Two study groups were included in this study, all of whom were familiar with cases from Sub-Saharan Africa: first contact clinicians, as our focus, and burn specialists, as a basis of comparison.

First Contact Clinicians

First contact clinicians treating burn injuries at the front line in Sub-Saharan African countries were targeted because they would be the ones using such an image-based automated diagnostic assistance in burn care. The inclusion criteria were therefore that the participant was a doctor or a nurse who may need regular or occasional advice for referral, diagnosis, or treatment of burn injuries in their practice. Another eligibility criterion was that one had to work in an emergency or trauma center (where patients with acute burns are brought) or at a specialized surgical unit that manages patients with burns. Furthermore, the participant had to be practicing, or have practiced in a Sub-Saharan African country.

Burn Specialists

Those who took part in this study were burn specialists who have an expert role in their setting when it comes to burns assessment and treatment; they completed a limited part of the questionnaire (see below), where they were asked about potential risks that may accompany the use of automated diagnosis for burns.

A total of 122 participants started the survey, of which 31 were excluded because: they did not complete the consent form (n=6), they did not complete the survey (n=18), they only practiced in a high income country (n=3), or they were prehospital paramedics (n=4). The analyses were performed on the remaining 91 participants.

Data Analyses

Intention to Use Automated Diagnosis for Burn Care

To explain the intention to use automated diagnosis for burn care, 8 hypotheses (presented in Table 2) were proposed based on the 7 constructs previously defined. To evaluate the accuracy and consistency of the developed measurement items with regard to their respective constructs, Cronbach α and composite reliability were measured. Any constructs that had a Cronbach

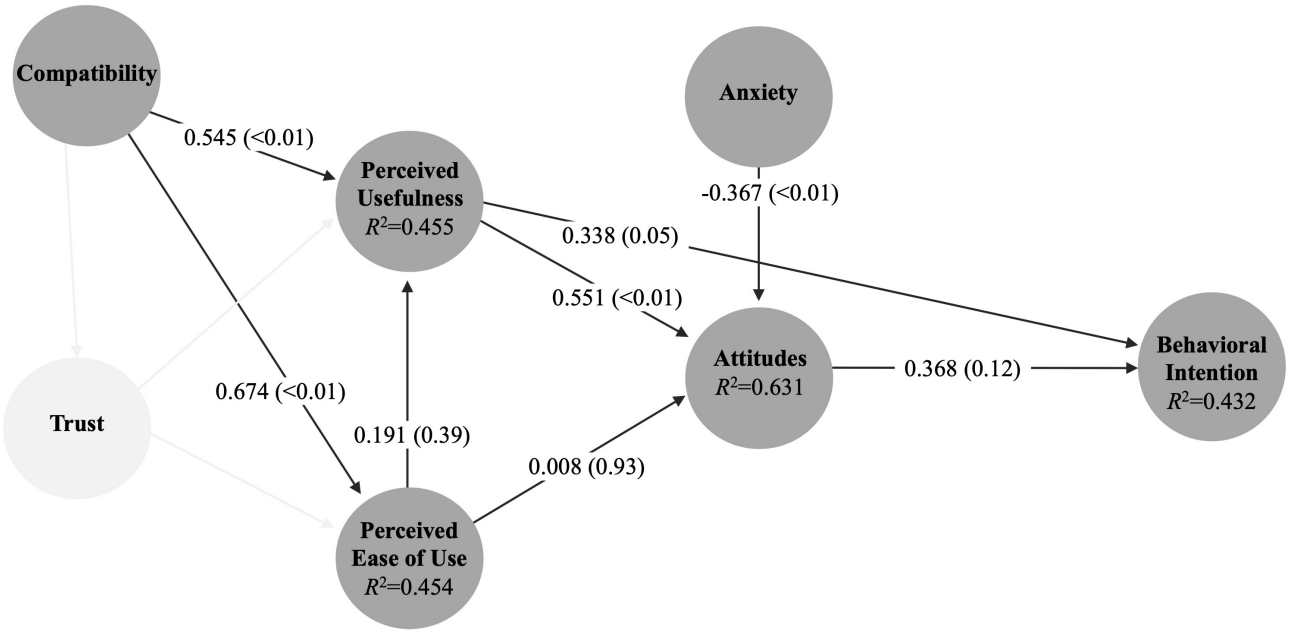
XSL•FO
RenderX

α lower than 0.7 or a composite reliability value lower than 0.6 were excluded from further analyses [31]. The results are presented in Table 3 and show that all constructs are consistent and reliable except for trust, for which the 2 measurement items do not yield an appropriate Cronbach α. This construct was therefore excluded from further analyses and the model.

Table . Hypotheses tested, definitions, and results obtained.

Hypothesis	Definition	Supported by the results
1	Perceived compatibility is positively related to the perception of the usefulness of automated diagnosis for burn care.	Yes
2	Perceived compatibility is positively related to the perception of the ease of use of automated diagnosis for burn care.	Yes
3	Perceived ease of use of automated diagnosis for burn care is positively related to the perception of its usefulness.	No
4	Perceived usefulness of automated diagnosis for burn care is positively related to attitudes toward using it.	Yes
5	Perceived ease of use of automated diagnosis for burn care is positively related to attitudes toward using it.	No
6	Anxiety is negatively related to attitudes toward using automated diagnosis for burn care.	Yes
7	Perceived usefulness of automated diagnosis for burn care is positively related to the behavioral intention to use it.	Yes
8	Positive attitudes toward using automated diagnosis for burn care are positively related to the behavioral intention of using it.	No

Table . Constructs summary (number of items and mean), consistency statistic (Cronbach α), and composite reliability measure.



Construct	Number of items	Mean (SD)	Cronbach α	Composite reliability
Behavioral Intention	1	5.4 (1.6)	—[a]	—
Attitudes	3	5.4 (1.1)	0.732	0.846
Perceived usefulness	8	5.3 (1)	0.918	0.934
Perceived ease of use	2	5.7 (1.2)	0.866	0.937
Trust	2	4 (1)	−0.658	0.332
Compatibility	2	5.4 (1.3)	0.886	0.946
Anxiety	5	4.7 (1.1)	0.701	0.803

[a]Not applicable.

We then used Partial Least Squares Structural Equation Modelling to examine the proposed model (Figure 1) and test the hypotheses. Partial Least Squares Structural Equation Modelling is a multivariate statistical analysis that allows for testing models with an established theoretical foundation and with latent variables [32]. Bias-corrected and accelerated bootstrapping using 5000 subsamples was used to measure statistical significance. We used a hard cutoff to define whether a hypothesis was supported or not, which was an obtained value higher than 0.2 with a P value <.05 [20]. Analyses were performed using SmartPLS (version 4.0).

XSL•FO
RenderX

Risks That May Occur With Implementation

Both first contact clinicians and burns specialists completed the survey section on potential risks. For each of these risks, the proportion of answers was reported in 3 categories. For the severity of each risk, the categories of insignificant or minor risk were combined and collapsed into one. A nonparametric Mann-Whitney U test was used to assess the differences in opinions between the 2 groups. For that, all data points for the 2 groups are ranked in ascending order, and the sum of the ranks (R1 and R2) are then calculated for both groups separately (first contact clinicians and burns specialists). The U statistic is then calculated for each group:

$U1=n1 \cdot n2+n1n1+12-R1$ for group 1 and $U2=n1 \cdot n2+n22+12-R2$ for group 2

where n1 and n2 are the sizes of the 2 groups. The smaller U value is then used to assess significance with a defined *P* value threshold of .05.

All analyses were performed using Stata BE (version 17.0; StataCorp LLC).

Ethical Considerations

This study was approved in South Africa by the Human Research Ethics Committee of the University of Cape Town (Dnr 823/2019) and in Sweden by the Ethics Committee (Etikprövningsmyndigheten [Dnr 2019 - 05122]). Informed consent was provided by participants prior to filling in the online survey. The data are deidentified and no compensation was provided for participating.

Results

Of the 91 respondents who completed at least 1 section of the survey, 62% (56/91) were first contact clinicians and 38% (35/91) were burn specialists. Table 4 presents the respective characteristics of the 2 groups with regard to their demographics and experience with burn care. Overall, these were mostly men (49/91, 54%), although the opposite was observed at first contact care, with over half being women (31/56, 55%). A total of 52% (29/56) of first contact clinicians managed patients with burns at no or few occasions per week, whereas 20% (7/35) of burns specialists manage patients at least once a week.

A total of 41 of the 56 (73%) first contact clinicians replied that they agreed or strongly agreed that they would use automated diagnosis for burns if it becomes available in their department. Figure 1 presents the results of the tested model for path coefficients. While perceived usefulness was positively and significantly related to the intention to use, attitudes toward the practice were not. Together, these 2 constructs explain 43% of the variance in intention to use for clinicians at the point-of-care. Almost two-thirds of the variance in attitudes toward the practice (R^2=0.631) could be explained by the 3 constructs of anxiety, perceived usefulness, and perceived ease of use. For its part, compatibility was positively related to the perception of both usefulness and ease of use. Overall, out of the 8 tested hypotheses, 5 were supported in the model (Table 2).

Table 5 indicates the position of the 2 groups of professionals concerning the likelihood of different risks. All respondents aggregated, the risk of complex burns not being recognized and that of clinicians feeling less responsible for the care they provide are the 2 risks that most often were considered as high or very high (23/79, 29% and 19/85, 22%, respectively). There are 2 risks where the opinions of the 2 groups differ significantly, and they concern the undermanagement of severe burns and the overmanagement of minor burns. In both instances, the risk is seen as high or very high by more first contact clinicians than burn specialists.

XSL•FO
RenderX

Table . Likelihood of each risk to happen as perceived by clinicians at first contact and burn specialists.

Risks assessed for likelihood	Do not know, n	Low or very low, n (%)	Moderate, n (%)	High or very high, n (%)	Mann-Whitney *P* value
That severe burns are missed, leading to undermanagement					.03
First contact clinicians	5	15 (31.3)	20 (41.7)	13 (27.1)	
Burn specialists	0	16 (45.7)	17 (48.6)	2 (5.7)	
All participants	5	31 (37.4)	37 (44.6)	15 (18.1)	
That minor burns are diagnosed as severe, leading to overmanagement					<.01
First contact clinicians	4	14 (28.6)	24 (49)	11 (22.5)	
Burn specialists	1	21 (61.8)	11 (32.4)	2 (5.9)	
All participants	5	35 (42.2)	35 (42.2)	13 (15.7)	
That clinicians feel less responsible for the care they provide					.11
First contact clinicians	3	25 (50)	11 (22)	14 (28)	
Burn specialists	0	23 (65.7)	7 (20)	5 (14.3)	
All participants	3	48 (56.5)	18 (21.2)	19 (22.4)	
That the emotional well-being of the patient will be neglected					.98
First contact clinicians	1	35 (67.3)	11 (21.2)	6 (11.5)	
Burn specialists	1	23 (67.7)	7 (20.6)	4 (11.8)	
All participants	2	58 (67.4)	18 (20.9)	10 (11.6)	
That the patient confidentiality will be breached					.38
First contact clinicians	3	31 (62)	16 (32)	3 (6)	
Burn specialists	0	20 (57.1)	8 (22.9)	7 (20)	
All participants	3	51 (60)	24 (28.2)	10 (11.8)	
That patients will be less empowered in decisions around their care					.22
First contact clinicians	2	35 (68.6)	10 (19.6)	6 (11.8)	
Burn specialists	1	27 (79.4)	6 (17.7)	1 (2.9)	
All participants	3	62 (72.9)	16 (18.8)	7 (8.2)	
That some complex burns may not be recognized by the algorithm					.2
First contact clinicians	8	6 (13.3)	24 (53.3)	15 (33.3)	
Burn specialists	1	8 (23.5)	18 (52.9)	8 (23.5)	
All participants	9	14 (17.7)	42 (53.2)	23 (29.1)	

Table 6 presents the perceived severity of each risk for both groups of respondents. For all risks, the severity is perceived as major to a higher proportion of first contact clinicians than burn specialists. Just as for the likelihood, all respondents aggregated, the risk for complex burns not being recognized is the risk for which severity is most often considered as major (45/82, 55%). A large proportion of clinicians (46/85, 54%) also rated as major the severity of the risk for severe burns being missed, although this is true especially for those at point of care (32/51, 63%). While almost 80% (27/34) of burns specialists considered the severity of minor burns being diagnosed as minor or insignificant, only 40% (21/52) of first contact clinicians did.

Discussion

Main Findings

This study is an attempt to bridge the gap between what is known about the potential performance of automated diagnosis for burn care and the readiness of first contact clinicians to endorse this as a practice. We showed that a majority of first contact clinicians from resource-poor African settings would be willing to use automated diagnosis for burns should the technology be made available in their departments. The concepts embedded in the AAM contributed moderately to explaining what the intention to use such a technology rests on. Of special interest is the association between the intention to use and perceived usefulness, but not with attitudes toward the technology. It is also of note that 5 of the 8 hypotheses derived from the model were supported.

When reflecting upon the risks that such technologies could imply, first contact clinicians showed more concerns than burns specialists. They were typically concerned with the consequences of poor diagnostic accuracy (ie, undermanagement of severe burns and overmanagement of minor burns) and, like their specialized peers, feared that clinicians' sense of responsibility would be reduced and that complex burns might not be identified. The latter was regarded as the risk with the most severe consequences across all clinicians, alongside that of severe burns not being identified. By contrast, first contact clinicians were less concerned with the risk of minor burns being diagnosed as minor or insignificant.

That first contact clinicians show a widespread acceptance of the intention to use automated burn diagnosis is well in line with previous research on the use of clinical AI in general, where 77% of the respondents from different parts of the world indicated being willing to use clinical AI if needed [33]. Perceived usefulness has already been suggested as a strong predictor of both behavioral intention and technology acceptance. This is true for technologies such as smart health care [34,35], whereas in the context of burns, it has been shown for the acceptance of mHealth [21].

As the model used does not pay attention to risk perception per se in the determination of intention to use, our results can shed light on it being a potentially underlying source of influence on the intention to use. Indeed, first contact clinicians' appraisal of the risk is more multifaceted than that of their specialized peers. A first explanation could be self-confidence, doubting their ability to interpret the output of an automated burn diagnosis [33]. Another one could be minimal experience of mHealth for burn diagnosis, while experience of the like is known to be associated with a decrease in perceived risks in the use of smart health care, thanks to technology transfer knowledge [35]. A third one could be a sense of loss in personal usefulness, first contact clinicians being more prone to answer positively to the fact that AI would replace them.

Strengths and Limitations

This is the first study performed in resource-poor settings specifically on the topic of acceptance of automated diagnostic acceptance among health care professionals. This can complement the work done on a similar population on the acceptance of mHealth for burn injuries [21], but also results in the acceptance of AI-based diagnosis among medical students, also performed in resource-poor settings [36]. Studies on intention to use are important to be performed for specific contexts and populations of interests as it has been shown previously that physicians from resource-poor settings may have different opinions regarding clinical AI than their counterparts from other regions of the world [33]. The perceptions might also depend on the qualification of the surveyed professional [21,33,35]. The development of new methodologies to analyze the obtained data (such as machine learning techniques) might also assist in the future in targeting more specifically what might influence the intention to use new technologies by survey participants. The study also focused on 7 different risks that are relevant for the diagnosis of burn care and for which the knowledge around clinicians' perceptions is important both for the development of algorithms as well as for implementation. It is likely that burns specialists, sharing a familiarity with the condition and aware of the progress made in assisted diagnosis are more inclined to trust the technology [37] and that, by contrasts to first contact clinicians, are more heterogeneous as a group as regards their knowledge and experience about burns, their skills and competences [21]. The sample was conveniently selected among clinicians attending 2 specialized conferences in South Africa for their interest in burn care and likelihood of using automated diagnosis would it be developed. This, however, comes with the limitation that the pool of people who can be included is relatively small, and the results cannot be generalized to other specialties or settings where the viewpoints of the professionals might differ. Furthermore, there might have been respondent bias with those accepting to fulfill the questionnaire having stronger opinions in favor of or against automated diagnosis for burns than those who did not respond. This study was cross-sectional and only assessed the intention to use a potential tool rather than

XSL•FO
RenderX

effectively measuring the clinicians' behaviors once automated diagnosis was implemented. While this information will be interesting to investigate in the future, the knowledge gathered in this study can further assist in the development of the algorithms themselves to respond most appropriately to the stakeholders' demands. It could also be of interest to assess users' perceptions with regard to different methodologies with varying performances, in particular when current advances in the technological domain are extremely promising.

Future Research

This study has implications for future research as the AAM model contributes poorly to informing what the determinants of the intention to use are beyond the perceived usefulness. There is a need to assess the input of clinical risk perceptions: this should be an integral part of the model in the future, and it should receive attention during the evaluation and implementation process. Furthermore, with the body of evidence growing on the potential for automated diagnosis in burn care and its potential benefit in resource-poor settings, research on the attitudes of medical professionals with regard to this technology is necessary for a successful implementation. Finally, it would be interesting to investigate, when implementing such a technology in practice, whether it would enhance the clinical abilities of first-contact clinicians, as well as improve diagnostic efficiency, given the current state of resources and the lack of specialist clinicians.

Conclusions

The results show that most first contact clinicians were inclined to seek automated advice for burn diagnosis if it was available. The conceptual model proposed contributes moderately to explaining what influences intention to use beyond perceived usefulness, with implications for clinical practice where the perceived usefulness makes little doubt. This is encouraging as there are good reasons to believe that the performance of automated diagnostic support will continuously improve. When seeking additional determinants, greater attention should be placed on clinical risk perceptions as well as negative attitudes due to bad experiences or unrealistic expectations. These dimensions should also naturally belong to any AI implementation process in practice, not least to ensure sustainability.

Conflicts of Interest

None declared.

Abstract

Background: Mental health challenges, including depression, anxiety, and burnout, have become increasingly prevalent among health care workers, who face high-stress environments, limited resources, and long working hours. The COVID-19 pandemic has intensified these issues, especially in regions like Latin America, where health care professionals experience heightened anxiety and depression. The urgent need for mental health support has prompted the development of mobile health (mHealth) solutions. These tools offer accessible, confidential interventions that help reduce stigma and encourage engagement. The "Psicovida" mobile app was designed to provide cognitive behavioral therapy (CBT)–based activities tailored to health care workers, supporting them in managing stress, anxiety, and depression.

Objective: This study aims to evaluate the effectiveness of Psicovida, a mobile app that delivers CBT-based interventions, in reducing depressive symptoms and emotional distress among health care workers over a 3-month period.

Methods: A quasi-experimental, nonrandomized controlled study was conducted with health care workers at a public hospital in Ecuador. Participants were recruited offline and assigned to either an intervention group that used the Psicovida app or a control group that received no intervention. The app provided weekly CBT-based tasks focused on stress management, cognitive restructuring, and emotional regulation. Data collection included demographic information, with mental health outcomes assessed pre- and postintervention using the Patient Health Questionnaire-9 (PHQ-9) to measure depression and the General Health Questionnaire-12 to assess overall psychological well-being.

Results: A total of 211 health care workers participated, with 88 in the intervention group and 96 in the control group, and 29 participants dropped out. Among the intervention group, adherence varied: 34% (30/88) used the app consistently for 10 - 12 weeks, 42% (37/88) for 7 - 9 weeks, and 24% (21/88) for fewer than 6 weeks. Significant improvements in mental health outcomes were observed among app users. The intervention group exhibited a statistically significant reduction in depressive symptoms, with PHQ-9 scores decreasing significantly (P<.001; 95% CI 6.17-9.36). Within this group, 20% (18/88) achieved complete remission of depressive symptoms (PHQ-9 scores <5), 32% (28/88) showed mild symptoms (PHQ-9 scores=5 - 9), and 48% (42/88) remained in the range requiring treatment referral (PHQ-9 scores ≥10). General Health Questionnaire-12 scores similarly showed substantial improvement in psychological well-being (P<.001; 95% CI 3.99-5.58).

Conclusions: The Psicovida mobile app demonstrates promise as an accessible, effective tool for reducing depression and anxiety among health care workers through CBT-based interventions. This study highlights the potential of mHealth technology to deliver targeted mental health support, especially in resource-limited settings. Future research should focus on evaluating long-term impacts and broader applications in varied health care environments.

Introduction

Background

Mental health has emerged as a global challenge affecting millions of individuals across geographical and cultural boundaries. Mental disorders, including depression and anxiety, now affect over 450 million people globally, according to the World Health Organization, posing serious consequences for quality of life and productivity. Events like the COVID-19 pandemic have only exacerbated these challenges, highlighting the urgent need for innovative and accessible solutions [1].

Health care workers, especially doctors and nurses, are among those most affected by the mental health crisis, facing high rates of depression, anxiety, and burnout. Research shows that nearly half of junior doctors report symptoms of depression, while over 63% experience significant anxiety. Physicians also face burnout rates 20% - 30% higher than those of other professions and are 1.4 to 2.3 times more likely to die by suicide [2]. Despite these concerning statistics, many health care workers hesitate to seek mental health support due to stigma and fear of professional consequences [3]. This hesitation highlights the critical need for accessible, confidential mental health resources that encourage help-seeking within health care environments, fostering a culture where mental health support is accepted and valued.

In Latin America, health care professionals contend with additional mental health challenges, worsened by systemic issues like insufficient health care infrastructure, extended work hours, and direct exposure to the COVID-19 crisis. Anxiety affects between 10.6% and 76.5% of health care professionals, with depression impacting up to 81% in some regions. In Ecuador, for example, 46.4% of health care workers report experiencing anxiety, while 34.5% report depression. Among female obstetricians in Peru, over half exhibit depressive symptoms [4]. Frontline workers, particularly young and female health care professionals, face heightened vulnerability due to high workloads, inadequate personal protective equipment, and ethical dilemmas, leading to both physical and mental exhaustion [5]. The prevalence of these mental health issues points to an urgent need for and met the inclusion criteria effective psychological support and systemic improvements in working conditions.

Addressing these challenges requires immediate attention to systemic reforms that include accessible and confidential mental health services. In this context, mHealth solutions have emerged as promising tools. Recent studies have assessed the effectiveness of mHealth interventions targeting various mental health issues, including depression [6,7], suicide [8], schizophrenia [9], substance use disorders [10], and psychosis [11], among others [12]. Recent systematic reviews focused on assessing smartphone apps for mental health demonstrated their ability to generate significant reductions in anxiety [13] and depression [13]. mHealth apps have been proven particularly effective in breaking down barriers to help-seeking, such as stigma and time constraints, and are shown to improve user engagement when co-designed with health care workers [14]. Additionally, mHealth tracking apps have been recognized for increasing self-awareness and enabling users to manage their symptoms by identifying triggers and patterns. This kind of proactive self-management can be highly beneficial for health care workers facing depression and burnout [15]. These digital tools, if implemented widely, could play a pivotal role in addressing the ongoing mental health crisis among health care workers.

Objective

This study aims to bridge the gap in understanding the effectiveness of mHealth interventions in mitigating mental health issues among health care workers. By conducting a quasi-experimental, nonrandomized controlled trial among health care workers in a public hospital in Ecuador, this research seeks to evaluate the impact of the “Psicovida” mobile app [16], a digital tool designed to support mental health through cognitive behavioral therapy (CBT)–based activities, on depression and emotional distress symptoms. The app offers structured interventions aimed at alleviating symptoms associated with mental health disorders, providing users with accessible and guided support. The unique challenges faced by health care personnel in Latin America, especially in regions like Ecuador, where systematic monitoring of mental health issues is lacking, underscore the importance of this research.

Methods

Study Design and Setting

This study used a quasi-experimental, nonrandom, parallel, controlled trial with pre- and postintervention assessments. It involved 2 groups with similar baseline characteristics: an intervention group receiving access to the Psicovida app and a control group without access. The study started in January 2023, coinciding with a surge in COVID-19 cases in Ecuador. This wave significantly impacted the health care system, creating heightened stress among health care workers [17]. The timing of the study underscores the critical need for effective mental health support mechanisms for this population.

The trial adheres to the Consolidated Standards of Reporting Trials (CONSORT) eHealth guidelines, and the detailed study protocol and statistical analysis plan are publicly available on ClinicalTrials.gov (NCT06650449) [18,19].

Rationale for Quasi-Experimental Design

The decision to use a quasi-experimental approach was driven by the desire to achieve homogeneity in key demographic characteristics (age, gender, marital status, education level, and profession) between the intervention and control groups. To achieve this, participants were purposefully assigned to 2 cohorts: those who used the Psicovida app and those who did not. This intentional grouping aimed to control for potential confounding variables, acknowledging the limitation that true random assignment was not used.

Participants

The study population comprised health care workers (doctors and nurses) from various departments of a public hospital in Quito, Ecuador. Participants were purposefully assigned to 2 groups—those who used the Psicovida app and those who did

XSL•FO
RenderX

not—to control for potential confounding variables, acknowledging the limitation that true random assignment was not used. At the request of hospital administrators, some staff from high-acuity wards, whose heavy workloads left no additional time for training, were kept in the control group, whereas personnel from outpatient clinics with more flexible schedules were placed in the intervention group. Inclusion criteria were (1) employment as health care personnel at the designated hospital for at least 12 months, (2) ownership of a smartphone, and (3) provision of informed consent. Participants included both men and women aged 18 years and older, regardless of marital status. These criteria ensured engagement with the Psicovida app and effective completion of study tasks.

Individuals not meeting any of the above inclusion criteria were excluded from participation.

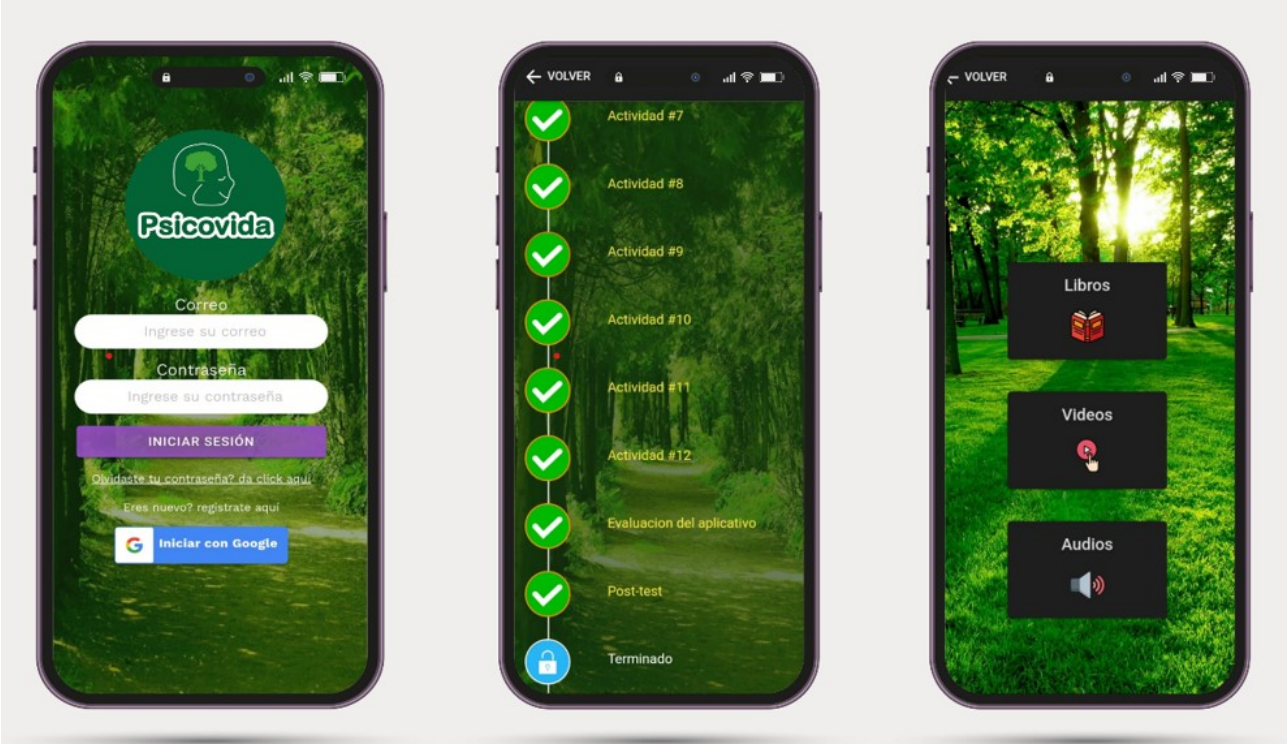
Recruitment and Data Collection

Recruitment and data collection occurred primarily through the Psicovida app between October 2022 and January 2023, using 3 strategies. First, informational meetings were conducted by the research team to explain the study and the Psicovida app and to obtain digital consent. Second, from an initial pool of 296 health care professionals who expressed interest and met the inclusion criteria, 211 eligible participants were selected based on EPIDAT software (EPIDETAL, developed by the Epidemiology Service of the Dirección Xeral de Saúde Pública, Consellería de Sanidade (Xunta de Galicia), with support from the Pan American Health Organization (PAHO/WHO) and CES University of Colombia) recommendations and assigned to either the intervention or control group. A double-entry table was used during the assignment to ensure balanced distribution across key variables such as profession and sex. Finally, baseline data were collected, including personal information (email, age, gender, and education level) for participant profiling, and psychological evaluations using the Patient Health Questionnaire (PHQ-9) and the General Health Questionnaire (GHQ-12) to assess emotional distress and depressive symptoms.

During the study design phase, a plan was implemented to account for potential dropout rates, including strategies to manage missing data and maintain sample integrity. The study was conducted remotely via the Psicovida app, with minimal direct interaction with the research team, except when participants opted to initiate communication.

Intervention

The Psicovida app is a free tool designed to support health care workers' mental health by providing CBT-based activities aimed at alleviating symptoms of depression and emotional distress. The app includes a structured program of 12 weekly activities, each taking around 2 to 10 minutes to complete, focusing on introspection, stress management, and the restructuring of negative thoughts. The modules cover various aspects of mental health and personal growth, delivered through interactive tasks that address emotional, cognitive, and physical dimensions.



The app was available to all interested users for download from the Google Play Store, without the requirement to belong to a specific group to access it. Participants did not pay for access, nor did they receive any financial compensation for their participation. During the onboarding phase, participants were encouraged to engage with the app regularly, completing the assigned activities over a period of up to 3 months. The app sent daily reminder emails to participants from Monday to Friday, encouraging consistent participation and improving user engagement. Users could adjust the settings for reminders, allowing flexibility in how they interact with the app. Users could adjust the settings for reminders, allowing flexibility in how they interact with the app. You can see the app interface in Figure 1.

Since its initial release, significant updates have been made to improve user experience, including expanding system bandwidth to address downtimes and enhancing the app's user interface based on feedback from previous users. These changes, validated by clinical psychology experts, ensure that the therapeutic quality of the activities remains intact, offering personalized support to health care workers. Developed as Discord Psicovida Version 1 by principal author (SMO), the program underwent rigorous evaluations to align with the needs of its user base. For digital preservation and access, the Psicovida app can be accessed via a dedicated link on the Open Science Framework repository [20]. Upon completing the program, participants received a notification thanking them for their participation and were provided with general recommendations for maintaining long-term mental health. The description of each activity is presented in Multimedia Appendix 1.

At the end of the app use period, participants provided feedback through a series of structured questions. This feedback will help guide improvements for future versions of the app, based on user experiences and suggestions.

XSL•FO
RenderX

Figure 1. Psicovida mobile app.

Assessments

Depression

The PHQ-9 was carefully implemented as a digital assessment tool to ensure data reliability and participant engagement. Participants provided informed consent online after being fully informed about the purpose of the PHQ-9, confidentiality measures, and their data privacy rights. The questionnaire maintained its standard, validated format with nine items, each required to be answered to ensure complete data collection. The questions were presented in a sequential, user-friendly interface that preserved the questionnaire's established structure without adaptive questioning or alterations.

Participant completion was monitored at both baseline and postintervention to assess adherence and track changes in depression severity over time. Unique identifiers were used to ensure that each participant completed the PHQ-9 only once at each time point, eliminating the risk of duplicate entries. Data security was prioritized through encryption and secure storage of responses. Although specific online validation was not conducted, the PHQ-9's high internal consistency (Cronbach α>0.80) and proven sensitivity and specificity in various settings support its reliability for this digital deployment [21].

Anxiety

The GHQ-12 was implemented digitally to assess emotional distress while upholding rigorous standards for data quality and user experience. Before beginning the GHQ-12, participants reviewed and agreed to informed consent details, which clarified the study's objectives, the role of the GHQ-12, and data protection practices. All 12 items were mandatory, ensuring comprehensive data for each participant and maintaining the GHQ-12's validated structure. The questionnaire was presented in a fixed, linear format, allowing participants to complete it with ease and consistency, without adaptive questioning or alterations.

Completion rates were monitored both at the beginning and end of the study to evaluate participant engagement and the tool's effectiveness in capturing changes in emotional distress. Each participant was assigned a unique identifier to track usage and prevent multiple entries, supporting data integrity. Responses were securely encrypted and stored, safeguarding participant confidentiality. While no digital-specific validation of the GHQ-12 was mentioned, its established reliability (Cronbach α ranging from 0.70 to 0.90) and consistent performance across studies reinforce its suitability for digital application [22].

Demographic and Lifestyle Variables

Information on age, gender, marital status, education level, profession, and toxic habits (alcohol and tobacco consumption) was collected to describe the study population and adjust for potential confounders.

