A series of engagement activities with each distinct group of partners was completed before a final workshop that brought all partners and results together to reach a consensus on final research priorities.

Perinatal Care providers

Perinatal care providers across British Columbia including physicians, midwives, nurses, and allied health were invited to share, rate, and explore their thoughts on digital perinatal health using a ThoughtExchange (version 6.4; Fulcrum Management Solutions Ltd). ThoughtExchange is a web-based survey tool that allows participants to share their thoughts in response to a prompt, which can be anonymously viewed and ranked by other participants. The platform then creates weighted rankings of the thoughts on the prompted topic to show participant priorities. The care providers were asked to respond to the following prompt: "What digital health tools are most valuable to your delivery of perinatal health care currently, and what do you think are the greatest areas of opportunity for digital innovation going forward?" The survey was promoted through all British Columbia health authority internal staff newsletters and through member email lists at Doctors of BC; Family Doctors of BC; and University of British Columbia Faculty of Medicine alumni, School of Midwifery, Departments of Obstetrics and Gynaecology, Pediatrics and Family Medicine. Three rounds of promotion were completed. Once the advertised deadline passed, the highest-ranked thoughts were reviewed by 2 research members of the steering committee (BAP and SXC), and key messages were developed through an inductive approach. Basic descriptive statistics were used to analyze the ranking of thoughts.

Health System Partners

Steering committee members from the British Columbia Ministry of Health (MoH), the PHSA, and the PSBC were each asked to review their organizations' recently published reports outlining their strategies for addressing current gaps in health. The reports reviewed were the BC Digital Health Strategy (BCDHS) [21] and the PSBC Maternity Services Strategy (MSS). Access to the MSS was provided through confidential personal communication with PSBC Director Robert Finch. These reports were presented at a steering committee meeting within the first 3 months of the project to identify priorities and alignments specific to perinatal digital health within these documents. The steering committee members from each organization outlined ongoing digital innovation projects in perinatal care and priorities specific to digital health solutions

for improving perinatal care. Each report, postpresentation, was summarized in lay terms to highlight priorities. These summaries were reviewed and edited by the health system partners to ensure that summaries were comprehensive, not leaving out key information.

Patients

A series of four 90-minute PAC meetings were held and recorded over Zoom (Zoom Video Communications). They served to ascertain current digital health use and perceived need for new innovation as well as to inform workshop development from a patient perspective. The meetings included a series of HCD and user-experience research activities, participatory discussions, and postmeeting homework that typically took an hour to complete. The first meeting served as an introduction to all members; the following 2 meetings were developed to allow patients to share their experiences and understand how they interact with the health care system in order to identify gaps, common touchpoints with health care systems and services, and needs (Table 1). For the final meeting, the PAC was provided the lay summaries from the engagement with other partners prior to the meeting. They were asked to review these and share their reflections during the meeting. In addition, they were asked to develop insight statements that identify a need or gap. All meetings were facilitated by the core research team consisting of BAP, SXC, HA, and MV, who were also steering committee members. Activities were carried out on Miro (version 2.0; Miro), a web-based collaborative workspace. Meeting notes were collected and circulated to all participants for review and input. After each meeting, study team members also recorded reflective notes.

Table 1. Patient engagement meeting plan.

Session number	Objective	Presession activity	Activities
1	Establish an environment where patients feel safe and comfortable sharing their experiences	• N/A[a]	• Ice breaker • Introduction to digital health • Empathy mapping activity
2	Gather patients' perspectives and experiences in the health system during pregnancy and after birth	• Complete an empathy map [22] and a 30-minute reflection on their experiences in perinatal care	• Share empathy map and experiences • Introduce user journey activity
3	Identify health system touchpoints and potential areas with opportunities for improvement	• Complete a user journey [23] • Reflect on fellow participants' empathy maps and reflections	• Open discussion regarding user journey and experiences • Introduce insightful statements
4	Prepare for workshops with patients	• Review summary of ThoughtExchange and health systems' report summaries • Insightful statements worksheet [24]	• Comment on summary results • Go over insightful statements • Plan workshop

[a]N/A: not applicable.

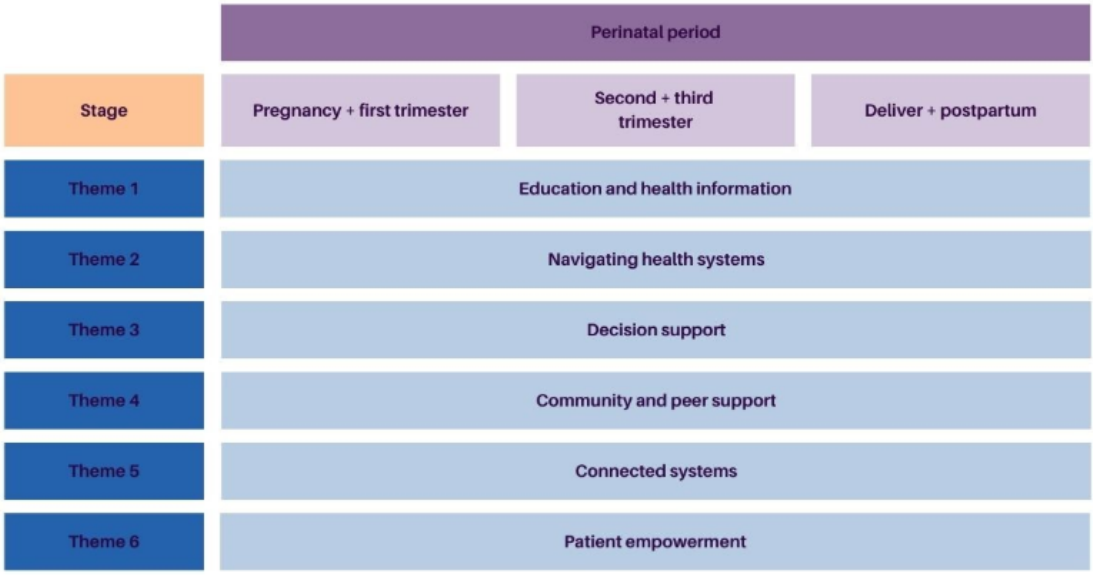
Final Consensus Workshop and Analysis

A final 90-minute workshop was held to bring together all the partners and interested parties to share and align on challenges and priorities collected from earlier engagement sessions. This workshop was composed of both existing members of each partner group: patients, clinical care providers, researchers and health system decision makers as well as additional participants recruited through snowball sampling.

In preparation for the workshop, the core study team (BAP, SXC, HA, and MV) reviewed insight statements from the patients, and using a combination of deductive (using the guiding principles of the BCDHS as a starting point) and inductive analysis, placed these into overarching and emerging themes and then further grouped statements based on relevance to a stage of the perinatal period as described in Figure 1. This grouping was done to make the review and brainstorming session more feasible to complete within our limited 90-minute time frame. Research representatives from the steering committee, BAP and MV, developed 2 example research questions for each thematic area to prime the workshop discussion. These questions were developed to prompt discussion during the workshop, considering many participants do not have a background in research.

Attendees were divided into the 3 perinatal stage–based groups based on their expertise. For example, an attendee who is a neonatologist was assigned to the delivery+postpartum group. Each group contained at least 1 member from each of the partner types in order to facilitate collaboration across groups and consensus building. Each group was asked to reflect on and revise the provided insight statements and example research questions as well as develop their own research questions in order to identify research priorities based on their knowledge and experience. At the end of the session, each group was asked to identify 3-5 priority research questions from their brainstorming exercise. Each group then presented their priority research questions to the full workshop, and collectively, all attendees further discussed and ranked the research questions in order of priority.

Figure 1. Workshop groups and themes.



After the workshop, the research team reviewed meeting recordings, notes, and research question rankings to finalize a list of priority research questions that reflected workshop consensus. These research questions were then reviewed a final time by the PAC to ensure patient needs were at the forefront. This final list of research questions was converted and deployed as a REDCap (Research Electronic Data Capture; Vanderbilt University) survey to all workshop attendees. Respondents were asked to select 3 research questions they believed to be of the highest priority for perinatal care. Survey rankings were summarized descriptively to identify priorities from within the defined research questions.

Results

Engagement activities occurred between September 15, 2022, and August 31, 2023. The steering committee met monthly during this time to review progress and plan adjustments to the strategy, as new knowledge was developed.

Thought Exchange With Clinical Care Providers

A total of 125 perinatal health care provider participants responded, 102 of whom shared what provincial health authority they were affiliated with. British Columbia is split by geographic regions into 5 regional health authorities with an additional province-wide authority focused on Indigenous health and the PHSA that provides oversight for all regions. Most participants came from PHSA (n=25, 24.5%), Fraser Health (n=19, 18.6%), Vancouver Coastal Health (n=16, 15.7%), or Island Health (n=16, 15.7%). There were no participants from the First Nations Health Authority, and 7 participants did not affiliate with any of British Columbia's 7 health authorities.

Of the 125 participants, 55 responded with 80 different thoughts; 51 participants rated the thoughts of their colleagues, resulting in a total of 1108 ratings. Analysis of the thoughts based on the built-in functions of the ThoughtExchange platform identified the highest-ranked themes, which were grouped and summarized. Five key takeaways were identified under the themes of health education and connected systems from the ThoughtExchange:

1. There is an urgent need to create more inclusive, responsive, and accessible digital health tools. The end user (patient or health care provider) must be involved in the design of these tools to make sure that they are useful and can solve the right problems.
2. Among all current digital health tools shared, "Zoom," which is a tool that allows videos and remote health visits, and the "Hyperbilirubinemia risk assessment tool," which is a way for doctors to check if a baby is at risk of developing a condition where their skin and eyes turn yellow, are the highest ranked. "Up to Date," a web-based platform that keeps clinicians up-to-date with the latest medical research and guidelines (the United States only), was mentioned but ranked lower. A tool like "Up to Date" that provides the latest guidelines specific to Canada was identified as a current need to support high-quality care.
3. Important clinical areas that were identified as being priority topics for digital innovation were postpartum lactation support and mental health services. There is a demand for innovation in these areas to be accessible to individuals residing in rural regions.
4. A 2-way communication system is needed to support sharing health information across the province and between patients and providers; this means patients should have equal access to their electronic medical records as their health care providers. Patients should also be able to freely share their information between various levels of health care units at their own discretion.
5. Provincially standardized, free, evidence-based, and user-friendly prenatal patient education was identified as a need that could be solved with digital innovation. Accessible prenatal education would support high-quality perinatal care for all patients in British Columbia.

Health System Partner Engagement

A review of the MoH and PSBC digital health reports and strategies with health system partners in the steering committee meetings identified opportunities where perinatal innovation could be used to improve the quality of the health care system in British Columbia.

The MoH report, BCDHS, identified the following gaps in care across British Columbia: lack of coordination between health care services, poor communication systems, and inadequate follow-up. Therefore, their digital health priorities include (1) empowering patients through participation in their health journey (eg, inclusive, trusted, and equitable health content provided digitally), (2) increasing the capacity for providers to deliver high-quality care (eg, improving digital literacy and promoting the use of digital tools), (3) establishing a connected health system that allows for the sharing of data (eg, interoperability across health authorities and provider level and collaborating on clinical solutions), and (4) infrastructure and business processes streamlined for efficiency (eg, modernizing British Columbia's health supply chain, data flow, asset tracking, and analytics). To accommodate these strategies and goals, PSBC is working on developing a digital platform that acts as a central place for patient information. Based on the identified gaps, strategies, and needed tools, three potential areas for research were identified: (1) What is the best way to use telecommunication and information technologies to provide health care services during pregnancy and childbirth remotely? (2) What is the best design and implementation strategy to enable a shared electronic antenatal health record that can be accessed by any health care provider and patient during pregnancy? (3) Can we validate the use of wearable devices that can track and monitor health data during pregnancy and childbirth (ie, remote blood pressure for hypertension in pregnancy and blood glucose monitoring for gestational diabetes)?

PSBC's MSS report focuses particularly on addressing modifiable factors such as maternal weight and nutrition, substance use, mental health, diabetes, infant sleep, and breastfeeding. They currently have a series of projects in progress, and those specific to digital health solutions include a personalizable information and tool resource hub for providers and patients, a single source of data that can be shared across multiple systems, leveraging access to clinical data for quality improvement, allowing for enhanced digital training opportunities, increasing access to telemedicine care, and updated screening protocols and quality control. Based on these approaches five areas for future research were identified: (1) With the implementation of new technologies, what gaps and biases arise that impact their inclusivity and equity? (2) Although we can assess the immediate and short-term benefits of these technologies, how do we assess their long-term impact on maternal and child health? (3) How do we improve interoperability between different digital platforms to enable seamless data sharing and communication? (4) What policies would need to be put in place to ensure that patient data and privacy are protected? How would this integrate patient consent? (5) How do we understand the needs of the user (patients and health care service providers) and design resources that are user-centered? How do we ensure that users will engage with these resources?

Patient Engagement Sessions

The 4 members of the PAC varied in languages spoken (1 Mandarin, 1 Cantonese, 1 Spanish, and 1 Arabic), age of their children (1 still pregnant at the start of the project, 1 younger than 6 months, and 2 between 6 months and 1 year), mode of delivery (2 vaginal birth and 2 cesarean section), and location of their birth experience (2 Vancouver Coastal Health, 1 Fraser Health, and 1 Interior Health). Over the course of our 4 group meetings, we completed empathy maps, user journeys (Multimedia Appendix 1), and insight statements and collected reflective notes and recordings of live discussions. Common challenges were experienced among all patient partners navigating the perinatal period. For example, all patient partners described difficulties in understanding the different types of perinatal care providers and how to find an available midwife or doctor in their region. They all also spoke of challenges in navigating the transition from pregnancy to early newborn care, particularly when they had nonurgent concerns about their new baby because many available health care resources focus on urgent and emergency conditions.

In the final PAC meeting, we reflected on the summaries of the ThoughtExchange, MSS report, and BCDHS to identify recurring themes, priorities, and gaps that were also expressed by patients, which were then presented in a master list of insight statements (Textbox 1). These insights were divided into 6 themes: education or health information, navigating health systems, decision support, community or peer support, connected systems, and patient empowerment. Overall, over the 4 meetings, patients clearly expressed that they wanted digital innovation that would support their confidence and ability to navigate the health system in all regions of the province of British Columbia where health care is currently distributed and often fragmented. This should come in the form of free and accessible educational resources and tools to navigate the perinatal health journey. All patient partners discussed how stressful it is to navigate the current system and the frustration of having to communicate their health information to different care providers repeatedly. Almost all of our patient partners moved during the course of their pregnancy and experienced challenges finding maternity care providers both initially and after they moved. Another universal experience was the challenge presented by our current system, which does not allow for the pairing of the mother's and infant's health records. This often resulted in logistical challenges in navigating postpartum and postnatal follow-up that were borne entirely by the new parents. As a result of the success of these sessions, the research team worked with the PAC to develop a toolkit for patient engagement that was made available for use by other research teams (Multimedia Appendix 2).

Textbox 1. Final list of insight statements.

Reliable health information is needed

- Patients who are accessing perinatal care are overwhelmed by navigating an abundance of resources, and they are not sure which ones are accurate to follow.
- When seeking health-related information on the internet, information is often conflicting or misleading.
- When seeking health information on the internet, information is only in English and can be difficult to understand or communicate to multilingual family members.
- Health information provided is in technical terms that patients are unfamiliar with leaving patients confused.
- Patients often rely on informal peer support, which adds to the conflicting information they receive, leaving them more confused and unsure of what information to trust.
- Due to the abundance of information available on the internet, patients feel like they are wasting or spending too much of their time filtering through the information.
- Patients indicated that it is challenging to understand the difference between an obstetrician and a midwife especially for newcomers or immigrants from a different health care system; they do not know how to choose the right professional for them.

Lack of supports

- Due to the duration between pregnancy and a patient's first obstetrician gynecologist appointment being too long, patients are left with the responsibility of seeking information independently.
- There are limited perinatal classes that are poorly advertised and are not free; therefore, not all patients have the means to access them.
- Patients are navigating aspects of the health care system during their perinatal journey that they have never had to use before; this often comes with little guidance and doubts about what steps need to be taken.
- Patients who are pregnant for the first time do not know where and what services to seek, leaving them feeling helpless and guilty if complications occur.

Need for continuum of care

- Patients' care is interrupted by the transfer of care to a different care provider especially after delivery. These periods of interruption leave patients uncertain and lost.
- After being discharged after delivery or from midwives, patients feel like their only support is the emergency room, especially if they do not have a family doctor.

Mental health challenges

- Complications during the perinatal period leave patients feeling incompetent and highly anxious about their own situations.
- Patients wanting to seek mental health support are discouraged because they are unaware of how to access them or told they are not in need of them.

Emergency screening

- Due to the long wait times in the emergency room and lack of knowledge of problems arising either during prepartum or postpartum, patients indicated a need to have an emergency screening process tailored to pregnant and newborn mothers by using the digital platform before they head to the hospitals to save or rule out unnecessary visits.

Uncoordinated transitions of care

- It was challenging for patients to find an appropriate obstetrician or midwife in a timely manner; they had to call a list of clinics on their own or find one through word of mouth in order to be accepted.
- When patients find out they are pregnant, they are frustrated by a lack of information on available care providers in their region.
- Patients are confused about when to choose a midwife or other type of doctor and why they may need to switch providers during pregnancy.
- Mom and baby's care is not coordinated in the health system after the birth of the baby because they are treated as 2 distinct patients.
- There is no standardized system to share health records between perinatal care providers, which leaves patients with the responsibility to communicate their health information when multiple types of caregivers are needed to support their pregnancy.
- When accessing care, services, or resources across different health authorities, health authorities do not follow standardized structures or guidelines acting as an additional barrier for patients as they learn to navigate a new health authority.
- There is a lack of communication and awareness among health authorities, therefore, interrupting patients' care.

Poor patient-centered care

- Care providers are dismissive of patient concerns and thoughts, resulting in patients advocating for themselves and leaving them stressed and isolated.
- Patients feel uninvolved in their health because they are often told what to do without direct and clear explanations or guidelines from their providers.
- Patients have to manage multiple appointments with different providers instead of an integrated care team, meaning that they often wait long periods of time before their needs are addressed.
- Patients would appreciate more visits and opportunities to meet with their care providers or a trusted source in order to discuss their concerns and ask questions.
- Patients want to hear follow-up from their care provider after every test, even if it is normal.

Final Workshop

The workshop had a total of 20 attendees: 4 core project team members, 4 patient partners, 2 researchers, 5 clinicians, and 5 health system partners. The workshop was held over Zoom. During the workshop, 3 research themes were chosen as priorities through the discussion process including patient autonomy and support, educational resources for patients and providers, and access to health information (Figure 2). Attendees chose to frame the final research questions around broad transformative goals rather than specific clinical care concepts or processes to make the final agenda broadly applicable across health settings in the British Columbia public health system. For example, although patients and clinicians identified a need for lactation support earlier in the engagement process, a decision was made not to name this clinical concern specifically, as it was felt to narrow the scope of the recommendations. Similarly, patients and care providers identified a need for more accessible support for nonurgent health concerns. Suggestions were made to create more digital resources, but in discussion, the group agreed that more foundational knowledge on the type of digital technology that would be found most usable and effective for providing health information is needed. This resulted in final research questions such as 1.3 and 2.3. A total of 12 final research questions to be included in the research agenda were developed to reflect the identified priorities and patient perspectives (Figure 3).

Figure 2. Three priority themes for perinatal digital health research.

Figure 3. Final list of priority research questions. RPM: remote patient monitoring.

A follow-up REDCap survey was sent to a total of 35 individuals, including all workshop participants, steering committee members, and patient partners, and we received 20 responses. Respondents included 5 researchers, 5 health system decision makers, and 6 perinatal health care providers with 4 patient advisors. When asked to select the top 3 priority research questions, respondents prioritized questions 1.4, 1.2, and 3.3 (Textbox 2). All of these questions focus on supporting patients' decision-making with better information and fall within the themes of improving patient autonomy and access to information. When comparing the priority of the overarching themes, overall questions from theme 1: patient autonomy and support were the most selected; however, if we adjust for the number of questions per category, questions from theme 3: access to health information were the most selected.

Textbox 2. Prioritization of research questions.

Number of times prioritized: 9

- Question 1.4: What aspects of perinatal care can be monitored, administered, or assessed using mobile devices (ie, remote patient monitoring, digital health visits, and peer support) to support empowered self-care? How do we implement these without widening the access to care gap experienced by already disadvantaged populations?

Number of times prioritized: 7

- Question 1.2: What digital tools and information can support patients' decisions in identifying and connecting with the right maternity care provider? What information do patients need to identify the right maternity care provider? How do we support this decision with digital tools?
- Question 3.3: How can the integration of patient-reported outcomes in a patient's record contribute to quality improvement and shared decision-making?

Number of times prioritized: 5

- Question 1.5: How do we monitor the mental health patients receiving perinatal care in order to provide timely support when needed and improve health outcomes and perinatal recovery?
- Question 2.1: What resources can be compiled into a starter kit to guide patients through their pregnancy? What resources can be compiled into a starter kit to guide patients who have just delivered their child? How do these resources impact patient and child health outcomes?
- Question 2.3: How do patients prefer to view and access health information and educational resources (eg, type of format such as audio vs video vs website)? How can we engage patients and providers in developing and designing these resources? Are there existing resources we can expand in function to meet patient needs (eg, 811 response, peer support, chatbots, or SmartMom)?
- Question 3.1: What is the effect of more transparent access to provincial dashboards such as HealthGateway (for both parent and child and linked together) on care quality, and access to care in both urban and rural or remote settings?

Number of times prioritized: 4

- Question 3.2: Can improved data access for patients and care providers lead to an increase in British Columbia's status against global benchmarks for health care quality?

Number of times prioritized: 3

- Question 2.2: What are the individual, organizational, and policy barriers and facilitators to providing standardized multilingual prenatal and postnatal education in British Columbia?

Number of times prioritized: 2

- Question 1.1: How do we best measure patient autonomy in the perinatal period?
- Question 1.3: What services and resources exist within British Columbia that support patient mental health, self-care, and patient autonomy in decision-making? How do we ensure providers are aware of them? How do we emphasize connecting patients to them?

Number of times prioritized: 1

- Question 2.4 What implementation strategies will work to make educational resources accessible across regions in British Columbia? How do we measure impact?

Discussion

Research Priorities and Implications for Practice

The RAPID project resulted in the co-design of a comprehensive research agenda for perinatal digital innovation that reflects provincial strategies and patient experience in British Columbia. During the project, a series of engagement activities allowed us to ascertain the current gaps and needs for digital health interventions for perinatal care and develop a research agenda that will address these needs. Our research agenda provides a foundation for identifying, developing, and implementing digital solutions that are responsive and feasible within the current British Columbia health care system landscape. The RAPID research agenda identified a core set of research priorities under 3 interdependent thematic areas that, if addressed, could lead to meaningful improvements in patient and clinician experience and health outcomes in the perinatal period. The priority themes identified are patient autonomy and support when navigating the health system, patient and provider access to education resources, and patients' ability to access health information. These themes align with the BCDHS and have broad support from health system leaders.

The research themes identified and research questions prioritized in this project suggest that further innovation is needed to properly leverage digital health tools to support perinatal care in British Columbia. Priority research questions and a major area of discussion with our patient partners focused on a need for better digital tools to support self-care and decision-making across the entire perinatal period, from pregnancy to the end of the first year of the infant's life. The ThoughtExchange also highlighted that, within the British Columbian health system, there is a limited number of tools in use that clinicians view as

valuable to care. This results in patients accessing numerous external digital resources that are not always of quality and relevance to their care. This agenda can be used to advocate for change at the provincial level and support the incorporation of digital health into the health system. Addressing research priorities identified by RAPID would improve the patient experience by providing needed solutions that allow patients to safely interact with their health care professionals through web-based platforms or through their mobile devices, access self-care tools and applications, use smartphones or other devices to manage and monitor their health, and adopt technology in their health plans.

Digital health innovation as suggested by our research agenda is appealing because it is not restricted by time or place [13] allowing for patient empowerment as well as patient participation in the decision-making of their own health. Addressing the RAPID research priorities can also improve the continuity of care and delivery of essential services, something that all partners in the RAPID project would clearly value. There is already evidence that digital innovation in perinatal care can lead to improved health outcomes for both the woman or pregnant person and their infant [1,12-14]. This agenda highlights that the perceived value of digital innovations for patients receiving perinatal care and their families cannot only be determined by traditional health outcomes. Digital innovations should also be measured against their ability to improve confidence and autonomy in decision-making, self-care, information sharing, and patient and clinical experience.

The digital health sector receives enormous investment, making available a vast number of solutions varying in quality and capabilities [17]. The existing literature has provided a broad understanding of the feasibility, acceptability, and effectiveness of digital tools outlining advantages and disadvantages [1,12]. However, this continued growth in digital solutions does not guarantee or equate to an increase in solutions that can be implemented to meet the actual existing needs of patients, providers, and health systems [17]. In this project, we used HCD methods to identify patient needs and priorities for digital innovation that are aligned with clinical care providers and health system priorities, but our identified priorities cannot exist in isolation from the current knowledge of socioecological factors. Although the RAPID priority research questions are defined based on need, these must be explored with consideration for the facilitators and barriers that contribute to engagement with digital health solutions. Previous research on digital health use has identified barriers and facilitators to implementation such as infrastructure, equipment, network access, motivation, and usability [25,26].

The effort was made to integrate the knowledge of barriers and facilitators to engagement and uptake of digital health innovations throughout the research agenda, such as geographic settings, data-security concerns, and diversity in health concerns. However, considerations for these barriers and facilitators should continue beyond what the questions have defined, as we work to action the agenda. Issues such as connectivity, user motivation, social support, digital literacy, user-friendly design, and credibility should continue to be examined throughout subsequent digital health research.

Strengths and Limitations

This project's use of a human-centered approach prioritized patient voices and provided the space for collaborative co-design of the final research questions. Limiting the number of patient partners and restricting the number of researchers in the patient advisory meetings allowed for better quality engagement through intimate and extensive discussions. The diversity of partners from across British Columbia allows for more generalizable results. However, a significant limitation was our lack of engagement with Indigenous clinical care providers or patients. There is a need to engage with Indigenous people's voices within all of the partner groups before moving research forward from this strategy. Related to this, although we were able to collect a diverse group of partners' opinions and bring these together to design a comprehensive research agenda, running the project under a knowledge translation initiative restricted the amount of data we could collect on engaged participants. As a result, it may be more difficult for others to apply this knowledge outside of the British Columbia health system. We also cannot explore if participant characteristics such as age or experience level (for health care providers) had any impact on their opinions of digital health priorities. An additional strength is our engagement with health system partners throughout the project, aligning in strategy and garnering early support from decision makers. As a result, outcomes of research informed by this agenda are more likely to be implemented and achieve long-term impact. There was strong collaboration throughout the project between researchers and knowledge users, allowing us to lead this work within the health system, leveraging developed partnerships, and articulating alignment with organizational goals and patient research priorities.

This HCD approach prioritized patient voices in developing research priorities; yet, our multipartner codevelopment approach recognizes that the ownness should not be on patients alone to identify a solution to the complex issues of perinatal health care delivery. The emphasis on people solving their own problems that is core to the HCD approach cannot be directly assumed in a health care context due to the complexity of the system and the multitude of interested parties that will be impacted by any system changes. In positioning our work to address patient needs while still aligning with health system priorities, we have aimed to support value-based care efforts in the British Columbia health system. Focusing further research and innovation efforts to address the RAPID research priorities can support improvements in value-based care, as they would improve outcomes and processes that matter to patients without an unreasonable increase in health care expenditure.

Conclusions

This project identified clear support and enthusiasm across partners for digital innovation to improve the quality of perinatal care in the province of British Columbia. Our research agenda highlights the need for better patient education and health information systems that are more accessible to patients and care providers with the overarching need for digital resources that can increase patient autonomy in decision-making throughout pregnancy and the transition to newborn care. Co-design of this research agenda is a first step in the research

process. Our priority now is to take action on identified research priorities. Action can occur through traditional research funding pathways but also by advocating to our health system partners to directly address needs identified by the RAPID research agenda within the health system.

Acknowledgments

The authors gratefully acknowledge that our project could not have been possible without the invaluable contributions of our patient partners AE, KJH, JMG, and LY. The authors thank Joanne Hepplewhite from the Provincial Health Services Authority Transformation development office for her support with the ThoughtExchange. This project was funded through a convening and collaborating grant (#C2-2022-2969) from the Michael Smith Health Research BC.

Abstract

Background: Patient-derived biospecimens are invaluable tools in biomedical research. Currently, there are no mechanisms for patients to follow along and learn about the uses of their donated samples. Incorporating patients as stakeholders and meaningfully engaging them in biomedical research first requires transparency of research activities.

Objective: In this paper, we describe the use of participatory design methods to build a decentralized biobanking "de-bi" mobile app where patients could learn about biobanking, track their specimens, and engage with ongoing research via patient-friendly interfaces overlaying institutional biobank databases, initially developed for a breast cancer use case.

Methods: This research occurred in 2 phases. In phase 1, we designed app screens from which patients could learn about ongoing research involving their samples. We embedded these screens in a survey (n=94) to gauge patients' interests regarding types of feedback and engagement opportunities; survey responses were probed during 6 comprehensive follow-up interviews. We then held an immersive participatory design workshop where participants (approximately 50) provided general feedback about our approach, with an embedded codesign workshop where a subset (n=15) provided targeted feedback on screen designs. For phase 2, we refined user interfaces and developed a functional app prototype in consultation with institutional stakeholders to ensure regulatory compliance, workflow compatibility, and composability with local data architectures. We presented the app at a second workshop, where participants (n=25, across 9 groups) shared thoughts on the app's usability and design. In this phase, we conducted cognitive walkthroughs (n=13) to gain in-depth feedback on in-app task navigation.

Results: Most of the survey participants (61/81, 75%) were interested in learning the outcomes of research on their specimens, and 49% (41/83) were interested in connecting with others with the same diagnosis. Participants (47/60, 78%) expressed strong interest in receiving patient-friendly summaries of scientific information from scientists using their biospecimens. The first design workshop identified confusion in terminology and data presentation (eg, 9/15, 60% of co-designers were unclear on the biospecimens "in use"), though many appreciated the ability to view their personal biospecimens (7/15, 47%), and most were excited about connecting with others (12/15, 80%). In the second workshop, all groups found the app's information valuable. Moreover, 44% (5/9) noted they did not like the onboarding process, which was echoed in cognitive walkthroughs. Walkthroughs further confirmed interest in biospecimen tracking, and 23% (3/13) had confusion about not finding any of their biospecimens in the app. These findings guided refinements in onboarding, design, and user experience.

Conclusions: Designing a patient-facing app that displays information about biobanked specimens can facilitate greater transparency and engagement in biomedical research. Co-designing the app with patient stakeholders confirmed interest in learning about biospecimens and related research, improved presentation of data, and ensured usability of the app in preparation for a pilot study.

Introduction

Background

Samples of blood, tissue, urine, and other biological products, collected from patients during a medical procedure, are invaluable tools in biomedical research. Reviews estimate that >600 research biobanks exist in the United States, housing tens of millions of samples from tens of millions of patients [1,2]. Biospecimens are used in a vast array of foundational, translational, and clinical research [3-6]. Research on biospecimens shows exceptional promise in studying cancer and developing new cancer treatments [4,7,8]. Cutting-edge specimen preservation methods offer high-fidelity disease models for genomic analysis, high-throughput drug testing, advanced imaging, and more.

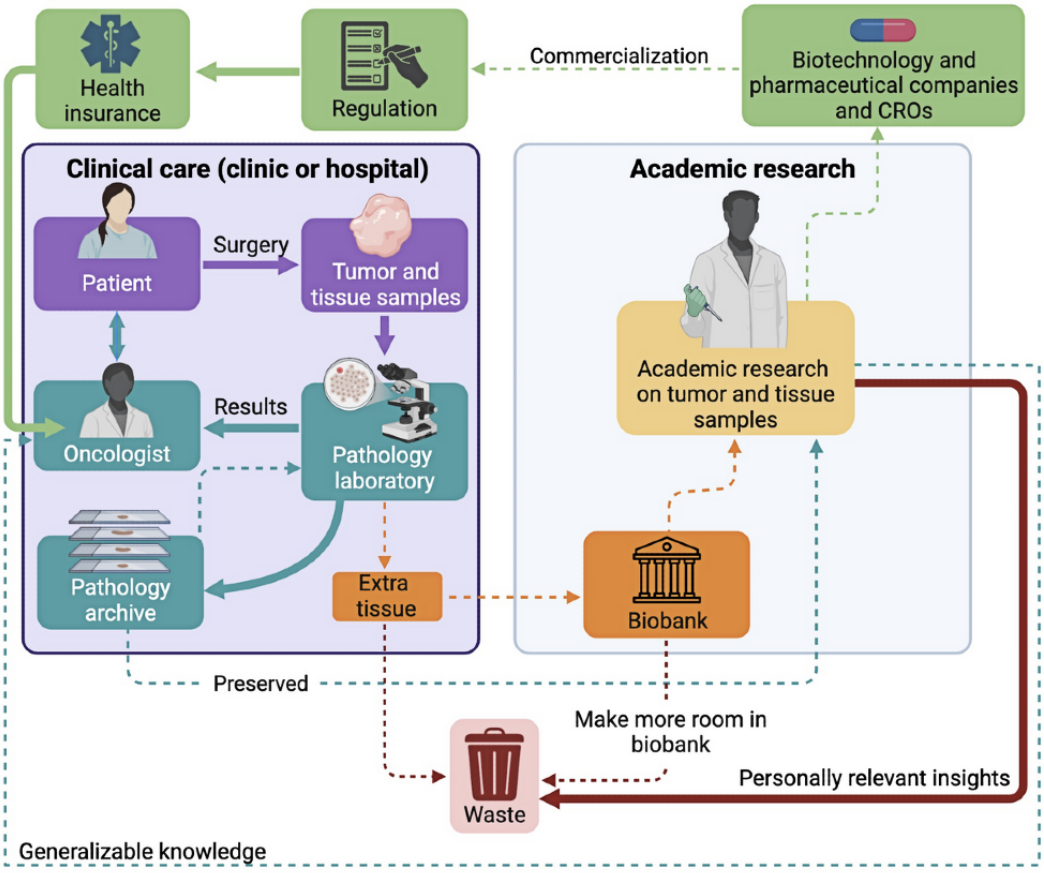
Typically, leftover surgical samples are collected after a 1-time informed consent process per the federal Common Rule in the United States, where patients receive information about the proposed research [9]. The terms of this consent include no expectation to follow up with pertinent research results after the form is signed and samples are collected [10]. In the transition from clinical by-product to banked research sample, patient identifiers are removed from biospecimen data [11]. Deidentification is meant to protect patient privacy by removing identifiable information; however, its conditions preclude scientists from sharing follow-up information about if, when, and how they use biospecimens for research [12]. Scientists receive deidentified biospecimens from the biobank and have no mechanism to directly communicate personally relevant insights or engage with the people whose samples they have received (Figure 1) [10]. Thus, while clinical results from pathology reports are communicated to patients, information on how their biospecimens are used and associated research findings are never shared.

Incorporating patients as stakeholders and meaningfully engaging them in biomedical research is increasingly recognized as critical to more ethical and effective scientific advancement [13]. Patients' lived experiences can help guide research questions, priorities, and methodologies, ensuring that the resulting knowledge aligns with their and their community's priorities. Various innovative technologies and techniques have enhanced patient engagement in research [14,15]; for instance, the James Lind Alliance method facilitates collaboration among clinicians, the public, and additional stakeholders, enabling their opinions to converge and inform the establishment of research priorities [16,17]. Digital platforms that assemble citizens from different backgrounds to share experiences and actively codevelop innovative health strategies have been proposed [18]. However, improving transparency surrounding the nature and extent of research activities is a prerequisite to achieving true patient engagement.

Decentralizing biobank information and empowering biospecimen donors with knowledge about how their samples are used lays the foundation for fostering trust and transparency in biospecimen research [19]. This is particularly vital in rebuilding trust with communities considered marginalized, which have historically been subject to exploitation and unethical research practices [20]. Building trust lays the foundation for further participation by diverse communities and ensures that research endeavors are accountable to those whose biospecimens make the research possible [21].

In previous work, we have demonstrated that there is unmet patient demand for increased transparency surrounding biospecimen research use [22]. We surveyed patients with breast cancer (n=109) about their interest in learning about biobank research and their individual biospecimens [22]. This survey measured patient interest in a broad range of information that they could theoretically learn about research on their samples. Notably, survey respondents were interested in learning information that is readily available within in local biobank and research databases, such as whether their samples had been used in research (66%), details about research conducted on their samples (53%), and the ability to see images of their biospecimens if available (68%).

Figure 1. Biobanking ecosystem: biospecimen supply chain from clinical by-products to institutionalized assets. In the current biobanking paradigm, personally relevant insights and extra tissue are often wasted, representing lost opportunity to advance patient care and maximize value from donated biospecimens. CRO: contract research organization.



Objectives

To address the unmet need for greater transparency and engagement between biobanks and patients, we sought to build an initial decentralized biobanking app—"de-bi"—to serve as a patient's "window" into an established biobank database. We aimed to build a composable platform that would be accessible and valuable to patients while being compliant with existing regulations, composable with data architectures and compatible with established workflows [23]. By viewing biobank data, patients can be empowered to "track" what happens to their biospecimens [24]. A patient-facing mobile app could overlay and display existing data, serving as a technological tool for increasing the transparency of research activities and as a mechanism for directly engaging with patients who have contributed to research, all within the current frameworks of consent and deidentification. Composability with institutional databases would also serve as a source of efficiency, easing the burden of the initial manual data transfer to an app interface and setting up easier future automation and scalability. This tool could then be piloted to measure its impact on patient participation, understanding, and attitudes about biobanking and biospecimen research and begin to answer outstanding empirical questions about effectively fulfilling obligations of transparency and engagement.

Including patients in the design phase was imperative to the future pilot's success. Before the tool was deployed, we sought to ensure that it was interesting, accessible, understandable, valuable, and easy and ideally pleasant to use. Here, we describe the process and results of using participatory design methods to define, design, and deliver a mobile app that enables patients to learn about their biospecimens collected for research, the status of the biospecimens' use in research protocols, and overall biobank collections, as demonstrated in a breast cancer biobank setting.

Methods

Overview

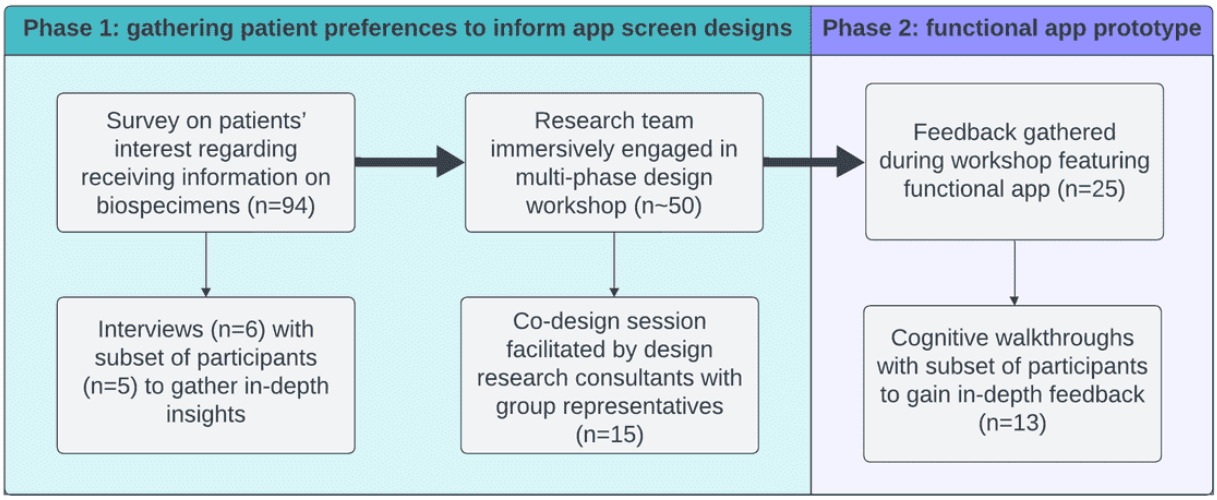
This multiphase participatory design study was conducted among patients of a breast cancer clinic at a large US academic institution. It consisted of surveys of patients (n=94), six semistructured in-depth follow-up interviews with five survey respondents (5/94, 5%), immersive design workshops with patients (workshop 1: approximately 50 participants, focusing on a subset of 15 codesign participants), workshop 2: n=25), and cognitive walkthroughs with individual patients (n=13) [25]. The data being presented represent a subset of broader participant engagement, including additional workshops and encounters with the local community of patients with breast cancer.

This research occurred in 2 phases (Figure 2). In phase 1, we designed smartphone screens containing different information that patients could learn about biobank and research activities

involving their samples. Embedding these screen designs in a survey, we sought to gauge patients' interest in receiving information about research or their biospecimens. We engaged a subset of survey respondents in short web-based interviews to discern their views on the importance of having this information and their opinions on its presentation and design. We held a design workshop at which participants gave feedback on the screens and suggested improvements.

For phase 2, we refined the user interfaces and developed a functional app prototype. As we developed the app, we consulted institutional stakeholders to enhance compatibility with regulations and composability of core app features, with one another and with local data architectures. We then distributed the app at a second design workshop, where participants shared thoughts on the usability and design of the app. In this phase, we conducted cognitive walkthroughs with individual participants to observe their success in using the app and to gain in-depth feedback on its functionality [26].

Figure 2. Overview of study methods.



Phase 1

App Screen Design

We used Whimsical and Figma for the initial wireframes and Flutter and Adalo for prototyping to develop the initial screen designs [27,28]. The content of these designs was informed by previous engagement with this patient population and limited by the content available within institutional biobank or research databases and publicly accessible research content. Previous survey results identified important data points to include in our patient-facing display and informed its design [22]. Working with investigators on the biobanking research protocol, their data managers, and the University of Pittsburgh Institutional Review Board, we selected data points that would be feasible and acceptable to return to patients in a future, functional solution. We then created a sample screenshot presenting a model set of samples and the corresponding hypothetical data points.

We designed 3 initial app screens presenting information about a hypothetical user's collection of biospecimens in the biobank (Figure 3). These screens were meant to be viewed sequentially, with increasing specificity of information presented about individual biospecimens in the biobank. The interface was inspired by the term "biobanking" and designed to resemble many banking apps where users first view a summary of their accounts and can click through to increase specificity about each one. Our first screen contained a summary list of a hypothetical individual's inventory of donated samples, including pictures of each. The second screen displayed high-level demographic information about each individual biospecimen: an image, its location, and the date it was collected. The third and final screen showed more details about each individual sample, such as its ID number, the medical procedure from which it was collected, the number of the freezer where it was stored, and more.

A fourth screen was created for potential users to learn about the biobank collection as a whole (Figure 4). This screen, called "connect," showed a list of subcommunities of biobank donors sorted into groups by their diagnosis code, including summary statistics indicating how many donors to the biobank shared a diagnosis (eg, invasive ductal carcinoma). The design suggests that users might be members of ≥1 of these groups (called "labs") and might use their membership to "connect" with other users, patients, or scientists.

Figure 3. The 3 "biowallet" screens, as developed in Adalo and featured in the survey, presenting different categories of specimens using accordion unfolding and individual sample–level details.

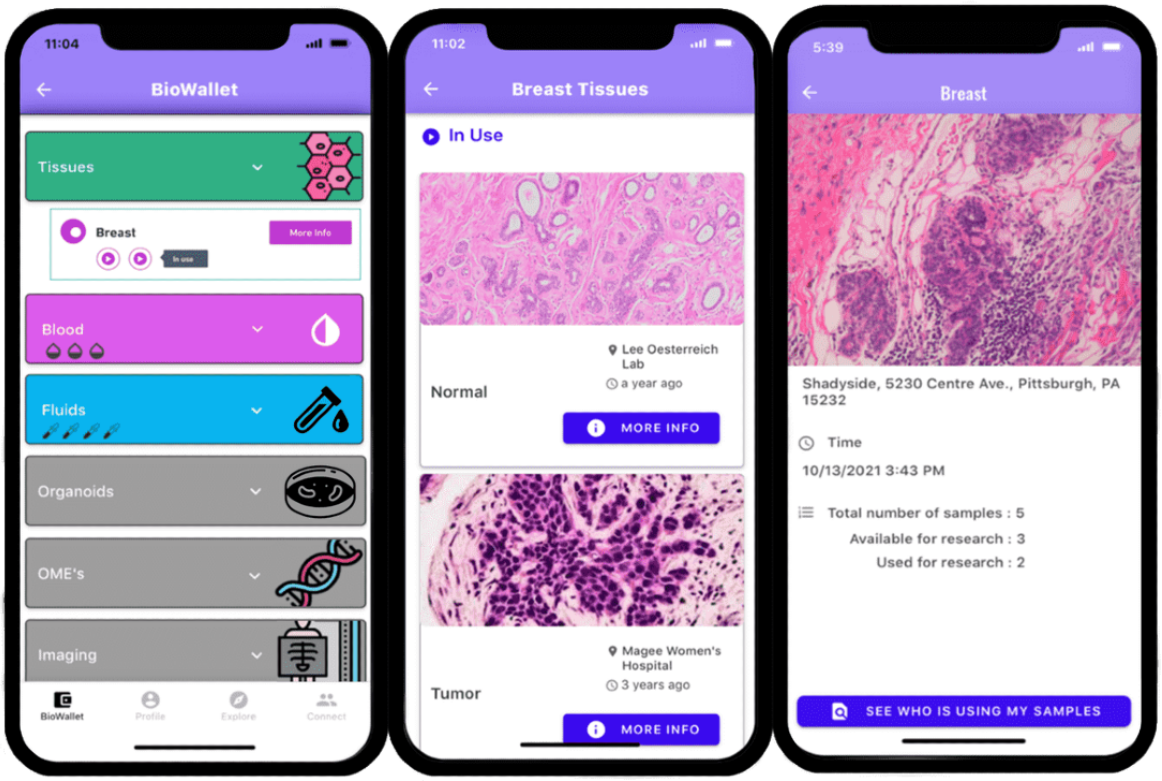


Figure 4. Biobank, research, and community screens. These screens, developed with Adalo, illustrate features explored in surveys, interviews, and workshops, including opportunities to learn about biobanking and specific specimens, follow scientists and learn about individual research programs, and connect with fellow donors and scientists.

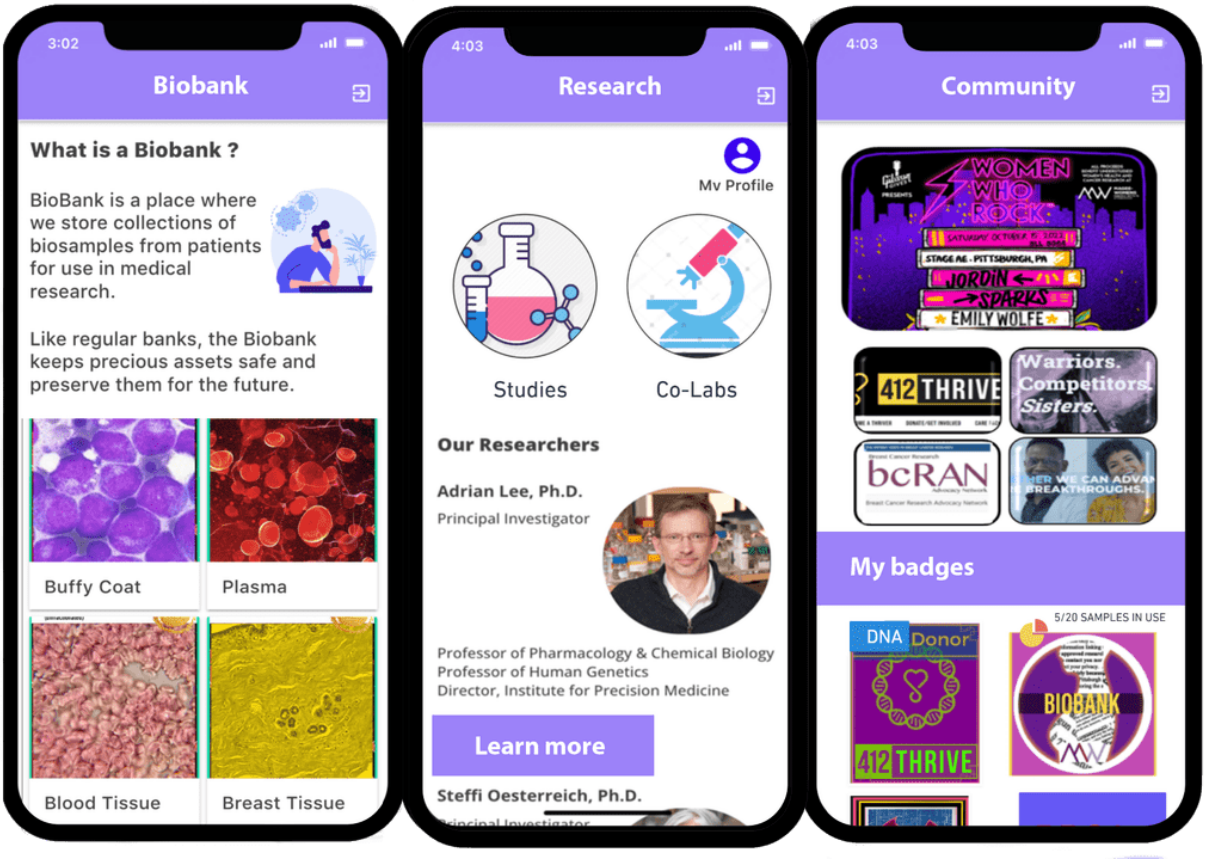

Surveys and Semistructured Interviews

After developing the initial app screens, we embedded them into a survey to gather further evaluation and feedback from patients [29]. We conducted the survey in 2023 with a convenience sample, recruiting patients via flyers posted in breast care clinics across the health system. Participants took the survey on their own devices. IP addresses were used to identify duplicate entries from the same users. At the end of the survey, participants were invited to participate in an optional follow-up semistructured interview to discuss their survey answers. Survey content was iterated and rotated as app screens were finalized and in response to saturation of data from responses and follow-up interviews. Thus, survey data are presented with the denominator reflecting the number of participants who received each specific question and chose to reply. In total, 94 participants completed the survey, of whom 5 (5%) participated in the follow-up interviews (one participant was interviewed twice; once before and once after her cancer diagnosis). Demographics of the survey respondents, including age, race, and cancer stage, are presented in Table 1. The "Unknown" category represents participants who chose not to answer that question.

The survey asked participants their level of interest in the information presented on the app screens. After viewing the "biowallet" screens, participants were asked which of the presented data points were of interest to them. After viewing the "connect" screen, patients were asked whether identifying and belonging to a subcommunity of donors to the biobank would be of interest to them and, if so, how they might want to use the app to connect with others; for example, they were asked whether they were interested in connecting with researchers who used their samples from the biobank and, if so, what information they would like to exchange with them. They were also asked about their interest in connecting with other, similar patients who might be members of the same subcommunity (eg, have the same diagnosis code) and, if so, how.

In the follow-up semistructured interviews, participants and members of the research team viewed the participants' survey responses via screen sharing on an audio-recorded web-based call. The participant's survey responses were walked through one at a time, and the participant was asked to go into further detail about their reasoning for their answers. These interviews were meant to validate the survey questions by identifying any confusing language or images and to gain a deeper understanding of the motivations, preferences, interests, and concerns of participants. Each interview lasted 35 to 45 minutes. Interview participants were selected to represent key subsegments of the survey population, for example, age, education, and time from diagnosis.

Survey responses were analyzed, and summary statistics are presented. Transcripts of the follow-up interviews were coded for emergent themes in response to each set of screens. The results from both analyses informed changes to the presentation of biobank data and adjustments to the design of the screens to meet participant preferences and clarify content.

Design Workshop 1

We sought feedback on the "biowallet" screens, the "connect" screen, and 2 additional screens: "explore" and "profile." The "connect" feature was expanded to include 3 screens showing a list of all "lab" groups and subcommunities, a description and membership details of 1 specific "lab," and an action button to "add my samples" to a "lab." The screen called "explore" contained additional biobank-level data about the collection of biospecimens. The last addition, "profile," contained a hypothetical user-chosen avatar to represent themselves, as well as a collection of hypothetical achievement badges representing activities that users might be able to complete both in the app ("claimed my biowallet") and in research participation ("signed a consent form"). It also contained a progress bar indicating the users' completion of in-app tasks and achievements. We presented the second iteration of the screens to approximately 50 members of a local support group for patients with breast cancer in an embedded participatory design workshop. Members of the research team presented the screens, gave a short overview of their contents, and explained the overall intent of decentralized biobanking as well as the purpose of the dedicated app codesign workshop.

Participants provided feedback about the overall approach during a three-day participatory engagement event where the research team presented to and engaged with the local breast cancer patient and previvor population in an immersive setting. In this paper, we focus on describing results for 15 group representatives who attended a professionally facilitated in-person codesign workshop where they provided detailed feedback on individual app screen designs. Participants were given printed images of the screens, along with stickers—thumbs up or a heart to signify something they liked, a question mark to signify something they were confused by, and an exclamation point or a frowning face to signify something they did not like. Participants were asked to discuss the screens as a group and to place stickers on the printed images, either to signal their reaction to the entire screen or specific parts of the image. Some groups wrote on the images or in the margins to elaborate on their responses. As not all participants responded to all app screens, workshop data for all subsequently described workshops and cognitive walkthroughs are presented with the denominator reflecting the number of participants who provided written feedback on a given screen, page or design element.

The printouts were collected after the workshop, and the research team performed a content analysis of the sticker placements and notes left by participants. The identified themes were considered along with design research synthesis from expert consultants, as well as analysis of survey responses, semistructured interviews, and immersive engagement. Taken together, these themes informed further design changes that were then incorporated into a functioning mobile app prototype.

Phase 2

App Prototype Development

We developed a functional mobile app using Flutter [30]. The front-end patient-facing interfaces contained 4 sections: "biowallet," "explore," "connect," and "profile." We also developed a backend data architecture in which real biobank data could be imported into the app so that users could see personalized, real-time information about their biospecimens contained in the biobank collection. During the app's development, we consulted with institutional stakeholders to ensure regulatory compliance and compatibility with existing data resources to minimize burdens on researchers and data managers. Elsewhere, we describe a "digital honest broker" approach that enabled pilot participants to be connected directly to their own deidentified biospecimens [31].

Design Workshop 2

We held a second design workshop with a second local advocacy and support group for patients with any cancer type. A total of 25 participants attended. Members of the research team presented the app screens, gave an overview of their contents, and explained the intent of the workshop. Participants were then instructed to access the app on their personal devices and given a sample log-in leading to a deidentified demonstration account with biobank-level data and individual biospecimen data populated. Participants were given a sheet of paper with three columns—"Things I Liked," "Things I Didn't Like," and "Didn't Meet Expectations"—and were asked to write corresponding reactions as they explored the app freely by themselves or with one or two other participants. The papers were collected from nine small groups. Content analysis was performed to identify common areas of interest, enjoyment, displeasure, and dissatisfaction.

Cognitive Walkthroughs

During the second design workshop, members of the research team invited individuals at random to participate in a cognitive walkthrough to evaluate the usability of the application. Of the 25 workshop participants, 6 (24%) completed the walkthrough exercise. Participants were asked to perform several in-app tasks and seek specific information presented in the app while narrating out loud what they were doing. Members of the research team observed them using the app and took notes about their narration, evaluating their success in completing the assigned tasks.

We held seven additional cognitive walkthroughs with users recruited from participants in the phase 1 survey who agreed to be contacted about future research. These participants were

patients at the collaborating health system and were guided through the onboarding process that connected them to their own biospecimen information, if any existed. All users were able to see the "explore" and "profile" screens. Users who had also consented to the biobanking protocol (which was manually verified by the research team) were able to see the "connect" screen. If the user had samples in the biobank, they could see the "biowallet" screen populated with real data about their samples. Participants were led through the same cognitive walkthrough and asked to complete tasks and seek out specific information while they narrated their process as researchers observed and took notes.

Cognitive walkthroughs measure usability by collecting qualitative, experiential data from users directly. Researchers can infer usability by noting whether the users understand the task and are trying to achieve the right outcome, whether they take the appropriate action to achieve their intended outcome, and whether they correctly identify their success or the information sought from them. By having a mix of participants viewing uniform, hypothetical data and those viewing personalized data, we were able to gain generalized insights into usability, as well as insights into the personal value and added joy or frustration when engaging with one's own data. Both sets of participants were asked to create an account; perform the necessary authentications to populate their biospecimen data; identify how many of their samples had been used in research and how many were available; and to find a protocol that had used their samples, or, if their samples were unused, to find a protocol that studied their particular diagnosis.

Ethical Considerations

This study was approved by the University of Pittsburgh Institutional Review Board and quality improvement committees (IRB22010118, IRB22020035, and QRC3958). Participants provided informed consent before engaging with the study. The voluntary nature of the study was emphasized, including that their decision to participate in the study would have no impact on their care. Participants were able to skip questions or withdraw at any time. To safeguard privacy, data were stored on a secure institutional server, with survey responses deidentified and stored separately from personal information. Survey participants were paid US $10 for their participation upon completion. A subset of survey participants who agreed to participate in the follow-up interview were paid an additional US $20.

Results

Phase 1

Surveys

In reaction to the "biowallet" screen, participants were asked about their interest in using such an app to track their biospecimens donated to research. Of the 89 respondents, 20 (22%) were extremely interested, 22 (25%) were moderately interested, 24 (27%) were neutral or not sure, and 23 (26%) were not interested. Survey questions presented potential app features related to sample tracking, research feedback, and community engagement (Table 2), and follow up questions drilled down on preferences regarding specific design elements and user priorities.

We next assessed participants' interest in receiving updates regarding how, and by which researchers, their samples were used (Table 2). Participants (61/81, 75%) were most interested in learning "the outcomes of studies that use my tissues, like publications or new discoveries." Of these 61 participants, 14 (23%) provided qualitative details in optional open-ended follow-up questions, describing how or why they were interested in learning about research on their samples. For example, one respondent noted "I believe research participants should have full access to the data that is collected from them...The idea that my genetic data is setting in a lab for a variety of research studies, but I have no access to any of that data or the related information generated by that data is not fair or in my best interest."

The second highest area of interest concerned learning the status of their biospecimens regarding whether they had been used in research (45/81, 56%). Only 23% (19/81) of the participants were interested in seeing how many samples they had compared to other patients with the same diagnosis. Other data points of interest were the medical procedure from which their sample was collected (12/27, 44%), the current location of their sample (11/27, 41%), and collection details (when, volume, etc; 10/27, 37%).

Subsequently, we asked participants about their broader preferences for updates from researchers using their biospecimens with respect to scientific findings, new developments, and modes of communication (Table 2). Participants (47/60, 78%) expressed the greatest interest in receiving patient-friendly summaries of scientific information. Updates on new drugs or tests that become commercially available (39/60, 65%) and findings that may inform care (38/60, 63%) were also highly valued. Fewer patients were interested in updates on new publications (28/60, 47%), patient-friendly videos (22/60, 37%), study enrollment numbers (19/60, 32%), and new research grants (15/60, 25%).

In reaction to the "connect" screen, respondents expressed interest in connecting with other patients. Participants were most interested in connecting with patients with a similar type of breast cancer to theirs (41/83, 49%) and patients in their age group (36/83, 43%). Of the 83 respondents, 24 (29%) were not interested in connecting with any others. Table 2 details additional areas of interest.

Table 2. Interest in potential app features: biospecimen tracking, research updates, and community engagement[a].

App feature interest	Survey responses, n (%)
Sample tracking ("biowallet") features (n=81)	
Outcomes of the studies that use my tissues, like publications or new discoveries	61 (75)
Learning if/when my biospecimens are shared with researchers	45 (56)
Seeing how my own samples look under the microscope	35 (43)
Learning about the individual researchers who are studying my biospecimens	27 (33)
Seeing how many samples I have compared to patients with the same diagnosis as me	19 (23)
None	12 (15)
Other	3 (4)
Research updates ("scientist labs") (n=60)	
A patient-friendly summary of the scientific information	47 (78)
If there are new drugs or tests discovered that become commercially available products	39 (65)
If there are findings that might help my doctor and I make decisions about my care	38 (63)
When new publications come out (with access to that publication)	28 (47)
Short patient-friendly videos describing the research	24 (40)
How many patients are included	19 (32)
If there are new grants awarded to that research	15 (25)
Community engagement ("donor labs") (n=83)	
Similar type of breast cancer	41 (49)
Patients in my age group	36 (43)
Patients in the same research study	30 (36)
Similar stage of breast cancer	25 (30)
None	24 (29)
Similar genetic risk of cancer	18 (22)
Patient advocates	12 (14)

[a]These are not the only survey questions posed, but represent three key areas that were included in the survey. Where appropriate, questions were iterated to include screenshots of the app designs or concepts as they were refined.

Semistructured Interviews

While learning the outcomes of research on their biospecimens was identified as a high priority, concerns arose in the follow-up interviews. Of the 5 participants, 3 (60%) expressed concern about imposing additional burdens on busy scientists. They had expressed interest in learning about research on their specimens but clarified in interviews: "only if it doesn't take away from the work" and "I don't want to bother researchers, who are very busy" (Table 3). However, participants valued the opportunity to learn more about their samples; participant 3 expressed how specimen tracking can provide transparency about "what it's [biospecimen] being used for," implying how transparency may build trust.

In the follow-up interviews, 3 (60%) of the 5 participants expressed an interest in and need for communities that connect patients to research in general, stating that existing patient organizations were focused on emotional support, living with cancer, and survivorship rather than on biomedical research or the latest advances in treatments. Participant 2 expressed frustration with the lack of medical and scientific expertise in many patient support groups (Table 3): "...It's frustrating sometimes to get the kind of information you're looking for as a patient...with metastasis."

One participant undergoing diagnostic workup for cancer expressed interest in an additional support group, but without the granularity of connecting with other patients involved in the same studies. In contrast, one interview participant with a longer duration of cancer survivorship expressed that they did not have a need for additional patient connections. Multiple participants (3/5, 60%) expressed an interest in contributing additional information to scientists to provide additional context to their biospecimens. This included integrating data from genetic tests (eg, 23andMe), wearable devices (eg, Fitbit), and personal medical histories to support scientists. The motivation for doing so seemed to stem from the opportunity to "help...the scientific community, the research for cancer" (Participant 1) and elucidate "genetic links to breast cancer" (Participant 5). Participant 3 expressed interest in being informed about "a list of studies" they might qualify for, indicating a proactive approach to supporting biomedical research.

Table 3. Qualitative interview insights. The interview quotes are organized around feature categories of biobanking education, specimen tracking, connecting with others, and dynamic data sharing. Key standout phrases are italicized,

Proposed features ("naming convention") and interview quotes	Emerging themes
Learn biobanking ("biobank")	
• "I *totally geek out* on this stuff, so as much as you guys are willing to share and whatever level detail, I'm all about it." (Participant 1, Interview 2) • "I would want to know outcomes of the studies. I am kind of *a science geek*, like that's my interest, it's not the field that I'm in whatsoever, and I was not educated in that, but I'm very interested. I've read a lot about science and especially like bioscience, so I would say, I would also like to know outcomes, with the studies that use my tissues." (Participant 3)	Valuing scientific knowledge and approaches
• "Whatever you guys are willing to share is perfectly fine...*I just don't expect that detailed level of personal information* about the researchers, but if they're willing to share...it's fascinating...it's just not one of the absolutely necessary things, I feel." (Participant 1, Interview 2) • "*I don't expect to have the ability*, or even the need to identify specific researchers who I can go to. It's like as many people can use that tiny little tumor that you guys got out of me as possible it's fine, so what, for whatever purpose and whoever needs it, for whatever reason, is fine." (Participant 1, Interview 1) • "It was my pre-op...my surgeon, and a nurse, she just had a whole pile of papers. It [the biobanking consent form] *was just one more paper she needed to get signed*." (Participant 3)	Recognized unfamiliarity with biobanking, limited expectations and agency of donors within in current model
Specimen tracking ("biowallet")	
• "I don't need to know about all the researchers and everyone who's touching it. Just in general, like *what you're looking at and...what you're doing with it.*" (Participant 1, Interview 2) • "I don't feel the need to have control over any of that stuff—You guys can do with it what you see fit." (Participant 1, Interview 1) • "I *don't want to bother researchers*, who are very busy." (Participant 2) • "It would be interesting to see my samples, and my tissue, but not necessary, I guess. So, sort of like an added bonus." (Participant 5)	Balancing gaining personalized insights versus resource constraints for scientists
• "I mean, worst case scenario, like these are my few... last few minutes on earth... It would bring meaning...I'm *suffering but I'm suffering for a reason.*" (Participant 4) • "...People are fearful of having their information being used in nefarious ways; I think *this is a way of being super transparent and also involving the candidate*...like it's personal, it's something [very] personal, especially for women with breast tissue, very personal." (Participant 4)	Recognition for personalized contributions as a source of purpose and meaning
Community engagement ("labs")	
• "Probably in the lines of a support group kind of thing, it would be kind of neat to see...what other people were experiencing and going through, but not necessarily with regards to the study itself." (Participant 1, Interview 1) • "You have questions in there, 'Do you want to be connected with other donors?' and [in the survey] I said no, 'I don't use social media,' but I would use this, and perhaps if I do have to get surgery or I...perhaps [have cancer]... *it's like people who have dogs from the same litter, you know it's like, 'How's your pup doing?'*" (Participant 3) • "You know, now that I am talking this through, I would also...need...the type, the stage, the genetic risk of patients in my age group. I might want any one of those options. I am thinking futuristically now that it's become an actual reality or possibility...*I would be more open to connecting to others...beyond the same research.*" (Participant 3)	Some felt existing support groups were adequate, while others sought camaraderie and citizen science
• "One of the limitations with the patient advocacy groups that I've been in so far is that *there is limited expertise in the groups*...so it's frustrating sometimes to get information you're looking for as a patient...for example, drugs for preventing metastasis...what are the researchers recommending at this point [for people like me]." (Participant 2) • "I think the research is important and I'm just interested in knowing what research is going on, just because I think it's interesting, but *I wouldn't necessarily need to know what's happening with other patients* and their stuff."(Participant 5) • "I want to help, do whatever is possible to help research continue, but I don't feel the need to use something like this to connect with other people [i.e., patients]." (Participant 5)	Unmet need for direct connection with scientists, as opposed to other patients

Proposed features ("naming convention") and interview quotes	Emerging themes
Data sharing ("profile")	
• "I have the ancestry/23andMe, I do Fitbit stuff, so yeah, that'd be very cool to be able to incorporate all that...Anything that would help in any way... the scientific community, the research for cancer, anything, advanced in any way, for whatever reason, whatever purpose." (Participant 5) • "There's so much that's not known in terms of...genetic links to breast cancer...*I would share more information if it would help.*" (Participant 5) • "I would like to see a list of studies that I might qualify for, *I would provide details about my medical history or treatment.*" (Participant 3) • "[If] you guys need additional information or stats or blood or anything from me, I'm more than happy to help." (Participant 1, Interview 1)	Eager to contribute more specimens and data
• "I keep throwing out those ads for...'All of us' *because they won't give you anything...that's my reason for not participating*...[since] you have all my genetic information, you have no idea where it's going to be five years from now...But you won't let me have any access to it." (Participant 2) • "I think it's brilliant and I also think that *more people would participate if this were available*...Because I've had opportunities in the past, and...the biggest question that I have, and other people have, even when we're asked, 'Would you donate organs'...is the lack of knowledge about what it's being used for...that's what makes people suspicious and, especially, in an era where we both have like open source, you can find out information about everyone." (Participant 3)	Demand for greater reciprocity and accountability for data exchange

Design Workshop 1

Participants of the first design workshop (n=69) confirmed their interest in the concept of the app as well as the content of the app screens and provided valuable feedback on its presentation. A subset of 15 participants who participated in a dedicated codesign session documented their reactions to individual app screens. The "biobank" screens were appreciated by participants who liked the ability to view the entire collection of one's personal samples (7/15, 47%), as well as the sample-level details under the individual "biowallet" (4/15, 27%), with several emphasizing the linkage between samples and other medical or genetic data. Some were confused or upset by the technical details presented about each individual sample and about some of the terminology related to their biospecimens (eg, questioning what it means for a sample to be depicted as "in use"; 9/15, 60%). Of 15 co-designers, 4 (27%) noted that they would have preferred their samples to be organized chronologically, corresponding to their lived experience of appointments and procedures as specimen collection events, rather than initially stratified by sample type (tissue, blood, urine, organoids, etc.). For example, one co-designer emphasized: "Everything is timeline for us [patients with cancer]."

Moreover, 80% (12/15) of co-designers provided positive reactions to the "connect" screens, where they hearted the framing of virtual "lab" groups as 'patient-led' (5/12, 42%) and appreciated that there seemed to be actions that a user could take, such as joining a virtual "lab" and adding their samples to the group (6/12, 50%). Of the 12, 4 (33%) expressed confusion about the "lab" groups, including who is supposed to join them and for what purpose, while 3 (25%) expressed concerns about the legitimacy of *patient-led* "labs" because they might relate to actual future research on their samples, and they worried about the potential for unmoderated, off-topic, and illegitimate activity, with 1 participant stating "It should not feel like social media. To me it should feel more like science."

The "explore" screen, showing high-level information about the entire biobank collection of samples, prompted the most confusion. Of the 14 co-designers who were able to review this screen, 12 (86%) were confused by ≥1 terms on this page (eg, "consent" and "protocols"), and 2 (14%) suggested the addition of a glossary to help users understand. Other co-designers (3/14, 21%) incorrectly assumed that the "explore" page contained information about an individual's samples instead of the entire collection.

Participants also generally misunderstood the intended features of the "profile" page. Of the 11 co-designers who reviewed this page, 7 (64%) expressed confusion or dislike of the badges feature, with concerns that they were "useless," "not important," or excessively similar to features on social media sites, which they did not like. Finally, 18% (2/11) of the co-designers expressed concerns about the visibility of individual profile data, similarly worried about the parallels to existing social media, where all users can see individual profile pages.

Phase 2

App Prototype Development

Taking participant feedback from phase 1 activities, we developed a functional app prototype with 4 sections corresponding to the screen designs. The "biowallet" screens had been well received, and minimal changes in content were made. We removed the diagnosis code from the "biowallet" page to avoid triggering negative memories and emotions in users. We maintained sample organization by type (tissue, blood, urine, etc) to more closely resemble the structure of biobank data, where the type of sample and medium of preservation are more valuable than the collection date. However, to address participants' desire for a chronological arrangement, we listed

samples from the most recently collected to oldest *within* the sample type category. The "biowallet" page also showed a record of the users' informed consent to join the biobanking protocol. Users could click on individual samples to find information such as size, location, date collected, freezer number, and more. A generic picture of the corresponding sample type (eg, a picture of urine crystals under a microscope) accompanied each sample. Users could see whether each sample had been used in a research protocol or whether it was still available in the biobank.

The "connect" feature included patient-led "labs" organized by diagnosis, as in the original designs. We added a second class of "researcher-led labs" based on individual researchers who had used the patients' samples. Due to the structure of deidentification of the initial biobank data, the names of the researchers and details about their work were blinded, with just a numerical code representing individuals (eg, principal investigator 4); summary statistics of their work (eg, 6 protocols using 75 samples); and similar blinded, summary information about specific research protocols using patient samples (eg, "Your samples were used in protocol #4, which used 25 samples"). Importantly, displaying this information did not impose any additional workload or data input responsibilities on researchers. The patient-led and researcher-led "labs" featured some cross-referencing. A patient-led group with a shared diagnosis was linked to researcher "labs" studying this diagnosis and to protocols using samples with this diagnosis. Using existing databases, we sorted individual users into the appropriate patient-led and researcher-led "labs," adding a third section, "My Labs," where users could view just the groups of which they were members. These 2 new groups of "labs" were developed to satisfy phase 1 participants' enthusiasm for learning about research both in general and specifically about their samples, while maintaining maximum interoperability with existing biobank databases and protocols.

We updated terminology on the "explore" page in response to widespread confusion expressed by participants at the design workshop. Rather than relying on institutional terms such as "informed consent," we framed participation in the biobanking protocol as being a "member." For each sample category, we clarified how many patients were represented and how many samples there were in response to participants' confusion about whether they were looking at 1 person's samples on the "explore" page or the entire biobank's samples. The "explore" page contained expandable information about the entire biobank collection, organized by sample type (eg, breast tissue, blood, and urine).

On the "profile" page, users could view the deidentified code that links their account on the app to the biobank database, populating their sample information. Rather than showing a hypothetical set of badges that users might be incentivized to collect, which were not well received, we showed just 1 indicator of whether users had successfully been connected to their sample collection. On the "profile" page, we also developed short questionnaires about potential future research topics of interest. This feature served as proof of concept for how the app might be used to engage participants in research design or be used as a data collection tool.

Design Workshop 2

The second participatory design workshop aimed to further validate the clarity and value of the information presented in the app. In addition, we received feedback on the user experience of navigating the live app.

All 9 groups of patients participating in this workshop (consisting of 25 patients total) liked learning the information presented to them on the app. Of the 9 groups, 3 (33%) specifically mentioned the "real-time" nature of the information, with one-third (n=1, 33%) stating that they liked being able to "follow along" with research. Of the 9 groups, 5 (56%) noted that they would prefer or require more information before using the app, such as background materials or guided onboarding, to better understand the information presented; 7 (78%) wished for more information (eg, details about research protocols); and 4 (44%) wished for more capabilities (eg, a search bar or the ability to make their biospecimen data more or less visible to others).

Of the 9 groups, 7 (78%) noted that the app was easy to use. However, 7 (78%) of the 9 groups also noted usability and navigation as something they disliked. Of the 9 groups, 4 (44%) noted that the onboarding process—downloading the app, creating an account, logging in, and verifying the user's identity—did not meet their expectations or was not liked; 6 (67%) did not like a design feature of the app (eg, the choice of icon and the order in which the screens appeared); and 3 (33%) listed unmet accessibility expectations, including the desire for use on a larger screen or the preference for a web platform rather than a mobile app.

Echoing concerns from the first workshop, of the 9 groups, 3 (33%) were dissatisfied with the lack of explicit security assurances or data use terms, while 1 (11%) liked the fact that users' identities were not featured on the app and were instead represented by a unique deidentified code.

Cognitive Walkthroughs

Cognitive walkthroughs with 13 patients also gauged the usability of the app. The walkthroughs illuminated an onerous and confusing onboarding process, where participants had to create an account and submit information to link their biobank data, after which they received a notification and request for more information once their biospecimen data were populated in the app. For users who were participants in the biobank, the interim waiting period for biospecimen data was as long as 1 week, and users often mistakenly thought they had done something incorrectly. Nearly all walkthrough participants expressed confusion and uncertainty about the onboarding and biospecimen data verification process, even when completed successfully.

Once they successfully logged in and were able to view biospecimen data, most of the participants successfully described their biospecimen data, including how many of their samples were available for research. Those participants who were members of the biobank, viewing their own biospecimen data, were curious as to why their samples had not been used and expressed a willingness to take action to ensure that their samples were used in research (eg, by offering to donate more

samples or to pool samples with other participants). Overall, the success rates of completing this task indicated the usability of the app. Lower usability, namely the inability to identify successful completion of the task, arose in specific contexts applicable only to those participants who were attempting to view their own biobank data. Of the 13 participants, 3 (23%) had consented to participate in biobanking, but none of their clinical biospecimens made it to the biobank. Thus, their "biowallet" page showed no samples, although their "membership" was verified. This was a source of confusion, and participants incorrectly assumed that they had made a mistake in the onboarding process.

Participants were able to correctly identify a protocol that had used their samples or that had studied their disease. These participants successfully navigated from the "biowallet" screen to the "connect" screen and correctly understood the information presented about the protocol they identified. Some of the participants (7/13, 54%) expressed disappointment in the limited amount of information presented about the protocol or the associated researcher. Consistent with the initial survey findings, participants were most interested in learning the details and outcomes of the research conducted on their samples or their disease. In sum, the cognitive walkthroughs showed the usability of and interest in the app and revealed the need to improve the onboarding process and to better explain less intuitive scenarios, such as having no banked samples as a consented biobanking participant. The walkthroughs also confirmed participant interest in learning what happened to their biospecimens and about research on banked biospecimens.

Discussion

Key Findings

Throughout the design process, participants indicated a strong interest in and demand for learning about biobanking. They found intuitive value in the ability to track their own biospecimens. Indeed, participants positively received almost all of the information presented and commonly expressed a desire for more. In all phases, participants were most interested in learning about the research being conducted on their disease or specifically using their biospecimens, including the results of this research. They noted that they were not able to find this information on their own and were not able to satisfy general curiosity about research by participating in existing patient advocacy and support groups. These findings add to existing literature confirming public interest in greater transparency and engagement in biomedical research [32-36].

Mixed responses about the usability of the app demand further research and attention. Overall, participants in all stages were interested in using the app, although the content and presentation of information needed improvement. Some of the participants sought language and design similar to that of their medical records. Presenting research information in this way may make it more intuitively understandable but may also contribute to therapeutic misconception by misleading participants into believing that the research information and participation are of a similar clinically actionable quality. Thus, careful onboarding and framing of research information must ensure participant understanding and offer opportunities to overcome confusion.

Participants expressed a demand for a "legitimate" platform that did not suffer from what they saw as the risks and ills of social media: data misuse, a lack of privacy, and the potential for negativity or misinformation. While mobile phones and apps are widely used [37], concerns about mobile apps may make them an unacceptable platform for some. An additional facet of building trust with participants can be achieved through transparency surrounding how their biospecimens are being used. An interview participant expressed the following:

> *The biggest question that I have and other people have even when we're asked you know, would you donate organs...is...the lack of knowledge about what it's being used for.*

This approach to rebuilding trust reflects ongoing movements in biomedical research aimed at improving transparency and accountability, such as interactive and accessible "data walks" designed to engage communities and stimulate dialogue [38].

However, the de-identification of biospecimens presents challenges for direct transparency and engagement. Other challenges exist as well—meaningful transparency and engagement with patients is time and labor intensive [39,40]. Even when community engagement is required or encouraged, there are few tools or guidelines for success, and interactions may be transient and transactional [40]. Biobanking and scientific research are deeply technical disciplines that historically have minimally interfaced with the public, and require extensive time, skill, and technology to translate into accessible, meaningful plain language [39]. Finding relevant patient communities and sustaining meaningful, collaborative relationships with them might prove beneficial to biobanks, or scientists themselves, but this is not required, supported, or incentivized by traditional academic reward systems or many institutions [41-43]. Engaging patients in biobanking might fulfill obligations of respect; however, evidence of its long-term impact on research participation, understanding, and attitudes is the subject of ongoing work [40].

Our experience confirms the need for specialized skills and dedicated time and resources to deliver transparency and engagement effectively and safely. New technologies, eg blockchain and generative artificial intelligence, are essential for these endeavors to be more efficient and scalable, but their development remains time and labor intensive. Participants were largely unfamiliar with biobanking, research processes or related jargon. Thoughtful, readily digestible and personalized education about each unique research context may be a critical aspect of the app onboarding process. Participants were confused about less intuitive but common scenarios, such as having consented to biobanking but having no samples in the bank. While this confusion may stem from a lack of recall or understanding of the initial informed consent for biobanking, delivering follow-up information about actual participation (or lack thereof) presents new risks of misunderstanding that must be managed.

While our study focused on patients with breast cancer, the demand for transparency and engagement may extend to other medical fields. We found that the survey participants (61/68, 90%) were most interested in learning the outcomes of research using their tissue samples. Thus, conditions with active research and strong patient interest in new treatment paradigms, such as additional cancer types and sickle cell disease, are potential areas where this platform may be effective. Further research is needed to assess the feasibility, acceptability, and effectiveness of this platform across diverse medical contexts and patient demographics.

Finally, in light of the strong reception and demand by participants, it must be acknowledged that returning deidentified, individual-level research information to participants is uncommon and unaccommodated by existing paradigms. Existing data architectures are built for a research enterprise from which participants are intentionally excluded. Working to disrupt the paradigm by allowing participants to view research data and activities presented both technological and regulatory implications. While participants were unaccustomed to receiving this type of information and, as a result, sometimes struggled to understand it, biobanks were also unaccustomed to sharing this type of information and, as a result, were sometimes hesitant to do so. Any technological tool aiming to enable transparency and engagement in research must be acceptable to all stakeholders. Careful and inclusive co-design is imperative.

Limitations and Next Steps

The patient population we engaged in this work consisted of only women due to the nature of breast disease. Our participants were mostly White (64/94, 68%) and were more educated and had higher incomes than the national average, although they more closely resembled local demographics. Our participant population may also reflect self-selection bias—those interested in learning about research on their biospecimens or in general may have been more likely to participate in any research, including ours. Our technology was intended for piloting among this group and was therefore tailored to their preferences. For these reasons, further research will be necessary to validate interest in and usability of the technology in other patient populations (eg, men and healthy individuals).

Moreover, most of the patients we engaged with throughout all stages of design and development were unfamiliar with the term "biobank." This underscores a key challenge associated with delivering an accessible and patient-friendly biobanking app. This variation in patient knowledge regarding biobanking, even among those who already consented to biospecimen donation, limits the ability to fully capture and address diverse patient preferences.

Across the surveys and workshops, questions and app content were iterated upon as app screens were finalized, new topics were raised by participants, and data saturation was reached through survey responses and follow-up interviews. As a result, the sample size of participants exposed to specific materials varied, leading to disproportionately lower sample sizes for certain areas of inquiry. Additional work is needed to investigate a larger sampling of patients' design preferences. New technologies can facilitate meaningful transparency in biomedical research to patients in a personalized yet efficient way. This research showed that patients desire transparency and revealed the specific information they were interested in learning about their biospecimens. By deeply engaging patients and other stakeholders in participatory methods, siloed and specialized research data can be translated into meaningful patient engagement. We worked to design a mobile app that allows patients with breast cancer to track and learn about their donated biospecimens. Surveys, interviews, design workshops, and cognitive walkthroughs helped to make the app maximally valuable and usable for patients while maintaining efficient integration with existing data assets.

By creating this decentralized biobanking app, we built a platform upon which methods of transparency and engagement can be tested in subsequent pilots; for example, further research can measure the app's impact on patients' willingness to consent to biobank research, to remain enrolled and engaged longitudinally, and to actively participate in community-engaged research.

Acknowledgments

The authors thank Diana Mendoza Cervantes, Sneha Vaidhyam, and Dmitriy Babichenko, as well as Raelynn O'Leary and Ashley Deal of Dezudio, for their contributions to study design and execution. The authors also thank Sam Moatz, Jen Kehm, the members of 412Thrive, and the members of Cancer Bridges. Finally, the authors express utmost gratitude to the participants of this study: "Your openness, honesty, and trust motivate all that we do."

Conflicts of Interest

AH, WS, and MG are consultants for de-bi, co. All other authors declare no conflicts of interest.

Abstract

Background: In health care, the use of nursing technological innovations, particularly technological products, is rapidly increasing; however, these innovations do not always align with nursing practice. An explanation for this issue could be that nursing technological innovations are developed and implemented with a top-down approach, which could subsequently limit the positive impact on practice. Cocreation with stakeholders such as nurses can help address this issue. Nowadays, health care centers increasingly encourage stakeholder participation, which is known as a bottom-up cocreation approach. However, little is known about the experience of nurses and their managers with this approach and the innovations it results in within the field of nursing care.

Objective: This study aims to explore nurses' and their managers' experiences with a bottom-up cocreation approach in order to assess the impact of this way of working and the resulting nursing technological innovations in an academic hospital. This insight can also inform decisions on whether the bottom-up cocreation approach should be more widely disseminated.

Methods: A qualitative study using semistructured interviews was conducted with 15 participants, including cocreator nurses, end-user nurses, and their managers. First, the data were thematically analyzed. In addition, a strengths, weaknesses, opportunities, and threats analysis was conducted.

Results: The various experiences of the participants were described in 3 main themes: enhanced attractiveness of the nursing profession, feeling involved due to a cocreation environment, and experienced benefits and challenges in using cocreated products. In addition, numerous strengths and opportunities perceived by the participants were identified as associated with the bottom-up cocreation approach and resulting useful products within nursing care; for example, cocreation contributed to job satisfaction and substantially contributed to the ease of use of the innovations that were developed.

Conclusions: The findings underscore that cocreation with nurses enhances the appeal of the nursing profession and aligns nursing technological innovations with practical nursing challenges. Embracing a culture of cocreation has the potential to foster a culture of continuous improvement and innovation in nursing care.

KEYWORDS

stakeholder participation; cocreation; nursing; innovation; bottom-up approach; diffusion of innovation; qualitative research; nurses

Introduction

Background

Nowadays, technological products and other innovations are being used more frequently in the health care sector [1-3] to minimize physical strain, such as lifting patients or transporting beds, and encourage ergonomic approaches during nursing tasks. Nurses need to use these innovations during patient care to manage various health care challenges, such as the increasing demand and complexity of health care [4,5]. An example of a technological product, which will be referred to as a "nursing technological innovation" in this paper, is the TrulyEasy clamp, designed for convenient 1-handed adjustment of the arterial line to the correct height [3]. Another example of a technological product is LineConnector, a product designed to efficiently organize infusion lines and prevent tangling [3].

Unfortunately, technological solutions aimed at solving nursing issues do not always align with daily nursing practice [2,6]. A potential explanation for this lies in the top-down approach used during the development and implementation of many innovations. Policy makers may prioritize regulatory and payment interests, while technicians focus on the functionality of innovations, without fully understanding the user perspectives and the nursing context [6-8]. Consequently, some solutions may inadequately align with the needs of the nursing profession, leading to limited impact on nursing practice [2,6]. Improving the adoption of innovations in nursing practice can be addressed in the development and implementation phase of these innovations through stakeholder participation [1,5,9-12].

A growing number of health care centers are facilitating an environment that allows stakeholders to participate in the development and implementation of nursing technological innovations [1,6,9,10,12]. This involvement, also called cocreation [13], with a bottom-up approach [8], involves an interaction in which various stakeholders work together to produce an outcome that is valued by all stakeholders involved [13]. The bottom-up approach allows stakeholders to share their knowledge or opinions about issues presented in daily activities and suggest potential solutions [8,14]. This approach can support the development of nursing technological innovations that may have an impact on nursing care [1,5,9-12]. FlushEgg is an example of a cocreated nursing technological innovation. Nurses reported experiencing challenges and discomfort while flushing the narrow central lines in neonates. Therefore, a syringe attachment was designed to enhance comfort in the palm during the application of pressure [3]. Another example of a cocreated nursing technological innovation is KoosGuard, which includes a holder that can be placed in the bed through which the cables and infusion lines are guided without becoming tangled or pinched [3].

However, the bottom-up approach requires nurses to invest time, which is challenging considering many nurses face time constraints [15,16]. If these nursing technological innovations lack the required quality, this could result in decreased application in nursing practice [2,6]. Furthermore, a poorly developed nursing technological innovation could lead to resistance from nurses, resulting in a negative attitude toward these innovations [9,17]. To fully use the potential of innovations in nursing practice, the innovations need to be adequately designed, which requires the involvement of nurses [9,18]. Despite the increasing involvement of nurses in the cocreation of nursing technological innovations, little is known about how this approach and its resulting innovations are experienced by nurses. Therefore, this study seeks to explore the experience resulting from the bottom-up approach of cocreation with nurses and the resulting nursing technological innovations developed through this approach. The perspectives of nurses, both as cocreators and end users, and their managers are key to understanding the impact of this collaborative process. These results could offer a deeper insight into how nurses, both as cocreators and end users, along with their managers, perceive the bottom-up cocreation approach and its resulting nursing technological innovations. A comprehensive understanding of their experiences, both positive and negative, can significantly contribute to the overarching goal of enhancing patient care and nursing practice, making it safer and more effective.

Aim

This study explores nurses' and their managers' experiences with a bottom-up cocreation approach in order to assess the impact of this way of working and the resulting nursing technological innovations in an academic hospital. This insight can also inform decisions on whether the bottom-up cocreation approach should be more widely disseminated.

Methods

Study Design

This study used an exploratory, descriptive, qualitative research design using individual interviews conducted at an academic hospital in the Netherlands between February and April 2023. This design facilitated the exploration of participants' experiences, which were further analyzed through a thematic analysis and subsequently through a strengths, weaknesses, opportunities, and threats (SWOT) analysis [19]. The methods and subsequent results were reported according to the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist [20].

Population and Setting

The study population consisted of three subgroups: (1) nurses with experience in cocreation, (2) nurses with experience as end users, and (3) health care managers from the nursing departments at an academic hospital where the innovations were implemented. In addition, all eligible nurses and managers were required to have at least 1 year of experience within the nursing department where the innovations were implemented. The 1-year experience criterion ensured that nurses and managers were

sufficiently familiar with the innovations and context. The setting comprised an innovation department established within the academic hospital.

Sampling Strategy and Recruitment

To gain more understanding and in-depth information from a broader perspective, a heterogeneous group of nurses and their health care managers were included through purposive sampling [19,21,22]. Potential nurse cocreators and managers for this study were recruited and informed via an email by OH about participating in the interviews. Interested individuals were required to actively contact SvS by email. Upon receiving an email, SvS responded with a participant information letter and an informed consent form. Once participants agreed to participate in the study, interviews were scheduled at a mutually convenient time. For the nurse end users, SvS visited the nursing departments where nursing technological innovations were integrated into nursing practice. Interested nurse end users were able to participate in an interview during their shifts at a time convenient for them. The nurse end users were informed via a participant information letter. After informed consent was given, the interviews started. The face-to-face interviews were conducted at the academic hospital.

Sample Size

A total of 14 to 20 participants were required to obtain saturation of knowledge with a heterogeneous sample group [19]. Therefore, the aim of this study was to include at least 14 participants [19]. The study involved 15 participants, including 10 (67%) women and 5 (33%) men.

Data Collection

Data were collected through semistructured interviews using an interview guide based on literature and expert opinions [19]. The interview guide covered various topics (Table 1), including the participants' attitude [23] toward technology, the bottom-up cocreation approach, and the nursing technological innovations developed through this approach. It also explored the acceptance [9,10,23], usability [12,23], and adoption [10,23] of these innovations in nursing care as well as their impact on patient care and nursing practice [1,11,12,24]. Demographic characteristics (age, gender, and specialization), along with the adoption rate, provided an overview and background information of the participants in this study. The adoption rate proposed by Rogers [25] allowed the measurement of individuals' attitudes toward innovations, providing valuable insights into how the participants generally perceive and approach innovations. The adoption rate according to Rogers [25] was measured by asking the participants which category they identified with. They could choose one of the following five categories: (1) driven by change and introduction of innovations, (2) leading in adopting innovations, (3) deliberately adopting innovations, (4) adoption is an economic necessity and a response to social peer pressure, and (5) have a traditional view and are more skeptical about innovations [25]. A pilot test was conducted to refine the interview guide and involved expert assessment and field testing with one participant. After the interviews, the first author created memos recording thoughts that arose due to the interviews [19]. The interviews were audio recorded and conducted by SvS, a nurse with no prior experience at the hospital where the research took place. SvS was trained in conducting interviews. Throughout the data collection process, discussions were held with the research team, including investigators SvS, TvH, and OH, to refine the interview questions and ensure that they effectively addressed the research question.

Table 1. Interview guide topics and prompt questions.

Topics	Prompt questions for nurses (end users)	Prompt questions for cocreator nurses	Prompt questions for managers
Attitude	• What are your impressions regarding the fact that a coworker from your department contributed to this nursing technological innovation? • What is your opinion on dedicating time to enable nurses to create and execute nursing technological innovations for nursing care?	• Can you elaborate on how the cocreation process began and how it evolved? • What is your opinion on dedicating time to enable nurses to create and execute nursing technological innovations for nursing care?	• What are your thoughts on the fact that a nurse from the nursing department has made a substantial contribution to this nursing technological innovation? • What is your opinion on dedicating time to enable nurses to create and execute nursing technological innovations for nursing care?
Acceptance	• What were your initial impressions of the nursing technological innovation when you first began working with it?	• What were your initial impressions of the nursing technological innovation when you first began working with it?	• What responses did you observe from nurses when they were introduced to the nursing technological innovation for the first time?
Adoption	• In what ways do you integrate the nursing technological innovation into your daily nursing tasks and responsibilities?	• In what ways do you integrate the nursing technological innovation into your daily nursing tasks and responsibilities?	• What are the viewpoints within the department regarding the utilization of the nursing technological innovation?
Usability	• What is your experience with the nursing technological innovation at work?	• What is your experience with the nursing technological innovation at work?	• What are the experiences of the nurses regarding the use of the nursing technological innovation?
Nursing practice	• What transformations do you observe in nursing practice as a result of the application of the nursing technological innovation?	• What transformations do you observe in nursing practice as a result of the application of the nursing technological innovation?	• What transformations do you observe in nursing practice as a result of the application of the nursing technological innovation?
Patient care	• What changes do you perceive in patient outcomes as a result of the application of the nursing technological innovation?	• What changes do you perceive in patient outcomes as a result of the application of the nursing technological innovation?	• What changes do you perceive in patient outcomes as a result of the application of the nursing technological innovation?

Data Analysis

The semistructured interviews were transcribed verbatim [19]. A 6-step thematic analysis approach (Table 2) was applied using ATLAS.ti software (version 23; Lumivero) [26]. Open coding and constant comparison techniques were used during the analysis [19]. An iterative process was used between data collection and data analysis. Refining the interview questions made the collection of the data more focused and specific as the process developed [19]. Audio recordings were transcribed, read, and reread by SvS in order to become familiar with the data. Data were initially coded using open coding by SvS. The 1st, 3rd, 6th, and 10th transcripts were coded separately, both by SvS and TvH. The initial codes of SvS and TvH were compared and discussed until consensus was reached. Main themes were generated through an iterative process, including constant comparison, and further elaborated and finalized by SvS, TvH, and OH. A codebook was used for insights into coding and code development [19].

Table 2. Thematic analysis.

Phase	Explanation
Phase 1: familiarization with the data	SvS conducted interviews with the participants and transcribed them. Transcripts were read and reread by SvS to familiarize herself with the data and obtain an overall impression.
Phase 2: generation of initial codes	Data were extracted from the transcripts and initially coded using open coding by SvS. The 1st, 3rd, 6th, and 10th transcripts were coded separately, both by SvS and TvH. The initial codes of SvS and TvH were compared and discussed until consensus was reached. The memos were processed systematically. Codes remained linked to the transcriptions (quotes) and the data extracts, using ATLAS.ti (Lumivero).
Phase 3: broader levels of themes	SvS developed broad potential main themes by comparing the initial codes. During meetings with SvS, TvH, and OH, consensus was reached, resulting in potential main themes derived from the data. During follow-up meetings with SvS, TvH, and OH, a description of the potential main themes was created and deliberated upon.
Phase 4: reviewing and refining the candidate themes	SvS compared the potential main themes with the coded data extracts and the raw data (transcriptions), discussing inconsistencies with TvH and OH. This process led to the identification of the main themes, which were visualized with a thematic map. The themes were refined by SvS and peer reviewed by TvH and OH.
Phase 5: defining and naming themes	SvS revisited the data extracts to define the content of each main theme. In meetings, SvS, TvH, and OH discussed the essence of each theme and developed the overall story line, resulting in the final naming of the main themes.
Phase 6: producing the report	SvS drafted the report and included detailed examples and quotes supporting the main themes. TvH and OH provided feedback, and adjustments were made accordingly. Final recommendations were implemented in the report.

In addition to the thematic analysis, we performed a secondary analysis using the SWOT matrix. This secondary analysis was carried out to make the data more accessible for the readers and support strategic changes within an organization. The SWOT analysis has been shown to be a valid method in previous studies for facilitating data interpretation for readers and informing strategic planning and decision-making in practice [27,28]. In several meetings, detailed examples of the results, with related quotes of the main themes, were discussed and analyzed and subsequently linked to a component of the SWOT matrix.

Rigor and Reflexivity

Different techniques were used to enhance trustworthiness [19]. The credibility of this study was established by the investigators by creating a nonjudgmental ambiance during the semistructured interviews to obtain the participants' perspective. The chance for bias was reduced by transcribing the content of the interviews verbatim. Member checking was used to ensure the accuracy of the transcripts, with participants reviewing the transcripts to validate their thoughts and ideas [19]. The performed member check resulted in minimal textual changes to the data.

Memos were reported during data collection and analysis to support the investigation process and the thoughts that had occurred to the investigator. The conformability of the interpretation and credibility of the data were both enhanced by investigator triangulation during the data analysis and peer feedback during researcher meetings, including the investigators SvS, TvH, OH, and HSMK. Due to peer feedback, potential meanings and a wider range of perspectives were revealed. Reflexivity, ensured by the investigator's critical view of the interview process and comments from other investigators, increased depth and improved accuracy.

A thick description was pursued to ensure the transferability of this study through the diversity of the population base, the number of participants, and the length of the interviews for imitability. To enhance the reflexivity and transparency of the investigators, a logbook was kept, detailing all changes and decisions made throughout the process of this study [19].

Ethical Considerations

Throughout this study, the principles of the Declaration of Helsinki and the code of conduct for health research were followed [29,30]. The study was examined and approved by the medical ethics review committee of the Erasmus Medical Center for a nonmedical scientific research application (MEC-2023-0021). Participants were informed and invited to the study by OH. They received the investigator's email and had 1 week to express interest. Nonresponders received a reminder. The investigator sent a participant information letter and informed consent upon contact. Participants could ask further questions via email. Interviews were scheduled after participants confirmed their approval. Before the interview, they provided written informed consent. The participants did not receive any compensation for their participation in the study. During the study, data collection was conducted with confidentiality, and data were processed anonymously according to the European Union General Data Protection Regulation [29]. Only the investigators SvS, TvH, OH, and HSMK had access to the source data.

Results

Characteristics of the Participants

The duration of the interviews ranged from 26 to 62 minutes, with an average duration of 44 (SD 10.8) minutes. Participants' ages ranged from 20 to 67 years. Various departments, including the intensive care unit, children's ward, and the recovery department, were represented in the study. Table 3 presents detailed demographic information, including gender, age range, department, adoption rate, number of nurses participating as cocreators and end users, and the number of health care managers.

Table 3. Demographic data of the participants (N=15).

Characteristics	Participants, n (%)
Gender	
Women	10 (67)
Men	5 (33)
Age range (y)	
20-29	1 (7)
30-39	5 (33)
40-49	3 (20)
50-59	3 (20)
60-67	3 (20)
Department	
ICU[a] (adults)	7 (47)
ICU (thoracic surgery and cardiac monitoring)	2 (13)
Center for home ventilator and respiratory disorders in children	2 (13)
ICU (children)	1 (7)
Recovery	1 (7)
Day treatment (children)	2 (13)
Adoption rate[b]	
Innovator[c]	10 (67)
Early adopters[d]	3 (20)
Early majority[e]	2 (13)
Late majority[f]	0 (0)
Laggards[g]	0 (0)
Profession	
Nurse (cocreator)	6 (40)
Nurse (end user)	5 (33)
Health care manager	4 (27)

[a]ICU: intensive care unit.

