driven usability testing, we identified a variety of both similar and unique issues across the traumatic brain injury venous thromboembolism CDSS. Of the 66 unique issues identified, the percentage attributed to each method was as follows: usability testing (43 issues, 65%), heuristic evaluations (17 issues, 26%), and both methods together (6 issues, 9%). Although the mean severity scores of the identified problems did not differ significantly between the 2 methods, issues that were ranked as severe and catastrophic were exclusively found through usability testing by the end users. The most common issues identified across both methods were related to a lack of supporting evidence, operational barriers, and formatting consistency or lack of following standards. Heuristic evaluations primarily identified issues related to formatting consistency or lack of following standards, user control, suboptimal language clarity, and consistency. In contrast, usability testing revealed a broader range of issues, where lack of supporting evidence, operational barriers, and suboptimal data retrieval and display were found to be the most common.

Using a combination of these 2 methods can identify a wider range of usability issues. This aligns with prior evidence suggesting that combining 2 methods of usability evaluation can facilitate the development of an optimal CDSS [24]. We found that the majority of issues identified by usability testing were only discovered by end users, as compared to the experts. Although the experts identified fewer issues, they pinpointed more granular issues related to the layout, formatting, and consistency. In contrast, end users were more concerned with larger, more consequential issues, such as the lack of supporting evidence to increase their trust and confidence and fragmented workflow (primarily sending form test environment-related constraints). The findings from this study validate many of the claims made in previous comparisons of heuristic evaluations and usability testing [31,32] such as heuristic evaluations being more cost-effective in terms of time and resources, and the ability of each method to identify distinct sets of usability issues with very small convergence rates (9% in our study). Heuristic evaluation findings were limited to identifying issues, whereas end users engaged in usability testing provided both strengths and weaknesses. For example, end users appreciated the clarity of the premier questionnaire (which covered the critical issue for risk profiling), as well as the straightforward alert verbiage. They also appreciated that the creatinine clearance value was apparent in the laboratory order results, eliminating the need to navigate to find it.

Limitations

There are some limitations to this study. First, the usability evaluation was conducted at a single institution (M Health Fairview) using a single electronic health system (Epic). We had 5 clinicians participate in the end user testing. Several usability evaluation resources suggest that testing with 5 individuals is often considered appropriate for identifying usability issues, especially in qualitative analysis [26]. However, a larger sample size would have strengthened the generalizability of the findings for quantitative analysis. Additionally, we did not examine whether participants' amount of experience in their

XSL•FO
RenderX

respective fields or their overall familiarity with digital technology influenced their insights.

Usability testing being conducted in the Epic test environment introduced some constraints that users had to adjust to, such as manually shortened refresh time frames to decrease testing time, which resulted in some unusual system behaviors. To simulate the passage of time, users had to right-click anywhere and hit "refresh" after responding to alerts. For the testing session, test results and imaging reports were simplified and appeared shorter in length. Consequently, the insights gathered during the simulation may not completely represent the realities and challenges faced by clinicians working in high-pressure environments, caring for their patients who are critically ill. Finally, the IT team faced challenges due to system constraints, as the systems were hardwired with limited ability for upgrades. We were, however, able to incorporate several build-related upgrades through close collaborations. We are still in the process of upgrading the tool based on the observations made during our evaluations and the feedback collected from end users since the tool went live.

Implications for Future Directions

Concerning further CDSS implementation in different hospital settings, we plan to scale and assess the effectiveness of the CDSS for venous thromboembolism prophylaxis guidelines in patients with traumatic brain injury. This will consist of a stepped wedge hybrid effectiveness implementation trial to scale the CDSS across 9 sites within 4 trauma systems.

Conclusions

By using dual usability evaluation methods, leveraging both expert and end user input during the early phases of system development in an iterative manner, we were able to identify a diverse range of usability issues. These issues varied in severity and were relevant to each evaluator based on their respective experience and role. Through conducting this study and our continued efforts to gather feedback from end users, we have been able to optimize the design and functionality of the traumatic brain injury–CDSS to align more effectively with clinicians' needs and workflow. This comprehensive approach has provided us with valuable insights in refining CDSS, ultimately improving its usability and effectiveness in clinical practice.

Acknowledgments

We acknowledge M (Minnesota) Health Fairview information technology and data sciences, Vincent Peta, PhD, and the staff at Stanson (Stanson Premier Inc) for their support in these efforts. We are grateful to clinicians at the Minneapolis location who facilitated our running the pilot and enabling dissemination of the decision support solution. This research was supported by the Agency for Healthcare Research and Quality (AHRQ; R18HS028583, CJT and GBM-M [principal investigators], and the AHRQ and Patient-Centered Outcomes Research Institute [PCORI; grant P30HS029744], Minnesota-Learning Health System scholar program [MN-LHS], and the National Institutes of Health's [NIH] National Center for Advancing Translational Sciences [UM1TR004405, K12TR004373, T32HL007741]). Additional support for MN-LHS is provided by the University of Minnesota Office of Academic Clinical Affairs, Clinical Translational Science Institute, and Center for Learning Health System Sciences. The content is solely the responsibility of the authors and does not necessarily represent the official views of AHRQ, PCORI, NIH, or MN-LHS.

Abstract

Background: In 2016, the National Health Service (NHS) England sought to drive digital transformation within select NHS trusts through the Global Digital Exemplar (GDE) program. While the program did advance the NHS's integration with digital technologies, disparities in digital maturity persisted between GDE-funded and nonfunded NHS trusts. The Department of Health and Social Care (DHSC) launched a data strategy in 2022 that aimed to develop the appropriate technical infrastructure and data architecture to enable more effective and efficient use of its data. Given the diversity in digital capabilities, open-source adoption, and interoperability standards within NHS services, official guidance has continued to struggle to provide effective unification. Data about capabilities and technologies from application development teams in the NHS trusts, crucial for advancing these areas, remains insufficient.

Objective: This study aimed to further document the capabilities and technologies used in the NHS to develop digital capacity, comparing those with standard funding against those with additional GDE funding. This comparative analysis provides a foundational understanding for evaluating current practices and identifying potential areas for improvement in the NHS digital transformation efforts.

Methods: This study was conducted using Freedom of Information (FOI) requests and systematic website searches. The Freedom of Information Act (FOIA) allows individuals to request information held by public authorities. This process supports transparency and accountability by ensuring public access to government data. Data were compiled from two sources: (1) FOI requests submitted to NHS trusts between July 2020 and December 2020, and (2) systematic website searches for technology conducted between August 2020 and July 2021. A series of chi-square tests was conducted to validate and strengthen the robustness of the FOI questions.

Results: A total of 191 (84.5%) of the then 226 NHS trusts completed the FOI request, and 161 of the 191 (84%) had software and app development, website, or innovation teams. A total of 112 (69.6%) teams developed front-facing service user websites and apps. Out of 191, 150 (93.2%) worked with clinical staff to formulate innovative ideas, 55 (34.2%) carried out developments for other trusts and external entities, 35 (21.7%) had attempted to secure an innovation grant, and 138 (86%) disclosed the technologies they use. A total of 25 (15.5%) said they always used open-source technology, and 24 (17%) disclosed technologies associated with interoperability standards in their responses.

Conclusions: The NHS must adopt a cohesive strategy and refine policies to ensure the success of its digital, open-source technology and interoperability standards initiatives. Five recommendations toward greater organizational interoperability are made by the authors. Future research should examine digital innovation across NHS trusts, focusing on barriers such as limited resources, organizational culture, and technical expertise. Identifying these challenges is essential for developing strategies to reduce disparities and promote equal progress.

Introduction

Background

In 2022, the Department of Health and Social Care (DHSC) released its data strategy, "Data Saves Lives: Reshaping Health and Social Care with Data," to improve how the National Health Service (NHS) uses data [1]. A key goal of the strategy was to develop the appropriate technical infrastructure to ensure that the data architecture underpinning the NHS works in unison, enabling more effective and efficient use of data. The data strategy would be carried out via a commitment to develop and publish a draft of the standards alongside an interoperability strategy to ensure that fit-for-purpose standards are widely adopted across health and adult social care. The anticipated standards would reuse and build upon international standards where applicable. However, the NHS's current ability to fulfill this strategy across hospitals and other facilities is not well understood due to a lack of visibility into its digital development capabilities.

The Global Digital Exemplar (GDE) program was conceived in 2016 by NHS England to achieve digital transformation in select NHS trusts. It was hoped that the program would create a knowledge-sharing ecosystem to spread learning to other NHS trusts [2]. The program resulted in the creation of 16 GDE acute trusts [3,4], 3 GDE ambulance trusts [5,6], and 7 GDE mental health trusts [7].

While the GDE program improved the use of digital within the NHS, studies carried out since have highlighted that NHS trusts and social care providers still lack digital maturity [8], and that a digital divide has emerged between NHS trusts with and without GDE funding [9,10].

The "Data Saves Lives" strategy uses user stories to describe various systems that can work together in a secure, safe, accessible, and interoperable manner. Within this strategy, the UK Health Security Agency (UKHSA) aims to prioritize FAIR (findability, accessibility, interoperability, and reusability) principles [11]. In the context of FAIR, interoperability is defined as "the data need to interoperate with applications or workflows for analysis, storage, and processing." However, interoperability should not be viewed solely from a data perspective; it must also encompass system interfaces, the methods by which data are produced and consumed across the NHS ecosystem. While a universal approach to the architecture of NHS systems is impractical, achieving interoperability requires a commitment to key design considerations across data and application interfaces. This ensures the secure, safe, and effective use and reuse of data and information across system and organizational boundaries.

To complement interoperability, NHS England's Transformation Directorate is also in pursuit of making source code within the NHS freely available and downloadable through the use of open-source. Both open-source and interoperability can save NHS services from duplicating effort and help them build better services faster through shared resources [12]. The NHS Transformation Directorate presently promotes the open-source languages Python (Python Software Foundation) and R (R Foundation for Statistical Computing) through their network and engagement communities as common standards for programming [13].

Current Study

The digital capabilities of NHS services in England are diverse, with ever-evolving services providing differing levels of digital capability, open-source use, and interoperability standards. Official recommendations and advice struggle to unify the NHS effectively. NHS trust application development teams play a vital role in uptake in these areas, but in the present landscape, the NHS has limited visibility of these teams and their capabilities. NHS trust application development teams are focused on the creation and deployment of digital technologies designed to improve clinical care, patient outcomes, health system efficiency, and user engagement. This includes the development of software applications for clinical workflows or patient self-management, websites that provide access to health information or services, and innovative technological solutions such as artificial intelligence tools, remote monitoring systems, or digital diagnostics that address existing challenges or create new capabilities within health care delivery. The key objective of this paper is to illuminate the current state of NHS trust application development teams in England by documenting their capabilities and technologies, while comparing standard trusts with those that have received extra funding via the GDE program, thus providing a starting point for the evaluation of current practice.

Methods

Design

We documented the capabilities and technologies used in the NHS to develop digital products and services. Our data source was Freedom of Information (FOI) requests sent to NHS trusts in England. In our FOIs to NHS trusts, we asked for the disclosure of all departments and teams handling application and software development, websites, and technical innovation, along with the number of team members and roles. Further information regarding the teams was requested, covering technologies and software design methodologies used, use of open source, development of service user websites and apps, innovative collaboration with clinical staff, tenders for system development, developments for others, selling systems commercially, and use of innovation grants. Eleven of the 14 FOI questions were designed to elicit clear binary responses (1=yes, 0=no), which made them straightforward to answer and reduced the potential for variability or interpretation bias across NHS trusts. Respondents could still provide additional detail if

XSL•FO
RenderX

available, but the core data remained consistent (Table 1). To ensure the information received was relevant, focused, and reflective of genuine NHS digital capabilities, all trusts were appraised against the inclusion criterion of having teams and departments handling application and software development, websites, and technical innovation. To meet this criterion, the NHS trust had to respond "yes" to question 1 (Table 1). The explicit exclusion criteria were trusts without dedicated teams handling application and software development, websites, or technical innovation; trusts that did not respond or declined to provide information; and those that submitted their FOI response after December 31, 2020.

Table . Questions asked of National Health Service trusts.

Question	Wording
1	Does your trust have teams/departments that handle any of the following: application/software development, websites, or technical innovation? (Yes/No). If yes, please name these teams/departments.
2	How many members are in these teams/departments? What roles are the teams/departments made up of?
3	What technologies do the teams/departments use? For example: HTML5, C#, SQL, and .NET Core 2.0.
4	Are the developments of the teams/departments open source? (Yes/No). If yes, please provide any details you may be able to disclose regarding this.
5	What software methodology do the teams/departments use? (For example, one or more of the following: PRINCE2, AGILE, or Waterfall).
6	Do the teams/departments develop front-facing service user websites/apps? (Yes/No). If yes, please give any details you may be able to disclose regarding this.
7	Do the teams/departments work with clinical staff to formulate any innovative ideas they may have? (Yes/No). If yes, please give any details you may be able to disclose regarding this (digital innovation refers to the application of digital technology to existing business problems).
8	Have the teams/departments ever gone for external tenders for health care system developments? (Yes/No). If yes, please give any details you may be able to disclose regarding this.
9	Have the teams/departments ever done developments for other trusts/external entities? (Yes/No). If yes, please provide any details you may be able to disclose regarding this.
10	Have the teams/departments ever sold a development they produced commercially? (Yes/No). If yes, please provide any details you may be able to disclose regarding this.
11	Have the teams/departments ever attempted to secure an innovation grant? (Yes/No). If yes, please provide any details you may be able to disclose regarding this.
12	Were the teams/departments used during the COVID-19 crisis? (Yes/No). If yes, please provide any details you may be able to disclose regarding this. If no, please explain why they were not used.
13	Does your service provide mental health services? (Yes/No). If yes, have the teams/departments been involved in developing these digitally/online?
14	Do the teams/departments feel they have good visibility within the trust regarding the services they can offer? (Yes/No). Please provide any details you may be able to disclose regarding this.

All technologies were appraised against the inclusion criterion of being a programming language, framework, library, database, query language, interoperability standard, application programming interface, web service, or version control and collaboration platform. To meet this criterion, it had to be possible to find the technology via a Google search when the technology's name was entered as the search term, and the returned results identified the technology as matching one of the inclusion criteria. Examples of matches that were deemed acceptable included legitimate sources such as developer websites, corporations, and media outlets.

Procedure

On June 8, 2020, a list of NHS trusts in the United Kingdom was requested through an FOI email to NHS England, asking for the contact details of all NHS trusts within the United Kingdom. This yielded a list of 226 NHS trusts. During July 2020, the FOI email address and FOI contact form for each trust

XSL•FO
RenderX

were identified, and an FOI email request was sent to the Freedom of Information Act (FOIA) officer or department of each of the 226 trusts. The questions asked are reported in Table 1. Each initial question had a further open-ended subquestion asking for more details when a trust confirmed the existence of any associated information. Since FOI responses vary in format and structure across NHS trusts, the data had to be interpreted on a case-by-case basis rather than through a uniform extraction template. According to the FOIA, requests must be answered within 20 working days of receipt [14]. Due to the COVID-19 pandemic, the author allowed until December 31, 2020, for a response to keep all data within the same year. Retrospective ethical approval was requested from the Aston University Department of Business and Social Sciences Ethics Committee.

Content and Data Analysis

A conceptual content analysis methodology was used to conduct the data analysis. This approach facilitated the extraction of both quantitative and qualitative insights from the open-ended responses obtained via FOI requests. Specifically, it enabled the generation of a high-level statistical overview of digital capabilities across NHS Trusts, as well as a more granular examination of the technologies and methodologies reported by these institutions in relation to the study objectives.

To support systematic analysis, a codebook was developed to categorize the FOI responses (Textbox 1). Based on this codebook, the lead author designed and implemented a bespoke data management system through which the FOI response data were processed. Following data entry, the coded responses were exported as a complete dataset for statistical analysis using SPSS (IBM Corp).

XSL•FO

Textbox 1. Codebook.

Question 1: Does your trust have teams/departments that handle any of the following: application/software development, websites, technical innovation?

Response options:

1. No
2. Yes
3. N/A

Number of teams: if option 1 was coded, calculate the total number of teams based on the response.

Question 2: How many members are in these teams/departments?

Response options:

1. Undisclosed
2. Disclosed
3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

Number of team members: If 1 response 1 was coded, calculate the total number of team members based on the response.

Question 3: What technologies do the teams/departments use? For example: HTML5, C#, SQL, and .NET Core 2.0.

Response options:

1. Undisclosed
2. Disclosed
3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

Technologies and technology categories: if response 1 was coded, list all technologies in the response and code each technology against one of the following categories:

- Programming language: a language used by a programmer to communicate with computers. They are mainly used to develop desktop, website, and mobile apps.
- Framework: a structure upon which software can be built. They serve as a foundation, so a programmer does not have to start entirely from scratch every time they write a new program.
- Library: a collection of prewritten code that programmers can use to optimize tasks.
- Database: an organized collection of structured information, typically stored electronically in a computer system.
- Query language: a language used to make queries in databases and information systems.
- Interoperability standard: a standard that enables the operational processes, underlying exchange, and sharing of information between different systems.
- API or web service: a technology that enables the transfer of data between separate software applications.
- Version control and collaboration platforms: facilitate coordination, sharing, and collaboration across the entire software development team. Version control software enables teams to work in distributed and asynchronous environments, manage changes and versions of code and artifacts, and resolve merge conflicts and related anomalies.
- Other

Question 4: Are the developments of the teams/departments open source? (Yes/No). If yes, please give any details you may be able to disclose regarding this.

Response options:

XSL•FO
RenderX

1. No
2. Yes
3. Sometimes
4. Ambiguous
5. Not applicable
6. Unanswered
7. Unheld information
8. Declined under a section of the Freedom of Information Act.

Question 5: What software methodology (eg, PRINCE2, AGILE, or Waterfall) do the teams/departments use?

Response options:

1. Undisclosed
2. Disclosed
3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

Software design methodologies: if response 1 was coded, all methodologies should be appraised and coded against the inclusion criterion of being a software design methodology.

Question 6: Do the teams/departments develop front-facing service user websites/apps? (Yes/No). If yes, please give any details you may be able to disclose regarding this.

Response options:

1. No
2. Yes
3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

Question 7: Do the teams/departments work with clinical staff to formulate any innovative ideas they may have? (Yes/No). If yes, please give any details you may be able to disclose regarding this.

Response options:

1. No
2. Yes
3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

Question 8: Have teams and departments ever done developments for other trusts or external entities?

Response options:

1. No
2. Yes

XSL•FO
RenderX

3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

Questions 9: Have teams and departments ever attempted to secure an innovation grant?

Response options:

1. No
2. Yes
3. Ambiguous
4. Not applicable
5. Unanswered
6. Unheld information
7. Declined under a section of the Freedom of Information Act.

A detailed classification of the types of data extracted from the FOI responses is provided in Table 2, as categorized using the codebook. The dataset predominantly consisted of dichotomous variables.

Table . Collected data types from content analysis.

Question	Collected data types
1	• Yes or no (dichotomous) • Number of teams (numerical) • Details (qualitative)
2	• Number of members (numerical) • Details (qualitative)
3	• Technology names (nominal) • Technology categories (nominal) • Technology companies (nominal) • Uses legacy tech (dichotomous) • Details (qualitative)
4	• Yes or no (dichotomous)
5	• Methodology names (nominal) • Details (qualitative)
6	• Yes or no (dichotomous) • Details (qualitative)
7	• Yes or no (dichotomous) • Details (qualitative)
8	• Yes or no (dichotomous) • Details (qualitative)
9	• Yes or no (dichotomous) • Details (qualitative)

To establish whether the answers to these questions differed as a function of trust funding (standard or GDE), tests of association were used. A series of chi-square tests was conducted as an additional layer of validation to enhance the robustness of the findings for questions 1, 3, 4, 6, 7, 9, and 11. For analysis, “No” and “N/A” responses were collapsed into a single category, and only “Yes” and “No” responses were included in the final tests. Assumptions were checked, and when violated, a Fisher extract was used instead. All analyses were conducted using SPSS for Windows (version 25; IBM Corp).

Ethical Considerations

The Aston University Department of Business and Social Sciences Ethics Committee has reviewed and granted approval for the study. The study used UK FOIA data from NHS trusts, a process that supports transparency and public access to government-held information. The ethical considerations primarily focused on ensuring adherence to FOIA guidelines and that the requests were legitimate, appropriate, and respectful of the privacy rights of individuals and NHS trusts involved.

As the study did not involve human participants directly, and the data requested were publicly available, there were no concerns regarding private or sensitive data. Ethical issues related to informed consent and participant confidentiality were not applicable. However, all data requests were made in alignment with the principles of transparency, fairness, and public accountability set out by the FOIA.

In addition, the study adhered to best practices for data handling and reporting, ensuring that the requested data were used responsibly and in compliance with data protection laws where applicable. Any personal or sensitive information was either excluded or anonymized to protect confidentiality. To ensure fairness and safeguard the identity of NHS trusts, all reporting was done in a manner that made it impossible to trace data back to individual organizations, unless the FOI responses were requested directly from the NHS Trusts.

Results

Overview

We present the data pertaining to (1) response rates, (2) capabilities, (3) technologies, (4) open source, and (5) interoperability standards.

Response Rates

Out of 226 trusts, 191 (84.5%) completed the FOI request, 23 (10.2%) acknowledged receiving the FOI request but never provided followed up with answers, 7 (3.1%) had merged with another NHS trust, 2 (0.9%) sent partial information consisting of an organizational plan, 2 (0.9%) refused the FOI because it would take too long to complete, and 1 (0.4%) FOI email address no longer accepted emails. In total, 161 (84.3%) met the inclusion criteria by having teams or departments handling application and software development, websites, and technical innovation. The final sample comprised 83% (134/161) standard trusts and 17% (27/161) GDE trusts.

Capabilities

Have Software and App Development, Website, and Innovation Teams

Overall, 161 out of 191 (84%) trusts said they had software and app development, website, and innovation teams. The chi-square assumptions were marginally violated, with 25% of the cells (1 out of 5) having an expected count of less than 5; the minimum expected count was 4.87, so a Fisher exact test was run. According to the Fisher exact test, there was a nonsignificant association between trust type and having teams (P=.79). This suggests no difference in team presence between standard and GDE trusts.

Developing Front-Facing Service User Websites and Apps

Overall, 112 out of 161 (69.6%) trust teams developed front-facing service user websites and apps. A total of 43 (26.7%) trusts said no, 3 (1.9%) said the question was not applicable, 1 (0.6%) declined to answer the question on grounds of security, 1 (0.6%) stated the information was uncaptured, and 1 (0.6%) did not answer the question. There was a nonsignificant association between trust type and developing front-facing service user websites and apps (χ^2_1=1.47; P=.23). This suggests no difference between standard and GDE trusts.

Work With Clinical Staff to Formulate Innovative Ideas

Overall, 150 out of 161 (93.2%) of trust teams work with clinical staff to formulate innovative ideas. A total of 8 (5%) trusts said no, 2 (1.2%) said the question was not applicable, and 1 (0.6%) stated the information was uncaptured. The chi-square assumptions were marginally violated, with 25% of the cells having expected counts less than 5, and the minimum expected count was 1.69, so a Fisher exact test was run. According to the test, there was a nonsignificant association between trust type and the work with clinical staff to formulate innovative ideas (P=.21). This suggests no difference between standard and GDE trusts.

Carried Out Developments for Other Trusts and External Entities

Overall, 55 out of 161 (34.2%) trust teams carry out developments for other trusts or external entities. One hundred (62.1%) of trusts said no, 3 (1.9%) said the question was not applicable, 1 (0.6%) declined to answer the question on grounds of security, 1 (0.6%) stated the information was uncaptured, and 1 (0.6%) did not answer the question. There was a nonsignificant association between trust type and carrying out developments for other trusts and external entities (χ^2_1=0.031; P=.86). This suggests no difference between standard and GDE trusts.

Attempted to Secure an Innovation Grant

Overall, 35 out of 161 (21.7%) trust teams have attempted to secure an innovation grant. A total of 118 (73.3%) trusts said no, 3 (1.9%) said the question was not applicable, 4 (2.5%) stated the information was uncaptured, and 1 (0.6) declined to answer on the grounds of security. There was a nonsignificant association between trust type and attempting to secure an innovation grant (χ^2_1=1.57; P=.21). This suggests no difference in attempts to secure innovation grants between standard and GDE trusts.

Technologies

Overall, 138 out of 161 (86%) trusts with teams disclosed the technologies they used. A total of 84 technologies were identified: 27 programming languages, 19 frameworks, 10 libraries, 11 databases, 1 query language, 7 interoperability standards, 5 application programming interfaces or web services,

XSL•FO
RenderX

and 4 version control and collaboration platforms. All technologies are summarized in Table 3.

Python, the programming language used and promoted by NHS England and the NHS Transformation Directorate, was disclosed by 7 out of 138 (5.1%) trusts with teams that disclosed technologies. R, the programming language used for statistics

XSL•FO
RenderX

and data science, was disclosed by 2 out of 138 (1.4%) trusts with teams that disclosed technologies. The most disclosed query language was Structured Query Language with 88 out of 138 (63.8%) trusts, and the most disclosed programming language was C# with 81 out of 138 (58.7%) trusts.

Open Source

Overall, 25 out of 138 (15.5%) trust teams said they always used open-source technology, and 9 out of 138 (5.6%) said they used open-source sometimes. In total, 119 (73.9%) trusts said no, 6 (3.7%) said the question was not applicable, and 2 (1.2%) declined to answer on the grounds of security. There was a nonsignificant association between team type and open-source use (χ^2_1=0.014; *P*=.91). This suggests no difference in the use of open source between standard and GDE teams. Eight out of 138 (5.8%) trusts with teams that disclosed technologies indicated they used version control and collaboration platforms. A total of 4 platforms were identified in this review. The most used was Git, reported by 5 out of 138 (3.6%) trusts with teams that disclosed technologies.

Interoperability Standards

Overall, 24 out of 138 (17%) trusts with teams that disclosed technologies referred to interoperability standards in their responses. A total of 7 interoperability standards were identified. The most disclosed interoperability technology was HL7, mentioned by 11 out of 138 (8%) trusts.

Discussion

Principal Findings

This study is the first attempt to document the capabilities and technologies of NHS trust application development teams at a particular point in time. While these capabilities and technologies are changeable, the paper provides future researchers, commissioners, and policy makers with a baseline from which to build. The data presented raise several interesting questions relating to capabilities, open-source use, interoperability use, and programming languages.

Data Accessibility, Quality, and Limitations

The study was reliant on the provisions of the UK FOIA (2000) for data collection. Approximately 85% of NHS trusts responded to the request. Although this represents a large sample of trusts, it is difficult to ascertain the extent to which they are representative of all trusts. FOI requests rely on the expertise of those responsible for handling them in any given NHS trust, and the author was unable to determine how accurate and thorough individual responses were. During the data collection period, trusts were under immense pressure due to the COVID-19 pandemic, meaning that many may not have had the capacity to respond accurately. While most trusts addressed the questions posed, some declined to respond on security grounds. These data gaps, however, were minimal.

Capabilities

Digital maturity across NHS trusts is presently considered to be underdeveloped, with previous reports highlighting the need for the NHS to bridge the digital divide to avoid the creation of a 2-tier secondary care system [10]. While this may still be true in some cases, the data presented here highlights that in-house processes to develop digital capability are well established in 84% of responding trusts. Overall, no statistical differences were found between trust types and these results. This may indicate that increasing in-house capability to carry out digital projects was not a consideration when trusts received GDE funding. These results also highlight an issue with digital maturity measures such as HIMSS EMRAM (Healthcare Information and Management Systems Society: Electronic Medical Record Adoption Model). The measure exclusively focuses on technological functionality, such as electronic health records, and does not consider human and organizational capabilities [2]. The apps lead to an incomplete picture of a trust's digital maturity. While no significant differences were found between trust types, the overall results for each question highlight some interesting findings.

A review by Sood and McNeil [15] highlighted that it would be impossible for the NHS to become a modern, effective, and efficient health care system without fully embracing the digital agenda. The results of this survey reveal that trusts are working toward overcoming Sood and McNeil's [15] concern, with 69.6% of respondents reporting the creation of websites and apps to help service users.

A study by Asthana et al [16] investigated how, despite having a tax-funded NHS and a strong policy toward eHealth innovations, the English NHS had been limited in the extent to which it exploited digital potential. The survey results indicate that 93% (150/161) of respondents help clinical staff formulate innovative ideas. So, despite the suggestion of limited exploitation, NHS trusts are actively working to enable their clinical staff to innovate. However, the data do not reveal why, if this practice is commonplace, it has not been exploited to its full potential. Possible reasons may include limited resources regarding time, staffing, and funding.

The NHS Global Exemplar program was implemented to establish a knowledge-sharing ecosystem to spread learning among NHS trusts [2]. The survey results indicate 34% (55/161) carry out this practice. NHS England needs to do more to promote digital collaboration between trusts. Encouraging more digital development between organizations would help innovation and the leveling up of digital NHS services. Making trust teams aware of collaboration platforms such as the FutureNHS, that is used to support the right technology solutions to health and social care [17], could enable better sharing of technical innovations between trusts.

Innovation is critical in NHS England achieving the ambitions set out in the mandate, to increase the pace and scale of change. The NHS's Accelerated Access Collaborative (AAC) reported 2708 innovations being developed in 2019/2020 [18]. Survey data indicate that only 21.7% of respondents had applied for innovation grants. NHS England needs to do more to promote the innovation funding available to trusts. Academic Health Science Networks (AHSNs), now known as the Health Innovation Network, were established by NHS England in 2013 to spread innovation, improve health outcomes, and generate economic growth [19]. If the Health Innovation Network were

XSL•FO
RenderX

made more accessible to trust development teams, the internal potential of trusts to unlock innovation could help to maximize their benefit and better fund digital maturity. In addition, trusts could use the funding streams advised by the Health Innovation Network to independently create new digital innovations. Unfortunately, there is a limited amount of investment available, and not all trusts can benefit from this type of funding, but more should be done to encourage trusts to apply for these grants.

Open-Source Technology

NHS England has tried to instill open-source technology within the NHS for nearly a decade through multiple strategic programs such as the Open-Source Program and Code4Health. The latter aimed to serve as a vessel for promoting open-source technology through clinicians [20]. The survey results revealed that 73.9% of trust development teams do not use open-source approaches, suggesting that previous initiatives have had limited cultural influence, with developers still opting for closed-source methods. Recent publications, such as the report by Goldacre et al [21], have helped to put forward proposals for using open-source implementation and draw focus to NHS data analysts.

GitHub is the NHS's preferred platform for publishing open-source code [13]. However, the results of the survey show that only 5.8% of respondents listed using version control and collaboration platforms, and none of these gave reference to GitHub. NHS England needs to better communicate its desire for the NHS to use GitHub and open source and to work to promote this across all services. Without a unified approach to implementation, GitHub and open-source practices will continue to be used inconsistently across the NHS. The NHS data strategy has committed to making all new source code that is produced or commissioned open and reusable by default [1]. For this commitment to succeed in the NHS, the DHSC needs to go beyond publication of policy and digital guidance. Training and tools will be required to enable this at a regional level, meaning significant investment would be required, as services currently do not have the funding capacity.

There are presently 3 network and engagement communities run by NHS England's Transformation Directorate: Analyst X, NHS-R, and NHS Python [22]. The NHS Python community is focused on the promotion of open-source practices. However, this is done purely in conjunction with the Python programming language. Survey results showed that only 5.1% of respondents disclosed using Python. For open-source to be more widely adopted, a new open-source program of activity is required for the NHS. This should be aimed at the full spectrum of roles within the data process cycle and focus on dominant technologies used by NHS services. This, in turn, will make the community more inclusive to all NHS services and help to increase the adoption of open-source technology. The program should be coordinated at a regional level, with open-source champions that have both technical knowledge and understanding of data processing at the helm. The actions required to carry out this recommendation would be a large undertaking, and whether NHS England has the time or capacity to do this in the current climate should be considered; it may not be feasible. It will also be reliant on trusts being willing to involve themselves in the program.

Interoperability Standards

The objective to improve interoperability has been included in several NHS plans, and the end benefits of advanced interoperability are well recognized [23]. The primary benefit of interoperability is the ability to offer safe and reliable information transfer across the care pathway, reducing the possibility of adverse clinical outcomes [24]. The survey showed 17% listed interoperability standards in the technologies they disclosed. The DHSC has emphasized that it wants the NHS to use Fast Healthcare Interoperability Resources (FHIR) to achieve interoperability (DHSC, 2020). Unfortunately, the most disclosed standard was HL7, the predecessor to FHIR, disclosed by 8% of trust teams. Better promotion of the NHS Digital Interoperability Toolkit would benefit NHS trusts by helping them to standardize their technology and interoperability specifications [25]. Uptake, however, would be reliant on trust and willingness to use the toolkit.

Technologies

Interoperability is reliant on the NHS using technologies that are capable of communicating with one another. The most used programming language named in the survey was C# with 58.7%, a language that differs from NHS England's preferred programming language of Python, which was disclosed by 5.1% of those in the study. The difference in programming language standards puts the Transformation Directorate's push for open source and code sharing at odds with the wider NHS. There is still a benefit to code sharing, but some of this is lost because of the overhead involved in migrating between programming languages. A focus on the most consistently used languages across the NHS services would help to unify the NHS. There will be a strong reliance on the languages they have become accustomed to, and moving away from these is difficult to implement. Any coding examples NHS England develops should be written in the programming languages most appropriate for NHS services. Ensuring the use of modern languages will enable the NHS to keep a competitive advantage and help to retain staff looking to work on more relevant and modern languages over time.

Recommendations

Some of the insights derived from the study and related discussion suggest that the NHS has a solid foundation in certain areas. While trusts may not yet be fully aligned in their use of shared code, source control systems, or in leveraging all available opportunities, such as relevant grants, there is clear evidence of technology utilization across the organization. To build upon these foundations, this paper offers the following recommendations as steps toward achieving a more comprehensive digital maturity.

Promoting Digital Collaboration

Enhancing digital development between organizations can foster innovation and elevate digital NHS services. By making trust development teams aware of collaborations, such as the FutureNHS platform, we can enhance the sharing of technical innovations across trusts.

XSL•FO
RenderX

Leveraging the Health Innovation Network for Innovation

Increasing the accessibility of the Health Innovation Network to trusted development teams could unlock significant internal innovation potential, aiding in the funding and advancement of digital maturity. Trusts could independently develop new digital innovations by using funding streams advised by the Health Innovation Network.

Promoting Open-Source Usage

NHS England should better communicate its advocacy for using GitHub and open-source technologies and actively promote this initiative across all services. The NHS Data Strategy aims to make all new source code open and reusable by default. However, to achieve this, in addition to publishing policy and digital guidance, substantial investment in training and tools is required at a regional level, as current services lack sufficient funding capacity.

Increasing Open-Source Adoption

The survey revealed that only 5.1% of respondents use Python, indicating a need for a comprehensive open-source program across the NHS. This program should target all roles within the data process cycle and focus on the prevalent technologies used in NHS services. By making the community more inclusive, the adoption of open-source technology can be increased. The program should be regionally coordinated, with open-source champions possessing both technical expertise and an understanding of data processing leading the initiative.

Aligning Programming Language Standards

The variation in programming language standards presents a challenge to the Transformation Directorate's push for open source and code sharing across the NHS. Although there are benefits to code sharing, the overhead involved in migrating between different programming languages diminishes some of these benefits. Focusing on the most widely used languages across NHS services could unify efforts. It is essential to ensure that coding examples provided by NHS England are developed in languages most appropriate for NHS services, thereby maintaining a competitive advantage and retaining staff interested in working with modern technologies.

Future Research Needs

Future research should analyze digital innovation across NHS trusts, focusing on barriers such as limited resources, organizational culture, and technical expertise. Understanding these challenges is crucial for creating strategies to reduce disparities and promote equitable progress. Research should also explore ways to increase the adoption of open-source technologies, evaluating programs such as NHS Python and Analyst X, and expanding their reach. Investigating the programming languages and digital tools used across NHS trusts, aligned with NHS England's standards, can enhance interoperability and improve code sharing. In addition, assessing the feasibility and impact of unified programming standards within the NHS's digital infrastructure is essential. Research in these areas could significantly accelerate the NHS's digital transformation, ensuring services remain efficient, innovative, and inclusive, thereby improving health care delivery and stakeholder satisfaction.

Conclusion

Interoperability principles enable the use of data and information across system and organizational boundaries. Embracing interoperability addresses the unrealistic expectation for a one-size-fits-all system for the NHS, or that heterogeneous systems will communicate with one another out of the box. Interoperability reduces the need for greater oversight across the spectrum and allows the NHS to demonstrate maturity at crucial sinews and joints between systems and services.

Without interoperability, much-needed digital maturity will not be gained, and the divide between NHS trusts with and without GDE funding will continue to grow. As the NHS continues to advance its plans for the use of digital, open-source technology and interoperability standards, it is essential that a unified approach is followed. This study has provided a snapshot of the digital development technology landscape and the areas of digital implementation policy that need the most refinement to improve their success.

Abstract

Background: Health care professionals and patients frequently use the internet to access medical information. However, health-related mobile apps have yet to become fully integrated into routine clinical practice. Although the demand for eHealth apps has grown only modestly, studies suggest that such tools hold significant potential to enhance medical care and improve the quality of life, particularly for patients with cancer. To successfully implement these technologies in everyday practice, it is essential to understand the specific needs and preferences of the target population.

Objective: The aim of this study was to assess internet and eHealth use among patients with cancer receiving chemotherapy at an outpatient ward and to evaluate how the COVID-19 pandemic influenced internet and eHealth app use.

Methods: Between May 2021 and September 2021, a total of 303 patients receiving outpatient care at the hemato-oncology and gynecology departments of a Comprehensive Cancer Center were surveyed using a 21-item paper-based questionnaire, adapted from a validated information and communication technology–use survey. The questionnaire provided patient-reported information related to general internet abilities and use rates including health-related apps and changes during the COVID-19 pandemic. Data analysis was conducted using descriptive statistics, chi-square tests, Mann-Whitney *U* tests, and Spearman correlations.

Results: In total, 98.7% (299/303) of participants reported regular internet use, 72.6% (217/299) reported using the internet to search for health-related information, and 79.1% (235/297) expressed readiness to communicate digitally with health care providers. Decreasing age and higher internet literacy correlated with a more frequent use of eHealth apps (P<.001). A total of 24.7% (68/275) reported increased internet use during the pandemic.

Conclusions: The majority of patients were regular internet users and expressed an openness to eHealth apps. Factors such as internet literacy and average age are important to consider when implementing new eHealth apps in a clinical setting. Despite the positive influence of the pandemic on internet use, there remains a gap between self-reported readiness and real use of eHealth apps.

KEYWORDS

eHealth; mobile health; health-related internet use; health literacy; patients with cancer; COVID-19; oncology

Introduction

The internet and its wide scope of application possibilities is indispensable in our everyday life. In Germany, approximately 92% of the population uses the internet daily, and the number of nonusers decreases steadily every year [1,2]. While internet use is more common among the younger age groups, data show that already over 90% of people younger than 65 years of age use the internet daily [2]. Internet use among the older generation is concurrently steadily increasing. According to recent data, 27.7% of the internet users are ≥60 years of age [3,4].

At the same time, the importance of digital technologies in health care is rising. This trend is captured under the term

XSL•FO
RenderX

"eHealth," defined as the cost-effective and secure use of information and communication technologies in support of health and health-related fields [5,6]. In the medical context, the internet is used particularly frequently by medical professionals and patients to search for information [7-9]. However, the adoption of more advanced digital health tools—particularly mobile health apps—remains limited. These apps extend beyond mere information retrieval and offer functionalities such as patient-provider communication, symptom monitoring, therapy management, and the collection of patient-reported outcomes [10]. Practical examples of these apps include the Corona-Tracing-App [11], the digital COVID-19 European Union–vaccination certificate [12], or cancer-specific solutions such as CANKADO [13-15]. Despite their potential, such tools have not yet been widely integrated into routine clinical care [16]. Nevertheless, van Eenbergen et al [17] documented that the demand for eHealth apps among patients has increased to a very small extent in the years between 2005 and 2017 [9,17].

Among patients with cancer, internet use is often driven by the desire to understand their disease and treatment options and to connect with other patients or peer support groups [8,18]. While approximately three-quarters of patients with cancer turn to the internet for health-related information, only about half of these users are considered autonomous—able to navigate the internet independently without external assistance [18]. Despite this widespread use for informational purposes, only a small fraction of patients actively engage with more advanced eHealth apps beyond basic web-based searches [7,18-21].

Nevertheless, emerging evidence indicates that the use of eHealth apps has the potential to improve medical care and increase quality of life among patients with cancer. Some studies even demonstrate a link between eHealth app use and an improvement in overall and progression-free survival [22,23]. However, before introducing and using such tools in clinical practice, it is important to understand the target group. Therefore, the aim of this cross-sectional single-point cohort study was to determine if patients with cancer receiving outpatient treatment within our Comprehensive Care Center have access to, and are open to, the use of digital health apps.

Methods

Recruitment

This single-point cohort study was conducted at the outpatient hemato-oncology and gynecology departments of the Comprehensive Cancer Center at LMU Klinikum (Ludwig-Maximilians-University Hospital) in Munich, Germany. LMU Klinikum is one of the largest university hospitals in Europe, serving a diverse patient population from both urban and rural regions across Bavaria.

Between May 1, 2021, and September 30, 2021, patients receiving outpatient care in the aforementioned departments were invited to participate. Study personnel screened patients daily to assess eligibility. All patients aged 18 years or older were eligible for inclusion. Individuals with significant language barriers or functional impairments, as assessed using the Eastern Cooperative Oncology Group performance status, were excluded.

Eligible patients were approached in person during their scheduled visits and received verbal information about the purpose of the study. The survey was paper-based, completed on-site, and required approximately 5 to 10 minutes to complete. Assistance was offered if needed.

Participation was entirely voluntary. Due to the anonymous nature of the data collection, no personal or demographic information was recorded for nonparticipants. As a result, no formal comparison between participants and nonparticipants could be conducted. However, we acknowledge the potential for selection bias—particularly a tendency toward participation among individuals with higher digital literacy or a greater interest in digital health. This may limit the generalizability of the findings to populations with lower levels of internet access or digital affinity.

Questionnaires

The 21-item questionnaire was a modified version of the extended "use of information and communication technologies questionnaire (ICT) developed and validated by Seifert et al [24] for people aged 65 years and older in Switzerland in 2015" (Multimedia Appendix 1).

The first 3 of the 21 items collected basic demographic data including gender, year of birth, and diagnosis. The second part, the core of the questionnaire, consisted of 9 items relating to aspects of the patient's internet use. Analogous to Seifert et al [24], we collected data regarding which internet-enabled devices they own in the household (ie, computer and mobile), which one of these devices they most frequently use, and how often they use the internet. Patients who did not use the internet were asked for reasons. Furthermore, we gathered information regarding the age, the operating system, and the software of the mobile device. The remaining items referred to the patient's ability to use the internet and install apps.

The third part of the questionnaire consisted of 6 items related specifically to eHealth apps. We asked the patients to specify which eHealth apps they already use and which type of eHealth apps they would be willing to try to use.

The final 3 items focused on internet use during the COVID-19 pandemic. The first 2 items referred to the use of the "Corona-Warn-App," which was developed and released by the German government in order to simplify and expand contact tracing [25]. The last item used self-reported data to elicit information regarding how the pandemic has changed the frequency of internet use and if they have begun using eHealth apps during the pandemic. Patients were defined as "completers" when 90% of the items on the questionnaire were filled out (ie,≤2 items of 21 items were missing). All data are therefore presented based on completers only.

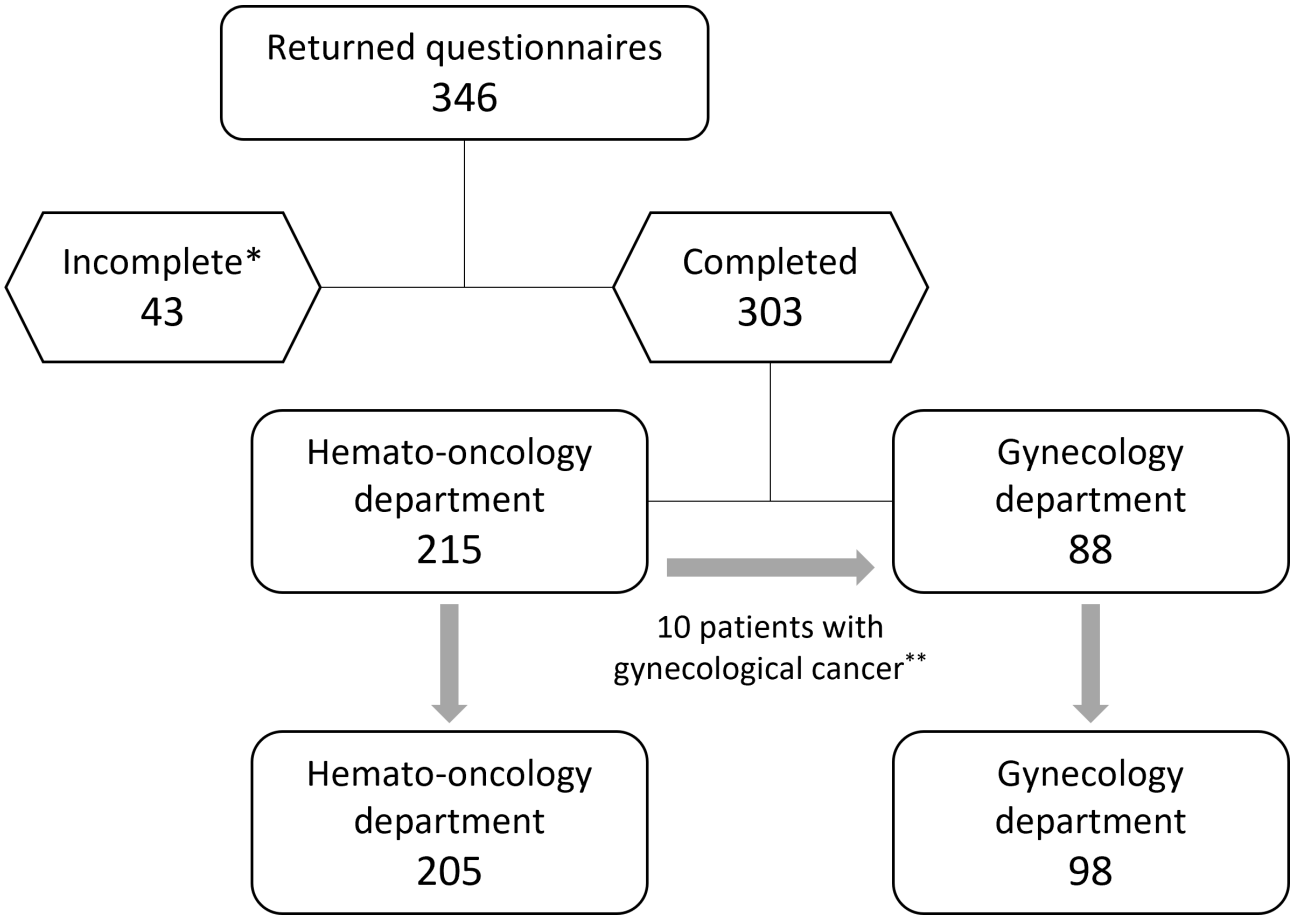
In future studies, the inclusion of open-ended questions—such as patient suggestions for desired features or concerns about digital health tools—may provide valuable qualitative insights and complement the quantitative findings.

XSL•FO
RenderX

Statistical Analysis

All data analysis was conducted with SPSS (version 26; IBM Corp) for Windows. Demographics and recruitment data were analyzed using descriptive statistics. Descriptive statistics were also used for analyzing internet user patterns of patients. The 2-tailed *t* test and Mann-Whitney *U* test were used to analyze group differences for numeric variables (ie, number of used apps). The chi-square test of independence and contingency analyses were used to analyze categorical variables. The Spearman correlation analysis was chosen to explore associations between ordinal variables (eg, perceived digital confidence and willingness to use eHealth) and continuous variables (eg, age), as many of the relevant variables were nonnormally distributed or measured on an ordinal scale. After analyzing the complete dataset, the data were then reanalyzed for differences between the 2 cohorts of patient groups from the 2 different departments (hemato-oncology and gynecology) using Mann-Whitney *U* tests and chi-square tests of independence. All tests were 2-sided, and the significance level was set to .05.

Ethical Considerations



The Medical Ethics Committee of the University of Munich determined that no formal ethics approval was required for this study, as the data were collected entirely anonymously and no personal identifiers were retained (project: KB 20/015). This decision is in accordance with institutional policies for research involving fully anonymized and nonreversibly deidentified data. Participation in the study was entirely voluntary. Patients were informed verbally about the purpose and content of the questionnaire during their outpatient visit, and the completion of the anonymous questionnaire was considered as implied informed consent. All data were collected and processed in a way that ensured full anonymity; no personally identifying information was recorded, and responses were nonreversibly anonymized prior to analysis. No compensation was provided to participants for their participation in the study.

Results

Overview

Of 403 eligible patients approached, 346 returned the questionnaire, yielding a response rate of approximately 85.9%. In total, 303 (87.6%) of them were categorized as complete. A total of 97.3% (285/293) were oncology patients. As a few patients with multiple sclerosis were receiving chemotherapy in the hemato-oncology department, our collective also included 2.7% (8/293) of patients without cancer. In total, 10 patients did not specify their diagnosis, and due to the anonymous nature of the questionnaire, it was not possible to obtain this information. Figure 1 provides an overview of the recruitment and participation process.

Figure 1. Study implementation. *Questionnaires with 2 or fewer missing variables were defined as “complete.” **For the purpose of this analysis, 10 patients with gynecological cancer who were receiving care at the hemato-oncology were moved into the group derived from the gynecology department.

XSL•FO
RenderX

Demographics

The mean age of the respondents was 59 (SD 14.064) years. In total, 55.8% (169/303) were women, and 44.2% (134/303) were men. Table 1 shows the distribution of the participants' primary diagnoses. The most common primary diagnosis was a gynecological tumor, followed by gastrointestinal tumors (defined as a tumor on an organ located in abdominal cavity, with the exception of kidney).

Table . Participants' gender and diagnoses.

	Values, n (%)
Gender (n=303)	
Women	169 (55.8)
Men	134 (44.2)
Diagnosis (n=294)	
Gastrointestinal tumor[a]	88 (29.9)
Gynecological tumor[b]	96 (32.7)
Lymphoma	25 (8.5)
Neuroendocrine tumor[c] (undefined)	13 (4.4)
Sarcoma	9 (3.1)
Urological tumor[d]	17 (5.8)
Bronchial carcinoma	6 (2.0)
Leukemia	5 (1.7)
Oropharyngeal tumor	4 (1.4)
Others	31 (10.5)

[a]All tumors of the following organs were designated as gastrointestinal tumors: liver, gall bladder, bile ducts, stomach, intestine (small and large), pancreas, esophagus, and any neuroendocrine tumors located in these mentioned organs.

[b]A total of 60.4% (58/96) of these were mamma carcinoma; all participants with other gynecology-related cancers were counted to "others."

[c]Other neuroendocrine tumor not located in abdominal cavity.

[d]Urological tumors we defined kidney, ureter, bladder, urethra, and prostate. No participants had penile and testicle cancer.

Access to and Use of the Internet

Only 3 patients did not have an internet-enabled device in their household, while 88.4% (268/303) of the patients reported having 2 or more internet-enabled devices. The most commonly used device was the mobile phone (199/288, 69.1%). In contrast, just over a third of the households had and used a stationary computer (Table 2).

Table . Ownership of web-enabled devices (n=303).

Web-enabled device available in the household	Values, n (%)
Smartphone	279 (92.1)
Notebook	209 (69)
Tablet	169 (55.8)
PC	110 (36.3)

Internet Use Patterns and Digital Confidence

Most of the patients reported using the internet several times a day (244/299, 81.6%), and 91.6% (274/299) reported using the internet at least once a day (Table 3). In total, 17 (5.6%) patients (average age 73, SD 9.5 years) reported technical difficulties and no perceived benefit as their reasons for hardly using the internet. Additionally, 4 patients declared themselves as noninternet users and were therefore excluded from the complete final dataset. In total, 299 of the 303 questionnaires were included in the final results for this part of the evaluation.