Procedure

The Psicovida quasi-experimental trial followed a structured process to ensure participant engagement and data collection. After recruitment and eligibility confirmation in January 2023, participants were randomly assigned to either the intervention group, which used the Psicovida app, or the control group, which did not receive app access.

Both groups completed baseline assessments, including demographic data collection and psychological evaluations using validated tools (PHQ-9 for depression and GHQ-12 for emotional distress). Following this, the intervention group started app use, while the control group received standard mental health support information. Outcome assessments were

XSL•FO
RenderX

conducted at two time points: (1) baseline (start of the study) and (2) study completion (end of 3 months). Participants received periodic email reminders to encourage adherence to the study protocol and completion of assessments. The intervention group was encouraged to engage with the app weekly for up to 12 weeks, with each activity designed to take 2 - 10 minutes. Upon completing the study, participants had the option to continue using the app, subject to updates or maintenance periods.

The study ran from January 2023 to March 2023, spanning three months.

Data Management and Monitoring

All study data were collected and recorded electronically through the Psicovida mobile app. The data, including identifiable information such as participants' email addresses and demographic details, was stored in a secure, encrypted database managed by the research team. Identifiers were removed during data processing to ensure confidentiality before analysis. Weekly backups of all data were conducted by the research team during the data collection phase, and backups were securely stored in a password-protected environment. Only approved members of the research team and designated technical staff had access to the data.

Trial Harms and Risk Management

Given the sensitive nature of mental health content, it was possible that some participants could experience distress while using the Psicovida app. Although no serious adverse events were anticipated based on previous trials of similar apps, the research team recorded and monitored any adverse events reported by participants. Adverse events were defined as any reported psychological distress or health impacts resulting from app use. The principal investigator documented and notified the ethics committee within 24 hours of any adverse events. If necessary, a data safety monitoring board consisting of independent clinical reviewers assessed the situation and recommended whether the study should continue. The app also provided direct access to mental health support services via a "reach out" button on the app's home screen, allowing users to contact help if needed.

Data Analysis

To determine the appropriate sample size for this study, EPIDAT, a specialized statistical software, was used with a one-sided hypothesis anticipating improved outcomes in the intervention group. Based on a 95% CI and a 5% margin of error, EPIDAT recommended reducing the initial pool of 296 health care personnel to a final sample size of 211 participants. Of these, 96 were allocated to the control group and 115 to the intervention group. However, there was an approximate loss of 29 participants, representing about 15% of the recommended sample size, due to personnel leaving the hospital or not completing the study.

As the study required active participant engagement with the Psicovida app, blinding participants to group allocation was not feasible. However, outcome assessors and data analysts were blinded to group assignments to reduce bias during data collection and analysis. Fortunately, there was no attrition during the study period, ensuring that all participants completed both baseline and postintervention assessments, thereby preserving the integrity of the data and the validity of the findings.

Descriptive statistics were used to summarize demographic characteristics, with chi-square tests for categorical variables and *t* tests (2-tailed) for continuous variables to compare distributions between groups. The impact of the Psicovida app on depression and emotional distress was analyzed using paired *t* tests for within-group comparisons and independent *t* tests to assess changes between groups. Effect size calculations were performed to evaluate the clinical significance of these findings.

To further understand the intervention's impact, binary logistic regression models were constructed to examine predictors of depression (PHQ-9 scores) and emotional distress (GHQ-12 scores) at the end of the study, considering factors such as app use, baseline psychopathology, and demographic variables. All statistical analyses were conducted using SPSS software (IBM Corp), with significance set at $P<.05$, based on data sourced from the Psicovida app database as of March 2023.

Ethical Considerations

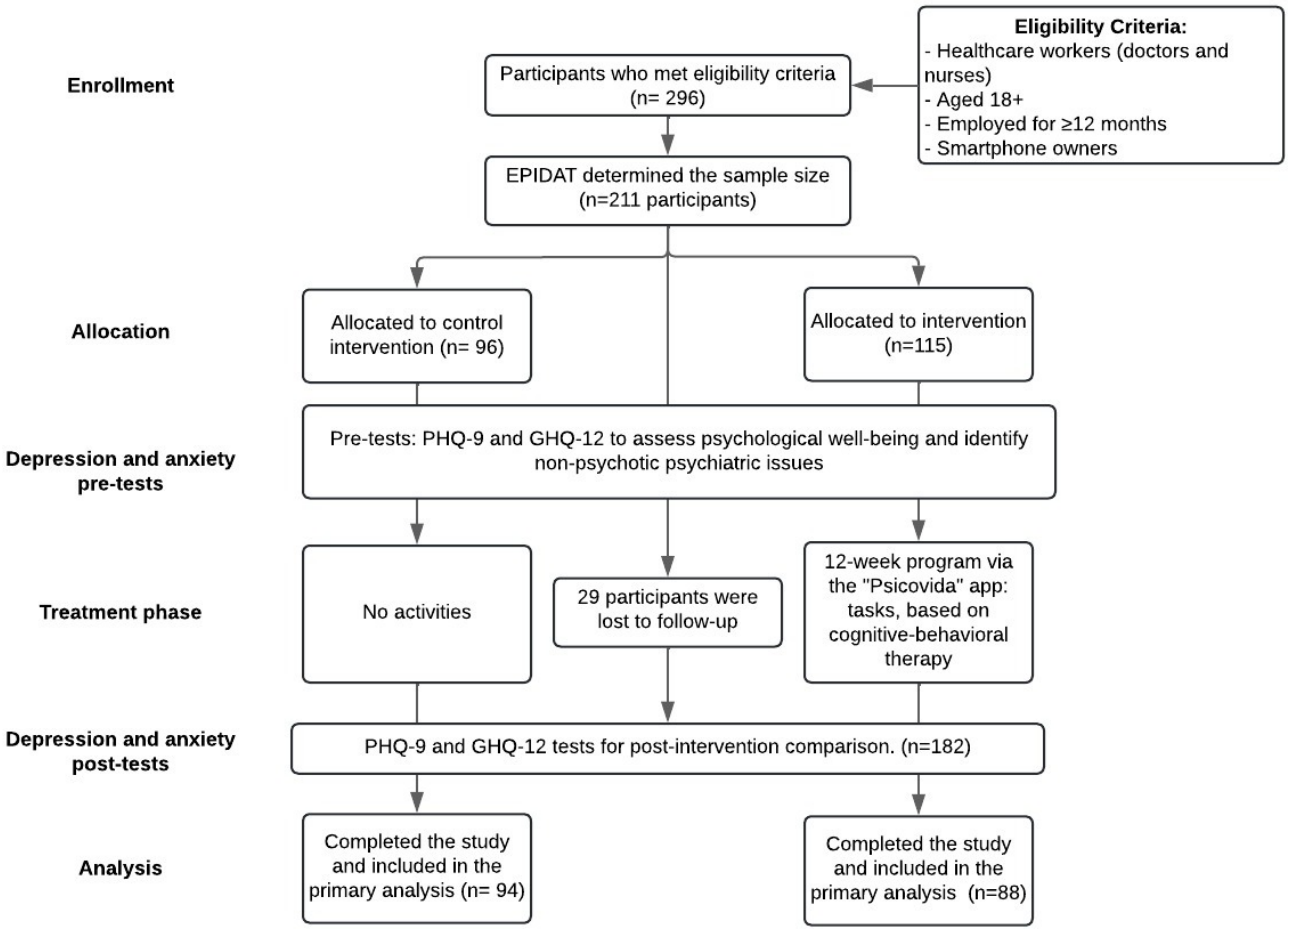
This study received approval from the Human Research Ethics Committee of the Carlos Andrade Marín Hospital (registration number IESS-HCAM-CEISH-2022 - 0007) on April 21, 2022. All procedures adhered to the ethical standards of the institutional and national research committee, as well as the principles of the Declaration of Helsinki. No exemptions from ethical review were sought, as the study involved human participants.

Participants provided informed consent digitally before enrolling in the study. The consent process included detailed information on the study's purpose, objectives, potential benefits, risks, and confidentiality measures. Participants confirmed their voluntary agreement by checking a digital consent form. They were informed of their right to withdraw from the study at any time without repercussions.

To ensure participant privacy and confidentiality, all data collected through the Psicovida mobile app were anonymized prior to analysis. Identifiable information, such as email addresses, was encrypted and stored in a secure database accessible only to the research team. Unique identifiers were used to link participant data while preserving anonymity during analysis. No personally identifiable information was included in the final dataset.

Participants were not provided with financial or material compensation for their participation in this study. Instead, they were thanked for their contribution to advancing mental health research and given general recommendations for maintaining long-term mental health upon completing the study.

Results



Overview

Between January 2023 and March 2023, 296 health care workers expressed interest in participating in the Psicovida study. Based on EPIDAT's recommendations, the sample size was reduced

XSL•FO
RenderX

to 211 eligible participants who provided informed consent and were assigned to either the Psicovida intervention group (n=115) or the control group (n=96). However, due to a 15% dropout rate, approximately 29 participants discontinued their involvement. As a result, the final distribution included 94 participants in the control group and 88 in the intervention group, who were evaluated for the primary outcome. The procedure for the Psicovida quasi-experimental trial is presented in Figure 2.

Figure 2. Psicovida study participation flowchart based on the CONSORT (Consolidated Standards of Reporting Trials) 2011 statement recommendations. GHQ-12: General Health Questionnaire-12; PHQ-9: Patient Health Questionnaire-9.

In terms of app use, 34% (30 participants) in the intervention group used the app for the full duration of 10 - 12 weeks, 42% (37 participants) used it for 7 - 9 weeks, and 24% (21 participants) used it for fewer than 6 weeks. This variation in usage was taken into account in the analysis to understand the impact of exposure levels on primary outcomes.

Table 1 reveals a distinct age group distribution within the app use group, primarily due to the higher percentage of individuals aged between 18 and 25 years. Both groups exhibited a uniform distribution of sex and marital status, with females and single individuals prevailing. Similarly, the predominant education level was undergraduate studies, consistent with the most common age group. As for profession, despite having inversely proportional frequencies in the study groups, there was no statistically significant difference. Overall, less than 11% (n=19) of the studied participants engaged in alcohol or tobacco consumption.

Evaluation of Depression Symptoms at the Beginning and End of the Groups With and Without Use of the App (With the PHQ-9 Test)

Table 2 shows the scores in both groups at the start and end of the research. We categorized the PHQ-9 variable to discern the proportion of subjects with associated psychopathology according to the applied test evaluation.

The group using the app showed significant improvements (*P*<.001), with a 95% CI, with a difference of 6.17 - 9.36. This suggests that in a sample similar to the one studied, the application of the app is anticipated to result in a decrease in the PHQ-9 test score from 6 to 9 points with 95% CI.

At the end of the application, 20% (18/88) of the participants met the criteria for complete remission or no symptoms of depression (PHQ-9 scores <5), 32% (28/88) met the criteria for recovery or mild symptoms (PHQ-9 scores=5 - 9) and 48% (42/88) continued to meet the referral criteria for treatment (PHQ-9 ≥10). In the group that did not use the app, although a significant improvement was observed in some participants and there was a significant decrease in the mean in the final measurement (*P*=.03), the percentage that met the referral criteria for treatment (PHQ-9 scores ≥10) increased by 4%.

Table . Comparison of the results of the PHQ-9[a] test in the study groups at the beginning and end of the research.[b]

	Start	End	*P* value
PHQ-9, mean (SD)			
Cluster with use of the app	16.77 (7.37)	9.00 (4.88)	<.001
Group without use of the app	16.13 (−7.1)	14.62 (5.48)	.03
PHQ-9 ≥10, n (%)			
Cluster with use of the app	78 (89)	42 (48)	<.001
Group without use of the app	79 (84)	83 (88)	.34

[a]PHQ-9: Patient Health Questionnaire-9.

[b]Source: Database of the Psicovida mobile app, March 2023.

The following graph (Figure 3) shows the differences between the groups. The initial scores on the PHQ-9 test showed no statistically significant differences between the groups, but significant disparities emerged in the final scores. In the app user group, a decrease in the average was observed, and a large effect size was calculated (d=0.95).

Figure 3. Comparison of the results of the PHQ-9 test in the 2 study groups. ES: estimated standard error; PHQ-9: Patient Health Questionnaire-9.

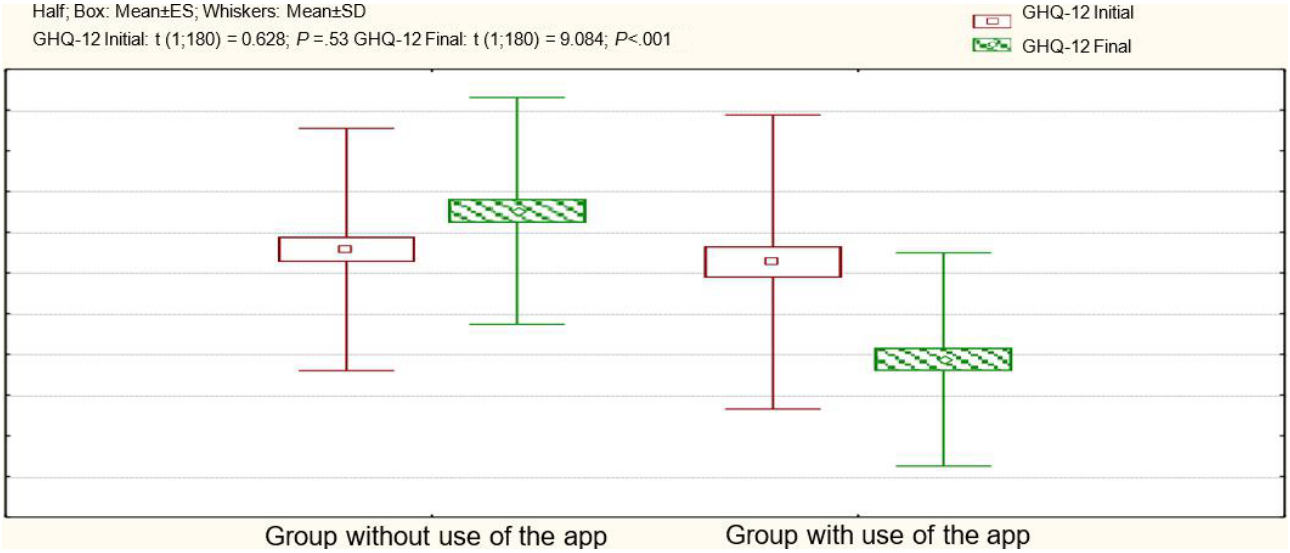
Evaluation of the Symptoms of Emotional Distress at the Beginning and End of the Research Groups (With the GHQ-12 Test)

Similarly, for the GHQ-12 test (Table 3), we see significant improvements in the group using the app (*P*<.001), with a 95% CI for the difference of 3.99 - 5.58. This means that in a similar sample, using the app is expected to result in an average decrease in the GHQ-12 test score between 4 and 5 points, about 95% of the time.

XSL•FO
RenderX

Table . Comparison of the results of the GHQ-12[a] test in the study groups at the beginning and end of the research.[b]

	Start	End	*P* value
GHQ-12 , mean (SD)			
Cluster with use of the app	14.53 (7.22)	9.75 (5.24)	<.001
Group without use of the app	15.15 (5.95)	17.04 (5.57)	<.001
GHQ-12 ≥16, n (%)			
Group with use of the app	55 (57.29)	10 (11)	<.001
Group without use of the app	41 (44.71)	54 (57)	.008



[a]GHQ-12: General Health Questionnaire-12.

[b]Source: Database of the Psicovida mobile app, March 2023.

In this group, 89% (78/88) of the participants met the criteria for complete remission or showed no distress symptoms (GHQ-12 scores <16), and only 11% (10/94) still met the referral criteria for treatment (GHQ-12 scores ≥16). Meanwhile, for the group without app use, the percentage of participants with psychopathology increased, and this difference became statistically significant compared to the initial proportion.

Figure 4 shows the GHQ-12 test results. Initially, both groups had similar scores. Towards the end, there are significant differences favoring the app users, with a noticeable effect (d=1.12). The group without app use also exhibits an increase in final scores.

Figure 4. Comparison of the results of the GHQ-12 test in the 2 study groups. ES: estimated standard error; GHQ-12: General Health Questionnaire-12.

Binary Logistic Regression of the PHQ-9 Test

The PHQ-9 results in our study were dichotomized to categorize participants into 2 distinct groups based on their depression severity levels. Individuals scoring 10 or above were classified as having moderate to severe depressive symptoms, indicating a need for further clinical evaluation. Those with scores below 10 were considered to have minimal to mild depressive symptoms, suggesting lower levels of depression. This dichotomization allowed for a clearer analysis of the relationship between demographic factors such as sex, age group, marital status, educational level, or profession, and depression severity.

Despite this categorization, our findings revealed no significant relationships between these demographic variables and the final PHQ-9 results.

The model (Table 4) had the presence of psychopathologies at the end of the research (PHQ-9f≥10) as the dependent variable. It includes 2 independent variables: the use of the Psicovida app (with the use of the app) and the variable (PHQ-9i≥10) representing the presence of psychopathologies at the beginning of the investigation, determined by the PHQ-9 test itself. This model shows a significance of less than .05 in the omnibus test, indicating that it contributes to explaining the observed event.

XSL•FO
RenderX

Table . Variables in the equation, PHQ-9[a]. Variables introduced in step 1: with use of the app and PHQ-9i≥10.

Variables	b	SE	Wald chi-square (*df*)	*P* value	Odds ratio (95% CI)
With use of the app[b]	−2.269	0.398	32.513 (1)	<.001	0.103 (0.047-0.226)
Step 1a PHQ-9i≥10[c]	2.196	0.498	19.458 (1)	<.001	8.987 (3.388-23.841)
Constant[d]	−0.166	0.419	0.157 (1)	.69	0.847 (N/A)[e]

[a]PHQ-9: Patient Health Questionnaire-9.

[b]With use of the app denotes a binary indicator that captures whether participants engaged with the mobile app during the intervention period (coded 1 for use, 0 for nonuse).

[c]Step 1a PHQ-9≥10 is a baseline severity flag identifying individuals whose initial PHQ-9 score met or exceeded the clinical threshold of 10, indicating moderate-to-severe depressive symptoms (coded 1 for ≥10, 0 otherwise).

[d]Constant represents the model intercept—the log-odds of screening positive when both predictors are set to zero (that is, for nonapp users with a baseline PHQ-9 <10).

[e]N/A: not available.

The independent variables of the model explain up to 37% of the dependent variable, and the correct classification level of the model is 72%. The first independent variable, the use of the Psicovida app, has a negative coefficient, an odds ratio (OR) <1, and therefore represents a protective factor, contrary to what happens with the initial presence of psychopathologies, which shows a positive coefficient, an OR>1; therefore, it is considered a risk factor.

Binary Logistic Regression of the GHQ-12 Test

There were no significant relationships between sex, age group, marital status, educational level, or profession in the final GHQ-12 results. As well, no association was observed between the initial or final values obtained in the PHQ-9 test (Table 5).

Table . Variables in the equation, GHQ-12[a]. Variables introduced in step 1: with use of the app and GHQ-12i≥16.

Variables	b	SE	Wald chi-square (*df*)	*P* value	Odds ratio (95% CI)
With use of the app[b]	−3.859	0.612	39.697 (1)	<.001	0.021 (0.006-0.070)
Step 1a GHQ-12i≥16[c]	3.093	0.588	27.695 (1)	<.001	22.054 (6.968-69.798)
Constant[d]	−0.778	0.292	7.085 (1)	.008	0.459 (N/A)[e]

[a]GHQ-12: General Health Questionnaire-12

[b]With use of the app denotes a binary indicator that captures whether participants engaged with the mobile app during the intervention period (coded 1 for use, 0 for nonuse).

[c]Step 1a GHQ-12i≥16 is a baseline severity flag identifying individuals whose initial GHQ-12 score met or exceeded the clinical threshold of 16, indicating moderate-to-severe anxiety symptoms (coded 1 for ≥16, 0 otherwise).

[d]Constant represents the model intercept—the log-odds of screening positive when both predictors are set to zero (that is, for nonapp users with a baseline GHQ-12 <16).

[e]N/A: not available.

The model used a dependent variable representing the presence of psychopathologies at the conclusion of the study (GHQ-12*f*≥16), and as independent variables, the use of the Psicovida app and the variable (GHQ-12i≥16), which represents the presence of psychopathologies at the beginning of the research (determined by the GHQ-12 test itself). The model demonstrates a *P* value below .05 in the omnibus test, suggesting it significantly contributes to understanding the event in question.

The independent variables of the model explain up to 54% of the dependent variable, and the correct classification level of the model is 83%. The first independent variable, the use of Psicovida application, has a negative coefficient, an OR <1, and therefore represents a protective factor, contrary to what happens with the initial presence of psychopathologies, which shows a positive coefficient, an OR >1; therefore, it is considered a risk factor.

Discussion

Principal Findings

In this study, we evaluated the effectiveness of Psicovida, a mobile app–based CBT intervention, in reducing depressive symptoms and emotional distress among health care workers. The results demonstrated its efficacy as a mental health treatment option, with high user engagement, positive feedback, and significant reductions in depression severity—nearly half of the participants showed improvement, and 20% achieved full remission after three months. These findings, comparable to those from face-to-face CBT, indicate that Psicovida could be a scalable solution in resource-limited settings.

Moreover, the data revealed that demographic factors such as age, sex, education, profession, and marital status did not significantly influence the intervention's success, particularly in urban areas like Quito. This suggests that mHealth

XSL•FO
RenderX

applications like Psicovida can be effective across diverse user profiles, making it a versatile tool for addressing mental health challenges in health care workers.

Perspectives

A pivotal aspect of this investigation centers on the efficacy of Psicovida in ameliorating symptoms of anxiety and depression. The initial findings indicated that 16.77% of app users reported persistent symptoms of anxiety and depression, a figure that notably declined to 9% following the app's use. This contrasted with the control group, which exhibited a negligible shift in symptomatology, underscoring the app's potential therapeutic value. This outcome resonates with the results observed in other mHealth interventions, such as the MHapp app, which amalgamates three components (Moodkit, MoodPrism, and MoodMission) rooted in CBT principles, achieving similar reductions in anxiety and depression symptoms [23].

Similarly, the Mindset for Depression app, which combines structured cognitive behavioral tasks with therapist guidance, has demonstrated comparable reductions in depression severity [24]. In contrast, user-driven apps focusing on self-management and flexible health-tracking features, as highlighted in another study, show the importance of personalization in enhancing user engagement and outcomes. These parallels further underscore Psicovida's potential in reducing depression and emotional distress, even without direct therapist involvement, demonstrating the scalability and accessibility of its design in supporting mental health among health care workers.

Intellicare, another app developed with Intervention Technology and incorporating diverse media such as videos, audio files, and animations [25], mirrors Psicovida's approach in behavior and cognition modification. A distinctive feature of Intellicare is its provision of brief individualized assistance by professionals, a facet absent in Psicovida. Despite this difference, Intellicare's impact on reducing anxious and depressive symptoms, as assessed by the PHQ-9 and Generalized Anxiety Disorder-7 questionnaires, showcases significant parallels with Psicovida, reinforcing the potential of varied mHealth designs to effectively address mental health challenges.

The discourse extends beyond symptom reduction to the enhancement of positive psychological attributes, as evidenced by apps like OneUS and My Coping Plan [26]. These apps aim to cultivate positive emotions and thoughts, thereby elevating general well-being. The OneUS app, for instance, demonstrated a significant uplift in psychological well-being among its users, suggesting that mHealth interventions can play a crucial role in not only mitigating mental health symptoms but also in promoting positive mental states. This dual capability underscores the transformative potential of mHealth solutions in both therapeutic and preventive mental health contexts [27].

Writing exercises have long been recognized as a valuable tool in digital therapeutic interventions for their ability to foster self-reflection and cognitive restructuring. In Psicovida, these activities serve as a core component, encouraging users to explore their thoughts and emotions in a structured manner to facilitate changes in thinking patterns [28]. Compared to apps like Wysa, which use artificial intelligence (AI) for real-time, adaptive responses to users' concerns, Psicovida emphasizes a guided and introspective process. However, integrating AI into Psicovida could enhance interactivity by offering personalized feedback or tailored guidance during writing tasks. This hybrid model would merge the depth of structured exercises with the adaptability of AI, potentially increasing user engagement and broadening its appeal [29].

Despite the encouraging trajectories observed in Psicovida and similar mHealth apps [30], the research landscape in Latin America, and indeed globally, reveals a pronounced scarcity in scientifically rigorous studies validating the clinical efficacy of these digital interventions. The prevailing emphasis on app usability and feasibility studies, while critical, underscores a nascent field that is yet to fully embrace the rigorous evaluation of clinical effectiveness [31]. This gap highlights an urgent need for comprehensive, long-term studies that can provide a robust evidence base to inform the integration of mHealth solutions into standardized mental health care practices, especially in Latin America [32].

Psicovida's adaptability is further demonstrated by its potential to serve diverse user groups. For instance, adaptations inspired by Stay Strong, an app used to support the emotional well-being of Australian Indigenous groups [33], could make Psicovida effective in addressing stress and anxiety in incarcerated populations. Similarly, features from Intellect, which aids medical students in managing subclinical obsessive-compulsive disorder symptoms [34], could be incorporated to support those facing high stress levels. In the aftermath of global crises, such as the COVID-19 pandemic, Psicovida could adopt elements from apps like Foundations to provide structured and accessible mental health support [35].

The success of mHealth apps like Psicovida, however, depends on addressing both patient needs and mental health professionals' recommendations. Psychiatrists often cite barriers such as a lack of individualization, inadequate data privacy protections, and the perception of these tools as supplements rather than replacements for in-person therapy, especially in complex cases [36]. Psicovida addresses many of these concerns by using CBT principles, offering an intuitive design, personalized content, and flexible scheduling, which optimize user experiences and complement traditional treatments. Nevertheless, maximizing the impact of such tools requires respecting the therapeutic relationship and reinforcing clinical work, ensuring their acceptance by both patients and professionals [37].

In synthesizing these insights, it becomes evident that mHealth applications like Psicovida hold considerable promise in transforming mental health interventions. Their capacity to transcend traditional demographic limitations, coupled with their efficacy in reducing mental health symptoms and enhancing positive psychological well-being, positions them as valuable assets in the mental health care continuum [38-41]. However, the journey towards their full integration into mainstream mental health services necessitates a concerted effort to bolster the scientific rigor of efficacy studies, ensuring these digital tools can be deployed with confidence in clinical and preventive mental health settings. As this field continues

XSL•FO
RenderX

to evolve [42-44], the intersection of technology and psychology heralds a new era in mental health care, characterized by accessibility, personalization, and a holistic approach to well-being.

Limitations

Despite the significant improvements observed in mental health outcomes for health care workers using the 'Psicovida' mobile app, it is important to acknowledge and critically assess several limitations inherent to these findings, aligning with the best guidelines for eHealth practices [37]. First, the quasi-experimental design presents limitations. While the study ensured comparable characteristics between groups, a fully randomized controlled trial (RCT) would enhance internal validity by further reducing the likelihood of confounding variables influencing outcomes.

Second, this study was conducted in a single public hospital in Quito, Ecuador, which may limit the generalizability of the findings to other health care settings or regions. Factors such as organizational culture, health care policies, and available resources vary across institutions and countries, potentially impacting the app's effectiveness in other contexts. Expanding future studies to include multiple institutions in diverse geographic locations would provide more robust evidence of the app's applicability.

Third, the study intervention lasted only 3 months, making it challenging to assess the long-term sustainability of the app's impact on mental health outcomes. Mental health interventions often require ongoing support to maintain improvements, and it remains unclear whether participants' mental health would regress postintervention without continued app use or alternative support mechanisms. Additionally, participant engagement with the app varied, with 34% of participants using it for 10 - 12 weeks, 42% (n=37) for 7 - 9 weeks, and 24% (n=21) for fewer than 6 weeks. However, the study did not explore how these variations in engagement levels might have influenced outcomes. Understanding the relationship between frequency and intensity of app use and mental health improvements would offer valuable insights into optimal usage patterns.

Another limitation involves the reliance on self-reported measures, such as the PHQ-9 and GHQ-12, which may introduce bias as participants could underreport or overreport symptoms due to social desirability or personal perception. While these instruments are widely validated, incorporating objective measures of mental health, like clinical interviews or physiological data (eg, sleep patterns or stress biomarkers), could provide more comprehensive and unbiased assessments.

Finally, typical limitations in eHealth trials apply here, including the lack of blinding for participants, which could introduce expectation bias. Additionally, the multiplicity of outcomes assessed increases the risk of type I errors. Privacy concerns and technical issues, though minimal, were not fully explored in this study but should be considered in future research, as unintended effects in eHealth interventions may also include both negative and positive incidental findings.

In this non-RCT, structured reminders and prompts were used to encourage regular app engagement, which may have positively influenced adherence and outcomes. However, in a routine application setting, these elements may be absent, potentially impacting user adoption and consistent usage. Additionally, the level of technical support and structured monitoring available during the trial might not be feasible in typical usage scenarios. The absence of these supportive features in everyday settings could lead to decreased engagement, highlighting the need for integrating alternative engagement strategies, such as in-app notifications or occasional follow-up messages, to maintain effectiveness outside the structured environment of a clinical trial.

Generalizability

The findings of this trial have implications for similar health care settings but may have limited generalizability to broader populations. Given that this study focused specifically on health care workers, the results may not directly apply to a general internet population or patients outside of the study setting. Health care workers face unique stressors and mental health challenges, which may not be reflective of other groups, limiting the applicability of the intervention's effects in different contexts.

Moreover, certain elements of the non-RCT, such as periodic reminders and structured monitoring, may have positively influenced user engagement and adherence. In a routine application setting, the absence of these supportive elements could reduce both app usage and its effectiveness. To improve generalizability, future implementations should consider integrating support features, such as reminders or optional human guidance, which may enhance engagement and outcomes outside of a controlled trial environment. Such adaptations could facilitate the adoption and sustained use of eHealth interventions, making them more practical and effective in broader health care and community contexts.

Further Research

Future research should address these limitations to strengthen the evidence supporting the Psicovida app and similar mHealth interventions. A fully RCT design could enhance internal validity by minimizing biases that may arise from a quasi-experimental approach. Expanding the study across multiple health care institutions and regions, particularly in Latin America, is essential. The lack of robust mental health research in this region, especially among health care workers, underscores the need for broader evaluations to assess the app's effectiveness in diverse and underrepresented contexts.

As this study concluded, Psicovida serves primarily as an adjuvant to traditional mental health treatments rather than a standalone solution. Future research should explore how app-based interventions like Psicovida can be integrated with conventional therapeutic approaches to maximize effectiveness. This is particularly relevant for individuals with more severe mental health conditions, where professional support and structured treatments are indispensable.

Longitudinal studies are needed to evaluate the long-term effects of the Psicovida app. While this study demonstrated promising short-term outcomes, further investigation is required to determine whether the observed mental health improvements

XSL•FO
RenderX

persist over time and to identify the optimal frequency or duration of app use. These studies should also explore the potential need for supplementary interventions to sustain benefits, ensuring the app remains effective as a supportive resource.

Comparative studies between Psicovida, other mHealth apps, and alternative therapeutic interventions would provide valuable insights into best practices for app design and implementation. Such research could help refine strategies to address the unique challenges faced by health care workers and adapt interventions to specific cultural or occupational contexts.

Additionally, future research should examine the app's effectiveness across various health care roles (eg, doctors, nurses, and administrative staff) and investigate the influence of workplace stressors or social support. Understanding how user engagement impacts mental health outcomes is critical, as it can inform strategies to optimize adherence and enhance effectiveness. Incorporating objective mental health assessments, such as clinical interviews or physiological measures, alongside self-reported outcomes would further bolster the evidence base.

By addressing these research gaps, future studies can help refine and expand the application of Psicovida and similar tools, making them more practical and effective in broader health care and community contexts.

Conclusions

The Psicovida app represents a significant advancement in the accessibility and convenience of mental health resources, offering a valuable tool for users to access support anytime and anywhere. This is particularly beneficial for individuals facing barriers to traditional mental health services due to geographic, social, or economic constraints. The app incorporates a variety of therapeutic approaches, including CBT and mindfulness, and provides interactive tools for emotional support, therapeutic guidance, and progress monitoring.

Despite its benefits, Psicovida should not be seen as a replacement for face-to-face therapy, but rather as a complementary resource. The effectiveness of the app can vary based on the user's specific condition, the app's design quality, and the user's engagement. Therefore, it's crucial to have realistic expectations based on scientific evidence and to view such apps as part of a broader mental health strategy.

Acknowledgments

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. The study was financially supported by the principal author (SLM-O).

Data Availability

Research data supporting this publication are available from Open Society Foundations (OSF) repository [19].

Authors' Contributions

SLM-O conceived and designed the study, curated and analyzed the data, developed the methodological framework and software tools, led the investigation, managed project resources and administration, supervised the research team, validated and visualized the results, drafted the original manuscript, and coordinated all subsequent revisions. RVAM refined the methodological approach and contributed substantial edits during manuscript revision. DSG provided critical editorial feedback and improved the clarity of the manuscript. JP-B reviewed the manuscript and enhanced its coherence and style through targeted edits. MF-H performed additional formal analyses and worked on manuscript revisions to ensure analytic accuracy. All authors reviewed and approved the final manuscript.

Conflicts of Interest

One of the authors, SLM-O, is the developer and owner of the "Psicovida" app used in this study, which may present a potential conflict of interest. However, the research was conducted with transparency, and all findings were independently analyzed to ensure objectivity. No additional commercial or financial relationships influenced the outcomes of this study.