[b]Adoption rate was measured by asking the participants which category they identified with.

[c]Driven by change and introduction of innovations.

[d]Leading in adopting innovations.

[e]Deliberately adopting innovations.

[f]Adoption is an economic necessity and a response to social peer pressure.

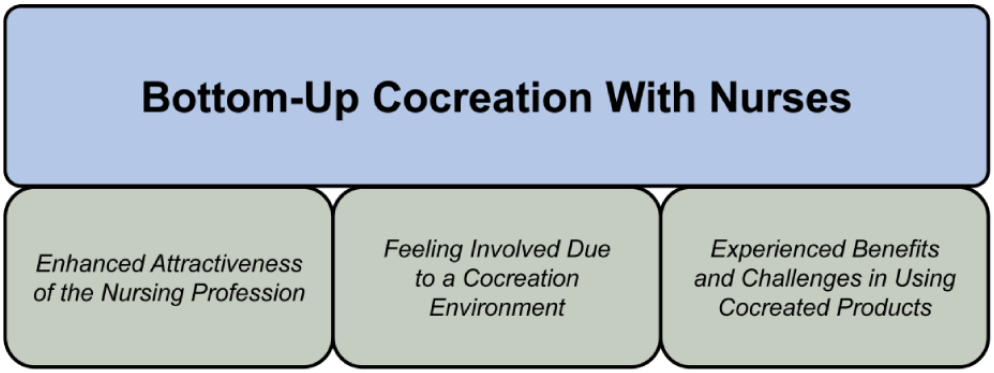
[g]Laggards have a traditional view and are more skeptical about innovations [26].

Bottom-Up Cocreation With Nurses

Overview

The thematic analysis uncovered the following three main themes concerning the participants' experiences with the bottom-up cocreation approach and resulting nursing technological innovations: (1) enhanced attractiveness of the nursing profession, (2) feeling involved due to a cocreation environment, and (3) experienced benefits and challenges in using cocreated products. Figure 1 provides a visual representation of the main themes.

Figure 1. Thematic map with the 3 main themes.



Enhanced Attractiveness of the Nursing Profession

All participants experienced that the bottom-up cocreation approach with nurses contributed to the overall attractiveness of the nursing profession. The nursing profession's attractiveness was enhanced as participants were enthusiastic about participating in cocreation, finding it enjoyable and engaging. Moreover, some participants felt that they were taken more seriously as nurses as they were the ones who actually experienced the problems in practice and were given an opportunity to use their expertise to address these challenges and drive improvements in nursing practice:

> *It makes work more enjoyable. You feel taken seriously as a nurse. You can share your ideas. You can use your expertise to improve something. So I think that's a lot of fun and very inspiring, and it also leads to something useful in the end.* [P11, cocreator]

Some participants emphasized the importance of having affinity with cocreation. Most participants felt a sense of pride in having a cocreation department within the organization and being a part of a cocreation process. A few participants expressed modesty about contributing to the cocreation product:

> *Well, I think we were genuinely proud to be able to offer the product to the patient. It was a joint effort and of course it was also very important for us that our name was set out on the product. So another team could not say, "Look at this!" It really makes you feel good if you, if you can make something that you really like to use, then that is actually really nice.* [P8, end user]

In addition, nurses were more attracted to the profession because they assumed multiple roles during cocreation. They acted as developers among designers, students, and the nursing department, actively contributing ideas and promoting products within the departments. Some participants expressed that the opportunity to become involved in cocreation made their work more interesting, and, due to this, they did not look for employment elsewhere. Cocreation with nurses was also inspiring for some participants. It motivated other nurses to address practical problems encountered during their work and explore possibilities for solving them:

> *But you're then involved in care in just a slightly different way than in standard care. And that also gives new energy and new ideas. And maybe other colleagues could also get new ideas and think, well, I have seen it a few times now, so what if I can come up with some ideas like this. Then they might think, oh well, perhaps this is something that we can also work on. This could also inspire others.* [P13, cocreator]

Feeling Involved Due to a Cocreation Environment

All participants reported enhanced collaboration through bottom-up cocreation involving various stakeholders. Collaboration included clear communication and teamwork among nurses, designers, and technically oriented students. Most participants mentioned that collaboration within the organization increased their willingness to adopt certain products that were aligned with nursing practice. One participant preferred internal product development but acknowledged that external innovations could still benefit end users:

> *If you get everyone involved, then you will have much more support and that is also the case with new things. I have experienced a few times in my life that we were getting an email on Sunday night. "From Monday we will do it like this." Well, then nurses will be digging in their heels. Whereas if you say, we're working on this, and who wants to contribute their views? Then you create support; much more people will then be willing to take it from there.* [P9, cocreator]

> *I like it when the product comes from us, I like that, but it does not necessarily have to come from us.* [P8, end user]

Some participants highlighted that collaboration among nursing departments, other hospitals, and organizations contributed to knowledge exchange, product distribution, and external production. However, one participant mentioned poor communication among nursing departments concerning new developments within the organization:

> *But we, we do note things, and we share them. It's important that you know this. We're not all working in separate groups.... On the contrary, a lot of information is shared among the four of us. Because we have to intervene and know what the other thinks.* [P10, manager]

> *No, that is also very poorly communicated. And the same applies to these products.* [P9, cocreator]

Some participants mentioned encountering practical problems but found it challenging to address these problems without the support of an innovation department with a cocreation group. The presence of such a department allowed the active participation of nurses and patients in creating specific products. Furthermore, a subgroup of participants engaged in cocreation with both patients and their parents, resulting in products tailored to their specific desires and needs. Patients were enthusiastic and felt heard, leading to the active use of end-user products:

> *Yes, parents have been involved in the co-creation process. That is, in the entire process of designing, they were not just allowed to give input, but were also able make direct choices, about what benefits them the most.* [P12, manager]

An aspect experienced by most participants was the need for support during the cocreation process. Several participants emphasized the importance of a supportive manager in facilitating and allocating dedicated time for the cocreation process. They noted that cocreation was unlikely to occur without managerial backing. Participants reported that supportive managers who recognized the value of cocreation and its potential to save time in nursing care were more proactive in addressing and resolving practical problems:

> *Managers can stimulate it. I think that people working in healthcare can be very creative, but often think, what shall I say, in boxes, because it's not possible, because we're too busy. But actually that is such a shame, because we just have a lot to offer and we have the knowledge and experience to be able to create something beautiful. And I think if a manager who (A) stimulates and (B) gives the space that is required, this will ensure that people are more motivated to contribute. Because they're aware that improvement is possible.* [P11, cocreator]

Experienced Benefits and Challenges in Using Cocreated Products

Benefits

Participants found the products resulting from the bottom-up approach to be highly practical and user-friendly when used during their nursing tasks. All participants expressed immediate positivity toward the product due to its straightforward design. They could use the product without needing special training. Nurses also immediately experienced positive outcomes during their tasks. For instance, one participant mentioned that a newly created clamp for placing pressure transducers at the correct height on infusion poles improved nursing efficiency. They also reported that this clamp alleviated wrist complaints:

> *It is faster, yes, you press it and put it on the pole, loosen it and put it back on the transport cart.* [P6 end user]

Some participants found that the products improved their ability to organize and manage nursing tasks. For example, a product named KoosGuard contributed to an improved organization of patient monitoring wires, providing enhanced structure during nursing care. Another product, the cannula emergency bag, ensured that nurses, patients, and parents had all the materials neatly arranged in case of an emergency, enhancing preparedness and efficiency:

> *Overview yes, you immediately have a clear overview. Because it's easy to open it, everything is in place and it's compact. And because it was developed together with the parents and the nurses, of course, they really like that. It fits their needs.* [P12, manager]

Several participants emphasized the importance of the products' quality and safety. Participants highlighted that the professional appearance of the product and its suitability for nursing practice served as indicators of quality. Participants reported that these well-suited products reduced the need for makeshift solutions, resulting in fewer inconvenient situations during their work:

> *Yes, the well-known example is that we often use band-aids and things, but that is to help you out for the time being. But practice has already shown that there are much more convenient solutions.* [P11, cocreator]

Certain participants emphasized the role of the products in enhancing patient safety. Participants noted that a specific product effectively prevented infusion line entanglement and tension, thus reducing the risk of accidental removal. In addition, participants mentioned a product designed to decrease the risk of postsurgery wound contamination, promoting improved healing outcomes:

> *You really want those lines to be properly arranged. To make sure that not one of them is hidden from your view, because if one of those lines is pulled, the infusion may accidentally get disconnected or the patient can accidentally end up lying on top of that line because you can't see it.* [P14, manager]

Challenges

In addition to the benefits of the products, participants also experienced some challenges in their use. Some participants mentioned that some product designs had flaws, which hindered their effectiveness. For example, a participant heard from some patients that they still thought that the cannula emergency bag was too large to be used conveniently, and, due to this, it was no longer used. In addition, it was indicated that some products looked disposable, so nurses threw them away:

> *The only negative feedback came from a patient. She just thought the bag was too big.* [P8, end user]

A few participants pointed out that some products were prone to getting lost or becoming untraceable. It was emphasized that these products should be readily available to nurses at designated and standardized locations. Otherwise, the product will be used less or not used at all. Furthermore, some participants shared their struggle with making changes, leading to a heightened risk of reverting to old routines:

> *Then it takes a lot of time anyway. And you think: well, I'll just do it in the old-fashioned way, using a gauze.* [P3, end user]

SWOT Analysis Findings

Detailed examples of the main themes were divided into the 4 components of the SWOT matrix. Multimedia Appendix 1 presents an overview of all the main themes, along with detailed examples, illustrative quotations, and the corresponding SWOT categorization. The “strengths” and “weaknesses” encompass the experienced advantages and disadvantages associated with the bottom-up cocreation approach and the products developed through this approach. The “opportunities” and “threats” are examples that could be associated with potential future opportunities and challenges of the bottom-up cocreation approach and developed products. Most of the examples were connected to the components “strengths” and “opportunities.”

Discussion

Principal Findings

In this study, we sought to explore hospital nurses’ experience with a bottom-up cocreation approach and the resulting nursing technological innovations developed through this approach. Notably, through a SWOT matrix, we mainly revealed positive experiences of participants cocreating nursing technological innovations, with several strengths and opportunities. Participants’ experiences can be described in 3 themes: enhanced attractiveness of the nursing profession, feeling involved due to a cocreation environment, and experienced benefits and challenges in using cocreated products. The findings indicate that participants found the nursing technological innovations easily applicable in nursing practice due to their user-friendly design, the ability to enhance nursing efficiency, patient safety, and time-saving potential during nursing work. A collaborative culture may lead to higher work satisfaction among nurses, inspire cocreation, and promote nursing pride.

Comparison With Prior Work

This study shows how cocreating nursing technological innovations positively impacts the attractiveness of the nursing profession. The attractiveness of the nursing profession was enhanced by nurses finding joy in their roles, feeling a sense of pride, and being taken seriously in their work. This aligns with findings from a cross-sectional study, which emphasizes the significance of decision-making involvement in health care services, such as equipment, technologies, and processes for employment preferences of nursing students [31]. In addition, it aligns with a systematic review indicating that an increase in career opportunities and challenges positively impacts nurse retention. It reduces nurses’ desire to leave a particular workplace [32].

Furthermore, this study emphasizes several collaboration advances due to a cocreation environment within the organization, such as clear communication and teamwork among nurses, designers, and technically oriented students. Moreover, a cocreation environment within the organization contributed to knowledge exchange, product distribution, and external production. An in-depth case study [14] reinforced the importance of an innovative environment within the organization. It could increase the diffusion of nurse-led innovations within and outside the organization. Particularly, managers seem to have an important role in collaborating and communicating with each other about innovations and supporting working methods in nursing departments. Existing literature [33,34] reinforces the notion that supportive leadership is crucial for fostering a culture of innovation and enhancing the sustainability and impact of health care innovation settings.

In addition, this study shows that innovations cocreated with nurses led to multiple benefits for nursing practice. Cocreated nursing technological innovations were described as user-friendly, highly practical, and easy to integrate into nursing tasks, consistent with findings from a quasi-experimental study [35]. In this quasi-experimental study, trained innovative nurses were able to identify issues in nursing practice and apply creative thinking strategies to create innovative products that matched their nursing work routines. Furthermore, the cocreated nursing technological innovations met nursing quality requirements and reduced the need for improvised solutions, thereby minimizing inconvenient situations in nursing practice. Patient safety was also enhanced by the cocreated products, which prevented issues such as infusion line entanglement and reduced the risk of wound contamination. The incubator traffic light is an example from the literature of a cocreated nursing technological innovation that meets quality standards and enhances patient safety. The incubator traffic light features a visual feedback system for neonatal incubators designed to enhance hand hygiene compliance [1,2]. Incubators with the incubator traffic light visual feedback system demonstrated significantly higher compliance with the correct drying times compared to those without this feature. This could potentially enhance patient safety by reducing infection rates in neonatal intensive care units [1]. Although the cocreated nursing technological innovations offered several advantages, the study also encountered certain challenges in their use, for example, flaws in the design of the innovations, which hindered their effectiveness or ability to make changes in the nursing routines. This study shows that changes in nursing processes may increase the risk of reverting to old routines, which aligns with findings from a cross-sectional survey that indicated how changes in nursing work processes could influence established work habits [36].

While this study did not include patients or parents directly, the participants acknowledged the significance of their perspective during the innovation process. It was mentioned that some of the cocreated innovations were developed in collaboration with patients and parents, resulting in innovations aligning with their expectations and needs. This is consistent with existing literature, where patients, family caregivers, and clinicians cocreated a mobile health app for heart failure self-management tailored to the specific health care context [37]. Furthermore, it matches with a qualitative co-design article including family, physicians, researchers, patients, and industry partners. The study revealed important differences between the participants’ preference for functional requirements of a mobile health app [38].

Limitations

Limitations of the study include its single-site focus on a specific academic hospital and limited transferability to other health

care settings [19]. Furthermore, there may be a sampling bias, as interested individuals were required to actively contact the investigator via email to participate in this study. These individuals might have been more likely than other professionals to embrace the innovations and encourage their adoption within their teams. In addition, all the participants scored themselves above average on the adoption rate scale (Table 3), and 10 (67%) of the 15 participants considered themselves to be "innovators" [25]. Literature shows that only 2.5% of the population belongs to the group of innovators [25]. This suggests a potential bias in the participant group. Including nurses as cocreators may have introduced selection bias, as their enthusiasm and assertiveness toward innovations may have influenced the results in a more positive manner [39]. Finally, the sample size consisted of 6 (40%) nurses as cocreators, 5 (33%) nurses as end users, and 4 (27%) managers. The limited insights from the managers' perspective may affect the comprehensiveness of the findings in the study [19].

Implications and Further Research

The findings of this study suggest several implications. Health care organizations could consider adopting the bottom-up cocreation approach with nurses as it has the potential to enhance nurses' work satisfaction, a sense of pride among nurses, and adoptable nursing technological innovations in nursing care. Furthermore, cocreation can contribute to accessible collaborations between stakeholders inside and outside the organization. In addition, cocreation with nurses has the potential to facilitate the development of innovations that enhance the efficiency of nursing work. Simple, professional, and time-saving innovations created through this approach could improve nursing practices.

Further research is recommended to explore the impact of the bottom-up cocreation approach and the resulting nursing technological innovations in other health care centers, aiming to improve the transferability of this way of working. Moreover, to better address patients' expectations and needs during the cocreation process and resulting innovations, further research is recommended to investigate their experiences throughout the cocreation process and its outcomes.

Conclusions

This study highlights substantial positive experiences of cocreating nursing technological innovations in nursing care. The findings underscore that cocreation with nurses enhances the appeal of the nursing profession. Participants perceived cocreation as enjoyable, leading to heightened work satisfaction and a sense of pride in their nursing role. Moreover, cocreation with nurses fosters the development of nursing technological innovations that align with nursing practice challenges, thereby facilitating their adoption within nursing care. Ultimately, embracing a culture of cocreation has the potential to foster ongoing improvements and innovations in nursing care, further contributing to the professionalization of the field.

Acknowledgments

The authors extend their appreciation to Myrthe van der Zanden, MSc, nursing scientist, for reviewing the interview guide and participating in the pilot interview.

Data Availability

The datasets generated or analyzed during this study are not publicly available due the participants involved in this research did not authorize the public dissemination of their data through written consent.

Authors' Contributions

SvS contributed to conceptualization, writing the original draft, data curation, formal analysis, investigation, methodology, project administration, and visualization. OH contributed to recruitment, conceptualization, reviewing and editing the manuscript, formal analysis, investigation, methodology, project administration, and supervision. HSMK contributed to conceptualization, methodology, and reviewing and editing the manuscript. TvH contributed to conceptualization, reviewing and editing the manuscript, data curation, formal analysis, investigation, methodology, project administration, and supervision.

Conflicts of Interest

None declared.

Abstract

Background: Increasing use of computational methods in health care provides opportunities to address previously unsolvable problems. Machine learning techniques applied to routinely collected data can enhance clinical tools and improve patient outcomes, but their effective deployment comes with significant challenges. While some tasks can be addressed by training machine learning models directly on the collected data, more complex problems require additional input in the form of data annotations. Data annotation is a complex and time-consuming problem that requires domain expertise and frequently, technical proficiency. With clinicians' time being an extremely limited resource, existing tools fail to provide an effective workflow for deployment in health care.

Objective: This paper investigates the approach of intensive care unit staff to the task of data annotation. Specifically, it aims to (1) understand how clinicians approach data annotation and (2) capture the requirements for a digital annotation tool for the health care setting.

Methods: We conducted an experimental activity involving annotation of the printed excerpts of real time-series admission data with 7 intensive care unit clinicians. Each participant annotated an identical set of admissions with the periods of weaning from mechanical ventilation during a single 45-minute workshop. Participants were observed during task completion and their actions were analyzed within Norman's Interaction Cycle model to identify the software requirements.

Results: Clinicians followed a cyclic process of investigation, annotation, data reevaluation, and label refinement. Variety of techniques were used to investigate data and create annotations. We identified 11 requirements for the digital tool across 4 domains: annotation of individual admissions (n=5), semiautomated annotation (n=3), operational constraints (n=2), and use of labels in machine learning (n=1).

Conclusions: Effective data annotation in a clinical setting relies on flexibility in analysis and label creation and workflow continuity across multiple admissions. There is a need to ensure a seamless transition between data investigation, annotation, and refinement of the labels.

Introduction

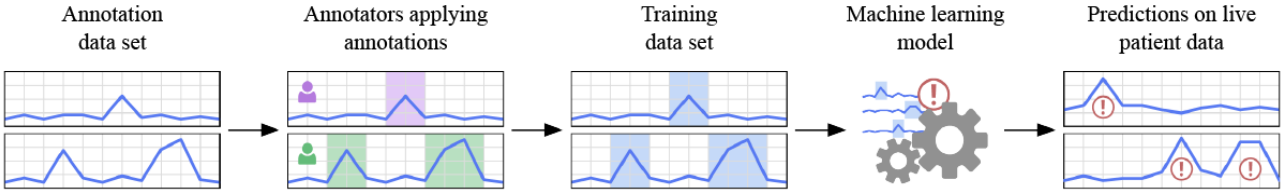
Background

Artificial intelligence (AI) is a field concerned with leveraging computers to mimic human cognitive functions, such as problem-solving and decision-making [1,2]. Depending on the task, this process can use a variety of methods and take many forms ranging from relatively simple rule-based expert systems (following if-then pathways) through regression (modeling the relation between different variables to predict their values) and clustering (grouping objects with similar properties together) to more complex systems such as artificial neural networks (computing systems imitating the anatomy of human brains capable of modeling nonlinear processes) [1,3,4]. Particularly complex problems may require solutions that cannot be achieved by traditional approaches, such as preprograming the desired behavior. Instead, techniques such as machine learning (ML) form a subset of AI in which the algorithms are used to analyze large amounts of data to derive a method for computing a solution [5]. In ML, the practice of arriving at a solution is called "learning" (or training), and the produced output is known as the ML model. The heavy reliance on data in ML highlights the importance of ensuring the appropriate quantity and quality of data and signifies its impact on the effectiveness of the created model [6]. The continuously increasing popularity of ML and its rapid adoption rate in life sciences suggest that AI is at the forefront of bringing innovation to health care [7,8].

Intensive care units (ICUs) are busy and complex health care environments where critically ill patients frequently require continuous monitoring and multiple-organ support. To provide care for those patients, clinicians working in the ICUs use a broad range of medical devices, such as ventilators, monitoring devices, and intravenous pumps and lines among many others. The information captured by those devices, as well as that entered by the ICU staff, is collected and collated in a clinical information system, which enables health practitioners to access large quantities of data routinely required as part of their job. This data-rich nature and the direct influence of data on the provision of care provide a tremendous opportunity for the deployment of ML models in health care and in particular ICUs [9].

While the data gathered in the ICUs can often be used directly, for example, to present the correlation between different vital signs and the patient prognosis, complex tasks that rely heavily on clinical experience and expertise may require human involvement to provide further guidance [10]. This guidance, most frequently referred to as labels or annotations [11], can deliver additional information or context to the existing data. An example of such a label could be a "yes" or "no" indicator of whether a patient is ready for discharge, or the type and size of tumor present on a radiograph. With this further knowledge, ML models can take advantage of the human experience to tackle complex problems and deliver solutions that could not be inferred from raw data alone [12] (Figure 1).

Figure 1. Annotating data can provide additional information and context necessary to train machine learning models.



While the large volumes of data available in intensive care offer significant opportunities, working with these data also presents a unique set of challenges, as the effort required to annotate the dataset increases proportionally to its size [13]. Furthermore, the complex nature of the health care data and the fact that applying a single label can require clinicians to look at multiple parameters, patient history, and laboratory results make the annotation task highly labor-intensive. With the clinician's time being a remarkably valuable resource, ensuring the effectiveness of the data annotation workflow is paramount. The lack of an annotation system tailored to the unique nature of the health care data (eg, accessing a subset of relevant variables from a list of potentially hundreds of parameters [14]) further complicates this problem.

In addition to the difficulties associated with working within clinical settings, it is equally important to consider the inherent challenges of data annotation in their own right. These include the need to account for multiple different types of bias that could be introduced throughout the process [15]. For example, the annotators themselves may have their own preferences and preconceptions that will guide the approach they assume when annotating data. This could stem from the amount and diversity of their clinical experience in a context specific to the annotation task, such as the familiarity with the clinical problem, the specific population within which they have treated it, or even the specific tools and methods they have used in the past. Similarly, by annotating historical data that span the entire duration of the admissions, annotators may create labels with an inherent temporal or selection bias. Alternatively, annotators tasked with creating specific annotations may focus on a subset of the admission where they would expect to create the annotation, such as reliance on medication, which may decrease toward the end of the admission but could equally change throughout its overall course.

Current literature on the applications of computational methods within health care highlights data annotation as a primary bottleneck in the ML pipeline [16]. This effect is attributed to the need for domain-specific knowledge and therefore access the expert population, as well as the considerable investment of their time [16-18]. Because of this, existing methods aim to reduce the number of required annotations required for positive results by using a variety of techniques including active learning [17], machine-assisted annotation [19], or synthetic data generation [20]. Nevertheless, the majority of studies continue

to rely on human annotations in the cases where labels cannot be easily derived, or are inadequately documented in structured data [16]. Designing a tool for the annotation of large clinical datasets is therefore a problem that needs to be approached carefully. The expert nature of the annotators means that both their numbers and time are limited and are therefore resources that need to be used efficiently [16]. Furthermore, clinical datasets frequently aggregate data spanning several years, resulting in a volume of data that is infeasible for manual annotation, suggesting a need for a semiautomated approach that could scale up to an entire dataset with limited input from the domain experts.

Involving end users in the design process of new tools prior to their development is an important aspect of designing effective software [21]. It minimizes the risk of creating a system that is inefficient and helps ensure that the developed solution meets users' expectations and requirements [22,23]. In the context of the data annotation software used by experts in intensive care, this participatory design is especially critical, as each of the variety of roles (eg, junior doctors, doctors, nurses, and consultants) can generate a unique set of requirements. Furthermore, while the staff working in the ICUs are experts in the medical domain trained to treat patients, extracting their knowledge through data annotation is an entirely different process. For this reason, it is crucial to deploy a strategy that will ensure that the design of the tool follows a structured and systematic approach that can capture a wide variety of perspectives from its end users while also accounting for the needs and priorities of the data science experts who will use the created annotations.

Objectives

The primary objective of the research is to establish a set of criteria for the design of a data annotation tool that can be used effectively by clinicians to annotate time-series datasets from intensive care. To achieve this goal under the limitations of working within the health care setting, the system needs to account for limited access to the annotators and large volumes of data. Finally, to ensure the efficiency of the process, the subtleties of how clinicians approach the problem of data annotation need to be understood and accounted for in the design. The overarching goal is, therefore, to gather requirements for a data annotation platform that is purpose-built for the intensive care data and clinicians and, as such, one that facilitates an efficient annotation workflow in that domain.

Methods

Study Design

To understand how clinicians approach and reason about the data annotation process, we conducted an experimental study that involved members of the clinical staff from the ICU manually annotating excerpts of time-series data printed on paper. Observations taken during task completion served as a basis for analysis and were used to derive the requirements for the data annotation software. This choice of methodology was influenced by constraints associated with working within the clinical setting, such as the high demand and short supply of participants' time, and the direct relationship between the task completion and the requirements for the digital tool, which allowed for a natural and unobstructed data collection.

Participant Recruitment

Our participant recruitment followed a mixture of convenience and snowball sampling comprising an invitation email sent to the staff working in the ICU who had prior experience with mechanical ventilation treatment and signposting through the internal network at our research site—University Hospitals Bristol and Weston NHS Foundation Trust. This recruitment process yielded a sample size of 7 participants across 2 distinct job roles (6 junior doctors and 1 doctor), which provided limited feasibility for suitable analysis of the interrole differences in approach to annotation but was sufficiently rich for establishing the software requirements for the tool we set out to design. Comparative sample sizes can be observed in similar research in the field [24-26]. Before data collection, the annotation task was piloted with a clinical member of our team experienced in mechanical ventilation treatment, as well as 2 other members of our team from the ML background. The insights collected from the pilot activity allowed us to refine the set of clinical parameters used throughout the activity, devise the inclusion criteria for the underlying admissions, and diversify the data extracts to form a sample representative of a typical dataset. Our research site had a preestablished research partnership with the University of Bristol and a technologically enhanced ICU with widespread adoption of digital systems.

Theoretical Framework

To analyze the participants' actions performed during the simulated activity, we used a framework that served as a basis for characterizing the data annotation process and identifying the challenges and opportunities associated with performing the task. Our framework followed the Norman's Interaction Cycle (NIC) model which assumes that the interaction is a process of evaluation and execution between the user and the technology [27]. It outlines a 7-step process that begins at the goal and, through evaluation of available means and strategies, as well as the execution of these strategies, leads to achieving that goal in practice. The framework emphasizes the breakdown of the preproduction stage into planning (formulating the problem that needs to be solved), specification (outlining the strategies that can be used to tackle the problem), and performance (specifying actions that need to be taken to deploy the strategy). Furthermore, it highlights the importance of presenting the user with feedback over 3 separate stages including perception (tracking the outcome of performed actions), interpretation (analyzing the effect of the outcome), and comparison (evaluating whether their actions resulted in achieving the goal) [27]. Finally, the model captures the disparities between user intentions and actions permitted by the technology (gulf of execution) and the effort required to correctly interpret the results of their actions with regard to the desired outcome (gulf of evaluation) [27,28].

Data Collection

To facilitate data collection, we simulated a data annotation activity involving manual annotation of real intensive care patient data using pens and highlighter pens on excerpts of data

printed on paper sheets. The data were formatted to resemble the clinical information system present at the research site and displayed patient demographics in addition to a table with time-series data. Each column of the table corresponded to an hour of the day and each row corresponded to a specific parameter; the table's cells contained the readings of a parameter for a given hour (Figure 2). The outline brief for the activity prompted participants to create annotations, allowing them to create multiple annotations for a single admission. Crucially, no additional instructions were provided regarding the annotation format. Before the data collection, the activity was piloted internally with an experienced intensive care consultant (CB) and 2 ML experts (RSR and CMW), which helped us establish inclusion criteria for the selected admissions, broaden the characteristics of our admission sample, and refine the included parameters. The activity took place as a single in-person workshop, lasting approximately 45 minutes, during which each of the 7 participants annotated the same set of 5 unique admissions (Figure 3).

Participants were observed for the duration of task completion by a single observer who took field notes throughout the entire activity. These field notes captured the interactions of the participants with the annotation tasks and described the actions taken when annotating specific admissions, how multiple admissions were annotated, and questions asked by the participants during the task. The collected notes were then aggregated across the different stages of NIC and the annotated printouts were collected and used to supplement the analysis of the methods used by the participants to label the data.

Figure 2. The provided excerpts of time series data were formatted to resemble the interfaces of the clinical information system present at the research site (the depicted table contains data for illustrative purposes only and is trimmed for conciseness). Figure 3. Participants annotated data in a variety of ways using pen and paper during the workshop held in the intensive care unit.

Task Selection

Capturing data labels in a manner representative of the general annotation process relied on selecting an appropriate task. On the one hand, the desired label could not be trivial and needed to pose a significant challenge, complex enough to prompt an in-depth analysis of the data. On the other hand, this task also needed to fall within the subset of domain knowledge that participants were familiar with and could therefore solve with a relative degree of confidence. Annotating weaning from mechanical ventilation satisfies both of these criteria due to its challenging nature and the relative bias of the person who performs it. The process of weaning can be characterized by great variability in practice [29], in which both the timing of when the weaning begins and the method in which it is delivered largely depend on the clinician in charge of the treatment [29,30]. Together with the lack of personalized guidelines [31] and a wide variety of ways in which patients can be weaned, mechanical ventilation weaning constitutes a label that is difficult to derive from data and requires domain expertise, which makes it suitable for this task. While in the context of mechanical ventilation the term "weaning" comes with an inherent ambiguity due to a number of conflicting definitions [32-36], for the purpose of this activity it was explicitly defined as "the reduction of support delivered by the mechanical ventilator with an end goal of extubation." Consequently, the activity brief prompted participants to annotate periods during which mechanical ventilation weaning takes place and allowed multiple annotations for any individual admission.

Admission Data

The data used in the activity came from a deidentified intensive care dataset called "Medical Information Mart for Intensive Care IV version 2.0" [37]. The eligibility criteria required that subjects were at least 18 years of age at the time of admission, had undergone an invasive mechanical ventilation treatment that lasted for a minimum of 24 hours, their stay in the ICU lasted for a minimum of 4 days, and that their stay did not end with death, including up to 48 hours after discharge. The time-series parameters used in the data extract were limited to those relevant to mechanical ventilation weaning and were selected by 2 independent clinicians working in the ICU. The data were extracted using a structured query language script run on the PostgreSQL installation of Medical Information Mart for Intensive Care IV version 2.0 with the concept tables computed [38]. The script aggregated the selected parameters on an hourly basis for each eligible admission and limited it to the range surrounding the period of mechanical ventilation treatment.

Ethical Considerations

This work was approved by the Faculty of Engineering Research ethics committee at the University of Bristol (case 2022-150, research ethics committee reference 22/HRA/2166). Information regarding the study was circulated with the invited participants electronically alongside the recruitment email. Informed consent was captured electronically using digitally signed consent forms prior to enrollment in the study. Data obtained from this study were deidentified and stored securely in an encrypted database. The access to the database was password-protected and only the research team had access to these data. All participants were able to quit without any explanation at any point during the study. Participation in the study was voluntary, and no financial or other form of compensation was provided to the participants.

Results

Data Annotation Analysis

During the simulated data annotation activity, we observed participants following a series of discrete steps when annotating data. To understand how these actions fit into the annotation process, we analyzed the observations in the context of NIC and aggregated them into the distinct phases of the model.

Planning

Following the distribution of the printout sheets containing the admission data, participants began the process of familiarizing themselves with the data. This stage involved selecting a single excerpt from the available admissions, analyzing the patient demographics, and browsing through the time-series data. During the process, participants frequently cycled through the entire length of the time-series data from the initial admission until discharge and back.

Specifying

Upon familiarization with the specific admission, participants began searching for individual points in time suggestive of the weaning taking place. Some participants preferred to start with the end of treatment, where weaning led to extubation, while others analyzed the data to find the points in time when weaning began. This involved focusing on specific parameters (as suggested by following the specific rows with the pen tip) while browsing through the time-series data across different columns.

Performing

Upon finding the thresholds for the start or end of weaning, the participants annotated the printed sheets directly. To create the labels, a variety of techniques were used, which differed both between the individual annotators and the distinct admissions. These included circling the start and end dates in the header row of corresponding columns, drawing vertical lines on the edges of the columns to mark the start and end periods, and drawing a box around the portion of the dataset spanning the duration of the label. Similarly to the analysis process, some participants preferred to first annotate the end of the weaning process, rather than its start. In some cases, participants also provided additional information in the form of written comments that justified the created label (eg, "mode of ventilation changed from A to B" or "delivered oxygen reduced—indicative of weaning") and underlined values within cells of parameters that prompted annotation.

Perceiving

Following the act of annotating the data, participants frequently verified their labels. This was expressed by browsing through the time-series data again and ensuring that the start and end dates corresponded to the parameter readings that suggested the annotation in the first place.

Interpreting

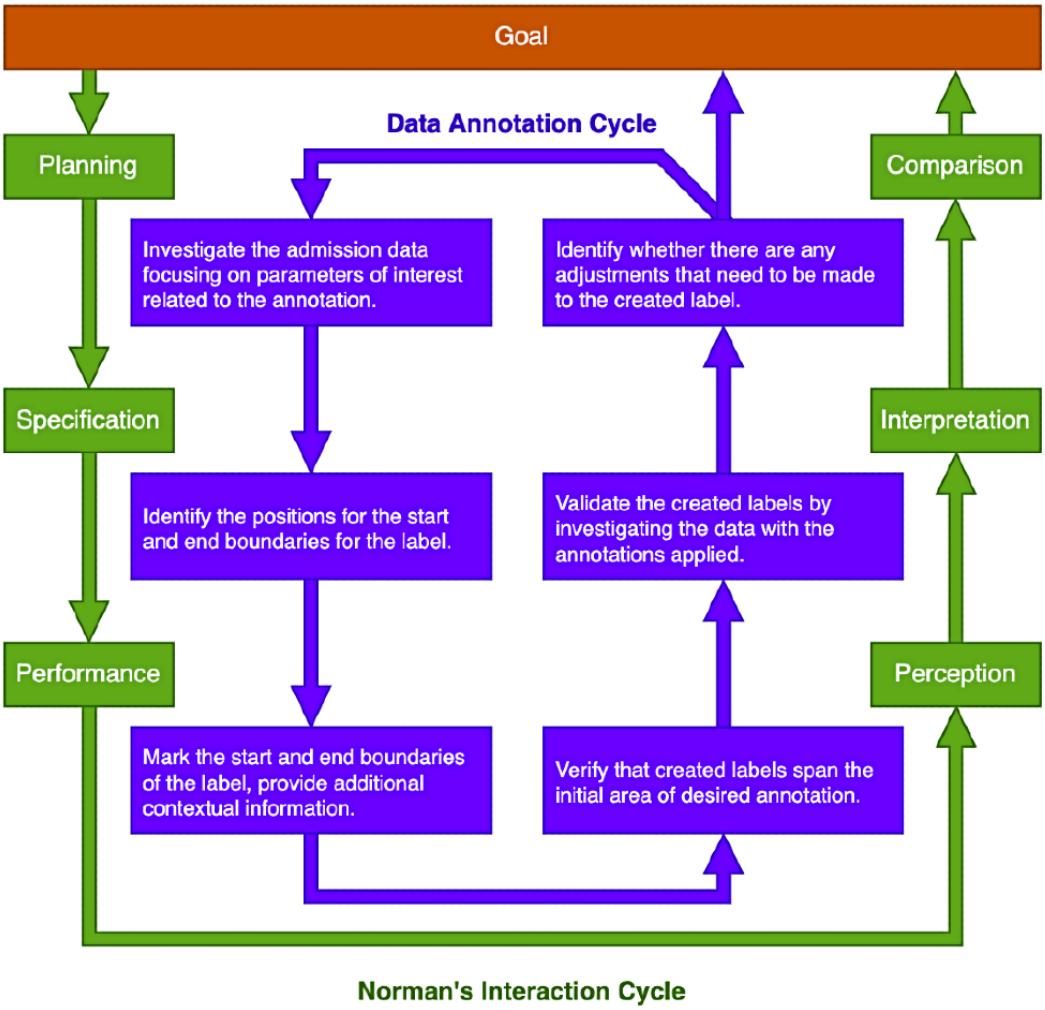
In some cases, participants derived additional insights from the data when investigating them with their labels already present. These insights frequently manifested in the form of retracing the admission data over the span of the created label, which resulted in a reevaluation of the created label and its underlying data.

Comparing

Finally, participants who identified the need for amendments returned to the planning stage to repeat the annotation process, whereas those satisfied with their annotations frequently sought feedback from the activity facilitator on the desired annotation count and the next steps involved in the process.

Crucially, by contextualizing the annotation process within the NIC model we identified that the overall approach to annotation followed a cyclic process of investigation of the data, creation of the labels, reevaluation of the data with the labels applied, and refinement of previously created labels (Figure 4).

Figure 4. Data annotation followed a cyclic process involving investigation of data, label creation, reevaluation of data with labels applied, and refinement of created annotations.



User Requirements

Observations from the workshops captured key characteristics of participant interactions with the task, forming a basis for establishing the functional requirements of the digital tool. Coupled with the operational constraints of data annotation in clinical settings and the specific needs for future label use in the ML context, these characteristics informed the user requirements for the digital annotation tool.

Annotation of Individual Admissions

Familiarization with admission data during the planning and specification stages suggested that the primary goal of participants at the early stage of the process was to obtain a high-level overview of the patient's characteristics and their stay in the ICU. This was supported by the frequent cycling through different parts of the admission, allowing participants to establish a broad timeline of events and the overall treatment trajectory without focusing on the minutia of its delivery. The interface of the tool should allow end users to conduct a similar analysis digitally, incorporating both the patient demographics and the time-series data.

Once familiarized with the admission data, participants shifted their focus to a more task-oriented analysis by narrowing the list of parameters to a subset significant for the task, suggesting

different relevance of specific parameters to the target label. Furthermore, the fact that in certain cases participants found it easier to first search for the end of weaning, rather than its start, suggests that their confidence in the accuracy of the created label, its precise start or end, might be different across annotations. Similarly, each of the participants displayed different preferences for creating annotations favoring first marking either the start of the weaning process or its end. Despite this, they all shared a common set of actions of marking the beginning and end of the label, even when the order of these operations was not the same. To make the annotation process as unobtrusive as possible, the digital data annotation tool should therefore allow flexibility in not only how the data are viewed and analyzed but also how the annotations are being created. As such, the interface needs to display a continuous dataset without constraining it to a subset of time or parameters and allow the end users to freely mark the boundaries of the label in the order of their preference.

Following the creation of a label, participants frequently continued to investigate the underlying data and further adjusted the labels, indicating the need to reflect on their immediate performance and refine the annotations. Adjusting labels upon their reevaluation indicates that when the data are viewed with the annotations applied, the annotator's perception of these data changes allowing for additional insights to be derived. As such, the digital tool should allow for the display of the created annotations on top of the data and facilitate a similar ability to adjust and modify them once they are created.

Participants also frequently provided additional information to support their labels, such as comments or specific parameters that led them to create the annotation. This contextual information could be used as a surrogate for the thought process of the annotators and further inform the importance of specific parameters on the target label. The digital tool should therefore incorporate the ability to provide additional data, such as parameters of interest, confidence in the accuracy of created labels, and free-form text that provides further context.

Finally, the feedback sought upon completing the annotation indicated the need for both a progress indicator and the importance of preservation of the continuity of the annotation process on retaining participants' focus. A digital tool could account for this by displaying the count and information about the already created labels and making it easy and efficient for participants to annotate consecutive admissions. As such, the functional requirements for the digital data annotation tool can be specified as follows:

- R1: Data analysis in which participants are free to navigate through the entire span of the admission data, as well as underlying patient demographics.
- R2: Label creation functionality which is flexible enough to allow end users to select the start and end of annotation independently and in any order.
- R3: Label adjustment capability that facilitates an easy and convenient way to amend the created label, particularly with that label presented on top of data.
- R4: Label supplementation feature that allows participants to provide additional context for the created annotation, including confidence in the label accuracy and relevance of different parameters.
- R5: Workflow continuity that ensures a cohesive process of annotation and keeps the end users engaged and focused on the task.

Semiautomated Annotation

Facilitating a semiautomated approach to annotation that allows for creating labels for an entire dataset is a separate but closely related task. As such, it can benefit from the analysis of the manual annotation process and use it to further inform the requirements for the digital tool. The annotation of a single admission could be described as a bottom-up approach, in which end users are presented with data specific to a single admission and asked to annotate them directly (optimally until the entire dataset is annotated). Conversely, adopting an approach that automates the process would likely involve the annotation of an entire dataset based on a single user input, constituting a top-down approach. A semiautomated approach would therefore focus on creating labels for the whole dataset without focusing on individual admissions during their creation but potentially using them to evaluate the annotations and refine them upon further analysis. To that extent, the digital tool needs to allow its end users to establish annotation strategies that are independent of individual admissions during their formulation.

The process in which participants interacted with the individual admissions suggested several key requirements that needed to be adapted for the semiautomated approach. To close the loop of investigating, annotating, evaluating, and refining that the participants exhibited during the simulated activity, the semiautomated annotation approach facilitated by the platform should also allow for analysis of the effectiveness of the annotation in the context of both the entire dataset and individual admissions. In particular, the interface should allow the end users to view individual admissions with the created annotations applied, providing additional explanations for why the label was created, and in turn, allowing them to refine their annotation strategies. Consequently, the requirements for the digital tool facilitating a semiautomated annotation are defined as follows:

- R6: Annotation and evaluation loop captured as one continuous process that preserves the focus of the end users and facilitates effective annotation.
- R7: Label analysis of individual admissions with the overlay of created annotations on the time-series data and justification for their presence.
- R8: Dataset-wide performance metrics that capture the effectiveness of the annotation in the form of aggregate statistics computed across the entire dataset.

Operational Constraints

In addition to the requirements identified through the analysis of participants' approach to the annotation task, there are further operational constraints that need to be reconciled to deliver an effective annotation workflow. To accommodate the busy schedules of the ICU staff, the tool should allow its end users to access it in a way that suits their needs and does not impose strict time commitments. As such, end users should be able to perform the annotation asynchronously and access the platform

remotely. Furthermore, to preserve the focus and ensure that the end users' time is used efficiently, the system should provide a responsive and time-efficient workflow that enables them to create and evaluate annotations in a short span of time. This is particularly important for the semiautomated approach in which the timely annotation of a large volume of data is critical to preserve the continuity of the annotation and evaluation loop. The operational requirements for the annotation tool are therefore defined as follows:

- R9: Asynchronous and remote annotation that allows the end users to perform the task at their convenience without further complicating their busy schedules.
- R10: Responsiveness of the system that provides feedback on the created annotations in a timely manner, particularly in the case of the semiautomated annotation.

Labels for ML

Finally, having identified the functional and operational requirements, we analyzed the platform in the wider context of using the created labels in ML workflows. To that extent, the discussion between data science experts within our research team surfaced several key factors that the tool should account for to ensure that the captured data can seamlessly integrate into ML pipelines.

The most important one to consider is the need to achieve a careful balance between the number of annotated admissions and the confidence in the created annotations. On one hand, increasing the total number of annotated admissions and their diversity would result in a larger training dataset and, consequently, improve the performance of the resulting ML model. On the other hand, to account for the biases of individual annotators, there needs to be some overlap of admissions annotated by distinct annotators that would allow for a comparison of their approaches and biases. Furthermore, for this to happen, additional metadata surrounding the confidence in the specific annotations and relating the created annotations to their authors also needs to be collected. Only then, will the data scientists be able to evaluate each of the annotators individually, compute their biases, and adjust their annotations accordingly to improve the robustness of the training dataset.

Depending on the volume of the data that needs to be annotated, the nature of the annotation task, and the number and experience of the annotators, this balance might be substantially different. Because of this, the system needs to facilitate a dynamic and adjustable configuration for how specific data are assigned to the annotators. This suggests that in addition to the previously established requirements, the tool should also aim to satisfy the following ML-specific requirement:

- R11: Flexible data-splitting solution that allows for adjustment of the data assigned to each participant and keeps track of the label authorship.

Discussion

Principal Results

This study aimed to explore how intensive care experts approach data annotation to establish requirements for a digital tool designed for annotating large datasets in intensive care. We conducted a manual data annotation activity, observing participants as they completed the task and analyzing their actions to gain insights into their annotation strategies. This analysis informed the development of software requirements for a digital data annotation platform.

Our findings revealed that the time-series annotation process follows a cyclical annotation-evaluation loop, which includes data investigation, label creation, reevaluation of data with the labels applied, and refinement of the created labels. From this analysis, we constructed 11 key requirements: 5 directly related to facilitating the annotation of individual patient admissions, 3 adapted for implementing a semiautomated annotation feature, 2 operational requirements focused on the effectiveness of the annotation workflow, and 1 requirement addressing the future use of labels in the ML context (Table 1).

Table 1. Requirements generated from analysis of observations made during simulated annotation activity.

Category	Requirement description
Annotation of individual admissions	
R1	Data analysis in which participants are free to navigate through the entire span of the admission data, as well as underlying patient demographics.
R2	Label creation functionality which is flexible enough to allow end users to select the start and end of annotation independently and in any order.
R3	Label adjustment capability that facilitates an easy and convenient way to amend the created label, particularly with that label presented on top of data.
R4	Label supplementation feature that allows participants to provide additional context for the created annotation, including confidence in the label accuracy and relevance of different parameters.
R5	Workflow continuity that ensures a cohesive process of annotation and keeps the end users engaged and focused on the task.
Semiautomated annotation	
R6	Annotation and evaluation loop captured as one continuous process that preserves the focus of the end users and facilitates effective annotation.
R7	Label analysis of individual admissions with the overlay of created annotations on the time-series data and justification for their presence.
R8	Dataset-wide performance metrics that capture the effectiveness of the annotation in the form of aggregate statistics computed across the entire dataset.
Operational constraints	
R9	Asynchronous and remote annotation that allows the end users to perform the task at their convenience without further complicating their busy schedules.
R10	Responsiveness of the system that provides feedback on the created annotations in a timely manner, particularly in the case of the semiautomated annotation.
Use in machine learning	
R11	Flexible data-splitting solution that allows for adjustment of the data assigned to each participant and keeps track of the label authorship.

Approach to Annotation

The observations made during the manual annotation activity highlighted important characteristics of how experts from a clinical background approach the annotation task. While the sample of our study produced no discernable differences in how participants from different roles approached the task of data annotation, we observed a variety of strategies used to complete the task. These included several techniques for initial familiarization with the data, prioritization of different parameters during the investigation process, and different order of operations when creating the label. Crucially, we observed that irrespective of the specific strategies, annotators followed a cyclic process of investigation, annotation, reevaluation, and refinement when annotating data. By modeling the process using NIC, we were able to analyze the observations made during the task completion stage and formulate the requirements for the software interface of a digital data annotation platform.

In our analysis, we found that the nature of how annotators choose to analyze the data is largely preferential and, therefore, requires a degree of flexibility in how the software presents the data and allows its users to navigate through it. The cyclic nature of the process suggested that to ensure effective annotation, it must facilitate a continuous and intuitive loop of annotation, allow users to perform actions in varying order, and seamlessly adapt to different stages of the process. Since these requirements were derived from the simulated annotation of individual admissions but captured the characteristics of the overall problem of data annotation, the requirements for the semiautomated approach were adapted to ensure the continuity of the annotation-evaluation loop and flexibility in analysis.

Finally, the fact that annotators frequently sought feedback after creating labels further emphasized the importance of ensuring a seamless and uninterrupted annotation workflow and suggested the need to integrate progress indicators within the digital platform. Together with individual preferences for focusing on different parameters during the analysis and supplying additional information as part of the created labels, this also highlighted the need to capture contextual information alongside labels, which could be beneficial for their later use in the ML pipelines.

Design Implications

This literature on involving clinical staff in the collaborative design of software interventions shows that it can have profound effects on user acceptance and uptake upon release [23,39]. However, it is important to highlight that effectively engaging in such collaboration can be a challenging task, particularly when research activities require substantial time commitment [40]. Collaborating with intensive care clinicians, whose time is in high demand and short supply, may therefore require additional accommodations to be effective. In the context of annotating data, these accommodations translate into additional

requirements that adapt the process to the busy schedules of the clinical staff by allowing them to annotate data both asynchronously and remotely. This further reinforces the need to ensure that the software delivers an intuitive and time-efficient annotation workflow and places additional constraints on its design. Specifically, to facilitate the responsiveness of the annotation-evaluation loop in the semiautomated approach, where users can frequently simultaneously annotate the entire dataset, the software should incorporate a solution that dynamically adapts to both the number of active users and the volume of data that needs to be processed.

Limitations and Future Work

The activity focused on capturing the approach to data annotation was conducted with a limited number of participants, which resulted in a limited diversity of clinical roles and, potentially, perspectives from the ICU. This suggests that some of the requirements established in this research could be particularly applicable to annotators in junior doctor positions and therefore not necessarily generalizable across entire staff working in ICUs. The selection of the task for the manual annotation activity was made to provide an annotation experience that could be extrapolated beyond the specifics of the task. Despite this, we acknowledge that the results it produced could be biased specifically toward the annotation of weaning from mechanical ventilation.

Furthermore, our approach to capturing the annotation process during the simulated activity with only a single observer had a significant impact on the quantity and quality of observations that were collected. Due to the imbalance in the number of annotators and observers, some of the actions undertaken by the participants during the annotation could have gone unnoticed. Furthermore, the presence of a single observer created an inherent bias in the collected observations, as the observed actions could have been perceived differently by observers with different backgrounds or characteristics. These limitations suggest that the observations collected during the activity come with a degree of incompleteness and inaccuracy, which may have impacted the elicited requirements.

We acknowledge that further work in establishing the requirements for the digital tool could strengthen the understanding of how clinicians approach the data annotation task. To that extent, we suggest that further research in this area focuses on capturing the requirements that expand beyond the confines of a single annotation task and within a broader and more diverse population from the ICUs. Capturing a wider range of perspectives could inform the applicability of the elicited requirements and, in consequence, strengthen the resulting design of the digital tool.

The nature of the activity itself was focused strictly on the direct annotation of individual admissions rather than the use of any assistive or automated technologies. Although several requirements elicited in this context applied to the overall annotation process, including a semiautomated approach, additional requirements not captured in this study may also exist. Further research should therefore focus on the evaluation of the proposed requirements and their use and limitations in real-world applications. Therefore, these requirements should be used to design and implement a digital data annotation platform that should be trialed within a clinical setting. Conducting a study that investigates the feasibility of a semiautomated approach to the data annotation, particularly in comparison with the direct annotation of individual admissions, could further inform the requirements for data annotation tools.

Conclusions

In this study, we investigated how clinical staff from ICUs approach the task of data annotation and established 11 key requirements for a digital data annotation tool that could be deployed within the health care setting. Our findings revealed that data annotation is a cyclic process that demands flexibility in how annotators investigate and annotate the data. Preservation of the workflow continuity across different admissions and fluid transition between analysis, annotation, and refinement of the label are essential to facilitating effective data annotation in the clinical domain. Adaptations for the semiautomated annotation need to consider these factors by providing a responsive interface that dynamically adapts to the volume of data and allows for analysis on both an individual and a dataset-wide basis. The significance of these findings is evident in their potential to guide the development of a data annotation tool that capitalizes on the considerable data generated in the ICUs and the expanding use of computational methods in health care.

Abstract

Background: Technology can be an effective tool for providing health services and disease self-management, especially in diabetes care. Technology tools for disease self-management include health-related applications for computers and smartphones as well as the use of robots. To provide a more effective continuity of care and to better understand and facilitate disease management in middle-aged and older adult patients with diabetes, robots can be used to improve the quality of care and supplement community health resources, such as community pharmacies.

Objective: The aim of this study was to develop a health care robot prototype that can be integrated into current community pharmacies.

Methods: Three user-centered approaches were used: (1) review of the literature on technology use among older adults, 2) reference to the seven key diabetes self-care behaviors by the American Association of Diabetes Educators (AADE), and (3) meeting with health care providers in the community. Field investigations and interviews were conducted at community pharmacies and diabetes health education centers to determine the appearance, interface, content, and function of the robot.

Results: The results show that diabetes health care prototype robots can be established through user-centered design. The following important features were revealed: (1) perceived ease of use is considered a friendly operating interface; therefore, we used less than 3 buttons in an interface; (2) minimization of the interface between blue and yellow, which is unfriendly to older adults; (3) the health education mode was the most preferred mode with sound, image, and video presentation; (4) the most predilected functions are health education resources and health records, and that patient data can be easily collected through health education games and dialogue with robots; and (5) touching the screen is the most preferred operation mode.

Conclusions: An evidence-based health care robot can be developed through user-centered design, an approach in which a model that connects medical needs to people with health conditions can be built, thereby facilitating the sustainable development of technology in the diabetes care field.

KEYWORDS

robot; diabetes; self-management; middle-aged adult; community pharmacy; older adult; prototype

Introduction

Diabetes is a significant global health issue, with the number of people affected by the disease continually rising [1]. According to the International Diabetes Federation Diabetes Atlas, the global number of people with diabetes reached 537 million in 2021 and is expected to continue rising, reaching an estimated 783 million by 2045 [2]. The most prevalent form of diabetes is type 2 diabetes, which affects more than 90% of all individuals with diabetes [2]. Uncontrolled diabetes over time can lead to severe complications, including cardiovascular diseases, lower-limb amputation, kidney damage (nephropathy), nerve damage (neuropathy), and blindness (retinopathy) [2,3]. Age is one of the risk factors for type 2 diabetes, with its prevalence and mortality rates rising as individuals get older [4,5]. According to statistics from Taiwan's Ministry of Health and Welfare, the prevalence of diabetes increases significantly from the age of 45 years for both men and women [6]. As the duration of diabetes and patient age increase, patients with diabetes face not only a higher incidence of complications but also challenges related to multiple medications and comorbidities [7]. This underscores the importance of focused

health care management for middle-aged and older adult patients with diabetes.

In recent years, technology has emerged as a crucial tool for disease management, including diabetes [8,9]. The demand for digital health care has surged, evidenced by the introduction of more than 90,000 new health-related apps on platforms like the Apple Store and Google Play in 2020 alone, contributing to a total of over 350,000 health care applications available globally [10]. Among these technological advancements in health applications, health care robots are one of the future trends in health technology [11], driven by the ongoing digitization of health care services.

Community pharmacies play a vital role in providing health care services, offering convenient access to medications and health services that support local health care needs. There are currently more than 7400 health insurance pharmacies across Taiwan [12], and a 2016 survey indicated that over 80% of these pharmacies are open for at least 12 hours, with around 40% operating almost year-round [13]. Compared to hospitals, community pharmacies face less pressure from time constraints and space limitations, positioning them as key players in bridging the gap between individuals and larger medical institutions.

Despite the availability of professional medical information in clinical settings, there remains a challenge in ensuring that patients effectively absorb and apply health education and professional advice once they return to their communities. This gap highlights the need for technological tools that support continuous care, especially for middle-aged and older adults managing diabetes. Integrating robots into community health resources, such as community pharmacies, could enhance the quality of care, improve health management, and advance health promotion within the community. The expertise of pharmacists, coupled with the high accessibility of community pharmacies, makes them an ideal setting for such interventions.

However, current technology development for disease management often excludes medical professionals from the design process and lacks real-world testing [14]. Additionally, there is no clear evidence that technology can effectively integrate with community medical resources or bridge the gap between medical institutions and personal care. Therefore, the aim of this study was to design and develop a prototype of a diabetes care robot that meets the needs of middle-aged and older adult patients with diabetes, aligns with the perspective of community pharmacist care, and can be integrated into the current community pharmacy setting.

Methods

Participants

The design and development of the prototype robot in this study were primarily conducted through literature-based theories and expert team meetings [15]. The development of the prototype robot involved the researcher synthesizing the literature and conducting field visits to pharmacies and health education units. The development goals and direction were then jointly decided during team meetings. The development of the prototype robot began in March 2018. The team included 1 expert in technology, 1 expert in gerontology, 2 physicians, 12 to 15 engineers and research assistants, and 1 researcher. To maintain progress and continuously refine the prototype robot, the team held regular meetings 1 - 2 times per month until a more complete interactive functionality was established to enhance the user experience. Furthermore, to gain a more realistic understanding of the feasibility and initial results of the robot's application in community health care, 30 middle-aged and older adult patients with diabetes, along with 10 community pharmacists, were also included to provide user feedback.

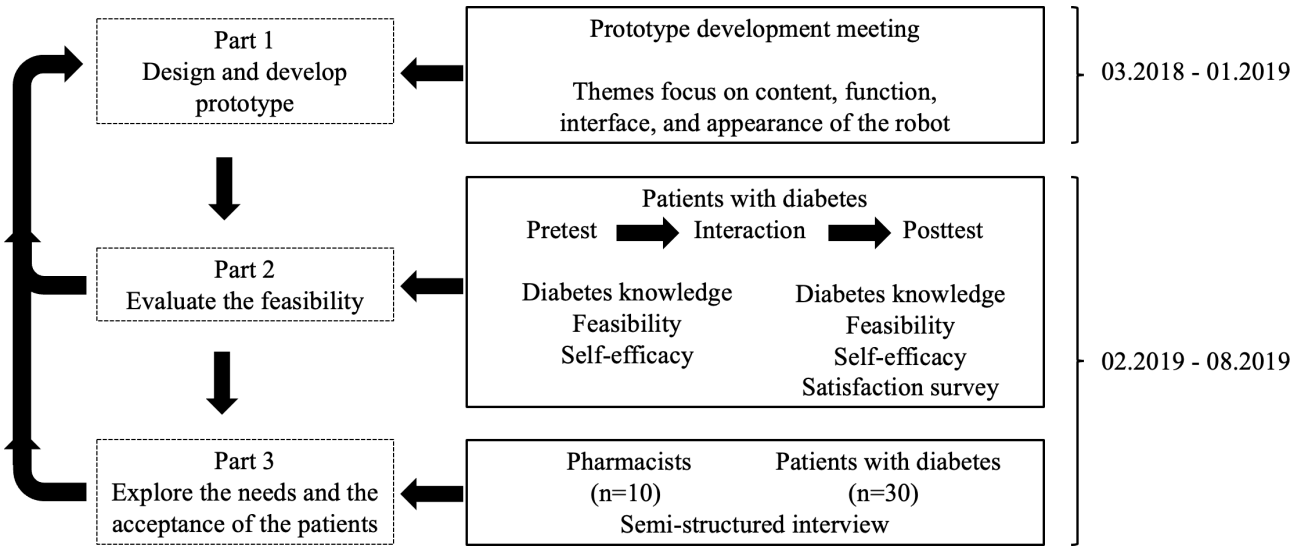
Ethical Considerations

This study was performed in accordance with the relevant guidelines and regulations, including the Declaration of Helsinki and was approved by the Institution Review Board (IRB) of National Cheng Kung University Hospital in Taiwan (No. A-ER-105 - 509). All the participants provided signed informed consent, and all study data were deidentified to protect the identity of participants. Participants did not receive any financial or material compensation for their participation in this study.

Procedures

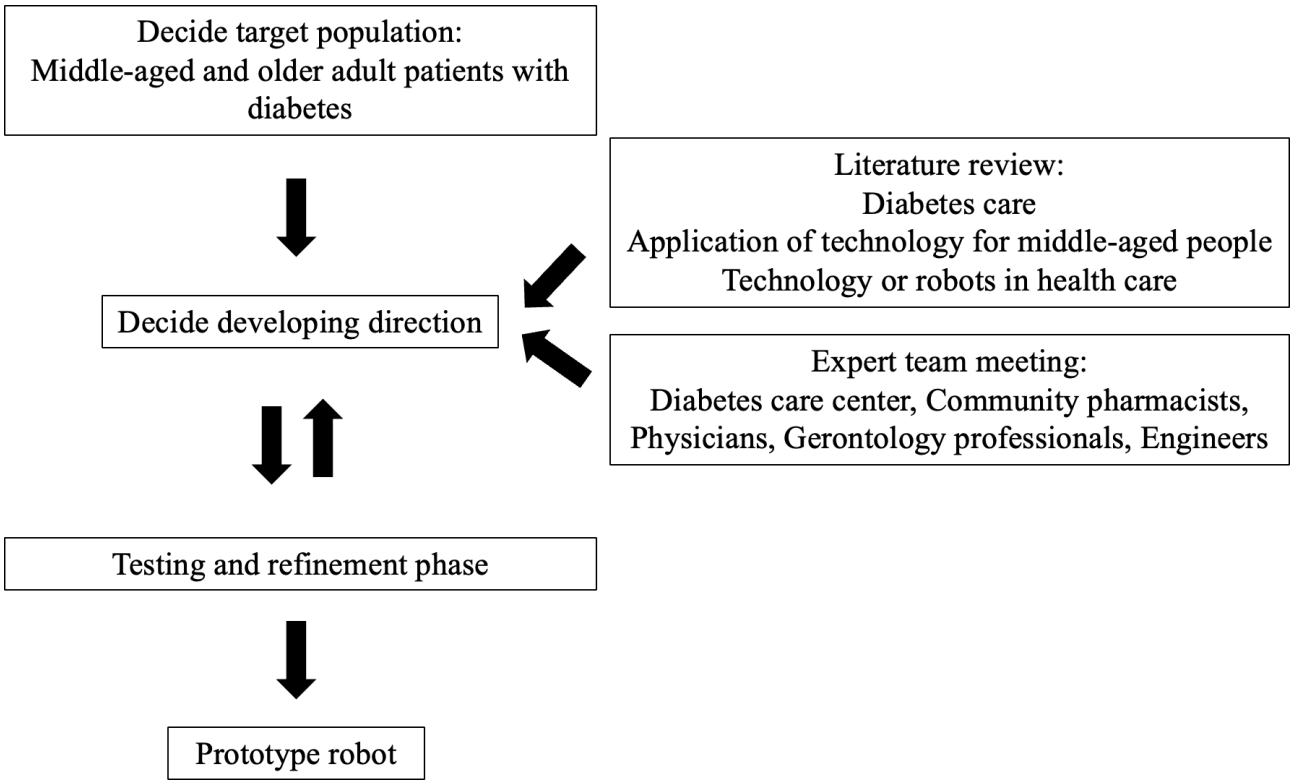
The research design framework for the prototype robot comprised three steps: using an evidence-based literature review and team meeting to design and develop the robot prototype, evaluating feasibility through collecting pre- and postassessment questionnaires, and exploring needs and acceptance through interviews with the target population, as illustrated in Figure 1.

Figure 1. The research design framework for the prototype robot used in community-based diabetes care.



Although robotics is an emerging technology, there is a lack of understanding about the applications of robotics. To gain a better understanding of user needs, a high-fidelity prototype can be used to provide users with real-world experience and stimulate their needs, thus enabling them to provide more in-depth insights for future development and design [16]. Therefore, the first part of the study was to design and build a prototype community-based diabetes care robot to facilitate user experience, as illustrated in the detailed flowchart shown in Figure 2.

Figure 2. Process showing how to build a prototype community-based diabetes care robot.



The second and third parts were dedicated to testing and evaluating the prototype robot. In the second part, it took 15 - 20 min for the patients with diabetes to interact with the robot. Before and after the interaction, questionnaires including a diabetes knowledge test, self-efficacy for diabetes, and feasibility of use of the robot were administered. In the third section, semistructured qualitative interviews were conducted with middle-aged and older adult patients with diabetes and community pharmacists about their experiences and visions for using the robots. The detailed methods and results of the pre- and postassessment questionnaires, including a diabetes knowledge test, self-efficacy for diabetes, and the feasibility of using the robot in patients with diabetes, as well as the in-depth interviews with both pharmacists and patients with diabetes, were addressed in our previously published study [17]. This prior study demonstrated that robot interaction significantly improved patients' diabetes knowledge and the perceived feasibility of its use in pharmacies. Both patients and

pharmacists gave positive feedback, with patients valuing self-directed learning, comfortable interaction, and vivid engagement, while pharmacists highlighted real-world applicability and new service potential. These findings offer foundational insights that inform the design and objectives of our current research.

Design and Construction of a Prototype Community-Based Diabetes Care Robot

As the goal of this research is to develop a prototype for a community-based diabetes care robot and to gather and understand the perspectives and needs of patients with diabetes and community health care providers, the initial team meetings decided to use an existing robot with foundational functions. This robot was optimized and gradually modified to develop interactive features relevant to diabetes care, aiming for efficiency and smooth user operation. The robot developed in this study uses Zenbo (ASUS), a smart home product from ASUS. The appearance and specifications are shown in Figure 3 and Textbox 1, respectively.

Figure 3. Appearance of the Zenbo robot.

Textbox 1. Zenbo robot specifications and functions; source: ASUS.

Specifications:

- External dimensions: 37 × 37 × 62 cm (length × width × height)
- Weight: 10 kg
- Operating system: Android
- Display screen: 10.1" LCD screen
- Language skills: Chinese
- Functions: Listening, speaking, seeing, emotional expression, playing music and videos, movement, internet connection, and learning

LCD: liquid crystal display

The concept for the prototype robot is primarily derived from research and theory, which must align with the needs of the target population, namely middle-aged and older adult patients with diabetes. Therefore, this study focused on theories and care indicators related to diabetes care [18], collected and organized the design and limitations of technology applications for middle-aged individuals [19,20], and examined the development and application of current technology or robots in health care, as well as the connection between the use of technology and health in middle-aged people and the mode for delivering health services [21], to establish the development objectives [22,23]. Three user-centered approaches were used in the design and construction of a prototype community-based diabetes care robot: (1) a review of the literature on technology use among older adults, (2) reference to the seven key diabetes self-care behaviors by the American Association of Diabetes Educators (AADE), and (3) meetings with health care providers in the community. The literature review search strategy of this study involved collecting studies related to the application of robots in the elderly population [24-27]. Field investigations and interviews were conducted at community pharmacies and diabetes health education centers to determine the design of the robot. Because patients with diabetes go to community pharmacies to take their medications, and in addition to providing pharmaceutical services, community pharmacies can also offer related information on disease care. Therefore, in addition to collecting service experiences from the community pharmacists, the choice of a community pharmacy as the testing site for the prototype is driven by the fact that these pharmacies provide a secure, private, and professionally consultative environment.

The design framework of the community-based diabetes care robot was devised to collect and compile data in four main areas: appearance, interface, content, and function. For appearance, we collected data about the appearance and size of the robot. For interface, data were collected about the color, text size, arrangement, and other screen design. For content, the system was responsible for building the information that needed to be conveyed, with the user's needs as the primary consideration. For function, we collected data about the presentation of the interactive process and information transfer.

Once the direction of development has been established, a prototype robot is initially built that can be used in practice. The development of technology does not only rely on past and proven experience, but also must be tailored to the needs of real users. Therefore, the prototypes need to interact with the users in real life and give them a real experience in accordance with the proposed development directions. It is only after this that users can give practical advice.

Results

Using a literature search and practical experience, this study focused on data collection in four main areas: appearance, interface, content, and function of robot design. The development directions and options for prototype robots are listed in Table 1.

Table . Development directions and options for prototype robots.

	Literature and theory	Interviews and team discussions	Results and design directions
Appearance	• Type: The humanoid type is less well accepted. The doll type, on the other hand, is seen as a toy for children [22]. Prototype robots should avoid being too complex or trendy. However, if the prototype lacks a humanoid feel, it will not be favored by senior citizens [23]. • Application mode: The focus of the robot varies between different appearances. Appearance will affect whether it is presented in a functional or interactive way [28,29].	• Size: The prototype robot must fit into the space of the pharmacy. • Height: It should be at a height at which middle-aged to older adults can sit and see it horizontally.	• It must be confirmed that this model is not complicated and is expected to be well-accepted because it is a non-humanoid model. However, it may be seen as a toy because of the cute non-humanoid appearance. The model does not have hands and feet to operate and therefore operates mainly in a conversational manner. It must be confirmed that the angle and height of the interaction mode (eg, the height of the table or chair on which the robot can be placed) can be adjusted.
Interface	• Colors: Blue and yellow are less recognizable [19]. Yellow and green combinations, and red and purple combinations, are prone to recognition errors [20]. • Operation: Per the Technology and Acceptance Model [30], the interface and operation must be simple because it is used by older adults. The font should be large and clear. The interface should have a maximum of four buttons. All other interfaces have two buttons for simple selection [31].	• The interface should be simple. A single screen does not need much emphasis. Text should be enlarged.	• The color scheme of the interface is highly contrasting to avoid confusion over similar color schemes. The use of blue and yellow colors is reduced and the number of buttons on the interface is 2 - 3. The content is centered, and apart from the main screen, the content is mostly presented as a single theme. The font size ranges from a minimum of 30sp to a maximum of 50sp (sp being the text unit in the Android system).
Content	• Seven key diabetes self-care behaviors by the American Association of Diabetes Educators [18]	• Applications addressing various everyday challenges and health education videos on common diseases in community pharmacies.	• The content of the system is based on the seven diabetes self-care behaviors, with games and interactive dialogues to present a variety of health education methods. To make the content more relevant to the public, common disease symptoms and complications of diabetes are presented.
Function	• Operation: Technology and Acceptance Model [30]. • Health education: Multisensory perception stimulates learning [21], with a core health education focus each time. • Technology applications: The applications of robots in health management can include disease management, monitoring of physiological data, and interactive health education [26,32,33]. The use of technology in diabetes health management focuses on recording and reminding, as well as providing information and entertainment [34-36].	• There are games, friendly greetings, and flexible interaction times.	• The health education mode is presented with sound, images, and video, avoiding a focus on the use of a single sense. The functionality of the current model will be considered and the information on functionality available in the literature will be further researched.

Appearance

Although the robot's appearance was determined based on the available resources, the chosen model features a cute, non-humanoid design to better align with the preferences of older adults and enhance user acceptance. Although the robot's height is a limiting factor, placing the robot on elevated surfaces, such as tables or chairs, can correct height-related issues, making it easier for users to operate.

Interface

As the interface is critical to the overall smoothness of the robot, the presentation of the interactive interface must meet the needs of middle-aged and older adults in terms of the ease of use of technology products and text reading as much as possible. In addition, according to the Technology and Acceptance Model [30], the perceived ease of use should be considered as a whole and should take into account the user-friendliness of the interface so that the user can experience the clearest and easiest process.

In the interface development, to make it easiest for older adults to operate, each screen will display a maximum of two main options, with options clearly framed to reduce the likelihood of users being unsure of their choices. Information and selection buttons will be centrally placed and maximized on the screen to help users quickly focus on key points. The main screen will feature simple text and image displays. To avoid causing difficulties in recognition for older users, the background will be a single color, and the overall interface will use no more than two main color tones. The main screen and option areas will predominantly use a black-on-white color scheme, with high contrast to make text easier to read.

Content

The main content of the development includes the seven key diabetes self-care behaviors according to the AADE standards. The overall main content and functions presented by the prototype robot are detailed in Table 2 and aligned with the seven AADE diabetes care indicators.

The main functions of the system are health education resources and health records. Health education resources are presented through health education quizzes, pamphlets, and videos. The health records section includes health values, discomfort, and nutrition. The concept of this record is to help patients with diabetes manage their records, including basic physiological data such as blood pressure, blood glucose, and blood lipids. The relevant data are entered and the corresponding standard values are provided. The focus of the "Discomfort" program is to understand and record the various conditions in the patients with diabetes and to compare the complications associated with diabetes with the common problems of the family. By reminding and advising patients to be more alert to their health conditions, they can gain a better understanding of their health conditions. The results are recorded for follow-up. All interactions can be fed back to the user in the form of paper or communication software messages.

Table . Functional development and presentation of prototype robots.

Theme	Subtheme	Theme content	Presented at the American Association of Diabetes Educators
Health education resources	Health education test	Questions focus on the seven major areas of diabetes care and common diabetes health problems	Healthy eating, regular exercise, blood glucose monitoring, proper medication use, problem solving, health adaptation, and risk reduction
	Health education leaflet	Share and recommend links to help filter relevant content	Healthy eating, regular exercise, blood glucose monitoring, proper medication use, problem solving, health adaptation, and risk reduction
	Health education videos	Share and recommend links to help filter relevant content	Healthy eating, regular exercise, blood glucose monitoring, proper medication use, problem solving, health adaptation, and risk reduction
Health records	Health values	Alert and record blood pressure, blood glucose and lipids, and provide standard values	Blood glucose monitoring
	Discomfort	Presented in a lifestyle format to remind patients of complications and other problems they may encounter and link them to their disease conditions	Problem solving, health adaptations, and risk reduction
	Nutrition	Ask each other about their dietary status in a simple conversation to help them develop a balanced diet	Healthy eating

Function

To establish the overall function, we should first understand the current mode of application of technology in disease and health management, including the application of health technology for older adults, diabetes management technology tools, and the application of robots in health management, and consider the current operation fluency and feasibility of using robots.

According to the current functional status of the robot, the main functions are primarily simple question-and-answer interactions with pictures and images, so the main functions are presented in a health education manner. A game was used to transfer knowledge on diabetes-related care content, and a thematic health education video was shown as feedback to the patients according to their wrong answers.

The main objective of the development of this prototype robot is to enable patients with diabetes to experience actual interaction with the robot and to understand the possible interaction patterns, in order to understand the experience and perspective of the user. During the development process, the prototype robot is adapted to meet the needs of the community and medical personnel based on the health education needs of the Diabetes Health Centre and the feasible applications of the community pharmacy. In view of the time and cost of development as well as the operation of the technology, the functions were not expanded extensively and were mainly presented in the form of a basic framework. After the patient with diabetes or community health care worker has confirmed the suitability of the directions and content, the functions will be expanded and built. To allow each participant to experience the same features, the most stable and fully developed part (ie, the health education test, a game with the robot, that focuses on diabetes-related knowledge) is used as the main axis for participant interaction. The rest of the developed functions are presented as introductions and simple demonstrations.

Discussion

Principal Findings

This study demonstrated that an evidence-based health care robot can be developed through user-centered design, facilitating the sustainable advancement of technology in the field of diabetes care. The use of technology in patient management can be beneficial to patients. However, the applications of technology that are readily available on the market are not always effective. While the current technology interventions are mostly aimed at behavioral change, they are rarely supported by therapeutic guidelines and theories [35,37], making the development process too subjective or deviating from reality. The core elements of technology development must therefore be user-centered. Thus, based on the technology being developed and designed for diabetes disease self-management, Goyal et al proposed four stages of user-centered development [38]. The first is the so-called development process, which must be evidence-based and analyze possible barriers and problems and must be culturally and environmentally appropriate. In the second stage, the feasibility of the system must be understood. The third stage involves further evaluation of effectiveness. The fourth stage requires more long-term monitoring. At the same time, as the four stages are in a continuous cycle and interact with each other, it is necessary to revise and review them repeatedly to build a technology tool that meets the needs of users [38]. Furthermore, personal health information must also be protected. While this prototype requires login, ongoing efforts should be made to enhance and ensure information security.

Comparison With Prior Work

In previous studies of diabetes care robots, the main focus has been on younger age groups of patients with type 1 diabetes [32,33,39], and less on middle-aged patients with type 2 diabetes. Even in the case of older adult care, the functional applications of robots are mainly companionship-based or focus on social functions for older adults. There should be less involvement in behavioral change, but this is also an important part of health messaging. Therefore, this study uses the seven key diabetes self-care behaviors by the AADE to consider the basics of healthy eating, regular exercise, blood glucose monitoring, and proper medication use as core health-enhancing skills, and to help patients with diabetes better understand their disease and their health. These seven self-care behaviors are interlinked with diabetes disease self-management and not only directly contribute to disease management (eg, reminders and records), but also enhance the overall quality of care for the disease by building up the correct concepts of patients with diabetes. This content is presented as a basic health education leaflet and a health education video to convey information. The health education resources are sourced from relevant health education websites and reference links from major hospitals and institutes, and can be categorized to help patients quickly search and link to relevant functions. In terms of the functions, we should first understand the current mode of application of technology in disease and health management, including the application of health technology for older adults, diabetes management technology tools, and the application of robots in health management, and consider the current operation fluency and feasibility of using robots. The robot itself has basic functions such as playing videos and documents. Based on the current functionality of the robot, the main focus of further development is on the simple interaction with pictures and images. The main function is therefore presented in the form of health education. To make the health education interaction more efficient and interesting, a health education game was used to transfer knowledge about diabetes-related care content, and at the end of one stage of the game, a health education video on the relevant topic was selected and shown as feedback based on the questions that the patient answered incorrectly, to deepen the patient's understanding of the concept.

Past studies have also supported the idea that a multimedia approach to health education can help patients understand the content of health education [40,41]. The health education model is more stimulating, as it delivers information to patients in a variety of ways, such as videos and animations, which in turn produces better health education results. This is one of the main advantages of robots for the implementation of health education [40]. The robot's rich expressions and gestures, as well as its voice-to-voice interactions, are an advantage in teaching [41]. The prototype utilized in this study is a nonhumanoid robot. While humanoid robot interactions are more human-like, their realistic appearance can often induce fear, leading to lower acceptance. In contrast, nonhumanoid robots, though cute, might be perceived more like toys, resembling a game. The advantage lies in a more engaging interaction, but the downside is that they may be seen merely as playthings, potentially overshadowing the educational information they convey.

In the delivery of health services by robots, there is a need for a thorough consideration of the technological side, the professional side, and the patient side. Therefore, in addition to the professional development in the field of technology, the initial development should also identify and create a suitable development direction from the perspective of medical professionals, and build a prototype robot. Later on, the prototype robot can be used to enable patients with diabetes to experience the interaction with the robot, and through this interaction, to gather more in-depth information on patients' thoughts and experiences on the application of technology. In the context of the rapid expansion of technology, it is important to have more detailed information on the user experience so that subsequent developers can have a clearer direction, and at the same time, have the most relevant technological tools for the core users (ie, older adult patients).

Strengths

The main advantage of the robot developed in this study is that the prototype was developed using data from professional team meetings, literature, real-world data, and experience interviews, as well as the participation of people from the relevant professional fields. This comprehensive approach ensured the prototype is robust. In addition, the development of the prototype robot was not a one-off exercise. The aim was to create a prototype that would enable actual interaction with patients with diabetes, not just from the developer's perspective. Each time further progress is made, it will be compared and revised with clinical practitioners to create a more realistic diabetes care robot that can actually interact with patients with diabetes in the real world.

Limitations

The literature reviewed in this study primarily comes from Western countries, which may not fully correspond to the disease characteristics of East Asian populations. Differences in illness, age, and cultural backgrounds may affect users' perspectives. To mitigate this limitation, future studies could be conducted in Western countries to validate the findings and evaluate their applicability in different contexts. In addition, the testing site for this study was a community pharmacy in an urban area, so it does not provide insights into how elderly individuals with different lifestyles or from different regions perceive and use the robot. Consequently, the findings may not be fully applicable to all health care settings. Future research could extend to rural community pharmacies or other community health care settings, including community hospitals, clinics, and chain pharmacies, to test the application of health care robots. Moreover, the size and functionality of the robots used in this study, along with the critical role of the internet in their operation, may limit their capabilities. For example, uninterrupted and smooth conversations rely on a stable network connection. Interruptions or network issues can hinder the robot's performance. Efforts were made to ensure a stable network environment during testing, but future studies should consider testing in various network conditions to better understand the impact of connectivity on robot functionality.

Conclusion

The prototype diabetes care robot was developed using data from the literature, professional team meetings, and practical interviews, with the aim of creating a more evidence-based health care robot that can actually give patients with diabetes a realistic experience for their disease care and enable them to give clearer and more specific feedback for the subsequent development and application of technology in disease care.

Acknowledgments

This work was supported by a grant from the Taiwan Ministry of Science and Technology (MOST 108-2634-F-006 -006-). The Taiwan Ministry of Science and Technology had no role in the design of the study, data collection, data analysis, data interpretation, or writing of the report.

Abstract

Background: Dementia is a widespread syndrome that currently affects more than 55 million people worldwide. Digital screening instruments are one way to increase diagnosis rates. Developing an app for older adults presents several challenges, both technical and social. In order to make the app user-friendly, feedback from potential future end users is crucial during this development process.

Objective: This study aimed to establish a user-centered design process for the development of digiDEM-SCREEN, a user-friendly app to support early identification of persons with slight symptoms of dementia.

Methods: This research used qualitative and quantitative methods and involved 3 key stakeholder groups: the digiDEM research team, the software development team, and the target user group (older adults ≥65 years with and without cognitive impairments). The development of the screening app was based on an already existing and scientifically analyzed screening test (Self-Administered Tasks Uncovering Risk of Neurodegeneration; SATURN). An initial prototype was developed based on the recommendations for mobile health apps and the teams' experiences. The prototype was tested in several iterations by various end users and continuously improved. The app's usability was evaluated using the System Usability Scale (SUS), and verbal feedback by the end users was obtained using the think-aloud method.

Results: The translation process during test development took linguistic and cultural aspects into account. The texts were also adapted to the German-speaking context. Additional instructions were developed and supplemented. The test was administered using different randomization options to minimize learning effects. digiDEM-SCREEN was developed as a tablet and smartphone app. In the first focus group discussion, the developers identified and corrected the most significant criticism in the next version. Based on the iterative improvement process, only minor issues needed to be addressed after the final focus group discussion. The SUS score increased with each version (score of 72.5 for V1 vs 82.4 for V2), while the verbal feedback from end users also improved.

Conclusions: The development of digiDEM-SCREEN serves as an excellent example of the importance of involving experts and potential end users in the design and development process of health apps. Close collaboration with end users leads to products that not only meet current standards but also address the actual needs and expectations of users. This is also a crucial step toward promoting broader adoption of such digital tools. This research highlights the significance of a user-centered design approach, allowing content, text, and design to be optimally tailored to the needs of the target audience. From these findings, it can be concluded that future projects in the field of health apps would also benefit from a similar approach.

Introduction

Dementia is a widespread syndrome that currently affects over 55 million people worldwide, with annually almost 10 million new cases. The diagnosis of and treatment for people with dementia are going to be among the biggest challenges for health care systems worldwide [1]. A study by Eichler et al [2] found that 60% of people living with dementia in Germany had no formal diagnosis. Another problem lies in the long diagnostic periods. In the Bavarian Dementia Survey (BayDem) study, Wolff et al [3] found that the median time between the first perceived symptoms and diagnosis in Bavaria was 16 months. As Barth et al [4] were able to show, rural areas are also particularly affected here due to a high difficulty in accessing the facilities needed to diagnose and treat patients with dementia.

Screening instruments are one way of improving the diagnosis rate. A study with 146 participants has shown that diagnoses could be increased by almost 50% through upstream cognitive screening [2]. Internet-based screening tools offer the additional advantage that they can be used at a low threshold, regardless of time and place [5]. Digital technologies and the internet are already playing an increasingly central role in the everyday lives of older people. The proportion of people with internet access is growing across all age groups. In recent years, the number of German senior citizens (79 - 84 years) who regularly use the internet has more than doubled (18.8% in 2011 vs 39.4% in 2017). There is also an increased interest in health websites among older people [6]. In the 2021 report published by the German Federal Office for Information Security, it was stated that around 163,000 different health apps existed [7]. However, there is a lack of high-quality dementia apps. As analyzed in an earlier study, for only 6 of 20 identified dementia apps, scientific evaluation studies have been published. In none of those studies, the effectiveness of the respective screening app could be proven. Among the published app evaluations, screening apps received the worst overall quality rating. In summary, the analysis showed that the existing apps at this time did not provide reliable information and results [8].

Thus, in the digiDEM Bayern project (Digital Dementia Registry Bavaria), we have not only focused on the establishment of a digital registry for persons with mild cognitive impairment and mild to moderate dementia [9,10], but also on the development, scientific evaluation, and sustained provisioning of innovative eHealth tools and digital apps [11,12]. The goal of our current project, in this context, was to establish a user-centered design process for the development of digiDEM-SCREEN, a user-friendly app to support the early identification of persons with slight symptoms of dementia. The objective of this publication is to illustrate the iterative and agile user-centered development process consisting of 8 phases to move from a conceptual idea to an early prototype and a final prototypical implementation with continual involvement and feedback process from stakeholders and intended future users.

Methods

Overview

In order to achieve the goal of a user-friendly screening app for people with slight dementia symptoms, a user-centered iterative development approach comprising the following steps was chosen:

1. A systematic literature research of scientifically evaluated digital and nondigital dementia screening tests.
2. An early prototype (V1) development based on the guidelines for graphic design and textual formulation criteria for people with cognitive impairments. Graphical requirements include an easy-to-understand layout, standardized navigation elements, and a clear division of instructions into several steps [13]. In addition, textual guidelines such as short and concise sentences, logically structured sections with headings and an active approach to the user should be observed [14]. Furthermore, the expertise of 3 clinicians from different disciplines with long-term experience in dementia research and 2 professors of medical informatics with expertise in developing mobile health apps, supported by their teams was incorporated into the development.
3. Conduction of an initial evaluation of the early prototype (V1) based on a focus group discussion (FGD) with potential end users (older adults ≥65 years with and without subjective cognitive impairments) [15]. The group discussion was recorded and transcribed afterward. The results were then categorized and analyzed based on a previously published qualitative content analysis [16]. The following categories were extracted: general linguistic adaptations, task-related linguistic adaptations, menu navigation, general navigation, and specific design changes to individual components.

1. Incorporating the FGD feedback and results into the specification for the prototypical implementation of digiDEM-SCREEN (V2).
2. The second evaluation with a new group of potential users (older adults ≥65 years with and without subjective cognitive impairments) was based on the think-aloud method, where participants speak their thoughts and wishes aloud during the test and are observed by a researcher who also takes notes [17].
3. Incorporating the user feedback and think-aloud evaluation results into the enhanced specification for the subsequent digiDEM-SCREEN development step (V3).
4. Conduction of an additional focus group evaluation of the improved beta version of the app (V3) with people with migration background (nonnative German speakers).
5. Development and deployment of the first ready-to-use digiDEM-SCREEN version (V4).

Recruitment of the facilities for participation (steps 4, 5, and 7) was based upon the network of research partners in the project

digiDEM. The older adults from the facilities were informed about participation options in former group meetings (informed consent). After consenting, participants were invited to take part in the respective focus groups.

In steps 3 and 5, the System Usability Scale (SUS) has been calculated for the respective prototype versions by applying the German version of the standardized SUS questionnaire [18]. The scale can take values between 0 and 100; the higher the value, the higher the user-friendliness is categorized [19]. In addition, also in step 7, a self-assessment was used to determine technology use, interest, and expertise, each on a 5-point Likert scale (1 - 'Does not apply at all'; 5 - 'Applies completely'). The participants gave their subjective assessment and considered if they could use the app on their own (on a scale of 1 to 10) of the app and the specific components [20]. Furthermore, the participants were asked to name the most considerable problems associated with the app and if they wanted to change something.

Thus, our user-centered software design and development process included qualitative and quantitative evaluation methods at 3 different stages of the development process.

Ethical Considerations

This study was approved by the Ethics Committee of the Medical Faculty of the Friedrich-Alexander Universität Erlangen-Nürnberg (application number: 20-253_1-B; August 14, 2023). Written consent was obtained prior to the user testing and focus group discussion. All participants data were pseudonymized. The list of reidentifying data was stored separately from the analyzed data, and only authorized individuals have access to them. No one was paid to test the app.

Results

Steps 1 and 2: Development of the First Prototype (V1)

Prior to developing the screening test, we conducted systematic literature research. The search terms are shown in Multimedia Appendix 1. Criteria for the decision on a suitable screening tool were the scientifically examined psychometric properties (sensitivity and specificity), the availability of being a free to use app (not paid), and the technical feasibility of a tablet/smartphone. The main source of information was the systematic reviews of Chan et al [21] as well as the specific studies of the screening tools [22,23]. The decision on the Self-Administered Tasks Uncovering Risk of Neurodegeneration (SATURN) was based upon a group discussion about the aforementioned criteria as well as the (methodological) quality of the screening tools and the underlying scientific studies in general.

The SATURN [24] proved to be a test with particular promising diagnostic values (sensitivity: 0.92; specificity: 0.88 in dementia cases vs controls) [21]. The test is usable via a tablet. Administration time is about 10 minutes, which can be especially beneficial for older adults as shorter tests might induce less fatigue and therefore be more suitable for repeat administration compared with lengthier instruments [25]. Thus, the SATURN provides the foundation for the development and validation of a German adaption of the test usable as an app via smartphone and tablet.

To date, there is no German version of the SATURN test. The translation of the English version of the SATURN into German was carried out independently by 2 research assistants from the digiDEM Bayern project (MZ and ND) using the translate-retranslate method. Apart from some general adaptations, such as the correct assignment of the users' residence, linguistic aspects were also taken into account, and the texts were adapted to the German-speaking context. In some translations, the number of letters in the word increased noticeably (eg, farm - Bauernhof). A shorter related word (field - Feld) was then used in these places. Additional instructions were developed. The test adaptations aimed to ensure that both the implementation and the evaluation could be carried out entirely by the user or the system alone. At the start of the original SATURN test, the participant was asked to read aloud the task (close your eyes) and perform it [24]. Without a handler to check the action, there could be no subsequent evaluation (What phrase did you first read from this tablet?). Therefore, the researcher chose an alternative task (tap on the yellow circle) that also involved reading and performing an action.

The final screening test consists of tasks from 6 different cognitive domains: Comprehension, Visuospatial, Orientation, Memory, Calculation, and Executive Function. Points are awarded for each task, which adds up to a maximum score of 30. The tasks must be completed without the help of other people. Participants may use their visual aids to complete the tasks; all other aids (eg, paper and pencil) are not permitted. A detailed description and illustrations of the individual test tasks can be found in Multimedia Appendix 1.

Another innovation is that the authors are developing the app as a tablet and a smartphone version. Due to the smaller display sizes, new components like the word selection task shown in Figure 1 had to be created. The researcher also developed some new logic to prevent larger adjustments, for example, that the user is only allowed to undo the last connection at the last task (tap on the circle with a blue background; Figure 2).

The following table (Table 1) shows the baseline characteristics of the participants in the usability analysis. This is followed by a description of the details of the individual events.

Figure 1. Word selection task as visible on a smartphone.

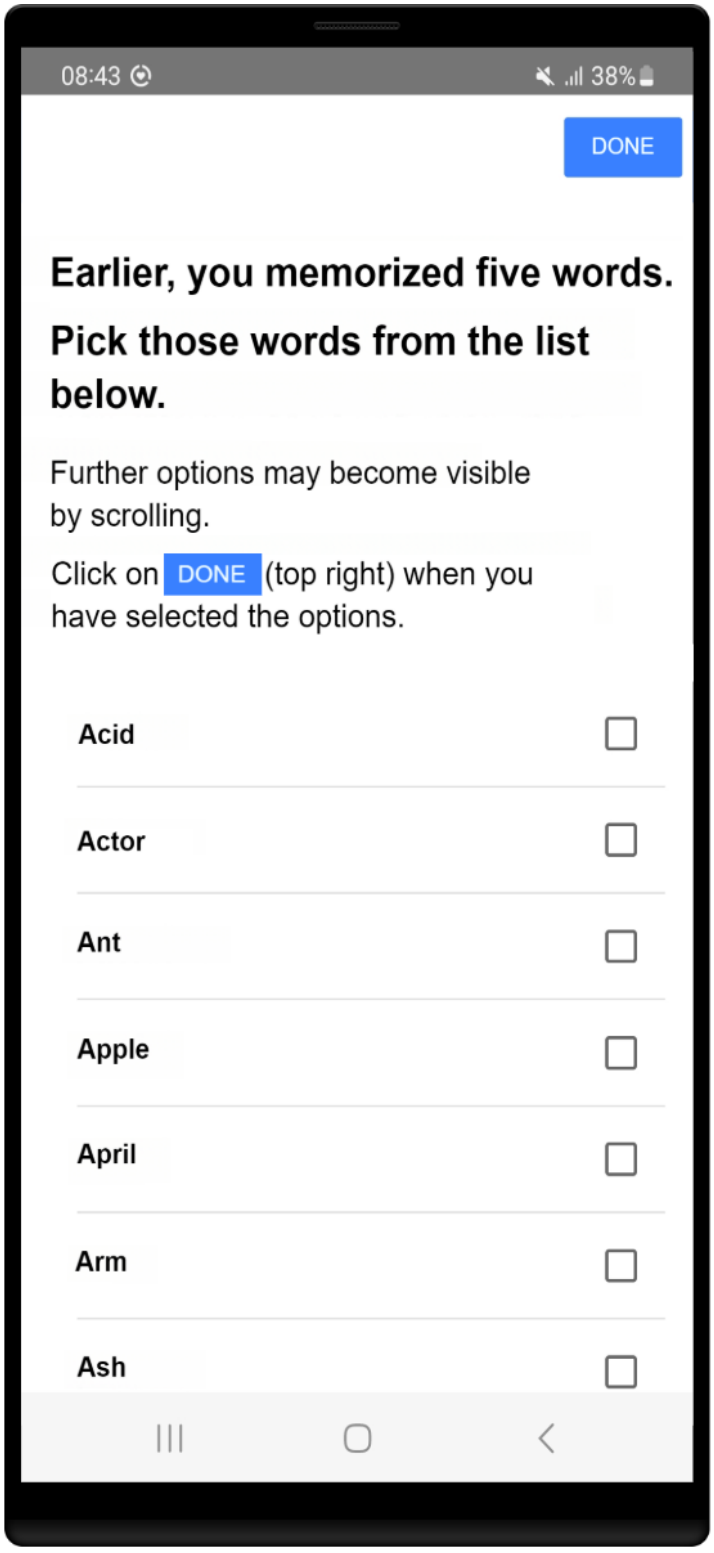

Figure 2. Trail Making Test as visible on a tablet.

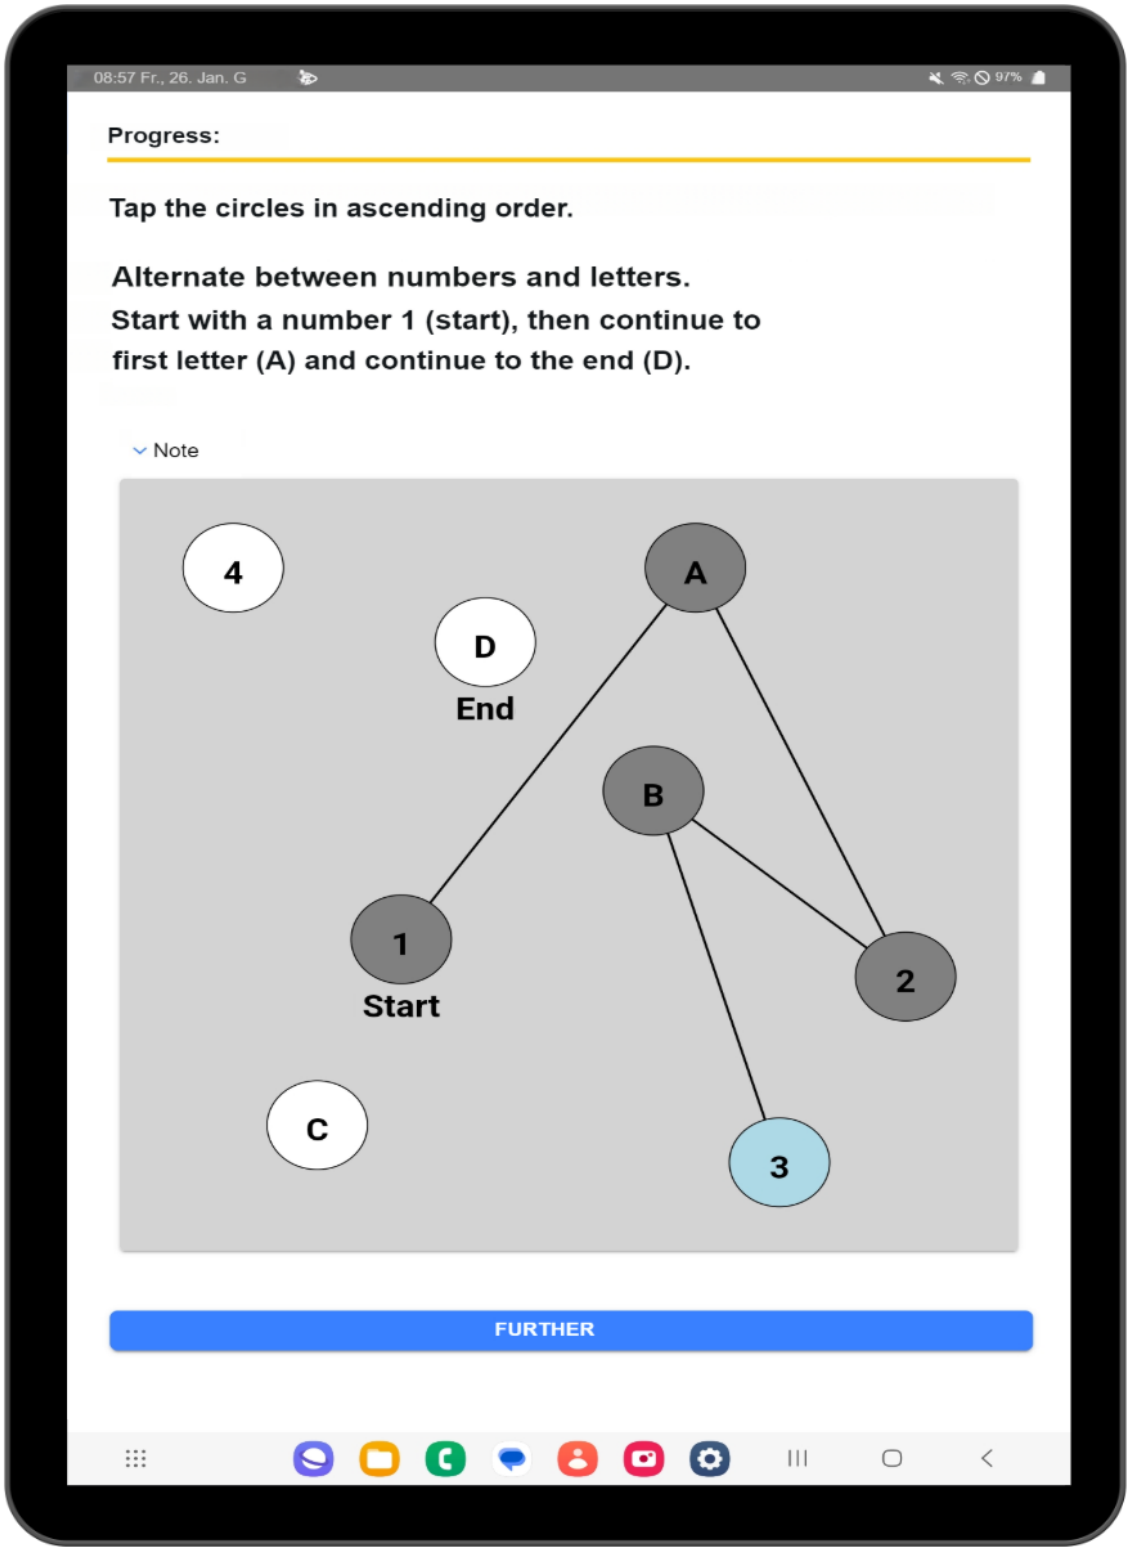

Table . Baseline characteristics.