The frequency of internet use was age dependent and increased with decreasing age (ρ=0.211; P<.001). In total, 40% (119/298) of the internet users always felt confident navigating the internet. A total of 18.5% (55/298) reported feeling confident in their ability to use the internet most of the time, and 33.9% (101/298) reported feeling confident using simple apps. Only 7.7% (23/298) reported that they did not feel at all confident using the internet. In total, 70% (208/297) reported that they have installed an app, and 9.4% (28/297) estimated their ability for this purpose as sufficient. A total of 17.5% (52/297) required help from others when installing apps; yet, only 3% (9/297)

XSL•FO
RenderX

were of the opinion that they do not have the skills required to install an app.

Among the internet users, the majority (254/293, 86.7%) could receive updates and install them and have the current software version installed (shown in Table 4). These data are also reflected by the age of the devices owned by most patients. More than half of the devices (201/299, 67.2%) were at most 3 years old.

Table . Internet use.

Frequency of internet use	Values (n=299), n (%)	Age (years), mean (SD)
Minimum 1 time per day	274 (91.6)	57.77 (14.082)
Minimum 1 time per week	18 (6)	64.39 (11.387)
Less often	7 (2.3)	65.29 (10.242)

Table . Characteristics of most used devices.

	Values, n (%)
Age of device (years) (n=299)	
<1	49 (16.4)
1 - 3	152 (50.8)
3 - 5	71 (23.7)
>5	27 (9)
Operating system[a] (n=292)	
Android	110 (37.7)
iOS	98 (33.6)
Windows	89 (30.5)
Other	19 (6.5)
Current software version (n=293)	
Updates available	254 (86.7)
Updates available but not installed	24 (8.2)
No updates available	15 (5.1)

[a]The questionnaire items targeted the primary internet-enabled device used by each participant. Nonetheless, some participants gave multiple answers.

Use of the Internet and eHealth Apps

In total, 72.6% (217/299) of the patients reported using the internet for medical-related queries. These patients most frequently searched for information regarding their medical condition (170/299, 56.9%), followed by communication with the health insurance (112/299, 37.5%). Women tended to use the internet more frequently compared to men to communicate with other survivors of cancer (ϕ=0.184; *P*=.001). More than a third of the internet users already used 2 or more of the eHealth apps (Table 5). Younger participants tended to use eHealth apps more often than older ones (ρ=0.295; *P*<.001). A correlation was also found between the number of used apps and the increasing perceived competence in navigating the internet (ρ=0.320; *P*<.001) and navigating apps (ρ=0.330; *P*<.001). Perceived confidence navigating the internet and apps was significantly associated with a principal readiness to use more eHealth offers in the future (ρ=0.373 and 0.490, respectively; *P*<.001). Table 5 illustrates that patients most frequently reported readiness to use web-based platforms for communication with health care professionals and their health insurance. The least popular apps among this patient group were eHealth apps for the purpose of prevention. In total, 87.3% (261/299) of the internet users did at least specify that they are prepared to use 1 or more of the listed eHealth apps. However, increasing age correlated negatively with the number of eHealth apps that the participants were willing to use in the future (ρ=0.390; *P*<.001). In fact, significantly younger patients reported readiness to digitally manage health data for the following purposes: communicating with health care professionals, health insurance companies, or platforms certified by the government (*P*≤.001). Similar gender-related patterns could be detected. Between both collectives, our data revealed that men rather than women prefer to manage their health data digitally (ϕ=0.141; *P*=.02).

XSL•FO
RenderX

Table . Use of eHealth.

	Values, n (%)
Patients reported using the following eHealth apps (n=299)	
Searching for information	170 (56.9)
Communication with health care providers	40 (13.4)
Communication with health insurance	112 (37.5)
Communication with other survivors[a]	23 (7.7)
Keeping a symptom diary	22 (7.4)
Tracking vital parameters	27 (9)
Therapy apps[b]	7 (2.3)
Readiness to use the following eHealth apps (n=297)	
Organization of health data	200 (67.3)
Communication with health care providers	235 (79.1)
Communication with health insurance[c]	222 (74.5)
Use of a medical app approved by the German government[d]	190 (67.4)
eHealth apps for the purpose of (n=299)	
Health care[e]	179 (59.9)
Administrative processes	193 (64.5)
Prevention	110 (36.8)
Research	161 (53.8)
Therapy programs	137 (45.8)

[a]Definition of cancer survivor: “One who remains alive and continues to function during and after overcoming a serious hardship or life-threatening disease. In cancer, a person is considered to be a survivor from the time of diagnosis until the end of life” [26].

[b]For example, Diabetes- or Tinnitus-Trainer.

[c]n=298.

[d]n=282.

[e]For example, a videoconference with a clinician.

The type of operating system also seemed to affect patients’ affinity toward eHealth apps. For the following analysis, the 3 most common operating systems were considered: Android, iOS, and Windows. Patients with iOS on their device more often reported the use of therapy apps (ϕ=0.125; *P*=.03)—including examples such as Diabetes-Trainer and Tinnitus-Trainer [27,28]—and, in comparison with Android users, were also tended to use the internet more often to search for medical information (ϕ=0.148; *P*=.04). Here, no association could be shown with age or gender.

Digital Medicine and COVID-19

In total, 36% (107/298) of the patients had installed the German government–issued “Corona-Warn-App” (Corona-Tracing-App) on their mobile phones at the point of participation in this investigation. Patients who had installed the app were on average 55 (SD 14.327) years of age and were thereby significantly younger than those who had not yet installed the app (mean 60, SD 13.388 years; 2-tailed *t* test; *P*=.001). Among the 170 patients who did not yet have the app installed, 51.1% (87/170) reported that they did not use the “Corona-Warn-App” because they did not see a benefit. However, 27.6% (47/170) of patients reported that they did not use the “Corona-Warn-App” due to technical problems (incompatible operating system and problems with the installation), and 15.3% (26/170) of patients had not heard about the app. In total, 10% (17/170) of patients did not use the “Corona-Warn-App” because they did not want to share their infection status through a digital means. An additional 2.9% (5/170) of the patients did not want to know about their own infection status. A total of 24.7% (68/275) of participants reported that their internet use changed due to the pandemic. In fact, 5.8% (16/275) began to use eHealth apps during the pandemic. In total, 62.5% (10/16) of these patients had installed the government-issued “Corona-Warn-App” as the first eHealth app on their mobile phone. While decreasing age correlated with increased eHealth app use during the pandemic (ρ=0.367; *P*<.001), women tended to be more likely to increase their use during the pandemic, while men did not report any pandemic-related changes (Cramer ϕ=0.241; *P*=.001).

Comparison Between the Collective of Gynecology and Hemato-Oncology

Patients from the gynecology and hemato-oncology departments were also analyzed separately and compared. Patients from the gynecology department were significantly younger than those of the hemato-oncology (56 years compared to 60 years; *P*=.01).

XSL•FO
RenderX

When comparing the 2 collectives, patients from the gynecology department reported feeling more competent using the internet (P=.02), used the internet more frequently (P=.04), and also tended to use more eHealth apps (P=.004). Gynecology patients also reported using web-based forums more often compared to other patients (ϕ=0.183; P=.002). Furthermore, they tended to measure and report vital parameters more frequently within the apps (ϕ=0.139; P=.02). Additionally, patients from the gynecology department communicated with their health insurance through digital apps more frequently (ϕ=0.136; P=.02) and kept digital symptom diaries more often when compared to the patients from the hemato-oncology department (ϕ =0.140; P=.01).

Discussion

Principal Findings

The fact that the overwhelming majority of patients own and use an internet-enabled device provides the foundation for widespread use of eHealth apps. In fact, the majority of the patients reported feeling confident navigating the internet and apps most of the time. Among those who reported lower levels of internet literacy, almost all could receive help when required. It can thus be ascertained that the fundamental conditions, the technical resources, and the know-how for the implementation of digital health apps are all given. In fact, in comparison with other studies, access to and use of the internet is rather high for our collective [20,21,29]. This allows the assumption that implementing eHealth may be even simpler among our patients when compared to other patient settings.

Our patients reported using the internet most frequently to search for and obtain medical information. While these results are consistent with existing literature [18,19], our results do not show quite a high tendency to use the internet to seek information about their disease as previous literature reports. This could be due to the fact that patients from both the gynecology and hemato-oncology departments are routinely made aware of the problems of misinformation through the internet and explicitly instructed not to seek information about their disease through a Google search. Instead, they are provided with evidence-based websites they can refer to when necessary. The next most common reasons cited for internet use among our collective were as follows: communication with health insurance companies (112/299), communication with physicians (40/299), and tracking of vital parameters (27/299). The number of patients who communicate digitally with physicians among our collective is 6.2% higher than that which Makowsky et al [30] report among their collective. However, Makowsky et al [30] investigated internet use among healthy patients, and this may explain the discrepancy. Furthermore, 1 in 13 patients reported using web-based forums to interact with other survivors. These findings align with prior studies, suggesting that patients with cancer seek digital-based peer communication and emotional support, which may serve as a coping mechanism and source of empowerment [8,31,32]. This postulation may also be supported by the fact that women tended to be more likely to participate in such forums than men.

In congruence with previous results [9,21], age influences use as well as openness to eHealth. As expected, the younger the patient, the more frequent the internet use, and the more confident the patients are when navigating the internet. Generally, younger patients are more open to digital health apps. Nevertheless, studies show that the older generation is also becoming increasingly familiar with the internet [33], indicating that the target group for the use of eHealth will continue to grow. Our data reflect this trend by demonstrating that almost all of our patients are regular internet users even though the average age was 59 years.

Whereas a younger age is consistently associated with increased internet use and competency, data regarding gender differences are not as consistent. Our results show that women are more likely than men to use internet forums to communicate with other survivors, but men report a higher readiness for managing health data digitally. These results are consistent with Harrison et al [34], who also demonstrated that, on average, women seek social support more than men. Harrison et al [34] explained this difference in reference to the classical gender stereotype that women are more communicative than men. This may also explain why women are more likely to search the web for support or more ready to participate in support groups [31,32]. However, our data did not confirm gender as an overall predictor of eHealth app use. To explore this further and rule out gender bias, future studies should apply multivariate analyses that control for age and internet literacy.

Among the 3 most frequently used operating systems (Android, iOS, and Windows), our results showed that iOS users tend to be more open-minded toward eHealth apps in comparison to patients who use other operating systems. In fact, iOS users were significantly younger than patients who used other operating systems. However, we found no relationship between age or the current operating system with regard to the use of therapy apps and using the internet to seek information. This may suggest an existing relationship between the operating system and the readiness for using digital medicine. For example, Ubhi et al [35] demonstrated that iOS users more often installed an app to help them stop smoking.

In line with existing literature, our data show that internet literacy is a strong predictor of eHealth readiness, often moderated by sociodemographic factors such as age, gender, and education [26-28]. Therefore, we recommend that before the implementation of eHealth apps, it is important to be familiar with the potential patient's internet literacy. However, if time is lacking, our results, as well as results from previous studies, indicate that studies with patients younger than the age of 65 years may be more successful [2,9,21].

Both internet use in general and the use of eHealth apps increased during the pandemic. This could be due to the fact that when faced with social distancing restrictions and fear of infection, the domain of eHealth and digital health experienced an upswing [36]. Algumzi [37] confirmed this postulation, reporting that during the pandemic, the use of eHealth apps such as telemedicine and digital health increased in acceptance and use. These authors suggest that the reason could be due to fear of infection. This is also reflected in the fact that during the

XSL•FO
RenderX

pandemic, many health care facilities, including our clinical facilities, reduced in-person consultations and switched to telehealth or digital options [38,39]

Although studies with similar timelines report that between 46% and 66% of the population use the government-issued "Corona-Warn-App," only 36% (107/298) of our collective installed the Corona-Warn-App. The main reason cited for not using the "Corona-Warn-App" among all the studies was that the patients did not perceive any benefit from the app. Whereas previous studies cite privacy concerns and the perception of being monitored by the government, our patients named these reasons only sporadically. Nevertheless, our patients were more likely to cite technical problems (47/170, 27.6%) as an obstacle compared to 3.5% reported by Horstmann et al [40]. Our results did reflect a previously reported relationship between decreasing age and use of the government-issued Corona-Warn-App [40,41].

Our data revealed an existing gap between reported readiness to use eHealth apps and the reality of current use. While 79.1% (235/297) of our population reported readiness to use digital apps to communicate with health care professionals, only 13.4% (40/299) reported that they currently use a digital app to communicate with health care professionals. Similarly, while 74.5% (222/298) of the patients reported readiness to use eHealth apps to communicate with health insurance companies, only half (112/222) were currently using such methods, although they are widely available.

Comparable studies reflect these results [19]. In fact, consistent evidence shows that although health care professionals see great potential for eHealth apps to augment care, the step to real use is still hindered by various practical factors such as data protection, time restraints, and resistance to change among health care professionals [42]. Beyond these structural and technical barriers, additional challenges must be considered—particularly concerns about data privacy, trust in digital tools, and the influence of physician encouragement, all of which play a critical role in patients' willingness to engage with eHealth solutions [43].

To bridge this gap, several practical strategies could be implemented: physician-mediated introductions to digital tools during consultations may foster trust and promote engagement; intuitive, low-threshold app designs can reduce usability barriers [44,45]; and tailored support—such as one-on-one training or digital health navigators as introduced in a national study in Germany [46]—could help patients build both competence and confidence. System-level integration of eHealth into routine care processes may further normalize use and promote sustainable adoption.

As our participant pool was limited to patients receiving outpatient therapy in hemato-oncology and gynecology, further studies are needed to explore whether these observations hold true across other clinical settings.

Practice Implications

The gap between readiness and actual use of eHealth apps among oncology patients is decreasing. A slow and careful introduction of eHealth apps into the clinical routine and understanding of the population increases the likelihood of success. In general, this population seems open to eHealth tools; however, dedicated resources for support and assistance may promote growth in real-time use.

Limitations

This study has several limitations. First, convenience sampling was used to recruit patients, which may have led to participation only by those patients who were interested and open to the topic of digital health. To rule out skewed results, patients who did not participate were screened to rule out a lack of knowledge or use of the internet. Furthermore, patients who were not interested or did not use the internet were not excluded from completing the questionnaire. However, a small number of patients (n=4) reported that they did not use the internet. The significantly younger age of the gynecology patients [47,48] must be considered as a possible confounding factor when analyzing our results. However, although there was a mean age difference between the 2 groups, we did not find a relationship with age or gender difference in the willingness to use digital apps to keep symptom diaries in the entire collective. Therefore, it can be postulated that we accounted for this confounding factor adequately. Second, due to the cross-sectional design of this study, no causal inferences can be made regarding the relationship between age, digital literacy, and actual or intended eHealth use. Future longitudinal research is needed to better understand the temporal dynamics and potential causality of these associations. Finally, more demographic data—such as education level, socioeconomic status, or digital access barriers—could have allowed us to account for the influence of education level on patients' responses, and this factor could be considered a limitation when interpreting our results.

Conclusions

Our study demonstrates the existence of the necessary basic conditions for implementing the use of eHealth apps among our collective. In fact, the majority of our patients already use the internet regularly and reported a high readiness to use eHealth. Nevertheless, as only a small percentage of the population currently uses a digital app, although they have access to and are aware of their existence, this study identified a gap between reported readiness to use eHealth apps and the reality of current use. More comprehensive research is necessary in order to identify ways to close this gap. Nevertheless, reported acceptance of different apps is high in almost all domains of eHealth. Positive predictors for use of the internet and eHealth include declining age, higher internet literacy, current use of the iOS operating system, and the number of currently used eHealth apps. While men are more likely to use eHealth for organizational functions, women tended to search for emotional support. As the pandemic caused a surge in eHealth use and acceptance, this may be an impulse for further use of eHealth apps and create an ideal environment for conducting further studies on this topic.

Acknowledgments

The authors received no financial support for this study's research, authorship, and publication.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

NE was primarily responsible for the study design (conceptualization and methodology and manuscript writing and revision). SS and NJ led the data collection (investigation). SS contributed to writing the original draft and project administration. SS conducted formal data analysis along with TF, NE, and DN. TF, NE, and DN provided substantial revisions to the manuscript (reviewing and editing), with DN also contributing expertise in digital health (supervision). RW, ST, JC, and VH supervised the clinical components and contributed to the overall study concept (supervision, conceptualization, and resources). All authors approved the final version of the manuscript.

Conflicts of Interest

NE has received speaker honoraria from Audi BKK, Baxter, Beiersdorf, CSL Behring, Fresenius, Freiraum, Fraunhofer Institut, Janssen-Cilag GmbH, Cognitando GmbH, and GHD. She served on the expert advisory board at Baxter and received consulting fees from Fresenius. None of these activities were related to the content of this paper. RW received honoraria for consultancy, advisory boards, and travel support from Agendia, Amgen, APOGHEVA, Aristo, Astra Zeneca, Bayer, Celgene, Clinsol, Daiichi-Sankyo, Eisai, Esteve, Exact Sciences, Gilead, Hexal/Sandoz, Lilly, MSD, Mundipharma, Mylan, Nanostring, Novartis, Onkowissen, Paxman, Palleos, Pfizer, Pierre Fabre, PINK, Riemser, Roche, Seagen, Sidekick, Stemline, Tesaro Bio, Teva, Veracyte, Viatris, Wiley, Thieme, Digimed, Eickeler, FOMF, Art Tempi, Aurikamed, Clinsol, Pomme Med, iMEDInstitut, medconcept, MCI, MediSeminar, Medicultus, H+O Communications, New Oncology Concepts, SPCC, streamed up, medupdate GmbH, and institutions: SPCC, WSG, AGO, and DKG.

Abstract

Background: Providers spend a large percentage of their day using electronic health record (EHR) technology and frequently report frustration when EHR tasks are time-consuming and effortful. To solve these challenges, artificial intelligence (AI)–based enhancements to EHR technology are increasingly being deployed. However, AI-based implementations for EHR features often lack user-centered evaluation.

Objective: This study evaluates, using a user-centered approach, the implementation of an AI-powered search and clinical discovery tool within an EHR system.

Methods: We conducted a mixed methods study consisting of interviews, observations, and surveys for 5 months.

Results: High adoption rates for the AI-based features (163/176, 93% users after 3 months) and significant increases across key metrics, including user satisfaction (U=49; P<.001) and perception of time saved (U=49; P<.001), demonstrated that the AI-based features were not only successfully integrated into various clinical workflows but also improved the user experience for clinicians.

Conclusions: Our results underscore the feasibility and effectiveness of using a user-centered approach for the deployment of clinical AI tools. High adoption rates and positive user experiences were driven by our user-centered research program, which emphasized close collaboration with users, rapid incorporation of feedback, and tailored user training. This study program can be used as a starting framework for the design and integration of human-centered research methods for AI tool deployment in clinical settings.

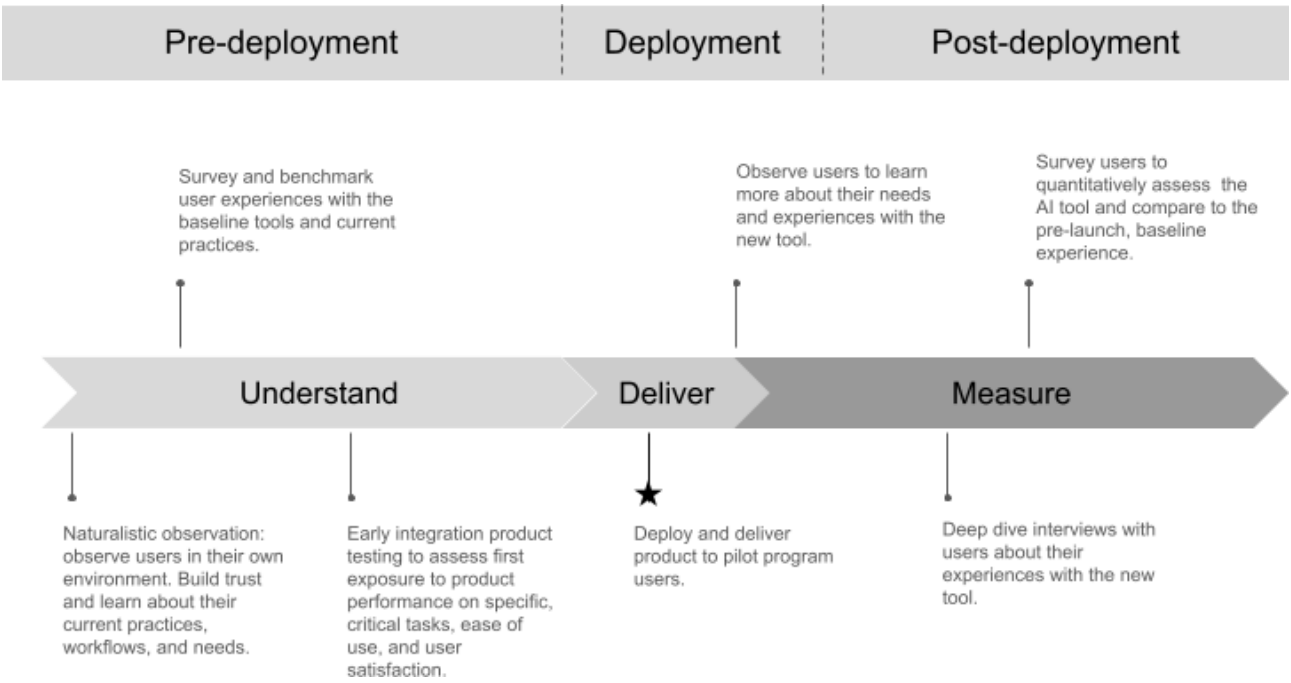
KEYWORDS

user-centered research; software design; delivery of healthcare; implementation science; electronic health record

Introduction

Artificial intelligence (AI)–based tools have permeated culture and industry, generating excitement, hesitation, and visions of opportunity [1-3]. This is especially true in health care: AI-based tools have transformative potential, despite known challenges spanning implementation, security, infrastructure, user experience, and product performance [4-7]. While electronic health records (EHRs) have been transformative in moving health care professionals to a more digital and connected way of working, challenges of use can lead to increased time spent using the system, increased feelings of frustration, and general dissatisfaction among users [8-14]. As EHR systems incorporate AI-based features into their products, questions remain about whether these solutions will improve the clinical user experience.

The incorporation of human-centered research methods, including the engagement of end users throughout the development process, is critical to the development of usable products that meet clinical users' needs [15,16] and has a long history within the field of human-computer interaction [17,18]. Previous research has demonstrated the value and feasibility of user-centered research methods during the development of AI-based clinical tools [19-21]. In this paper, we build upon previous research by demonstrating how user-centered evaluations can extend to the evaluation of clinical AI tools during the final stages of implementation.



Through this research, we sought to understand if an AI-based search and summarization tool [22], previously used side by side with an EHR, could be successfully integrated directly within the EHR. To test the implementation approach and measure the experiential impact on users at a health care system, we developed a multitouchpoint user-centered study program

XSL•FO
RenderX

that emphasized strong partnerships, close collaboration with users, and robust evaluations focused on newly unlocked product capabilities. The research methods draw from long-established practices in user experience design and research [23-25], as well as newer guidelines for AI-based research [26], which were adapted for use within the clinical environment.

This paper makes two primary contributions. First, we introduce a collection of research activities that form a novel, user-centered framework for implementing and evaluating AI-based clinical tools (Figure 1). This framework emphasizes the importance of conducting both qualitative and quantitative methods to evaluate the user experience and collecting signals from users throughout multiple stages of implementation and deployment. Further, there is flexibility in the specific methods that can be used in a collection such as this, making it an adaptable means of conducting human-centered research.

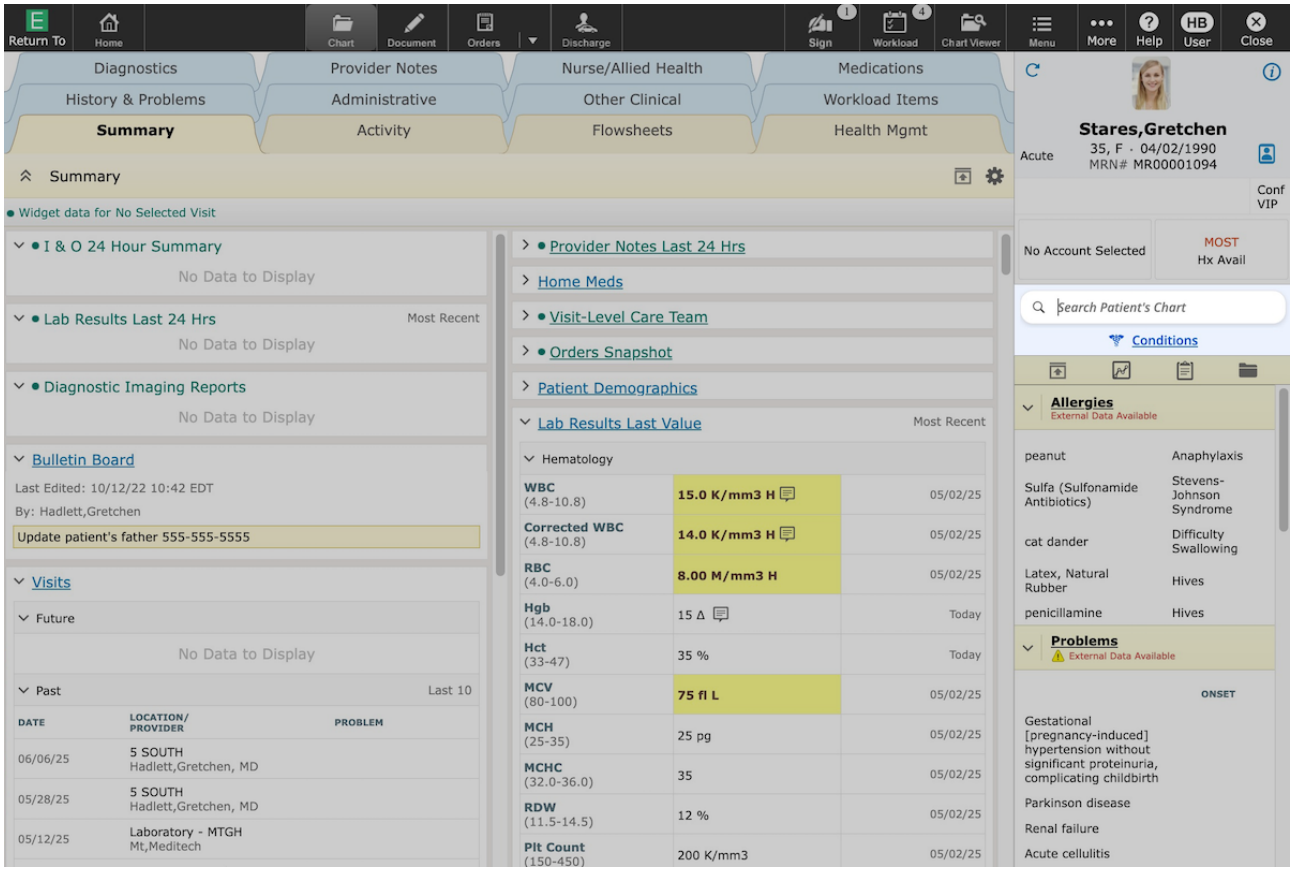


Figure 1. User-centered study program timeline. AI: artificial intelligence.

Second, we apply this framework through a case study of the delivery of Expanse Navigator (Google and MEDITECH; Figures 2 and 3; Multimedia Appendix 1), an AI-powered search and summarization tool accessible within MEDITECH's Expanse EHR. Through this case study, we show both the feasibility of the approach and how it enabled rapid incorporation of insights into the delivery strategy, including factors influencing use, potential risks, and user satisfaction.

Methods

Overview

A multistep, mixed methods, user-centered study was developed and run for 5 months. The goal of this research program was to measure the qualitative and quantitative experiential effects of an AI-based search and summarization tool (referred to as Expanse Navigator) within MEDITECH's Expanse and to understand the feasibility of incorporating user-centered methods during the implementation phases of AI-based clinical tools.

Program Site and Participants

Mile Bluff Medical Center is a 40-bed acute-care hospital and outpatient care center in Mauston, Wisconsin, United States. A total of 176 health care professionals were provided access to a clinical pilot of Expanse Navigator in January 2024; this includes 53 medical doctors or advanced practice providers, 61 registered nurses, 48 allied health professionals, and 14 health information management specialists across 24 distinct clinical and operational departments.

All pilot participants were invited to participate in the user-centered research program. A sample of 128 out of the 176 (72%) pilot program members opted into the program.

Materials

Expanse Navigator offers advanced search capabilities and an AI-generated, comprehensive view of a patient's health history (Figures 2 and 3; Multimedia Appendix 1). It works together with and is accessible directly within MEDITECH's Expanse. The tool offers new capabilities, unlocks valuable data (eg, PDFs and faxes), and makes them quickly and easily accessible to users via a modern search experience. The search capabilities handle misspellings and abbreviations, provide suggested search terms, and give results ranked by relevance. The tool is powered by AI rather than keyword matching.

Naturalistic Observation

The first component of the user-centered program was clinical observation. Before the deployment of Expanse Navigator, 21 representative users from the hospital, ambulatory care, outpatient clinics, and the emergency department were observed in their normal clinical environments (outside of patient care). Observations provided an understanding of users' existing tools, workflows, environments, and experiences before the deployment of Expanse Navigator. Further, this effort helped to establish collaboration and build rapport with clinical users.

XSL•FO
RenderX

Survey Program

The second component of the user-centered program focused on experiential measurement through the use of pre- and postdeployment surveys. To develop the survey measures, MEDITECH and Google jointly developed a set of primary metrics: user satisfaction, product helpfulness across specified tasks (Multimedia Appendix 2), and perceived time savings. Survey questions used fully labeled 5-point scales, following industry best practices [27], and are available in the Multimedia Appendix 3. Survey questions were optional; respondents were not required to answer all questions.

Before deploying Expanse Navigator, we measured prelaunch metrics of MEDITECH's Expanse via a baseline survey. Four weeks following deployment, we distributed a postlaunch survey to collect identical metrics on users' experiences with Expanse Navigator.

Surveys were administered to all pilot program participants. There were 94 out of 176 (73%) responses and 73 out of 176 (57%) responses to the baseline survey and postlaunch survey, respectively.

Early Integration Product Testing

The third component of the user-centered program involved early integration of product testing. The purpose of this assessment was to test the integrated product's ability to support key clinical tasks, to collect feedback based on users' first exposure to the product, and to ensure that no issues that could prevent easy and efficient use were present ahead of widespread launch.

During a single 60-minute session, participants viewed 3 minutes of prerecorded onboarding content and had 5 minutes of unstructured exploration with the product. Immediately thereafter, participants were prompted with 12 structured tasks to complete using Expanse Navigator features (Multimedia Appendix 4). Tasks were scored as "completed," "completed with difficulty," or "not completed." The tasks were informed by findings from naturalistic observation sessions and designed to reflect responsibilities fulfilled in the course of daily work. Sessions were conducted until data confidently showed that users could complete key tasks. In our case, this research phase ended after sessions with 3 users showed high levels of success. This methodology facilitated unique feedback related to intuitiveness and ease of use and also highlighted areas of focus for user onboarding and education.

User Interviews

The final component of the user-centered program was qualitative interviews. Approximately 6 weeks after launching Expanse Navigator, we conducted 60-minute interviews with 4 users. We sought to capture qualitative data around the impact of the product, users' experiences, high-priority use cases, and self-reported engagement. Participants spanned distinct roles and specialties and had not previously participated in one-on-one user-centered research sessions.

Data Analysis

Completed survey responses were analyzed using descriptive statistics (eg, percentage of users reporting satisfaction, perceived helpfulness, and time savings). To measure the experiential impact of the AI tool, a within-subjects Mann-Whitney *U* test (1-tailed) was run on each metric, using data from respondents who completed both baseline and postlaunch surveys. Qualitative interviews were analyzed by conducting a thematic analysis of detailed interview notes [28].

Ethical Considerations

This research was reviewed by the Advarra institutional review board and determined to be exempt from IRB oversight. All participants provided informed consent before participating.

Results

Early integration testing demonstrated that users completed tasks with relative ease, having received minimal instructions, and no major obstacles to efficient and easy use were observed, clearing the way for further deployment. Results from this research stage highlighted the need to explicitly onboard users to the new structure and categories by which information was organized.

Postdeployment, our 3 primary metrics for Expanse Navigator, described above in the "Introduction" section and Figures 2 and 3, saw strong ratings from users (Table 1): 62 out of 72 (86%) respondents reported high satisfaction, 45 out of 60 (75%) respondents described high helpfulness, and 63 out of 69 (91%) respondents reported that Expanse Navigator felt faster than the baseline system.

Table . Experiential ratings of the artificial intelligence (AI)–based experience from participants who completed the postlaunch survey: primary metric scores as percentages.

Metric	Postlaunch survey, n (%)
Satisfaction (N=72)	
Users who reported being "somewhat" or "very" satisfied	62 (86)
Helpfulness (N=60)	
Average % of users who rated the product as "very" or "extremely" helpful in accomplishing the 7 specific tasks	45 (75)
Perceived time savings (N=69)	
Users who rated the system as "somewhat" or "much" faster than the previous system	63 (91)

XSL•FO
RenderX

Notably, when compared to baseline results, users rated the AI-based experience more favorably across all metrics (Tables 2-4). Qualitative analyses showed that clinicians had use for the product at all points of care, identified the key value derived, and provided data to inform potential future features.

Table . Within-subjects comparison of ratings among participants who completed both baseline and postlaunch surveys: primary metric scores as percentages.

Metric	Baseline survey, n (%)	Postlaunch survey, n (%)
Satisfaction, N=19		
Users who reported being “somewhat” or “very” satisfied	2 (11)	15 (79)
Helpfulness, N=15		
Users who rated the product as “very” or “extremely” helpful in accomplishing the 7 specific tasks averaged across tasks on average	2 (13)	8 (53)
Perception of time savings, N=18		
Users who rated the system as “somewhat” or “much” faster than the previous system	9 (50)	17 (94)

Table . Within-subjects comparison of user satisfaction and perceived time savings: 1-tailed Mann-Whitney *U* test results. Effect size is given by the rank biserial correlation.

Mann-Whitney *U* test	U	*P* value	Rank-biserial correlation (*r*)	SE of rank-biserial correlation
Satisfaction score	49.00	<.001	−0.729	0.188
Time savings score	74.50	.002	−0.540	0.193

Table . Within-subjects comparison of helpfulness: 1-tailed Mann-Whitney *U* test results. Effect size is given by the rank biserial correlation.

Helpfulness scores per task	U	*P* value	Rank-biserial correlation (*r*)	SE of rank-biserial correlation
Task 1	35.00	<.001	−0.689	0.211
Task 2	68.00	.03	−0.396	0.211
Task 3	46.50	.003	−0.587	0.211
Task 4	32.00	<.001	−0.716	0.211
Task 5	88.00	.15	−0.218	0.211
Task 6	73.00	.08	−0.305	0.215
Helpfulness task #7	51.50	.009	−0.510	0.215

Results from the program at large demonstrated that the AI-based experience was highly adaptable across various clinical and operational settings. In addition, the user-centered approach provided the clinical and AI teams with rapid data on the tool’s effectiveness and identified valuable focus areas for user training. This data-driven approach, paired with positive word-of-mouth and user experiences, fueled rapid delivery and adoption. When measured 3 months post rollout, 163 out of 176 (93%) participants had accessed Expanse Navigator, and over 4000 searches had been performed.

Discussion

Principal Findings

The results of this study not only demonstrate that the AI-powered search and clinical discovery tool led to significant improvements in user satisfaction, helpfulness, and perception of time saved, but also demonstrate the feasibility of evaluating the clinical experience through a mixed method, user-centered approach.

AI-based tools are becoming increasingly common in clinical settings. As these technologies continue to advance, so will user expectations for high-quality product experiences. It will become increasingly important to measure the user experience of these tools with robust approaches that can be flexibly applied within a clinical environment. This research program was intentionally designed to evaluate product experience, refine understanding of user mental models, and optimize our onboarding program for the greatest impact when deploying an AI tool.

Incorporating user-centered research during predeployment stages allowed for the collection of benchmark measures of user satisfaction, helpfulness, and speed. It also informed the design of onboarding experiences and custom training for cohorts with

XSL•FO
RenderX

specialized workflows. Furthermore, the activities during this stage led to a strong partnership with hospital leadership, which, in turn, increased awareness about the upcoming product launch.

The deployment and postdeployment research allowed the team to measure the impact of the AI tool from a clinical user's point of view. The results of our case study demonstrate that the AI-based search and summarization experience, accessible directly within an EHR, provides users with new capabilities and increased levels of satisfaction, helpfulness, and speed.

Both the lift and feasibility of a user-centered approach were demonstrated through strong user participation, survey completion rates, and the overall duration of data collection (60 minutes per one-on-one study session).

The design of this study program follows previous work showing the importance of assessing the user experience during all phases of the product development life cycle: design, development, and deployment [29,30], and addresses calls for an increase in human-centered evaluative research alongside AI clinical deployments [31]. It extends past research that outlines approaches to user-centered research during design and development stages of AI-based clinical tools [19-21], and provides a framework for assessments that can occur during the later stages of clinical implementation.

Limitations

There are several limitations to this research. First, while the research involved a large percentage of users for the AI-based tool within MEDITECH's Expanse, across a wide range of clinical roles and specialities, it did so with users from a single medical center. Though we demonstrate feasibility for the user-centered study program presented in this paper, future research is needed to demonstrate generalizability. Second, while the findings from the case study show positive improvements in the user experience for this AI-based EHR integration, further research would be needed to demonstrate the impact across additional clinical measures.

Conclusions

By developing and executing a mixed methods, user-centered program for AI tool deployment, we enabled trust, collaboration, and frequent communication between clinical end users and AI practitioners, and a robust collection of key product metrics. This data-driven and user-centered approach championed end users' experiences and surfaced those findings pre- and postproduct launch, highlighting specific areas for curated user training and optimizing the opportunity for rapid deployment. Integrating user-centered research as part of the deployment process ensures that AI tools are not only technologically advanced but are also relevant, usable, useful, and safe for use in any setting; notably, all of these benefits are of critical importance for tools used in health care and clinical settings.

Prioritizing a human-centered research program for AI-based tool deployment supports effective product integration and user satisfaction; further, it supports the thoughtful delivery of products and services in high-stakes health care environments where patient safety is the utmost priority.

Acknowledgments

The authors thank Lynsi Garvin and Pete Clardy for their assistance with this study, and Rory Sayres for his helpful comments on the manuscript. This study was funded by Google LLC.

Authors' Contributions

MS, LMV, and HB contributed to the conceptualization and methodology of the study. MS and HB were responsible for the data curation and investigation. LMV was responsible for funding acquisition and study supervision. TS was responsible for the design of the software and visualization. HB and CS led project administration, and RB provided resources. MS prepared the original draft, and CS, HB, LMV, RB, and TS contributed to the review and editing of the manuscript.

Conflicts of Interest

MS, HB, TS, and LMV are employees of Google LLC, and CS is an employee of MEDITECH, representing a potential conflicts of interest. Throughout the study design, data collection, and analysis, efforts were made to reduce potential bias and to report findings based solely on objective study data.

Abstract

Background: Cases of the occupational lung disease silicosis have been identified in workers processing artificial stone in the stone benchtop industry (SBI). In the Australian state of Victoria, the Regulator commissioned a screening program for all workers in this industry.

Objective: To facilitate systematic data collection, including high-quality exposure assessment, an electronic data capture tool (EDCT) was developed.

Methods: A multidisciplinary team developed an EDCT using Research Electronic Data Capture (REDCap; Vanderbilt University). The needs of the EDCT were (1) data entry by multiple clinicians and the workers attending for screening and (2) systematic collection of data for clinical and research purposes. The comprehensibility and utility of the tool were investigated with a sample of workers, and the EDCT was subsequently refined.

Results: The EDCT was used in clinical practice, with capacity for data extraction for research. Testing of comprehension and utility was undertaken with 15 workers, and the refined version of the Occupational Silica Exposure Assessment Tool (OSEAT) was subsequently developed.

Conclusions: The refined OSEAT has been determined to be comprehensible to workers and capable of collecting exposure data suitable for assessment of risk of silicosis. It was developed for workers in the SBI in Australia and is adaptable, including translation into other languages. It can also be modified for SBI workers in other countries and for use by workers from other industries (mining, construction) at risk of silica exposure, including in lower-income settings.

silicosis; occupational history; electronic data capture tool (EDCT); REDCap; occupational respiratory screening; occupational hazard; exposure; silica; fibrotic lung disease; lung disease; respirable crystalline silica; mining; construction; workers; occupational lung disease; occupational; Australia; screening

Introduction

Silicosis is an incurable, potentially life-threatening, form of fibrotic lung disease caused by inhalation of respirable crystalline silica (RCS) [1]. The disease has been recognized globally for over 100 years, and lung disease screening is recommended for high-risk industries, including mining and construction [2]. Cases of silicosis were identified in 2010 among workers in the stone benchtop (countertop) industry (SBI) working with artificial stone (AS; Textbox 1) [3-12]. Subsequently, a number of cases of artificial stone-associated silicosis were diagnosed in Australia [3,13]. AS has a very high crystalline silica content, often over 90% [14]. Processing AS by drilling, polishing, cutting, or grinding generates fine particles of dust containing RCS, which can cause silicosis when inhaled [15].

Textbox 1. Timeline of artificial stone (AS) and silicosis in Australia

Early 2000s: AS introduced to Australia
2010: First case of silicosis associated with AS reported in Italy
2015: First case of silicosis associated with AS reported in Australia (conference abstract)
2017: First case of silicosis associated with AS reported in Australia
2019: Screening program of stone benchtop industry workers begins in Victoria, Australia (paper-based data collection)
2021: Screening program first incorporates electronic data capture tool (EDCT)
2021-2023: Refinement of EDCT informed by data cleaning and evaluation study with workers

An investigation of the effects of RCS exposure in the SBI was commissioned by the Victorian regulator, WorkSafe Victoria [16], and developed into a screening program by Monash University. It included (1) exposure assessment from a detailed occupational history; (2) collection of respiratory symptoms; (3) recording of investigations including spirometry, chest x-ray, and high-resolution CT of the chest; (4) screening for comorbidities associated with silica exposure, including autoimmune diseases and tuberculosis [4,17]; and (5) a mental health instrument.

The initial paper-based questionnaire was developed by a multidisciplinary team, including respiratory physicians, an occupational hygienist, and occupational physicians [16]. Simplicity was prioritized, as many industry workers were born outside Australia and spoke English as an additional language [18].

Up to 6 jobs in the SBI could be recorded in the occupational history. The proportion of time spent on specified *tasks* in each job and the proportion of time spent on dry cutting of stone and working near someone doing dry cutting were recorded. *Exposure control measures* (ventilation and respirator use) were identified for each job. Other information collected included the country, start and (if relevant) finish date; days per week worked; number of people in the organization; and type of stone predominantly worked with (AS or natural stone). Other silica-associated occupations (eg, mining, quarrying) and any non-occupational activities that involved dust exposure (including hobbies and home repairs, eg, tiling, plastering) were also recorded.

Data were collected from multiple users, including respiratory physicians, multidisciplinary team, workers, and administrative staff, and capture all the elements listed earlier. The data were cleaned and entered into an electronic data capture tool (EDCT) held on the secure REDCap platform [19,20]. The data were used for both clinical and research purposes. In 2021, screening was centralized and carried out at a single site, which led to a need for direct data entry to the EDCT by the worker.

Exposure calculations from the occupational data have been used to identify roles within the SBI with greater RCS exposure, such as factory machinists and installers, and that exposure intensity and cumulative exposure were associated with dyspnea and radiological abnormalities consistent with silicosis [21]. The screening program data has also been used to describe the numbers of cases of silicosis diagnosed to date [18], the rates and determinants of psychological distress, and the psychometric properties of the mental health instrument [22,23].

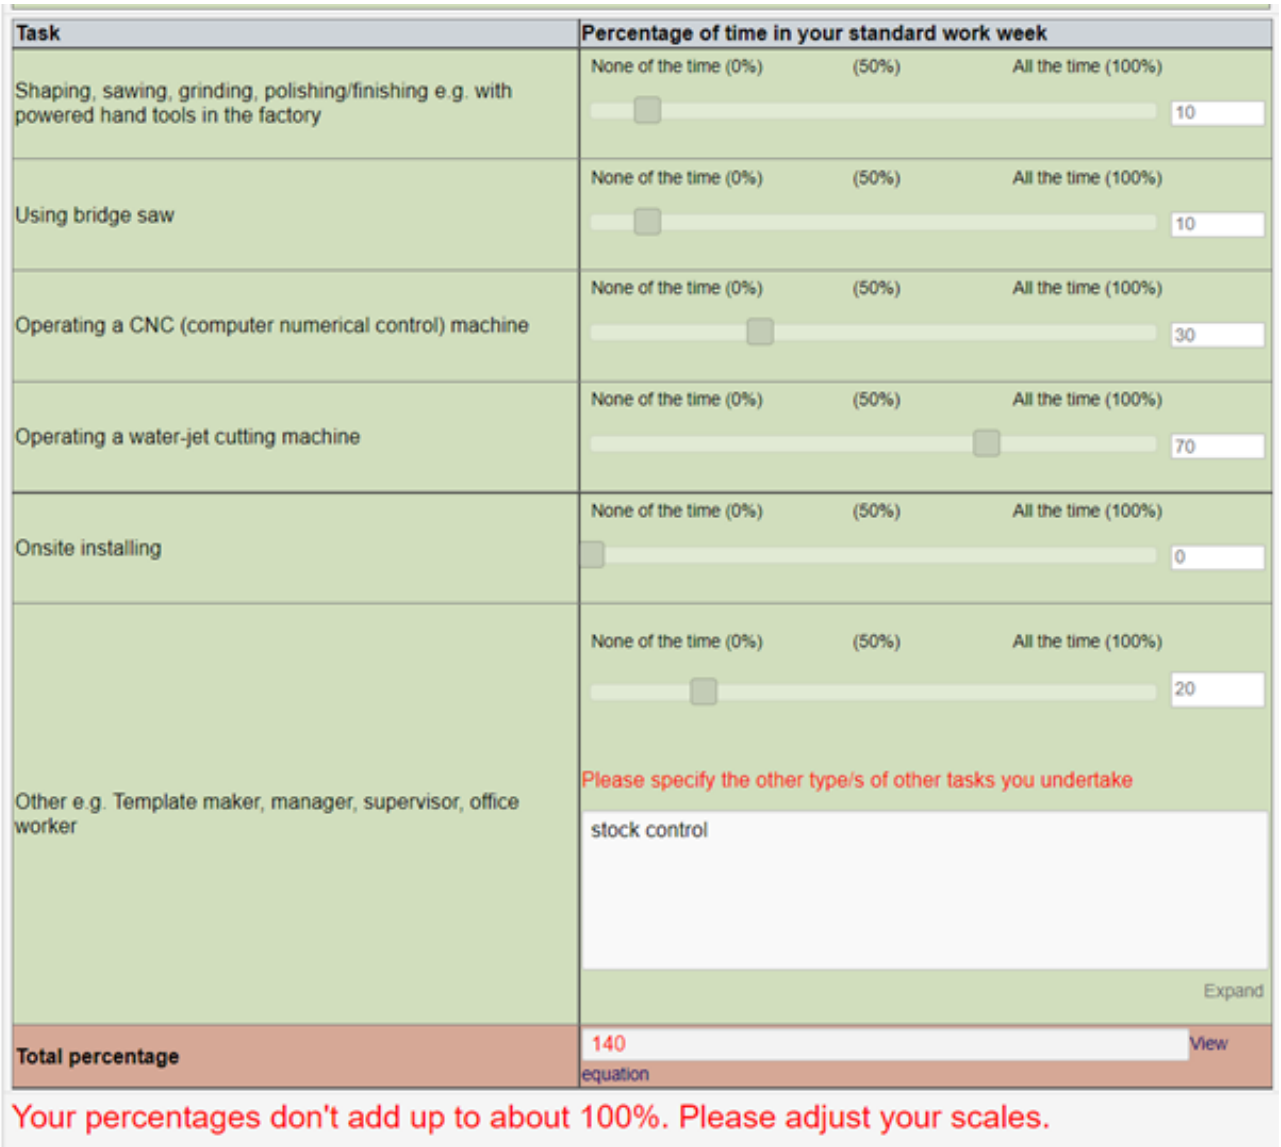
The aim of this study was to describe the development of the EDCT, present its refined content, and describe the results of an audit of its clinical utility undertaken with a sample of workers.

Methods

Overview

The original team reviewed the exposure questionnaire, which overall had been well understood, and identified items that required substantial data cleaning. The team redeveloped the questions, which included, for example, adding illustrations of dry and wet cutting examples and the types of respirator and ventilation options that were sourced from workplace health and safety organizations [24-26]. Further, additional optional responses were added from free text replies, for example, water jet cutting.

In the first draft questionnaire, participants were asked to apportion their tasks (Figure 1).



The percentages seldom added to 100%, as shown in the example in Figure 1, so in the revised questionnaire, a sliding bar was provided that provided visual input of the proportions (Figure 2). A pop-up trigger was included if the task proportions were out of range, as shown in Figure 2.

Prior to attending for screening, workers were emailed a link to the EDCT containing the revised questions in order to

XSL•FO
RenderX

complete their occupational history. The final page completed by workers included optional electronic consent for sharing data with Monash University.

Other data collected during screening included medical history, smoking status, respiratory symptoms, physical examination findings, diagnosis, return-to-work assessment, and results of all relevant investigations, including chest x-ray, high-resolution CT, pathology, and spirometry.

In 2023, an investigation of the comprehensibility, feasibility, and face validity of the occupational history section of the EDCT was completed with workers.

A total of 15 workers participated in the investigation, which was conducted between February and May 2023. Workers were interviewed about their responses on the EDCT, using a pre-developed proforma to prompt feedback. They were asked: "Were there any words you did not know?" "Did you understand what was meant by 'dry work'" "Are there any other tasks in your workplace that expose you to dust?" and "Did the list of ventilation options include what you use in your workplace?" For all questions, respondents could reply yes or no and provide additional comments. If a worker reported no dry cutting in their current or most recent job but had exposure to dry cutting from previous jobs, they were asked to respond to questions referring to their former job.

Ethical Considerations

Workers were eligible to participate if they had completed their occupational history using the EDCT, did not require an interpreter for their appointment, and had provided electronic consent to share data with Monash University. All participants were provided with a written information sheet and asked to provide verbal consent for participation. Responses were deidentified, and workers did not receive compensation for their participation. Approval was granted by the Alfred Hospital Research Ethics Committee as a substudy of project 292/21.

Results

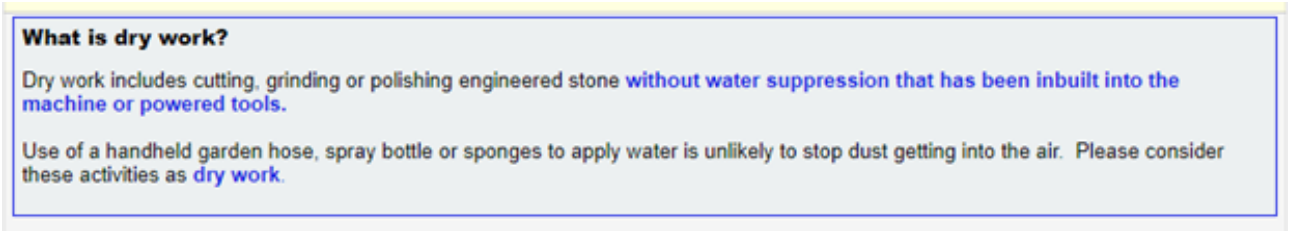
The demographics of the workers are presented in Table 1. Most participants were male, and they covered a range of ages and years of employment in the SBI. They included machinists, installers, and office workers.

Table . Demographics of participants.