Abstract

Background: Digital patient registries are actively used to monitor long-term diseases. However, their potential in symptom management remains underused.

Objective: This study aimed to report on the Finnish registry-based protocol to screen and manage cognitive symptoms and fatigue in multiple sclerosis (MS). Data on a sample collected during the first 2 years are presented.

Methods: At the beginning of 2021, a Finnish protocol to screen and manage patient-perceived concerns related to cognition and fatigue, together with self-assessment of disease severity, symptoms, and quality of life (QoL) annually, was introduced. The Symbol Digit Modalities Test (SDMT), the Multiple Sclerosis Neuropsychological Questionnaire (MSNQ), the Fatigue Scale for Motor and Cognitive Functions (FSMC), as well as the Patient-Reported Expanded Disability Status Scale, the Visual Analog Scales, and the Euro QoL-5 Dimension were implemented into the Finnish MS registry. To support symptom management, patients were offered feedback reports based on the results of the FSMC and the MSNQ. The implementation of the protocol was evaluated in 5 Finnish wellbeing services counties.

Results: Our sample from the beginning of 2021 to the end of 2022 includes data on 430 patients. A total of 86 (20%) patients have been assessed with the SDMT, whereas 329 (76.5%) patients have filled out the FSMC, and 172 (40.0%) patients have completed the MSNQ. The mean SDMT score is 49.0 (SD 13.56), MSNQ score is 35.3 (SD 9.39), total FSMC score is 63.0 (SD 22.49), and subscores for motor and cognitive fatigue are 31.6 (SD 11.43) and 31.5 (SD 11.68), respectively. The SDMT did not correlate with the MSNQ or the FSMC. Instead, the SDMT, MSNQ, and the FSMC correlated significantly with QoL.

Conclusions: Fatigue and cognitive problems have an effect on QoL. In our preliminary sample, patient reports of cognitive problems and especially fatigue were conducted more frequently than the objective evaluation of processing speed. Although the Finnish MS registry offers a digital platform for the systematic screening of fatigue and cognitive problems, further education is needed to support the implementation of the protocol.

Introduction

Multiple sclerosis (MS) registries are in active use in many European countries [1], and the need to develop registry-based data collection is recognized worldwide [2]. Registries help with patients' follow-up and care [3,4]. There is a need to increase patient involvement and the collection of patient-generated data. Tools to identify and manage the wide range of patient-perceived MS-related concerns are needed. Moreover, there is a special need for early recognition of symptoms and factors that affect productivity and quality of life (QoL).

According to a mapping survey, there are 19 MS registries in Europe [1]. Patient-reported outcomes (PROs) are included only in 7 registries. One of those is the Finnish MS registry with a unique patient interface. The Finnish MS registry was launched in 2014 to enable digital treatment monitoring, systematic follow-up of incidence and prevalence, as well as the course of the disease [5]. At present, the registry is used in 18 out of 21 of Finland's wellbeing services counties, including all 5 university hospitals. A patient interface for PROs was created in 2017, allowing patients to contribute health data on their symptoms, QoL, and overall well-being to inform health care professionals (HCPs) and to support patient-centered treatment decisions [6,7]. The PROs implemented in the patient interface include validated patient-reported outcome measures (PROMs) as well as more informal PRO data.

Fatigue has been presented as the most common symptom of MS, with a rate of up to 80% [8-10], whereas approximately 50% of patients with MS have been shown to have cognitive deficits [11]. The negative effects of cognitive problems and fatigue on working ability have been shown in registry-based studies [12,13]. Self-perceived cognitive problems and fatigue have shown a linear relationship with days on sick leave and a decrease in weekly working hours and self-perceived working ability [12]. Furthermore, impaired processing speed as evaluated by the Symbol Digit Modalities Test (SDMT) has been found to be related to decreased work productivity as measured by days on sick leave and total annual income [13]. Cognitive deficits and fatigue, as invisible symptoms, often remain underdiagnosed, and treatment options are considered too late to promote working ability. Despite these findings, patient reports on fatigue or cognitive problems are not systematically included in MS registries [1]. Because the underlying mechanisms of fatigue are multifaceted and no clear definition for the symptom exists, the assessment is particularly challenging and relies heavily on patient report [8]. The fact that fatigue and cognitive concerns have been reported to be confounded with depression and problems with mood further complicates the assessment of the symptoms [14]. At the same time, the detrimental effects of fatigue and cognitive concerns on employment call for early diagnostics and treatment.

In 2020, a Finnish initiative called Invisible Symptoms in MS was presented to meet the need to consider cognitive symptoms and fatigue systematically and in a cost-effective way already at the early phases of the disease. The primary aims of the initiative were to promote early and holistic evaluation and treatment of MS and to offer patients tools to evaluate and manage fatigue and cognitive problems by themselves. The objective of this paper is to describe the protocol to screen and manage fatigue and cognitive problems by using the Finnish MS registry. Furthermore, descriptive statistics are reported on the data collected during the first 2 years following the implementation of the procedure, based on a sample from 5 well-being services counties.

Methods

Finnish MS Registry

The Finnish MS registry is a browser-based registry for public health care organizations [5]. The software service is provided by StellarQ Ltd. The use of the registry is voluntary, and each well-being services county has decided individually whether to acquire it. At the time of the study, 17 out of 21 counties used the registry with data on over 12,500 patients with MS. This is estimated to cover approximately 90% of all patients with MS in Finland [6]. The content of the registry is described in detail elsewhere [5]. All patients registered in the clinician-based registry can use the patient interface, called MyMS (patient interface of the Finnish MS registry), which can be accessed with the national Finnish electronic authorization. A total of 1201 patients with MS were reported to have recorded data into MyMS by the beginning of 2023 [6]. The content of the patient interface is described in our previous studies [6,7]. MyMS has existed since 2017 with the possibility to record background and lifestyle factors, suspected relapses, medications, need for assistance and social support, rehabilitation, and other diseases. Furthermore, 3 self-rating questionnaires, the Fatigue Severity Scale, the Multiple Sclerosis Impact Scale-29, and the 15D QoL scale have been available for users to assess their conditions since 2017 [6].

Registry-Based Protocol for Screening of Fatigue and Cognitive Problems

The protocol for registry-based evaluation of cognitive problems and fatigue, along with the patient-perceived disability and QoL, was accepted by the Expert Academic Advisory Board of the Finnish MS registry. The protocol has been available since the beginning of 2021. The annual protocol includes the SDMT [15] as well as the following PROMs: the Patient-Reported Expanded Disability Status Scale (PREDSS) [16,17], the Visual Analog Scales (VASs) on neurological symptoms, the Euro QoL-5 dimensions [18], the Multiple Sclerosis Neuropsychological Questionnaire (MSNQ) [19,20], and the Fatigue Scale for Motor and Cognitive Functions (FSMC) [20,21]. The questionnaires are scored according to the standardized procedures of the instruments. The content of the protocol is described in Table 1.

XSL•FO
RenderX

Table . The annual protocol for screening and management of fatigue and cognitive problems by using the Finnish multiple sclerosis (MS) registry.

Assessment tool	Domain assessed	Assessment method / scoring	Role in the protocol
Symbol Digit Modalities Test (SDMT) in clinical MS registry	Cognitive processing speed	Assessed by a nurse; the patient matches symbols with digits in 90 seconds.	Screens for cognitive impairment. Neuropsychological assessment is recommended if the score declines by more than 10% or 4 points compared with baseline or previous assessment.
Patient-Reported Expanded Disability Status Scale (PREDSS) in MyMS[a]	Disease severity	Patient-reported evaluation of disease severity on a scale from 0 to 9, corresponding to the clinician-rated Expanded Disability Status Scale (EDSS).	Provides a perspective on patient-perceived disease severity.
Visual Analog Scales on Neurological Symptoms (VAS) in MyMS	Neurological symptoms	Patient-reported evaluation of symptom severity using a 0 to 100 scale, where 100 indicates the worst possible symptom.	Provides perspective on patient-perceived symptom severity. VAS mood score can be used to control the effect of mood on fatigue and cognition.
Euro Quality of Life-5 Dimension (EQ-5D) in MyMS	Quality of life	Patient-reported QoL evaluation using an index score from 0 to 1, where 1 indicates perfect QoL.	Provides perspective on patient-perceived quality of life.
Fatigue Scale for Motor and Cognitive Functions (FSMC) in MyMS	Motor, cognitive, and overall fatigue	Patient-reported; consists of 10 items on motor fatigue and 10 on cognitive fatigue, scored from 1 (totally disagree) to 5 (totally agree). Motor and cognitive subscores up to 50 each, total score up to 100.	Provides perspective on patient-perceived fatigue. Offers feedback to the patient including score interpretations and practical guidance for managing motor and cognitive fatigue in daily life.
Multiple Sclerosis Neuropsychological Questionnaire (MSNQ) in MyMS	Cognitive problems	Patient-reported; consists of 15 items assessing cognitive problems, each scored from 0 (does not occur) to 4 (very often/very disruptive), yielding a total score ranging from 0 to 60.	Provides perspective on patient-perceived cognitive problems. Offers feedback to the patient including score interpretation and practical guidance for managing cognitive difficulties in daily life.

[a]MyMS: patient interface of the Finnish MS registry.

According to the Invisible Symptoms protocol, patients with MS were familiarized with MyMS by the MS nurses in the hospital clinics. Educational material was offered for the nurses. Patients were provided with a leaflet containing instructions on how to use MyMS (Multimedia Appendix 1).

Study Sample and Statistical Analysis

A preliminary sample collected from 5 well-being services counties between the beginning of 2021 and the end of 2022 was analysed. Date imputation, as the middle of the month or year, was used for clinical variables with partial dates. Date imputation was not needed for patient-reported data. The date of the first data entry in the patient interface was considered the index date to calculate age and disease duration. Descriptive statistics for demographics and PRO measures included means, SDs, medians, and IQRs for continuous variables, and counts and proportions for categorical variables. In addition, the proportion of missing data was reported.

For the correlation analysis, each pair of samples was created by matching the earliest dates of 2 PRO recordings that occurred within 28 days of one another. Correlation coefficients and testing were based on Pearson's product-moment correlation. For controlling and checking the false discovery rate, the Benjamini-Hochberg procedure was used as a correction for multiple comparisons. *P* values under .05 after the correction were considered significant. All data analyses were done using RStudio (version 2021.09.1; Posit, PBC).

Ethical Considerations

According to Finnish legislation, the approval of an ethical committee was not required as the study was a noninterventional registry study in which patients were not contacted. Patients permit the use of the data for research purposes including the secondary use when they log into the registry. Patients did not get any compensation for participation in the study. All used data were permitted via Finnish Social and Health Data Permit Authority Findata, which is responsible for data permits considering secondary use of data with multiple data sources and registry keepers (permission numbers THL/1809/14.02.00/2022 and THL/2104/14.05.00/2023 findata-rems-2023). Clinical data such as age at diagnosis, course of disease, disease duration, and Expanded Disability Status Scale (EDSS) [22] were extracted from the clinical MS registry and PRO data from the patient interface. All the data was analyzed in pseudonymized form, and in audited secure processing environment. Only anonymized information can be exported from the secure processing environment, and patient-level data is not publicly available to either authors or third-parties.StellarQ Ltd is the data processor for all data extracted.

Results

The Invisible Symptoms protocol was available in 17 out of 21 Finnish well-being services counties at the time of the analysis. For the purposes of the study, we evaluated a sample from 5 Finnish well-being services counties: Southwest Finland, Satakunta, Pirkanmaa, Central Finland, North Savo. The population in these 5 counties represents approximately 30% of the total population in Finland and approximately 40% of the national MS population. The 5 counties represent areas with different population density and prevalence of MS. The implementation of the protocol was voluntary and depended on the resources the clinics had to administer the SDMT and introduce MyMS to the patients.

Altogether, 430 patients in the 5 well-being services counties had recorded data related to the Invisible Symptoms protocol into MyMS. The demographic and clinical variables of the protocol sample are listed in Table 2. The mean age of the patients at the first PRO recording was 42.5 years, the median disease duration was 4.1 years, and the median EDSS score was 2.5. Over 80% of patients were women (357 out of 430) and had a relapsing-remitting course of the disease (354 out of 430).

Table . Demographic and disease-related variables of the patients with data related to the Invisible Symptoms protocol.

Variable	Protocol sample (n=430)
Age at MS[a] onset (years)	
Mean (SD)	33.1 (10.18)
Missing data, n (%)	108 (25.1)
Age at MS diagnosis (years), mean (SD)	35.5 (10.13)
Age at first PRO[b] recording (years), mean (SD)	42.5 (10.28)
Sex (female), n (%)	357 (83.0)
Disease course, n (%)	
RRMS[c]	354 (82.3)
SPMS[d]	20 (4.7)
PPMS[e]	22 (5.1)
UNS[f]	34 (7.9)
Disease duration (years), median (Q1-Q3)	4.1 (0.6-11.3)
EDSS[g]	
Median (IQR)	2.5 (2.0-3.5)
Missing data, n (%)	50 (12)
Education (total years)	
Mean (SD)	14.3 (2.73)
Missing data, n (%)	118 (27.4)
Smoking (yes), n (%)	
Number	39 (10)
Missing data	24 (6)

[a]MS: multiple sclerosis.
[b]PRO: patient-reported outcome.
[c]RRMS: relapsing-remitting MS.
[d]SPMS: secondary progressive MS.
[e]PPMS: primary progressive MS.
[f]UNS: unspecified disease course.
[g]EDSS: Expanded Disability Status Scale.

Of the 430 patients, 349 (81.2%) patients have filled out the PREDSS with a mean score of 2.9 (SD 1.67) (Table 3). Table 3 summarizes the coverage of data on the SDMT as well as the PROMs related to the Invisible Symptoms protocol. The SDMT assessment was performed on 86 (20%) patients. The PROM on fatigue, the FSMC, was completed by 76.5% (329 out of 430) of the patients, whereas the PROM on cognitive problems, the MSNQ, was completed by 40.0% (172 out of 430). When a patient completes the FSMC, they receive a feedback report summarizing the results. The report also includes information about fatigue, along with practical tips for managing it in daily life. An example of the feedback report is presented as the

XSL•FO

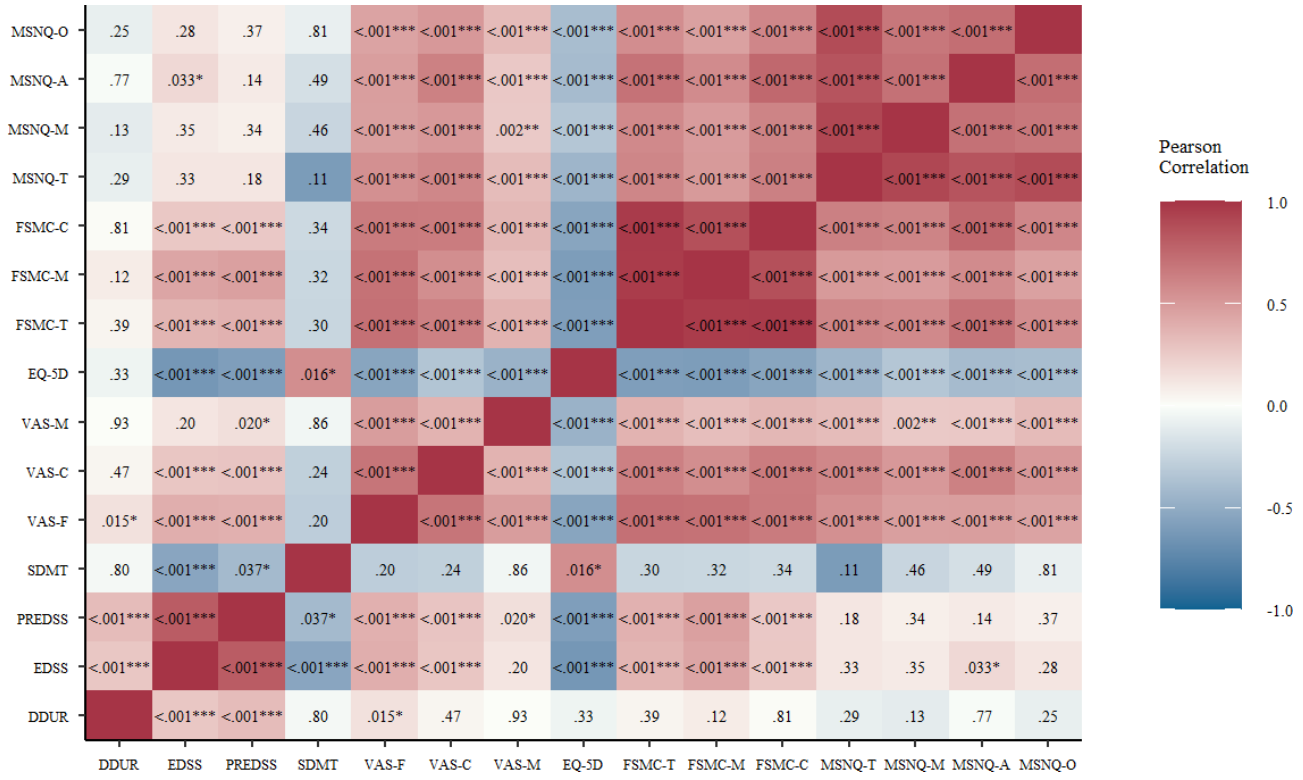
Verbal, problem-solving, and behavior	199 (46.3)	2.0 (0.64)	2.0 (1.5-2.3)

[a]PREDSS 0 - 9 where 0 stands for no disability and 9 for bedridden most of the time.

[b]VAS: Visual Analog Scale. VAS scores where 0 stands for no problems and 100 for worst possible problems.

[c]EQ-5D: Euro Quality of Life–5 Dimension. Higher scores refer to better quality of life in EQ-5D (range 0 - 1).



[d]FSMC: Fatigue Scale for Motor and Cognitive Functions. Higher scores refer to more severe symptoms/problems in the FSMC (total score range 20 - 100, subscore range 10 - 50).

[e]MSNQ: Multiple Sclerosis Neuropsychological Questionnaire. Higher scores refer to more severe/frequent cognitive problems in MSNQ (total score range 0 - 60, subscores are means and range from 0 to 4).

In the present sample, a significant relationship was observed between disease duration and both the EDSS and the PREDSS (Figure 1). Disease duration did not show a significant relationship with any of the measures on mood, fatigue, cognition, or QoL except for the VAS-F. The EDSS correlated significantly with the SDMT, the VAS scores on fatigue and cognition, QoL, FSMC scores, and attentional items of the MSNQ. The PREDSS showed a correlation pattern similar to that of the EDSS. In contrast to the EDSS, it also correlated significantly with the VAS-M, but not with the MSNQ scores. The SDMT did not correlate significantly with the self-reports on mood, fatigue, or cognition. Instead, a significant correlation was observed between the SDMT and QoL. The VAS scores on fatigue, cognition, and mood correlated consistently with each other and the Euro Quality of Life–5 Dimension. Both the FSMC and MSNQ scores showed significant correlations with self-reports on fatigue, cognition, mood, and QoL.

Figure 1. Correlation analysis of DDUR, disability (EDSS and PREDSS), SDMT performance, and PROMs on quality of life, fatigue, cognition, and mood. DDUR: disease duration; EDSS: Expanded Disability Status Scale; EQ-5D: Euro Quality of Life–5 Dimension; FSMC: Fatigue Scale for Motor and Cognitive Functions; MSNQ: Multiple Sclerosis Neuropsychological Questionnaire; PREDSS: Patient Reported Expanded Disability Status Scale; SDMT: Symbol Digit Modalities Test; VAS: Visual Analog Scale. *P<.05, **P<.01, ***P<.001.

Discussion

The Finnish invisible symptom initiative presents a protocol for registry-based screening and management of fatigue and cognitive concerns. It includes an annual assessment of processing speed using the SDMT, as well as patient-reported measures of disease severity, QoL, and symptoms, with an emphasis on cognitive symptoms and fatigue. For symptom management purposes, patients are provided with a feedback report on self-perceived fatigue based on the FSMC and on self-perceived cognitive problems based on the MSNQ. Our sample from 5 Finnish well-being services counties shows that the implementation of the protocol has been gradual, and patient-reported assessments have been conducted more frequently than objective assessments of processing speed. The descriptive statistics of the present sample support earlier findings on the important role of fatigue and cognitive symptoms in QoL [7,10,12,13,23].

Our protocol for the screening and management of problems and fatigue aligns with the recommendations by Kalb et al [24] for baseline screening and annual follow-up of cognitive performance in MS using the SDMT. The SDMT has been introduced as the most sensitive measure of cognitive performance and processing speed in MS [25]. The Finnish validation of the brief international cognitive assessment in MS showed that the SDMT was the most sensitive measure, also in Finnish patients with MS [20]. In the same study, the MSNQ and the FSMC were found to be suitable for self-evaluation of fatigue and cognitive symptoms, provided that the effects of mood state are adequately controlled. To assess patient perspective, the MSNQ and the FSMC were thus implemented into the patient interface of the Finnish MS registry. The VAS score on mood was used to control the effects of mood on fatigue and cognitive concerns.

Only 20% (86 out of 430) of the patients in the present sample were assessed with the SDMT. The mean SDMT score in the present registry-based sample was higher than that observed in the Finnish validation study with older and more disabled patients [20] but in line with international studies with patients of similar age and EDSS [26-29]. Over 50% (291 out of 430) of the patients of the present sample had completed the MSNQ, and over 70% (337 out of 430) of the patients had completed the FSMC, at least partially. Based on the FSMC [21], the patients of the present sample reported severe overall fatigue and moderate motor and cognitive fatigue. Based on the MSNQ [19], they also perceived at least occasional problems with cognitive functions. The patients of the present sample reported more fatigue and cognitive concerns than the patients in the Finnish validation study [20]. Further, the FSMC scores of the present sample were higher than those in another Finnish study involving patients with relapsing-remitting MS [10]. The present sample is likely overrepresented by patients with pronounced fatigue and cognitive symptoms, as these individuals were probably more often instructed to complete the questionnaires to support symptom management.

In the present sample, physical disability as measured by either the EDSS or the PREDSS correlated with all the self-report measures used, except the MSNQ. On the contrary, disease duration did not have a significant relationship with the self-reports, certifying the earlier findings that invisible

XSL•FO
RenderX

symptoms may emerge at any phase of the disease [30]. The SDMT correlated with both the EDSS and the PREDSS. The SDMT did not show a significant relationship with the self-report of depression. On the contrary, self-reports on fatigue and cognitive problems correlated significantly with those on depression. These results are in line with earlier findings that concerns with fatigue, cognition, and mood are interrelated and should all be considered in the screening and search for optimal treatment methods [11,14,19,20].

In the Invisible Symptoms initiative, feedback reports based on the patient's answers in the MSNQ and the FSMC were developed. Digital self-management tools could be further developed into web-based rehabilitation programs that integrate assessments, feedback, and strategies with individual goal setting and professional counseling. Positive effects on the management of cognitive symptoms in MS have been demonstrated not only through neuropsychological and cognitive rehabilitation, but also through the use of digital applications [31-33]. Especially cost-effective, individualized, and holistic intervention with an input from HCP has been called for [11].

This study has several limitations. The procedure for screening and managing fatigue and cognitive concerns has been in use for only 2 years and is not yet fully implemented across all regions, resulting in a relatively small sample limited to 5 of Finland's 21 wellbeing services counties—though these account for approximately 40% of the national MS population. Adoption of the protocol has likely been slowed by limited resources for conducting the SDMT and challenges in interpreting and integrating PROM data into routine clinical decision-making. Additionally, the patient interface has so far been available only as a web-based tool, which may have reduced usability; a mobile app is currently under development in response to patient feedback, particularly from younger individuals. The sample may also over-represent individuals with fatigue and cognitive symptoms, as participation is voluntary and allows patients to choose which questionnaires to complete. It is also unknown whether patients have engaged with the feedback provided. Despite these limitations, the model offers clinics a structured means to guide annual assessment and symptom management through the digital registry. Ideally, this approach would be applied systematically and include both PROMs and the SDMT, which is internationally recommended for evaluating cognitive function in people with MS.

Comprehensive management of invisible symptoms requires effective communication between HCPs and patients [34,35]. The Finnish Invisible Symptoms initiative provides a systematic approach to addressing patient-perceived cognitive problems and fatigue. Cognitive performance and patient-perceived symptoms, including fatigue and cognitive concerns, can be assessed annually using validated tools, with results accessible to patients via the patient interface and to HCPs via the clinician interface. According to a European survey published in 2019 [1], only 7 out of 19 identified MS registries include patient-derived measures. Digital registries can serve as platforms for patient-reported data, empowering individuals to take an active role in managing their disease, adhering to treatment, and making beneficial lifestyle choices. As stated by Lakin et al [34], by pairing clinical knowledge with an understanding and consideration of the patient perspective, HCPs are equipped to foster patient-centered dialogue that encourages shared decision-making and high-quality care. The need for innovative interventions addressing invisible symptoms is increasingly recognized. Positive experiences with digital solutions have already been reported, highlighting the importance of continued development and evaluation [31,33,36].

Acknowledgments

The authors gratefully acknowledge the contribution of the StellarQ IT team for building and continuously developing the Finnish MS Register IT platform. All members of the Steering Committee of the Finnish MS registry, as well as patients who have participated in the development of the patient interface of the Finnish MS registry (MyMS), are gratefully acknowledged. Building up the Finnish MS registry and the patient interface has received funding from Biogen Idec, Merck, Novartis, Roche, Sanofi Genzyme, Teva, and Business Finland. The Invisible Symptoms initiative received additional funding from Novartis. The preparation of the manuscript was in part funded by the Strategic Research Council (SRC) established within the Academy of Finland (funding number 358415).

Data Availability

The datasets generated or analyzed during this study are not publicly available due to Finnish legislation. Data are analyzed based on the Act on the Secondary Use of Social and Health Data, which restricts patient-level data from being handled only for a granted purpose, in pseudonymized form, and in an audited secure processing environment. Only anonymized information can be exported from the secure processing environment, and patient-level data are not publicly available to either authors or third parties.

Abstract

Background: The growing demand for hospital-based care, driven by aging populations and constrained resources, has accelerated the adoption of telehealth tools such as teleconsultations and remote monitoring in hospital-at-home (HaH) programs. Despite their increasing use in delivering acute care at home, studies exploring health care providers' experiences and perceptions of these tools within HaH settings remain limited.

Objective: This study aimed to understand the experiences and perspectives of health care providers toward teleconsultations and vital signs monitoring systems within a HaH program in Singapore to optimize effectiveness and address challenges in future implementation.

Methods: A convergent mixed methods approach that combines qualitative in-depth interviews with an electronic survey designed based on the 5 domains (usefulness, ease of use, effectiveness, reliability, and satisfaction) of the Telehealth Usability Questionnaire was used.

Results: In total, 37 surveys and 20 interviews were completed. Participants responded positively to the use of both teleconsultation and vital signs monitoring with a mean total score of each method being 4.55 (SD 0.44) and 4.52 (SD 0.42), respectively. Significantly higher mean ratings were observed among doctors compared with other health care providers for usefulness (P=.03) and ease of use (P=.047) in teleconsultations. Health care providers with fewer years of clinical experience also perceived the use of vital signs monitoring to be more effective (P=.02) and more usable (P=.04) than those with more years of experience. Qualitative analysis identified four themes: (1) benefits of telehealth for health care providers such as improved work convenience, efficiency, and satisfaction; (2) challenges of telehealth implementation relating to communication and technology; (3) perspectives on telehealth impact; and (4) enablers for successful implementation. Comparing both datasets, qualitative findings were aligned with and confirmed quantitative results.

Conclusion: This study highlighted the benefits and usability of telehealth among health care providers. However, challenges relating to patient communication, technological issues, and delivery of care were also discussed along with enablers for successful implementation. These insights can inform strategies to optimize future implementation of telehealth in HaH.

Introduction

As health care systems worldwide face growing challenges from aging populations, the demand for hospital-based care continues to rise, putting increasing pressure on limited health care resources [1,2]. In response, innovative care models such as hospital-at-home (HaH) have been developed to meet these demands [3]. Although the concept of HaH is not novel, its adoption has gained momentum in recent years driven by advancements in digital health technologies, with successful implementations in the United States, Europe, Australia, and Singapore [4,5]. By leveraging these technologies, HaH aims to optimize health care delivery, allowing more patients who require hospital admission to receive treatment at home and supporting the early discharge of patients whose care can safely

XSL•FO
RenderX

continue outside the hospital [6,7]. Likewise, HaH played a critical role in supporting health care systems during the COVID‐19 pandemic [8-11], drawing attention to its potential as a promising care model that extends coverage for pandemic and nonpandemic times.

The integration of digital health tools, such as remote monitoring systems and telecommunication technologies in HaH, allow health care providers to remotely assess patients via video or telephone consultations and monitor self-reported vital signs and symptoms, creating a seamless and efficient care experience [10-12]. Studies have consistently shown that these approaches are both safe and effective, with low mortality and return to hospital admissions rates [10,11,13,14], and high patient satisfaction levels, as patients feel reassured knowing their conditions are remotely monitored [13-17].

Despite these promising outcomes, there remains a lack of research exploring the experiences and perspectives of health care providers using telehealth and remote monitoring tools in the HaH setting. Existing studies that have explored health care provider experiences with telehealth use have primarily focused on routine follow-up in outpatient clinics [18-20], long-term care [21,22], and palliative setting [23] rather than in the HaH setting caring for acutely ill patients. Understanding these experiences can help design appropriate training for health care workers looking to work in HaH settings and develop appropriate support systems to ensure health care workers' well-being, the fourth domain of the Quadruple Aim [24] .

To address this gap, we aimed to understand the experiences and perspectives of health care providers toward teleconsultations and vital signs monitoring systems within an HaH program.

Methods

Study Design

This study adopted a convergent mixed methods design. Quantitative data from an electronic telehealth usability survey and qualitative data from in-depth interviews were collected simultaneously during a single data collection phase. These datasets were then analyzed separately before being interpreted collectively [25]. The mixed methods approach was chosen for its capacity to enhance data interpretation by leveraging the complementary strengths of each method. The quantitative survey data offer statistical evidence and a general overview of health care providers' perceptions regarding the usability of telehealth in HaH. On the other hand, qualitative interviews provide valuable contextual information and deeper insights. By integrating both datasets, a more comprehensive understanding of health care providers' experiences and perspectives can be achieved [26].

Setting and Sample Frame

The National University Health System (NUHS) is one of Singapore's 3 public health care clusters, responsible for taking care of the Western population of Singapore. The HaH program at NUHS, known as NUHS@Home, offers home-based hospitalization services to 3 acute hospitals within the health care cluster [4]. In September 2021, NUHS@Home expanded its services to include patients with COVID-19 to manage the surge in cases. To accommodate the larger volume of patients, patients' daily clinician review transitioned from in-person home visits to teleconsultations (both video and audio) with the care team that consists of doctors, nurses, pharmacists, and allied health professionals.

Patients admitted in NUHS@Home during the study period were primarily older adults with COVID-19 infection. Most were proficient in smartphone use or have younger caregivers comfortable with using technology to manage patient care at home. Patients received daily regular scheduled teleconsultations using their own mobile devices and reported their home-monitored vitals through a chatbot with an online reporting form. For patients less proficient with technology, automated vital sign monitoring kits were provided, which transmitted home-monitored vitals to the care team and included a tablet for teleconsultations. Instructions on remote vital signs monitoring and frequency of teleconsultations were provided to patients or their caregivers before their admission to NUHS@Home.

Purposive sampling was used to select participants for this study. All health care providers who were involved in delivering care within NUHS@Home between September 2021 and December 2022 were sampled. Those that have used teleconsultation, vital signs monitoring, or both telehealth methods to provide care in NUHS@Home, were eligible for the study.

Data Collection

Overview

Participants were recruited via an email invitation sent out by the primary investigator of the study (SQK) between November 2022 and January 2023. Recruitment for the study concluded when no new survey responses were received, and data saturation was achieved for the qualitative component of the study.

Surveys

We chose to adopt the Telehealth Usability Questionnaire (TUQ), which assesses usability across 5 domains, that are usefulness, ease of use, effectiveness, reliability, and satisfaction [27]. The TUQ was selected as it has been widely used to capture user perspectives on telehealth utilization [28]. It has demonstrated strong content validity and internal consistency, with Cronbach α values ranging from 0.81 to 0.93 for each domain [27]. The electronic survey included 21 TUQ questions specific to teleconsultation and the same set of 21 questions related to vital signs monitoring. Demographic information of health care providers, their roles in NUHS@Home, previous telehealth experience, and years of clinical experience were also collected. Survey questions were presented in English, and responses to TUQ questions were rated on a 5-point Likert scale (ranging from strongly disagree [−1] to strongly agree [−5]).

In-Depth Interviews

Participants who completed the electronic survey were also invited to participate in an additional in-depth interview. A semistructured interview guide was developed based on the TUQ domains and existing literature on health care providers'

XSL•FO
RenderX

telehealth experiences [29-32]. The interview guide was pilot tested with 2 other health care providers before the actual interviews. All interviews were conducted online in English via Zoom (Zoom Communications, Inc) video call and audio recorded for analysis. Each interview lasted approximately between 30 and 90 minutes. The interviews were conducted and transcribed by the first author of this paper (SYL), a Master of Public Health graduate student with qualitative training. Given the comprehensive nature of the interview data collected, no repeat interviews were conducted, and transcripts were not returned to participants for clarification.