Study sample characteristics	FGD[a] 1 (Prototype V1)	Usability test (Prototype V2)	FGD 2 (Prototype V3)
Study population	13	21	7
Age (years), mean (range)	75.8 (66-84)	70.2 (65-80)	60.8 (53-69)
Sex, n (%)			
Male	1 (7.7)	8 (38.1)	0 (0.0)
Female	12 (92.3)	13 (61.9)	7 (100.0)
Education, n (%)			
Low	4 (30.8)	0 (0.0)	1 (14.3)
Medium	5 (38.4)	10 (47.6)	1 (14.3)
High	4 (30.8)	11 (52.4)	5 (71.4)
Self-perceived cognitive impairment, n (%)	5 (38.4)	5 (23.8)	0 (0.0)
Nonnative German speaker, n (%)	0 (0.0)	2 (9.5)	7 (100.0)
SUS[b] (0 - 100), mean (SD)	72.5 (1.6)	82.4 (16.1)	—[c]
App rating (1-10), mean (SD)	7.3 (2.1)	8.7 (1.5)	8.7 (1.2)
Independent app use (1-10), mean (SD)	7.5 (2.9)	8.95 (1.3)	8.5 (1.0)

[a]FGD: focus group discussion.

[b]SUS: System Usability Scale.

[c]Not applicable.

In both the first 2 focus groups, the SUS score was slightly lower in people with subjective cognitive impairment (FGD1: healthy older adults=74.4; people with subjective cognitive impairment=69.5; FGD2: healthy older adults=83.5; people with subjective cognitive impairment=82).

The SUS score decreased with advanced age (FDG1: ≥80 years old=63.8, 79 - 70 years old=73.9, ≤70 years old=85.0; FDG2:≥80 years old=75.0, 79 - 70 years old=77.5, ≤70 years old=85.0). People with a medium-level education had the best scores on the SUS (FDG1=85.0; FDG2=83.3), followed by people with a high-level education (FDG1=73.8; FDG2=83.0) and people with a low-level education (FDG1=55.6).

Steps 3 and 4: Focus Group Discussion V1

The first FGD took place as part of a memory training group. A memory training group is a frequent meeting of older adults, in which those adults perform different memory training exercises under the supervision of a group leader. Frequent excursions are also part of this service. The service is offered by a nonprofit organization (German: Wohlfahrtsverband) and is led by a research associate in the project digiDEM. The group consisted of a total of 13 participants. Their baseline characteristics are shown in Table 1. On average, they used modern technologies frequently (3.39) and showed an average interest in technological innovations (3.00). Their self-assessment of their competence in using modern technology was moderate (2.39), but the fear of failure played only a moderately important role (2.69).

Due to the large number of participants, 3 small groups were formed for the test. Participants were able to extensively test the app prototype and contact a research assistant with any questions. The individual components of the prototype achieved a subjective app rating of 7.3 (out of 10) points and an SUS score of 72.5. Participants also generally felt able (7.5 out of 10) to use the app independently without outside help. Subsequent group discussion of the results took place again in a large group.

The 2 most significant areas of improvement were observed in all the 3 small groups. Many participants recognized the letter I as T due to the inverted commas (‘I’) and had problems answering this task correctly. Participants also did not always recognize the selected word, as only the radio button on the right-hand side of the prototype showed their selection. The app prototype (V1) is shown in Figure 3. Participants therefore specifically requested that the entire line be colored when a selection was made. The 2 adjustments are shown in Figure 4.

Figure 3. Illustration of the prototype (**V1**).

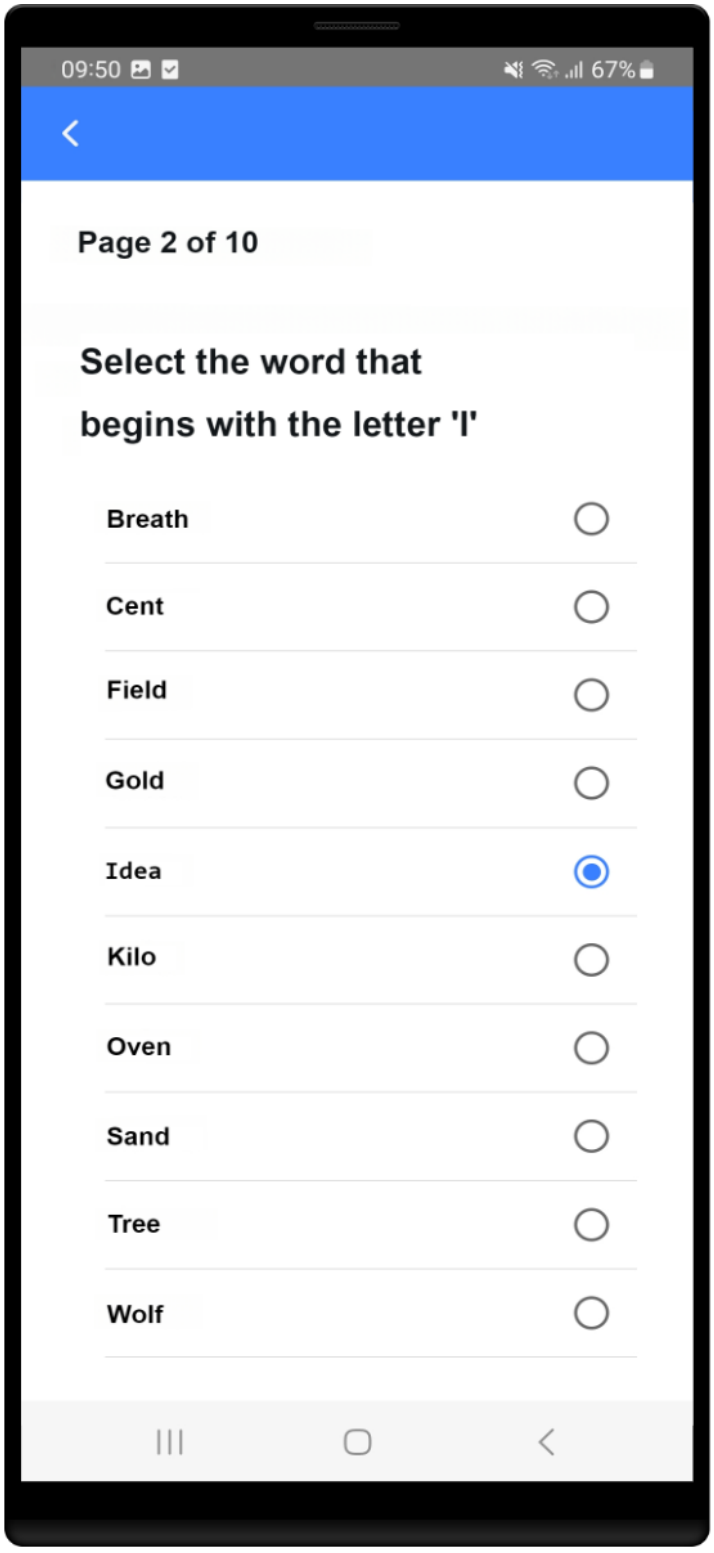

Figure 4. Final visualization (**V4**).

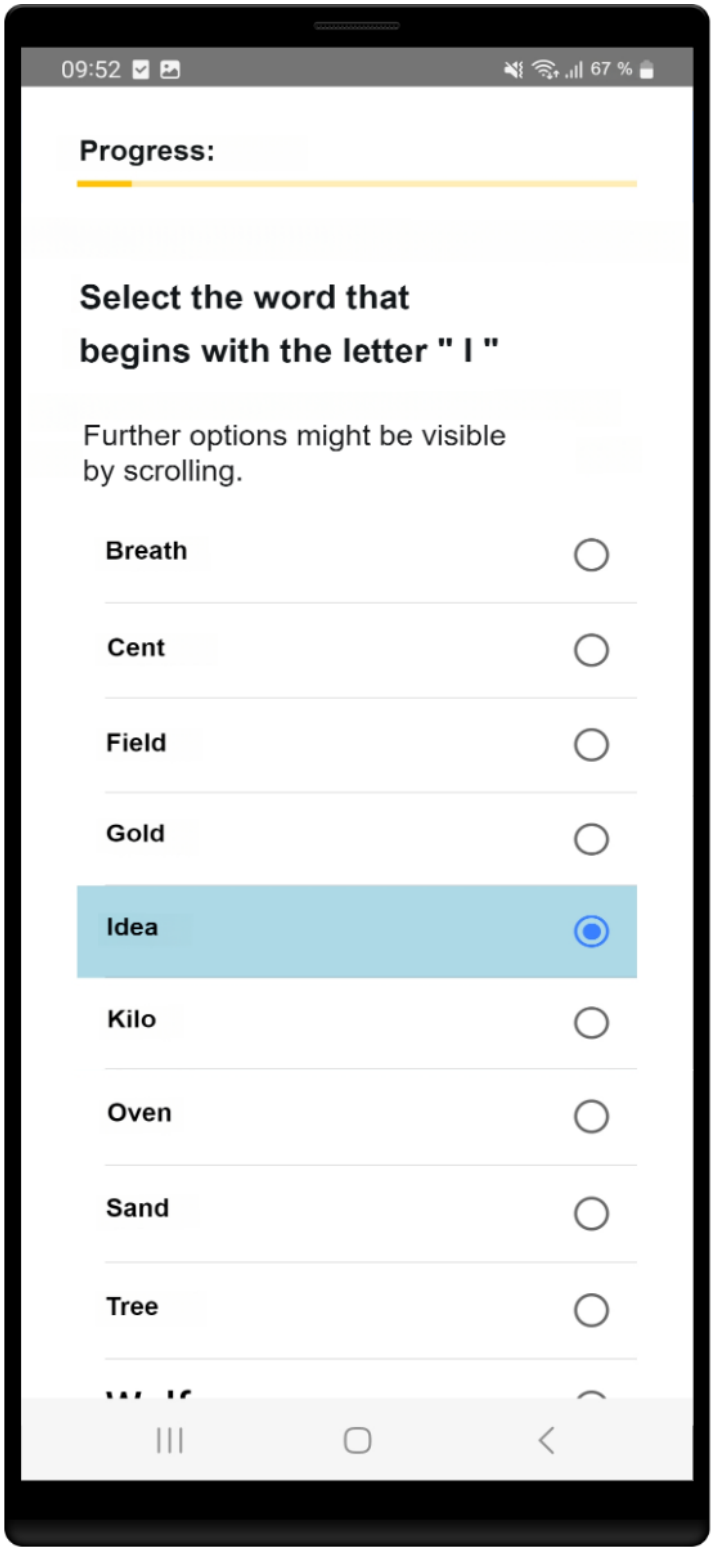

In addition, minor inconsistencies were noticed in this test, such as the fact that sometimes “Next” and sometimes “Done” were used to move on to the next task. The participants also wanted the selected images to be marked more clearly and the contrast and color intensity to be adjusted so that the colors could be recognized more clearly. One participant commented that she liked the “simple design” and that it did not distract from the actual content. Another participant mentioned that the instructions were too complex (“They were good instructions that you could actually understand. But I really had to read very carefully”). Therefore, the descriptive text has been simplified. Feedback on the user-friendliness of the FGD was predominantly positive. One participant particularly liked the fact that she could use the app without having much prior knowledge. The general consensus was that the app was easier to use on a tablet than on a smartphone due to the larger screen size. However, the smartphone version was also rated as usable by participants. These points mentioned were discussed with

the developers and incorporated into the second prototype accordingly.

Steps 5 and 6: Think-Aloud Usability Evaluation (V2)

A total of 21 older adults, who were randomly selected from participants in a dementia prevention event for older adults (≥65 years), participated in this usability test. Their baseline characteristics are shown in Table 1. They most frequently use modern technology (4) and are interested in technical innovations (3.62). They rated their competence in modern technology as average (3.33), while the fear of failure did not play a significant role (2.48).

The quantitative key figures collected increased compared with the first version. This prototype achieved a subjective app rating of 8.7 (out of 10) points and an SUS score of 82.4. The participants' assessment of using the app independently, without external help, also increased significantly (8.95 out of 10).

Based on the researchers' observations and the participants' statements minor adjustments and precisions, such as allowing €67 and €67.00 as the correct answer in the calculating task, were made. Some users also commented negatively about the last task's descriptive text. Due to the length and complexity of the content, the question was often not solved or only solved with a hint from the research assistant. Based on this feedback, the language of the text was revised again.

Step 7: Focus Group Discussion With Nonnative Speaker (V3)

The last user test took place under the aspect of accessible language and comprehensibility. To this end, an FGD was conducted with people with a migration background. Seven older adults took part in this FGD. Their baseline characteristics are shown in Table 1. They came from 4 different countries (Iraq, Kuwait, Sri Lanka, and Syria) and were all nonnative German speakers. They most frequently use modern technology (3.86) and are interested in technical innovations (3.57). They rated their competence in modern technology as average (3.14), while fear of failure played a minor role (2.58).

The quantitative indicators collected were similar to those of the German-speaking users. This prototype achieved a subjective app rating of 8.7 (out of 10) points. These participants also rated the success of using the app independently, without external help, at 8.5 (out of 10). Unfortunately, no SUS score could be obtained from this group due to the language barrier.

Two relevant changes emerged from the group discussion. First, a note on scrolling (Figure 4) was added in the appropriate places, and second, the language was adapted. A total of 5 of the 7 participants answered one of the initial questions (Select the fruit from the list.) incorrectly. The participants confused 2 words "Kirsche (cherry)" and "Kirche (church)," which are very similar in German. As this error does not indicate a possible cognitive decline, the word "Kirche (church)" was changed to "Kapelle (chapel)."

Step 8: Development and Deployment of the First Ready-to-Use digiDEM-SCREEN Version (V4)

In this step, the digiDEM-SCREEN test was finalized as a screening app for recording the current cognitive status of users. A validation study is currently underway. The test will be administered to patients in outpatient memory clinics and its sensitivity and specificity will be evaluated in the context of existing diagnoses and other nondigital cognitive tests. As part of the validation, cut-off values for categorizing current cognitive ability will also be determined as part of the validation. Depending on the test result, the user is given a short recommendation and options for action. If the result is above the threshold value calculated in the validation study, the screening does not indicate memory impairment. It is recommended that the test be repeated at regular intervals to monitor changes in memory performance. If the final result is below the threshold, further neuropsychological assessment in a memory outpatient clinic is recommended.

A study is currently underway to determine the sensitivity and specificity of the developed screening test (V4) and its correlation with the Montreal Cognitive Assessment [26]. For increased transparency, the research group has registered the project in the German Clinical Trials Register (DRKS) (registration number: DRKS00033764). After validation, the test will be available free of charge to anyone interested. Different randomization options have been used to minimize the learning effect. There are 5 versions of the test, which differ in the order of the numbers to be memorized. In addition, the position of each answer option is randomized for each test session. There are also plans to offer the screening test in different languages in the future. The possibility of multilingualism has already been taken into account in the programming of the app. This will be easy to implement once further translations have been validated.

Discussion

Principal Findings

There is a lack of evidence in the field of freely accessible apps for people with dementia, especially screening apps. A study published in 2023 showed that there are not any scientific studies to prove the effectiveness of any of the German-speaking screening apps [8].

A user-friendly app should have 3 main characteristics: typography appropriate for the target group (eg, recognizable icons), intuitive operation, such as fewer clicks to the desired action, and simplicity (eg, simple navigation) [27]. Three key stakeholder groups were involved in developing the digiDEM-SCREEN app: the digiDEM research team, the software development team, and the target user group (older adults ≥65 years with and without subjective cognitive impairments). Developing an app for older adults presents several challenges, both technical and social. Older adults may have less technology experience and difficulty understanding complex user interfaces [28]. Many older adults also have age-related limitations, such as visual or hearing impairments [29]. Cognitive abilities can decline with age, making complex

apps more difficult to use. The app should be tailored to the cognitive needs of older users, for example, by providing clear instructions and simple interactions. Considering these challenges when developing an app for older adults can help to create a user-friendly and accessible application that improves the lives of older people and promotes their independence [27]. In order to make the app as user-friendly as possible, feedback from potential future end users is essential. A critical examination of the study population shows that the participant structure is dominated by women in terms of gender. This could lead to a distortion of the results, as the findings may not be transferable to the entire target group. However, an empirical comparison of the usability of a mail app between male and female users showed that there are no statistically significant differences in the performance criteria of efficiency, effectiveness, and satisfaction between the 2 groups [30]. Another study examined whether there were systematic differences between women and men in the evaluation of the user experience of 3 websites and showed that there were no significant differences between the genders. Personal attitudes and preferences have a greater influence on the results [31].

The activities summarized under the term “patient and public involvement” enable patients to be actively involved in the planning and development of new products. International associations such as Alzheimer Europe as well as scientists are very interested in encouraging the active involvement of people with dementia in research for brainstorming and counseling [32].

Digital health apps often struggle with low adherence. One possible reason for this is users’ personal frustration with the content of the intervention, the way it is presented, and the nonintuitive handling [33]. The selected user-centered design could sustainably increase adherence. Users have unique knowledge, perspectives, and experiences that can influence a product’s quality, appropriateness, and user-friendliness. User testing is an essential part of the iterative development process and contributes to increasing the quality and success of the app [34]. Prototypes make it possible to recognize potential problems or weaknesses in user interaction or design at an early stage. By discovering these problems at an early stage, expensive changes or new developments in later phases of development can be avoided [35]. Thus, using the prototype design in the first workshop provided the team with a cost-effective way to get feedback and evaluate the idea. In the user tests, the tablet prototype of the app performed better than the smartphone version. The participants mainly criticized the smaller font and display size, which made it somewhat difficult to enter answers in some places. Despite these criticisms, the smartphone version was still rated as user-friendly. Smartphones are the most common mobile devices. A study by Weber et al [36] from 2020 found that an average of 41.4% of 71.6-year-old participants used their own smartphone. Due to the high availability of smartphones among seniors, the research team decided to stick with both versions. The mobile app also works offline, so no internet connection is necessary. Those decisions made it possible to reach a larger number of potential users. During the test phases, the participants did not use their devices, which they were familiar with in everyday life, but devices provided by the research team. For example, the display size, operating system (or at least the version), and individual settings may differ from their device. It is expected that user-friendliness will be even higher when users utilize their own smartphone or tablet.

The workshop participants were positive about the experience and gave constructive comments on the app. In addition, the SUS score also increased with each iteration of the app version. Bangor et al [37] described that products with a SUS score of 90 points and above were rated as exceptional, products with a SUS score of 80 points were rated as good, and products with a SUS score of 70 points were rated as acceptable. Anything below 70 points had usability issues that were a cause for concern. That means all SUS assessments are above the average and at least rated as acceptable. The prototype V1 gained a SUS score of 72.5 from the participants of the FGD. The rating of the second app version was notably better (SUS score: 82.4) and, therefore, rated as good. Due to some comprehension difficulties, unfortunately, no SUS score could be raised in the second FGD. Whenever questionnaires are used directly with people with dementia, the questions should be short and understandable (no technical terms), and double negatives should be avoided [27].

The results of the user evaluations showed that a user-friendly screening test for people with subjective cognitive impairments could be developed for the German-speaking population.

The main focus of the focus groups was on minimizing potential sources of error. Nevertheless, there is still a residual risk that the test cannot be carried out properly. If the first 3 simple test tasks are not answered correctly, an end screen appears with the message that the test cannot be carried out due to technical or language barriers. In this case, the user is advised to visit a specialized clinician. In the general instructions before the start of the test, participants are also informed that for example visual aids should be used.

Strengths

Different potential end users were included in the development process of the digital screening test as an app in order to improve usability and avoid technical or linguistic barriers. Moreover, additional languages and other extensions like a dementia prevention module can be added to the app.

Limitations

There was no random sampling of participants. Furthermore, although the SUS scale is the most frequently used scale to assess the user-friendliness of IT applications, it also has its weaknesses. The results of a systematic review show that some studies found that the double-negative questions from the SUS are challenging to understand for people with dementia [27]. With this knowledge in mind, we used simple language and no double negatives for the remaining questions we phrased. In the first FGD, the researchers had to explain individual questions to the group, and no SUS score could be collected in the last FGD. Most of the participants needed help understanding the questions. They were, therefore, unable to give reliable answers.

Conclusions

The development of digiDEM-SCREEN serves as an excellent example of the importance of involving experts and potential end users in the design and development process of health apps. From the initial stages of the project, experts were engaged in the content and design realization, providing a solid foundation for further development. The intensive testing phase, in which various end users tried out the app prototype in several iterations, clearly demonstrated the value of early and continuous feedback for improving the final product. This research highlights the significance of a user-centered design approach, allowing content, text, and design to be optimally tailored to the needs of the target audience. From these findings, it can be concluded that future projects in the field of health apps would also benefit from a similar approach. Research teams and app developers should integrate user-centered design practices into their development processes to ensure that the applications they create are not only functional but also user-friendly and appealing to the target audience. Such an approach could significantly enhance the acceptance and effectiveness of health apps, thereby making a valuable contribution to digital health care. A close collaboration with end users leads to products that not only meet current standards but also address the actual needs and expectations of users. This is a crucial step toward improving health technology and promoting broader adoption of such digital tools.

Acknowledgments

The present work was performed by MZ in partial fulfillment of the requirements for the degree “Dr. rer. biol. hum.” at the Faculty of Medicine of the Friedrich-Alexander-Universität Erlangen-Nürnberg. The project is funded by the Bavarian State Ministry of Health, Care and Prevention (funding code: G42d-G8300-2017/1606-83).

Authors' Contributions

MZ, ND, RP, PH, PKR, and HUP contributed to the conceptualization of the study. MZ and ND conducted the investigation, while MZ, ND, and HUP developed the methodology. Project administration was managed by RP, PH, EG, PKR, and HUP. The app programming was carried out by FH, JH, KK, and RP. Supervision was provided by MZ, ND, PKR, and HUP. MZ was responsible for writing the original draft, and MZ, NDI, EG, KK, and HUP contributed to the review and editing of the manuscript.

Conflicts of Interest

RP is a partner in Lenox UG, a company focused on applying scientific findings in digital health applications. Lenox UG holds shares in HealthStudyClub GmbH. This company is responsible for developing the app presented in the paper. RP received consultancy fees, reimbursements for conference attendance, and travel expenses in connection with the topics of mobile health and e-mental health. KK is also a shareholder in HealthStudyClub GmbH and has joined the company as chief technical developer. FH and JH work as freelancers for HealthStudyClub GmbH.

Abstract

Background: Muscle fatigue, characterized by reduced force generation during repetitive contractions, impacts older adults doing daily activities and athletes during sports activities. While various sensors detect muscle fatigue via muscle activity, biochemical markers, and kinematic parameters, a real-time wearable solution with high usability remains limited. Plantar pressure monitoring detects muscle fatigue through foot loading changes, seamlessly integrating into footwear to improve the usability and compliance for home-based monitoring.

Objective: This study aimed to investigate the effects of muscle fatigue on plantar pressure measurements using a self-developed wearable plantar pressure system.

Methods: Twelve healthy participants completed a 5-minute calf muscle fatigue protocol. The plantar pressures and surface electromyography (sEMG) activity of the gastrocnemius muscles were recorded before and after exercise. The plantar pressures at 6 regions and the median frequency (MDF) of sEMG were analyzed to quantify fatigue.

Results: The self-developed foot pressure system showed a significant decrease in plantar pressure peak values at the heel of the left (P=.003) and right feet (P=.001) and at the lateral toe of the left (P=.001) and right feet (P=.026). A significant increase was observed at the metatarsal head of both the left foot (P=.001) and the right foot (P=.017). The MDF of sEMG signals significantly decreased in the left (P=.001) and right gastrocnemius (P<.001).

Conclusions: Plantar pressure changes and sEMG signals effectively detect gastrocnemius muscle fatigue using the proposed wearable system, supporting the development of a wearable solution for detecting muscle fatigue suitable for home-use.

KEYWORDS

muscle fatigue; plantar pressure sensors; wearable devices; home-based monitoring

Introduction

Muscle fatigue, characterized by the reduced ability to generate adequate force during repetitive contractions [1], affects performance across different groups and activities including daily activities of older adults as well as athletes during sports. Muscle fatigue disrupts the neuromuscular system and affects different aspects such as muscle strength, force production, and movement patterns, resulting in stiffness of the muscles and joints, impaired motor control, and poor balance [2], thereby increasing the risk of injuries. For instance, in badminton players, muscle fatigue impairs neuromuscular coordination, by reducing input from the foot sole receptors, and muscle force production, leading to weaker responses and decreased reaching distance performance [3]. Running-induced fatigue reduces lower limb muscle activity, decreases shock absorption capacity, and alters plantar pressure distribution [4], thus increasing the risk of running-related injuries such as stress fractures in the foot [5]. Mello et al highlighted how fatigue delays the gastrocnemius muscle's activation by 1 second relative to the center of pressure, thus impairing balance [6]. Furthermore, Morrison et al found that muscle fatigue in older adults (aged 60 - 79 years) significantly increased reaction times, postural sway, and fall risk compared to younger individuals (aged 30 - 59 years) [7].

Muscle fatigue can be detected through various methods, including blood lactate concentration [8], electromyography (EMG) [9], mechanomyography (MMG) [10], near-infrared spectroscopy (NIRS) [11], and kinematic parameters using inertial measurement units (IMUs) [12]. While the lactate concentration provides an estimation of global fatigue, it cannot monitor fatigue in real-time [8]. MMG, NIRS, and IMUs can be used in wearable forms; however, the use of NIRS and MMG has challenges owing to issues such as time lags, the use of

MMG has susceptibility to motion artifacts [13], and the use of IMUs needs further research regarding the relationship between kinematic parameters and muscle fatigue [14]. Surface electromyography (sEMG) is a widely used wearable method for real-time monitoring of local muscle fatigue by measuring myoelectric activity [15]. Fatigue reduces muscle fiber conduction velocity, shifting the sEMG power spectrum to lower frequencies (eg, decreased median frequency) and increasing signal amplitude. sEMG captures these changes and quantifies muscle fatigue using time-domain or spectral parameters [8]. However, the use of sEMG in a home setting is difficult, owing to the challenges of correctly attaching the electrodes and regularly wearing the device without assistance [16].

Adherence is a critical factor for effective daily monitoring, as meaningful and continuous data are required for accurate analysis [17]. Wearable devices integrated with mobile apps present promising healthcare solutions for home-based monitoring. The integration of hardware sensors and software mobile apps enables continuous and unobtrusive monitoring, thereby providing real-time data analysis that can support timely interventions [18]. A suitable alternative wearable approach for muscle fatigue monitoring is the use of plantar pressure sensors, which can be seamlessly integrated into a shoe's insole for daily comfortable wear. Wearable plantar pressure sensors in the foot insole are widely used for the detection of diabetic foot ulcers [19], gait analysis, and the measurement of the ground reaction force [20] and the center of pressure [6]. Muscle fatigue impacts body mechanics and alters foot loading patterns, measurable through plantar pressure at different foot regions. Considerable research has explored changes in plantar pressure following various physical activities linked to lower limb muscle fatigue, such as badminton [21], walking [22], and long-distance walking [23].

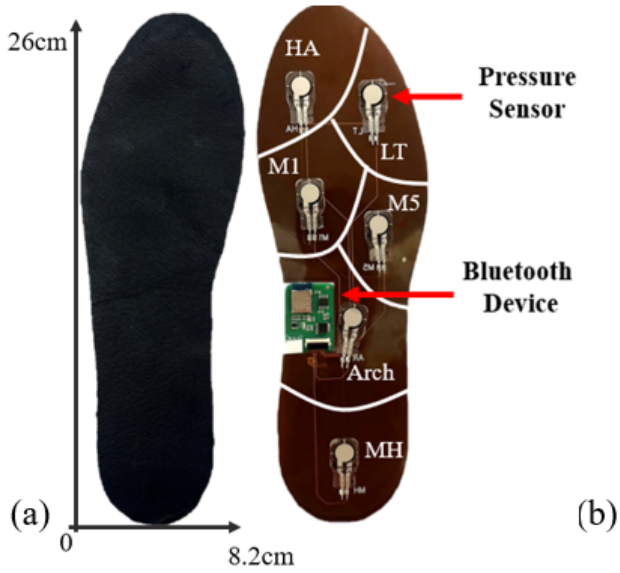
Despite the aforementioned advancements, wearable foot plantar systems for detecting muscle fatigue in everyday physical activities have yet to be designed. In this study, the effect of calf muscle fatigue in healthy participants was investigated using a self-developed wearable plantar pressure system that was suitable for daily use. The results can provide a muscle fatigue detection method for developing a wearable plantar pressure monitoring system

Methods

The Digital Foot Pressure System

A self-developed digital foot pressure system was utilized in this study. Figure 1 shows the wearable plantar devices for both the left and right feet as well as the measurements of the devices. Each device, designed to be worn comfortably with shoes, is equipped with 6 pressure sensors (A301 Flexiforce, Tekscan Inc.). The system also has a nRF52840 microprocessor (Nordic Semiconductor) used for the analog-to-digital converter measurement of foot plantar pressure, a wireless Bluetooth 5.0 module for data transmission, and a lithium-ion battery for power supply. The system operates with a sampling rate of 100 Hz, ensuring high-resolution data capture. The data from the 6 pressure sensors in both the left and right devices can be transmitted wirelessly in real time via Bluetooth to a custom-developed Android mobile app. This app facilitates real-time data display, analysis, and cloud storage, as shown in Figure 2. The pressure sensors are strategically arranged on the foot insole to cover 4 main plantar anatomical areas: the toes, metatarsals, arch, and heel. This general layout enables accurate measurement of natural gait; the layouts of the toes and metatarsals are further divided into 2 parts to capture plantar pressures along the mediolateral axis during walking [24].

Figure 1. Wearable plantar pressure device in an insole format. (**A**) Foot insole with 6 regions of pressure measurements: hallux (HA), lesser toe (LT), first metatarsal (M1), fifth metatarsal (M5), arch, and medial heel (MH); (**B**) Coordinates of the 6 pressure sensors on the insole.



(b)

	X axis (cm)	Y axis (cm)
Hallux (HA)	5.8	21.3
Lesser Toes (LT)	2.4	21.1
First Metatarsal (M1)	6.2	16.2
Fifth Metatarsal (M5)	2.7	14.5
Arch	4.2	4.2
Medial Heel (MH)	4.7	3.9

Ethical Considerations

The research was approved by the Ethics Review Board of the Chung Yuan Christian University for Human Subjects Research (No. 8800-4-07-002). The participants were informed of the requirements and procedures of the entire experiment, and written consent was obtained before testing.

Subjects

A briefing session was conducted to familiarize the participants with the fatigue protocol and the walking test to be used in the research. Twelve healthy participants from the Chung Yuan Christian University, Taiwan, were recruited for the research. The mean (SD) age of the participants was 23.7 (2.6) years, and their mean (SD) weight was 62.4 (6.3) kg. The dominant limb of each participant was determined by identifying which foot would step out first once they started walking. The exclusion criteria included participants with plantar fasciitis or flatfoot and those who could not run independently for 5 minutes. Given that these foot disorders were excluded, experiments for minimizing variability could be performed. Then, suitable foot insole sizes were given to the participants.

Experimental Procedures

The experimental procedures were divided into 4 main steps. First, baseline tests were performed to measure the EMG of muscle activity and foot plantar pressure in both the legs. During the baseline test, the sEMG activities of the participants' gastrocnemius and rectus femoris muscles in the right and left legs were recorded using sEMG electrodes (T709, Comepa, France) and a data acquisition instrument (MP36, Biopac Inc., USA). The skin of each participant was cleaned with alcohol before the electrodes were attached. The sEMG muscle activities were recorded at a sampling rate of 2000 Hz. The plantar pressures at 6 locations in the left and right legs were measured simultaneously with sEMG. The plantar pressures were recorded using the wearable foot plantar device that was developed specifically for this study. Then, timed up-and-go and 10-meter walk tests were conducted; the participants were asked to rise from a standard chair, walk for 10 meters at their most comfortable speed, turn around, walk back. and sit down again [25].

After the baseline test, each participant was instructed to perform a fatigue exercise. All the participants were asked to place a weight-bearing apparatus on each leg and perform forefoot running for 5 minutes. The weight-bearing apparatus was 1/20th of a participant's weight [26]. sEMG data were collected from the gastrocnemius and rectus femoris muscles to capture the electrical activity associated with muscle contractions, and the wearable foot plantar pressure device was used to monitor changes in pressure distribution under the feet. This dual approach allowed the fatigue levels in both the muscles to be evaluated and quantified. After the exercise, the rating of perceived exertion (RPE) scale was used to assess and document each participant's perceived level of fatigue. Postfatigue measurements were recorded immediately after the fatigue protocol, while the participants performed timed up-and-go and 10-meter walk tests, and sEMG and foot plantar pressure measurements for both legs were collected.

EMG Muscle Fatigue Analysis

Three consecutive sEMG signals from the gastrocnemius and rectus femoris muscles were averaged for prefatigue and postfatigue analyses. The sEMG envelope was calculated from the raw sEMG signal through a 20 - 500–Hz finite impulse response bandpass filter. The signal was then processed via fast Fourier transformation to calculate the power spectrum median frequency (MDF) of the sEMG. A shift in the MDF to a lower frequency during exercise is considered localized muscle fatigue [27]. This method allowed researchers to determine whether muscle fatigue was induced in the gastrocnemius muscles, thereby increasing confidence in these data's correlation with foot plantar pressure data. The MDF is the frequency at which the EMG power spectrum is transmitted, and it is given by

(1)∑j=1MDF Pj=∑j=MDFM Pj=12∑j=1M pj,

where Pj is the power spectrum of the EMG at frequency bin *j*. The MDF splits the power spectrum of the EMG into two equal-amplitude regions.

The RPE Scale Analysis

The RPE scale was utilized to assess each participant's self-reported fatigue level. This subjective measurement tool is widely employed in the fields of physical activity, exercise, and sports to evaluate an individual's perceived effort and fatigue during physical tasks [28]. Participants rate their exertion based on sensations such as increased heart rate, breathing rate, muscle fatigue, and overall physical strain. The Borg RPE Scale, ranging from 6 to 20, is one of the most commonly used versions, with higher scores indicating greater levels of exertion [29].

Foot Plantar Pressure Analysis

Foot plantar pressure data, obtained using the developed digital foot plantar system and the commercial system, were simultaneously collected with the EMG data. The 6 plantar pressures in the left and right feet obtained in this research represent 6 anatomical areas of the foot: hallux (HA), lesser toe (LT), first metatarsal (M1), fifth metatarsal (M5), arch, and medial heel (MH). The peak pressures (Pa) in these 6 anatomical areas were analyzed and calculated from the raw plantar pressure data via MATLAB version R2022a (Mathworks Inc.). The measurements for the three consecutive prefatigue and postfatigue tests were averaged and compared. On the basis of the preliminary results, changes in the mean peak pressure of the 6 anatomical areas before and after the fatigue protocol were determined.

Statistical Analysis

In this study, the MDFs of the sEMG signals and the mean peak plantar pressures in each anatomical area for each participant before and after the fatigue protocol are presented as the means (standard errors). A paired *t* test with repeated measures was used to compare the MDFs of sEMG signals from the gastrocnemius and rectus femoris muscles before and after fatigue exercise. Then, a paired *t* test with repeated measures was used to detect significant differences in the 6 anatomical areas (ie, HA, LT, M1, M5, arch, and MH) before and after muscle fatigue exercise for the wearable plantar pressure system. All the statistical tests were performed with the significance level of $P<.05$.

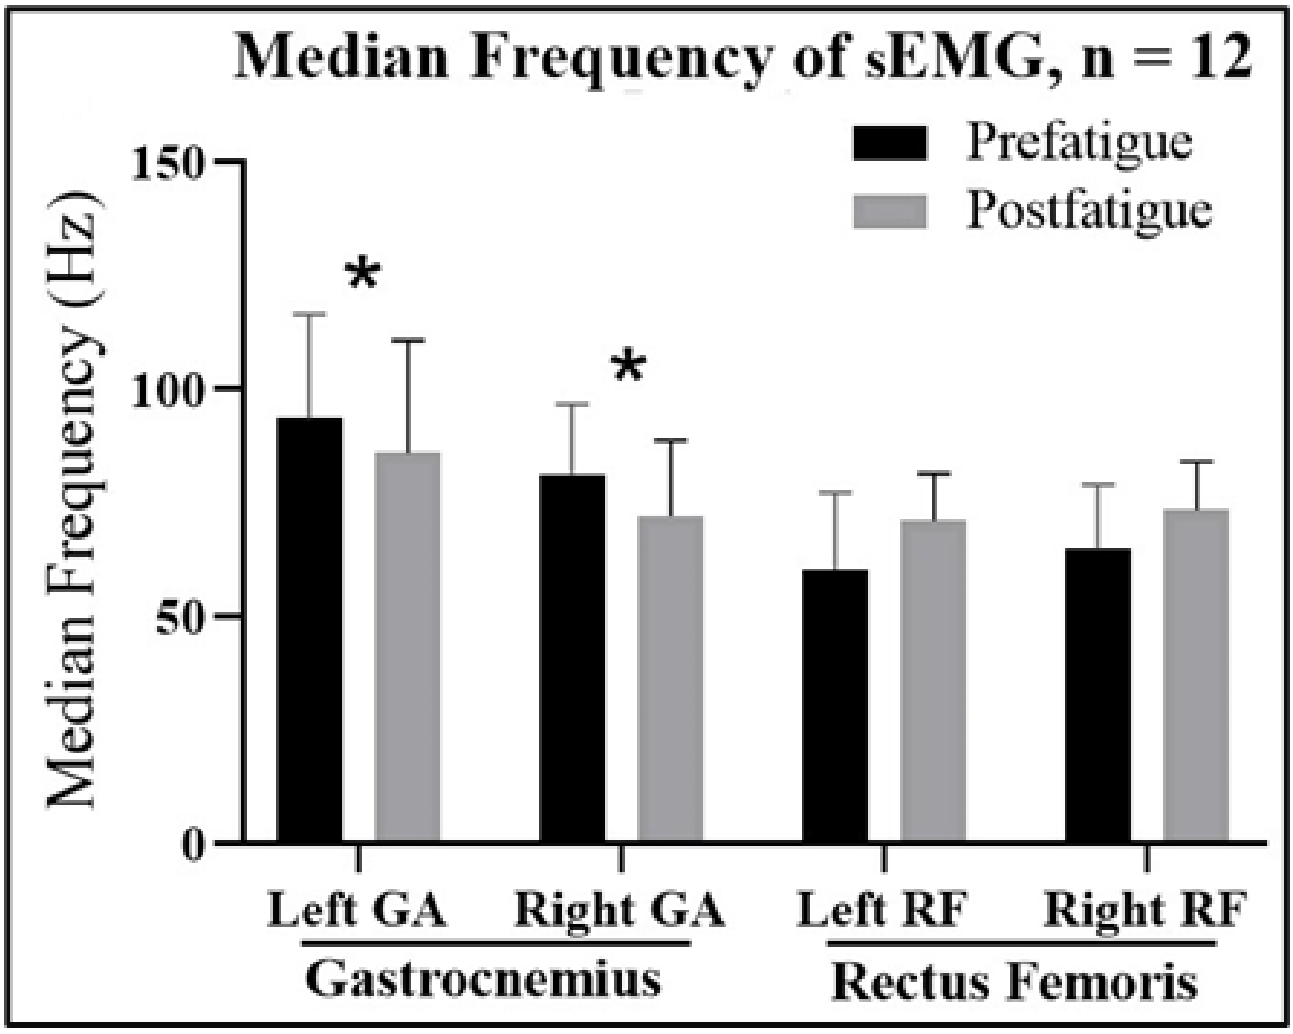
Results

The data for muscle fatigue, RPE, and mean plantar pressure were collected and analyzed using a paired *t* test.

MDFs of sEMG in Detecting Muscle Fatigue

The MDFs of the sEMG data of the gastrocnemius and rectus femoris muscles are presented in Figure 3. The MDFs (SD) of the sEMG data of the left and right gastrocnemius muscles significantly decreased from 93.6 (22.8) Hz to 86.1 (24.6) Hz in the left foot and from 81.3 (15.5) Hz to 72.1 (16.6) Hz in the right foot after exercise for muscle fatigue ($P=.001$ and $P<.001$, respectively). However, the MDF of the sEMG before and after muscle fatigue exercise did not significantly differ between the left and right rectus femoris muscles.

Figure 3. Medium frequency of the sEMG for the gastrocnemius (GA) and rectus femoris (RF) muscles in the left and right legs before the fatigue exercise (prefatigue) and after the fatigue exercise (postfatigue). sEMG data of the left and right gastrocnemius muscles significantly decreased after the exercise for muscle fatigue (*P*=.001 and *P*<.001, respectively).



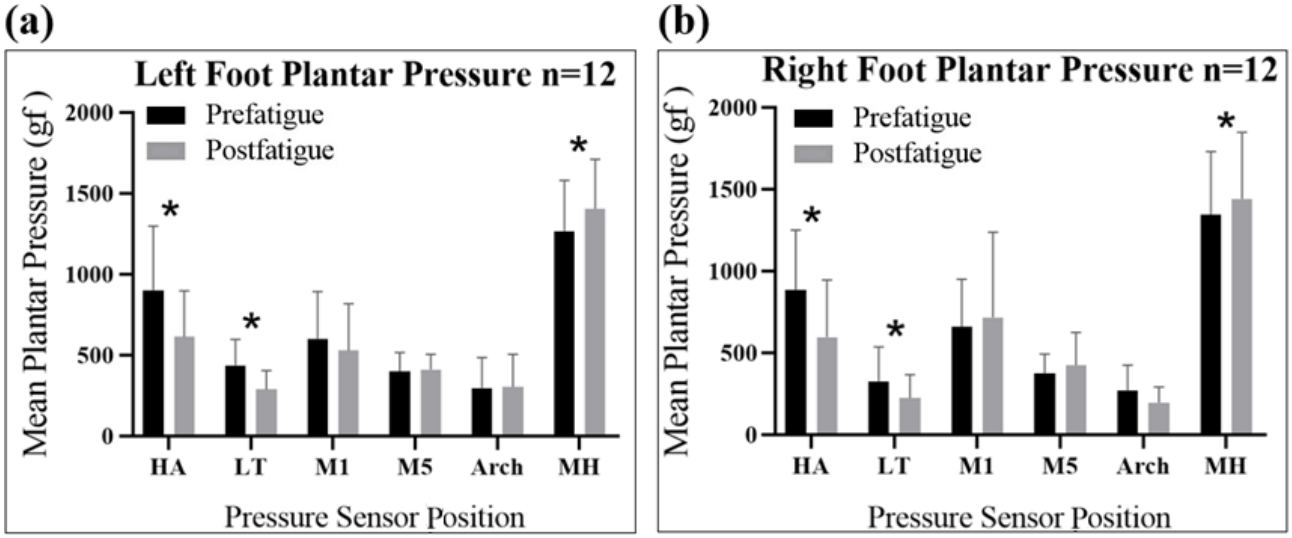
The RPE Scale in the Muscle Fatigue Protocol

The RPE scale was used in the experiment to assess the muscle fatigue levels of the 12 participants. All the participants reported that the level of fatigue in the gastrocnemius muscle was greater than that in the rectus femoris. The analysis of the average RPE scores revealed that the mean fatigue level for the gastrocnemius muscle was 14.3 (SD 1.3), whereas the mean fatigue level for the rectus femoris was 7.0 (SD 1.3). The significant difference in fatigue levels (P <.001) between the two muscles aligns with the analysis of MDF in the sEMG data. These findings confirmed that the gastrocnemius muscle experienced greater fatigue than the rectus femoris did during the experiment.

Foot Plantar Pressure in Detecting Muscle Fatigue

The data for the left and right feet (Figure 4A and B, respectively) were obtained using a developed digital plantar pressure measurement system. Figure 4 shows the changes in plantar pressure before and after fatigue. The changes were noticeable in terms of the plantar pressure at the HA, LT, and MH on both feet after gastrocnemius muscle fatigue. The pressure values at other locations also changed, but they were not statistically significant.

Figure 4. Mean peak plantar pressure before the fatigue exercise (prefatigue) and after the fatigue exercise (postfatigue) by sensor positions: hallux (HA), lesser toe (LT), first metatarsal (M1), fifth metatarsal (M5), arch, and medial heel (MH) in the (**A**) left foot: a statistically significant decrease in the mean plantar pressure peak values was observed in the HA (*P*=.003) and LT (*P*=.001), while the MH showed a statistically significant increase (*P*=.001) after the fatigue exercise; and (**B**) right foot: a statistically significant decrease in the mean plantar pressure peak values was observed in the HA (*P*=.001) and LT (*P*=.026). A significant increase was noted in the MH position after fatigue (*P*=.017).



The mean plantar pressure values were measured using the self-developed foot pressure system. A significant decrease was observed in the mean plantar pressure peak values in the HA of the left foot (*P*=.003) and right foot (*P*=.001) and in the LT of the left foot (*P*=.001) and right foot (*P*=.026). A significant increase was observed in the mean plantar pressure peak value in the MH position after fatigue in both the left and right feet (*P*=.001 and *P*=.017, respectively). The mean plantar pressure peak value in the right HA decreased by 32.6%, from 883.2 (366.8) gf to 595.1 (349.2) gf, and that in the left HA decreased by 31.9%, from 900.7 (396.2) gf to 612.8 (284.0) gf. The mean plantar pressure peak value in the right LT decreased by 31.1%, from 325.8 (210.6) gf to 223.7 (141.4) gf, and that in the left LT decreased by 33.9%, from 435.6 (162.0) gf to 287.8 (115.8) gf. The mean plantar pressure peak value in the right MH increased by 7.2%, from 1343.4 (385.7) gf to 1440.3 (406.8) gf, and that in the left MH increased by 11.0%, from 1265.5 (313.0) gf to 1404.9 (304.4) gf. The changes in the mean peak pressure in the M1, M5, and arch positions were not significant. However, the M1 and arch positions showed a change in the mean peak pressure in both the left and right feet. In contrast, we observed an increase in the mean peak pressure in the M5 position in the left and right feet of 12.5 (24.5) gf and 52.0 (79) gf, respectively. The details of the changes in the mean peak plantar pressures before and after fatigue exercise by sensor position via the wearable plantar pressure system are shown in Multimedia Appendix 1.

Discussion

Principal Findings and Comparison With Previous Works

The results of this study demonstrated that muscle fatigue in the gastrocnemius significantly affects the plantar pressure in the HA, LT, and MH regions in both the legs. In particular, the mean peak plantar pressure in the HA and LT regions significantly decreased and that in the MH regions significantly increased after 5 minutes of muscle fatigue exercise in the gastrocnemius compared with the value before the fatigue exercise. This finding was determined using the self-developed wearable foot plantar pressure system proposed in this research. Muscle fatigue exercise in this study induced muscle fatigue solely in the calf area, which corresponded with a significant decrease in the MDF of the sEMG of the gastrocnemius muscle but not in the MDF of the sEMG of the rectus femoris. As presented, sEMG is highly muscle-specific and effective for detecting localized muscle fatigue; it is not useful to detect muscle fatigue in deeper muscles like the tibialis posterior in the calf area [5]. Pressure sensors offer an alternative by measuring the fatigue in muscles through shifts in loading patterns, providing a broader and more accessible assessment.

The findings of this study align with existing literature, showing that muscle fatigue in the lower limb induces a significant decrease in the mean pressure in the HA area and a shift in plantar pressure from the forefoot to the hindfoot [21,23,30,31]. This could be due to individuals starting to adapt their plantar pressure pattern from the forefoot to the hindfoot to avoid overuse of the forefoot [23]. The literature also revealed a significant decrease in the first metatarsal region. Similar findings were observed in this study, but the results in the first and fifth metatarsals and arch regions were not statistically significant. This discrepancy could stem from differences in fatigue protocols, as more intensive activities, such as 30-minute runs, lead to greater pronation and increased medial midfoot loading, whereas walking shows no such midfoot differences [32-35]. Additionally, subject variability, including anatomical factors such as arch height and leg-length differences, may contribute to variance in medial midfoot pressure [30,36]. For instance, flat feet increase loading on the medial longitudinal arch, while high arches shift the load to the lateral edge [37].

In this study, a shift in loading from the forefoot region including the HA and LT to the hindfoot including the MH after 5 minutes of fatigue exercise results in gastrocnemius muscle

fatigue. This finding could serve as an indicator for real-time monitoring of lower limb muscle fatigue, aiding in the prevention of injuries or falls in older adults and athletes. When a healthy person participates in sports such as badminton or running, muscle fatigue of the lower limb may be expected. These fatigued muscles can result in compromised reaction times, joint stability, and dynamic balance, thereby reducing impact absorption, which heightens the risk of injuries [21,38]. Athletes and coaches should monitor for fatigue alerts and ensure timely rest to recover muscle strength, preventing performance issues and injuries [39]. For older populations, particularly those at high risk of falls, such as patients with sarcopenia [40] or stroke [41], this system enables continuous home-based monitoring of plantar pressure patterns. A shift in plantar loading from the forefoot to the hindfoot could trigger alerts for rest to individuals or caretakers, minimizing fall risks associated with muscle fatigue.

Usability is a key factor in the adoption of digital health technologies such as the proposed wearable plantar pressure system [42]. Compared to sEMG, MMG, NIRS, or IMU wearable devices, its shoe-based form offers a user-centered design for daily wear, eliminating the need for users to remember and attach it correctly, thereby enhancing acceptance and compliance in home settings. A previous study highlighted the importance of face-to-face interactions with physicians in increasing their trust in digital health technologies [43]. Clinical or expert recommendations play a critical role in encouraging patients to adopt the device. The system's ability to support effective remote patient management allows both users and experts to review and monitor past performance or clinical conditions, thus fostering engagement [44]. These features, combined with its user-friendly design and portability, enhance the system's feasibility and scalability for home-based applications, promoting widespread adoption.

Limitations

This study has some limitations. First, direct evidence for the development of muscle fatigue in the gastrocnemius could not be provided by this study, given that muscle force was not directly measured. Instead, the MDF of the sEMG signal, which shifted to a low frequency, was used as an indicator of muscle fatigue; this approach is a common research method for measuring muscle fatigue [45-47]. The decrease in MDF was likely caused by changes in the properties of the muscle fibers, such as decreased conduction velocity and increased muscle fiber recruitment [48]. The MDF of the sEMG measurement might also be affected by factors other than fatigue, such as the muscle fiber type [49] and motor unit firing rate [50]. However, this limitation was compensated by the RPE scale questionnaire. Second, the effects of fatigue were measured only in the rectus femoris and calf gastrocnemius muscles; the effect of upper leg fatigue on plantar pressure was ruled out. sEMG measurements of other calf muscles, such as the tibialis anterior, can provide insights into a particular calf muscle's interaction with plantar pressure. The short test duration and limited wearing time (10 - 20 min) in this study may not accurately represent real-life scenarios, necessitating extended testing to better simulate prolonged activities. In addition, wearable devices must adapt to various environments and wearing conditions, as factors such as daily wear and tear, temperature, humidity, flooring, and uneven terrain can impact sensor performance.

Conclusions

The results of this study demonstrated a significant decrease in the mean plantar peak pressure in the HA and LT and an increase in the mean plantar peak pressure in the MH as an indicator of the onset of muscle fatigue in the gastrocnemius. This work is an exciting proof-of-concept outcome showing that muscle fatigue in the gastrocnemius can be detected via a wearable plantar pressure system. These findings can be used to further develop a wearable lower limb muscle fatigue monitoring system for minimizing injury risk in sports or during the daily activities of older adults.

Acknowledgments

The author would like to thank the participants for their time and willingness to take part in this study. This work was supported by the Taiwan National Science and Technology Council (Grant No. 110-2222-E-033-006-MY3).

Abstract

Background: Targets of bullying are at high risk of negative socioemotional outcomes. Bullying programming in rural schools is important as bullying is more prevalent in those schools compared to urban schools. Comprehensive, school-wide bullying programs require resources that create significant barriers to implementation for rural schools. Because technology-based programs can reduce implementation barriers, the development of a technology-based program increases access to bullying prevention in rural settings.

Objective: We aimed to conduct usability testing of a bystander bullying intervention (STAC-T). We assessed usability and acceptability of the STAC-T application and differences in usability between school personnel and students. We were also interested in qualitative feedback about usability, program features, and feasibility.

Methods: A sample of 21 participants (n=10, 48% school personnel; n=11, 52% students) recruited from 2 rural middle schools in 2 states completed usability testing and a qualitative interview. We used descriptive statistics and 2-tailed independent-sample *t* tests to assess usability and program satisfaction. We used consensual qualitative research as a framework to extract themes about usefulness, relevance, needs, barriers, and feedback for intervention development.

Results: Usability testing indicated that the application was easy to use, acceptable, and feasible. School personnel (mean score 96.0, SD 3.9) and students (mean score 88.6, SD 9.5) rated the application well above the standard cutoff score for above-average usability (68.0). School personnel (mean score 6.10, SD 0.32) and students (mean score 6.09, SD 0.30) gave the application high user-friendliness ratings (0-7 scale; 7 indicates highest user-friendliness). All 10 school personnel stated they would recommend the program to others, and 90% (9/10) rated the program with 4 or 5 stars. Among students, 91% (10/11) stated they would recommend the program to others, and 100% (11/11) rated the program with 4 or 5 stars. There were no statistically significant differences in ratings between school personnel and students. Qualitative data revealed school personnel and students found the application useful, relevant, and appropriate while providing feedback about the importance of text narration and the need for teacher and parent training to accompany the student program. The data showed that school personnel and students found a tracker to report different types of bullying witnessed and strategies used to intervene by students a useful addition to STAC-T. School personnel reported perceiving the program to be practical and very likely to be adopted by schools, with time, cost, and accessibility being potential barriers. Overall, findings suggest that the STAC-T application has the potential to increase access to bullying prevention for students in rural communities.

Conclusions: The results demonstrate high usability and acceptability of STAC-T and provide support for implementing a full-scale randomized controlled trial to test the efficacy of the application.

Introduction

Background

National statistics indicate that bullying is a national public health issue in the United States, with 19.2% of students aged 12 to 18 years reporting being bullied at school in the past year [1]. Bullying peaks in middle school, with 26.5% of sixth-grade students reporting being a target of school bullying, followed by 26.3% of seventh graders and 25.1% of eighth graders. Among students who report being bullied, 21.6% report being bullied online. Findings from a meta-analysis examining consequences of bullying have indicated that students who are targets of bullying report a wide range of negative mental health outcomes, including symptoms of anxiety, posttraumatic stress, depressive symptoms, nonsuicidal self-injury, suicidal ideation, and suicide attempts [2]. Similarly, being a target of cyberbullying is associated with internalizing symptoms, suicidal ideation [3-5], and alexithymia and psychotic experiences [6]. Thus, it is imperative to develop effective interventions for middle school students that are accessible and easy to implement to reduce bullying and the associated negative consequences.

Youth in Rural Schools

Students attending school in rural communities are at high risk of experiencing both school bullying and cyberbullying [7-9]. According to US national statistics, the highest rates of bullying among rural youth in the past decade were reported in 2019, with 27.7% or rural students reporting being bullied compared to 22.4% of students in urban areas [10]. Although rates of bullying peaked in 2019 for both rural and urban students, the most recent US national statistics indicate that the prevalence of school bullying victimization continues to be higher among students in rural areas (23.8%) than among students in urban areas (19%) [1]. Furthermore, among targets of bullying, students attending rural schools are also more likely to report being bullied online (23%) compared to students attending urban schools (19.5%). Rural students also report a higher rate of being bullied with repetition (18.8%) compared to urban students (14.4%). Among middle school students attending schools in rural communities, bullying victimization is associated with poor school relationships, negative school experiences [11], and depression and anxiety [11,12]. These data suggest the importance of developing school-based bullying prevention programs specifically for students in rural communities.

School-Based Bullying Interventions

Comprehensive, school-wide interventions are effective in reducing bullying and the associated negative mental health outcomes [13]. Furthermore, bystander training (eg, teaching students who witness bullying to intervene in bullying situations) is an important intervention component [13]. Although up to 80% of students report witnessing bullying [14], only 20% intervene [15]. Because students report that they do not know how to intervene when they witness bullying [16], bystander training is a promising approach to bullying prevention. However, few comprehensive school-based programs incorporate bystander training. In addition, comprehensive, school-wide bullying prevention programs are expensive, complex, and time intensive and require extensive training [17]. Because these interventions require substantial resources, many schools face implementation barriers. Schools in rural communities may also face economic disparities, creating further implementation challenges [18], including a lower tax base, increased training costs due to bringing in expert trainers, frequent staff turnover, school closures, staff overload, and lack of program advocates in bullying prevention [19]. Challenges related to logistical problems, training requirements, and limited funding can negatively impact program adoption and sustainability [19].

Shifting to a Technology-Based Bullying Intervention

Technology-based interventions have the potential to improve access to programming and decrease implementation barriers experienced in rural communities [19]. Although some rural areas have higher rates of poor internet connectivity, eligible schools in rural communities can receive discounts for internet and broadband services [20]. Federal grants to build broadband infrastructure in rural areas are also available [21]. In addition, research conducted with key middle school personnel (ie, administrators, teachers, and school counselors) in rural communities indicates both a strong interest in technology-based bullying prevention programs and positive implementation conditions (eg, administrative support and technology readiness) [22]. Thus, most students in rural communities have access to the necessary infrastructure to support technology-based programs, and key personnel in rural middle schools indicate that schools are interested and ready for technology-based bullying interventions.

Although there is strong interest and need for online bullying prevention programming, very few US bullying prevention programs include a technology component. Programs that do offer it as an adjunct to in-person delivery [13]; often rely on simple texting, not multimedia interfaces; and they do not train student bystanders to intervene. For example, the Build Respect, Stop Bullying program for middle schools uses an online platform [23] but is part of a large program with staff or family components without bystander training. Other available technology programs include (1) an SMS text messaging program pairing youth with a “text buddy” [24]; (2) apps that encourage students to report cyberbullying, block websites attracting cyberbullying, and notify parents and school personnel of cyberbullying; and (3) online social media campaigns and educational resources (eg, videos, testimonies, and quizzes) [18,25,26]. Although there are programs that incorporate technology into bullying prevention and intervention, none appear to offer a route to a technology-based, interactive bystander training for middle school students.

The STAC Intervention

STAC [27] is a brief, stand-alone bystander intervention that includes didactic and experiential training followed by 2 booster sessions. The 75-minute didactic training includes education about bullying and cyberbullying, the consequences of bullying, and bystander roles and a description of the four STAC strategies: (1) "Stealing the show"—using humor or distraction to interrupt the bullying situation removing the attention away from the target, (2) "Turning it over"—informing an adult about the bullying and asking for help, (3) "Accompanying others"—befriending or providing support to the targeted student, and (4) "Coaching compassion"—gently confronting the perpetrator to increase empathy for the target. The experiential training comprises a series of role-plays during which students practice using the STAC strategies through bullying scenarios. The STAC training is followed by two 15-minute booster sessions to reinforce learning. The STAC intervention is effective in reducing bullying [28,29] as well as mental health risks for bystanders [30-34]. STAC has also been adapted to be culturally appropriate for middle school students in rural communities [35-37]. Research on the adapted STAC intervention demonstrates both bullying reduction [35,38] and improved mental health [35,39] among students trained in the program.

The Technology-Based STAC Intervention

The technology-based STAC intervention (STAC-T) is an online application developed to shift intervention delivery from in-person implementation to a technology-based format, thereby increasing accessibility and reducing barriers to intervention implementation. STAC-T is designed to be easily disseminated to large groups of students, who can access the intervention from a computer, tablet, or smartphone. In addition, the 40-minute STAC-T application is designed to be modular, increasing implementation flexibility. The initial training is followed by one 15-minute booster session designed to reinforce skill acquisition through virtual role-plays. The program is interactive, including knowledge checks, personalized feedback, and the selection of avatars to respond to bullying scenarios. Initial development included the design and testing of a STAC-T prototype. The design of STAC-T was developed based on the content of the in-person STAC intervention for rural middle schools as well as feedback from an expert advisory board and key middle school personnel in rural communities. In addition, students attending rural middle schools participated in 3 iterative focus groups, providing feedback on program usefulness, content, and functionality [40]. Once developed, the STAC-T prototype was evaluated through usability testing, which provided feedback from end users on program functioning [41]. The results from usability testing with key personnel and students from 2 rural middle schools indicated that the STAC-T prototype was easy to use, acceptable, and feasible, supporting the full-scale development of the STAC-T application [40].

This Study

Bullying is a significant public health concern for students attending rural schools [7-9]. Comprehensive bullying intervention programs that incorporate bystander interventions are the standard for practice [13]; however, they place a high demand on schools for implementation [17] and can contribute to disparities in rural schools [19-22]. STAC-T has the potential to reduce barriers and increase access to bullying prevention for middle school students in rural settings [40]. Therefore, the purpose of this study was to evaluate the usability and acceptability of the full-scale STAC-T application to determine readiness for a large, multisite randomized controlled trial to evaluate the efficacy of the STAC-T application for middle school students in rural communities. Usability testing is an important step in the process of intervention development as it predicts the likelihood of program adoption [42]. To achieve this aim, we implemented usability testing with key stakeholders (ie, school personnel and students) at 2 middle schools in rural communities in 2 states (N=21) using a mixed methods design. This study had the following objectives: (1) to assess usability and acceptability of the STAC-T application and (2) to assess differences in usability between school personnel and students.

Methods

Participants

Participants were key school personnel (ie, administrators, teachers, and school counselors; 10/21, 48%) and students (11/21, 52%) recruited from 2 middle schools in rural, low-income communities in the Northwestern and Southern regions of the United States. Between 5 and 10 usability testers are needed to identify most usability issues [43]. The schools were selected based on previous and ongoing research partnerships. The 2 schools were Title 1 schools, with 95% and 99% of the student population at the 2 schools eligible for reduced or free lunch. Among school personnel, the ages ranged from 26 to 55 years (mean 43.4, SD 9.8 years), and most (9/10, 90%) were female. School personnel self-reported ethnicity or racial background as White (5/10, 50%), Hispanic or Latino (3/10, 30%), and Black or African American (2/10, 20%). Among students, ages ranged from 11 to 15 years (mean 12.8, SD 1.3 years), with 36% (4/11) in grade 6, a total of 18% (2/11) in grade 7, and 45% (5/11) in grade 8. Students self-reported gender as female (6/11, 55%) and male (5/11, 45%). Students self-reported ethnicity or racial background as White (4/11, 36%), Black or African American (4/11, 36%), and Hispanic or Latino (3/11, 27%).

Development of the STAC-T Application

The translation from the STAC in-person intervention to STAC-T was guided by persuasive system design, a theoretical guide for translating clinical aims to health-related technology frameworks [44-46]. The STAC-T application was developed using Agile programming, a collaborative and incremental programming methodology [44-46]. The application was functional on all web browsers that support HTML5 and was built on a full-stack web application using HTML and JavaScript as the main interface. React.js was used as the front-end framework. The look and feel of the program were designed using Adobe Illustrator and Photoshop and developed using HTML elements plus SVG, PNG, JPG, WAV, MP4, and GIF images, audio, and video graphics. The system is accessible on desktop computers and iOS and Android tablets and smartphones. All design and programming elements were

aligned, and stakeholders' inputs were incorporated throughout the multistage development. Programmers produced the STAC-T application; alpha and beta tested it in-house for stability and code errors; tested it for usability; and revised it following an iterative, Agile production process.

In previous studies, as well as the in the iterative interviews and focus group conducted in this study, participants indicated that increasing program interactivity, adding more color, and including more realistic images such as avatars were important to increase engagement [40] and promote behavior change [47]. Therefore, design elements such as space (bright colors and visual space), components (realistic characters and familiar objects), and mechanics (actions reported by students that occur in rural middle schools) were established for the program features. In addition, STAC strategy practice was designed to require students to select an avatar, view bullying scenarios and select actions to operationalize the STAC strategy, view the avatar enacting the selected action, and receive feedback on its effectiveness. An artist hand illustrated and styled 6 avatars. The avatars had light-, medium-, and dark-colored hair in different styles as well as light, medium, and dark skin tones for students to choose from to best represent themselves and stimulate engagement. To reward learning and bolster adherence, "badges" (visual reward icons; eg, "Show Stealing Badge") were included as intermittent awards to encourage user engagement (Figure 1).

The STAC-T application content comprises three modules: (1) What is Bullying?—users are presented with background information on bullying, including bullying definitions (ie, physical, verbal, and relationship bullying as well as cyberbullying), bullying facts and statistics, characteristics of students who bully, and negative consequences of bullying; (2) What are Bystanders?—users are taught what a bystander is and how bystanders affect bullying outcomes (this module explains the 4 bystander roles: *assistants*, those who intentionally help the bully; *reinforcers*, those who are not directly involved in hurting another student but encourage the bully by standing around, laughing, or watching quietly; *outsiders*, those who do not take sides while witnessing bullying; and *defenders*, those who do something to stop the bullying situation or help the target in some way); and (3) STAC Strategies—users are introduced to the 4 STAC strategies, which are "Stealing the show," "Turning it over," "Accompanying others," and "Coaching compassion" (this module also includes STAC strategy practice using avatars selected by the user). The booster session includes additional practice with bullying scenarios and STAC strategy use.

Iterative interviews (15/21, 71% of the participants; 7/15, 47% female and 8/15, 53% male; 6/15, 40% White; 6/15, 40% Black or African American; 3/15, 20% Hispanic or Latino) and 2 rounds of iterative focus groups (20/21, 95%; 11/20, 55% female and 9/20, 45% male; 6/20, 30% White; 9/20, 45% Black or African American; 3/20, 15% Hispanic or Latino; 2/20, 10% other) conducted with middle school students attending schools in rural communities in 2 states informed program development before usability testing. Students participating in the interviews provided feedback on design aspects of the program, including color scheme, narration, and cartoons. Students were given a sample slide in 5 color schemes, 3 narrator voice samples, and 3 cartoon-style character depictions. Students were asked to rank a series of questions about each program aspect and then rank their preferences. Feedback and ranked choices were used to select color schemes, the narrator, and the program artist. Iterative focus groups were then conducted to gather feedback from students related to content and stylistic aspects of the program. Overall, the program was well received; students reported that the content was helpful and they liked the look and feel of the teacher who appears throughout the training. Students in the first round of focus groups provided specific feedback to incorporate more cyberbullying scenarios (eg, having bullies use their phones to record their peers without their knowledge), make the appearance of the characters more realistic (eg, changing clothing, adding eyes to all the characters, and changing hairstyles), and improve the function of the program to make navigation more user-friendly. Students also expressed disliking a particular activity, which was removed from the program. Students' feedback was incorporated into the program before conducting the second round of focus groups. The students in the second round of focus groups provided additional feedback about how to make the appearance of the characters more realistic (eg, adding emotion to the characters), as well as adding background images to make the scenarios look more like what they are used to seeing at school and school-related activities, such as sporting events (eg, adding teachers, lockers, wall hangings, and bulletin boards). They also provided specific feedback about how to make student behaviors more realistic (eg, having the target look sad instead of crying and changing the type of bullying from physical to verbal in front of adults). Input from the focus groups informed the development of the final STAC-T application used in this study.

Figure 1. Samples from the technology-based STAC application.

Procedures

Participant recruitment and usability testing occurred in 2024. The researchers provided the liaisons (eg, school counselor and principal) from each school with an email script describing the purpose and procedures of the study. Inclusion criteria for school personnel consisted of being employed as a principal, teacher, or school counselor at the partnering school; speaking English or Spanish; consenting to participate; and having a desire to make a positive difference in the school climate. For students, inclusion criteria consisted of being enrolled in the partnering school, speaking English or Spanish, having parental consent and student assent, and having a desire to make a positive difference in the school climate. To assess desire to make a positive difference, school liaisons were provided with rubrics developed by the research team to identify key school personnel and students who exhibited the following characteristics assessed by the rubric: caring for students; having a desire to be a positive influence on the school climate; being approachable to students; caring about addressing the problem of bullying; and having leadership qualities in the case of school personnel or leadership, maturity, responsibility, caring toward others, influence, and a desire to be a positive influence on their peers in the case of students. For each item, school personnel and students were assessed on a 3-point scale, which included the ratings of *yes*, *somewhat*, or *no* for each item described previously. School personnel and students who scored *yes* or *somewhat* on all inclusion criteria were eligible to participate. Exclusion criteria for the study for both school personnel and students included having participated in a previous STAC study, speaking a language other than English or Spanish, and not providing consent or assent to participate.

The school liaison used the inclusion and exclusion criteria and the rubric to identify and contact key school personnel and students and then used the script to invite them to participate in the study.

Similarly to our previous usability research [40], we conducted the usability testing and interviews remotely. Research supports remote usability testing as a viable approach to gather high-quality user experience feedback [48,49]. To mitigate technology-related problems, before the testing session, a team member worked with the school liaison to ensure that they could open and operate the program using the school's computers and firewall. When problems occurred during the testing session, participants switched to a different device or, in one case, rescheduled the testing session.

During the usability testing, participants were asked to review the entire STAC-T application, including the booster session. Participants were asked to talk aloud while completing the tasks, identifying problems and the solutions attempted. The researchers and users were on videoconference and shared their screens. The researchers could see what the participants were doing, and they were able to communicate with each other in real time. The researchers observed the users as they worked through the tasks and asked questions to gather more data. After completing the STAC-T application, participants were asked to complete a brief usability survey followed by a semistructured interview and then a demographic questionnaire. All participants were asked to provide information about their perceptions of (1) program utility, (2) relevance and appropriateness of program content, (3) ways in which they would improve the program, and (4) using a bullying and strategy use tracker after the training. School personnel were also asked about (1) their thoughts on implementation feasibility, (2) the likelihood of school program adoption, (3) their thoughts on companion trainings for teachers and parents, and (4) barriers to program use. All individual interviews lasted 1 hour and were video recorded.

Measures

Demographics

Participants self-reported their age, ethnicity or race, and gender. Students also reported their grade level.

Program Usability

Usability was assessed using the System Usability Scale (SUS) [50]. The SUS is a widely used 10-item validated tool that measures the usability and acceptability of technology-based programs. Responses are measured on a 5-point Likert scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). To calculate the SUS score, responses are converted as follows: (1) for odd-numbered items, 1 is subtracted from the response; (2) for even-numbered items, 5 is subtracted from the response; (3) the converted responses are added; and (4) the total is multiplied by 2.5. The final SUS score ranges from 0 to 100. An SUS score of ≥68 is considered above average [51].

Program User-Friendliness

One item selected from previous usability research [40] was used to assess the user-friendliness of the program. Participants were asked to rate the user-friendliness through the following question—"Overall, I would rate the user-friendliness of this program as:"—using a 7-point scale ranging from 0 (*worst imaginable*) to 7 (*best imaginable*).

Program Satisfaction

In total, 2 items selected from previous usability research [40] were used to assess program satisfaction. Participants were asked the following question—"Would you tell your friends/colleagues to use the program?"—with *yes*, *no*, and *don't know* as response choices. Participants were also asked how many stars they would give the program (1 star being the lowest and 5 stars being the highest).

Interview Questions

Following usability testing sessions, participants were asked a series of open-ended questions about the utility and relevance of the application prototype, as well as ways to improve the application, likelihood of program use, and potential implementation barriers. School personnel and students were asked the following: (1) "Please talk about your perception of how useful this program could be to helping to address the problem of bullying at school," (2) "Please share your thoughts on whether you think the content of this program is relevant and appropriate for students at your school and your community," and (3) "Can you talk about ways that you would improve the program?" Students were also asked the following: "If your school asked you to continue using the tracker, would it be useful?" School personnel were also asked the following: (1) "What are your thoughts on how practical or workable you think it would be to use this program at your school?" (2) "What do you believe is the likelihood that your school would use this intervention?" (3) "Do you think an online, brief teacher training and parent training module would be a helpful addition to this program?" (4) "What, if anything, would keep you from using this program?" (5) "How would you envision using the tracker, if at all, after completing the training modules and the two boosters?"

Data Analysis

Quantitative Analysis

Quantitative data from the questionnaires were analyzed using SPSS (version 29.0; IBM Corp). Before conducting statistical analyses, we examined the data for missing data points. We found no missing data. The data were also examined for outliers, defined as >3.3 SDs above the mean [52]. We found no outliers. To ensure that continuous data met statistical assumptions for parametric statistical tests, we assessed acceptable normality by using established guidelines for examining skew and kurtosis [53]. All continuous variables were within the acceptable range for skew and kurtosis. Descriptive statistics were used and are presented separately for school personnel and students. We examined differences between school personnel and students using 2-tailed independent-sample *t* tests for continuous variables and chi-square analyses for categorical variables. All statistical assumptions were met for the *t* tests and chi-square analyses. We controlled for type I error using the Bonferroni correction. On the basis of the calculated Bonferroni correction, all analyses were considered significant at $P<.004$.

Qualitative Analysis

Qualitative data from open-ended questions were analyzed separately for school personnel and students. In total, 3 team members, 2 of whom conducted the usability tests, transcribed the data verbatim. We used consensual qualitative research as a framework for data analysis. We used thematic analysis [54,55] to identify, analyze, organize, describe, and report themes found within the qualitative data. A faculty member with expertise in qualitative data analysis, along with 2 graduate students, 1 PhD student and 1 masters of art in counseling student, with previous experience in qualitative data analysis, analyzed the data. The faculty member led the data analysis team. The team met 2 times via Zoom (Zoom Video Communications). During their first meeting, the faculty member discussed the analysis protocol with the 2 students, as well as expectations and biases that they needed to be aware of as they analyzed the data. Each team member analyzed the transcripts for the school personnel and students separately to arrive at initial themes for each open-ended question from the interview protocol. Next, the team met one more time via Zoom and conducted additional email communication over a 4-week period to arrive at a consensus on themes and frequency categories supported by participant quotations. During their meetings, the team members shared their themes for each question and discussed agreement or disagreement about themes. The analysts relied on participant quotes to resolve disagreements. Once the team members reached a consensus, an external auditor reviewed the interview transcripts and themes for the school personnel and students. The auditor agreed with the team's findings. Interview data were deidentified to ensure anonymity, and quotes were identified by participant type (ie, school personnel or students).

Ethical Considerations

This study was registered with ClinicalTrials.gov (NCT05572398). All research procedures were approved (101-SB21-205) by Boise State University's institutional review

board. Researchers obtained informed consent from school personnel and parental consent and student assent in the case of students. For students, school liaisons met briefly with potential participants identified through the inclusion criteria to explain the project, and interested students were sent home with a letter describing the project as well as an informed consent form for the parent or guardian to sign. English and Spanish translations were provided in schools with a large Hispanic student population. Parents were also emailed the information and consent form. Parents could choose to sign the consent form via pen and paper or electronically. If they did not provide consent electronically, students were asked to return the signed consent form to the school liaison. Parents were provided with the study principal investigator's contact information and were encouraged to contact her if they had any questions or concerns. Students who returned the signed consent form were then provided with an opportunity to assent immediately before the interview, focus group, or usability testing session. In addition, several steps were taken to protect confidentiality: participants were informed that they were free to refrain from answering any questions, all data were identified only by a personal identifier number, and all research team members completed required training in protection of human research participants. School personnel received a US $50 Amazon gift card as an incentive for participation in the usability testing and individual interview. There were no incentives for student participants.

Results

Quantitative Analysis

Program Usability

Usability scores on the SUS are presented in Table 1. Overall, scores for both school personnel and students suggested a very high level of usability, functionality, and acceptability. As shown in Table 1, there were no differences in the scores on any of the individual items or the SUS total score between school personnel and students, with both participant groups scoring the STAC-T application at a very high level of usability.

Table 1. Means and SDs of the System Usability Scale scores from school personnel and students[a].

	School personnel (n=10), mean (SD)	Students (n=11), mean (SD)	*t* test (*df*)	*P* value
"I think that I would like to use the program frequently."	4.60 (0.52)	4.18 (0.60)	–1.70 (19)	.11
"I found the program to be more complex than it needed to be."	1.20 (0.42)	1.64 (0.92)	1.37 (19)	.19
"I thought the program was easy to use."	4.90 (0.32)	4.91 (0.30)	0.07 (19)	.95
"I think that I would need the support of a technical person to be able to use this program."	1.10 (0.32)	1.36 (0.67)	1.13 (19)	.27
"I found the various functions in the program were well put together with each other."	4.40 (1.27)	4.55 (0.69)	0.33 (19)	.74
"I thought there was too much inconsistency in this program."	1.00 (0.00)	1.55 (1.04)	1.66 (19)	.11
"I imagine that most people would learn to use this program very quickly."	4.90 (0.32)	4.55 (0.82)	–1.28 (19)	.22
"I found the program very awkward to use."	1.00 (0.00)	1.18 (0.40)	1.42 (19)	.17
"I felt very sure that I could use the program correctly."	4.90 (0.32)	4.55 (0.69)	–1.49 (19)	.15
"I needed to learn a lot of things before I could get going with this program."	1.00 (0.00)	1.55 (0.93)	1.84 (19)	.08
System Usability Scale total score	96.00 (3.94)	88.64 (9.51)	–2.27 (19)	.04

[a]Responses were scored on a 5-point Likert scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*).

Program User Friendliness

School personnel and students rated the program highly on user-friendliness. Among school personnel, scores on user-friendliness ranged from 6.00 to 7.00 (mean 6.10, SD 0.32). Among students, scores on user-friendliness ranged from 6.00 to 7.00 (mean 6.09, SD 0.30). There were no differences in scores between school personnel and students on user-friendliness (t_{19}=–0.07; *P*=.95).

Program Satisfaction

Program satisfaction ratings are presented in Table 2. Overall ratings suggested that school personnel and students were satisfied with the program. There were no differences in scores between school personnel and students on program recommendation (χ^2_1=1.0; *P*=.33) or star ratings (χ^2_1=2.8; *P*=.25).

Table 2. Program satisfaction results for school personnel and students.

	School personnel (n=10), n (%)	Students (n=11), n (%)
Would recommend the program		
Yes	10 (100)	10 (91)
No	0 (0)	0 (0)
Unsure	0 (0)	1 (9)
Star rating		
1 star	0 (0)	0 (0)
2 stars	0 (0)	0 (0)
3 stars	1 (10)	0 (0)
4 stars	5 (50)	3 (27)
5 stars	4 (40)	8 (73)

Qualitative Analysis

Overview

Qualitative feedback for the STAC-T application supported the quantitative findings and was very positive overall, with both school personnel and students sharing the perception that the STAC-T application is useful, relevant, and appropriate, as well as providing feedback on ways to improve the program. In addition, school personnel shared positive thoughts about program practicality and adoption, including interest in a teacher and parent training, and discussed barriers to program adoption. Both school personnel and students talked about the benefits of tracking students' reports of different types of bullying and strategies they used to intervene both as part of the program and as a stand-alone feature to be used after the training. The results are presented in the following sections organized by the following themes: (1) usefulness, (2) relevance and appropriateness, (3) program improvement, (4) program tracker, (5) practicality and adoption, (6) teacher and parent training, and (7) barriers.

Usefulness

All school personnel (10/10, 100%) and students (11/11, 100%) indicated that the program was useful and increased students' knowledge to intervene in bullying situations. For example, a school personnel member shared the following:

> *...the program that you guys are creating, will definitely inform the students what they need to look for, how they can become an active positive person.*

A student also stated the following:

> *I think it'll be helpful by telling other kids that it's not right to bully other kids because you don't know how they feel, and you don't know what they go through.*

In terms of increasing knowledge, a school personnel member indicated the following:

> *I like how it has all the different ways for the students to see how you can step in you know...that there's things they can do.*

Another one added the following:

> *...it gives students the tools that they might feel like they lack in general when bullying happens.*

A student stated the following:

> *It can teach ways on how to and when bullying is happening, how do we handle it, and make it stop quicker.*

Another student added the following:

> *...if people are making fun of a person about how they look or the way they eat, and they post a video on social media, I can like easily screenshot, show it to the principal, my teachers, to get these people to stop and like get them to stop the bullying.*

Relevance and Appropriateness

All school personnel (10/10, 100%) and students (11/11, 100%) reported that the program content was relevant and relatable and taught students empathy and prosocial attitudes. For example, one school personnel member shared the following:

> *I think the content was really relevant. It's things that you actually see at school or that you hear about or that we, that get actually reported.*

Another school personnel member added the following:

> *Oh yeah, absolutely. I think that they [students] can relate to cafeteria situations, getting on the bus and you know posting things especially you know on social media or on Instagram or TikTok or whatever.*

A student shared the following:

> *I think that is really, really relevant and I think that a lot of the situations that were used in this app as examples can be used. They can be real life situations.*

In terms of empathy and prosocial attitudes, a school personnel member said the following:

> *I think this program would help...teach more empathy cause when students have more empathy, they're less likely to exhibit those bullying behaviors.*

A student indicated the following:

It basically says that bullying is not okay and if you do see it here are a few ways on how to stop it.

Program Improvement

Both school personnel (9/10, 90%) and students (6/11, 55%) offered feedback on how to improve the program and talked about the importance of having the program be fully narrated. School personnel talked about ways to improve student engagement and user experience. For example, a school personnel member stated the following:

...making it so that all of the pop-ups and scenes are narrated.

A student also said the following:

Once you add that narrative it is going to be good because most middle schoolers they aren't going to want to read it.

In terms of improving engagement and user experience, a school personnel member said the following:

Just there was one [activity] where you had to click the arrows to move on and I feel like just making it a little bit more simple.

Another school personnel member added the following:

Slowing down the captions on the cartoons because to allow kids to see the picture to get a frame of mind of what's going on and then read the words.

Program Tracker

All the school personnel (10/10, 100%) and students (11/11, 100%) indicated that they would find using a bullying and strategy use tracker useful if their school asked them to continue to use it. When asked about how they would envision using the tracker, school personnel indicated that they would use it for data collection for programmatic feedback and prevention as well as ongoing teaching and student support. For example, when asked about the usefulness of the tracker, a school personnel member stated the following:

Yeah, you know, I think that would be good.

Another one added the following:

You can bring that data up and say, you know, you know, we're, we're seeing this type of bullying going on.

A student said the following:

Oh, yeah. Because it would let more people know that bullying has been going on and stuff.

Practicality and Adoption

All the school personnel (10/10, 100%) agreed that the program would be practical and workable, and almost all school personnel (9/10, 90%) stated that they would be likely to use the program at their school. For example, one school personnel member said the following:

...our students would definitely get on and be able to, you know, go through that program without any problems at all.

Another school personnel member stated the following:

Practical. I think that it addresses the needs of our students in their day-to-day interactions.

In terms of likelihood of use, one school personnel member stated the following:

I think it would be highly likely.

Another school personnel member added the following:

This will be helpful and they [schools] will use it because it wouldn't take too much time away from the academics, academic goals that we have.

Teacher and Parent Training Modules

All school personnel (10/10, 100%) reported that a brief online teacher and parent training would be useful, and almost all (9/10, 90%) stated that it would provide a common language and a means for future collaboration. For example, one school personnel member shared the following:

It's teaching the parents and the teachers what that looks like, you know, conversation or tools to help our kids.

Another school personnel member added the following:

Yes. Yes, so that you have this so that we're all working together as a team. And using that common language.

Barriers

When asked about barriers to using the program, most school personnel members (7/10, 70%) reiterated that they would use the program, but many of them (8/10, 80%) discussed barriers. For example, one school personnel member stated the following:

I can't think of one negative reason or one reason I wouldn't want to use it.

However, other school personnel identified potential barriers, with one member stating the following:

Not being accessible on the devices that the kids have available.

Another school personnel member said the following:

Time. But I don't see that as a factor for us because we could fit it into our advisory class.

A third school personnel member added the following:

Only thing I can think of is funding.

Discussion

Principal Findings

The purpose of this study was to examine the usability of the STAC-T application, a technology-based bystander bullying intervention designed specifically for middle schools in rural communities. We were interested in feedback from middle school personnel as they are in the position of making decisions related to adopting and implementing bullying interventions and from students as end users. The primary aim of this study was to test the usability of the STAC-T application and assess

program utility, user-friendliness, and relevance as well as feasibility and ways to improve the program. Overall, both the quantitative survey results and qualitative interview findings indicate that participants perceived the STAC-T application to be useful, user-friendly, and appropriate for students at their schools and reported high levels of satisfaction with the program. The findings of this study indicate that the STAC-T application is relevant and feasible for implementation in middle schools in rural communities. The quantitative and qualitative findings are consistent with our previous usability testing research [40].

The findings of this study provide support for the usability of the STAC-T application. Both school personnel (mean 96.0, SD 3.9) and student (mean 88.6, SD 9.5) scores on the SUS demonstrated a very high level of usability, exceeding the standard cutoff score of 68 [51]. Both school personnel and students also rated the user-friendliness of the STAC-T application as very high, with all participants rating the program at ≥6 on a scale ranging from 0 to 7. We found no differences between school personnel and students on SUS scores or user-friendliness ratings, suggesting that both groups of users found the STAC-T application to be highly usable. The qualitative data supported these results, with both school personnel and students indicating that they perceived the program to be useful as well as relevant and appropriate for middle school students in rural communities. Furthermore, both school personnel and students reported high levels of satisfaction with the program, with 100% (10/10) of school personnel and 91% (10/11) of students indicating that they would recommend the program to others. Furthermore, most participants (20/21, 95%) gave the program 4 or 5 stars on a scale ranging from 1 to 5 stars. These findings are particularly important as usability and acceptability are associated with both program adoption and implementation [42].

In terms of practicality and adoption of the intervention, school personnel believed that their school would be likely to use the STAC-T application and identified cost, time, and access as potential barriers. Our results are aligned with those of previous studies that indicate that school administrators in rural communities feel favorably about adopting and implementing online programs to address the problem of bullying [20]. In addition, our findings are similar to those of previous studies that identify cost [7,20], time [56], and access to technology [57] as notable barriers to online programming implementation in schools located in rural areas.

School personnel and students reported positive perceptions of the STAC-T program, as well as feedback for program improvement. The results of the qualitative analyses showed that both school personnel and students thought that the STAC-T content was relevant and relatable and increased students' knowledge of how to intervene in bullying situations. School personnel also stated that the program taught students empathy and prosocial attitudes. Furthermore, school personnel stated that the program was practical and workable and would be used at their school and that teacher and parent trainings would be useful additions to STAC-T to provide a common language among stakeholders. These findings suggest a need for bystander bullying intervention programs in rural schools that teach students how to intervene when they witness bullying behaviors through conducting role-plays to practice strategies across different bullying scenarios. In terms of program improvement, both school personnel and students highlighted the importance of having the entire program narrated to students. School personnel also talked about ways to improve user engagement by simplifying and slowing down a few program activities. Both students and school personnel also saw value in the posttraining tracker. Including these program modifications is likely to increase user engagement [40], which, in turn, can influence positive behavior change [47], potentially increasing the efficacy of STAC-T.

Limitations

This study supports the usability, relevance, and feasibility of the STAC-T prototype. However, certain limitations must be noted. Participants were recruited from 2 schools in rural, low-income areas from 2 states, one in the Northwestern region and one in the Southern region of the United States. Although participants were recruited from 2 different states to increase generalizability, school personnel and students from different regions of the country may have a different perspective. Future research including a broader geographic sample would increase generalizability. Furthermore, most of the school personnel participants in this study were female, further limiting the generalizability of the study. In addition, because of the small sample size, we were unable to explore differences in demographic factors, limiting information that could guide improvements to the STAC-T application. Finally, it is also possible that social desirability influenced participants as they were aware that the goal of the study was to translate the in-person STAC intervention to a technology-based format.

Implications

This study has important implications for the development and implementation of STAC-T in middle schools in rural communities. First, participants provided very high usability ratings for the STAC-T application, with qualitative data supporting the usability, utility, and relevance of the program. The findings also provided valuable information about the program itself, including the need for program narration and the utility of a type of bullying and strategy tracker that could be used after the training. School personnel also provided feedback about the importance of both teacher and parent modules to foster collaboration. These modules could be developed and offered to schools as companion modules for STAC-T. School personnel could provide teachers with the STAC-T teacher training during professional development time at school and provide parents with a link to the parent training via email. Training teachers, parents, and students could provide a common language and increase buy-in from all stakeholders [58,59]. In addition, participants indicated that program implementation is feasible as long as the program is cost-effective, brief, and students can access it on their school devices. Translating STAC from an in-person modality to an online platform can help decrease barriers to implementation, increasing implementation feasibility for rural schools by decreasing program costs and reducing the demand on schools by decreasing the need for staff training, in-class time, and

expert support. Overall, the findings of this study provide valuable feedback and a strong scientific premise for moving forward with a large, multisite randomized controlled trial to examine the efficacy of the STAC-T application.

Conclusions

Bullying is a significant public health concern for students in rural middle schools. Training students to intervene and developing programming that increases access are important factors in addressing this problem. The findings of this study demonstrate the usability, relevance, and feasibility of the STAC-T application. The preliminary data from this study support conducting a large, multisite randomized controlled trial to assess the efficacy of the STAC-T application for middle school students in rural communities. Technology-based bullying interventions, and STAC-T in particular, could be an instrumental approach to decreasing educational and mental health disparities in rural schools and helping address the problem of bullying.

Abstract

Background: Telemedicine has emerged rapidly as a novel and secure tool to deliver medical information and prescriptions. A secure, connected health care app (WiStim) has been developed in order to facilitate dialogue between patients and the medical team during an ovarian stimulation cycle for medically assisted reproduction (MAR).

Objective: This study aimed to evaluate the patients' and midwives' levels of satisfaction with the connected mobile app.

Methods: We conducted a prospective, observational, single-center study at Lille University Hospital, France. From May 1 to July 31, 2021, all women undergoing ovarian stimulation started to receive their treatment advice through the mobile app. A total of 184 women were included and they filled out the 30-item Usefulness Satisfaction and Ease-of-Use (USE) questionnaire, which examines the users' opinions in 4 dimensions: usefulness, ease of use, ease of learning, and satisfaction. The women also answered a series of closed and open questions. The 5 midwives in our assisted reproductive technology center filled out the French version of the 10-item System Usability Scale (SUS) when the app was implemented and then after 3 and 6 months of use. We also performed semistructured interviews with the midwives.

Results: Overall, 183 women using the app completed the questionnaire. None refused to use the app, and 1 withdrew from the study. The mean scores for the four USE dimensions were all significantly greater than 4, that is, the middle of the response scale. The women liked the app's ease of use, the access to tutorial videos, and the reminders about appointments and treatments. In particular, the women liked to be able to (re)read the information; this reassured them, might have reduced the number of missed appointments and treatments, and made them more independent during the day, especially when they were working. Some of the women regretted the loss of direct contact with the midwife. The mean SUS score was 76 (SD 13.54) at the start of the study, 75 (SD 17.16) after 3 months, and 84 (11.21) after 6 months. According to the adjective rating scale, these scores corresponded to good usability for the app. After the requisite training and a familiarization period, the midwives reported that using the app saved them 2 hours a day. The mobile app enabled better transmission of information and thus probably helped to decrease treatment errors.

Conclusions: The WiStim connected mobile app is one of the first reliable, secure apps in the field of MAR. The app reassured the patients during the ovarian stimulation. Women and the medical team considered that the app was easy and intuitive to use. Given the growth in demand for MAR programs and the medical team's workload, the time savings provided by the app constitute a nonnegligible advantage.

Introduction

In 2018, the European Society of Human Reproduction and Embryology's 22nd report on medically assisted reproduction (MAR) in Europe highlighted a continuous increase in the number of treatment cycles and the broad range of techniques used [1].

Every day, around the world, thousands of women undergo hormone assays and ultrasound scans of the pelvis as part of their MAR program. These burdensome, complex procedures can generate stress and anxiety for the women and their partners [2-4]. The women consulting in MAR departments are young, active, and, in many cases, occupied by work and family activities. Furthermore, health care professionals have to deal with a growing administrative burden and increasing demand for MAR while still providing high-quality patient care and support.

A large number of "eHealth" smartphone apps are being developed [5-8]. WiStim is a secure mobile app created in 2016 to facilitate communication between MAR patients and medical teams. The app provides access to a variety of documents and media (eg, test results and tutorials on self-injection) and gives daily advice on treatment during the ovarian stimulation phase. The objectives are (1) secure communication with patients, (2) better traceability, (3) a lower frequency of treatment errors caused by poor understanding, and (4) time savings for the care team. At present, the patient has to pay a subscription fee; however, some hospitals are considering whether to subsidize or cover this fee.

During each in vitro fertilization, frozen embryo transfer, or intrauterine insemination cycle, the midwife calls the women daily in order to adjust the treatment, check on adherence, and answer any questions. These calls are time-consuming and can be replaced with a connected app.

The primary objective of the current study was to evaluate levels of satisfaction with the connected app, according to both the patients and health care professionals. The secondary objectives were to identify potential difficulties in the use of the app and to study any app-associated changes in the health care professionals' practices and work organization.

Methods

Overview

We conducted a prospective, observational, single-center study in the MAR department at Lille University Hospital (Lille, France) from May 1 to July 31, 2021.

Ethical Considerations

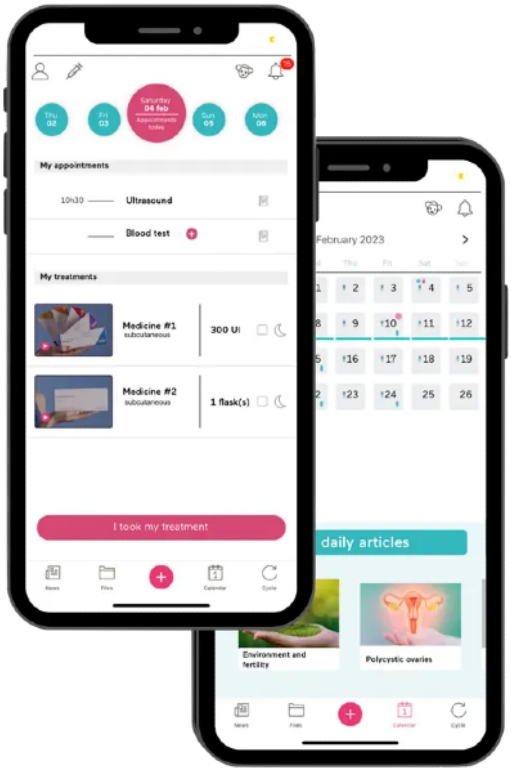
In line with the French legislation on human and social science surveys of routine clinical practice using anonymized personal data [9], approval by an independent ethics committee was neither required nor sought.

Connected Mobile App

The WiStim platform includes a mobile app for the patient (Figure 1) and a web-based management module for the medical team. The mobile app gives the patient access to advice on treatment, including the dose, the administration route, and any changes in the regimen. Tutorials on self-injections are also available. Every evening, the patient receives a reminder about her treatment and the date of her next appointment. The medical team sends information about the treatment and the next appointment through a secure web server (accredited by the French Ministry of Health) and is informed in real time about the woman's treatment.

The app requires a monthly subscription. However, Lille University Hospital has chosen to pay this cost on the patient's behalf during an initial test year.

Figure 1. The mobile app for the patient.



Patients

During a consultation, the gynecologist explained the app's principles to the patient and gave the latter an information sheet explaining how to download, install, and use the app. The patient then installed the app on her mobile phone and created an account. Once the stimulation phase had started, the patient received treatment advice through the app.

At the end of the MAR procedure, the women filled out a questionnaire (Multimedia Appendix 1). The questionnaire's closed questions concerned the type of MAR and the impact of using the app. The patient was able to write a comment for each closed question. Several open questions probed the woman's opinion of the app and the app's strengths and weaknesses. Next, the woman filled out the 30-item Usefulness Satisfaction and Ease-of-Use (USE) questionnaire, which measures the user's feelings in four dimensions: usefulness, ease of use, ease of learning, and satisfaction (Multimedia Appendix 2) [10,11]. The participants were not paid for their participation in the study.

Midwives

The five midwives in our MAR center filled out the French version of the System Usability Scale (SUS) when the app was implemented and then after 3 and 6 months of use [12]. The SUS (Multimedia Appendix 3) is a standardized, 10-item questionnaire for assessing the level of satisfaction with a technology's usability. For each of the 10 items, the midwives were invited to rate their level of agreement on a 5-point Likert scale ranging from "strongly disagree" to "strongly agree." We also performed semistructured interviews with the midwives 6 months after the implementation of the app in order to evaluate their opinion of the connected app, identify any changes in their work organization, and assess the app's acceptability (as defined in the unified theory of acceptance and use of technology [UTAUT]) [13]. The interviews were audio-recorded and transcribed.

Statistical Analyses

Statistical analyses were performed using Jamovi software (Jonathon Love, Damian Dropmann, and Ravi Selker, version 2.2.5, 2021), and thematic analyses of qualitative data were performed using QualCoder 3.0 (C Curtain). Data on the women's characteristics were used to describe the sample and perform subgroup analyses. The women's answers to the closed questions were analyzed using descriptive statistics, and the comments were analyzed qualitatively in order to highlight recurrent themes. Emerging themes in the qualitative analyses were not quantified; the goal was to understand the variety of the user's points of view. The data on the USE items and dimensions were analyzed with descriptive and inferential statistics. The threshold for statistical significance was set to $P<.05$. The results of the various questionnaires were compared in order to identify similarities and differences between the answers.

The SUS satisfaction score ranges from 1 to 100. Perceived satisfaction and usability are considered to be good when a score of 75 or more is obtained. To qualify the level of satisfaction, the mean SUS score was assessed against Aaron et al [14] grade scale and adjective rating scale. Semantic units (ie, sets of words representing the same idea) were extracted from the interviews with the midwives. An ergonomist attributed each semantic unit to one of the following themes: the opinion of the app, changes in practice, and dimensions of UTAUT acceptability (facilitating conditions, effort expectancy, social influence, and performance

expectancy). Within each theme, several subthemes were developed to represent the semantic units' diversity.

Results

Patients

Overview

During the recruitment period, 250 paper questionnaires were randomly distributed, and 184 patients responded (intrauterine insemination: 12%, in vitro fertilization: 73%, egg donation: 2%, frozen-thawed embryo transfer: 9%, fertility preservation: 4%). A total of 91 respondents had already been followed up by phone before the implementation of the app, 90 were monitored with the connected app alone, and 3 did not answer this item in the questionnaire. One woman discontinued use of the app prematurely, preferring direct contact with a midwife, and 2 women failed to complete the USE questionnaire.