Characteristics		Values
Males, n (%)		14 (93)
Age (years), mean (SD)		38.1 (10.9)
Years in stone benchtop industry, mean (SD)		9.6 (7.85)
Born in Australia, n (%)		5 (33)
Language other than English spoken at home, n (%)		6 (40)
Most recent SBI job held, n		
	Director	3
	Installer	4
	Stonemason	5
	Foreman	2
	Other	1

All participants were asked to report about their *comprehension* of an introductory statement, and one worker commented that it took a while to read and understand, and did not feel like he understood it fully. All workers reported that they comprehended what was meant by "dry work." When asked about *tasks* that exposed them to dust that were not already listed on the EDCT, 2 workers identified new relevant tasks: emptying bins containing benchtop fragments and cleaning of the final benchtop product, onto which the dust-containing water used in wet cutting had dried. In total, 4 workers reported that their *ventilation* option was not included in the list on the EDCT, nor was it pictured. However, after discussion, the alternative options they were describing were "air conditioning," "garage door," "no ventilation," and "ventilation in the wall," all of which were listed.

For *respirators*, 14 workers identified the type they used from the descriptions and pictures in the EDCT, and the only worker that did not see their device described use of one similar to that depicted. Of 8 workers who were asked if they could easily remember and estimate the percentage of time they spent wearing a respirator, 7 responded in the affirmative. One worker had worn his respirator for 6 hours out of an 8-hour shift (approximately 75%), but had estimated that he wore it for 35% of the day. One worker commented that he wore his respirator all day, regardless of the task, whilst another pointed out that each job was different, with some jobs being "perfect" (ie, not requiring any adjustments), whereas others required adjustments onsite, adding to the difficulty of responding to this question accurately.



If a worker reported dry cutting in their current job, they were asked whether or not practices around dry cutting had changed (this was because dry cutting without suitable protection had been officially banned recently in Australia). Of the 11 workers who completed this question, 10 understood the question and were able to complete it accurately, but one worker expressed some confusion around the wording of the question. Workers

XSL•FO
RenderX

also described measures other than ventilation and respirators that their employer had introduced including changing clothes at work and using water systems for dust suppression when loading stone.

Subsequently, modifications were made to improve accessibility for the workers: simplification of the language used in descriptive statements and instructions, modification of the color scheme to improve readability, and addition of commonly reported responses (eg, "home maintenance," "tiling," and "plastering") as a prompt on the non-occupational (eg, hobby) dust exposure history section. One of the simplified statements was an introductory statement that defined "dry work" (Figure 3). An image accompanied the text with examples of dry and wet cutting [26]:

Figure 3. Refined EDCT for clarification of the definition of dry work.

The current version of the Occupational Silica Exposure Assessment Tool from the EDCT is presented in Multimedia Appendix 1.

Discussion

Principal Findings

Since 2019, over 1000 SBI workers have undergone screening for silicosis in Victoria, Australia, through a protocolized screening program. In this study, we described the development of the screening questionnaire into an EDCT, the Occupational Silica Exposure Assessment Tool, and have described how it was refined as a result of our experiences and after assessment of its acceptability and comprehension among this worker population. The results of the investigation suggested that the usability and comprehension of the refined EDCT are acceptable among English-speaking workers.

The benefits of EDCTs for improving patient care [27]; improving accuracy of data collection compared to paper methods [28]; and facilitating data collection from multiple users, including patients and health care providers [29], have been established in many settings. Moreover, EDCTs are able to capture and retain large volumes of data, maximizing cost- and time-efficiency in clinical and research settings [29,30]. As demonstrated, the development of this EDCT has already provided all of these benefits and enabled us to create a streamlined and efficient screening program for workers in the artificial stone benchtop industry.

Benchtops made from AS are a popular kitchen product globally, and there are concerns that cases of silicosis among workers who produce them are underreported in the literature [31,32]. Globally, silica deaths were estimated to be more than 12.9 thousand in 2019 [33], and the highest rates were recorded in low- and middle-income countries [33,34]. Silicosis has been seen in a range of industries, including construction, jewelry production, quarrying, tunneling, dental material manufacturing, denim jean production, and ceramic and pottery manufacturing [35]. There is therefore an urgent need for occupational screening for large numbers of workers exposed to RCS, for which reliable instruments are needed. The Occupational Silica Exposure Assessment Tool can be deployed in settings in which workers are exposed to RCS, whether for workers in the SBI or modified for other occupational settings.

In addition to assessing SBI workers at risk of silicosis, the data collected from the Occupational Silica Exposure Assessment Tool (OSEAT) can be used to estimate an individual's level of RCS exposure. In previous work, occupational history data collected using the OSEAT were used to group SBI workers by extent of silica exposure, using a combination of the proportion of time working with AS and the proportion of time spent dry cutting [21]. Both cumulative exposure and exposure intensity were found to be associated with symptoms of dyspnea and chest x-ray abnormalities [21]. This illustrates the ready utility of having added the e-consent function to the EDCT within REDCap, facilitating extracting data from the OSEAT to use for research purposes.

One consideration when introducing a REDCap-based EDCT in a clinical setting is its reliance on workers having adequate internet connection. This has been a limiting factor for the utilization of similar instruments, in which open-source software that was not reliant on internet connection was preferred [28,36]. In some resource-poor settings, REDCap was the preferred platform [37,38], and REDCap has now developed a mobile app that can be used offline that may overcome internet connection limitations [20].

A limitation of this study was the small number of workers included, none of whom required interpreters. Its comprehensibility is therefore unknown among those who require interpreters. Furthermore, these workers were recruited consecutively and recently from the clinic and consequently are not necessarily representative of the wider workforce. Another limitation was that the original instrument was not co-designed with consumers (workers in the SBI), something that we addressed in this study. We were unable to investigate floor or ceiling effects within the scope of this work, which would be a necessary step if the tool is to be used in translated versions.

A strength of the OSEAT is that it has been used and improved for close to 3 years with demonstrably good comprehension by SBI workers.

Future development of the OSEAT will include its translation into other languages using the REDCap multilanguage module.

XSL•FO
RenderX

The commonest languages other than English among the workers attending screening at our center have been Vietnamese, Persian, Chinese, and Arabic, and are therefore a priority for translation and inclusion into the module.

Conclusions

This study has presented the development, comprehension, utility, and refinement of the OSEAT, a purpose-built EDCT for use among SBI workers undergoing assessment for silicosis that included input from workers and has the capacity for modification and use within other silica-exposed occupational settings.

Acknowledgments

This project was funded by WorkSafe Victoria, and FHL was supported by a PhD project stipend from WorkSafe Victoria. The manuscript was prepared by the Monash Centre for Occupational and Environmental Health, Monash University. The opinions, findings, and conclusions expressed in this publication are those of the authors and not necessarily those of WorkSafe Victoria.

Data Availability

The datasets generated and analyzed during the current study are not publicly available for ethical and privacy reasons. Patient consent did not include sharing of data external to Monash University. If data need to be shared, additional approval from Monash University HREC and Alfred Hospital HREC would be required.

Authors' Contributions

FHL provided the concept and study design. Input into study design was provided by KWB and DCG. The EDCT was built by CD with input from RH, DG, FHL, MRS, JJM, and KWB. Data acquisition was performed by FHL. Data analysis was completed by FHL, with interpretation by FHL, KWB, and DCG. The manuscript was drafted by FHL, with significant contributions by KWB, RFH, and DCG, and additional editing provided by MRS, JJM, CD, and JF.

Conflicts of Interest

FHL was supported by a PhD project stipend from WorkSafe Victoria. The authors have no further interests to declare.

Abstract

Background: A smart medication dispenser called "spencer" is a novel generator of longitudinal survey data. The patients dispensing medication act as a survey panel and respond to questions about quality of life and patient-reported outcomes.

Objectives: Our goal was to evaluate panel persistency, survey response rates, reliability, and validity of surveys administered via spencer to 4138 polychronic patients residing in the United States and Canada.

Methods: Patients in a Canadian health care provider's program were included if they were dispensing via spencer in the June 2021 to February 2024 time frame and consented to have their data used for research. Panel persistency was estimated via discrete survival methods for 2 years and survey response rates were computed for 1 year. Patients were grouped by mean response rates in the 12th month (<90% vs ≥90%) to observe differential response rate trends. For reliability and validity, we used a spencer question about recent falls with ternary responses value-coded −1, 0, and 1. For reliability, we computed Pearson correlation between mean scores over 2 years of survey responses, and transitions between mean score intervals of [0, 0.5), [−0.5, 0.5), and [0.5, 1]. For validity, we measured the association between the falls question and known factors influencing fall risk: age, biological sex, quality of life, physical and emotional health, and use of selective serotonin reuptake inhibitors or serotonin-norepinephrine reuptake inhibitors, using repeated-measures regression for covariates and Kendall τ for concomitant spencer questions.

Results: From 4138 patients, dispenser persistency was 68.3% (95% CI 66.8% - 69.8%) at 1 year and 51% (95% CI 49% - 53%) at 2 years. Within the cohort observed beyond 1 year, 82.3% (1508/1832) kept surveys enabled through the 12th month with a mean response rate of 84.1% (SD 26.4%). The large SD was apparent in the subgroup analysis, where a responder versus nonresponder dichotomy was observed. For 234 patients with ≥5 fall risk responses in each of the first 2 years, the Pearson correlation estimate between yearly mean scores was 0.723 (95% CI 0.630 - 0.798). For mean score intervals [0, 0.5), [−0.5, 0.5), and [0.5, 1], self-transitions were the most common, with 59.8% (140/234) of patients starting and staying in [0.5, 1]. Fall risk responses were not significantly associated with sex (P=.66) or age (P=.76) but significantly related to selective serotonin reuptake inhibitor or serotonin-norepinephrine reuptake inhibitor usage, quality of life, depressive symptoms, physical health, disability, and trips to the emergency room (P<.001).

Conclusions: A smart medication dispenser, spencer, generated years of longitudinal survey data from patients in their homes. Panel attrition was low, and patients continued to respond at high rates. A fall risk measure derived from the survey data showed evidence of reliability and validity. An alternative to web-based panels, spencer is a promising tool for generating patient real-world data.

KEYWORDS

real-world data; real-world evidence; patient-reported outcomes; longitudinal studies; survey methods

Introduction

Background

The use of patient data collected in real-world settings has never been more impactful. The US Food and Drug Administration's Real-World Evidence (RWE) Program has elevated real-world data (RWD) as a tool to support new indications for already approved drugs [1-3], the European Medicines Agency has published their RWE framework [4], and Canada's Drug and Health Technology Agency has published their guidance document [5].

XSL•FO
RenderX

RWD may take the form of claims records, electronic health records, registries, or patient-generated data, with patient-reported outcomes (PROs) as an important subset. Longitudinal surveys, where patients are surveyed at 2 or more points in time, generate data that allow for the analysis of within-unit change as well as aggregations over time [6]. This results in greater "causal leverage" than cross-sectional surveys [7] and is ideal for submissions to regulatory bodies.

Web-based panels, or "registered persons who have agreed to take part in online studies on a regular basis," rose in attractiveness with the proliferation of the web [8]. Recently, however, shortcomings of longitudinal studies based on web-based panels have undermined their reputation as a high-quality data source. Panel attrition, where subjects in earlier waves cease to respond in later waves, has become worse since the 1990s [7,9-11]. While web-based panel data are also prone to quality problems (eg, false answers, careless responses, and multiple panel memberships [12]), these problems have been exacerbated by innovations in automation and improvements in large language models, where human reviewers are unable to consistently detect automated responses [13]. This has become a corrupting force in web-based survey sampling [14].

Amazon Mechanical Turk (MTurk) was considered a representative and convenient source of web-based longitudinal survey data [15] but has seen its reputation deteriorate within the last decade. For example, a study that used MTurk to build a diabetes panel failed after only 5.8% (13/224) were deemed eligible for future survey research [16]. Researchers noted declines in MTurk data quality starting around summer 2018, as evidenced by degraded psychometric properties of well-understood metrics [17]. A warning was issued in the journal *Perspectives on Psychological Science* after an exercise revealed that only 2.6% (14/529) of MTurk samples were valid [18].

Alternatives to web-based panels exist in populations of patients using web-connected hardware, also known as "smart" products. One interesting subset is the population of patients using smart medication dispensers, as these products sit in the home amidst a public health need for digital adherence solutions [19]. A 2023 review of smart medication adherence products reviewed the features of 51 products without mention of survey administration capabilities [20]. One of these products, a dispenser named "spencer" [21,22] (manufactured by Spencer Health Solutions, Inc), has a touch screen display that allows it to administer survey questions following on-time medication dispenses (Figure 1).

At the time of writing, in-home spencer devices have generated more than 3 million longitudinal responses from more than 4000 unique patients to quality of life and PRO measures from a polychronic population residing in the United States and Canada. These are patients of Canadian health care provider Custom Health, Inc, a company offering "a personalized, connected service that goes beyond medication management and ensures medications are working as they should" [23]. Patients or caregivers can express interest directly via a collection of sign-up forms [24,25] or they may be directed to spencer via their health plans that have partnered with Custom Health [26]. When a health plan partners with Custom Health, their services are provided to members "who require a high degree of clinical oversight, those managing multiple medications or those experiencing medication adherence challenges" [27].

Objectives

The study's aim was to evaluate the spencer smart medication dispenser as a longitudinal survey platform for a polychronic patient population. Panel persistency, survey response rates, and measurement reliability and validity were assessed.

Methods

Recruitment

Patients of Custom Health were included if they met the criteria enumerated in Textbox 1.

Textbox 1. Inclusion criteria for patients in the study.

1. The patient entered Custom Health's intake process either by self-selection or based on the recommendation of a health care provider.
2. Custom Health professionals decided to pair the patient with a spencer smart medication dispenser.
3. The patient agreed to the Custom Health consent form.
4. The patient agreed to the Spencer Health Solutions End User License Agreement, permitting his or her deidentified data to be used for research purposes. This occurred on the spencer unit's touch screen.
5. The patient's first scheduled medication dose was between June 3, 2021, and February 14, 2024.
6. The patient dispensed a medication dose by March 14, 2024. In this paper, dispensing medication refers to dispensing multidose packs containing oral solids.

After completing Custom Health's intake process, spencer devices were shipped to patients' homes. Once set up, the devices displayed both current local time and the scheduled time of the next medication dispense via a touch screen display. Refills containing medication strips (multidose adherence packaging) prepared by a pharmacy were shipped to the patients' homes and were inserted by the patient or care nurse into the top of the unit via an electronically controlled door. At scheduled dosing times, the unit alerted the patient through sound, light, and a message on the touch screen display. After the patient pressed the dispense button on the touch screen, the unit dispensed 1 or more medication pouches. After an on-time dispense, a question was presented to those patients who had not explicitly opted out of surveys.

Data Generation and Processing

The question and response mechanism is further elaborated here. If a dose was dispensed on time and the patient had not opted out of surveys, 1 question was displayed on-screen. To answer, a single button press was needed to select from a multiple-choice answer set. This was followed by a review step (also serving as the completeness check) where the patient could confirm the selection or go back and change the answer. If a patient did not make the confirmation in the review step, the questionnaire would not be submitted to the database and later analyzed as an instance of nonresponse. If left attended to, a question would remain on the screen until the next scheduled dose.

In collaboration with health care professionals at Custom Health, 35 survey items were designed to measure the spencer experience, quality of life, and PROs. To avoid copyright infringement, these questions were not taken from any existing validated scale. Questions were scheduled one-to-one with doses in a predefined sequence that repeated indefinitely. Response options were consistently listed from most positive sentiment (eg, "Excellent") toward the top of the screen to least positive sentiment (eg, "Poor") toward the bottom of the screen. Questions were manually answered on test devices in a quality assurance laboratory before being released to patients, and patients could call into a support line to provide feedback regarding the questions or to request that they be turned off.

As is typical of web-based panels, the panel formed by the selection criteria in Textbox 1 constitutes a convenience sample. The target population best described by the sample is polychronic patients taking multiple medications daily. Since the surveys were administered as part of routine patient monitoring, no institutional review board (IRB) approval was needed.

Survey responses were sent to the application database through either cellular connection (the default) or Wi-Fi. In cases where the spencer lost connectivity, a store and forward mechanism sent data to the cloud database once connectivity was reestablished. The database is managed by Spencer Health Solutions that has received both ISO27001 [28] and Data Privacy Framework [29] certifications.

Date of birth, biological sex, and residential postal code were entered into a web-based portal by health care providers when patients were recruited. These fields were retrieved from the application database March 4, 2024. Dates of birth that were within 2 years of the database entry date were replaced with missing values, and age was computed as the difference between the first dispense date and date of birth. Within the United States, 5-digit postal codes were converted into US states via the *zipcodeR* R package. For Canadian postal codes, a function was written that maps the first letter of the postal code to the associated province. Prescription information was created by the pharmacies at the time of refill creation and sent to the database.

Statistical Analysis

Panel Attrition

Patients may leave the spencer dispensing platform for multiple reasons, including life transitions to higher care services or natural death. Leaving the dispensing platform is the primary mechanism of spencer panel attrition. To estimate dispenser persistency, we used the discrete survival analysis framework described by Allison [30], where the periods start on the first

XSL•FO
RenderX

day a patient is scheduled, are 30 days in length, and an attrition event occurs when a patient is not scheduled during an entire 30-day period. There is a *resurrection* mechanism: when a patient is scheduled in a later period after previously meeting the definition for an attrition event, the attrition flag is reset for all previous periods.

For readability, we will refer to a 30-day period as a *month*, 12 thirty-day periods as a *year*, and so on. Furthermore, we will refer to the time in years between the first scheduled dose via spencer and the analysis date as *tenure*. A patient's tenure represents the amount of experience a patient has had with the spencer platform as of an analysis date.

Beyond dispenser attrition, the second source of panel attrition is when patients request that their questions no longer appear on-screen following a dispensing event. To study this phenomenon, we computed rates of requested question discontinuation for the first 12 months of tenure for patients who remained dispenser persistent for more than a year.

When pursuing the subset of patients who were dispenser persistent for more than a year, the subset taken was patients who remained on the spencer platform through the 14th month. In addition to our operational month being shorter on average than a calendar month (by a fraction of a day), the 2 additional months of persistency provided a buffer against the decreased interaction with the device that often precedes full platform discontinuation.

Survey Response Rates

On the survey platform, nonresponse occurs when patients do not enter a response after a question is displayed and the question is cleared. We computed rates of nonresponse by month and plotted the resulting series. We knew from prior analyses that some patients consistently respond to the questions, and we wanted to observe this phenomenon. For patients who were still receiving surveys in the 12th month, we created 2 groups: those with 12th-month response rates of <90% and those with 12th-month response rates of ≥90%. For both groups, we computed the frequency of patients, plotted response rates by month, and provided a qualitative description of the patterns observed.

Psychometric Analysis

Reliability

A reliability analysis in the context of a platform requires a narrowing of focus to a specific measure, as both reliable and unreliable measures may be generated from any platform. Inspired by the Falls Efficacy Scale-International, a reliable measure of fear of falling known to be related to both past and future falls [31,32], we chose an existing question from our rotation that asks the patient about recent falls. Hereafter referred to as Q_FALL, the question text read "Have you experienced a fall in the past month?" The response options were "No," "Not Sure," and "Yes" (a 1-letter variation in capitalization occurring after September 2022, where "Not sure" was replaced with "Not Sure"), which were value-coded as 1, 0, and −1, respectively.

One conceptualization of reliability is test-retest reliability and can be quantified using Pearson correlation between a measure's values at 2 time points [33]. For a comparative baseline in the literature, Falls Efficacy Scale-International measurements taken by the same patients at different time intervals had Pearson correlations ranging from 0.66 to 0.83 for measurements taken up to a year apart [34].

The Pearson correlation coefficient is known to suffer bias when distributional assumptions are violated, a concern because Q_FALL has only 3 response levels and there were different response counts between patients and years. The use of averages and bootstrap resampling were thus employed to address these factors. First, we limited attention to a subset of 234 patients from the persistency analysis who answered Q_FALL at least 5 times in both a full first year and a second year of tenure, hereafter referred to as year 1 and year 2. Second, we used the bootstrap to obtain a bias-corrected estimate of the Pearson correlation along with a nonparametric 95% CI [35]. This allowed us to perform inference on the coefficient of determination (R^2) for the equivalent regression of the year 2 means regressed on the year 1 means.

Averaging the ternary scores allowed us to work on a continuum where rare fallers and never fallers appear close together on the resulting scale, a notion supported by similarities between these groups in a 1-year cohort study [36]. To circumvent the limitations of a linear correlation analysis, we performed an additional discrete state transition analysis. We examined the frequency of transitions to and from mean Q_FALL scores of [−1, −0.5), [−0.5, 0.5), and [0.5, 1.0] in year 1 and year 2, expecting self-transitions to be the most frequent.

Validity

To assess the convergent validity of the recent falls question administered via spencer, the mean scores for year 1 and year 2 were compared with the following established risk factors of fall risk: increased age, biological sex, previous fall frequency, low quality of life, depressive symptoms, physical impairment, and medication use [31,34,37]. Many patients in this population were prescribed selective serotonin reuptake inhibitors (SSRIs) or serotonin-norepinephrine reuptake inhibitors (SNRIs), and these are associated with falls in the older adults [38,39]. A meta-analysis found that 95% (70/74) of studies reported gender or sex differences in fall-related outcomes with females at a higher risk than males [40]. Canonically, increased age is a risk factor for falls [41]. The validity analysis was split into 2 parts, each based on the 234-patient subset from the reliability analysis.

We first conducted an analysis of the relationship between raw Q_FALL values and covariates age, sex, and SSRI or SNRI usage, as these were known before any responses were received (medication can be discontinued but medication classes tend to be stable within patient). To accommodate the repeated measures received from each patient, we used a generalized estimating equation approach to model the relationship between the coded value of Q_FALL and an exchangeable working correlation structure. This was accomplished with the *geepack* package in R, which reports SEs that are robust to both the choice of working correlation structure and nonnormality of the response. For age and SSRI or SNRI usage, we expected to see negative

XSL•FO
RenderX

relationships. For biological sex, we expected that female patients would be associated with lower mean Q_FALL than male patients.

For evidence of association between Q_FALL and other relevant variables, including quality of life, depressive symptoms, and hospital visits, we selected the questions listed in Table 1 as contemporaneous survey-based measures that had face validity for concepts of interest. Their responses are integer-coded and arranged by sentiment, and thus we expected positive correlations with Q_FALL.

The robust Kendall τ measure was used to test for associations, as the sample sizes of the questions from Table 1 may be arbitrarily small within patient. Kendall τ is more appropriate for ties and has an accompanying 2-sided nonparametric test for testing the null hypothesis of zero association [35]. For a nonparametric 95% CI on τ, we used the *kendall.ci* function from the R package *NSM3* [42], which provides a bootstrap CI.

Table . Standard spencer questions relating to known risk factors of falling.

Question text	Possible responses	Values coded	Construct[a]
Rate your recent quality of life.	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Quality of life
How is your emotional health today?[b]	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Depression
How would you rate your physical health today?	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Physical health
Rate your ability to perform activities today.	Excellent | Very good | Good | Fair | Poor	5 | 4 | 3 | 2 | 1	Ability or disability
Are you able to accomplish what you have planned today?	Completely | Mostly | Moderately | A little | Not at all	5 | 4 | 3 | 2 | 1	Ability or disability
Hospital, ER[c], or urgent care in the past month?	No | Not sure | Yes	1 | 0 | −1	ER visits from falls

[a]Construct is based on face validity of the spencer standard questions.

[b]This question has been in rotation for multiple years, but in September 2022, the number of responses changed from 3 (“Poor,” “Good,” and “Excellent”) to 5 (“Poor,” “Fair,” “Good,” “Very good,” and “Excellent”). We coded the 3-response set as 1, 3, and 5, and the 5-response set as 1, 2, 3, 4, and 5, respectively.

[c]ER: emergency room.

Ethical Considerations

This study used operational data collected from a commercial medication dispensing system used in routine patient care and was not subject to IRB review requirements, so IRB approval was not pursued. Users of the spencer device provided consent for data collection through the End User License Agreement, which covers the collection of medication adherence data and responses to quality of life and PRO surveys as part of the system’s standard operation. No additional compensation was provided to users beyond the normal terms of their device usage agreement. All data analyzed in this study were deidentified prior to analysis. Spencer Health Solutions has achieved both ISO27001 [28] and Data Privacy Framework [29] certifications, and the system uses industry-standard encryption and security measures.

This research analyzed data collected during standard clinical care and device usage. All results are presented as anonymous aggregate statistics. The original data collection occurred as part of routine clinical practice, with patients providing consent for research use through the device terms of service and care management agreement. Under Canadian TCPS 2 Article 2.4, research ethics board review is not required for research that relies exclusively on secondary use of anonymous information where the process does not generate identifiable information. Under US regulation 45 CFR 46.104(d)(4)(ii), IRB review is not required when information is recorded by the investigator in such a manner that subjects cannot be identified, directly or through identifiers linked to the subjects, the investigator does not contact the subjects, and the investigator will not reidentify subjects.

Results

Patient Population

The patient population was majority female (2552/4133, 61.7%), with 0.1% (5/4138) of the biological sex fields missing. The mean age was 54.4 years (SD 19.9, range 5-104 years). Most patients (3736/4138, 90.3%) resided in Canada, with 1 address unmapped at the country level. Patients were scheduled to take multiple drugs per day (mean 9.6, SD 5.1). Of the 2805 unique compounds scheduled during the observation window, 70.2% (1970/2805) were mapped to an Anatomical Therapeutic Chemical classification system second-level code, with a modified “Vitamins & Supplements” that included dietary supplements. Table 2 contains the 20 most frequently observed subgroups observed during the observation window.

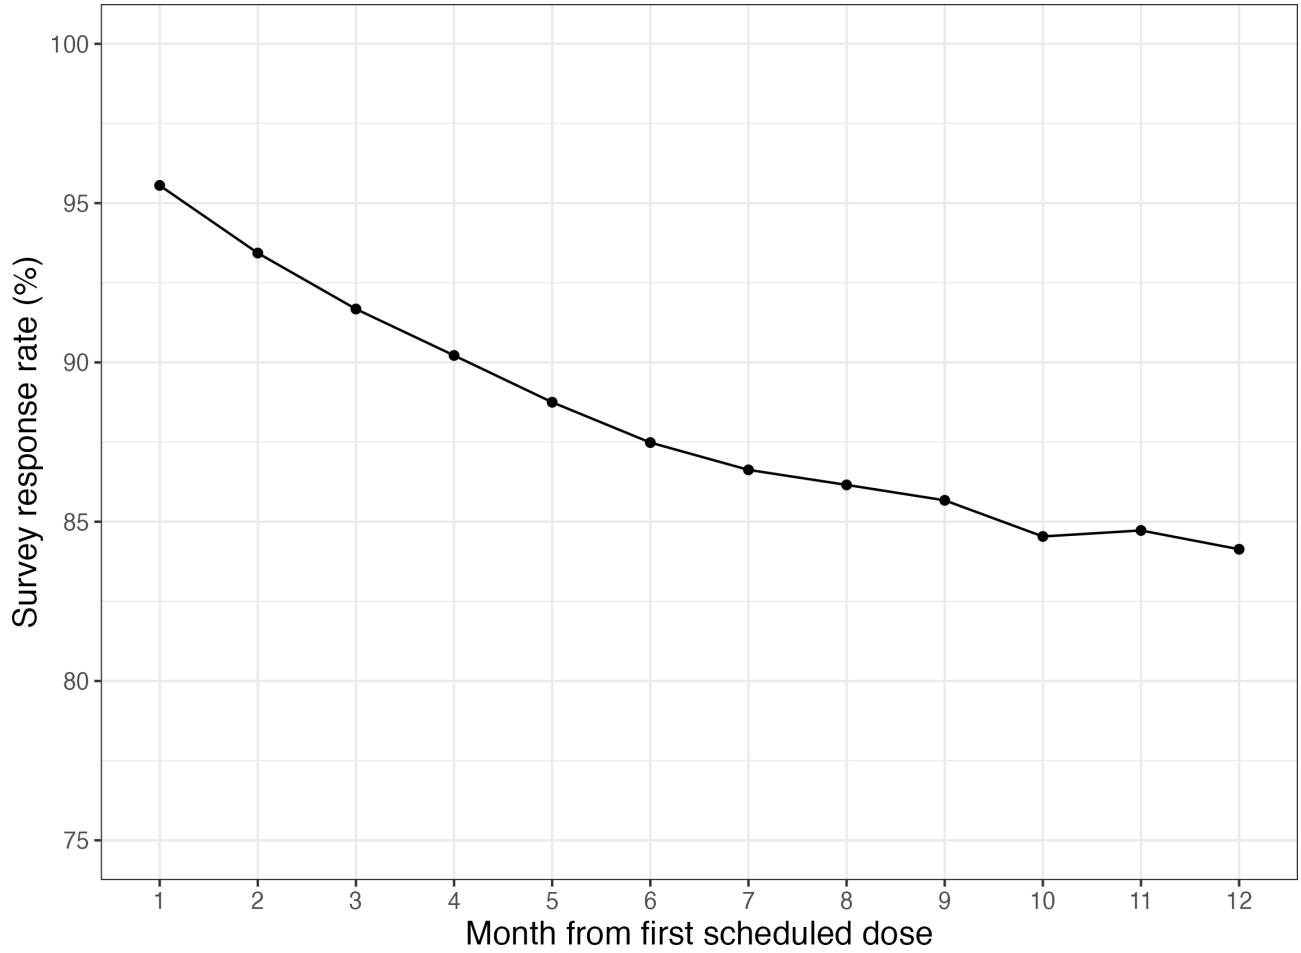
Panel Attrition

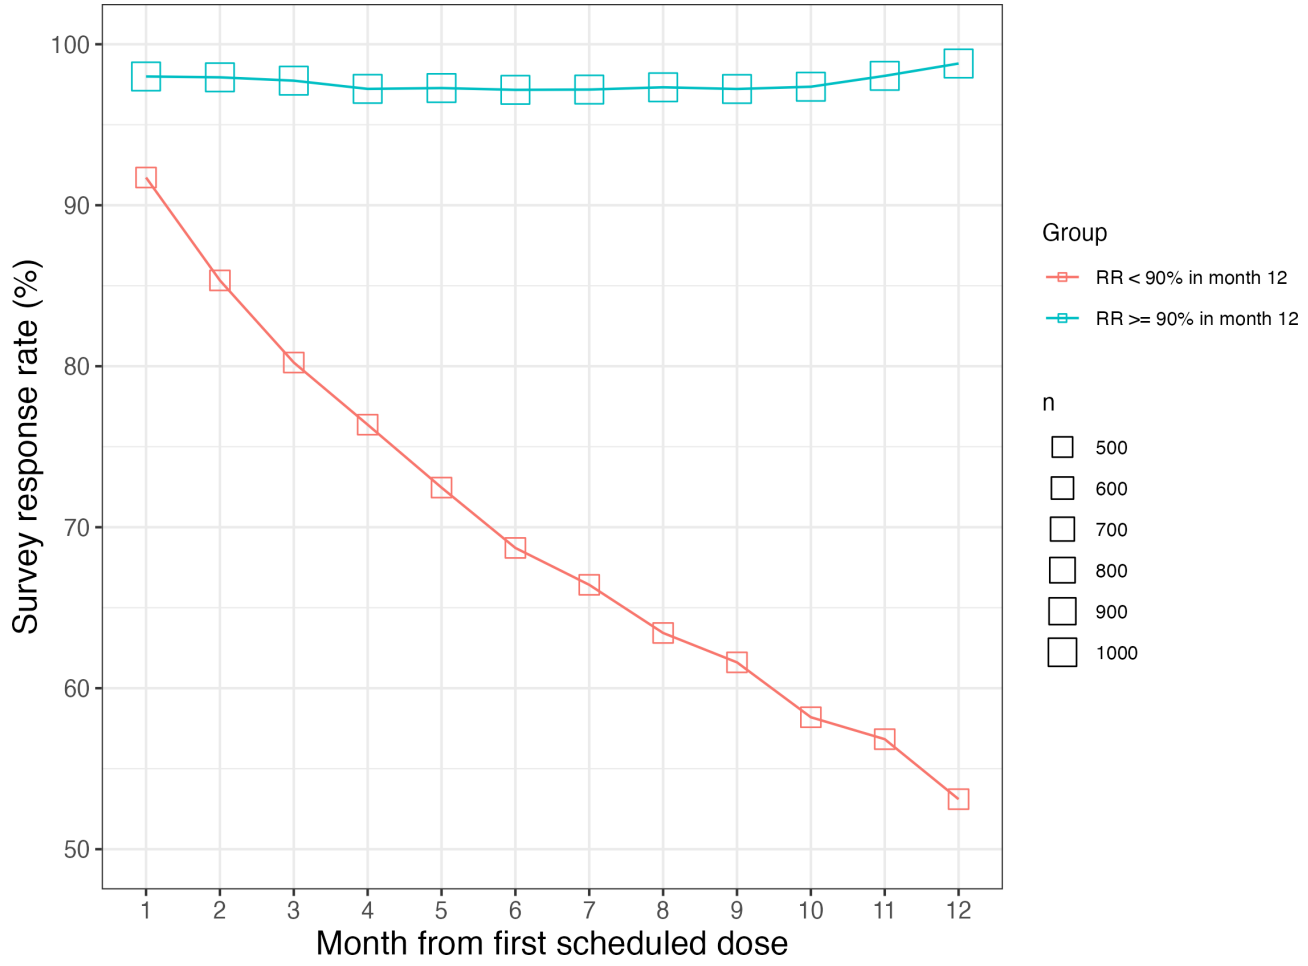
From 4138 patients, dispensing persistency was estimated to be 68.3% (95% CI 66.8% - 69.8%) at year 1 and 51% (95% CI 49% - 53%) at year 2. Among the patients who stayed on the dispensing platform past year 1, 82.3% (1508/1832) kept surveys enabled through the 12th month. The rates of question opt-out slowed during the year, as can be seen in Figure 2.

Figure 2. Dispenser persistency and percentage of patients with surveys enabled by month on platform.



Survey Response Rates

Among the 1508 patients who kept their surveys enabled through year 1, the mean response rate was 95.6% (SD 11.9%) in the first month and 84.1% (SD 26.4%) in the 12th month, with the rate of decline slowing in the second half of the year (Figure 3). For patients with surveys enabled in the 12th month, 67.9% (1024/1508) had response rates at or above 90% and 32.1% (484/1508) had response rates below 90%. Figure 4 shows the trajectories of both groups, where the high-response group maintained near perfect response rates while the low-response group experienced a substantial decline by the 12th month.



XSL•FO
RenderX

Figure 3. Mean survey response rate (%) for patients with enabled surveys by month on platform.

XSL•FO
RenderX

Figure 4. Mean survey RR by month on platform, grouped by RR in the 12th month. RR: response rate.

Reliability

Among 234 patients, the bootstrap estimate of the Pearson correlation between the year 1 and year 2 mean Q_FALL was 0.723 (95% CI 0.630 - 0.798), and the estimate of R^2 for the equivalent regression on year 2 versus year 1 means was 0.523 (95% CI 0.397 - 0.637).

Mean Q_FALL interval transitions from year 1 to year 2 are shown in Table 3. As hypothesized, self-transitions were the most common, with 59.8% (140/234) of patients starting and staying in [0.5, 1]. These rare fallers in the [0.5, 1.0] interval in year 1 remained in this interval during year 2 in 83.8% (140/167) of cases. For the frequent fallers in the [−1.0, −0.5) interval during year 1, 66.7% (12/18) remained during year 2.

XSL•FO
RenderX

Table . Mean score range transitions from year 1 to year 2[a].

Year 1 and year 2 (n=234)		Frequency, n (%)
Frequent fallers [−1.0, −0.5) (n=18)		
	[−1.0, −0.5)	12 (66.7)
	[−0.5, 0.5)	5 (27.8)
	[0.5 to 1.0]	1 (5.6)
Occasional fallers [−0.5, 0.5) (n=49)		
	[−1.0, −0.5)	5 (10.2)
	[−0.5, 0.5)	24 (49)
	[0.5 to 1.0]	20 (48.8)
Rare fallers [0.5, 1.0] (n=167)		
	[−1.0, −0.5)	1 (0.6)
	[−0.5, 0.5)	26 (15.6)
	[0.5 to 1.0]	140 (83.8)

[a]A mean score of +1.0 would be a "perfect score" of no reported falls, a mean score of −1.0 indicates that all responses indicated that a recent fall had occurred, and scores in between span the interval (−1.0, 1.0). One patient who moved from [−1.0, −0.5) to [0.5, 1.0] had a score of exactly 0.5 (the boundary), with only 6 measurements in year 2.

Validity

Covariates

For 232 patients, the generalized estimating equation model results of Q_FALL on these covariates are shown in Table 4. The coefficients associating biological sex and age to Q_FALL were not significantly different from zero; this was unexpected. However, the coefficient indicating the presence of an SSRI or SNRI medication was negative and highly significant, indicating more falls in the SSRI or SNRI group adjusted for sex and age.

Table . Generalized estimating equation linear model summary for sex, age, and whether the patient was prescribed a selective serotonin reuptake inhibitor or serotonin-norepinephrine reuptake inhibitor during the observation window.

Coefficient	Estimate	SE	Wald	*P* value
Intercept	0.684	0.127	28.857	<.001[a]
Sex (male)	−0.030	0.069	0.195	.66[b]
Patient age	0.001	0.002	0.092	.76[b]
SSRI[c] or SNRI[d]	−0.232	0.062	14.092	<.001[b]

[a]The *P* value corresponding to the hypothesis of the intercept being zero is included by convention but is not a meaningful statistic.

[b]These *P* values correspond to the 2-sided test of the hypothesis of a zero regression coefficient.

[c]SSRI: selective serotonin reuptake inhibitor.

[d]SNRI: serotonin-norepinephrine reuptake inhibitor.

Contemporaneous Outcomes From the Spencer

The analysis of correlations between Q_FALL and other contemporaneous spencer questions, based on Kendall τ, is shown in Table 5. Interpretation of correlation coefficients varies, for example, 0.2 may be characterized as either "weak" or "poor," and 0.3 as "weak," "moderate," or "fair" [43], and in the bivariate normal case, a τ value of 0.200 corresponds to a Pearson correlation of 0.309 [44]. While the strength of association between mean Q_FALL and the contemporaneous response outcomes was consistently weak to moderate, *P* values were uniformly small, indicating positive relationships of these questions with the measure of recent falls.

XSL•FO
RenderX

Table . Contemporaneous association between survey questions administered via spencer.

Question	Patients, n[a]	Average responses per patient, n	Kendall τ	95% bootstrap CI for τ	*P* value[b]
Rate your recent quality of life.	233	14	0.15	0.058-0.244	<.001
How is your emotional health today?	233	54	0.21	0.120-0.293	<.001
How would you rate your physical health today?	164	8	0.18	0.071-0.296	<.001
Rate your ability to perform activities today.	232	35	0.23	0.140-0.316	<.001
Are you able to accomplish what you have planned today?	197	9	0.18	0.083-0.276	<.001
Hospital, ER[c], or urgent care in the past month?	192	9	0.20	0.096-0.299	<.001

[a]Number of unique patients who responded to each question at least once and also responded at least 5 times to Q_FALL in year 1 and year 2.

[b]Derived from Kendall τ test, a nonparametric hypothesis test used to measure the ordinal association between 2 variables.

[c]ER: emergency room.

Discussion

Principal Findings

Although its primary function is dispensing medication, the spencer platform doubled as a web-based longitudinal panel where polychronic patients answered survey questions at high rates and exhibited low panel attrition over years of platform tenure. Measures generated from the responses where stable through time (ie, evidence of reliability) and were associated with other theoretically related variables (ie, evidence of validity). For polychronic patients residing in the US and Canada, the home medication dispenser is a promising source of reliable and valid measures of important health constructs.

As with all survey panels, there was attrition and nonresponse. Panel attrition could be decomposed into attrition from the dispensing platform and survey opt-outs for patients remaining on the dispensing platform. These losses were cumulative. Based on the estimates presented, starting with 100 patients, 68 would still be dispensing via spencer by the end of the first year, with 56 still receiving questions following their dispenses.

In our literature review, persistency was often a serious issue in the context of longitudinal patient studies. For 8 remote digital studies conducted between 2014 and 2019, researchers found that more than half of all participants discontinued their participation within the first week of the study [9]. In a web-based study during the COVID-19 pandemic, of 2734 participants who completed wave 1, only 964 participated in wave 3 [10]. In a study of smartphone app usage to improve oral anticoagulation adherence, a retention rate of 27% at 6 months was reported [11]. Considering these results, keeping more than half of the initial patients actively participating in surveys at the end of the first year represents favorable retention.

The rate of new survey opt-outs also decreased substantially through the year, setting up milder losses in year 2.

By the end of first year, the average survey response rate for patients taking surveys on spencer was 84%. While 80% has been considered excellent in the context of primary care research studies [45], multi-item surveys administered at a single point in time are an imperfect benchmark. Ecological momentary assessment, a survey methodology that addresses phenomena as they occur, typically sees compliance rates from 50% to 90% [46]. By either standard, the response rates observed in spencer surveys were good.

We can speculate on why some patients responded to fewer spencer questions over time than others. Survey fatigue is a well-known phenomenon that occurs when respondents become weary of repeated survey tasks [47], and although surveys administered via spencer are brief, they are frequent. In addition to fatigue, some patients may not have been aware of how the questions were being used to monitor their well-being. Developing interventions to improve survey response rates is a topic for future research.

Noncoverage in web-based surveys, often defined as lack of access to the web, is thought to be a more serious problem than nonresponse, which is an unwillingness to participate [48]. Since every participant has a connection to the web through the device itself (the spencer units have both cell and Wi-Fi connections), there is no noncoverage in the sense of lack of web access, although machines do go offline for varying durations.

With sufficiently high panel persistency and response rates, attention focuses on the quality of the data that are generated. We showed that a measure about recent falls generated from a spencer question exhibited temporal stability, a form of reliability. The measure showed expected associations with most theoretically related variables. One exception was the

XSL•FO
RenderX

demographic factors of age and biological sex, which failed to achieve significance in a regression where medication use was significant ($P<.001$). While additional data may reveal the expected relationships, we surmise that in a polychronic population taking many medications, demographic factors may be weaker predictors of falling than in the general population.

Limitations

First, since the patients studied in this paper were polychronic patients enrolled in a care management program and residing in the United States and Canada, inferences to other populations may not be warranted.

Second, our validity analyses were limited to data collected entirely within the spencer ecosystem. While correlations between spencer survey responses suggest meaningful patterns, these questions, although having face validity, lack validation against established instruments. The observed correlations might partly reflect the consistent presentation format on the device, where responses are always ordered from most to least positive sentiment. Our validity arguments would be substantially stronger with independent measurements, particularly comparisons between spencer responses and validated traditional instruments measuring the same constructs.

Third, this study did not consider sensitivity to change, which is important in the context of RWE because it allows researchers and clinicians to detect change resulting from a minimal intervention [49]. While we focused on reliability by treating fall risk as a stable construct, and although fall risk is sufficiently stable to support our reliability analysis, treating it as static was a limitation of this research. Future research could explore methods for estimating changing states from longitudinal survey data, building on established approaches in the literature [50,51].

Conclusions

Administering longitudinal surveys via spencer, a smart medication dispenser, effectively generated high-quality RWD from patients in their homes. Patients persisted on the platform for years and maintained high response rates. A measure derived from longitudinal surveys assessing fall risk demonstrated both reliability and validity. The performance of spencer as a longitudinal survey platform offers a promising alternative at a time when web-based survey data quality is deteriorating.

Because medication dispensing is a fundamental component of the survey-generating mechanism, RWD from the spencer platform offers an ideal opportunity to study medication effectiveness and health outcomes, providing evidence to support new drug indications and demonstrate relationships between health outcomes and economic factors.

Acknowledgments

This work was funded by Spencer Health Solutions, Inc, a private corporation headquartered in Morrisville, North Carolina. The authors wish to thank University of Maryland professor Greg Hancock for his perspective on presenting this new source of patient-reported outcomes. The authors thank Devi Kodavanti, a member of the data team at Spencer Health Solutions, for computing many reliability coefficients in the past that gave them confidence to do this research. Their resident designer Lew Wilson created the table of contents image. Finally, the authors thank Alan Menius, the scientist behind the evolution of the spencer standard questions.

Data Availability

The dataset analyzed during this study is not publicly available to protect patient privacy and comply with health care privacy regulations, since it contains patient-reported outcomes collected through medication-dispensing devices. While the data are deidentified, they represent longitudinal health-related information of single patients alongside demographic information; it is difficult to guarantee that reidentification, however unlikely, is impossible. However, controlled access to specific portions of the data are available from the corresponding author on reasonable request, which should include (1) a brief research proposal outlining their intended use of the data, and (2) documentation of their institution's data security protocols.

Authors' Contributions

All authors participated in the conceptualization, review, and revision of the final manuscript draft for submission. BO proposed the methodology, performed the formal analysis, and wrote the original draft. TR supervised the research through all stages and performed validation activities.

Conflicts of Interest

Authors BO and TR are current employees of Spencer Health Solutions, Inc, the developer of the spencer platform. Author ES was employed at Spencer Health Solutions during the initial research and manuscript development phase.

Abstract

Background: The integration of health care and social welfare services together with the consolidation of health care information systems (HISs) and client information systems (CISs) has become a timely topic. Despite this development, there is a scarcity of systematic research on physicians', registered nurses' (RNs) and social welfare professionals' (SWPs) experiences of participating in the development of HISs and CISs.

Objective: This study aimed to examine how physicians, RNs and SWPs experience collaboration with HIS or CIS vendors, and what kinds of end users have participated in HIS or CIS development.

Methods: National cross-sectional usability surveys were conducted in Finland among RNs and SWPs in 2020 and physicians in 2021. Questions concerning participation experiences were analyzed by professional group, working sector, managerial position, and age.

Results: In total, 4683 physicians, 3610 RNs, and 990 SWPs responded to the surveys. In all 3 professional groups, those working in nonmanagerial positions and the youngest respondents participated least in HIS or CIS development, and 76% (n=3528) of physicians, 78% (n=2814) of RNs and 67% (n=664) of SWPs had not participated at all. When comparing the groups, physicians were least aware of feedback processes and least satisfied with vendors' interest in end-user feedback and the manner and speed of HIS development. Those who had dedicated working time for HIS or CIS development were less critical of vendors' interest and responsiveness to development ideas than those who had not participated at all. In all 3 professional groups, the youngest were most dissatisfied with HIS and CIS vendor collaboration.

Conclusions: Experiences of participation in HIS and CIS development were relatively negative across all 3 professional groups, with physicians being the most critical. Dialogue and collaboration between developers and end users—also the youngest ones and frontline workers—need improvement; simply increasing allotted working time is unlikely to produce more positive participation experiences.

Introduction

Background

The increasing collaboration between health care and social care and the consequent need for integrated information systems (ISs) warrants studies on the end-user participation viewpoints of all major user groups. Physicians [1-5], nurses [1,2], and social welfare professionals (SWPs) [6] are not satisfied with the usability or daily work support of health care information systems (HISs) and client information systems (CISs) [7]. Furthermore, these professionals experience collaboration with HIS and CIS vendors and developers to be unsatisfactory. However, the majority would be willing to participate in

XSL•FO
RenderX

information system development, but suitable means are lacking [1,2,6,8-11].

End users' participation in IS development is considered to lead to a better user experience and increased user acceptance [12,13]. However, the characteristic inherent complexity of HISs and CISs complicates the implementation of many user participation methods [14,15]. Although end-user participation is regarded as essential in HIS and CIS development [16], without careful management throughout the software development process, participation alone does not guarantee system success [17-19]. End-user participation may even cause more problems than benefits, particularly if the ISs are expected to solve organizational problems [20]. Users may experience that their participation does not affect IS functionalities in a desired manner [1,4,6,16]. In addition, emphasizing administrative information needs and wishes instead of the needs of frontline professionals can complicate work processes by increasing the requirements for data entry and thus impair the workflows [21]. IS users in leadership positions have different needs for ISs than frontline professionals [22].

Comprehensive HISs and CISs are complex ISs used by dozens of user roles in a wide variety of use contexts [23,24]. Many countries, including Finland, are integrating health and social welfare services and consequently ISs [25-27]. One of the rationales behind this development is that those with high numbers of visits to health care often need social welfare services and vice versa [28]. From the point of view of patients and clients, treatment and service packages often include both health care and social services [29-33], which emphasizes the need for fluent information exchange between professional groups to guarantee high-quality and safe care. Consequently, end users from the major professional groups are needed in the IS development processes.

Context of the Study: Health Care, Social Welfare and HISs and CISs in Finland

Until 2023, municipalities (n=309 in 2022) were responsible for organizing social welfare services and primary health care (health centers) in Finland. A total of 20 hospital districts, jointly owned by the municipalities of the region, organized specialized medical care; 5 university hospitals provided tertiary care. Although one-third of outpatient visits to physicians are to private providers (eg occupational health care), the variety of services provided by the private sector is narrow; for example, there are no private intensive care units (ICUs) or labor and delivery units [34]. In social welfare, municipalities or federations of municipalities often purchase some services from private service providers and non-governmental organizations (n=3971 in 2017) [27]. In 2018, there were 19,627 working-age physicians, 70,198 RNs, and 34,523 SWPs in Finland [35-37].

In Finland, the first HISs and CISs were implemented in the 1970s [27]. While only every tenth US hospital used electronic health records (EHRs) as late as in 2010 [38], in Finnish public health care, HIS coverage had already reached 100% by 2007, and by 2014 CISs covered almost all public social services [39,40]. By contrast, in 2020, a quarter of nonpublic social welfare organizations still operated on paper [27,41].

All public hospitals and health centers had joined the Kanta services (national patient data repository and electronic prescription system) by 2015 [42,43], but implementation of the national data repository for social welfare services only began in 2020 [44]. This has required considerable resources from both health care and social welfare organizations and IS vendors over the years [45].

During 2020‐21, in public health care, 2 leading specialized care and 2 leading primary care EHR brands were in wide use. In addition, 4 EHR brands covered both primary and specialized care, of which 1 also covered tertiary care (including functionalities for eg, operating rooms, ICUs, radiology, and emergency departments) and 6 out of the 7 nationally defined social welfare service lines. In addition, 1 EHR brand covered most private sector health care. In public social welfare, 2 CIS brands were in use in most municipalities [46]. In addition, EHR brands were also used in social welfare [41]. In 2018‐21, a new IS was deployed in Southern Finland with 47,000 end users.

Research Questions

In this study, we examined the experiences of physicians, registered nurses (RNs) and SWPs of participating in HIS or CIS development. The data were gathered in 3 large Finnish national surveys in 2020 and 2021. The research questions were as follows:

1. What experiences do physicians, RNs and SWPs have of collaboration with HIS and CIS vendors?
2. Do participation experiences vary by managerial position, employment sector, or age?
3. What types of physicians, RNs and SWPs have participated in HIS and CIS development?

Methods

Survey

This study was part of large national cross-sectional HIS and CIS usability surveys conducted among SWPs and RNs in 2020, and physicians in 2021 [47]. The survey questionnaires and data are available online [47]. The surveys were based on the validated National Usability-Focused HIS Scale [48] and included a section on end users' experiences of participation in HIS or CIS development (Table 1). The statements were originally created and piloted for the national physician survey in 2010 [4,5], and the same statements have been used in later surveys for physicians [1], for RNs [8,49], and SWPs [6]. The survey method and the questionnaire have been described in detail previously [4,5,48].

XSL•FO
RenderX

Table . Questionnaire statements.

Questions and statement/option designations		Statements and options
Question (1) What has been your experience of providing feedback on the information systems you use and their development? please assess the following statements based on your experience. Response options: Fully agree / Somewhat agree / Neither agree nor disagree / Somewhat disagree / Fully disagree		
	Statement A	I know how and to whom I can send feedback about the system if I wish to do so.
	Statement B	The system vendor is interested in feedback about the system provided by the end users.
	Statement C	The system vendor implements corrections and change requests according to the suggestions of the end users.
	Statement D	Corrections and change requests are implemented within a reasonable time frame.
Question (2) Have you participated in information systems development work?		
	Option A	Yes, some of my working time has been allocated for such development work
	Option B	Yes, in addition to my work
	Option C	No

The link to the survey questionnaire was sent to the members of the Finnish Medical Association (FMA) (>90%) (email address available, n=19,142), RN members of the Finnish Nursing Association, the National Association of Health and Welfare Professionals, and the National Professional Association (n=58,276), and SWPs with at least a Bachelor's degree who were members of the following trade unions: the Union of Professional Social Workers, the Trade Union for the Public and Welfare Sectors, or the Social Science Professionals union (n=12,471) [9,50,51] .