Data Analysis

Survey data, including participant characteristics and TUQ scores, were analyzed and summarized using descriptive statistics. Percentages of responses for each Likert scale point were calculated for each question. The TUQ total score was obtained by calculating the mean of responses for all 21 questions. TUQ subscale scores were calculated with the mean of the responses for the questions in each of the 5 domains. Means and SDs of TUQ total and subscale scores are presented. As the TUQ total and subscale scores did not follow a normal distribution, the Mann-Whitney *U* test was used to examine differences in scores between professional groups, years of clinical experience, and previous telehealth experience. The significance level was set at α=.05. Statistical analysis was conducted using the R statistical software version 4.2.2 (R Core Team).

All audio-recorded interviews were transcribed verbatim, excluding any local Singaporean slang, and participant identifiers were omitted during the transcription. The transcripts were analyzed using an inductive reflexive thematic approach outlined by Braun and Clarke [33] and Byrne [34]. Transcripts were coded line-by-line using ATLAS.ti Web software v5.16.1-2023-10-14 (Lumivero) by SYL with no second coder, prioritizing the researcher's reflexive and thoughtful engagement with both the data and the analytic process. To ensure the rigor and trustworthiness of emerging subthemes and themes, the meanings of codes were compared and discussed monthly among all authors of this study in an iterative and collaborative process.

Upon completing analysis for both sets of data, qualitative findings were compared with quantitative results by TUQ domains to assess confirmation, expansion, or discordance between the datasets and to draw meta-inferences [35]. Data integration was completed by SYL, and the Good Reporting of a Mixed Methods Study criteria [36] guided the reporting of results to ensure reporting quality (Multimedia Appendix 1).

Ethical Considerations

This study was approved by the National Healthcare Group Domain Specific Review Board (Ref 2021/00896). Since the survey was anonymous, the requirement for informed consent from survey participants was waived. To maintain anonymity for the survey, respondents who were interested in participating in the interviews were asked to voluntarily provide their contact information in a separate, optional section of the survey. This ensured that survey responses remained anonymous and unlinked to identifying information unless the respondent explicitly chose to participate in the interview. Informed consent was only obtained from participants who expressed interest in participating in the in-depth interviews. All data collected and analyzed were anonymized. Each interviewed participant was also compensated for their time and involvement with SGD $20 (SGD $1=US $0.75).

Results

Participant Demographics

A total of 49 health care providers were invited to participate in the study. Among the 49 eligible health care providers, 37 responded and completed the electronic survey, resulting in a response rate of 76%. Out of the 37 survey participants, 20 also took part in the interviews. While 59% (22/37) of the participants were doctors, the remaining participants represented a diverse mix of health care providers of various professions such as nurses, pharmacists, and allied health professionals (Table 1). In total, 76% (28/37) of participants reported using both teleconsultation and vital signs monitoring in NUHS@Home. The participants had a median of 7 (IQR 4‐10) years of clinical experience, but 35% (13/37) of them did not have any previous experience with telehealth.

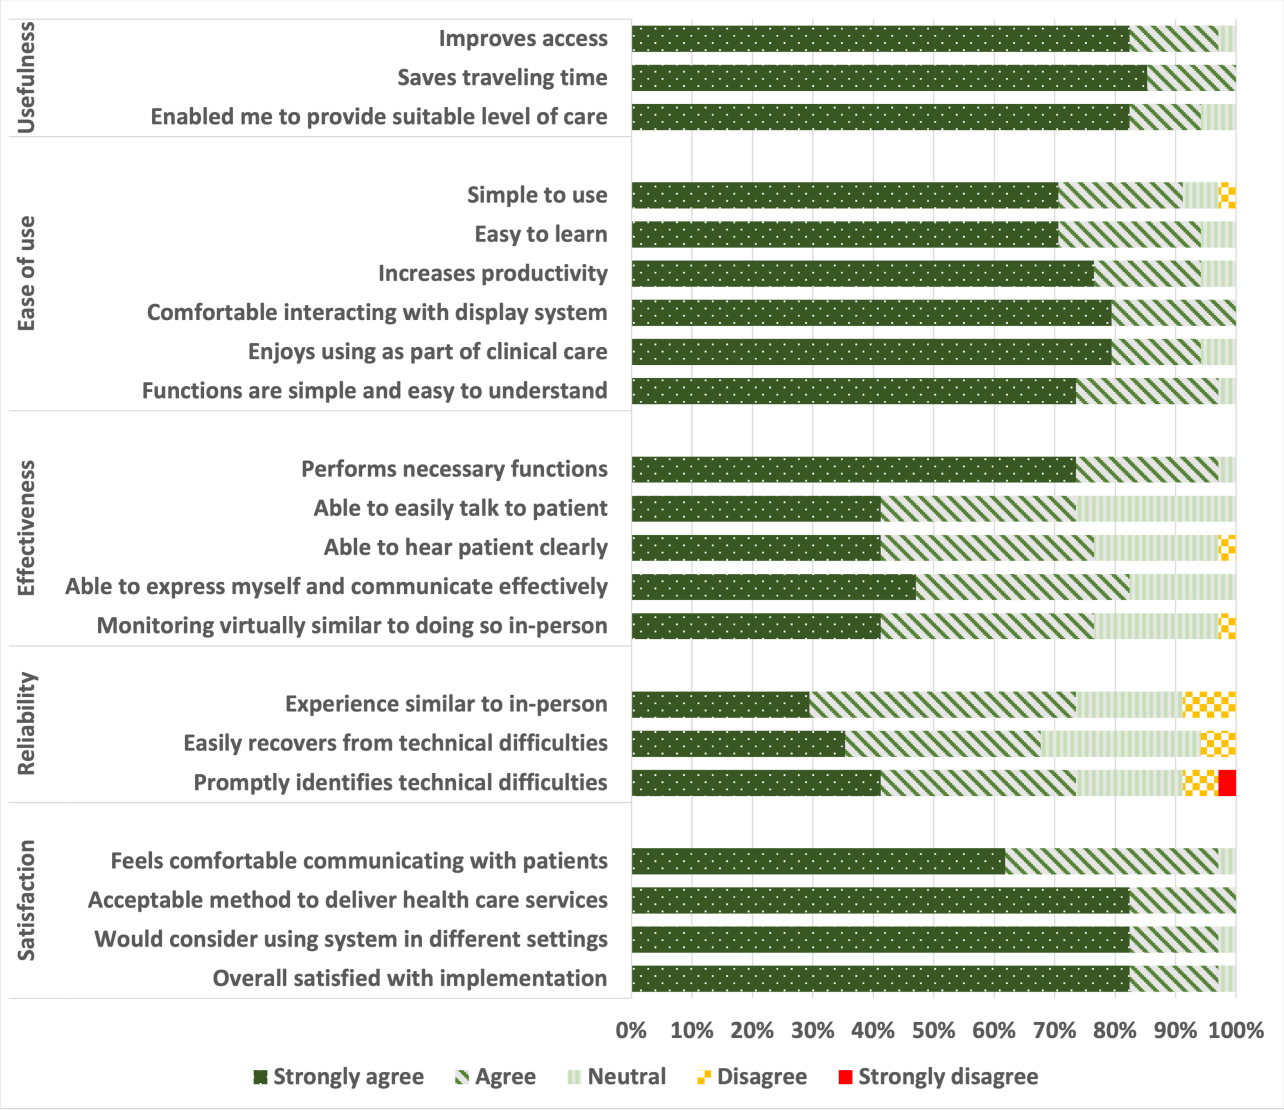
	9 - 12 months	3 (8)	0 (0)
	>12 months	8 (22)	8 (40)

Survey Results

In total, 31 responses were collected for the use of teleconsultation in NUHS@Home. The TUQ total score for teleconsultation ranged from 3.4 to 5, with a mean score of 4.55 (SD 0.44). For teleconsultation, the mean TUQ subscale scores for each domain, from highest to lowest scores, were as follows: “usefulness” (mean 4.84, SD 0.30), “satisfaction” (mean 4.73, SD 0.43), “ease of use” (mean 4.72, SD 0.49), “effectiveness” (mean 4.31, SD 0.61), and “reliability” (mean 4.06, SD 0.57) (Figure 1). Furthermore, 34 responses were collected for vital signs monitoring. The TUQ total scores for vital signs monitoring ranged from 3.5 to 5, with a mean score of 4.52 (SD 0.42). For vital signs monitoring, the TUQ subscale scores for “usefulness” (mean 4.8, SD 0.36), “satisfaction” (mean 4.75, SD 0.35), and “ease of use” (mean 4.7, SD 0.43) were high (Figure 2). However, “effectiveness” (mean 4.29, SD 0.59) and “reliability” (mean 3.98, SD 0.87) scored slightly lower. Further breakdown of TUQ scores is available in Multimedia Appendix 2.



XSL•FO
RenderX

Figure 1. Telehealth Usability Questionnaire responses for teleconsultation.

XSL•FO
RenderX

Figure 2. Telehealth Usability Questionnaire responses for vital signs monitoring.

Doctors perceived teleconsultation to be more useful compared with other health care providers (mean usefulness 4.91 vs 4.67; *P*=.03). Similarly, doctors found teleconsultation easier to use compared with other health care providers (mean ease of use 4.87 vs 4.35; *P*=.047). No significant differences in TUQ subscale scores between doctors and other health care providers were observed for other TUQ domains of teleconsultation or vital signs monitoring. Health care providers with fewer years of clinical experience perceived the use of vital signs monitoring to be more effective (mean effectiveness 4.48 vs 4.04; *P*=.02) and more usable (mean 4.63 vs 4.39; *P*=.04) than those with more years of clinical experience. No significant differences in TUQ scores were observed for teleconsultation or other TUQ domains of vital signs monitoring based on years of clinical experience. Furthermore, no significant differences in TUQ scores were found when comparing health care providers based on previous telehealth experience for both teleconsultation and vital signs monitoring (Multimedia Appendix 3).

Interview Results

Thematic analysis of the interview transcripts yielded 62 unique codes, which were grouped into 4 overarching themes and 8 subthemes. The 4 themes identified are benefits of telehealth tools for health care providers (23 codes and 135 quotes), challenges of telehealth implementation (16 codes and 133 quotes), perspectives on telehealth impact (14 codes and 84 quotes), and enablers for successful implementation (9 codes and 66 quotes). A summary of themes, subthemes, and examples of codes and participant quotes is presented in Table 2.

XSL•FO
RenderX

Table . Summary of participants' themes, subthemes, codes, quotes.

Themes, subthemes, and codes			Examples of quotes
Benefits of telehealth for healthcare providers			
	Improved work convenience, efficiency, and productivity		
		Easy to learn and use vital signs monitoring systems	"…it's a very straightforward system that is very easy to learn to navigate, very easy to use." [ID9, male doctor]
		Reduced need for traveling	"So I think teleconsult has it's good because we actually cut down traveling and received a lot of time in return. The patient is just a phone call or a video call away… You just have to have a set of working equipment in front of you, and you can just sit in front of that and provide care for your patients." [ID15, female nurse]
		Ability to use telehealth methods to effectively identify signs of deterioration	"…through the patients submitting their vitals, actually see and catch any red flags immediately. You know, like persistent high blood pressure, then we know there's something going on. So we can provide treatment immediately." [ID1, female allied health professional]
	Enhanced work satisfaction and confidence		
		Improved teamwork and collaboration	"…because it's all tele, so the team can be physically close together. That means the doctors, the nurses, the pharmacists, all in like one room… I think it's good for like collaboration or when they have issues or when we have questions, it's much easier to just reach them…" [ID5, male pharmacist]
		Facilitated physical distancing and protecting care providers against infectious diseases	"We don't need to gown up and wear all the PPE. Yeah, so in terms of the safety of the staff and with infection control, this is definitely a plus point." [ID20, female pharmacist]
		Improved care provider's confidence in using telehealth	"…I come from a time where physical consultation is extremely important… So at the start, I don't think my confidence was very high to do telemedicine. But after going through [HaH], the interactions with patients have been mostly pleasant… I think it has increased my competence and confidence in managing patients at home using telemedicine." [ID13, male doctor]
Challenges of telehealth implementation			
	Difficulties in patient communication and engagement		

XSL•FO
RenderX

Themes, subthemes, and codes			Examples of quotes
		Difficulty assessing nonverbal information and conducting physical assessments	"You don't get to physically examine your patients. On top of that, because you are not seeing them fully, you can't read their body language, you can't assess a lot of things. So you end up having to talk a lot more to glean more information from a patient to make a clinical decision, as compared to in a ward or in a clinic where you can size up patient pretty fast." [ID9, male doctor]
		Difficulty conveying information to patients	"I guess it's a lot of repetition. Sometimes they don't understand, or they can't hear clearly over video [call]…. Or they can't really operate the video calls very well." [ID11, female doctor]
		Difficulty contacting noncompliant patients and patients at certain time of the day	"You get a few [patients] who just don't want to comply with the rules like they don't want to submit their vitals, they don't want to turn on video because they're sleeping, or they don't want to pick up their phone call." [ID17, female doctor]
	Technological inconveniences related to telehealth systems		
		Care providers encountering technical issues with vital signs monitoring systems	"Audio call, sometimes… including the video calls as well, sometimes it can be quite choppy. We then need to make the calls multiple times. So it tends to get a bit frustrating also." [ID7, female nurse]
		Slow and tedious process to recover and manage technical issues	"Actually, we have feedback to the [vital signs monitoring system vendors] team. But somehow the team also can't quite troubleshoot it when there's problem." [ID15, female nurse]
		Inconveniences encountered due to lack of interoperability of information technology platforms	"…you need to ensure you enter the patient's details correctly. Because [vital signs monitoring system] itself, the patient details is not like an auto flow from [electronic medical records]. So if you enter wrongly or when you create the entry wrongly, then the data error sort of carries forward." [ID3, male doctor]
	Operational issues		
		Increased risk of compromising patient privacy during virtual consults or unconducive environment to conduct virtual calls	"…it got a bit noisy, which is not that good and also can potentially compromise confidentiality because the guy next to you might be talking very loudly, asking for the NRIC number of his or her patients, and your patient might potentially hear the whole conversation." [ID16, male doctor]

XSL•FO
RenderX

Themes, subthemes, and codes			Examples of quotes
		Labor intensive for care providers to set up automated vital signs monitoring system	"The use of the automated kind of system where the vitals can automatically transmit into the system… involves a bit more resource setup, because someone needs to go to the patient's house and set up the system there." [ID14, male doctor]
Perspectives on telehealth impact			
	Perceived patient benefits		
		Perceived improved patient experience due to increased convenience and comfort	"…a shorter hospital stay, convalescing in a very comfortable home environment. So in terms of the experience for [the patients], it's a lot better." [ID12, male doctor]
		Improves patient empowerment	"[Patients] will have more self-awareness of their health. I think they will be more in control of their health when they monitor the blood pressure themselves." [ID6, female nurse]
	Potential benefits to health care systems		
		Reducing need for hospital admissions and saving hospital resources	"…during COVID, one of the big issues was a lack of beds. So [telehealth] definitely helps to free up a lot of beds, especially for patients who are technically stable, who didn't really need to be in [the hospital]." [ID17, female doctor]
		Increased capacity to care for more patients	"We can manage a large group of patients at once. We don't need to visit all of them physically." [ID10, male doctor]
	Potential risks and challenges		
		Concerns with accuracy of patient vitals submission	"Technically, it's very difficult to find out if someone is actually, you know like faking the vitals reading… I think the readings that are taken at home will have some degree of lower reliability compared to in the hospital because the operators are the patients themselves and the caregivers rather than the nurses or the healthcare assistants." [ID14, male doctor]
		Concerns of "overmonitoring"	"So we get patients who are very tired of being chased after to measure [vital signs] three times a day because they wouldn't have otherwise be required to monitor their health at all… Also because of the timing that we would like to see the vital signs, we also ask them to do it at 7am, which is not their usual wake up time." [ID7, female nurse]
Enablers to successful implementation			

XSL•FO
RenderX

Themes, subthemes, and codes		Examples of quotes
	Suitability of using telehealth to manage patients with COVID-19	"…for COVID in particular, majority of the patients are fairly stable… there's no reason to believe that they might deteriorate in front of your eyes. And I honestly tell you, medicine and monitoring are probably the preferred and sensible route… So honestly patients just need to go home…and can be monitored at home safely." [ID12, male doctor]
	Importance of care provider-patient trust	"I think trust is implicit, we just have to trust that the numbers they are submitting is truly what they're doing." [ID13, male doctor]

Integrating Survey and Interview Results

Quantitative and qualitative findings were summarized and meta-inferences were drawn in Table 3. Overall, high levels of usefulness were attributed to perceptions of increased convenience, efficiency, and usefulness. High satisfaction rates were attributed to a positive work environment, teamwork and collaboration, protection from infectious diseases, and high levels of acceptance described by participants. Systems were generally found to be easy to learn and use; however, lack of interoperability with electronic health records and noncompliant patients were cited as key challenges. The comparatively lower scores for effectiveness were likely associated with challenges relating to patient communication and engagement. Finally, the lower scores in the "reliability" domain were associated with technical inconveniences, such as connectivity issues and having a lengthy turnaround time to resolve technical issues.

XSL•FO
RenderX

Table . Integration of findings and the mixed methods meta-inference.

TUQ[a] domain	Quantitative results	Qualitative results	Meta-inference
Usefulness	Mean TUQ subscale scores of 4.84 and 4.8 for the use of both teleconsultation and vital signs monitoring respectively. 100% and 98% of participants rated positively[b] to use of virtual consultation and vital signs monitoring, respectively.	Benefits of telehealth: • Improved convenience due to reduced need for traveling • Increased flexibility and ease of reaching out to their patients • Efficient identification of early signs of deterioration Perceptions: • Perceived patient benefits (eg, patient empowerment, patient comfort, and convenience) • Potential benefits to health care system (eg, saving hospital resources and increased capacity to care for more patients) Enablers: • Suitability of using telehealth to care for patients with COVID-19	• Confirmation: participants' positive experiences relating to improved convenience and efficiency, as well as their perception of the suitability of using telehealth to provide care for patients with COVID-19, align with the high scores observed in the "usefulness" domain. • Expansion: participants also shared on their perceived benefits of using telehealth to both patients and the health care system, thus expanding on the concept of usefulness of telehealth not just for health care providers but also for patients and health care system.
Satisfaction	Mean TUQ subscale scores of 4.73 and 4.75 for the use of both teleconsultation and vital signs monitoring, respectively. 98% and 97% of participants rated positively[b] to use of virtual consultation and vital signs monitoring, respectively.	Benefits of telehealth: • More opportunity for collaboration and sharing of expertise • Improvement in work conditions • Enjoyable virtual interactions • Increased confidence and acceptance of telehealth	• Confirmation: improvements in work conditions, protection from infectious diseases, improved teamwork and collaboration, and increased acceptance of telehealth described by participants were able to explain and confirm the relatively high scores rated for the "satisfaction" domain.
Ease of Use	Mean TUQ subscale scores of 4.72 and 4.70 for the use of both teleconsultation and vital signs monitoring, respectively. 94% and 95% of participants rated positively[b] to use of virtual consultation and vital signs monitoring, respectively.	Benefits of telehealth: • Easy to learn and use vital signs monitoring systems Challenges of telehealth: • Difficulty dealing noncompliant patients • Inconveniences due to lack of interoperability between systems • Labor intensive to set up automated systems Enablers: • Using familiar platforms for virtual consultation	• Confirmation: the majority of participants reported that the vital signs monitoring systems were easy to learn and use, with the utilization of familiar platforms for teleconsultations as an enabler. These findings corroborate the high scores observed in the "ease of use" domain. • Expansion: a handful of the negative experiences encountered by the participants relating to inconveniences caused by the lack of interoperability between systems and setting up of automated systems, and difficulty dealing with noncompliant patients, could explain the lower percentage of participants who rated positively for the "ease of use" domain in telehealth use.

XSL•FO
RenderX

TUQ[a] domain	Quantitative results	Qualitative results	Meta-inference
Effectiveness	Mean TUQ sub-scale scores of 4.31 and 4.29 for the use of both virtual consultation and vital signs monitoring, respectively. 83% and 81% of participants rated positively[b] to use of teleconsultation and vital signs monitoring, respectively.	Challenges of telehealth: • Inability to assess nonverbal information • Difficulty communicating with older adult patients • Difficulty engaging and establishing rapport • Unconducive environment Perceptions: • Accuracy of patient vital signs submissions • Fear of making wrong clinical decisions	• Confirmation: the negative experiences reported by participants, specifically regarding challenges in patient communication and engagement, align with, and provide an explanation for the lower scores observed in the "effectiveness" domain.
Reliability	Mean TUQ subscale scores of 4.06 and 3.98 for the use of both teleconsultation and vital signs monitoring, respectively. 81% and 72% of participants rated positively[b] to use of teleconsultation and vital signs monitoring, respectively.	Challenges of telehealth: • Technical issues with vital signs monitoring system • Connectivity issues during virtual consultations • Process of resolving such issues was often slow and cumbersome	• Confirmation: recounts of negative experiences associated with the technical inconveniences related to telehealth systems, align with and confirm the lower scores observed in the "reliability" domain.

[a]Telehealth Usability Questionnaire.

[b]Rating either "strongly agree" or "agree."

Discussion

Principal Findings and Comparison With Previous Work

In this mixed methods study exploring health care providers' engagement in teleconsultations and vital signs monitoring for acute care at home, "usefulness," "satisfaction," and "ease of use" received the highest ratings, while "effectiveness" and "reliability" received lower ratings. These findings were corroborated during interviews, where overall positive perceptions were highlighted alongside key challenges related to patient communication and engagement, and technological issues.

Our study contributes both fresh insights and confirmation of existing literature on health care providers' experiences with telehealth. Consistent with previous research [37], participants emphasized the convenience and flexibility of teleconsultations and vital signs monitoring, particularly in optimizing health care resources during the COVID-19 pandemic. This marks a shift from previous reports favoring telehealth use for chronic diseases [38] or palliative care [39] to acute care settings, possibly due to the unique demands of the pandemic. Challenges of managing noncompliant patients in HaH setting differed from stable chronic conditions in outpatient virtual settings, due to the acuity and risk of deterioration of these patients [40]. Concerns regarding vital signs accuracy and making clinical judgments using telehealth tools were also novel observations, possibly attributed to the adjustment from face-to-face consultations to telehealth adoption, especially among more experienced health care providers. Another noteworthy finding is that telehealth use in a multidisciplinary HaH setting brought health care providers closer together, fostering collaboration and shared learning opportunities.

On the other hand, participants who stressed the importance of interoperability between telehealth systems and electronic medical records were aligned with existing literature advocating for seamless integration and data exchange for successful telehealth implementation [41]. Reports of communication difficulties and patient engagement issues also mirror previous findings, underscoring the need for specific communication skills development among health care providers [42]. In addition, our study reaffirmed the impact of technological issues on telehealth reliability [43], emphasizing the need for robust technical support to ensure system stability, though participants mainly struggled with the slow resolution of problems rather than frequent connectivity or technical difficulties. Finally, participants' high satisfaction with telehealth use echoes previous research [37,39,44], highlighting its acceptance and benefits across diverse care settings.

Health care providers' real-world experiences offer vital insights that can help policy makers understand practical implications and identify policy gaps. Considerations for the real-world implementation and context can aid in crafting practical telehealth and HaH guidelines that reflect the realities of these settings. Health care systems can also learn from these experiences to create adaptable telehealth-ready systems to meet the needs of an aging population and improve health care accessibility, efficiency, and quality. Based on our findings, we recommend 3 key actions. First, strengthen health care provider training in developing skills for telecommunication, remote assessment, and decision-making, along with early exposure to digital health care tools. Second, ensure the reliability of telehealth systems through regular checks, updates, and robust technical support, and additionally integrate systems with electronic medical records to ensure efficient data exchange. Finally, promote multidisciplinary collaboration by designing

XSL•FO
RenderX

physical spaces that facilitate effective communication and allocate private areas for teleconsultations to ensure patient confidentiality.

Limitations

Our study has several limitations. First, the health care providers sampled were from a single HaH program, and their perspectives may not fully represent those of providers in other programs that use different telehealth tools or operate in varying contexts. Nonetheless, we included a diverse range of health care professions in both the survey and interviews to ensure a broad representation of experiences.

Second, the sample size in this study may be considered small, potentially limiting the statistical power of the quantitative analysis. However, the integration of qualitative data through a mixed methods approach mitigates this limitation by providing a more comprehensive and nuanced understanding of trends observed in the quantitative findings.

Third, there is a potential for recall bias among participants who were no longer actively staffing the service during the data collection period. In addition, the qualitative data analysis was conducted by a single coder and not independently in duplicate as per best practice. While this approach may introduce bias, the reflexive thematic approach used during analysis emphasizes the researcher's interpretative engagement with the data over consensus or reliability measures [34]. This enables a richer, more cohesive analysis that upholds reflexivity and interpretative rigor. Nevertheless, future studies could enhance richer and deeper interpretations of the data by incorporating multiple coders in a collaborative and reflexive manner.

Furthermore, the clinical context during the data collection period was exclusively shaped by COVID-19, which presents unique challenges and care requirements compared with nonpandemic conditions typically managed in HaH programs. Despite this, our findings offer valuable insights into the use of telehealth tools, which remain relevant as HaH programs continue to expand and scale.

Finally, while the TUQ has demonstrated strong validity and reliability for assessing telehealth usability, it was originally developed for general telehealth users rather than providers. Nonetheless, we selected the TUQ for its comprehensiveness in evaluating core usability dimensions that are also relevant to health care providers. The comprehensive triangulation of data underscores the novelty of our study, as it demonstrates the adaptability of the TUQ beyond traditional end user settings and highlights its effectiveness in capturing the multidimensional experiences of health care providers engaging with telehealth within HaH.

Conclusions

In summary, this study suggests that this generation of health care providers, though not considered to be formally trained in the use of telehealth tools, were generally adaptable and held positive perceptions regarding the usability of telehealth. Our findings further emphasize the equal importance of the health care providers as key stakeholders and end users (in addition to patients) in the development of telehealth tools. As HaH programs continue to scale internationally, further studies are needed to design and evaluate telehealth training programs for HaH healthcare providers and explore the influence of physical workspace design on health care provider effectiveness when using telehealth tools.

Acknowledgments

Generative artificial intelligence was not employed to develop ideas or informational content for this manuscript. However, ChatGPT was used in the proofreading process to improve the clarity of the writing. The authors would like to acknowledge the doctors, nurses, allied health professionals, pharmacists, and operations staff who have contributed to the development and implementation of the NUHS@Home program. This work was supported by the Health Services Research Grant from the National Medical Research Council HSRGMS20nov-0004 and the Practicum Fund from the National University of Singapore, Saw Swee Hock School of Public Health, Master of Public Health program.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to institutional data sharing policies. However, they may be obtained from the corresponding author on reasonable request.

Authors' Contributions

This study was conceived by SQK. All authors contributed to the design of the study. SYL and SQK were involved in the data collection process. All authors participated in the analysis of data collected. SYL drafted the manuscript while SQK and IYHA edited the manuscript. All authors reviewed the final manuscript.

Conflicts of Interest

SQK is the lead of NUHS@Home on which the study setting is based. This relationship however did not influence the study design, data collection, analysis, or interpretation of the findings.

Abstract

Background: The burden caused by the use of electronic health record (EHR) systems continues to be an important issue for health care organizations, especially given human resource shortages in health care systems globally. As physicians report spending 2 hours documenting for every hour of patient care, there has been strong interest from many organizations to understand and address the root causes of physician burnout due to EHR burden.

Objective: This study focuses on evaluating physician burnout related to EHR usage and the impact of a physician engagement strategy at a Canadian mental health organization 5 years after implementation.

Methods: A cross-sectional survey was conducted to assess the perceived impact of the physician engagement strategy on burnout associated with EHR use. Physicians were invited to participate in a web-based survey that included the Mini-Z Burnout questionnaire, along with questions about their perceptions of the EHR and the effectiveness of the initiatives within the physician engagement strategy. Descriptive statistics were applied to analyze the quantitative data, while thematic analysis was used for the qualitative data.

Results: Of the 254 physicians invited, 128 completed the survey, resulting in a 50% response rate. Among the respondents, 26% (33/128) met the criteria for burnout according to the Mini-Z questionnaire, with 61% (20/33) of these attributing their burnout to EHR use. About 52% of participants indicated that the EHR improves communication (67/128) and 38% agreed that the EHR enables high-quality care (49/128). Regarding the physician engagement strategy initiatives, 39% (50/128) agreed that communication through the strategy is efficient, and 75% (96/128) felt more proficient in using the EHR. However, additional areas for improvement within the EHR were identified, including (1) medication reconciliation and prescription processes; (2) chart navigation and information retrieval; (3) longitudinal medication history; and (4) technology infrastructure challenges.

Conclusions: This study highlights the potential impact of EHRs on physician burnout and the effectiveness of a unique physician engagement strategy in fostering positive perceptions and improving EHR usability among physicians. By evaluating this initiative in a real-world setting, the study contributes to the broader literature on strategies aimed at enhancing physician experience following large-scale EHR implementation. However, the findings indicate a continued need for system-level improvements to maximize the value and usage of EHRs. The physician engagement strategy demonstrates the potential to enhance physicians' EHR experience. Future efforts should prioritize system-level advancements to increase the EHR's impact on quality of care and develop standardized approaches for engaging physicians on a broader Canadian scale.

Introduction

Background

The burden caused by the use of electronic health record (EHR) systems continues to be an important issue for health care organizations, especially given human resource shortages in health care systems globally [1-4]. As physicians report spending 2 hours documenting for every hour of patient care, there has been strong interest from many organizations to understand and address the root causes of physician burnout due to EHR burden [5]. This is particularly important given the growing digital maturity of many health systems coupled with broader health care challenges, specifically an overburdened health system and a health care workforce crisis [2-4]. Over the last few years, many organizations, including the American Medical Informatics Association [6], the Canadian Medical Association [2-4], and the American Medical Association [7], have recognized and advocated for strategies to target these challenges .

As a result, there have been many initiatives focused on mitigating the impacts of EHR burden on physicians. For example, the 25 × 5 initiative, led by American Medical Informatics Association and including a task force representing health professionals or systems, policy or advocacy, impact, and technology requirements, is focused on developing a multi-level approach (vendor, health systems, and government) to reducing documentation burden by 25% in 5 years in the United States [6,8]. Through these work streams, a toolkit has been developed that provides recommendations and next steps at the organization and system levels [8]. In addition, others have explored unique initiatives to identify and address EHR-related burden within their own organizations [9]. An example of this is the Getting Rid of Stupid Stuff initiative from the University of Colorado, which focuses on removing redundant processes from the EHR [10]. Other initiatives include more agile delivery of personalized training and system optimization targeting the pain points of the end-users [11-13].

However, a key challenge that has impacted the ability to develop strong recommendations on approaches to address EHR-related issues has been limited insight into the impact of these initiatives [9,14,15]. In particular, most of these evaluations have been limited to a single-site pilot with a limited duration and small participant size. Moreover, since these studies examined the intervention immediately after implementation, there is little information about the long-term impact of these initiatives on EHR end-user experience [16]. To better understand the impact of initiatives to reduce EHR burden, it is essential to evaluate them in large-scale real-world environments with numerous users, as studies of digital tools indicate that effectiveness must be tested across diverse settings. Overall, this study focuses on evaluating physician burnout related to EHR usage and the impact of a physician engagement strategy at a Canadian mental health organization 5 years post-implementation.

Physician Engagement Strategy

The physician engagement strategy [17] was developed in 2018 through feedback from an organizational benchmark survey, which was conducted to understand the contributors of EHR-related burden and burnout rate among physicians across a large Canadian academic hospital [18]. In the benchmark survey, full-time and part-time physicians at the organization were invited to provide their perceptions and concerns in order to co-develop the first iteration of the physician engagement survey. Briefly, from the benchmark survey, about 75% (155/208) of physicians with symptoms of burnout reported that the EHR was a major contributor to burnout. In addition, participants highlighted process and infrastructure issues that can be improved through an organization-wide strategy.

As such, the physician engagement strategy was created and implemented and consists of 4 key components.

The "SWAT" Initiative

One of the main challenges has been an approach to rapidly identify and address bottlenecks and issues related to the EHR. As a result, we developed the "SWAT" initiative, which focuses on bringing an interdisciplinary team to rapidly triage and address issues related to the EHR in an agile manner [19].

Physician Think Tanks

Given the ongoing challenges of ensuring that decisions made for the EHR are aligned with the needs of end-users, a medical staff subcommittee was convened to engage in discussions on EHR and digital health matters. These think tanks meet on a monthly basis, and a representative from each medical division attends to provide feedback and discuss relevant issues.

Communication, Education, and Informatics Strategies

In order to address the outstanding issues from the benchmark survey, numerous initiatives were implemented. Several peer education videos to provide peer support on common issues that physicians encounter in using the EHR. In addition, a monthly newsletter was implemented to communicate new changes that have been implemented to the EHR. Lastly, speech recognition technology (SRT) was procured and implemented to improve efficiency in documentation. SRT allows physicians to dictate their documentation directly into the EHR instead of typing [20].

Using EHR Usage Log Data to Guide Further Optimizations

In order to assess the impact of these interventions on the EHR, back-end usage log data are being collected and reviewed. The solution is included as part of the EHR system and includes metrics such as documentation time per patient and after-hours use of the EHR (pajama time).