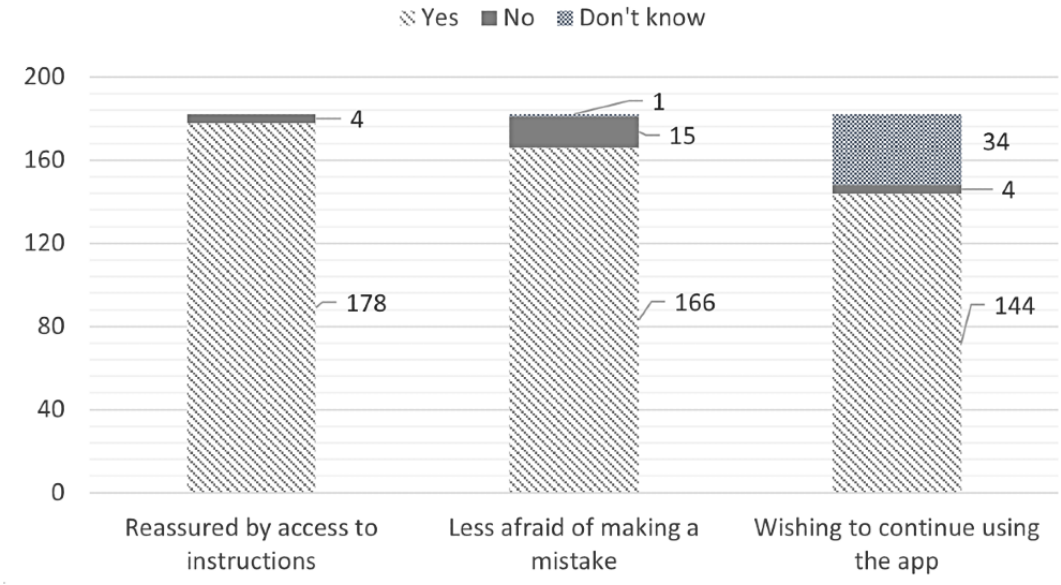
The mean scores for the four USE dimensions were all significantly greater than 4, that is, the middle of the response scale (usefulness, n=5.66, t_{180}=13.4, P<.001; ease of learning, n=6.25, t_{178}=18, P<.001; ease of use, n=5.96, t_{180}=16, P<.001; satisfaction, n=5.90, t_{177}=15.4, P<.001). The scores did not appear to be influenced by whether or not the women had been followed up by phone before the use of the app.

This good level of perceived usability was corroborated by our analysis of the women's comments and answers to the open questions. In all, 172 women described what they liked about the app. The app was seen as being easy to use in a guided, stepwise manner ("simple to use," "intuitive," and "clear"). Another reason for liking the app was its match with the women's needs and activities. The women mentioned the gain in efficiency linked to the app's centralization of information on treatment, follow-up, and appointments.

A total of 178 (97.8%) of the 182 respondents considered that the ability to access advice through the app was reassuring (Figure 2). The participants, having initially been followed up by phone, stated that they felt surer about the advice with the app because the instructions had to be rapidly written down during the phone call; with the app, the advice was available round the clock. The women also liked the additional information (eg, how to perform an injection) and the automatic reminders about appointments and treatments. A total of 166 (91.7%) of the 181 respondents considered that with the app, they were less stressed about making a treatment mistake. The participants liked the independence that the app provided; they no longer had to wait for the phone call from the midwife; previously, the call could come at any time in the afternoon.

Overall, 34 women did not reply to the question about wanting to continue to use the connected mobile app or not. 97.3% of the respondents said that they would be annoyed if they had to stop using the app (Figure 2). The 4 participants, who said they would feel relieved if they had to stop using the app, had all initially been followed up by phone and preferred direct communication with the medical team.

Figure 2. Answers to the following closed questions: "Does access to advice in the mobile app reassure you?" "Have you felt less stressed since you starting using the mobile app?" "Would you like to continue using the mobile app?".



Some weaknesses were mentioned: appointment errors, the lack of tutorials about some older models of self-injector pens, and late treatment reminders (ie, given after the scheduled time). Certain women expressed the need for direct interaction with the team of midwives via a chat function; the MAR department had decided not to offer this function because the women had already been given an email address for any questions.

A total of 53 (58.2%) of the 91 women who had initially been followed up by phone did not perceive any change in how they managed their treatment since the implementation of the app. In contrast, 38 (41.7%) women stated that the app modified the management of their treatment; they highlighted the lower mental burden, the easy, permanent access to information, the reassuring nature of the treatment reminders and app reminders,

and the fact their day no longer had to be organized around the call from the midwife.

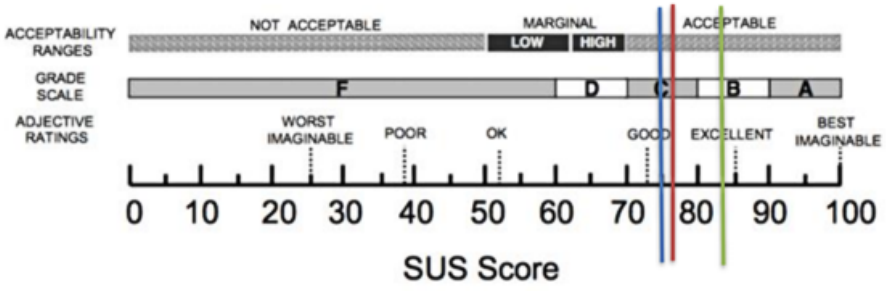
Midwives

The five midwives working in the MAR department at the time of the study filled out the SUS and were interviewed. The mean age was 43.6, and the midwives had been working in the department for an average of 6 years. The mean SUS score was 76 at the start of the study (n=4 respondents), 75 after 3 months (n=5), and 84 after 6 months (n=4; Figure 3). According to Aaron et al [14] adjective rating scale, these scores corresponded to good usability for the app.

A total of 207 semantic units were extracted from the semistructured interviews and analyzed. Even though the midwives stated that they needed some time to learn how to use the app and that the use of the app reduced the level of human contact with the women, they were generally very satisfied. The midwives found the interface pleasant to use and considered that the app was useful for the women and for the nurses who visited the women at home on a routine basis; the app modernized the midwives' practices.

During the interviews with the midwives, 3 of the 4 UTAUT dimensions emerged: facilitating conditions, effort expectancy, and performance expectancy. The social influence dimension did not emerge.

Figure 3. The mean System Usability Scale (SUS) score at the start of the study (76, SD 13.54) and after 3 months (75, SD 17.16) and 6 months (84, SD 11.21).



Facilitating Conditions

The midwives said that for the installation of the app, some IT equipment (computers) had been purchased and that they had attended training sessions on the use of the app. The midwives emphasized the good availability and responsiveness of the WiStim team when questions arose.

Effort Expectancy

The midwives viewed the app as a rather simple-to-use tool once they had been trained in its use. The app's different functions enable them to consult the patients' data, communicate with them, plan their appointments, and monitor their adherence to treatment.

Given that the app had not been integrated into the hospital information system at the time of the study, the midwives could not enter appointments into the hospital information system's diary from the app or vice versa; hence, to make appointments, they had to work on two IT tools in parallel. Even though the app had a simple-to-use interface, the fact that it was a web-based tool meant that the transitions were sometimes slow. Hence, data sometimes had to be entered twice: once on paper and then on the app.

Performance Expectancy

Use of the app was associated with a fall in the number of daily calls from midwives to patients. Nevertheless, the midwives continued to phone the women when the medical team had decided to stop the treatment or when the women had not ticked the boxes for adherence to treatment. This enabled them to optimize the dialogue by phone. Certain women continued to call or email the midwives regardless, to check that they had correctly understood the treatment procedures and advice specified by the app or to change an appointment. The midwives replied to these questions by email or by phone. The frequency of these requests tended to fall over time, as the midwives and the patients became more familiar with the app.

In order to ensure that the women were using the app correctly, the midwives helped some of them (especially those who did not understand or speak French sufficiently well) to install the app and explained how to use it. Furthermore, the advice stored in the app can be presented in several languages.

The decrease in the number of phone calls freed up an average of 2 hours per day, which enabled the midwives to perform other tasks (consultations, patient education sessions, etc).

Discussion

Principal Findings

On an annual basis, our center performs around 1400 oocyte retrieval procedures, 900 frozen embryo transfers, and 700 intrauterine inseminations. This corresponds to 30 to 50 women per day seen for ultrasound scans and hormone assays, and the volume of activity is increasing. Until now in France, MAR has only been available to heterosexual couples on medical indication. The law on bioethics, to be promulgated in 2021, extends MAR to female couples and single women. Activity in MAR centers has therefore risen sharply. Use of the connected mobile app was associated with a considerable decrease in the number of phone calls during the day. This resulted in significant time savings for the medical team, who were therefore able to perform other tasks. The women received their treatment advice in a secure manner, which had not been the case previously. The women felt reassured and less stressed about making treatment mistakes.

We did not question the partners, but in the open-ended questions, some of them said that they were reassured to be able to read the treatment instructions and felt more involved in the care compared with the phone call.

At present, it is difficult to quantify the extent of treatment errors during an ovarian stimulation program. Till date, no study has been published in the literature on this subject. Nevertheless, along with the treatment reminders, the fact that the woman's prescription is given in writing in the app and can be accessed at any time (and in several languages, if required) probably helped to reduce forgetfulness and treatment administration errors. This traceability is essential for secure communication between patients and professionals. Barrière et al [15] conducted an observational, real-life, longitudinal study involving 488 patients from 28 infertility centers in France to evaluate patient–infertility care provider relationships and communication in Assisted Reproductive Technology centers and investigate whether the quality of the care provided had an impact on patient adherence to treatment and monitoring protocols. They showed that even when patient-physician relationships appear to be satisfactory, patient miscomprehension and noncompliance during infertility treatment may be underestimated, and improvements in communication are also required.

Several studies [16,17] and reviews of the literature [18-20] have shown that stress is a major risk factor for impaired quality of life and a poor experience of infertility treatment. It also exposes patients to the risk of abandoning assisted reproduction procedures, thereby reducing their chances of pregnancy. It is therefore conceivable that mobile apps can reassure patients undergoing infertility treatments and consequently reduce the stress inherent in these procedures, as suggested in a recent review [21]. Further studies using standardized questionnaires and comparing the anxiety levels of the app users with those of nonusers could answer this hypothesis. The risk of dropping out of infertility management procedures could also be compared between these two groups.

Over the last decade, huge progress has been made in information and communication technology. "eHealth" and smart (connected) devices have brought together services that facilitate communication with the patient and thus improve the overall quality of care (teleconsultations, electronic health records, smart eHealth apps, etc) [22]. Telemedicine enables medical data to be shared with the patient or between health care professionals. Many connected health apps have been developed – notably in the fields of radiology and cardiology [23]. A recent study showed that connected health technologies can facilitate access to cancer care and improve the patient's psychological well-being and quality of life [24]. Recently, connected apps have been developed for use in gynecology and obstetrics [25]. There are probably other connected apps in the world in the field of fertility, but to date and to our knowledge, there are very few publications on this subject. Boivin et al [26] were interested in the development of a mobile app (MediEmo) to provide support during medically assisted reproduction. MediEmo is an app combining patient medication diary management and ease of integration into clinic systems with emotional support and data capture. They showed that 98% of patients expressed willingness to use the app, and almost 80% did so. Thus, the development of smartphone apps can contribute to fertility care and should be encouraged.

The profile of women in MAR programs is particularly suitable for this type of development: they are young and active and they all use a smartphone.

The protection of the patients' personal data is a crucial aspect in the development of connected health technologies [27,28]. WiStim complies with the European Union's General Data Protection Regulation, and the app's host is accredited by the French Ministry of Health.

One limitation is that the app is currently fee-based, although various funding options are being considered. In the present case, our hospital paid for the subscription to the app, and so it was cost-free for the users. However, the hospital's finance department is currently carrying out a medical-economic survey to assess the profitability of financing the app in relation to the time saved by the midwives. In fact, the midwife who used to call patients back can now do consultations instead.

Another limitation is the relatively small number of questionnaires analyzed and the fact that this was a single-center study. These are preliminary results, and they pave the way for further investigations in a larger population. Indeed, a multicenter study, with more questionnaires and over a longer period would be desirable to confirm these data.

Moreover, the questionnaires were distributed as soon as the app was installed in the department, so a learning curve was necessary for both patients and professionals. Overall satisfaction is probably higher now that the tool is better understood. Till now, all our patients have used the app.

Conclusion

Our results showed that the use of the connected health care app reassured women during the ovarian stimulation phase of a MAR program. Both the women and the medical team considered that the app was easy and intuitive to use. The information on treatment was sent in a secure manner and could be accessed around the clock by the patient. Connected health care apps have been developed widely in recent years. WiStim is one of the first reliable, secure apps in the field of MAR. Given the growth in demand for the MAR program and the medical team's workload, the time savings provided by the app constitute a nonnegligible advantage.

Abstract

Background: Symptoms of insomnia, nightmares, and trauma are highly prevalent. However, there are significant barriers to accessing evidence-based treatments for these conditions, leading to poor mental health outcomes.

Objective: This pilot trial evaluated the feasibility of a 4-week, digital self-paced intervention combining cognitive behavioral therapy for insomnia and exposure, relaxation, and rescripting therapy for nightmares in survivors of wildfires from Australia, Canada, and the United States.

Methods: Study participants were recruited between May 2023 and December 2023 through social media platforms, workshops, conferences, and radio interviews. Participants had to meet at least one of the following criteria: a score of ≥8 on the Insomnia Severity Index, a score of ≥3 on the Nightmare Disorder Index, or a score of ≥31 on the PTSD Checklist for DSM-5. In total, 30 survivors of wildfires were allocated to either the treatment group (n=16, 53%) or the waitlist control group (n=14, 47%) in a sequential manner. Participants' ages ranged from 18 to 79 years, with a mean age of 52.50 (SD 16.26) years. The cohort consisted of 63% (19/30) female and 37% (11/30) male participants. Participants also completed self-report secondary outcome measures, including the Generalized Anxiety Disorder–7, the Patient Health Questionnaire–9, and the Pittsburgh Sleep Quality Index, via the HealthZone digital platform. Assessments were conducted at baseline, the posttreatment time point, and the 3-month follow-up, with the waitlist group undergoing an additional assessment at the pretreatment time point, after 4 weeks of waiting and before crossing over to treatment. This study used intention-to-treat analysis as a primary analysis and per-protocol analysis as a secondary analysis.

Results: Mixed-effects linear regression models and difference-in-differences analyses were used to assess the intervention's effects. The intention-to-treat analysis revealed significant improvements over time (main effect of time), with a 1.64-point reduction (P=.001) on the Nightmare Disorder Index and 10.64-point reduction (P=.009) on the PTSD Checklist for DSM-5 at the postintervention time point. No significant changes were observed in insomnia symptoms. On the secondary measures, there was an interaction effect of condition × time, with a 2.22-point reduction (P<.001) on the Pittsburgh Sleep Quality Index, and a main effect of time, with a 6.48-point reduction (P<.001) on the Patient Health Questionnaire–9. No changes were detected on

the Generalized Anxiety Disorder–7. The per-protocol analysis yielded comparable results for both the primary and secondary measures.

Conclusions: The findings of this pilot trial demonstrated a reduction in nightmares and trauma symptoms. Future research studies should aim at evaluating the intervention in a more definitive trial with a larger sample size.

Introduction

Background

The consequences of wildfires can be devastating, resulting in significant losses of life, property, and livelihood. According to the Emergency Events Database, wildfires have been responsible for 1890 fatalities and 14,360 injuries between 2000 and 2023, with the highest tolls observed in Australia, New Zealand, Southern Europe, and North America [1]. The impact of wildfires extends far beyond the immediate loss of life and property, with survivors often experiencing a range of physical and emotional challenges that can have long-lasting effects. Physical injuries, such as bodily burns, smoke inhalation, and eye irritation, as well as increased risk of myocardial infarction and certain types of cancers, are a significant concern for survivors [2-4]. In addition, the proximity of wildfires to residential areas can have a profound impact on overall well-being, with research showing that life satisfaction decreases significantly in areas within 0 to 15 km of the fires [5]. The traumatic experience of a wildfire can also leave a lasting emotional impact, with survivors often reporting persistent feelings of fear and unsafety that can linger long after the initial event [5].

Beyond the physical and emotional challenges, many survivors face significant financial pressures, including the cost of rebuilding or relocating. For those who have lost their homes, the decision of whether to rebuild can be a difficult and emotional one, with financial pressures and the loss of a sense of security and community adding to the burden [3]. Others may experience stressors related to the loss of a workplace, hardship, and financial uncertainty. Therefore, the availability and timing of government relief and community support services are critical in facilitating the recovery of communities and individuals, with initiatives such as rehousing and recovery projects, psychological support, and primary producer repair and restoration [3,5] helping mitigate the impact of wildfires. However, when such support is not provided in a timely manner, emotional and psychological distress can intensify, leading to multiple psychological problems that can become highly resistant to treatment.

This is particularly concerning as research has shown that exposure to wildfires can have a significant impact on emotional well-being. Over the past decade, there has been a growing interest in investigating the impact of wildfire trauma on mental health [6,7]. Posttraumatic stress disorder (PTSD) is among the more severe mental health conditions that may arise immediately or in the months following exposure to traumatic events [7]. Exposure to wildfires, which pose a significant threat to life or well-being, can increase an individual's risk of developing PTSD. People with PTSD may exhibit symptoms such as reliving traumatic events through nightmares or flashbacks; sleeping difficulties; irritability; intrusive memories; feelings of horror, shame, and anger; avoidance of reminders of the traumatic event; alterations in arousal state or mood and cognition; and difficulties with work and daily activities [8].

Sleep disturbances are prominent features of PTSD and are frequently reported following trauma [9,10]. The onset of sleep disturbances following exposure to traumatic events is a strong predictor of the development of PTSD [11]. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*), insomnia and nightmares fall under the re-experiencing and the hyperarousal clusters of PTSD symptoms [8]. Insomnia is the most prevalent sleep disturbance in survivors of wildfires and is characterized by difficulty initiating or maintaining sleep or early-morning awakening [8]. Survivors of trauma also frequently experience nightmares, which are repeated distressing and well-remembered narrative dreams that lead to the individual waking up in a fight-flight state of alertness and having difficulty returning to sleep or even trying to avoid sleeping [8]. A study examining sleep disturbances and PTSD in survivors of wildfires revealed that approximately 49.2% (n=126) experienced symptoms of insomnia, 28.7% experienced nightmares, and 77.9% reported PTSD symptoms [12].

Studies suggest that cognitive behavioral therapy for insomnia (CBTi); cognitive behavioral therapy (CBT) for PTSD; and exposure, relaxation, and rescripting therapy (ERRT) for nightmares are effective treatments for insomnia, nightmares, and other trauma symptoms [13-18]. CBTi includes stimulus control, sleep hygiene, sleep restriction, cognitive restructuring, and relaxation training [19,20]. Nightmare treatment using ERRT is effective in giving those who experience nightmares a sense of control over the nightmare through writing benign dreams that can be rehearsed verbally or mentally [21]. The treatment focuses on addressing the themes presented in the nightmare and incorporates rescripting, imagery or verbal rehearsal, relaxation, and sleep hygiene elements [22,23].

Most research on trauma and sleep disorders has been conducted with military veterans, who have been the primary focus of clinical trials and studies in this area [24-26]. There is a need to focus on developing treatments for people who have experienced the trauma of natural disasters, including wildfires. There have only been 2 clinical trials addressing the treatment of sleep disturbances and PTSD in survivors of wildfires [27,28]. Both trials have shown that the administration of sleep dynamic therapy and CBTi therapist-assisted self-help interventions led to a significant reduction in insomnia and PTSD symptoms following treatment.

Objectives

While studies support the effectiveness of CBT, CBTi, and ERRT in treating trauma symptoms, insomnia, and nightmares, accessing these treatments can be challenging, particularly when wildfires cause destruction to infrastructure. This, in turn, causes difficulty in the delivery of counseling services to remote locations where large numbers of people are affected and in great need. Digital therapies can bridge this gap by delivering evidence-based treatments in communities affected by the trauma of wildfires [29,30]. However, the feasibility of digital therapies should be first examined in clinical trials before they are operationalized in the field [27,31]. Therefore, a brief, digital, self-paced, multicomponent therapeutic approach incorporating CBTi for insomnia, CBT for PTSD, and ERRT for nightmares was developed. The main objective of this pilot trial was to assess the feasibility of an intervention called Sleep Best-i in alleviating symptoms of insomnia, nightmares, and PTSD among survivors of wildfires. A secondary research objective was to undertake a comparative analysis of the degree of symptom reduction between the intervention and the waitlist control groups, with a view to informing an assessment of the feasibility of conducting a future definitive randomized controlled trial. Specifically, this assessment aimed to evaluate the acceptability and usability of the Sleep Best-i intervention. This clinical pilot trial tested the following hypotheses: (1) Sleep Best-i will result in significant reductions in insomnia, nightmares, and PTSD symptoms from baseline to the posttreatment time point compared to the waitlist group; (2) Sleep Best-i will also lead to significant reductions in anxiety and depression scores and improvements in sleep quality from baseline to the posttreatment time point compared to the waitlist group; and (3) both groups (within-group effects) will experience significant improvements in all measures (insomnia, nightmares, PTSD symptoms, anxiety, depression, and sleep quality) from baseline to the posttreatment time point, and these improvements will be maintained at the 3-month follow-up after receiving Sleep Best-i.

Methods

Study Design

This study used a parallel-arm, sequential alternation method of randomizing participants to either the intervention or waitlist group in a 50:50 ratio, with a crossover of the latter group. The alternation method ensures the ability to answer questions about the effectiveness of treatments to inform decision-making in clinical practice [32]. The treatment group completed self-report assessments at baseline, at the posttreatment time point following the administration of Sleep Best-i, and at the 3-month follow-up. The waitlist group completed the same assessments at baseline, at the pretreatment time point (following 4 weeks of waiting and before crossing over to treatment), at the posttreatment time point following the administration of Sleep Best-i, and at the 3-month follow-up. The CONSORT (Consolidated Standards of Reporting Trials) checklist was followed [33]. Please refer to Appendix 1 for the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (Multimedia Appendix 1).

Ethical Considerations

Following ethics approval from the Federation University Human Research Ethics Committee (approval 2022-153), an advertisement about the study was distributed. Survivors of wildfires interested in the study read a plain-language information statement (PLIS) about the study and provided baseline data. Participants who met the selection criteria provided informed consent by checking a box on a digital consent form hosted on Federation University's HealthZone platform, thereby indicating their agreement to take part in the study. Participants were informed that their participation was voluntary. To ensure the secure storage and handling of collected information, data were stored on a password-protected digital health platform (HealthZone) during the trial accessible only to the researchers involved in the study. To protect participants' confidentiality, names were replaced with unique identifiers, and only country of residence was collected, with no addresses recorded. The data will be retained for 15 years before being destroyed. To manage any potential risks, participants were provided with emergency contact numbers relevant to their country of residence. As a gesture of appreciation, participants who completed the study were offered an Aus $100 e-voucher (approximately US $66.70).

Participants

Participants were recruited between May 2023 and December 2023 via social media platforms, including international Facebook campaigns, radio broadcasts, LinkedIn, Reddit, and online community noticeboards. This study was also advertised on the Natural Hazards Research Australia and the Australian Institute for Disaster Resilience websites.

Adult survivors of wildfires from Australia, Canada, and the United States aged ≥18 years were invited to take part in the clinical pilot trial if they had experienced wildfires at any point in the past and had sleep or trauma symptoms.

An a priori power analysis indicated that a sample size of 50 was required to detect meaningful differences between the intervention and waitlist groups considering an α value of .05, a value of *d* of 1.0, an attrition rate of 20%, and 80% power [34].

Inclusion Criteria

To be eligible to take part in the trial, participants had to (1) provide digital consent; (2) have a score of ≥8 on the Insomnia Severity Index (ISI), (3) a score of ≥3 on the Nightmare Disorder

Index (NDI), or (4) a score of ≥31 on the PTSD Checklist for DSM-5 (PCL-5); (5) be fluent in the English language; and (6) have access to the internet. Exclusion criteria included not being a survivor of a wildfire, diagnosis of a psychotic disorder, suicide risk, diagnosis of sleep apnea or restless leg syndrome, diagnosis of alcohol or drug dependence, and attendance to psychotherapy for either sleep or PTSD conditions. In addition, participants were excluded if they were currently using steroids for any health condition; medications that promote sleep, such as benzodiazepines (eg, alprazolam, clonazepam, and temazepam); or medications that may affect sleep, such as opiates or other pain medications. By excluding these individuals, this study aimed to ensure that participants were suitable for the trial and that the results would not be confounded by other factors.

Procedure

The trial was registered prospectively in the Australian New Zealand Clinical Trials Registry (ACTRN12623000415606). Since its initiation, this study's protocol has undergone only minor revisions, specifically an update to the statistical analysis methodology to include linear mixed methods and intention-to-treat (ITT) analysis.

An advertisement of this pilot study with a URL was distributed on social media platforms displaying Federation University and the Natural Hazards Research Australia affiliations. This study was also promoted in national conferences, sleep workshops delivered to communities affected by wildfires, the Red Cross, and group meetings for people with sleep disorders in Australia. Radio interviews were also undertaken to promote the study. Survivors of wildfires who were interested read a PLIS (refer to Multimedia Appendix 2 for PLIS); signed a digital consent form (refer to Multimedia Appendix 3 for the consent form) to register an account on Federation University's digital HealthZone platform; and provided baseline data by completing a demographic questionnaire as well as self-report measures on insomnia, nightmares, and trauma symptoms. Participants had the option of providing a pseudonym if they wished. However, they needed to provide a valid email address to allow for communication about the study. Their email addresses were also directly connected to their personal dashboard on HealthZone. The baseline data were viewed by 2 researchers to decide eligibility. Those who were eligible (assessed by FI and GAK, both clinical psychologists) were contacted via email to notify them of their eligibility and their randomization and receive instructions on how to access their personal dashboard on HealthZone. Participants were sequentially allocated via simple randomization in the order of their enrollment (using a computer-generated simple randomization sequence), and they were informed about the purpose, allocation, and structure of the study as explained in the PLIS. However, they were not informed about the study's hypotheses. Once participants gained access to their personal dashboard within HealthZone, they were able to access information about the trial, complete the self-report secondary measures, and access the treatment modules consecutively. The treatment modules were provided at no cost, allowing participants to use their own devices and access the program and its modules on various platforms, including mobile devices, tablets, and desktop computers. HealthZone features a responsive web design compatible with both iOS and Android operating systems, making it easily accessible. Participant response data were captured on all devices. The modules were released sequentially to participants over 4 weeks. All data were collected through self-report measures at prespecified intervals. Participants were instructed to complete a module or a set of 2 modules each week along with the required interval assessments. Automated email reminders alerted participants about the release of each module and the specified assessments. If the modules were not viewed within the first 3 days of their release, an automated email reminder was sent to participants, and a second reminder was sent on the seventh day of their release. Automated email reminders at a similar frequency were also used for the primary and secondary measures (self-report scales). The personal dashboard was accessible to participants at any time. A "Contact us" tab was available on the personal dashboard that allowed participants to contact the research team and ask questions about the study or express any concerns. A total of 7% (2/30) of the participants were unsure about how to access the modules, and 3% (1/30) had an inquiry about one of the modules.

The research team sent 2 follow-up emails spaced 2 weeks apart to participants who registered, were randomized, but did not commence treatment, serving as a reminder about the study and to gauge their ongoing interest in participating.

The modules were available to participants from the start of the trial to the end of the follow-up period. Participants were able to access their dashboard for 4 weeks following the 3-month follow-up data collection. HealthZone recorded data about the number of log-ins, number of pages visited, and date of commencement and duration of participation for each participant. Each module was 17 minutes in duration. Therefore, participants were expected to spend at least 3 hours over the 4 weeks to indicate adherence to treatment. This time is optimal for viewing all modules and completing all assessments. No statistical analyses were conducted in the interim of the study. HealthZone was monitored daily during the trial to track any potential concerns or issues associated with the site or the participants.

Treatment Protocol

Sleep Best-i Intervention

Sleep Best-i was specifically designed for this clinical trial by some of the researchers who conducted this study (FI, BK, and GAK). The collated treatment manual draws from evidence-based treatment manuals authored by other sleep researchers [19,21,35-39]. The main therapeutic methods used in the manual were CBTi and ERRT. The recorded digital modules feature human-recorded voice and animated videos using VideoScribe (Sparkol) [40] that explain concepts related to sleep and trauma symptoms. The intervention also offers 2 role-plays of therapeutic sessions to demonstrate the administration of cognitive restructuring, dream rescripting, and sleep scheduling. Sleep Best-i consists of 6 modules administered over a 4-week period. In addition, the program is accessible via a platform that uses a responsive web design, with no requirement for a specific app or download. This allows participants to access the program from a variety of devices

(including mobile phones), as well as their preferred web browser. By being web based, the program can be easily accessed from anywhere at any time, making it a convenient and flexible intervention.

Participants were encouraged to complete the entire Sleep Best-i program, but completion of each module was not mandatory. This allowed individuals to engage with relevant content tailored to their specific needs, whether they experienced nightmares, PTSD, insomnia, or a combination of these conditions. Furthermore, participants had the flexibility to stop and start the program as desired, and all modules were available for the entire study period, enabling them to revisit specific modules should they wish to do so.

Table 1 shows the therapeutic modality offered in each module. Once released, the modules remained unchanged throughout the trial, and the intervention was successfully implemented without encountering technical difficulties. There were periodical checks to ensure that the modules were compliant with the treatment manual. All links have been archived in the Wayback Machine (Internet Archive).

Table 1. Sleep Best-i modules and the treatment offered in each module. All modules were approximately 17 minutes in duration.

Module	Strategies offered
Module 1 (psychoeducation)	Offered at week 1, the module provided psychoeducation about sleep and insomnia, the stages of sleep, and the neurobiology of sleep [14].
Module 2—part 1 (cognitive restructuring and sleep hygiene)	Offered at week 1, the module focused on the cognitive component of CBTi[a], types of unhelpful thoughts, methods to challenge unhelpful thoughts, and sleep hygiene [30].
Module 2—part 2 (sleep scheduling and stimulus control)	Offered at week 2, the module educated participants about specifying regular sleeping and waking up times with as little variation as possible between the 2. Stimulus control restricted the bedroom or the bed to sleep only [34].
Module 3 (trauma, PTSD[b], and flashbacks)	Offered at week 3, the module provided psychoeducation about trauma, PTSD, flashbacks, and how trauma leads to sleep difficulties. It also provided behavioral interventions for trauma symptoms.
Module 4 (nightmares)	Offered at week 4, the module explored nightmare disorder, how nightmares develop, and how to rescript the nightmare into a more neutral dream [16].
Module 5 (relapse prevention)	Offered at week 4, the module focused on identifying early warning signs and methods preventing relapse of symptoms [33].
Mindfulness module	This module offered a recorded progressive muscle relaxation mindfulness, and it was available to participants throughout the study.

[a]CBTi: cognitive behavioral therapy for insomnia.

[b]PTSD: posttraumatic stress disorder.

Waitlist Control Group

Following a waiting period of 4 weeks, the waitlist control group received Sleep Best-i in the same sequence in which it was released to the treatment group.

Measures

Overview

All scales were digital, self-report measures that were administered through HealthZone. The self-report measures as well as the modules were tested by 2 research team members (FI and BK) before being released to participants. The order of the modules and the questions were the same for all participants in the 2 groups.

Demographic Data

Participants provided the following information: name, email address, age, sex, employment status, educational level, marital status, country of residence, experience with wildfires, history of taking steroids, diagnosis of sleep apnea or restless leg syndrome, diagnosis of a psychotic disorder, use of alcohol or drug dependence, type of medications used to assist with sleeping, history of antidepressant use, and whether they were attending psychotherapy for sleep or PTSD.

Primary Measures

ISI Measure

The ISI [41] includes 7 items that assess insomnia severity through the subjective experience of sleep. The score varies from 0 to 28, with higher scores indicating more severe insomnia symptoms. A score of ≥8 indicates the presence of a subthreshold insomnia. Previous studies have demonstrated strong internal consistency for the ISI, with Cronbach α values ranging from 0.87 to 0.92, indicating high reliability [42].

NDI Measure

This scale consists of 5 items that assess symptoms of nightmares according to the DSM-5 criteria by screening for the occurrence of nightmares in a given week. The 5 items are summed to obtain a score between 0 and 20, with higher scores representing greater nightmare severity. The NDI exhibits good internal consistency, with a Cronbach α of 0.80 [43].

PCL-5 Measure

The PCL-5 [44] includes 20 self-report items assessing the presence of PTSD symptoms over a 1-month interval. A global score that ranges between 0 and 80 is obtained by summing the 20 items. A cutoff score of 31 provides optimal sensitivity and specificity in providing a provisional diagnosis of PTSD [45].

The PCL-5 has good psychometric properties, with an internal consistency of Cronbach α=0.94 [46].

Secondary Measures

Generalized Anxiety Disorder–7

This scale is a 7-item, self-report measure that assesses anxiety symptoms over a 2-week interval. A score from 0 to 21 is obtained by summing the 7 items. The Generalized Anxiety Disorder–7 (GAD-7) [47] has a good internal consistency, with a Cronbach α ranging between 0.82 and 0.93 [48]. A cutoff score of 10 discriminates between mild and severe symptoms of anxiety [48].

Patient Health Questionnaire–9

This scale consists of 9 items assessing symptoms of depression over the last 2 weeks. The overall score is obtained by summing all the 9 items and ranges from 0 to 27. A cutoff score of 10 is considered optimal in discriminating between mild and severe symptoms of depression [49]. In this study, the Cronbach α for the Patient Health Questionnaire–9 (PHQ-9) was 0.86.

Pittsburgh Sleep Quality Index

The Pittsburgh Sleep Quality Index (PSQI) [50] consists of 19 items assessing sleep quality and disturbances related to sleep over a 1-month interval. A global score ranging between 0 and 21 is generated by summing 7 components of sleep quality. A global PSQI score of >5 is considered a sensitive and specific cutoff to discriminate between good and poor sleep quality [51]. The PSQI has a good internal validity, with the Cronbach α ranging between 0.79 and 0.81 [51].

Satisfaction and Level of Engagement With Treatment

One question was designed for this study to measure satisfaction with Sleep Best-i. Participants were asked to rate how likely they were to revisit the Sleep Best-i modules on a 5-point Likert scale from *strongly disagree* to *strongly agree* (0-4). To assess level of engagement with treatment, the number of log-ins and amount of time that each participant spent on the site were monitored.

Data Analysis

Data analyses were conducted using the Stata statistical software package (version 18; StataCorp) [52]. All variables were inspected for normality and outliers. An inspection of histograms and *Q-Q* plots revealed normally distributed data. Upon inspection of box plots on all scales, 1 outlier was identified on the PCL-5 at the 3-month follow-up assessment, a second outlier was detected on the PHQ-9 at the 3-month follow-up, and a third outlier was detected on the PSQI at the waitlist assessment (3-month follow-up assessment). The results did not differ upon removing the outliers from the analyses; therefore, the outliers were retained [53,54]. To ensure a robust evaluation of the intervention's feasibility, the ITT analysis with 30 participants and the per protocol (PP) analysis with a sample of 20 were used, allowing for a comprehensive assessment of treatment outcomes, thereby enhancing the accuracy and generalizability of the findings [33,55,56].

For both analyses, missing data were addressed using multiple imputation by chained equations. This approach is more robust than other methods such as single imputation because it generates multiple predictions for each missing value, accounting for uncertainty in the imputations and yielding more accurate SEs [57]. To impute missing data, background variables such as age, sex, educational level, employment status, country, and relationship status; baseline measures; and the most recent observations of each outcome were used.

To address uncertainty, each missing value was imputed 20 times using predictive mean matching based on the 3 nearest values across multiple iterations to create 100 imputed datasets. The imputed values were then averaged to create the final estimates [58]. Predictive mean matching, a partially parametric method, is preferable to fully parametric linear regression as it remains effective even when the normality assumption of the underlying variable is violated. This method also helps preserve the distribution of observed values in the missing data [59]. Missing value analysis indicated that the data were missing completely at random (Little missing completely at random test: $\chi^2_{867}=0.0$, $P>.99$), meaning that the differences between the missing and observed data were related to observed characteristics [60].

Adjusted analyses of intervention effects were conducted using mixed-effects linear regression models. Both fixed and random effects were estimated to assess the impact of the intervention on the change in all outcomes (primary and secondary) over time and by condition. Given that observed covariates were balanced between the 2 conditions (waitlist and treatment), the difference-in-differences (DID) effect for the fixed part of the mixed-effects models was tested by including interaction terms for time point and condition. DID is considered the most appropriate measure to assess causal effects in time-series designs as it effectively controls for time-invariant confounding variables. By doing so, DID reduces bias and enhances internal validity, providing a more accurate estimate of the treatment effect [61].

The appropriateness of the mixed-effects model for each outcome was assessed using chi-square statistics ($P<.05$). Random-intercept linear models were compared with random-intercept, random-slope models using likelihood ratio tests. The random-intercept, random-slope model was reported only if the likelihood ratio test indicated $P<.05$; otherwise, the simpler random-intercept model was selected. A significant effect of the intervention or difference in outcome between groups was assessed using a 2-tailed test of significance with $P<.05$.

A sensitivity analysis was conducted to test whether the model and covariance structures were misspecified. Several major types of covariance structures, including independent, unstructured, exchangeable, identity, and autoregressive structures, were examined. In addition, the model parameters using both maximum likelihood and restricted maximum likelihood methods were estimated. Although the results were generally consistent across different covariance structures, the model with an exchangeable structure was deemed the best fit.

Clinical Significance

Clinical significance was assessed for the 2 groups from baseline to the 3-month follow-up. To evaluate the clinical significance on sleep and trauma measures, specific criteria were used for each scale. For example, for the ISI, a cutoff score of ≤8 with a ≥6-point reduction in scores was used to assess whether participants reached a minimal clinically significant change (MCSC) [26,62]. For the NDI, there are no established criteria for MCSC; therefore, a cutoff score of ≤7 as suggested by Dietch et al [43] was used. Marx et al [63] recommend a score of ≤28 and a drop of ≥18 points on the PCL-5 as a guide for MCSC.

Results

Overview

A total of 33 participants responded to the advertisement, registered an account with Federation University's digital HealthZone platform, and provided baseline data. In total, 9% (3/33) were excluded because they did not meet the selection criteria, and 91% (30/33) were randomized to either the intervention or the waitlist group. A total of 53% (16/30) were randomized into the intervention group, and 47% (14/30) were in the waitlist group (for the participant CONSORT chart, refer to Figure 1). Ages ranged between 18 and 79 years (mean 52.50, SD 16.26 years; N=30), with most participants (19/30, 63%) being female (vs 11/30, 37% male). A total of 67% (20/30) of the participants completed the trial, and their data were analyzed as PP. The ages of the latter group ranged from 18 to 79 years (mean 53.75, SD 16.54 years), with most participants (14/20, 70%) being female (6/20, 30% were male). Demographic variables for the treatment and waitlist groups are shown in Table 2.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flowchart showing participant flow through allocation to the treatment and waitlist conditions. ISI: Insomnia Severity Index; ITT: intention to treat; NDI: Nightmare Disorder Index; PCL-5: PTSD Checklist for DSM-5; PP: per protocol.

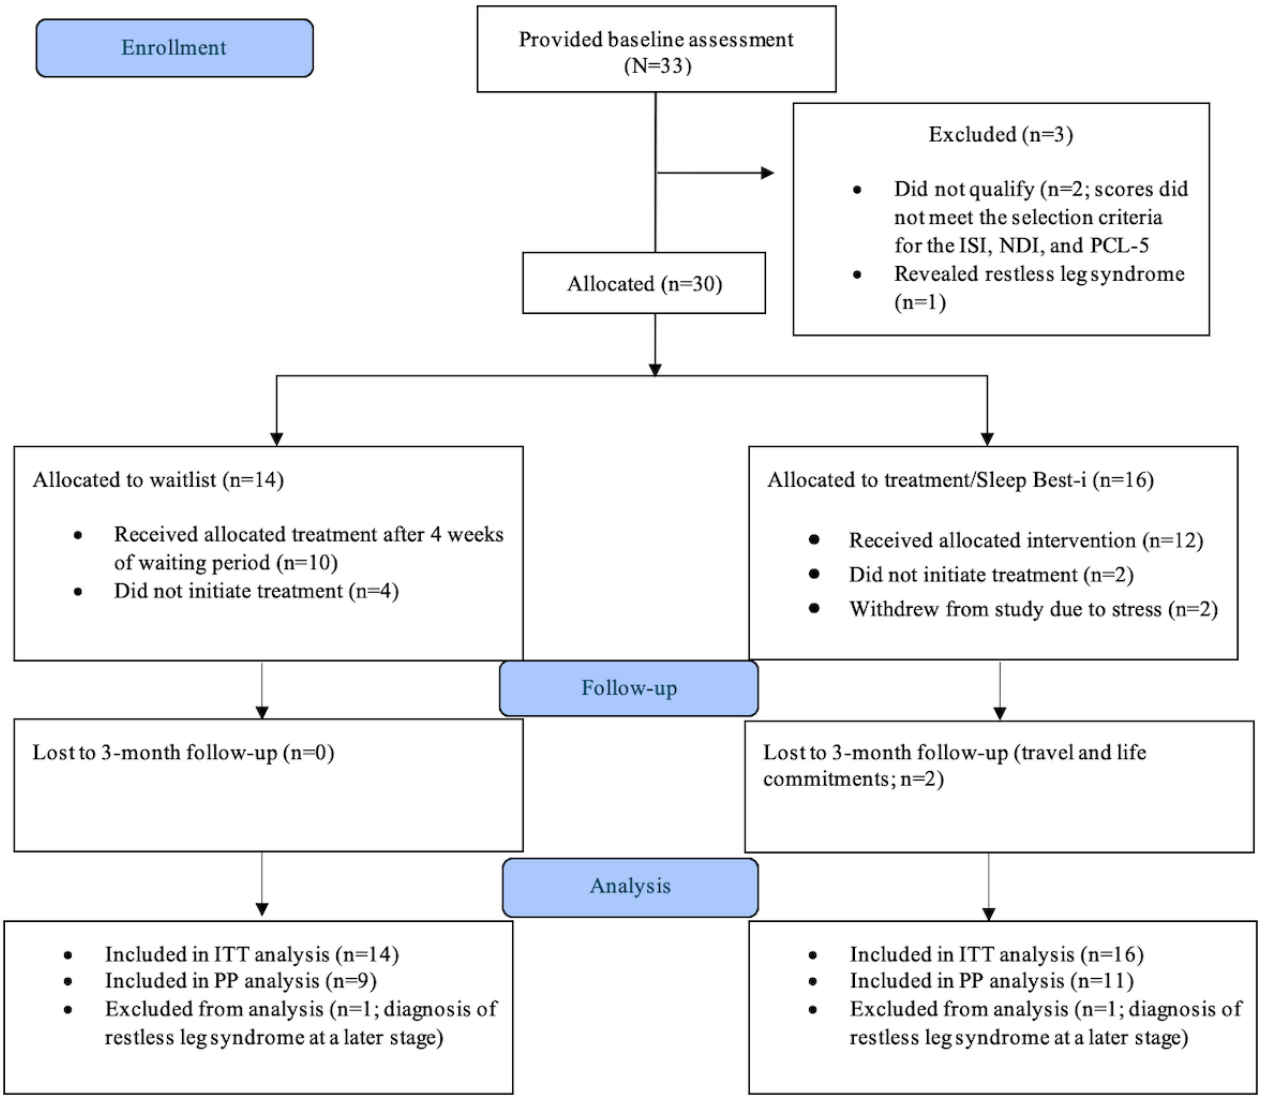

Table 2. Demographic variables for the treatment and waitlist groups and differences between the 2 at the baseline assessments.

Demographics	Treatment (n=16)	Waitlist (n=14)	Statistic	*P* value[a]

[a]Significance level at $P<.05$.

[b]Not applicable.

A total of 4 participants were excluded from the PP analysis for the following reasons: 2 (50%) participants, who completed the pilot trial and provided a complete set of data, revealed that they had restless leg syndrome that was not initially reported during the screening process; 1 (25%) participant received 1 treatment module but withdrew from the study due to illness, providing only baseline measures; and a fourth participant (25%) who provided and completed 50% of the data and modules withdrew due to illness and family commitments. Therefore, the PP analysis was conducted on a sample of 20 participants.

In total, 20% (6/30) of the participants provided baseline data; however, they did not initiate treatment and did not respond to emails sent by the research team. Table 1 indicates that there were no significant differences in demographic variables between the intervention and waitlist groups at the baseline assessment (age, *P*=.28; biological sex, *P*=.51; education level, *P*=.75; employment status, *P*=.64; and relationship status, *P*=.05).

To address hypothesis 1, ITT analysis of the mixed-effects regression, including the effect sizes of the DID in the fixed-effects component and the variability in the random-effects component, showed that, at baseline, the waitlist group had mean scores of 3.16, 0.39, and 45.29 on the ISI, NDI, and PCL-5, respectively. At the postintervention time point, the main effect of time, these scores significantly decreased by 1.64 points on the NDI (*P*=.001) and 10.64 points on the PCL-5 (*P*=.009), but no significant (*P*=.06) change was detected on the ISI. The treatment group showed slightly lower baseline scores than the waitlist group, with mean differences of 0.45, 0.04, and 9.20 for the ISI, NDI, and PCL-5, respectively, suggesting that the 2 groups were relatively balanced at baseline. The adjusted DID effects following the treatment indicated that the treatment group experienced greater improvements in mental health measures compared to the waitlist group, with differences of 1.54 points for the ISI, 1.22 points for the NDI, and 4.98 points for the PCL-5. Notably, the improvement in the NDI was marginally significant (*P*=.06), whereas the improvements in the ISI and PCL-5 were not statistically significant (*P*=.26 and *P*=.37, respectively; Table 3).

Table 3. Mixed-effects linear regression analysis of the effect of the intervention on primary outcomes (intention-to-treat analysis; N=30)[a].

Variable	Model 1 (n=60[b]; ISI[c])		Model 2 (n=60[b]; NDI[d])		Model 3 (n=60[b]; PCL-5[e])

[a]All models were adjusted for the baseline measure to address the regression-to-mean issue except for model 3, where the baseline measure was excluded for simplicity and convergence.

[b]*n* represents the number of observations in the data with long format to support mixed-effects modeling.

[c]ISI: Insomnia Severity Index.

[d]NDI: Nightmare Disorder Index.

[e]PCL-5: PTSD Checklist for DSM-5.

[f]Model fit—*P*<.001 (Wald chi-square test) and *P*=.03 (likelihood ratio test [LRT]) to compare the mixed-effects models with random-intercept linear models.

[g]Model fit—*P*<.001 (Wald chi-square test) and *P*=.001 (LRT) to compare the mixed-effects models with random-intercept linear models.

[h]Model fit—*P*<.001 (Wald chi-square test) and *P*=.19 (LRT) to compare the mixed-effects models with random-intercept linear models.

[i]Not available.

[j]N/A: not applicable as the random-intercept model better fit the data than the random-intercept, random-slope model. Given its better fit, random-intercept model parameters were reported.

In the random-effects part, there was substantial variability among individuals, with average deviations of 1.41, 0.82, and 10.82 points for the ISI, NDI, and PCL-5, respectively, around both the baseline and postintervention means. This suggests considerable individual variability in the outcomes. The positive correlation coefficients between the time point and the intercept indicate that participants with higher baseline scores (above the overall sample mean) were more likely to experience greater decreases in their scores over time compared to those with lower baseline scores. All mixed-effects models for the ISI, NDI, and PCL-5 were statistically significant (*P*<.001). Specifically, the random-intercept, random-slope model was appropriate for the

ISI (*P*=.03) and NDI (*P*=.001), whereas a random intercept–only model was sufficient for the PCL-5, which also fit the data but with a nonsignificant *P* value (*P*>.05 and *P*=.19; Table 3). Figure 2 illustrates the changes in primary outcome measures (ISI, NDI, and PCL-5) from before to after treatment based on the ITT analysis.

For completers only, PP analysis of the mixed-effects regression showed that, at baseline, the waitlist group had mean scores of 5.58, 0.46, and 13.37 on the ISI, NDI, and PCL-5, respectively. At the postintervention time point, these scores did not significantly change for the 3 measures (ISI; *P*=.68, NDI; *P*=.24, PCL-5; and *P*=.35). The treatment group baseline scores were balanced compared to those of the waitlist group, with mean differences of 0.99, 0.04, and 3.05 for the ISI, NDI, and PCL-5, respectively. However, the adjusted DID effects indicated an interaction effect of condition × time, with the treatment group experiencing greater and more significant improvements on the NDI with a decrease of 2.27 points (*P*=.049) and a decrease of 13.46 points on the PCL-5 (*P*=.03) but no significant improvements on the ISI (*P*=.25; Table 4).

There was a substantial variability among individuals, with average deviations of 3.41, 1.81, and 9.42 points for the ISI, NDI, and PCL-5, respectively, at the postintervention time point, suggesting considerable individual variability in the outcomes. All mixed-effects models for the ISI, NDI, and PCL-5 were statistically significant (*P*<.001), with a random-intercept model being appropriate for the 3 measures (Table 4).

In relation to the second hypothesis, the ITT analysis showed that, at baseline, the waitlist group had mean scores of 1.66, 12.01, and 0.69 on the GAD-7, PHQ-9, and PSQI, respectively (Table 5). Only the depression scores decreased significantly (*P*<.001) by 6.48 points at the posttreatment time point (main effect of time) in comparison to the waitlist group. The treatment group showed slightly lower baseline scores than those of the waitlist group on the secondary measures, with mean differences of 0.47, 0.90, and 0.04 on the GAD-7, PHQ-9, and PSQI, respectively, suggesting that the 2 groups were balanced at baseline. The adjusted effects at the postintervention time point indicate that the treatment group experienced greater improvements than the waitlist group on all measures but with only significant results on the PSQI (with a difference of 2.22 points; *P*<.001).

There was variability among individuals, as shown in Table 5, with average deviations of 0.91, 4.89, and 0.73 points for the GAD-7, PHQ-9, and PSQI, respectively, around both the baseline and postintervention means. The positive correlation coefficients for the GAD-7 and PSQI between the time point and the intercept indicate that participants with higher baseline scores (above the overall sample mean) were more likely to experience greater decrease in their scores over time compared to those with lower baseline scores. Mixed-effects models for the 3 measures were statistically significant (*P*<.001). Specifically, the random-intercept, random-slope model was appropriate for the PHQ-9 and PSQI (*P*=.007 and *P*=.001, respectively), whereas a random intercept–only model was sufficient for the GAD-7 (*P*=.08). Figure 3 shows the difference in decrease in scores between the intervention and waitlist groups for the GAD-7, PHQ-9, and PSQI from the ITT analysis.

For those who completed the study, PP analysis showed that the waitlist mean baseline scores were 11.78, 12.22, and 13.00 on the GAD-7, PHQ-9, and PSQI, respectively. These scores decreased significantly only for the PHQ-9 measure by 6.22 points at the posttreatment time point (*P*<.001). There was also a main effect of condition on the GAD-7 measure with a decrease of 4.14 points (*P*=.04) for the treatment group and an interaction effect of time × condition on the PSQI (*P*=.02), suggesting that the treatment group experienced significantly better sleep quality than the waitlist group following the treatment (Table 6).

Table 6 also shows a great variability among individuals on the random effects, with average deviations of 3.69, 3.16, and 2.82 points for the GAD-7, PHQ-9, and PSQI, respectively, around both the baseline and postintervention means. This suggests substantial individual variability in the outcome measures. Mixed-effects models for the 3 measures were statistically significant (*P*<.001), with the random-intercept, random-slope model being appropriate for the PHQ-9 (*P*=.004), whereas a random intercept–only model was sufficient for the GAD-7 and the PSQI (*P*=.28 and *P*>.99, respectively; Table 6).

To address the third hypothesis, separate mixed-effects linear model analyses were conducted for each group (intervention and waitlist) on all primary and secondary outcome measures. The analysis incorporated data from the following time points: baseline, posttreatment time point, and 3-month follow-up for the intervention group and pretreatment time point, posttreatment time point, and 3-month follow-up for the waitlist group. ITT analysis for the intervention group showed a significant reduction in insomnia, nightmares, and trauma symptoms as measured using the ISI, NDI, and PCL-5 both at the posttreatment time point (*P*<.001) with an effect of 3.42, 2.86, and 15.62 points, respectively, and at the 3-month follow-up (*P*<.001) with an effect of 8.64, 4.20, and 22.83 points, respectively (Table 7).

A great variability among individuals was detected on the random effects, with average deviations of 1.56, 0.32, and 11.09 points for the ISI, NDI, and PCL-5, respectively, around both the postintervention and 3-month follow-up means. Mixed-effects models for the 3 measures were statistically significant (*P*<.001), with the random-intercept, random-slope model being appropriate for the ISI and the PCL-5 (*P*=007 and *P*=.02, respectively), whereas the random-intercept model was appropriate for the NDI (*P*=.16; Table 7). Figure 4 shows the decrease in scores over time at the postintervention time point and 3-month follow-up for the intervention group.

For those who completed the study, the PP analysis showed comparable results to those reported in the ITT analysis, with a significant reduction in symptoms at both the postintervention time point (ISI; *P*=.04, NDI; *P*<.001, PCL-5; *P*<.001) and 3-month follow-up (*P*<.001 in all cases). The adjusted effects showed a continued reduction in symptoms from the postintervention time point to the 3-month follow-up, with a difference of 7.81, 4.86, and 23.71 points on the ISI, NDI, and PCL-5, respectively (Table 8).

The analysis also showed a substantial variability among individuals, with average deviations of 1.64, 1.03, and 1.81 points for the ISI, NDI, and PCL-5, respectively, around both the baseline and postintervention means. The positive correlation coefficients between the time point and the intercept on the NDI indicate that participants with higher baseline scores (above the overall sample mean) were more likely to experience greater decreases in their scores over time compared to those with lower baseline scores. All mixed-effects models for the ISI, NDI, and PCL-5 were statistically significant (P<.001), with a random-intercept model being sufficient for all 3 measures with a nonsignificant P value (ISI, P=.18; NDI, P=.07; and PCL-5, P=.42, Table 8).

On the secondary measures, the ITT analysis showed that the intervention group experienced significant improvements on the PHQ-9 and PSQI at both the posttreatment time point and the 3-month follow-up (P<.001). No significant reduction in symptoms was observed for the GAD-7 at the posttreatment time point (P=.21; Table 9). However, all participants in the intervention group experienced a significant reduction in symptoms at the 3-month follow-up (P<.001) on the 3 measures, with adjusted effects showing a decrease of 4.05, 7.50, and 5.12 points on the GAD-7, PHQ-9, and PSQI, respectively. Table 9 also shows variability among individuals on the random effects, with average deviations of 0.001, 5.46, and 0.82 points for the GAD-7, PHQ-9, and PSQI, respectively, around the postintervention and 3-month means. The 3 models were statistically significant (P<.001), with the random-intercept, random-slope model being appropriate for the PHQ-9 and PSQI (P=.03 and P=.002, respectively) and the random-intercept model being appropriate for the GAD-7 (P=.34). Figure 5 shows a change in secondary outcomes over time in the intervention group (ITT analysis).

Comparable results were also detected on the PP analysis, with individuals experiencing significant reductions in symptoms following the intervention and also at the 3-month assessments (P<.001 in all cases) except for the GAD-7, which was found to be not significant at the postintervention time point (P=.29). Participants experienced a greater reduction in symptoms at the 3-month assessment, with adjusted effects indicating a reduction of 3.88, 6.98, and 4.62 points on the GAD-7, PHQ-9, and PSQI, respectively (Table 10). The 3 models were statistically significant (P<.001), with the random-intercept model being appropriate for the 3 measures (GAD-7, P=.32; PHQ-9, P=.56, and PSQI, P=.05).

Similarly, ITT analysis results of the mixed-effects regression showed that, at baseline, participants in the waitlist group had mean scores of 10.79, 5.42, and 13.93 on the ISI, NDI, and PCL-5, respectively. The adjusted effects at the postintervention time point indicated that the symptoms significantly reduced by 6.36, 5.78, and 19.37 points, respectively (P<.001), and a significant reduction of 8.21, 7.74, and 27.96 points was observed at the 3-month follow-up for the ISI, NDI, and PCL-5, respectively (P<.001; Table 11).

In the random-effects part, there was substantial variability among individuals, with average deviations of 9.80, 6.18, and 1.73 points for the ISI, NDI, and PCL-5, respectively, around both the postintervention and 3-month means. This suggests considerable individual variability in the outcomes. All mixed-effects models for the ISI, NDI, and PCL-5 were statistically significant (P<.001), with a random-intercept model being appropriate for the 3 measures with a nonsignificant P value (P>.05; ISI, P=.45; NDI, P=.59, PCL-5, P=14 Table 11). Figure 6 shows the changes in primary outcomes over time for the waitlist group at the postintervention time point and 3-month follow-up.

The PP analysis showed similar results, with significant improvements at both the postintervention and 3-month follow-up assessments on the ISI, NDI, and PCL-5 (P<.001 in all cases; Table 12). The mixed-effects models for the ISI, NDI, and PCL-5 were all statistically significant (P<.001). The random-intercept model was used for the 3 measures (P>.05; ISI, P>.99; NDI, P>.99; and PCL-5, P=.34, Table 12).

For the secondary measures, ITT analysis showed that the waitlist group had baseline mean scores of 0.78, 0.36, and 3.31 on the GAD-7, PHQ-9, and PSQI, respectively. The adjusted effects at the postintervention time point indicated that these scores decreased significantly by 4.72 and 5.07 points for the GAD-7 and the PSQI, respectively (P<.001). However, no significant changes were observed on the PHQ-9 at the postintervention time point. Furthermore, adjusted effects showed a significant reduction of 6.51 points on the GAD-7 and 5.00 points on the PSQI (P<.001) against the baseline but no changes on the PHQ-9 at the 3-month follow-up (Table 13).

There was variability among individuals, with deviations of 1.47, 0.06, and 0.92 points for the GAD-7, PHQ-9, and PSQI, respectively, around the postintervention and 3-month follow-up means. The positive correlation coefficients between the time point and the intercept indicate that participants with higher baseline scores (above the overall sample mean) were more likely to experience greater decreases in their scores over time compared to those with lower baseline scores. All mixed-effects models for the GAD-7, PHQ-9, and PSQI were statistically significant (P<.001). Specifically, the random-intercept, random-slope model was appropriate for the GAD-7 and PSQI (P<.001 and P=.02, respectively), whereas a random intercept–only model was sufficient for the PHQ-9, which also fit the data but with a nonsignificant P value (P>.05; P=.17, Table 13). Figure 7 shows the changes in secondary outcomes at the postintervention time point and at the 3-month follow-up for the waitlist group.

For those who completed the study, PP analysis showed similar results for the waitlist group, with significant reduction at the postintervention and 3-month assessments only for the GAD-7 and the PSQI (P<.001); however, no significant changes were detected for the PHQ-9 at either the postintervention time point or the 3-month follow-up (P=.61 and P=.92, respectively; Table 14). For those who experienced significant reductions, there was great variability, with deviations of 1.98 and 1.00 points for the GAD-7 and PSQI, respectively, around the postintervention and 3-month follow-up means. All mixed-effects models for the GAD—7, PHQ—9, and PSQI were statistically significant (P<.001). Specifically, the random-intercept model was appropriate for the 3 measures

with a nonsignificant *P* values (*P*>.05; GAD-7, *P*=.05, PHQ-9, *P*=.47, PSQI, *P*=.24, Table 14).

Figure 2. Change in adjusted estimates of primary measures, including the Insomnia Severity Index (ISI); Nightmare Disorder Index (NDI); and PTSD Checklist for DSM-5 (PCL-5), from before to after the intervention based on the intention-to-treat analysis.

Clinical Significance

Table 15 presents the number of participants achieving clinical significance from baseline to 3-month follow-up, based on intention-to-treat (ITT) analysis. The results show that a higher percentage of waitlist group participants achieved clinically significant changes in nightmare symptoms (mean change 7.74, SD 5.12) and PTSD symptoms (mean difference 27.96, SD 16.56) compared to the treatment group (mean change 4.20, SD 4.21 for nightmare symptoms and mean change: 22.83, SD 17.09 for PTSD symptoms). In contrast, a higher percentage of treatment group participants achieved clinically significant changes in insomnia symptoms (mean difference 8.65, SD 5.28) compared to the waitlist group (mean change 8.21, SD 6.96). Two participants were missing 3-month follow-up data on the ISI, NDI, and PCL-5.

The per-protocol (PP) analysis (Table 16) yielded similar results to the ITT analysis. Specifically, a higher percentage of waitlist group participants achieved clinically significant changes in nightmare symptoms (mean change 7.11, SD 5.71) and PTSD symptoms (mean change 28.44, SD 18.58) compared to the treatment group (mean change 4.67, SD 3.04 for nightmare symptoms and mean change: 24.84, SD 18.62 for PTSD symptoms). Conversely, a higher percentage of treatment group participants achieved clinically significant changes in insomnia symptoms (mean change 7.33, SD 5.87) compared to the waitlist group (mean change 7.00, SD 8.34). However, the differences between the two groups were not statistically significant.

Table 15. Distribution of clinically significant responders by condition—intention-to-treat analysis (N=30).

Outcome	Waitlist (n=14), n (%)	Treatment (n=16), n (%)	*P* value
ISI[a]	8 (57)	10 (62)	.77
NDI[b]	13 (93)	10 (62)	.05

Satisfaction and Engagement With Treatment

Participants were asked to rate how likely they were to revisit the treatment modules on a 5-point, single-item Likert scale. A frequency analysis showed that most participants responded with *strongly agree* (9/20, 45%) and *moderately agree* (7/20, 35%). In total, 10% (2/20) of the participants responded with *moderately disagree*, and 10% (2/20) of the participants did not respond to this question. The number of log-ins to the site was observed as an indicator of the level of engagement by participants with the modules, and it was found that the 20 participants who were included in the PP analysis had an average of 8.5 log-ins during their engagement with Sleep Best-i. A total of 5% (2/20) logged in 12 times to the site; 5% (3/20) logged in 5 times; 5% (2/20) logged in 7 times; 10% (3/20) logged in 6 times; 15% (4/20) logged in 11 times; and 20% (6/20) logged in 8, 9, and 10 times. On average, participants spent 116 minutes on the site visiting modules and completing assessments.

Discussion

Principal Findings

The aim of this clinical pilot trial was to assess the feasibility of a brief (6 modules over 4 weeks), self-paced, digital intervention for the treatment of insomnia, nightmares, and PTSD symptoms in an international sample of survivors of wildfires. The first hypothesis was partially supported. The PP analysis revealed a significant interaction effect of condition × time on both the NDI and the PCL-5, indicating that Sleep Best-i effectively reduced symptoms of nightmares and PTSD from before to after the intervention in the treatment group compared to the waitlist group. However, no significant changes were observed in insomnia symptoms. The ITT analysis yielded similar findings, with a significant main effect of time showing a reduction in nightmare and PTSD symptoms at the posttreatment time point for the intervention group but no significant changes in insomnia symptoms. In examining the 2 groups separately, Sleep Best-i significantly reduced symptoms of insomnia, nightmares, and PTSD from baseline to the postintervention time point, and this improvement in symptoms was maintained at the 3-month assessment for the 2 groups across both the PP and ITT analyses. This study's findings diverge from those of previous research using CBTi to treat insomnia in survivors of wildfires [27,28] and veterans [25,26]. This discrepancy may be attributed to the brief duration of insomnia treatment in our study, which spanned only the first 2 weeks, unlike in other clinical trials that used CBTi in ≥6 sessions. Research suggests that an average of 6 to 8 sessions is typically required to significantly reduce insomnia symptoms [13,64]. The shorter session duration used in this study may have contributed to the differing outcomes. Nevertheless, the maintenance of improvements at the 3-month follow-up is a promising indicator of the intervention's long-term effectiveness.

These findings further substantiate the efficacy of ERRT in reducing the severity and frequency of nightmares, aligning with those of previous studies [36,65-67]. These results are also consistent with those of other clinical trials demonstrating that CBTi and ERRT can lead to significant reductions in PTSD symptoms at the posttreatment time point [36,68]. Notably, it is possible that symptoms of trauma and nightmares are more malleable and responsive to treatment, whereas insomnia symptoms may be more entrenched and less amenable to change with brief interventions, suggesting a potential explanation for the observed differences in treatment outcomes.

In relation to the second hypothesis, the PP analysis revealed that Sleep Best-i not only alleviated symptoms of nightmares and trauma but also significantly reduced anxiety symptoms (main effect of condition) in the treatment group compared to the waitlist group at the postintervention time point. In addition, the treatment group experienced a significant reduction in depressive symptoms at the posttreatment time point (main effect of time) and a significant interaction effect of time × condition on sleep quality, indicating more pronounced improvements in sleep quality at the postintervention time point compared to the waitlist group. The ITT analysis yielded similar findings, with significant reductions in depressive symptoms at the postintervention time point and a significant interaction effect of time × condition on sleep quality. However, the reduction in anxiety symptoms was no longer significant in the ITT analysis. This is notable as research suggests a strong relationship between insomnia and anxiety symptoms, with the expectation that successful insomnia treatment would lead to a reduction in anxiety symptoms [69].

When analyzing the 2 groups separately, both the PP and ITT analyses yielded similar results, with few exceptions. Notably, both groups showed significant reductions in anxiety symptoms at the 3-month follow-up, although this improvement was only sustained for the waitlist group at the postintervention assessment. In terms of sleep quality, both groups showed significant improvements at both the postintervention and 3-month follow-up assessments. However, only the intervention group exhibited significant reductions in depressive symptoms at both the postintervention and 3-month follow-up assessments.

This study's findings align with those of existing research demonstrating the effectiveness of CBTi-based treatments for comorbid conditions [13,70]. While part of this study's findings corroborates those of previous studies showing a significant reduction in symptoms of depression following CBT treatment for insomnia [27,28], the lack of improvement in symptoms of depression in the waitlist group is not well understood. One possible explanation is that the insignificant improvements in insomnia symptoms may have contributed to the absence of change in depression levels [69]. In addition, external life difficulties may have influenced symptoms of depression during the study period. Notably, the 2 groups had distinct intervention experiences, which may have impacted the outcomes. Specifically, the 3-month follow-up assessment for the waitlist group occurred 4 weeks after the treatment group's follow-up, potentially introducing passage-of-time effects that may have influenced the results. This study's findings are also in line with those of other studies that found improved sleep quality on the PSQI following the administration of CBTi [71].

In terms of clinical significance, a substantial proportion of participants achieved MCSC (according to the PP analysis) in insomnia (9/18, 50%), nightmares (13/18, 72%), and PTSD symptoms (11/18, 61%). Notably, the MCSC rates for insomnia and PTSD in this study were slightly higher than those reported in previous clinical trials using CBTi and imagery rehearsal therapy. For example, Ulmer et al [26] found that 55.4% and 50% of their sample (N=22) achieved clinical significance in insomnia and PTSD, respectively. In contrast, the MCSC rates in this study were lower than those reported by Belleville et al [27], who found that 64.7% and 70.6% of participants achieved MCSC for insomnia and PTSD at the posttreatment time point, respectively, and 64.7% and 58.8% achieved MCSC for insomnia and PTSD at the 3-month follow-up, respectively. The discrepancy in MCSC rates between our study and others may be attributed to the shorter treatment duration of Sleep Best-i (4 weeks) than those of the other trials (6-12 weeks) [26,27].

A significant proportion of participants expressed a high level of satisfaction with the intervention, with approximately 80% (18/20) of users reporting a positive experience. Furthermore, the level of engagement by participants with the modules was measured using the number of log-ins into the site. The 20 participants included in the PP analysis had an average of 8.5 log-in times during their engagement with Sleep Best-i. The log-in frequency was varied, with 5% (2/20) of the participants logging in 12 times; 5% (3/20) logging in 5 times; 5% (2/20) logging in 7 times; 10% (3/20) logging in 6 times; 15% (4/20) logging in 11 times; and 20% (6/20) logging in 8, 9, or 10 times. On average, participants spent 116 minutes on the site visiting modules and completing assessments.

Limitations

This clinical pilot trial has limitations that warrant consideration. The sample consisted of self-selected individuals, and the absence of clinical assessments to confirm diagnoses of insomnia, nightmares, and PTSD introduces a potential source of bias. The small sample size is another impediment, underscoring the need for further testing with a larger and more diverse population to establish the external validity of the intervention. One major concern in relation to Sleep Best-i is the PTSD module and its potential for triggering trauma symptoms. Although this risk was anticipated, participants were provided with emergency numbers. Moreover, throughout the initial 2-week treatment period, participants received training in cognitive and behavioral strategies to effectively manage stress. It is important to note that our study was conducted as an open-label trial. Future research should prioritize addressing the identified gaps and limitations, thereby enhancing the validity and generalizability of the findings in this field.

Future Directions

This feasibility trial provides valuable insights into the effectiveness of the Sleep Best-i intervention, a CBT-based program for survivors of wildfires. While our findings are promising, we recognize that future research could further enhance our understanding of its efficacy and effectiveness. One potential direction for future research could involve stratifying the assessment of outcomes based on the type of survivor by dividing the population into subgroups based on specific characteristics, such as demographic characteristics such as age, sex, and income; life experiences, including previous trauma and social support; experiences with wildfires, such as severity of exposure and proximity to the fire; losses experienced as a result of wildfires, including property damage and loss of loved ones; social support from family, friends, and community resources; and institutional support provided during the recovery phase, including access to mental health services and financial assistance. By doing so, researchers can identify patterns and trends within each subgroup, compare outcomes between subgroups, and develop targeted interventions that address the unique needs of each subgroup. In addition, ecological assessments over longer time frames could provide a more comprehensive understanding of the intervention's impact in real-world settings. We propose that future studies consider these approaches to build on our findings and inform the development of more targeted and effective interventions for survivors of wildfires.

Conclusions

Taken together, these findings indicate that Sleep Best-i incorporating CBTi and ERRT improved nightmares, PTSD, sleep quality, and symptoms of depression from baseline to the posttreatment time point. This positive impact was sustained at the 3-month follow-up for the 2 groups, with some variations on anxiety and depression. Participants in the intervention group, when assessed separately, experienced improvements on all measures from before to after treatment and at the 3-month follow-up, with the exception of anxiety symptoms at the posttreatment time point. The waitlist group experienced a significant reduction in symptoms on all measures from before treatment to after treatment and at the 3-month follow-up except for symptoms of depression. This clinical trial is the first in the field of sleep disturbances to use a concise, digital, self-paced intervention over 4 weeks among survivors of wildfires.

Acknowledgments

The research team would like to thank Dr Samia R Toukhsati for reviewing the ethics application and the treatment manual and for her contribution to the design of the trial; Dr Mirella DiBenedetto for her involvement in the early stages of this research project; and Dr Abby Bloom, Dr Kate Brady, Mr John Richardson, Mr Adam Dent, Ms Mona Naeimi, and Mr Nathan Maddock for their efforts in recruiting participants. The authors would also like to thank Mr Owen Cole for his assistance with the HealthZone platform. FI is supported by an Australian Government Research Training Program Fee Offset scholarship administered through Federation University. This study received funding from Natural Hazards Research Australia through an awarded scholarship to FI.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to ethical restrictions, but are available from the corresponding author on reasonable request.

Authors' Contributions

FI contributed to conceptualization; methodology; validation; formal analysis; data curation; writing—original draft preparation, review, and editing; visualization; project administration; and funding acquisition. BK contributed to conceptualization, methodology, validation, data curation, writing—review and editing, visualization, and supervision. HN contributed to methodology, validation, formal analysis, writing—review and editing, and visualization. SW provided supervision and writing—review and editing. GAK was responsible for the conceptualization, methodology, validation, formal analysis, data curation, writing—review and editing, visualization, and supervision. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

FI, BK, and GAK are the primary creators of Sleep Best-i. All other authors declare no other conflicts of interest.

Tang et al's recent study published in *JMIR Human Factors* [1], titled "The Use of Mobile Health Care Among Medical Professionals in the Sichuan-Chongqing Region: Cross-Sectional Survey Study," captured my attention. Their analysis of mobile health (mHealth) device use and influencing factors, using chi-square and multivariable logistic regression analyses, revealed a significant association between age and mHealth use. This study provides valuable insights from China's western region.

However, I would like to offer a few comments and suggestions that I believe would further enhance the study's methodology and findings.

First, the study's reliance on a web-based questionnaire may introduce potential selection bias, as respondents, by nature of accessing web-based surveys, may be more likely to use digital devices and have a stronger interest in digital health in general. A more diverse, mixed-methods approach to questionnaire distribution could help mitigate this potential self-selection toward mHealth use and prevent the exclusion of individuals with limited experience or interest in mHealth.

Second, the study could benefit from a standardized and rigorous methodological framework for survey design and reporting. For instance, categorizing age into three broad groups may overlook essential trends. A finer measurement scale for satisfaction and usage, such as a Likert scale, could provide deeper insights into health care professionals' attitudes. Furthermore, for questions where "uncertain" responses outweigh "yes" or "no" responses, a qualitative or mixed-methods research approach could yield a more nuanced understanding of the underlying reasons. Finally, incorporating years of work experience as a variable could add valuable insights, given its potential correlation with age. Unlike professional titles, years of work experience could provide a more direct measure of professional tenure, potentially enriching the data analysis.

Third, ethical considerations of this study merit further attention. Identifying specific hospitals in the report may compromise confidentiality. Additionally, the exemption of review by an institutional review board (IRB) raises concerns, as the study involves gathering potentially sensitive information from human participants (ie, health care professionals) regarding personal perspectives, workflows, and technology use. Such studies often warrant an ethics board review to protect participant privacy, minimize psychological or social risks, and ensure adherence to ethical standards [2].

Fourth, before conducting logistic regression analysis, normality tests on both independent and dependent variables are recommended to confirm the validity of the chosen statistical methods [3]. If data are not normally distributed, adjustments should be considered.

Lastly, as noted in the "Limitations" section [1], the reliance on convenience sampling may affect the study's generalizability. Only public, district-level hospitals were included, excluding primary and tertiary institutions—this limits the representation of China's complete health care hierarchy in the analysis. Furthermore, only urban areas were sampled, overlooking rural populations. Women comprised 77.1% of the study sample, raising questions about gender representation. A multi-level sampling approach would likely yield a more comprehensive and representative dataset.

To conclude, I would like to highlight that these feedback points are not to challenge the integrity of the authors' work. Instead, I hope they can contribute to ongoing discussions on mHealth research and the development of robust methodologies in this field.

Abstract

Background: The internet is a key source of health information, but the quality of content from popular search engines varies, posing challenges for users—especially those with low health or digital health literacy. To address this, the “tala-med” search engine was developed in 2020 to provide access to high-quality, evidence-based content. It prioritizes German health websites based on trustworthiness, recency, user-friendliness, and comprehensibility, offering category-based filters while ensuring privacy by avoiding data collection and advertisements.

Objective: This study aims to evaluate the acceptance and usability of this independent, noncommercial search engine from the users’ perspectives and their actual use of the search engine.

Methods: For the questionnaire study, a cross-sectional study design was used. In total, 802 participants were recruited through a web-based panel and were asked to interact with the new search engine before completing a web-based questionnaire. Descriptive statistics and multiple regression analyses were used to assess participants’ acceptance and usability ratings, as well as predictors of acceptance. Furthermore, from October 2020 to June 2021, we used the open-source web analytics platform Matomo to collect behavior-tracking data from consenting users of the search engine.

Results: The study indicated positive findings on the acceptance and usability of the search engine, with more than half of the participants willing to reuse (465/802, 58%) and recommend it (507/802, 63.2%). Of the 802 users, 747 (93.1%) valued the

absence of advertising. Furthermore, 92.3% (518/561), 93.9% (553/589), 94.7% (567/599), and 96.5% (600/622) of those users who used the filters agreed at least partially that the filter functions were helpful in finding trustworthy, recent, user-friendly, or comprehensible results. Participants criticized some of the search results regarding the selection of domains and shared ideas for potential improvements (eg, for a clearer design). Regression analyses showed that the search engine was especially well accepted among older users, frequent internet users, and those with lower educational levels, indicating an effective targeting of segments of the population with lower health literacy and digital health literacy. Tracking data analysis revealed 1631 sessions, comprising 3090 searches across 1984 unique terms. Users performed 1.64 (SD 1.31) searches per visit on average. They prioritized the search terms “corona,” “back pain,” and “cough.” Filter changes were common, especially for *recency* and *trustworthiness*, reflecting the importance that users placed on these criteria.

Conclusions: User questionnaires and behavior tracking showed the platform was well received, particularly by older and less educated users, especially for its advertisement-free design and filtering system. While feedback highlighted areas for improvement in design and filter functionality, the search engine’s focus on transparency, evidence-based content, and user privacy shows promise in addressing health literacy and navigational needs. Future updates and research will further refine its effectiveness and impact on promoting access to quality health information.

Introduction

Background

The internet has become a crucial resource for accessing medical information, making it a valuable tool for individuals seeking knowledge about health. In Germany, medical professionals, notably physicians, have long been the primary source of health care information for the general population [1,2]. However, the landscape is evolving, and the internet now stands as the second most significant channel for health-related information [1], indicating a new trend in how people seek medical knowledge. A study conducted by the Bertelsmann Foundation showed a strong and increasing demand for health-related information online, including a rapidly increasing demand by older generations [3]. In 2020, approximately 70% of the German population used the internet to actively engage in searching for health-related content [4]. While these numbers have varied in recent years, there is an overall trend of an increased use of the internet [4].

A major complaint that users have about health-related information online is the lack of clarity regarding the trustworthiness and seriousness of existing websites. The information online has varying levels of quality [5,6]. Frequently used and popular websites are regarded as reliable by users, irrespective of the actual quality of their content, while independent public websites are not as well known and do not seem to be more reliable to users [3]. The reliance on digital platforms for health information also poses a challenge due to the profound influence of the order of the results generated by popular search engines. Users often initiate their search for medical information through well-known search engines, predominantly relying on the first few search results displayed on the search engine results page (SERP), which are often advertising [7-10]. Unfortunately, these top hits are not only clicked on more frequently but are also perceived as more trustworthy, despite the variation in information quality [3,9]. This highlights the ambiguity of users feeling incompetent in finding reliable information online, while at the same time trusting the top results and being satisfied with the information they find. A more recent study evaluated the quality of online health and nutrition information related to cancer supplements through a Google search, using the Health Information Quality Index [11]. The 160 relevant search results yielded median and mean Health Information Quality Index scores of 8, with one-quarter of the results scoring high (10-12). No correlation was found between high quality scores and an early appearance of these results, indicating potential limitations in using Google for obtaining accurate information on dietary supplements and cancer, particularly given the prevalence of advertisements outnumbering search results [11].

The problem with the reliance on search engines becomes even clearer when considering the low health literacy and digital health literacy of the German population [12-14]. The first Health Literacy Survey Germany study in 2014 [13] underscored a significant health literacy challenge in Germany, with 54.3% of the population reporting health literacy problems. This result pointed to challenges in navigating the health care system and understanding health-related information, with identified associations with factors such as age, migrant background, self-assessed social status, and functional literacy. The second Health Literacy Survey Germany study in 2020 [14] reinforced previous concerns with a further increased rate of individuals (58.8%) struggling considerably with health information. Even more so than in 2014, evaluating the trustworthiness of health-related information presented difficulties [15]. Up to 45% of the German population exhibit “problematic” or even “inadequate” internet skills [16]. Many individuals face so-called navigational needs. They depend on support from others to efficiently search and evaluate health information online [17]. As the amount of digital health information grows each year, the challenge of effectively navigating through this vast array of content becomes increasingly daunting, raising concerns about misinformation and health-related misconceptions.

During the work on the comprehensive GAP (Gut informierte Kommunikation zwischen Arzt und Patient, meaning "Well-informed communication between physician and patient" in English) project, which addressed evidence-based information [18-26], we studied the needs and requirements of internet users for health information online [18]. We developed criteria to assess web domains according to these needs. Assessing the quality of websites is nothing new. There are existing seals of approval, such as the afgis (Aktionsforum Gesundheitsinformationssystem eV, meaning "Action Forum Health Information System eV" in English) and Health On the Net Foundation Code of Conduct seals, which check whether the website operator meets certain transparency and quality standards. An afgis certificate is valid for 1 year. However, with Health On the Net Foundation Code of Conduct, there were several issues [27], and on December 15, 2022, the Health On the Net Foundation discontinued its services. Different seals potentially signify different standards of certification. Another issue with these seals is that the pages that have a seal cannot easily be found via a central search. To address these issues by centrally and consistently rating domains inside a search platform, we developed a search engine in 2020. This search engine was originally called "GAP search" and later renamed as "tala-med Suche" in German and "tala-med search" in English.

The topic of data retrieval in medicine is generally relevant and widely researched. Efforts ranging from decentralized search systems for patient data in registries [28] to tools such as Informatics for Integrating Biology and the Bedside (i2b2) [29] that allow the creation of cohorts, for which data security plays an important role [30], have been investigated. In addition, for public data, such as the Medical Subject Headings (MeSH), search capabilities play an important role [31], including the requirement for an intuitive user interface design [32]. In terms of scraping web content, which could be used to create a search platform, the Sampled German Health Web [33,34] created an index of German-language health-related web pages using a special focused crawler. The Sampled German Health Web index was restricted to pages from the top-level domains .de, .at, and .ch, and the domains were automatically filtered for health-related content while crawling using a support vector machine. By contrast, the new tala-med search engine, which was used in this study, relied on hand-picked, high-quality, German-language health websites. These domains—more than 50 of them—underwent a rigorous evaluation process. This evaluation was based on the categories *trustworthiness* (with the subcategories *authority*, *independence*, and *evidence based*), *recency*, *user-friendliness*, and *comprehensibility*. The ratings of these categories influence the order of the results on the SERP. The search engine also values user privacy by avoiding data collection and advertising. The detailed design of the search engine is described in the *Methods* section and in Multimedia Appendices 1-3.

By assessing the acceptance and usability of this new technology, we aimed to improve the implementation of the search tool. Numerous studies in the field emphasize the significance of outcome measures as crucial indicators of a technology's effectiveness, user-friendliness, and potential for widespread adoption. User acceptance, often determined by perceived usefulness, ease of use, and individual attitudes, is critical for a technology's long-term viability [35,36]. Moreover, the usability of a technology, including learnability, efficiency, and user satisfaction, significantly affects user experience and reduces possible adoption barriers [37]. Evaluating these dimensions can provide insight into how well technology meets users' expectations, addresses their needs, and contributes to successful implementation. In the context of health care technology, this scrutiny is particularly relevant because effective tools for accessing medical information can significantly impact health care outcomes [17,38].

In this study, the acceptance and usability of our newly developed search engine was evaluated by means of a questionnaire study and actual use by tracking user behavior during the first months of operation.

Related Works

The usability and accessibility of digital platforms are essential for ensuring that all users, including those with disabilities, can effectively engage with websites and mobile apps. Mateus et al [39] conducted a systematic mapping of accessibility issues, revealing that automated tests covered <40% of accessibility problems on websites and even fewer on mobile apps. The study stressed the importance of including users with disabilities in evaluations because user testing uncovered many issues missed by automated tools and expert inspections. This underscores the need for a comprehensive evaluation approach that combines expert and real-world user input to improve accessibility.

Petrie and Bevan [40] expanded on this by exploring the interplay between usability, accessibility, and user experience. The authors defined usability in terms of effectiveness, efficiency, and satisfaction, focusing on aspects such as learnability, flexibility, and safety. Importantly, they emphasized that accessibility is an integral component of usability and that digital systems should cater to the widest possible range of users, including those with disabilities. They also introduced the concept of user experience, which goes beyond usability to include users' emotional responses and satisfaction with a system. This holistic approach is essential for creating digital platforms that are both functional and engaging for all users.

Belinda et al [41] provided a deeper look into the internal and external usability factors that affect website performance. The authors used automated tools such as GTmetrix and Website Grader to measure internal attributes such as performance, load time, and page size, while external attributes such as ease of navigation and user satisfaction were assessed through surveys. Their findings revealed that some websites performed well from a user perspective but were found lacking in technical performance, particularly in terms of load times and page requests. This highlights the need to address both internal and external usability factors to create well-rounded digital platforms.

Kritz et al [42] explored the online resources and tools used by European physicians to gather medical information. The authors found that physicians frequently relied on general search engines and faced significant barriers in accessing high-quality,

trustworthy medical content. Medical specialists were more likely to use medical research databases, while general practitioners often faced barriers such as lack of time and language restrictions. The study highlighted the need for improved medical search tools tailored to the specific needs of different physician subgroups. Kritz et al [42] concluded that user-centered medical search tools could significantly improve accessibility and the quality of online medical information.

Strecker et al [32] also contributed to the usability of medical search tools, focusing on the MeSH Browser. The authors evaluated a newly developed multilingual MeSH Browser, which introduced improvements in user interface design to enhance the accessibility and usability of medical literature searches. The results showed that contemporary web design principles led to significant improvements in navigation and overall user satisfaction, further underscoring the importance of continual evaluation and enhancement of information systems in the medical realm.

Eysenbach and Köhler [43] studied how consumers search for and appraise health information on the internet. The qualitative study revealed that users, despite using suboptimal search techniques, were able to retrieve health information quickly. However, users rarely checked critical indicators of credibility, such as the “About us” sections or disclaimers, relying instead on superficial factors such as professional design and ease of use. This reliance on superficial credibility indicators poses risks, particularly in the health care field, where the accuracy of information is paramount. Eysenbach and Köhler [43] suggested that further research is needed to develop educational and technological tools that guide users toward high-quality health information.

Zhang [44] expanded the understanding of how consumers select sources for health information by identifying 5 categories of factors that influence source selection: source-related factors, user-related factors, user-source relationships, characteristics of the problematic situation, and social influences. The study also identified a range of criteria that mediate the influence of these factors on source-selection decisions, including accessibility, quality, usability, interactivity, relevance, usefulness, and familiarity. Zhang [44] concluded that a personalized approach to health information systems is necessary to provide effective access to health information because different consumers prioritize different factors when selecting sources. This insight strongly indicates the need for more personalized information services that cater to individual user preferences and needs.

In conclusion, the literature emphasizes the critical role of accessibility, usability, and user experience in the design of digital platforms, especially health care websites. While Saad et al [45] have highlighted general usability problems in health care websites, the studies by Kritz et al [42], Eysenbach and Köhler [43], and Zhang [44] focus on the challenges that users face in retrieving and assessing the credibility of health information online. A personalized and user-centered approach to the design of health care information systems would improve the accessibility and quality of health information, meeting the diverse needs of consumers and health care professionals alike [40,44].

Methods

Search Engine Development

Requirements

The functional requirements for the tala-med search engine included the ability to crawl and index health information websites, implement quality assessment filters, and provide search term suggestions and synonym handling. The nonfunctional requirements focused on maintaining user privacy through self-hosting, ensuring a user-friendly interface, and optimizing performance to handle large sets of synonym mappings efficiently.

Implementation

Design

To implement tala-med search, we used software with a self-hosting capability because of privacy considerations. Furthermore, modern technology with single-page application design using a web application programming interface was required to compete with modern search engines. Therefore, the selection available was limited. As no single product met all our requirements, we built a search engine stack ourselves, consisting of crawler, middleware, and front end, using existing components and established technologies.

Back End

We created the web index using the open-source crawler software Fess [46]. For boilerplate removal, we used Mozilla’s Readability tool to strip HTML tags and display core content, cleaning up crawled websites for our search index [47]. As middleware, we used Elastic App Search [48] (now part of Elastic Enterprise Search [49]), which relies on Elasticsearch. This software allows for setting up weighting mechanisms for the search equation (Multimedia Appendix 1) and configuring filters. In our case, a set of criteria for quality assessment were developed, which we integrated as filters. These quality assessment criteria were adapted from a systematic review by Eysenbach et al [6] that identified criteria used from 1969 to 2001 for evaluating the quality of health information online. We identified 74 criteria [18] to assess the content quality of different health-related websites and rigorously evaluated >50 German-language health information providers (Multimedia Appendix 2) using these criteria, assessing 1 main page and 5 randomly selected subpages per provider. To compile the list of relevant providers, we started with a list from a Bertelsmann study [3] and adapted it with the help of domain experts. The 74 quality criteria were later condensed into 4 categories: *trustworthiness*, *recency*, *user-friendliness*, and *comprehensibility*. The scores of these categories were added to the search index after boilerplate removal and divided into 4 value ranges reflecting the quality of each category, using 4 quantiles for differentiation. These scores served as quality indicators and filter categories, influencing the order of the results on the SERP. More details about the internal mechanisms of the search ranking can be found in Multimedia Appendix 1.

App Search supports the consideration of synonyms, which is crucial in medical language due to varied etymology and numerous abbreviations. Our goal was to enable the search engine to handle synonyms effectively. In App Search, sets of up to 32 synonyms can be created, allowing synonyms of a matched word to be considered in searches. We generated synonym sets by collecting word types and pairs from the document text, filtering against a German stop word list, resulting in approximately 6 million unique entries. These entries were matched against an experimental German interface terminology—SCT-GIT—linked to Systematized Nomenclature of Medicine–Clinical Terms (SNOMED-CT) [50], yielding approximately 40,000 mappings to SNOMED-CT codes. Synonym links in SCT-GIT were then used to add synonyms for each matching string, finding at least 1 synonym for approximately 30,000 SCT-GIT terms. We limited the number of synonym sets to 500 to maintain performance, using only sets with at least 4 synonyms, resulting in a median set size of 4.

Front End

The front end was custom developed with a slim design inspired by Strecker et al [32], featuring search term suggestions and a user-friendly filter selection (Figure 1). After entering a search term, the interface displayed a SERP with evaluated German-language health information providers, showing their scores in the 4 filter categories through graphical indicators (Figure 2). Hovering over these graphics revealed explanations, and the bottom of the page included pagination and a footer with logos and links to pages displaying the imprint and data protection information.

Figure 1. Landing page of the search displaying the initial search query field.

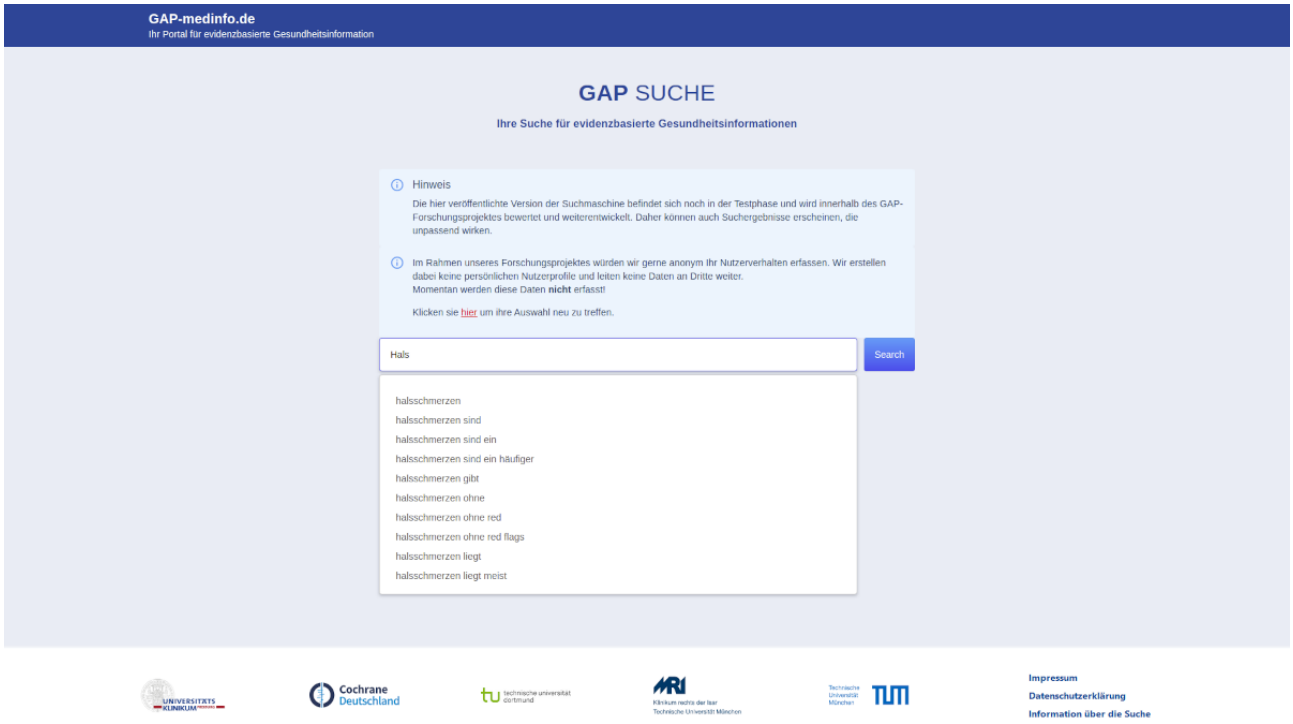

Figure 2. The search engine results page consists of 3 areas. (A) The search query. (B) List of search results. Each search result shows the quality in the 4 filter categories. (C) Slide controls allow users to set a threshold for each filter category (aktuell: recency, nutzerfreundlich: user-friendliness, vertrauenswürdig: trustworthiness, and verständlich: comprehensibility). In each of these areas, more information can be displayed by means of tooltips, as shown in the graphic (next to each label).

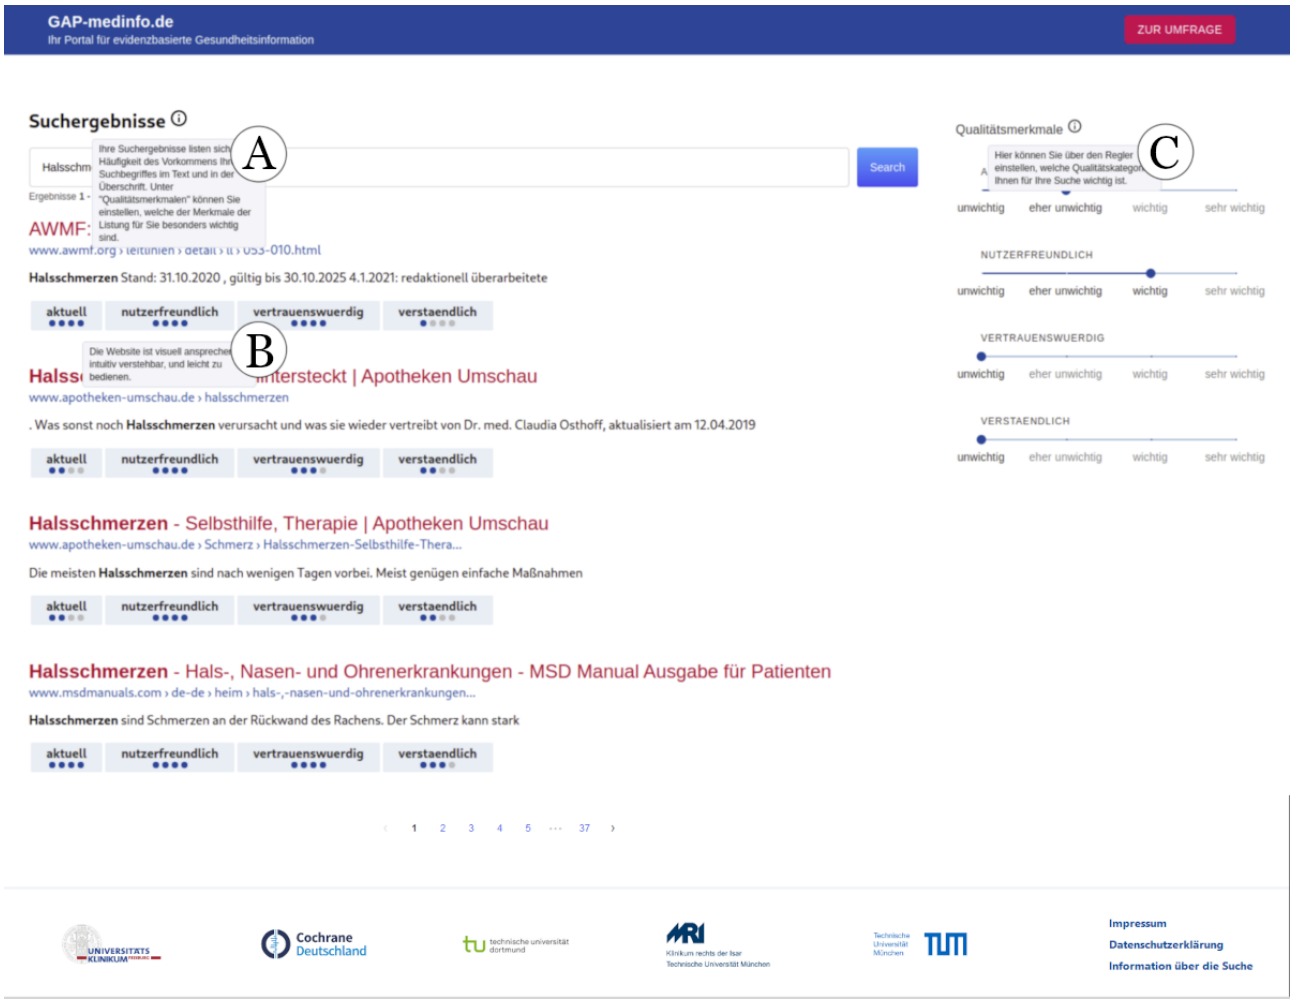


Pilot Testing

The search engine was pilot-tested between October 2020 and the end of June 2021. Adapting to the challenges posed by the COVID-19 pandemic, the pilot testing format shifted from a face-to-face setting to a web-based setting with a small group of academic staff from the University of Freiburg. The evaluation, involving 12 participants, consisted of screen recordings of search tasks and a qualitative survey regarding user-friendliness. After the pilot tests, technical enhancements were implemented, guided by the qualitative insights. These findings formed the basis for the subsequent questionnaire study.

Availability

The current version of the search engine can be accessed on the web [51]. Please note that there have been some significant changes to the website structure since this study was conducted.

Evaluation

Design

We used 2 data collection methods to evaluate user behavior. First, we asked users to fill out a questionnaire (self-perception). Second, we recorded user behavior via web tracking independently and unreferenced to the questionnaire (external perception). The study protocol was published in 2019 [22].

Questionnaire Study

The study used a cross-sectional design with data collected through a web-based questionnaire. The questionnaire was developed after pilot testing of the search engine and underwent an internal pretesting round before recruitment began.

Recruitment

The study used a recruitment strategy aimed at enrolling 200 participants. The first rounds of recruitment, starting in October 2020, which involved sending email invitations to local health initiatives, professional networks for physicians, and personal contacts, were unsuccessful in obtaining the desired number of participants. Participants were then recruited from the WisoPanel, an established online panel of German-speaking individuals [52]. The panel provided a pool of 14,900 potential respondents who had previously expressed an interest in participating in research studies. The survey was open for anyone accessing the link, but only participants from the panel (>70% of the data) were included in the analysis of this study to maintain a credible sample. Recruitment via the panel took place in May 2021. The survey ended at the end of May 2021.

Panel members were invited to participate in the study via email. The email informed participants about the project and the aspects distinguishing the new search engine from other platforms.