The section addressing end-user participation experiences in HIS or CIS development (Table 1) was identical for the physicians and the SWPs with 5-point Likert scale response statements (fully agree; somewhat agree; neither agree nor disagree; somewhat disagree; or fully disagree). However, for the 2020 RNs' survey, a sixth option "Prefer not to respond / Don't know" was added. Furthermore, unlike in the physicians' and SWPs' surveys, it was not possible for RNs to not respond at all. Up to 25% of RNs chose this sixth option. To make the surveys more comparable, we formed a sixth category also for physicians and SWPs of those who had not responded to the statements. In addition, for the descriptive statistics in Figures 1-4 and Table S1 in Multimedia Appendix 1, we combined the responses "Fully agree" and "Somewhat agree" to form a new category "Agree" and included those from the sixth category in the denominator.

The statement on having allocated time to participate in IS development was identical in all 3 surveys, and the background questions included in this study were all optional in all 3 surveys, so nonrespondents were not included in these numbers.

Statistical Analyses

Statistical analyses were carried out with SPSS 28 (IBM Corp). The χ^2 test or Fisher exact test was used as appropriate. Statistical significance was determined as $P<.05$.

Ethical Considerations

According to the national ethical instructions for research, the studies did not require ethical approval (Finnish Advisory Board on Research Integrity 2023) [52].

The autonomy of research subjects was respected, there was informed consent, no harm was possible to the participants and confidentiality of the subjects, and research data were protected. The researchers were not able to identify individual respondents. However, as the data for the RN and SWP studies were collected by a national authority (Finnish Insititute for Health and Welfare), the ethical approval (THL482/6.02.01/2020) was provided by its institutional review board.

Results

Respondent Characteristics

The demographics of the respondents to all 3 surveys are provided in Table 2. In 2021, 4683/19,142 physicians (24.5% of email invitation recipients) participated in the survey, and in 2020, 3610/58,276 RNs (6.2% of email invitation recipients) and 990/12,471 SWPs (7.9% of the theoretical target group) participated in the survey [35-37].

Leadership position			
Works in a leading or managerial position	1139 (24.3)	406 (11.2)	172 (17.4)
Works in other positions	3543 (75.7)	3204 (88.8)	818 (82.6)

[a]The email invitation was received by 19,142 physicians, 58,276 registered nurses, and 12,471 social welfare professionals. Of these, 4683 (24.5%) physicians, 3,610 (6.2%) registered nurses, and 990 (7.9%) social welfare professionals responded to the survey.

Participation Experiences of the 3 Professional Groups

Physicians appeared to be least knowledgeable of how and where to send feedback, with only 41% (1920/4683) agreeing with statement 1, as compared to 61% (2204/3610) of RNs and 56% (556/990) of SWPs (Figure 5). In terms of vendors' interest in end-user feedback and the manner and speed of IS development, physicians were also least satisfied, with 16% (776/4683), 14% (672/4683), and 9% (407/4683) of them, respectively, agreeing with statements 2, 3, and 4, as compared to 26% (960/3610), 19% (707/3610), and 13% (481/3610), respectively, of RNs and 25% (225/990), 19% (180/990), and 13% (122/990), respectively, of SWPs (Figure 5). In total, 76% (3528/4683) of physicians, 78% (2814/3610) of RNs and 67% (664/990) of SWPs had not participated at all in HIS or CIS development (Figure 6).

XSL•FO

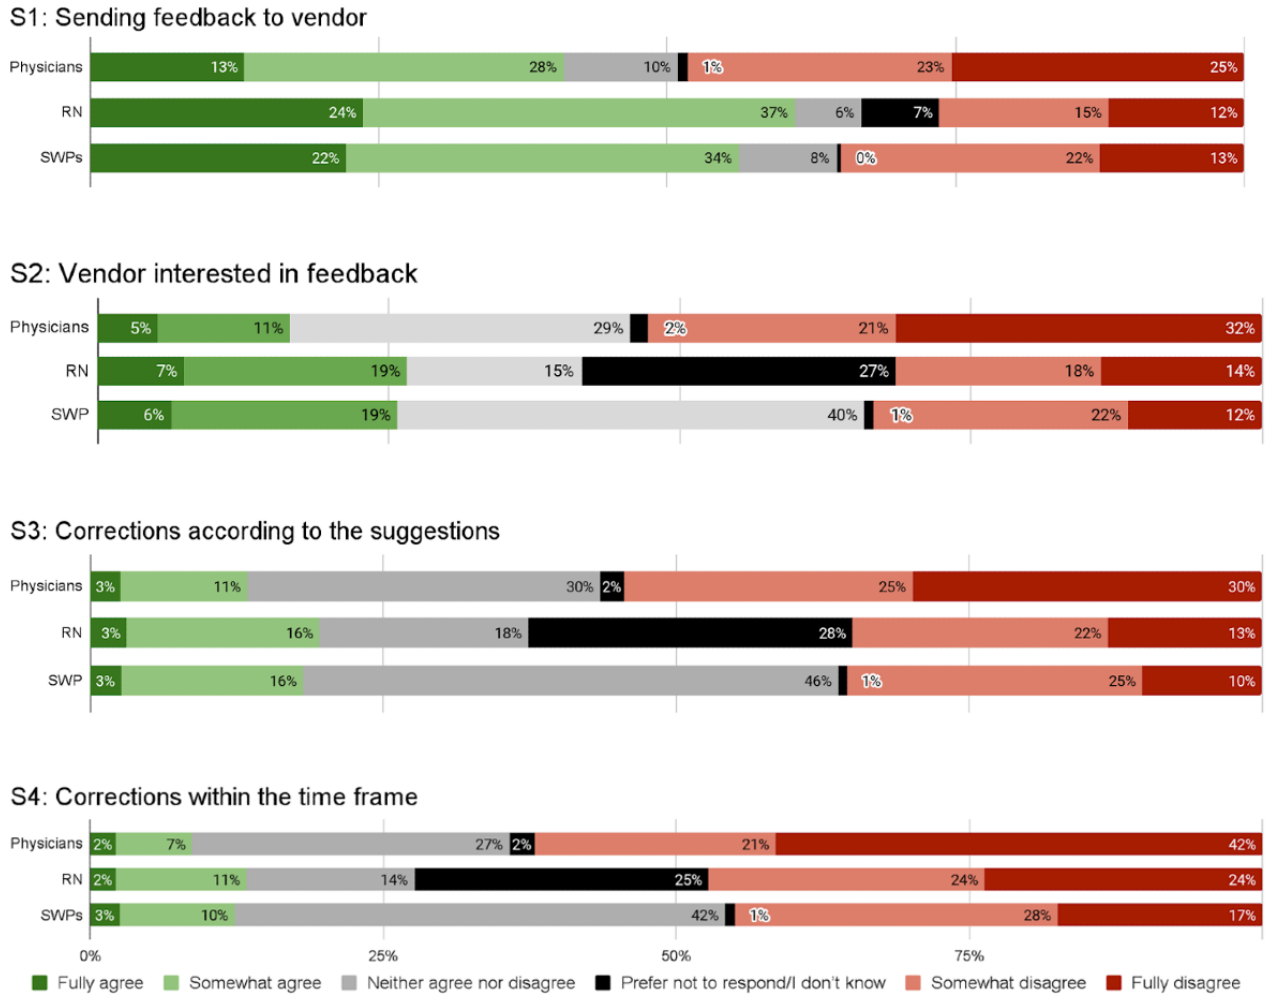
Figure 5. Experiences of physicians, RNs and SWPs of collaboration with health care information system and client information system developers. RN: registered nurse; SWP: social welfare professional.



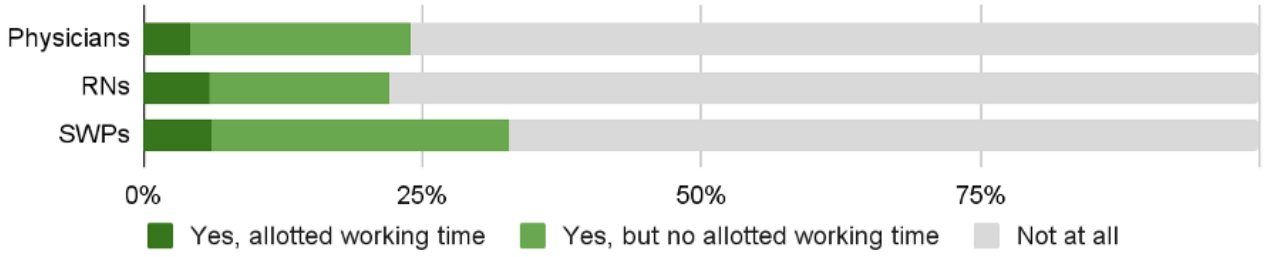


Figure 6. Participation in information system development work by professional group. RN: registered nurse; SWP: social welfare professional.

Factors Associated With Participation Experiences

Leaders, particularly among RNs, were more aware of how and where to send system feedback (statement 1) than those working in nonmanagerial positions (Figures 1-4). Leaders in all 3 professional groups were more satisfied with the system vendor collaboration (statements 2 - 4) than the others. The working sector did not impact end users' experiences. In all professional groups, the youngest appeared least aware of how and where to send feedback and least satisfied with the collaboration. Those who had participated in HIS or CIS development considered IS vendors more interested in feedback and were more satisfied with the manner and speed of system improvements and corrections.

Factors Associated With Having Participated in HIS or CIS Development

In all 3 professional groups, leaders had participated more in IS development than their colleagues in nonleadership positions (Figure 6).

Among physicians and RNs, but not SWPs, those working in the private sector had participated less than their public sector colleagues (Table 3). In all 3 professional groups, the youngest had participated the least (Table 3).

Discussion

Overview

To our knowledge, this is the first study to assess how the major professional groups in the health care and social welfare sector, that is, physicians, RNs, and SWPs, view HIS and CIS development participation. The responses were analyzed by managerial position, employment sector, and age group. Furthermore, we examined which types of professionals have participated in HIS and CIS development.

RNs and SWPs Highly Aware of to Whom and How to Send Development-Related Feedback

The majority of RN (2204/3610, 61%) and SWP (556/990, 56%) respondents knew how and to whom to send development-related feedback; the respective proportion for physicians was 41% (1920/4683). The difference may be explained by mentoring or superuser and training programs during and after HIS implementations among RNs [9,53]. On the other hand, since the response rate among RNs and SWPs was relatively low, those who responded were probably more interested in ISs and thus more aware of HIS and CIS development than those who did not. The findings concur with our earlier studies, which have shown that physicians tend to be more critical towards their HIS compared with RNs and SWPs [2,5].

Leadership and its competence play an important role in the implementation of ISs and investment of resources in digitalization [22,54].

In this study, leaders in all professions and those with allotted working time for HIS or CIS development were more aware of feedback processes than others. These are usually responsible for the orientation of personnel, furthermore, they are often the ones to whom other personnel report development ideas or problems with HIS or CIS use. In all 3 professional groups the youngest were least aware of the feedback processes; whereas the youngest often have mentors who also help with HIS or CIS related problems, it is also probable that the currently available means are not suitable for the younger generations.

Leaders Critical About Cooperation

Although leaders had more often dedicated working time and participated more often in the development of HISs or CISs than the others, they were critical about cooperation with vendors. Their information needs, informatics competencies, and partly also the ISs differ from those working in nonmanagerial positions [55]. The particularly negative viewpoints of physician leaders may be impacted by most of them regularly using HISs for direct patient care, unlike RN or SWP managers who mainly use HISs or CISs for managerial purposes [56]. The most recent study shows that RN managers are able to use HISs for their managerial duties. Due to poor system integration, they need to gather data from different systems for management, which wastes resources inefficiently [22].

Those With Dedicated Working Time Less Dissatisfied With Vendor Cooperation

Those who had dedicated working time for HIS or CIS development were less dissatisfied with vendors' interest and responsiveness to development ideas than those who had not participated at all. They are likely to be more aware of the development processes and timelines of their respective HISs or CISs. Furthermore, since they have been chosen by their respective organizations as participants in HIS or CIS development, their ideas are more likely to become realized. Earlier studies have also found that user participation increases acceptance and active use of HISs contributes to the acceptance and increased active use of HISs [57]. Although not all development ideas are suitable for execution and not all end users can be expected to spend considerable working time on HIS or CIS development, to achieve better engagement in the use of ISs, users need to experience that they are heard and understood [57].

The Youngest Least Satisfied With Vendor Cooperation

Similar to the findings of our previous studies [1,4,6], the youngest were the most dissatisfied with vendors' interest in feedback. This is a particularly important finding as it suggests that the current ways of engaging professionals will not become more suitable or even acceptable to future generations. Barchielli et al [58] also found that younger nurses rely on their colleagues' opinions of health technology use, while older nurses rely on their own experiences.

What Kinds of Users Have Participated in HIS or CIS Development?

Previous studies have shown that impactful participation in IS development requires dedicated working time [58]. Of those working in nonmanagerial positions, 72% - 82% responded that they have not participated at all in HIS or CIS development, whereas the respective proportion for leaders was 45% - 57%. Physician and RN leaders were most likely to have allotted working time for HIS development. Our findings agree with several studies suggesting that managerial viewpoints are likely to become overrepresented in IS development [59,60]. Although the data produced by the ISs is essential for leadership and management purposes, if the participating leaders are not engaged in clinical work or practice the solutions may end up not supporting the needs of frontline workers [61,62].

Health care professionals working in the private sector participated less than their public sector colleagues, among SWPs the differences were minimal. As the majority of Finnish private sector physicians work as private practitioners, their participation would usually result in decreased earnings. It is also likely that the lack of most complex patients in private healthcare reduces the need for HIS development.

In all 3 professional groups, the youngest participated the least. This may be because they are at the stage of learning the clinical content of their work and their employers may not want to invest their time in HIS or CIS development. Khairat et al [62] also

XSL•FO
RenderX

report underrepresentation of physicians in specialization training in HIS development groups. Although not possessing advanced professional skills, the youngest are not burdened with old, often paper-based workflows, which could assist in redesigning processes and enhance the use of newer technologies [62].

How to Improve Satisfaction in HIS and CIS Development

The development processes of large-scale complex systems such as HIS and CIS are typically dominated by cooperative activities involving multiple stakeholders [63-65]. Different information needs must be identified, prioritized, and communicated clearly enough to the IS designers and developers [65].

It remains challenging to increase user input and select appropriate participants and human-centered design methods through the different phases of the participatory development cycle [15,20]. Identifying other factors that influence user experiences, such as decisions made by regulators, policymakers, and administrators, may assist in developing better HISs and CISs [66]. Previous studies have recognized the importance of clinical informaticists who also use HISs or CISs in clinical work in communicating end users' needs and feedback to designers and developers [6,67-75]. From the organizational perspective, the benefits can be seen beyond the IS implementation phase [76]: informatics competent social and health care professionals have been found to be able to improve patient safety and patient care outcomes [67]. In social welfare, however, this role is still being developed [74,75].

Limitations

Our study has some limitations. First, compared with physicians, the lower response rates among RNs and SWPs are likely to have resulted in the selection of more involved and interested participants among these professional groups.

Second, the response rates were highest for physicians. The FMA, which was responsible for collecting the physician data, has a long history of conducting surveys among physicians, the results of which are used in FMA policies. However, the number of participating professionals from all 3 professional groups in the national level studies can be considered high compared to other similar studies [50].

The RNs questionnaire respondents, comprising nurses from various sectors including hospitals, health centers, private practice, and social care, were found to align with the target population according to Statistics Finland's employment data for nurses, midwives, and community nurses [9].

During data collection with SWPs questionnaire, incomplete contact information in membership registries limited survey outreach. To compensate, survey invitations were distributed also through sector networks and social media. The study's final sample comprised 990 SWP respondents, with an estimated response rate of 8%. It's important to note this limitation when interpreting findings. Nonetheless, the sample size was considerable and exhibited diversity in age, service backgrounds, and geographical representation across Finland [51].

Third, our questionnaire did not cover how end users were involved in HIS or CIS development and whether the means of participation would impact satisfaction with the process and the end results. Further research is needed on best practices of user participation in the development of complex HIS and CIS systems.

Conclusion

The fluent use of HISs and CISs is a prerequisite for efficient and safe health care and social welfare, as currently professionals spend a considerable part of their working time with ISs and rely on them as their primary source of information. User participation of all major professional groups—physicians, RNs and SWPs—and their involvement in development are essential for the success of complex HIS or CIS. Compared with RNs and SWPs, physicians appeared to be more critical towards IS vendors and the success of participatory HIS development. As even those with allotted working time were mostly dissatisfied with vendor cooperation, it is evident that simply allocating more end users' working time for HIS and CIS development will not guarantee satisfaction; rather, dialogue between end users and developers needs improvement. New means are needed to better engage all end-user groups, particularly the youngest ones and those working in nonmanagerial positions.

Acknowledgments

This study was part of larger projects supported by the Strategic Research Council of the Academy of Finland (projects 303607 and 327145) and the Ministry of Social Affairs and Health (project 112241). We thank the Finnish Medical Association, the University of Oulu, University of Eastern Finland, the Union of Health and Social Care Professionals in Finland, the Finnish Nurses Association, the National Association of Health and Welfare Professionals, the National Professional Association, the Union of Professional Social Workers, the Trade Union for the Public and Welfare Sectors, and the Social Science Professionals Union for their collaboration. We would also like to thank the respondents to the questionnaires. According to the local and national ethical instructions for research (Finnish Advisory Board on Research Integrity) instructions, this study did not require ethical approval.

Authors' Contributions

SM was responsible for the main supervision, writing and visualization of the research output. TL was mainly responsibile for the statistical analysis. All authors contributed to the analysis and writing of the research output. In addition, SM, JV, and TL

XSL•FO
RenderX

contributed to the design of methodology of all 3 studies, SS to the design, data curation and investigation of the SWP study, and UMK to the design of the registered nurse study.

Conflicts of Interest

SM has been previously employed by 2 of the health care information system (HIS) and client information system (CIS) software vendors included in the study. SS has been previously employed by a publicly owned in-house HIS and CIS vendor included in the study. TL has been previously employed by a publicly owned in-house HIS and CIS software vendor included in the study. The employers did not provide any support, financial or otherwise, to the study. Furthermore, these vendors were not involved in the design of the study or in the collection, analysis or interpretation of the data.

Multimedia Appendix 1
Experiences of participation in system development.

Abstract

Background: Through third party applications, patients in the United States have access to their electronic health record (EHR) data from multiple health care providers. However, these applications offer only a predefined organization of these records by type, time stamp, or provider, leaving out meaningful connections between them. This prevents patients from efficiently reviewing, exploring, and making sense of their EHR data based on current or ongoing health issues. The lack of personalized organization and important connections can limit patients' ability to use their data and make informed health decisions.

Objective: To address these challenges, we created Discovery, an experimental app that enables patients to organize their medical records into collections, analogous to placing pictures in photo albums. These collections are based on the evolving understanding of the patients' past and ongoing health issues. The app also allows patients to add text notes to collections and their constituent records. By observing how patients used features to select records and assemble them into collections, our goal was to learn about their preferred mechanisms to complete these tasks and the challenges they would face in the wild. We also intended to become more informed about the various ways in which patients could and would like to use collections.

Methods: We conducted a think-aloud evaluation study with 14 participants on synthetic data. In session 1, we obtained feedback on the mechanics for creating and assembling collections and adding notes. In session 2, we focused on reviewing collections, finding data patterns within them, and retaining insights, as well as exploring use cases. We conducted reflexive thematic analysis on the transcribed feedback.

Results: Collections were useful for personal use (quick access to information, reflection on medical history, tracking health, journaling, and learning from past experiences) and clinical visits (preparation and raising physicians' awareness). Assembling EHR data into reliable collections could be difficult for typical patients due to considerable manual work and lack of medical knowledge. However, automated collection building could alleviate this issue. Furthermore, having EHR data organized in collections may have limited use. However, augmenting them with patient-generated data, which are entered with flexible richness and structure, could add context, elevate meaning, and improve actionability. Finally, collections might produce a misconstrued health picture, but bringing the physician in the loop for verification could increase their clinical validity.

Conclusions: Collections can be a powerful tool for advancing patients' proactivity, awareness, and self-advocacy, potentially facilitating patient-centered care. However, patients need better support for incorporating their own everyday data and adding meaningful annotations for future reference. Improvements in the comprehensiveness, efficiency, and reliability of the collection assembly process through automation are also necessary.

(JMIR Hum Factors 2025;12:e50331) doi:10.2196/50331

Introduction

Background

Digital technologies play a pivotal role in facilitating patient-centered care that focuses on understanding patients' needs and fostering shared decision-making with their health care providers [1]. However, this approach relies heavily on well-informed patients and on effective patient-provider communication [2]. In the United States, a major step toward meeting these requirements was enabling patients to access their medical records from multiple providers through third-party applications [3,4]. While this is a significant achievement, enabling patients to engage in making sense of these data and turn the insights they gain from this process into actionable steps remains a challenge. Consequently, many patients lack a satisfactory understanding of their health, feel discouraged to self-advocate, and have mediocre communication with their providers, which is at odds with the core values of patient-centered care. Therefore, addressing the challenges around sensemaking and the usability of health data will be important to advancing patient-centered care and empowering patients to take an active role in their health journey.

Making sense of data, or *sensemaking*, is a cyclic process that involves cognitive activities for answering complex questions [5]. These activities involve repeated access to artifacts, identifying relevant information, finding information relationships, and presenting the answers in an understandable format [6]. Patients face a plethora of sensemaking challenges to manage their health. They need to assemble health information from different providers and identify outliers, correlations, and trends to become educated on health topics, drive decision-making, and formulate discussion points with health care providers [7]. Unfortunately, robust platforms to support patients in making sense of their clinical data are lacking.

Several commercial mobile apps such as Apple Health Records [8], iBlueButton [9], OneRecord [10], and 1upHealth [11], along with the academic web application Discovery [12], advance patient sensemaking by offering data visualizations and specialized views for data exploration. These views help patients uncover interesting patterns related to prevalence, periodicity, co-occurrence, and pre-post analysis of medical events. Typically, these solutions organize electronic health record (EHR) data by type, time stamp, or provider. However, such approaches provide very little support for patients in finding deeper connections between their medical records that are required for understanding health issues, reflecting on medical history, or preparing for clinical encounters.

Moreover, these apps do not allow patients to annotate their medical records or save their sensemaking progress, forcing them to remember findings or record them elsewhere. This necessitates patients to revisit the same data repeatedly to refresh inferences and recreate mental notes. Such work is typically tedious and frustrating, leading to anxiety and missing crucial information. Consequently, patients can form skewed health impressions, resulting in poor decisions or risky actions. In clinical visits, the inability to communicate the sensemaking insights to physicians may hinder optimal treatment, leading to repeated tests or medical errors.

To address these limitations, we explored an alternative solution that organizes EHR data into collections based on health issues and ongoing problems [13]. Inspired by findings that a problem-based view of EHR data improves clinician awareness, prioritization, and decision-making in the intensive care unit [14], we adapted a similar approach for patients anchored in the *data-frame* sensemaking theory [15]. Data frames (ie, structured mental models) or *collections* of health data, as we refer to them in our previous work [13], systematically break down problems and help in answering complex questions. These capabilities of the collections hold significant potential for managing health data effectively for all sorts of patients, particularly those with complex medical histories or multiple comorbidities [13]. By organizing abundant data around health issues, collections help patients avoid fragmented health impressions, a common challenge for those with multiple comorbidities. Patients who see multiple specialists can use collections to track the development of specific issues and share insights across providers, raising awareness and improving care coordination.

More precisely, our proposed concept of *collections* allows patients to dynamically organize, adapt, and explore their health information based on evolving needs and available data. For example, a patient managing cardiovascular issues might create a Blood Pressure collection to consolidate related records, which could later branch into more specific collections such as Extreme Blood Pressures or Blood Pressure Lab Work. These refined groupings help uncover patterns and dependencies among factors such as BMI, diet, cholesterol levels, and blood pressure, enhancing understanding and facilitating proactive management of health conditions. Gathering insights from the collections may also help patients have more productive discussions with their providers.

In our study, we extended the capacity to transform EHR data into collections and facilitated reasoning regarding them. As patients' sensemaking of health data is driven by finding outliers, correlations, and trends [7,16], we enabled capabilities to identify data patterns within the collections. In addition, we supported the assembly of relevant medical records for the collections by helping patients visually explore, find temporal patterns [17-20], and make sense of their EHR data within a single, context-preserving view [12]. Acknowledging patient requests for automation [13], we offered manually assembled and system-assembled collections. We also allowed for personal data input through free-text notes, fulfilling previously identified patient needs [13].

A notable advancement in our work is moving from mock-ups [13] to a fully functional mobile app, Discovery. The app

XSL•FO
RenderX

provides patients with a realistic platform to interact with collections, uncovering deeper insights into preferred mechanisms for creating, refining, and using these collections. Moreover, we intended to motivate patients to see collections as tools for self-advocacy during clinical visits, which was identified as a key use case in our earlier research [13].

Objectives

In this study, we used the Discovery app to explore patients' needs, preferences, and desired interactions for organizing EHR data and delve into potential use cases. More concretely, we asked the following research questions (RQs):

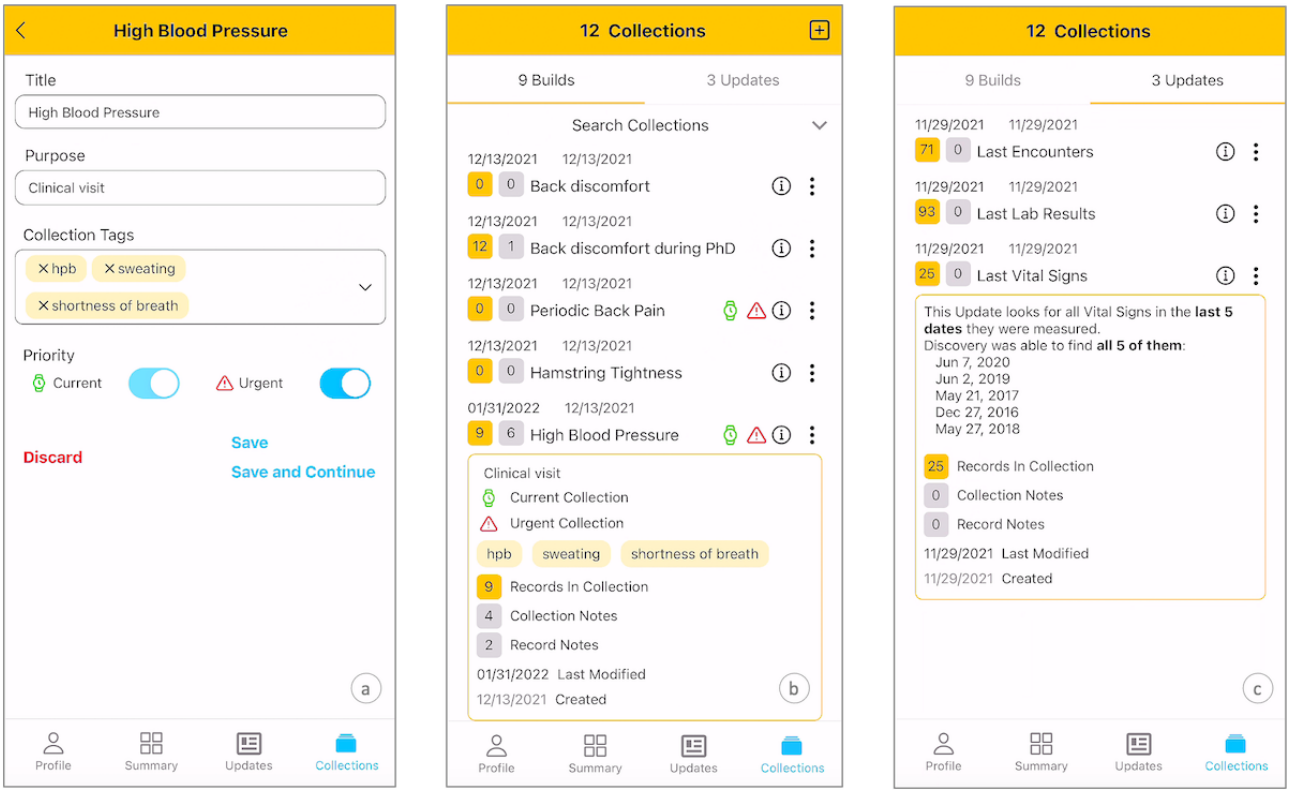
- What are the needs and feature preferences for organizing EHR data from multiple providers? (RQ 1)
  - What are the patients' experiences with creating and building collections?
  - How effectively does our app allow patients to organize their EHR data using the concept of collections?
  - How can we better meet patients' needs for meaningful EHR data organization?
- What purpose would organizing the EHR data in collections have? (RQ 2)

To answer these RQs, we conducted a qualitative evaluation study with 14 participants.

Methods

Description of Discovery

General Overview



Discovery is a noncommercial iPhone app designed to help patients make sense of their EHR data. It introduces a novel concept that organizes EHR data into personalized, problem-based collections. In addition, it allows patients to add their own observations and insights, providing context and complementing their medical records with patient-generated data (PGD).

For this study, the app was restricted to accessing synthetic EHR data through a Fast Healthcare Interoperability Resources (FHIR) format [21] from the SMART Health IT repository [22]. Discovery accesses only structured EHR data and relies on a 2-level hierarchy. At the highest level, there are the record categories ("Conditions," "Immunizations," and "Vital Signs"). Each record category has multiple record types ("Vital Signs: Body Height," "Body Weight," and "Blood Pressure"), and each record type can have multiple instances ("Blood Pressure: systolic: 125, diastolic: 90," and "date: 02/01/2022"). Each instance of data in our app is called a record and corresponds to an FHIR resource with standardized attributes.

Organizing Records in Collections

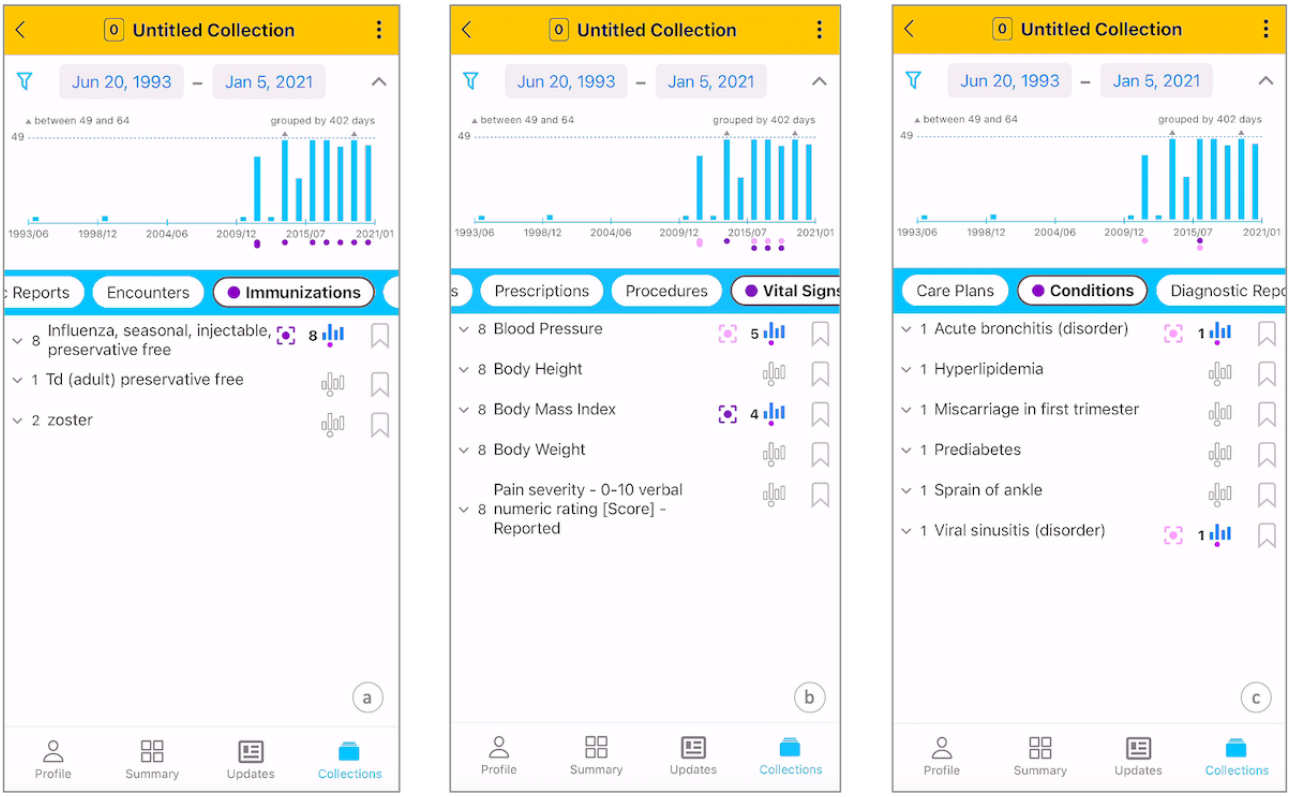
The manually created collections are called Builds (creation shown in Figure 1A and list shown in Figure 1B), whereas the app-assembled collections are called Updates (Figure 1C).

Figure 1. (A) Creation of a new collection; (B) list of patient-built collections—Builds; (C) list of system-generated collections—Updates.

Patients can manually create a new collection (Figure 1A) by entering a name and additional metadata. To prioritize and distinguish the collections, we introduced descriptors: purpose, tags, and priority. For example, in Figure 1A, the patient created a High Blood Pressure collection with the purpose Clinical Visit for an upcoming appointment. They also added tags such as

XSL•FO
RenderX

hpb, sweating, and shortness of breath for reference. The priority descriptor indicates that the collection addresses a current and urgent issue. Patients can modify any of this information as the collection develops and changes.



As patients repeatedly create collections, their EHR data transform into a problem-based list, as shown in Figure 1B, which includes health issues such as back discomfort, hamstring tightness, and high blood pressure. Collections are displayed with their name, creation and last modification dates, record count, number of patient-added notes, and labels for current (green clock) and urgent (danger sign) issues. An information button provides a summary with explanations. For example, the High Blood Pressure collection was created on December 31, 2021, and last modified on January 31, 2022. An information panel summarizes its contents: 9 records, 6 notes (4 for the collection and 2 for individual records), and tags for detailed search (hpb, sweating, and shortness of breath).

Updates automatically familiarize patients with the latest relevant events without requiring any action on their part (Figure 1C). The app scans all records and matches predefined templates, such as recent encounters, laboratory test results, and vital signs. In Figure 1C, 3 Updates are listed—Last Encounters, Last Lab Results, and Last Vital Signs—based on the last 5 dates when corresponding records were logged by the provider. The list entry follows the same structure as that of the Builds without the labels for currency and urgency. Although records in an Update cannot be changed, patients can add and remove notes. Patients can also clone an Update into a new Build and rename it if needed, allowing them to reuse and customize the assembled records for specific purposes. The reason for having this distinction between Updates and Builds is to delineate what the system and the user have produced and which entity is responsible for the collection that might have led to certain actions.

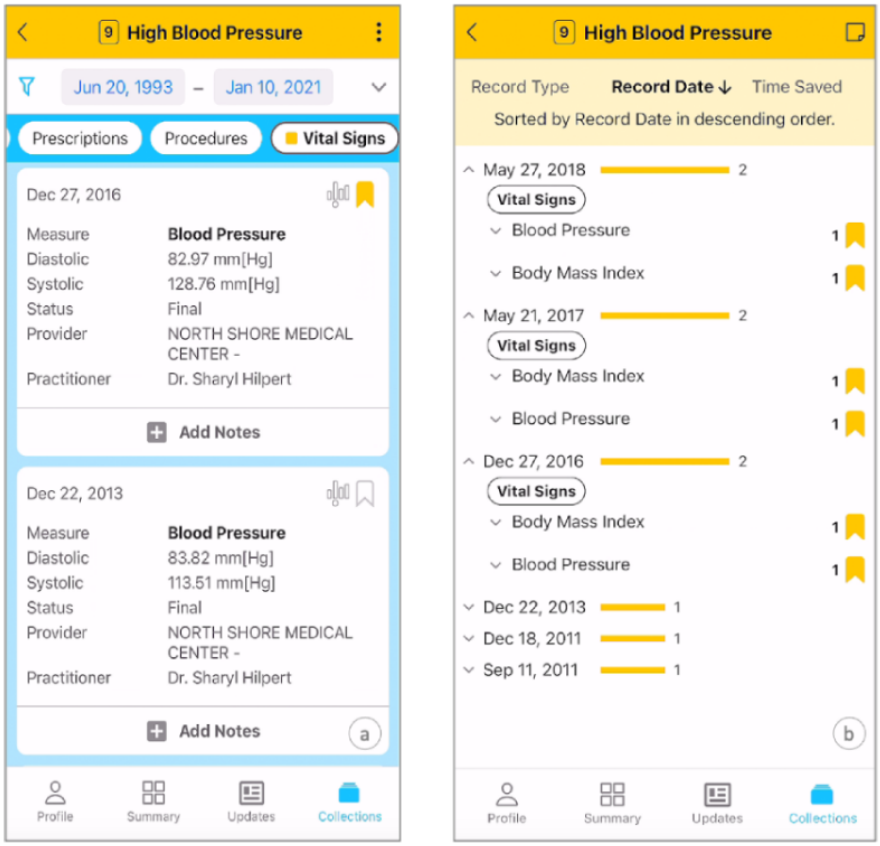
Identifying Relevant Records and Patterns for Collections

Discovery offers an interactive visualization to find patterns within records. The Timeline depicts record counts in equal time intervals, showing the prevalence of medical events. A dotted horizontal line marks the threshold above which the volume of records is considered abnormal, corresponding to the mean record count per interval. Gray triangle glyphs indicate values between the mean and 2 SDs, whereas red triangles highlight values of >2 SDs. By highlighting individual records or entire record types, patients can explore patterns that may be saved in existing collections or trigger the creation of new collections. For example, Figure 2A shows periodicity of influenza shots (when and how frequently influenza shots were administered), Figure 2B shows the co-occurrence of high blood pressure and high BMI, and Figure 2C shows the absence of respiratory conditions after an amoxicillin prescription.

Figure 2. Finding medical event patterns: (A) periodicity of influenza shots (showing when and how frequently influenza shots were administered), (B) co-occurrence of high blood pressure and high BMI, and (C) absence of respiratory conditions after an amoxicillin prescription.

The FHIR resources (ie, medical records) are represented with Record Cards, which display the clinical information in human-readable format. Patients can use a Filter and Date Picker to narrow down record categories and time frames for displayed records. Selected record categories appear in a Sliding Tabs control, allowing patients to swipe left or right for immediate access. Clicking on a record category in the Sliding Tabs organizes it by record type, represented with Accordions (eg,

XSL•FO
RenderX



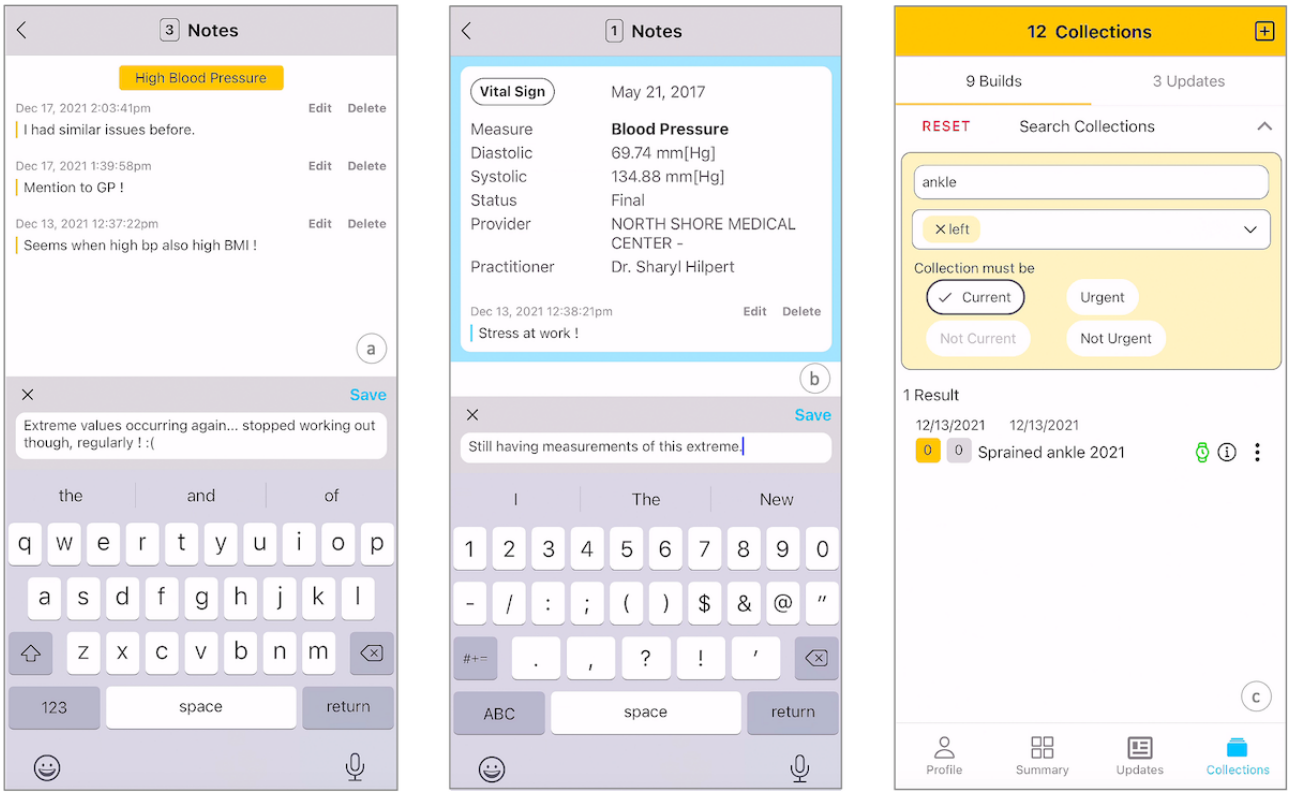
the Accordion for Immunizations category will have 3 sections for the Flu shot, Tdap, and Zooster record types). Patients can expand the Accordion sections to scroll through individual Record Cards. For example, Figure 2A shows 8 Record Cards for the influenza shot under the Immunization Accordion section. Accessing and revisiting records involves swiping the Sliding Tabs and selecting record categories, with Accordions retaining their expanded or collapsed state and scrolling position. This method is more context preserving compared to existing solutions, which require repeated back-and-forth navigation through different views for each record category and record type.

Producing Insights for the Collection

Patients can save individual records or entire record types by tapping the bookmark icon in the corresponding Record Card or Accordion section. Figure 3A demonstrates adding individual Blood Pressure records to a collection using a Record Card. Records can be removed from collections by tapping the selected bookmark again.

To identify data relationships and produce insights, patients can inspect a collection in the Collection Review (Figure 3B). Here, records can be viewed by type, date recorded in the provider's EHR system, or time added to the collection. When sequence matters, records can be ordered chronologically. Patients can also remove records in the Collection Review by tapping the selected bookmark. For example, in Figure 3B, the patient views records grouped by recording dates in descending order, with yellow bars indicating record counts by date. They observe high blood pressure and high BMI co-occurring 3 times, suggesting a pattern that may need further investigation or discussion with a physician.

Figure 3. (A) Saving a record to a collection and (B) reviewing the collection and inspecting data patterns.



Supporting PGD

Patients can enter notes for a collection (Figure 4A) or individual records within it (Figure 4B) to add personal insights, progress, observations, details, or disease journal entries. Notes can be modified or removed at any time. In Figure 4A, the first note provides context on past high blood pressure experiences. The second note serves as a reminder to mention occasional high blood pressure to the general practitioner. The currently created note adds context about noticing changes in blood pressure after stopping regular workouts. In Figure 4B, the patient contextualizes a high blood pressure measurement taken during a stressful period at work and notes the recurrence of high values.

XSL•FO
RenderX

Figure 4. (A) Adding a note to a collection, (B) adding a note to a record, and (C) searching the collections.

Searching the Collections

Free-text search targets the collection name, purpose, and notes (Figure 4C), as well as tags and priority. Results dynamically update as the search query is constructed.

Study Design

Participants

We recruited 14 participants from our email list compiled from previous recruiting efforts and Craigslist. This number is sufficient to uncover usability issues and provide rich findings as per current design research practices [23] and literature on user feedback quality [24]. We balanced the sample by age, gender, and medical history (including healthy individuals, those with acute episodes, and those with chronic illnesses). Eligibility criteria included adults fluent in English; possessing an iPhone (iPhone 6 or above) and a laptop or desktop computer (screen size of 13“ or more) with a stable, fast internet connection for both devices; and with normal or corrected vision, no color blindness, and medical records from one or more providers. Medical history was self-reported.

Table 1 illustrates the detailed participant demographics collected using the questionnaire from Table S1 in Multimedia Appendix 1. Our 14 adult study participants included 10 (71%) women and 4 (29%) men aged 24 to 61 years (mean age 35.6, SD 12.6; median 30.5 years). All had some college experience: half (7/14, 50%) held bachelor’s degrees, 14% (2/14) had some graduate experience, and 14% (2/14) had completed master’s degrees. Participants had between 2 and 15 health care providers, with half (7/14, 50%) having ≥6. The 29% (4/14) of the participants who were healthy saw physicians a few times a year. Those with chronic illnesses had been managing their diseases for 1 to 20 years.

All participants were comfortable with daily technology use, and 21% (3/14) had work experience in data analytics. Most (11/14, 79%) used third-party apps to track mental health, weight loss, sleep, and exercise. All but 1 (13/14, 93%) used provider-patient portals to review test and laboratory results, refill prescriptions, and schedule appointments. However, participants found it cumbersome to remember multiple passwords and difficult to find specific information due to interface issues. Data sharing among providers was often slow or impossible, forcing participants to print and assemble records for clinical visits.

Table 1. Participant demographics.

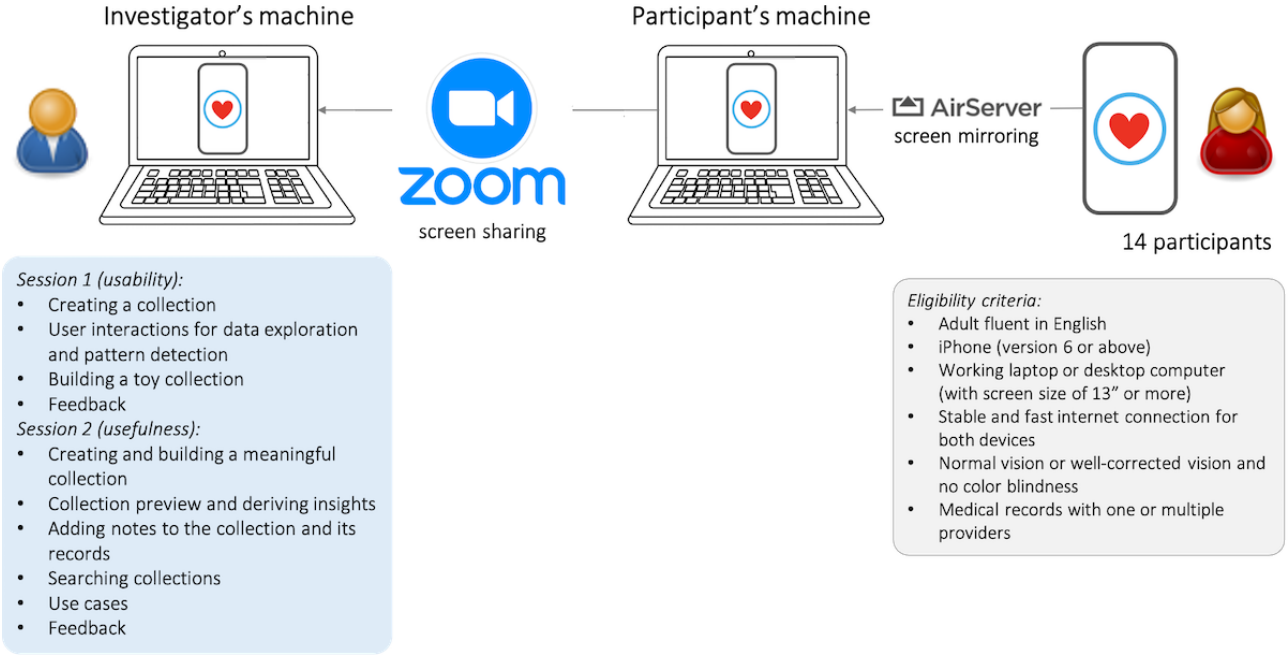
Participant ID	Age (y)	Sex	Educational level	Medical issues	Health care providers, N
P1	61	Male	2-year college	High blood pressure, sleep apnea, fatty liver (stage 3), and liver transplant	7-8
P2	45	Female	Some college	High blood pressure, prediabetes, obesity, and hypothyroidism	6-7
P3	51	Male	Some graduate school (incomplete degree)	Hypertension and gout	2
P4	24	Male	Bachelor's degree	Childhood asthma, recent hernia surgery, and mental health therapy	5
P5	24	Female	Bachelor's degree	No chronic issues	2
P6	27	Female	Bachelor's degree	No chronic issues	3-4
P7	28	Male	Graduate degree	Physical and mental (20 years)	Approximately 13
P8	37	Female	Master's degree	Thyroid condition (many years)	3-5
P9	29	Female	3 years (incomplete degree)	Chronic migraines (10 years) and hemiplegic migraines (1 year)	≥12
P10	59	Female	Bachelor's degree	Yes—5 years	10-15
P11	25	Female	Bachelor's degree	No chronic issues	3-5
P12	33	Female	Master's degree	Anemia (2 years) and IBS[a] (10 years)	3
P13	19	Female	Some college (incomplete degree)	Asthma (since she was a baby) and EDD[b] (10 years)	>5
P14	32	Female	Master's degree	No chronic issues	3

[a]IBS: irritable bowel syndrome.

[b]EDD: eosinophilic digestive disease.

Procedures

Inspired by existing patient portal usability studies, the study procedures were tailored to our RQs [23,25,26] and are presented in Figure 5. The study was conducted remotely via Zoom (Zoom Video Communications) meetings. Participants downloaded our app on their iPhone using Apple TestFlight for beta testing [27] and mirrored their iPhone screen on their laptop using AirServer (App Dynamic ehf.) [28]. The laptop screen was then shared with the researcher for observation.



Participants attended an initial 60-minute session (session 1) and a follow-up 45-minute session (session 2). Both sessions used the concurrent think-aloud protocol to gather rich qualitative data on user needs, perceptions, and preferences efficiently [29]. Textbox 1 illustrates 2 example topics and detailed tasks for creating a toy collection and realistic collection from sessions 1 and 2, respectively. The full set of 13 topics for both sessions and their detailed tasks that follow a similar structure are shown in Tables S2 and S3 in Multimedia Appendix 1.

In session 1, the researcher first collected demographics and digital health consumer information from participants (Table S1 in Multimedia Appendix 1). The session then evaluated the usability of the app (RQ 1). Participants were introduced to the app's key concepts and features and were then given tasks to learn the interactions for creating and assembling relevant records in collections. After each task block, participants provided feedback. Tasks included creating a toy collection, adding descriptors, exploring scoping mechanisms for record categories and time ranges, navigating records using the Sliding Tabs, and inspecting the interactive Timeline visualization. Participants also completed tasks related to finding periodicity, co-occurrence, and pretest-posttest analysis of medical events using the Timeline; saving records to a collection; and reviewing it. The session concluded with feedback on the intuitiveness, usability, and usefulness of creating, building, and reviewing collections, as well as data exploration and pattern detection features (Textbox 2).

Session 2 focused on the usefulness of collections in real-life settings (RQ 2). Participants performed tasks involving creating a collection tied to a specific issue (eg, high blood pressure) and purpose (eg, clinical visit). After each task block, participants provided feedback. Tasks included creating a High Blood Pressure collection, adding descriptors for a clinical visit, selecting records related to high blood pressure, identifying patterns in selected records, adding notes to the collection and specific records for clinical context, and using the search feature to find other collections. The session concluded with feedback on the usefulness of collections, brainstorming real-life use case scenarios, and suggesting potential improvements (Textbox 2).

XSL•FO
RenderX

Figure 5. Study design—14 participants for 2 one-on-one sessions with a researcher. Session 1 focused on usability, and session 2 examined usefulness. Feedback was collected on how participants would use collections for their own data and needs.