While smaller evaluations have been conducted on individual components [19-21], there remains a gap in understanding how the overall strategy has supported improvements in EHR use over the past 5 years. It is vital to explore opportunities for continuously advancing the strategy as new technologies, such as generative artificial intelligence, are integrated into the environment [22-28]. This is particularly useful given the growing issue of physician burnout and the rapid growth of digital tool adoption in health care organizations outside of Canada [29-32]. The core contribution of this manuscript is to demonstrate the impact and lessons learned from implementing

XSL•FO
RenderX

a multi-pronged organizational strategy focused on reducing EHR burnout in a real-world environment, as well as some of the outstanding areas of focus. This work helps support our limited understanding of these initiatives. This is particularly relevant to other countries and hospitals as they gain more advanced, comprehensive EHRs such as the ones being used at this hospital. EHR-related burnout is a global issue, and these initiatives can be translated to other organizations facing similar challenges.

Objectives

In this study, we present our findings from a survey conducted 5 years after the implementation of the physician engagement strategy. The primary objective is to understand the impact and perceptions of the strategy's 4 components and identify opportunities for further improvement. In order to do so, a survey was developed that asks questions related to the effectiveness of each of the components of the strategy. These findings may be valuable for Canadian health care organizations seeking to adopt a long-term strategy to enhance physician experience and reduce EHR-related burden.

The specific aims of this study were to evaluate overall burnout rates and the extent to which they are linked to the EHR 5 years after implementing the physician engagement strategy; assess the perceived effectiveness of the different components within the physician engagement strategy; and pinpoint key areas for future improvement and optimization of the physician engagement strategy to further alleviate EHR-related burden.

Methods

Overview

A cross-sectional survey was conducted in January 2023 for 6 weeks, to evaluate the impact and challenges in delivering the physician engagement strategy at a large, urban, Canadian mental health hospital.

Participants and Settings

In order to identify physicians who are eligible for the survey, we obtained a list from the Medical Affairs department. The inclusion criteria for physicians are as follows: a staff physician, resident, or fellow at the organization having a full-time or part-time appointment at the organization as of November 2022, and having a psychiatry, addictions, or hospitalist role that provides care across inpatient, outpatient, emergency, outreach, and community settings.

Physicians who joined after November 2022 were not invited to participate in the survey due to their limited exposure and use of the EHR prior to completing the survey.

In terms of setting, the large academic mental health hospital is located in Toronto, Ontario, and provides care to over 34,000 patients a year. The EHR system was implemented in 2014 and is being used for all facets of patient care. In 2017, the organization achieved Healthcare Information Management Systems Society (HIMSS) stage 7 on the Electronic Medical Record Adoption Model (ENRAM) [33], which is used to identify gaps in EHR usage, guide digital transformation, improve data access and patient outcomes, and reduce grunt work. Achieving the highest level, stage 7, of this model is a testament to the high adoption and use of the EHR for clinical care and requires our organization to use our EHR in dynamic ways and leverage analytics and insights.

Data Collection Approach

A web-based survey was deployed to physicians via the REDCap survey tool (developed by Vanderbily University) [34,35]. The survey was developed using a co-design approach with members of the Physician Think Tanks and was informed by the Benefits Evaluation Framework, benchmark survey data, and relevant literature. The survey underwent testing with the Physician Think Tank members to refine its topics, content, and wording. It was available from January to March 2023, with biweekly reminders sent to encourage participation. The Chief Medical Officer (SS) and the Division Chiefs encouraged physicians to participate in the survey. The survey has 4 components, which can be found in Multimedia Appendix 1. The first comprises demographics, which include age, gender, appointment, and years of experience in the organization. The second component focuses on burnout, which includes the Mini-Z Burnout questionnaire [36], as well as a question on the perceived contribution of the EHR to burnout. The third section contains questions related to the perceived impact of the initiatives within the physician engagement strategy, as well as emerging issues of interest outlined by the Physician Think Tanks. The last section is an open-ended question for participants to outline opportunities for improvement in terms of the use of the EHR and initiatives within the physician engagement strategy.

Data Analysis

Both quantitative and qualitative approaches were used to analyze the data. For Likert scale questions, descriptive statistics (eg, mean, standard deviation) were generated. In addition, one-way ANOVA and Chi-squared tests were used to compare burnout rates from the benchmark survey. For qualitative data, a content analysis approach was used to identify the main themes [37,38]. The analysis was led by authors TT and BL. TT conducted a review of the qualitative responses and developed an initial codebook. BL then reviewed and identified any discrepancies. Any discrepancies were reviewed and discussed with the rest of the project team. Based on the revised codebook, TT completed the coding of the qualitative responses. BL then reviewed the coding to identify and discuss any additional discrepancies. To ensure the trustworthiness of the data, 2 reviewers have analyzed the data using the approaches outlined by Elo et al [39]

Ethical Considerations

This work has received approval by the Quality Project Ethics Review (QPER) Board at the Centre for Addiction and Mental Health (QPER 2018 - 2019 #014) as it was a quality improvement project and did not require approval from our Research Ethics Board. Informed consent was obtained for physicians participating in the project. Numerous safeguards were also implemented to ensure the confidentiality of participants. First, data were collected anonymously. Participants were instructed not to share identifying information in their

XSL•FO
RenderX

responses. All survey data were de-identified before analysis if individuals entered identifying information in the survey. Second, findings were reported only in aggregate form to both internal and external audiences. Compensation was not provided to participants.

Results

Participants

Of 254 staff physicians eligible to complete the survey, 128 participants completed it and were included in the analysis (50%). There were 18 individuals who opened the link to the survey but did not submit the survey. While we had originally invited residents and staff fellows to the survey, despite our extensive efforts in recruitment, we had received very few responses resulting in a negligible response rate. Hence, they were not included in the analysis of the survey. The findings of the survey are described below.

Respondent Characteristics

The demographics reported by participants who completed the survey (n=128) are outlined in Table 1. Respondents were primarily staff physicians with outpatient duties and provided psychiatric care to adult populations. There was a range in years of experience of respondents, with 27% (35/128) of participants, reporting 0 - 5 years of experience. In terms of gender identity and ethnicity, there was about equal responses from participants identifying as a man (45%, 58/128) or woman (42%, 54/128), and 53% of individuals (68/128) identified with a white ethnic group.

Burnout and Perceptions of the EHR

The level of burnout reported by participants using the Mini Z questionnaire [32] is outlined in Table 2. About 26% (33/128) of individuals reported a description that meets the threshold of burnout. However, only 4% (5/128) of individuals reported being at the highest and second-highest levels of burnout. Of those who indicated a level that meets the threshold of burnout, 61% (20/33) of the respondents indicated that the EHR contributed to their burnout often or always. There was no relationship between burnout levels and age, ethnicity, or years of experience.

Table . Reported levels of burnout for benchmark survey and follow-up survey.

	Burnout, n (%)	
Characteristic category	Baseline survey (N=208) [18]	Follow-up survey (N=128)
I enjoy my work. I have no symptoms of burnout.	45 (22)	27 (21)
Occasionally I am under stress, and I don't always have as much energy as I once did, but I don't feel burned out	111 (53)	68 (53)
I am definitely burning out and have one or more symptoms of burnout, such as physical and emotional exhaustion	35 (17)	28 (22)
The symptoms of burnout that I'm experiencing won't go away. I think about frustration at work a lot.	15 (7)	4 (3)
I feel completely burned out and often wonder if I can go on. I am at the point where I may need some changes or may need to seek some sort of help.	1 (1)	1 (1)

There were no significant differences in burnout level (t(283)=.191, P=.85) between the current survey and the previously conducted benchmark survey [18]. Of those who reported burnout, there is a considerable reduction in the number of individuals who reported that the EHR contributes to burnout all or almost all the time (t(63)=−1.255, P=.21).

With regard to the perceptions towards the EHR, over half the participants (74/128) agreed or strongly agreed that the EHR adds to their daily frustration (Table 3). From a benefits perspective, a similar proportion of participants also felt that the EHR improved communication within their circle of care (67/128), enabled the delivery of high-quality care (49/128), and kept patients safe (50/128).

[a]EHR: electronic health record.

SWAT Initiative—Rapid Handling of EHR Issues

In the survey, participants indicated whether the SWAT initiative improved documentation, order entry, and chart navigation within the EHR (Figure 1A). Of those who provided a response, about 54% of participants reported that the SWAT initiative had made some or major improvements across documentation (69/128) and order entry. For chart navigation, the numbers of respondents were marginally less, with 40% of participants indicating that SWAT has made some or major improvements to the functionalities related to chart navigation (51/128).

XSL•FO
RenderX

Figure 1. Impact of SWAT (agile approach for resolving electronic health record (EHR)-related issues) initiative on EHR burden (n=128).

In terms of overall experience (Figure 1A), approximately 59% (75/128) of respondents reported that the SWAT initiative has made some or major improvement to their use of the EHR. Similarly, about 42% (54/128) of participants agreed or strongly agreed that the initiative made them feel their needs were acknowledged and 45% (58/128) agreed that it provided a platform to discuss issues pertinent to their practice (Figure 1B).

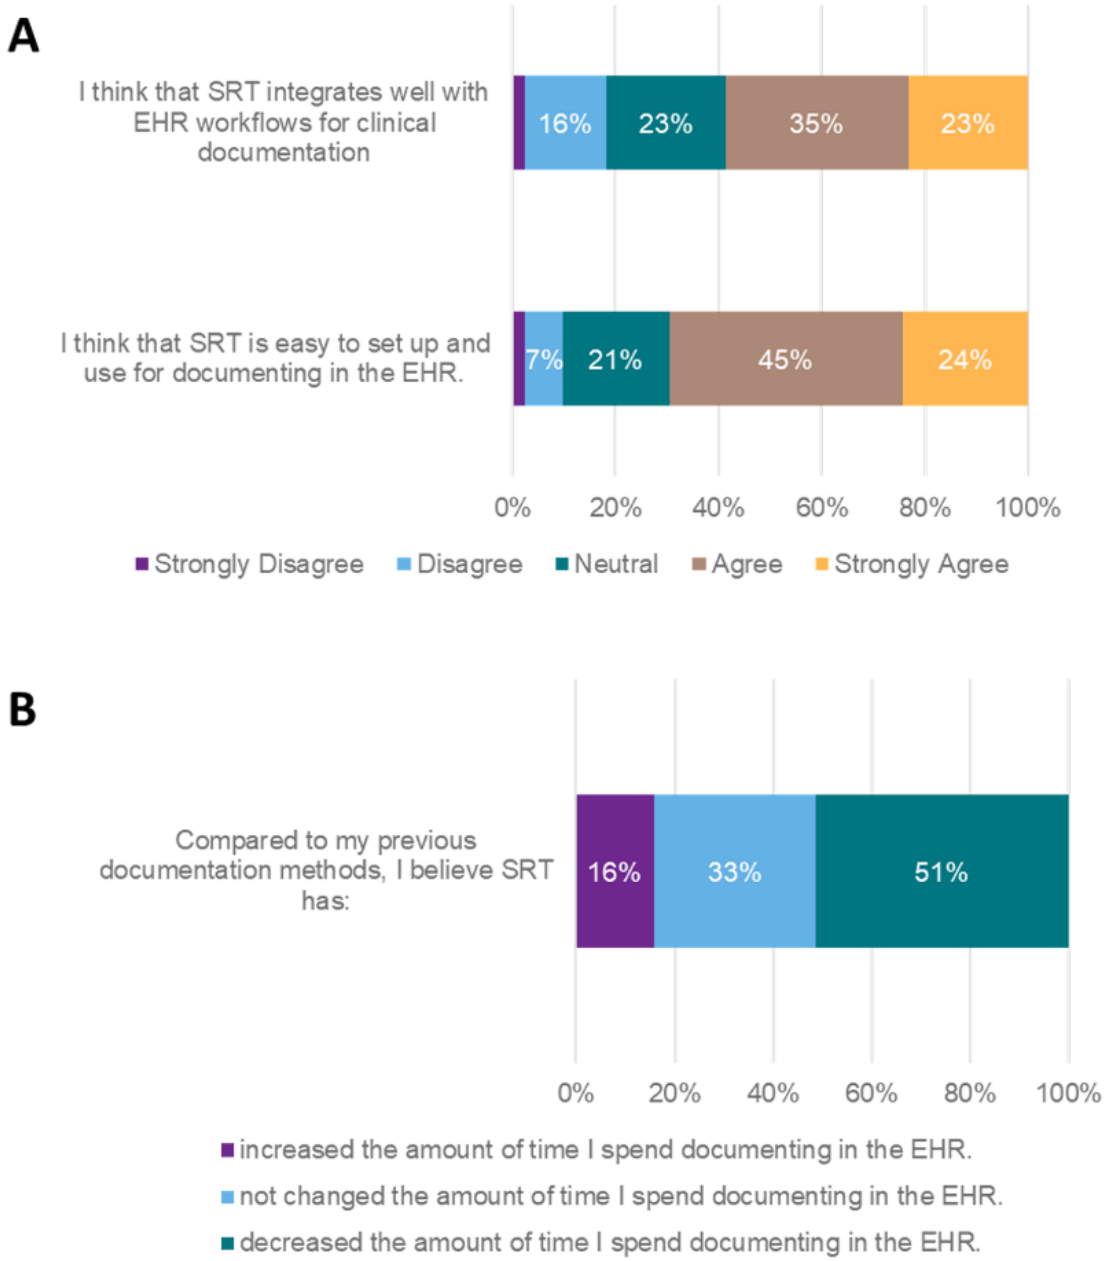
Communication and Education

With regard to communication, about 77% (98/128) of respondents recall reading the monthly newsletter that is sent out from the strategy (Figure 2A). Of those who have read the newsletter, about half (50/98) suggested that the communication of EHR changes is efficient through this method.

XSL•FO
RenderX

Figure 2. Impact of communication and education initiatives (n=128). EHR: electronic health record.

For education, about 64% (82/128) of individuals believe they are proficient with the use of the EHR, yet only 39% (50/128) of individuals thought that the education support provided by the organization is available and sufficient (Figure 2B). Regarding peer education videos (Figure 2C), about 32% (41/128) of individuals reported watching 1 of the 3 peer education videos released to date. For those who did not watch a video, about 57% (73/128) of respondents were not aware that peer education videos existed. Among the 41 individuals who watched a video, 68% (28/41) of individuals reported that the video was useful, and 66% (27/41) of individuals believed that the length and details were appropriate.



Informatics Tools (SRT Documentation and Continuity of Care)

With regard to documentation, about 64% (82/128) of respondents reported trying to use SRT for documentation (Figure 3A). Of those who indicated using SRT, 69% (57/82)

XSL•FO
RenderX

of individuals reported that it was easy to set up and use, and 58% (48/82) of respondents indicated that it integrates well with the EHR (Figure 3). About 51% (42/82) of respondents believed that the use of SRT decreased their documentation time (Figure 3B).

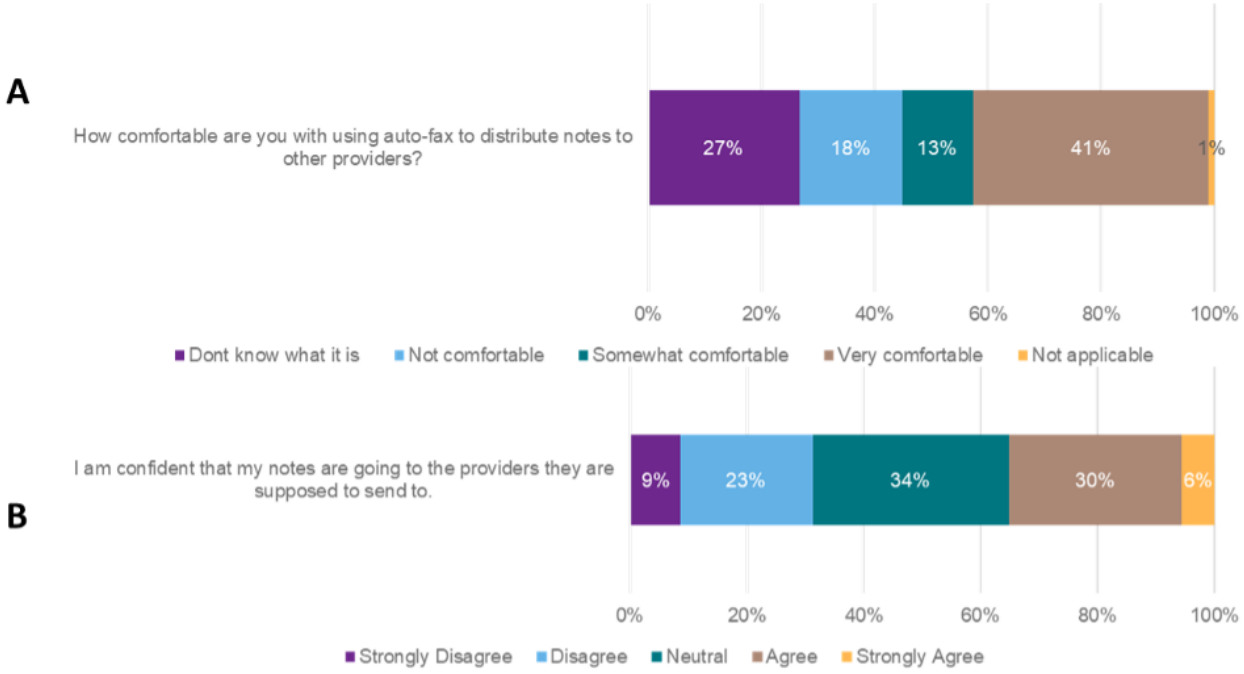


Figure 3. Impact of speech recognition technology on documentation in the electronic health record (EHR; N=128). SRT: speech recognition technology.

For continuity of care, participants were asked to comment on their confidence level regarding delivery of notes to external health care providers. Only 35% (45/128) of individuals agreed that they are confident that notes are sent to the provider as intended (Figure 4A). With automated fax transmission being the default approach for document delivery within the EHR, 54% (69/128) of respondents indicated that they are somewhat or very comfortable with sending their notes through the current automated fax transmission process instead of sending notes through health records distribution process (Figure 4B).

RenderX

Figure 4. Perceptions of continuity of care in the electronic health record (n=128).

Areas of Focus

From the qualitative findings, 4 themes were identified. These include (1) medication reconciliation and prescriptions processes; (2) chart navigation and information retrieval; (3) longitudinal medication history; and (4) technology infrastructure challenges. These themes are detailed below.

Medication Reconciliation and Prescriptions Processes

Physicians had concerns about the current capabilities of the EHR with regard to medication reconciliation and transmission of prescriptions. While medication reconciliation and communication of prescriptions were identified as highly important for supporting patient care, the processes involved were identified as cumbersome and time-consuming. As one physician outlines:

> *Outdated and clunky interface - navigation is clumsy and could be streamlined. More like 2010 than 2023 software…Med Reconciliation is a slow and laborious chore - great when pharmacists do it.* [Psychiatrist, SC-FT-246]

Another physician also highlights the lack of intuitive search functionality with the current EHR system:

> *Discharge med rec is frequently broken and unsafe. Search function is desperately needed. For example, cognitive testing hard to find or not accessible, not organized, not uploaded.* [Geriatrics Psychiatry Physician, GE-APP-47]

Collectively, these limitations of the system can make the process unsafe for patient care. Furthermore, the impact on continuity of care back to the community also affects the process at discharge. Fax is still commonly used for transmission of prescriptions and documents to community providers and pharmacies, but the limitations of this technology represent a significant burden for clinicians. This is particularly outlined from a physician who engages in telepsychiatry practice:

> *The prescription function on [the EHR] is awful for telemedicine prescriptions. First, I have to enter the prescription on the software. Next, I have to download the PDF, find that, and sign manually. Finally, I have to open separate software [company] to fax the prescription. This whole process takes 5 - 10 minutes, whereas with the other EMR software I can send a prescription in<1 min. Since I send many prescriptions per day, I can waste anywhere between 30 - 60 min of a clinical day on this cumbersome prescription faxing process.* [Telemedicine Psychiatrist, AD-AP-22]

Collectively, the administrative burden spent on faxing prescriptions can take a significant toll on physicians. More importantly, the lack of feedback from the process hinders the ability of the physician to know if the process worked for the patient:

> *Sending external lab requisitions and prescriptions, especially when delivering virtual care is non-obvious, tedious, time-consuming and error prone. For instance, for nearly 3 months my prescriptions had a return fax number that no one could tell me if and where returned faxes from pharmacies were going to.* [Addiction Psychiatrist, AP-AD-6]

Given the growing adoption of team-based care within the community, continuity of care through current medication reconciliation processes and faxing significantly hinders the value and utility of the EHR.

XSL•FO
RenderX

Chart Navigation and Information Retrieval

Given the complexity and chronicity of the patient population, chart navigation was another critical theme outlined by physicians. For example, several physicians highlighted issues about being able to view other notes while documenting:

> *It is horrific that one cannot simultaneously see a document and type into a note. I don't know who designed such a system, they do not understand physician work at all. Opening an ED note locks you out of seeing other documentation.* [Addiction Psychiatrist, AD-FT-33]

> *Being unable to quickly click through the pages, for example have a tab to click one month back or to be able to skip an inpatient admission. Being unable to have a note open while I am also looking at other applications. Have to write the draft note somewhere else and paste it. [General Adult Psychiatrist, GA-FT-171]*

As such, being able to review and generate new documentation can be burdensome and can result in developing workarounds that are not aligned with best practices. Another key limitation of the system is the limited ability to search for relevant documentation. Given that some patients have many previous consultations, searching through prior documentation efficiently is critical. One physician highlighted that it:

> *It can be hard to find needed documentation if the chart is extensive because the filtering system isn't great/doesn't let you just search for the things you need.* [General Adult Psychiatrist, GA-FT-158]

As such, this can hinder the ability for physicians to understand the broader clinical picture in a timely manner through the EHR.

Longitudinal Medication History

A review of past medication history often informs decision-making regarding which medication regimen to trial next for a particular patient. However, currently, there is a limited ability to review the medication histories of patients in a longitudinal way:

> *[The EHR] is not well set up for longitudinal care. Medication histories, for example, are not well captured, nor are key pieces of information easily parked somewhere that can be referenced later without having to scroll through many progress notes.* [Schizophrenia Physician, SZ-AP-220]

Having to review numerous progress notes can make it difficult for physicians to grasp the patient's history and develop an evidence-based treatment plan.

Challenges with Technology Infrastructure

Since the implementation of the EHR 10 years ago, physicians have reported growing issues with regard to the challenges with IT infrastructure. For example, one psychiatrist highlights how the application slows down the system when open and takes excessive amounts of time to complete tasks within the EHR.

> *The program freezes frequently and then it is a process to restart it. [The EHR] often has a lag and this slows down work for outpatient work, there is no easy way to fax prescriptions. What I do is create a PDF, open it in program (Premium which I pay for personally), sign it, save it, then open the [fax] program, and then send it. The fax process itself takes 5+ minutesand isn't an effective use of physician time.* [General Adult Psychiatrist, GA-FT-184]

This process becomes especially challenging when physicians must act under pressure, such as during an emergency code:

> *To work on multiple units when on call- Duty Doctor is very time consuming as clinicians are required to start up their [EHR] on a new computer on each unit and the initializing process to get into the platform to access [EHR] takes 5 - 10 minutes sometimes which is very delayed when responding to a code where a clinician is required to order meds/restraints etc.* [General Adult Psychiatrist, GA-FT-114]

Since IT infrastructure is fundamental to EHR usability, it is crucial that it remain up to date to ensure the system operates efficiently and effectively over time, particularly in critical situations.

Discussion

Principal Findings and Comparison With Previous Work

This study examines the current findings from the physician engagement strategy at a Canadian mental health hospital in Toronto, Canada. Although extensive literature has investigated the causes of EHR-related physician burnout and proposed various approaches to address these issues [6], there is limited research on how physician engagement strategies and their components interact strategically to mitigate burnout through a health informatics perspective. To our knowledge, this work is among the first to involve a large number of Canadian physicians in assessing the impact of these initiatives within a cohesive and supportive environment. The findings from this work are critical given that many of the current studies are pilot or feasibility studies in a small setting or clinic. This work provides preliminary insights into how these interventions can be expanded to an organization and their impact. This is particularly important given the growing adoption of advanced EHRs with decision support, artificial intelligence, and other capabilities [40-44]. Overall, the physician engagement strategy has positively impacted perceptions and value of the EHR among physicians. However, there are still many opportunities for improvement, particularly at the system level. The implications of these findings are described below.

We found that while the physician overall burnout rate remained unchanged from the benchmark survey in 2018, the perceptions of the EHR's impact on physician burnout have considerably improved. Physicians who used the physician engagement initiatives reported enhancements in EHR usage, communication, education, and documentation, which are key components of the overall strategy [18]. These findings are consistent with the growing literature on the role of perceptions of physician burnout. Several studies have highlighted how

XSL•FO
RenderX

perceptions can influence overall satisfaction and utility of the EHR, despite its impact from a quantitative (objective) perspective [45]. Studies that take a sociotechnical perspective suggest that characteristics of the individual and the environment can have a profound impact on burnout rate and EHR usage patterns [46]. With this in mind, it is likely that understanding EHR-related burnout requires a broader consideration of the environment and the system at play.

Since the evaluation was conducted 5 years post-implementation of the strategy, improvements seem to be sustained over time. This provides promising support for the long-term impact of initiatives such as a physician engagement strategy, which is an area that has not been widely investigated [6].

Several areas for improvement have been identified since the strategy's inception, many of which necessitate system-level interventions. For example, through the qualitative SWAT interviews, issues related to the transmission of prescriptions and documentation continue to be critical EHR-related barriers to continuity of care. In the Canadian setting, initiatives supporting electronic prescribing continue to progress at a slow pace, despite the high interest and discussion over the last decade [47]. In addition, functional interoperability could be used to support better continuity of care and the sunsetting of aging technology such as faxing [48]. As such, while these initiatives have made improvements to the use of the EHR, there continues to be a significant requirement for novel, system-level solutions that fall outside the scope of a single organization or single digital tool. As a next step from this work, the project team will focus the efforts of the strategy on addressing these challenges.

Finally, this work makes a significant contribution to the international literature on interventions to reduce EHR burden for physicians. To date, most of the literature, including the 25 × 5 toolkit and the Getting Rid of Stupid Stuff initiative, has a strong focus on the US context [10]. However, these constraints do not necessarily apply to the Canadian and international context. As such, the impact observed in this study provides suggestive evidence of the broad impact these tools can have, irrespective of clinical and administrative environments. Future work should focus on examining the impact of similar initiatives and strategies in other geographical and cultural contexts.

This work has broad-reaching implications for health care organizations and health systems. At the organization level, clinicians and health administrators can consider building and evaluating similar strategies within their own organizations. By leveraging similar evaluation approaches and methodologies (eg, Mini-Z for burnout), it will enable comparison and optimization of the initiatives outlined in this strategy. For researchers, it would be useful to explore how theoretical frameworks from implementation science and change management can be used to further understand the impact and key success factors in rolling out these initiatives across complex health care environments. At the health policy and system level, policy makers and health care organizations can leverage the findings from this study to inform the development of system-level recommendations and initiatives to address the root causes that are consistent across the health care system (eg, interoperability).

Limitations

The study's findings should be interpreted with caution due to several limitations. Foremost, the strategy is currently being evaluated in a single health care organization for staff physicians only. Despite our efforts to recruit residents and fellows through engagement of leadership and communications, the rapid turnover and limited time at the organization make it difficult to recruit learners to complete the survey. Future work should focus on exploring ways to enhance reach and engage these groups in EHR-related burden. Moreover, due to the limited number of time points available in the evaluation, this study fails to examine how the broader environment and the temporal nature of events can influence the impact of this strategy on EHR burden. In addition, there are currently limited validated instruments to examine the effectiveness of these interventions. As such, the questions of the survey were based on the feedback from the liaison members of the Physician Think Tank and the members of the project team. Future work should focus on developing validated survey instruments to assess initiatives for reducing EHR-related burden [6]. Lastly, this study did not examine objective data sources like EHR usage logs, which could provide a more comprehensive understanding of the initiatives' impacts.

Conclusions

This study evaluates the impact of a physician engagement strategy on improving physician experience and reducing EHR burden at a Canadian mental health organization. The study highlights the ongoing challenges and perceptions of staff physicians regarding the EHR system, emphasizing its impact on burnout, workflow efficiency, and patient care. While physicians recognized that the EHR improved communication and supported high-quality care, the system also played a significant role in daily frustration for many physicians, with many citing the usability of the system as a major challenge. However, the cross-sectional survey suggests significant improvements in EHR use since the inception of the strategy in 2018. In addition, the findings from the survey demonstrate the feasibility and preliminary effectiveness of these initiatives on reducing EHR burden at an organizational level. Despite some positive findings, additional interventions and system-level changes are needed to further reduce EHR burden and enhance physician experience and patient care. Gaps continue to persist in areas such as medication reconciliation, chart navigation, and the reliability of IT infrastructure. Targeted improvements such as streamlining prescription processes, enhancing search functionalities, and addressing system inefficiencies could alleviate some administrative burdens and improve physician satisfaction. Addressing these concerns is essential to optimizing the usability of the EHR and supporting physician well-being in clinical practice. Future work should also focus on exploring how these system-level changes can be adopted and explored in other health systems.

Abstract

Background: The Swedish health care system is undergoing a transformation. eHealth technologies are increasingly being used. The System Usability Scale is a widely used tool, offering a standardized and reliable measure for assessing the usability of digital health solutions. However, despite the existence of several translations of the System Usability Scale into Swedish, none have undergone psychometric validation. This highlights the urgent need for a validated and standardized Swedish version of the System Usability Scale to ensure accurate and reliable usability evaluations.

Objective: The aim of the study was to translate and psychometrically evaluate a Swedish version of the System Usability Scale.

Methods: The study utilized a 2-phase design. The first phase translated the System Usability Scale into Swedish and the second phase tested the scale's psychometric properties. A total of 62 participants generated a total of 82 measurements. Descriptive statistics were used to visualize participants' characteristics. The psychometric evaluation consisted of data quality, scaling assumptions, and acceptability. Construct validity was evaluated by convergent validity, and reliability was evaluated by internal consistency.

Results: The Swedish version of the System Usability Scale demonstrated high conformity with the original version. The scale showed high internal consistency with a Cronbach α of .852 and corrected item-total correlations ranging from 0.454 to 0.731. The construct validity was supported by a significant positive correlation between the System Usability Scale and domain 5 of the eHealth Literacy Questionnaire (P=.001).

Conclusions: The Swedish version of the System Usability Scale demonstrated satisfactory psychometric properties. It can be recommended for use in a Swedish context. The positive correlation with domain 5 of the eHealth Literacy Questionnaire further supports the construct validity of the Swedish version of the System Usability Scale, affirming its suitability for evaluating digital health solutions. Additional tests of the Swedish version of the System Usability Scale, for example, in the evaluation of more complex eHealth technology, would further validate the scale.

Introduction

In the rapidly evolving landscape of global health care, the advent of eHealth technologies has emerged as a transformative force that promises innovative solutions to the multifaceted challenges faced by health care systems worldwide [1,2]. The Swedish health care system is currently transforming along these lines. The use of digital applications and other digital contact methods, collectively described under the term eHealth, is increasing. The World Health Organization (WHO) defines eHealth as "the use of information and communication technologies (ICT) for health." These technologies include a wide range of systems interventions, applications, and devices such as mobile health and telehealth [3]. There is compelling evidence for the increasing influence of eHealth on the provision of health care globally today and how it is enhancing the efficiency and responsiveness of health systems to meet people's needs and expectations [3]. It is essential to ensure that health technologies are designed appropriately to meet the needs of end users before deploying them as health interventions [4].

XSL•FO
RenderX

Employing robust evaluation methods to ensure high-level usability has been recognized as a crucial component of good practice for achieving this goal [5].

Usability is defined as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [6]. To determine the potential usability of a digital solution, the System Usability Scale (SUS) has been widely adopted as a standardized evaluative device. In 1996, Brooke [7] published the SUS as an instrument that could easily measure usability. Since then, it has been used to evaluate computer systems, applications, and other digital solutions in a wide range of areas [8-10]. The SUS is a questionnaire, consisting of 10 items each scored on a 5-point Likert scale from "strongly disagree" to "strongly agree." It is easy to administer and has been shown to generate results with good reliability and validity [7,8,11]. The instrument is free, and no fees are required to use it [7]. With an international reach, it is the most widely used standardized questionnaire for the assessment of perceived usability today [10]. The SUS can be used to evaluate a wide range of usability in products, including digital applications, mobile devices, and web pages [8-10].

However, as psychometric properties are sample dependent, it is essential to evaluate the psychometric properties when using patient-reported outcome measure in new settings or populations [12]. The SUS has been translated into numerous languages such as Chinese [13], Finnish [14], French [15], Hindi [15], Indonesian [16], and Polish [17]. It has undergone psychometric validation [18], including in Arabic [19], Danish [20], Dutch [21], German [22], Italian [23], Malay [24], Persian [25], Portuguese [26], Slovene [27], and Spanish [28]. The psychometric properties that have resulted from these studies show that adapted versions of the SUS are a reliable tool for usability assessments. However, a number of these studies adopted a general focus and examined only the total sum in the test. Only a small number of studies have tested the instrument at an item level [19-28], with none of them in Swedish. This emphasizes the need for a comprehensive testing of a Swedish version of the SUS on an item level. Determining the robustness is critical for ensuring that the measurement instrument has sufficient validity in the proposed context.