To ensure that participants had firsthand experience with the platform before proceeding to the survey, they were asked to test the search engine first. We recommended that participants carry out 1 or 2 searches and familiarize themselves with the SERP and the features and functions of the website.

Survey Administration

The hyperlink that led participants to the search engine was sent to the panel members by email. Subsequently, the link to the survey was displayed as a pop-up element after 10 to 20 seconds of interaction with the search engine. Throughout the assessment phase, a button to access the survey was strategically positioned in the top right corner of the website to allow a direct link to the survey interface. No registration was required to complete the survey, ensuring seamless and voluntary participation. Participants had the option to cancel their responses at any time, and there were no time restrictions regarding the completion of the questionnaire. Back buttons allowed participants to review their answers before submitting the survey. Conventional technical methods, such as cookies, were used to prevent visitors from submitting their survey more than once.

The web-based survey was conducted using the Unipark tool [53], with the survey page seamlessly embedded into the search page via a modal window. After inviting panel participants, the survey remained accessible for 11 days and closed at the end of May 2021.

Before filling out the survey, participants were provided with an introductory text outlining the anticipated time commitment, project objectives, details about anonymity, the option to terminate the survey at any point, data protection measures, and contact information for queries. To proceed, participants were required to confirm their understanding by checking a box and consenting to the specified use of their data (informed consent). No personal data were collected in the survey, and participants were instructed not to provide any identifying information in their open responses. Access to the data was restricted to members of the institutions participating in the study.

Survey Characteristics

On the basis of established scales (the German version of the self-assessment eHealth Literacy Scale [G-eHEALS] [54] and the System Usability Scale [55] adapted by Quirmbach [56] and Magin et al [57]), we developed a 25-item questionnaire across five dimensions: (1) sociodemographic data; (2) internet use; (3) digital health literacy; (4) usability, acceptance, and innovative aspects of the search engine; and (5) search filters. The final questionnaire contained 24 single-choice questions and 1 open-ended question (Tables S1 and S2 in Multimedia Appendix 4). The items in the questionnaire were not randomized. No form of adaptive questioning was used. All questions, except for the open-ended question, were mandatory; nonresponse options were not provided. Thus, there was no additional consistency or completeness check before submission. The survey took approximately 5 minutes to complete.

Statistical Analysis

Descriptive statistics were used to summarize the characteristics of the study participants, including age, gender, occupation, educational level, and internet use for health information, as well as self-perceived digital health literacy. Only completed questionnaires were analyzed. No statistical correction was applied to adjust the sample. To assess the acceptance and usability of the search engine, Likert-scale items related to these dimensions were combined to create scale values. The acceptance scale measured participants' willingness to use the search engine again and to recommend it to others. The usability scale evaluated participants' agreement with statements related to comprehensibility, clarity, the effectiveness of the search, confidentiality, advertising, the ease of learning, and using the search engine.

One reviewer analyzed the content of the open-ended question and assigned the comments to different categories inductively.

Multiple regression analyses were conducted to explore predictive factors influencing the acceptance of the search engine. The factors tested in the regression analyses included age, gender, occupation, educational level, the frequency of internet use for health information, and self-perceived digital health literacy.

Reporting

This study is reported based on the guidelines of the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [58].

User Behavior Tracking

Behavior tracking data were collected from all consenting users accessing the search engine between October 2020 and June 2021 using the web analytics software Matomo (Matomo.org) [59]. Matomo is a powerful open-source web analytics platform designed to help website owners and organizations gain insights into their online presence while respecting user privacy. Its primary purpose is to track website traffic by tracking website visitor behavior. What sets Matomo apart from services such as Google Analytics is its commitment to data privacy and General Data Protection Regulation (GDPR) compliance. Matomo allows users to maintain control over their data by hosting the data on their own servers, ensuring that sensitive information is not shared with third parties. Matomo is easy to integrate into web pages and can also be customized to track specific custom data. Ripp and Falke [60] successfully used Matomo to track user behavior in their research project, where they analyzed search behavior for certain keywords on the online information system Grammis.

We installed Matomo on our own server and integrated the tracking into our search engine's front end. We enabled the tracking to record the filter settings and capture the search term beyond the standard visit data, such as how long users spent on the website, and which of the results they clicked on. Structurally, Matomo records several actions for each visit, containing the duration among other data (Figure S1 in Multimedia Appendix 5). However, for the last action of a visit, the duration is not recorded. We have filled the empty value

with the median of all actions from the particular visit to obtain a more realistic value for the entire visit duration.

Only data from consenting users was recorded and subsequently descriptively analyzed for the 9-month time period. Therefore, this sample differs from the sample of the questionnaire study but may also include users who completed the questionnaire. The data processing for the data analysis was realized with a Python script directly accessing Matomo's database using specific SQL queries.

Ethical Considerations

The study was approved by the institutional review board at the University of Freiburg (Ethikkomission-Freiburg 559/17) as an extension to the GAP study [22], and a document on data protection was agreed upon. As an incentive, the questionnaire study participants could take part in a prize draw for 1 of 25 vouchers to a bookstore worth €20 (US $24.33) after completing the survey.

Results

Questionnaire Study

Participants

During the time the survey was open (from October 2020 to the end of May 2021), there were 1577 unique site visitors to the search engine website, with 1426 (90.4%) visitors to the first survey page. Of these 1426 visitors, 1250 (87.7%) agreed to participate in the survey. Of these 1250 participants, 1123 (89.8%) completed the survey.

Of the 1123 survey respondents, 802 (71.4%) were from the panel described in the Recruitment subsection. The age distribution of these participants was approximately normal, with a little more than a quarter of the participants (215/802, 26.8%) falling into the age category of 50-59 years. The gender distribution was also fairly balanced between male and female, with a little more than half of the respondents (432/802, 53.9%) self-identifying as female. Regarding occupational background, the majority of the participants (726/802, 90.5%) did not work in a medical profession.

Educational levels were notably higher than in the general population due to recruitment through the scientific panel, with 69.3% (556/802) of the participants having completed upper secondary education (at least level 3 in the International Standard Classification of Education [ISCED]-2011) and 46.3% (372/802) holding a bachelor's or master's degree or higher (ISCED-2011 levels 5-8).

The study participants recruited from the web-based panel reported searching for health information online more frequently than the general population, with 65.4% (524/802) searching several times a month at the minimum and 27.7% (222/802) searching at least several times a week. Only 1.5% (12/802) of the participants indicated that they "never" searched the internet for health information.

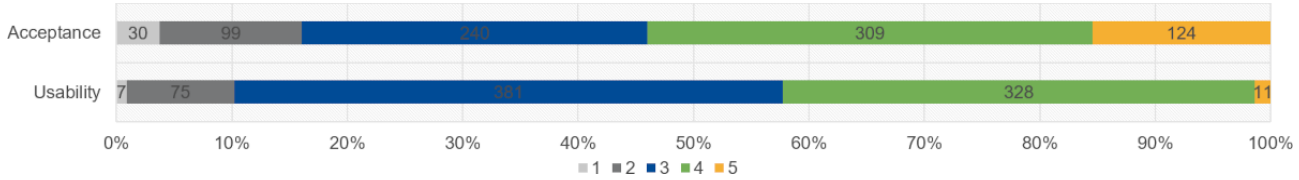
Participants' self-perceived digital health literacy was measured by the G-eHEALS items. Of the 802 participants, 291 (36.2%) felt confident in making health-related decisions based on internet information, while 461 (57.5%) felt capable of distinguishing reliable from questionable information online.

More information about the participants is available in Table S3 in Multimedia Appendix 4.

Acceptance and Usability

Scale values were created by combining items relating to the acceptability and usability of the search engine (Figure 3).

Figure 3. Scale values for acceptance and usability (n=802). The Likert-scale response options were as follows: 1=strongly disagree, 2=disagree, 3=partially agree, 4=agree, and 5=strongly agree. There was one negative question, which was adjusted for calculating the scale values.



The results show agreement regarding the acceptance and usability measures of the new search engine (Figure 3 and Table 1). In particular, more than half of the participants expressed their willingness to use the search engine again (465/802, 58%) and to recommend it to others (507/802, 63.2%). In addition, 79.3% (636/802) of the respondents agreed or strongly agreed that using the search engine was quick to learn, and 77.3% (620/802) to 98.6% (791/802) agreed at least partially with other statements related to usability aspects.

Table 1. Detailed items for acceptance, usability, and innovative aspects (n=802). The Likert-scale response options for acceptance and usability were as follows: 1=strongly disagree, 2=disagree, 3=partially agree, 4=agree, and 5=strongly agree. The Likert-scale response options for the innovative aspects item were as follows: 1=very unimportant, 2=unimportant, 3=neither unimportant nor important, 4=important, and 5=very important.

Content	Scores, mean (SD)
Acceptance	
Item 1: potential reuse	3.58 (1.02)
Item 2: recommendation to others	3.68 (1.03)
Usability	
Item 1: quick to learn	4.03 (0.86)
Item 2: efficient scannability of the SERP[a]	3.63 (1.00)
Item 3: clarity of the SERP	3.75 (1.00)
Item 4: functions *not* comprehensible[b]	2.37 (1.29)
Item 5: appreciation for the absence of advertising	4.66 (0.66)
Item 6: functionality meets expectations	3.45 (1.03)
Item 7: careful handling of personal data	3.59 (0.88)
Item 8: no commercial bias	3.55 (0.95)
Item 9: fast access to relevant information	3.77 (0.99)
Item 10: innovative approach	3.58 (1.03)
Innovative aspects of the search engine (anonymous searches)	4.50 (0.76)

[a]SERP: search engine results page.

[b]Item 4 (comprehensibility of functions) was a negated question.

Users particularly appreciated the absence of advertising on the platform, with 93.1% (747/802) agreeing or strongly agreeing that the absence of advertising was a significant benefit. The search engine's user-friendly interface and the ability to adjust search results through the use of filters were also well received by participants. Furthermore, the unique features of the search engine, notably the anonymous searches without the creation of user profiles and independence from sponsors, received high importance ratings from 91.3% (733/802) of those surveyed.

More detailed results are available in Tables S4-S6 in Multimedia Appendix 4.

Of the 802 participants, 561 (70%) to 622 (77.6%) indicated that they used the filter functions that could be enabled to change what was displayed on the SERP (Table 2; Figure 2). Furthermore, 92.3% (518/561), 93.9% (553/589), 94.7% (567/599), and 96.5% (600/622) of those users who used the filters agreed at least partially that the filter functions were helpful in finding trustworthy, recent, user-friendly, and comprehensible results, respectively. The *recency* filter was particularly well received, with 46% (286/622) of the users strongly agreeing that it was helpful. More detailed results are available in Table S7 in Multimedia Appendix 4.

Table 2. Helpfulness of filters (n=802). The Likert-scale response options were as follows: 1=strongly disagree, 2=disagree, 3=partially agree, 4=agree, and 5=strongly agree.

Content	Participants, n (%)[a]	Values, mean (SD)
Helpfulness of filters for each filter		
Item 1: trustworthiness	599 (74.7)	4.11 (0.92)
Item 2: recency	622 (77.6)	4.25 (0.84)
Item 3: comprehensibility	589 (73.4)	4.05 (0.93)
Item 4: user-friendliness	561 (70)	3.91 (0.93)

[a]All other participants answered, "I did not use this function, I cannot evaluate this question."

In the open-ended question, which aimed to supplement the data with qualitative results, participants were asked to share their comments and suggestions for improvements. Of the 802 participants, 263 (32.8%) replied to the question. Multiple aspects were mentioned. In an inductive approach, 10 main themes were identified (Figure 4). Many of the participants commented on the usability aspects of the website. Of the 236 comments, 76 (32.2%) included constructive criticism and specific suggestions for improving the website in the future. Many commenters made suggestions for improving the design because they found some aspects unclear or overwhelming. Others did not fully understand the methodology behind the

evaluation of the selected providers or the reason why only specific providers, including commercial web pages, were shown on the results page and asked for more clarification. Some commenters were happy with the site as it stood and did not ask for any changes, while some conveyed disappointment with the results they discovered on the SERP.

Figure 4. In the analysis of 263 comments in response to the open-ended question, 10 main themes were identified inductively: design; search results and filter functions; selection of providers; technical details; method of evaluating the website; target audience; text on the website; comments about the survey; general positive responses; and critique, dissatisfaction, and other comments. The illustration shows a hierarchical visualization, with the size of the elements indicating the quantity of comments.

Predictors of Acceptance

We conducted multiple regression analyses to examine the predictive factors influencing responses to the acceptance scale. Age, gender, occupation, educational level, frequency of internet use for health information, and self-perceived digital health literacy were tested as influencing factors. All factors were first tested individually and subsequently tested simultaneously due to the potential error introduced by multiple testing. Overall, only minor discrepancies were identified. Significance levels were set at $P<.05$. Table 3 presents more details.

Table 3. Predictive factors for acceptance (n=802). Categorical variables were dummy coded.

Predictive factors for acceptance	Individual testing of each predictor				Simultaneous testing of all predictors[a]			
	B (SE)	*F* test (*df*)	*P* value	R^2 (%)	B (SE)	*F* test (*df*)	*P* value	η_p^2 (%)
Age	*0.07*[b] *(0.02)*	*7.97 (1)*	*.005*	*0.99*	*0.07 (0.03)*	*7.27 (1)*	*.007*	*0.91*
Gender		0.04 (2)	.96	0.01		0.20 (2)	.82	0
Diverse	0.01 (0.49)	0.00 (1)	.99		−0.07 (0.49)	0.02 (1)	.89	
Female	0.02 (0.07)	0.09 (1)	.77		0.04 (0.07)	0.35 (1)	.55	
Male	Reference	Reference	Reference	Reference	Reference	Reference	Reference	Reference
Occupation		1.82 (2)	.16	0.45		1.14 (2)	.32	0.29
Medical doctor	0.12 (0.12)	0.92 (1)	.34		0.07 (0.12)	0.28 (1)	.59	
Other medical profession	−0.56 (0.35)	2.62 (1)	.11		−0.49 (0.35)	1.93 (1)	.17	
Not working in a medical profession	Reference	Reference	Reference	Reference	Reference	Reference	Reference	Reference
Highest level of educational attainment		*2.57 (4)*	*.04*	*1.27*		1.55 (4)	.19	0.78
No formal secondary education (ISCED[c] levels 0-1) or lower secondary education (*Hauptschulabschluss*, ISCED-2011 level 2)	*0.51 (0.19)*	*6.81 (1)*	.009		*0.41 (0.20)*	*4.22 (1)*	.04

[a]Variance resolution of simultaneous testing: R^2=5.02%.

[b]Factors with significant predictions (*P*<.05) are shown in italics.

[c]ISCED: International Standard Classification of Education.

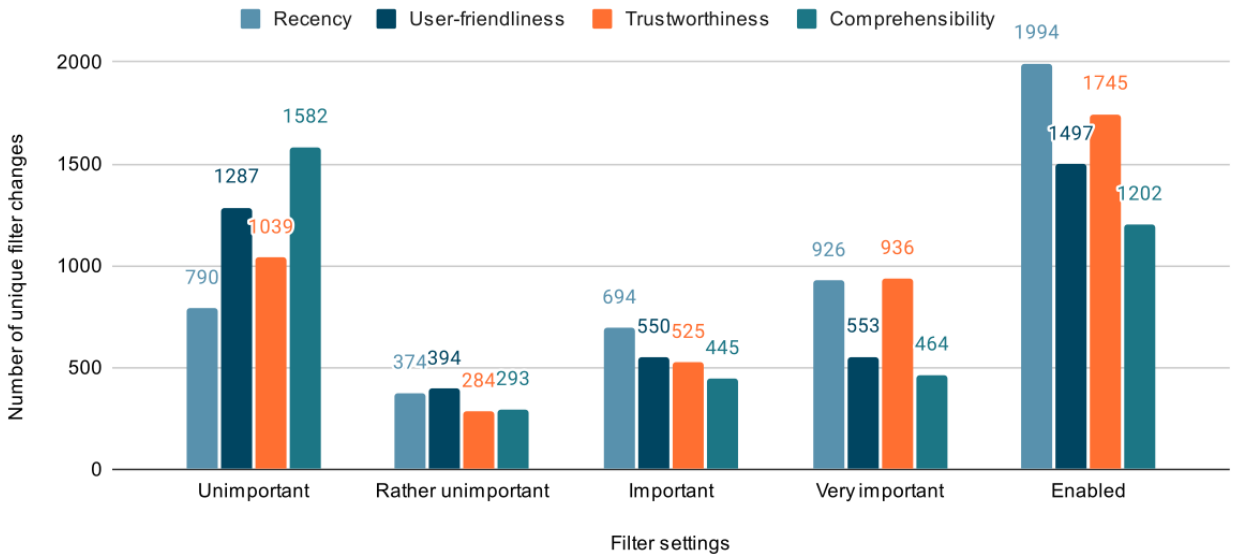
There were 2 significant results in predicting the acceptance of the search engine. First, the acceptance rating increased with age, rising by 0.07 scale points (B=0.07) for each additional 10-year age group. Second, the ratings for acceptance were higher among participants with more frequent internet use for health information.

The factors "highest level of educational attainment" and "self-perceived digital health literacy" only showed significant correlations with the acceptance ratings in the individual tests and slightly lower correlations in the simultaneous tests. Participants with lower levels of education showed stronger acceptance ratings than those with higher levels of education. For this predictor, the reference category was set as "doctorate degree" (ISCED-2011 level 8). Acceptance ratings among persons without any formal secondary education (ISCED-2011 levels 0-1) or with a lower secondary education (*Hauptschulabschluss*, ISCED-2011 level 2) were 0.41 scale points higher than among persons with a doctorate degree (B=0.41). However, if we examine the effect strength using partial eta–squared (η_p^2), only small effects were shown overall for all factors (1%=small effect, 6%=medium effect). No significant results were found for the factors *gender* or *occupation*.

User Behavior Tracking

For a period of 9 months (from October 2020 to the end of June 2021), user behavior of consenting users was tracked using Matomo. The main aspects recorded were the search queries and the use of the filter functions. The data indicated that 1631 visitor sessions had taken place, with 3090 searches using 1984 different search terms across 1924 visits. The search terms had an average lexical token count of 1.74 (SD 1.14). Of the 1984 search terms, 1096 (55.24%) had a lexical token count of 1, while 888 (44.76%) had a lexical token count of >1. The maximum lexical token count was 13. We observed that 28.9% (893/3090) of the search queries were conducted through mobile devices such as smartphones and tablets. On average, visitors conducted 1.64 (SD 1.31) searches per visit, with an average duration of 137.45 (SD 278) seconds and a median duration of 49 (IQR 24-119) seconds. The top 3 search terms were "corona," "rückenschmerzen" (back pain), and "husten" (cough; Table S1 in Multimedia Appendix 5). Each search term was queried 1.57 (SD 3.46) times on average; of the 1984 search terms, 1621 (81.7%) were entered just once. Users could personalize the order of the displayed search results, depending on the prioritization of the different filter categories (*trustworthiness*, *recency*, *user-friendliness*, and *comprehensibility*), all of which were initially set to "unimportant" by default. Within the search interactions, overall, 47,532 actions were performed, among which were 1358 (2.86%) outlink actions (ie, external domains clicked by website visitors) and 34,490 (72.56%) filter changes in total. The high number of filter changes was due to the fact that the filters were often switched back and forth in a search, which led to multiple occurrences of the same filter settings. This behavior was probably observable due to the fact that, given the limited corpus, the result set could be empty for certain search terms in combination with a narrow filter setup; therefore, it was necessary to change back the filter to obtain results. Excluding these repeated changes, of the 34,490 filter changes, 5534 (16.05%) were unique. In addition, after removing the initial filter setup where all categories were set to the default value, we ended up with 2784 nondefault unique filter changes used in 15.37% (475/3090) of the searches. *Recency* was used the most, followed by *trustworthiness*, *user-friendliness*, and *comprehensibility* (Figure 5). Consistent with the results on the usefulness of the filter function from the questionnaire study, the user behavior data showed that the filters for *recency* and *trustworthiness* were adjusted most frequently.

Figure 5. Distribution of the filter settings of the 2784 nondefault unique filter changes across filter categories. We consider a filter category to be "enabled" if a filter category is not set to "unimportant.".



Discussion

Principal Findings

In this study, we evaluated the independent, noncommercial tala-med search for German-language medical information, placing a primary focus on transparency, independence, and evidence-based information. Our questionnaire study and user behavior tracking provide insights into the acceptance and usability of this innovative platform.

The survey resulted in a mean acceptance score of 3.63 (SD 0.98) and a mean usability score of 3.76 (SD 0.61) on a scale of 1 to 5 (1 signifying strong disagreement and 5 signifying strong agreement with acceptance and usability statements). Given that our user interface is similar to that of popular search engines such as Google and Bing and is advertisement-free, it is unsurprising that it was well received. However, there is still a need for optimization to achieve a higher reuse potential and a greater willingness to recommend the platform. Within the usability measures, item 1, which reflected the learnability of the search, achieved a high mean value of 4.03 (SD 0.86; Table 1). In terms of the effectiveness and clarity of our design (refer to items 2, 3, and 9 in Table 1), we still see room for improvement but are satisfied with the results for the initial release. Our findings align with those of Petrie and Bevan [40], who emphasized that usability, particularly learnability, is crucial for ensuring the platform's effectiveness and user satisfaction. Similar to the study by Petrie and Bevan [40], our study highlights the need to continually evaluate and refine

digital systems to cater to user needs and improve overall usability. The survey also revealed that the filters were used by >70% of the 802 users. Among these users, the filters were highly accepted on average, which matches with the tracking statistics revealing the high use of the filter functionality. The most used filter was *recency*, followed by *trustworthiness*, matching the survey outcome, which asked about the helpfulness of the filters. This was not the case for the 2 remaining filters. Although the filter for *user-friendliness* was used more often in our tracking data than the one for *comprehensibility*, it was perceived as less helpful than comprehensibility. In the future, we might inspect these filter categories in more detail and potentially improve their estimation. The insights support our decisions, including basing the design of our search engine on the insights of Strecker et al [32], which demonstrated how improvements in user interface design could lead to higher user satisfaction. The high acceptance of the filters for *recency* and *trustworthiness* in our study also echoes the findings of Strecker et al [32], who highlighted that content navigation and relevance contribute to overall user satisfaction. Nevertheless, the insights encourage us to improve and possibly expand the filters and the design. The fact that our search engine does not share any data with partners or advertisers and does not record the visitor's behavior to create profiles was rated as very relevant, with a mean score of 4.5 (SD 0.76). This result confirms the importance of our general endeavor driven by data privacy and noncommerciality as our fundamental motivations for creating the search engine. This finding is consistent with the work of Eysenbach and Köhler [43], who found that while internet users claimed to prioritize credibility when assessing health information online, they often relied on superficial factors such as website design and ease of use, rather than more reliable indicators such as the "About us" sections or disclaimers. Our platform addresses these shortcomings by offering more explicit filters, such as *trustworthiness*, which help users find credible information without having to rely solely on superficial design elements. In our calculations on the predictors of acceptance, it can be concluded that while the effects may be small, the search engine was particularly well accepted among older users, users with a high frequency of internet use for health information, and those with lower levels of education. This finding suggests that the new search engine may effectively cater to segments of the population with lower health literacy and digital health literacy and greater requirements for navigational assistance, bridging the gap in accessing reliable medical information online. As discussed by Kritz et al [42], general practitioners and medical specialists often face barriers in accessing high-quality medical content due to limited time and the overwhelming amount of information online. Our search engine's focus on evidence-based information and user-friendly design helps mitigate these issues, making it a suitable tool for both health care professionals and the general public.

This reinforces the necessity to consider navigational needs in health information platforms. Digital health literacy has improved in recent years, particularly among persons with low levels of education [14]. The ability to assess health information has also improved over time and over the course of the COVID-19 pandemic. Digital health literacy improved for younger but not for older people over the course of the pandemic [15]. Even with some of these improvements, health literacy is still low within the German population and particularly among people with low levels of education. This observation aligns with the findings by Zhang [44], who identified that source selection for health information is influenced by a wide range of factors, including accessibility, quality, usability, and personal relevance. Our platform's appeal to older users and those with lower health literacy supports the conclusion drawn by Zhang [44] that a personalized approach, considering different user-related factors, is crucial for effectively meeting the diverse needs of consumers when they access health information. The correlation between low educational levels, low social status, higher age, and lower health literacy rates has become even stronger [14]. This emphasizes the need to address low health literacy to improve social inequities. The new search engine attempts to address this need by assessing health information online and by making high-quality information easily searchable.

Many of the comments highlight the fact that at the time of the survey, participants used the first version of the search engine, which still had some technical and appearance-related weaknesses. Since the survey was conducted, a number of revisions have been made, some of which correspond to suggestions made in the comments, such as adding more information about the principles of the quality assessment and the functions of the websites and removing certain commercially funded information sources.

The platform's emphasis on anonymous searches and independence from advertising and sponsors resonated especially well with the participants, underscoring the importance of developing alternatives to commercial search platforms. The usability of our platform, free from external advertising influence, aligns with the findings by Belinda et al [41], who evaluated both internal factors (such as page load time and performance) and external factors (such as ease of navigation and organization of information) as critical to the overall user satisfaction with websites. Our platform similarly emphasizes ease of use and efficient performance, which were key contributors to its positive reception. The general results align with previous findings on the importance of user-friendly interfaces [61-63] and the impact of advertising on users' perceptions [64].

Limitations

Limitations of the Technology

Some participants expressed dissatisfaction with the displayed results. Several respondents found the design of the SERP and individual results confusing due to an overload of information in one place. Potential design changes have been suggested to improve clarity. Currently, some search results are duplicated on the results page. To enhance the appearance of the SERP, it is desirable to deduplicate the search index. This would mean displaying more relevant information and fewer distracting results. To address the fact that sometimes no results were displayed due to strict filter settings, we could display results with nonexact matches for the filter category score below the exact matches and visually indicate them.

Participants encountered difficulties in understanding how the evaluation process worked. Efforts should be made to make the evaluation process easier to understand when using the website. Some improvements have been made over time, such as providing brief explanations of the filter categories when hovering over the graphic showing the score for each domain.

In addition, further clarification is necessary regarding the domains chosen, which comprise both independent and commercial providers. Over time, certain websites were excluded from being displayed on the site because of the conflicts of interest of their publishers (such as the site "Zentrum der Gesundheit" and a site funded by a pharmaceutical company). Currently, the website no longer displays commercial providers.

Limitations of the Questionnaire Study

While the questionnaire study provides valuable insights into the acceptance and usability of the new search engine, several limitations should be acknowledged. First, the recruitment methodology, relying on web-based panel recruitment, unintentionally led to an overrepresentation of individuals with higher educational levels than the general population and potentially more frequent internet use due to the online recruitment process. Among our participants, 46.3% (371/802) had completed tertiary education compared to only 18.5% of the general German population with a university degree or equivalent [65]. Similarly, 65.4% (524/802) of our participants reported searching for health information only at least once a month, while a Bertelsmann Foundation 2018 study indicated that only approximately 50% of the general German population seek such information at least once a month [2]. This potentially influences acceptance and usability ratings. Participants' self-perceived digital health literacy, as measured by the G-eHEALS items, approximately aligned with that of the sample of the validation study of the German version of the questionnaire by Söllner et al [54]. However, this information should be viewed with caution because Kim et al [66] discovered a discrepancy between self-assessments and actual ability. Actual ability was not assessed in our study.

Second, as some of the participants only interacted with the search engine and its features for a brief duration, this short testing time proved to be a limiting factor, hindering the formation of comprehensive first impressions. The responses to the open-ended question suggest that some participants tested the features of the search engine for only a few seconds. This was caused by the pop-up window linking to the questionnaire opening after interacting with the website for 10 to 20 seconds. Such a brief interaction period was likely insufficient for users to thoroughly explore and understand the functionalities and benefits of the search engine. Consequently, the feedback provided by users on the acceptance and usability of the platform may not accurately reflect its true potential. The limited duration of testing may lead to superficial evaluations, whereby participants may base their judgments on initial impressions rather than informed use. This can result in an inaccurate assessment and therefore impact the results presented for the acceptance and usability measures. More extended testing periods could offer a more accurate assessment of the platform's acceptance and usability over time. Furthermore, the implementation of controls for the length of the testing period could provide more reliable data, thereby ensuring that all participants have sufficient time to engage with the platform before completing the questionnaire.

Limitations of the User Behavior Tracking

As Matomo does not record the last action, we decided to substitute this missing value with the median of all actions from the particular visit. However, a more optimal solution would be to record of the last action, which could be triggered when closing the browser, but Matomo does not support this feature.

Unfortunately, due to data protection regulations, we were unable to link the search behavior with the survey data. It would have been interesting to see to what extent the search behavior and the questionnaire would have provided more information.

Future Work

Further Evaluation of the New Search Engine

As these results are based on the first impressions of a group of users, data on long-term use and satisfaction have yet to be compiled. Future work should therefore address the need to evaluate long-term acceptance and usability measures of the site using a longitudinal study design. This could provide valuable insight into whether users actually use the search engine when they have an acute need to seek out medical information and whether they return to the site over time.

Future research should also consider comparing the search engine with other existing and established platforms to gain a deeper understanding of its unique advantages. Such investigations might involve participants executing identical search queries on both the novel search engine and other platforms and sharing their impressions of each experience, similar to the study by Strecker et al [32]. Particular attention should be given to participants' abilities to assess the quality and reliability of the information found. Furthermore, a comparison of the specific results retrieved from both search engines could be undertaken, examining both the congruence and discrepancies in the results.

Further Improvements to the Search Engine

Ongoing revisions and updates to the search engine, including integration on partner websites, hold promise in expanding its reach and use, ensuring that it remains relevant and effective in addressing users' health information needs. Since the data collection for this study was completed, there have been several revisions to the website.

As the qualitative survey showed, some users found the SERP complicated. To address this issue, a potential solution could be a clearly linked help page with a video explanation. Another solution could be to provide an animated assistant that guides users through the page.

One major disadvantage of the search engine in its current state stems from the fact that the evaluation of the domains—more than 50 of them—according to the quality criteria was performed in 2020, and there has not been any update to the evaluations thus far. The domains' quality may have improved or declined

in the time since the evaluation. A continual process with constant reevaluations of the domains is necessary to ensure an up-to-date rating of the domains accessible through the search engine. As we currently do not have the capacity to perform another evaluation or to establish a continual evaluation process for the domains, we have temporarily disabled the display of the filter category scores and the option to adjust the results based on these scores because the scores do not reflect the actual quality of the domains in their current state.

Thus, in future, inspired by Zowalla et al [34], we intend to evaluate various criteria automatically. In the study by Zowalla et al [34], the readability of the language was analyzed supported by a support vector machine. We plan to use more sophisticated approaches that also model contextual context. Therefore, we plan to create classifiers based on Bidirectional Encoder Representations from Transformers (BERT) [67]. We have in mind the domain-specific models GerMedBert [68] and BioGottBERT [69], the latter being a model of the German monolingual Robustly Optimized BERT Pretraining Approach (RoBERTa) [70] model GottBERT [71] specialized on medical language. A further improvement might be the enrichment of the texts with MeSH terms, similar to PubMed. Such approaches would enable us to process and rate documents individually, rather than evaluating domains using random samples.

From a technological standpoint, there are still notable areas for enhancement of the middleware, which could be implemented in the future. As App Search is proprietary and monolithic, to make it customizable and more extensible, we are currently exploring potential improvements. In particular, we are considering alternative technologies, as used by Scheible et al [31]. This would enable us to add features based on modern technologies. Specifically, we are contemplating a different approach to computing synonyms. Instead of using discrete structures, we plan to train and use a FastText model [72].

Conclusions

The development of the independent, noncommercial tala-med search marks a step toward improving access to reliable and evidence-based health information online. By prioritizing transparency, independence, and high-quality content, the platform has the potential to bridge the gap in health information accessibility, especially for older and less-educated individuals. This study achieved its objective of evaluating the acceptance and usability of the platform, using user questionnaires and behavior tracking, and the results have been encouraging. The search engine was well received, with users appreciating its advertising-free design and filtering system, which addresses the navigational needs of individuals with lower health and digital health literacy.

User feedback also highlighted areas for improvement, particularly in the clarity of the design and filter functionality. Nevertheless, the platform's emphasis on anonymous searches and independence from advertising resonated strongly with participants, reinforcing the importance of alternatives to commercial search engines. These findings are based on initial impressions, with long-term use and satisfaction data still to be collected. Future research should compare the search engine with existing platforms to further explore its unique advantages, while ongoing updates and potential integration on partner websites will enhance its reach and relevance.

In conclusion, the tala-med search demonstrates a promising step toward enhancing health literacy and empowering individuals to make well-informed health decisions. By addressing users' navigational needs and promoting equitable access to high-quality, evidence-based medical information, the search engine has the potential to positively impact health literacy, reduce health disparities, and promote patient empowerment in the digital age.

Acknowledgments

The study was funded by the Innovationsausschuss of the Gemeinsamer Bundesausschuss (01NVF17010) as part of the GAP (Gut informierte Kommunikation zwischen Arzt und Patient, meaning "Well-informed communication between physician and patient" in English) project. Furthermore, this work was supported by the German Ministry for Education and Research (01ZZ1801B, 01ZZ1804A, 01KX2121, and 01ZZ2304A). Finally, we acknowledge support by the Open Access Publication Fund of the University of Freiburg.

Klaus Koch of the Institute for Quality and Efficiency in Health Care supported the domain selection for the search index. Julia Serong and Jakob Henke of the TU Dortmund University contributed to the evaluation concept.

Authors' Contributions

RS, NK, and CW planned and carried out the implementation of the search engine supported by FT under the supervision of MB and SV-R. RS carried out the mathematical framework for the search engine and filter estimation with the help of LS. KW and AS-L worked out the criteria with which the domains were evaluated. MS created the procedure for the weighting of the filter categories and evaluated the pages. MS developed the questionnaire under the supervision of AM. CS prepared the data analyses for the predictors of acceptance under the supervision of EF-G. CS and RS prepared the data analyses of the web tracking. RS and LS wrote the manuscript with the help of all authors and under the supervision of AM. The manuscript has been read and approved by all named authors.

Abstract

Background: As artificial intelligence (AI) evolves, its roles have expanded from helping out with routine tasks to making complex decisions, once the exclusive domain of human experts. This shift is pronounced in health care, where AI aids in tasks ranging from image recognition in radiology to personalized treatment plans, demonstrating the potential to, at times, surpass human accuracy and efficiency. Despite AI's accuracy in some critical tasks, the adoption of AI in health care is a challenge, in part because of skepticism about being able to rely on AI decisions.

Objective: This study aimed to identify and delve into more effective and acceptable ways of integrating AI into a broader spectrum of health care tasks.

Methods: We included 2 qualitative phases to explore podiatrists' views on AI in health care. Initially, we interviewed 9 podiatrists (7 women and 2 men) with a mean age of 41 (SD 12) years and aimed to capture their sentiments regarding the use and role of AI in their work. Subsequently, a focus group with 5 podiatrists (4 women and 1 man) with a mean age of 54 (SD 10) years delved into AI's supportive and diagnostic roles on the basis of the interviews. All interviews were recorded, transcribed verbatim, and analyzed using Atlas.ti and QDA-Miner, using both thematic analysis for broad patterns and framework analysis for structured insights per established guidelines.

Results: Our research unveiled 9 themes and 3 subthemes, clarifying podiatrists' nuanced views on AI in health care. Key overlapping insights in the 2 phases included a preference for using AI in supportive roles, such as triage, because of its efficiency and process optimization capabilities. There is a discernible hesitancy toward leveraging AI for diagnostic purposes, driven by concerns regarding its accuracy and the essential nature of human expertise. The need for transparency and explainability in AI systems emerged as a critical factor for fostering trust in both phases.

Conclusions: The findings highlight a complex view from podiatrists on AI, showing openness to its application in supportive roles while exercising caution with diagnostic use. This result is consistent with a careful introduction of AI into health care in roles, such as triage, in which there is initial trust, as opposed to roles that ask the AI for a complete diagnosis. Such strategic adoption can mitigate initial resistance, gradually building the confidence to explore AI's capabilities in more nuanced tasks, including diagnostics, where skepticism is currently more pronounced. Adopting AI stepwise could thus enhance trust and acceptance across a broader range of health care tasks, aligning technology integration with professional comfort and patient care standards.

Introduction

Background

As artificial intelligence (AI) continues to advance, its potential to revolutionize health care is unquestionable. AI systems are increasingly capable of performing tasks that range from routine data analysis to complex decision-making processes that were once the sole domain of human experts. These technologies offer the promise of more accurate predictions [1], more precise patient condition explanations [2], autonomous diagnoses [3], and personalized treatment plans [4]. Despite these capabilities, there remains an evident hesitancy among health care professionals and patients alike to embrace AI-driven recommendations fully. This skepticism is partly rooted in worries about AI's capacity to grasp patients' nuanced, individual scenarios [5], to integrate the crucial human elements of empathy and understanding [6,7], and to deal with complex ethical considerations in health care [8].

The literature on trust in AI highlights concerted efforts to foster trust by exploring strategies to address trust issues between AI systems and users. For example, some studies suggest that redefining AI as a supportive adjunct to professionals rather than a standalone solution could promote acceptance [9,10]. In addition, showcasing instances where AI surpasses human experts in specific tasks may enhance humans' trust in AI [5,9,11]. Emphasizing transparency and providing understandable explanations of AI processes are crucial, with evidence showing users how AI works can greatly diminish skepticism [12-15]. For example, applying explainable AI (XAI) techniques to explain the basis of AI-generated predictions can, in certain contexts, enhance human trust and understanding [12]. Although XAI can potentially be valuable in increasing trust and understanding, the specific implementation of XAI (eg, the complexity and relevance of the explanation) is crucial in achieving those goals [16]. However, despite these positive developments, fully integrating AI into practice remains challenging, and professionals and laypersons often still prefer human judgment and intuition over AI recommendations [6,7,10,17].

AI's potential applications within health care are vast and multifaceted. Its well-established ability to detect diseases such as cancer and predict various health conditions highlights its substantial role in diagnostics. Not only does AI excel in recognizing patterns within medical images for early disease detection, offering a level of precision that can sometimes surpass traditional methods [3,18,19], but also its influence extends beyond diagnostics. AI assumes a crucial supportive role in health care operations, such as triaging in emergency departments where algorithms prioritize care based on urgency and outcomes, thereby optimizing resource allocation and ensuring timely patient attention [20]. Furthermore, AI's capacity for enhancing operational efficiency is evident across a spectrum of health care activities. It predicts bed availability and automates the conversion of patient consultations into concise summaries, thereby freeing health care professionals from administrative work. This enables more patient-centered care and marks AI as a transformative tool in health care [21].

This study seeks to delve deeper into health care providers' perspectives on AI's current and potential role and value in their field. While previous studies often focus on assessing trust in already developed AI systems, this study takes a different approach by involving health care professionals from the outset in identifying potential applications of AI. Early engagement allows us to determine where AI is anticipated to be most valuable, fostering a more collaborative and user-centered integration that aligns with professionals' needs and expectations. By engaging directly with health care professionals who are the prospective users of these AI applications, the study seeks to pinpoint areas where AI integration would be most advantageous and eagerly anticipated by practitioners. Through this inquiry, we aspire to pave the way for more effective and user-endorsed integration of AI in health care, aligning technological advancements with health care professionals' real-world needs and preferences.

Objective

Our study explores health care providers' perceptions of AI's potential benefits in patient care and operational efficiency, with examples including risk assessments and diagnostics. The effectiveness of AI technologies depends on their advanced capabilities and, more crucially, on their acceptance by health care professionals. Without their acceptance, achieving a truly successful implementation becomes only partial, leading to the largely unrealized potential of AI. Thus, we aim to understand these professionals' perspectives on AI adoption, emphasizing the development of trust and integration strategies and identifying approaches that position AI as a valuable tool complementing human expertise, not replacing it [10]. Consequently, the central research question we propose is as follows: How can AI be effectively integrated into practice in a way that ensures health care professionals' acceptance and trust in its advice?

We adopt a qualitative approach to address our research question, focusing on the FootCheck (RondOm Podiatrists) app (in Dutch: Voetencheck app). This app, specifically designed for the daily monitoring of patients with diabetes in the Netherlands, sends daily push notifications to guide these patients through a foot screening process, featuring instructional videos and questions. This enables patients to submit photos to podiatrists to evaluate potential issues such as wounds or ulcers. During its successful pilot phase, which occurred amid the COVID-19 pandemic, the app was used by over 1700 individuals, leading to more than 43,000 screenings [22]. Recognizing the growing interest of stakeholders in leveraging

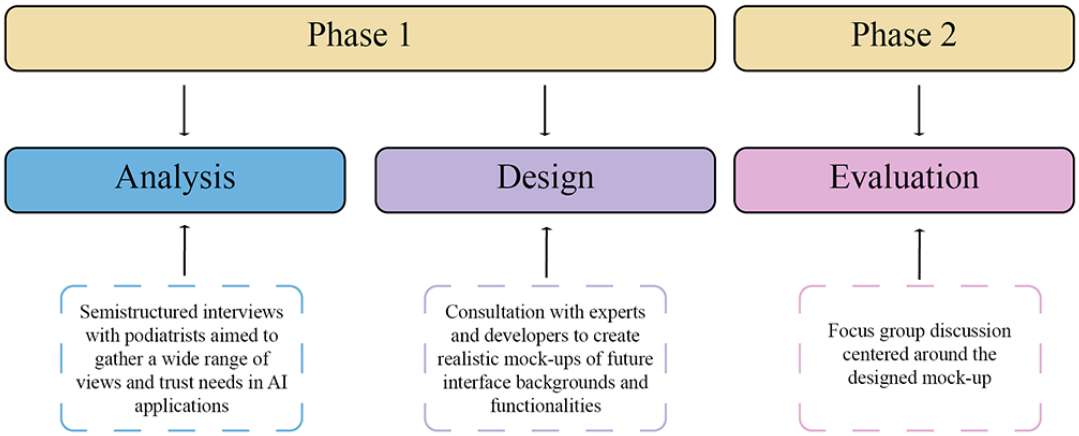
AI to enhance efficiency and health care quality, we believe the FootCheck app provides an ideal basis for exploring AI's potential. It is important to note that the app still lacks AI integration, highlighting the potential benefits of AI for future enhancements. Our study includes interviews with diverse podiatrists, encompassing current and potential future app users. These interviews aim to understand their experiences and perspectives regarding using the app as it is and the prospects for integrating AI into the screening process of future versions of the app.

Methods

Design and Setting

We conducted a qualitative study structured in 2 phases to investigate trust and acceptance in AI. In phase 1, we sought to capture diverse perspectives and needs from podiatrists regarding their trust in and acceptance of AI technologies through semistructured interviews. The insights gathered from these interviews served as input to the mock-up design process. Phase 2 aimed to further explore specific AI applications through a focus group session. Figure 1 provides a visual representation of these phases.

Figure 1. A visual presentation of the 2 phases of the study. AI: artificial intelligence.



The FootCheck App and Decision-Making Process

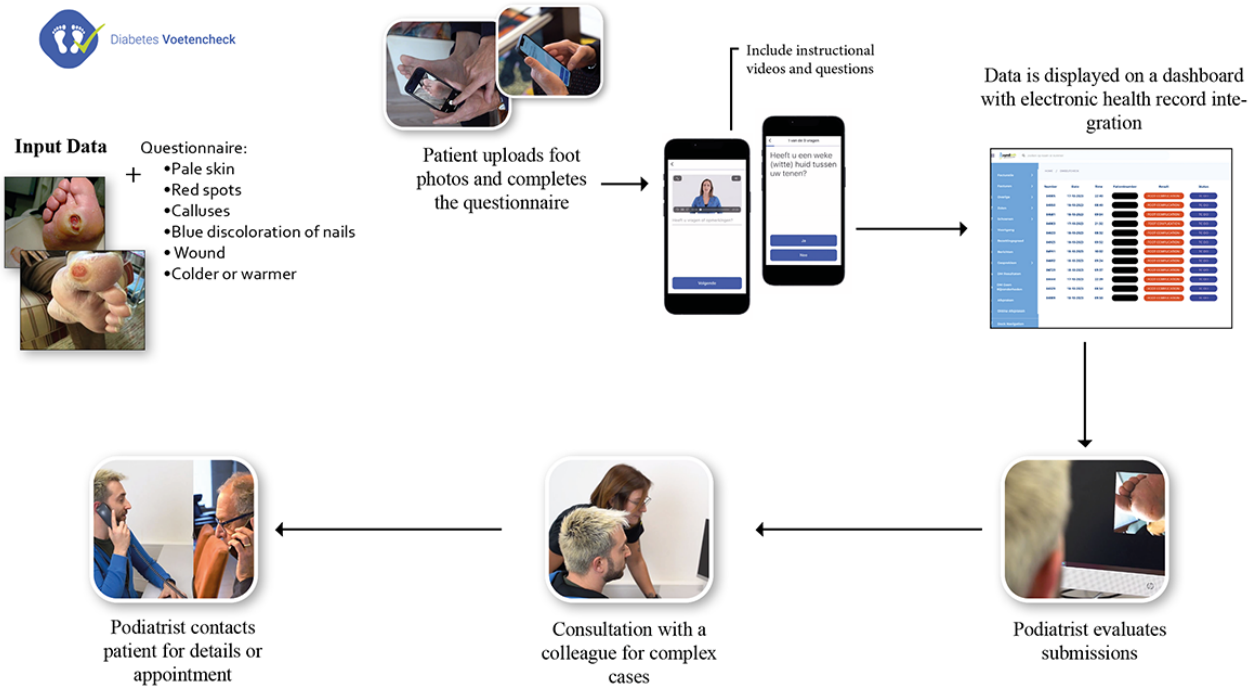
The practical application of AI in health care settings we studied was the FootCheck app, developed for RondOm Podiatrists. As one of the largest podiatry chains in the Netherlands, RondOm Podiatrists introduced this app during the COVID-19 pandemic to ensure continuous care for their patients. The app has since been used to facilitate daily monitoring of foot health for patients with diabetes, allowing patients to submit photographs for screening. The workflow from patient submission to professional evaluation is illustrated in Figure 2.

RondOm Podiatrists are keenly interested in the potential of AI to enhance their app and streamline decision-making processes. The system does not use AI currently, but there are numerous potential areas where AI could provide substantial benefits. For example, AI could be instrumental in assessing the suitability of submitted photos for evaluation. This capability would significantly reduce the workload on professionals by automatically filtering out low-quality or irrelevant images, ensuring that only those suitable for review are presented. This efficiency gain is crucial as it allows podiatrists to focus their expertise where it is most needed rather than on preliminary sorting tasks.

Moreover, AI could assist in prioritizing cases on the basis of urgency. Currently, podiatrists must manually open and evaluate all submitted photos, which is time-consuming and potentially less effective in quickly identifying urgent cases. By implementing AI to perform a preselection of instances based on predetermined criteria of urgency, the system could ensure that patients requiring immediate attention are identified and prioritized, thereby optimizing patient care and resource allocation.

Another critical area in which AI could have a significant role is aiding in the diagnosis of foot conditions. The increasing number of patients with diabetes and a relative shortage of podiatrists present a growing challenge. AI can alleviate some of this burden by providing preliminary assessments based on the analysis of photos. While the professional community may have reservations about relying entirely on AI for diagnoses, its role in offering support and preliminary assessments could be invaluable. This assistance could help bridge the gap in service provision, ensuring that more patients receive timely and effective care.

Figure 2. Workflow from patient submission to professional evaluation.



Phase 1: Participants and Recruitment Process

In the first phase of our study, we engaged in interviews with 9 podiatrists from 4 distinct practices, aiming to gather diverse insights into the use and perception of the health care app in question. The actual use of the current app varied considerably among participants, encompassing some who used the app daily and others who, while not yet current users, were familiar with its functionalities. Furthermore, participants' professional expertise spanned different aspects of podiatric care, including both foot care for patients with diabetes and general foot health services.

The recruitment of participants was facilitated through a collaborative effort with the Fontys University of Applied Sciences, one of the leading institutions for podiatry education in the Netherlands. This collaboration was essential for 2 reasons. First, Fontys University maintains strong ties with its alumni, many of whom stay actively engaged with the university through professional networks, alumni events, and workshops. Second, Fontys University's Health Innovations & Technology research group maintains regular collaborations with health care institutions, ensuring strong connections within the field. Through these partnerships, we recruited a diverse group of motivated podiatrists who voluntarily participated in the study. By using Fontys University's network and its respected position within the field, we ensured the participation of podiatrists with varying levels of experience and expertise across different areas of podiatric care, contributing to a representative sample for our study. To accommodate our participants' varying schedules and preferences, the interviews were conducted using a hybrid approach; some were held in person, taking advantage of the natural setting of the participants' practice environments, while others were carried out through the Teams (Microsoft Corp) platform.

Data Collection

We started an extensive literature review on trust in AI, both generally and within the health care context, from which we identified key topics. These topics were categorized into 4 groups as follows: knowledge of AI, trust in humans and AI advice, AI's added value to daily tasks, and factors affecting trust in AI. On the basis of these categories and codes, we formulated initial interview questions. Next, we sought feedback on these initial questions from experts in human and machine interaction. We incorporated their feedback and refined the questions to ensure their relevance and comprehensiveness. To validate the clarity and comprehensiveness of these questions, we conducted a preliminary interview with an experienced podiatrist. This pilot interview served to ensure the questions were understandable and relevant for the prospective interviewees, and it also provided an opportunity to identify any missing questions from the practical perspective of podiatry. The resulting interview guide is detailed in Multimedia Appendix 1.

Participants were briefed on the study's objectives—namely, to explore their perceptions of AI, identify factors influencing trust in AI among podiatrists, examine the impact of trust on AI adoption, and assess their needs for trusting AI in patient care. They were requested to share demographic information via a link before the interview sessions. The specific interview questions were withheld in advance to preserve the authenticity of responses. The interviews were conducted from July to September 2023.

Consent for recording was obtained from all podiatrists, with the sessions captured either on a voice recorder or through the Teams platform, depending on the interview format. These recordings were transcribed verbatim, using Amberscript [23] for efficiency and accuracy. For interviews conducted on the

Teams platform, we leveraged the platform's transcription functionality. Each interview spanned approximately 30 to 45 minutes, with podiatrists having provided explicit consent, either written or digital, for participating and recording their responses. They were also assured of their right to withdraw from the study at any time.

Data Analysis of the Semistructured Interviews

We used a dual-coding strategy, where 2 researchers independently analyzed the interview transcripts to ensure a robust examination of the data. Researcher 1 (MAT), a PhD candidate with a solid background in qualitative research methodologies, and researcher 2 (Ruben Gloudemans) used distinct software tools for coding—Atlas.ti (version 11; Atlas.ti Scientific Software Development GmbH) and QDA-Miner (version 6.0; Provalis Research). This divergence in tool use stemmed from their prior experiences and the software licenses available.

Following the thematic analysis by Braun and Clarke [24], we initiated our analysis by thoroughly reading the transcripts to gain an initial understanding and verify their accuracy. First, we labeled the transcripts without predefined categories, using an inductive approach leading to an extensive list of initial codes directly derived from the data. For example, codes such as human interaction, urgency ranking, efficiency, risk detection, and false advice were formed. We then examined these initial codes to determine if they overlapped with the topics we had previously identified from the literature and combined them if needed. For example, urgency ranking and risk detection were put together since both are related to the topic added value of AI. In this step, we started a deductive approach, where we applied existing theoretical frameworks to refine our codes into coherent themes. We repeated this analytical process several times, refining our approach each time to ensure the emergence of concrete themes. This process yielded a preliminary set of themes.

Subsequently, our individually identified themes were compared in a meeting, discovering significant overlap. For some themes where our interpretations initially diverged, we reached consensus through discussion, using inductive and deductive reasoning. These discussions revealed that, despite using different terminologies, we were referring to the same thematic content. Our thematic analysis was refined further through this iterative process of inductive and deductive coding.

Mock-Up Design

Guided by our research question on how AI can effectively integrate into the FootCheck app's existing screening process with user acceptance, we sought the podiatrists' insights on how they would like to receive advice and in which forms to ensure their confidence in it. Various suggestions emerged, such as explaining the reasoning behind the advice, photos pinpointing potential complications on the feet, and color-coding systems for triage. However, the first phase did not conclusively determine which forms of applications and the level of transparency would foster greater trust.

To further explore these possibilities, we organized a focus group featuring mock-ups. Presenting a realistic representation was crucial, particularly considering that currently, the app and its screening process do not use AI.

1. The first mock-up was designed to assess the effectiveness of AI in a supportive role, specifically in scheduling and prioritizing patient consultations based on an array of time indicators.
2. The second mock-up aimed to explore the potential of AI in diagnosing conditions by analyzing photographs submitted by users and identifying common foot complications such as ulcers or calluses.

We aimed to delve deeper into assessing these AI roles by examining their functionality and acceptability among podiatrists. We crafted 3 distinct design variations for each mock-up to achieve this, guided by needs and concerns expressed in the first interviews with the podiatrists. Our primary reason for this approach was to facilitate a broad discussion by presenting transparency levels varying from low to medium to high. This method allowed us to not only compare the discussions across different AI applications but also delve into the discussions within each level of transparency. Thereby, we aimed to explore the range in podiatrists' perceptions and acceptance extensively.

In designing these mock-ups, we used the current interface environment to ensure familiarity for users. In addition, we consulted with experts during the design process to ensure the mock-ups were practical and reflective of current best practices in the field. For an illustration of mock-up 1 with a high transparency level, see Figure 3; for the diagnostic mock-up set in a medium transparency, refer to Figure 4. For a detailed overview of all variants, refer to Multimedia Appendix 2.

Figure 3. Mock-up 1: high-transparency variant.

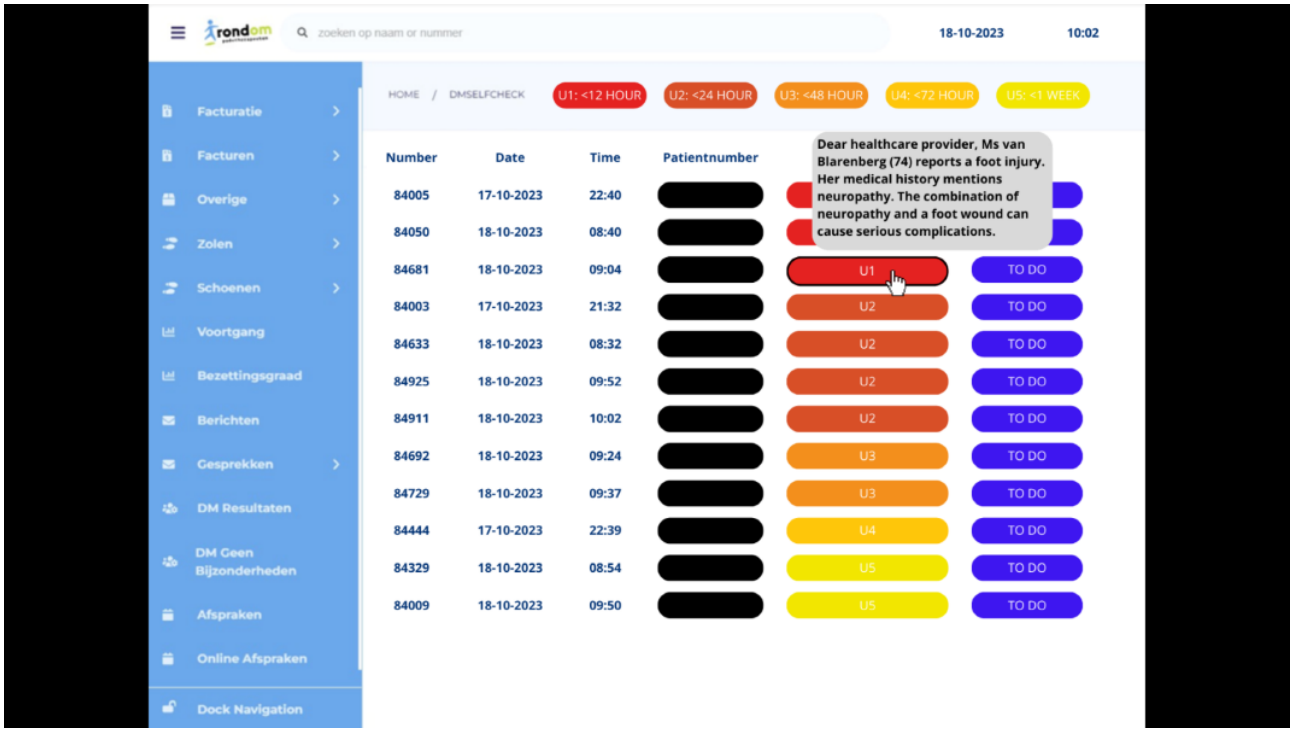


Figure 4. Mock-up 2: medium-transparency variant.

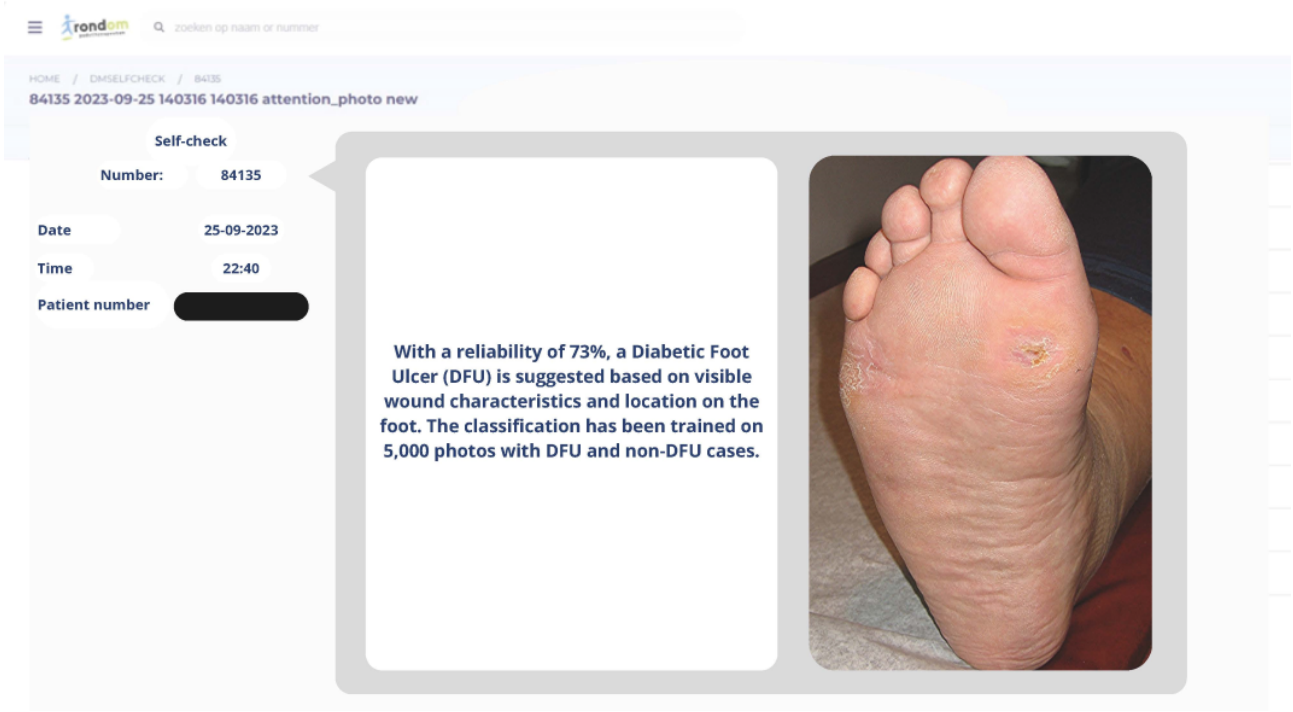


Phase 2: Participants and Recruitment Process

Phase 2 was aimed at enriching our understanding and validating the outcomes of the first phase. Initially, we used the same approaches that had effectively recruited participants for phase 1, including relying on Fontys University's network and existing partnerships within the podiatry field. We also reached out to contacts from our previous interviews. However, these efforts alone were insufficient to meet our needs for new participants for phase 2. To broaden our reach, we engaged with potential candidates on social media platforms such as LinkedIn (LinkedIn Corp) and Facebook (Meta Platforms, Inc) and attended podiatrist conferences to connect with new professionals. Through these combined efforts, we recruited 4 new podiatrists who had not been involved in the first phase and reinvited one participant from phase 1. The focus group session was organized at the Fontys University of Applied Sciences' inspiration space in December 2023.

Procedure for Focus Group and Data Collection

To evaluate our mock-ups, we created an interview guide on essential topics derived from the findings of phase 1: trust in AI's role, transparency preferences, and AI's effect on decision-making, outlined in Multimedia Appendix 3. During the focus group session, participants were thoroughly briefed on the structure of the session that was divided into two 45-minute segments with a break in between. The first session explored mock-up 1, while the second delved into mock-up 2.

The roles of MAT and Ruben Gloudemans within the session were clearly defined for participants; MAT served as the observer, summarizing discussions and posing questions, whereas Ruben Gloudemans led the session and presented the materials. Participants provided written consent by signing a consent form.

After a brief introduction, participants were provided two A3-sized sheets, each showcasing 3 mock-up variants highlighting different transparency levels. Before initiating the group discussions, participants were asked to individually rank these variants from 1 to 3, with 1 being their top preference, and to write down comments next to each variant explaining their choices. This step was designed to minimize mutual influence and ensure that each participant's initial reactions and thoughts were captured independently. Following this individual reflection, detailed group discussions were held, focusing on participants' rationale regarding their preferences and trust in the AI advice shown in each variant.

Data Analysis Focus Group

All participants attended in person for the data collection of phase 2. Initially planned as two 45-minute segments with a 15-minute break in between, the session ultimately lasted 70 minutes in a single stretch. This was shorter than anticipated, primarily because the first segment was concluded earlier than expected, and participants opted to proceed without taking the scheduled break.

We adopted a more structured coding method as we progressed to the second phase, building on the codes and themes identified in the first phase. This shift was enabled by implementing a thematic framework approach, a systematic strategy that helped us to systematically organize and interpret the data [25].

After verifying transcription accuracy and familiarizing ourselves with the transcript, we developed an analytical framework. This framework included predefined themes from phase 1: AI's roles, transparency levels, data reliability, trust development, and the significance of human interaction. This step laid the groundwork for indexing, where we systematically tagged the data with our framework's themes. Next, through charting, we distilled participants' responses into structured summaries, aligning them with the thematic framework. In the indexing and charting phase, we organized the data into themes linked to our research goals, creating visual charts. This approach helped us spot patterns and differences, uncovering insights that enhanced our understanding.

Ethical Considerations

No medical devices were used in the studies, and no physical interventions were performed on participants. The image used in mock-up 2 originated from publicly available internet sources and was appropriately licensed. Consequently, under regulations stipulated by the Dutch Medical Research Involving Human Subjects Act (WMO), the necessity for ethics approval from a national ethics committee was circumvented. However, ethical clearance was proactively obtained from the internal ethics committee of Fontys University of Applied Sciences, documented under project numbers 050324 and 080324. There were no conflicts of interest between the participants and the FootCheck app. None of the participants had any financial, developmental, or other professional ties to the app.

Results

Phase 1: Semistructured Interviews

Participants

Participant demographics for phase 1 are listed in Table 1. In total, 9 individuals, all with backgrounds in podiatry, participated in the first phase of our study. A distinguishing characteristic of this cohort is their active engagement in clinical practice, that is, their extensive practical experience.

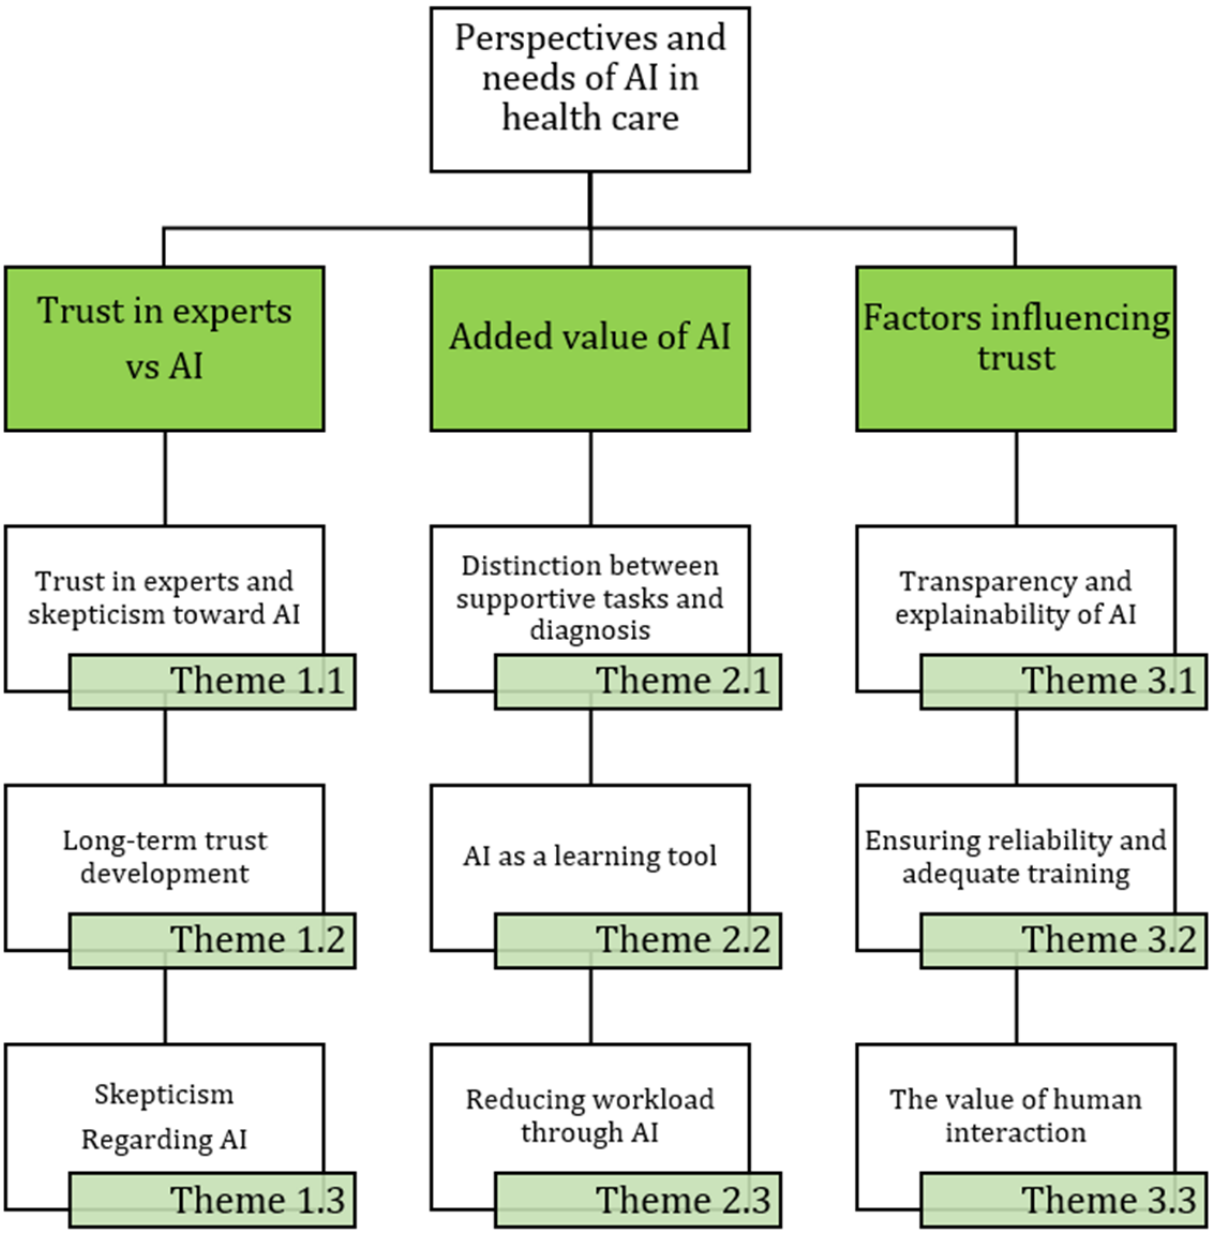
Table 1. Participants' characteristics from semistructured interviews in phase 1 (n=9).

Characteristics	Participants, n (%)
Sex	
Female	7 (78)
Male	2 (22)
Age group (y)	
20-30	1 (11)
31-40	2 (22)
41-50	3 (33)
51-60	2 (22)
61-70	1 (11)
Education level	
Bachelor's	4 (44)
Master's	4 (44)
PhD	1 (11)
Specialized education: foot care for patients with diabetes	
Yes	4 (44)
No	5 (56)
Experience (mo)	
0-6	1 (11)
6-12	2 (22)
12-24	4 (44)
24-36	2 (22)
Experience with the app	
Yes	2 (22)
No	7 (78)

Themes From the Interviews

The interviews with podiatrists revealed 3 critical themes regarding podiatrists' perspectives and requirements for AI integration in the FootCheck app and related decision-making process: trust in human experts versus in AI, the added value of AI, and the factors influencing trust in AI. Each theme is further divided into 3 subthemes. A detailed overview of these key themes can be found in Figure 5.

Figure 5. Generated themes and subthemes from phase 1: perspectives of experienced podiatrists on the FootCheck app and decision-making process. AI: artificial intelligence.



Theme 1: Trust in Experts Versus AI

In the initial phase of the interview, we began by asking participants about their understanding of AI and their trust in it compared with their colleagues (ie, experts). We aimed to uncover how AI impacts their trust levels and the underlying reasons for these views.

Theme 1.1: Trust in Experts and Skepticism Toward AI

Podiatrists expressed trust in the advice from expert colleagues, on the basis of their extensive knowledge and experience. They recognized that making mistakes is part of being human and considered it normal for colleagues to err every now and then. Conversely, when receiving advice from AI, direct trust is not immediately established for most podiatrists. They maintained a critical stance, emphasizing the need to verify the accuracy of AI-generated advice:

> *I trust a colleague, sometimes blindly, because they have much experience.* [Participant 7, female, age group 61-70 years]
>
> *I see the added value of AI advice. But I still want to check it or have something alongside it.* [Participant 2, female, age group 51-60 years]
>
> *I do have trust in advice from colleagues. I've considered practical situations, and nine times out of ten, I agree with them just fine. And there are always nuanced differences because you see things slightly differently with your experience, perspective, and view. But let me put it this way: I firmly trust it.* [Participant 8, male, age group 41-50 years]

Theme 1.2: Long-Term Trust Development

Participants indicated that AI may initially struggle to provide accurate advice due to the limited data available and the learning phase required for the model. They also mentioned their initial lack of experience with using AI, which leads to uncertainty about its performance. However, participants felt their trust can increase as they gain more experience with the AI model:

> *In the beginning, I was sceptical, but as it sees and evaluates more photos, my trust grows.* [Participant 9, female, age group 20-30 years]
>
> *Yes, AI needs to prove itself first, and then it can add value.* [Participant 7, female, age group 61-70 years]
>
> *Indeed, my trust in AI would significantly increase if, over time, the technology evolves to a stage where the AI system is fully operational and applicable.* [Participant 6, female, age group 41-50 years]

Theme 1.3: Skepticism Regarding AI

Participants expressed significant concerns about the potential errors an AI system might make and the severe consequences that could arise from such mistakes. In addition, they highlighted a notable limitation of AI: its inability to conduct physical examinations on patients. Such examinations are often essential for a thorough understanding of a patient's foot health, indicating a gap in AI's capabilities in health care settings:

> *Yes, if a patient says: "I have pain in my foot, for example, in the ankles." Well, AI can't see that or physically feel or move it.* [Participant 9, female, age group 20-30 years]
>
> *We're not talking about a patient getting advice to buy Shoe A, and then they say it's too big and buy another shoe.... We're talking about serious outcomes, like the loss of a foot, a leg, or even a life, and that's a significant responsibility.* [Participant 4, female, age group 31-40 years]
>
> *The consequences are quite significant if you miss something there.* [Participant 7, female, age group 61-70 years]

Theme 2: Added Value of AI

Overview

In exploring AI's potential impact on podiatry, we engaged participants in discussions about integrating AI into their everyday practice. This dialogue revealed 3 insightful subthemes, each shedding light on AI's role in enhancing podiatric care. The following sections delve into these emergent themes.

Theme 2.1: Distinction Between Supportive Tasks and Diagnosis

Nearly all participants agreed that AI should be used for support tasks such as triage. They highlighted that significant time is spent retrieving missing information not provided by patients and addressing issues with incorrect photo submissions that impede accurate assessment. They were of the opinion that these tasks could be efficiently managed by AI, thereby streamlining the process and improving overall efficiency. However, opinions varied on whether AI can diagnose foot conditions in patients with diabetes. Most participants were of the opinion that AI is incapable to do so, emphasizing the need for physical examinations by human experts to come up with an accurate diagnosis. They pointed out that photos fail to reveal crucial details, such as hidden wounds beneath calluses, which are not directly visible in pictures. Furthermore, participants noted the importance of physically assessing the feet for swelling and temperature variations (ie, warmth or coldness) that cannot be discerned from photos alone:

> *If it can highlight specific areas of concern, suggesting "pay attention here, this is alarming," then I do place my trust in it.* [Participant 3, female, age group 41-50 years]
>
> *AI can't make complete diagnoses; you need to hold the foot in your hands.* [Participant 2, female, age group 41-50 years]
>
> *I'm considering integrating a feature for predicting situations where an immediate consultation is crucial and distinguishing those from cases where it might not be as urgent.* [Participant 1, male, age group 41-50 years]
>
> *If it integrates well with practical needs, like photos can be easily uploaded directly into the file, making follow-up simpler. Yes, so it actually assists in your work.* [Participant 6, female, age group 41-50 years]

Theme 2.2: AI as a Learning Tool

Participants acknowledged the potential of AI as a valuable learning tool, particularly for identifying unfamiliar diseases and suggesting innovative treatment strategies. They expressed optimism about AI's ability to broaden their diagnostic and therapeutic horizons:

> *Maybe the AI will uncover a disease pattern I haven't encountered before, offering me an opportunity to expand my knowledge.* [Participant 1, male, age group 41-50 years]
>
> *Hey, AI sees things differently, and that's something I can learn from. I do see the added value in that.* [Participant 5, female, age group 20-30 years]
>
> *In this light, I believe that when an AI indicates, "this is the optimal treatment," it becomes incredibly fascinating. It prompts a collective inquiry: "Why hadn't this occurred to us before? Is this indeed the correct approach? Or is there already a hospital implementing this method?"* [Participant 4, female, age group 31-40 years]

Theme 2.3: Reducing Workload Through AI

Participants highlighted the health care sector's challenge of increasing workloads, worsened by a decreasing number of podiatrists and a growing number of patients with diabetes. There was widespread agreement on AI's ability to alleviate this load. By automating processes such as triage, AI can significantly reduce the workload, freeing podiatrists to focus on the more crucial parts of patient care:

As the pressure continues to increase, I see AI as a great tool to indeed perform a kind of triage to ensure that the workload doesn't become overwhelming. [Participant 3, female, age group 41-50 years]

But yes, to be completely honest, looking towards the future, we definitely need to reduce the workload; otherwise, we'll end up with even fewer people having to help more individuals. [Participant 4, female, age group 31-40 years]

Theme 3: Factors Influencing Trust

Overview

Finally, we delved into the pivotal elements that shape trust in AI-provided advice. We also probed when participants might be inclined to defer to AI's judgment over their own. This investigation unveiled 3 subthemes, each shedding light on the interaction between humans and AI systems.

Theme 3.1: Transparency and Explainability of AI

All participants agreed that clear explanations and transparency are essential, considering them as fundamental to trusting AI. They wished to comprehend the methodology AI uses to arrive at its recommendations. They proposed several methods to enhance transparency, such as providing concise explanations of the criteria AI uses for its evaluations, statistical performance data, or visual aids such as photos with overlaying layers or color coding:

I believe factors like the colour of the callus, the size of the area, its location, and history also play a role. Has there been a wound in that spot before? Yes, things like that. [Participant 8, male, age group 41-50 years]

For example, I want to see a number of photos of the foot along with some explanation about them. I want to understand how the evaluation system is designed and the data it uses. [Participant 2, female, age group 51-60 years]

It increases my confidence in knowing the sources from which AI retrieves its information or the ones I've provided to it. [Participant 1, male, age group 41-50 years]

Theme 3.2: Ensuring Reliability and Adequate Training

Participants were of the opinion that AI should be advanced enough from the beginning, emphasizing that a more extensive database of photos would increase their trust in the system. They would like AI to provide consistent advice, ideally on par with a fellow podiatrist. Training was highlighted as a crucial element for enhancing AI's performance. In addition, understanding who the designers are and the data used for training is considered necessary. If participants know the designers are experts in their field, they feel more confident in the AI tool's reliability:

Well, if you've only input three things into it, I won't trust it. But if you've input 300,000 things, then at some point, you really know better. [Participant 2, male, age group 41-50 years]

Well, I'm not quite sure how that works, but if that's the case, then the people involved in setting it up need to have the right background knowledge, the right experience with the subject; they need to be specialists, so to speak. [Participant 2, female, age group 51-60 years]

Theme 3.3: The Value of Human Interaction

Participants emphasized that future AI applications must not compromise their interaction with patients, highlighting each patient's uniqueness and background. They cautioned that AI may not always account for these personal nuances, underlining the importance of maintaining the human touch in health care:

I still believe that personal human contact will never disappear. [Participant 3, female, age group 41-50 years]

All those kinds of things. Yes, they're slightly different for everyone. [Participant 1, male, age group 41-50 years]

But you still maintain human contact between the client and yourself, allowing them to easily ask additional questions, for instance, to you. [Participant 5, female, age group 61-70 years]

Moving From Phase 1 to Phase 2

The findings from phase 1 revealed that AI can significantly improve various practical aspects of podiatry, particularly by alleviating workloads and serving as a learning tool. A clear preference was observed for using AI in supportive tasks rather than diagnostic roles. This reflects a cautious attitude of podiatrists toward AI-generated advice and raised the question: Will AI support be more readily accepted in supportive than in diagnostic tasks, and what factors influence this difference in acceptance?

Therefore, phase 2 of our study sought to explore the specific applications of AI in supportive versus diagnostic roles within podiatry in detail. Given the ongoing reluctance toward its role in diagnostics, this study aimed to understand the elements that can foster trust in AI for supportive tasks. By introducing a new group of podiatrists, phase 2 of our study aimed to gather fresh insights and assess whether the findings observed in phase 1 align with new professional perspectives.

Phase 2: Focus Group

Participants

Table 2 outlines an overview of the demographics of the focus group participants. The group consisted of 5 participants, 4 of whom were new podiatrists who engaged in the discussion. This group consisted of specialists in foot care for patients with diabetes, who primarily provide daily consultations to these patients.

Table 2. Participants' characteristics from focus groups in phase 2 (n=5).

Characteristics	Participants, n (%)
Sex	
Female	4 (80)
Male	1 (20)
Age group (y)	
41-50	2 (40)
51-60	2 (40)
61-70	1 (20)
Education level	
Bachelor's	2 (40)
Master's	3 (60)
Specialized in foot care for patients with diabetes	
Yes	5 (100)
No	0 (0)
Experience (y)	
20-30	4 (80)
31-40	1 (20)
Experience with the app	
Yes	2 (40)
No	3 (60)

In phase 1 of our study, we opted for a flexible approach, allowing themes to emerge directly from the transcribed data. This exploratory phase enabled us to capture many insights directly from participants' experiences and perspectives. Moving into phase 2, we shifted toward a more structured approach, using themes, which were relevant for phase 2 and predefined in phase 1. This transition allowed us to refine our analysis, focusing on the detailed examination of specific, predetermined themes to gain deeper insights and understanding of the topics at hand.

For a clear overview, we first present the key findings from the participants about various transparency levels for the 2 mock-ups in Table 3. Subsequently, in Table 4, we display the other themes carried forward from phase 1 for further analysis in phase 2, ensuring a comprehensive and structured exploration of the data.

Table 3. Thematic framework analysis for key findings and preferences of transparency levels in AI[a] applications.

Theme: transparency and explainability of AI	Mock-up 1: AI support (triage and scheduling)	Mock-up 2: AI diagnosis (photo analysis)
Low (variant A)	Podiatrists perceive this variant as a "black box," with unclear determination of urgency and relevance of the presented information	Feedback indicates general dissatisfaction and a lack of clarity on how AI reaches its conclusions
First preference	—[b]	P4 and P5 (n=2)
Second preference	—	—
Third preference	P1-P5 (n=5)	P1-P3 (n=3)
Medium (variant B)	Podiatrists express concerns over the reliability of patient feedback as input for AI, pointing out a lack of crucial information such as wound location	While the text is deemed acceptable, this variant raises questions about the necessity of repeating information
First preference	—	—
Second preference	P1-P5 (n=5)	P1-P5 (n=5)
Third preference	—	—
High (variant C)	Preference is given to detailed information, including specific medical details and clear patient identification	Podiatrists appreciate the clarity and added layer of understanding this variant provides but question the necessity of certain statistics, such as a reliability percentage
First preference	P1-P5 (n=5)	P1-P3 (n=3)
Second preference	—	—
Third preference	—	P4 and P5 (n=2)

[a]AI: artificial intelligence.

[b]Not applicable.

Table 4. Thematic framework analysis for AI[a] applications and predefined themes.

Themes	Participant 1 (female; age group 51-60 y)	Participant 2 (female; age group 41-50 y)	Participant 3 (male; age group 41-50 y)	Participant 4 (female; age group 51-60 y)	Participant 5 (female; age group 61-70 y)
Distinction between supportive tasks and diagnosis	Prefers AI for triage due to speed and accuracy. Skeptical about diagnostic capability without physical examination	—[b]	Values AI's ability to prioritize photos based on urgency, enhancing patient care efficiency	Believes AI is incapable of handling complex diagnostic tasks, such as differentiating between types of wounds	Asserts that computers cannot replace human nuanced observation in diagnostics, emphasizing AI's use in triage
Ensuring reliability and adequate training	Values the volume of feedback, similar to how reviews inform vacation choices	Trust is reinforced by a large volume of photos, indicating data reliability	Importance of data diversity, including training AI on poor-quality photos	Questions the repetitive mention of the photo database size suggest it is only necessary in training	Trust depends on knowing the AI's advice is based on an extensive and diverse photo database
Long-term trust development	—	Trust in the algorithm grows over time with proven accuracy	Initial skepticism evolves into trust after multiple positive experiences	—	Anticipates a future shift in acceptance of AI's advice, especially without a photo, within a decade
The value of human interaction	—	—	—	Asserts that physical tools and examination are indispensable for accurate diagnostics	Stresses the irreplaceable role of human involvement in making accurate diagnoses

[a]AI: artificial intelligence.

[b]Not applicable.

For the frameworks (Tables 3 and 4), instead of using quotes from focus group participants, we chose to provide summaries of the key findings, following the common practice in thematic framework analysis. By creating summaries, we were able to handle the complex discussion, which involved a record with 7 speakers, more easily.

Interpretations of Thematic Framework Analysis

On the basis of the thematic framework analysis of podiatrists' preferences for AI integration in clinical settings, a clear pattern emerges regarding the desired application and form of transparency in AI systems for triage. Podiatrists prefer using AI in triage, emphasizing the importance of transparency that goes beyond just being open. They are looking for a kind of transparency that involves clinically relevant and detailed information—such as patient history, specific conditions such as the presence of vascular diseases, and exact wound locations—that significantly augment the decision-making process:

> *The added value for me is that the ranking is done by the AI, so photos are prioritised based on urgency.* [Participant 3, male, age group 41-50 years]
>
> *My preference is for triage; an AI can perform it much faster than a human. Well, I believe that AI is capable of making a risk assessment.* [Participant 1, female, age group 41-50 years]
>
> *Key abnormalities must be quickly recognised and addressed, achievable through triage.* [Participant 5, female, age group 61-70 years]

In the domain of triage, skepticism toward patient-reported data as the sole basis for AI-generated advice is evident (eg, medium transparency mock-up 1). The concern centers on the reliability of such data, highlighting a preference for AI systems that incorporate a comprehensive training dataset to inform their assessments. This reflects a broader apprehension regarding the accuracy of AI recommendations based on potentially incomplete or inaccurate patient self-assessments:

> *I'm not entirely convinced by the patients' responses. If they say they have a wound on their feet, then yes, I might believe it, but if they don't have a wound, I'm sceptical.* [Participant 1, female, age group 41-50 years]
>
> *Patients often do not have a clear understanding of complications.* [Participant 3, male, age group 41-50 years]

Podiatrists recognize the potential benefits but are cautious regarding the use of AI for diagnostic applications, particularly those involving the analysis of photographic evidence of foot conditions. This caution is based on the understanding that certain conditions cannot be fully diagnosed through images alone, emphasizing the need for AI systems to supplement rather than replace traditional diagnostic methods:

> *Computers can't replace humans in diagnostics, especially not for tasks requiring nuanced observation, like identifying underlying issues beneath a callus that AI might miss.* [Participant 5, female, age group 61-70 years]
>
> *AI is incapable of making diagnoses. AI cannot handle complex conditions like distinguishing between warm and cold wounds.* [Participant 4, female, age group 51-60 years]
>
> *Even a human can't make a diagnosis just from an image. The foot needs to be examined in person and potentially opened up for an accurate assessment.* [Participant 1, female, age group 41-50 years]

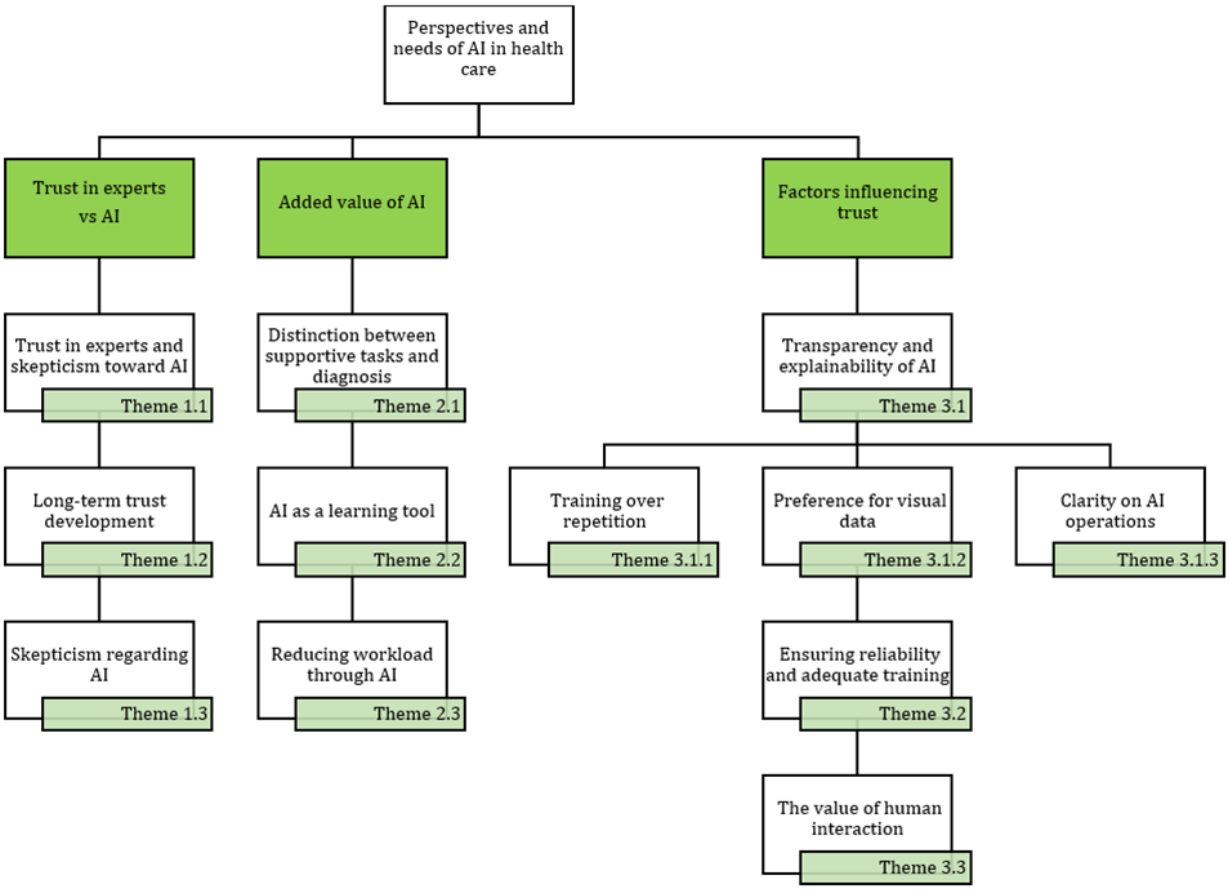
The desired level of transparency in diagnostic AI varies among podiatrists. While some value additional explanatory features, such as annotated images or textual diagnostics, others caution against the potential for such features to overly focus attention on a specific area, possibly leading to the overlooking of important symptoms in other areas. This division highlights the need for a careful balance in using AI; while it is beneficial to receive detailed, actionable insights, it is crucial to ensure that these insights do not overshadow the importance of using one's own professional knowledge and experience in decision-making:

> *Works well for me; the layer aids in understanding the basis of the text.* [Participant 3, male, age group 41-50 years]
>
> *Also, here, the text is okay. I also like the layer, so now I know what the text is referring to.* [Participant 1, female, age group 41-50 years]
>
> *The explanatory text doesn't interest me much; I'll take it on faith what it's based on.* [Participant 4, female, age group 51-60 years]
>
> *And that layer, I can see that for myself, too. Adding a layer can also be risky; I see even more things, and now AI dictates where I should look. A less experienced podiatrist might then focus solely on that.* [Participant 5, female, age group 61-70 years]

In addition to emphasizing transparency in integrating AI into clinical podiatry practice, our analysis has other predefined themes within the framework (Table 4). These themes enrich our understanding of how AI can be effectively applied in triage and diagnostics, emphasizing the need for clear, actionable insights and the importance of trust and data reliability as foundational elements. Reflecting on the preferences expressed by podiatrists, it becomes apparent that alongside transparency and explainability, considerations around data reliability, human interaction, trust development, and trust establishment align with sentiments from the first phase of our study.

However, we have defined 3 additional themes that resonated strongly with the initial input for transparency and explainability. Figure 6 presents a comprehensive overview of all the themes, including the 3 subthemes (ie, 3.1.1: Training Versus Repetition; 3.1.2: Preference for Visual Data; and 3.1.3: Clarity on AI Operations) and their implications for integrating AI into podiatry. The following sections detail these additional subthemes further.

Figure 6. Generated themes and subthemes from phases 1 and 2: perspectives of experienced podiatrists on the FootCheck app and decision-making process. AI: artificial intelligence.



Subtheme 3.1.1: Training Versus Repetition

While participants in phase 1 primarily highlighted concerns among podiatrists regarding data reliability, phase 2 revealed a nuanced understanding of how and when this information should be introduced. This is particularly relevant during the initial training sessions where podiatrists are first taught how to use the AI system. Feedback on mock-up 2 indicated that emphasizing data reliability in every AI recommendation is not always seen as necessary. Some participants supported this viewpoint, while others preferred having this information included. In addition, there was consensus that explanations should offer insights beyond basic knowledge, aiming to augment understanding rather than merely repeat well-known information:

> *In the introduction (training), mention somewhere that the data is based on 5000 photos, but that doesn't need to be in every piece of advice.* [Participant 4, female, age group 51-60 years]
>
> *I expect an AI to be backed by a vast photo database, so it's unnecessary to reiterate that point for me.* [Participant 5, female, age group 61-70 years]
>
> *The text is helpful; it lets me know what the AI is based on.* [Participant 3, male, age group 41-50 years]

Subtheme 3.1.2: Preference for Visual Data

There is a significant inclination toward incorporating visual data alongside algorithmic risk assessments. Participants consider combining photos with textual advice crucial, enhancing their ability to make knowledgeable decisions. The need for visual confirmation to solidify trust in AI-generated advice is highlighted, with participants expressing reservations about relying entirely on text-based recommendations. Although color-coded elements are appreciated for their clarity, the facility to view photos directly via pop-ups is deemed essential for building confidence in the advice provided:

> *The colour coding in mock-up 1 is helpful, but I'd prefer to see the photos appear as pop-ups.* [Participant 4, male, age group 41-50 years]
>
> *Just text, without a photo, doesn't inspire my trust.* [Participant 3, female, age group 51-60 years]
>
> *It seems like a small ask to quickly review the photo for a better trust in the advice.* [Participant 4, female, age group 51-60 years]

Subtheme 3.1.3: Clarity on AI Operations

Podiatrists highlight the necessity for transparency regarding the process behind AI-generated advice, which is essential for building trust and enabling users to understand when and how to rely on these recommendations. Opinions vary on the best way to present this information, with some finding objective data in photos and layered visuals helpful for understanding the advice's basis, as seen in mock-up 2. Others question the interpretability of numerical data, such as "73%," without seeing the patient in person:

> *Now, with a photo and layer, the information is more objective; you know what the text is about.* [Participant 3, male, age group 41-50 years]
>
> *I appreciate it, as then I know what it's based on, mock-up 2.* [Participant 1, female, age group 51-60 years]

Discussion

AI in Supportive Roles Versus Diagnostic Tasks

Our study aimed to discern the multifaceted roles AI could assume in health care, specifically focusing on how AI can be effectively integrated into practice in a way that ensures health care professionals' acceptance and trust in its advice. The findings from our studies suggest a preference for deploying AI in supportive roles. For instance, AI's use in triaging processes is evident; by evaluating submitted photos for urgency, AI can advise health care providers in prioritizing patient consultations. This enables a more efficient allocation of resources, ensuring that patients requiring urgent care receive it promptly, while less-critical cases are appropriately prioritized. Such applications align with and enrich suggestions from the literature, including studies by Verma et al [10] and Longoni et al [5], suggesting the supportive use of AI to foster trust within health care settings. However, a contrasting perspective is presented in another experiment by Longoni et al [5], where preference leans toward human expertise over automated systems for triage tasks. This discrepancy from our findings may stem from differing viewpoints, with the study results of Longoni et al [5] being based on patient perspectives, whereas our study was performed among health care providers.

Another critical insight from our study highlights health care professionals' hesitancy to embrace AI for diagnostic purposes, a sentiment that aligns with previous research findings [5,7,9,10,18]. While there is acknowledgment of AI's proficiency in critical functions, such as making diagnoses, with results that match or even surpass human expertise, there remains skepticism among participants about AI's current proficiency in performing these tasks accurately. The observed reluctance may stem from unfamiliarity with the full scope of AI's capabilities, as evidenced by the fact that particularly participants without prior AI experience expressed reservations. Moreover, the conversations uncovered that identifying conditions such as diabetic foot complications poses distinct obstacles for AI. The participants pointed out that superficial evaluations, such as analyzing diabetic wounds via photographs, could be inadequate without the physical removal of calluses to reveal the actual problem, an action AI is incapable of without a physical examination. This underlines the importance of direct human interaction in specific diagnostic processes, highlighting limitations in the potential application of AI.

Algorithm Aversion Among Podiatrists

The observed phenomenon of algorithm aversion among podiatrists, particularly their preference for human expertise over AI-generated recommendations, reflects a trend noted across various fields where AI competes with human judgment [26-29]. For example, Önkal et al [30] demonstrated a similar inclination among forecasters to favor expert opinions in forecasting decisions. A notable factor contributing to this aversion is the concern over mistakes made by AI systems [26], with our podiatrists voicing worries about the grave repercussions of such errors, including the risk of limb amputation. Although the significance of decisions ranges from health care to forecasting tasks in logistics, the underlying dread of AI-induced errors remains pervasive.

However, in our studies, this aversion was primarily directed at diagnostic tasks rather than supportive functions. Participants expressed confidence in the expertise and experience of their colleagues but also showed openness to considering AI-generated advice for tasks such as triage. This nuanced view suggests a complex relationship between podiatrists and AI, where trust may be contingent on the specific task at hand and the perceived reliability of AI in enhancing rather than replacing human judgment.

Transparency and Explainability

The discussions surrounding transparency and explainability in our studies mirrored the diversity of perspectives found in the broader literature on these subjects [12,14,19]. The need for explanation and transparency depends significantly on podiatrists' individual preferences. Our study provides 3 key insights regarding the implementation of explainability and transparency in AI systems.

First, precise and valuable explanations that avoid redundancy are essential for enhancing user understanding and trust in AI. Second, visual aids alongside textual advice can boost confidence in AI recommendations more than text alone, by making the motivation behind complex decisions more accessible. Finally, it is important to remind users to balance AI advice with their professional judgment, highlighting the crucial role of human oversight in AI decision-making.

However, these discussions were particularly animated regarding the scenario involving AI-generated diagnoses, where participants displayed heightened criticality toward the information received from AI. This suggests that individuals are particularly cautious about relying on AI for diagnostic tasks, scrutinizing the transparency and explainability of such systems with greater intensity. Interestingly, these issues were less extensively debated in contexts involving AI for supportive tasks. This observation highlights an area for future research.

Development of Trust Over Time

Most participants indicated a higher level of trust in their colleagues than in AI systems, suggesting that trust in AI might evolve positively with increased exposure and evidence of AI's efficacy. However, this remains speculative, as our participants have not extensively experimented with AI in their professional practice. The notion that repeated interactions with AI could enhance trust aligns with existing literature [31,32]. This area, highlighting the dynamic interplay between growing familiarity with AI and the shifting landscape of trust and reliance, remains underexplored in our studies and represents a fruitful avenue for further research.

Strengths and Limitations

Our research is strengthened by several methodological approaches that enhance the credibility of our findings. The employment of 2 independent researchers for parallel data coding in both studies significantly contributed to the reliability of our results, as evidenced by the substantial agreement in their coding outcomes [33].

The relatively small sample sizes of 9 podiatrists in the first phase and 5 in the second phase may seem to be a limitation for generating general conclusions. However, qualitative research often reaches a point of data saturation, where small samples are already sufficient to uncover dependable themes. In our study, we observed that no new codes or themes emerged after 7 interviews in the first phase, indicating that data saturation had been reached. This aligns with the findings of Guest et al [34], who noted that most codes are identified within the first 6 interviews. Guest et al [35] also supported this by providing a systematic method for assessing saturation, further validating our sample size.

The significant expertise of the podiatrists involved, that is, all specialists in the area considered, adds depth to our insights and strengthens the credibility of our findings. In addition, the second phase, with mostly new participants, confirmed the results of phase 1. By focusing on how AI might be more accepted in supportive tasks compared with diagnostic tasks, we were able to further validate the earlier findings and ensure that no new themes emerged, indicating that saturation had been reached.

Conclusions

In conclusion, the findings reveal podiatrists' complex attitudes toward AI in health care, demonstrating openness to AI assistance for supportive tasks while being cautionary regarding its application for diagnostics. This underscores the necessity for developers and policy makers to prioritize trust-building strategies, starting with opportunities that allow podiatrists to experience firsthand how AI can support their role. Such initial experiences could clarify AI's benefits and capabilities to users, reduce perceived threats, and facilitate a smoother transition toward acceptance. With a foundation of trust established through the application of AI for supportive tasks, podiatrists may become more receptive to exploring AI's potential for diagnostic tasks. Gradually expanding AI's role from foundational tasks, including decision support, to areas requiring deeper trust, such as diagnostics, could enhance acceptance and integration of AI technologies in podiatric practice.