Textbox 1. Example tasks from sessions 1 and 2.

Session 1: creating a collection (5 min)

- For the purposes of learning the basic mechanics around building a Collection from scratch, first Create a new Collection and name it "Toy Collection."
- Now, let's add some descriptors about the Collection.
  - Please add a purpose to the Collection, something related to learning about this app.
  - Now, add a couple of tags to further describe, summarize or annotate the Collection for future quick access.
  - Finally, specify the priority of this Collection by marking it as urgent.
- What was your experience with creating the new Collection?
  - How intuitive was it? Have you seen similar interactions elsewhere?
  - How useful do you find the descriptors for the Collection?
- Now, let's go back to the list of Collections. Let me know how can you see the details about the Collection you just created?
  - How intuitive was it?
- What are possible improvements?

Session 2: building a collection (15 min)

- You will now create a Collection that is more realistic and meaningful for use in a real-life scenario. We will assume that you are preparing for an upcoming visit to your physician's office related to potential issues with high blood pressure. Create a collection called "High Blood Pressure."
  - Add the purpose for the Collection
  - Add a few tags
  - Mark its priority
- Add the Records with blood pressure with systolic value over 120 and BMI over 30.
- What was your experience with assembling the Records for the Collection?
  - How laborious was it?
  - What are some ways in which we can make this assembling process more efficient?
  - How do you feel about having the system prepopulate the Collection for you and let you modify it afterwards?

XSL•FO
RenderX

Textbox 2. Feedback collected at the end of the study sessions.

Session 1 example tasks

- What was your impression of this app?
  - What did you like?
  - What did you dislike?
- How intuitive was the app?
- How easy or hard was it to explore the data?
- How useful were the features in the app to identify patterns in the data?
- How did you like the mechanism for saving Records in the Collection?
- What are some improvements you would like to see?

Session 2 example tasks

- How useful do you think the Collections can be for you?
- What are some use cases for the Collections that you can think of?
- What are some improvements you would like to see for the Collections?
  - Automatic support for building Collections?
  - Automatically finding data patterns in the Collections?
  - Patient-generated data?

Data Collection

We recorded the Zoom meetings for audio and video capture of the entire interaction. The first author also took notes during the meetings.

Data Analysis

Audio recordings were transcribed using Rev (Rev.com, Inc). We analyzed video recordings for additional context and a deeper understanding of participant comments during the think-aloud protocol. Video annotations were added to the transcripts and session notes [23] for reflexive thematic analysis [30]. The first author began by open coding the textual data. Emerging categories were reconciled in meetings with the second and last authors to identify use cases and detailed approaches to organizing and annotating EHR data. These themes were validated in a group meeting with researchers unfamiliar with the collection concept and with our app.

Ethical Considerations

The Harvard Faculty of Medicine Institutional Review Board approved this study (protocol IRB20-1757). Participants signed a consent form, which also allowed them to opt out of the study at any point. Each participant received a US $40 Amazon gift card as compensation. The data obtained from the study sessions did not include any identifiable information about the participants and were stored on a password-protected computer with encryption. Only the research team had access to these data.

Results

Overview

The results from our study are organized and analyzed around five qualitative themes, two applicable to RQ 2 and three applicable to RQ 1: (1) using collections for personal benefit (RQ 2), (2) using collections in a clinical setting (RQ 2), (3) creating and building collections (RQ 1), (4) enhancing collections (RQ 1), and (5) accessing collections (RQ 1). In the remainder of the Results section, we characterize the participants and report on these themes using 16 quotes from 11 different participants. The participants are labeled as P1 to P14.

Purposes for Organizing the EHR Data in Collections

Using Collections for Personal Benefit

Quick Access to Information

Participants perceived the Collections feature as a way to index information at a suitable level of granularity for health issues, topics of interest, or conditions to monitor. They expected that this would give them quick access to current or urgent problems that were being managed:

> *Personally I would like to monitor my asthma because I am using medication for that, the typical inhaler, but I would like to monitor, these days I had certain attacks or shortness of breath, so collections, having it back for that specific condition is very useful to me, because I wouldn't have to speculate about when my last attack was or when my last appointment date was, it's right here for me to access.* [P13]

XSL•FO
RenderX

Reflection on Medical History

Participants viewed collections as a tool to construct and understand their medical history. They expected collections to serve as a repository for the health issues they faced, aiding in reflecting on the existence, prevalence, and development of their health conditions:

> *This will be able to find what happens when I have, in my case, headaches related to my high blood pressure and nothing else, or if you're sick for the flu, influenza and you have fever, it's just related to the influenza, not to the COVID.* [P1]

Keeping Track of Health Status

Most participants envisioned using collections to track their health status proactively. This included monitoring urgent issues needing immediate attention, unstable conditions requiring frequent observation, and treatments needing careful monitoring. Participants also wanted collections to track abnormal laboratory test results and vital sign values across various health issues:

> *Well, for me, it's kind of good [to have medical records organized in collections], especially, for example, blood samples, especially those with high triglycerides or something. Maybe I can collect them and see whether there's a trend for this month, or for January, I'm high in this one. Then second month, I'm also high, so maybe I can lower it down...For collections, just categorize those. Which are high, which are low.* [P5]

Journaling Daily Events

Most of the participants envisioned using collections as a personal diary for coping with diseases and logging measurements and their effects on lifestyle. They wanted to track challenges, successes, and progress toward finding solutions and monitor disease developments:

> *What I've done is I've taken all of my videos and stuff since February. Like I said, I've been to eight different doctors and I've shown them, this is the progress of what's happened from...I've had two surgeries before this surgery where they lanced it, cut it, drained it. Nothing happened. The cyst came back and then it went into my bone. So I'm able to bring these photos, I'm able to bring this timeline, I'm able to bring my frustrations and show this doctor within 30 seconds [using a collection], look, this is what it looked like. And this is my own diary, my own history. It's very important because they're a doctor. They don't know me, they don't know what it looked like on day one.* [P10]

Learning From Past Experiences

Nearly all participants wanted to use collections to identify trends and patterns in their ongoing health experiences, including co-occurring symptoms and treatment effects. They also intended to log food intake, sleep, activity, or stress factors to find triggers for symptoms:

> *I think I could definitely use them there. It's a lot easier now because I could highlight the certain event, and put like my triggers down with it, like migraine on the third was this, you could even put what you took with it. So for me, I would look back and be like, "Oh, I can tell my doctor that, I've had 10 migraines. I took a medication with these three. What's my options." So I think that would be great, it's a great tool that I can actually do that with this app.* [P9]

Using Collections in a Clinical Setting

Preparation for the Clinical Visit

Most participants would use collections to prepare talking points for clinical visits combining personal measurements and notes with medical records from other providers (eg, laboratory and test results). This was crucial because their physicians often did not have access to external data:

> *For collections, I would say that if I'm meeting with multiple providers about one health issue, I could see myself combining all my records there so that multiple providers can see each other's records...I would probably [use the notes], if I needed to jot down a certain time that I took a measurement, or if my doctor told me keep track of what you ate that day, or kind of anything that I would want to have the details for the next time that I go and see the provider.* [P6]

Relying on Collections During Clinical Visits

All participants wanted to share collections with their physicians during clinical visits to establish ground truths, raise awareness of other providers' information, and provide transparent talking points. They believed that adding PGD to collections could describe what happened between visits and raise their physicians' awareness:

> *If you have a condition, you need to check on your blood pressure. You need to communicate that with your doctor, so you can add a note [in the collection] saying like, "Latest, highest blood pressure from this week," from a date.* [P14]

In addition, most participants felt that taking in-visit notes and saving them in a collection could help them understand care plans and take appropriate actions afterward:

> *Maybe [taking notes in the collection for the clinical visit] just for your own personal reference or if you wanted to bring it up later on in another appointment or something, or just maybe, I guess, just general recording of something that happened during that visit.* [P11]

All participants saw physicians as essential partners in reviewing collections and deciding on actions based on their contents. This was primarily because most participants doubted their expertise in determining what should go into collections or which collections to create. While they were very open to include their physicians in the collection curation, some feared that they might overburden physicians with verification inquiries:

> *I guess I would definitely do that [look for patterns in the data and store them in a collection] just*

XSL•FO
RenderX

> *because I can actually consult the doctor. Is this actually correlated or will I have to change my diet because it affects this? At least you can ask the doctor, or confirm whether that is true or not.* [P5]

Needs and Feature Preferences for Organizing EHR Data in Collections

Creating and Building Collections

Manual Workflow for Creating and Building Collections

Overall, all participants expressed satisfaction with the clarity and simplicity of the mechanics to create collections and save records in them. However, those with less medical knowledge and disease experience (relatively healthy and recently diagnosed individuals) thought that initiating and building collections was challenging. For them, it was not always clear what issues deserved separate collections, what records to include in a collection due to delicate dependencies, and why they should invest substantial time and effort in assembling collections. In contrast, the more experienced (chronic) patients were relatively confident in their ability to carve a personalized view of their EHR data. However, some did acknowledge that they might not be as exhaustive and reliable in their data organization.

Participants quickly mastered using the Sliding Tabs with Accordions and appreciated the context-preserving record exploration. However, most of the participants found it challenging to assess the relevance of individual records due to unexplained clinical language and attribute values. Participants requested explanations, prominent visual cues for abnormal values to attract their attention, and time-series visualizations for additional context and noticing trends. They also wanted to be able to sort by date or attribute value, with filtering capabilities that also included adding the filtered records in bulk to a collection.

Some participants desired collections with richer internal structures, recognizing the need to identify subsets of records and their importance within a collection. They suggested linking groups or individual records using specific annotations for easy identification during visual inspection or search:

> *...maybe if certain records are related to each other. So I would want to mark that. And then maybe just have a way of sorting down based on certain labels.* [P8]

Automatic Support for Building Collections

Participants were highly receptive to discussing ideas that could automate building collections. They were interested in seeing their records automatically put into collections based on provenance (provider, physician, hospital, location, and date) and clinical meaning (condition, disease, organ, organ system, and abnormality of the values across records). Some also suggested grouping records into collections based on personal annotations. For all these groupings, they wished to be able to edit the collection manually:

> *If I had neurological problems, neurology collection. If I had urological problems, urology collection. I think that for me at least would seem a more straightforward way to categorize them. But from the categories I've already seen, I find those useful.* [P4]

Several participants suggested using a "seed" to automate collection building, such as naming a collection, adding keywords, or including a few records:

> *And I think a lot of patients don't know where to start, what data to begin with. So if it's something that's already preset, they say, "Okay, I'm suffering from depression or I have diabetes." And the system pulls the different data points that they would need to look at for someone who's diabetic or someone who's dealing with depression, I think that's helpful. Because sometimes, the problem is you don't know where to start and you don't know what to look for.* [P11]

Finally, most of the participants wanted to receive automated help to add or remove records for a collection that had already been created. Few described wanting to choose from a list of suggested records based on the existing content of a collection, revealing records and record patterns otherwise invisible to them. Others saw this automated record offering more as an idea generation approach—needing some follow-up validation, including taking it up with their physicians:

> *When I work, I want to listen to some music and then I'm like, okay. I just don't know what's next. I need something similar to this, the same vibe, but I just can't think about that. And then there is suggestions. And yes, some of it's weird. But maybe like the doctor can also have some help here, and when you review the collections together, they might say, "Hey, listen, this is what the system gave you and that's great. Let's remove a few things. I would suggest you add a couple others. And whatever you put there, it's also fine. And let's keep it that way."* [P6]

Enhancing Collections Through Personally Provided Data

Making Collections Complete

Participants strongly expressed the need to complement their EHR data with daily entries from sensors; self-monitoring devices; and manual measurements of symptoms, treatments, and outcomes in various formats (text, photos, videos, and scanned documents):

> *Actually, I think you can sort of restructure the whole core of the collections on top of two main pillars. The first one would be all of the doctor's data, which is basically hard data, which allows you to diagnose, allows you to run statistical analysis...That could be part of the core data, but all of the context, maybe I'm getting this shortness of breath in my home, watching my TV, might be added by the notes. You have these two types of data. By adding the user data, would allow me to get context, give context, which is important and will allow me to, on a daily basis, keep a record, which in case of data like shortness of breath, I'm having, I'm not having. Would allow the*

XSL•FO
RenderX

> *doctor to have a really unbiased input on symptoms I'm having.* [P7]

Participants wanted to log detailed observations and measurements, pairing treatments with outcomes and symptoms with triggers. They suggested dedicating a special PGD record category for these data, with some preferring complex structures and others favoring simple data entry options:

> *I would probably use the notes quite often just to maybe outline the symptoms I was experiencing and the steps I took to alleviate those symptoms or which doctors I contacted.* [P13]

Making Collections Distinguishable

Participants liked the existing collection descriptors and suggested additional ones. They wanted labels for clarity (clear, unclear, or potential issue), stability (stable or unstable), progress toward resolution, development stages (nonthreatening or threatening), and a list of involved providers and physicians. When collections were related to clinical visits, participants wanted to specify the targeted physicians.

Making Collections Actionable

Participants believed that organizing medical records by health issues in collections was a good start but thought that actionability could be improved with specific insight notes and annotations applied to entire collections:

> *And then as far as the purpose of adding a note to the whole category, I would say that, like you said, if you happen to notice any patterns when you're looking at the data, or basically I would use it for any general or bigger-picture takeaway that I wanted to tell my doctor, "Hey, I noticed this" or something and I wanted to bring it to their attention.* [P6]

Participants envisioned using collection-wide notes to summarize contents or purpose, track progress, describe issue development, and highlight special events. They also wanted notes representing care plans and actions prioritized in a to-do list. Participants intended to use collections to prepare for clinical visits with questions, reminders, and critical measurements. They also saw value in adding collection notes about visit outcomes, key takeaways, and next steps.

Some participants wanted to annotate and highlight keywords or add tags to free-text notes for organized review and pattern identification.

Accessing the Collections

All participants emphasized the importance of fast, reliable access to collections and their contents. They primarily relied on collection descriptors but also desired a deep search feature that would scan through individual records, notes, and annotations within collections.

Discussion

Principal Findings

We identified 3 principal findings of our study. First, participants embraced the collection concept. Unrestrictedly organizing EHR data into collections that map medical records to health issues and track ongoing concerns gave participants a sense of ownership. They felt empowered by developing personalized health narratives that could aid in self-management and communication with their physicians, enhancing their self-advocacy. Second, while participants easily mastered the interface for initiating and adding records to collections, they found the process laborious. They lacked confidence in selecting appropriate records due to limited medical knowledge and requested additional visual cues, explanations, and automatic collection features. There was concern about potential self-misguidance without physician verification. Third, collections would need richer PGD capabilities for adding contextual information not found in participants' EHR data, logging observations, and labeling data. This would enhance the comprehensiveness and accuracy of their health narratives and support foraging, sensemaking, and action taking.

Interpretation of the Findings and Contributions

Overview

On a broader scale, this work contributes to patient-centered care. This is achieved by demonstrating potential to enhance patients' grasp of their health, encourage self-advocacy, and improve patient-provider communication. More accurately, there are several concrete contributions of our work that can be considered as proxies toward achieving the aforementioned objectives: (1) encouraging patient ownership of their EHR data by organizing them into personalized, health issue–based collections; (2) understanding patients' perceptions and preferences for creating, building, and using these collections; and (3) offering design insights for automating collections, integrating rich PGD, enhancing access to collection contents, and using collections to facilitate patient-provider communication.

Going forward, we will situate our findings within a sensemaking framework and discuss contributions related to 3 key patient needs: increasing awareness through independent health sensemaking, proactivity through efficient action taking, and self-advocacy through incorporating evidence-supported patient perspectives into patient-provider communication. We will elaborate on how collections can meet these needs and offer design implications to enhance their capabilities.

The Role of the Collections in Supporting Sensemaking

To explain the collections' role in sensemaking, we used the model by Pirolli and Card [6], which divides the sensemaking process into 2 subcycles: the foraging loop and the sensemaking loop. On the basis of this model, collections can be described as a space for assembling relevant data about a topic, finding relationships between them, and storing outcomes from the sensemaking. In the foraging loop, patients gather relevant records to answer questions such as the following—"Is there a relationship between my weight and blood pressure?"—and save them in a collection, such as Weight vs. Blood Pressure. In the sensemaking loop, patients identify information relationships within the collection that they capture in notes, such as instances where there was co-occurrence of high blood pressure and high body mass. These notes help argue hypotheses such as the following: "My blood pressure is high when I'm

XSL•FO
RenderX

overweight." The outcome of this sensemaking process could be a comprehensive note for a clinical visit.

While, in their current form, collections respond to the needs of the sensemaking model by Pirolli and Card [6], improvements can be made to make this more efficient. This study revealed that medical records alone are not enough for reliable sensemaking. Adding PGD such as symptoms, measurements, outcomes, and everyday events is essential for creating comprehensive collections. The foraging loop can be made less laborious and time-consuming if there are additional visual cues, medical explanations, filtering capabilities, and automatic support to improve the relevance and reduce the effort of assembling collections. The sensemaking loop could be improved by adding more schematization capabilities such as annotating medical records and PGD to identify patterns later (eg, symptom triggers, medication effects, and correlations) and grouping records within collections, labeling those groups, and establishing group relationships with explanations (eg, linking "cholesterol lab results" with "food intake" as "food effects on cholesterol" in a High Blood Pressure collection).

Reliability of Collections

According to our study, there are 4 main factors that can influence the reliability of the collections: robust coverage of health issues, provision of PGD, grouping and linking of medical records and PGD within a collection, and verifying the contents of the collections. This reliability is related to collections' capability to aid in creating personalized but realistic health issue narratives, support self-management, and stimulate awareness and proactivity.

Robust Coverage of Health Issues: Relevance Assessment

Collections should ensure that patients can create collections for their most important health issues to support awareness and proactivity. Participants desired visual cues, explanations, and automatic support to determine which collections to create and what records to include.

While participants found the context-capturing data exploration using Sliding Tabs and Timeline convenient, they needed more to identify relevant records quickly. Future tools could incorporate Accordions that summarize record types, graph values over time, and highlight abnormal or extreme values. In addition, patients should be able to expand individual records to see explanations of clinical terms and clinical meaning interpretations. While there is existing work related to visualizing time series of EHR data [17-20] and automatic provision of short explanations [31], this study shows the need for combining them in a new way to support relevance assessment for a novel purpose—constructing collections. Finally, patients should be able to order and filter records by attribute for quicker browsing and bulk addition to a collection.

Automatic support should also be provided for creating and building collections to save time and ensure robust, reliable coverage of health issues. Our previous work highlighted the need for automating collections [13], and this study highlights a clear preference for automatically grouping medical records by clinical meaning—whether *thematically* or *guided by patient input*. Thematic collections would be those that tie records together based on conditions (bronchitis or diabetes) and procedures (stent placement or appendix removal) or with respect to organs (heart or kidneys) or organ systems (cardiovascular or renal). Alternatively, patients could specify a seed by setting parameters such as the collection's name, tags, or initial records. The system can offer candidate records to include or delete with confidence scores and explanations. Patients could then refine these system-generated collections by adding or removing records, PGD, and tags.

Addressing automatic support for collections may be challenging due to subtle relationships between medical records [32-34]. However, starting with easier constructs such as *time stamps* (eg, medical records from the same day, week, or month), *FHIR links* (eg, medical records from the same encounter or physician), *abnormal values* based on well-established clinical guidelines (eg, high or low blood pressure or cholesterol), *test findings* (eg, positive and negative), and *patient tags* (eg, triggers or pivotal events) is a feasible approach.

Provision of PGD: Sensemaking Data Completeness

Collections should include PGD to improve data completeness for sensemaking. Previous research has suggested that maintaining consistent PGD logging over time is difficult [35]. However, this should not be considered a barrier or a prerequisite for the collections' success. Patients' motivation and preferences for PGD logging intensity vary based on their disease self-management state [36]. When setting goals and learning strategies, patients prefer meticulous data collection. Once goals and strategies are in place, logging intensity decreases. In addition, if physicians require PGD logging for treatment planning, patients are motivated to engage in it [36,37].

Thus, collections should enable flexible and efficient PGD logging. Disease-specific contexts such as irritable bowel syndrome [38], diabetes [7], and migraine [39] have explored health sensemaking without focusing on diverse data types. This contrasts with patients' desire to log PGD for various medical issues within a single application [40,41] using a universal logging model for different observations [42,43]. To address this issue, we propose a straightforward workflow where patients initiate free-text entries and use tags to specify the type, quality, or other details. This mechanism allows for quick data capture and embellishment at convenient times.

Tags can classify PGD as *clinical observations*, *everyday life events*, or *notes*. Further specification can be added using tags such as *symptom*, *measurement*, *treatment*, and *outcome* for observations; *meal*, *exercise*, *meeting*, and *deadline* for life events; and *context*, *personal note*, and *visit note* for notes. Additional tags such as *absent*, *normal*, *high*, *low*, *extreme*, *improvement*, *deterioration*, *pivotal event*, *trigger*, or *relaxer* can be used for further detail that captures the quality and importance of the logged data. In addition to these system-offered tags, patients can also create their own custom tags for better personalization.

XSL•FO
RenderX

Grouping and Linking Within Collections: Schematization Capabilities

Patients need to connect medical records and PGD within collections for easier sensemaking. Future tools should add structure by enabling record grouping and linking of groups or individual records. This helps highlight important subsets of records and trace major conclusions as collections grow.

We recommend using a simple yet powerful tagging concept. Records sharing the same tag can form a group, whereas links between groups can be specified using related tags. The same mechanism can link individual records with other records or groups, providing nuanced sensemaking. This approach aligns well with the proposed PGD tagging model that can be applied to medical records as well.

Collection Verification

Collections represent the patient's personalized perception of their health and issues. As such, they should undergo occasional verification by the patient's physician for safe decision-making and action taking. While collection verification may add to the physician's workload, it can inspire and enable patients to manage health issues more independently. That said, patients should consider the physician's workload before requesting verification [44].

Future tools could allow for the conversion of a collection into a well–laid-out PDF document capturing all its contents. This document can be printed for review during a clinical visit or shared as a PDF attachment in the patient portal for verification at the physician's convenience.

Taking Actions Based on Collections

While annotating PGD is known to aid learning and disease self-management [7,45], our findings reveal that annotations can also enhance EHR data, creating synergy with PGD. Participants expressed a desire to annotate their data for various purposes: identifying triggers to avoid or encourage certain behaviors, marking pivotal events to remind them of shifts in health attitudes and management, and labeling outcomes as desired or undesired to evaluate treatments and strategies. These capabilities can be easily implemented using the previously elaborated tag-based design for linking records.

To increase the awareness and prioritization of collections, we previously proposed *collection descriptors* such as topic, urgency, currency, and sentiment [13]. Participants found value in these descriptors but expressed a need for additional ones that can be classified as *patient specified* and *data driven*. Future tools may include patient-specified descriptors for *clarity* (eg, is the diagnosis clear?), *stability* (eg, is the treatment working consistently?), *severity* (eg, is there a significant medical risk?), and *progress markers* (eg, is the issue substantially resolved?). Data-driven descriptors could be derived from the collection data, indicating the *time span* (from the oldest to the latest record) or listing the *physicians involved* (the providers and physicians the records came from). Both types of descriptors should be optional for patients to use as needed.

Providing an inner structure, enabling annotations, and describing collections can improve information access and expedite decision-making. Powerful search engines can use these metadata to allow patients direct and easy access not only to individual collections but also to their specific contents.

While these features can enhance collections' actionability, it is important to note that collections are not meant for making independent clinical decisions by patients. Collections should be verified by a physician to serve as reliable tools for sensemaking and health self-management. However, collections can always be invaluable tools for patients to understand their health; organize thoughts, hypotheses, and insights; and communicate effectively with their physicians.

Collection Use for Patient-Provider Communication

As observed in our findings, patients can use collections to prepare for a clinical visit by devising checklists and organizing thoughts supported by evidence. During the visit, collections can be used for *note taking* and, afterward, for *recording reminders* and *follow-up actions*. These uses indicate how collections can start addressing known challenges during clinical visits, such as problem presentation [46], information retention [47], setting common ground, aligning goals, and understanding instructions [48]. To effectively tackle such challenges, the Collections feature should support richer note capturing and collaborative data analysis in a collocated setting [49,50].

Future improvements in capturing PGD could make collections more appealing to physicians. For physicians, PGD play a crucial role in understanding the boundaries and context for accurate diagnosis and optimal treatment [51]. However, physicians often face problems with PGD, such as incomplete data, inconsistent data structures, and insufficient time for reviewing due to poor organization [52]. These issues arise because patients use disjointed platforms to log their data, lacking consistent models for logging different types of data [52,53], and face challenges in efficiently using these platforms [42,52]. Collections can help overcome these issues by providing a single platform for logging PGD for various health issues in a simple, universal way that allows for flexibility, organization, and standardization.

An alternative approach to enhancing collections as a communication tool and fostering physician collaboration in their creation and verification is to introduce them as a *shared resource* similar to Google Docs [54,55]. While this may seem unconventional, it builds on the principles of OpenNotes [56]. OpenNotes provides access to and transparency regarding clinical notes, enabling patients to improve their treatment and EHR data quality by taking an active role in detecting errors, raising concerns, asking questions, or seeking clarifications [56,57].

Similar to OpenNotes, *shared collections* would follow the principle of asynchronous communication and transparency. However, shared collections could eliminate the expressiveness constraints and lack of efficient ways to provide granular and tailored context observed in existing messaging systems [58,59]. In addition, shared collections would enable direct editing of underlying data in collaborative ways, minimizing communication overhead.

XSL•FO
RenderX

Moreover, shared collections would introduce a new communication channel between patients and providers outside the traditional patient portal. Synchronizing the digital traces of care in collections with the provider's EHR system to avoid discrepancies and legal issues should be a top consideration in future design iterations of the shared collection concept.

A Glimpse Into the Future: Collections and Generative Artificial Intelligence

In the future, we should explore the potential of generative artificial intelligence (GenAI) models to support patient sensemaking through collections. Tools such as ChatGPT [60] and Med-PaLM [61], which have demonstrated substantial medical knowledge [62-64], can replace the need for custom-made machine learning algorithms for knowledge-intensive tasks.

In particular, GenAI tools can aid in automatic and iterative collection construction with explanations and guidance. They can analyze the data within collections for insights, including medical records, PGD, notes, and tags. In addition, GenAI can assist in composing case narratives and talking points for clinical encounters. By offering this level of automation, GenAI can help tackle the significant knowledge challenges while lowering the labor barrier for patients' sensemaking activities.

Using GenAI models, collection construction could rely on natural language instructions such as the following: "Group my EHR data by condition," "Find all records related to my bronchitis," or "Identify records that don't belong to this collection and those that are missing." GenAI models could also deliver context, explaining why certain records are included or excluded and providing educational material such as term definitions and clinical implications.

In addition, patients can issue commands for identifying relationships within their annotated data, such as "List all triggers for my headaches over the last year." Finally, they can ask for help in constructing case presentations for clinical visits (eg, "Based on my 'High Blood Pressure' collection notes, write a 100-word summary").

To be useful for sensemaking, GenAI tools do not need to achieve complete accuracy. While still striving for maximum reliability, their main value should come from providing an environment that enables and encourages patients to refine artificial intelligence–generated outputs. As such, the contribution of GenAI toward sensemaking would be evaluated on its ability to help the patient efficiently produce a satisfactory solution with minimal physician input.

Finally, existing approaches for supporting sensemaking through search and interactive visualizations should not be disregarded. Exploring the integration of GenAI, search, and visualization is a prudent strategy as different sensemaking tasks related to collection assembly, editing, and analysis may require diverse approaches based on complexity, patient skills, and artificial intelligence reliability.

Limitations

This study has several limitations. First, the cohort skewed younger, likely due to recruitment via Craigslist (less popular with older adults) and the complexity of the remote setup. Second, participants used data from a fictitious patient, which may have reduced their motivation to learn the app and their ability to suggest real-life use cases. Third, participants had limited time to learn how to interact with collections, possibly affecting their perceptions of usability and utility. Future studies should have participants use their own data with automatic interaction logging. Despite these limitations, this study provided valuable insights into designing patient-facing sensemaking tools for organizing and augmenting EHR data.

Conclusions

Collections can potentially improve patient-centered care by involving patients more in decision-making and encouraging self-advocacy. Current assumptions often expect patients to have the necessary skills, tools, and motivation. We believe that collections can lower these barriers, encouraging patients to *increase engagement* with their health data, better *educate themselves*, and *communicate more effectively* with their care providers.

Our study suggests that EHR data can be better used and more useful for patients through *improved organization* and *annotation*. This approach can incentivize patients to engage more deeply with their EHR data, develop insights, and reflect on their experiences. Patients felt that this empowered their awareness, resourcefulness, and proactivity regarding health issues, making them more prepared and better informed for clinician interactions.

These findings support our premise that collections are a crucial step toward *patient empowerment* and *self-advocacy*. With appropriate improvements, collections can enhance patients' expertise by facilitating sensemaking activities and enabling insightful discussions with their physicians. First, collections motivate patients to construct health models based on their issues and ongoing problems. Second, patients gain medical education by actively participating in the evolution of collections through independent or system-assisted assembly and editing. Finally, patients acquire additional medical knowledge by engaging in meaningful discussions with their physicians and considering their feedback on collection verification.

Our study highlighted the importance of integrating PGD with EHR data. We envision a synergy in which patients use clinical data as a foundation, augmenting them with their observations, notes, and annotations to create personalized health narratives that support better health management and provider communication.

In the future, we should explore GenAI models to support patient sensemaking through collections. These models could help patients build collections, analyze the data within them, and produce health narratives more efficiently. Such enhancements may also reduce physicians' workload for verifying collection contents, leading to more focused, evidence-driven discussions during visits.

Promising ideas from this work should be advanced carefully, with gradual design improvements tested in real-life settings. Respecting existing clinical practices and workflows can facilitate quicker adoption and more significant changes in the

XSL•FO
RenderX

future. We believe that collections can revolutionize how patients interact with their medical records and communicate with their providers.

Abstract

Background: In response to the COVID-19 pandemic, the United States extended regulatory flexibilities to make telemedicine more accessible to providers and patients. Some of these flexibilities allowed providers to intake patients over telemedicine and prescribe certain scheduled medications without an in-person visit.

Objective: We aim to understand providers' parameters for their comfort in prescribing over telemedicine and report on solutions providers have adopted in response to potential barriers and challenges in prescribing via telemedicine.

Methods: As part of a larger mixed methods study between February and April 2024, we conducted 16 semistructured interviews with mental health providers who prescribe via telemedicine within the United States. We used the results of a web-based, cross-sectional survey to develop a codebook and support recruitment. We analyzed a subsection of the 16 interviews using content analysis to capture comfort, barriers, and workarounds in telemedicine prescribing. We reported codes by frequency and by provider.

Results: Participants were typically male (11/16, 69%), provided care mostly or completely over telemedicine (11/16, 69%), and were psychiatrists (8/16, 50%) or other physician (3/16, 19%). Providers' primary states (10/16, 62%) of practice included Oregon, Texas, New York, and California. The content analysis yielded a total of 234 codes, with three main codes—comfort (98/234, 41.9%), barriers or challenges (85/234, 36.3%), and workarounds or solutions (27/234, 11.5%)—and two subcodes—uncomfortable prescribing (30/98, 31%) and comfortable prescribing (68/98, 69%) over telemedicine. Participants reported being comfortable prescribing over telemedicine as long as they could meet their main parameters of working within their expertise, having access to needed patient health information, and being compliant with rules and regulations. Participants reported frustrations with e-prescription workflows and miscommunications with pharmacies. Solutions to ease frustrations and alleviate discomforts in prescribing over telemedicine included developing workflows to help patients complete laboratory tests and physical examinations and directly communicating with pharmacies.

Conclusions: By applying content analysis to the semistructured provider interviews, we found that physicians are comfortable prescribing via telemedicine when they feel they are practicing within their personal parameters for safety. While many providers experience frustrations such as miscommunication with pharmacies, these barriers appear to not prevent them from telemedicine prescribing. With expected changes in 2024 and 2025 to the US laws and regulations for telemedicine prescribing, we may see changes in provider comfort in prescribing.

Introduction

During the height of the COVID-19 pandemic, health care visits moved to telemedicine when possible to help stem the spread of infection [1]. In the United States, the public health emergency (PHE) and regulatory flexibilities were instrumental in streamlining this effort by waiving specific requirements, such as the providers' ability to see patients outside the states where they are licensed and to prescribe over telemedicine with fewer restrictions [2,3]. Due to these temporary changes, providers could prescribe via telemedicine less restrictively and determine what level of care they felt comfortable providing over telemedicine.

The US Drug Enforcement Administration extended prescribing flexibilities past the May 11, 2023, PHE deadline and is in the process of finalizing a rule regarding telemedicine prescribing [4,5]. There has been concern that waiving elements of the Ryan Haight Act, which previously required providers to meet with patients in person before prescribing certain controlled substances, would adversely impact patient outcomes [6,7]. The concurrent opioid epidemic has also provided a new level of scrutiny in the space of telemedicine and prescribing scheduled medication for the treatment of substance use disorder (SUD) [8-10]. As US providers await the promulgation of this final rule, evidence continues to grow regarding positive patient outcomes via mental health prescribing over telemedicine [11]. One Medicaid data study following over 90,000 patients showed remarkable positive outcomes from telemedicine initiation of buprenorphine treatment, including better odds of 90-day treatment retention than if initiation occurred in person [12]. In a scoping review from 2008 to March 18, 2021, reviewers found that telehealth technology in SUD treatment increased access and adherence to buprenorphine and generally showed higher patient satisfaction and comparability to in-person retention rates [11]. Especially within the space of buprenorphine prescription, evidence supports that telemedicine offers comparable treatment to in-person care and can be an effective method for increasing patient access to mental health treatments [8,11].

With the flexibilities, providers can now choose the extent to which they use telemedicine. One study reported psychiatrists felt telemedicine use in a hybrid scenario allowed for treatment adaptation based on client needs and access [13]. The study's participants emphasized their need to consider each patient's unique case in determining whether they could successfully leverage telemedicine to initiate care or ensure continued visits over time [13]. For example, one psychiatrist in the study noted the following:

> *When you have these patients who are at risk for falling out of care, if you don't offer them telemedicine, but [they] are also at risk for getting slightly suboptimal care when you do offer them telemedicine, it is a very case-by-case judgment call in terms of the risks and benefits of enabling the telemedicine.*

Such sentiments support the call for greater provider autonomy and options, as well as the focus on including telemedicine as part of the holistic health care model [13-15].

Though there is evidence supporting the safety of prescribing certain scheduled substances over telemedicine (even without an initial in-person visit) [8,11,12], there is a need for greater insight into mental health providers' experiences in prescribing scheduled medications during and after the PHE. A better understanding of providers' perspectives, experiences, and comfort in prescribing for their patients over telemedicine would build a more accurate understanding of what providers view as actual challenges and limitations. This knowledge would add to the discourse regarding updates in policy and guidelines, especially necessary for policy makers as they deliberate over proposed rules and regulations [16]. To the best of our knowledge, no previous studies have focused on mental health providers' experiences regarding general prescribing—including scheduled medications—over telemedicine. In early 2024, we conducted a mixed methods study that included a web-based, cross-sectional survey and semistructured interviews of mental health providers who prescribe via telemedicine. The survey aimed to assess provider perceptions, experiences, comfort, and perceived patient safety in prescribing medications over telemedicine [17]. The interviews aimed to get a better understanding of providers' general telemedicine use, challenges and solutions specific to prescribing over telemedicine, and providers' knowledge and experiences regarding compliance with prescribing over telemedicine. In this study, our objectives were (1) to understand better providers' parameters for safe prescribing over telemedicine and (2) to report practices or workflows providers have adopted to accomplish safe prescribing via telemedicine. The results of the study will help stakeholders reassess long-standing policies—made at the beginning of these technological advances—that may now be causing unintended harm as the technology has improved and become more accessible to laypeople.

Methods

Study Design

We performed exploratory content analysis of semistructured interviews with tele–mental health care providers as part of a larger, mixed methods study. We used an explanatory sequential design, building upon a previously reported, web-based, cross-sectional survey [17].

XSL•FO
RenderX

Interview Development

After an initial literature review, we developed the semistructured interview guide with consultation and pretesting from 5 providers. We estimated that interviews would take 60 minutes. The interview attempts to capture context regarding what factors affect providers' views and comfort in prescribing medications via different scenarios and combinations of in-person and telemedicine visits. The interview guide covers the topics of (1) the provider's practice, such as specialty, telemedicine use, patients, and general difficulties with telemedicine; (2) challenges and solutions concerning prescribing over telemedicine; and (3) knowledge pertaining to laws and regulations of prescribing to telemedicine (see Multimedia Appendix 1 for the interview guide). This study focuses specifically on answers to the challenges and solutions concerning prescribing over telemedicine (Multimedia Appendix 1).

Participants and Recruitment

We recruited participants for the semistructured interviews from among participants in a research survey. The survey sampling, recruitment, and results are reported elsewhere [17]. In brief, we recruited a sample of US tele–mental health care providers from a telemedicine research panel, TelehealthEngage [18]. A total of 115 participants fully completed the survey. Participants were predominantly White (83/115, 72.2%), non-Hispanic or Latino (97/115, 84.3%), female (66/115, 57.4%) providers who were physicians (69/115, 60%) seeing their clients most to all of the time (50%-100% of visits) over telemedicine (82/115, 71.3%) [17].

Participants who agreed to be contacted at the end of the survey were invited to participate in follow-up interviews. Of the 115 completed surveys, 59 (51.3%) participants showed interest in being interviewed. Research team member JI (a White, immigrant female individual with a background in medical anthropology, psychology, and biomedical informatics) sent out interview invitations and completed interviews between February and April 2024. We aimed to complete 20 interviews or until we reached content saturation [19].

Data Analysis

One author (JI) performed an exploratory content analysis of 6 interviews. The codebook for content analysis, consisting of three main codes and two subcodes, was specified on the basis of prior survey findings (Table 1) [17]. The codebook was developed to test our expectations that providers will feel comfortable when their personal parameters for patient safety have been met and when the telemedicine visit is within the scope of provider practice and expertise. We used content analysis of the interviews to identify codes related to personal parameters for comfort in prescribing over telemedicine, named barriers and challenges of telemedicine prescribing, and the types of workarounds providers have found useful within those situations [19].

Table 1. Demographics as reported by providers during the interview[a].

Demographics for content analysis	Value, n (%)
Sex (n=16)	
Male	11 (69)
Female	5 (31)
How often telemedicine is used (n=16)	
None to seldom	1 (6)
Fairly often (about half the time)	4 (25)
Mostly or completely	11 (69)
Provider type (n=16)	
Psychiatry	8 (50)
Family medicine or general practice physician	3 (19)
Nurse practitioner	3 (19)
Physician assistant	2 (13)
Type of practice (n=21)	
Private practice	12 (57)
Statewide health system	4 (19)
Community health center	2 (10)
Solo practice	1 (5)
City-run program	1 (5)
Outpatient rehabilitation center	1 (5)

[a]Some demographic values sum to more than 16 as some providers worked in multiple practices.

XSL•FO
RenderX

We transcribed and deidentified completed interviews using Dovetail software (Dovetail). We confirmed transcripts for accuracy prior to deleting video data of interviews and uploaded transcripts to MAXQDA 2024 software (MAXQDA) for analysis. A single author (JI) coded the interviews over three iterations using the previously developed codebook, and coauthor HS (an Asian, immigrant female individual with a background in biomedical informatics and human factors research in behavioral health) reviewed the codes and codebook for validity and accuracy. We resolved discrepancies through consensus to ensure consistency and accuracy in the qualitative method [20,21]. The unit of analysis was meaningful phrases. Although we calculated the total frequency of code instances, we primarily focused on the frequency of codes by individual participants [19]. Additionally, contextual subtopics within the main reported codes were often double coded—as participants provided multiple examples, explanations, and reasoning—resulting in percentages over 100. We reported participant characteristics in the aggregate to ensure participants' confidentiality. For context, we included participants' numbers (1 through 16) after each quote.

Ethical Considerations

This study was reviewed and approved by the BRANY Institutional Review Board (IRB00010793). We attained verbal informed consent for the interviews in addition to the written informed consent from the survey protocol. Participants had the opportunity to opt out of our research. Participants were compensated with a US $75 e-gift card for their time. While there is always a risk of selection and other compensation-related biases, the amount was deemed appropriate for US mental health professionals who were the focus of recruitment. We use deidentified data for the purposes of this research.

Results

Demographics

We completed 16 semistructured interviews between February 22 and April 26, 2024. There were 11 (69%) male and 5 (31%) female participants (see Table 1 for demographics). Participants primarily practiced in the following states: Oregon (n=3, 19%), Texas (n=3, 19%), New York (n=2, 12%), Illinois (n=2, 12%), California (n=1, 6%), Florida (n=1, 6%), Michigan (n=1, 6%), Washington (n=1, 6%), Indiana (n=1, 6%), and Tennessee (n=1, 6%). The majority (n=11, 69%) provided care mostly or completely over telemedicine (75%-100% of visits), 4 (25%) providers reported an even mix (40%-60% of telemedicine and in-person visits) in their hybrid practice often depending on the weather, and 1 (6%) provider reported almost complete in-person care except for emergencies. Providers included psychiatrists (n=8, 50%), family medicine or general practice physicians (n=3, 19%), nurse practitioners (n=3, 19%), or physician assistants (n=2, 12%). Providers reported working in private practice (n=12, 75%), statewide health systems or clinics (n=4, 25%), community health centers (n=2, 12%), a solo practice (n=1, 6%), a city-run program (n=1, 6%), and an outpatient rehabilitation center (n=1, 6%). Some providers worked in multiple positions or practice types.

Content Analysis

A total of 234 code instances were identified, corresponding to three main codes and two subcodes. Table 2 shows the frequency of code instances corresponding to each main code and subcode. Frequencies of instances of *generally uncomfortable* and *generally comfortable* subcodes add up to the total frequencies of the *comfort* main code instances.

Of the 98 (41.9%) out of 234 total code instances under *comfort* in prescribing medications over telemedicine, 69% (68/98 code instances) were related to describing positive comfort in prescribing from all 16 providers. However, the majority of providers (10/16, 62%) also reported varying discomfort (30/98, 31% code instances) in prescribing over telemedicine even though it was less frequently mentioned.

Providers reported (85/234, 36.3%) varied barriers and challenges (85 code instances, 14 providers), providing information regarding problems that both providers and their patients face when prescribing medications over telemedicine. Providers reported fewer (27/234, 11.5%) workarounds and solutions (27 code instances, 11 providers).

XSL•FO
RenderX

Table 2. Content analysis results with the frequency of instances by main codes and subcodes[a].

Name	Frequency of code instances, n	Definition	Example
Comfort (main code)	98	Any direct discussion regarding feelings of comfort or ease in prescribing over telemedicine	"I just don't wanna like, yeah, miss something. And like, actually probably more so with the Benzos than with, than with stimulants because I feel like the stimulants you can: see if people are kind of like … when people are on Benzos they might be more drowsy, that you're just not picking up with, on the, the, the, the virtual…" [Participant 1]
Generally uncomfortable (subcode)	30	Any direct discussion regarding feelings of discomfort or unease in prescribing over telemedicine	"I feel less comfortable with over telemedicine because sometimes just like the cadence of a conversation is hard. Sometimes if there's a lag in telehealth or like whatever it may be. As for prescriptions, I would say, like your level twos and level threes are ones that I would not consider prescribing unless I'd at least seen them once in person…" [Participant 3]
Generally comfortable (subcode)	68	Any direct discussion regarding positive feelings of comfort or ease in prescribing over telemedicine	"And I would say that it's really about the same, the actual prescribing is pretty darn smooth. So, I feel like the mechanics of the prescribing are the same. I do not prescribe differently because I, I've got a sense, I don't know this person as well because I'm not me. No, I feel like I know my patients really well. Certainly, before I'm gonna be prescribing, I know what the story is in my mind. I may be wrong, but I've got that level of certainty. So, I don't think the telehealth platform impacts my decision-making or the mechanics around prescribing significantly." [Participant 6]
Barriers and challenges (main code)	85	Any direct discussion where a provider mentions a problematic situation that affects their decision-making to prescribe over telemedicine or affects a patient's ability to receive treatment	"But I would say, yes, it's difficult to feel comfortable, directing someone in another state to something that they may need without really knowing where that resource, who that resource is." [Participant 7]
Workarounds and solutions (main code)	27	Any direct discussion where the provider describes a way they adapt their process or decision-making due to a barrier or challenge	"So, a lot of times I give them information on how to find a particular how to vet another practitioner, but that's about the best [I can do]." [Participant 7]

[a]Main code and subcode definitions were developed based on survey analysis.

Parameters for Comfort in Prescribing Over Telemedicine

Overview

Providers brought up three main parameters as they contextualized their comfort or discomfort with prescribing medications over telemedicine: (1) limits of telemedicine and personal expertise, (2) knowledge of patients and access to their relevant health information, and (3) liability concerns.

Limits of Telemedicine and Personal Expertise

Five (31%) of the 16 providers established that they felt comfortable when the interaction stayed within their perceived limits of telemedicine and occurred within their realm of expertise. One provider pointed out that these parameters essentially establish criteria for a successful telemedicine visit:

> *So the direct answer to the question is I feel very comfortable [prescribing over telemedicine]. But I think the reason that I feel very comfortable has to do with the patients: who I see and who I won't see on telemedicine. So again, doing this is like a philosophical thing. I'm a big believer in getting people to the right place. And a lot of times that's me and a lot of times that's not me when it comes to mental health and telehealth, I try to, there are things that I, I don't personally feel comfortable or think would be appropriate to, to treat. So in general, if someone is like in a manic state, if they're psychotic, if they're actively suicidal, like suicidal with a plan intending to act on it, that sort of stuff, I won't see them through telehealth or if I have a patient who starts to experience those things, I will refer them for a higher level of care and we'll be pretty insistent on it. Not that I'm not gonna see them anymore, but it's just I want to get you to the best place.* [Participant 13]

Regarding the parameter of experience and expertise, 3 (19%) providers reported feeling uncomfortable prescribing over telemedicine when they thought they did not have the expertise to treat a particular diagnosis. One provider described feeling nervous about such a scenario:

> *I don't have anybody that I'm treating for narcotic abuse or opiate stuff. So I, not that I wouldn't, but I don't have anybody and I don't have a lot of experience with that. So that would make me nervous, especially over telemed. I just because I don't do it much in person either.* [Participant 9]

XSL•FO
RenderX

In this case, the provider notes they would feel uncomfortable treating such a patient in person and that seeing such a case over telemedicine would increase that feeling.

Knowledge of Patients and Access to Their Relevant Health Information

This parameter encompassed several topics including working with established patients and accessing needed patient health information such as labs or physical exams. A total of 4 (25%) providers identified knowledge of a patient's history—especially in regard to them being an established patient—as a crucial element of feeling comfortable prescribing for them.

> *So, certain medication that requires good monitoring for that level that may make me not want to prescribe medications on this platform. But I don't think it has anything to do with virtual platforms, any providers or psychiatrists would do so in, in person also. So I'm not, I'm trying to think if, unless the only time I don't prescribe is if someone makes the first appointment and say I'm on this medicine and I need refill, I don't do that because that's not a good practice. It's like, OK, unless I have some data or previous records or not a very strong medication, then you can continue. But if someone comes with a specific request for medicines that are not appropriate, then I wouldn't consider that as an OK to do it as a virtual practice.* [Participant 10]

This provider noted that in the scenario provided, they would need more information about the patient before prescribing, regardless of whether the visit is in person or via telemedicine. Meanwhile, one of these providers mentioned the importance of generally knowing their patients and their health status as they determine whether telemedicine visits are sufficient for care:

> *...If you have somebody who's a fragile diabetic, you need to have a different level of observation for that person. But if you have a stable diabetic, then you can just continue to prescribe that whatever it might be…* [Participant 15]

Inherent in this explanation is that the provider felt they have sufficient knowledge regarding a patient's current and past health status and feeling personally able to diagnose and treat in the presenting situation.

A total of 4 (25%) providers commented on the importance of having established patients in a scenario to make providers feel more comfortable prescribing over telemedicine. One of these providers underlined the importance of having such a relationship, especially when seeing patients for SUD treatment, as they may be able to pick up on potential concerns requiring more oversight via telemedicine or in person:

> *I mean, people with substance use problems. Now that brings a whole host of challenges itself because of confidence in, in history, you know, and confidence of just general reporting ... So I have a special, I have a different kind of relationship with [specific patient with SUD]. I can tell when somebody's bullshitting. And I can call them pretty well on it. I rarely get blindsided because I've been doing this for a long time. So I come with enough experience, I think also that allows that to happen. But suffice to say that if I have an issue with someone there, I'll put more controls over it, and we'll go to task if needed. If they need to come in, I need to see them in person...* [Participant 15]

In this case, the provider leveraged not only their years of experience in the specific field (expertise parameter) and having known the patient for a long time but also their hybrid practice, as they can have the patient come for an in-person visit.

A total of 3 (19%) providers mentioned they feel comfortable prescribing over telemedicine because they have such an option. In addition to this, 4 (25%) providers also pointed out that having a way to check on their patient's safety, whether it be having local resources for the patient or being able to view a Prescription Drug Monitoring Program, influences their comfort positively. One of these 4 providers described that knowing they can get patient health information quickly and seamlessly made them comfortable prescribing for an individual:

> *If they have established care, either someone who can update me on their vitals or regular monthly visits and have some kind of formal evaluation for me to backtrack the diagnosis. And then there is a way to order urine drug screens to make sure they're not abusing any other drugs on the top of. So, if that makes it an easy flow for us, then, yeah. Yeah. I think that's not a big problem. It's just how to coordinate that care sometimes makes it harder...* [Participant 10]

Additionally, 4 (25%) providers stated the importance of developing and adhering to a protocol with their patients. Providers discussed this concept within the patient information parameter in everything from the formal quality of care processes to simply expecting to see a patient in person for all intakes. Adhering to protocols appears to be driven by the need for patient health status and history, as providers often discussed continuity of care and procurement of labs and exams.

> *So, I think patients who are, really complex, I feel less comfortable with prescribing over telemedicine because sometimes just, like, the cadence of a conversation is hard. Sometimes if there's a lag in telehealth or whatever it may be. As for prescriptions, I would say, your level two's and level three's are ones that I would not consider prescribing unless I'd at least seen them once in person. I know personally, our clinic does random drug tests on our patients...* [Participant 3]

Liability Concerns

A total of 5 (31%) providers noted that they maintain their comfort in prescribing over telemedicine by simply refusing to prescribe certain controlled substances or not accepting specific diagnoses in their practice, especially due to their wariness of laws and regulations. One of these providers explained that while they treat SUDs, they do not prescribe certain medications and are aware of prescribing barriers:

XSL•FO
RenderX

> *...I do see a lot of patients with substance use disorder...just the fact that it's [buprenorphine] more accessible now is amazing for these patients. I've heard there are still some barriers with methadone in particular...it hasn't been an issue for me because I don't prescribe that medication in particular.* [Participant 16]

Indeed, 2 (12%) providers indicated they avoid prescribing over telemedicine unless they feel they have to for the patient.

> *I generally refrain from prescribing anything scheduled over telemedicine ... just because of the, the insane liability with it ... the unbalanced liability, I would say that physicians shoulder in this industry.* [Participant 7]

Here, the provider also touched on the issue of compliance and liability inherent in this situation.

Barriers and Workarounds in Prescribing Over Telemedicine

Of the 85 (36.3%) out of the 234 total code instances that describe barriers (14 providers), 37 (44%) of the 85 instances specifically mentioned that the e-prescription platform and the pharmacies caused challenges in prescribing medicines or picking up medicines (13 providers). There were 17 (20%) instances of providers describing difficulties with the actual e-prescription platform they use.