Lewis [10] outlines the essential requirements for translating the SUS into multiple languages and conducting validations across diverse countries. In Sweden, one translation of the SUS has been published in a scientific journal [29], although several unpublished versions exist [9]. However, the linguistic discrepancies between these translations give room for ambiguities, and a united translation with a rigorous psychometric testing in a Swedish context is warranted.

In 2016, an initial vision was for Sweden to be "the best in the world" in eHealth by 2025. However, a more realistic view today is that Sweden has made significant progress in this area. Within the European context, Sweden demonstrates a distinct approach to digitalization in health care, emphasizing collaboration and innovation to address specific challenges and opportunities [30].

With this in mind, there is a great need for a nationally united SUS that has been rigorously tested and proven effective. A robust process of evaluating the psychometric properties of a Swedish SUS will foster participatory usability research and ultimately improve the quality of health care services on a broader scale. Although there are different Swedish translations of the SUS, there is still a lack of psychometric testing showing their robustness. Before any Swedish SUS can be recommended for use, both translation and psychometric evaluation of the instrument are necessary. Therefore, the aim of this study was to translate and psychometrically evaluate a Swedish version of the SUS.

Methods

Overview

This study consists of 2 steps. In step 1, the SUS was translated and adapted into Swedish. In step 2, the psychometric properties of the Swedish version were tested: data quality, scaling assumptions, acceptability, convergent validity, and internal consistency. The translation, adaptation process, and psychometric evaluation adhered to the COSMIN (Consensus-Based Standards for the Selection of Health Status Measurement Instruments) checklist [31].

The SUS Instrument

The SUS instrument consists of 10 items (statements). The items are divided equally into positively and negatively worded statements. Requests for a response are graded on a scale of agreement ranging from strongly disagree (1) to strongly agree (5). The score is calculated as follows: for positively worded items (1, 3, 5, 7, and 9), the score is the position on the scale (1-5) minus 1, and for negatively worded items (2, 4, 6, 8, and 10), the score is the position on the scale minus 5. Individual item scores, therefore, can range from 0 - 4. The sum of all 10 scores is then multiplied by 2.5, resulting in a total score ranging from 0 - 100, with higher numbers representing greater usability [7,8].

To date, factor analysis has not been able to show conclusively whether the SUS consists of one factor (usability) or two (usability and learnability) [11]. Efforts to replicate these findings have led to the conclusion that addressing the instrument as 2 dimensional has no practical or theoretical interest. This study, therefore, treats the SUS as a unidimensional instrument of perceived usability [32].

Translation and Adaption

According to Brooke's [7] original formulation of the SUS, no formal permission is needed for translation, and it can be used free of charge. Further, Brooke [7] allows for the possibility to, in any version, exchange the wording of the scale to a word or expression suitable for the situation. The translation process adopted in this study was inspired by Beaton et al [33]. First, the original instrument was translated from English to Swedish by one of the researchers (CC), proceeding from the versions presented by Bangor et al [34] and Lewis [10]. During the process, perceived difficulties and uncertainties were noted. This first version was then reviewed and discussed by the group, consisting of researchers familiar with eHealth, until consensus

XSL•FO
RenderX

was reached. Second, an authorized translator, naive to the research field, carried out a back translation on the instrument and the notes taken during the research process. Finally, the research group reviewed all versions of the translation, with all notes attached, and finalized a second version of a Swedish SUS. This version was then compared to other SUS translations within the Scandinavian countries for content validity and the original version for expressions and conceptions that could have been culturally influenced. Following this last step, the group then decided upon a final version by consensus. The response options were structured in the same way as the original questionnaire, although the phrases “strongly disagree” and “strongly agree” were exchanged for the Swedish equivalents of “totally disagree” and “totally agree.”

Psychometric Evaluation

Sample

The evaluation of the psychometric properties was carried out in conjunction with a larger intervention study evaluating eHealth, the eChildHealth tablet study [35]. Parents of children with a range of illnesses and health conditions who were patients in the pediatric department of a level-3 hospital in the south of Sweden were invited to take part. A total of 66 parents to 52 unique children gave informed consent and were included in the eChildHealth tablet study. Of these parents, 62 provided information on the SUS, resulting in a total of 82 measurements.

Data Collection

Parents were introduced to an app on a tablet computer through which they could communicate with health care staff after their child had been discharged from hospital. The app made it possible to continue to communicate with hospital staff whom the parents knew well, through chat messages, sending photos, video calls, and predesigned questionnaires. Using a questionnaire, data on various aspects of eHealth were collected for each parent. The SUS was one aspect, and the eHealth Literacy Questionnaire (eHLQ) [36] was another. A study-specific questionnaire was used to collect demographic data such as age and level of education. Between October 2022 and October 2023, the 66 parents were included in study. Data were collected after 1 - 2 weeks of use and at a second time point for those participants who used a tablet for more than 1 month. These parents constitute the eligible participants for this study. A sufficient adequate sample size of approximately 80 measurements was based on recommendations from COSMIN [31] and Beaton et al [33].

Data Analysis

The psychometric properties of the SUS were analyzed with IBM SPSS Statistics for Windows (version 28.0, IBM Corp). Descriptive statistics (mean, SD, and percentage) were used to visualize participants’ characteristics along with data quality, scaling assumptions, and acceptability. Construct validity was evaluated by convergent validity, and reliability was evaluated by internal consistency.

For data quality, use within the clinical setting was determined by item nonresponse and missing scale scores, as they reflect the acceptance and understanding of a measure [37]. Data quality was determined as high if the percentage of missing data per item was low (<10% acceptable). In this study, there were missing data in 5 items (ranging from 1/81, 1% to 3/81, 4%), representing high data quality. Participants with more than 3 unanswered questions were excluded (n=1), while mean imputation was carried out for those with 1 or 2 missing items (n=6, all missing 1 item) [38]. This resulted in a total of 81 measurements being included in the final analysis.

Regarding scaling assumptions, the dimensionality of the SUS has been evaluated previously [32]. In accordance with these studies, this study assumes that the SUS is to be treated as unidimensional (all items measure the same construct). Instruments composed of Likert-scale items can be summarized if they have similar means and SDs. Furthermore, item-total correlations (the correlation between each individual item score and the total score) would indicate if all items contribute equally to the total score. In line with Hobart et al [37], item-total correlations with values of $r \geq 0.3$ were regarded as sufficient for summing up the items to a total sum score.

To evaluate the acceptability of score distributions, ceiling and floor effects along with skewness were calculated. Ceiling and floor effects were regarded as present if they exceeded 90%, that is, the percentage of responses for the lowest and highest scores. Skewness statistics should preferably be within the range of −1 to +1 [37].

Construct validity was explored through convergent validity. It was evaluated with the correlation between the high total sum of the SUS and one of the domains of the eHLQ [36], with the hypothesis that it would correlate with the total score of the SUS. Both instruments were distributed to the parents at the same time points. The eHLQ has already been translated, adapted, and validated within a Swedish context [39]. The eHLQ consists of 7 domains across 35 items, with each domain being extractable and treatable as a separate scale. Responses to each domain on the eHLQ are recorded on a Likert scale from 1 (strongly disagree) to 4 (strongly agree). The eHLQ was designed to be used to understand and evaluate people’s interaction with digital health services [36,39]. The research group independently reviewed the eHLQ and, after discussion, decided to use domain 5, measuring the motivation to engage with digital services. The correlation between the instruments was assessed using the nonparametric correlation coefficient of Kendall Tau-b. With regard to the comparative instrument not being used in total (only 1 domain), the correlation was regarded as acceptable if it was moderate or greater (>0.3) [40] and with the level of significance being $P<.05$.

Internal consistency—how items are related to each other—was explored according to the indicators recommended by Hobart et al [37]: corrected item-total correlations and Cronbach α. The cutoffs were >.04 for acceptable corrected item-total correlations and >.8 for Cronbach α [37,41]. The internal consistency was completed with an SEM to analyze the measurement error of the instrument. The SEM represents the smallest difference in scores and indicates a change on a group level. SEM was analyzed with $SD_{baseline} \times \sqrt{1}$ – reliability and complemented with a CI 95% [12].

RenderX

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki [42] and approved by the Swedish Ethical Review Authority (2021 - 05077). The invited parents were recruited through gatekeepers at the pediatric department. Information regarding the study was initially provided orally and then followed up by written information, before written informed consent was obtained by a study nurse. Data were handled confidentially, and participating parents were able to quit without any explanation or impact on the care their children received. Participation in the study was voluntary, and no financial or other form of compensation was provided to the participants.

Results

Translation and Adaption

Both translations (forward and backward) were similar and did not differ substantially. Overall, the conformity of phrasing was high, with some discrepancy for phrasing in statements 2 (I found the system unnecessarily complex) and 8 (I found the system very cumbersome to use). In statement 2, the word “complicated” was suggested in the back translation from the Swedish word “komplex.” In statement 8, the word “awkward” was suggested instead of the original word “cumbersome.”

All such discrepancies were discussed within the research group and a consensus was reached for the final version. The final step, comparing the Swedish version to other Scandinavian versions, generated no further changes. Table 1 shows the original English version and the final Swedish version of the SUS.

Table . Original English version [7] and the proposed Swedish version of the System Usability Scale, including (1) response alternatives and (2) statements.

Component	English version	Swedish version
Response alternatives	• 1 - Strongly disagree • 2 • 3 • 4 • 5 - Strongly agree	• 1 - Instämmer inte alls • 2 • 3 • 4 • 5 - Instämmer helt
Statements	1. I think that I would like to use this system frequently 2. I found the system unnecessarily complex 3. I thought the system was easy to use 4. I think that I would need the support of a technical person to be able to use this system 5. I found the various functions in this system were well integrated 6. I thought that there was too much inconsistency in this system 7. I would imagine that most people would learn to use this system very quickly 8. I found the system very cumbersome to use 9. I felt very confident using the system 10. I needed to learn a lot of things before I could get going with this system	1. Jag tror att jag skulle vilja använda denna applikation ofta 2. Jag uppfattar denna applikation som onödigt komplex 3. Jag tycker att denna applikation är enkel att använda 4. Jag tror att jag skulle behöva stöd för att kunna använda denna applikation 5. Jag upplever att de olika funktionerna i denna applikation var väl integrerade 6. Jag tycker att applikationen är inkonsekvent 7. Jag föreställer mig att de flesta personer skulle lära sig att använda denna applikation väldigt snabbt 8. Jag upplever denna applikation som krånglig 9. Jag känner mig trygg med att använda denna applikation 10. Jag behövde lära mig många saker innan jag kunde komma igång med denna applikation

[a]In this study, the Swedish instruction was as follows: "Markera det alternativ som bäst beskriver din reaktion för applikation i surfplatta idag," meaning “Please indicate your agreement with the following statements, one at a time.”

Psychometric Evaluation of the Swedish Translation

A total of 62 individuals were included in this study. Of these, 20 answered the questionnaire, including the SUS, twice. This resulted in a total of 81 measurements included in the analysis. Demographic data for the participants are shown in Table 2.

Data Quality

The percentage of missing data per item was low (ranging from 0/81, 0% to 3/81, 4%) across all items. A tendency could be seen for a higher percentage within the 3 highest steps of the scale, resulting in 5 items having 0% in the lowest points of the 5-point scale (Table 3).

Table . Missing data (n and %) and item frequency distribution (%) of answers per response alternative in each question of the Swedish System Usability Scale (n=81). The item “0” equals the response of “1” on the scale, etc.

Item	Missing data, n (%)	Item frequency distribution, n (%)				
		0	1	2	3	4
1	0 (0)	1 (1)	5 (6)	21 (26)	36 (44)	19 (23)
2	1 (1)	0 (0)	4 (5)	16 (20)	9 (11)	52 (63)
3	0 (0)	1 (1)	0 (0)	10 (12)	24 (29)	47 (58)
4	2 (2)	0 (0)	0 (0)	6 (7)	16 (20)	58 (71)
5	0 (0)	2 (2)	2 (2)	21(26)	32 (39)	25 (31)
6	3 (4)	2 (2)	3 (4)	21 (25)	13 (16)	40 (49)
7	1 (1)	0 (0)	1 (1)	4 (5)	34 (42)	42 (51)
8	2 (2)	1 (1)	1(1)	5 (6)	10 (13)	63 (77)
9	0 (0)	0 (0)	0 (0)	6 (7)	28 (34)	48 (59)
10	0 (0)	0 (0)	1 (1)	4 (5)	14 (17)	63 (77)

Scaling Assumptions

Item means ranged from 2.82 to 3.70 (Table 4). The item-total correlations showed that each item contributed substantially to the total score with correlations ranging from 0.454 to 0.731 (Table 5), thus indicating that the scale can be summarized. The total sum for the SUS in the data ranged between 50 and 100 (mean 84, SD 13).

XSL•FO

Table . Item descriptive statistics for the Swedish version of the System Usability Scale (n=81).

Item	Score, mean (SD)	Skewness
1	2.82 (0.904)	−.550
2	3.35 (0.964)	−1.094
3	3.41 (0.800)	−1.490
4	3.65 (0.618)	−1.585
5	2.93 (0.940)	−.766
6	3.09 (1.076)	−.876
7	3.44 (0.652)	−1.038
8	3.66 (0.762)	−2.682
9	3.51 (0.633)	−.943
10	3.70 (0.622)	−2.203

Table . Item-total statistics for the Swedish version of the System Usability Scale (n=81).

Item	Scale mean if item deleted	Corrected item-total correlations	Cronbach α if item deleted
1	30.80	0.463	.847
2	30.30	0.731	.820
3	30.22	0.534	.840
4	30.00	0.657	.833
5	30.72	0.479	.847
6	30.57	0.463	.852
7	30.21	0.454	.846
8	29.99	0.687	.827
9	30.12	0.675	.831
10	29.96	0.585	.837

Acceptability

As indicated by the item mean score (range 2.82-3.70; Table 4) and item-frequency distribution (Table 3), the instrument showed acceptability. For 3 items (4, 8, and 10), the item frequency was above 70%, which is still within the acceptable range for the absence of a ceiling effect. Skewness statistics were below or near the acceptable range of −1 for a total of 7 items, thus indicating that the distribution was excessively skewed (Table 4).

Convergent Validity

Convergent validity was evaluated with the correlation between the total sum of the SUS and the total sum of domain 5 in the eHLQ. As expected, there was a positive correlation between the total score of the instruments (correlation coefficient 0.305), which was significant (*P*=.001) and supported the construct validity of the Swedish version of the SUS.

Internal Consistency and Measurement Error

Cronbach α for the scale was .852. Corrected item-total correlations were between 0.454 and 0.731, as shown in Table 5, indicating internal consistency for the different items. For all items except item 6 (I thought there was too much inconsistency in this system), the α value if the item deleted was lower than the Cronbach α for the scale. The SEM was 5.05 (95% CI –4.84 to 14.954) points for the Swedish version of the SUS.

Discussion

Principal Findings

This study presents a new Swedish version of the SUS that is psychometrically tested. This study seeks to establish the new Swedish version of the SUS as a reliable and valid instrument for assessing system usability. Overall, the psychometric testing showed high data quality, good scaling assumptions, high internal consistency, and fair convergent validity. Together, these analyses support the validity and reliability of the new Swedish version of the SUS.

The translation process of the new Swedish version of the SUS was executed incrementally, both within and outside the research team, involving an authorized translator who conducted a back translation. This method facilitated thorough scrutiny and comparison of the translation from multiple perspectives. The approach also helped reduce the risk of bias and improved the scale's validity by incorporating multiple viewpoints [43].

The psychometric testing regarding internal consistency showed that the Cronbach α values were satisfactory and that all items

XSL•FO
RenderX

contributed to the instrument's total score. This indicates that the Swedish translation of the SUS is a stable instrument to use in a Swedish context.

Convergent validity showed fair correlation between the SUS and domain 5 of the eHLQ, which measured the motivation to engage with digital services (I find that digital technology support me in taking care of my health). This supported our hypothesis that a generally positive attitude toward digital solutions would correlate with a high usability score. This hypothesis is also in line with previous research, which shows that positive expectations directed toward a product generate positive subjective usability ratings [14].

There was an indication of a ceiling effect for 3 items on the Swedish version of the SUS (items 4, 8, and 10). They presented above 70% in item frequency distribution and a high mean total score, which is in line with studies indicating a generally high score for the SUS [10]. Previous studies have also shown ceiling effects of the SUS but only for the total score [15,44], thus the responses on the different items can not be justly compared between studies. This study, however, explores the SUS in much more detail and in line with recommended psychometric evaluations, as it explores the psychometric properties for each item separately [12,37]. Further, the distribution was excessively skewed. This could be an expected result of the nonnormal distribution, since negatively skewed variables are assumed to have a ceiling effect [37,45]. Also, the robustness of skewed distribution as the sole indicator of ceiling effect has been questioned [45].

However, based on the skewness result of the items, the question arises as to whether the range of the response options is wide enough (5-point scale) and if the wording in the response options ("strongly disagree" to "strongly agree") is a sufficient description. It could be interesting to expand the number of response options but, arguably, there could be obstacles with revising such a widely used and widespread instrument.

Regarding the high mean scores for both the total sum and the items of the SUS, it should be noted that the population had a mean age of 33 years and are, therefore, used to digital solutions. This could have influenced their experience of the app. Therefore, the high item scores of the SUS could also indicate a product that is perceived to have usability for this group. A recommendation for future studies would be to test the instrument in other contexts and with different age groups. This app was designed to support users who were in exactly the same situation as the participants in this study: parents in a specific situation. Going home with a child after hospitalization can be stressful; the parents in this study reported this eHealth solution as supportive [46]. The SUS has previously been tested for its sensitivity in different digital solutions and has shown a high scoring (ceiling effect) within the best-of-class products [44].

The Swedish government has envisioned Sweden as a leading country of eHealth in the near future. It has declared the need for individual users to act as the cocreators of such solutions [30]. Within eHealth, there has already been a call for a participatory design to increase the equality of access to digital solutions [47]. Even though digital technology and eHealth are intended to enhance access to health care, for example, despite geographical distances. It may also result in the opposite, as people have different knowledge in using digital solutions. For example, younger people tend to use and access digital solutions differently than older people, which is why solutions should be adapted to the intended end users [48]. In this study, the population was younger, as previously discussed, which could have influenced the result. To have a project design of cocreation often means that end users are involved from the start of the project as collaborators. Coproduction, on the other hand, often involves the end users during the implementation phase [49]. Arguably, the end users are invaluable in all steps of the process, and the usability of products needs to be evaluated where instruments such as the SUS can be useful [50]. This study could therefore be regarded as enhancing the possible participation of end users in the future development of digital solutions and eHealth in a Swedish context.

In conclusion, this study indicates that this developed and psychometrically tested Swedish version of the SUS can be recommended for use within the Swedish adult context.

Limitations

There are some methodological challenges in this study. First, the sample could be regarded as small (N=62), although it was sufficient according to the recommendations [31,33]. A larger sample might enable different methods of analysis, such as Rasch analysis, which might offer deeper psychometric insights.

Second, the 1-year interval for data collection could be considered long in a rapidly changing world. This length of time could influence how the app was perceived. That said, the digital product was not changed to any great extent during this period, so the perception of usability should not have been influenced to any great extent. Additional data collection was carried out after COVID-19 restrictions were essentially withdrawn in Sweden. There is, however, always the possibility of perceptions fluctuating, as the product could be used in various ways according to the circumstances of the parents.

Third, there was an intention to pursue a data quality test for reproducibility as some of the participants answered the SUS twice. Regrettably, the test-retest sample (n=20) was regarded as too small in this study, and such analyses need to be considered in future studies. In addition, the use of imputation can be discussed. There was a low number of missing data, with a noncomplete frequency of only 9 responses in total. The percentage of missing data per item was also low across all items. This resulted in only 6 imputed scores across the items, and based on mean score for the item, this was regarded as not influencing the result noticeably.

Conclusions

This study presents a new Swedish version of the SUS. It is the first study to carry out a psychometric evaluation of a Swedish SUS, to establish the Swedish version of the SUS as a reliable and valid instrument for assessing system usability. Overall, the psychometric testing showed high data quality, good scaling assumptions, high internal consistency, and fair convergent validity, all of which support the validity and reliability of the new Swedish version. The results from this study are promising. They raise the possibility that the Swedish version of the SUS

XSL•FO
RenderX

could be used to evaluate digital health solutions. To further strengthen the usability of the scale, we suggest additional analysis on data that evaluate more complex eHealth technology and include a wider participant age group, both younger and older.

Acknowledgments

We would like to express our sincere gratitude to the participants in the study. We would like to acknowledge Inger Kristensson Hallström, who passed away in 2024, for her extensive work, deep commitment to the field of pediatric nursing, and expertise dedicated to the eChildHealth program. Additionally, we wish to express our appreciation to Magnus C. Persson, for the design of the questionnaires in REDCap (Research Electronic Data Capture) and assisting in data transfer, as well as Desirée Lemmen and other gatekeepers for their assistance with participant inclusion and the distribution of questionnaires to the study participants. This study was funded by the Swedish Research Council for Health, Working Life and Welfare, Sweden (grant 2018-01399).

Authors' Contributions

All authors have made substantial contributions to all of the following: (1) the conception and design of the study, the acquisition of data, or the analysis and interpretation of data; (2) the drafting of this paper or its critical revision for important intellectual content; and (3) final approval of the manuscript version to be submitted.

Abstract

Background: Evaluating digital health service delivery in primary health care requires a validated questionnaire to comprehensively assess users' ability to implement tasks customized to the program's needs.

Objective: This study aimed to develop, test the reliability of, and validate the Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) questionnaire for evaluating the implementation of maternal and child digital health information systems.

Methods: A cross-sectional study was conducted in 2 phases. The first phase focused on content item development and was validated by a group of 10 experts using the content validity index. The second phase was to assess its psychometric testing for reliability and validity.

Results: A structured questionnaire of 65 items was constructed to assess the TPC-OHCIS delivery for primary health care use based on literature and has been validated by 10 experts, and 319 respondents answered the 65-item TPC-OHCIS questionnaire, with mean item scores ranging from 1.99 (SD 0.67) to 2.85 (SD 1.019). The content validity, reliability, and face validity showed a scale-level content validity index of 0.90, scale-level content validation ratio of 0.90, and item-level face validity index of 0.76, respectively. The internal reliability was calculated as a Cronbach α value of 0.90, with an intraclass correlation coefficient of 0.91. Scales were determined by the scree plot with eigenvalues >1, and 13 subscales were identified based on principal component analysis. The Kaiser-Meyer-Olkin value was 0.90 (P<.049). The total variance explained was 76.07%, and factor loading scores for all variables were >0.7. The Bartlett test of sphericity, determining construct validity, was found to be significant (P<.049).

Conclusions: The TPC-OHCIS questionnaire is valid to be used at the primary health care level to evaluate the TPC-OHCIS implementation. It can assess health care workers' work performance and job acceptance and improve the quality of care.

telehealth; electronic health; eHealth; public health information system; psychometric analysis

Introduction

Background

Digital health is mostly used interchangeably with eHealth, telehealth, or mobile health in the literature [1,2]. It requires integrated and interdisciplinary sector involvement to use knowledge information and communication technology in health (eg, medicine, public health, pharmaceutical, dentistry, and health management) [1-8]. It enables the national health system to ensure population access to health services and the ability to monitor and evaluate health system delivery performance [1,2,9]. Electronic health records are created from digital health systems for case management monitoring and can be shared

XSL•FO
RenderX

across health care settings [9]. The data sharing platform allows access to integration interfaces that include electronic medical records, appointments, electronic prescriptions, e-commerce, public health surveillance, system monitoring such as vaccination, environmental health, institutional health management, and an online platform for teaching and learning among health care workers (HCWs) [10-16].

Malaysian Digital Health

Malaysia began integrating digital health into its health care system in 1998 [4,5]. The Telemedicine Act 1997 (Act 564) was enacted to regulate telemedicine practices in the country [4,5,17-25]. Later, the telemedicine blueprint was created to outline the government's vision for digital health implementation and align it with the 7 National Multimedia Super Corridor flagship applications [19-22]. The initiative was referred to as telemedicine and later restated as telehealth. The telehealth system serves as a platform for digital health services in Malaysia [20]. The National Telehealth Policy was launched to support the Vision 2020 agenda, focusing on four key components: (1) lifetime health plan, (2) mass customized health information and education, (3) continuous medical education, and (4) teleconsultation application [1]. The policy was formulated during the Eighth Malaysia Plan and managed by the National Health Informatics Centre Division [4,17,19-22]. The lifetime health plan covers health services from womb to tomb [19]. The telehealth system also includes the clinical support system and health information management and support services, and it encompasses the hospital information system and the Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) [18-24]. The TPC-OHCIS is a comprehensive electronic medical record system for primary health care [22-24]. It was initially developed for outpatient services at primary health care clinics (PHCs), and later, it incorporated maternal and child health (MCH), oral health, and other life stage health services to ensure continuity of care [21,22]. The development of TPC-OHCIS was a collaborative effort between the Ministry of Science, Technology, and Innovation; the Ministry of Health, Malaysia; and the Malaysian Institute of Microelectronic Systems, Berhad [21-24]. The system was first tested in the PHCs of Seremban District, Negeri Sembilan, and later expanded to 34 PHCs across 3 states (ie, Perlis, Sarawak, and Selangor) [17,21]. To date, the TPC-OHCIS has been implemented in 108 PHCs across 7 additional states [22,25]. The TPC-OHCIS is a web-based platform that allows HCWs to enter data during clinic services or home visits, automatically updating when connected to the internet [23,24].

Role of Digital Health in Service Quality Performance

The recent COVID-19 pandemic revealed a significant public health issue in health care system delivery to provide comprehensive quality care [2,26-28]. Malaysia has experienced various health service delivery disruptions at PHCs during the critical phase of the COVID-19 pandemic [29]. MCH services include a wide range of services covering school health programs that experienced substantial disruptions due to closing and movement control orders, thus preventing mothers and children from receiving adequate health care services [22]. During the COVID-19 pandemic, many countries have improved health care delivery through digital technology, enhanced resource coordination, and facilitated universal health coverage [29,30].

The HCWs at the PHCs worked on the frontlines, assessing risks, monitoring care treatment, and promoting health empowerment in the community [17]. Most of the administration work related to patient care is recorded manually. Even with the implementation of TPC-OHCIS, many facilities still need to record data manually and enter it into the system because of internet instability at some PHCs [22]. At present, there is no specific policy published by the Ministry of Health to completely replace manual recording of patient information monitoring with digital health. The HCWs monitor patients during home visits and conduct outreach activities to cover areas inaccessible to health facilities [17,22]. Therefore, it is important to continue patient using manual data recording when services are provided offline. The TPC-OHCIS is an electronic medical record system used as a daily operating system and in "real time" at PHCs [22-24]. However, the TPC-OHCIS implemented in selected facilities in Malaysian PHCs is used mostly to record data and monitor patient care only [22-24].

Specific Study Measurement Tool

The conceptualization of this study diverges from earlier studies primarily in its integration of advanced technological modalities and emphasis on patient-centered care delivery, unlike traditional telehealth frameworks, which often focus on providing remote consultations or basic medical services [1,3,18,25]. The TPC-OHCIS incorporates elements of comprehensive primary care delivery, leveraging telehealth technologies to facilitate longitudinal patient-provider relationships, care coordination, and proactive health management. Moreover, this study's conceptualization places a heightened emphasis on the integration of patient health data, wearable devices, and digital health platforms to enhance care delivery and patient engagement. The TPC-OHCIS can remotely monitor patient health metrics, deliver personalized interventions, and empower individuals to take an active role in their health management [24]. The importance of interdisciplinary collaboration and team-based care is crucial in the implementation of the TPC-OHCIS at PHCs. Hence, it is important to assess the implementation of TPC-OHCIS by focusing on technology, organization, environment, or human resource components, as suggested in the literature [3-5,9]. Earlier studies were conducted to evaluate the effectiveness of the TPC-OHCIS in improving health care quality; however, there is limited evidence on assessing HCWs' perceived usefulness and ease of use [9,18,25]. A comprehensive study of HCWs' perspectives is important to provide a shred of extensive knowledge and evidence on the TPC-OHCIS implementation in PHCs.

Therefore, this study aimed at developing, testing reliability, and validating the TPC-OHCIS questionnaire, which was designed as a survey instrument to collect data on the implementation of the TPC-OHCIS at the PHC setting among HCWs related to various aspects of primary care services, including MCH services. It aims to ensure that the TPC-OHCIS questionnaire is a robust and effective tool for assessing the

XSL•FO
RenderX

implementation of MCH services, which are the core services for PHCs. The research question formulated was as follows: "Is a customized questionnaire on digital health information system (TPC-OHCIS) able to assess the HCWs' perception of its implementation process in the delivery of MCH services at the primary care level?" A thorough design of the TPC-OHCIS questionnaire validation helps increase the questionnaire's relevance and usefulness for decision-making purposes, as it is designed to facilitate monitoring and evaluating the TPC-OHCIS operability among the HCWs working at PHCs. To the best of our knowledge, there is no valid questionnaire available to measure the implementation evaluation of any digital health information system for the primary care level that focuses on MCH services, which is a priority service component of PHC and which was monitored regularly for sustainable development goals performance achievement [17].

Methods

Study Design

This study involved several steps for questionnaire development (phase 1), reliability, and validation (phase 2).

Phase 1: Questionnaire Development

The questionnaire is adapted from literature and document review [4,5,9,17-25,31-36]. The TPC-OHCIS questionnaire was developed based on various theoretical models, which may address multiple aspects of remote primary care and patient information systems. The questionnaire was created based on a combination of the technology-organization-environment (TOE) theory [31], the technology acceptance model (TAM) theory [32,33], the human organization technology-fit (HOT-fit) model [34,35], and the diffusion of innovation (DOI) theory [36]. There was a 65-item questionnaire with a 4-point Likert scale (1=highly disagree, 2=disagree, 3=agree, and 4=highly agree) developed based on the aforementioned theories [31-36]. The score scale is created according to the Likert scale that indicates the following: 1=strongly agree, 2=agree, 3=disagree, and 4=strongly disagree. In this study, the researcher did not put a neutral on a scale of 3 to avoid respondent bias [37]. The 4-point Likert scale does not impact the reliability and validity of the questionnaire [2,37].

The development of the questionnaire items was partly adapted from various questionnaires available from previous studies conducted in Malaysia, based on selected theoretical models, using a 4-point scale questionnaire: (1) technology, (2) organization, (3) environment, and (4) human [31-36] (Multimedia Appendix 1 [4,5,9,17-25,31-36]). Therefore, we classified the 65-item TPC-OHCIS questionnaire into 4 scales (Multimedia Appendix 2), described below.

- Domain A, technology: this comprised 17 items and four subscales that include (1) relative advantage (items 1-5), (2) compatibility (items 6-9), (3) complexity (items 10-13), and (4) security concern (items 14-17).
- Domain B, organization: this contained 18 items and four subscales that include (1) the presence of a specified liaison officer (BCHAMP: items 18-22), (2) infrastructure (BINFRA: items 23-26), (3) top management support (BTP: items 27-31), and (4) financial resources (BFIN: items 32-35).
- Domain C, environment: this focuses on vendor support (CVEN: items 36-39).
- Domain D, human: this contained 26 items and six subscales that include (1) staff competency in information systems (DPT: items 40-44), (2) knowledge of the TPC-OHCIS system (DEISK: items 45-50), (3) clinical information technology competency (DCIT: items 51-54), (4) perceived innovativeness of the IT officer (DCIO: items 55-57), (5) perceived ease use (DPEU: 58-61), and (6) perceived usefulness (DPU: items 62-65).

The 65-item TPC-OHCIS questionnaire was developed based on the requirement of the TPC-OHCIS implementation plan for the PHCs in Malaysia. A total of 15 items (item numbers 10, 11, 12, 13, 33, 40, 41, 42, 48, 49, 50, 53, 54, 58, and 39) were written as negative items. The Likert scale score of negative items was reversed for scoring analysis before data were entered into the SPSS software (version 26.0; IBM Corp).

Phase 2: Questionnaire Validation

On the basis of the steps suggested by Boateng et al [38], the second phase involved scale development, which consists of pretesting questions, sampling and survey administration, item reduction, and extraction of latent factors. The scale evaluation requires tests of dimensionality, reliability, and validity. A cross-sectional study was conducted to assess the psychometric properties of the questionnaire.