Acknowledgments

The authors extend their heartfelt gratitude to all individuals who generously shared their insights and experiences, making this research possible. Special thanks are extended to Ruben Gloudemans for his invaluable assistance with conducting interviews, engaging in thorough analyses and participating in wide-ranging discussions that significantly enriched this work. The authors appreciate RondOm Podiatrists for providing access to the FootCheck app, an essential resource for our study. This work is part of the project Vertrouwen in Algoritmes (project number 023.017.109), under the auspices of the Promotiebeurs voor Leraren program, generously funded by the Dutch Research Council (NWO). Additionally, this study was part of the Technology Support for Diabetes project, which is subsidized by SIA RAAK EXZ.EXZ.01.004. The research efforts of the authors were greatly supported by these contributions, for which they are profoundly grateful.

Abstract

The study explored older adults' perceptions after participating in an online survey about medication decisions, finding that approximately 80% of participants provided positive feedback about the research methodology and their experience.

(JMIR Hum Factors 2025;12:e65684) doi:10.2196/65684

KEYWORDS

older adults; gerontology; geriatric; older; aging; online; internet; survey; questionnaire; research engagement; engagement; study subject; participant; medication decisions

Introduction

Older adults are underrepresented in research, often due to age-related biases and stringent exclusion criteria; this limits generalizability and leaves knowledge gaps [1].

The increasing prevalence of online research has the potential to increase older adult participation, given the rising internet use among this demographic [2]. While research has primarily focused on improving recruitment of older adults, an understanding of their experiences of online research is needed to effectively engage older people [3]. While most surveys include some form of piloting, they rarely capture or share participants' perceptions of the research process. We sought to explore older adults' perceptions after participating in an online experimental survey, given the potential high accessibility of this type of research.

Methods

Overview

We previously reported the main findings from a vignette-based online experiment conducted among adults aged 65 years and older from Australia, the Netherlands, the United Kingdom, and the United States [4]. Participants were recruited for this 15-minute survey through a panel of internet users administered by Qualtrics Research Panels. The study focused on contextual factors influencing how older adults (mean age 71.5, SD 5.1 years) think about deciding to stop a cardiovascular disease medication. In this study, we conducted a content analysis of free-text comments (Textbox 1). The final analysis framework included 17 codes that were subsequently consolidated into 14 themes. Descriptive statistics were used to assess the frequency of each theme.

Textbox 1. Summary of methodology for the content analysis.

1. A vignette-based online experiment was conducted among adults aged 65 years and older from Australia, the Netherlands, the United Kingdom, and the United States using sampling quotas to ensure balanced representation by country and gender. This study was registered at ClinicalTrials.gov (NCT04676282). At the end of the survey, participants were provided the opportunity to leave "any comments about this study."
2. A content analysis was conducted among participants who received the vignette about a hypothetical patient, Mrs EF. Participants from the Netherlands were excluded, as the study team for the content analysis was not fluent in Dutch.
3. Study authors read through the comments to inductively generate codes.
4. Two investigators (SEV and YM) independently coded comments, resulting in >80% agreement.
5. All discrepancies in codes were discussed until consensus was reached.

Ethical Considerations

The online experiment was registered at ClinicalTrials.gov (NCT04676282) and was deemed exempt by the University of Michigan Health Sciences and Behavioral Sciences Institutional Review Board (HUM00183129); by extension, a waiver of consent was granted. All data were collected anonymously. Participants were compensated based on the terms of their panel agreement.

Results

Participants (N=1789) most frequently did not provide any feedback in the free-text comment field (n=784, 43.8%) or wrote that they had no comments (n=487, 27.2%). Three participants (0.2%) gave unclear statements.

Participants' comments (n=515, 28.8%) were primarily positive (415/515, 80.6%), such as that the study was interesting (116/515, 22.5%). Themes and representative quotes are reported in Table 1. Participants said it made them think about their health (80/515, 15.5%) and some participants shared further health information about the study topic (48/515, 9.3%). Participants provided feedback on how to improve the study, categorized as question-specific comments (21/515, 4.1%), general suggestions (12/515, 2.3%), or country-specific comments (3/515, 0.6%). Few participants (16/515, 3.1%) provided negative feedback about the survey.

Table 1. Older adults' feedback about an online survey using a hypothetical vignette by theme, with representative quotes among respondents who provided feedback (n=515).

Themes	Representative quotes (participant code)	Participants, n (%)
Positive feedback (n=415, 80.6%)		
Interesting	• "An interesting study" (919) • "This was an interesting survey to complete" (2200)	116 (22.5)
Thought provoking	• "Interesting and insightful. Made me think a little more about how best to manage my health" (1872) • "Very good survey to ponder thoughts and beliefs" (481)	80 (15.5)
Positive feedback	• "Great stuff. Keep up the good work" (2574) • "Very good" (764)	67 (13)
Thanks for opportunity to participate	• "Thanks" (42)	43 (8.3)
Positive feedback about survey questions or structure	• "Love the format, so easy to see, follow, and understand" (1904) • "Very good questions regarding whether or not to stop a medication when you've been on it for an extended time" (2026)	35 (6.8)
Enjoyed taking survey	• "Enjoyed it" (328) • "Love doing your studies" (287)	34 (6.6)
Unusual study design	• "Very different enjoyed the variety" (540) • "Unusual but interesting" (1853)	19 (3.7)
Interested in results	• "Interested in purpose of results" (1863) • "Very interesting! Now I need to see the final results" (3481)	15 (2.9)
Interested in future studies	• "Great study, I'd do more" (4815) • "Need more like this" (2516)	6 (1.2)
Neutral feedback (n=48, 9.3%)		
Shared personal experience	• "I am afraid of going to see the dr for worries about my health" (1526) • "Thanks; my prescription drugs fall under the Federal Government program where they are funded nearly 100%" (2645)	48 (9.3)
Negative feedback or suggestions for improvement (n=52, 10.1%)		
Question-specific feedback	• "The percentage charts were confusing" (2403) • "One question said check all that apply but only one was allowed" (4279)	21 (4.1)
Negative feedback	• "Boring" (1409) • "Too many generalizations" (1102)	16 (3.1)
General suggestions for improvement	• "Consider adding a progress bar to the survey" (2027) • "Good study could be shorter" (2433	12 (2.3)
Country-specific feedback	• "Some questions are designed for the USA" (1471) • "Prescription insurance? In UK if you are over 65 prescriptions are free" (4075)	3 (0.6)

Discussion

Among older adults who provided feedback about their experiences completing an online survey, approximately 80% (415/515) of the comments were positive. Our findings signal general acceptability of the methodology, and we have implemented the practical feedback to improve our online surveys. We have become more mindful of the survey length, selected straightforward question types, and have conducted pilot testing in all target countries to ensure that questions are appropriate for all participants.

Our study had several limitations. First, less than one-third of the study participants provided any comments. Second, participants were asked if they had any comments, as opposed to more specific questions about their experience taking the survey. Finally, we acknowledge that we coded a single primary theme per comment given the short statements that were provided.

With an aging population who may spend many years in retirement, participating in research can offer benefits such as reducing social isolation and loneliness, fostering a sense of

purpose, and providing mental stimulation, and it may provide monetary incentives [5]. While our online study lacked the social benefit of in-person interaction typical of traditional research, participants reported enjoying the survey; they found it prompted self-reflection on their health, and they expressed interest in the study's outcomes and future research.

Online research is becoming more prevalent; therefore, it is important to make sure this methodology is inclusive of older adults [5]. More than half of adults older than 65 years use the internet, yet they are the least likely to have a home computer [6]. While some researchers attribute this limited use to age-related functional decline, others argue that the main barriers are negative attitudes such as fear, anxiety, and low motivation—barriers that are modifiable. Anxiety about using the internet and digital technologies often leads to self-imposed limitations and low confidence, with older adults frequently underestimating their knowledge and abilities compared to younger users [6]. This underscores the importance of studies like ours that highlight the positive experiences of older adults in online research.

Acknowledgments

This study was funded by award R24AG064025 from the US Deprescribing Research Network via the Northern California Institute for Research and Education through the National Institute on Aging; a Swiss Government Excellence Scholarship (KRW), the Swiss National Science Foundation Scientific Exchanges (grant IZSEZ0_213475/1; KRW), and an Emerging Leader Research Fellowship (2017295) from the Australian National Health and Medical Research Council (KRW). The funders had no role in the design or conduct of the study; collection, management, analysis, or interpretation of the data; preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication. KRW and SEV had full access to all of the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.

Abstract

Background: Mobile health care (mHealth) apps are emerging worldwide as a vital component of internet health care, but there are issues, especially among older adults.

Objective: We aim to investigate the factors influencing the intention to use (ITU) mHealth apps, focusing on those with and without prior mHealth experience.

Methods: A cross-sectional study conducted from August 2022 to July 2023 included Thai citizens aged 45 years or older. Self-reported questionnaires collected data on sociodemographic information, health conditions, smartphone or tablet ownership, and mHealth usage experience. The Thai mHealth Senior Technology Acceptance Model questionnaires with a 10-point Likert scale evaluated mHealth acceptance. A multivariable logistic regression analysis, adjusted for age, gender, education, income, and living area, was performed for 2 subgroups: those who used ITU mHealth apps and those who did not.

Results: Of 1100 participants, 537 (48.8%) intended to use mHealth apps, while 563 (51.2%) did not. The ITU group had a younger average age, higher education levels, higher income, and fewer underlying diseases compared to those who did not intend to use mHealth apps. For those who had never used mHealth apps, having a smartphone was strongly associated with higher odds of ITU (adjusted odds ratio 2.81, 95% CI 1.6 to 4.93; P<.001), while having any underlying disease was associated with lower odds of ITU (adjusted odds ratio 0.63, 95% CI 0.42 to 0.97; P=.034). Higher acceptance levels, characterized by a positive attitude toward mHealth and lower fear of making mistakes, were also associated with higher ITU. For those with prior mHealth experience, acceptance in areas such as perceived ease of use, gerontechnology anxiety, and facilitating conditions was significantly associated with ITU.

Conclusions: Among inexperienced users, a positive attitude toward mHealth significantly enhanced ITU. Conversely, having an underlying disease decreased ITU, indicating a need for tailored mHealth apps. For experienced users, acceptance levels in areas such as ease of use and gerontechnology anxiety were crucial. Future research should explore specific mHealth apps for more targeted insights.

KEYWORDS

mHealth; mobile healthcare; older adults; elderly; aging; questionnaire; smartphone; mHealth usage; intention to use

Introduction

Mobile health care (mHealth) apps, a vital component of internet health care, are emerging worldwide. These apps have attracted a wide range of health care services and are proven effective in solving health problems. The functions of mHealth are diverse, including patient monitoring, diagnosis, personal care, psychological health, educational apps, and social networking [1]. There is growing evidence of the health benefits of mHealth. Mobile devices, with their integrated sensors and features, help health care professionals treat patients with continuous connectivity. These apps are useful for collecting data related to physical activity, human body images, and other health care aspects [2,3]. For example, using mHealth in chronic disease management has shown improvements in symptoms and reduced hospitalizations for patients with asthma, chronic obstructive pulmonary disease, heart failure, and diabetes [4].

However, there are several issues with current mHealth apps, particularly among older adults. Studies show that only 60% of older people intend to use mHealth [5]. Older adults may have physiological changes according to aging such as visual and hearing decline. They may also be unfamiliar with technology and face difficulty learning new skills [6]. Some users experience technical problems with their smartphones when using these apps. Additionally, public awareness of mHealth apps is low, and their usability is not as good as expected [7].

Understanding the factors that affect the intention to use (ITU) mHealth among people with and without prior experience is crucial for enhancing its future usage [8]. Therefore, the primary objective of our study was to investigate the factors associated with ITU, focusing on 2 specific subgroups: those with prior experience using mHealth apps and those without. This study also examined information regarding device ownership, experience with mobile apps and mHealth, and technology acceptance. These findings aimed to gain a better understanding of mHealth usage and identify potential opportunities for implementing mHealth in a community-dwelling population, especially among older adults.

Methods

Study Design

We conducted the cross-sectional study from August 2022 to July 2023 using a nationwide web-based survey and a community survey. The online survey was disseminated through various social media platforms, such as department websites, Facebook, Line, Twitter, and Instagram. The investigator teams, which included medical students and health care personnels from primary care units across 10 subdistricts in Chiang Mai province, distributed the community survey. The respondents to both the online and community surveys used the REDCap (Research Electronic Data Capture; Vanderbilt University) survey platform to self-complete the questionnaires. The STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement guided this study's reporting [9].

Ethical Considerations

The institutional review board of the Faculty of Medicine, Chiang Mai University approved this study's ethical consideration (COM-2565 - 09079). Before participating in this survey, all respondents provided their informed consent in accordance with the screening questionnaire and study information page. Participants were compensated with an incentive of 100 Thai Baht (3 USD) for completing the questionnaires. No identification data were recorded, and respondents were permitted to remain anonymous during the online survey. The community survey used the identification data of eligible participants exclusively for recruitment purposes within each target area. These data were not documented in either the survey form or the study database.

Participants

Study participants were middle-aged Thai citizens aged 45 - 60 years or older at the time of the survey [10,11]. Our study's inclusion criteria required participants to be able to read and communicate in Thai and to have no underlying conditions or diseases that would hinder their ability to complete the survey or use mHealth apps (eg, dementia, active psychological problems, or severe visual impairments). This study excluded respondents who did not complete the survey, spent less than 2 minutes on it, or spent more than 60 minutes on it.

Data Collection

Participant Characteristics

We used self-reported questionnaires to collect data on participant characteristics, including sociodemographic data, underlying health conditions, owning a smartphone or tablet, and experience using the devices and mHealth apps. The initial section of the questionnaires included information regarding mHealth to ensure that the participants comprehended its definition, related concepts, and intended use.

The sociodemographic data included age, gender, marital status (single, married, and separate, divorced, or widowed), living status (alone, with family, and with others), living areas (urban, suburban, and rural), education levels (no education, primary, secondary, high school, vocational training, preuniversity, bachelor's degree, and master's degree), and income per month (<10,000 in Thai Baht, US $ 274; 10,001 - 30,000 in Thai Baht, US $275-$819; and >30,001 in Thai Baht, US $820). The questions inquiring about underlying medical conditions included hypertension, dyslipidemia, diabetes mellitus, chronic renal disease, visual impairments, and hearing impairments. We also gathered data on other related variables, such as wearing glasses or contact lenses, using hearing aids, and a number of current medications.

Experience Using Mobile Apps and mHealth

mHealth apps, or mobile health apps, refer to the practice of medicine and public health supported by mobile devices. The term "mHealth apps" encompasses the use of mobile communication devices such as smartphones and tablets for health care purposes [12,13]. For information on owning and experience using the devices and mHealth, questionnaires asked for smartphone or tablet usage experience (year), owning smartphones or tablets, internet usage experience (year), and previously used mobile apps and mHealth apps.

mHealth Acceptance and ITU

The acceptance of mHealth was evaluated using the Thai mHealth Senior Technology Acceptance Model (STAM) questionnaires. This instrument has been adapted from the 38-item STAM questionnaire [14] and validated for accessing mHealth acceptance in a Thai context. According to the reported psychometric analysis, the Thai mHealth STAM demonstrated satisfactory psychometric properties in terms of validity and reliability. We used instrument items in the following domains as the potential associated factors of an ITU mHealth: attitude toward using, perceived usefulness, perceived ease of use, perceived barriers, gerontechnology anxiety, and facilitating condition. The structure of the Thai mHealth STAM was a 10-point Likert scale. The highest point indicated a high level of acceptance. The participant's ITU mHealth was assessed by the structural question "If there are available mHealth apps for you, do you want to use them? (Yes/No)."

Sample Size

To derive statistics that represent the parameters for the target populations, a minimum sample size of 500 total participants is required. This minimum sample size can accurately detect low to large effect sizes, as suggested by Bujang et al [15]. Based on our primary objective, it aimed to explore the associations between ITU and predetermined variables, including characteristics, ownership, and experience using devices and mHealth, and mHealth acceptance, in 2 specified subgroups of participants: those with experience using mHealth apps and those without. To explore unbiased effect estimates, 18 independent variables were analyzed with adjustments for 5 confounding variables. The sample size calculation, based on the formula n=100+(10 - 50 event per variable)*i*, where *i* refers to the number of independent variables, was conducted to ensure our effect estimates from a multivariable logistic regression had sufficient precision to yield medium to large effect estimates in the subgroup analysis [15]. With 23 independent variables, a minimum sample size of 330 participants per subgroup was needed according to the given formula with 10 per independent variables.

Statistical Analysis

For descriptive analysis, we presented categorical data using frequency and percentage. We described continuous data using a mean with SD, a median with a range (minimum-maximum), or an IQR, as appropriate. The comparison in characteristics, owning and experience using the devices and mHealth, and mHealth acceptance between participants who had ITU and those who did not was examined using an independent 2-tailed *t* test or Wilcoxon rank sum test for continuous data and Fisher exact test for categorical data.

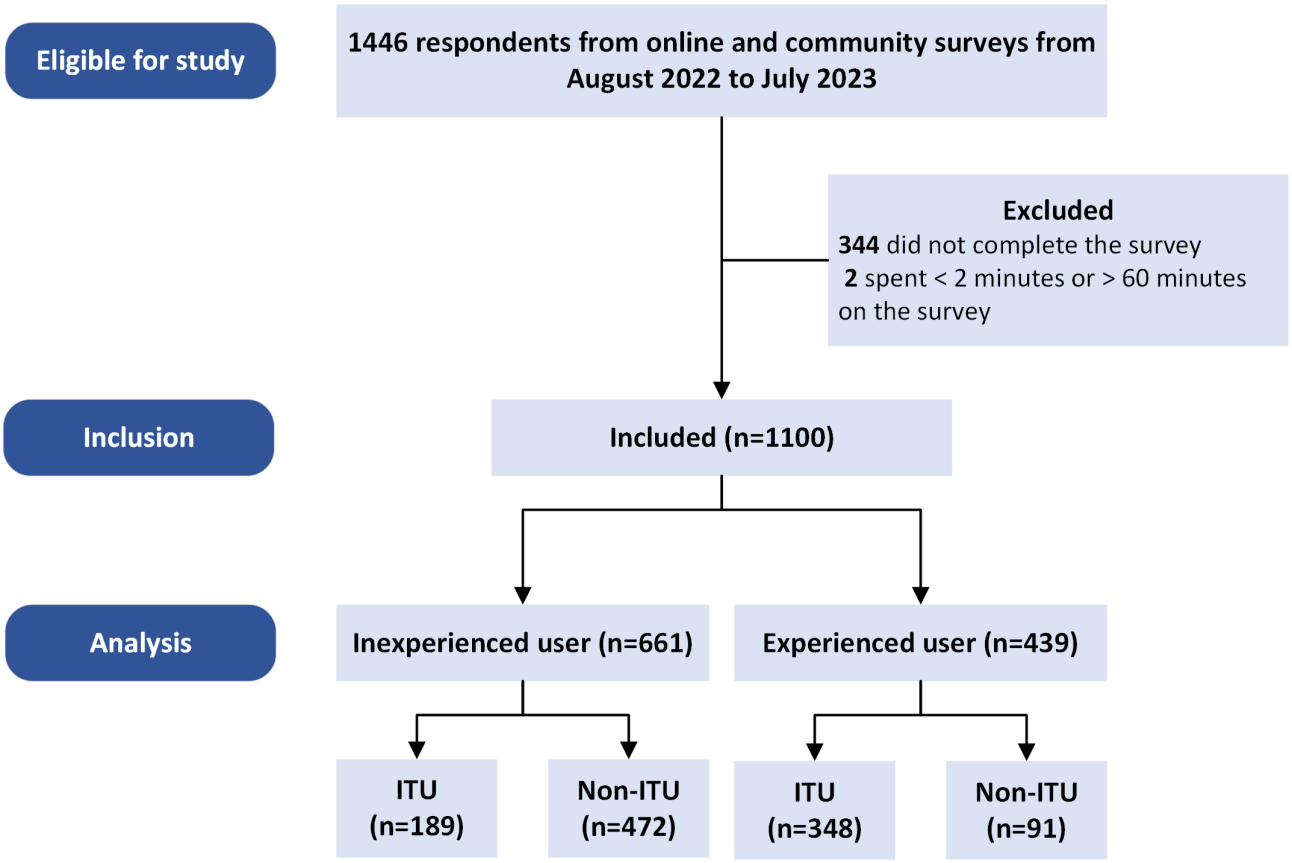
For the analysis of the primary objective, we hypothesized that the factors associated with ITU would be different for participants who had previously used mHealth and those who did not. We performed a multivariable logistic regression for 2 specified subgroups, adjusted for the confounders including age, gender, education levels, income, and living area. The predetermined characteristic variables included having any underlying disease, owning a smartphone, the number of years of experience using it, and an interaction term based on both ownership and experience. We entered each item's mHealth acceptance into the model as continuous data, using a 10-point scale. The magnitude of associations was presented using an adjusted odds ratio along with 95% CIs and *P* value. All statistical analyses were conducted using STATA (version 17.0; Stata Corp, LP). The visualization for this study was created using Microsoft Excel (Microsoft Corporation, 2021). The level of statistical significance for descriptive analysis was set at a *P* value below .05.

Results

Participant Characteristics

Of 1100 participants, the majority were female (776/1100, 62.3%), with a mean age of 62.3 (SD 8.8) years. This study flow diagram is presented in Figure 1. Most of the participants were married and resided with their families primarily in rural, suburban, and urban areas, respectively. For socioeconomic status, 86.2% (948/1100) had a low income (<10,000 Baht, US $274), and 65.9% (725/1100) had the highest education level at primary school. The common underlying diseases were hypertension and dyslipidemia. More than half reported having a vision problem, and 65.2% (n=399) wore glasses or contact lenses. Only 3.3% (4/1100) of respondents required a hearing aid, while 10.9% (120/1100) of respondents reported having hearing problems.

Figure 1. Study flow diagram. ITU: intention to use.



There were 537 participants who had ITU (48.8%) and 563 participants who did not (51.2%). When comparing the participants who had ITU mHealth apps with those who did not, the ITU group had a significantly younger average age, higher education levels, higher income, and a lower proportion of underlying diseases. Furthermore, 94.4% (507/537) and 92% (494/537) of the ITU group reported having experience using a smartphone or tablet and the internet; 91.2% (490/537) and 3.4% (18/537) had owned a smartphone and tablet, respectively. These percentages in the ITU group were significantly higher than those in the non-ITU group. The overall median (IQR) year of experience using the devices was 5 (0 - 10). When comparing the ITU to non-ITU groups, the median years of device usage experience in the ITU were significantly higher than non-ITU (median 6, IQR 3 - 10 versus median 3, IQR 0 - 9, P<.001). In addition, 66.9% of those in the ITU group had experience using mHealth apps, which was a significantly higher proportion than the non-ITU group of 17.4%. The details of participant characteristics are presented in Table 1.

Table . Participant characteristics.

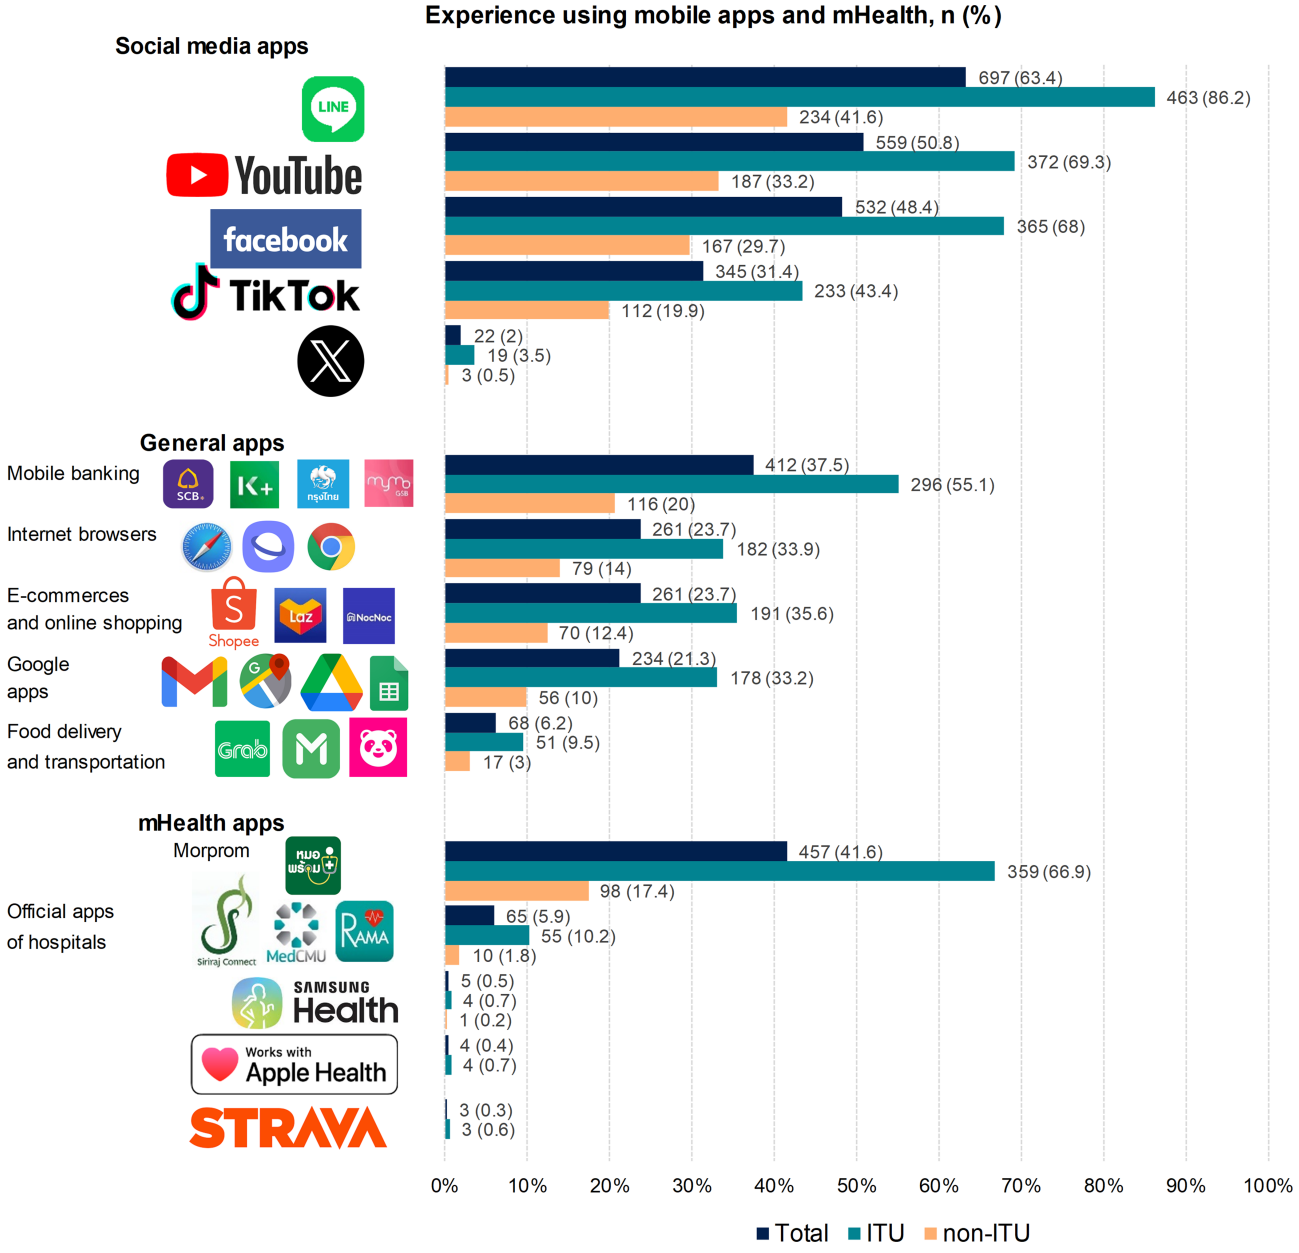
Characteristics	Total (N=1100)	Had intention to use mHealth apps		*P* value
		Yes (n=537)	No (n=563)	
Age (year), mean (SD)	62.3 (8.8)	60 (8.4)	64.4 (8.6)	<.001
Male, n (%)	324 (29.5)	140 (26.1)	184 (32.7)	.02
Marital status, n (%)				.002
Single	96 (8.7)	57 (10.6)	39 (6.9)	
Married	747 (67.9)	377 (70.2)	370 (65.7)	
Separated, divorced, or widowed	257 (23.4)	103 (19.2)	154 (27.4)	
Education levels, n (%)				<.001
No education	18 (1.6)	2 (0.4)	16 (2.8)	
Primary school	725 (65.9)	291 (54.2)	434 (77.1)	
Secondary school	97 (8.8)	65 (12.1)	32 (5.7)	
High school and vocational training	162 (14.7)	110 (20.5)	52 (9.2)	
Preuniversity	11 (1)	8 (1.5)	3 (0.5)	
Bachelor’s degree	79 (7.2)	54 (10.1)	25 (4.4)	
Master’s degree	8 (0.7)	7 (1.3)	1 (0.2)	
Income per month, n (%)				.001
<10,000 Baht (US $274)	948 (86.2)	442 (82.3)	506 (89.9)	
10,001 - 30,000 Baht (US $275 - 819)	138 (12.5)	86 (16)	52 (9.2)	
>30,001 Baht (US $820)	14 (1.3)	9 (1.7)	5 (0.9)	
Living status, n (%)				.86
Alone	108 (9.8)	50 (9.3)	58 (10.3)	
With family	988 (89.8)	485 (90.3)	503 (89.3)	
With others	4 (0.4)	2 (0.4)	2 (0.4)	
Living area, n (%)				.38
Urban	220 (20)	99 (18.4)	121 (21.5)	
Suburban	377 (34.3)	192 (35.8)	185 (32.9)	
Rural	503 (45.7)	246 (45.8)	257 (45.6)	
Had any underlying disease, n (%)	726 (66)	330 (61.5)	396 (70.3)	.002
Hypertension, n (%)	495 (45)	212 (39.5)	283 (50.3)	<.001
Dyslipidemia, n (%)	375 (34.1)	187 (34.8)	188 (33.4)	.62
Diabetes mellitus, n (%)	184 (16.7)	76 (14.2)	108 (19.2)	.03
Chronic kidney disease, n (%)	17 (1.5)	8 (1.5)	9 (1.6)	.88
Vision problems, n (%)	612 (55.6)	304 (56.6)	308 (54.7)	.53
Wore glasses or contact lens, n (%)	399 (65.2)	210 (69.1)	189 (61.4)	.045
Hearing problems, n (%)	120 (10.9)	54 (10.1)	66 (11.7)	.38
Used hearing aids, n (%)	4 (3.3)	2 (3.7)	2 (3)	.84
Number of medications, median (IQR)	1 (0 - 2)	1 (0 - 2)	1 (0 - 2)	.55
Had experience using a smartphone or tablet, n (%)	873 (79.4)	507 (94.4)	366 (65)	<.001
Had own smartphone, n (%)	843 (76.6)	490 (91.2)	353 (62.7)	<.001
Had own tablet, n (%)	20 (1.8)	18 (3.4)	2 (0.4)	<.001
Had experience using the internet, n (%)	784 (71.3)	494 (92)	290 (51.5)	<.001

Characteristics	Total (N=1100)	Had intention to use mHealth apps		
		Yes (n=537)	No (n=563)	*P* value
Had experience using mHealth apps, n (%)	439 (39.9)	348 (64.8)	91 (16.2)	<.001

Experience Using Mobile Apps and mHealth

Figure 2 illustrates participants' experience using mobile apps and mHealth. There are many types of mobile apps and mHealth including social media apps, general apps, and mHealth apps. Among the middle-aged and older adults who had previously used mobile apps and mHealth, social media apps had the highest percentages (63.4%), followed by mHealth apps (41.6%), and apps for general purposes (37.5%). The use percentages of almost all mobile apps and mHealth were statistically and significantly higher in the ITU compared to non-ITU groups (*P*<.001), except for mHealth apps with a low use percentage (Samsung Health, Apple Health, and Strava). The use percentages of the top 3 social media apps (Line, YouTube, and Facebook) were greater than other apps. For general purposes, most participants used mobile apps for online banking services, surfing the internet, and shopping. For mHealth, the Ministry of Thai Public Health app, "MorProm," had the highest use (41.6%), followed by the official apps by hospitals (5.9%), while the other mHealth apps from public providers showed a very low use percentage.

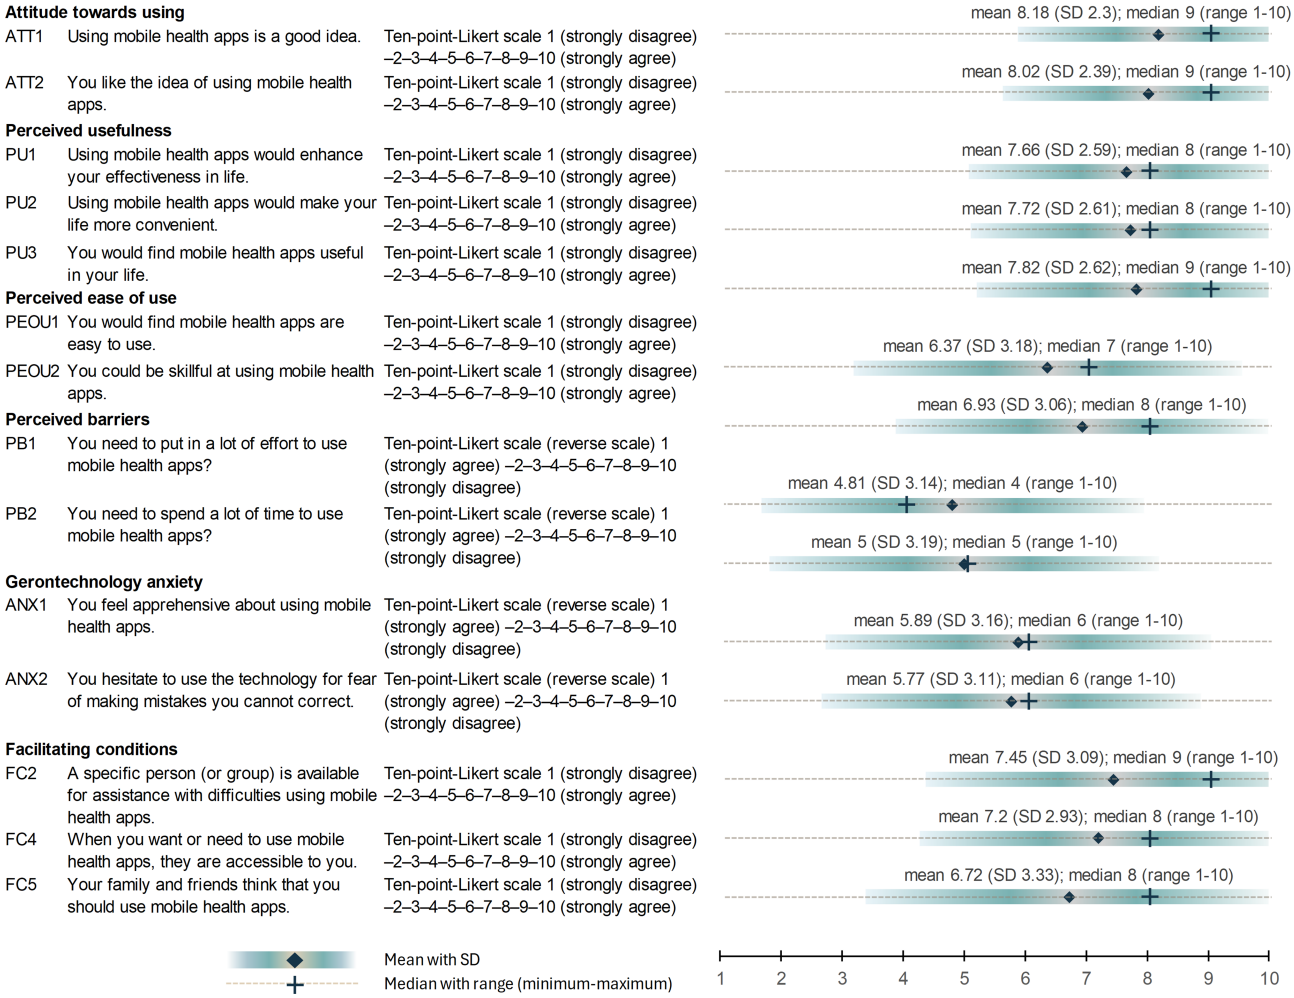
Figure 2. Participants' experience using mobile apps and mHealth. ITU: intention to use.



mHealth Acceptance

We assessed the participants' mHealth acceptance using the Thai mHealth STAM questionnaires in the domains, including attitude toward using, perceived usefulness, perceived ease of use, perceived barriers, gerontechnology anxiety, and facilitating condition. Figure 3 displays the structure of the questionnaires and the participants' responses. Overall, participants' acceptance of mHealth fell within the range of agreeable attitudes toward using, perceived usefulness of mHealth apps, and facilitating conditions. On the other hand, we observed responses in the range of neutral to low acceptance across the domains of perceived barriers, gerontechnology anxiety, and perceived ease of use.

Figure 3. Participants' responses to mHealth acceptance questionnaires. ANX: gerontechnology anxiety; ATT: attitude toward using; FC: facilitating condition; PB: perceived barriers; PEOU: perceived ease of use; PU: perceived usefulness.

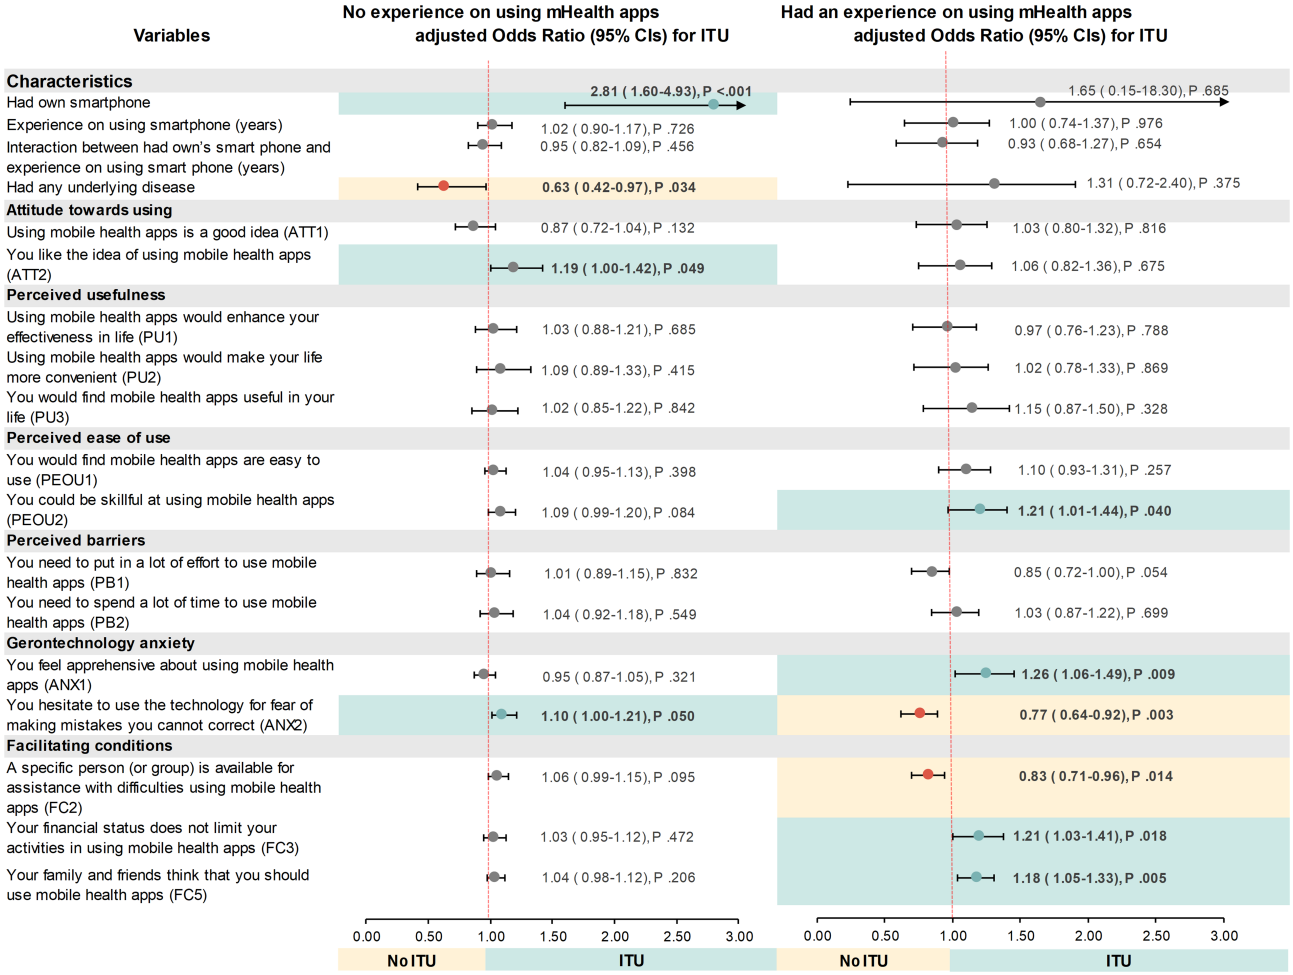


When compared between the ITU and non-ITU groups, mHealth acceptance levels assessed by the questionnaires showed a significant difference in all items, as presented in Table S1 in Multimedia Appendix 1. Participants who used an ITU mHealth app had higher mean scores in all items. The domain of perceived barriers yielded the lowest mean mHealth acceptance score in both groups.

Factors Associated With ITU mHealth Apps

In this study, we focused on exploring factors associated with ITU mHealth apps in the subgroup of participants who had experience using mHealth apps and who did not. We performed a multivariable logistic regression analysis using predetermined factors including owning a smartphone, experience using a smartphone, underlying disease, and mHeath acceptances. The analysis also adjusted for the confounders consisting of age, gender, education levels, income, and living area. Multivariable analysis results are presented in Figure 4.

Figure 4. Factors associated with intention to use mHealth apps using a multivariable logistic regression. aORs were estimated as adjusted for age, gender, education levels, income, and living area. aOR: adjusted odds ratio; ANX: gerontechnology anxiety; ATT: attitude toward using; FC: facilitating condition; ITU: intention to use; PB: perceived barriers; PEOU: perceived ease of use; PU:perceived usefulness.



For the subgroup of people who had never used mHealth apps before, having a smartphone was substantially associated with higher odds of ITU (adjusted odds ratio 2.81, 95% CI 1.60 to 4.93; *P*<.001), while having any underlying disease was significantly related to a low ITU. Higher levels of acceptance, which are characterized by a higher score of attitudes toward the idea of using mHealth and a lower fear of making mistakes that cannot be corrected when using it, were also significantly associated with a high ITU.

For the subgroup of individuals who had prior experience using mHealth apps, the pattern of associations between predetermined factors varied from the subgroup of those who did not have prior experience. There were no predetermined characteristics relating to ITU. The levels of mHealth acceptance were significantly associated with ITU in the domains, including perceived ease of use, gerontechology anxiety, and facilitating conditions. Perceived ease of use, which individuals could be skilled at using, was significantly associated with a greater odds of ITU. Regarding the level of anxiety associated with mHealth usage, less apprehensiveness about using mHealth significantly increased the odds of ITU. Conversely, a low ITU was associated with a lower fear of making mistakes when using mHealth. Having facilitated support from family and friends to use mHealth and having fewer financial constraints on using mHealth showed a significant positive association with ITU, whereas the support from others was negatively associated with ITU.

Discussion

Principal Findings

To investigate the factors associated with ITU, we found that people who had never used mHealth apps before, having a smartphone associated with a higher ITU, while having any underlying disease was significantly related to a low ITU. Higher levels of acceptance, which are characterized by a higher score of attitudes toward the idea of using mHealth and a lower fear of making mistakes, were also significantly associated with a high ITU. For the subgroup of individuals who had prior experience using mHealth apps, there were no predetermined characteristics relating to ITU. The levels of mHealth acceptance were significantly associated with ITU in the domains, including perceived ease of use, gerontechology anxiety, and facilitating conditions.

Compared to previous studies, several patient characteristics significantly influence the ITU mHealth. Older patients are less likely to use mHealth due to their unfamiliarity with technology. Despite efforts to adopt new technology, many older adult individuals still struggle with it, and the rapid pace of technological advancements leaves them unable to keep up

[16,17]. Additionally, there is a lack of promotion and support for using medical technology among older adults [18]. Socioeconomic status is another crucial factor affecting the ITU mHealth [19,20]. Patients in low-income groups not only lack support for using mHealth, but their daily routines and various burdens also reduce their intention to use these technologies [21]. This is closely related to the level of education [19]; patients with higher educational levels are more likely to understand and recognize the health benefits of mHealth, thus increasing their intention to use it [20]. Chronic diseases also play a role [19]. Patients without comorbidities and those who could effectively manage their chronic conditions tend to have better health management skills and a stronger desire to maintain good health, which positively influences their ITU mHealth [22,23].

Many factors influence the ITU mHealth among people without prior experience. One critical factor is the availability of equipment, such as mobile phones, patient testing devices, personal digital assistants, and other wireless tools. Health care professionals must ensure these facilities are accessible to patients when initiating mHealth services. Providing the necessary equipment and educating patients on its use can reduce inequity, particularly among older populations. The previous studies also showed that when health care systems provide access to such equipment, it enhances user confidence and intention to adopt mHealth, particularly among older adults who may otherwise face barriers due to digital inequality (eg, lacking smartphones or internet access) [24,25]. Empowering patients to access and use smartphones not only enhanced their ITU mHealth but could also improve self-rated, physical, and psychological health levels, as evidenced by the previous studies on the effects of smartphones and smart devices [26-28]. Underlying health conditions also impact the ITU mHealth. Patients with poor health behaviors or low motivation for self-care are less likely to adopt mHealth. The previous studies found that older adults with heart failure [29] and adults with hypertension [30] faced significant barriers to mHealth adoption, including low motivation and limited health literacy, which hindered their engagement with self-management technologies. These support our finding that underlying health conditions may reduce mHealth adoption, as individuals often lack the motivation to use health-promoting technologies. Conversely, some studies suggest that the presence of chronic health conditions can actually motivate individuals to engage with mHealth solutions. The study by Askari et al [31] found that older adults who were able to control their chronic diseases often expressed a greater ITU mHealth, as these tools can provide essential support for self-management and health monitoring. This indicated that while health conditions could pose barriers, they can also motivate the adoption of mHealth solutions, particularly when patients recognize the potential benefits for their health management. Another study also suggested that health conditions could influence older adults' readiness to engage with eHealth resources, with those experiencing chronic illnesses showing a higher willingness to use digital health tools for self-care [32]. This suggests that the context of the health condition is vital in influencing attitudes toward technology use, rather than the notion that poor health behaviors uniformly result in reduced intentions to use mHealth. Confidence in their ability to effectively use mHealth apps is crucial, as a positive attitude toward mHealth increases the likelihood of its use [33]. The positive finding on attitude toward using mHealth is also consistent with the recent systematic reviews on the impact of mHealth interventions, which highlighted that the effectiveness of these interventions is often linked to user confidence and positive attitudes toward technology [4]. To promote mHealth for people without prior experience, health care professionals should educate patients about its benefits and how it can aid in self-care. Additionally, patients must develop eHealth literacy, defined as "the ability to seek out, find, evaluate, and appraise, integrate, and apply what is gained in electronic environments toward solving a health problem." [34].

For participants with prior experience using mHealth, various factors influence their intention to continue its usage. These individuals often possess a positive attitude toward mHealth and recognize its benefits. They may also have experience in overcoming barriers, such as troubleshooting difficulties or correcting errors independently. Consequently, they perceive the benefits of using mHealth to outweigh the risks or challenges. Our finding indicated that perceived self-capability to use mHealth and lower concerns was associated with higher ITU among participants with prior mHealth experience. This finding is aligned with the study by Opoku et al [35], which emphasized that enabling resources, such as the durability and simplicity of mobile technology, significantly influence patients' perceived ease of use of mHealth interventions. This implies that when patients are informed and experienced about the user-friendly nature of mHealth apps, their confidence in using these tools increases, thereby enhancing their likelihood of adoption. In contrast to participants without prior experience using mHealth, those with experience did not avoid using mHealth out of fear of making mistakes. However, the expressed greater concerns about mHealth itself, such as its effectiveness, data security, and privacy, were associated with a low ITU. Our findings align with the studies on experienced users' attitudes toward mHealth [36,37], emphasizing the importance of addressing concerns related to security, privacy, and perceived effectiveness. Therefore, future mHealth interventions should not only focus on enhancing user confidence through health education or instruction by technical and health care providers but also on building trust in technology itself. Additionally, patients, especially older adults, value support from family or caregivers. mHealth for older adults may require assistance at various stages, including tool usage guidance, instructions, and caregiver involvement [16]. Financial considerations also play a crucial role, as increased costs associated with mHealth can affect the ITU for it. To initiate and improve mHealth usage, health care professionals need to identify patients willing to use mHealth, ensure the availability of necessary equipment, and address any financial constraints. Educating patients on the evidence and benefits of mHealth is also essential. Where possible, families and caregivers should be included in the mHealth care plan [38].

The strength of this study lies in its relatively large sample size, which included participants from rural, suburban, and urban areas. This study comprehensively explored various factors

potentially associated with mHealth use, using reliable and validated standard tools to evaluate acceptance. However, some limitations existed. The cross-sectional nature of this study limited establishing causal relationships between the ITU mHealth and associated factors. Further research designs, including longitudinal studies or randomized controlled trials of specific mHealth interventions, are necessary to overcome these limitations and provide a more comprehensive understanding of the factors influencing mHealth usage. Furthermore, the term "mHealth" was defined in a broad and general sense in the questionnaire but was not explicitly specified for participants' conditions. Defining "mHealth" in general could hinder the participants' acceptance and use of mHealth, particularly in the group of participants with underlying diseases and specific health problems. This hypothesis could explain the observed association between having any underlying disease and low ITU in the group of participants who had never used mHealth before. Accordingly, our study primarily aimed to explore mHealth usage in general for community-dwelling adults. Our findings may not generalize enough to provide specific insight into the specific use case of mHealth in a particular population. Hence, we encourage future studies to aim for an in-depth understanding of each type of mHealth and acceptance in the specific context.

Conclusion

This study identified key factors influencing the ITU mHealth and positive attitudes toward using significantly enhancing ITU in both inexperienced and experienced users. Conversely, having an underlying disease was associated with a decrease in ITU, indicating that this group of individuals may require mHealth's specific requirements for their conditions rather than the general purpose. For experienced users, acceptance levels in areas such as ease of use and gerontechnology anxiety were critical. Health care professionals should identify patients open to using mHealth, ensure access to necessary equipment, address financial barriers, and educate patients on its benefits. Future investigations should also explore specific mHealth apps to provide more targeted insights.

Abstract

Background: With the increasing prevalence of digital technology, adolescent internet addiction (IA) has become a global concern. Excessive internet use, especially among adolescents, has been linked to various negative outcomes such as poor academic performance, social isolation, and mental health issues. Conducted among adolescents of Arab origin, our study addressed the limitations of the literature, which predominantly focuses on Western, educated, industrialized, rich, and democratic populations.

Objective: This study aimed to differentiate between essential and nonessential internet use and how they relate to IA in early and middle adolescents, as well as the relationship between subjective happiness with the amount of time spent on nonessential internet use and IA.

Methods: A cross-sectional survey was conducted among 377 students from 16 schools in Qatar. The survey measured essential and nonessential internet use, subjective happiness with nonessential use, and IA symptoms using the Internet Addiction Diagnostic Questionnaire, as well as participant demographics. To explore age-specific associations, participants were categorized into early (age 11-13 years) and middle (age 14-17 years) adolescents. Factorial analysis, multiple regression, and logistic regression were used for statistical analysis.

Results: Nonessential internet use significantly predicted IA in both early (P<.001) and middle (P<.001) adolescents, with early adolescents showing a stronger association. Subjective happiness with nonessential internet use negatively predicted IA only in middle adolescents (P<.001) as greater dissatisfaction led to a higher IA risk. Essential internet use did not predict IA in either group.

Conclusions: Differentiating between essential and nonessential internet use is crucial in understanding IA. This study highlights the importance of developmental differences in shaping IA symptoms. The findings suggest that interventions aimed at addressing IA should be age specific and focus on addressing nonessential use specifically rather than considering internet use and screen time in general as a single entity. Cultural and regional factors also play a role in shaping internet use patterns and IA in the Middle East, necessitating context-specific, culturally sensitive approaches to IA prevention.

internet addiction; internet use; early adolescence; middle adolescence; mobile phone

Introduction

Background

Adolescent internet addiction (IA) has become a growing concern in today's society as the use of technology and the internet has become increasingly prevalent in the lives of young people. According to a study conducted by the Pew Research Center, since 2014 to 2015, there has been a modest increase in the proportion of adolescents who said that they used the internet daily or more often [1]. In a follow-up study in 2022, a total of 97% of adolescents said that they used the internet daily compared to 92% of adolescents who said the same in 2014 to 2015. It is understandable that many adolescents struggle with IA given the widespread use of the internet. Studies have shown that approximately 10% of adolescents are at risk of IA, with even higher rates reported in countries such as Hong Kong, China, and South Korea [2-5]. For example, a survey conducted in South Korea found that nearly 30% of junior high school students were either addicted to the internet or at a risk of IA [6]. While some internet use can be beneficial for educational and social purposes, excessive use can lead to negative consequences such as decreased academic performance, social isolation, and even mental health issues [7-9]. Therefore, it is important to understand the prevalence of IA among adolescents and its contributing factors.

IA is defined as the inability to control internet use, leading to disruptions in everyday functioning and symptoms of withdrawal and tolerance [10]. Although not officially recognized as a disorder in the most recent edition of the *Diagnostic and Statistical Manual of Mental Disorders*, IA has received considerable attention in scientific literature and is regarded as a growing concern [11]. Opinions in the literature differ, with some researchers suggesting distinct diagnostic criteria and subtypes of IA, such as video game and online gambling addiction [12]. However, there is still a lack of consensus regarding the internet's addictive nature and IA diagnostic criteria [13]. While there is still debate regarding the exact nature and criteria for IA, it is clear that excessive internet use can have negative consequences, particularly for adolescents. Understanding the prevalence and factors contributing to IA is important for addressing this growing concern, promoting healthy internet use, and developing appropriate interventions for those who may be affected.

Most psychological research studies predominantly rely on samples from Western, educated, industrialized, rich, and democratic (WEIRD) populations [14]. However, when examining the effects of excessive internet use on adolescent mental health, it is crucial to consider that the experiences of adolescents from non-WEIRD populations may vary owing to many factors, such as different cultural norms and access to technology [15]. This emphasizes the importance of including more diverse samples in research to gain a comprehensive understanding of the global impact of technology on mental health. Cultural context significantly shapes adolescence, with the experiences of young individuals varying widely across different cultures [16]. To address this gap, our study focused on adolescent IA in the Middle East, where limited research on IA has been conducted. In doing so, we aimed to shed light on the specific dynamics of IA in this region and contribute to a more inclusive and comprehensive understanding of this phenomenon.

Qatar has one of the highest internet penetration rates in the world at 99% [17]. The country's internet users have grown significantly from 69% in 2012 to 100% in 2022 [18]. This increase raises the possibility of an increase in IA prevalence rates, as does the spread of mobile device use and the constant release of new technology updates. Furthermore, adolescents may unintentionally be encouraged to spend more time inside streaming online content, playing online games, and spending time on-screen due to Qatar's humid and hot weather, which lasts for more than half the year.

In addition to Qatar's unique technological landscape and climate, broader Middle Eastern cultural factors play a crucial role in shaping adolescent internet use patterns. The region's complex environment, which is characterized by its unique family dynamics, societal expectations, and cultural values, may contribute to the elevated prevalence of IA among adolescents [19,20]. In various Middle Eastern societies, conservative norms that prioritize modesty and restraint frequently conflict with the liberties that online platforms provide. As adolescents navigate their identities and seek communities that are consistent with their evolving values, this cultural tension can motivate them to engage with the internet differently. In addition, it is also argued that the limited opportunities for social interaction outside the home, along with societal pressures to conform, may encourage adolescents to seek connection and validation online, potentially nurturing addictive behaviors [19]. Culturally informed research can inform tailored intervention strategies that address the specific needs of adolescents in the Middle East. For example, studies suggest that effective interventions should involve families and schools, recognizing the significant role that these environments play in shaping adolescents' internet behaviors [21,22].

Excessive screen time is often identified as a prominent indicator of IA, contributing to an unhealthy relationship with the internet and development of negative habits [23,24]. In numerous studies examining adolescent IA, the amount of time spent on the web is commonly regarded as a key factor in determining the presence of IA [25,26]. The COVID-19 pandemic has further heightened the reliance on technology for remote learning and socializing among adolescents [27]. The term *screen time* is frequently used without sufficient attention being paid to the specific activities undertaken during that period. However, this lack of specificity has several methodological limitations. To address these limitations, this study aimed to differentiate between the time spent on essential and nonessential internet use activities, providing a more nuanced understanding of IA in adolescents. However, IA is not just a matter of excessive

screen time; it has also been linked to mental health issues such as loneliness, low self-esteem, sleep problems, depression, social phobia, and anxiety [28,29]. Adolescents who struggle with these conditions may turn to the internet as a coping mechanism, further exacerbating their addiction [30]. Ultimately, IA can have a significant negative impact on adolescents' lives, from decreased academic performance to strained relationships with loved ones [31].

Adolescence is a crucial period for identity exploration and formation during which individuals may encounter situations in which their emerging beliefs and values conflict with societal expectations or their own behaviors, which may lead to cognitive dissonance [32]. This aspect of adolescent development is relevant to the exploration of subjective feelings regarding digital technology use and its association with IA. Cognitive dissonance theory offers an understanding of this relationship by examining potential conflicts arising from adolescents' subjective feelings regarding their digital technology use and addictive behavior. According to the cognitive dissonance theory, individuals experience psychological discomfort when they hold contradictory beliefs, attitudes, or behaviors [33]. In the context of digital technology use and IA, cognitive dissonance may arise when adolescents recognize the negative consequences of excessive digital technology use but continue to engage in it. The literature suggests that subjective positive feelings about one's own life conditions are negatively correlated with IA [34]. It is reasonable to hypothesize that similar correlations may exist between subjective feelings regarding digital technology use and IA. However, there is a lack of specific studies exploring this association. Given this gap in the literature, this study aimed to address this by examining the association between subjective feelings about digital technology use and IA.

Adolescents are growing up in an era characterized by rapid technological advancements, and the use of smartphones has become a common part of their daily lives. This pervasive technology has greatly influenced their interactions with the internet, particularly social networking sites [35]. Consequently, this has had a profound impact on various aspects of their lives, including social dynamics, cognitive development, and emotional well-being. The literature indicates notable distinctions between early and middle adolescents in terms of cognitive and psychological development [36]. It is critical to distinguish between early and middle adolescence when investigating adolescent IA owing to the distinct developmental traits, experiences, and coping strategies that arise throughout these separate phases of adolescence [37]. Early adolescence is a critical period defined by the start of puberty and the transition from childhood to adolescence. This stage is distinguished by rapid physical, cognitive, and social changes, as well as identity exploration and self-concept construction [38,39]. Furthermore, early adolescence is a critical time for the initiation and development of mental health issues [40]. Middle adolescence is characterized by managing the complications of moving into young adulthood [41]. Individuals become more self-sufficient, engage in complex social connections, and gain feelings of autonomy [42]. If these aspects of development are not addressed properly during adolescence, consequences may have a lasting impact in their adulthood. Researchers must examine the diverse vulnerabilities, risk factors, and patterns of internet use among early and middle adolescents while studying IA during these different phases. Early adolescents may be more vulnerable to IA because they are constantly trying new things, including online platforms, to define their identities and connect with friends [39]. Middle adolescence, on the other hand, is characterized by the emergence of more stable patterns of behavior, including internet use, as adolescents approach young adulthood and deal with increasing academic and social demands [43]. Furthermore, research has shown that the characteristics that influence IA change between early and middle adolescence [21]. For example, parental supervision and advice may have a greater effect among early adolescents, but peer influence and social support may become more significant in middle adolescence [44,45]. Furthermore, in middle adolescence, the onset of academic commitment and the need for self-regulation might alter internet use patterns and addiction risks. IA has become a growing concern among adolescents, with symptoms presenting both in relation to oneself and in interactions with others. However, the cognitive development and behavioral patterns of early and middle adolescents differ significantly, suggesting the need for a critical examination of IA symptoms according to age. Although previous research has highlighted the multifaceted nature of IA symptoms, little attention has been paid to the potential differential manifestation of symptoms based on the age of adolescents. Understanding how IA symptoms manifest differently in early and middle adolescence is crucial for tailoring prevention and intervention efforts. Understanding the differences between early and middle adolescence is critical when examining IA. Our study aimed to address the existing knowledge gap by investigating aspects that have not been thoroughly explored in the field of adolescent IA.

Adolescent technology use can be categorized into distinct types depending on type of use: essential and nonessential [46,47]. Activities that are essential for everyday life, such as educational pursuits or personal improvement–related activities, are included in essential use. On the other hand, nonessential use includes leisure activities such as gaming, social media engagement for nonspecific developmental purpose, and other forms of entertainment [46]. Although researchers have investigated the correlations between excessive internet use and IA, there is a noticeable absence of studies that explicitly distinguish between essential and nonessential use patterns. We suggest that the use of the internet for essential activities related to education and personal development can improve efficiency and time management and may not be linked to IA. In contrast, the excessive use of the internet for nonessential activities may help change mood and increase bonding but may also result in diminished productivity and potential adverse consequences [48]. Given this distinction, our study endeavored to examine the distinct effects of essential versus nonessential internet use on adolescents, thereby contributing to resolving a critical gap in the current literature and offering valuable insights for comprehending healthy internet use patterns.

Objectives

While extensive research has been conducted on IA among adolescents, several significant gaps remain. First, there is a lack of studies focusing on non-WEIRD populations, particularly in the Middle East, where unique cultural factors may influence IA. Second, the potential significance of the distinction between essential and nonessential internet use in relation to IA has not been adequately investigated. Third, there is a scarcity of research on the correlation between subjective emotions related to the use of digital technology and IA. Finally, while the developmental differences between early and middle adolescence are well documented, there are few studies that have investigated the potential differences in the manifestation of IA symptoms and their relationship to technology use across these age groups. We aimed to answer the following three research questions (RQs) through this study:

1. Do essential and nonessential types of internet use predict IA in early and middle adolescents? (RQ 1)
2. Can subjective happiness with nonessential internet use predict adolescent IA? (RQ 2)
3. Does the impact of time spent on essential and nonessential internet use, as well as subjective feelings regarding nonessential internet use, on IA differ between the early and middle adolescence stages? (RQ 3)

Methods

Participants

This study involved school students residing in Qatar, and their participation was secured through web-based surveys administered via SurveyMonkey (SurveyMonkey Inc). The survey invitation was sent out to multiple schools in Qatar through an open call using the mailing list of head teachers and educators. One of the authors works at an education policy institute with a network of schools that attend events and participate in research activities. This facilitated outreach. A total of 16 schools accepted the study invitation, comprising an equal number of public (n=8, 50%) and private (n=8, 50%) schools. Public schools in Qatar are government funded and managed by the government and primarily enroll Qatari citizens as they provide free education with Arabic as the language of instruction. These schools are also gender segregated, meaning that male and female students attend separate institutions. Private schools, on the other hand, are funded by tuition fees and managed by private organizations and predominantly enroll expatriate students. These schools follow a variety of government-reviewed international curricula and are typically not gender segregated. Data were collected between March 2022 and May 2022.

Before administering the survey, students were provided with an induction session by their head teacher, who explained the distinction between essential and nonessential internet use. Essential use was defined as internet activities connected to study, academic work, and personal development, whereas nonessential use was defined as activities that do not directly contribute to these aims. This briefing was designed to establish a common understanding among participants, guaranteeing that their answers precisely reflected these definitions. The authors acknowledge the difficulty in standardizing what adolescents consider essential versus nonessential. Therefore, our study and results should be interpreted as reflecting the subjective views and self-reports of the adolescent participants. This interpretation follows an induction on general understanding, which aimed to reduce diversity in perceptions.

We used the formula by Green [49] to calculate the optimal sample size for our research. The formula indicates that a linear regression analysis requires a minimum sample size of 50 plus 8 times the number of independent variables p ($50 + 8 \times p$). This indicates that a minimum sample size of 74 participants was suitable for our study. In addition, to ensure correlation stability [50], our aim was to have a sample size of >250 individuals. This sample size is consistent with recommendations for maintaining statistical power in studies with multiple predictors [49,50]. Furthermore, the male sample was deemed too small to segregate the analysis by gender.

After excluding participants who did not meet the inclusion criteria, such as those who provided incomplete responses, 64.3% (377/586) of the initial students were included in the analysis, which fulfilled the criteria of a 5% margin of error at the 95% CI. Of these 377 students, 86 (22.8%) were male and 291 (77.2%) were female. The gender distribution in our sample reflects the timing of data collection, which coincided with final exams, as well as the demographic characteristics of the responding schools. Specifically, 12% (2/16) of the schools that responded to the survey were predominantly female-only public schools, which significantly contributed to the observed gender imbalance. It is important to note that gender was not included as a variable in our analysis as the study's primary focus was on essential and nonessential internet use. On the basis of the estimates of the sample size and the need for adequate statistical power in our regression analysis, it was not possible to divide the sample by gender for separate analyses.

The average age of the participating adolescents was 13.19 (SD 1.24; range 11-17) years. The participants in the study were requested to explicitly provide their ages. Participants were categorized into 2 groups: early adolescents (aged 11-13 years) and middle adolescents (aged 14-17 years). The classification of adolescents into these developmental phases was determined based on the existing literature [51].

Ethical Considerations

This study was approved by the institutional review board of Hamad Bin Khalifa University (QBRI-IRB 2021-05-094). School permissions were obtained to distribute the survey. The parents and adolescents were informed beforehand of the study, and their written informed consent and assent were collected. Participants were informed about the study's purpose, and their involvement was voluntary, allowing them to skip questions or withdraw from the survey if desired. During data collection, no identifiable information was collected. The researchers ensured that all deidentified data were stored on a password-protected laptop that only the primary investigators of the study had access to. Participants were not compensated for taking part in this study.

Measures

Overview

The survey included questions regarding participants' demographics, digital technology use, subjective happiness with nonessential internet use, and IA. The questionnaire was distributed in both English and Arabic to accommodate language preferences, and the accuracy of the Arabic translation was ensured using the back translation method [52] (see Multimedia Appendix 1 for both versions of the survey). Our study included a comprehensive and multistep procedure for validating the survey questions to establish its reliability and suitability for the adolescent population. We began by conducting think-aloud protocols with a subset of 3 adolescents, asking them to verbalize their thought processes while answering the survey questions [53]. This approach helped us identify potential ambiguities or misunderstandings, leading to revisions in translation that ensured clarity and suitability for the target age group yet without departing from the original meaning of the questions in the English version. In total, 3 authors with extensive expertise dealing with adolescent groups in the Arab area offered expert advice. Furthermore, the questions in the survey were culturally appropriate, did not use any jargon, and were free of unclear language.

Internet Addiction Diagnostic Questionnaire

The Internet Addiction Diagnostic Questionnaire (IADQ) consists of 8 items, each representing a symptom used to identify IA [10]. The questionnaire uses a binary response format, with participants indicating *no* or *yes* to each symptom. The total score on the IADQ ranges from 0 to 8 and is obtained by summing the values assigned to each of the 8 binary questions. The symptoms assessed by the IADQ are *preoccupation* (question 1), *tolerance* (question 2), *unsuccessful efforts to limit or stop Internet usage* (question 3), *withdrawal* (question 4), *loss of control of time spent on the Internet* (question 5), *risk/lose relationships or opportunities* (question 6), *lies to conceal the extent of involvement* (question 7), and *dysfunctional coping* (question 8) [54]. Participants who answered *yes* to ≥5 symptoms were categorized as addicted to the internet (dependent internet users), whereas the others were categorized as nondependent internet users. Previous studies on the IADQ have reported Cronbach α values ranging from 0.60 to 0.72 [55]. The reliability of the IADQ in this study was deemed acceptable, with a Cronbach α value of 0.66 [56] and a McDonald ω value of 0.67. In addition, the research conducted by Lozano-Blasco et al [57] found that using lesser answer categories led to decreased Cronbach α values. The dichotomous character of the questions in the IADQ, which means that they only allow for replies of *yes* or *no*, leads to lower Cronbach α values that are within the acceptable range for dependability. To establish content validity [58], the initial item pool was reviewed by a panel of 3 experts who has extensive experience working with adolescents in the Arab region. This process resulted a questionnaire that comprehensively covered the construct of interest.

Essential and Nonessential Internet Use

Adolescents were presented with a set of questions regarding their use of digital technology for both essential and nonessential purposes on both weekends and weekdays. The weekend is officially observed on Fridays and Saturdays in Qatar. By focusing on weekdays and weekends separately, we aimed to capture any behavioral variations influenced by the shift from weekend to workweek and vice versa. Participants were asked the following questions to encompass four different situations: (1) How many hours do you use digital technology for study purposes daily on weekdays (Sunday-Thursday)? (2) How many hours do you use digital technology for nonessential reasons daily on weekdays (Sunday-Thursday)? (3) How many hours do you use digital technology for study purposes daily on weekends (Friday and Saturday)? (4) How many hours do you use digital technology for nonessential reasons daily on weekends (Friday and Saturday)?

Essential internet use on weekdays and weekends was combined, and their average was used to compute essential internet use time. Nonessential internet use on weekdays and weekends was combined, and their average was taken to compute nonessential internet use time.

Subjective Happiness With Nonessential Internet Use Time

Adolescents were asked to express their feelings regarding the extent of their nonessential use of digital technology. Their responses were collected using a five-point Likert scale: (1) "I am happy with it," (2) "I am somewhat happy with it," (3) "Neither happy nor unhappy with it," (4) "I am somewhat unhappy with it," and (5) "I am unhappy with it."

Statistical Analysis

Multiple linear regression analyses were conducted separately for early and middle adolescents to examine the relationship between nonessential internet use, essential internet use, and subjective happiness with nonessential internet use time and their IA status. The significance level for the statistical tests was set at $P<.05$. All statistical analyses were carried out using JASP (version 0.17.1) [59].

Exploratory factor analysis with oblique (promax) rotation was performed [60]. The determination of the number of significant components to retain for rotation was based on two criteria: (1) the scree plot indicating the number of extracted factors and (2) ensuring that the factor solution allowed for a coherent interpretation of the results.

Results

Descriptive Statistics

The descriptive statistics of the participants are presented in Table 1.

Table 1. Descriptive statistics—internet use patterns and internet addiction (IA).

Variable	Early adolescents (n=242)	Middle adolescents (n=135)
Essential internet use time (h), mean (SD)	2.22 (1.76)	2.96 (2.12)
Nonessential internet use time (h), mean (SD)	4.45 (2.74)	4.52 (2.35)
Subjective happiness with nonessential internet use time, n (%)		
"I am happy with it" (rating of 1)	90 (37.2)	44 (32.6)
"I am somewhat happy with it" (rating of 2)	77 (31.8)	40 (29.6)
"Neither happy nor unhappy with it" (rating of 3)	46 (19)	35 (25.9)
"I am somewhat unhappy with it" (rating of 4)	17 (7)	11 (8.1)
"I am unhappy with it" (rating of 5)	12 (5)	5 (3.7)
IA		
Total IA score (0-8), mean (SD)	3.26 (1.98)	3.47 (2.17)
IA prevalence, n (%)		
Addicted internet users	63 (26)	50 (37)
Nonaddicted internet users	179 (74)	85 (63)

Exploratory Factor Analysis of IA Symptoms

To identify underlying dimensions within the IA symptoms and reduce the data into meaningful factor scores, an exploratory factor analysis was conducted on the dataset. The Kaiser-Meyer-Olkin (KMO) test, a measure of sampling adequacy, was used in this study to evaluate multicollinearity in the data to determine the feasibility of conducting a factor analysis. The overall KMO measure was 0.76, denoting "middling" adequacy. Individual KMO measures were all of >0.68, ranging from the "mediocre" to the "marvelous" categories according to the classification system by Kaiser and Rice [61]. The Bartlett test of sphericity was statistically significant (P<.001), indicating that the data were likely factorizable.

The analysis extracted 2 components, which accounted for 26% of the variance. Our scree plot was compatible with the 2-factor model. We interpreted the 2 factors as representing internal IA symptoms (factor 1; 18% of the total variance)—those symptoms primarily related to the individual's self, such as preoccupation with internet use—and external IA symptoms (factor 2; 9% of the total variance)—those symptoms primarily related to interaction with others. Factor loadings for factor 1 and factor 2 ranged from 0.31 to 0.55 and from 0.33 to 0.78, respectively. Factor scores were derived by adding the scores of individual items within each empirical domain (sum score) and dividing the sum scores by the total number of items (mean item score). The component loadings and uniqueness of the rotated solutions are presented in Table 2.

Table 2. Factor analysis of internet addiction symptoms.

Item	Factor 1 loadings	Factor 2 loadings	Uniqueness
"Preoccupation" (question 1)	0.49	—[a]	0.79
"Tolerance" (question 2)	0.31	—	0.91
"Unsuccessful efforts to limit or stop Internet usage" (question 3)	0.50	—	0.76
"Withdrawal" (question 4)	0.55	—	0.62
"Loss of control of time spent on the Internet" (question 5)	0.50	—	0.77
"Risk/lose relationships or opportunities" (question 6)	—	0.78	0.48
"Lies to conceal the extent of involvement" (question 7)	—	0.33	0.75
"Dysfunctional coping" (question 8)	0.45	—	0.79

[a]The factor does not comprise this item.

Early Adolescents

Predictors of Total IA Scores

Overview

Multiple regression analysis was used to determine factors that predicted early adolescents' total IA scores and internal IA symptoms. No outliers were observed in the data. The Pearson correlation was also used to analyze the associations between total IA, which was the dependent variable, and the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time.

Correlation Analysis of Variables

The correlations between the variables are presented in Table 3.

Table 3. Pearson correlation table between the variables in early adolescents.

	Total IA[a]	Internal IA symptoms	External IA symptoms	Subjective happiness with nonessential internet use time	Essential internet use time	Nonessential internet use time
Total IA	1	—[b]	—	—	—	—
Internal IA symptoms	0.95[c]	1	—	—	—	—
External IA symptoms	0.58[c]	0.30[c]	1	—	—	—
Subjective happiness with nonessential internet use time	0.04	0.03	0.03	1	—	—
Essential internet use time	0.07	0.04	0.10	0.04	1	—
Nonessential internet use time	0.41[c]	0.41[c]	0.18[d]	0.07	0.12	1

Regression Analysis of Total IA Scores

Table 4 shows the results of the multiple regression that was run to predict the total IA score from the subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time among early adolescents. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.93. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q*-*Q* plot. The multiple regression model significantly predicted the total IA score ($F_{3, 238}$=15.72; $P<.001$; R^2=0.17; adjusted R^2=0.15). Within the model, nonessential internet use time (β=.40; $P<.001$) was the only significant predictor of early adolescents' total IA scores.

Table 4. Multiple linear regression analysis predicting internet addiction in early adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	5.73 (3)	<.001
Subjective happiness with nonessential internet use time	.00923	0.16 (3)	.88
Essential internet use time	.02	0.36 (3)	.72
Nonessential internet use time	.40	6.74 (3)	<.001

[a]R^2=0.17; adjusted R^2=0.15; $F_{3, 238}$=15.72.

[b]Not applicable.

Predictors of Internal and External IA Symptoms

Multiple regression analysis was used to determine factors that predicted internal IA symptoms with the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time, and an ordinal logistic regression model was used to predict external IA symptoms. Table 5 shows the results of the multiple regression that was run to predict the internal IA symptom score from the subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.98. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q*-*Q* plot. The multiple regression model significantly predicted the internal IA symptom score ($F_{3, 238}$=15.95; $P<.001$; R^2=0.17; adjusted R^2=0.16). Within the model, nonessential internet use time (β=.41; $P<.001$) was the only significant predictor of early adolescents' internal IA symptoms.

Table 5. Multiple regression analysis predicting internal internet addiction symptoms in early adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	6.18 (3)	<.001
Subjective happiness with nonessential internet use time	.00318	0.05 (3)	.96
Essential internet use time	−.00431	−0.07 (3)	.94
Nonessential internet use time	.41	6.86 (3)	<.001

[a]R^2=0.17; adjusted R^2=0.16; $F_{3, 238}$=15.95.

[b]Not applicable.

An ordinal logistic regression analysis was conducted to examine the relationship between the 3 predictor variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) and the outcome variable (external IA symptoms; Table 6). The variables included in the ordinal logistic regression analysis met the assumptions of the statistical model—the dependent variable (ie, external IA symptoms) was treated as an ordinal variable, and the independent variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) were treated as continuous variables. The assumption of no multicollinearity was assessed by examining the variance inflation factors (VIFs), and the result (VIFs<1.1) indicated no multicollinearity. The results revealed that nonessential internet use time was associated with increased external IA symptoms (odds ratio [OR] 1.13, 95% CI 1.02-1.24; *P*=.02). Meanwhile, essential internet use time was not associated with any change in external IA symptoms (OR 1.11, 95% CI 0.96-1.28; *P*=.17). Similarly, subjective happiness with nonessential internet use time was not associated with any change in external IA symptoms (OR 0.99, 95% CI 0.78-1.25; *P*=.94) in early adolescents.

Table 6. Ordinal logistic regression predicting external internet addiction symptoms in early adolescents.

Predictor	OR[a] (95% CI; SE)	*P* value
Subjective happiness with nonessential internet use time	0.99 (0.78-1.25; −0.01)	.94
Essential internet use time	1.11 (0.96-1.28; 0.10)	.17
Nonessential internet use time	1.13 (1.02-1.24; 0.12)	.02

[a]OR: odds ratio.

Binary logistic regression was conducted to examine the relationship between subjective happiness with nonessential internet use time and the likelihood of being a dependent internet user (addicted) compared to a nondependent internet user (unaddicted) in early adolescents. The reference category, representing nondependent internet users, was coded as class 1. The OR of 0.93 (95% CI 0.73-1.20) indicated the effect size. However, the results did not reveal a significant association between subjective happiness with nonessential internet use time and IA (*P*=.58).

Middle Adolescents

Predictors of Total IA Scores

Overview

Multiple regression analysis was used to determine the factors that predicted middle adolescents' total IA scores and internal IA symptoms. No outliers were observed in the data. The Pearson correlation was also used to analyze the associations between total IA, which was the dependent variable, and the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time.

Correlation Analysis of Variables

The correlations between the variables are presented in Table 7.

Table 7. Pearson correlation table between the variables—middle adolescents.

	Total IA[a]	Internal IA symptoms	External IA symptoms	Subjective happiness with nonessential internet use time	Essential internet use time	Nonessential internet use time
Total IA	1	—[b]	—	—	—	—
Internal IA symptoms	0.95[c]	1	—	—	—	—
External IA symptoms	0.66[c]	0.39[c]	1	—	—	—
Subjective happiness with nonessential internet use time	0.34[c]	0.28[d]	0.32[c]	1	—	—
Essential internet use time	0.21[e]	0.15	0.26[d]	0.18[e]	1	—
Nonessential internet use time	0.35[c]	0.33[c]	0.24[d]	0.13	0.05	1

Regression Analysis of Total IA Scores

Table 8 shows the results of the multiple regression that was run to predict middle adolescents' total IA score from the subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.83. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q-Q* plot. The multiple regression model significantly predicted the total IA score ($F_{3,\ 131}$=12.96; P<.001; R^2=0.23; adjusted R^2=0.21). Within the model, nonessential internet use time (β=.31; P<.001) and subjective happiness with nonessential internet use time (β=.27; P<.001) were significant predictors of middle adolescents' total IA score.

Table 8. Multiple linear regression analysis predicting internet addiction in middle adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	1.16 (3)	.25
Subjective happiness with nonessential internet use time	.27	3.44 (3)	<.001
Essential internet use time	.15	1.90 (3)	.06
Nonessential internet use time	.31	3.94 (3)	<.001

[a]R^2=0.23; adjusted R^2=0.21; $F_{3,\ 131}$=12.96.

[b]Not applicable.

Predictors of Internal and External IA Symptoms

Multiple regression analysis was used to determine factors that predicted internal IA symptoms with the independent variables of subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time, and ordinal logistic regression was used to predict external IA symptoms. Table 9 presents the results of the multiple regression. The linearity of the sample was assessed by examining the residuals versus predicted plots, whereas residuals versus dependent plots were used to evaluate homoscedasticity in the data. All the assumptions of linearity, normality, homoscedasticity, and multicollinearity were satisfied. Residuals were independent, as assessed via a Durbin-Watson statistic of 1.82. There was no evidence of multicollinearity, as assessed via tolerance values of >0.1. The assumption of normality was met, as assessed using a *Q-Q* plot. The multiple regression model significantly predicted the internal IA symptom score ($F_{3,\ 131}$=9.15; P<.001; R^2=0.17; adjusted R^2=0.15). Within the model, nonessential internet use time (β=.29; P<.001) and subjective happiness with nonessential internet use time (β=.22; P=.007) were significant predictors of middle adolescents' internal IA symptoms.

Table 9. Multiple regression analysis predicting internal internet addiction symptoms in middle adolescents[a].

Predictor	Standardized	*t* test (*df*)	*P* value
Constant	—[b]	2.10 (3)	.04
Subjective happiness with nonessential internet use time	.22	2.76 (3)	.007
Essential internet use time	.10	1.20 (3)	.23
Nonessential internet use time	.29	3.65 (3)	<.001

[a]R^2=0.17; adjusted R^2=0.15; $F_{3, 238}$=15.95.

[b]Not applicable.

An ordinal logistic regression analysis was conducted to examine the relationship between the 3 predictor variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) and the outcome variable (external IA symptoms; Table 10). The variables included in the ordinal logistic regression analysis met the assumptions of the statistical model—the dependent variable (ie, external IA symptoms) was treated as an ordinal variable, and the independent variables (ie, subjective happiness with nonessential internet use time, essential internet use time, and nonessential internet use time) were treated as continuous variables. The assumption of no multicollinearity was assessed by examining the VIFs, and the result (VIFs<1.1) indicated no multicollinearity. The results revealed that all 3 predictors were associated with changes in the external IA symptoms. Nonessential internet use time was associated with an increase in external IA symptoms (OR 1.19, 95% CI 1.03-1.39; *P*=.02). Essential internet use time was associated with an increase in external IA symptoms (OR 1.24, 95% CI 1.05-1.46; *P*=.01). Similarly, a higher unhappiness with nonessential internet use time was associated with increased external IA symptoms (OR 1.75, 95% CI 1.28-2.44; *P*<.001).

Table 10. Ordinal logistic regression predicting external internet addiction symptoms in middle adolescents.

Predictor	OR[a] (95% CI; SE)	*P* value
Subjective happiness with nonessential internet use time	1.75 (1.28-2.44; 0.56)	<.001
Essential internet use time	1.24 (1.05-1.46; 0.21)	.02
Nonessential internet use time	1.19 (1.03-1.39; 0.18)	.01

[a]OR: odds ratio.

A binary logistic regression was performed to assess the impact of subjective happiness with nonessential internet use time on the likelihood of being a dependent internet user (addicted) versus a nondependent internet user (unaddicted). The reference category was coded as class 1, representing nondependent internet users. The OR of 0.66 (95% CI 0.47-0.92) indicated the effect size. The *F*-measure was 75%. The results indicated a significant association between subjective happiness with nonessential internet use time and IA (*P*=.01), suggesting that higher levels of unhappiness were associated with a decreased likelihood of being unaddicted to the internet.

Discussion

Principal Findings

This study aimed to enhance our understanding of adolescent IA by addressing 3 key RQs. First, we examined the significance of differentiating between essential and nonessential internet use in relation to IA, offering a more nuanced view of IA beyond that of total screen time that is found in previous research. Second, we investigated whether subjective happiness linked to time spent on nonessential internet use could predict IA in adolescents. Finally, by studying early and middle adolescents separately, we identified age-specific differences in how time spent on essential and nonessential internet use and the related happiness contribute to IA.

Consistent with the extensive existing literature on IA, our study demonstrated that excessive engagement in nonessential internet activities, such as social media and online gaming, positively correlate with IA overall [62-64]. Furthermore, in our study, essential internet use did not exhibit a significant correlation with IA (*P*=.94 for early adolescents and *P*=.06 for middle adolescents), suggesting that essential internet activities such as remote learning or using the internet for school-required work may not carry the same level of addiction risk. This is similar to the results obtained in other studies [65,66]; Salubi et al [65] found that there was no correlation between essential internet use and IA among 390 surveyed university students in South Africa, whereas Pjevac et al [66] found that IA was lowest among adolescents who mostly used the internet for school purposes. This distinction of the purposes of internet use enables the development of targeted interventions and strategies to effectively address this issue. As digital technology becomes increasingly integral to tasks that once operated without it, acknowledging this technological shift is essential in our evolving digital society. It is necessary to recognize the evolving landscape of digital technology use and interpret digital technology use with caution, as emphasized by Squire and Steinkuehler [67], before delving into the complexities of IA. This caution entails considering the specific activities carried out on the internet, the motivations driving them, and the duration for which they occur.

Our study highlights similarities and key differences in IA between early and middle adolescents as our results revealed that, among early adolescents, nonessential internet use significantly predicted IA and its internal symptoms (related to the self). However, middle adolescents exhibited a more complex relationship with IA as both nonessential and essential internet use, in addition to unhappiness with nonessential internet activities, significantly predicted IA and its external symptoms (related to others).

Our results suggest that early adolescents are more likely to develop IA and experience internal IA symptoms as a result of nonessential internet use, whereas this influence seems to decrease as they get older. This finding is in line with the results of a meta-analysis (of 20 studies) on IA in adolescents reporting that IA is inversely proportional to age [57]. This difference suggests that the impact of nonessential digital technology use on IA may vary according to the developmental stage of adolescents. One possible explanation is that early adolescents are actively navigating their new identity and seeking peer acceptance, which can make them more susceptible to excessive use of digital technology [68]. The pressure to conform to peers' behaviors and expectations may override their ability to exercise self-control and resist the allure of digital technology [69]. Furthermore, in early adolescents, only nonessential internet use increased the likelihood of external IA symptoms. Our results are similar to those of a recent study that examined sociodemographic factors related to IA among a sample of 1664 adolescents in Serbia. The study reported the lowest IA rates among the younger adolescents and among those who used the internet for the purpose of schoolwork [66]. Our results could be interpreted as early adolescents not facing the same academic pressures and responsibilities that drive older adolescents to the excessive use of the internet for essential activities. Instead, early adolescent IA is more related to recreational online activities, underscoring the importance of tailoring preventive interventions to focus on nonessential use, such as social media and gaming, to equip early adolescents to develop healthier digital habits. Parental involvement and supervision play a vital role in preventing IA in early adolescents. Actively engaging with children, establishing open communication channels, and monitoring their digital technology use can create a supportive environment and set boundaries for healthy digital behaviors [27,70]. Emphasizing balance is also essential, highlighting the need for a well-rounded lifestyle that includes academic tasks, physical activities, face-to-face interactions, and nondigital recreational pursuits [71]. Self-control in early adolescents may be enhanced through self-control–training activities and participation in self-control–promoting programs [72].

In contrast to the results for early adolescents, our results demonstrated a more complex relationship between internet use and IA in middle adolescents. Our study found that, while nonessential internet use remains a significant predictor of IA, subjective happiness with nonessential internet activities also plays a role. Specifically, the unhappier middle adolescents were with the time spent on nonessential internet use, the more likely they were to experience IA. These findings are consistent with the findings of a similar study that surveyed a sample of adolescents and young adults (aged 15-24 years) and adults (aged 25-64 years), where dissatisfaction with smartphone use was linked to higher problematic internet use [73]. Our results contribute to the literature as there is a lack of research examining subjective happiness with digital technology use in relation to IA in adolescents.

This can be attributed to the increased academic pressure and the need to manage uncertainty, which drive middle adolescents to spend more time on essential internet activities, such as online educational tasks. The combination of information overload, academic demands, and the desire to avoid having to deal with uncertainty may lead to excessive internet use, further exacerbating IA.

Moreover, middle adolescents exhibited a broader range of factors influencing their external IA symptoms.

While, in early adolescents, only nonessential internet use increased the likelihood of external IA symptoms, in middle adolescents, both nonessential and essential internet use, as well as unhappiness with the time spent on nonessential internet use, increased external IA symptoms. This can be attributed to the intensified academic pressure in combination with information overload, leading them to neglect other aspects of their lives and driving them to the excessive use of the internet to meet academic demands [74,75]. The combination of these factors heightens the risk of IA [76-78]. Furthermore, these academic pressures can further impact social interactions as middle adolescents prioritize academic performance, leading them to show signs of stress in their engagement with others [74,79], manifesting in external symptoms of IA, as observed in our study. Recognizing the unique challenges faced by adolescents at different developmental stages is crucial for effectively tailoring preventive measures and interventions.

While our study focused on examining individual factors related to IA, considering factors related to the specific context in which our results were obtained should not be overlooked and could provide a more holistic understanding of IA among adolescents. Adolescents' internet use and their susceptibility to IA are influenced by cultural values, societal norms, and regional habits. For instance, in the Middle East, where our study was conducted, cultural expectations regarding academic achievement and family roles may contribute to heightened stress and pressure on adolescents [80,81], leading them to spend more time on online activities such as social media and gaming. The emphasis on academic success in our context combined with limited outdoor recreational opportunities due to the extremely hot climate might be driving adolescents to spend more time indoors and engage in online recreational activities, increasing their risk of IA.

In addition, the rapid digital transformation in the Middle East has created new challenges and opportunities for adolescents [82,83]. The increased availability of smartphones and internet access as well as a growing digital culture have made it easier for people to spend long hours on the web. While there are positive aspects of digitalization, it also raises concerns about the potential for excessive use and the development of IA. The addition of environmental factors such as the local affluent culture of convenience, the wide availability of digital devices even at very young ages, and the wide presence of high-speed

internet further influences how adolescents interact with digital technology.

Our study has important implications for the field of IA and for promoting healthier digital technology use habits in adolescents. The findings suggest that interventions aimed at addressing IA should focus on nonessential use specifically, particularly in early adolescents, rather than considering internet use as a whole. Because IA is a complex outcome influenced by multiple physical, psychological, and technological factors rather than a single issue, this targeted approach can help effectively address the factors contributing to IA while considering the developmental factors of adolescents. While there is a dearth of data from the region, there is evidence from a systematic literature review on policy and prevention approaches for disordered gaming and internet use suggesting that, due to the global prevalence of the phenomena and the geographically dispersed nature of preventative programs, it is imperative that prevention efforts be integrated across national borders while taking cultural differences into consideration [84].

The following recommendations are a recapitulation of the evidence produced by the limited international reviews that have examined the effectiveness of programs and interventions in the prevention of IA [71,84-87].

Early identification and intervention are key to addressing IA among adolescents. Schools can implement evidence-based prevention programs specifically targeting IA. These programs can incorporate educational components, skill-building exercises, and peer support networks to help adolescents develop healthy online habits and balance their time between essential and nonessential activities [87]. Comprehensive school-based programs are essential to effectively address IA. These programs should focus on increasing awareness, develop coping strategies, and promoting responsible digital technology use. These programs can be integrated into the school curricula and should include methods to improve self-control and enhance knowledge of the underlying processes that contribute to excessive online activity, such as constant notifications [88,89]. In addition, schools can implement practical digital well-being initiatives, such as mindfulness exercises and the integration of technology breaks into the daily schedule, to promote healthier digital habits. Moreover, promoting digital literacy and responsible digital technology use is crucial for educating adolescents on the potential risks and consequences associated with excessive digital technology use [90]. Given that adolescents' behaviors are largely shaped by other external factors such as their families and external environments [21], schools play a crucial role in extending these preventive programs to parents and caregivers. Understanding children's intentions when interacting with the internet is crucial and emphasizes the need for smarter digital parenting tools that provide enhanced monitoring and guidance. A healthier digital environment can be created by considering intentionality and using smart tools. Devices and programs should be designed to isolate essential and nonessential uses, advising children to avoid installing or visiting purely nonessential social media applications and sites on the same device in which they engage in essential activities.

These recommendations must be supported by designing and enacting policies. Policy makers can design programs targeting the broader environment in which adolescents live, addressing the underlying factors contributing to maladaptive coping, such as reducing academic pressure and improving family support. By reducing dependence on nonessential internet use, these policies, in turn, can empower adolescents to navigate their digital environments more responsibly.

Certain limitations of this study must be considered when interpreting the results. First, due to the cross-sectional design of our study, the generalizability of our findings is limited. Another limitation of our study was that the responses provided by the adolescents were based on self-report, potentially introducing reporting bias. It is possible that the adolescents did not accurately report the time spent on essential and nonessential activities and symptoms of IA. To mitigate the influence of reporting bias, future studies should incorporate objective measures, such as using data on actual screen time, instead of relying solely on self-reported information. Another limitation of this study is that the context of essential and nonessential internet use could have been interpreted by adolescents based on their subjective experiences and perceptions. For example, spending time with friends on social media during the examination period may be considered essential for adolescents who want to receive moral support from their colleagues. Nevertheless, our study left it at the discretion of the participants. The impact of the specific activity or content that adolescents consume or spend excessive time on and the effect it has on them should be scrutinized in more detail and is an area that requires attention. Our sample's gender imbalance, which was characterized by a higher proportion of female participants, may restrict the generalizability of the results to both genders. Furthermore, we adhered to sample size estimates using the method by Green [49] to guarantee sufficient statistical power for our study. The deliberate choice not to segregate the sample by gender was made to ensure that the sample size remained sufficient for obtaining consistent and dependable regression results. The male sample was relatively too small to allow for that option. Although the existing literature on gender differences in IA is inconclusive, with research presenting inconsistent findings [91-95], it is important to exercise caution when interpreting the results of this study due to the higher proportion of female participants. Future studies should aim for a more even gender distribution to comprehensively investigate any disparities in IA between male and female individuals.

The strength of our study lies in its inclusion of a non-WEIRD population, specifically focusing on adolescent IA in the Middle East, where limited research on this area has been conducted. Another strength of our study is that it addresses the research gap by examining both essential and nonessential internet use in the same sample. While previous research has explored the different online activities that contribute to IA [65,96], few studies have specifically investigated the impact of essential and nonessential internet use within a single study. Another strength of our study lies in the separate analysis of IA factors in early and middle adolescents, which allowed us to capture the unique dynamics and influences shaping IA in each age

group, thus enhancing the understanding of IA in relation to developmental stages.

Conclusions

In conclusion, this study sheds light on the complex relationship between digital technology use and IA among early and middle adolescents. For many years, screen time has been widely used as a prominent measure to assess the extent of IA among adolescents. As the digital society continues to evolve rapidly, relying on screen time as a stand-alone criterion fails to provide a comprehensive understanding of phenomena such as IA. Therefore, it is imperative to distinguish between essential and nonessential digital technology use, acknowledging diverse activities and their implications for a better understanding of individuals' engagement with digital technology. The findings of our study provide valuable insights for researchers, practitioners, and policy makers in addressing IA among adolescents. By recognizing the distinct nature of internet activities and considering developmental factors, effective interventions and strategies can be developed to promote healthy digital technology use and prevent IA in adolescents.

Abstract

Background: Dispensing errors significantly contribute to adverse drug events, resulting in substantial health care costs and patient harm. Automated pill verification technologies have been developed to aid pharmacists with medication dispensing. However, pharmacists' trust in such automated technologies remains unexplored.

Objective: This study aims to investigate pharmacists' trust in automated pill verification technology designed to support medication dispensing.

Methods: Thirty licensed pharmacists in the United States performed a web-based simulated pill verification task to determine whether an image of a filled medication bottle matched a known reference image. Participants completed a block of 100 verification trials without any help, and another block of 100 trials with the help of an imperfect artificial intelligence (AI) aid recommending acceptance or rejection of a filled medication bottle. The experiment used a mixed subjects design. The between-subjects factor was the AI aid type, with or without an AI uncertainty plot. The within-subjects factor was the four potential verification outcomes: (1) the AI rejects the incorrect drug, (2) the AI rejects the correct drug, (3) the AI approves the incorrect drug, and (4) the AI approves the correct drug. Participants' trust in the AI system was measured. Mixed model (generalized linear models) tests were conducted with 2-tailed *t* tests to compare the means between the 2 AI aid types for each verification outcome.

Results: Participants had an average trust propensity score of 72 (SD 18.08) out of 100, indicating a positive attitude toward trusting automated technologies. The introduction of an uncertainty plot to the AI aid significantly enhanced pharmacists' end trust (t_{28}=–1.854; P=.04). Trust dynamics were influenced by AI aid type and verification outcome. Specifically, pharmacists using the AI aid with the uncertainty plot had a significantly larger trust increment when the AI approved the correct drug ($t_{78.98}$=3.93; P<.001) and a significantly larger trust decrement when the AI approved the incorrect drug ($t_{2939.72}$=–4.78; P<.001). Intriguingly, the absence of the uncertainty plot led to an increase in trust when the AI correctly rejected an incorrect drug, whereas the presence of the plot resulted in a decrease in trust under the same circumstances ($t_{509.77}$=–3.96; P<.001). A pronounced "negativity bias" was observed, where the degree of trust reduction when the AI made an error exceeded the trust gain when the AI made a correct decision (z=–11.30; P<.001).

Conclusions: To the best of our knowledge, this study is the first attempt to examine pharmacists' trust in automated pill verification technology. Our findings reveal that pharmacists have a favorable disposition toward trusting automation. Moreover, providing uncertainty information about the AI's recommendation significantly boosts pharmacists' trust in AI aid, highlighting the importance of developing transparent AI systems within health care.

Introduction

Background

Pharmacists play a pivotal role in ensuring patients receive the correct medications as prescribed by health care providers. This involves a critical verification task, where pharmacists must match the medication dispensed in filled bottles with the prescription labels. Dispensing errors, defined as instances when patients receive the wrong drug or dosage, significantly contribute to preventable adverse drug events, leading to approximately 700,000 emergency department visits and 100,000 hospital admissions each year [1]. Several challenges contribute to these errors including, but not limited to, limitations in current technology; lack of standardized procedures; and the high cognitive workload imposed on pharmacy staff, who often manage numerous tasks simultaneously [1-4]. To enhance patient health outcomes, reduce unnecessary health care costs, and alleviate the burden on pharmacists, it is essential to develop and implement reliable tools that minimize the risk of dispensing errors [5].