> *But Epic, they started putting in all these like hard blocks like you need to click this before you can do what you're trying to...I think the way that they went about it sometimes, it was really like a hassle for the workflow when you add it all together.* [Participant 2]

Providers also often noted their patients' prescription order was not received or not fulfilled by the pharmacy due to shortages in medicines or misunderstandings in prescribing over telemedicine (20/85, 24%). One provider noted how such a situation acted as a barrier for patients receiving their necessary prescriptions:

> *But I had a pharmacy once, call me that said that...they weren't going to allow my patient to fill a pack of the prescription because I hadn't provided an estimated glomerular filtration rate or creatinine clearance with my prescription. But like that's because they now have the ability to prescribe that on their own. But I sent the prescription. I'm assuming the responsibility. I already checked that all you're doing is throwing up another barrier to this patient, getting their medication when you do that, which I get. You don't want to be audited or whatever, but you're not the one prescribing it. I am, you know what I mean? I just like the pendulum has swung so far the other way since the opioid epidemic that they're really trying to tighten the noose and on all this stuff, and I just think it's going to end up harming patients who are calling for their beta blockers or, you know, whatever.* [Participant 2]

Providers reported shortages of certain medicines, usually stimulants, in pharmacies, requiring patients to find pharmacies with stock and providers to resend prescriptions. Providers' complaints regarding the e-prescription platforms and pharmacies' inability to provide the medications ranged from workflow nuisances to concerns that their patients could not receive necessary medications promptly.

Other mentioned barriers (49/85, 58%) were related to general telemedicine concerns and issues such as patient health concerns (17/85, 20% codes; 11/16, 69% providers), rules and regulations (16/85, 19% codes; 7/16, 44% providers), and reimbursement concerns (9/85, 11% codes; 2/16, 13% providers). Patient safety concerns mainly touched on worries that patients are not having their follow-up appointments, exams, and labs in a timely manner, which can affect patient health outcomes, as well as the ability of providers to prescribe medications for them.

> *I will put a child on a medication and I'll say I need to have you call me in two or three days because this medicine doesn't take a long time to start working. And I need to know so we can make adjustments. And invariably 99% of the time they wait till the next month, scheduled appointment and we could have made some, you know, needed changes. And that was difficult even when we were in the office...* [Participant 11]

Concerns regarding rules and regulations more closely align with providers seeing patients across state borders. Some providers felt such regulations hindered their ability to treat patients but also created unnecessary frustrations.

> *So, yeah, it's interesting navigating all of that because, and honestly, I think it's just so stupid having state-dependent licensing system when they all use the same criteria.* [Participant 7]

While providers recognized the need for laws and regulations, their current struggles often placed them in positions having to choose between seeing their (often established) patients or complying with regulations.

> *It reminds me of another patient, he's in college in North Carolina and, he had really good, he had a psychiatrist through his school but then the school had canceled the contract with that [psychiatrist] and he's like, what now am I supposed to do? And like, he wasn't exactly, he wasn't unstable but he wasn't stable. Like, you know, in that gray zone and he's like, can't you see me?...And I would love to see you. I feel my heart goes out to you, but like, you're in North Carolina, like, I...I, I will see you all through Christmas break, summer break. But like, I don't know what to do. Like, if you're having a crisis, definitely call me like, and I will, you know, I will just override it. But like, if you're going there and, you know, like you need the help, like you gotta, I don't know, I don't know what to tell you. Like, I feel terrible if you.* [Participant 1]

XSL•FO
RenderX

Providers often reported that mobile patients such as college students are the ones most strongly affected by these types of laws and regulations.

Providers reported far fewer workarounds or solutions (27/234, 11.5% codes; 11/16, 69% providers) to mentioned barriers relating to prescribing over telemedicine. Direct responses to barriers and challenges included—as subtopics—streamlining how they receive patient health data (8/27, 30%), finding new pharmacies for patients to use (5/27, 19%), using reminders and new ways to connect with patients quickly (5/27, 19%), responding to regulatory pressures (3/27, 11%), and making individual adaptations in their practice (6/27, 22%; due to double coding of subtopics, percentages add up over 100) The most common solution providers reported was finding an easier way to receive laboratory tests, examinations, and vitals from their patients (8/27, 30% codes; 5/16, 31% providers). While providers were able to direct their patients to local laboratories or request that their patients invest in a blood pressure cuff, one provider noted their practice found certain tests to be beneficial for telemedicine visits:

> *Hm, we do drug screens online. So, we do saliva testing online and drug screens. And so that's if we don't always have to have people go pee somewhere or go to the lab, they can do those at home. So, I guess that's something that we found just as a, not really a workaround, well, kind of a workaround, and I guess to allow them to stay at home, but just to incorporate it as something that's a little bit more convenient.* [Participant 5]

Providers further noted the emphasis on streamlining patient processes by using novel ways to communicate with them regarding simple questions or requests. For example, one provider noted the following:

> *[Patients] can just text me a question...A few patients of mine have learned that they come and sit in the waiting room if they have a question. And so, I see them sitting in my waiting room, and sometimes I'm done. I'm like, "What's up?" And they say, "Yes, you know, hey, I need a refill.*" [Participant 12]

In this case, the provider sought to have secure, simple messaging with a patient. Other solutions related to streamlining processes with patients included actively talking with pharmacies in the patients' area (5/27, 19%), moving to a new e-prescription platform (1/27, 4%), and creating a protocol for helping their out-of-state patients find health resources (1/27, 4%).

Providers mentioned two differing approaches to handling the barriers created by laws and regulations in prescribing over telemedicine. Some (2/16, 13%) providers chose to unequivocally adopt the strictest state and federal regulations within their practice, and another explained that they would continue with a process that works for their patients but was admittedly in the gray zone legally.

Content analysis of barriers affecting provider comfort in prescribing over telemedicine identified 85 code instances over 16 interviews. With 27 code instances of workarounds and solutions directly relating to these noted barriers, the qualitative analysis identifies areas in telemedicine where progress still needs to be made.

Discussion

Principal Findings

By leveraging the results of our more extensive mixed methods study [17], we framed our content analysis to provide needed context for understanding mental health providers' comfort in prescribing over telemedicine. This qualitative study identified vital parameters that constitute comfort for mental health providers who prescribe via telemedicine. Our results show that providers feel most comfortable prescribing over telemedicine when they are practicing within its inherent limitations and their own professional expertise, with access to patients' relevant health information, and within clearly defined legal and regulatory confines. In addition, we identified related barriers that affect these parameters and the potential solutions that providers have used to alleviate these challenges. Content analysis revealed providers found the e-prescription platforms and the miscommunications with pharmacies receiving prescriptions as substantial sources of frustration and concern in the prescribing process. Ultimately, providers prescribe medications over telemedicine within the bounds of their perceived comfort parameters but would like to see changes in streamlining the prescribing workflow, assurance of timely patient examinations and laboratory tests, and clarity in the laws and regulations surrounding prescribing over telemedicine.

Overall, even while providers reported feeling comfortable prescribing over telemedicine, they were aware their comfort was due to practicing within their established personal parameters. Providers noted their comfort in prescribing over telemedicine was attributable to their specialty and providing care to patients who require specific types of medications that providers may be generally hesitant to prescribe. Research using claims data between 2020 and 2023 shows that certain specialties (ie, psychiatry) were seen to initiate treatment for alcohol use disorder over telemedicine more than others (ie, primary care physicians) [22]. Within the same study, researchers observed a different rate of telemedicine initiations dependent on the types of medications being prescribed (eg, naltrexone at 14.6% vs topiramate at 11.8%). Our results support these findings as psychiatrists are better versed in treating mental health disorders and have tacit knowledge regarding certain medications and patient symptoms. Unsurprisingly, in this study, some providers emphasized that their comfort in prescribing decreased when faced with diagnoses they have little experience treating. From a 2023 review of pandemic-era research on telemedicine use in SUD treatment in the United States, authors noted providers would vary the number of days (supply) of prescribed medication based on their judgment of each patient interaction and context [23-26]. These findings are supported by our results as providers work within their personal parameters and determine how to proceed with prescribing based on their interaction with each patient.

Additionally, providers' personal parameters likely echo current guidelines regarding telemedicine use and limitations [27,28].

XSL•FO
RenderX

Such guidelines proffered protocols and practices based on earlier telemedicine research and stricter rules and regulations [29]. Considering that guidelines emphasize compliance with state and federal laws and regulations, we may be seeing providers' personal parameters reflecting these policies even when they feel comfortable and capable of prescribing over telemedicine [30]. Updates of such guidelines would help reframe providers' understandings of telemedicine prescribing limitations and liabilities; however, lagging legal progress limits the ability for such revisions [31,32]. With the loosening of laws and regulations regarding telemedicine prescribing, new evidence has shown that providers can care for their patients effectively while maintaining positive patient outcomes [29].

Providers also emphasized the importance of access to patient's health information, especially timely updates of exams and labs needed to prescribe certain medications such as stimulants. Certainly, the content analysis showed multiple workarounds focused on streamlining the process of accessing patient health information. Understandably, providers also noted that they feel more comfortable working with established patients, where patient health history and a personal repertoire with the patient can provide context to a telemedicine visit. Interview results suggest that an established patient—via telemedicine or in-person visit—is a central factor in how providers view their needs for timely patient health updates. This parameter is relevant for in-person and telemedicine visits. Nevertheless, with the inflated fear of liability when using telemedicine, providers show increased concern when operating outside their parameters for comfort in telemedicine prescribing [33]. Similar findings show providers may feel that additional assessment, such as physical examination, reinforces their decision-making and allays liability fears [34].

Our content analysis shows that the ultimate tipping point in whether providers prescribe via telemedicine is whether the clinical situation falls within the provider's personal parameters for comfort in prescribing. The obstacles we identified in the study, such as the e-prescription platform errors, were predominantly situations that caused frustrations in the prescribing process but were insufficient reasons for providers to discontinue prescribing medications. Of course, particular barriers, such as miscommunications with pharmacies and not receiving patient examinations or laboratory tests promptly, directly impact patient safety and outcomes. Our results support prior research showing that providers and patients faced challenges with e-prescriptions where pharmacies faced a dearth of certain medications such as buprenorphine [23,35,36]. Providers emphasized the importance of patient safety with their noted solutions: the most frequently mentioned solutions revolved around streamlining the receipt of patient health information and ensuring patient access to needed medications. Given the current, typical support infrastructure in the United States, telemedicine is not as effective for treating disorders that require laboratory examinations [37]. However, telemedicine is becoming a permanent mode of health care delivery, and successful solutions for assessment, such as diagnostic testing and information access, will be a priority for providers and other stakeholders. As a result, there is a growing support infrastructure including at-home laboratory options ranging from technicians coming to your home to home tests that can be done during a telemedicine visit [38,39]. While large health institutions such as Yale School of Medicine may have such resources available for their patients [38], small clinics or solo providers face difficulties in connecting their patients to these resources, especially in relation to an individual patient's insurance coverage [39].

Our results show that providers prescribe within the scope of their personal parameters determined by perceived limitations of telemedicine and professional expertise, provider access to relevant patient health information, and liability concerns. Once providers met their individual parameters, they expressed higher comfort in prescribing over telemedicine. With an increase in legal clarity and simplification of prescribing over telemedicine, providers may feel more capable and comfortable with the process, as guidelines would reflect the loosening of restrictions [30]. These personal parameters exist in the context of current legal and regulatory considerations; therefore, making PHE telemedicine-related policy flexibilities permanent may help expand the situations in which providers feel comfortable prescribing. Such progress may also improve patient access to mental health care services—providers may feel more comfortable expanding their patient base for telemedicine, thus alleviating access and inequity issues for mental health care treatment [40].

Limitations

This study used interviews from providers recruited through nonprobability convenience sampling via the TelehealthEngage research panel. Our findings are not generalizable to all US mental health providers. It reflects the view of interview participants, including providers from solo, small private practices; statewide health systems and clinics; and other types of mental health care settings. Additionally, as we included all prescribing mental health providers, the prescribing challenges, workarounds, and level of comfort we captured in the study may differ for other providers based on their practice focus. Future research should include a larger sample of participants including those practicing in larger health systems and academic health sciences centers, who were underrepresented in our sample.

Conclusions

Through content analysis of semistructured provider interviews, we determined that the participating providers feel comfortable prescribing over telemedicine when they practice within perceived limits of telemedicine and their own expertise, with sufficient access to patient health information, and when they do not have liability concerns. Providers mentioned multiple hindrances to prescribing over telemedicine. However, the ultimate reason they refer patients to other providers or convert encounters from telemedicine to in-person visits is that their comfort parameters are not met, and thus, patient safety is at risk. Future research, including inductive-deductive qualitative analysis of the interviews, will help create a more robust understanding of provider perspectives on telemedicine prescribing and inform future implementation and policy of prescribing over telemedicine.

Abstract

Background: The rising demand for advanced home care services, driven by an aging population and the preference for aging in place, presents both challenges and opportunities. While advanced home care can improve cost-effectiveness and patient outcomes, gaps remain in understanding how eHealth technologies can optimize these services. eHealth tools have the potential to offer personalized, coordinated care that increases patient engagement. However, research exploring health care professionals' (HCPs) perspectives on the use of eHealth tools in advanced home care and their impact on the HCP-patient relationship is limited.

Objective: This study aims to explore HCPs' perspectives on using eHealth tools in advanced home care and these tools' impact on HCP-patient relationships.

Methods: In total, 20 HCPs from 9 clinics specializing in advanced home care were interviewed using semistructured interviews. The discussions focused on their experiences with 2 eHealth tools: a mobile documentation tool and a mobile preconsultation form. The data were analyzed using content analysis to identify recurring themes.

Results: The data analysis identified one main theme: optimizing health care with eHealth; that is, enhancing care delivery and overcoming challenges for future health care. Two subthemes emerged: (1) enhancing care delivery, collaboration, and overcoming adoption barriers and (2) streamlining implementation and advancing eHealth tools for future health care delivery. Five categories were also identified: (1) positive experiences and benefits, (2) interactions between HCPs and patients, (3) challenges and difficulties with eHealth tools, (4) integration into the daily workflow, and (5) future directions. Most HCPs expressed positive experiences with the mobile documentation tool, highlighting improved efficiency, documentation quality, and patient safety. While all found the mobile preconsultation form beneficial, patient-related factors limited its utility. Regarding HCP-patient relationships, interactions with patients remained unchanged with the implementation of both tools. HCPs successfully maintained their interpersonal skills and patient-centered approach while integrating eHealth tools into their practice. The tools allowed more focused, in-depth discussions, enhancing patient engagement without affecting relationships. Difficulties with the tools originated from tool-related issues, organizational challenges, or patient-related complexities, occasionally affecting the time available for direct patient interaction.

Conclusions: The study underscores the importance of eHealth tools in enhancing advanced home care while maintaining the HCP-patient relationship. While eHealth tools modify care delivery techniques, they do not impact the core dynamics of the relationships between HCPs and patients. While most of the HCPs in the study had a positive attitude toward using the eHealth tools, understanding the challenges they encounter is crucial for improving user acceptance and success in implementation. Future development should focus on features that not only improve efficiency but also actively enhance HCP-patient relationships, such as facilitating more meaningful interactions and supporting personalized care in the advanced home care setting.

Introduction

Advanced Home Care

Advanced home care, also known as advanced health care in the home, involves providing medical care or treatment directly at a patient's home, serving as an alternative care to inpatient care. The World Health Organization defines home care as "an array of health and social support services provided to clients in their residence. Such coordinated services may prevent, delay, or be a substitute for temporary or long-term institutional care" [1]. According to a study by Barakat et al [2], the components of home care include preventive actions and assessments, postdischarge actions, and evaluations, with objectives focused on enhancing or maintaining the quality of life, optimizing functional health status, and promoting independence. The composition of health care professionals (HCPs) providing home care varies depending on the patient's needs and the extent of services they require. This team may involve various HCPs, such as physicians, nurses, assistant nurses, physical therapists, occupational therapists, speech-language pathologists, home health aides, home infusion nurses (specialized nurses who administer intravenous medications in patients' homes), hospice caregivers, and medical social workers [3]. Patients receiving home care may have a wide range of health conditions and diseases, including chronic conditions, such as diabetes, hypertension, and heart disease; neurological conditions, such as Parkinson disease, dementia, and stroke; respiratory conditions, such as chronic obstructive pulmonary disease, asthma, and sleep apnea; cancer; individuals requiring wound care; and those in need of palliative care [3].

The increasing demand for home care services is driven not only by an aging population but also by the growing preference among many individuals to age in place, remaining in their own homes. The primary goal of advanced home care is to enhance patients' quality of life and clinical outcomes while simultaneously reducing health care costs and hospital readmissions [4].

Use of Electronic Health in Advanced Home Care

Organizational suppliers of health care are increasingly delivering medical care directly to patients' homes, which has created a growing reliance on medical technologies and eHealth tools [1] to support health care staff in managing not only older people care but also palliative and end-of-life care and patients with multiple comorbidities or complex diseases. The increased presence of eHealth tools also highlights the importance of considering the competencies and requirements of HCPs for using eHealth tools in older people care [2].

eHealth's vital role in advanced home care includes using telehealth, remote patient monitoring, and mobile health apps to deliver health care services to patients with complex medical needs in their homes [5]. eHealth tools facilitate communication between patients and HCPs, support medication management, monitor vital signs and symptoms, and offer educational resources to patients and caregivers. Furthermore, integrating eHealth into advanced home care can also enable organizational suppliers of health to deliver personalized and coordinated care, increase patient engagement and self-management, and improve overall patient satisfaction [2].

In Sweden, the national policy emphasizes home assistance and home care over institutionalized care, with various programs supporting long-term care for older people, assistance for people with disabilities, end-of-life care, palliative care in hospitals or hospices, and advanced palliative home care administered by municipalities. In 2017, home care met 72% of long-term care needs, while institutions served the remaining 28% [6]. Given the substantial reliance on home care for health care delivery, there is a significant need for resources, making eHealth services, such as those mentioned earlier, highly beneficial [7].

A study by Rydenfält et al [8] outlined the implementation of eHealth services in Swedish home care nursing, listing national patient summaries, mobile documentation, digital locks, digital medical lists, digital security alarms, and camera supervision as the most commonly used services. Organizational suppliers of health care had implemented mobile documentation most widely among these services at the time of the study, with plans for its continued use in the future for home care nursing.

Traditional Documentation

Health care staff have long used traditional methods, such as pen-and-paper notes, to document patient encounters, including observations, assessments, signs, symptoms, and communications during clinic consultations and home care visits. While some remnants of this traditional documentation method may persist in current practices, health care organizations have adopted information and communication technology solutions [9] and notable mobile communications [10] to address the inherent challenges of traditional documentation. Traditional documentation methods occasionally lead HCPs to omit crucial information inadvertently, record data inaccurately, produce illegible handwriting, and misunderstand patients' accounts, while requiring significant time for documentation [11].

Patient Experiences With eHealth

Researchers have extensively explored patient experiences with eHealth, particularly in home and palliative care settings, and have revealed a range of benefits and challenges. Steindal et al [3] found that telehealth applications in palliative home care enhance access to HCPs, helping patients feel more secure and safe. Similarly, Widberg et al [4] highlighted that eHealth applications facilitate better communication between patients and HCPs in palliative care. Karlsen et al [12] focused on older adults' use of telecare in home care services and emphasized their desire to age in place. These studies show that patients view technology as a valuable tool to achieve this goal, although

XSL•FO
RenderX

some resist adopting new technologies, struggle with digital proficiency, and worry about privacy and security [5].

Older patients face notable challenges when using eHealth tools. These include their preference for direct contact with HCPs, age-related cognitive decline, the stigmatization of telemonitoring devices, and the potential loss of social interactions, which are essential for well-being [5,13]. Experts emphasize the importance of balancing in-person care with eHealth use for certain populations, such as older patients with chronic conditions. Despite these obstacles, studies highlight that eHealth improves care accessibility and patient autonomy [3,5,12].

Specific eHealth applications directly benefit patients. For instance, an eHealth app tested in home care settings allowed patients to report health concerns and increased their sense of security [10] by reducing the frequency of phone calls to nurses, enabling them to prioritize care based on the app's alerts. However, frequent reporting through the app led HCPs to perceive minor health issues as significant, which increased their workload [10]. These findings illustrate the nuanced impact of eHealth on patient experiences and underline the need to carefully address patients' needs and contexts.

The Acceptance and Perspectives of HCPs on eHealth

HCPs play a pivotal role in adopting and successfully implementing eHealth solutions, as their acceptance and perspectives directly influence outcomes. Li et al [14] identified key factors that affect HCPs' acceptance of eHealth. These factors include HCP characteristics, voluntariness of use, performance and effort expectancy, and how organizational conditions either support or hinder eHealth adoption. HCPs emphasize patient autonomy, personalization, and continuity of professional support as facilitators of eHealth adoption, while they note advanced patient age as a primary barrier [15].

Qualitative studies offer additional insights into HCPs' attitudes toward eHealth. In an interview study, general practitioners expressed positive attitudes toward eHealth as a means to promote healthy lifestyles for patients and themselves [16]. They showed confidence in transitioning from traditional paper-based approaches to digital solutions, particularly those incorporating patient-reported outcome measures. Similarly, Das et al [17] examined the impact of an eHealth portal on HCP-patient interactions and reported that HCPs value the portal for its ability to provide comprehensive patient information, foster accountability, and serve as a clinical tool. However, they also identified organizational challenges, such as a lack of incentives and time constraints, which hinder eHealth integration.

Understanding HCPs' experiences and perceptions is essential for optimizing eHealth tools. While eHealth enhances health care quality, efficiency, and accessibility, its success depends on addressing the barriers that HCPs face. Targeted training and strategies to overcome organizational constraints can improve HCP satisfaction and ensure seamless integration of eHealth into clinical practice [18].

Aim of the Study

Despite extensive research in eHealth, there remains a limited understanding of how eHealth tools affect the relationship between HCPs and patients in advanced home care settings. While some studies have explored patient perspectives, fewer researchers have focused on HCPs' experiences and perceptions.

The aim of this study is to explore HCPs' perspectives on using eHealth tools in advanced home care and their impact on HCP-patient relationships. This research is particularly relevant in the context of Sweden's robust home care system.

Methods

Methodology Overview

This study used qualitative research methods, collecting data through semistructured interviews with HCPs working in advanced home care at Aleris in Sweden. Aleris is one of the major private organizational suppliers of health care in Sweden, offering a range of medical services, including advanced home care and other specialist medical treatments [19]. This approach suited the study's objective, which aimed to gain a deep understanding of HCPs' perspectives on using eHealth tools in advanced home care and their impact on relationships with patients. The flexibility of qualitative research allowed nuanced meanings to emerge from participants, captured through direct quotations from interview transcripts. The study adopted an exploratory design to further explain the role of eHealth tools in advanced home care as perceived by HCPs and examined how these tools influence their interactions with patients. This design proved beneficial in uncovering connections between ideas that were either underrepresented or not previously demonstrated in the literature [20]. An inductive approach [21] analyzed the data, aligning with the study's objectives.

The eHealth Tools

The eHealth tools used in the study are part of the SwipeCare health care process management system, which partially integrates into TakeCare, the electronic health record (EHR) system used by HCPs in their daily practice. TakeCare serves as the main repository for patient information and is used for routine clinical documentation. SwipeCare functions as an overlay on TakeCare, enhancing the existing EHR system by adding functionalities, such as iPad (Apple Inc)-based questionnaires, calculations, creating and sending questionnaires to patients, and patient reminders [22]. SwipeCare controls and coordinates the patient care process from diagnosis and treatment to aftercare and follow-up. It allows the organizational suppliers of health to define and manage the entire health care process, initiating actions within that process, some performed by SwipeCare itself (like sending out questionnaires) and others by HCPs or other units. SwipeCare interacts with TakeCare only when it needs to read from or write to the patient's record, thus complementing rather than replacing the EHR.

The 2 tools chosen for the evaluation were a mobile documentation tool and a mobile preconsultation form. The tools were chosen for their complementary nature and potential to capture a wide range of HCP-patient interactions. While the mobile documentation tool was used by the HCP, or

XSL•FO
RenderX

collaboratively by HCP and patients, during in-person visits, the mobile preconsultation form was completed independently by patients at home. This diversity in tool use allowed a comprehensive exploration of eHealth's impact on HCP-patient relationships across different contexts.

The iPad-based mobile documentation tool consists of different predefined standardized forms, which HCPs, either themselves or together with the patient, fill in. Such a form could, for example, cover the required information related to the admission of the patient to a ward or a checklist for evaluating the patient's physical status after an adjustment in the treatment. The questions in the form consist of predefined categories designed to guide HCPs in documenting patient information. Caregivers have the discretion to determine which answers are available for HCPs to fill in. In some cases, there is a designated "comments" section where HCPs can provide additional explanations or insights. However, in other instances, caregivers may choose to limit responses to predefined alternatives. This limitation mirrored traditional documentation methods, such as pen-and-paper systems, where options were similarly restricted. In addition, certain calculations, such as the Mini Nutritional Assessment (MNA) [23] or the National Early Warning Score 2 (NEWS2) [24], necessitate numerical input and cannot accommodate text responses. This further underscored the importance of predefined answer alternatives within the tool. In addition, the forms ensure no relevant aspects are missed, as questions can be made mandatory to answer.

The second tool, the mobile preconsultation form, is part of the patient portal in the system, which enables the patient to access their own portal, or web page, on their mobile or equivalent digital device. The patient first receives an SMS text message with a link to their patient portal. The patient logs in using a secure method and can then access the preconsultation form. The patient answers the questions at their own pace and time and finally sends the answers back to the caregiver. This enables HCPs to review the status of the patient before traveling to the patient's home, avoiding the time spent on questioning and filling in answers. Instead, it allows that time to be spent caring for the patient where the patient has its needs, for example, pain in the foot or problems with digestion. The intention is to free HCPs from administration to devote time to the care of the patient and encourage patients to take a more active role in their own care.

Data Collection and Participant Selection

The recruitment process involved contacting selected participants via email, facilitated by managers from each of the 9 participating clinics in Stockholm, Sweden. Clinics were selected to ensure geographic diversity across the Stockholm region, including clinics from the north, south, and other areas. Clinic heads collaborated in identifying suitable participants with experience using the eHealth tools. This selection strategy aimed to capture a comprehensive range of perspectives, strengthening the validity of the findings. Inclusion criteria for participants comprised individuals aged ≥18 years, officially employed at these clinics, and experienced in using the eHealth tools in their professional roles. The diversity in HCPs' roles and experience levels allowed for capturing a broad view of eHealth tool use in advanced home care.

Interviews took place between March and May 2023. Participants received the informed consent form via email before the interviews, which they reviewed and signed in person at the beginning of the interview session. Audio recordings and notes documented each 30- to 45-minute interview. A structured interview guide provided consistency while allowing the interviewer flexibility to explore topics relevant to HCPs' perspectives further. For example, one question from the interview guide asked participants to describe how they adapted their use of eHealth tools based on individual patient needs, providing deeper insights into their experiences and perceptions regarding the patient-HCP relationship.

The characteristics of the 20 HCPs who participated in the interviews varied across the 9 clinics. Each clinic contributed between 1 and 4 HCPs, with a median of 2, ensuring a good spread of perspectives across the clinics involved. Participants were aged between 24 to 59 years, with a mean of 45 (SD 9.3; IQR 41-52) years.

Table 1 presents participants' characteristics, categorized by profession, years of practice, duration of using mobile documentation tools, and duration of using mobile preconsultation forms. All (20/20, 100%) participants used the mobile documentation tool, while only 60% (12/20) of them used the mobile preconsultation form. This difference in tool use reflects the phased implementation approach common in health care settings, allowing for the gradual adoption and refinement of new technologies. The relatively short duration of eHealth tool use for many participants (0-2 years) illustrates the dynamic nature of health care staffing, characterized by a high turnover rate [25]. HCPs joining from other organizational suppliers of health care or units typically lacked previous experience with these specific eHealth tools. This limited experience duration accurately represents the reality found in many health care units and provides valuable insights into the initial adoption phase of eHealth tools in advanced home care.

These factors—the selection process, varied tool familiarity, and relatively short use duration—shaped the findings by offering a realistic snapshot of eHealth tool adoption in health care units where staff turnover is common. While this scenario limits observations on long-term impacts, the study offers a pragmatic view of eHealth tool implementation, helping stakeholders set realistic expectations and develop strategies that account for the realities of staff turnover and varying levels of tool familiarity in health care settings.

[a]Clinical practice: total time spent as health care professionals across all settings, including advanced home care clinics.

[b]Not applicable.

Data Analysis

The interview, recorded in audio format, underwent verbatim transcription and subsequent review for accuracy and completeness. Following the transcription of the data, participants' responses were systematically organized and categorized. The analysis was conducted using a content analysis approach grounded in the methodology described by Graneheim and Lundman [26]. The process began with a thorough data familiarization. To gain a deep understanding of its content, we immersed ourselves in the material, reading it carefully multiple times. Once a comprehensive understanding of the data was achieved, we identified *meaning units*—specific segments of text that conveyed key information relevant to the study's objectives. These meaning units were then condensed to retain their core meaning while eliminating unnecessary details. Each condensed meaning unit was assigned a code, which served as a concise label capturing its essential message. The codes were reviewed and grouped into *subcategories* based on shared patterns and similarities, providing a more detailed and refined understanding of the data. These subcategories were subsequently combined into broader *categories* that represented the distinct dimensions of our study. We then merged related categories and identified key subthemes. Ultimately, we consolidated these findings into an overarching theme. This theme captured the core insights from the data, highlighting both the benefits and challenges of eHealth tool use in advanced home care from HCPs' perspectives.

Ethical Considerations

This research was conducted in Sweden. According to the Swedish Ethical Review Act (SFS 2003:460) [27,28], this study does not require ethics approval as it does not involve the handling of sensitive personal information, as defined by the European General Data Protection Regulation (GDPR), Regulation (EU) 2016/679 [29]. However, we acknowledge that ethical principles still apply and have been followed in accordance with relevant regulations and research guidelines.

Prospective study participants received an invitation email outlining the study's purpose. Those who agreed to participate were contacted via email, SMS text messages, or phone calls to schedule interviews according to their preferences. Before beginning the interviews, participants were provided with a comprehensive explanation of the study objectives, interview procedures, and their rights. Both verbal and written consent were obtained from each participant, with informed consent signed by the participant and the researcher. The consent form included information regarding the aim of the study, potential risks and discomforts, potential benefits, how confidentiality would be handled, the right to withdraw, and consent

XSL•FO
RenderX

procedures. It also assured participants of their confidentiality. All participants were informed of their right to withdraw from the study at any stage. Furthermore, no monetary or nonmonetary compensation was provided to any participants. Finally, they were assured that all raw data, comprising audio recordings and interview notes, would be stored on a secured laptop with biometrics log-in (fingerprint) for enhanced data security.

Results

Overview of Data Analysis

The data analysis identified one main theme—*optimizing health care with eHealth: enhancing care delivery and overcoming challenges for future health care*. Two subthemes emerged: (1) enhancing care delivery, collaboration, and overcoming adoption barriers and (2) streamlining implementation and advancing eHealth tools for future health care delivery. Five categories were also identified: (1) positive experiences and benefits, (2) interactions between HCPs and patients, (3) challenges and difficulties with eHealth tools, (4) integration into the daily workflow, and (5) future directions. Table 2 shows the subcategories, categories, subthemes, and themes that emerged after coding.

The overarching theme highlighted the study's central focus on the HCPs' perspectives on the use and integration of eHealth tools in their daily practice. It emphasized how these tools impact the dynamics of health care delivery, including their influence on the relationships between HCPs and patients, and how they shape the overall patient care experience.

Table 2. Overview of the *optimizing health care with electronic health: enhancing care delivery and overcoming challenges for future health care* theme, subthemes, categories, and subcategories.

Subtheme and categories	Subcategories
Enhancing care delivery, collaboration, and overcoming adoption barriers	
Positive experiences and benefits	• Efficiency • Better documentation and enhanced patient safety
Interactions between HCPs[a] and patients	• Unaffected HCP-patient relationships • Enhanced patient engagement • Communication barrier
Challenges and difficulties with eHealth tools	• Technical and resource challenges • Patient-related factors
Streamlining implementation and advancing eHealth tools for future health care delivery	
Integration into the daily workflow	• Ease of use • System integration and application
Future directions	• Staff recommendations • Continuity of use

[a]HCP: health care professional.

Enhancing Care Delivery, Collaboration, and Overcoming Adoption Barriers

Positive Experiences and Benefits

The participants highlighted several benefits of using the mobile documentation tool. One significant advantage was the decreased documentation time during patient consultations. The mobile tool allows HCPs to document directly during patient encounters, which increase *efficiency* by eliminating the need for double documentation [30] and reducing the time spent on paperwork. Approximately two-thirds (13/20, 65%) of the HCPs indicated that the mobile documentation tool helped them save time on documentation:

> *I think it [the mobile documentation tool] decreases my work time [taking clinical notes during consultation].* [Nurse 6]

> *It saves me time because I document while I am at the patient's house.* [Nurse 9]

Another benefit mentioned was the standardization of content for clinical note-taking. The use of standardized templates within the mobile tool ensured that all relevant information was captured consistently, which is crucial for effective patient care. Participants also expressed an enhanced sense of safety and security for patients when using the mobile documentation tool. This improvement was attributed to more accurate and timely documentation of health status, which contributed to better patient outcomes. The time saved through efficient documentation potentially translated to improved patient care quality. With reduced administrative burden, HCPs could devote more time to meaningful patient interactions, allowing more in-depth discussions about health concerns and treatment plans.

While most (13/20, 65%) participants perceived the mobile documentation tool as beneficial, some noted challenges. A few (7/20, 35%) participants reported that it disrupted their routine workflow by prolonging consultation times. They found that carrying the iPad during home care visits added to their equipment load, making it inconvenient:

XSL•FO
RenderX

> *I think it [the mobile documentation tool] increases my work time. My usual consultation is about 20-30 minutes, with it [the mobile documentation tool], it can take 45-50 minutes. We carry a lot of equipment during home care visits, including a laptop, and it can be heavy. The iPad is an additional weight.* [Nurse 1]

> *Because we cannot do everything we need in the [mobile documentation] tool, it kind of doubles the work for us.* [Nurse 4]

Among users of the mobile preconsultation form, participants highlighted several advantages, including knowing the patient's medical concerns in advance and saving time on preparations. This previsit work done by patients reduced the administrative workload on HCPs, allowing for a more efficient use of consultation time.

Standardizing documentation through the mobile documentation tool and preconsultation form may lead to more consistent and thorough patient assessments across different HCPs. This standardization ensures that all relevant information is captured systematically, potentially improving the continuity of care and reducing the risk of overlooking critical patient data.

The use of eHealth tools in advanced home care led to *better documentation practices while enhancing patient safety*. The majority (13/20, 65%) of the participants found the standardized content of the mobile documentation tool beneficial, noting that it ensured they would not overlook critical information:

> *It is kind of nice that the [mobile documentation] tool has a lot of information that can help with taking notes. Also, the setup is the same for everyone, so I think the note-taking is sort of standardized.* [Nurse 1]

This standardized approach to documentation not only improved consistency across different HCPs but also potentially enhanced the quality of patient care. By ensuring comprehensive data collection, the tool might lead to more informed clinical decision-making and improved continuity of care. The structured format guided HCPs through specific assessment points, helping to ensure that all relevant aspects of patient care were addressed during consultations. Improved documentation through eHealth tools contributed to patient safety and security. Participants noted that accurate information recorded in EHRs reassures patients, helping them feel more secure in their care:

> *When we use [the mobile documentation tool], we can check the necessary things we have to ask the patient. We will not forget anything because we have a guide, I think that is good for the patient...it can increase patient security.* [Nurse 13]

> *I think they [patients] feel safer when I can write everything in the [mobile documentation] tool while I am with them, and they can check what I write.* [Nurse 8]

The ability for patients to review clinical notes during consultations further enhanced their confidence, fostering a sense of transparency in the health care process and further strengthening the relationship. This aligned with the principle of "equal care" in Sweden, which emphasizes the importance of providing consistent quality care to all patients, regardless of their location or the HCPs they encounter [31].

By standardizing documentation practices, eHealth tools contributed to this principle by ensuring that all relevant patient information is consistently captured and accessible to different HCPs. This standardization not only improved continuity of care but also enhanced trust between patients and HCPs. The structured format of the mobile documentation tool facilitated comprehensive data collection, allowing HCPs to focus on critical issues during consultations. This approach optimized patient interactions and strengthened the overall quality of care provided, aligning with Sweden's commitment to equitable health care access.

Interactions Between HCPs and Patients

All (20/20, 100%) participants indicated that their *relationship with patients remained unaffected* by the implementation of both the mobile documentation tool and the mobile preconsultation form. This finding suggested that HCPs were able to maintain their interpersonal skills and patient-centered approach while integrating eHealth tools into their practice:

> *I think nothing has changed in how I interact with patients when using it [the mobile documentation tool].* [Nurse 5]

The consistency in relationships despite introducing new technology highlighted the adaptability of HCPs in maintaining effective communication with patients. While the eHealth tools introduced new elements to patient interactions, such as the physical presence of devices, HCPs appeared to successfully navigate these changes without compromising the quality of their patient relationships. Furthermore, the mobile preconsultation form may have enhanced patient engagement by allowing patients to provide more comprehensive information before consultations. This previsit work could potentially lead to more focused and in-depth discussions during face-to-face interactions, without negatively impacting the HCP-patient relationship.

The mobile preconsultation form emerged as a tool that potentially *enhances patient engagement* in their care. Some (3/12, 25%) participants noted that certain patients provided more comprehensive information through written responses on the mobile preconsultation form than during face-to-face interactions with the HCPs. This suggested that the tool may lead to more informed and collaborative interactions during consultations:

> *If you send out the form, I think you can get more information from the patients because they [patients] have more time to think about it rather than when we ask them in person.* [Nurse 7]

The previsit work done by patients allowed them to elaborate on both current problems and positive aspects of their health status. This more comprehensive written information might shift the dynamics of face-to-face interactions, potentially allowing more focused and in-depth discussions during consultations. Furthermore, the mobile preconsultation form's ability to highlight patients' medical concerns in advance

XSL•FO
RenderX

enabled HCPs to prepare more effectively for consultations. This preparation may contribute to more efficient and patient-centered interactions, as evidenced by one participant's comment:

> *We send out the form once every four weeks for when we do the team rounds, it can help us in doing the team rounds, making it faster and more efficient, in my experience.* [Nurse 5]

By facilitating more comprehensive information gathering and allowing HCPs to focus on critical issues, the mobile preconsultation form may enhance patient engagement and potentially improve the quality of HCP-patient interactions in advanced home care settings.

Participants mentioned *communication barrier* as a challenge. While the eHealth tools offered numerous benefits, 20% (4/20) of the participants observed noted challenges in their use during patient interactions. These HCPs noted that the iPad (mobile documentation tool) could sometimes be a barrier to effective communication:

> *When I am holding the iPad in front of the patient, it kind of becomes a barrier between us.* [Nurse 6]

> *When using the iPad, you tend to look down instead of looking at the patient directly.* [Nurse 9]

> *Maybe some patients find it rude [using an iPad during consultation], but most of them understand that we do it to get everything right. Also, I think sometimes I have a less open conversation with patients.* [Nurse 10]

Most (16/20, 80%) participants did not report communication issues, suggesting that the majority of HCPs were able to integrate the eHealth tools without significant impact on patient interactions. Compared to traditional pen-and-paper methods, the eHealth tool presented both advantages and challenges for patient-HCP communication. While pen-and-paper notes may feel less intrusive during patient interactions, the eHealth tool offers improved legibility, standardization, and ease of data retrieval, potentially enhancing the quality of information shared with patients. However, the physical presence of the device could create a perceived barrier for some HCPs and patients. The eHealth tool's structured format ensures comprehensive documentation, potentially reducing the risk of omitting crucial information compared to freeform paper notes. This standardization may lead to more consistent and thorough patient assessments across different HCPs, indirectly benefiting patient care and communication. However, this structure might sometimes limit the flexibility in capturing nuanced patient narratives.

Regarding focus on issues and medical decision-making, the eHealth tool's ability to provide instant access to patient history and standardized assessments can potentially enhance HCP's ability to focus on critical issues during patient interactions. However, as noted by some participants, the tool might occasionally divert attention from direct patient interaction. These observations highlighted the need for balanced use of eHealth tools, combining their benefits with maintaining effective patient communication. HCPs may need to develop strategies to integrate these tools seamlessly into their patient interactions, ensuring that technology enhances rather than hinders the HCP-patient relationship.

Challenges and Difficulties With the eHealth Tools

While most (14/20, 70%) participants reported no technical issues, some HCPs encountered *technical and resource challenges* when using eHealth tools in advanced home care. Specifically, 30% (6/20) of the participants faced technical problems with the mobile documentation tool, including log-in difficulties, frequent software updates, and issues importing clinical notes to the patient's EHR:

> *First, when you come in to work, you have to log in to the [mobile documentation tool]. Sometimes, it's a problem. Now, with the frequent updates—they do updates like every week—there is often something wrong after each update...* [Nurse 3]

Notably, 100% (12/12) of the participants who used the mobile preconsultation form reported no technical issues at all. Resource limitations were a more widespread concern. All (20/20, 100%) participants noted the need to share iPads among staff members, potentially limiting access and flexibility in documentation:

> *The staff has to share iPads [with the mobile documentation tool] within the team.* [Nurse 9]

These challenges highlighted the importance of robust IT infrastructure and adequate resource allocation in eHealth implementation. While technical issues affected only a minority (6/20, 30%) of users, device sharing impacted all (20/20, 100%) participants, potentially influencing HCP efficiency and, consequently, patient care quality.

Patient-related factors, such as patient characteristics, influenced the adoption and use of eHealth tools in advanced home care. Approximately 55% (11/20) of the participants noted that the patient's age and health conditions affected receptiveness to eHealth tools, particularly the mobile preconsultation form:

> *Not all patients are open to using the [mobile preconsultation] form. Usually, older patients or those with difficult diseases are not open to it.* [Nurse 12]

HCPs demonstrated adaptability by adjusting their approach based on patient characteristics. This flexibility was crucial for maintaining quality care across diverse patient populations. However, it also raised concerns about potential disparities in care delivery between technologically proficient patients and those less comfortable with eHealth tools. Some patients expressed skepticism about using the mobile preconsultation form, particularly due to privacy concerns:

> *There are patients who are skeptical about using it [the mobile preconsultation form], as it involves using their [personal information] BankID [a Swedish electronic identification system].* [Nurse 11]

On the other hand, a subset of patients, predominantly younger individuals, demonstrated an openness to using eHealth tools, according to 55% (11/20) of the participants. This varying receptiveness highlighted the need for a personalized approach in implementing eHealth tools in advanced home care settings,

XSL•FO
RenderX

ensuring that all patients receive appropriate care regardless of their technological proficiency.

Streamlining Implementation and Advancing eHealth Tools for Future Health Care Delivery

Integration Into the Daily Workflow

Regarding *ease of use*, 75% (15/20) of the participants found the mobile documentation tool easy to use. The initial introduction and demonstration of these eHealth tools to HCPs lasted an hour and was perceived as sufficient by all the 12 (12/12, 100%) participants who received it. Some (4/20, 20%) participants had the opportunity to familiarize themselves with the tool beforehand as part of the implementation team, while 12 (12/20, 60%) participants received information during introductory seminars at their clinics. Some (4/20, 20%) participants only underwent introductory training after using the mobile documentation tool:

> *I have tried it [the mobile documentation tool], honestly, without any training... I tried to use it... I think it is easy.* [Assistant Nurse 2]

> *My colleague taught me how to use it [the mobile documentation tool].* [Nurse 8]

In addition, 25% (5/20) of the participants reported that the log-in process and navigating through all the components of the mobile documentation tool required some time to become familiar with, but they gradually improved with more use:

> *As I continue to use it [the mobile documentation tool], I learn more about it, which makes me better at using it.* [Nurse 2]

Regarding *system integration and adaption* all (20/20, 100%) participants highlighted challenges in integrating eHealth tools into existing systems and their practical *application* in advanced home care. A key limitation was the incomplete integration of the mobile documentation tool with the existing EHR system, TakeCare. While clinical notes could be uploaded to the patient's journal, other crucial data remained inaccessible through the mobile tool, requiring staff to rely on computers for a complete view of patient information:

> *It [the mobile documentation tool] doesn't have all the functions that you have in the EHR.* [Nurse 7]

> *[B]ecause with the computer, I can do and see everything on the patient's EHR, but not with the iPad.* [Nurse 4]

The lack of full system integration disrupted seamless workflows and raised concerns about potential inconsistencies in documentation and delays in accessing critical information during consultations. Participants expressed a strong desire for improved interoperability to ensure that all necessary data are accessible on the mobile device.

Regarding practical application, HCPs generally found the mobile preconsultation form useful for integrating into their existing workflows. However, its applicability was perceived as limited for certain patient groups and care scenarios. For example, HCPs noted that sending the form before every consultation was unnecessary for patients with chronic conditions requiring long-term care as their primary clinical concerns often remained consistent:

> *For example, I have had this patient for a very long time, and the patient has a chronic condition. I don't need to send the form [before] every visit because the status is still the same.* [Nurse 11]

Despite these limitations, participants acknowledged the value of the preconsultation form for new patients or those with changing health conditions. It allowed HCPs to gather detailed information in advance, facilitating more focused consultations. These findings underscored the importance of improving system integration to enhance workflow efficiency while adapting eHealth tools to meet diverse patient needs in advanced home care settings.

Future Directions

HCPs shared *recommendations* on enhancing the effectiveness of the eHealth tools in their daily workflow in advanced home care. Most (16/20, 80%) participants expressed that completely integrating the mobile documentation tool with the patient's EHR system would improve efficiency. They suggested that accessing the same information as in the patient's EHR directly on the mobile device would eliminate the need to switch between the iPad and the computer for clinical documentation, improving their workflow:

> *Lab results and checking off the to-do list, that is what is still missing, I think...and an easier login.* [Nurse 9]

All (12/12, 100%) HCPs who used the mobile preconsultation form found it adequate. However, 17% (2/12) of the participants suggested further enhancements to the interface, including languages other than Swedish:

> *The [mobile preconsultation] form does not look very good, in my opinion. It can be better.* [Nurse 11]

Regarding equipment use, half (10/20, 50%) of the participants expressed that having sufficient iPads for all staff members would be advantageous, reducing the need for frequent logging in and out.

Approximately two-thirds (14/20, 70%) of participants anticipated *continuity of use* of the 2 eHealth tools in advanced home care, acknowledging the emergence of the new technologies. In addition, 45% (9/20) of the HCPs expressed optimism regarding the increased patient acceptance of technology in health care:

> *I think they [patients] will use them [eHealth tools] more and more in the future.* [Nurse 7]

Discussion

Principal Findings

The aim of this study was to explore HCPs' perspectives on using eHealth tools in advanced home care and their impact on HCP-patient relationships. In total, 20 HCPs from 9 different advanced home care clinics participated in the interviews, leading to the identification of five categories: (1) positive experiences and benefits, (2) interactions between HCPs and

XSL•FO
RenderX

patients, (3) challenges and difficulties with the eHealth tool, (4) integration into the daily workflow, and (5) future directions.

Overall, most (13/20, 65%) HCPs expressed a positive perspective regarding the 2 eHealth tools used in the study: the mobile documentation tool and the mobile preconsultation form. The results showed that HCPs identified several benefits for themselves and their patients. Notably, 65% (13/20) of the participants reported that the mobile documentation tool allowed them to document directly during patient encounters, eliminating double documentation and saving time. Standardized templates within the tool ensured consistency in clinical note-taking, which participants believed enhanced patient safety by reducing errors and omissions.

While most (13/20, 65%) HCPs reported increased efficiency, 35% (7/20) experienced the opposite, suggesting that user acceptance of eHealth is multifaceted. These participants reported that the mobile documentation tool disrupted their routine workflow by prolonging consultation times and adding to their equipment load during home care visits. This highlights the importance of considering individual user experiences in eHealth implementation. The ease of use of the eHealth tools was a significant factor in their integration into daily workflows. Most (15/20, 75%) of the participants found the mobile documentation tool easy to use, indicating successful integration. This high level of usability likely contributed to the overall positive reception of the tools and suggested that well-designed eHealth solutions can be effectively adopted in advanced home care settings.

However, HCPs noted challenges, both tool-related and patient-related. Some (6/20, 30%) of the participants faced technical problems with the mobile documentation tool, including log-in difficulties and issues importing clinical notes to the EHR. These technical challenges highlight the need for robust IT infrastructure and ongoing technical support in eHealth implementation. Resource limitations were a widespread concern, with all participants noting the need to share iPads among staff members. This sharing potentially limits access and flexibility in documentation, impacting workflow efficiency. Future eHealth implementations should consider resource allocation to ensure adequate device availability for all HCPs.

Patient characteristics influenced the adoption of eHealth tools, particularly the mobile preconsultation form. Approximately 55% (11/20) of the participants noted that patient age and health conditions affected receptiveness to these tools. This finding underscores the importance of tailoring eHealth implementations to diverse patient populations and considering alternative approaches for patients less comfortable with technology. The mobile preconsultation form emerged as a tool that potentially enhances patient engagement. Some (3/12, 25%) of the participants using this tool noted that certain patients provide more comprehensive information through written responses than face-to-face interactions with HCPs. This previsit work allows for more focused and efficient consultations, potentially improving the quality of HCP-patient interactions.

Regarding the HCP-patient relationship, all (20/20, 100%) participants reported that the use of eHealth tools had no significant impact on the relationship with patients. This suggests that HCPs successfully maintained their interpersonal skills and patient-centered approach despite introducing new technology. However, 20% (4/20) of the participants noted that using devices such as iPads could occasionally act as a communication barrier during consultations, highlighting the need for strategies to seamlessly integrate technology into patient interactions.

Looking to the future, 70% (14/20) of the participants anticipated continued use of the eHealth tools in advanced home care, reflecting their perceived long-term value despite existing challenges. In addition, 45% (9/20) of the HCPs expressed optimism about increased patient acceptance of technology in health care. While participants did not report changes in HCP-patient interactions, they emphasized that current eHealth tools successfully maintain existing relationships without negatively impacting communication or rapport.

Comparison With Prior Work

Mathijssen et al [32] highlighted a similar finding of positive perception of eHealth by HCPs in home care. Despite recognized challenges such as inadequate training and support, data privacy concerns, and the necessity for more user-friendly technology, eHealth in home care is seen as a promise to enhance care quality. A study focusing on a specific eHealth tool, electronic medication administration records, emphasized the importance of cautious implementation due to potential unintended consequences [33]. Participants noted that the electronic medication administration records introduced new tasks alongside existing nursing tasks. In contrast, our study found no perceived changes in the workflow or work situation due to eHealth tools, potentially contributing to their overall positive reception.

Carlqvist et al [34] conducted a qualitative interview study examining how an eHealth application can serve as a value-creating resource from the perspective of HCPs. Their findings indicated that while such applications can enhance proactive communication and support patient engagement in self-care, challenges remain. Notably, patients' difficulties in using the application or performing measurements sometimes led to value destruction, requiring time-consuming recovery efforts by professionals. This contrasts with our study, where HCPs reported no significant workflow disruptions due to eHealth tools, potentially contributing to their positive acceptance.

Nakrem et al [35] explored the introduction of digital medicine dispensers in home health care services and their influence on patient-caregiver relationships. They found that while such technologies can improve efficiency and enhance patient independence, they may also strain patient-caregiver relationships if not aligned with patients' needs and safety concerns. However, in our study, HCPs did not perceive eHealth tools as affecting their relationships with patients, suggesting that the specific type of technology and its implementation context play crucial roles in acceptance and impact.

Furthermore, Ramachandran et al [36] conducted a review examining the impact of eHealth on patient-HCP and HCP-HCP relationships in primary care. They found that eHealth can have

XSL•FO
RenderX

both positive and negative effects on relationships and trust, influenced by factors, such as technology design, patient demographics, and organizational implementation strategies. This aligns with our findings, where the successful integration of eHealth tools without perceived workflow disruptions may be attributed to effective implementation strategies and user-centered design.

Future Research

Future studies could explore strategies for seamlessly integrating eHealth tools into patient interactions without compromising communication quality. In addition, research into personalized eHealth solutions that accommodate diverse patient needs and preferences could address challenges related to patient characteristics. Investigating the long-term impacts of eHealth tools on care quality, patient outcomes, HCP-patient relationships, and HCP job satisfaction would provide valuable insights for future implementations.

Another important area for investigation is the development and implementation of features that actively enhance HCP-patient relationships in advanced home care environments. For instance, improving patient education modules or creating shared decision-making tools tailored to home care settings could address some of the gaps identified in this study, such as maintaining meaningful interactions while using eHealth tools.