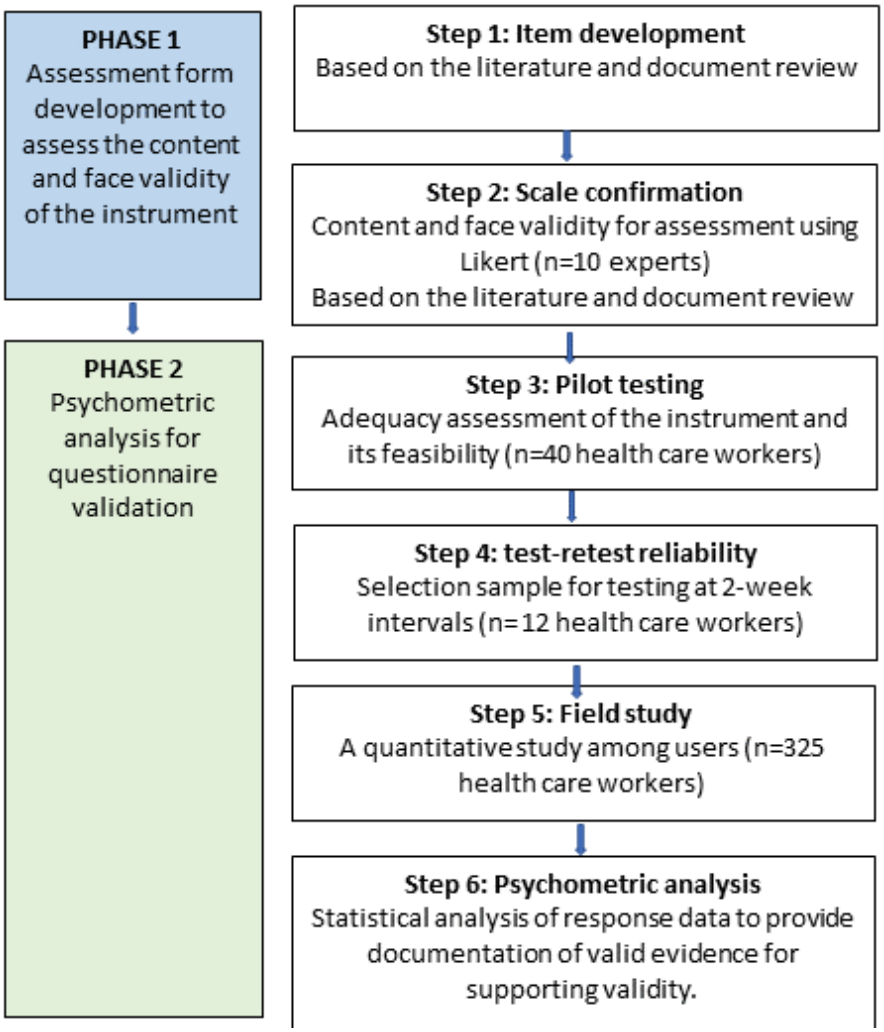
Study Sample

The sample for each step was calculated and listed in Table 1.

The sample-to-item ratio was decided based on the number of items in the questionnaire. The ratio per item was determined using 5 to 20 samples per item [39,40]. In this study, the survey included 65 items. Therefore, the total calculated sample size required was 325 respondents.

Table 1. Calculated sample size for each validation step.

Steps and aims	Sample size required, n	Reference
Pilot study and face validity: to test the adequacy of instrumentation in which the outcome is in the form of a scale	40	[3]
Test-retest reliability: to test the degree of consistency exhibited when a measurement is repeated under identical conditions	12	[4]
Field survey: to test the psychometric analysis of the questionnaire based on tests of dimensionality, reliability, and validity	325	[5]



XSL•FO
RenderX

Content Validity Index

The flow process of questionnaire validation was conducted based on Figure 1.

On the basis of Figure 1, a total of 6 steps were taken to perform content validity for the questionnaire.

Figure 1. Flow process for questionnaire validation.

Step 1: Assessment Form Development for Content and Face Validity

In our literature review search [37,39-41], we listed items to determine the content and face validity. We used the clarity scale of 1 to 3 to indicate the relevance of each item (1=not clear, 2=revision needed, and 3=very clear). The essentiality of the questionnaire was identified using a 1 to 3 scale (1=not essential, 2=useful but not essential, and 3=essential). A similar form was used to assess face validity in evaluating the language, feasibility, readability, and style formatting consistency [37,41].

Step 2: Content and Face Validity (Expert Review)

Face validity was conducted among the experts who were involved in designing and using the system at the primary care level. Ten experts were invited to review the 65-item Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) questionnaire. All experts have extensive experience and knowledge related to the TPC-OHCIS. Of the 10 experts, 3 (30%) were from the TPC-OHCIS division, 3 (30%) were public health researchers, 2 (20%) were from the maternal and child health unit services in the Selangor State Health Department, and finally, 2 (20%) were individuals who worked directly with the TPC-OHCIS system and also served as system liaison officers at health clinics. The adaptation of questionnaires from earlier studies [41-43] was checked for content suitability and appropriateness before forward translation was performed. Scale evaluation was performed by experts using a developed form. Owing to time constraints and lockdown because of the COVID-19 pandemic, a face-to-face method for collecting data from the experts was impossible. A Google form (Google LLC) link was created and sent via WhatsApp (Meta Platforms, Inc) to assess the face and content validity. The selected 10 experts were asked to evaluate the scale for content and face validation. All 10 experts' comments were used to improve the questionnaire. Experts were encouraged to provide both verbal and written comments regarding the questionnaire items. Verbal comments were collected via phone call, and written comments were collected via the Google form.

XSL•FO
RenderX

Step 3: Pilot Study

A pilot study was conducted to assess the adequacy of the instrumentation, which measured outcomes to ensure that the instruments used were appropriate and effective for the intended purpose. Through the pilot study, face validity was evaluated to confirm that the 65-item TPC-OHCIS questionnaire developed was constructed accurately and comprehensively. We purposively invited health care workers (HCWs) who were involved in the initial pilot-tested version of the TPC-OHCIS in Seremban District, Negeri Sembilan [17]. The questionnaire was sent after a thorough face and content validity assessment by the experts. Correction and fine-tuning were conducted by the researchers based on their feedback.

Step 4: Test-Retest Reliability

We selected 12 HCWs who were familiar with the TPC-OHCIS involved in the pilot study mentioned above to test the degree of consistency exhibited when a measurement is repeated under identical conditions. The same questionnaire was sent to the same respondents 2 weeks after the first time the survey was conducted.

Step 5: Field Study

A cross-sectional study was performed to assess the item reduction and extraction factors among the HCWs of the TPC-OHCIS public health care clinics (PHCs) in selected states in Malaysia. The TPC-OHCIS is a system used in the PHCs. The PHC is headed by a family medicine specialist who supervises staff from various disciplines (eg, physicians, nurses, medical assistants, pharmacists, laboratory technicians, and record officers).

Step 6: Performing an Analysis for Content Validity, Face Validity, and Test-Retest Reliability

The item-level content validity index (I-CVI) and scale-level content validity index (S-CVI) were used. I-CVI is defined as the proportion of content experts giving items a relevance rating of 3 and 4. S-CVI was calculated by the proportion of understanding by experts (universal agreement [UA] of S-CVI), which gave ratings of 3 and 4, or by average scores given (average of S-CVI). The average of S-CVI is defined as the average of the I-CVI scores for all items on the scale or the average of proportion relevance judged by all experts. The UA of S-CVI is the proportion of items on the scale that achieve a relevance scale of 3 or 4 by all experts. UA score is given as 1 when the item achieved 100% agreement by all experts; otherwise, the UA score is given as 0 [39]. First, we calculated the experts in agreement. Second, a score of 1 was given to items that achieved 100% agreement by all experts, while a score of 0 was given to items that did not achieve 100% agreement. Third, experts in the agreement were divided by the total number of experts (calculated for I-CVI). The fourth step was to divide the results obtained in the third step by 65, which was the total number of items in the questionnaire (calculated for average of S-CVI). Finally, we divided the UA result from step 2 by 65 items (calculated for UA of S-CVI). The face validity index was used to evaluate the form of clarity and comprehensibility of language and instructions used in the questionnaire [41]. The respondents were requested to rate the comprehensibility of each item using a scale of 1 to 4 (1=not understandable, 2=somewhat understandable, 3=understandable, and 4=very understandable). The item-level face validity index was computed for each item by dichotomizing the 4-point scale, where items scoring either 1 or 2 were recorded as 0 and items scoring 3 and 4 were recorded as 1. The values later were added up according to each item, and the total values were divided by the total number of respondents. Test-retest reliability was used to define whether the questionnaire was answered by respondents due to chance. The internal reliability of questionnaires was assessed using the Cronbach α coefficient. The Pearson correlation and intraclass correlation coefficients of the scores of the 2 tests were calculated. The test-retest reliability is achieved when the value of intraclass correlations is 0.6 to 0.8 (good reliability), and values >0.8 indicate excellent reliability, which means the higher the correlation, the higher the test-retest reliability, with values close to 0 indicating low reliability [38].

Forward-Backward Translation

The questionnaire was translated from English to the Malay language, then underwent content assessment, and its cross-cultural validity was evaluated by 3 experts representing Malaysia's diverse ethnic backgrounds (Malay, Chinese, and Indian), proficient in both English and Malay. After the questionnaire had been reviewed, the forward-backward translation was sent to Proofreaders United company for translation and proofreading.

Ethical Considerations

Ethics approval was granted by the National University of Malaysia (FF-2021-124) and the Ministry of Health Malaysia National Medical Research Registry (NMRR-21-599-58521, investigatory initiated research). Meanwhile, the researcher also needed to obtain verbal permission and a signed consent letter from the respondent as evidence of consent to participate in the study. Respondents were informed that their participation was voluntary and they would not receive any payment. All research information collected was treated as confidential. The data are displayed anonymously without the name, address, or any identity that describes the respondent when presented as the study output.

Statistical Analysis

The internal reliability was assessed using Cronbach α. The validity index was calculated based on the content validity index (CVI). The Bartlett test of sphericity was used to determine the construct validity. The Kaiser-Meyer-Olkin measure and total variance explained (TVE) were evaluated. Factor analysis was performed using varimax rotation in principal component analysis (PCA) to verify construct validity (ie, discriminant and convergent validity). Items loading >0.60 were considered for further analysis [38].

Results

CVI Evaluation

Out of 10 experts evaluating the 65-item TPC-OHCIS questionnaire (TPC-OHCIS questionnaire in Multimedia

XSL•FO
RenderX

Appendix 2), the scale-level CVI (S-CVI) average for item 1 of domain A, relative advantage, to item 65 of domain D, perceived usefulness, was 0.9. The average of S-CVI (based on item-level CVI) was 7.415, the average of S-CVI (based on proportion) was 0.742, and the universal agreement of S-CVI was 0.045. The universal agreement of S-CVI was calculated based on the proportion of items on the scale that obtained a relevance value of 3 or 4 from all the experts (Multimedia Appendix 3).

Face Validation

The face validity index was assessed for clarity, language comprehensibility, and instructions used in the questionnaire. The calculated item face validity index was 0.785 and fulfilled the face validity criteria, which was >0.6 [41].

Test-Retest Reliability

The 65-item survey's internal reliability score for Cronbach α was 0.90 for the whole instrument and exceeded the suggested minimum value of Cronbach α=0.70 [38]. Pearson correlation coefficient was 0.90, and the intraclass correlation coefficient was 0.91.

Descriptive Analysis

There were 319 respondents (Table 2) who answered the 65-item TPC-OHCIS questionnaire, with mean item scores ranging from 1.99 to 2.85 (Table 3). Our study found that a high mean score was achieved in all subscales except for the item 17 in domain A, security concerns (*how much can I trust the vendor)*. The subscale mean scores were lowest at 1.93 (SD 0.751) and 1.99 (SD 0.832) for item 63 in domain D, perceived usefulness (*TPC-OHCIS application improved the quality of my work, respectively).* The mean score for communication was the highest for item 38 in domain C, vendor, with a mean score of 3.45 (SD 0.819), and item 39 in domain C, vendor, with a mean score of 3.39 (SD 0.805).

Table 2. Respondent profile for field study (N=319).

Variables and category	Frequency, n (%)
Occupation	
Family medicine specialist	5 (1.6)
Medical officer	69 (21.6)
Matron	2 (0.6)
Head nurse	17 (5.3)
Nurse	138 (43.3)
Community nurse	88 (27.6)

Table 3. Descriptive statistics for item mean score of the Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) questionnaire.

Item question	Question statement	Scores, mean (SD)
ARA[a] 1	Using the TPC-OHCIS application enables me to do my work quickly.	2.05 (0.865)
ARA 2	Using the TPC-OHCIS application improves the quality of my work.	1.99 (0.832)
ARA 3	Using the TPC-OHCIS application enhances my effectiveness on the job.	2.01 (0.864)
ARA 4	Using the TPC-OHCIS application increases my productivity.	2.04 (0.825)
ARA 5	Using the TPC-OHCIS application makes my job easier.	2.02 (0.795)
ACOM[b] 6	TPC-OHCIS application can be easily accessed across multiple platforms (laboratory results, x-ray, and other related patient data).	2.53 (0.941)
ACOM 7	TPC-OHCIS user interfaces provide transparent access to all platforms (e-notification and VEKPRO[c]).	2.62 (0.931)
ACOM 8	Data received from other devices (tablet/laptop/ smartphone) outside health facilities in the TPC-OHCIS application can be easily merged into the database for analysis.	2.74 (0.932)
ACOM 9	Information is shared seamlessly across our organization regardless of location.	2.74 (0.839)
ACOMPLEX[d] 10	I do not know enough about the TPC-OHCIS application to handle my job satisfactorily.	2.86 (0.870)
ACOMPLEX 11	I need a long time to understand and get familiar with the TPC-OHCIS application.	2.82 (0.961)
ACOMPLEX 12	I do not find enough time to study and upgrade my technology skills before using the TPC-OHCIS system.	2.71 (0.870)
ACOMPLEX 13	I often find it too complex for me to understand and use the TPC-OHCIS application.	2.99 (1.019)
ASEC[e] 14	I feel secure in using the TPC-OHCIS application, keying in patients' data, and sharing it across my organization.	2.05 (0.855)
ASEC 15	I would feel safe using the TPC-OHCIS application to retrieve patient data.	2.80 (0.754)
ASEC 16	I am concerned about data patient leakage.	2.07 (0.785)
ASEC 17	I am concerned about how much I can trust the vendor.	1.93 (0.751)
BCHAMP[f] 18	A specified liaison officer will provide useful information to top managers and vendors about the TPC-OHCIS application faulty.	2.02 (0.736)
BCHAMP 19	A specified liaison officer plays a role in upgrading the TPC-OHCIS application for users' needs.	2.01 (0.760)
BCHAMP 20	A specified liaison officer has a good relationship with both vendors and top managers.	2.22 (0.851)
BCHAMP 21	A specified liaison officer can bring staff to use the TPC-OHCIS application well.	2.41 (0.972)
BCHAMP 22	A specified liaison officer provides training/courses for the users a few times a year.	2.54 (0.895)
BINFRA[g] 23	We have enough computers for the TPC-OHCIS application use.	2.27 (0.743)
BINFRA 24	We have a reliable computer network in our use.	2.11 (0.767)
BINFRA 25	Appropriate hardware, software, and network infrastructure were in place before TPC-OHCIS implementation.	1.90 (0.749)
BINFRA 26	We have integrated IS[h] applications encompassing different functional areas (laboratory and pharmacy).	2.05 (0.775)
BTP[i] 27	Top management always supports and encourages the use of the TPC-OHCIS application for job-related tasks.	2.15 (0.785)
BTP 28	Top management provides most of the necessary help and resources to enable people to use the TPC-OHCIS system.	2.17 (0.746)
BTP 29	Top management provides good access to hardware when staff need it.	2.15 (0.732)
BTP 30	Top management gives feedback to vendors on every dismayed or unsatisfactory comment from staff.	2.44 (0.822)

Item question	Question statement	Scores, mean (SD)
BTP 31	Top management provides good access to the TPC-OHCIS application when staff need it.	2.55 (0.842)
BFIN[j] 32	There is enough financial aid from the organization for the coordination of the system implementation.	2.44 (0.901)
BFIN 33	I find difficulties in using the TPC-OHCIS application because it cannot be upgraded due to not having enough budget.	2.75 (0.814)
BFIN 34	Enough computers are available to access the TPC-OHCIS application.	2.29 (0.743)
BFIN 35	We easily obtain obsolete computer replacements.	2.28 (0.729)
CVEN[k] 36	Vendors entertain each of our complaints dutifully.	2.41 (0.704)
CVEN 37	The vendor can upgrade the TPC-OHCIS according to our needs.	2.41 (0.771)
CVEN 38	The system vendor attends technical meetings quite frequently.	3.45 (0.819)
CVEN 39	I have a platform to voice out problems regarding the TPC-OHCIS application directly to the vendor.	3.39 (0.805)
DPTC[l] 40	I do not know how to use computers.	3.19 (0.874)
DPTC 41	I never used to work online.	2.11 (0.849)
DPTC 42	I need people's help to use a computer.	2.15 (0.859)
DPTC 43	I like to work using the online system.	2.29 (0.836)
DPTC 44	The TPC-OHCIS application is easy to operate.	2.33 (0.794)
DEISK[m] 45	I have enough training before working with the TPC-OHCIS application.	2.25 (0.836)
DEISK 46	It took me only a few days before I could master the TPC-OHCIS application well.	2.85 (0.920)
DEISK 47	The TPC-OHCIS facilitates task management.	2.63 (0.912)
DEISK 48	The TPC-OHCIS application is hard to use.	2.61 (0.900)
DEISK 49	I have to open many interfaces just to key in 1 patient's data.	2.05 (0.730)
DEISK 50	The TPC-OHCIS application takes much time because I have to open so many interfaces.	2.50 (0.715)
DCIT[n] 51	I have confidence in my ability to operate the TPC-OHCIS application.	2.60 (0.725)
DCIT 52	I have the expertise regarding Information technology to provide valuable knowledge to the organization.	2.23 (0.737)
DCIT 53	It does not make any difference whether I add/share knowledge with others related to the use of the TPC-OHCIS application.	2.22 (0.688)
DCIT 54	I feel that other employees can provide more valuable knowledge about the system's use.	2.22 (0.688)
DCIO[o] 55	The ITO[p] is actively considering the introduction of new technology to solve to organization's problem.	2.34 (0.672)
DCIO 56	The ITO tries to keep a technological leading edge by adopting new technology early.	2.84 (0.823)
DCIO 57	The ITO tends to take risks in the decision-making of new technology introduction.	2.80 (0.847)
DPEU[q] 58	I often become confused every time I use the TPC-OHCIS application.	2.11 (0.810)
DPEU 59	Interacting with the TPC-OHCIS application is frequently frustrating.	2.18 (0.768)
DPEU 60	I find that the TPC-OHCIS application makes my job easier.	2.28 (0.846)
DPEU 61	The TPC-OHCIS application provides useful guidance in performing tasks.	2.06 (0.764)
DPU[r] 62	My job would be hard to perform without the TPC-OHCIS application.	2.13 (0.835)
DPU 63	Using the TPC-OHCIS application improves my job performance.	2.18 (0.767)
DPU 64	Using the TPC-OHCIS application saves me time.	2.13 (0.851)

Statistical Analysis

The 65-item TPC-OHCIS questionnaire was created based on a mix of items adapted from various sources in the development of the questionnaire. It was adapted by a combination of the TOE theory [31], the HOT-fit model [34,35], the DOI theory [36], and the TAM theory [32,33]. The content validity was assessed by experts according to the 4 scales (ie, technology, organization, environment, and human), as highlighted in the previous studies [33-35]. In this study, we explored the constructs generated from this initial group of 65 items, which were developed based on their multidimensional nature. An exploration of the subdimensions based on the 65-item TPC-OHCIS questionnaire at the initial phase found that there were 13 factors, without being restricted to 4 domains. Exploratory factor analysis (EFA) determined the quantity of components (or themes) that emerged for the questionnaire items. The process involved grouping the measurements of comparable themes. The scree plot reveals that there were 13 components in a 65-item questionnaire (Figure 2).

A PCA with varimax rotation yielded 13 components with an eigenvalue of >1. The eigenvalue for the first component was 17.71 and accounted for 27% of the variance. The difference between the first and second components was 11.98, while the subsequent eigenvalues were small (4.91, 4.64, and 3.40). The Kaiser-Meyer-Olkin value was 0.908, which showed sample adequacy. The Bartlett test of sphericity value for the approximate chi-square was χ^2_{2080}=18,219.9; this was significant (P=.001).

Table 4 shows that the eigenvalues from 1.01 to 17.71, corresponding to the extraction sums of squared loadings of 13 subscales of the questionnaire. The highest eigenvalue accounted for 17.71% of the total variance, while the lowest eigenvalue explained 1.01%. The result also shows that the extraction eigenvalue does not vary much from the rotation eigenvalue. Therefore, 65 items loaded strongly on 13 factors at the extraction level.

Table S1 in Multimedia Appendix 4 provides the scale construct and its item. All 13 components had acceptable internal reliability (Cronbach α>0.7). All construct eigenvalues were >1. The deleted items were 14 and 15 of domain A, relative advantage, and 56 and 57 of domain D, chief information officer innovativeness, and the deletions were done because their factor loadings were <0.6. After discussing with the experts, questions for items 56 and 57 of domain D, chief information officer innovativeness, were rephrased for clarity. Question for item 15 of domain A, relative advantage, was omitted, and question for item 14 of the same domain remained as it was.

Table S1 in Multimedia Appendix 4 provides a detailed breakdown of various items and their corresponding domain scores, reflecting their relative contribution to each domain. The items are identified by numbers and grouped under distinct domains. For instance, items 18, 19, 22, 20, 21, 16, 17, and 14 display scores ranging from 0.493 to 0.854, indicating their relevance within a particular domain. Similarly, items 63, 65, 62, 64, 61, 60, 59, and 58 exhibit scores from 0.636 to 0.807 and, therefore, were grouped in another domain. The third domain was categorized based on items 40, 42, 44, 43, 41, 38, and 39, with scores ranging from 0.701 to 0.927. The fourth domain includes items 48, 46, 49, 47, 45, and 50, with scores between 0.0715 and 0.829, and the last domain covers items 27, 31, 30, 29, and 28, with scores ranging from 0.773 to 0.822.

Figure 2. Scree plot revealing the 13-factor components extracted from principal component analysis with varimax rotation.

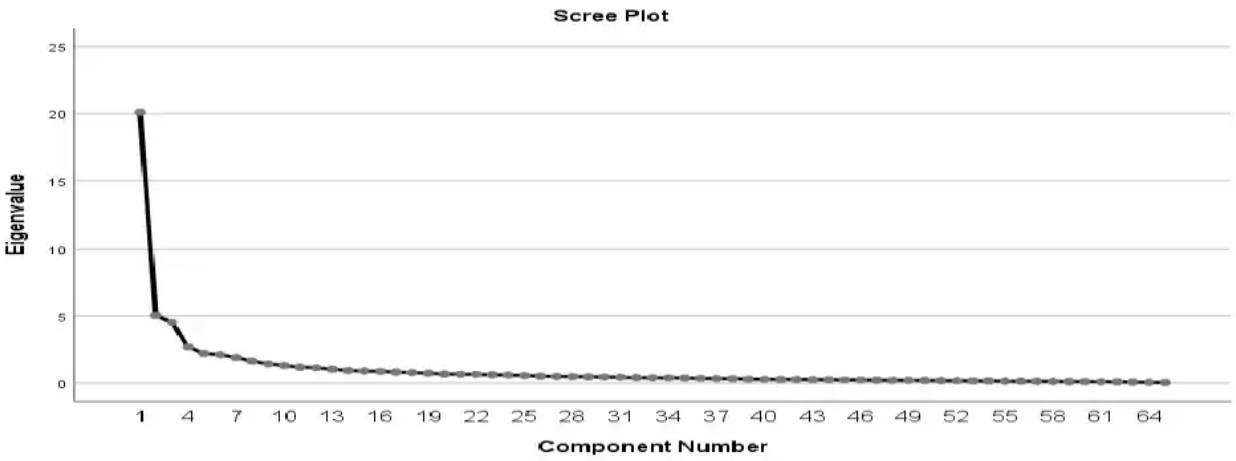

Table 4. The total variance explained.

Factor	Initial eigenvalues			Extraction sums of squared loadings		
	Total, n	Variance (%)	Cumulative (%)	Total, n	Variance (%)	Cumulative (%)
1	18	27.2	27.2	18	27.2	27.2
2	6	8.8	36.1	6	8.8	36.1
3	5	7.6	43.6	5	7.6	43.6
4	5	7.1	50.7	5	7.1	50.7
5	3	5.2	55.9	3	5.2	55.9
6	3	4.3	60.3	3	4.3	60.3
7	2	2.9	63.2	2	2.9	63.2
8	2	2.7	65.9	2	2.7	65.9
9	2	2.6	68.6	2	2.6	68.6
10	1	2.2	70.7	1	2.2	70.7
11	1	2.1	72.8	1	2.1	72.8
12	1	1.7	74.5	1	1.7	74.5
13	1	1.6	76.1	1	1.6	76.1

Discussion

Principal Findings

This study aimed to validate a specific tool used in health care delivery in Malaysia's health care system, a new technology telehealth application called TPC-OHCIS, making this evaluation timely. The 65-item TPC-OHCIS questionnaire demonstrated a comprehensive and reliable tool ready to be used for the assessment of the implementation of the digital application system for monitoring the health service program at the PHCs. Monitoring any health care service performance requires a periodic and ongoing operation to ensure that it can be delivered as planned and with good tracking of progress. Evaluation of how the program should be implemented needs to have a valid tool that can give relevant and appropriate results. A validated tool can be used to replicate similar studies in the future for evaluation and comparison.

Developing and validating a locally customized questionnaire for specific program service delivery is important. Therefore, this study used 4 theories, including the HOT-fit model, DOI theory, TOE theory, and TAM theory. The TPC-OHCIS questionnaire was proven valid based on content, face, and construct validities, as well as good psychometric analysis reliability. A total of 4 scales created using PCA did not align with a local study [17] that assessed the hospital information system implementation in Malaysian hospitals. Measuring implementation of technology in different service set-ups and levels of care, at either hospitals or PHCs, should use a customized tool. No similar research paper is available to check for disagreement or benchmarks on other tools, to compare them with the TPC-OHCIS questionnaire validation. Our findings showed that the 13 scales were validated based on the local population working in the PHC with the TPC-OHCIS. In comparison, an earlier study conducted local testing on the hospital information system and identified 4 scales [18]. Our

XSL•FO
RenderX

analysis focuses on the MCH services, which are the routine and regularly monitoring health services delivered at PHCs.

A CVI score of 0.90 is generally considered very high and indicative of strong content validity for a measurement tool, particularly in the academic context. Content validity refers to the extent to which the items in a measurement instrument represent the entire range of content that the instrument is intended to measure [39]. A CVI of 0.90 provides strong evidence that the measurement tool has undergone rigorous development and validation processes.

Face validity has been widely used not only in questionnaire development but also in questionnaires that were adopted from other researchers' tools, which required local forward-backward translation [37-41]. Experts in the field who were recruited to determine face and content validity in our study gave feedback regarding content relevance, wording, quantity of items, the amount of information, and other related issues. The analysis results for the CVI from 10 experts indicated good quality (>0.9), which complies with the recommendations in the literature [41].

Internal reliability assessment using Cronbach α revealed how close the selected items are to one another when measuring the construct [39]. The Cronbach α value of the 65-item TPC-OHCIS questionnaire was 0.90, which exceeded the suggested minimum value of 0.70 [39]. By measuring Cronbach α, the tool's accuracy and reliability have been verified. Our findings demonstrated that the variables are correlated with the components as constructed through PCA, and it proved that they are internally consistent.

The EFA also determined the TVE for the construct. The TVE illustrated the precision with which the measuring objects and their constituent parts estimate the construct. This study found that the TVE was 76.08%, which exceeded the required minimum of 60%, indicating that the overall variance explained was satisfactory [39]. PCA is the most common EFA method for dimension reduction. The EFA results using varimax rotation with maximum likelihood showed that the TPC-OHCIS questionnaire has 13 subscales.

The study may provide evidence-based recommendations for policy makers and health care stakeholders regarding the implementation and optimization of the TPC-OHCIS in the MCH service delivery monitoring. By identifying key factors influencing the TPC-OHCIS implementation and effectiveness, the study offers actionable insights into policy development, resource allocation, and quality improvement efforts aimed at strengthening MCH care systems. The study may contribute methodological innovations to the field of TPC-OHCIS evaluation, such as novel approaches to questionnaire development, validation, and implementation. By documenting the methodological processes and challenges encountered in assessing the TPC-OHCIS questionnaire validation, the study adds to the methodological toolkit available to researchers and practitioners working in the field of digital health.

Overall, the TPC-OHCIS study offers novel insights into the evaluation of the TPC-OHCIS, which focuses on the MCH services, highlighting the importance of tailored assessment tools, cross-cultural adaptation, policy considerations, and methodological innovations. These insights contribute to a deeper understanding of the complexities and opportunities associated with the integration of digital health technologies into health care delivery and provide a foundation for future research and practice in this area. The TPC-OHCIS questionnaire is validated for evaluating other health information systems, as it takes into account the outcome aspects of health services, technology, organizations, vendors, and human resources. Future researchers can replicate studies to validate the findings of the TPC-OHCIS questionnaire in different populations, settings, and contexts. By replicating studies using a valid and reliable tool with diverse samples, researchers can assess the generalizability and robustness of the questionnaire across various demographic, cultural, and organizational contexts.

Suggestions to Stakeholders

There is a need to integrate machine learning and artificial intelligence into the TPC-OHCIS so that data can be extracted faster and can be used in line with precision medicine. The validated TPC-OHCIS questionnaire can help stakeholders make effective evidence-based decisions in managing patient-centered care. The system needs to be more stable, easier to use, and faster in terms of data collection, without the need for complicated training, and easy to download from the system itself. Awareness related to the importance of complete and accurate data from an organizational perspective needs to be understood at the level of clinic users and data administrators because they will then enter, process, and ensure that the data entered are complete and accurate. These crucial issues were addressed in our study during the content and face validity assessment of the tool.

The COVID-19 pandemic made us see the need for the TPC-OHCIS to be rolled out to wider PHCs in Malaysia. With <10% of the TPC-OHCIS currently implemented, the vision to having a digital health system in Malaysia by the year 2030 needs to be facilitated. The TPC-OHCIS should be developed as a comprehensive package that includes embedded training and health education to facilitate its delivery. The issue of data security can be compared to the concept of banking system apps in Malaysia, where users only need to download the app on their mobile phones to share information with other health care providers, unlike the TPC-OHCIS, which ensures continuity of care. Otherwise, printing a duplicate report is sufficient for the time being while the country works on transitioning all clinics into a digital system.

Study Strength

The study demonstrates the development of a tailored questionnaire specifically designed to assess the implementation process and the effectiveness of the TPC-OHCIS in the context of MCH health services at the primary care level. This tailored approach acknowledges the unique challenges and complexities of MCH service delivery and highlights the importance of designing measurement tools that are sensitive to the needs of this population. The study determined comprehensive items to measure the integration implementation of the TPC-OHCIS, which is one of the digital health technologies focusing on

XSL•FO
RenderX

priority services, such as MCH service delivery at the primary care level. The study sheds light on the practical considerations, barriers, and facilitators associated with the adoption and use of digital health solutions in MCH care settings. The study offers insights into the cross-cultural adaptability assessment tools, particularly in diverse multiethnicity population settings. By evaluating the linguistic and cultural appropriateness of the TPC-OHCIS questionnaire, the study highlights the importance of considering cultural context and language preferences in developing and validating measurement instruments for MCH services.

Limitations of This Study

This study was conducted in 2021 when movement control orders were implemented in Malaysia. The study was conducted entirely online, and all surveys were distributed to the respondents' superiors without proper briefing about the survey and the overall idea of the research except for study information highlighted at the beginning of the online survey questionnaire form. Therefore, each respondent answered as they saw fit, without recognizing the true meaning of the survey. In addition, the deployment of staff during the COVID-19 pandemic could have caused fatigue among them, which was likely to cause them to answer the questions lightly without focus. Meanwhile, the distribution of questionnaires through Google Forms contributed to the risk of bias among respondents when there was no supervision or explanation that could be given as a guide to answering the questionnaire.

Conclusions

The psychometric validation process of the questionnaire was done comprehensively for all iterative stages, including initial reliability tests, potential modifications based on these tests, and integration with existing digital health assessment frameworks. The novelty of the study lies in its unique approach to conceptualizing the implementation of the TPC-OHCIS. This may offer new insights into the integration of life stage records, with a focus on priority services at PHCs, such as MCH services, for its development. Cross-cultural adaptability was considered to ensure wider applicability, and the rigor of the process was demonstrated in part by high CVI scores, which is important in an academic research setting. Likert scale points were carefully chosen to capture nuanced responses, and while the TPC-OHCIS has certain academic limitations, its robustness paves the way for future research on policy implications and telehealth. Comparison with existing literature establishes its validity and reliability, showing its potential impact on policy development.

Acknowledgments

The authors would like to especially thank the Selangor Health State Department, Kuala Lumpur and Putrajaya Health State Department, and Pahang Health State Department for their support in the study. The authors would also like to thank the Director General of Health Malaysia for his permission to conduct the study and publish this paper. This work was supported by a research grant from the Ministry of Higher Education (FRGS/1/2021/SKK04/UKM/02/1) and by the Medical Faculty of Universiti Kebangsaan Malaysia, which contributed to the publication costs of this paper.

Authors' Contributions

SI, RS, and RI conceived the scope of the review to meet the study objectives. Literature search, data collection, analysis, and interpretation were conducted by SI and verified by RS. SI drafted the first iteration of the manuscript, which was revised and improvised by RS. All authors made substantial contributions to the critical review, editing, and revision of the manuscript. All authors approved the final version of the manuscript.

Abstract

Background: Patient-reported outcome (PRO) data refer to information systematically reported by patients, or on behalf of patients, without the influence of health care professionals. It is a focal point of the health care system's ambition toward becoming more involving and personalized. It is recognized that PROs provide valuable data. However, despite this recognition, there are challenges related to both patients' and clinicians' accurate interpretations of the quantitative data. To overcome these challenges, this study explores text vignettes as a representation of PROs.

Objective: This study aimed to develop data-informed text vignettes based on data from the Readiness and Enablement Index for Health Technology (READHY) instrument as another way of representing PRO data and to examine how these are perceived as understandable and relevant for both patients and clinicians.