Since the 1990s, the implementation of barcode scanning systems has been advocated as a means to reduce medication errors [6]. The adoption of such systems within pharmacies and broader health care environments has led to a notable reduction in medication errors [7-10]. Nevertheless, research indicates that barcode scanning systems are not immune to workarounds and human errors [11-13]. Moreover, these systems do not adequately address the challenges faced by overburdened pharmacists [14-17].

In response to these challenges, pill counting and verification or recognition systems using image classification technologies have emerged [18-21]. Innovations like Eyecon and VIVID use vision-based methods to count medications placed on the tray. More recently, advancements have been made in automated pill identification through feature engineering. For example, Yu et al [22] and Yu et al [23] proposed an automatic pill recognition method based on pill imprints, achieving an accuracy of 86.01% and 90.46%, respectively. Caban et al [18] used a modified shape distribution technique to determine the shape, color, and imprint of a pill to identify the drug. The proposed technique was evaluated with 568 of the most prescribed drugs in the United States and achieved a 91.13% accuracy.

The advent of deep learning has further enhanced the capabilities of automated pill recognition systems [5,24]. For instance, Larios Delgado et al [5] developed a pill recognition method using 2 deep learning models. They used a deep convolutional neural network model for pill blob detection to isolate the pill from the background and then passed the output to a deep learning–based classifier to identify the 5 most likely pills with 94% accuracy [5]. Similarly, Wong et al [25] proposed a deep convolutional network model and achieved a mean accuracy of 95.35%. Lester et al [24] trained a ResNet-18 deep learning model to predict the labeled features of a medication product using an image showing medication inside a filled prescription bottle. In a test set containing 65,274 images of 345 unique oral drug products, the overall macroaverage precision, that is, the mean of precision values for each class, was 98.5%.

Despite the impressive strides in model accuracy, realizing the potential of these technologies is only possible if people establish appropriate trust in them. Trust in automation, defined as "the attitude that an agent will help achieve an individual's goals in situations characterized by uncertainty and vulnerability" [26], is one of the most crucial factors determining the use of automation [27,28]. There is a growing body of research examining people's trust in autonomous and robotic technologies in various domains, including transportation [29-31], health care [32,33], education [34], and defense [35,36]. In addition, researchers have developed various methods to enhance people's (proper) trust in automation or autonomy [37,38], including the use of various graphical representations [37,39-42].

For example, a military perimeter defense experiment conducted by Mercado et al [43] aimed to investigate the role of intelligent agent transparency on operator trust. Participants were tasked with selecting optimal routes for unmanned vehicles, assisted by an artificial intelligence (AI) agent. The AI agent operated at three levels of transparency: (1) basic details only; (2) basic details supplemented with reasoning and rationale; and (3) comprehensive information, including basic details, reasoning, rationale, and uncertainty indication, in a text description. They observed a positive correlation between transparency levels and participant trust. They concluded that providing operators with the agent's reasoning process and uncertainty metrics fostered a deeper understanding of the system's capabilities, thereby enhancing trust and increasing usability [43]. This finding emphasizes the importance of transparent AI systems in supporting effective human-machine collaboration.

Another study investigated the impact of visual explanations on human trust in machine learning systems [40]. Participants performed leaf classifying tasks with or without visual explanations. The leaf examples were presented in 2 formats: images and feature charts. Results revealed that providing visual explanations enhanced trust and confidence in participants' decision-making. Interestingly, the feature charts were designed with intentional omissions of detailed explanations of features to prevent information overload. However, this simplification led participants to struggle to interpret the charts, and expert users expressed a need for more comprehensive feature descriptions to inform their decisions [40]. This insight reveals the importance of integrating visual explanations with a thoughtfully managed information load for appropriate human trust.

Signal detection theory (SDT) is commonly used to study trust in automation by modeling the reliability of automated systems used by human operators. SDT evaluates how AI systems distinguish signals from noise, categorizing the state of the world as either "signal present" or "signal absent." Based on SDT categorization, AI performance results in 4 outcomes: hit (error flagged correctly), miss (error not flagged), false alarm (FA; no error, but flagged incorrectly), and correct rejection (CR; no error and no flag). Correct identifications (hit and CR) increase trust, while incorrect ones (FA and miss) decrease trust [44,45]. Research indicates that FAs typically reduce trust less than misses, prompting designers to design more liberal systems (ie, more willing to flag an error) with higher rates of FAs to ensure potential issues are flagged [46-48]. In the context of pill dispensing, FAs may lead to minor disruptions, while misses could lead to dispensing errors, indicating that a more liberal AI system prioritizing safety by minimizing misses is beneficial.

Objectives

This study, therefore, aimed to explore pharmacists' trust in automated pill verification technology, which is designed to assist with the critical task of medication dispensing. Specifically, we aimed to study the role of presenting AI uncertainty information on pharmacists' trust in the system. The primary hypothesis was as follows:

- H1: Presenting AI uncertainty information of predicted probability in a visualization format will increase AI transparency, leading to enhanced pharmacists' trust in pill verification technology.

Beyond this primary focus, we also explored how pharmacists' trust behavior varied across different AI performance patterns categorized by SDT. Drawing from these arguments, we derived the following hypotheses:

- H2: Misses would result in a more significant decline in trust compared to FAs.
- H3: Furthermore, given the differing consequences associated with the 4 SDT patterns, we speculate that presenting AI uncertainty information might have varying effects depending on the specific type of patterns.

Methods

Ethical Considerations

This research was exempt from institutional review board oversight by the University of Michigan (HUM#00213493). Before participating, participants signed an electronic informed consent form, and all data were collected anonymously. Participants received US $150 upon completion of the study.

Recruitment and Participants

Recruitment emails were dispatched to pharmacists through the Minnesota Pharmacy Practice-Based Research Network and the University of Michigan College of Pharmacy Pharmacist Preceptor Network. To meet the inclusion criteria, pharmacists were required to (1) be licensed pharmacists in the United States, (2) be aged at least 18 years, and (3) have access to a laptop or desktop computer with a webcam. Pharmacists who (1) require assistive technology to use the computer; (2) wear eyeglasses with more than one power; (3) have uncorrected cataracts, intraocular implants, glaucoma, or permanently dilated pupils; and (4) have eye movement or alignment abnormalities (eg, lazy eye, strabismus, nystagmus) were excluded from participation in the study (Figure 1). A total number of 30 licensed pharmacists in the United States completed the study. Table 1 shows the demographic information.

Figure 1. Participant recruitment timeline.

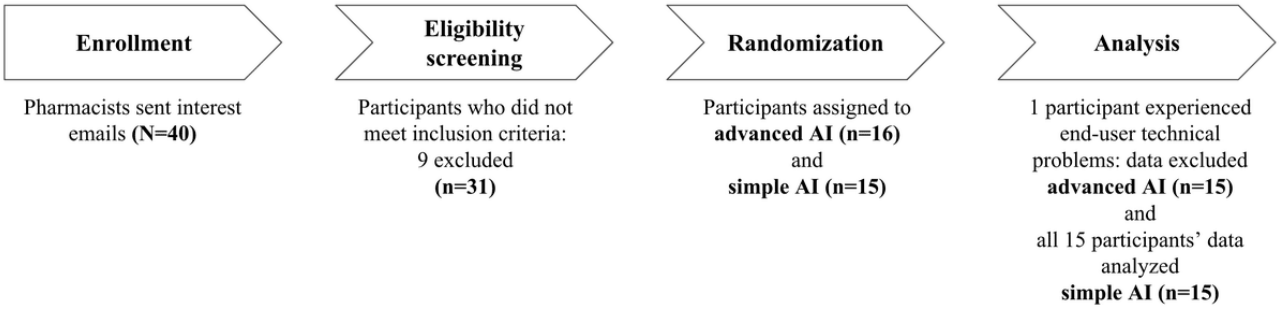

Table 1. Participant demographic information (n=30).

Characteristic	Value
Age (years), mean (SD)	39.40 (11.23)
Sex, n (%)	
Female	17 (57)
Male	13 (43)
Practice setting, n (%)	
Community pharmacy	15 (50)
Hospital pharmacy	6 (20)
Specialty pharmacy	1 (3)
Grocery store or mass merchandise pharmacy	1 (3)
Other	7 (23)
Years worked, n (%)	
1-5	7 (23)
6-10	7 (23)
11-20	10 (33)
21 or more	6 (20)

AI Model

The AI model used in this study is a Bayesian neural network that predicts the National Drug Code (NDC), a unique identifier assigned by the Food and Drug Administration to catalog drug products in the United States [49,50]. The Bayesian neural network used a technique known as random dropout [51], applied to a ResNet-34 convolutional neural network architecture [52] to estimate the probability associated with each NDC (ie, each class). The model produced 50 different predictions, where each prediction is a probability vector that quantifies the probabilities that an input belongs to each of the NDCs. The predicted NDC was then attained by finding the highest average probability derived from the 50 predictions.

To train the AI model, we acquired a dataset of 432,974 images from a mail-order pharmacy in the United States. This pharmacy uses a robotic system that counts pills, fills and labels the bottle, captures the images of the contents, and seals the bottle with a cap. The image dataset consists of 1 year's worth of robot-captured images of oral medications, such as tablets and capsules, inside prescription bottles filled by the robotic system. Each image in the dataset is associated with an NDC label and various attributes of color, shape, size, manufacturer, tablet scoring, and imprint. The number of images available for each NDC varied, ranging from 3 to 12,105, with a median of 540 (IQR 257-1291). The medications featured in these datasets were classified into 12 different colors and 7 distinct shapes. The detailed classification is shown in Table 2.

Table 2. Percentage of medication characteristics featured in the training dataset (N=260,119).

Experimental Testbed and Stimuli

In the experiment, participants performed a pill verification task with the help of an imperfect AI aid that recommends whether to accept or reject a filled medication. The participant's task was to verify whether the filled medication matched the reference image. If the reference image and filled medication did not match, the correct action was to click "reject." If the reference image and filled medication matched, the correct action was to click "accept."

The user interface was designed following pharmacists' feedback from a focus group study conducted by the research team [50]. The interface displayed an image of a filled medication, a reference image, prescription information, and AI aids. There were 2 types of AI aids powered by the same AI model: one aid augmented with an uncertainty plot indicating the degree of certainty (or uncertainty) of the AI recommendation, and the other aid without this feature. Both AI aids recommend the action the pharmacist should take, using 4 checkboxes. A recommendation to accept was indicated when all four checkboxes turned green (Figure 2); otherwise, the recommendation was to reject. For the AI aid with the uncertainty plot, an additional histogram was integrated (Figure 3). The histogram displayed the distribution of the 50 probabilities for the predicted NDC, generated by the 50 predictions. The purpose of the histogram was to provide a visual representation of the certainty or uncertainty level associated with the AI's NDC prediction.

With the help of an AI aid, participants performed a block of 100 pill verification trials. The experimental stimuli for the 100 trials, including the reference NDC and the filled medication, were carefully selected from the dataset of 432,974 images. The selection process ensured a broad representation of colors and shapes (Table 3), while blurry images were excluded to maintain clarity. To minimize learning effects, each reference NDC was intentionally shown no more than twice throughout the experiment.

Figure 2. Interface for the AI aid without the uncertainty plot. Checkboxes indicate AI's recommendation. When all 4 checkboxes are green, the AI advises to accept; otherwise, it advises to reject. AI: artificial intelligence; NDC: National Drug Code.

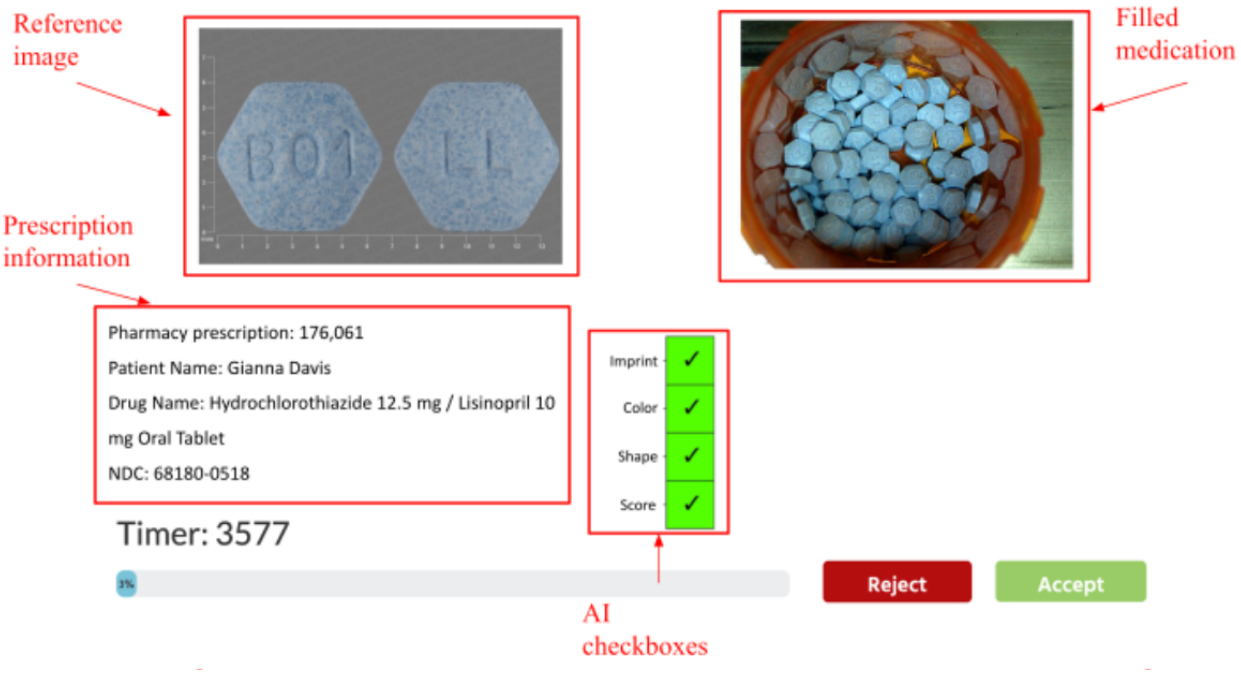

Figure 3. Interface for the AI aid with the uncertainty plot. In addition to Figure 2, the histogram shows the distribution of the 50 predicted probabilities associated with the predicted NDC. AI: artificial intelligence; NDC: National Drug Code.

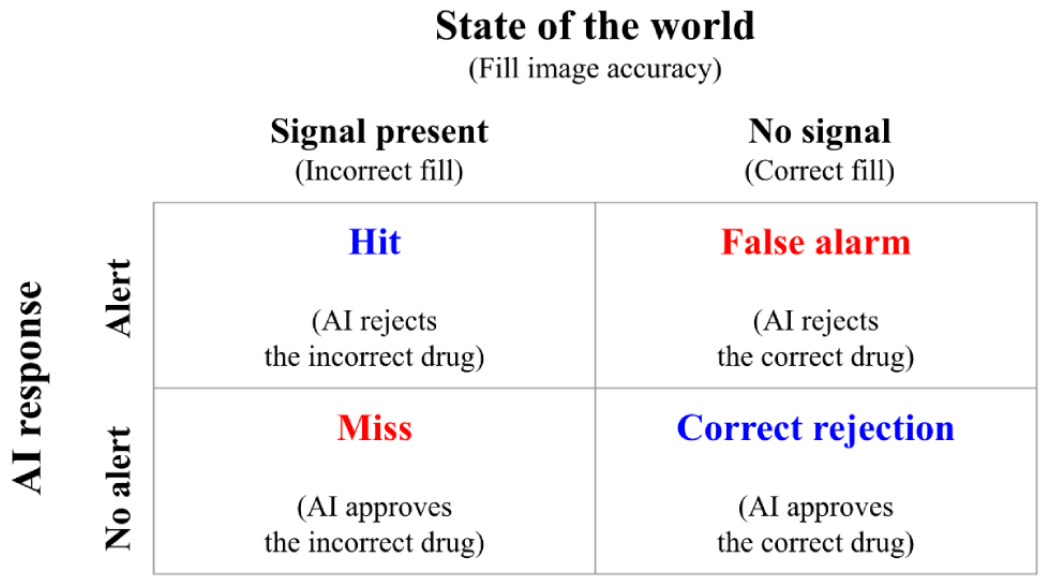
Furthermore, the AI aid was not perfect for the 100 trials, that is, it occasionally offered incorrect recommendations. Based on SDT, we mapped out the relationship between the AI's recommendation and the true state of the world [53]. In the context of this experiment, a signal in the world was an incorrectly filled medication. The extent to which the AI recommended rejecting an incorrectly filled medication reflects its ability to detect the signal. The combination of the state of the world and the AI's recommendation resulted in four potential outcomes: (1) the AI rejects the incorrect drug (hit), (2) the AI approves the incorrect drug (miss), (3) the AI rejects the correct drug (FAs), and (4) the AI approves the correct drug (CRs), as shown in Figure 4.

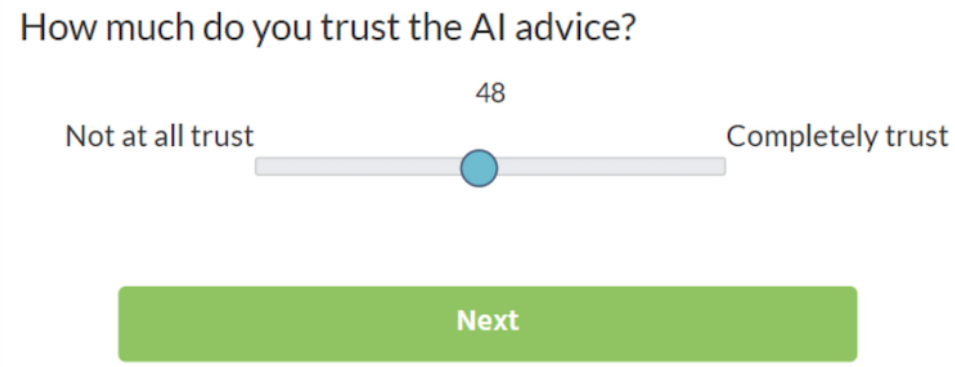
Figure 4. Four potential AI performance patterns according to signal detection theory. AI: artificial intelligence.



Benchmarking prior literature [54], the base rate was set to be 24%, that is, 24% of the trials contained wrongly filled medication. The AI accuracy was set as 82% to ensure that the AI would be perceived as useful while providing sufficient misses and false alarms [55]. By combining the filled image accuracy and AI accuracy, there were 60 cases of the AI approving the correct drug, 22 cases of the AI rejecting the incorrect drug, 2 cases of the AI approving the incorrect drug, and 16 cases of the AI rejecting the correct drug.

After each trial, participants received performance feedback indicating the correctness of their decision to accept or reject, as well as whether the prescription bottle was correctly or incorrectly filled (ie, "Your decision was correct. The medication was correctly filled"). Following this step, participants reported their trust in the recognition AI on a visual analog scale, with the leftmost point labeled "Not at all trust" and the rightmost point labeled "Completely trust" (Figure 5) [44,56,57].

Figure 5. Participants reported their trust in the recognition AI on a visual analog scale. AI: artificial intelligence.



Experimental Design

The experiment used a mixed subjects design. The between-subjects factor was the type of AI aid, distinguished by the presence or absence of an uncertainty plot. The within-subjects factor was the four potential outcomes: (1) the AI rejects the incorrect drug, (2) the AI rejects the correct drug, (3) the AI approves the incorrect drug, and (4) the AI approves the correct drug (Figure 4).

Half of the participants used the AI aid without the uncertainty plot, and the other half used the AI aid with the uncertainty plot. Each participant completed 2 blocks of 100 trials each. One block involved using the AI aid (either with or without the uncertainty plot), and the other block required participants to perform the task manually. The order of the 2 blocks was counterbalanced. Additionally, benchmarking prior literature [45], the trial sequence was fixed for the 100 trials in each block.

As this study is focused on the pharmacists' trust in AI, data from the manual task block were excluded from the analysis, concentrating the study's findings on interactions involving the AI aid.

Measures

Trust propensity

Before the experiment, we measured participants' trust propensity using the 6-item survey used by Merritt et al [58]. Trust propensity is "a stable, trait-like tendency to trust or not trust others" [59], and the propensity to trust machines reflects a person's tendency to trust machines in general rather than in a particular machine.

End Trust

End trust, *Trust*(*100*), is the participant's final trust rating after interacting with the AI help scenario.

Average Trust

Average trust denotes the mean of moment-to-moment trust ratings collected throughout the experiment.

Trust Change

After each trial *i*, participants reported their *Trust*(*i*) in the AI. We calculated a trust change as follows.

$$\text{Trust change } (i) = \text{Trust}(i) - \text{Trust}(i-1), \text{ where } i=2, 3, \ldots, 100.$$

Since the moment-to-moment trust was reported after each trial, 99 trust changes were obtained from each participant.

Experimental Procedure

The experiment was conducted remotely with interested participants who met the inclusion criteria. Each interested individual was phone screened to determine their eligibility. Before each experiment, participants had a brief web-based meeting with a member of the study team to ensure that the physical environment, including lighting conditions, was suitable for the experiment. Subsequently, the pharmacists were directed to Labvanced's website on their computer and presented with a 15-minute video tutorial that explained how to perform a simulated medication verification task using the testbed interface. Pharmacists were informed that the objective of the task was to determine whether an image of a filled medication

bottle matched a known reference image. The tutorial also explained the 2 AI aids.

Before engaging in the verification task, participants were directed to complete a demographics survey and a trust propensity survey [58]. Additionally, they went through a set of calibration procedures for the eye-tracking software. Participants then completed a block of 100 verification trials using an AI aid—either with or without the uncertainty plot—and another block of 100 verification trials manually, conducted in a counterbalanced order. Upon completion of the 200 trials, participants filled out a postexperimental survey and answered nonmandatory free-response feedback questions. All participants finished each block within the time limit of 60 minutes.

After completing all the tasks and surveys described earlier, participants were invited to a 30-minute debriefing session with one of the study team members. Study team members described 6 concepts of automation evaluation: observability, predictability, directing attention, exploring solution space, adaptability, and calibrated trust [60], and provided an example scenario for each concept. After each description and example, the participants were asked to provide their thoughts on how the concept relates to our system.

Statistical Analysis

Participants' trust propensity, end trust, and trust change when using both types of AI aids were analyzed. First, we conducted a descriptive analysis of the participants' trust propensity. Then, to test our directional hypothesis that AI aids with uncertainty will result in higher end and average trust, we conducted a 1-tailed *t* test. Finally, we analyzed how trust increased and decreased after participants experienced each of the 4 AI performance patterns using mixed-linear models with random intercept. Regression 2-tailed *t* tests were conducted to compare the means between the 2 AI aids for each AI performance pattern. The Kenward-Roger method was used to estimate degrees of freedom. Mixed model (generalized linear models) tests were conducted using the R (version 4.2.2; R Foundation for Statistical Computing) *lme4* package [61]. All statistical significance was determined at the α=.05 level and analyses were carried out using R statistical software [62].

Results

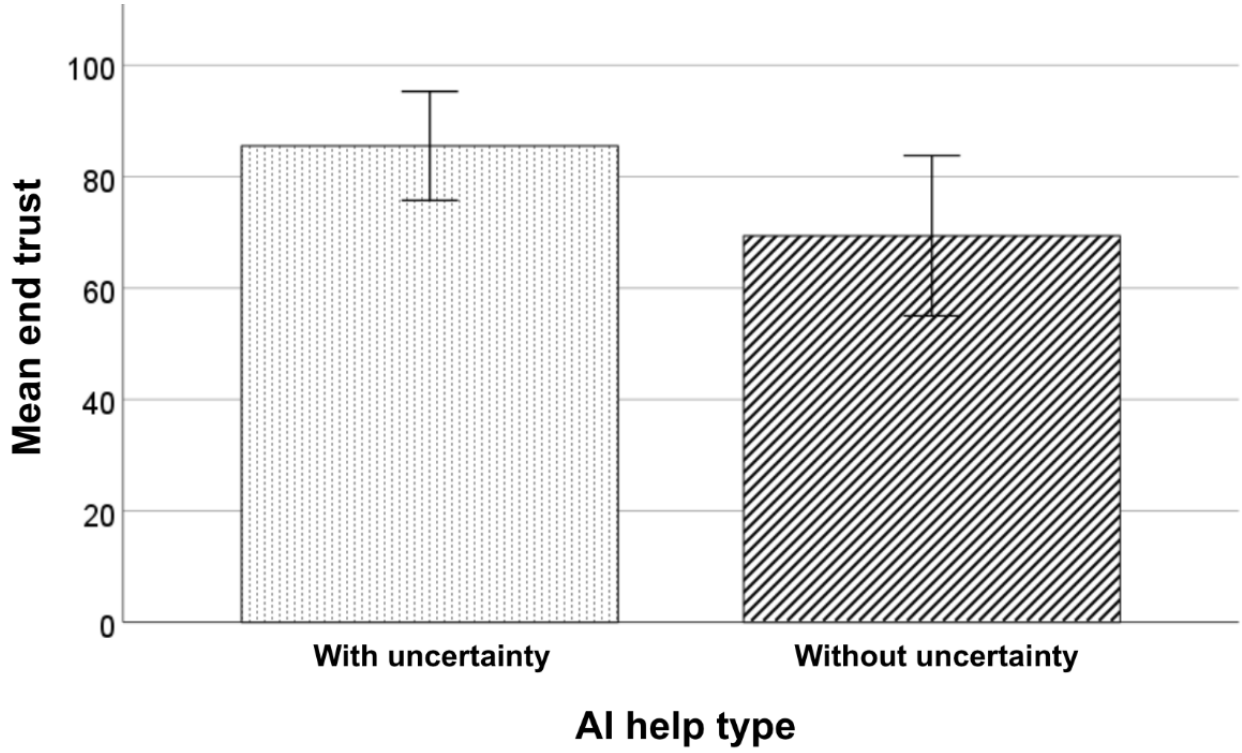
Trust Propensity

Participants had an average trust propensity score of 72 (SD 18.08) out of 100, indicating the participants generally had a positive attitude toward trusting automated technologies. There was no significant difference between the 2 AI aids (t_{28}=–0.854; *P*=.20; Cohen *d*=.312).

End Trust Toward AI Aid

The 1-tailed *t* test indicated that participants trusted the AI aid with the uncertainty plot significantly more than the AI aid without the plot at the end of the experiment (t_{28}=–1.854; *P*=.04; Cohen *d*=–.677; Figure 6).

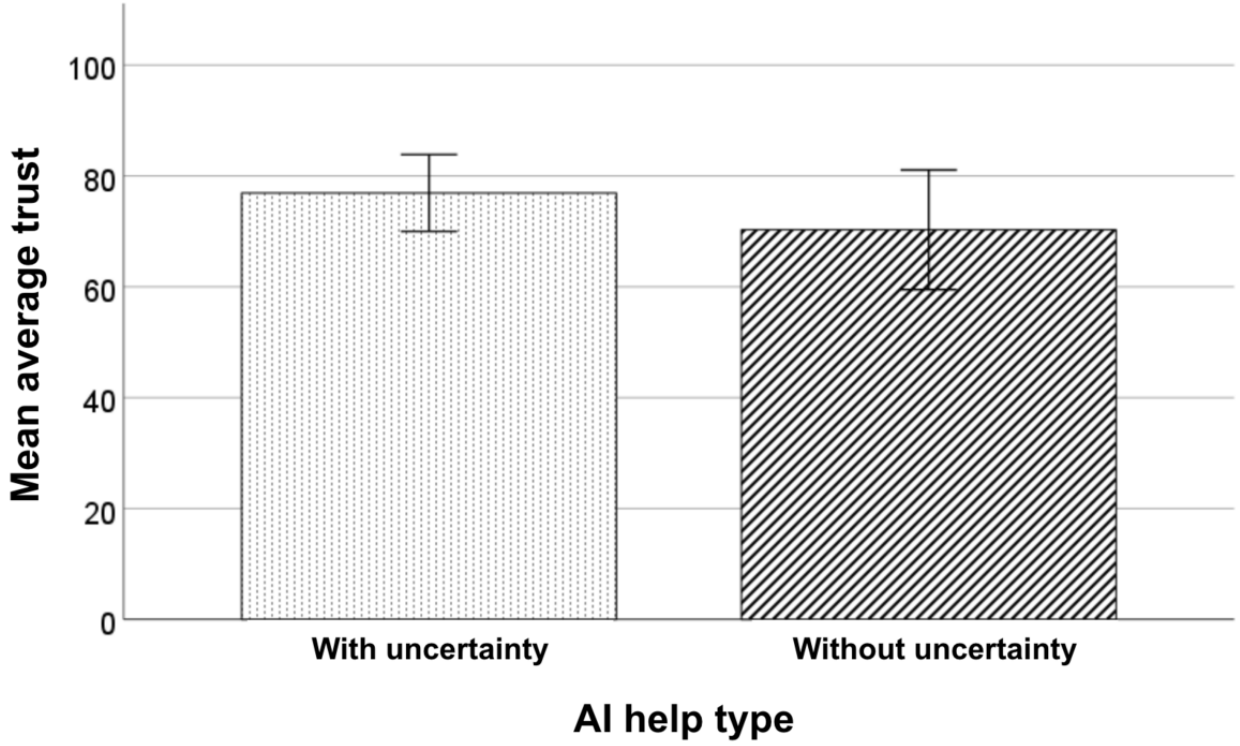
Figure 6. Mean end trust by AI aid help type (with or without the uncertainty plot). The error bars represent a 95% CI. AI: artificial intelligence.



Average Trust Toward AI Aid

Participants showed a slightly higher average trust in the AI aid in the with-uncertainty condition (mean 76.92, SD 13.42) than in the without-uncertainty condition (mean 70.29, SD 20.88; Figure 7). However, the difference did not reach statistical significance (t_{28}=–1.036; *P*=.16; Cohen *d*=–.378).

Figure 7. Mean average trust by AI aid help type (with or without the uncertainty plot). The error bars represent a 95% CI. AI: artificial intelligence.



Trust Change

Figure 8 shows the trust change after participants experienced the 4 AI performance patterns. When the AI approved the correct drug, there was a significantly greater trust increment when participants used the AI aid with the uncertainty plot compared to the one without ($t_{78.98}$=3.93; *P*<.001; Cohen *d*=.214); When the AI approved the incorrect drug, there was a significantly greater trust decrement using the AI aid with the uncertainty plot ($t_{2939.72}$=–4.78; *P*<.001; Cohen *d*=.712). Interestingly, when the AI rejected the incorrect drug, we observed a decrement of trust for participants using the AI aid with the uncertainty plot ($t_{509.77}$=–3.96; *P*<.001; Cohen *d*=.312). When the AI rejected the correct drug, both AI help types showed a decrease in trust and there was no statistical difference between them ($t_{856.57}$=–0.68; *P*=.49; Cohen *d*=.045). Overall, participants using the AI aid with the uncertainty plot displayed a large magnitude of trust adjustment. In addition, we observed a significant "negativity bias" in that the magnitude of trust change when the AI made an error (ie, the AI approves the incorrect drug or the AI rejects the correct drug) was significantly larger than the magnitude of trust adjustment when the AI provided correct recommendations (generalized linear model test; *z*=–11.30; *P*<.001).

To examine variation in pharmacists' trust behavior across different AI performance patterns categorized by SDT, we initially combined the data from both the with and without uncertainty help scenarios. Trust decreased significantly more when the AI approved the incorrect drug compared to when the AI rejected the correct drug (t_{509}=–4.687; *P*<.001; Cohen *d*=.475). This trend was observed in the with-uncertainty AI help scenario (t_{254}=–4.91; *P*<.001; Cohen *d*=.758). However, in the without-uncertainty AI help scenario, although there was a greater trust decrease in trust when the AI approved the incorrect drug than when the AI rejected the correct drug, the difference was not statistically significant (t_{254}=–1.14; *P*=.255; Cohen *d*=.014).

As we measured participants' trust toward AI continuously, we calculated the autocorrelation between the trust ratings. Autocorrelation measures the relationship between a variable's current value and its past values in a time series. Figure 9 shows the mean autocorrelation as a function of time separation between the ratings. For both AI aids, the correlation decreased as the time separation increased. The AI aid with the uncertainty plot had a lower mean autocorrelation compared to the aid without the uncertainty plot (Figure 9).

Figure 8. Trust change for different AI performance patterns. Red shades represent negative trust change, and blue shades represent positive trust change.

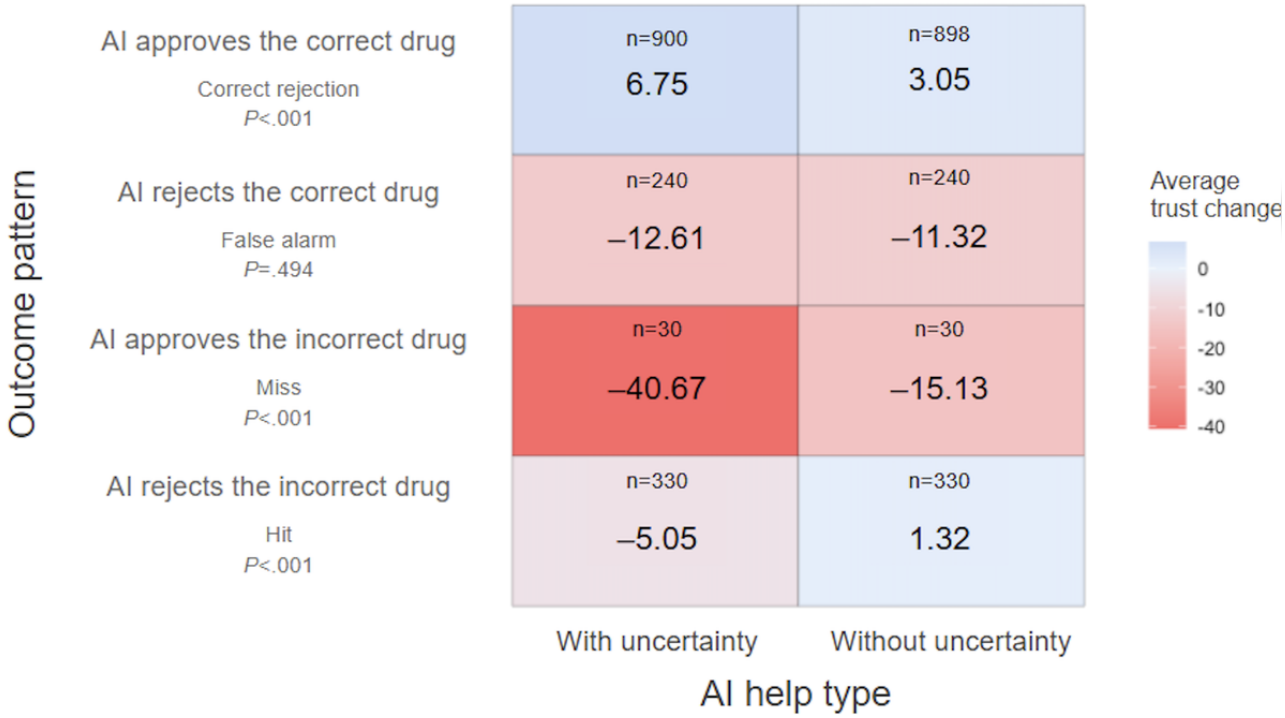


Figure 9. Autocorrelation of trust as a function of time separation. The blue solid line represents AI aid with the uncertainty plot, and the red dashed line represents the AI aid without the uncertainty plot. The error bars represent 2 SEs. AI: artificial intelligence.

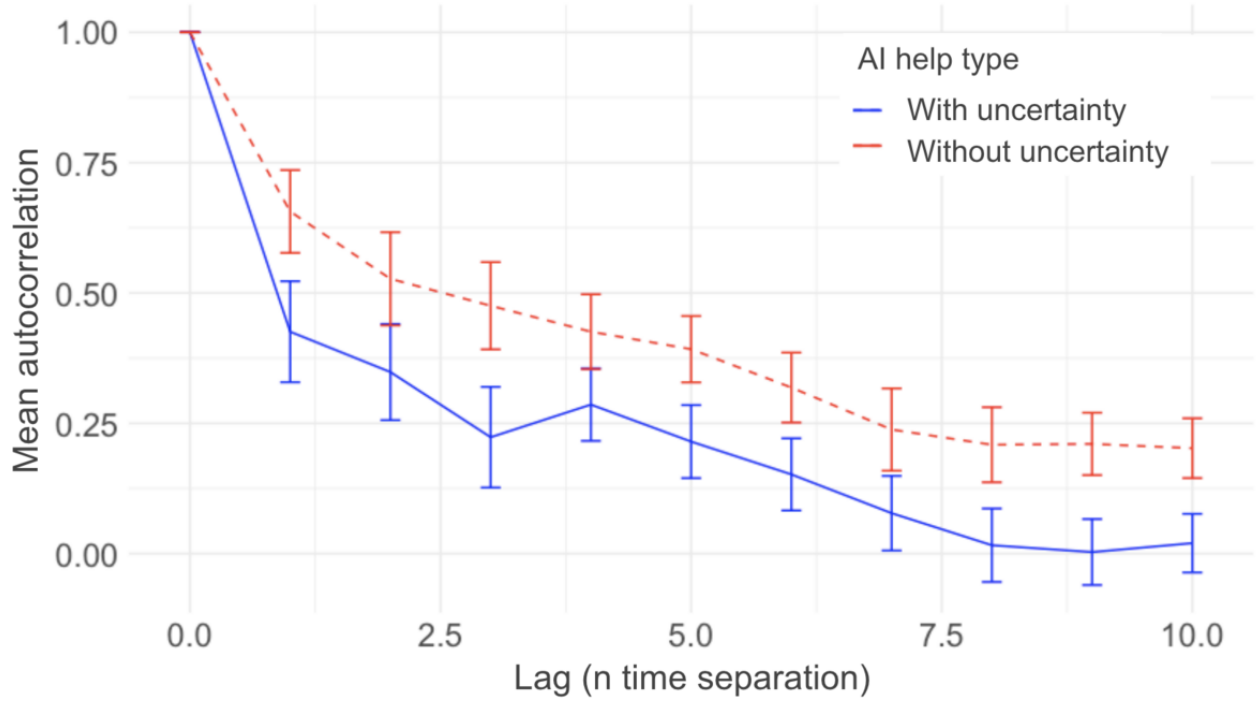


Discussion

Principal Findings

This study aimed to investigate pharmacists' trust in automated pill verification technology and how the presentation of AI uncertainty information would influence them. Overall, the findings revealed that pharmacists have a favorable disposition toward trusting automation, and including the AI's uncertainty information increases pharmacists' trust in the AI recommendation *(*Figure 6*)*.

Comparison With Prior Work

The propensity to trust automation refers to an individual's general inclination to trust automated or autonomous systems, shaped by their past experiences and future expectations [58,59]. Research has shown that levels of trust propensity vary among

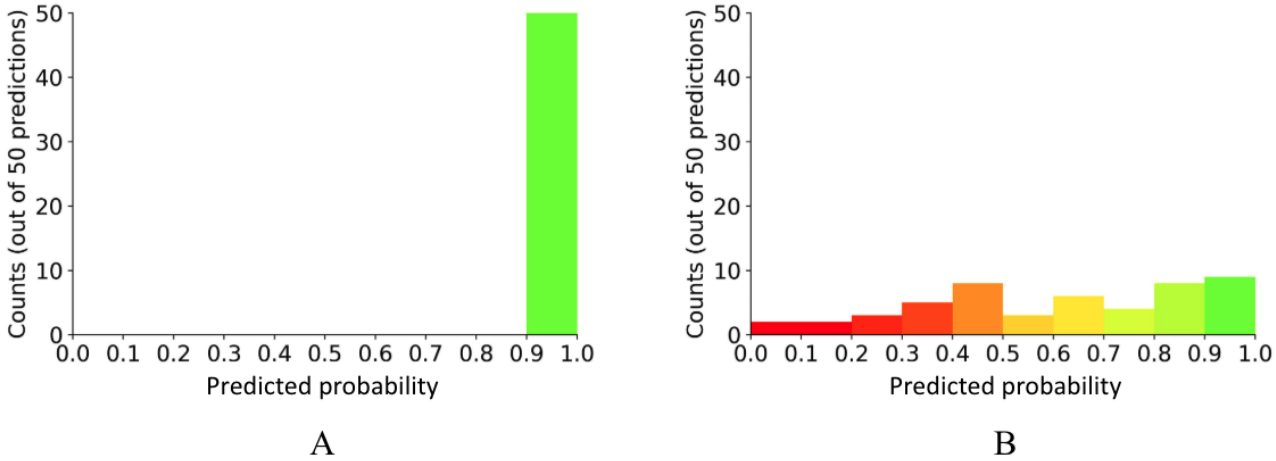
individuals. For example, an early study by Merritt et al [58], which included 69 college students (average age of 25 years), found an average trust propensity of 3.56 (SD 0.6) on a 7-point Likert scale [59]. More recently, Montag et al [63] surveyed 289 participants aged between 18 and 70 years and reported their propensity to trust automation to be 4.98 (SD 1.06) after converting to a 7-point Likert scale. Similarly, Miller et al [64] reported a trust propensity score of 4.97 (SD 1.21) from a smaller cohort of 28 participants aged between 18 to 60 years. Another investigation by Yang et al [65] with 75 adults (mean age 23.0) split into 3 groups reported trust propensity scores of 72.6 (SD 14.8), 69.4 (SD 10.4), and 69.4 (SD 14.4), equivalent to average scores of 5.08 (SD 1.89), 4.86 (SD 1.62) and 4.86 (SD 1.86) on a 7-point Likert scale.

In line with these findings [63-66], our study revealed that pharmacists generally have a favorable disposition toward trusting automation, with an average rating of 72 (SD 18.08) on a 100-point scale, or 5.03 (SD 2.09) on a 7-point Likert scale. This positive attitude may be attributed to the frequent use of automated technologies, such as barcode scanners and pill counters in their daily work [6,7]. Additionally, as expected, no significant difference was observed between the groups using different AI aids because the participants were randomly assigned to use either of the AI aids.

Examining pharmacists' end trust, our findings reveal that the AI aid with the uncertainty plot significantly enhanced the end trust scores. We attribute this enhancement to the increased transparency achieved through the presentation of a histogram showing the distribution of 50 predicted probabilities. While AI advancements promise to improve human performance, a prevailing issue is the perception of AI as a "black box." This lack of transparency contributes to a lack of trust in AI and can undermine team performance [66-68]. The higher end trust observed in participants using the AI aid with the uncertainty plot indicates that making the AI more transparent by revealing its decision-making process can foster a higher level of trust in automation. Participants 14 and 24 captured this sentiment well stating: "As soon as the uncertainty plot became red and yellow, I slowed down, which could be helpful because sometimes slowing down when there is uncertainty, just knowing there's uncertainty, is enough" (P14) and "if the uncertainty plot was all green bar and AI thought it was doing a 100% accurate job then it was easier to make my decision" (P24).

Regarding the dynamics of trust, that is, moment-to-moment trust change, when AI approved the correctly filled bottle, we noted trust increments for both AI aids. Furthermore, the inclusion of uncertainty information led to a larger increment in trust compared to when such information was absent. When the AI mistakenly approved the incorrect drug, we observed a significant trust decrement for both AI aids, potentially attributed to the adverse outcome associated with the wrong medication. Furthermore, the trust decrement was significantly larger when the uncertainty information was shown. This pronounced trust decrement could have resulted directly from the distribution of the histogram: participants were shown a histogram indicating a high level of certainty (Figure 10A). Therefore, participants may have perceived the error made by the AI aid as a "confident" error and therefore reduced their trust even more. Studies examining likelihood alarms reported that highly likely alarms (ie, "confident" alarms) engender a greater decline in momentary trust upon automation failures [57,69].

Figure 10. Uncertainty plots with (A) narrower and (B) wider IQRs. IQR is a measure of statistical dispersion, or how spread out the data points are.

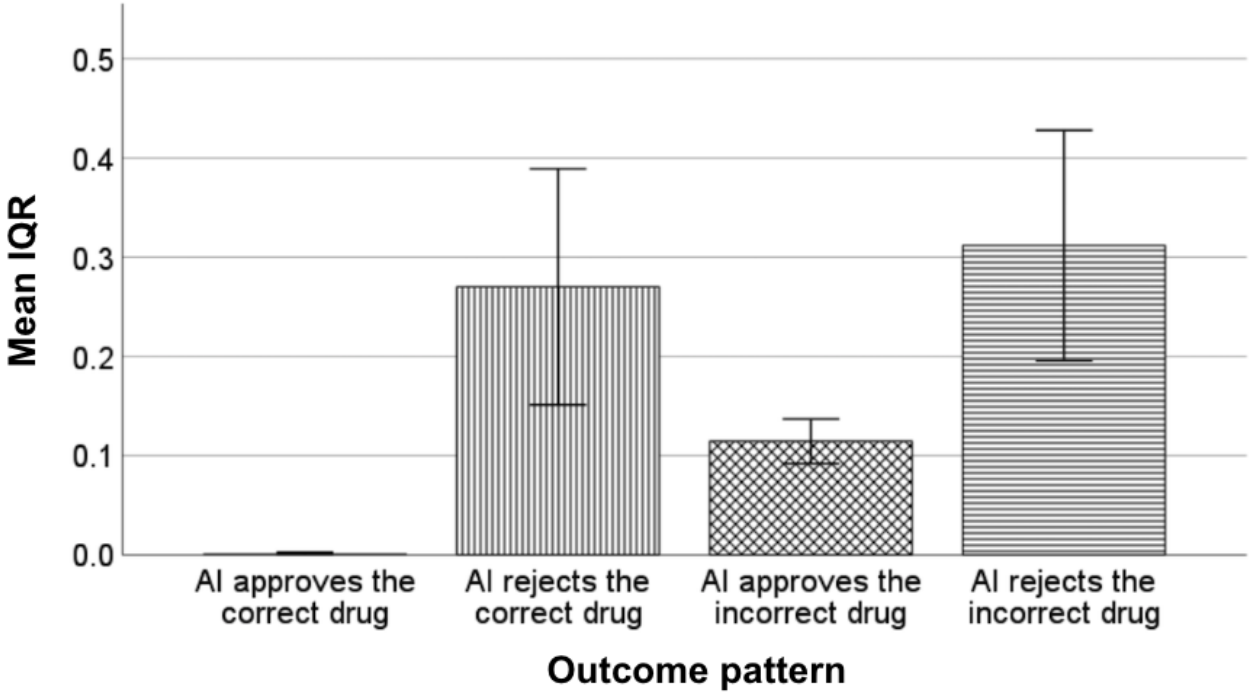


Our study also offers additional validation of prior findings regarding the SDT modeling of trust [47,48]. When the AI mistakenly approved the incorrect drug (miss), a greater trust decrease appeared compared to when the AI rejected the correctly filled bottle (FA). However, the difference was statistically significant only in the with-uncertainty AI help type. This finding may provide further evidence that "confident" AI errors lead to a greater trust decrement [57,69].

Intriguingly, when the AI rejected an incorrectly filled bottle, the absence of uncertainty information resulted in an increase in trust, whereas the presence of such information led to a decrease in trust. Such contrasting results could have stemmed from the uncertainty plots influencing the participants' decision-making process. When the AI approved the correct drug, all uncertainty plots presented to participants showed a consistent solid green bar (Figure 10A). However, when the AI rejected the incorrect drug, the IQR of the uncertainty plot was broader, indicating the lack of certainty (Figure 11). A total of 16 (73%) out of 22 uncertainty plots displayed a wider spread with mixed color bars (Figure 10B). This ambiguity might

unintentionally cause the human participants to doubt the capability of the AI aid with the uncertainty plot, resulting in a decrease in their trust, as evidenced by P18's statement: "When the checkboxes were not all green and the histogram had a bunch of colors (variability), I was even less trusting of the AI tool." This perspective is also supported by P25, who noted: "When the uncertainty plot had some red, it made me double check and decreased my confidence for sure."

Figure 11. Mean IQR by outcome pattern. The error bars represent a 95% CI. AI: artificial intelligence.



Finally, when AI rejected the correctly filled bottle, trust decrements occurred, with no significant differences between the 2 AI aids. If this circumstance happened in the real world, the pharmacists would reinspect the filled prescription. It will likely lead to an increased workload, fatigue, and stress, which could potentially lead to a lower quality of work and a higher frequency of errors [70,71]. However, P21 offered a contrasting viewpoint that more flagging would be better than AI approving the incorrect, highlighting: "I didn't lose as much trust when AI rejected the correct drug. I feel like AI should be there as a cautionary tool."

The observed trends in the moment-to-moment dynamics of trust indicate a greater degree of trust adjustment when participants were assisted by the AI with the uncertainty plot. This observation is further confirmed by the autocorrelation analysis. Specifically, the trust autocorrelation plot (Figure 9) reveals a lower autocorrelation between trust ratings when the uncertainty information was presented. This suggests that current trust levels were less influenced by past trust levels, implying more significant changes in trust from moment to moment. Pharmacists relied less on previous trials and more on the information presented in the present trial, highlighting the advantages of a more transparent display.

In addition, for both AI aids, participants displayed a larger trust decrement due to incorrect automation predictions. Even though these observations may seem alarming initially, they align with the prior literature addressing negativity bias. The study suggests that failure in automation typically has a more significant negative impact on trust than a positive impact from successful automation [56,65].

Limitations and Future Directions

We acknowledge several limitations of this study and propose directions for future research. First, as a pioneering investigation in this domain, we did not strictly control the interquartile range of the uncertainty plot (Figure 11). Future investigation should systematically examine the effects of presenting different distributions within the uncertainty plot on pharmacists' trust. Exploring similar variations in the IQR among different outcome patterns could provide a deeper understanding of how outcome patterns could impact trust while avoiding potential confounding factors.

Second, the uncertainty plot used in this study displayed the distribution of only 1 (2%) out of 50 probabilities for the predicted NDC. Future research should consider incorporating additional contextual information to enhance the interpretability of these distributions. A notable challenge identified was that users unfamiliar with statistical representation found the uncertainty plot difficult to understand. P11 suggested simplifying the uncertainty presentation because "it would be a little bit too much for some people not as comfortable with statistics or technology." Nonetheless, there is potential for pharmacists to become more comfortable with these plots with prolonged use and training, as evidenced by P30's remark: "I started skeptical because it's something I'm not familiar with, but as I got more examples of it, my trust built up quickly." Consequently, researchers should continue to develop alternative visualization techniques that provide a more comprehensive and intuitive representation of the AI's uncertainty, while maintaining a low complexity to accommodate users with varying degrees of statistical proficiency.

Third, this exploratory study was limited by a small sample size, which may have impacted the statistical power of the analyses on trust propensity, end trust, and average trust. This limitation likely contributed to the lack of significance observed in some results. However, despite being underpowered, our analysis still revealed a significant difference in end trust, indicating a large effect size. Regarding trust change, to maintain the AI's perceived usefulness while still providing enough examples of both misses and FAs, we incorporated only 2 trials of the AI approving the incorrect drug (miss) and 16 trials of the AI rejecting the correct drug (FA), setting the accuracy at 82%. The statistical power to detect significant differences may have been compromised by the small sample sizes. Future research should aim to include larger participant pools to enhance the generalizability and robustness of the findings.

Finally, this study only focused on pharmacists' trust and trust change and did not include the analysis of accuracy and reaction time. Even though focusing on trust alone is an accepted practice [53], a more comprehensive analysis linking performance with trust would likely reveal the relationship between performance and trust calibration.

Conclusions

Dispensing errors are significant contributors to adverse drug events, which lead to considerable health care expenses and harm to patients. Despite progress made in developing automated technologies to aid pill verification, pharmacists' trust in these systems has not been thoroughly investigated. Our research represents an initial exploration into pharmacists' trust in automated pill verification technology, marking a significant step in understanding the integration of such systems into health care settings.

Our findings reveal that pharmacists have a favorable disposition toward trusting automation, which can likely be attributed to their frequent use of automated technologies in their daily work. Moreover, providing uncertainty information about the AI's recommendation significantly boosts pharmacists' trust in the AI aid, highlighting the importance of transparency in AI development. The dynamics of trust vary depending on the AI's performance. Pharmacists using the AI aid with the uncertainty plot had a significantly larger trust increment when the AI approved the correct drug and a significantly larger trust decrement when the AI approved the incorrect drug. Intriguingly, the absence of the uncertainty plot led to an increase in trust when the AI correctly rejected an incorrect drug, whereas the presence of the plot resulted in a decrease in trust under the same circumstances. In addition, a pronounced "negativity bias" was observed, where the degree of trust reduction when the AI made an error exceeded the trust gain when the AI made a correct decision.

Abstract

Background: Due to the rising prevalence of Alzheimer disease and related dementias, easily deployable tools to quantify risk are needed. Smartphones and smartwatches enable unobtrusive and continuous monitoring, but there is limited information regarding the feasibility, adherence, and acceptability of digital data collection among racially diverse older adults.

Objective: This paper examined the feasibility, adherence, and acceptability of a 4-week combined smartwatch monitoring and ecological momentary assessment (EMA) study in a racially diverse sample of older adults.

Methods: A total of 44 older adults (aged ≥55 y) with either mild cognitive impairment or healthy cognition completed an informed consent comprehension quiz, baseline cognitive testing, training regarding digital data collection, and questionnaires. Participants were instructed to wear a Garmin Vivosmart 4 smartwatch for 23 h/d for 4 weeks, sync 2 smartphone apps (Garmin and Labfront) daily, and complete a daily EMA survey with automated prompts for surveys and charging. Training time, smartwatch adherence (eg, wear time), daily EMA survey response rate, and performance on the consent quiz were quantified. Associations between feasibility and adherence metrics and participant factors were evaluated. Self-reported usability of the apps and smartwatch was collected at study end.

Results: Consent comprehension quiz scores were high (mean 97.33%, SD 6.86% correct), and training sessions lasted on average 17.93 (SD 6.89) minutes. During the 4-week study, participants wore the smartwatch for an average of 21 h/d (SD 1.53) and showed an average response rate of 94% (SD 9.58%) to daily EMA surveys. In unadjusted bivariate analyses, age, race, and cognition were associated with feasibility and adherence measures, but only age and race remained significant in multivariate models. After accounting for all participant factors, older age was a significant predictor of longer training time, and Black race was a significant predictor of lower daily wear time. On the usability survey, all participants (45/45, 100%) indicated willingness to participate in future smartwatch studies, >80% (37/45) had a positive experience, and >90% (41/45) were satisfied with smartphone app syncing.

Conclusions: Smartwatch monitoring, requiring daily wear, smartphone syncing, and daily EMA survey completion, is highly feasible in older adults because adherence to daily wear and EMA surveys was high, as was general satisfaction on usability surveys. Although older participants may require more training on smartwatch and smartphone procedures and automated prompting during the study period, longitudinal monitoring with the Garmin Vivosmart 4 smartwatch and Labfront app is acceptable and feasible for collecting nearly continuous data in Black and White older adults, including those with mild cognitive impairment and those without.

cognitive impairment; smartwatch; longitudinal monitoring; ecological momentary assessment; aging

Introduction

Background

With the prevalence of Alzheimer disease (AD) and AD and related dementias (ADRD) increasing alongside the aging population and the availability of new treatments, there is a need to quantify risk and detect cognitive decline at the earliest stage [1]. It is estimated that only a small minority of older adults with mild cognitive decline are accurately identified early [2], missing an opportunity for early intervention. Missed or delayed diagnoses are even more common in Black and African American older adults, who are also at increased risk for AD/ADRD [3]. Personal digital devices such as smartwatches have been proposed as a potential tool for the early detection of AD/ADRD. Although recent data show that smartwatches have been increasingly adopted by older adults [4], the utility of personal digital tools for AD/ADRD monitoring is dependent upon consistent smartwatch use and syncing with associated software. This study examined the feasibility of and adherence to daily smartwatch wear and ecological momentary assessment (EMA) survey completion in a racially diverse sample of older adults enrolled in a 4-week study. We also investigated older adults' comprehension of study details that are relevant to informed consent. The participant characteristics associated with smartwatch adherence and the comprehension of consent were explored to optimize adherence and ethical research conduct in future studies.

Observable yet subtle cognitive, sensory, and motor changes precede and predict the clinical manifestations of AD/ADRD [1,5] and may be measured by sensors in commercially available smartwatches; for example, the Garmin smartwatch has been validated against conventional clinical measures of sleep [6], activity [7,8], and heart rate variability [7], which are associated with dementia risk [9-11]. The Garmin Vivosmart 4 smartwatch also has shown positive results in a 2-week feasibility study of stress in adults undergoing psychotherapy [12]. Thus, digital measures of stress, low heart rate variability, reduced physical activity, and sleep alterations have great potential as low-cost digital biomarkers for AD/ADRD that may be measured continuously, longitudinally, and passively, requiring relatively little effort.

EMA questionnaires delivered directly to participants via their personal digital devices enable high-frequency data collection in the participants' natural setting. EMA can be useful for contextualizing passive metrics [13]; for example, EMA data may facilitate the interpretation of atypical data as clinically significant or not (eg, elevated heart rate due to a cardiac event vs a day at an amusement park). EMA data also provide insight into participants' immediate perceptions and mood states without the confounds of recall bias [14]. There is potential for passive and EMA data collection via personal digital devices, but limited data exist on the feasibility and adherence of device use for health monitoring in older adults. In addition, the extent to which cognitive ability level influences adherence is not known. Adherence to daily EMA surveys and key tasks, such as wearing, charging, and syncing digital devices, is crucial for valid and reliable measurement and requires cognitive resources. This raises an important question: are those who could benefit the most from digital health monitoring more likely to show poor adherence?

Our review of the literature identified few studies on the feasibility and adherence of smartwatch use in digital health research. The results of the available studies suggest several important moderating factors, including the study procedures and participant factors. In-person studies and study designs that include interaction with a member of the study team show much higher retention and adherence than fully remote studies [15]. Adherence also varies depending on task demands, with different adherence rates for smartwatch wear versus syncing versus EMA completion. Adherence to wearable device use, which is relatively less demanding, versus the completion of daily EMA surveys has been estimated to be approximately >90% and 70%, respectively, in studies that are not fully remote [16-19].

Participant factors also play a role in retention and adherence. Although age is commonly considered a barrier to the adoption and acceptability of smartwatches due to low digital literacy [20], empirical data aggregated across several studies of smartwatch data show that older age was associated with greater retention [15]. A study requiring older adults with healthy cognition to wear a Fitbit device for 30 days during waking hours reported high rates of adherence to daily wear (89% of study days) and syncing (85% of study days) [21]. Other studies have demonstrated the effects of race, sex, and memory ability on adherence such that White participants [15], women [22], and people with better memory abilities [21] are more adherent when asked to engage in digital health research studies that involve interacting with a smartphone app.

In addition to the importance of learning about smartwatch adherence and feasibility, it is also crucial to understand older adults' comprehension of informed consent procedures for studies using novel technology. With the large amount of health data collected from a smartwatch and the need for long-term data storage, it is vital for older adult participants to fully understand data privacy and security limitations and the associated risks of study participation. Older adults also may be more wary of sharing personal health information in the context of digital health research. To assess older participants' understanding of informed consent procedures, interactive quizzes have been developed for use in fully remote studies [23]. For this study, which included face-to-face interactions with members of the study team, a 10-item comprehension quiz was modeled after a quiz used by Hackett et al [13] that was designed according to published guidelines [24,25]. The consent quiz focused on the novel technology used in the study (eg, where participants' data are stored and the right to request digital data to be deleted at any time). Hackett et al [13] reported high accuracy rates on a similar quiz in a sample of older adults and significant associations between quiz scores and education level.

Quiz scores also varied by race, with Black participants scoring lower than White participants.

Objectives

In this study, feasibility and adherence were evaluated over a 4-week monitoring period that required wearing the smartwatch daily (23 h/d), charging it, syncing apps, and completing EMA surveys. Feasibility and adherence were assessed by tracking participant retention and measuring the following: (1) time required to complete study training on syncing apps and completing EMA surveys, (2) the comprehension of informed consent information, (3) daily smartwatch wear time, (4) adherence to smartwatch daily wear, and (5) the completion of daily EMA surveys. We also investigated associations between feasibility and adherence measures and participant characteristics (demographics, cognition, and self-reported functional and cognitive decline). Finally, we explored participants' perceptions regarding the usability of the Garmin Vivosmart 4 smartwatch and the study-related apps (syncing process). To address these aims, we recruited a racially diverse sample of older adults, including those with mild cognitive impairment (MCI) and those without. It was hypothesized that older age, worse cognitive function, and greater self-reported functional decline would be associated with lower daily wear time, adherence to wear time, and survey completion, as well as lower comprehension of consent.

Methods

Participants

A total of 47 community-dwelling older adults aged ≥55 years classified as having healthy cognition or MCI were recruited from the Temple University Cognitive Neuropsychology Laboratory cohort in Philadelphia, Pennsylvania. This cohort includes >200 adults who have participated in ongoing federally funded studies since 2020 and represent the racial, ethnic, and economic diversity of the Philadelphia area. Participants met the following inclusion criteria: (1) oral and written fluency in English (to complete study questionnaires and measures) and (2) no history of large vessel stroke, Parkinson disease, major traumatic brain injury, seizures, schizophrenia, or significant neurological conditions other than dementia. The exclusion criteria included (1) current psychiatric disorder (eg, bipolar disorder or major depressive disorder), (2) intellectual disability, and (3) severe motor and sensory deficits precluding the use of a computer touchscreen. Participants from the laboratory cohort were contacted and screened for the following inclusion criteria for this study: (1) aged ≥55 years, (2) cognitive status classified as healthy or MCI, (3) current smartphone user (Android or IOS), and (4) not currently wearing a smartwatch or willing to wear only the study smartwatch during the study period. The exclusion criteria included (1) a diagnosis of dementia and (2) scheduled surgery or travel during the 4-week study period. Approximately 80 participants from the laboratory cohort were contacted as part of the recruitment efforts. The most common reasons for nonparticipation were not having a smartphone or a lack of interest in completing a month-long study.

Of the 47 participants recruited for this study, 1 (2%) was excluded because they required a walker for mobility, which precluded accurate step count recording, and 1 (2%) was excluded from the analyses of feasibility and adherence because their smartphone malfunctioned, and they required the monitoring period to be extended. Moreover, 1 (2%) of the 47 participants dropped out after 1 day, citing discomfort from the smartwatch band being too tight. Thus, of the 47 enrolled participants, 3 (6%) were excluded, resulting in a final sample of 44 (94%) participants for the feasibility and adherence analyses. The participant who extended their monitoring period because of the smartphone malfunction was retained for the usability analyses.

Ethical Considerations

This study was approved by the Temple University Institutional Review Board (Protocol Number: 29712). All participants provided written informed consent and received a US $50 gift card as compensation for their time. Data storage and procedures were Health Insurance Portability and Accountability Act–compliant and only approved study personnel had access to study data.

Procedures

Overview

Participation in the study involved 3 phases. First, participants completed an initial in-person study visit lasting 2 to 4 hours, which included comprehensive cognitive testing, training for the study, and questionnaire completion. Second, participants wore the smartwatch for 4 weeks, answered daily questions on their smartphone, and synced the smartwatch with a smartphone app once a day. Finally, all participants completed a debriefing session. More details of each study phase are provided in the following subsections. Textbox 1 shows the study timeline. The cognitive tests administered during study visit 1 are listed in Table 1.

Textbox 1. Study timeline.

Study visit 1

- Informed consent and comprehension quiz
- Installation of Garmin and Labfront apps
- Study training on syncing and daily survey
- Questionnaires and cognitive testing

4-wk monitoring period

- Participants engage in daily activities as usual
- Wear smartwatch for 23 h/d
- 9-question ecological momentary assessment survey once a day
- Sync Labfront and Garmin apps once a day to securely collect and transmit deidentified data

Study visit 2

- Uninstall apps and unpair smartwatch
- Debriefing questionnaire
- Payment of US $50

Table 1. Cognitive domains and corresponding neuropsychological measures.

Cognitive domains	Neuropsychological measures
Attention	• Trail Making Test part A [26] • Digit Span Forward [27]
Executive function	• Trail Making Test part B [26] • Digit Span Backward [27]
Language	• Letter fluency (S and P) and category fluency (animals) [28] • Boston Naming Test, 30-item version [29]
Processing speed	• Salthouse Letter Comparison Test [30] • Salthouse Pattern Comparison Test [30]
Episodic memory	• Hopkins Verbal Learning Test: immediate recall, delayed recall, and recognition trial [31] • Brief Visual Memory Test–Revised: immediate recall, delayed recall, and recognition trial [32]

Initial Study Visit

Participants completed the following during study visit 1, which lasted 2 to 4 hours: (1) informed consent and 10-item consent comprehension quiz on the specific features of the study (eg, data security and privacy; refer to Multimedia Appendix 1 for the quiz items); (2) gold standard cognitive tests (Table 1) and questionnaires; (3) installation and configuration of study apps and training on wearing a Garmin Vivosmart 4 smartwatch daily (23 h/d of wear; 1 h/d of charging time) for 4 weeks, syncing the smartwatch, and completion of a daily EMA survey. At the end of the first study session, a follow-up visit was scheduled for a date at least 4 weeks later. Further details of the procedures during the initial session are provided in the following subsections.

Smartwatch Data Collection

At the initial study visit, 2 apps (Garmin and Labfront) were downloaded onto the participant's smartphone to facilitate deidentified passive (raw sensor) and active data collection for the daily survey. The Garmin app facilitated data collection from the smartwatch sensors. The Labfront [33] app is a research platform that collects and organizes the Garmin smartwatch data and enabled the study team to monitor adherence and data collection in real time and remotely through a user-friendly study dashboard. The Labfront app was also used to deliver the daily EMA surveys.

A Garmin account was created for each participant using the Garmin Connect mobile app on their smartphone with deidentified information. The Labfront Companion app was then downloaded to the participant's smartphone. The Labfront app uses a randomized 6-digit ID to connect the participant's smartwatch to the app and to connect the Garmin and Labfront accounts. The Garmin smartwatch connects to the Garmin and Labfront apps via Bluetooth. Daily in-app Garmin and Labfront syncing required a Wi-Fi network or an LTE cellular data connection. Once the Garmin and Labfront apps were connected,

data were available for real-time download by the study team in CSV format. Daily syncing of the apps enabled the aggregation of minute-by-minute data.

Participants were asked to wear the Garmin Vivosmart 4 smartwatch for 23 h/d on their nondominant wrist for 4 weeks and to charge it for approximately 1 h/d. Alarms were set in participant smartphones twice daily at times of the participant's choosing to serve as reminders for the following: (1) charging the watch in the morning and (2) syncing the Garmin and Labfront apps and completing the daily survey on the Labfront app at night before going to sleep. To minimize the influence of external cues as well as behavior and health tracking information on participant behavior, all notifications were disabled on the study smartwatch, and additional features were removed from the Garmin app at the initial study visit.

Standardized training procedures with training criteria were used to teach participants how to charge the watch, sync the apps, and complete the daily survey. The training included demonstrations and a practice run during which participants were required to independently complete all daily study steps. Repetitions were recorded for practice runs, and the training session was timed. At the end of the training, participants were given a binder to take home and refer to during the study. The binder contained detailed instructions on how to charge the watch, sync the apps, and complete the daily survey during the study. The contents of this training binder are available in Multimedia Appendix 1.

4-Week Monitoring Period

Participants were told to go about their daily life during the 4-week monitoring period while wearing the smartwatch for 23 h/d and to charge it for 1 h/d. Sleep duration, beat-to-beat heart rate variability, and physical activity data such as step count were collected but are not reported in this paper. Participants were also asked to complete the daily EMA survey delivered to their smartphones through the Labfront app. The EMA survey included 9 questions (Multimedia Appendix 1). The purpose of the EMA survey was to guide the subsequent interpretation of smartwatch data (estimated time to complete the survey: 5 min).

During the course of the study, adherence was monitored through Labfront software by study personnel. If participants were nonadherent for >4 consecutive days, which was defined as wearing the watch for <16.67 h/d or not completing the daily surveys, they were contacted by the study team to determine the reason for nonadherence and to possibly reschedule the follow-up study session to extend the study period and obtain at least 28 days of data collection. The duration of the monitoring period (in days) was tallied for each participant. It is important to note that only 1 (2%) of the 47 enrolled participants required an extension of the monitoring period due to >4 consecutive days of missing data caused by a malfunction of their smartphone. Consequently, this participant was excluded from all feasibility and adherence analyses. For some of the participants (18/44, 41%), the monitoring extended beyond 4 weeks because the follow-up visit could not be scheduled on the study end date due to scheduling conflicts; in these cases, the follow-up visit was scheduled as soon as possible but no more than 1 week later.

Follow-Up Visit

After the study period, participants returned for a brief second visit (study visit 2) during which we collected data on their study experience, the usability of the apps and smartwatch, and barriers to future participation in wearable device research. At this visit, smartwatches were synced a final time to capture any aggregate-level data that had not been previously uploaded to the app. Subsequently, deidentified data obtained during the monitoring period were downloaded in CSV format for each participant from the Labfront researcher user interface for processing and analysis.

Measures of Participant Characteristics

Cognitive tests and questionnaires used in standard clinical evaluations for cognitive decline were administered during study visit 1.

Cognition and Clinical Classification

IQ was estimated with the Hopkins Reading Test [34]. The 5 cognitive domains and 10 cognitive tests that were administered are listed in Table 1. Scores from each of the 10 tests were standardized (T score) after adjusting for demographic variables (age, education, sex, and estimated IQ score [28]). Clinical classification (ie, healthy cognition vs MCI) was based on published criteria [35] that define MCI as T scores of ≤40 (<1 SD) on both measures from at least 1 cognitive domain. A total composite score and cognitive domain–specific composite scores were calculated by averaging demographically corrected T scores (refer to Table 1 for all neuropsychological measures). These neuropsychological tests are used widely in research and clinic settings, have been extensively validated, and show strong psychometric properties [28].

Self-Reported Cognitive and Functional Decline

The average score from the Everyday Cognition (ECog)–short form [36] was used to estimate self-reported functional decline across a range of abilities (eg, memory and language), with scores ranging from 1 (no decline over the past 10 y) to 4 (worse decline over the past 10 y). The optimal cut score for distinguishing between healthy cognition and MCI is 1.32. The original validation study estimated a Cronbach α value of 0.96 [36].

Smartwatch Feasibility and Adherence Measures

Training Time

The amount of time spent training (in minutes) during study visit 1 was recorded. Training procedures were standardized (Multimedia Appendix 1). Training began with a review of procedures for charging the watch and ended when the examiner observed that the participant independently demonstrated charging the watch, syncing the apps, and completing the daily survey.

Comprehension of Consent

Comprehension of consent was assessed using a 10-item quiz (Multimedia Appendix 1), which included questions on study-specific risks, data privacy, and security. The following is an example item: "The Garmin/Labfront apps collect the *content* of my texts and phone calls" (correct answer: no). To

ensure informed consent, if participants answered any item incorrectly, study personnel immediately provided feedback to clarify the correct response.

Smartwatch Adherence

The total number of days that participants did not wear the watch was tallied, and 2 measures were used to evaluate adherence to the instruction to wear the watch for 23 h/d. First, the average daily wear time (in hours) per participant across all possible days of wear was collected. Wear time was derived from minute-to-minute heart rate data; therefore, wear time reflects the accumulation of heart rate data from the watch. Weekly averages of wear time were also computed (weeks 1, 2, 3, and 4) to examine adherence over time.

On the basis of published recommendations [37], daily watch data were considered valid if the participant wore the smartwatch for at least 16.67 hours that day. Therefore, watch adherence also was assessed as the "percentage of valid smartwatch days" during the monitoring period, calculated as the number of days the participants wore the watch for ≥16.67 h/d divided by the total number of days they were in the study.

EMA Survey Adherence

Adherence to the daily survey was calculated as the number of daily surveys completed divided by the total number of days that each participant was in the study. This percentage ranged from 0% to 100%, with 100% indicating perfect adherence.

Usability Measures

A self-administered usability survey was completed by participants at the follow-up visit (study visit 2) to provide qualitative information on smartwatch use. The survey questions focused on the smartwatch and Labfront and Garmin smartphone apps, which were used for daily EMA surveys and syncing. Participants were also asked to report their likelihood of participating in another future study that included the smartwatch and daily surveys. This survey was administered to 45 (96%) of the 47 enrolled participants, including the participant whose monitoring period was extended.

Statistical Analyses

Descriptive statistics were used to characterize feasibility: average daily wear time, study training time, percentage correct on consent comprehension, the percentage of completed EMA surveys, the percentage of valid smartwatch days, and responses to the study debriefing questionnaire. To examine univariate associations between feasibility and adherence measures and participant characteristics, Spearman correlations and Mann-Whitney *U* tests were used for continuous and categorical variables, respectively, with Bonferroni correction applied to interpret statistical significance. Friedman rank tests for 1-way repeated measures of ANOVA were used to analyze whether wear time differed from week 1 to week 4, with Bonferroni correction applied to interpret statistical significance. Nonparametric statistical tests were used due to the skewed distributions of the variables of interest. Multiple linear regressions were conducted to examine multivariate associations between demographics (ie, age, sex, race, and education) and cognitive variables (ie, ECog, cognitive composite scores, and cognitive status) on all feasibility and adherence measures. Separate models were conducted for each cognitive variable to avoid multicollinearity. As the dependent variables were not normally distributed, we used bootstrapping (5000 replications) to estimate robust SEs and CIs for coefficients, leading to more reliable testing of significance.

All analyses were conducted using SPSS software (version 28.0; IBM Corp) or, for bootstrapped regressions only, R (version 2023.12.1+402; R Foundation for Statistical Computing).

Results

Participant Characteristics

A total of 44 older adults ranging in age from 55 to 83 years participated and were included in the feasibility and adherence analyses. On average, participants were college educated with estimated IQ scores in the high average range (Table 2). Self-report of cognitive and functional decline was well within the normal range (ECog; range 1-2.5). The cognitive composite T score ranged from 35.40 to 63.40. The sample comprised mostly women (26/44, 59%) and primarily individuals identifying as Black or African American (11/44, 25%) or White, non-Hispanic (31/44, 70%). Of the 44 participants, 8 (18%) met the Jak-Bondi criteria for MCI. The participants were relatively active, with an average of 5999.74 (SD 2872.38) steps per day. Of the 44 participants, 17 (39%) owned a smartwatch before the study, with most owning a Fitbit device (n=9, 50%) or an Apple Watch (n=9, 50%). Those who currently or previously owned a smartwatch reported the main motivations for use as activity monitoring, followed by improving fitness and improving health. Of those who had not owned a smartwatch, most (17/44, 39%) indicated that they would consider buying one after their study experience.

Yes	17 (39)
No	10 (24)
Already have smartwatch	17 (39)
Smartwatch feasibility and adherence measures, mean (SD)	
Percentage correct of consent comprehension	98.00 (6.86)
Average training time (min)	17.93 (6.89)
Average daily smartwatch wear time (h)	21.04 (1.53)
Percentage of valid smartwatch days	92.00 (10.39)
Percentage of completed daily surveys	94.00 (9.58)

[a]MCI: mild cognitive impairment.

[b]ECog: Everyday Cognition.

Retention Rate and Duration of Monitoring Period

A total of 47 participants were enrolled, of whom 1 (2%) dropped out after 1 day citing discomfort from the smartwatch band being too tight. All other participants (46/47, 98%) completed the study. However, 2 (4%) of these 46 participants were excluded from feasibility data analysis: 1 (50%) was excluded because their monitoring period was extended to 46 days due to a smartphone malfunction, and they did not complete the EMA survey for 1.5 weeks during the originally scheduled 28-day study; consequently, they were asked and agreed to extend their monitoring period. As a result, this participant was excluded from the analytic sample used for feasibility and adherence analyses. No other participants extended their monitoring period for reasons other than scheduling conflicts. Another participant was excluded due to mobility issues. Thus, the final analytic sample for the feasibility analyses comprised 44 participants.

The number of days monitored with the smartwatch ranged from 27 to 35. The mode for study days was 27 days,

corresponding to exactly 4 weeks because the date of the initial study visit was excluded from analyses. The average number of days in the study was 29 (SD 3.46) days. Feasibility and adherence measures were computed using all available monitoring days.

Feasibility and Adherence

Average feasibility and adherence measures are shown at the bottom of Table 2.

Comprehension Quiz

On average, participants obtained a score of 97% (range 70%-100%) correct on the consent comprehension quiz, approaching a perfect average score. The most frequently missed response was indicating "yes" to "Using the Garmin and Labfront apps will help improve my cognitive functioning."

Training Time

Participants took an average of 17.93 (range 12-53) minutes to complete the study training during study visit 1. Training time was mostly spent independently practicing study tasks, such as syncing apps.

Smartwatch Adherence

Of the 44 participants, 11 (25%) did not wear the watch for at least 1 entire day (n=9, 20% missed only 1 d; n=1, 2% missed 2 d; and n=1, 2% missed 4 d). All participants wore the watch for ≥16.67 h/d for ≥14 days during the monitoring period. Of the 44 participants, 5 (11%) had ≥27 days of wear time that exceeded 16.67 h/d. On average, participants exceeded 16.67 h/d of wear time on 92% (range 53%-100%) of total study days. As the monitoring period extended beyond 4 weeks for some participants due to scheduling conflicts, watch adherence measures also were calculated over 27 days, with the average percentage of days exceeding 16.67 h/d of wear time remaining unchanged at 92% (range 55%-100%).

On average, participants wore the watch for 21 (range 15.71-22.44) h/d across the 4-week study period. Of the 44 participants, 3 (7%) had an average wear time of <18 h/d, 2 (5%) had an average wear time of <16.67 h/d, and 39 (89%) wore the watch for ≥20 h/d on average.

The distribution of average watch wear time per week is shown in Figure 1. Pairwise 2-tailed *t* tests showed no significant difference in average wear time across the 4 weeks (refer to Multimedia Appendix 1 for full results).

As shown in Figure 2, on average, 91% (40/44) of the participants wore the watch for at least 19 h/d, within 4 hours of the required 23 h/d. In fact, on average, participants on average wore the watch for 21 h/d, within 2 hours of the required 23 h/d.

Figure 1. Daily wear time across participants was averaged across weeks 1 to 4 in the study. The y-axis represents the mean daily smartwatch wear time in hours. The error bars represent –1 to +1 SD.

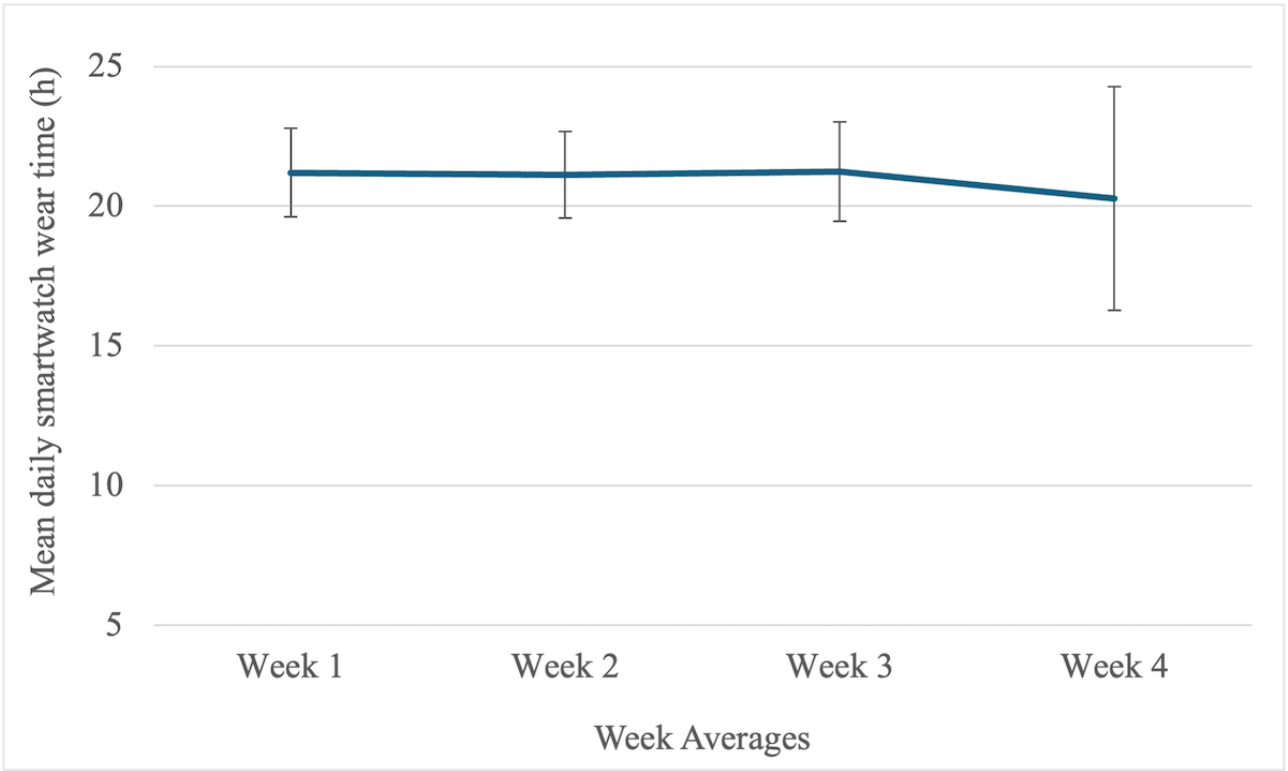

Figure 2. Average wear time discrepancy for the entire sample. The y-axis represents each participant's average daily wear time subtracted from the required 23 h/d. The x-axis shows participant ID numbers from the feasibility analyses. Each dot represents a participant.

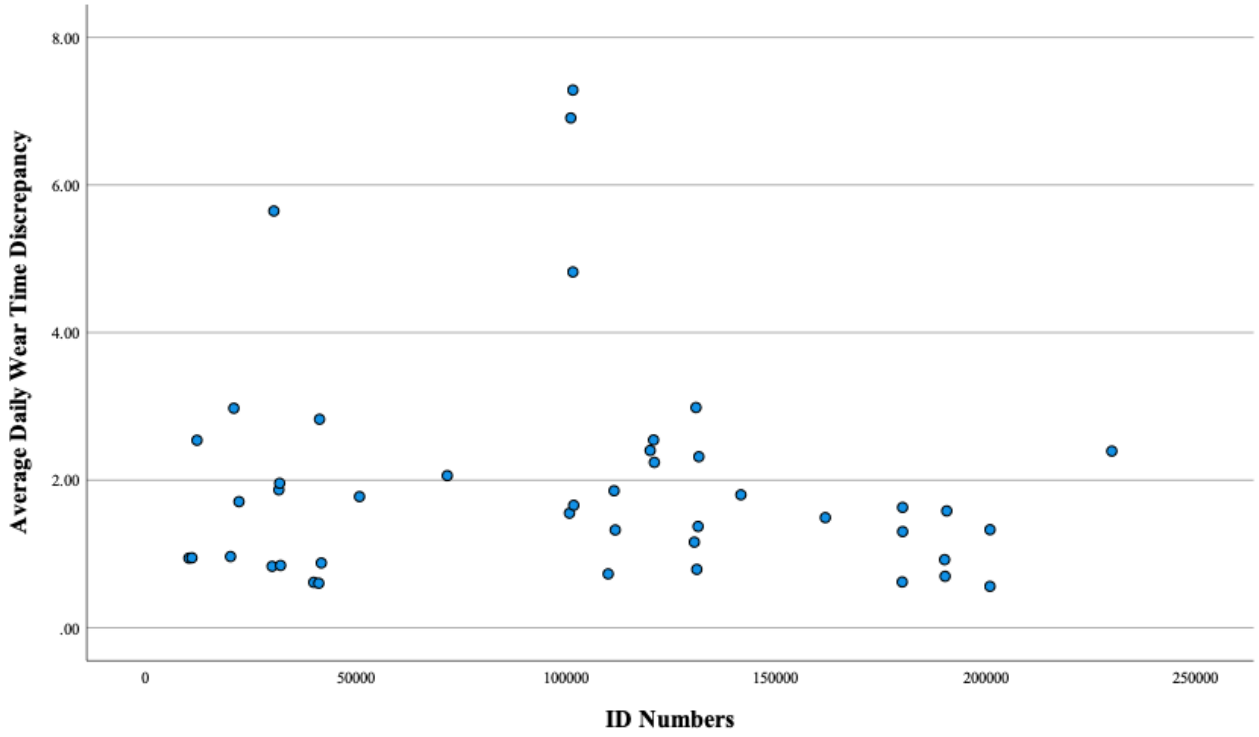

EMA Survey Adherence

On average, participants completed surveys on most study days (94%; range 58%-100%). Of the 44 participants, 3 (7%) completed <70% of the surveys, while 41 (93%) completed >85% of the daily surveys.

Correlations Among Smartwatch Feasibility and Adherence Metrics

As shown in Table 3, a greater percentage of daily surveys completed was significantly associated with longer study training time, but the *P* value for this association did not survive Bonferroni correction (ie, *P*=.005 and below). Correlations between the 2 measures of smartwatch adherence and between smartwatch adherence measures and the percentage of daily surveys completed were significant and survived correction for multiple comparisons. The correlations indicated that participants who completed a higher percentage of daily surveys also wore the watch for longer durations and had more days of valid smartwatch wear time.

[a]Not applicable.

Associations Between Participant Characteristics and Feasibility and Adherence Metrics

As shown in Table 4, only age and self-reported cognitive and functional decline (ECog) were significantly associated with feasibility and adherence metrics. Specifically, older participants required longer study training times, and participants who reported greater cognitive and functional decline (ECog) had lower daily average wear time. However, these significant correlations did not survive Bonferroni correction (P=.003). No other correlation coefficients were statistically significant (Table 4).

Table 4. Correlation coefficients between smartwatch feasibility metrics and demographic and clinical factors.

[a]ECog: Everyday Cognition.

There were no significant sex differences in consent comprehension, training time, watch adherence measures, or the percentage of daily surveys completed (data reported in Multimedia Appendix 1). Participants with MCI and those with healthy cognition differed on only 1 measure (data reported in Multimedia Appendix 1): participants with MCI (median 20.64, IQR 2.74 h) had significantly lower daily wear time than participants with healthy cognition (median 21.53, IQR 1.18 h; U=71.00; P=.03). This result is consistent with the significant correlation between ECog and daily wear time reported in Table 4, suggesting an association between lower cognitive abilities and less smartwatch wear time.

Between-group analyses comparing Black and White participants were not statistically significant, except for daily wear time (data reported in Multimedia Appendix 1). Black participants (median 20.76, IQR 0.91 h) had significantly lower daily smartwatch wear time than White participants (median 21.83, IQR 1.02 h; U=74.00; P=.004).

Multivariate associations between participant characteristics and feasibility and adherence metrics were investigated using multiple regression analyses with bootstrapping to estimate the significance of the coefficients. Separate regressions were run, including one for each cognitive variable (cognitive composite scores, ECog, and cognitive status; refer to Multimedia Appendix 1 for all tables), to avoid multicollinearity. The results showed that race remained a significant predictor of daily wear time, even after controlling for age, sex, education, and measures of cognition, with White participants having longer daily wear times than Black participants. Multivariate analyses also showed that age was significantly associated with training time even after controlling for sex, education, race, and measures of cognition, with older age associated with longer study training time. By contrast, associations between the measures of cognition and feasibility and adherence metrics were not statistically significant in regression analyses, including demographic variables (age, sex, education, and race).

Usability Survey

The results of the usability survey are shown in Table 5 (Garmin smartwatch) and Table 6 (Labfront smartphone app). Overall, participants expressed favorable views of both the smartwatch and the smartphone apps and especially enjoyed their involvement in research. When asked, “Would you wear this Garmin smartwatch without being asked to wear it as part of the study?” 55% (25/45) of the sample reported “yes.” However, all participants indicated they were likely (11/45, 24%) or very likely (34/45, 76%) to participate in a future study asking them to wear a Garmin smartwatch daily. Of the 45 participants, 36 (80%) either somewhat or strongly agreed that they had a positive experience using the Garmin smartwatch during the study period (Table 5). Most of the participants (31/45, 68%) reported that the smartwatch was comfortable or very comfortable. Most of the participants (32/45, 71%) were satisfied or very satisfied with the functioning of the watch. The majority of the complaints about the smartwatch were regarding low battery life (17/45, 38%), followed by discomfort (8/45, 18%) and technical issues (8/45, 18%). Of the 45 participants, 17 (38%) reported no complaints about the smartwatch. Participants suggested the following improvements for the watch: changing wristband material (18/45, 40%), increasing

the display size (15/45, 33%), and increasing the wristband size (10/45, 22%).

App usability and overall experience are reported in Table 6. Of the 45 participants, 41 (91%) were satisfied or very satisfied with the syncing process of both apps (Garmin and Labfront). Of the 45 participants, 35 (78%) indicated that they agreed or strongly agreed that the Labfront app was easy to use and that they felt very confident using it. Importantly, 64% (29/45) of the participants had a positive or extremely positive experience with the Labfront app. Moreover, 71% (32/45) of the participants indicated that the Labfront app was easy to use or extremely easy to use (Table 6).

Table 6. App usability and overall experience (n=45).

Discussion

Principal Findings

Overall, the results demonstrated that our longitudinal study requiring daily wear of a smartwatch and daily EMA survey completion in a racially diverse sample of older adults was feasible with excellent adherence. Participants with cognitive impairment and those without wore a commercially available smartwatch during waking and sleep hours for 4 weeks for an average of 21 h/d and showed an average response rate of 94% to daily EMA surveys. Only 1 (2%) of the 47 enrolled participants refused to complete the study after informed consent due to discomfort with the watch fit. On the basis of the results of our consent comprehension quiz, participants had no difficulty understanding the study procedures and risks, and completed smartwatch and app training in 18 minutes on average. After consent and training, participants remained in the study for at least 28 days. Average wear time did not decline significantly over the course of the study and on average never fell below 20 h/d. Although there are no benchmark standards for indicating good smartwatch adherence, a recent systematic review of activity trackers to monitor physical activity suggested that 3 valid days of at least 10 h/d may be a good adherence threshold for a week-long study [38]. Another study defined a "valid day" as one that includes at least 16.67 hours of data or at least 600 one-minute epochs of nonzero heart rate values [37]. In our study, participants wore the study watch for >16.67 h/d on 92% of the days on average. Thus, our results exceed the recent suggestions for adherence and validity and show strong support for the feasibility and adherence of our protocol to monitor older adults.

Smartwatch feasibility and adherence metrics were associated with each other as expected, and EMA survey adherence also was related to smartwatch adherence measures. However, feasibility and adherence metrics were differentially related to participant factors, indicating the importance of measuring adherence to each feature of a smartwatch and EMA study separately. EMA survey adherence was not related to any participant characteristic and was uniformly high, possibly because participants received smartphone reminder alarms to complete the daily survey and sync the apps at predetermined times at night before bedtime. There was no comparable alert to prompt participants to wear the smartwatch during the day or night. Future studies should consider adding prompts to facilitate smartwatch adherence.

In contrast to past studies [21], we observed no associations between participant's sex or education level on any measure of adherence and feasibility in our diverse sample. Smartwatch adherence was associated with race such that White participants wore the smartwatch for more hours per day (daily wear time) than Black participants during the study period. The effect of race remained significant, even after controlling for other demographic variables, including age, education, and cognition. The reason for the race difference is unknown but may be explained by different beliefs, attitudes, or daily habits between the racial groups. As wear time is measured using the photoplethysmography sensor, which relies on the absorption of infrared light into the skin, it is possible that the measures might have been less accurate for people with darker skin tone. If replicated, cultural factors and potential sensor limitations related to skin tone, which might explain racial differences in adherence, should be systematically explored. Although Black and White participants differed in daily wear time, race did not influence the percentage of days that reached the 16.67-hour threshold for "valid" wear time. Thus, the race difference in daily wear time was small and potentially inconsequential. Furthermore, race was not associated with any other feasibility and adherence measure.

Although cognitive ability level (both self-reported cognitive decline and MCI status) was associated with daily wear time in bivariate analyses, the effect of cognition was not significant in multiple regression models. These results contrast with past research that has shown cognitive ability to be related to adherence; for example, memory ability was related to adherence in a study requiring the daily syncing of a Fitbit device in a sample of older adults without cognitive impairment [21]. Our study protocol, including training and supports during the monitoring period (eg, the take-home binder and twice daily alarms [in the morning to charge the watch and at night to sync the apps and complete the surveys]) may have helped participants with cognitive difficulties adhere to the smartwatch wear requirements and EMA survey.

Age was not associated with watch or survey adherence, which is consistent with the results from a recent smartphone digital phenotyping study [15]. However, similar to a recent study from our laboratory [13], we found that age was associated with training time such that older participants required longer training times in the laboratory to learn how to sync the study-related apps and complete the daily EMA survey on their smartphone. The training required participants to independently complete each activity (syncing apps, charging the smartwatch, and completing the EMA survey) while a member of the study team observed, answered questions, and provided feedback. On average, participants took <20 minutes to complete the training. Older participants may have taken longer to complete the training due to lower digital literacy; they may have required more practice and may have asked more questions during the training. Although the number of people aged >65 years owning smartphones in the United States has steadily increased over the past decade, digital literacy is generally lower in older adults. The longer training time and the take-home binder, which summarized the training for review during the study period, may have consequently minimized age effects on smartwatch and daily EMA survey adherence. Smartwatch studies that incorporate a "human in the loop" have been found to have higher adherence than fully remote studies [15]. Even if a study is conducted fully remotely, providing some contact with study personnel (via teleconference) or training resources (in the form of a training binder, video tutorial, website, or web-based helpline) could be quite beneficial to increasing adherence, especially for older adults with low digital literacy.

Participants generally demonstrated solid knowledge of the informed consent information, including issues related to data security and privacy that are relevant to research using wearable devices; for example, responses to the study consent quiz

showed that participants understood that the study apps were Health Insurance Portability and Accountability Act–compliant and that they had control over their data such that they had the right to delete their study data at any time. In contrast to a study on smartphone digital phenotyping that found that education and race were associated with quiz accuracy [13], percentage correct on the consent comprehension quiz was not significantly related to any of the participant demographic factors, possibly because the scores on the quiz had little variability (ie, ceiling effects). Similar to a past study [13], the most frequently incorrect question concerned the potential benefits of the study, with many participants incorrectly reporting that their participation would improve their cognitive abilities. In these cases, the comprehension quiz enabled the study team to explain that wearing the smartwatch had no clear benefit and possibly preclude participants' disappointment at the end of the study.

Smartwatch usability reports were largely very positive, with most of the participants (37/45, 82%) agreeing that they had a positive experience using the Garmin Vivosmart 4 smartwatch in the study as well as high satisfaction regarding its comfort and functioning. This is in line with past research showing that the Garmin Vivosmart was rated as the most usable and acceptable smartwatch compared to 5 other smartwatches by older adults in a small study [39]. Although participants indicated that they needed to charge the Garmin Vivosmart 4 smartwatch daily, they were generally satisfied with battery life. Regarding app usability, almost all participants were satisfied with the syncing process of the Labfront and Garmin Connect apps (42/45, 93%), felt that the Labfront app was easy to use (35/45, 78%), and reported a positive experience using the Labfront app (29/45, 64%). There are currently no other studies examining the usability and acceptability of the Labfront and Garmin Connect apps.

Regarding the usability of the smartwatch and apps, participants were generally satisfied with the smartwatch and reported that they would wear it again in another study. It is important to consider that most of the participants (44/45, 98%) reported having to charge the watch daily, and low battery life was the most frequently cited complaint about the smartwatch. Thus, in future studies, participants should be trained and prompted to charge watches and other digital devices, and they should be informed about battery limitations to preclude complaints and dissatisfaction. Multiple chargers, including portable batteries, may be offered to participants to improve usability. Despite minor complaints regarding charging, most of the participants (37/45, 82%) reported a positive experience during the study using the smartwatch. Participants also reported high satisfaction and ease of use of the Labfront and Garmin apps, which were used for daily syncing to enable sensor and EMA data to be transmitted to the research team. Taken together, our findings are generally in line with prior research showing good acceptability and usability of wearable devices in research studies involving older adults [21].

Limitations

Although our sample included older adults of different races, the sample was relatively small and highly educated. Furthermore, only 8 (18%) of the 44 participants had MCI; therefore, analyses comparing participants with MCI and those with healthy cognition were underpowered. However, cognitive effects on adherence were also examined with a composite test score and self-reports of cognitive and functional abilities (ECog). Moreover, our monitoring period was limited to a 4-week period; therefore, the conclusions may not generalize to longer periods. Importantly, our study incorporated several supports for participants such as in-person training, a take-home binder, contact with study personnel, and reminder alarms set for times specified by participants. These study features likely influenced the high adherence to smartwatch wear and EMA survey completion in our study compared to fully remote studies with little to no support from study personnel. In addition, our study's EMA survey imposed minimal demands because it was required only once daily and completed at a time preferred by participants.

Conclusions

This study demonstrated the feasibility of a combined smartwatch monitoring and daily EMA study requiring nearly 24-hour wear time daily for a month in racially diverse older adults, including those with cognitive impairment and those without. Smartwatch feasibility and adherence metrics were not significantly intercorrelated and were differentially related to participant characteristics. The inclusion of a guided training for older adult participants on study procedures as well as a take-home binder and smartphone reminder alarms to complete study steps (syncing apps, charging the smartwatch, and completing the daily EMA survey) may have contributed to strong adherence and feasibility in this study, regardless of cognitive impairment. Participants reported high satisfaction regarding the usability of both the Garmin Vivosmart 4 smartwatch and Labfront app. Overall, longitudinal monitoring using a commercially available smartwatch with a daily EMA survey is acceptable and feasible for collecting nearly continuous data in Black and White older adults, including those with cognitive impairment and those without.

Acknowledgments

The research in this publication was supported by the National Institute on Aging (F31AG089944: SH; R01AG062503: TG). The publication of this article was funded in part by the Temple University Libraries Open Access Publishing Fund.

Abstract

Background: Binge drinking, which is linked to various immediate and long-term negative outcomes, is highly prevalent among US college students. Behavioral interventions delivered via mobile phones have a strong potential to help decrease the hazardous effects of binge drinking by promoting safer drinking behaviors.

Objective: This study aims to evaluate the preliminary efficacy of bhoos, a novel smartphone app designed to promote safer drinking behaviors among US college students. The app offers on-demand educational content about safer alcohol use, provides dynamic feedback as users log their alcohol consumption, and includes an interactive drink tracker that estimates blood alcohol content in real time.

Methods: The bhoos app was tested in 2 independent pre-post studies each lasting 4 weeks, among US college students aged 18 - 35 years. The primary outcome in both trials was students' self-reported confidence in using protective behavioral strategies related to drinking, with self-reported frequency of alcohol consumption over the past month examined as a secondary outcome.

Results: In study 1, bhoos was associated with increased confidence in using protective behavioral strategies. Students also endorsed the high usability of the app and reported acceptable levels of engagement. Study 2 replicated findings of increased confidence in using protective behavioral strategies, and demonstrated a reduction in the self-reported frequency of alcohol consumption.

Conclusions: Bhoos is a personalized, accessible, and highly scalable digital intervention with a strong potential to effectively address alcohol-related behaviors on college campuses.