Furthermore, exploring the role of relatives in supporting patients with eHealth tools could offer new avenues for enhancing patient engagement and care delivery [37]. Relatives could assist with completing preconsultation forms or managing digital tools for patients who face challenges due to age or health conditions. Recognizing relatives as key stakeholders alongside HCPs may improve overall patient support in advanced home care settings [38].

Limitations

This study focused specifically on advanced home care settings in Sweden, which may limit the applicability of findings to other health care contexts. The unique characteristics of advanced home care, such as the need for mobile documentation and remote patient monitoring, shaped the experiences reported by HCPs. In addition, the exclusive focus on HCPs' interviews represents another limitation. Incorporating patients' perspectives could offer valuable insights and contribute to a more comprehensive understanding of the implementation of eHealth tools in advanced home care.

Conclusions

HCPs in advanced home care recognize the value of eHealth tools in their daily work while maintaining the quality of their relationships with patients. The study provides insights into both the experiences of HCPs using eHealth tools and how these tools influence their interactions with patients in advanced home care settings. Positive experiences related to eHealth use and the level of integration of eHealth tools into daily work motivate staff to use these tools, potentially allowing for more time and focus on patient interactions. By contrast, negative experiences with the eHealth tools limit their use and acceptance.

Notably, HCPs reported no perceived changes in their relationships with patients when using the mobile documentation tool and the preconsultation form tool. This suggests that eHealth tools can be integrated into care delivery without compromising the personal aspect of HCP-patient interactions. Although most of the staff in the study had a positive view of their use of the eHealth tools, understanding the challenges they encounter is essential to increase acceptance and success in implementation further. Future development should focus on features that not only improve efficiency but also actively enhance HCP-patient relationships in the advanced home care setting.

Acknowledgments

The authors would like to thank all the health care staff members who participated in this study for their time and valuable insights. Artificial intelligence was used for writing assistance. ND was funded by the Health Informatics Center at Karolinska Institutet. The funding did not influence the study's design, data collection, analysis, or manuscript writing.

Authors' Contributions

EVR, ND, and UL participated in the study design. Data collection was conducted by EVR. EVR performed the initial analysis, which was then reviewed and refined through discussions with ND. The first draft of the manuscript was prepared by EVR, with all authors contributing to subsequent writing and review processes.

Conflicts of Interest

During this study, UL was employed by the medical technology company providing the eHealth tool. Therefore, UL did not participate in the data collection, analysis, and manuscript writing of the study and was limited to the initial part of the design phase and preparing and reviewing the manuscript.

Abstract

Background: The rapid advancement of next-generation sequencing has significantly expanded the landscape of precision medicine. However, health care professionals face increasing challenges in keeping pace with the growing body of oncological knowledge and integrating it effectively into clinical workflows. Precision oncology decision support (PODS) tools aim to assist clinicians in navigating this complexity, yet their current functionalities only partially address clinical needs. A lack of comprehensive needs assessment may result in unaddressed requirements, limiting the effectiveness of these tools in real-world practice.

Objective: This study aimed to explore clinicians' needs and expectations regarding the functionalities of integrated PODS tools, providing insights into essential features that could enhance their usability and impact.

Methods: We conducted a qualitative investigation at Peking University Cancer Hospital to explore clinicians' needs and expectations for the functions of integrated PODS tools. Data were collected through 143 structured participant observations during multidisciplinary team meetings and 17 in-depth semistructured interviews with a diverse group of oncology specialists, including physicians, surgeons, molecular biologists, radiotherapists, radiologists, and pathologists. Thematic analysis was applied to identify key functional requirements, and a requirements framework was formed.

Results: Three overarching functional needs emerged: (1) better access to oncological knowledge, including support for therapy selection (guidelines, conferences, and consensuses), clinical trials, drug and treatment information, and complex case knowledge, as well as improved diagnostic and prognostic insights; (2) clinical contextualization and resource navigation, referring to the process of contextualizing scientific knowledge within real-world clinical settings, including access to clinical trials and drugs, along with predictive models for treatment response; and (3) support abilities in the decision-making process, highlighting the need for integration of flexible biological knowledge and phenotypic data; automated patient information synthesis; improved data visualization; and optimized retrieval, recommendation, and question-answering functionalities. A functional framework for integrated PODS tools was proposed based on these findings.

XSL•FO
RenderX

Conclusions: The study conducted a qualitative descriptive observation and interview in the use, needs of integrated PODS tools. PODS tools serve as complex, multilevel decision support systems. A clear understanding of clinicians' actual needs is crucial for their refinement and practical adoption. By capturing perspectives directly from oncology professionals, this study provides actionable insights into the functional enhancements required for PODS tools, ultimately aiming to bridge the gap between genomic advancements and clinical decision-making in precision oncology.

Introduction

Background

Advancements in next-generation sequencing have paralleled the rise of precision oncology, leading to the discovery of numerous diagnostic biomarkers for cancer and the approval of many targeted drugs by regulatory authorities, such as the US Food and Drug Administration, European Medicines Agency, and National Medical Products Administration, as well as recommendations by prestigious organizations such as the National Comprehensive Cancer Network), European Society for Medical Oncology, and Chinese Society of Clinical Oncology (eg, tepotinib [1] and sunvozertinib [2]). Despite this progress, health care professionals face challenges in keeping pace with these advancements and determining the most effective treatment strategies, as well as handling complex genomic information, such as regularly updating information and understanding the clinical significance of genomic alterations [3].

Currently, clinicians mainly rely on genetic testing reports to acquire the genomic profile of patients with cancer and to understand the clinical significance of certain genetic variants [4]. With rapidly growing knowledge of precision oncology, the content of genetic testing reports has greatly expanded, which also brings the problem of inconvenience in reading and searching [5]. Moreover, the heavy clinical workload significantly limits the time available to review the full contents of genetic testing reports [6]. A fast and effective way to display comprehensive genomic information may help clinicians locate the needed information easily [7].

Under these circumstances, computer-based interactive precision oncology decision support (PODS) tools have emerged. In oncology, tools with high interactivity and interoperability, such as knowledge and clinical trial (CT) databases [8-10], therapy recommendation engines [11], literature search tools [12], and predictive algorithm–based models [13], have been developed and are anticipated as valuable resources for facilitating the timely update and informed interpretation of genomic data from bioinformatics research to clinical statistical analysis [14-17]. The literature has described the properties, opportunities, and future effects of these tools [18,19].

However, it should be noted that although these tools may bring broad prospects in oncology research, they may not fully meet the needs of practical clinical application [20]. There are already systems integrating some of these functions of PODS tools for clinicians [21,22], but 2 key issues of current clinician-oriented PODS tools remain unclear.

The first issue is that clinician-oriented PODS functions are scattered across different tools. When somatic mutations and germline variants were detected in patients with cancer, to make a more appropriate and individualized treatment plan based on the patients' genomic profile, some functions, such as (1) whether these variants are pathogenic or oncogenic [23], (2) how they are involved in tumorigenesis and cancer progression [24,25], (3) what their biological functions and clinical significance are [26,27], (4) to what extent they potentially affect the patients' diagnosis and treatment [28], and (5) whether they will influence the choice of certain therapeutic strategy or clinical management, may be clinicians' interests [29-32]. However, currently, a single available knowledge base could only meet 1 or 2 aspects of the abovementioned clinical requirements. To answer all these questions, clinicians must search in multiple knowledge bases using various search engines to achieve 1 goal, as different evidence may be scattered across diverse databases [33]. Such a process of switching tools normally costs a large amount of time with limited achievement.

The second issue is that some clinician needs regarding PODS tools remain unclear. Clinicians from different specialties may require different PODS functions, and while some commonalities could be found through needs analysis, the current lack of need analysis results in current PODS tools not yet meeting all practical requirements from clinicians. This fact restrains the clinical implementation of PODS tools and underestimates the clinical value of genomic data from patients with cancer [7]. Moreover, the lack of need analysis exposes the problem that there is currently no appropriate evaluation metric for the measurement of the quality of developing such metrics for PODS tools [34].

Objectives

This study aimed to explore clinicians' perceptions of functional needs in PODS tools. It also seeks to identify the existing urgent needs not met by current tools and outline a functional need framework for PODS tools.

Methods

Study Design and Theoretical Framework

This qualitative descriptive study, informed by a naturalistic perspective and grounded theory [35,36], investigates how clinicians use PODS tools in multidisciplinary teams (MDTs)

XSL•FO
RenderX

and routine clinical practice. Comprising experts such as molecular biologists, physicians, surgeons, radiotherapists, radiologists, pathologists, and specialists from other departments (Table 1), MDT plays a crucial role in integrating clinical data and molecular profiling to tailor targeted therapies [37-39]. In routine clinical practice, such as in outpatient services, clinicians see many patients with simple to complex medical conditions. When the course of disease and treatments has either no clinical guideline to be followed or lacks evidence to support standard treatments, the case is raised for discussion in an MDT. Therefore, structured observation of MDT discussion was selected to investigate the need for PODS tools for clinicians and to propose elements for a framework of PODS tools. These elements were then validated and further verified by in-depth semistructured interviews, which might not only reflect the perspective of clinicians and quickly capture their views as a complement to objective observation but also constantly explore the deep reasons behind the ideas for unclear clinical requirements.

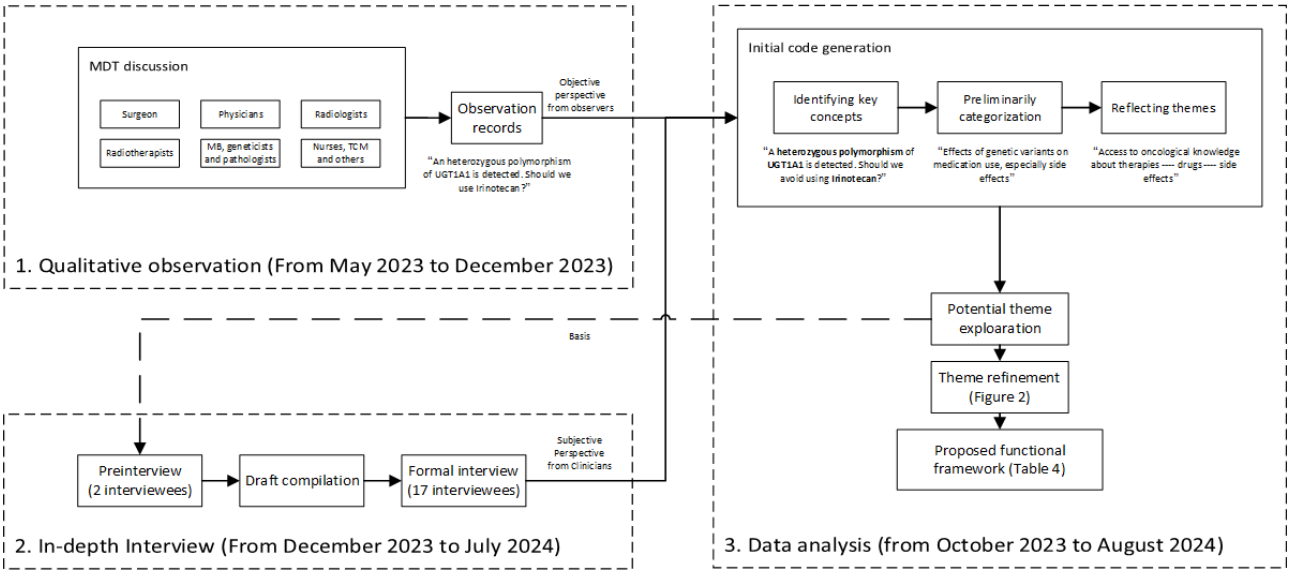
The study adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [40]. Conducted from June 2023 to June 2024, the study used a multiple qualitative approach, combining structured participant observation and in-depth semistructured interviews to comprehensively assess the use and integration requirements of PODS tools [41].

Setting and Data Collection



Structured participant observations and in-depth semistructured interviews were conducted at Peking University Cancer Hospital (PUCH). Participant observation data were collected during MDT meetings held by the Thoracic Oncology Center and Gastrointestinal Oncology Center; these meetings occurred weekly and involved large discussion groups, with an average of 19.92 (SD 5.51) participants per session.

The process of the research could be divided into 3 parts: qualitative observation, in-depth semistructured interview, and data analysis (Figure 1). MDT principals and interviewees all signed informed consent. Interviewees were selected using sampling theory and snowball sampling [42], based on the following criteria: (1) holding a medical certificate, (2) working in tumor-related clinical practice, (3) participating in MDTs, and (4) having experience using PODS tools or having heard of or observed the operation of PODS tools. Data saturation was defined as the point at which <5% of the total codes were new across 3 consecutive MDT observations. Snowball sampling

XSL•FO
RenderX

was terminated when no new codes or ideas emerged from the 2 most recent interviews. Each interview took place at the clinicians' lounge.

Figure 1. The process of the research. MB: molecular biologist; MDT: multidisciplinary team; TCM: traditional Chinese medicine.

Qualitative Structured Participant Observation

From May to December 2023, 2 team members, SZ and YF, observed MDTs at the Thoracic Oncology Center and Gastrointestinal Oncology Center. YF participated fully in MDT discussions as a member of the Molecular Diagnostic Center (MDC) and a participant-as-observer, while SZ, a doctoral candidate in medical informatics trained in qualitative research, took part as an observer-as-participant. The combination of the 2 observers balanced the perspectives of both clinical practice and informatics. SZ made preliminary records of the observations (Multimedia Appendix 1 [43-45]), and these records were subsequently refined in collaboration with YF. The MDT at PUCH can be divided into three parts: (1) patient information preparation before the MDT (*preparation*), (2) patient information briefing during the MDT (*briefing*), and (3) multidisciplinary discussion (*discussion*). The observation of this research mainly focused on the discussion part, which was recorded in detail to identify PODS needs related to genomic interpretation, diagnosis, therapeutic recommendation, and possible functional requirements of PODS tools that emerged during the discussion (a description of the phenomena, the process of MDTs, and detailed observation of the other 2 parts are provided in Multimedia Appendix 1). To ensure methodological rigor, we implemented a data saturation verification protocol. For proactive monitoring, we tracked emerging codes through real-time coding logs during observations and conducted weekly codebook audits using NVivo's (Lumivero) code frequency matrices to ensure that it achieved semantic saturation [46]. The slides presented during MDTs were obtained after the meeting to refine the records. The team observed 26 Thoracic Oncology Center MDTs (86 records) and 20 Gastrointestinal Oncology Center MDTs (57 records), with each session lasting approximately 35 minutes on average.

In-Depth Semistructured Interview

Semistructured, in-depth qualitative interviews were conducted from December 2023 to July 2024 by SZ and YF, with SZ serving as the main interviewer and having no prior interaction with the participants. YF, a colleague of the interviewees, assisted SZ in refining and complementing questions. The semistructured interview questions were developed based on the potential themes that emerged from the initially coded observation record data. Before the formal interview, 2 interviewees were invited to the preinterview session, during which the draft interview guide was compiled based on the initial coding of the qualitative observation records. Both interviewers maintained reflexive journals to document emergent assumptions and field observations. The formal interview guide was later standardized to focus on clinicians' use of genetic test reports and their needs and expectations for PODS tools (Multimedia Appendix 1). Clinicians were encouraged to provide additional perspectives on PODS and to share their experiences using PODS tools through open-ended questions during the interview. After each interview, potential themes were extracted. If data saturation had not been reached, additional interviewees were recruited. The demographic details are summarized subsequently. The interviews were conducted in Chinese, audiotaped with a digital recorder, transcribed verbatim, and edited by SZ. A total of 12 hours of individual interviews were transcribed, resulting in approximately 48,000 words. The interviews lasted approximately 40 (range 26-70) minutes.

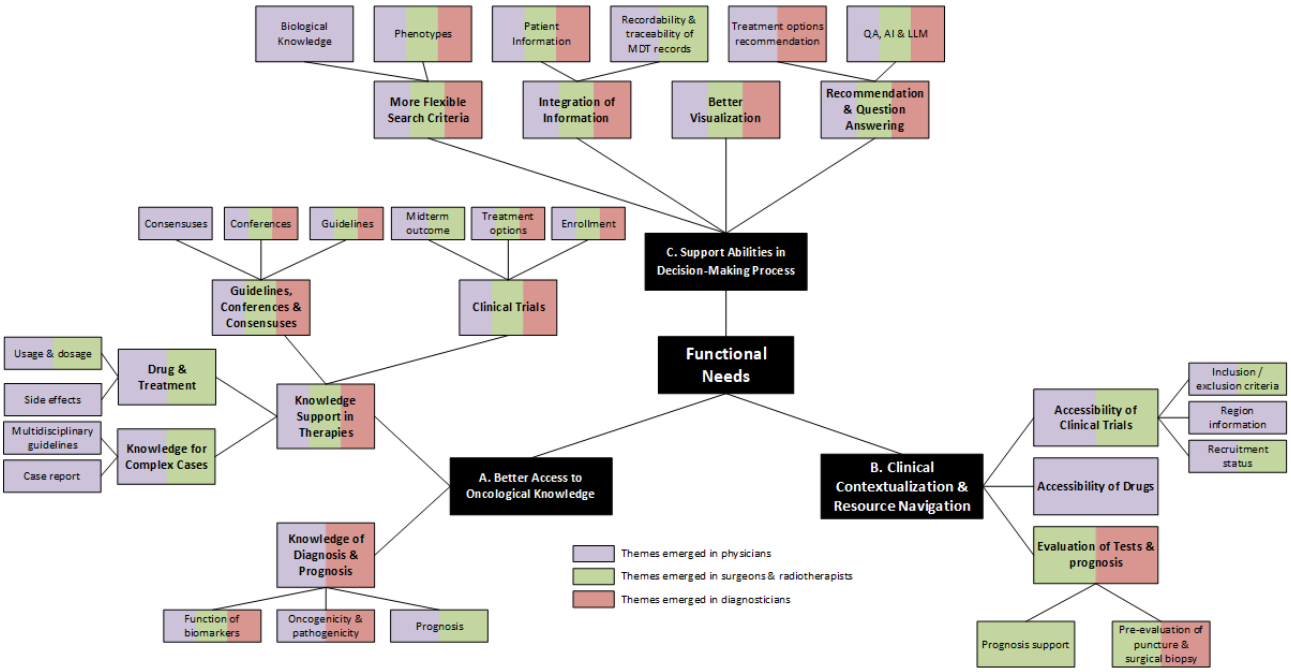
Data Analysis

The observation and interview data were thematically analyzed following the reflexive thematic analysis by Braun and Clark [47], which includes familiarization with the data, generating initial codes, exploring potential themes, reviewing themes, defining and refining themes, and finalizing findings. The data analysis was divided into 2 steps. Between the observation and interview phases, the observation record data were initially

XSL•FO
RenderX

coded, and the potential themes that emerged formed the basis of the interview. After each interview, the themes explored in the interview were compared with the initial potential themes as a form of constant comparison and validation [38]. This was considered part of the review process. Subsequently, the 2 classes of themes were combined and refined. The functional framework of PODS tools was extracted through the themes and concluded through a team discussion. The interviewees were invited to confirm whether their perspectives were fully represented during the construction of the framework. NVivo 14 software was used for the analysis, with coding performed by SZ and reviewed by YF. Cohen κ was calculated to confirm strong coding consistency. Discrepancies were resolved through team discussions.

Ethical Considerations



The study received ethics approval from the ethics committee of PUCH (2023KT35). Informed consent was obtained from all interview participants for both the interviews and the secondary analysis of the interview data. All observation and interview data were recorded anonymously. The interviewees received a small thank-you gift of approximately CNY ¥50 (US $7.00) after the interview.

Results

Qualitative Observation and Interviewee Characteristics

A total of 46 MDT discussions were qualitatively observed, involving treatment decisions for 143 patients (Table 1). For the 46 MDT observations, saturation was reached by the 41st MDT, and no new codes emerged in the 45th and 46th MDT (Figure S1 in Multimedia Appendix 1). After 6 months of observation, the research team began the first round of exploring potential themes. Potential needs for PODS tools emerged from our observations (Tables S2-S6 in Multimedia Appendix 1), which were refined and validated by the in-depth semistructured interviews and further constructed into the themes of functional needs in PODS (Figure 2). The MDT in the Thoracic Oncology Center had significantly more detailed information and longer discussion times for genetic testing and personalized targeted therapy compared to the MDT in the Gastrointestinal Oncology Center. In addition, the use of PODS tools was more prevalent in the Thoracic Oncology Center.

Figure 2. The 3 key themes emerging from the qualitative observation and interviews: (1) better access to oncological knowledge: clinicians emphasized the importance of precision oncology decision support (PODS) tools in facilitating access to high-level precision medicine evidence, including guidelines, treatment information (eg, use, dosage, and side effects), clinical trials, multidisciplinary guidelines, and case reports; (2) clinical contextualization and resource navigation: PODS tools aim to integrate fragmented clinical information, such as trial eligibility, drug accessibility, and evaluation models, enabling clinical contextualization and resource navigation for practical application; (3) support abilities in the decision-making process: clinicians anticipated that the PODS design would enhance decision-making efficiency. They also highlighted advancements in information systems, including user-friendly interfaces, enhanced search functions, chatbots, and large language model applications, as key features to improve workflow and clinical decision-making. AI: artificial intelligence; LLM: large language model; QA: question answering.

On the basis of these findings, we focused our interviews with clinicians in the Thoracic Oncology Center on their use of PODS tools. We also conducted interviews with clinicians from the Radiotherapy Department and the MDC.

A total of 17 clinicians participated in in-depth semistructured interviews (Table 2). For the 17 interviews, saturation was achieved by interview 15, with no new codes appearing in interviews 16 and 17 (Figure S2 in Multimedia Appendix 1). All 17 clinicians had experience using genetic testing reports, while 59% (n=10) had personal experience using at least 1 interactive PODS tool. However, all 17 clinicians had heard of or observed the use of PODS tools. The potential needs were screened and confirmed during the interview. After data

XSL•FO
RenderX

analysis, 3 themes emerged from our observations and interviews (Figure 2; Figures S3 and S4 in Multimedia Appendix 1; and Tables S2-S6 in Multimedia Appendix 1). Themes that emerged from the interview data and were organized by knowledge, feasibility, and support ability levels are described subsequently and presented in Table 3. From these 3 themes, the functional framework of integrated PODS tools is described in detail in the subsequent sections.

Table 2. Characteristics of the interviewees (N=17)[a].

Characteristics	Interviewees, n (%)
Sex	
Male	10 (59)
Female	7 (41)
Years of working	
<10	6 (35)
10-20	8 (47)
>20	3 (18)
Clinical duty	
Physician	9 (53)
Surgeon	5 (29)
Molecular biologist	2 (12)
Radiotherapist	1 (6)
Professional title	
Chief	2 (12)
Associate chief (deputy chief)	7 (41)
Attending chief (supervising)	5 (29)
Attending	3 (18)
Preparer	6 (41)
Had used at least 1 PODS[b] tool	10 (59)

[a]The characteristic “preparer” refers to a role in the multidisciplinary team, responsible for collecting patient information, preparing multidisciplinary team briefing slides, and presenting the information during the meeting. Further description of the preparer is provided in Multimedia Appendix 1.

[b]PODS: precision oncology decision support.

Table 3. Sources of themes from key informants, translated into English.

Theme and subtheme	Illustrative quote and quote number
Better access to oncological knowledge	
Knowledge support in therapies	
Guidelines, conferences, and consensuses	• "Before the MDT, Dr. [name] would like to share recent progress of [progress in treatment of specific disease]..." [Observation 008, 028, and 079] (Quote 1) • "The way I get access to the oncological knowledge are usually from WeChat official accounts, going to conferences, and newly updated information shared by peer expertise. Sometimes I also search for literatures or reviews in my spare time...What I'm most interested in is the change of the latest version update guideline, from which I could learn a lot...would be great if there is a notification of the changes..." [005, associate chief physician] (Quote 2) • "We usually discuss the latest progress of conferences before the MDT starts. If PODS tools could notify us this information in our spare time, it would help a lot in summarizing this information for discussion..." [006, associate chief physician] (Quote 3)
Clinical trials	• "About 25-50% of patients in our hospital would require enrollment in CTs...develop a real-time updating CT recommendation tool is the best..." [004, attending physician] (Quote 4) • "...The information in the website of CTs updates frequently...requires us to retrieve and summarize the latest eligibility criteria and enrollment every half month to one month...so time-consuming..." [009, associate chief surgeon] (Quote 5) • "...Latest progresses are often discussed in MDT...not so convenient to check...we want future PODS tools could capture these in real time..." [005, associate chief physician] (Quote 6) • "Before the MDT, Dr. [name] would like to share the midterm result of [progress of specific CT] for us..." [Observation 033 and 082] (Quote 7)
Drugs and treatment options	• "Genetic test reports that vormetinib is effective in LUAD patients with EGFR exon 20 insertion mutation...the descriptions are not particularly clear...we sometimes want to understand the mechanism of drugs..." [003, chief surgeon] (Quote 8) • "Osimertinib, vormetinib and almonertinib are commonly used among the third generation of EGFR-TKIs...there are differences in their use, which requires years of clinical experience...We hope PODS tool will support us in this regard..." [010, attending physician] (Quote 9) • "...Some drugs are needed for four cycles, but some patients' health condition is poor...We want to know whether can I reduce the dosage...sometimes drug suppliers would tell us some information, but that's not enough..." [005, associate chief physician] (Quote 10) • "...The two most common and risky side effects are vomiting and leukopenia...need prompt intervention...if PODS tools could have an alert or reminder function of these side effects, it would help us reduce unnecessary prescriptions to alleviate these side effects..." [001, associate chief physician] (Quote 11)
Knowledge for complex cases	• "...when the patient has other cancers...we would invite colleagues from the corresponding departments for MDT discussion, but it is brief...If we can learn easily from other disciplines, we can make treatment decisions more quickly..." [006, associate chief physician] (Quote 12) • "Today's discussion is about the patient with malignant pleural mesothelioma for whom conventional chemotherapy drugs did not respond...if any doctors have seen relevant case reports?" [Observation 046] (Quote 13)
Knowledge support in diagnosis and prognosis	• "...some colleagues asked me the differences between germline variants and somatic mutations...PODS tools could be a useful way to help my colleagues understand the biological knowledge like this..." [014, supervising molecular biologist] (Quote 14) • "...we sometimes want to know the biological function of molecular alterations, understanding why the alteration happens could better guide us to understand the mechanism of the disease..." [013, associate chief surgeon] (Quote 15) • "...previously encountered a LUAD patient with co-mutations in TP53, RB1, and EGFR...no appropriate standard treatment or diagnosis options but continued observation at the time...an article said that the concurrence of three variants may be induced to small cell cancer transformation, which is an important reference basis to do puncture for diagnosis...hope to have a better mechanism to search evidences..." [011, attending physician] (Quote 16[a]) • "...we often evaluate the prognosis between different therapies, like radiotherapies and targeted therapies...the knowledge of which could help us make decision better..." [017, attending chief radiotherapist] (Quote 17)
Clinical contextualization and resource navigation	

XSL•FO
RenderX

Theme and subtheme	Illustrative quote and quote number
Accessibility of CTs[b]	• "When there is a patient needs to be enrolled, we will look at the inclusion and exclusion criteria in the CTs we have printed (take out some hard copy of CTs) and compare the patient's medical status with the criteria item by item...it is very time consuming...Our CT screening usually follow this sequence: 'First, CTs held in our ward; Second, CTs held in our hospital; Third, CTs held in Beijing's Hospital; Fourth, different places other than Beijing in China; Lastly, we consider overseas'...CT enrollment is usually based on the screening order of inside the department, hospital, Beijing, China and foreign countries...We need to manually screen it ourselves...want an automatically sort..." [002, attending surgeon] (Quote 18) • "Sometimes we know there is an enrollment of CT, but we don't know the up-to-date recruitment status. Future PODS tools or CT website should update the status more frequently." [006, associate chief physician] (Quote 19)
Accessibility of drugs	• "...Osimertinib is covered in Drug Catalog, but vormetinib and almonertinib need to be paid at patients' own expense..." [001, associate chief physician] (Quote 20) • "Clear mark of drug catalog and price information of drugs can make us discuss the most suitable treatment option for with patient him/herself." [012, associate chief physician] (Quote 21)
Prediction models: the necessity of ordering diagnostic tests and prediction of prognosis	• "...some genetic tests are expensive...I have known that there are some radiology technologies to auxiliary identify whether there is a certain risk of mutations..." [012, associate chief physician] (Quote 22) • "...examinations like puncture examinations are invasive...we want to use PODS tools to help estimate the necessity of such invasive examinations..." [013, associate chief surgeon] (Quote 23) • "...common mutations like TP53 have a poor prognosis...We want to combine the molecular alteration with prognostic prediction..." [002, attending surgeon] (Quote 24)
Support abilities in the decision-making process	
Using more flexible biological knowledge and phenotypes as search criteria	• "...we once had a patient with MEK mutation and ERK wild type...there were not many drugs targeting MEK...wanted to find some CTs targeting ERK...had to reset the search criteria which was inconvenient...would like to have a flexible retrieval mechanism..." [008, associate chief physician] (Quote 25) • "...would be great if PODS tools could automatically match the inclusion criteria with patient's information and tell us directly whether this patient is a qualified candidate...helps us reduce a lot of comparison work..." [007, chief physician] (Quote 26)
Automatic integration of patient information	• "...would be great if we just input the ID of patient and click a button...all the information scattered in HIS, PACS...is organized..." [011, attending physician] (Quote 27) • "Acquiring the radiology information is inconvenient currently. We have patients all over the country, and they have a variety of formats and types of image information. We hope that the future of PODS tools could help us to reduce the burden of identification and input of these data." [010, attending physician] (Quote 28) • "Suppose there is a timeline of patient in MDT, and all the events of this patient are on the line. Click one button and the details of the event will be shown. That's amazing..." [002, attending physician] (Quote 29) • "Some patients will be discussed for several times. We want the PODS tools to record our discussion every time." [004, attending physician] (Quote 30) • "This patient was discussed [time] ago. Last time we decided to use [treatment option], but the disease progressed now..." [Observation 033] (Quote 31)
Better visualization of information	• "...Switching slides back and forth to watch the texts is inconvenient...hard to sort out the therapeutic relationships..." [010, attending physician] (Quote 32) • "...automatically generated timeline of history is more logical and visualizable..." [002, attending surgeon] (Quote 33) • "...when there is a patient with rare mutation...may want to find previous patients who have the same or similar mutation...may be helpful for diagnosis and treatment...some simple automated generated statistical distribution plots are intuitive to see and discuss..." [014, supervising molecular biologist] (Quote 34)
Optimization in retrieval, recommendation, and question answering	• "...would be great if PODS tools could automatically match the inclusion criteria with the patient information..." [005, associate chief physician] (Quote 35) • "...don't have enough time to read and search the evidences...we may just input some key search information to AI, and ask what latest information it finds..." [015, associate chief physician] (Quote 36) • "I wonder if there's a day if AI could be a real assistant for me. Nowadays there is chatGPT, I believe in future there will be a chatbot in oncology area, knows everything, tells us what is the best treatment option...future PODS tools may be like this..." [002, attending surgeon] (Quote 37)

[a]The interviewee referenced the study by Lai et al [43].

[b]CT: clinical trial.

XSL•FO
RenderX

The percentages in brackets in the sections below represent the percentage of interviewees who reported the corresponding functional requirements. The percentages reflect only the proportion of participants who mentioned a specific need during the interviews and do not indicate the relative importance of the needs.

Theme 1: Better Access to Oncological Knowledge

Oncological knowledge plays an important role in PODS, and the most frequently mentioned need for PODS was faster and better access to the latest oncological information. Precisely, comprehensively, and timely integrating the knowledge of diagnosis, treatment, and prognosis from various sources, such as knowledge bases, academic conferences, and guidelines, is the most valuable function of PODS tools.

Knowledge Support in Therapies (17/17, 100%)

All interviewees emphasized the importance of the function of knowledge acquisition for therapies in support of clinical practice in oncology.

Guidelines, Conferences, and Consensuses (12/17, 71%)

Clinicians paid much attention to the latest progress in oncology and updates released in guidelines, conferences, and consensuses. However, the current access to this information was mainly through manual search and information shared by colleagues (quote 1). To meet these requirements, a news update session is held before the MDT discussions in the Thoracic Oncology Center to review and interpret the latest updates released at academic conferences or by professional associations. However, once-a-week knowledge updates provided by the attending MDT may not meet the urgent needs during daily clinical practice. Clinicians hoped that this latest information could be updated in PODS tools in a timely manner (quotes 2 and 3).

CT Need (14/17, 82%)

All physicians referred to this need. Physicians had a greater need in this aspect, as most patients in the Thoracic Oncology Department present with advanced-stage conditions and require systemic treatment. After the failure of guideline-recommended therapies, appropriate CTs had to be considered. Approximately 25% to 50% of patients would require enrollment in CTs (quote 4), necessitating that physicians have a comprehensive understanding of the available options. The 2 major channels to access up-to-date CT information were manual searches of CT registration websites and information shared by physicians responsible for CT recruitment and data collection. However, frequent retrieval of this information imposed a burden on their workload. Timely and automatic updates of CT information could help alleviate this burden (quotes 4 and 5). Midterm outcomes of CTs were also given more attention (quotes 6 and 7).

Drugs and Treatments (8/17, 47%)

Surgeons and radiotherapists hoped to access the latest knowledge on targeted therapy, immunotherapy, and chemotherapy drugs through PODS tools (quote 8). Physicians had greater demands for drug information, including their use and dosage (quotes 9 and 10). Moreover, clinicians paid close attention to the side effects of the treatment regimens. It was important to be aware of and informed about the potential side effects of certain treatment options for every patient. At present, the prediction of side effects for certain therapeutic strategies still relies on clinicians' experience, while current PODS tools provide limited support (quote 11).

Knowledge for Complex Cases (4/17, 24%)

In some complex cases, physicians expressed a need to acquire more evidence, such as multidisciplinary guidelines and case reports. When encountering patients with a history of multiple primary cancers, convenient access to multidisciplinary guidelines was identified as an important need (quote 12). For example, a patient undergoing targeted therapy for lung cancer was found to have a mass during colonoscopy, but it remained unclear whether the lesion was a primary colorectal tumor or a metastasis from the lung cancer. Furthermore, clinicians hoped to find similar case reports when managing patients with rare tumor types (quote 13).

Knowledge Support in Diagnosis and Prognosis (6/17, 35%)

In addition, interviewees sometimes mentioned diagnostic and prognostic evidence as important for the selection of treatment options. Especially in the area of diagnosis, experts from MDC and the Pathology Department were often asked to explain the functions, oncogenicity, and pathogenicity of specific biomarkers and molecular alterations to interpret their potential clinical significance (quote 14). PODS tools could help collect and filter related evidence from various knowledge bases and assist in a more comprehensive explanation and interpretation (quote 15). Moreover, current PODS tools lack reliable search functions for these purposes (quotes 16 and 17).

Theme 2: Clinical Contextualization and Resource Navigation

When a treatment option was acknowledged or proposed, evaluating its real-world applicability, including insurance coverage criteria, availability of CTs and drugs, and relevant prognostic models, was necessary. Much of this work was repetitive and could be automated by the PODS tools, thereby accelerating decision-making and improving care coordination.

The Accessibility of CTs (9/17, 53%)

Whether patients had the channel to access appropriate CTs was as important as meeting the inclusion and exclusion criteria (quote 18). Geographic barrier seemed to be an important influencing factor that might directly affect CTs' accessibility (quote 18). Furthermore, the up-to-date recruitment status was another essential factor that could help clinicians filter the available CTs and improve the effectiveness of patients' enrollment (quote 19).

The Accessibility of Drugs (5/17, 29%)

The patient's affordability was 1 of the biggest factors, after medical condition, when considering treatment options (mentioned by all interview participants). The drugs mentioned in knowledge bases or clinical guidelines might not be practically accessible because of cost. In such cases, clinicians wanted to know whether the cost of certain therapeutic drugs

XSL•FO
RenderX

could be covered by the Chinese medical insurance policy or by commercial insurance, and they considered patient affordability when making decisions about a reasonable therapeutic regime (quotes 20 and 21).

Prediction Models: Necessity of Ordering Diagnostic Tests and Prediction of Prognosis (4/17, 24%)

Currently, genomic information can be acquired through genetic testing of a peripheral blood sample. However, tissue samples are sometimes needed to obtain more precise test results. The methods for obtaining tissue are usually invasive, such as puncture, bronchoscopy, or surgery, which often cause pain to patients. Clinicians were cautious about ordering invasive and unaffordable tests and preferred a less expensive way to assess the need for these tests (quotes 22 and 23). In addition, some surgeons reported using prognostic prediction models to help estimate the risk of surgery (quote 24).

Theme 3: Support Abilities in the Decision-Making Process

During MDTs, there was also a clear need for support in the decision-making process.

Using More Flexible Biological Knowledge and Phenotypes as Search Criteria (10/17, 59%)

Clinicians expressed a demand to incorporate biological knowledge, such as the function of variants or signaling pathways, into their searches for information (quote 25). They also wanted to combine phenotypes in the process of identifying better treatment options. The most frequently mentioned phenotypes were stage, number of treatment lines (ie, the treatment course), location of lesion, presence of multiple primary cancers, and physical conditions such as Eastern Cooperative Oncology Group score and complications. Automatic matching of patients based on phenotype and inclusion and exclusion criteria was also a frequently mentioned need (quote 26).

Automatic Integration of Information (8/17, 47%)

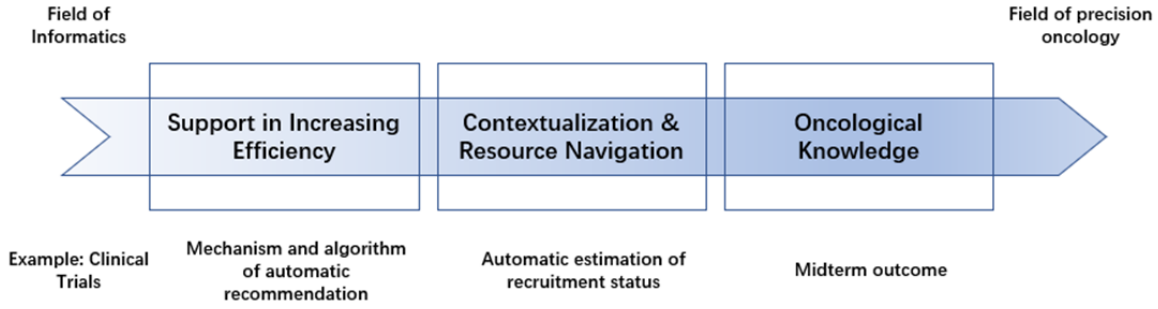
Summarizing information during the preparation phase was described as repetitive and time-consuming. All preparers mentioned that it would be beneficial to have an automatic patient information integration function (quotes 27-29). The ability to record the discussions in MDT was also considered a valuable function, as some patients were discussed several times. Tracking not only the patient's diagnostic and treatment history but also the previous MDT discussion conclusion was seen as extremely helpful (quotes 30 and 31).

Better Visualization of Information (3/17, 18%)

Some clinicians noted the inconvenience of slide-based presentations, especially when a patient's medical history was long and had to be spread across several pages. In such cases, it was not uncommon for gaps in the patient's diagnostic and treatment information to occur. They preferred a better visualization of patient information (quotes 32 and 33). Some clinicians were willing to see an automatic chart display function added to PODS tools to show statistical results from previous real-world genomic data more clearly. This improved data display function could potentially assist clinicians in viewing cancer mutation profile and understanding their relationship with clinical phenotype, therapeutic effectiveness, and prognosis more directly. Furthermore, such a function could not only help clinicians optimize clinical decisions based on previous in-house clinical evidence but also support scientists in designing clinical studies based on objective analysis (quote 34).

Optimization in Retrieval, Recommendation, and Question Answering (5/17, 29%)

In addition to search optimization (mentioned in Better Access to Oncological Knowledge section), clinicians wanted PODS tools to rank treatment options and CTs intelligently and to adjust recommendations as search conditions change (quote 35).



The popularity of language models has led clinicians to hope that artificial intelligence (AI) could help interpret clinical evidence in the literature through question answering (quotes 36 and 37).

The Categorization of the 3 Main Thematic Needs

During the thematic analysis, we maintained a central objective: to leverage rapidly advancing information systems technology to support decision-making in precision oncology. This objective naturally extends to 2 fundamental scenarios: 1 focused on assisting clinicians in understanding precision oncology knowledge, which is more aligned with the medical field, and the other focused on directly using advancements in IT to help clinicians improve diagnostic and treatment efficiency, which leans more toward informatics. During the data analysis process, we found that clinicians may seek data unrelated to clinical knowledge but still critically important or infer implicit clinical decisions from the data. These 2 scenarios may lie at the intersection of medicine and informatics. On the basis of this, we categorized the 3 main thematic needs according to the "direction of flow" from the field of informatics to the field of precision oncology (Figure 3). These themes are hierarchically layered and functionally independent. The theme, *better access to oncology knowledge*, forms the foundational theme, supplying the raw, up-to-date evidence base. Another theme, *clinical contextualization and resource navigation*, builds on that knowledge by translating it into locally relevant, feasible options—evaluating insurance coverage, resource availability, and the patient's socioeconomic context. The third theme, *decision support abilities in increasing efficiency*, leverages both themes to deliver actionable recommendations, visualizations, and workflow-integrated tools that streamline the clinician decision-making process.

XSL•FO
RenderX

Figure 3. Precision oncology decision support–related needs following the "direction of flow" from the informatics domain to the precision oncology domain, highlighting the interdependence among the themes.

Variety of Needs Among Specialties, Professional Titles, and Roles in MDT

We found that clinicians from different specialties exhibit varying preferences in their needs (Table S3 in Multimedia Appendix 1), which are likely influenced by the nature of their departments and the types of patients they encounter. Physicians are more likely to treat patients with advanced or progressive-stage conditions, and therefore, their needs for oncological knowledge are most pronounced, particularly in areas such as CTs and the management of complex cases. In contrast, surgeons tend to prioritize PODS-related knowledge related to the perioperative period, such as surgical risks and postoperative complication assessments.

There are also varying needs based on different professional titles. For senior physicians, such as department heads, their extensive clinical experience allows them to make rapid diagnostic and treatment decisions. Thus, they expect PODS to provide more up-to-date knowledge, particularly regarding cross-disciplinary insights and the latest drug research. In contrast, younger physicians tend to seek more support in oncology pharmacology and case reports.

As for the roles in MDT, preparers (Multimedia Appendix 1) seek PODS to support the data preparation and interface presentation phases of MDT. They have a more extensive need for visualized data and convenient retrieval functionalities.

The Functional Framework of Needs for Integrated PODS Tools

After the themes were extracted and confirmed, a functional framework of needs for integrated PODS tools was proposed. In the framework, the needs for PODS tools were basically divided into three dimensions: (1) to provide clinicians with up-to-date and straightforward oncology knowledge; (2) to enable clinical contextualization and resource navigation, offering suggestions for applicable and feasible clinical management; and (3) to offer comprehensive and efficient support for the decision-making process (Table 4).

XSL•FO
RenderX

Table 4. The functional framework of needs for integrated PODS[a] tools.

Dimension and subcomponents	Functions of needs	Recommendation
Up-to-date and straightforward oncology knowledge		
High-level evidence	• Access to high-level clinical evidence (eg, guidelines, conferences, and consensuses) • Concise overview of evidence, containing a general idea of medical information (eg, drug, therapy, and test results) • Labeling of credibility or describing the clinical significance or referability • Source of literature	High-level evidence (eg, guidelines, conferences, and consensuses) is always a priority for clinicians when making decisions about any patient. Clear labeling of the evidence level is also helpful for clinicians in determining the credibility of the evidence [44].
CTs[b]	• Information on inclusion and exclusion criteria (related to the accessibility of the CT function) • Provide midterm results, if available, for CTs that are ongoing and not recruiting • Provide enrollment information for recruiting CTs • Comprehensive description of medication information as outlined in the CT protocol	After the failure of guideline-recommended therapies, appropriate CTs should be considered.
Biological knowledge in diagnosis, treatment, and prognosis	• Description of basic biological information of biomarkers, such as nomenclature (eg, alias and transcript numbering), type (eg, point mutation, fusion, and copy number variation), structural information (eg, mutation site and location in chromosome), and basic biological function • Description of the medical function of biomarkers related to oncology, such as the role in tumor development (eg, oncogenic or tumor suppressor and driver or passenger), mechanism of involvement in tumor development (eg, kinase activation and DNA damage repair), and frequency of expression and mutation in different cancers • Description of the medical function of biomarkers directly related to patient information, such as clinical significance (eg, diagnosis, treatment, and prognosis) and pathogenicity • Description of inclusion in public evidence repositories of biomarkers • Source of evidence	A better explanation of biological knowledge will help clinicians understand the pathological mechanism. The integration will also improve the interpretation of the clinical significance of genomic testing results [45].
Drug and therapy information	• Information on the use, dosage, and side effects of drugs and therapy options from prior medication and literature	The use, dosage, and side effects information of drugs and therapy options help clinicians implement treatment accurately.
Case reports and preclinical evidence	• Source of the case reports related to the patient • Phase 1 to 2 CTs and animal experiments of drugs	Case reports and preclinical evidence are important references for complex or rare cases.
Multidisciplinary guidelines	• Clinical guidelines for different cancer areas	Although the proportion of patients with multiple primary cancers is small, the number of discussions about these patients is gradually increasing. These guidelines can be used to keep physicians updated on other cancer types outside of MDTs.
Clinical contextualization and resource feasibility support		
Accessibility of CTs	• Automatically match patient information with inclusion and exclusion criteria (refer to the information on the inclusion and exclusion criteria function) • Automatically estimate recruitment status • Provide an automatic geographic accessibility for eligible CTs	For patients, the enrollment criteria of CT are as important as the therapy itself. Letting the clinician know whether a certain CT could be accessed also matters.

XSL•FO
RenderX

Dimension and subcomponents	Functions of needs	Recommendation
Accessibility of drugs and treatment options	• Information on the insurance coverage status of drugs • Cost of drugs and treatment options • Approval information of drugs and treatment options	This function helps clinicians know about drug accessibility and could save time in screening available CTs and communicating with patients.
Application of prediction models	• Convenient interface to access prediction models	There are many prediction models in the oncology domain, such as operative risk assessment and risk of recurrence. However, the current PODS tools have not integrated these models yet. Integrating and applying these models could be helpful in decision-making.
Comprehensive and efficient support abilities in the decision-making process		
Individualized search criteria	• Incorporate biological knowledge (eg, the function of variants or signaling pathways) • Incorporate phenotypic features (eg, stage, number of treatment lines [ie, the treatment course], and the location of the lesion) into search criteria	Optimization in search criteria, such as biological knowledge and phenotypes, could help clinicians search for treatment options more precisely.
Automatic integration of patient information	• Automatically summarize the patient's diagnosis and treatment history • Automatically integrate the patient's health information from different systems in the hospital, such as the HIS[c], PACS[d], and LIS[e].	The automatic summarization of patient information could help reduce the *preparation* time.
Recordability and traceability	• An interface for recording MDTf discussion, preferably automatically	A timely recording of the MDT discussion function could help clinicians trace back, summarize, and analyze previous data easily.
Better visualization	• Chronological patient history • Logical display • Organization of information by priority • Clear hierarchy of information	Automatically generated timelines help clinicians read patients with a long history and complex treatment course straightforwardly, whereas graphs and tables can help them understand data better and interpret clinical significance more easily.
Treatment option recommendation	• Personalized ranking of drugs and treatments based on their advantages and disadvantages • Provide automated treatment recommendations	A treatment recommendation function with evidence classification, data matching, and a sorting algorithm could provide extra comprehensive support to clinicians during decision-making.
Question answering and dialogue	• Automatic dialogue and question answering • Large language model agents that automatically retrieve information or tools to support decision-making	The development of artificial intelligence and large language models may implement the function of multiturn question answering and dialogue, as well as provide precise information.

[a]PODS: precision oncology decision support.

[b]CT: clinical trial.

[c]HIS: hospital information system.

[d]PACS: picture archiving and communication system.

[e]LIS: laboratory information system.

[f]MDT: multidisciplinary team.

Discussion

This qualitative descriptive study aimed to gain a more in-depth understanding of clinician-oriented integrated PODS tools. The data were collected with structured observations and semistructured in-depth interviews.

Principal Findings

Needs in PODS

Three main themes of needs in PODS were extracted: (1) the *oncology knowledge* theme underscores the necessity of a continuously updated, structured knowledge resource that synthesizes genomic, therapeutic, and guideline data into clinically digestible formats; (2) the *clinical contextualization and resource navigation* theme highlights the importance of situating this knowledge within real-world practice to ensure that treatment recommendations are feasible and equitable; and (3) the *support abilities in the decision-making process* theme streamlines clinician decision-making and improve care efficiency.

XSL•FO
RenderX

Prospects for PODS Tools Based on the Proposed Framework

A functional framework for the needs of integrated PODS tools was proposed. Providing timely and updated oncology information was the most frequently mentioned need by clinicians. Currently, most clinicians still obtain the latest cancer knowledge through literature reviews; data released and presented at academic activities and conferences; or information shared by, for example, fellow experts and drug suppliers. An integrative PODS tool that properly meets the clinical requirements for up-to-date knowledge summarization and presentation is not yet available. However, clinicians are not satisfied with the tools that are currently available. The main issues include delayed updates, poor retrieval conditions, and insufficient integration with molecular biological evidence. PODS tools are supposed to incorporate the interpretation of available molecular testing results to meet the requirements of the precision medicine concept and to aid the molecular tumor board [21,22].

The framework suggests that integrated PODS tools related to oncology knowledge should include a timely updated and comprehensive knowledge base [48], incorporating drug approval information from official administrative authorities; clinical guidelines; and consensus from well-recognized organizations, released CTs' results from academic conferences, preclinical evidences from literature reviews, and open CTs' updates through official channels. This knowledge base should be highly structured and user-friendly to meet the advanced retrieval needs of clinicians, focusing on information regarding genetic variant data, molecular functional significance, evidence on therapies and prognosis, multidisciplinary guidelines, and case reports. The genomic profiles of patients with cancer are typically presented in genetic testing reports, which contain information on potential actionable targets with variant classification based on well-recognized guidelines and recommendations. However, clinicians were generally unfamiliar with the variant classification criteria, such as the 4-class systems for somatic mutations [49] and the five-class system for germline variants [44], and their clinical significance. Therefore, using a straightforward and clinically oriented way to display genetic results may help improve the effectiveness of the decision-making process. Furthermore, each clinical evidence for a given genomic variant is often presented separately in genetic testing reports, whereas clinicians often prefer a more integrated and comprehensive summary that synthesizes multiple related pieces of evidence, even when discrepancies exist.

In addition, most clinicians express a need for support with feasibility considerations in the diagnosis and treatment process. Although current drug insurance and CT information query systems are well developed, their integration with patient information is insufficient. Future feasibility-support PODS tools should integrate patient information from local or in-house hospital information system data with medication use, making it easier for clinicians to access relevant data. In addition, diagnostic and prognostic algorithms or models have broad potential applications in clinical practice, supporting clinicians in optimizing the decision-making process in various situations [45,50].

Support in the decision-making process is a less developed yet widely demanded aspect of existing PODS tools. Clinicians are interested in improvements in integrating patient information, optimizing information visualization, and enhancing search and recommendation methods [51] for a more efficient decision-making process. In particular, oncology knowledge–related PODS tools should feature an optimized recommendation function [52] and a matching algorithm based on the level of evidence and CTs to enhance clinicians' confidence in using these tools [53]. With the development of language models, knowledge acquisition through question answering or dialogue is also expected to become a future direction for knowledge-related PODS tools [54]. Currently, the integration of patient information in PODS tools is limited and often requires manual input [55]. Automatic integration of patient information and improved visualization would offer significant assistance in MDT meetings and routine clinical practice [10,56].

When adapting the framework to hospitals of different sizes, resource levels, and IT infrastructures, some previous experiences and frameworks may bring value to the development and deployment of a system in a real environment. The Nonadoption, Abandonment, Scale-Up, Spread, and Sustainability (NASSS) framework for complex health technologies will assist in predicting and evaluating the success of a PODS deployment [57]. The Exploration, Preparation, Implementation, and Sustainment framework will be a guideline in PODS implementation [58].

Comparison With Prior Work

PODS can be understood as a specialized form of a clinical decision support system (CDSS). Our work directly builds upon a substantial body of former research. The model by Hendriks et al [59] identified critical barriers, including guideline maintenance and electronic health record interoperability, aligning with our findings on the necessity of dynamic knowledge updating. However, our work extends this paradigm by systematically addressing 3 dimensions in PODS.

Walsh et al [17] examined existing oncology-focused CDSS platforms, identifying critical dimensions, such as data integration, AI capabilities, and stakeholder concerns, and highlighting how technical sophistication alone is insufficient without addressing clinicians' real-world concerns about data quality, user burden, and trust in AI-driven recommendations. Liao et al [60] documented the rapidly growing intersection of AI with clinical oncology workflows, suggesting that advanced natural language interfaces could improve information retrieval and decision support in tumor boards.

Since Kurnit et al [7] proposed the vision of PODS for harnessing genomic and molecular testing, alongside targeted therapy and immunotherapy insights to enable precision oncology at the point of care in 2018, a variety of PODS tools have emerged, driven by advances in next-generation sequencing, biomarker-driven therapeutics, and data-sharing initiatives [23,24,28,61,62]. However, despite these

XSL•FO
RenderX

technological strides, there is no comprehensive synthesis of what characteristics and functions PODS should offer or a clear mapping of clinicians' practical needs for such systems.

In contrast to prior studies that have predominantly focused on theoretical frameworks or technical prototypes, our study adopts a descriptive and user-centered approach. Through intensive qualitative observations of MDT discussions and in-depth interviews with clinicians of varied specialties and experience levels, we systematically identified and categorized the functional requirements of PODS.

Strengths and Limitations

Our contribution complements existing CDSS and PODS literature by moving beyond prototype descriptions and generic recommendations, instead offering a pragmatic, empirically derived framework for future PODS development that aligns tightly with the lived experiences of oncology practitioners.

However, the needs analysis should be considered in light of certain study limitations. First, the rapid development of precision oncology means that additional needs may arise in the future. Convening a multidisciplinary advisory group from different specialties from time to time to evaluate emerging technologies, therapies, and policy changes as stakeholder review cycles occur and using structured Delphi rounds to reach consensus on necessary revisions may help maintain a living functional needs framework for PODS, which could be applied to integrate perspectives from different departments to validate the prioritization outcomes. Moreover, the MoSCoW (must have, should have, could have, won't have) method is effective in distinguishing critical needs from optional ones during the PODS implementation phase. Second, this study was conducted in only 1 hospital in China, highlighting the need for broader investigations across more regions and clinical units. In addition, a follow-up survey across a larger sample and additional quantitative validations may help validate the identified needs and their relative importance. In practice, institutions can conduct a rapid workshop with local stakeholders to map existing workflows, data systems, and patient populations against the 3 framework dimensions proposed before PODS implementation. Prioritizing the needs when implementing PODS tools is also needed for further study. Third, the observation and interview processes were based on the subjective perspectives of researchers and interviewees, which may introduce some bias. While the study focuses on clinicians, the needs framework may change when considering other stakeholders (eg, hospital administrators and IT developers). A bigger study integrating their perspectives will be needed in the future. Future quantitative studies—such as developing questionnaires focused on areas of likely interest to nonclinical stakeholders, including cost management, data interoperability, IT infrastructure readiness, and organizational feasibility—can help identify key domains and contribute to broader integration, potentially leading to new thematic categories within the framework. Fourth, clinicians may express various needs for specific content, such as CTs, which might be dispersed across these 3 themes. We acknowledge that this is unavoidable. Nonetheless, we anticipate that this classification will provide a new perspective for PODS system developers, offering a way to consolidate the diverse needs of clinicians.

Future Directions

Although the development of PODS tools is rapid, the traditional genetic testing report will likely remain an irreplaceable support for genomic interpretation well into the future. The combination of the genetic testing reports and PODS tools may offer complementary advantages, providing new paradigms in oncology decision-making, which could be explored in further research. Advancements in AI, such as generalist models or large language model agents, may provide improved optimization and interaction capabilities for clinicians and PODS tool developers.

Conclusions

The rapid advancement of precision oncology has created an increasing demand for decision support tools to assist clinicians in navigating complex treatment choices. This study provides valuable insights into the current landscape of PODS tools, identifying and categorizing the needs and challenges that clinicians face in using these tools effectively. Our findings highlight key areas for improvement, including better access to oncological knowledge, clinical contextualization and resource navigation, as well as support abilities in the decision-making process. In addition, we propose a functional framework that outlines the essential features of an integrated PODS tool, which could enhance clinical decision-making in precision oncology. The results offer a foundation for future research and development, emphasizing the need for tools that are not only technologically advanced but also aligned with the practical needs of clinicians in diverse health care settings.

Acknowledgments

This study was conducted with support from the National Key Research and Development Program of China (code: 2022YFC2406804). The authors gratefully acknowledge the participants of this study for their time and insights.

Data Availability

The datasets generated or analyzed during this study are not publicly available due the privacy of patients and physicians in the structural observation and in-depth interviews, but are available from the corresponding author on reasonable request.

Abstract

Background: Personal health record (PHR) software has the potential of aiding with patient engagement and data collection in longitudinal research to better understand the long-term impact of treatments on patients with rare medical conditions. Neuroendocrine tumors (NETs) represent a rare condition with unique challenges related to symptom management, treatment tracking, and patient-provider communication.

Objective: This study aimed to design, develop, and evaluate PHR software tailored for patients with NETs as part of a longitudinal research study. Our goal was to create a patient-centered PHR that supports both self-management and research data collection.

Methods: This included activities spanning the entire development lifecycle from identifying user requirements through focus groups and surveys, iterative prototype refinement via cognitive walkthroughs, and usability testing of the functional PHR system. Feedback from patient advocacy organizations and clinical experts further informed PHR development.

Results: The resulting PHR allows patients with NETs to access condition-specific information, track symptoms, monitor treatment regimens, and share data with health care providers. Patients valued the ability to visualize personal health trends and patterns over time, enhancing both self-management and communication with medical teams. Usability testing indicated high levels of patient satisfaction with the system's functionality and design.

Conclusions: The development of this PHR demonstrates the value of engaging patients in the design process to ensure that health technologies address real-world needs. Our approach provides a model for designing PHR systems for other rare conditions, highlighting the importance of patient-centered design in supporting both clinical care and longitudinal research.

Introduction

The past 20 years have seen a revolution in the digitization of health records [1-3]. There are 2 aspects to this digitization that have been occurring in parallel. One is the advent of electronic health records in hospitals and doctor's offices [1,3], which are often accompanied by health portals providing patients with access to their health records [4,5]. The data in these systems almost exclusively originate from hospitals, laboratories, and doctor's offices. The other is patients using technology to capture or record personal health data. This latter aspect has involved automated capture of information (eg, steps taken from smartwatches or smartphones) [6], the use of smart health devices (eg, blood pressure monitors that connect with

XSL•FO
RenderX

smartphones or computers) [7], and the use of personal health record (PHR) software that enables patients to record information that may otherwise not be tracked (eg, symptoms) [8,9].

PHR software has also been proposed as a tool to facilitate medical research [10]. Many medical studies require long-term follow-up of patients with self-reported measures. The data collection necessary for such studies has traditionally involved mailing paper questionnaires to patients using the postal system or calling them on the phone. Using PHR software for the same purpose has the potential of lowering costs by avoiding mailings, transcriptions, or time spent on phone calls, while increasing data quality by avoiding errors in transcription and enabling patients to contribute data at a time and location and on a device that is most convenient for them [11,12]. In order for PHR software to successfully play a data gathering role for research studies it needs to provide a valuable service to patients, otherwise patients are less likely to use it [9,13]. Ideally, PHR software used for research studies would follow a model similar to that followed by free online services: users get a valuable service in exchange for their personal data. The difference in this case is that patients would explicitly consent to provide their data for a specific purpose ie, medical research.

One specific area of medical research that we believe could benefit from the use of PHR software for gathering data from patients is research on rare medical conditions. Knowledge gaps remain prevalent for most rare medical conditions due to systemic and structural challenges in health care and research. These include small, geographically dispersed patient populations, limited funding for research, and frequent diagnostic delays. The latter arise from the complexity of these diseases, limited practitioner training when compared to more common conditions [14], and the evolving understanding of disease characteristics [15]. There is also often a need for longitudinal research to better understand the long-term impact of treatments on patients with rare medical conditions [16] and PHR software could play a role in repeated data collection for such research. The challenge is that because these conditions are rare, it is unlikely that there are commercial PHR systems that are a good match for patient needs, unlike the case for more common conditions, such as asthma, diabetes, glaucoma, HIV, hyperlipidemia, and hypertension [14,17]. The sole example we found of a PHR designed for patients with a rare condition (idiopathic thrombocytopenic purpura) resulted from an adaptation of a generic PHR system based on advice from expert physicians [18]. We recommend, in addition to consulting with experts, engaging with patients in user-centered design activities, positioning patients as research partners.

In this article, we present our experience engaging with patients with neuroendocrine tumors (NETs) [19,20], a rare medical condition, throughout the design process of PHR software currently being used as part of a prospective cohort study of people with NETs [19-21]. NETs include a broad variety of tumors that can appear throughout the body, but are most common in the small intestine, pancreas, and lung [19,20].

Methods

Participant Recruitment

For all phases of the project, we recruited patients with NETs through 4 partnering NET advocacy groups in the United States (The Neuroendocrine Tumor Research Foundation, The Neuroendocrine Cancer Awareness Network, The Healing NET Foundation and Northern California CarciNET Community). Inclusion and exclusion criteria for volunteers in this study included adults (≥18 years old, any gender) with a confirmed diagnosis of any NET, able to read, speak, and understand English to participate in focus groups, surveys, and usability testing, a willingness to share personal experiences regarding symptom tracking, treatment management, and interactions with health care providers related to their NET, and access to a computer, tablet, or smartphone with internet connectivity to interact with the PHR system and participate in online activities. There were no other demographic or other requirements for volunteer participants including previous PHR experience. Overall, 89 patients with NETs participated in at least 1 activity (60 female, 18 male, 11 unknown gender; 75 White or Caucasian, 1 Black or African American, 1 Asian or Asian American, 12 unknown race; 2 Hispanic or Latino, 80 not Hispanic or Latino, 7 unknown; 32 with postgraduate degrees, 27 with college degrees, 16 with some college, 2 with a high school degree or GED, 1 without a high school degree or GED, 11 unknown educational level; 7 aged 18 - 40, 30 aged 41 - 60, 49 aged 61 - 80, and 3 aged >80 years). Participants who provided their home address (n=75) joined activities from 34 different states and one location outside of the United States.

Outline of Research Activities

Research activities involved a comprehensive, multiphase process designed to engage patients with NETs at every stage of the PHR development including: (1) 9 online design sessions with patients with NETs to develop requirements and a survey to validate these requirements with a broader set of patients, (2) another 9 online sessions to iteratively improve a low-fidelity interactive prototype, and (3) three sets of online usability testing sessions to refine the implemented PHR software (refer to Table 1 for details). The patient activities described in this report were reviewed and approved by the University of Iowa Institutional Review Board.

Table . Session activities organized by phase, strategy, format, and number of participants.

Strategy	Format	Participants, n	Activities
Phase 1: identifying requirements			
Brainstorming	Online focus groups (3 groups of people, first of 3 sessions)	16	• Imagine a superhero that can help with their condition – what would the superhero do? (Superhero construct frees patients from perceived constraints) • Research team compiles a list of potential features from participant discussions
Organizing	Online focus groups (same 3 groups of people, second session)	16	• Participants rank desirable or undesirable features • Prioritize features and provide more details on what they want • Research team reviews results and identifies what categories to implement in the NET[a] PHR[b] in two areas: (1) providing information on NETs; (2) tracking condition-related data
Organizing	Survey of focus group attendees	16	• Further prioritization of features and details on requirements
Confirmation	Online focus groups (same 3 groups of people, third session)	16	• Discuss survey results with each group to better understand the reasons behind survey answers • Probe what patients would expect from a PHR that implemented these requirements
Ranking and attitudes	Validation survey	52	• Prioritize categories of information or advice (high, intermediate, and low) • Preference of categories to track
Phase 2: prototype refinement			
Rapid prototyping	Cognitive walkthrough with users	27 (3 groups of 9)	• Rapid prototyping with wireframe software (Balsamiq) by research team • Patients provide feedback on prototype based on specific tasks • Iteratively improve between group activities until optimal design reached (3 rounds with each group of 9 patients)

XSL•FO
RenderX

Strategy	Format	Participants, n	Activities
Phase 3: usability testing			
Functional prototype	Usability testing (tasks, survey)	10	• Use functional prototype on Zoom with team • Patients complete prepared tasks using a test version of the tool, thinking aloud • Provide feedback via survey—NASA task load index administered after each task • Discussion at end on what worked well, what did not, and what they would change • Iteratively improve based on feedback (3 rounds of usability testing)

[a]NET: neuroendocrine tumors.

[b]PHR: personal health record.

Ethical Considerations

We obtained ethics approval from the University of Iowa's Institutional Review Board (202110283). All participants received an information and consent letter before enrollment and participation. Participants were compensated US $50 for Phase 1 and Phase 2 Zoom sessions, US $10 for the Phase 1 survey, and US $20 for Phase 3 usability Zoom sessions. To preserve participants' privacy and confidentiality, we took notes rather than record sessions and these notes are not associated with specific participants. In addition, the Phase 1 surveys were designed to ensure anonymity of participants by not collecting personally identifiable information.

Phase 1: Identifying Requirements (Online Focus Groups, 9 Sessions)

To identify requirements, we recruited 16 patients with NETs, divided them into 3 groups, and conducted 3 1-hour online sessions with each group using Zoom, for a total of 9 sessions.

For the first session, our goal was to obtain ideas for PHR software for patients with NETs without any constraints. After introducing the project and our overall goal, our instructions to patients during the first session were to imagine that there was a superhero that could help them with their medical condition, who could do anything except give them a cure. The idea behind the superhero discussion was to remove any constraints patients could think of with respect to what would be possible with technologies. When we met with subsequent groups, we started by getting ideas from them and then introducing ideas by previous groups if they had not mentioned them to obtain further feedback. We had previously used the superhero activity, albeit face-to-face, while developing a PHR focused on elder medication safety [13] and others later used it face-to-face with older adults as well [22].

During each superhero session, at least 3 researchers took notes on participants' ideas. To analyze these notes, we used an inductive coding process, similar to the one proposed by Gioia et al [23]. First, 2 of the researchers (JPH and KP) went through the notes and created 1 physical sticky note per unique concept, for a total of 51. Using these sticky notes, they then organized patient ideas, developing an affinity diagram, from which they produced a hierarchically organized list of requirements. The high-level themes in this hierarchy of requirements were information on NETs (eg, support groups, advocacy, education, and ideas for relief), tracking condition-related personal information, and managing logistics. These requirements were the basis for the second session with each group. We used this second session to validate the set of requirements, begin to prioritize them, and obtain more details on the requirements. We had pursued a similar approach in previous research, in particular with respect to information tracking, to understand the difference between information patients would like to track and information they would be willing to enter [13].

The research team met after the second set of sessions to consider the priorities identified by patients and the practical realities of what we could accomplish within the constraints of the project. One important area in which patients were interested that we were unable to pursue was managing logistics, from better integration of electronic health records across providers to managing prescriptions and appointments. Based on these considerations, we identified a set of requirements on which to focus. We then developed a web-based Qualtrics survey sent to the 16 participating patients with NETs to obtain more details on requirements and further prioritize them. We used the third set of sessions to discuss the results of the survey with each of the groups to better understand the reasons behind survey answers and get a sense for what patients would expect from PHR software that implemented these requirements.

XSL•FO
RenderX

After the third set of sessions, we created an electronic survey to be distributed to a broader set of patients with NETs to validate the requirements we developed with 16 patients. We believe it is important to validate requirements from participatory sessions with a larger group of patients due to potential biases related to who can be available and feel comfortable participating in such activities. Others have followed similar approaches to balance the depth of discussion in participatory sessions with the greater representativeness afforded by a survey [24]. Questions focused on preferred data tracking features, information needs, and feedback or output options (eg, personal trends and data visualizations). The 52 patients with NETs who answered the survey helped us validate and further prioritize the set of requirements we had developed. The result of Phase 1 was a list of specifications that would guide prototype development.

Phase 2: Prototype Refinement (Cognitive Walkthroughs, 3 Rounds, and 27 Participants)

Our next step was to design an interactive wireframe prototype using Balsamiq [25]. Balsamiq enables screen designs that look as if they were sketched with pen and paper and includes commonly used user interface elements (eg, buttons and images). The sketches are created so feedback on them can focus on those elements and navigation through the system, as opposed to aesthetic aspects. Screen sketches can be linked to each other, so the prototype is navigated by clicking on user interface elements (eg, menus and links) like a normal website.

We then sought to iteratively improve the prototype through 3 rounds of feedback from patients with NETs over Zoom using cognitive walkthrough with users techniques [26], which have previously been applied to wireframe prototypes [27]. We obtained feedback from 3 different groups of 9 patients with NETs, for a total of 27 subjects. Patient participation varied per round. For the first round, we had 24 patients participate, 20 for the second, and 17 for the third. During each session, a research team member would work with 2 - 3 patients at a time (ie, small group sessions), asking them how they would navigate the system for a given set of tasks. Participants verbalized their thought process (“think-aloud” protocol), highlighting usability issues and areas of confusion. Feedback from each round informed changes to the prototype (ie, iterative refinement), which were then reevaluated in subsequent rounds.

Phase 3: Usability Testing (3 Rounds, 10 Participants)

The following step was to develop a working web application based on the design of the Balsamiq prototype. This design incorporated more detailed functionality that could not be tested in Balsamiq and aesthetic aspects, such as fonts and colors. To implement the design, we used an existing system we previously developed, the Iowa PHR, and customized it based on the outcomes of Phases 1 and 2. The Iowa PHR is a Java 8 [28] Spring application [29] with a Microsoft SQL Server database [30]. It is hosted with Jetty [31] and fronted with Apache [32].

To iteratively improve this working system, we conducted 3 rounds of usability testing [33] with a total of 10 patients with NETs, 4 participated in the first session, 3 in the second, and 3 in the third. There were about 3 weeks between the first and second round of sessions, and about 6 months between the second and third rounds (in part due to competing commitments for the software developers), enabling our developers to make changes to the system.

At each session we asked participants to complete tasks involving the system’s most important features, including finding specific types of information about NETs and tracking a variety of data. After a group of tasks pertaining to similar features, we asked patients to fill out a NASA Task Load Index survey [34] to assess the ease or difficulty of those tasks. At the end of each session, patients provided qualitative feedback on what worked well, what did not work well, and what they would like to change about the system. From this feedback, after each round of usability sessions, we developed a list of changes for the PHR, which the development team completed before the following round of usability sessions.

Our patient advocacy organizations provided “test-drive” feedback through credentialed access to the PHR, followed by structured surveys (via Research Electronic Data Capture [REDCap]) [35] to capture their insights. In a similar way, useful feedback was also obtained from our NET specialists (ie, working oncologists and endocrinologists) who reviewed the PHR to suggest improvements related to medical terminology, treatments, information accuracy, and ordering or presentation of data.

After we incorporated all feedback into the PHR, we made it available to patients with NETs enrolled in an ongoing research study in March 2024. Subjects enrolled at the time were sent an email notification introducing the availability of those features. Further outreach is planned to promote awareness and gather more comprehensive feedback on long-term utility.

Results

Phase 1: Identifying Requirements

Identified Requirements

The requirements we identified fell into 2 categories: information on NETs and tracking condition-related personal information. The types of information in which patients were interested were related to the fact that NETs are rare, there are different subtypes of NETs, and research is still ongoing regarding optimum therapeutic management and treatment sequencing [19,20].

In terms of tracking personal information, most patients had a strong interest in tracking symptoms because some (eg, diarrhea) have a significant impact on quality of life [20]. Together with symptoms, they expressed interest in tracking factors possibly triggering symptoms including consumption of certain foods, medications, episodes of stress, and quality of sleep. They sought to share this information with their medical team but also visualize patterns and potential interactions over time.

Validated Requirements

In total, 52 patients with NETs completed the requirements validation survey. The survey focused on the 2 key aspects that emerged from our participatory sessions: providing information

XSL•FO
RenderX

on NETs and tracking condition-related data. Through the survey, we were able to both validate and prioritize the requirements obtained during Zoom sessions. Multimedia Appendix 1 shows preferred types of data to track and Table 2 lists preferred features related to tracking data. Multimedia Appendix 2 shows preferred types of information, education, or advice about NETs.

Table . How useful are certain feedback and output options for patients with neuroendocrine tumors.

Feedback or output option	Most useful, n	Least useful, n
Personal trends over time	39	1
Patterns	29	3
Comparisons of data from other users	13	19
Ability for other users to enter data	14	11
Simple graphs or charts	26	5
Two or multi axis graphs or charts between items	11	14
Printable data, graphs, or charts	25	6
Download raw data	11	21
Detailed reports and summaries	25	6
Allow users to select type of output	26	3
Snapshots or focused summaries	17	8
Option to save editable preferences	15	12
Flexibility in timeframe of outputs	12	13
Generic notifications or nudges	13	18

Phase 2: Prototype Refinement

The most difficult challenges we addressed through these sessions involved information architecture for the broad range of information patients thought should be provided about NETs. Due to the wealth of information available, challenges included decisions on the most reliable or updated data sources, and how to organize and categorize the information. In addition, we also obtained feedback on basic tracking capabilities during the first prototyping round, and on custom tracking features (enabling users to add their own custom tracking categories) during the second and third rounds.

Iteratively improving these interactive wireframe prototypes in Balsamiq enabled us to improve the design of the system at a low cost, since it is quick and easy to modify Balsamiq prototypes when compared to modifying a web application.

Phase 3: Usability Testing

Patients were provided with a set of 10 predetermined tasks, presented in an order of increasing complexity, concerning information seeking, data entry, and editing and deleting entries. At the end of each set of related tasks, patients were instructed to complete the NASA Task Load Index survey [34] which evaluated patients' responses across 6 dimensions including mental, physical and temporal demand as well as ease of performance, effort involved and frustration with the set tasks. Overall, the findings indicated a generally manageable task load, with the majority of patients scoring mental, physical and temporal demands across tasks negatively (ie, low demand). As expected, higher order tasks were associated with an increase in demands of effort, but most patients reported minimal frustration with the assigned tasks.

Together with the feedback obtained from our patient advocacy organization partners and NET clinician groups, usability testing feedback helped us identify minor bugs, make some information easier to find, make it easier for users to start tracking data, simplify some tracking options, and otherwise confirm that the system was ready for use.

The final version of the PHR app includes options for tracking data related to the condition. We identified 18 categories of data from our interactions with stakeholders (eg, skin flushing, food intake, pain, and medication intake), which are ready to be used with a design that aims to minimize the steps required to enter data. In addition, users can create their own custom category to track, which addresses the broad range of needs within NETs. An instructional video is available to patients explaining the PHR app's tracking capabilities and how to use them. The system also enables users to track the medications they are currently taking or have previously taken, with a user interface developed during previous research [10,13]. In addition, the PHR app also provides access to various types of information relevant to patients with NETs organized into tabs: about NETs, treatments for NETs, tips for managing care (many of these came from stakeholders and patients), and NET resources (eg, patient support groups and clinical trials).

A video walkthrough of the final PHR is available in the Multimedia Appendix 3.

Utility Assessment

Our PHR can now be accessed by patients with NETs enrolled in a research study where the emphasis is on completing study-related surveys. Patients enrolled in the study received one email announcing the newly designed features of the PHR.

XSL•FO
RenderX

These 1070 patients had access to the PHR, mostly as they waited completion of a subsequent study survey, with 110 logging in just to use the PHR. These 110 patients were the most active in using it. We are planning to further advertise the PHR to promote greater awareness for eligible patients.

Discussion

Principal Findings

As a result of extensive focus group-based participatory design and usability testing, we learned that patients with NETs were interested in keeping track of their symptoms and accessing many types of information about their disease, as well as the means to identify personal patterns, interactions and trends in these factors over time. Having the capacity to share these observations more efficiently with their health care providers was of high importance to them. They frequently expressed that they had to become advocates for their own disease management and that these features would help them communicate better with their providers. These findings were different from our previous study designing a PHR with older adults [10,13]. Participants often voiced their appreciation for being treated as partners in the design process, their feedback helped identify navigation issues, data visualization preferences, and feature requests. Their input and improvements based on real-time feedback were crucial to optimizing the PHR.

Rare diseases present a unique set of challenges for patients, health care providers, researchers, and society [36,37]. Rare diseases are often difficult to diagnose because many medical professionals are unfamiliar with them. Patients frequently go through a “diagnostic odyssey” that can take years, seeing multiple specialists before receiving an accurate diagnosis [38]. Moreover, symptoms of rare diseases often overlap with more common conditions, leading to misdiagnosis and inappropriate treatment. Since rare diseases affect a small percentage of the population, there is often less financial incentive for pharmaceutical companies to develop treatments, a phenomenon known as the “orphan drug” problem [39]. Many rare diseases have no approved treatments or cures, leaving patients with limited options for management and quality of life improvement. Specialists for rare diseases are often concentrated in a few medical centers worldwide (ie, centers of excellence), meaning patients may need to travel extensively to receive appropriate care or consultation. In particular, rural areas may lack access to these experts, further isolating patients and delaying necessary care. Furthermore, the rarity of these diseases can mean less public and governmental awareness, leading to fewer resources and funding opportunities for research, support services, and patient care. This has promoted the evolution and development of many patient advocacy organizations, often championed and spearheaded by patients with rare disease and their families in response to their own patient experiences. These groups are essential for raising awareness, driving research and elevating health-care standards, but often have limited resources themselves [40]. Unfortunately, this forces many patients with rare disease to advocate for their own disease, and their particular needs, whether they be informational, expertise or treatment related, physical or emotional. Due to the small patient populations, and often limited data available on them, protecting patient privacy while sharing valuable information for research also presents unique challenges in rare disease studies, and highlights the importance and potential of a coordinated effort between health care organizations, researchers, patient advocacy groups and industry to address these challenges.

NETs in particular are an excellent case-study among rare conditions for the development of a PHR. They are typically slow growing in nature with an unusually prolonged survival and significant symptom burden [41]. Their vague antecedent signs and symptoms cause significant delay and difficulty in their diagnosis and detection [19]. Metastatic disease is observed in up to 40% of NETs at initial diagnosis [42], and many patients with liver or other distant metastases experience carcinoid syndrome, a direct result of serotonin hypersecretion [43] manifesting clinical symptoms ranging from watery diarrhea and flushing to bronchospasm, hypotension and right-sided cardiac deficits (carcinoid heart disease). Thus, patients with NETs typically experience prolonged survival with active disease, and many have significant symptom burdens that may vary daily [44]. Treatment strategies for NETs depend on tumor grade, stage, location, and functional status. Usual treatment for low to intermediate grade gastroenteropancreatic (GEP-NETs, the most common NET subtype) remains surgery, but the requirement for adjuvant therapy is questionable [45-47]. Therapy with somatostatin analogues are established first-line agents for low-grade GEP-NETs, with demonstrated improvements in overall survival [48,49]. However, there are no clear consensus guidelines as to the optimum sequencing of other therapeutic options [50-52], leading many patients to read widely, and become advocates for their own disease and its appropriate management.

To our knowledge, only one previous study has been published evaluating the expansion of a web-based PHR in another rare disease setting. This was a 6-month prospective pilot study involving 43 patients diagnosed with chronic idiopathic thrombocytopenic purpura (ITP) in Marseille, France [18]. The primary objective of the study was to evaluate the usability of the Sanoia tool (a freely accessible web-based PHR) that was expanded with ITP-specific tools including links to validated ITP-related web resources, an emergency protocol based on updated national recommendations, and a section for personal notes, allowing patients to record symptoms, medications, and other relevant events. Health evaluations undertaken and assessed with the Sanoia Interface included quality of life (via an ITP Patient Assessment Questionnaire) and usability of the tool (measured by the frequency of tool usage and patient engagement with the personal notes section). The pilot study demonstrated good usability of the customized Sanoia interface for patients with ITP. While no significant impact on quality of life was observed, the tool facilitated patient engagement and information sharing with health care providers [18].

In comparison, our adaptation of the Iowa PHR was more extensive – whilst we similarly linked out to resources for patients with NETs, we spent more effort in development of new user interfaces to physically capture, visualize and document disease symptoms, track and compare these features over time, and record past and present medication use. An

XSL•FO
RenderX

advantage of the Sanoia interface is that patients could create their PHR, receive a unique personal identifier, and share this identifier with health care providers to facilitate access to their medical information in multiple languages.

When compared to generic PHRs, ours shares functionalities including medication management, education, and self-health monitoring [53]. Unlike some generic PHRs, it is not integrated with a hospital's or health system's records and therefore does not enable patients to access their health records, communicate directly with health care providers, or make appointments [53]. The patients with whom we interacted, all based in the United States, typically had to interact with multiple providers who often used different electronic health records systems. Hence, a PHR that could integrate with all these systems would require significant resources to implement and maintain, making these features beyond the scope of our project. Our PHR, however, addresses an aspect that is missing from most PHRs: personalization [53]. Our PHR is personalized not only to the specific needs of patients with NETs but also gives them the opportunity to further customize what information to track. Addressing patients with NETs needs not only makes the PHR more relevant to patients with NETs, but also more usable by reducing the number of steps necessary to access relevant information and functionality, when compared to a generic PHR.

Anticipated long-term impacts of the PHR could include future updates to extend the current tracking capabilities including refining symptom tracking, medication logs, and data visualization tools, making them more customizable and user-friendly. Adaptive user interfaces may also be possible, offering personalized dashboards and automated data entry suggestions. Similar to the Sanoia interface, a major future development would be integrating with hospital and clinic-based EHRs, allowing seamless data sharing between patients and providers. The PHR's ability to collect patient-reported data over time could contribute significantly to other research studies on rare diseases (ie, future cross-disease adaptations). Establishing ongoing engagement through user feedback surveys, focus groups, and iterative testing to refine features in response to user experiences would close the feedback loop and augment on-going user support and engagement. It may also be beneficial to consider further data privacy and security enhancements (ie, strengthening encryption, access control, and data-sharing policies to ensure continued regulatory compliance).

Overall, developing PHR software tailored to rare disease patients can offer numerous benefits, improving health care experiences, treatment outcomes, and providing research opportunities. Patients with rare disease and their caregivers often play an active role in managing their care. A PHR could provide them direct access to their medical data making it easier to monitor changes, track symptoms, and communicate with health care providers. Importantly, a PHR has the potential to consolidate all relevant health data—such as diagnoses, test results, medications, and treatment plans—into a single, easily accessible platform (ie, centralized medical information). This empowers patients with access to their own health information, promotes self-advocacy and informed decision-making.

Strengths

Through patient-centered design approaches, this project prioritized patient involvement throughout, ensuring that the final PHR addressed real patient needs effectively. Multiple phases of testing and refinement (focus groups, surveys, and usability testing) lead to a well-validated and user-friendly PHR system adapted for a NET population. The final PHR includes symptom tracking, custom tracking options, and access to relevant information and resources for patients with NETs, addressing both immediate and long-term patient information needs. Use of Balsamiq for wireframe development allowed for efficient and cost-effective testing of ideas before full implementation. Our emphasis on NETs addresses a critical gap in health care for rare medical conditions, which are often underserved. As a result, patients in the study have gained a tool that improves their understanding and management of their condition, empowering self-advocacy. The final adapted PHR facilitates longitudinal data collection, benefiting both medical research and patient care, a platform that could easily be tailored to other rare disease applications in similar research settings.

Limitations

A limitation is that the study PHR does not have interoperability with patient medical records or smart health devices. Features that integrate patient reported information with systems-derived clinical records should be developed. Incidentally, patients who participated in Phase 1 often had multiple providers and medical record systems. They reported significant challenges with lack of interoperability across their medical records from different providers.

NETs are not necessarily representative of other rare medical conditions. Simpler or more complex patient needs could result in a need to adjust the methods we presented. Despite the features, only 110 out of 1070 patients logged in specifically to use the PHR, suggesting a need for greater awareness and engagement efforts which we plan to promote. Although valuable, the insights may be skewed by the demographics and availability of the participants involved, potentially overlooking the perspectives of less active or digitally less literate patients.

Conclusions

PHR software can be a useful tool to collect data from patients with their permission as part of research studies while providing them with a valuable service. This strategy could be particularly useful for studies of rare medical conditions, where commercial PHR software may not be available and there is often a need to identify the most effective treatments and optimal therapy sequencing. We presented our experience designing and developing PHR software designed for patients with NETs, a rare medical condition. Our online, patient-centered approach altogether involved 89 patients with NETs in identifying requirements through participatory activities, validating them through a survey, providing feedback on an interactive wireframe prototype, and usability testing a fully implemented system. Not only was patient input valuable in helping us design a useful, usable system, but many of the participating patients enjoyed the activities, having their opinions valued, and in many cases meeting other patients with NETs for the first time. We

XSL•FO
RenderX

expect that the methods we used would work well for similar projects.

Abstract

Background: Current health care education methods in Pakistan use traditional media (eg, television and radio), community health workers, and printed materials, which often fall short of reach and engagement among most of the population. The health care sector in Pakistan has not yet used social media effectively to raise awareness and provide education about diseases. Research on the impact social media can have on health care education in Pakistan may expand current efforts, engage a wider audience, and reduce the disease burden on health care facilities.

Objective: This study aims to evaluate the perceptions of health care professionals and paramedic staff regarding social media use to raise awareness and educate people about diseases as a potential means of reducing the disease burden in Pakistan.

Methods: The study used two-stage structural equation modeling (SEM). Data analysis used AMOS 26.0 software, adopting scales from previous literature. Four-item scales for each social media usefulness and health awareness construct and 8-item scales for health care education constructs were adopted on the basis of their higher loading in alignment with psychometric literature. A 7-point Likert scale was used to measure each item. Data collection used convenience sampling, with questionnaires distributed to more than 450 health care professionals and paramedic staff from 2 private hospitals in Lahore, Pakistan. There were 389 useful responses received. However, 340 completed questionnaires were included in the data analysis.

Results: The study found that all the squared multiple correlation (SMC) values were greater than 0.30. Furthermore, convergent validity was measured using (1) standardized factor loading (found greater than 0.5), (2) average variance explained (found greater than 0.5), and (3) composite reliability (found greater than 0.7). The confirmatory factor analysis (CFA) of the measurement model indicated the fitness of the constructs (Chi-square minimum [CMIN]=357.62; CMIN/degrees of freedom [DF]=1.80; Goodness of Fit [GFI]=0.90; Adjusted Goodness of Fit Index [AGFI]=0.89; Buntler-Bonett Normed Fit Index [NFI]=0:915; Comparative Fit Index [CFI]=0:93; Root Mean Square Residual [RMR]=0:075; Root Mean Square Error of Approximation [RMSEA]=0:055). Moreover, the structural model fitness was also confirmed (CMIN=488.6; CMIN/DF=1.85; GFI=0.861; AGFI=0.893; NFI=0.987; CFI=0.945; RMR=0:079; RMSEA=0.053). Hence, the results indicated that social media usefulness has a positive and significant effect on health awareness (hypothesis 1: β=.669, *P*<.001), and health awareness has a positive and significant effect on health care education in Pakistan (hypothesis 2: β=.557, *P*<.001).

Conclusions: This study concludes that health care professionals and paramedic staff in private hospitals support the use of social media to raise awareness and provide health care education. It is considered an effective tool for reducing the disease burden in Pakistan. The study results also revealed that young health care professionals are more inclined toward social media usage and express the need for legislation to support it and establish a monitoring process to avoid misinformation.

Introduction

Background

In Pakistan, the health care system is resource-strapped, leading to challenges in preventing infectious diseases. The country has a high maternal mortality rate (186 deaths per 100,000 live births) and a high infant mortality rate (56 deaths per 1000 live births) [1]. Many complications arise from a lack of awareness and education about prenatal care, safe delivery practices, and postnatal care [2]. Moreover, poor understanding of nutrition has led to widespread malnutrition among children and pregnant

XSL•FO
RenderX

women in Pakistan [1,2]. Malnutrition in children leads to stunted growth, weakened immunity, and impaired cognitive development [2]. The prevalence of stunting in Pakistan is among the highest in the world, affecting approximately 38% of children under 5 years of age [3].

In this context, health awareness and education campaigns potentially lead to behavioral changes and alleviate the burden on health facilities [4]. Public health campaigns, particularly those focused on preventive measures like vaccination, hygiene, and lifestyle changes, have substantially reduced the incidence of various diseases [3,5]. For example, handwashing campaigns alone have reduced respiratory infections by up to 23% [6]. Awareness campaigns aimed at managing chronic conditions, such as diabetes and hypertension, through education on medication adherence and lifestyle modifications have reduced complications and hospital visits [7]. These interventions have been shown to improve health outcomes and reduce health care costs by up to 25% [8].

Among various tools and health interventions, social media has attained the most global attention to enhance health awareness and education to a wider population and discovered its significant impact in addressing health care issues [9,10]. According to social media statistics, social media users worldwide reached 5.04 billion in January 2024, representing 63% of the world's population, with users growing 6% annually [11]. On average, social media users spend 2 hours and 23 minutes daily on social media platforms and see various content [11,12]. Social media tools, such as Facebook (Meta), TikTok (ByteDance), Twitter (subsequently rebranded as X), Instagram (Meta), and YouTube (Google), facilitate health care professionals in educating and influencing perceptions, including networking, sharing ideas, disseminating information, demonstrating, coaching, consulting, and advertising [12,13]. Existing literature in the health care sector has exhibited the transformative potential of social media and its usefulness in spreading health awareness and education [9,10,12,13].

However, the existing literature lacks comprehensive insights into the role of social media in fostering health awareness and education within developing countries, particularly Pakistan. This study addresses this gap by applying Innovation Diffusion Theory to examine the mediating effect of health awareness and empirically testing the impact of social media on health care education among health care professionals.

Therefore, the primary objective of this study is to investigate the role of social media in enhancing health awareness and its subsequent impact on health care education in Pakistan. By addressing the gap in the literature concerning the adoption of social media for health care communication in developing countries, this research aims to provide empirical evidence and practical insights for leveraging digital platforms to improve health outcomes.

This section comprehensively reviews existing literature on social media usefulness, health awareness, health care education, and health care sector challenges in Pakistan.

Social Media Usefulness

The global adoption of social media platforms has led to scalable public health interventions, increased precision and effectiveness, and improved resource mobilization [14]. Social media has encouraged healthy behaviors and enabled informed choices through sharing tips, challenges, and success stories [9]. Health care professionals can provide accurate, evidence-based information as trusted sources [11]. Their involvement is vital due to their expertise, credibility, and ability to reach a wide audience. Campaigns through social media on vaccination, hygiene practices, mental health awareness, and other preventive measures have been helpful in countries like Germany and France [9,10].

Moreover, social media has been effectively used to combat the pandemic and other diseases during the COVID-19 pandemic [15]. The social media data were instrumental in tracking the spread of the COVID-19 virus and disseminating accurate information [16]. Campaigns on platforms such as Facebook and Twitter have been used to promote vaccination, leading to increased uptake in various regions [12]. Tailored messaging on HIV prevention for at-risk populations has shown to be more effective than generalized campaigns [13]. Moreover, existing literature has shown examples of successful public health campaigns, such as:

1. #SmearForSmear Campaign: this social media campaign aimed to raise awareness about cervical cancer screening and successfully increase screening rates by leveraging the reach of platforms such as Twitter and Instagram [17].
2. Truth Initiative: an antismoking campaign that effectively used social media to reduce teen smoking rates through engaging content and interactive platforms [18].

Health Awareness

Health awareness is termed as "Enhancing the ability of individuals to understand and use health information to make informed decisions about their health" [13]. Efforts for health awareness are varied and multifaceted, encompassing a wide range of activities aimed at educating the public about health issues, promoting healthy behaviors, and preventing diseases [16]. Health awareness campaigns lead to early detection and timely intervention, which benefits individuals by lowering their health care expenses and reducing the financial burden on the health care system [18]. Health awareness is generally performed using mass media, social media, posters, billboards, workshops, seminars, local outreach programs, influencers, and public figures [12]. However, social media is most useful in the current era due to its cost-effectiveness and wider audience engagement [17]. Social media allows targeted messaging based on demographics, interests, and online behavior [19]. This ensures that health messages reach the people most likely to benefit from them. Moreover, the effectiveness of health awareness through social media can be measured in a few easy ways, such as the number of impressions, likes, shares, comments, hashtag usage, and so on [18,19]. Hence, medical professionals can analyze the efficacy of their awareness messages. There have been several successful health awareness campaigns conducted through social media that have achieved significant outcomes (Textbox 1).

Textbox 1. Health care awareness campaigns.

- **ThisGirlCan (2015)**
  - Objective: Encourage women of all ages and backgrounds to be more physically active, regardless of their shape, size, or fitness level [20].
  - Execution: The campaign featured real women participating in various physical activities, promoting the message that women should feel confident about being active regardless of societal pressures or body image concerns.
  - Platforms used: Instagram, Twitter, Facebook, and YouTube.
  - Outcomes:
    - Widespread engagement: The hashtag #ThisGirlCan was used millions of times, with significant engagement from women sharing their own stories and photos.
    - Behavioral change: The campaign was credited with encouraging over 2.8 million women in the United Kingdom to become more active.
    - Long-term impact: The campaign continued beyond its initial phase, evolving into a broader movement that still influences public attitudes towards women and fitness.
- **#BellLetsTalk (Ongoing)**
  - Objective: Raise awareness about mental health issues and reduce stigma around mental illness in Canada [21].
  - Execution: For every tweet using the hashtag #BellLetsTalk, every text message sent by Bell customers, and every Facebook video view, Bell Canada donates 5 cents to mental health initiatives.
  - Platforms used: Twitter, Facebook, Instagram, and Snapchat.
  - Outcomes:
    - Record participation: The 2021 campaign saw 159 million interactions, raising nearly CAD $8 million (equivalent US $5.56 million) in a single day.
    - Sustained impact: Since its inception, the campaign has raised more than CAD $121 million (equivalent US $84.5 million) for mental health initiatives.
    - Increased conversations: The campaign has significantly increased public dialogue about mental health in Canada, contributing to reducing stigma and promoting mental wellness.

Health Care Education

Health care education refers to a deeper understanding of specific health topics, including the causes, symptoms, prevention, and treatment of diseases and how to maintain or improve health [20]. It involves having factual information and comprehension of health-related subjects [17]. Health care education encourages regular check-ups, screenings, and vaccinations, leading to early detection of diseases and more effective prevention strategies [19]. For those with chronic conditions such as diabetes, hypertension, or asthma, health care education is essential for managing symptoms, adhering to treatment plans, and avoiding complications [13].

In resource-limited economies, insufficient health care education has been reported among the population, which impedes individuals' ability to understand, access, and apply health information effectively [21]. Moreover, low-income individuals may have less access to health resources, education, and information, which hinders their ability to acquire and apply health education [22]. Addressing these barriers in resource-limited countries requires targeted strategies such as improving health literacy, offering culturally sensitive health care education, increasing access to technology, and combating misinformation [21].

Among these targeted strategies, social media has gained the most attention in the high-income world [20]. Health care education through social media has become an increasingly effective method for reaching diverse audiences with health information. Studies suggest that health care education campaigns on social media can achieve behavioral change success rates ranging from 20% to 40% [16,17]. For instance, social media campaigns promoting COVID-19 vaccination have seen varying success, with some countries reporting a 15% to 25% increase in vaccine uptake attributable to social media efforts [15]. Moreover, some campaigns that promote health services (eg, vaccination drives or mental health counseling) report conversion rates (actual service uptake) of 5% to 20%, depending on the call to action and the ease of access to the service [18]. The existing literature has discussed a few notable health care education campaigns executed through social media and validated their impact. One such campaign for spreading health care education is The Amyotropic Lateral sclerosis (ALS) Ice Bucket Challenge (Textbox 2).

Textbox 2. Health care education campaigns through social media.

1. The ALS Ice Bucket Challenge (2014)

- Overview: Participants dumped buckets of ice water over their heads, shared videos on social media, and nominated others to do the same, all to raise awareness and funds for Amyotrophic Lateral Sclerosis (ALS) research [23].
- Impact:
  - Financial: Raised over US $115 million for the ALS Association in just a few months.
  - Awareness: Dramatically increased global awareness of ALS, with millions participating worldwide.
  - Research Advancement: Funds contributed to significant research advancements, including the discovery of new ALS genes.

Pakistan Context

In Pakistan, the Federal and provincial governments jointly administer 60% of the health care system, with the private sector contributing 30%. Autonomous bodies support the remaining 10 percent [24]. The diverse structure and the country's economic challenges pose unique obstacles to effective health care delivery. The country's health care spending is at 2.95% of its Gross Domestic Product, and the Pakistani government always disregarded the economic survey data and faced criticism from the apex medical organization as it necessitated health allocations in line with global guidelines [25]. To provide quality health care, the Pakistan Medical Association (PMA) expressed the need for 6% of the country's Gross Domestic Product allocation, as recommended by the World Health Organization [17], which the country is unable to meet due to economic challenges [26].

Due to these financial limitations, there are reported disparities in health awareness, with urban areas generally having better access than rural regions [2]. Thus, communicable diseases, such as waterborne diseases and vector-borne diseases, remain a more significant concern in rural regions [1,3]. Moreover, with limited access to maternal health care and family planning services, Pakistan witnesses high maternal and child mortality rates [2]. Diseases such as malaria, tuberculosis, and hepatitis are prevalent, which exacerbates the situation [24]. Moreover, stigma about sexually transmitted infections results in inadequate prevention and treatment efforts that result in a psychological attack on patients [25]. Poor sanitation and hygiene contribute to outbreaks of diseases like cholera and dysentery in Pakistan and many preventable diseases, such as polio and measles, persist due to low vaccination rates [23].

Amid financial crises, health care awareness and education are known to be effective in reducing the disease burden rate [8]. There are several traditional efforts made by the Government of Pakistan Ministry of Health in the past to improve disease awareness and reduce the patient burden [24]. These include the following:

1. Engaging community health workers in disseminating health information, especially in rural areas. However, the number of community health workers to cover the target population is very limited and requires substantial spending [24].
2. Use of radio and television for health awareness programs, public service announcements, and talk shows but requires financial resources [27].
3. Newspapers, magazines, and pamphlets are also used to spread health information, but considering the low literacy rate and cost of print media, these are not found to be much effective for the target population [27].

However, among the modern techniques, social media has gained much attention from health care communities globally [7,10]. Pakistan has also witnessed the widespread of social media but in academics, e-commerce, entertainment, media, politics, sports, and religious sectors. In Pakistan, 29.5% of the population is on social media, whereas 77.8% has active mobile connections, meaning these users also have access to social media platforms [28].

The health care sector is structured to depend on government approval for any initiative [29]. The government has not devised any legislation to promote the use of social media for awareness [24,27]. This mainly restricts the government's health departments and health care professionals from using this tool to publicize health messages. Some efforts have been made to digitalize the health care sector using the eHealth concept and implement a few apps to initiate telehealth and telemedicine [30]. Also, mobile messaging and caller voice tunes are found to be significant in health care services awareness [30]. However, the interpretation and usage of social media tools are still scarce [31]. For this reason, it is imperative to investigate the social media usefulness among health care professionals in Pakistan and to identify whether these health care professionals support the use of social media for health awareness and education.

Theoretical Foundation

A few theories explain the behaviors toward acceptance of any new digitalized tool and address their attitude [32], including the innovation diffusion theory proposed by Rogers in 1962, the Theory of Reasoned Action proposed by Fishbein and Ajzen in 1967, the Self-Efficacy Theory proposed by Bandura in 1977, the Theory of Planned Behavior proposed by Ajzen in 1985, the Social Cognitive Theory proposed by Bandura in 1986, and the Technology Acceptance Model proposed by Davis in 1986 [32]. Among these various behavioral theories, the Innovation Diffusion Theory (IDT) offers a framework for understanding how new ideas, behaviors, or innovations spread within a population [33].

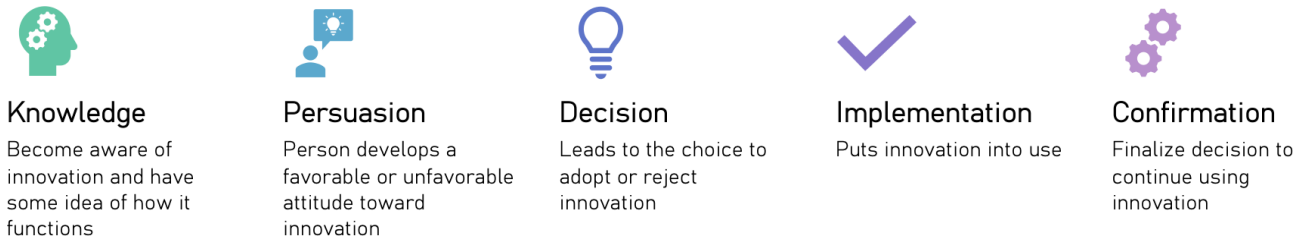
In public health, innovation diffusion theory helps explain how new health interventions, practices, or policies are adopted and disseminated within communities [33]. The theory identifies 5

XSL•FO
RenderX

stages individuals and communities pass when adopting an innovation: knowledge, persuasion, decision, implementation, and confirmation [34]. Figure 1 explains these five stages of the innovation-decision process.

To understand social media acceptance for health awareness and education, the theory has categorized individuals within a population into subgroups based on their readiness to adopt innovations. Innovators and early adopters are likely to adopt innovations early, while most of the population follows suit over time. Laggards are the last to adopt [33]. Figure 2 explains these subgroups of individuals.

Figure 1. Innovation diffusion process.



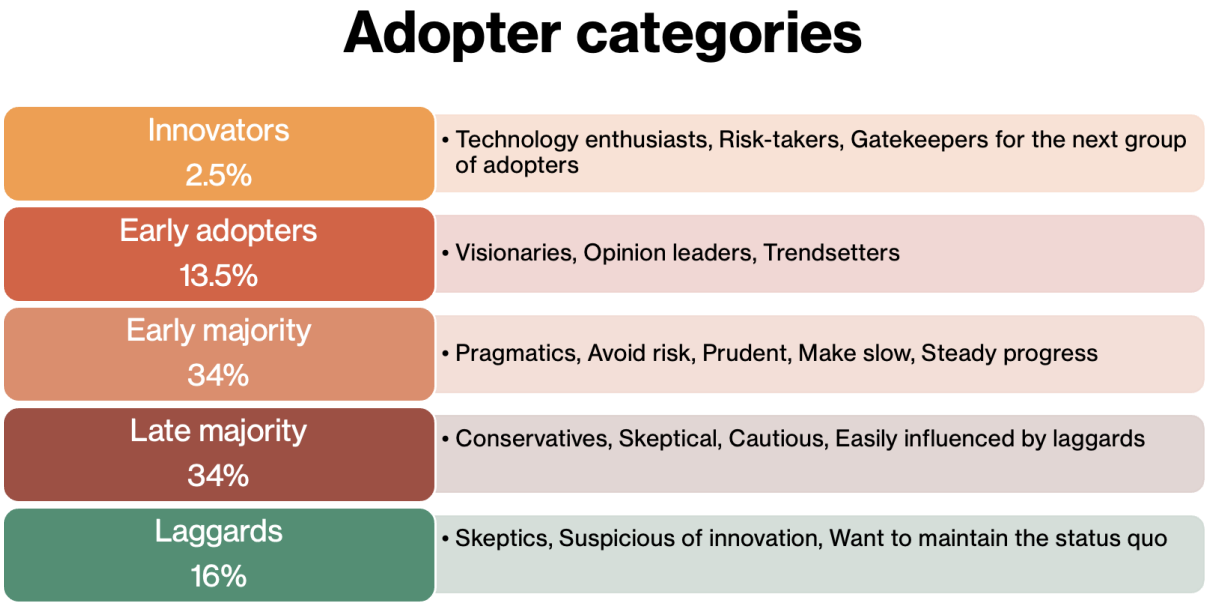


Figure 2. Adopter categories.

In health care education and awareness, the diffusion of innovation is used to fast-track the acceptance of crucial public health digitalized interventions that ordinarily intend to influence the behavior of a social system [34]. Thus, this theory provides the foundation for understanding social media usage and its adoption attitude in a particular community.