Introduction

Overview

Binge drinking, defined as consuming more than 5 standard drinks for men or 4 for women within a 2-hour period [1,2], is highly prevalent among US college students. This is concerning because binge drinking is linked to various immediate and long-term negative outcomes, including lower academic performance, a higher incidence of sexual assault, drunk driving, motor vehicle accidents, organ damage, and premature death [2-5]. Additionally, research shows that college students consume more alcohol than their noncollege-attending peers [6,7], which is troubling given that excessive drinking during late adolescence and early adulthood is a strong predictor of alcohol use disorders later in life [8]. Therefore, taking proactive steps to address binge drinking among college students is critical to reducing both the short- and long-term consequences in this population.

Alcohol Interventions in US Colleges

A common approach adopted by US colleges and universities to address hazardous drinking among students involves programs that focus on changing attitudes, increasing knowledge, and modifying behaviors related to alcohol use. Programs like the Brief Alcohol Screening and Intervention for College Students [9,10] typically include brief motivational counseling sessions aimed at reducing students' positive alcohol expectancies, increasing their awareness of the consequences of drinking, and enhancing their readiness to change [11-15]. Despite the

widespread implementation of such alcohol education and intervention programs, national data show that binge drinking rates among college students have remained relatively stable for over a decade [5], highlighting the ongoing difficulty in effectively addressing this public health issue.

Delivering Alcohol Interventions Through Smartphone Apps

Safer drinking interventions delivered through smartphones may offer distinct advantages in addressing binge drinking among young adults due to their ubiquity, high use, constant presence, and engaging features. Among all US demographic groups, college students have some of the highest rates of smartphone ownership and use [16]. Capitalizing on this widespread adoption provides an opportunity to develop personalized interventions that can effectively engage students and help regulate their alcohol consumption. Compared with in-person interventions, smartphone app-based alcohol interventions are highly accessible, cost-effective, scalable for large student populations, and can offer personalized feedback based on users' behaviors [17-19].

Researchers have begun exploring the use of smartphone apps to deliver alcohol interventions both in the general population [18-20] and among college students specifically [21-25]. Reviews generally support the feasibility and potential of app-based interventions for addressing outcomes of problematic drinking in college students, though results have been inconsistent across studies [21,23]. One potential reason for this inconsistency may be the lack of sufficient tailoring or personalization for US college students, given that incorporating strategies like gamification to personalize digital interventions may increase user engagement and improve outcomes [26,27]. For example, providing users with dynamic feedback about their drinking, such as their estimated blood alcohol level, may help them to better regulate their alcohol consumption during a night out with their friends to avoid negative consequences. Furthermore, providing users with graphical displays of their current and past alcohol consumption patterns may help them understand how their drinking has impacted other aspects of their lives, such as their academic performance and personal health.

Our team conducted a formative study to gain a detailed understanding of US students' preferences for interventions and their patterns of smartphone use [28]. Based on our findings and through conducting iterative user-centered design testing, our team developed bhoos (see below for a detailed description of the app and its functions). Similar to other app interventions, bhoos provides on-demand psychoeducational content about safer alcohol use. A novel feature of bhoos, however, is its just-in-time approach. Through an interactive drink tracking feature, students can log their consumption of alcohol in real time, enabling the app to provide dynamic feedback on recommended safe drinking behaviors based on estimated real-time blood alcohol content [28]. The primary goal of bhoos is therefore to promote safer drinking behaviors, in large part by increasing students' confidence in engaging in protective strategies, with the potential secondary outcome of reducing overall alcohol consumption.

The Current Studies

We investigated the feasibility and preliminary impact of bhoos in 2 pre-post studies conducted among students at a mid-Atlantic university in the US over a 4-week period. The hypothesis for study 1 was that bhoos would lead to an increase in students' confidence in using protective behavioral strategies (ie, behaviors that are used while drinking to reduce alcohol use or limit alcohol-related problems) from baseline to postintervention. A secondary hypothesis was that bhoos would lead to a reduction in self-reported alcohol consumption from baseline to postintervention. Study 1 also evaluated the impact of small monetary incentives on drinking outcomes and how students use the app to log their drinks. As study 1 was the first to test bhoos in college students, we examined students' engagement with the app and their ratings of its usability. Focus groups were conducted at the end of study 1 to gather feedback on the app from participants. Study 2 was conducted as a replication of self-reported drinking outcomes in study 1 to determine the potential of testing bhoos in a future randomized trial.

Ethical Considerations

Both studies reported in the manuscript were approved by the University of Virginia Institutional Review Board for Social and Behavioral Sciences (IRB-SBS #4020, 5334). All participants provided informed consent. Data are deidentified. Participants in study 1 received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $45). Participants randomized to receive added incentives in study 1 received an additional sum, up to US $30, based on their completion of 3 engagement milestones: US $10 for downloading the app, US $10 for logging 1 drink or dry day, and US $10 for logging a "streak" of 3 consecutive days of drinks or dry days. Participants in study 2 received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $25).

Study 1

Methods

Study Overview and Participants

Study 1 consisted of 3 phases. The first phase evaluated the bhoos app in a simple pre-post trial design. The second phase randomized (1:1) participants to receive small additional monetary incentives or not for using the bhoos app in a second pre-post trial. The third phase consisted of focus groups to capture impressions of the app by a subset of participants from the second phase.

For all phases of study 1, college students were eligible to participate if they met the following criteria: (1) aged 18 to 35 years, (2) current enrollment verified via a university email address, and (3) currently owned and used a smartphone. Students were enrolled using traditional, online, and social media methods. Recruitment spanned June through September 2021. Recruitment materials instructed applicants to complete a web-based interest form including contact information, demographic information, and questions to determine initial

study eligibility. Research coordinators verified student status and identity with the university's internal people search. Eligible verified applicants were invited to participate, signed a web-based consent form, and were enrolled in the study.

The phase 1 group included 83 participants (mean age 20.8 years, SD 1.6 years; 68% self-identified as female; 58% self-identified as White, 16% self-identified as Asian or Hawaiian/Pacific Islander, 4% self-identified as Black, 12% self-identified as multiracial, 4% prefer not to answer, and 6% chose to leave the item blank), and phase 2 group included 172 participants (mean age 20.1 years, SD 1.8 years; 60% self-identified as female; 48% self-identified as White, 19% Asian or Hawaiian/Pacific Islander, 8% Black, 11% multiracial, 1% prefer not to answer, and 13% chose to leave the item blank). Assessments occurred at baseline and postintervention, 28 days later. All participants received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $45). Participants in the phase 2 group who were randomized to not receive added incentives (n=86) were only provided compensation for completing the baseline and postassessments. However, those randomized to receive added incentives (n=86) received an additional sum, up to US $30, based on their completion of 3 engagement milestones: US $10 for downloading the app, US $10 for logging 1 drink or dry day, and US $10 for logging a "streak" of 3 consecutive days of drinks or dry days (see bhoos description, below).

To improve the app for future trials, the third phase of the trial included a subset of participants (n=18) from the phase 2 group who were invited to be part of debriefing focus groups that occurred 9 - 12 months after the initial pre-post trial. A total of 5 focus groups were conducted and qualitative information was collected regarding participants' general impressions of the app, what features of the app they liked most/least, and the degree to which the app helped them manage their drinking.

Intervention: Bhoos

Bhoos (pronounced [booz]) is an app whose name is a play on the word "booze," slang for alcohol, and the nickname for University of Virginia students, "hoos." The app provides on-demand educational content about safer alcohol use and dynamic feedback to users as they log their alcohol consumption in real time. Users can log the type of alcoholic drink they are consuming and each drink entry is time-stamped. The app provides real-time estimates of the user's blood alcohol concentration (estimated blood alcohol concentration) based on their self-identified sex, weight, and number and type of alcoholic drinks logged. In-app notifications are pushed to users based on their estimated blood alcohol concentrations, including information about recommended actions to stay safe and avoid overdrinking. Users can view their current and past drink history through a built-in dashboard. To encourage engagement with the app, users can establish a streak of logins whenever they log consecutive drinking days or dry days (ie, days in which users logged no alcoholic drinks). To encourage engagement, the app also allows users to rate activity level or sleep quality as a secondary health behavior. Materials about safe drinking tips and staying healthy can be accessed directly from the main page. Users can also learn about health-related resources in and around the university through the app on demand. The app design and content were informed by formative research and a think-aloud process with the target population prior to this trial [28].

Measures

Baseline Alcohol Use Severity

The 10-item Alcohol Use Disorders Identification Test (AUDIT) is the most widely used self-report measure of unhealthy alcohol use [29]. Scores range from 0 to 40, with higher scores indicating more unhealthy alcohol use. Prior studies on college students have suggested cutoff scores for low-risk drinkers (<7), hazardous drinkers (8-15), and alcohol-dependent drinkers (>15). Participants completed the AUDIT at baseline (Cronbach α=0.78) to characterize their alcohol use over the past year.

Alcohol Consumption in the Past Month

We used a modified 3-item measure based on the Daily Drinking Questionnaire [30] to assess students' self-reported drinking behavior. Students were initially asked "How often did you drink during the last month?" with response options ranging from 1 (did not drink at all) to 7 (once a day or more). Responses were analyzed as a single-item measure of the average number of days per week in the last month involving alcohol consumption, with higher scores indicating more days per week that involved alcohol consumption. Students who responded that they had drank at least once a month (ie, a score of ≥2) were then asked 2 follow-up questions: "Think of a typical weekend evening (Friday or Saturday) during the last month. How many standard drinks did you drink on that evening?" and "Think of the occasion (any day of the week) you drank the most during the last month. How many standard drinks did you drink?" Students responded to each of these questions by typing a number into an open field. Because these questions were intended to assess for average and maximum alcohol consumption, respectively, we analyzed responses to them as separate items.

Protective Behavioral Strategies

A modified version of the 20-item Protective Behavioral Strategies Scale [31-33] was administered at baseline (α=0.92) and postintervention (α=0.93) to assess students' confidence in using protective behavioral strategies, or behaviors adopted while drinking to limit their alcohol consumption or limit alcohol-related problems. Specifically, the instructions were modified from the original version to ask students to select the response option that "best fits your confidence level" for using various protective strategies when drinking. Participants responded to each item on a modified scale from 1 (extremely not confident) to 7 (extremely confident), with scores ranging from 20 to 140 [34,35]. Higher scores indicate more confidence in using protective behavioral strategies such as stopping or limiting alcohol consumption, changing the speed or frequency of drinking, and reducing the risk of serious harm by using a designated driver, going home with a friend, or protecting one's drink from adulterants.

App Usability

The 10-item System Usability Scale (SUS) [36] was administered postintervention to assess the usability of the bhoos app. The SUS provides a global view of subjective assessments of usability. We customized the items to specifically mention bhoos. Sample items include "I think that I would like to use bhoos frequently" and "I thought bhoos was easy to use." Responses to each item range from 1 (strongly disagree) to 5 (strongly agree). Possible scores on the SUS range from 0 to 100, with a higher score indicating higher overall usability of a system or program. The SUS has been used in roughly 3500 surveys within 273 studies evaluating a range of systems, interfaces, and programs [37]. Internal consistency of the SUS was good (α=0.84).

Plan for Analyses

To determine whether students' self-reported drinking outcomes differed across the 2 phases, including the incentive conditions in phase 2, 1-way ANOVAs were conducted using the phase 1, phase 2 incentivized, and phase 2 nonincentivized groups as within participants variables and difference scores for the drinking outcomes as the dependent variables. Difference scores in drinking outcomes between the baseline and postintervention time points served as the dependent variables. Next, for each of the phase 1 and phase 2 groups, paired *t* tests were conducted to obtain estimates of short-term changes in drinking and attitudinal measures from baseline to follow-up. Box-Cox transformations were performed for the drinking outcomes where there was evidence of nonnormality of data based on skewness (outside of −1 and +1) or kurtosis (outside of −2 and +2) being outside of the conventional acceptable ranges. The pattern of findings did not change when using transformed or raw variables. Analyses of self-reported drinking outcomes were performed using IBM SPSS Statistics (version 26.0.0). App use is described using descriptive statistics. Qualitative feedback from focus groups was reviewed by members of the study team (KI, CF, NA, and CC), and recurring themes were identified.

Results

Baseline Alcohol Use Severity

To characterize the sample, we examined AUDIT scores for all participants in study 1. Of the 234 students who completed at least the baseline measures, 133 (59%) were classified as low-risk drinkers (AUDIT Score ≤7), 93 (40%) were classified as hazardous drinkers (AUDIT Score between 8 and 15), and 8 (3%) were classified as alcohol dependent drinkers (AUDIT score >15).

Evaluating the Impact of Study Phases on Self-Reported Outcomes

There was no significant effect of the study phase or incentives on any of the self-reported drinking outcomes, for the average number of days per week in the last month involving alcohol consumption ($F_{2, 232}$=0.294, *P*=.75, η^2=.003), typical weekend evening drink consumption in the last month ($F_{2, 165}$=0.662, *P*=.52, η^2=.008), the maximum number of drinks consumed in the last month ($F_{2, 175}$=0.005, *P*=.99, η^2=.00), or protective behavioral strategies ($F_{2, 232}$=1.469, *P*=.23, η^2=.013). Table 1 contains all results of self-reported drinking outcomes, separately for each phase and incentive condition. Below, we report self-reported drinking-related outcomes overall for those in phases 1 and 2 combined, followed separately for each phase and incentive group.

Table . Self-reported drinking outcomes for study 1.

	Average number of days per week drinking in the last month, mean (SD)				Average number drinks per weekend in the last month, mean (SD)				Max number of drinks on one occasion in the last month, mean (SD)				Protective behaviors, mean (SD)			
	Pre	Post	*t* test (*df*)	*P* value	Pre	Post	*t* test (*df*)	*P* value	Pre	Post	*t* test (*df*)	*P* value	Pre	Post	*t* test (*df*)	*P* value
Phase 1	3.66 (1.31)	3.71 (1.34)	0.54 (75)	.59	3.64 (1.68)	3.61 (1.75)	0.11 (60)	.91	5.68 (3.16)	5.94 (3.12)	0.79 (65)	.43	98.20 (21.01)	100.30 (20.18)	0.98 (75)	.33
Phase 2 (no incentive)	2.99 (1.35)	3.01 (1.36)	0.22 (74)	.83	3.21 (2.06)	2.89 (1.95)	1.35 (50)	.18	4.53 (3.36)	4.59 (3.65)	0.27 (53)	.81	106.19 (24.74)	111.91 (23.28)	2.29 (76)	.03
Phase 2 (incentive)	3.05 (1.52)	2.99 (1.27)	0.55 (81)	.59	3.76 (1.92)	3.93 (2.75)	0.12 (52)	.91	5.93 (3.05)	5.98 (4.48)	0.64 (54)	.52	106.14 (26.05)	108.52 (24.56)	0.89 (80)	.38

Protective Behavioral Strategies

Overall, there was a significant increase in students' confidence in using protective behavioral strategies in drinking from baseline ($Mean_{pre}$ 103.58, SD 24.26) to postintervention ($Mean_{post}$ 106.97, SD 23.20; t_{233}=2.393, *P*=.02), such that students reported more confidence engaging in more protective behaviors while drinking to limit alcohol-related problems from drinking from baseline to postintervention.

As seen in Table 1, despite an increase in students' self-reported confidence in using protective behavioral strategies from baseline to postintervention for all 3 groups, the effect was not significant for students in the phase 1 group (t_{75}=0.98, *P*=.33), and the phase 2 incentive group (t_{80}=0.89, *P*=.38). There was,

however, a significant increase in confidence in using protective behavioral strategies for the phase 2 no incentive group (t_{76}=2.29, P=.03).

Alcohol Consumption in the Past Month

Overall, there was no significant change to the average number of days per week in the last month involving alcohol consumption, from baseline ($Mean_{pre}$ 3.23, SD 1.43) to postintervention ($Mean_{post}$ 3.25, SD 1.39; t_{232}=0.07, P=.95). There were also no significant changes to students' average number of drinks per weekend in the last month from baseline ($Mean_{pre}$ 3.52, SD 1.90) to postintervention ($Mean_{post}$ 3.44, SD 2.20; t_{164}=0.85, P=.40), nor were there significant changes to students' maximum number of drinks consumed in the last month from baseline ($Mean_{pre}$ 5.43, SD 3.46) to postintervention ($Mean_{post}$ 5.51, SD 3.83; t_{173}=0.20, P=.84).

As seen in Table 1, there were no significant changes to students' self-reported drinking frequency in the past month from baseline to postintervention for students in the phase 1 group (drinking frequency in the past month, t_{75}=0.54, P=.59; the average number of drinks per weekend in the last month, t_{60}=0.11, P=.91; the maximum number of drinks consumed in the last month, t_{65}=0.79, P=.43). This was also the case for the phase 2 no incentive group (drinking frequency in the past month, t_{74}=0.22, P=.83; the average number of drinks per weekend in the last month, t_{50}=1.35, P=.18; the maximum amount of drinks consumed in the last month, t_{53}=.27, P=.81), and the phase 2 incentive group (drinking frequency in the past month, t_{81}=0.55, P=.59; average number of drinks per weekend in the last month, t_{52}=0.12, P=.91; the maximum amount of drinks consumed in the last month, t_{54}=0.64, P=.52).

Usability of Bhoos

There was no significant effect of the study phase or incentives on self-reported usability of bhoos ($F_{2,\ 234}$=0.097, P=.908, η^2=.001). Usability scores for students in phase 1 ranged from 22.5 to 100 (mean 71.22, SD 17.21). Scores for students in the phase 2 nonincentive group ranged from 35 to 100 (mean 71.75, SD 16.96), and 37.50 to 100 (mean 72.38, SD 15.69) for those in the phase 2 incentive group. The average usability score (mean 71.80, SD 16.54) placed bhoos in the third quartile of all programs evaluated by the SUS [37].

Engagement With Bhoos

Nearly all participants (93.33%, 238 of 255) in study 1 downloaded the app. The majority of participants (85.49%, 218 of 255) logged at least 1 drink or dry day. Roughly two-thirds (160 of 255) of the participants logged at least 1 alcoholic drink, whereas nearly 3-quarters (189 of 255) logged at least 1 dry day. Slightly more than half (145 of 255) logged at least 1 streak. On average, participants used the app for 12.67 days (SD 9.96 d) of the 28 days of the intervention period.

Overall, providing added incentives did not seem to impact how students used the app to log their drinks. Among those in the phase 2 group, students randomized to receive incentives logged, on average, 11.16 drinks (SD 8.92) while those randomized to receive no added incentives logged, on average, 13.04 drinks (SD 16.62), t_{130}=0.924, and P=.357. Moreover, students randomized to receive incentives logged, on average, 15.50 dry days (SD 9.39) while those randomized to receive no added incentives logged, on average, 15.90 dry days (SD 8.81), t_{169}=0.282, and P=.78.

Qualitative Feedback From Focus Groups

The feedback obtained from focus groups revealed several common themes. Students found the bhoos app to be visually appealing and user-friendly. They expressed that the drinking chart within the app raised their awareness of their drinking habits over time, and they appreciated the ability to review their drinking history within the app. However, some students felt that the psychoeducational content within the app was too static, and they suggested that incorporating videos would be beneficial. Additionally, many students expressed a desire to track a broader range of secondary behaviors, including mood and stress.

In response to this feedback from the focus groups, we made several iterative improvements to the bhoos app in preparation for the next pilot study (study 2). Specifically, we enhanced the psychoeducational content by adding 4 short videos on relevant topics, including information on helping an intoxicated friend, knowing the signs of alcohol overdose, learning about alcohol tolerance, and understanding standard drink amounts. We also included more information on safety tips while drinking. We refined the app's functionality for users to track their mood or stress to identify patterns related to drinking events. Last, known bugs and glitches that students reported while using the app were addressed, enhancing bhoos' overall performance and reliability.

Discussion

Collectively, the results from study 1 provide preliminary support for the feasibility and usability of bhoos among college students in the United States. While the students in this sample did not report a reduction in drinking frequency, findings indicate that they were more confident in their ability to engage in protective behaviors while drinking, potentially enhancing their safety. Both app engagement data and mixed methods results confirm the usability of bhoos, while providing added monetary incentives did not seem to impact any of the observed outcomes or how students used bhoos to track their drinking. The qualitative feedback from students was instrumental in identifying areas for app improvement to enhance usability and engagement. Building on these findings, study 2 was conducted to examine whether the impact of bhoos on drinking-related outcomes would be replicated in an independent sample of college students.

Study 2

Methods

Study Overview and Participants

Eligibility criteria were identical to study 1. College students were recruited over the 2022 Fall semester using advertisements in dining halls. Although the initial goal was to enroll up to 200

students, the recruitment timeline was hampered by the continuation of the COVID-19 pandemic and a tragic event that occurred on university grounds on November 13th, 2022 (a shooting on University grounds that resulted in the murders of 3 students). The latest baseline questionnaires were completed before the event and enrollment of new participants was halted after the event. Participants who completed baseline questionnaires were permitted to complete the study and complete the postintervention questionnaires. In total, 43 students were recruited (60% students self-identified as women; 24 students self-identified as White, 12 students self-identified as Asian or Native Hawaiian, 2 students self-identified as Black, and 5 students self-identified as multiracial). Once again, assessments were administered at baseline and postintervention, 28 days later. All participants received gift cards via the web as compensation for completing the baseline (US $20) and postassessments (US $25). An added incentivization group was not included in study 2.

Measures and Plan for Analyses

The same self-report measures were administered in study 2 as in study 1. Specifically, baseline alcohol use severity was assessed by the 10-item AUDIT [29] (α=0.82). Alcohol consumption in the past month was assessed at baseline and postintervention with the 3-item measure used in study 1. Each item was treated as a separate single-item scale. The modified 20-item Protective Behavioral Strategies Scale [31-33] was administered at baseline (α=0.90) and postintervention (α=0.91) to assess students' confidence in using protective behavioral strategies. Finally, the usability of the bhoos app was assessed postintervention using the SUS [36] (α=0.75).

Paired *t* tests were used to investigate short-term changes in drinking and protective behaviors from baseline to follow-up. Due to the limited sample size, if the normality assumption was not met some analyses were computed again with the paired Wilcoxon Signed Rank Test. This did not change the interpretation of any of the results]. Analyses were performed using R (version 4.3.3; R Core Team). App use is described using descriptive statistics.

Results

Baseline Alcohol Use Severity

Of the 43 students, 25 (58%) were classified as low-risk drinkers (AUDIT Score ≤7), 11 (26%) were classified as hazardous drinkers (AUDIT Score between 8 and 15), and 6 (14%) were classified as alcohol dependent drinkers (AUDIT score >15).

Protective Behavioral Strategies

As expected, there was a significant increase in students' confidence in using protective behavioral strategies after using bhoos from baseline ($Mean_{pre}$ 107, SD 17.19) to postintervention ($Mean_{post}$ 113.37, SD 15.87; t_{31}=-2.79, *P*=.01), such that students reported confidence in engaging in more protective behaviors while drinking to limit alcohol-related problems from drinking after the intervention compared with before.

Alcohol Consumption in the Past Month

There was a significant decrease in the average number of days per week drinking alcohol in the last month from baseline ($Mean_{pre}$ 2.32, SD 1.27) to postintervention ($Mean_{post}$ 2.06, SD 1.15; t_{33}=2.32, *P*=.031). Among students who reported drinking, there was no significant change to their typical weekend evening drink consumption from baseline ($Mean_{pre}$ 3.83, SD 2.80) to postintervention ($Mean_{post}$ 3.87, SD 2.30; t_{29}=0, *P*=.92), nor was there a significant change to the maximum number of drinks they consumed in a single occasion the last month, from baseline ($Mean_{pre}$ 5.17, SD 4.07) to postintervention ($Mean_{post}$ 5.34, SD 4.50; t_{28}=0.24, *P*=.82).

Usability of Bhoos

Usability scores ranged from 55 to 98 (out of a possible 100). Overall, students reported higher usability of the revised version of bhoos (mean 77.93, SD 11.92) than in the original version tested in study 1. The average score placed bhoos in the upper 75% (fourth quartile) of all programs evaluated by the SUS [37].

Discussion

Collectively, the findings from study 2 reproduce the drinking-related results from study 1. Specifically, the findings of study 2 replicate the finding that bhoos is associated with an increase in confidence in using protective behaviors while drinking. It is worth noting that students in study 2 also reported reduced frequency of drinking, which may have resulted from improvements to the app from study 1, which is supported by our finding that students rated the app as more usable in study 2 than in study 1.

Overall Discussion

Principal Findings

Developing effective, accessible, and scalable interventions to address excessive drinking among college students is critical due to the significant public health concerns posed by alcohol misuse on college campuses. In 2 studies, we observed promising and consistent results regarding the impact and usability of the bhoos app, which effectively promoted confidence in using protective behaviors related to drinking among US college students.

The results suggest that bhoos' features, such as drink tracking and dynamic feedback, help to encourage responsible drinking behaviors, including monitoring alcohol intake, planning for safe transportation after drinking, or seeking help when needed. The ability to provide personalized, real-time feedback increases the relevance of the app to the individual needs and experiences of its users. By offering recommendations based on the user's drinking patterns and risk factors, bhoos may engage users more effectively than a generic one-size-fits-all program which enhances the likelihood of behavior change. Moreover, this more personalized approach to providing risk feedback aligns with the principles of Motivational Interviewing [38,39] and follows proven strategies for promoting behavior change [40-42]. Smartphone app-delivered interventions like bhoos offer several advantages over traditional approaches, including

the ability to deliver actionable feedback at critical moments. Additionally, they provide the potential for widespread accessibility and scalability. College students, in particular, maybe the most receptive to mobile apps for obtaining information and support for health-related decisions, given their high smartphone use [16]. The ease of dissemination and the low cost of smartphone apps make them a practical option for broad implementation on college campuses.

Limitations and Future Directions

The findings from our studies should be considered in light of several limitations. First, the reliance on infrequent and static measures of drinking behaviors introduces the possibility of recall bias. Moreover, the primary outcomes of both studies reflected students' confidence in using various protective behaviors while drinking and not the actual behaviors they engaged in. Future research could benefit from incorporating more ecologically valid approaches, such as ecological momentary assessment, perhaps administered within the app, to assess for actual protective behaviors related to drinking while limiting recall bias. Additionally, the pre-post design of our study limits our ability to evaluate the efficacy of bhoos, which could be better assessed through a randomized controlled trial. The short time frame between baseline and postassessment (4 weeks) restricts our understanding of the long-term sustainability of the app's effects. Future studies should explore the app's impact over longer periods, such as a full college semester. Moreover, a large percentage of students in both studies were White and female which may limit the generalizability of our findings to minorities and men. Finally, the tragic shooting that occurred on university grounds may have influenced students' drinking behaviors in study 2, although the extent of this impact is unclear. Future studies should examine how such events, and events more broadly (eg, political elections, performance of University athletic teams), affect student drinking behaviors.

General Conclusion

In summary, preliminary findings across 2 studies indicate that bhoos shows strong potential as a tool for promoting protective behaviors related to alcohol use among college students. While these studies help advance highly accessible and scalable approaches to address the consequences of binge drinking by US college students, further research is needed to fully understand the app's role in comprehensive alcohol harm reduction efforts within this population. Its personalized approach, combined with its accessibility and scalability, suggests that bhoos could be a valuable addition to the range of interventions available to address alcohol-related issues on campuses.

Acknowledgments

The authors thank the Board of Visitors and the President of the University of Virginia for funding this project through the Strategic Investment Fund. The authors also appreciate the support and guidance of the Executive Committee for the project "Reducing the Burden of Addictions in Virginia": Dr Robert Klesges, Dr Lee Ritterband, Dr Nassima Ait-Daoud Tiouririne, Dr Karen Ingersoll, Dr Christopher Holstege, and Dr Margaret Shupnik. Finally, the authors thank the undergraduate research assistants for this study: Grace Biegger, Aasritha Natarajan, David Vann, and Shruti Vachhani. We would also like to thank our development team, Gabe Heath, Nicole Le, and Brendan Murphey, for the design and development of the bhoos app intervention.

Abstract

Background: Artificial intelligence (AI) chatbots have been customized to deliver on-demand support for people with mental health problems. However, the effectiveness of AI chatbots in tackling mental health problems among the general public in Hong Kong remains unclear.

Objective: This study aimed to develop a local AI chatbot and compare the effectiveness of the AI chatbot with a conventional nurse hotline in reducing the level of anxiety and depression among individuals in Hong Kong.

Methods: This study was a pilot randomized controlled trial conducted from October 2022 to March 2023, involving 124 participants allocated randomly (1:1 ratio) into the AI chatbot and nurse hotline groups. Among these, 62 participants in the AI chatbot group and 41 in the nurse hotline group completed both the pre- and postquestionnaires, including the GAD-7 (Generalized Anxiety Disorder Scale-7), PHQ-9 (Patient Health Questionnaire-9), and satisfaction questionnaire. Comparisons were conducted using independent and paired sample *t* tests (2-tailed) and the χ^2 test to analyze changes in anxiety and depression levels.

Results: Compared to the mean baseline score of 5.13 (SD 4.623), the mean postdepression score in the chatbot group was 3.68 (SD 4.397), which was significantly lower (*P*=.008). Similarly, a reduced anxiety score was also observed after the chatbot test (pre vs post: mean 4.74, SD 4.742 vs mean 3.4, SD 3.748; *P*=.005), respectively. No significant differences were found in the pre-post scores for either depression (*P*=.38) or anxiety (*P*=.19). No statistically significant difference was observed in service satisfaction between the two platforms (*P*=.32).

Conclusions: The AI chatbot was comparable to the traditional nurse hotline in alleviating participants' anxiety and depression after responding to inquiries. Moreover, the AI chatbot has shown potential in alleviating short-term anxiety and depression compared to the nurse hotline. While the AI chatbot presents a promising solution for offering accessible strategies to the public, more extensive randomized controlled studies are necessary to further validate its effectiveness.

Trial Registration: ClinicalTrials.gov NCT06621134; https://clinicaltrials.gov/study/NCT06621134

KEYWORDS

AI chatbot; anxiety; depression; effectiveness; artificial intelligence

Introduction

An estimated 1 in 7 people in Hong Kong experience a common mental disorder in their lifetime, with anxiety and depression being the two most common mental health issues in Hong Kong, accounting for 19% and 14% among the generation population, respectively [1,2]. Nearly three-quarters of individuals experiencing a mental health disorder do not seek professional help for various reasons such as high cost of services, fear of judgment, or stigma [3]. To address these potential problems, artificial intelligence (AI) chatbots have been incorporated into digital interventions, particularly web- and smartphone-based apps, to enhance user experience and optimize individualized mental health [4,5]. Chatbots can provide a safe and confidential space for people to seek help for their mental health concerns. Additionally, they are available at any time throughout a study, making them a convenient option for those who may lack access to traditional mental health services or require support beyond regular business hours. Further efforts toward strengthening implementation of chatbots are needed, and their application to the general public should be explored to improve perceptions of general mental health and increase awareness of the importance of premedical interventions in the future [6].

Chatbot models have been developed in various countries and are widely used in psychology and clinical practice. For example, Tess, a psychological AI service, has been tailored to provide immediate assistance to caregiving specialists, individuals receiving care, and family caregivers within a nonprofit organization in the United States and Canada [7]. Among university students, chatbot applications have showed a significant decrease in anxiety symptoms [8]. Anna, an AI-driven chatbot, simulates the function of a therapist and offers gamified versions of evidence-based activities drawn from various therapeutic approaches. Participants who engaged in activities facilitated by Anna provided more detailed responses containing a higher number of positive relational terms [9]. A review of users' opinions, satisfaction, and attitudes regarding depression and anxiety chatbot apps found that users felt supported and confident while they used apps that were easy to navigate, affordable, and free of cost [10]. In Hong Kong, the first AI-driven Cantonese psychological support tool, the Pai.ACT mobile app, was developed for parents of children with special education needs [11]. However, there is currently a lack of evidence on the effectiveness of AI chatbots in tackling mental health problems in the general public.

Given the risk of anxiety and depression in Hong Kong and the limited availability of mental health services during the epidemic, this study aimed to compare the effectiveness of the developed AI chatbot with that of a conventional nurse hotline in alleviating psychological anxiety and depression in the general public. Additionally, this study also aimed to understand user satisfaction with chatbot usage and gather preliminary data for larger randomized controlled trials to advocate for the AI chatbot as a psychological support tool for individuals seeking information on the chatbot platform.

Methods

Recruitment

This study was designed as a randomized controlled trial (RCT) with two parallel groups. Participants were parents recruited through two school principal's networks. The inclusion criteria included (1) being able to use smartphones proficiently to interact with the AI chatbot, (2) being fluent in Chinese language used in the study to effectively communicate with the AI chatbot, and (3) providing an electronic consent form. Parents who were unwilling or unable to commit to the entire research process and had difficulties in reading and understanding Chinese were excluded. Invitation letters were sent to kindergarten and primary school principal groups from chief schools, and 124 parents responded to this study and provided an electronic consent form. Participants were then randomly allocated in a 1:1 ratio to either the AI chatbot or the nurse hotline group using block randomization with blocks of four. Participants immediately filled out the posttest questionnaires after communicating with the AI chatbot or nurse. Those who did not respond immediately received reminders until they completed the posttest questionnaires. Participants with risky mental health problems were followed up by phone calls and were encouraged to ask to connect with necessary medical services and mental health clinical departments.

Ethical Considerations

This study was approved by the Institutional Review Board of the University of Hong Kong/Hospital Authority Hong Kong West (approval number: UW21-344). Informed consent was obtained from all participants in the study, ensuring that they were fully aware of the nature and possible consequences of their participation. Participants were informed that they had the right to opt out at any time without penalty. The original consent and approval covers secondary analysis without additional consent. Data collected from participants were deindentified to ensure privacy and confidentiality. Identifying information, including names, initials, or hospital numbers, was removed from all datasets to protect participant identities. Participation was voluntary, and individuals were informed that no financial or material incentives would be provided. Consolidated Standards of Reporting Trials (CONSORT) reporting guideline was adhered to in this study [12].

AI Chatbot Development Procedures

The development of the AI chatbot involved 7 key steps. First, the developer analyzed requirements by understanding common queries and focusing on providing accurate information to the public and assisting nurses. Relevant data was then collected from credible sources, and natural language processing (NLP) algorithms were used to train a robust model on diverse questions and answers. By integrating large language models, the chatbot could provide detailed responses. Next, the developer designed and developed the backend infrastructure, including databases, application programming interfaces, and integration with University of Hong Kong's website and WhatsApp. Extensive testing and validation ensured the chatbot's accuracy and user-friendliness, with a beta version tested by selected users. Finally, the chatbot was deployed on University of Hong

Kong's website and made accessible through WhatsApp, with a nurse hotline version developed to assist health care professionals in handling public inquiries.

The AI chatbot system comprises several essential components to provide accurate and relevant information. It begins with context identification, where the chatbot analyzes keywords and phrases to understand the user's query, ensuring accurate interpretation and relevant response. Next, the system conducts query analysis using NLP techniques to determine the user's intent and extract specific details such as dates, locations, and vaccination information. The query response system then leverages the trained NLP model and large language model–generated responses to provide accurate and contextually appropriate answers tailored to users' needs. Finally, the chatbot relies on a regularly updated and comprehensive dataset containing the latest information on COVID-19 vaccinations, government regulations, and health care procedures, ensuring the delivery of reliable and accurate responses.

Questionnaires

The Patient Health Questionnaire-9 (PHQ-9) is a self-assessment tool consisting of 9 questions that measure the frequency and severity of depressive symptoms over the last 2 weeks. Each question is derived from the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (*DSM-IV*) criteria and is rated on a scale of 0 (not at all) to 3 (almost daily) [13]. The Generalized Anxiety Disorder Scale-7 (GAD-7) is a 7-item self-report scale that evaluates the frequency and severity of anxious thoughts and behaviors during the last 2 weeks. Items are based on the diagnostic criteria of the *DSM-IV* and scored from 0 (not at all) to 3 (nearly every day) [14]. The service satisfaction survey is a 3-item questionnaire for participants to report their degree of satisfaction after using the two platforms. The rating score ranges from 0 to 10, representing an increasing satisfaction from not at all likely to extremely likely. Based on the standardized cutoff that determines the severity of anxiety and depression, participants were divided into two groups: the no-risk group (total score<4) and the risk group (total score>4) [15].

Statistical Analysis

Quantitative variables were tested for normal distribution using the Kolmogorov-Smirnov test. Normally distributed continuous variables were expressed as mean (SD) and categorical variables were expressed as numbers and percentages. A per-protocol analysis was performed for all outcomes when comparing the 2 groups. The independent *t* test (2-tailed) was employed to compare the preanxiety or predepression, postanxiety or postdepression, pre-post difference scores, and service satisfaction between the AI chatbot and nurse hotline groups, respectively. The paired *t* test (2-tailed) was used to compare scores before and after group chat. Linear regression was conducted to analyze the difference in posttest scores between the AI chatbot and nurse hotline groups adjusted by pretest scores. Categorical variables were compared with the χ^2 test. All analyses were conducted using SPSS software (version 29.0; IBM Corp).

Results

From October 2022 to March 2023, all the participants (N=124) answered prequestionnaires, and 62 (62/62, 100%) participants in the AI chatbot group and 41 (41/62, 66.1%) in the nurse hotline group completed both the pre- and postquestionnaires (Figure 1). Comparisons within groups before and after the test are displayed in Table 1 and Figure 2. Compared to the mean baseline score of 5.13 (SD 4.623), the mean postdepression score 3.68 (SD 4.397) was significantly lower in the chatbot group (*P*=.008). Similarly, a reduction in anxiety score was also observed after using the chatbot test (pre vs post: mean 4.74, SD 4.742 vs mean 3.4, SD 3.748; *P*=.005).

Figure 1. Diagram of the study design. AI: artificial intelligence. PHQ-9: Patient Health Questionnaire-9; GAD-7: Generalized Anxiety Disorder Scale-7.

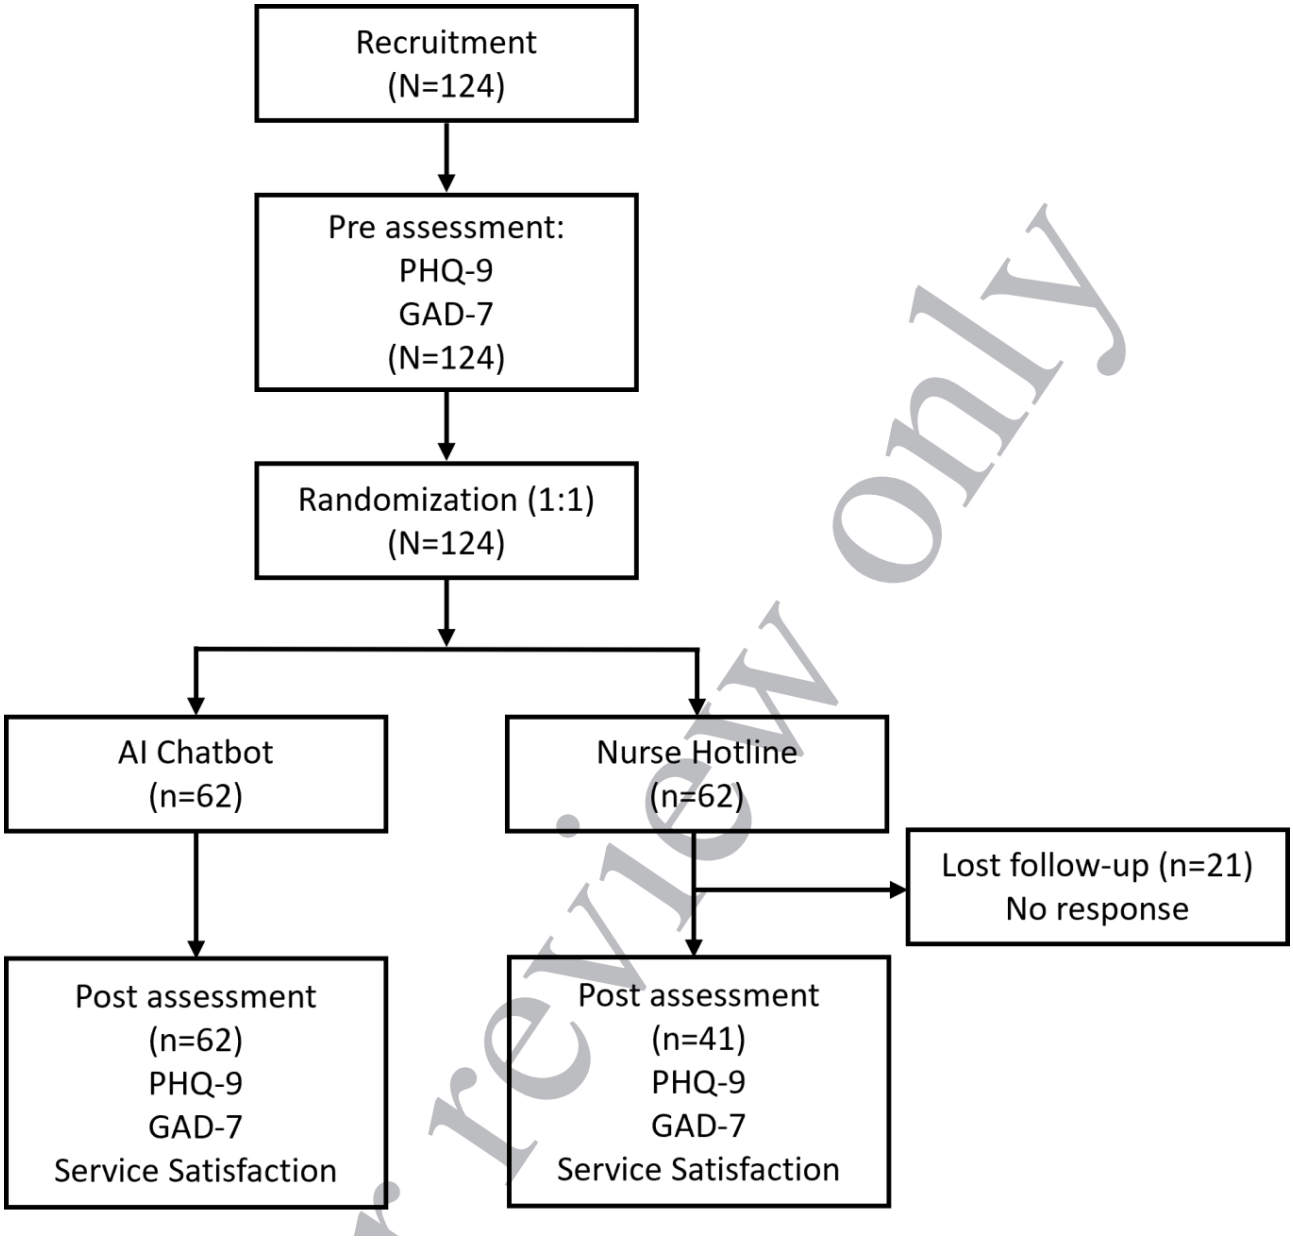

Table . Comparison of the anxiety and depression scores within groups before and after the test.

Questionnaires and groups (N=124)[a]	Pretest score, mean (SD)	Posttest score, mean (SD)	*P* value
PHQ-9[b]			
AI[c] chatbot (n=62)	5.13 (4.632)	3.68 (4.397)	.008
Nurse hotline (n=41)	5.46 (6.4)	4.76 (4.346)	.28
GAD-7[d]			
AI chatbot (n=62)	4.74 (4.742)	3.4 (3.748)	.005
Nurse hotline (n=41)	4.37 (5.439)	4.05 (4.455)	.63

[a]n=21 participants were lost to follow up.

[b]PHQ-9: Patient Health Questionnaire-9.

[c]AI: artificial intelligence.

[d]GAD-7: Generalized Anxiety Disorder Scale-7.

Figure 2. Comparison of anxiety and depression scores within groups pre- and postintervention. GAD-7: Generalized Anxiety Disorder Scale-7; PHQ-9: Patient Health Questionnaire-9; ns: nonsignificant. **P<.05.

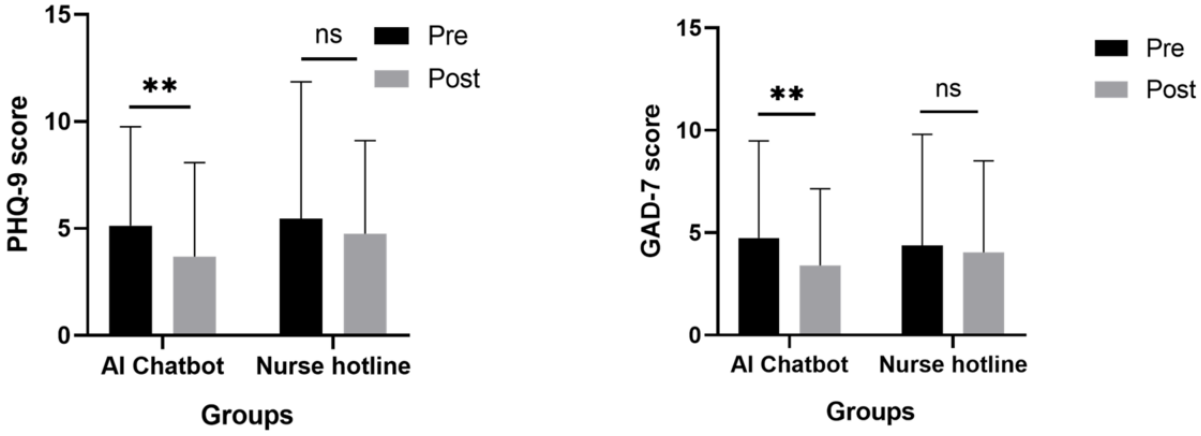

Table 2 shows there were no statistically significant differences at baseline between groups in depression (P=.76) and anxiety scores (P=.71). Although the postdepression and postanxiety scores in the chatbot group were slightly lower than those in the nurse hotline group, there was no statistical difference (all Ps>.05). No statistically significant difference was observed in service satisfaction between the 2 service platforms (P=.32). In the nurse hotline group, there were no notable differences in depression and anxiety scores before and after the test.

Table . Comparison of the before and after PHQ-9[a], GAD-7[b], and service satisfaction scores between the AI chatbot and nurse hotline groups.

Variables	AI chatbot scores (n=62), mean (SD)	Nurse hotline scores (n=41), mean (SD)	P value[c]
Pre–PHQ-9	5.13 (4.63)	5.46 (6.4)	.76
Post–PHQ-9	3.68 (4.40)	4.76 (4.35)	.43
Pre–GAD-7	4.74 (4.74)	4.37 (5.44)	.71
Post–GAD-7	3.40 (3.75)	4.05 (4.46)	.22
Service satisfaction	16.11 (6.88)	17.39 (5.59)	.32

[a] PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Scale-7.

[c]Independent t test.

No significant variations were observed in the pre-post score differences for either depression (P=.38) or anxiety scores (P=.19) between the 2 groups (Table 3).

Table . Comparison of the pre-post anxiety and depression score differences between the artificial intelligence (AI) chatbot and nurse hotline groups.

Variables	Groups		
	AI chatbot (n=62), mean (SD)	Nurse hotline (n=41), mean (SD)	P value
Pre-post differences			
PHQ-9[a]	−1.452 (4.203)	−0.707 (4.161)	.38
GAD-7[b]	−1.339 (3.635)	−0.317 (4.15)	.19

[a]PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Scale-7.

[c]Independent t-test was used to calculate P value.

The various test groups were not associated with the postdepression score (β=−.902, *P*=.18) or the postanxiety score (β=−.845, *P*=.17), after adjusting the prescores (Table 4).

Table . Regression analysis on the posttest score between the artificial intelligence chatbot and nurse hotline adjusted by pretest score (n=103).

Questionnaires and groups	β estimate	Standard error	*t* test (*df=100)*	*P* value
Post–PHQ-9[a] (ref: nurse group)

[a]PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Scale-7.

Based on the PHQ-9 and GAD-7 cutoff, the pre- and postscores were categorized into no-risk group and risk groups. No significant differences were observed in the prevalence of anxiety and depression before and after using the nurse hotline or AI chatbot (Table 5).

Table . Comparison of the anxiety and depression prevalence before and after using the nurse hotline and artificial intelligence (AI) chatbot among participants.

Groups	No-risk group (score≤4), n (%)	Risk group (score>4), n (%)	*P* value
Pre–PHQ-9[a]			
Nurse hotline (n=41)	27 (65.9)	14 (34.1)	.20
AI chatbot (n=62)	33 (53.2)	29 (46.8)	
Post–PHQ-9[a]			
Nurse hotline (n=41)	26 (63.4)	15 (36.6)	.33
AI chatbot (n=62)	45 (72.6)	17 (27.4)	
Pre–GAD-7[b]			
Nurse hotline	27 (65.9)	14 (34.1)	.34
AI chatbot	35 (56.5)	27 (43.5)	
Post–GAD-7[b]			
Nurse hotline	27 (65.9)	14 (34.1)	.47
AI chatbot	45 (72.6)	17 (27.4)

Discussion

Principal Results

This study is among the first in Hong Kong to compare the effectiveness of AI chatbots and nursing hotlines in addressing mental health–related inquiries. The AI chatbot proved effective in reducing anxiety and depression during the COVID-19 outbreak and was comparable to the conventional nursing hotline. It suggests the potential use of AI chatbots as a complementary approach in mental health interventions, particularly when AI chatbots can provide timelier and uninterrupted 24-hour support to users in need during the challenging periods such as a pandemic.

Previous research comparing the effectiveness of the AI chatbot and humans in improving mental health is controversial. Our study found that both the AI chatbot and nurse hotline had similar effects in alleviating depression and anxiety. The results are consistent with another study comparing the text-only chatbot and voice-based digital human interactions as responders to mental health questions, which reported that the text-only chatbot was more user-friendly, although there were no significant differences in electroencephalography measurements [16]. No differences were observed in another RCT comparing the effects of AI chatbot (ie, ChatGPT-3.5) and nurse education on preoperative anxiety reduction among groups [17]. However, one study comparing physician and AI chatbot responses to patient questions posted on a public social media forum found that the chatbot generated higher quality and empathetic

responses to patient questions than physicians [18]. Additionally, the follow up process took less time for the nurse hotline group compared to the chatbot group. This was primarily because participants in the nurse hotline group were quicker in responding to follow up questionnaires while the chatbot group typically required more than one attempt to gather responses. It is feasible to use the AI chatbots to provide instant information to users about mental health knowledge and basic strategies to dissipate their temporary anxiety and depressed mood. However, the AI chatbot can only be a facilitator, and humans will not be replaced in the long-term professional treatment. The sample size in the above-mentioned studies is very small, which may have limited the power of statistical analysis. Therefore, more RCTs with larger sample sizes are necessary to confirm differences between the AI chatbot and human-based services.

Our study showed a significant reduction in the levels of anxiety and depression after using the AI chatbot. This finding is supported by a study from Argentina, which showed a substantial decrease in anxiety symptoms in university students using *Tess* [8]. Another study reported that the use of the Elomia chatbot for 4 weeks resulted in a significant decrease in the symptoms of anxiety and depression along with reduced negative effects [19]. AI chatbots can offer information to users in a quick and easy format. They can also be programmed to answer specific questions about a certain condition, such as what to do during a medical crisis or what to expect during a medical procedure. The AI chatbot could lower the barriers to care by helping patients access help more quickly and efficiently [20]. AI chatbots appear to have a positive impact on depression and anxiety in a wide range of populations, including university students [8], short-course treatment patients [21], and preoperative patients [17]. The potential benefit of chatbot–assisted mental health support is that it can provide helpful information about depressive moods, especially for users who have difficulty in communicating emotions to other humans [22]. Besides, the chatbot offers real-time relief, emotional support, and instant messages on basic knowledge about health-related questions. AI chatbots can help reduce anxiety and depression by providing accessible, anonymous, consistent, and immediate emotional support. They serve as a valuable supplement to conventional therapy and mental health care, offering users a safe space to express their feelings and find effective coping strategies.

Our study differs from previous ones by addressing a research gap in the broader population. Earlier studies primarily concentrated on specific groups, such as college students aged 18-33 [8], younger individuals aged 19-23 [19], and older adults aged 60 years [17]. The sample size in our study (N=124) aligns with past studies, which typically included approximately 100 participants. A study with a larger sample size of 412 younger participants [19] also found AI chatbots to be effective in alleviating anxiety and depression symptoms. Notably, our study was conducted during the COVID-19 pandemic, unlike previous studies, which were conducted under normal circumstances. Hence, additional research is necessary to understand the efficacy and impact of AI chatbots across different age groups, demographics, and environmental contexts.

Our study was carried out during the COVID-19 outbreak, revealing that AI chatbot interventions are versatile and can be applied in various situations, such as during future pandemics or for disseminating information to prevent other diseases. There is great potential in AI chatbot designing and application during an epidemic like COVID-19 [23]; AI chatbots not only help in reducing depression and anxiety at any given time but also can be embedded into the health care systems, to help patients describe their symptoms and provide preliminary guidance on whether they need to seek medical attention [24]. This can assist in triaging patients based on the severity of their symptoms. They can help patients book appointments with health care providers, reducing the burden on administrative staff. AI Chatbots can send reminders to patients to take their medications on time, improving medication adherence [24]. They can provide ongoing emotional support and coping strategies for individuals dealing with mental health issues like anxiety, depression, and stress. This can complement traditional therapy and make mental health care more accessible. Chatbots can also deliver personalized health education to patients, helping them understand their conditions, treatment options, and preventive measures.

The findings of this study comparing AI chatbots and nurse hotlines in alleviating the levels of anxiety and depression during the COVID-19 pandemic can be generalized to a certain extent, given that the general population was the target group. This broad target population ensures that the results are applicable to a wide range of individuals who may have experienced similar mental health challenges during the pandemic. However, the generalizability may be limited by factors such as the specific characteristics of the sample used in the study, including their demographics and the severity of their anxiety and depression symptoms. Additionally, the dynamic nature of AI chatbots, which can be influenced by various factors such as the phrasing of questions and ongoing optimization processes, may also affect the generalizability of the results. The study's design and methodology provide a solid foundation for replicability. The use of an RCT framework, which is a robust design for evaluating interventions, increases the likelihood that similar studies can be conducted with comparable results. The clear documentation of the study's procedures, including the recruitment process, data collection methods, and statistical analysis techniques facilitates replication by other researchers. Furthermore, the study's focus on a common and significant issue—mental health during a pandemic—ensures that there is a continued interest and relevance in conducting similar studies. However, replicability may be challenged by the need for access to similar populations and resources, as well as the evolving nature of AI chatbot technology, which may require adaptation of the intervention for future studies.

Although AI chatbots have a potential complementary function in mental health and health-related fields, certain drawbacks must be considered. For example, the safety and privacy concerns remain unclear [25]. Chatbots are unable to deliver the emotional support and personal bond that a certified mental health expert may provide. They cannot deliver a diagnosis or management strategy for mental health disorders. Therefore, it is crucial to use AI chatbots as a complement to, rather than a

substitute for, specialized mental health services. Moreover, further refinement to the AI chatbot is necessary for establishing an integrated system for recognition-alert-reporting system for mental health problems. After early detection and identification of depression and anxiety, the AI chatbot should be designed to automatically send self-regulation advice to the users to handle their negative emotions as well as send reminder messages to encourage them to seek medical services. Additionally, the question coverage of the AI chatbot is limited; it covers common mental health–related questions that may overlook the scope of other health problems. The scope of the population using chatbots should be expanded among the public. Further studies are required to draw solid conclusions about the effectiveness and safety of chatbots.

Limitations

One of the limitations of our study is the small sample size. Toward the end of the COVID-19 outbreak, there was a notable lack of enthusiasm among parents to participate in this study. Only two school principal groups were involved, which may have introduced a selection bias. Additionally, the study period was too short to recruit sufficient participants; however, the preliminary results showed a significant reduction in anxiety and depression after using the AI chatbot, supporting the applicability of using AI chatbots to relieve negative emotions during the next epidemic crisis. Demographic data and other confounding factors were not collected due to privacy concerns; these factors will be included in the following larger randomized control study.

Conclusions

The AI chatbot is as effective as the nurse hotline in answering mental health–related questions. Besides, the AI chatbot can reduce short-term anxiety and depression levels compared to the nurse hotline. The developed AI chatbot shows promise as a complementary tool to provide available intervention strategies to the public, particularly for families with limited access to mental health services. This study provides insights into the potential application of using AI chatbots to provide immediate information to the public and mitigate public emotional distress during future epidemic emergencies.

Abstract

Background: Hybrid work is the new modus operandi for many office workers, leading to more sedentary behavior than office-only working. Given the potential of digital interventions to reduce sedentary behavior and the current lack of studies evaluating these interventions for home office settings, it is crucial to develop digital interventions for such contexts involving all stakeholders.

Objective: This study aimed to reach expert consensus on the most feasible work strategies and the most usable digital elements as a delivery method to reduce sedentary behavior in the home office context.

Methods: A modified Delphi study including 3 survey rounds and focus groups was conducted to achieve consensus. The first Delphi round consisted of two 9-point Likert scales for assessing the feasibility of work strategies and the potential usefulness of digital elements to deliver the strategies. The work strategies were identified and selected from a scoping review, a systematic review, and 2 qualitative studies involving managers and employees. The median and mean absolute deviation from the median for each item are reported. The second round involved 2 ranking lists with the highly feasible strategies and highly useful digital elements based on round 1 responses to order the list according to experts' preferences. The weighted average ranking for each item was calculated to determine the most highly ranked work strategies and digital elements. The third round encompassed work strategies with a weight above the median from round 2 to be matched with the most useful digital elements to implement each strategy. In total, 4 focus groups were additionally conducted to gain a greater understanding of the findings from the Delphi phase. Focus groups were analyzed using the principles of reflexive thematic analysis.

Results: A total of 27 international experts in the field of occupational health participated in the first round, with response rates of 86% (25/29) and 66% (19/29) in rounds 2 and 3, respectively, and 52% (15/29) in the focus groups. Consensus was achieved on 18 work strategies and 16 digital elements. Feedback on activity progress and goal achievement; creating an action plan; and standing while reading, answering phone calls, or conducting videoconferences were the most feasible work strategies, whereas wrist-based activity trackers, a combination of media, and app interfaces in smartphones were the most useful digital elements.

Moreover, experts highlighted the requirement of combining multiple levels of strategies, such as social support, physical environment, and individual strategies, to enhance their implementation and effectiveness in reducing sedentary behavior when working from home.

Conclusions: This expert consensus provided a foundation for developing digital interventions for sedentary behavior in home office workers. Ongoing interventions should enable the evaluation of feasible strategies delivered via useful digital elements in home office or hybrid contexts.

Introduction

Background

Workplace sedentary behavior (SB) is associated with poorer health and work-related outcomes, such as musculoskeletal disorders, reduced mental and occupational well-being, job dissatisfaction, and fatigue [1-4]. According to the World Health Organization, the workplace is one of the main settings to reduce SB in the adult population [5], with office workers, who spend an average of 77% of their working day sitting [6], being a key target group [7]. After the COVID-19 pandemic, hybrid work, alternating work in the office and at home, has become the new work paradigm for many desk-based jobs [8-10]. Hybrid work results in even higher levels of SB than working solely in the office [11], increasing the risk of musculoskeletal health problems, mental health issues, and reduced work productivity [11,12].

Developing strategies to reduce and break up workplace SB, replacing it with activities other than sitting, such as walking or standing, has been the focus of recent studies [13,14]. In particular, the use of digital strategies in desk-based jobs (eg, delivered via mobile phone, activity tracker, or desktop computer) has the potential to provide scheduled prompts, deliver information, give automated tailored feedback, and mediate organizational support and social influences [15]. Recent evidence has highlighted the capability of digital interventions to reduce workplace SB and its associated harmful effects on health and work-related outcomes among office workers [16-18]. However, this research has focused on the traditional office environment, with a dearth of research available on the use of digital interventions to reduce of employees' SB while working remotely or undertaking hybrid work [19,20].

Multicomponent digital interventions that combine environmental and organizational changes and provision of information and counseling have been reported as more effective than single-component interventions in reducing occupational SB among office workers [16,21]. In addition, the grounding of interventions in a theory of behavior change is key in the success and behavior maintenance of multicomponent interventions [22-24]. Given the limited evidence base on the effectiveness of interventions targeting hybrid work, it is crucial to develop multicomponent digital interventions grounded in sound theory of behavior change to reduce occupational SB among home office workers.

Objectives

To contribute to a successful implementation of an intervention and, thereby, to its effectiveness, involving stakeholders such as researchers, experts in the addressed topic, and the target population in the development of interventions is necessary to identify needs, priorities, and potential solutions [25]. A previous qualitative study identified which factors influenced employees' ability to reduce SB when working from home from the employers' perspective, whereas additional qualitative evidence identified the factors influencing the reduction in SB from the employees' perspective [26]. This study aimed to go beyond the existing research gaps to incorporate expert opinions to gain a complete picture of all stakeholders and reach consensus on the feasibility of digital work strategies to reduce SB in a home office context. Therefore, the aim of this study was to reach expert consensus on the most feasible and usable digital work strategies as a delivery method to reduce SB in a home office context.

Methods

Design

A modified Delphi study was used to elicit a consensus from a spectrum of experts in the field of occupational health. It is a flexible approach combining quantitative and qualitative data. Qualitative data can be collected before, after, or between Delphi rounds [27,28]. This study encompassed 3 survey rounds and subsequent web-based focus group sessions. This study is part of the initial modeling of a multicomponent intervention and of a larger European project (ie, the Click2Move program) aimed at tackling the challenge of occupational sedentarism in hybrid office workers.

This study was based on the recommendations of the Conducting and Reporting Delphi Studies guidelines [29] and the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [30].

Ethical Considerations

This project was approved by the Research Ethics Committee of the University of Vic–Central University of Catalonia (250/2023). This study was conducted in accordance with relevant guidelines and regulations. The invitation email contained general information about the study and a link with further details of the participant information statement, including assurances of anonymity and confidentiality and emphasizing that participation was completely voluntary and participants

could withdraw at any time without any consequences. In compliance with ethical research practices, digital informed consent was obtained from all participants before initiating the survey. No incentives were provided to the participants for their involvement.

Participants and Recruitment

International experts (N=57) identified as leading or established researchers in the field of occupational health (with a specific focus on modification of physical activity [PA] behavior in the workplace), well-being, or computer- or desk-based jobs specialists identified by the research team were invited via email to participate. The experts were selected through a search of published articles that identified highly active authors in the field, whereas the job specialists were identified from professional networks of the involved institutions. The exclusion criterion was not being able to understand and communicate in English.

To maximize participation in the Delphi survey, a reminder email was sent within 1 week. After completing the 3 Delphi rounds, participants who signed the informed consent form for the Delphi study (29/57, 51%) were invited via email to participate in a focus group.

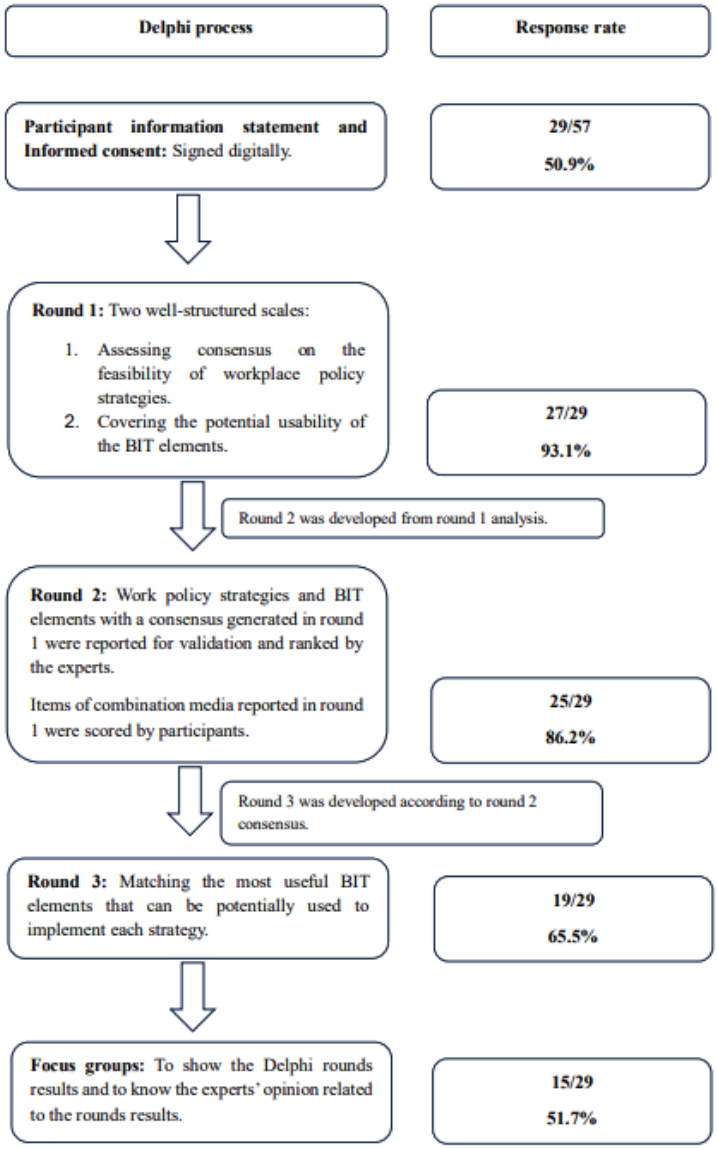
Procedure

Delphi Survey

Overview

In total, 3 survey rounds were conducted using the LimeSurvey software (LimeSurvey GmbH; Multimedia Appendix 1), which were piloted by 4 members of the research team to ensure the appropriateness of the questionnaire items, wording, and functionality and identify any issues or gaps. No changes in wording were made to the Delphi surveys. If participants agreed to take part, they received an automatic email with the link to the first survey. Participants had 10 days to complete each round of the survey. Individual responses were anonymized, and all participants were invited to complete the second and third rounds of the survey regardless of their participation status in the previous rounds. Attrition was prevented through a short period between rounds and by providing feedback on study findings. A summary of the entire Delphi process is provided in Figure 1.

Figure 1. Delphi process. BIT: behavioral intervention technology.



Round 1

Round 1 was carried out between January 13 and 23, 2023. Participants were provided with an explanation of the survey and were asked to provide demographic information (ie, age, gender, and employer organization). Two 9-point Likert scales were used.

The first scale assessed participants' opinions on the feasibility of work strategies (n=36) for reducing SB when working from home. The work strategies had been selected from a scoping review of the vast majority of real-life PA strategies implemented [31], a systematic review of effective digital interventions to reduce SB [21], and 2 qualitative studies that further explored the perceptions of managers and employees on the factors influencing the ability of employees to reduce their SB in a home office context [26]. The strategies were classified based on the Behavior Change Wheel (ie, environmental planning and service provision, 9/36, 25% of the strategies; regulation, guidelines, and restriction, 15/36, 42% of the strategies; and communication and social support, 12/36, 33% of the strategies) [32].

Participants were invited to score each work strategy. Scores ranging between 1 and 3 suggested a lack of feasibility, scores between 4 and 6 suggested neutral feasibility, and scores between 7 and 9 suggested high feasibility. This scoring was based on the 9-point Grading of Recommendations Assessment, Development, and Evaluation methodology [33]. The feasibility scores considered the 4 dimensions of feasibility: social validity or acceptability, integration into the existing system, practicality, and adaptability (Table 1) [34].

The second scale covered the potential usefulness of the technology-based behavior change elements according to the behavioral intervention technology (BIT) model (ie, messaging and social support [n=6 elements], push notifications [n=5 elements], information delivery [n=9 elements], report and visualization [n=4 elements], digital log [n=3 elements], and passive data collection [n=7 elements]) [35]. Scoring was based on the 9-point Grading of Recommendations Assessment,

Development, and Evaluation scale divided into 3 categories: not useful (1-3), neutral (4-6), and highly useful (7-9) [33]. Participants were also invited to provide additional items or observations through an open-ended question for each strategy or BIT element category.

Table 1. Feasibility dimensions for the strategies and the related research question for each dimension.

Dimension	Research question
Social validity or acceptability	Is the strategy appropriate, reasonable, fair, and potentially effective for home-based work?
Integration into the existing system	To what extent are the strategies aligned with the infrastructure of home office settings?
Practicality	Can the initiative be implemented using the available resources, time, training, and materials in home-work offices?
Adaptability	Is the initiative flexible enough to fit across the diverse needs of home office work?

Round 2

Round 2 started on February 6, 2023, and finished on February 16, 2023. Work strategies from round 1 were ranked based on the *highly feasible* scores for work strategies and *highly useful* scores for BIT elements. A total of 35 work strategies (rather than 36) were ranked in round 2 based on recommendations from round 1 (a similar approach was implemented for work strategies and BIT elements). In this second round, participants were asked to place each work strategy in order of preference considering the most feasible strategies to reduce SB when working from home. The same procedure was followed for the BIT elements. Additional items that appeared in the first survey were scored based on the round 1 approach (ie, the 9-point Likert scale).

Round 3

Round 3 was launched on February 17, 2023, and could be answered until February 27, 2023. According to the preferred order of the items ranked in round 2, participants were asked to match the most useful BIT elements that could potentially be used to implement each of the work strategies to reduce SB when working from home. The work strategies included in this round were those with a weight above the median.

Focus Groups

To explore in more depth the experts' opinions and understand their perspectives, focus groups took place.

Focus groups were conducted in English or Spanish by a researcher (AC or IP-S) and a moderator (IP-S, JB-R, or AMS-M) with previous experience facilitating focus groups. The focus groups were held on the web using Microsoft Teams in April 2023. The focus groups lasted a total of 60 minutes. The size of the groups was small (4 participants on average) due to scheduling difficulties and time zone differences among countries.

A guide was developed based on the 3 Delphi rounds (Multimedia Appendix 2). However, the researchers did not follow it in full detail, using the freedom to explore thoughts and ideas based on the responses from each group. First, there was a brief welcome and introduction to explain the aim of the focus group, obtain consent for the recording of the session, and introduce each participant. The results of every Delphi round were then shown. Subsequently, experts were asked about what factors they thought made some strategies more feasible than others considering the 4 dimensions (outlined in Table 1) and what factors may enhance participation among the BIT elements. The last element of the focus group covered the need for any adaptation before the implementation of the strategies in the hybrid work model. The focus groups were recorded, transcribed verbatim, and translated into English if necessary to be analyzed later.

Data Management and Analysis

Study uptake was calculated as the proportion of participants who accessed the round 1 Delphi survey to that of all potential participants identified. Retention rate referred to the proportion of completed responses for each round and participation in the focus groups. In round 1, responses to the Likert scale in the *highly feasible* or *highly useful* category (score from 7 to 9) were calculated. The median and mean absolute deviation from the median (MAD-M) for each item were also reported to assess the strength and extent of agreement. Medians of 7 to 9 were defined as strong support, medians of 4 to 6 were defined as moderate support, and medians of 1 to 3 were defined as no support. The MAD-M describes the variation in the median values [36]. In round 2, we calculated the weighted average ranking for each item to determine the most highly ranked work strategies and BIT elements for reducing SB among home office workers. The respondents' most preferred choice had the largest weight, and the least preferred choice had a weight of 1. For achieving consensus, the order-weighted average process was followed through the aggregation of the strategies evaluated in the previous round to be validated in round 2 [37]. Items that achieved consensus were those that were ranked with a weighted average above the median. The additional items that emerged from round 1 were assessed through a 9-point Likert scale in round 2, and the median and MAD-M were calculated. In round 3, the matched items for each work strategy and BIT element were reported, as well as the percentage of respondents.

The focus group analysis was conducted using the principles of reflexive thematic analysis [38,39]. First, a researcher (IPS) familiarized themselves with the data, reading and rereading carefully each transcript to obtain a general impression of the main opinion of the experts and identify repeated concepts. Subsequently, according to the subjectivity of the researcher, an initial open coding process was generated from interesting features and relevant data searching for evidence for themes, namely, patterns of shared meaning underpinned by a central organizing concept. Reflexive thematic analysis was approached

in an inductive, semantic, and realistic way. In other words, the construction of codes and themes was directed by the content of the data but not by a topic summary. Codes, concepts, and the core category were recoded and relabeled if necessary after each step until the codes provided the intended depth of the insights. The analytic outputs obtained from the codes and through the active engagement of the researcher with their data were then conceptualized in potential themes and subthemes. Finally, the themes were reviewed, defined, and named. At the end of each step, data were shared with an experienced supervisor (CV-C) for reflecting on how the data were initially coded and consider things that might have been overlooked. MAXQDA 2022 (VERBI GmbH) was used for the analysis.

To ensure a robust analytical process, we considered key aspects of quality and rigor. The first aspect was reflexivity, which involves critical reflection of researcher perspectives and its integration within the analysis and interpretation of the data to develop themes [40]. The study team comprised researchers with expertise in PA and SB in the workplace who have experienced working from home since before or after COVID-19 pandemic. IP-S, who carried out the analysis, is a Spanish physiotherapist and osteopath PhD student who has been working from home for 3 years; CV-C, the supervisor during the analysis, is an experienced nutritionist with a background in health promotion and qualitative research who has been working from home since the COVID-19 pandemic. Second, confirmability, the objectivity of the findings [41], was attained through a critical friend approach whereby an experienced supervisor reviewed interpretations and introduced alternative perspectives, increasing objectivity and confirming the accuracy of the findings. Third, dependability, the reliability and consistency of the study [41], was attained through detailed research procedures (ie, rigorous data collection techniques and well-documented procedures and analyses). Credibility was then built on the reflexivity and triangulation of the data, incorporating more than one researcher in the analysis process [42]. Furthermore, a critical friend approach was used whereby an experienced qualitative researcher, CV-C, critically analyzed the preliminary themes and ensured that the selected quotes provided support for the themes developed. Finally, transferability was enhanced through the transparent and detailed descriptions of the participants and research process [42].

Results

Participant Characteristics

A total of 51% (29/57) of the invited experts expressed their interest in participating in the study through the digital informed consent form. Of these 29 participants, 27 (93%) completed the first round, 25 (86%) completed the second round, and 19 (66%) completed the third round. Of those 29 participants, 15 (52%) joined the focus groups.

Most of the first-round Delphi respondents and focus group participants identified as women (16/27, 59% and 8/15, 53%, respectively), with 48% (13/27) of first-round respondents aged between 36 and 45 years.

A wide variety of countries across Europe were represented. However, non-European countries such as Australia (5/29, 17% of the participants) were also represented.

Delphi Survey

Feasibility of Work Strategies

Round 1

Multimedia Appendix 3 shows the results of round 1, which considered the 36 work strategies divided into 3 categories. A total of 69% (25/36) of the work strategies were ranked as highly feasible.

In total, 7 environmental planning and service provision work strategies were rated as highly feasible with strong support. Activity trackers (20/27, 74%; median 8, MAD-M 1.41); workstation accessories (19/27, 70%; median 8, MAD-M 1.59); and relocation of home office supplies such as the bin, printer, or water source (19/27, 70%; median 8, MAD-M 1.30) were the 3 work strategies considered as highly feasible for reducing SB when working from home. Active workstations equipped with treadmills were reported to be unfeasible (19/27, 70%; median 2, MAD-M 1.48).

In total, 53% (8/15) of the work strategies regarding guidelines, regulations, and restrictions were rated as highly feasible with strong support. Self-monitoring of sedentary and activity behaviors (20/27, 74%; median 8, MAD-M 1.30), substitution of sedentary tasks (eg, reading, answering a phone call, or participating in a videoconference) with standing or incidental movements (20/27, 74%; median 7, MAD-M 1.37), and creating an action plan (20/27, 74%; median 7, MAD-M 1.11) were the most highly useful. The least feasible strategy was the locking or blocking of the screen or keyboard for specific durations (11/26, 42%; median 5, MAD-M 2.19).

Regarding the communication and social support work strategies, feedback on activity progress and achievement of goals (22/27, 81%; median 7, MAD-M 1.74); providing information to increase awareness and knowledge (20/27, 74%; median 8, MAD-M 1.37); and the provision of awards, rewards, or incentives by the company to achieve goals (19/27, 70%; median 7, MAD-M 1) were ranked as the most feasible for reducing SB when working from home. Most of the work strategies included in this category (10/12, 83%) were rated by the respondents as highly feasible, and none of them were considered unfeasible. No new items emerged from open-ended questions.

Round 2

The ranking list of the work strategies with the weighted average (range 14.6-0.48) is reported in Table 2. Most items reported as highly feasible when working from home in round 1 (18/25, 72%) were scored above the median (3.64) in round 2, with the exception of self-selected reminders (3.24); active breaks such as stretching, walking, or strengthening exercises (2.36); real-time records (2.32); high or height-adjustable chairs (1.96); exercise accessories (1.52); and social networking for sharing experiences (0.48).

Table 2. Ranking of highly feasible work strategies (results of round 2).

Strategy	Weighted average score
Feedback on activity progress and goal achievement	14.6
Create an action plan—increase standing breaks or replace sitting time, how long, how often, when, and how (eg, when the phone rings)	13.04
Standing while reading, answering phone calls, or conducting videoconferences	13.04
Providing information to increase awareness and knowledge of the dangers associated with prolonged sedentary behavior and the potential benefits of reducing it or breaking it up	12.88
Self-monitoring sedentary and activity behaviors (ie, activity tracker or a diary log)	10.76
Short breaks (5-10 min) approximately every 60 min of sitting time	10.36
Scheduling (blocking) 5-10–min breaks between meetings on the calendar	8.6
Information and support about the strategies and goals and reminders	8.04
Setting tailored goals for reducing sitting time	7.24
Activity demonstrations to perform during the breaks	7.12
Height-adjustable desks or desk platforms	6.92
Relocation of home office supplies (eg, bins and printers)	6.8
Incidental moving while reading, answering phone calls, or conducting videoconferences	5.76
Awards, rewards, or incentives to achieve goals or recommendations	5.48
Standing desks	4.6
Point-of-choice or point-of-decision prompts	4.4
Workstation accessories (seated footrests, standing footrests, or sit-stand antifatigue mats for standing desks)	4.24
Motivational messages from managers	3.64
Wellness coaches supporting the employees during breaks	3.48
Self-selected reminders to achieve goals	3.24
Blocking the screen or keyboard for breaking up sitting time unless conducting a meeting	3.24
Active workstation with underdesk stepper or pedaling device	2.52
Short breaks (5-10 min) approximately every 30 min of sitting time	2.48
Team or individual activity challenges	2.4
Active breaks, such as stretching, walking, or performing strengthening exercises for ≥10 min	2.36
Scheduling (blocking) snack breaks on the calendar	2.32
Real-time records or feedback	2.32
Active lunchtime, such as Pilates, yoga, walking, or cycling	2.04
High chairs or height-adjustable chairs	1.96
Social comparison	1.68
Exercise accessories, such as rubber bands, wooden sticks, or mats	1.52
Active workstation equipped with treadmill	1.44
Short breaks (5-10 min) approximately every 40 min of sitting time	1.36
Competition among peers	0.92
Social networking for sharing experiences	0.48

Usefulness of BIT Elements

Round 1

Multimedia Appendix 4 shows the results of round 1 considering the usefulness of the BIT elements divided into 5 categories.

In total, 33% (2/6) of the BIT elements from the messaging and social support category were ranked as highly useful with strong support: social challenge features (20/27, 74%; median 7, MAD-M 1.22) and gamification (14/26, 54%; median 7, MAD-M 1.78). None of the messaging and social support items were considered not useful. Smartphone app and desktop application interfaces were identified to be the 2 most useful

BIT elements within the push notification category (12/27, 44%; median 7; and MAD-M 1.41 for smartphone app interface and 15/27, 56%; median 7; and MAD-M 1.18 for desktop application interface). The other 3 push notification elements were ranked as highly useful or neutral with medians between 5 and 6, indicating moderate support. A combination of different media was the preferred item in the delivery of information category (14/24, 58%; median 7, MAD-M 1.71), with the other elements within the category receiving moderate support and being considered neutrally or highly useful. A total of 15 new combined digital items, such as videos and images, moving images on websites, or reminders combined with social challenges, emerged from open-ended responses to the combination of media element in the information delivery category. Blending was considered more useful than isolated media. Real-time data (19/27, 70%; median 7, MAD-M 1.48) and data summaries via the app interface (14/27, 52%; median 7, MAD-M 1.67) were considered the most useful in the report and visualization category. The 2 remaining items (data summaries via email or SMS text message and websites) were ranked as neutral. The 3 most useful BIT elements to track activity were wrist-based activity trackers (17/26, 65%; median 7, MAD-M 1.69) and using a mobile phone diary (17/27, 63%; median 7, MAD-M 1.41) or smartphone sensors (13/26, 50%; median 7, MAD-M 1.61). The only element considered as not useful to track activity was waist-based activity trackers (10/26, 38%; median 5, MAD-M 1.85).

Round 2

Overall, BIT elements reported as highly useful to support work strategies were ranked at the top in each category (Table 3). In the messaging and social support category, items ranked above the median score (2.52) coincided with highly useful items in round 1 (ie, social challenge features and gamification), but chats (eg, WhatsApp groups) were added to the top of the ranking. SMS text messages were added to the 2 BIT elements in the push notification category considered as highly useful in round 1, which were scored above the median (2.00) in round 2. In addition to combination of media, videos, interfaces in smartphone apps and desktop applications (same as in the push notification category), images, and websites were among the items scored above the median (3.24) in the information delivery category. The new items that emerged from the open-ended responses in round 1, specifying potential combinations of media for information delivery described as highly useful, were a combination of mobile phone apps and desktop applications; a combination of personalized messages, reminders, and social challenges; a combination of videos, text, and images within an interactive website; and a combination of a mobile app with social media (Table 4). In the report and visualization category, the 2 items ranked as highly useful in round 1 remained above the median (2.32) in round 2. The median of the BIT elements to track activity was 3.56. In round 2, a total of 2 more items were added as highly useful to the 3 identified in round 1: leg-based activity tracker and computer software. In total, 17 BIT elements were considered highly useful in round 2.

Table 3. Ranking of highly usable behavioral intervention technology (BIT) elements (results of round 2).

BIT element to communicate information	Weighted average scores (SD)
Messaging and social support	
Social challenge features (cooperative activities, eg, reach 10,000 steps among all members of the department)	5.16
Gamification features (competition among colleagues)	4.48
Chats (eg, WhatsApp groups)	3.28
Emails	1.76
Calls	1.4
Forums	1.64
Push notifications	
App interface—text and sound and vibration in smartphones	4
Application interface—computer screen notification in desktop computers	3.08
SMS text messages	2
Chats	1.64
Emails	1.52
Information delivery	
Combination of media	7.6
Videos	6
App interface—smartphones	4.44
Images	4.36
Application interface—desktops	3.24
Websites	3.24
Emails	3.16
SMS text messages	2.36
Audios	1.44
Report and visualization	
Real-time data via app interface	2.96
Data summary via app interface	2.84
Data summary via email or SMS text message	1.8
Data summary via website	1.24
BIT elements to track activity	
Mobile phone diary (manual entry)	7.72
Web-based questionnaire (manual entry)	3.52
Computer software diary (manual entry)	1.6
Passive data collection	
Wrist-based activity tracker	8.6
Leg-based activity tracker	3.64
Smartphone sensors	3.6
Computer software	3.6
Waist-based activity tracker	3.28
Electronic workstation	3.08
Cushions on chairs	2.04

Table 4. Results for the new items from round 1 scored in round 2—behavioral intervention technology (BIT) elements.

New BIT element	Level of usefulness, n (%)									Median (MAD-M[a])
	Not useful			Neutrally useful			Highly useful

[a]MAD-M: mean absolute deviation from the median.

Round 3

After the description of the priorities of the expert panel, the BIT elements that were considered most suitable for implementing each of the work strategies are shown in Multimedia Appendix 5, including the 18 highly feasible work strategies and 16 rather than 17 highly useful BIT elements because social challenge features were considered within the gamification features in round 3.

The use of wrist-based activity trackers was identified as useful by 63% (12/19) of respondents for self-monitoring sedentary and activity behaviors. Using a computer software was considered useful to schedule 5- to 10-minute breaks between meetings (9/19, 47%), whereas a desktop application interface was considered useful to support strategies such as short breaks every 60 minutes of sitting time (6/19, 32%). Videos were described to be useful when delivering activity demonstrations to perform during the sitting breaks (9/19, 47%). Other BIT elements identified were gamification features, such as social challenges, which are used for providing awards and rewards and offering incentives (8/19, 42%). However, setting tailored goals (8/19, 42%); creating an action plan (6/19, 32%); standing while reading, answering calls, or conducting videoconferences (6/19, 32%); providing feedback on activity progress (4/19, 21%); and motivational messages (4/19, 21%) were mainly recognized to be best delivered through a smartphone app. Providing information and support was considered to be best delivered through a combination of media or a smartphone app (5/19, 26% each). Combination of media was also chosen by most of the respondents as the most useful mode for providing information to increase awareness and knowledge (5/19, 26%) and for promoting incidental movement (3/19, 16%).

Environmental strategies such as height-adjustable desks (11/19, 58%), relocation of home office supplies (5/19, 26%), standing desks (9/19, 47%), and workstation accessories (9/19, 47%) did not correspond with any BIT elements according to most of the respondents. For point-of-choice or point-of-decision prompts, there were no corresponding BIT elements to support their implementation according to most of the respondents for this strategy (4/19, 21% of the sample), although 16% (3/19) considered that this strategy could be delivered via computer software.

Focus Groups

Overview

A total of 2 indicative themes were generated from the analysis of the focus groups regarding the experts' perceptions in relation to the Delphi results on the potential feasibility and usefulness of strategies and digital elements to reduce SB in a home office context. The first theme referred to the integration of the digital strategies for reducing SB when working from home, which included 3 subthemes: social influences, physical environment, and individual factors. The second theme was related to the adaptability of the strategies to reduce SB in the office and home context.

Theme 1: Integration of the Digital Strategies for Reducing SB When Working From Home

Overview

This theme involves the importance of combining multiple levels of strategies to facilitate and maximize the strategies' implementation and their effectiveness in reducing SB when working from home. According to the experts, while organizational-level factors such as organizational support or policy changes may not be immediately feasible on their own, they are essential for achieving sustainable change. The same was considered true for information provision—it alone is not enough to motivate behavior change, although it is an important factor at the individual level to increase individuals' knowledge. In addition, environmental changes are required to promote less sitting and more movement during working hours. Therefore, experts highlighted that the following implementation levels need to work in tandem to achieve sustainable behavior change.

Social Support

Experts explained the need for the company to support the culture of active and healthy workplaces to motivate the employees' behavior change. Social support may be achieved by aligning the company policies and culture with the support of the manager (eg, motivational messages) to be able to increase the integration of digital strategies for reducing SB when working from home:

> *[I]t is based on what the management or the philosophy of the company or the company policy wants to refer to their workers. If those at the top are not proactive in...the chain, it will decrease.* [E13; focus group 4; paragraph 43]

While the target behavior is contextualized within the domain of working from home, participants identified interaction with colleagues as a relevant factor to motivate employees toward behavior change. For example, social modeling may motivate home office workers to reduce their SB by sharing activities around the sitting time breaks. However, social interaction can be perceived negatively if a competition component is present in the strategies. This may be due to competing against people whom they do not know or due to the bottom position of some workers during the challenges. Therefore, cooperative challenges may be the solution, in which every worker contributes to the challenge without a competition element:

> *[W]hen people find themselves in an environment where they've got to adapt behaviourally, seeing what can be done and observing how others might do it, can be quite powerful...we are social animals, monkey see, monkey do and that social modelling element to me jumps out as really quite important and not to be lost.* [E01; focus group 1; paragraph 44]

Physical Environment

The home office context was seen by some participants as a limiting factor in engaging in sufficient PA during work hours due to the reduced space compared to the office context. For example, having (normally) no more than 1 floor at home, implying the use of stairs, or the lack of large spaces for walking are barriers to be active while working at home. Although applying physical changes such as standing desks may be a solution to break up sitting time at work, it appears to be a less feasible strategy in the home office context due to the expensive cost for the companies:

> *I'm a big advocate of standing desks, standing workstations in terms of being effective but I appreciate that in this situation it's probably not feasible for them to be incorporated in the home-office.* [E10; focus group 3; paragraph 7]

Nevertheless, experts highlighted the importance of combining these environmental changes with prompts or reminders for the success of the behavior change integration when working from home. Regarding point-of-decision prompts, experts highlighted that mobile phone notifications were more feasible for reducing SB than desktop notifications because they cause less disturbance:

> *[W]hen we moved into our new offices a few years ago, we all got standing desks and just observing...I don't see anybody using. So, if there's something for me in there about prompting/reminders, do you know?... So, I think the prompting is really important.* [E011; focus group 3; paragraph 11]

Individual Factors

Experts mentioned the difference in literacy between *PA* and *sitting time*, believing that workers may understand the term *PA* more easily than the term *sitting time*. This may be due to the lack of knowledge on the importance of reducing sitting time behaviors, which could be perceived as a barrier when only reporting sitting time feedback. Therefore, educational material or information, one of the highlighted strategies to be used together with social support and physical environment strategies to achieve SB reduction when working from home, delivered through a combination of media (ie, smartphone, desktop, and

websites), was considered the most adaptative medium to increase the employees' knowledge. Experts emphasized that the information delivered must be simple and short, especially with the use of videos:

> *I think the combination of media is probably the way forward because I guess different organisations will also have different ways of rolling out information. I know a lot of companies nowadays that they all have their own company app, and they do a lot of communication via their app that all their employees have access to.* [E10; focus group 3; paragraph 42]

Furthermore, feedback on the respondents' own behavior was identified as a key strategy to motivate individuals and achieve behavior change. The best frequency at which to deliver feedback could be in real time as this adapts to each individual's schedule. However, a daily summary feedback approach was also considered helpful in combination with real-time feedback:

> *For the summary—daily maybe? But I probably go for the combination of the two, so you probably have some sort of summary data to share with them but still, it's nice to see at the moment what you did.* [E05; focus group 2; paragraph 67]

Theme 2: Adaptation to the Home Office Environment

This theme refers to the flexibility of the strategies to fit the diverse needs of hybrid work. All the experts mentioned the capacity of the strategies to be adapted to all environments without the need to be changed to fit in the home or office context:

> *I think you want to have the same or approach or whatever you use for say, remote working, I would also use for hybrid working because I guess a lot of strategies are going to be the same...So, I think you could maybe just replicate or duplicate what you're doing here for the hybrid workers.* [E10; focus group 3; paragraph 64]

However, some strategies need to be adapted to each individual depending on the type of work they perform. For example, walking while on a call may be a good strategy for a call center, but it might not work in another type of job. Therefore, it is valuable to provide different strategies to allow everyone to choose their preferred one to change their behavior:

> *[D]ifferent populations need a different approach, right? So very much dependent on the type of work that people are doing, you're going to have to approach them differently. So, the task set is going to help determine what options you actually have to still do your work but would be doing it sitting down all the time.* [E05; focus group 2; paragraph 29]

Therefore, experts highlighted the importance of providing a list of strategies that can be adapted to employees' needs for reducing sitting and moving more during their working hours:

> *So instead, you look towards providing a menu of strategies that you know are effective or have at least been shown to be feasible and acceptable and not shown to have any harm and you know, have benefits maybe in terms of cultural elements of it and that a lot of those would be applicable for the home environment but would also be applicable obviously for the workplace environment.* [E02; focus group 1; paragraph 65]

Summary

In general, no dissonance was found among the responses of the different experts. Strategies such as feedback, social modeling, breaks every hour, prompts via mobile phone every hour, educational material, and organizational support (eg, motivational messages) were the most discussed and considered the most feasible. Other strategies such as physical changes (ie, height-adjustable desks) were considered unfeasible despite being ranked higher in the Delphi rounds. Finally, although certain strategies such as the creation of an action plan, standing while reading and answering calls, blocking 5 to 10 minutes between meetings, or setting tailored goals for reducing sitting time obtained high scores in the Delphi rounds, these topics were discussed less among the experts during the focus groups.

Discussion

Principal Findings

This study achieved international expert consensus on 18 potentially feasible work strategies to reduce home office SB delivered through 16 potentially useful digital elements. These results seem to be transferable to both office and home settings based on experts' responses. Moreover, the experts highlighted the importance of multiple factors (ie, social, individual, and environmental) working in tandem to facilitate and maximize the strategies' implementation, as well as to achieve behavior change.

Comparison With Prior Work

Wrist-based activity trackers were identified by most of the experts (12/19, 63%) as useful for self-monitoring activity and SB. Previous research has highlighted the feasibility and usability of these devices for self-monitoring SB as well as workers' acceptability of these approaches in the office context [43,44]. In addition, these strategies have demonstrated effectiveness in reducing SB in such settings [44]. Some studies have highlighted limitations in recognition of postures and step detection when using wrist-based devices compared to leg-based devices [45-48]. However, few experts considered leg-based activity trackers for self-monitoring activity and SB due to the discomfort they may cause. This suggests that future interventions incorporating activity trackers with the aim of reducing SB should first validate the devices for their subsequent implementation and effectiveness evaluation in home office settings.

In the literature, computer visual feedback on activity patterns is considered to be an enabling factor for increasing motivation and awareness among office workers [49]. However, experts preferred smartphone apps as they are able to provide real-time feedback on activity progress. In addition, feedback may be an indication of progression toward a defined goal [43]. In this study, experts stated that smartphone apps could be a useful tool for setting tailored goals. Evidence has demonstrated the

effectiveness of smartphone apps in reducing SB and promoting PA in office settings [16]. Hence, smartphone apps may be a potential mode of delivery for setting tailored goals and providing feedback on the move, which should be evaluated in future home office environment interventions.

Previous research has demonstrated that short activity breaks (ie, walking) every 30 minutes result in reductions in office SB time [50] but also in reductions in fatigue and improvements in energy and mood [51]. However, in this study, experts considered breaks every 60 minutes more feasible. According to recent literature, a possible explanation may be related to the fact that workload and time pressure were identified by employees as the most common barriers for reducing and breaking up SB [52], making it difficult to stop more frequently. Moreover, replacing SB with active working tasks (eg, incidental moving while reading and answering calls) may overcome these barriers [49]. Working remotely increases opportunities to perform active tasks or even other light-intensity PA that may increase the potential benefits of reducing SB and its harmful health effects among office workers [9,10,53]. Experts reflected on the importance of providing clear instructions and modeling through video demonstrations as a key digital element to enhance active breaks among employees when working from home. This may have implications for future studies evaluating the most effective active break duration through video demonstrations and the implications of these breaks regarding SB time and its health effects in home office contexts.

On the basis of experts' responses, there is a literacy gap between the terms *PA* and *SB*, with activity trackers largely focused on PA instead of SB [52]. Therefore, educational material may be a key aspect to increase knowledge for behavior change and reduce the lack of understanding of SB and its subsequent health implications, which was highlighted by experts. Educational material is an essential and effective strategy for workers to increase awareness of SB's health consequences [52,54]. In our findings, a combination of media was preferred to deliver information to increase awareness and knowledge. Therefore, it is recommended that future studies include educational material to increase knowledge and awareness among home office workers.

Despite the relevance of knowledge and awareness to achieve behavior change, social and organizational support is a factor noted by workers in the current literature for facilitating and encouraging movement in the workplace [55-57], as well as by managers in the home office setting [26]. Home office work is more related to negative emotions than office work due to the isolation and loneliness; therefore, social support is even more important in this context [58]. Gamification features, including social challenges, were identified as a useful digital element to deliver strategies such as awards, rewards, or incentives to achieve goals or recommendations for reducing SB among home office workers. This strategy could provide social support and motivation. Motivational messages from managers are also an organizational support strategy, which experts suggest could be delivered through smartphone apps. Thus, future studies should evaluate the acceptability of these social and organizational strategies among both managers and employees, as well as their effectiveness in the home office context.

Environmental work strategies such as standing desks, height-adjustable desks, or workstation accessories were mostly not matched with any digital element. Moreover, experts recognized work strategies such as height-adjustable desks as unfeasible in the home office environment, primarily due to the associated costs. Recent evidence has demonstrated the high cost of such desks (eg, standing desks or height-adjustable desks) compared with nondesk interventions [59]. Workstation accessories (eg, desk platforms) or relocation of office supplies are less expensive strategies [60] that were deemed more feasible and usable by experts and may be implemented in home office settings. Therefore, home office interventions may include environmental work strategies in a similar way to office interventions but with a lower associated cost.

On the basis of the findings presented in this paper, physical environmental strategies need to work in tandem with social support and individual strategies to achieve behavior change. A recent systematic review showed that theory-based interventions, a relevant step in multicomponent intervention development [25], that include social, physical, and individual elements are more effective than non–theory-based interventions [21]. Furthermore, stakeholder engagement (eg, consultation or coproduction among researchers, experts on the topic, and the target population) should be encouraged throughout the development process [25]. Recent studies have highlighted the need for a top-down approach whereby managers should provide support to employers [26]; hence, the implementation of strategies should be an organizational initiative. Although evaluating effectiveness on outcomes has traditionally been the primary focus of interventions in this discipline, in particular to encourage their adoption in the real world, the feasibility, acceptability, cost-effectiveness, and scalability of interventions is increasingly important to ensure the translation of findings from research to practice [25,61]. This study provides new insights for future research on the design of home office interventions aimed at reducing SB based on the learned experiences of occupational health experts. However, we were not able to cover the entire audience's perspective, so new qualitative studies exploring the perspectives of different stakeholders (eg, end users) may further inform about the feasibility and usability of digital workplace strategies.

In addition, experts considered that no adaptations would be needed to transfer these home office strategies to hybrid work, the current modus operandi for many desk-based workers. However, the experts who participated in this study were mainly from high-income countries; therefore, such perceptions may vary among people from other regions. Hybrid work presents opportunities for promoting PA by providing flexibility to integrate occupational, leisure, lifestyle, and incidental activities [9] but also for improving health and well-being [62]. Hence, the results of this study may be transferable to hybrid work in high-income countries, whereas hybrid work should receive greater consideration in future interventions given cultural variability.

Strengths and Limitations

The main strength of this study is the novelty of the home office context to deliver strategies for reducing SB through digital

elements. The fact that focus groups were conducted after a Delphi study enabled us to elicit additional views and opinions on the Delphi results from the experts' perspectives, consolidating the consensus. Nevertheless, we did not share the analytical categories, interpretations, or conclusions from the thematic analysis with the experts, which may affect the analysis's credibility. The entire study was conducted in a rigorous manner, with high participant response rates and representation from international experts. However, some strategies may have been overlooked due to the nonsystematic search approaches used, and most of the international experts were from high-income countries, limiting the applicability of these findings to those communities. Some other limitations were present in the study. First, despite the rigor in the methodology used to engage experts, not all responses were complete, meaning that data were sometimes missing from some questions. Second, as is the case in any Delphi survey, the data gathered were based on subjective opinion and the expertise of the participants. Third, experts acted as representatives of the stakeholders; thus, the inclusion of other stakeholders such as end users would also have been important to address other, more diverse perspectives.

Conclusions

This study presents the consensus of international experts on feasible work strategies and useful digital elements as a mode of delivery of these work strategies to support the reduction in SB in home office or hybrid contexts. Consensus was achieved on 18 work strategies and 16 BIT elements. Future interventions should implement and evaluate the effectiveness of these strategies but also their feasibility and acceptability in home office settings.