Methods: The text vignettes were created from participant responses to the READHY instrument, which encompasses health literacy, health education, and eHealth literacy. The text vignettes were created from 13 individual text strings, each corresponding to a scale in the READHY instrument. This study consisted of 3 sequential parts. In part 1, individuals with chronic obstructive pulmonary disease completed the READHY instrument, providing data to be used to create vignettes based on cluster profiles from the READHY instrument. Part 2 focused on the development of scale-based strings representing all READHY dimensions, which were evaluated through iterative cognitive interviews. In part 3, clinicians and patients assessed the understanding and relevance of the text vignettes.

Results: Clinicians and patients both understood and related to the text vignettes. Patients viewed the text vignettes as an accurate reflection of their PRO responses, and clinicians perceived the text vignettes as aligned with their understanding of patients' experiences.

Conclusions: Text vignettes can be developed using PRO instruments, with individual scales as input strings. This provides an opportunity to present numeric values in a text format that is understandable and recognizable to most patients and clinicians. Challenges with the vignette's language and layout require customization and clinician training to ensure meaningful interpretation. Findings also support the need to expand the study and enhance clinical relevance with alternative or contextually relevant text vignettes.

Introduction

Background

Patient-reported outcome (PRO) data represent patients' self-assessed health status in terms of physical and mental health and do not involve health professionals [1]. PRO data can be used as a screening tool before outpatient visits as a supplement to in-person or virtual consultations, serving as a stratification tool to reduce the number of visits needed. PRO data can also be used during consultations to screen for symptoms or serve as a dialogue and decision tool. The use of PRO data during consultations may increase the patient's self-awareness and health literacy, facilitate joint decision-making, enable self-management, and lead to better health outcomes [1,2].

Health Literacy

Competence in health literacy and digital knowledge is fundamental for an accurate understanding of PRO data as well as knowledge about health behavior and health practices and how patients understand and interpret health information [3]. Challenges arise when data accessibility does not consider differences in health literacy. While aggregate-level understanding may tolerate some variations, individual patient pathways require a common understanding to capture nuances [4,5]. Therefore, it is crucial to account for patients' health literacy and cognition in the clinical use of PROs.

Interpretation of PRO Data

When incorporating PROs into individual patient pathways, it becomes crucial to ensure that patients fully understand the questions, fostering a shared understanding. In working with PRO data, an assumption is often made that people have the same needs, preferences, perceptions, and experiences and will attach similar importance to items in the questionnaire, thus leaving no room to capture different additions of value or uncover nuances [4]. The quantitative part of PRO data operates within a set of assumptions about the world, which states that the standardized numerical score is the objective representation of the respondents' health status and health-related quality of life, independent of an individual's unique life story [4].

For both clinicians and patients, it may be difficult to understand the meaning of PRO data when they are presented as values. Patients often prefer visual representations, such as bar charts and line charts, which prove useful for quick comprehension and comparisons over time [6]. However, the accuracy of interpretation is closely tied to the individuals' prior knowledge of these graphical representations [6].

Graphical presentations may be a challenge. Grossman et al [7] highlighted that individuals lacking prior knowledge of bar charts struggled to interpret them accurately. Furthermore, health literacy plays a crucial role in correct interpretation, with studies suggesting that patients with lower health literacy may find it challenging to grasp the longitudinal nature of PRO data [8]. There is a notable correlation between educational level and accurate interpretation, along with age-related difficulties in correctly interpreting graphic representations of PRO data [6,9]. Patients generally, regardless of educational level, prefer less-complex presentations of PRO data, but a correlation has been demonstrated between age and accurate interpretation, where patients aged >65 years had substantially more difficulty interpreting graphic representations of PRO data correctly [6,9]. In Denmark, 1 in 5 individuals is aged >65 years [10], which means that a relatively large proportion of all individuals will potentially have difficulty interpreting PRO data.

The use of traffic light colors, that is, green, yellow, and red, in representing PRO data adds another layer of complexity. While this method increases accuracy in interpretation across various graphical representations [6,11], it is not foolproof and 93% of patients in a study population were able to correctly interpret the meaning of traffic light colors [6]. Despite this visual aid, there remains a need for additional descriptive explanations to enhance understanding [9].

Patients' and health care professionals' perceived understanding of graphically presented PRO data often exceeds their actual comprehension [9]. In addition, studies indicate that there may be a discrepancy between patients' preferred form of visualization and the form of visualization they can interpret with the highest accuracy [9].

Patients may also view the use of PRO data in treatment as impersonal and nonbeneficial for the relationship between themselves and their clinicians because they experience that the focus shifts from their own perspective to quantitative goals [12]. This perspective highlights the significance of maintaining a patient-centered approach.

A Common Understanding of PROs

When patients and clinicians collaborate on data interpretation, potential errors may arise due to questionnaire misinterpretation. This divergence in understanding creates a need for a common language or understanding of the representations of colors, figures, or text. A challenge is that patients and clinicians possess distinct cognitive frameworks influencing their actions and comprehension [13]. Data interpretation involves understanding available data, extracting information, and supplementing it for comprehensive comprehension [13]. Clinicians are shaped by a positivist background and may differ from patients in cognitive approaches, impacting data interpretation. When PRO data are translated into quantitative targets, it may be unclear what data have been made available and what information can be extracted. Patients provide a wide range of data, but data visualization often only includes part of these data.

Despite psychometric validation, there is a need to address discordance in individual interpretations of PRO data. Discordance reasons include word interpretation mismatches, evolving patient circumstances, and differing expectations [14]. Awareness of these differences is crucial in interpreting PRO data [14]. PRO tools vary in complexity, leading to further potential errors if patients lack an accurate understanding. A study found that only 11% of 59 PRO questionnaires are readable by the average UK adult [15], emphasizing the need for a patient-clinician dialogue to enhance understanding and decision-making [5]. Numerical scores derived from PROs can represent a person's health status or health-related quality of life to a limited extent because some of the narrative is lost

XSL•FO
RenderX

along the way. In the representation of PRO data, there is a need to be able to give meaning to individual experiences [4]. Positivism argues that knowledge should be based on the objective world via empirically verified causal explanations based on "positive" facts and not on abstract inferences; however, according to Meadow [4], we cannot understand the patient if we do not also try to understand subjective and emotional meaning.

PROs as Text Vignettes

One approach to a more understandable and personalized representation of data about a group of patients or individuals is vignettes created based on a combination of clustered data, which are enriched with sociodemographic characteristics and interviews with individuals representing these clusters. An example of this is the Optimizing Health Literacy and Access (OPHELIA) process, where issues related to health care access and engagement are identified and addressed [16,17]. This way of creating data-informed text vignettes is a powerful tool to provide clinicians and policy makers with insights into a more detailed description of archetypes of patients [18]. In this way, text vignettes play a pivotal role in providing a nuanced understanding of the perceived status of various subgroups of patients in a specific context or area. The primary aim is to bring to life the "person behind the numbers," referring to PRO scores, addressing the challenge of visualizing the individuals behind the statistical data. To the best of our knowledge, this has not yet been done at the level of individuals by creating person-specific text vignettes.

In this study, inspired by the OPHELIA process, we will explore whether text vignettes can be developed from more structured text inputs and how this work can be advanced to create text vignettes that can be used at the individual level, rather than at the group level, to present personalized texts that reflect each patient's perception of their condition. The study uses the Readiness and Enablement Index for Health Technology (READHY) [19], which covers 3 key themes—self-management, social capital, and digital health literacy. This instrument was selected because, as its developers, we have extensive experience with its performance, and its design makes it well suited as a PRO tool for telehealth services. The study demonstrates the process of converting psychometric instrument scales into data-informed text vignettes, highlighting the challenges and implications to consider for ensuring understanding and relevance for both patients and clinicians.

Objectives

This study aimed to develop data-informed text vignettes based on data from the READHY instrument as another way of representing PRO data and to examine how these are perceived as understandable and relevant for both patients and clinicians.

Part 1 Introduction: Generating Vignettes Based on READHY Clusters Enriched With Sociodemographic Data

This part is a proof of concept, where cluster-based profiles were created to help develop representatives of characteristics of a patient population divided into subgroups. This enabled us to work with materials based on real-life data varying with respect to the 13 scale scores. This has provided insights into how dimension names can be phrased for text vignettes without a systematic approach, while also helping us establish a shared understanding of the OPHELIA [16] principles. These principles were operationalized in a data-informed manner, bridging the previously reported qualitative approach with a more quantitative-based methodology.

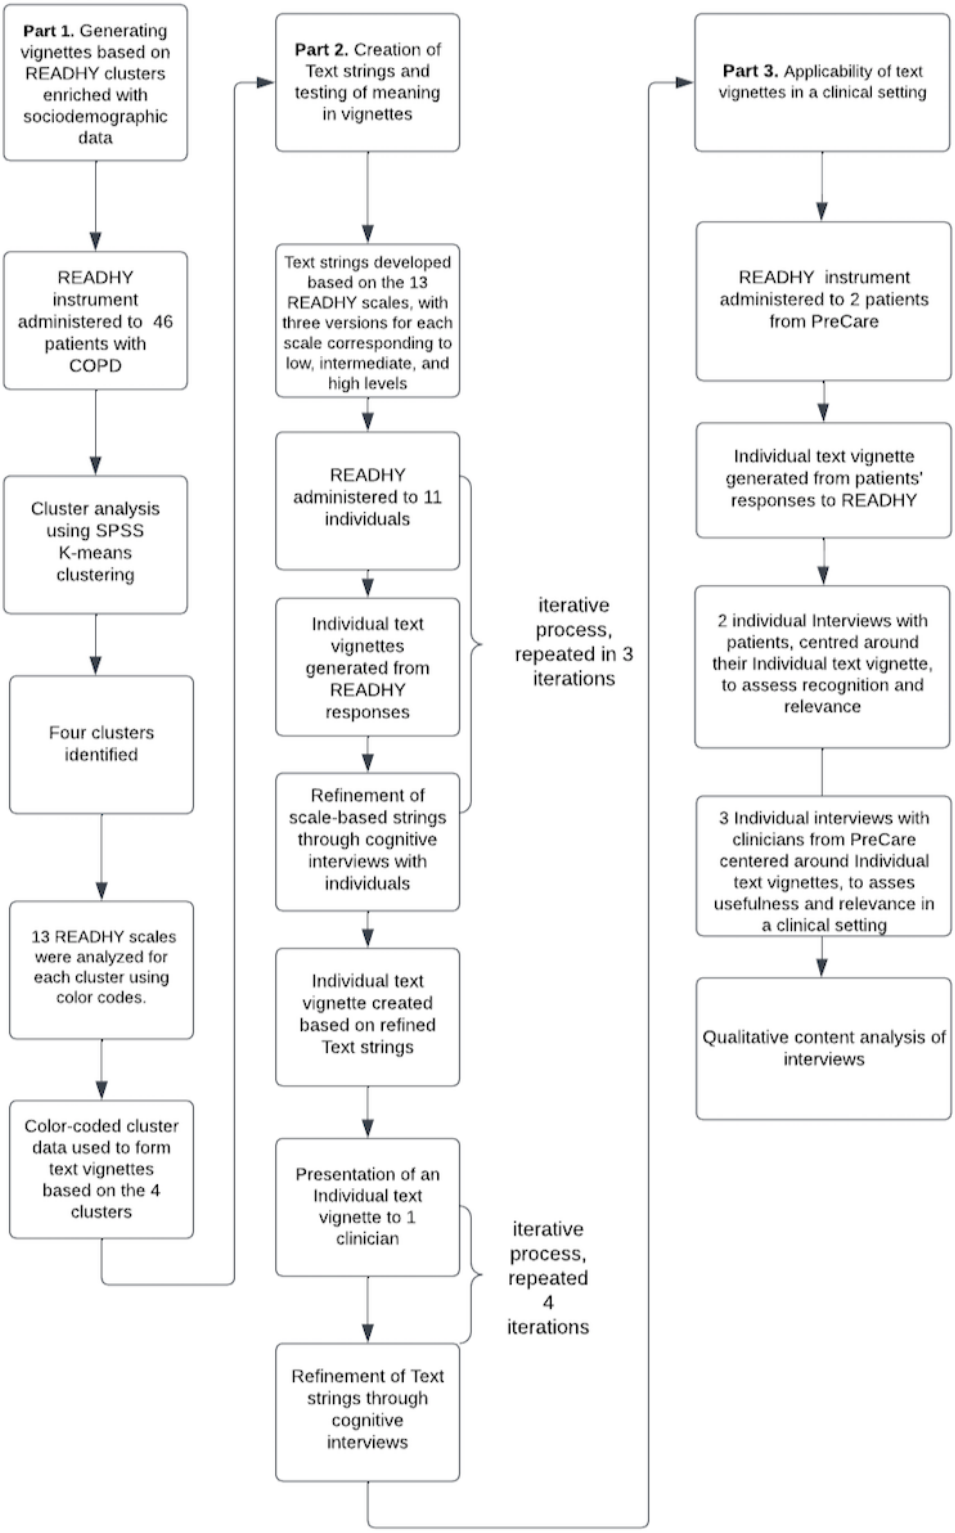
Part 2 Introduction: Creation of Text Strings and Testing of Meaning in Vignettes

In part 2, scale-based text strings describing the different dimensions measured in READHY were developed through a series of iterations. These were then combined into comprehensive text vignettes profiling the participants. For this process, the upper threshold was adjusted from 2.50 to 2.70 based on data from the study by Kayser et al [20]. The vignettes were continuously refined through cognitive interviews to evaluate and improve the participants' understanding and ability to comprehend the content.

Part 3 Introduction: Applicability of Text Vignettes in a Clinical Setting

The text strings iteratively created and validated in part 2 served as the foundation for the work in part 3. In part 3, the focus shifted to testing the applicability of individual text vignettes within a clinical setting. The emphasis was on how meaningful and relevant these text vignettes were in a setting involving both patients and clinicians within a telehealth service, where the READHY instrument was suitable as a PRO instrument. The clinical setting included here was the same as the one used to gather data for part 1.

Methods



Overview

The study comprises 3 parts, each building upon the previous one. In part 1, which was inspired by the OPHELIA process [16], the READHY instrument was administered to individuals living with chronic obstructive pulmonary disease (COPD). Data gathered from this group of participants served as the foundation for generating 4 clusters, which were characterized by high, intermediate, and low levels of the 13 READHY scales, which together with another Health Literacy Questionnaire (HLQ) scale, "actively managing my health and sociodemographics", were used to develop a proof of concept of how data-informed text vignettes could be used to illustrate the quantitative data qualitatively to better understand profiles of user groups. The text vignettes in part 2 were crafted as narratives, emphasizing the group's high or low scores. This approach created profiles that highlighted their resources and barriers. In part 2, we expanded on the idea by constructing scale-specific strings for each of the 3 levels for each scale in READHY. The text strings were created to constitute a list of variables, which in a later process could be combined based on an algorithm to form the text vignettes. This computer-based combination of the text strings is beyond the scope of this study that only addresses the development of our concept up to a technology readiness level of 3 [21]. Text vignettes are consequently created by manually combining the text strings.

XSL•FO
RenderX

In this process, the text strings were evaluated for clarity and understanding through multiple iterations of cognitive interviews with a diverse set of participants. In part 3, the refined scale-based strings were combined manually, informed by the 2 patients' READHY scores, into individual text vignettes, which were presented to clinicians and patients for assessment of their understanding, relevance, and recognizability (Figure 1).

Figure 1. Flowchart: the 3-part process for examining the use of text vignettes. COPD: chronic obstructive pulmonary disease; READHY: Readiness and Enablement Index for Health Technology.

Setting and Population

The setting for the reported activities was in part 1 and part 3 of a telehealth service, PreCare [22], which provides 24-7 access to a response and coordination center manned with registered nurses and backed up by an e-doctor. PreCare is organized based on the Epital care model [22,23]. The participants in part 2 were

XSL•FO
RenderX

recruited broadly among individuals in the eastern part of Denmark and clinicians not currently working in telehealth.

Participants

Part 1

The participants were 46 adults living with COPD, with a mean age of 74.4 (SD 6.8; range 59-91) years. They were patients recruited by convenience sampling from the European Commission funded project Smart Inclusive Living Environments, were enrolled in the PreCare project in Region Zealand, and were diagnosed with different severity levels of COPD [24]. The inclusion criteria were a COPD diagnosis and being active in the PreCare project. The patients should be able to understand and communicate in Danish.

Part 2

Individuals

A total of 11 individuals were recruited using a snowball technique in the Capital Region of Denmark and Region Zealand. Initially, 3 members of interest were identified and approached within their local areas. These individuals were then asked to refer others in their community who might be willing to participate. With their consent, we received the necessary contact information and subsequently reached out to the referred participants by phone to arrange their involvement in the study. The inclusion criteria for individuals' participation was that they had to be aged >18 years, able to understand Danish, capable of giving informed consent, and able to complete the READHY instrument, with assistance if needed (ie, the ability to read and write independently was not a criterion). The first 3 recruited individuals resided in the metropolitan area, had medium-length higher education (International Standard Classification of Education level 6-7) [25], and had an average age of 53 (SD 12.36) years. This group was expanded to include 8 participants, aged between 36 and 86 years, from the capital region, Lolland, and Jutland with educational backgrounds ranging from International Standard Classification of Education level 4 to 6 [25] to attain a more diverse and comprehensive perspective.

Clinicians

A total of 4 clinicians were also recruited using a snowballing technique. Initially, 3 clinicians were approached, but not all expressed interest in participating. These contacts referred to others, and with their consent, we obtained their contact information and contacted them. The clinicians who participated in the interviews were 1 registered nurse, 2 physicians, and 1 professional with a master's and PhD degree in biomedicine. Of the 4 physicians, 2 (50%) had prior knowledge of READHY as active researchers using the instrument. All physicians were involved in professional settings related to digital health in patient care, and they were all familiar with PROs.

Part 3

A total of 3 registered nurses and 2 patients from the PreCare clinic were interviewed about the understanding, recognizability, and relevance of individual text vignettes in a clinical setting.

The 2 patients, a woman aged 75 years and a man aged 80 years, lived in the region where the PreCare project is based. They were selected by PreCare staff based on the following inclusion criteria: a COPD diagnosis, active participation in PreCare, the ability to understand and communicate in Danish, clinic enrollment at the time of data collection, and prior consent through PreCare as well as informed consent specifically for this study. A total of 3 (75%) of the 4 nurses in PreCare were available for interviews.

Application of the READHY Instrument

READHY is a validated PRO instrument that combines several aspects of PROs to illuminate experienced support, digital health literacy, and coping with everyday life in relation to one's health [19]. The tool focuses on aspects of knowledge and skills related to health; self-care, disease, and health-related mindset; experiences with health technology and the individual understanding of these; as well as the extent to which users feel supported by relatives and health care professionals [19].

READHY has been used to identify different health technology readiness profiles within different patient groups, such as patients living with type 2 diabetes and patients with cancer [26,27].

READHY consists of 65 items comprising 13 dimensions or scales. The 13 scales are selected from 3 PRO instruments. Four scales are from the Health Education Impact Questionnaire (heiQ), which evaluates the effect of health education interventions on self-care [28]. These address aspects of self-management with relevance for a digital health context, such as insights and attitudes. Two scales from the HLQ, which assesses health literacy, including support from relatives, peers, and health professionals [29], and all 7 scales from the eHealth Literacy Questionnaire (eHLQ), which address patients' digital health literacy, were included [30]. The eHLQ informs about knowledge, skills, motivation, perceptions, and experiences in relation to digital health. The 13 dimensions of READHY, which correspond to its 13 scales, are presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. The 13 dimensions of the Readiness and Enablement Index for Health Technology framework.

- Health Education Impact Questionnaire (heiQ) 3: self-monitoring and insight
- heiQ4: constructive attitudes and approaches
- heiQ5: skill and technique acquisition
- heiQ8: emotional distress
- Health Literacy Questionnaire (HLQ) 1: feel understood and supported by health care providers
- HLQ4: social support for health
- eHealth Literacy Questionnaire (eHLQ) 1: using technology to process health information
- eHLQ2: understanding of health concepts and language
- eHLQ3: ability to actively engage with digital services
- eHLQ4: feel safe and in control
- eHLQ5: motivated to engage with digital services
- eHLQ6: access to digital services that work
- eHLQ7: digital services that suit individual needs

The READHY instrument uses a 4-point response scale for all items in the instrument [19], where 1 represents strongly disagree, 2 represents disagree, 3 represents agree, and 4 represents strongly agree. The results are 13 scale scores. For the scale heiQ8 (emotional distress), which includes 6 items, the scale is reversed by subtracting the scored value from 5. This adjustment simplifies interpretation, as higher scores now correspond to less impact.

Ethical Considerations

Written informed consent was obtained from all participants after providing information in accordance with the Helsinki II Declaration, including their right to opt out. Participants did not receive any salary or reimbursement of costs. Health science questionnaire surveys and interview studies that do not involve human biological material (section 14(2) of the Danish Act on Committees) do not require reporting or approval from the Danish National Center for Ethics [31].

Part 1 Methods

Data Sampling

The READHY instrument was handed out and collected with a combination of mail using prestamped envelopes by EKW and a researcher in PreCare in May 2021. A total number of 120 surveys including the READHY instrument were distributed.

Cluster Analysis

In managing the READHY data from the 46 patients, clusters were created using the K-means clustering function in IBM's software package SPSS Statistics (version 24) [32]. Three models were created with 3, 4, and 5 clusters. On the basis of an evaluation of which cluster model would be most meaningful from a clinical perspective, a 4-cluster model was selected. The final cluster constituted 41 valid cases and 5 missing cases out of the 46 responses. The number of cases in each cluster was as follows: 16 in cluster 1, 5 in cluster 2, 11 in cluster 3, and 9 in cluster 4.

The cluster data were then used to form the group-based text vignettes. For each cluster, the 13 scales were initially labeled with a color indicating whether the level was low, intermediate, or high. We used arbitrary thresholds informed by a regional survey, Sundhedsprofilen 2021 [33], which is the region where the PreCare project is based. All values <2.00 were assigned red, all values between 2.01 and 2.50 were assigned yellow, and values >2.50 were given green. This helped us create text strings that were specific for each of the colors indicating high or low average scores for each scale and assigning them to the cluster text vignette. The text strings were created from the dimension name and informed by the items in the scale. Additional data from an additional HLQ scale, "actively managing my health," and sociodemographic variables, such as educational level, experience living with, and number of chronic conditions, were added to the profiles to enrich them and create personas that were recognizable to the clinicians.

Part 2 Methods

Overview

The overall process for constructing the text vignettes involved several steps. First, text strings were developed based on the 13 READHY scales, with 3 versions for each scale corresponding to low, intermediate, and high levels. Next, participants completed the instrument. The average score for each scale was then manually calculated from their responses, and this average score was matched with the corresponding text string for that scale score. Finally, the 13 text strings were combined into an individual text vignette. The text strings were combined in a coherent order, prioritizing readability and clarity, rather than strictly following the numerical order of the scales. In part 2, the focus was only on the READHY scales and text vignettes; therefore, part 2 did not include sociodemographic information, as these are anticipated to be retrieved from other data sources such as electronic health records as they are specific at the individual level.

XSL•FO
RenderX

Constructing Data-Informed Text Vignettes

The text vignettes were created by combining 13 text strings into a cohesive PRO profile. Each sentence in the text vignette corresponds to a specific scale in READHY, describing the knowledge, skills, and attitudes that the scale items aim to capture.

Initially, 39 text strings were constructed—3 for each of the 13 READHY scales, representing different levels of knowledge, skills, or attitudes within each scale. These initial text strings were closely aligned with the scale names, as the scale names summarized the experiences the items were designed to encompass. For example, the scale "self-monitoring and insight" (heiQ3) assesses an individual's ability to monitor their health and their insight into their health [19]. An initial sentence for this scale might read as follows: "Has good insight into and control over his/her health and has a constructive attitude and approach to it."

The levels are determined based on the average score for each scale, with 3 categories: level 1 indicates problematic knowledge, skills, and attitudes; level 2 corresponds to limited or insufficient knowledge, skills, and attitudes; and level 3 signifies adequate knowledge, skills, and attitudes. To be classified as level 3, the average score must be >2.7, indicating agreement or strong agreement with the statement (Table 1). The cutoffs are estimates defined by the authors and have not been validated by other parties. However, they have been used and found relevant in other studies using HLQ and eHLQ scores [20,33].

Table 1. Breakdown of knowledge, skills, and attitude into levels based on average scores.

Average scale score[a]	Level of knowledge, skills, and attitudes
<2.00	Level 1
2 to 2.7	Level 2
>2.7	Level 3

[a]The cutoffs are author-defined estimates, unvalidated by others but found relevant in studies using the Health Literacy Questionnaire and eHealth Literacy Questionnaire [20,33].

These 39 text strings are organized in Table 2 with the 13 scales as rows and the 3 levels as columns. To construct a text vignette, the appropriate text strings were selected from the table based on the participant's average scale score for each scale. The 13 selected text strings were then manually combined into a coherent text vignette. The initial text strings were revised throughout part 2 of the study in an iterative process using cognitive interviews for accuracy and relevance.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

Data Sampling and Analysis

Data collection involved conducting cognitive interviews with each participant to validate the individual text vignettes developed from the individuals' READHY responses. These interviews allowed for iterative feedback and refinement of the text string to ensure their coherence and relevance. The analysis focused on identifying and addressing any issues in understanding and meaningfulness of the text strings and vignettes.

Iterative Validation of Data-Informed Text Vignettes

The text strings were validated through cognitive interviews with individuals and clinicians in an iterative process. Cognitive

XSL•FO
RenderX

interviews, often used for validating questionnaires, involve participants "thinking out loud" by verbally reporting their mental activity while engaging with an item in a questionnaire [34,35]. These interviews are conducted using a semistructured approach, with in-depth sessions where participants read a text vignette aloud and provide feedback by sharing their thoughts and insights throughout the process.

The interviews were conducted in 2 stages: first with individuals and then with clinicians. Before each individual's interview, they completed READHY, which was then used to create individual text vignettes. Each individual was presented with a full vignette, created based on their previous responses, to gather feedback on both individual text strings and the vignette as a coherent whole, evaluating its clarity and personal relevance.

After each interview, the data were analyzed individually to identify issues in the understanding and meaningfulness of the text vignettes. These individual findings were then aggregated across interviews to identify recurring problems, leading to adjustments of the text vignettes.

The iterative process included multiple stages of feedback incorporation. The first iteration considered feedback from 3 participants, with subsequent iterations incorporating feedback from additional participants—3 in the second and third iterations and 2 in the fourth.

Identified problems were categorized informally into 4 groups: scale-specific wording changes, need for further specification, issues with text vignette setup, and difficulties in answering the instrument [34].

Once all individual interviews were completed and the text vignettes and algorithm were adjusted, clinicians were introduced to the revised vignettes. The assignment of vignettes to clinicians was random, as they had no prior knowledge of or relationship with the individuals. Clinicians provided feedback on these vignettes, which led to further refinements. Each revised version was then presented to subsequent clinicians for additional input, ensuring that the final text was coherent and well understood.

Part 3 Methods

Data Sampling

First, 2 patients completed the instrument. From their responses, 2 individual text vignettes were constructed using the same method as applied in part 2. The average scale scores were calculated for each scale, and the scale score was then matched with the final adjusted corresponding sentence (Table 2). Afterward, the 13 text strings were combined to create an individual text vignette. These text vignettes were then presented to the 3 clinicians in 3 individual semistructured interviews designed to explore the text vignettes within an actual clinical environment and gain the clinicians' perspective. Each clinician was presented with 1 text vignette. Because all clinicians were somewhat familiar with booth patients, the specific vignette used in the interviews was randomly chosen based on which vignette was completed at the time of the interview.

Patients were also interviewed individually to assess their recognition of themselves in their text vignettes and whether it made sense for them in a clinical environment. However, the primary focus in part 3 was on the clinicians. Patient interviews were conducted via phone at the request of both patients. The interviews were recorded with consent and later transcribed.

The unique aspect lies in its exploration of text vignettes within clinical contexts, focusing on clinicians who interact with the patients described, and incorporating insights from their practical experience.

Analysis

Two interview guides were prepared, 1 for patient interviews and 1 for clinician interviews (Multimedia Appendix 1). These questions were grounded in the central inquiry: How can text vignettes generated by PRO data, as an alternative or supplement to traditional quantitative representations, improve dialogue and understanding between clinicians and patients regarding PROs?

All interviews were analyzed using qualitative content analysis using inductive coding to identify and describe patterns, categories, and meanings within the data [36]. The analysis was conducted using NVivo software (version 12.4.0; Lumivero) [37]. From the coding process, 4 main categories emerged: "recognition and confirmation," "challenges with context and conceptual understanding," "one size does not fit all," and "reflections on using text vignettes."

An example of a text vignette, as presented to both clinicians and patients, is shown in Textbox 2 (translated by the authors). This vignette is based on one of the patient's responses to the READHY instrument.

Textbox 2. Text vignette based on Readiness and Enablement Index for Health Technology.

She experiences having limited insight into her state of health, with limited knowledge of how to deal with health problems when they arise.

She finds that her health issues to some extent limit her from enjoying life.

She experiences having sufficient skills and techniques to deal with health problems as they arise and generally, experiences no emotional distress due to her health.

She feels adequately understood and supported by her social network and experiences adequate understanding and support from the healthcare professionals she has contact and access to.

She experiences having trouble understanding information about health and illness and may experience insufficient knowledge to have a conversation with others about this.

XSL•FO
RenderX

She finds that she has insufficient knowledge about how she can use technology to take care of her health and has insufficient knowledge of how to use technology to navigate healthcare systems.

She experiences having sufficient access to digital health systems that work and can be accessed by herself and others who need it, and that digital services can adequately adapt to her needs.

She finds that technology is helpful to a limited extent and helps her keep up with and take care of her health.

She feels comfortable with how her health data is used by others.

Results

Part 1

Four clusters with various levels of high, intermediate, and low average scores of scales within self-management, social capital, and digital health literacy were created (Table 3).

The mean value for each scale was presented for each of the 4 clusters that were informed. Values considered to represent a problematic level were indicated in red (<2.00), values considered to be below a sufficient level were indicated in yellow (2.00-2.50), and values considered to represent a sufficient level were represented in green (>2.50).

Table 3. Stratification using the Readiness and Enablement Index for Health Technology.

Metric (mean values)	Cluster 1 (n=16)	Cluster 2 (n=5)	Cluster 3 (n=11)	Cluster 4 (n=9)
heiQ3[a]: self-monitoring and insight	2.98	3.66	3.13	3.11
heiQ4: constructive attitudes and approaches	2.81	3.28	2.76	3.46
heiQ5: skill and technique acquisition	2.65	3.15	2.84	3.11
heiQ8: emotional distress	2.50	2.76	2.13	3.12
HLQ1[b]: feel understood and supported by health care providers	2.78	3.70	3.40	3.44
HLQ3: actively managing my health	2.68	3.40	2.92	2.68
HLQ4: social support for health	2.83	3.59	2.90	3.33
eHLQ1[c]: using technology to process health information	2.78	3.92	1.89	2.03
eHLQ2: understanding of health concepts and language	2.85	3.96	2.82	2.77
eHLQ3: ability to actively engage with digital services	2.95	3.96	1.99	2.65
eHLQ4: feel safe and in control	2.97	4.00	2.95	3.18
eHLQ5: motivated to engage with digital services	2.85	3.92	2.11	2.60
eHLQ6: access to digital services that work	2.86	3.96	2.42	2.97
eHLQ7: digital services that suit individual needs	2.78	3.80	2.04	2.68

[a]heiQ: Health Education Impact Questionnaire.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

On the basis of the thresholds, a focused text vignette was constructed almost as a narrative for each cluster together with key sociodemographic characteristics to create 4 text vignettes, wherein each represented an archetype of the profile—termed a "persona" (Multimedia Appendix 2). To simplify the information in this initial phase, only scales with high (initial green color) or low (initial red) average scores (>2.50 or <2.0) were included in the text vignettes, thereby creating focused text vignettes highlighting potential areas of barriers and resources.

EKW and LK then presented these text vignettes to colleagues in the Smart Inclusive Living Environments project. On the basis of the insights gained from the proof of concept with text vignettes at group or personal level, it was decided to proceed to part 2, focusing on the development of structured text strings that encompass high, intermediate, and low average score levels.

Part 2

A total of 39 initial text strings were created, with 3 strings for each of the 13 READHY scales, reflecting different levels of knowledge, skills, or attitudes within each scale. These text strings were designed to align with the scale names, which summarize the relevant experiences. The initial text strings are included in Multimedia Appendix 3.

Immediate feedback from the first 3 participants indicated that they could easily recognize themselves in the text vignettes, found them meaningful, and saw how their responses were reflected in them.

In the first iteration of text vignette validation, participants largely recognized themselves but identified issues related to the structure of the text vignettes and the completion of the instrument. Feedback included suggestions to revise lengthy sentences and reduce academic language, with specific terms

XSL•FO
RenderX

such as “health professionals” and “health-related concepts” being difficult to understand. Participants also struggled with the term “technology” used in the text vignette, such as in the description of scale eHLQ3.

On the basis of cognitive interviews, “healthcare providers” was changed to “healthcare professionals” and “health-related concepts” was simplified to “information of health and illness.” The order in which the scales were presented was also slightly changed. The order of HLQ4 and HLQ1 was adjusted to create a more natural flow when reading through the vignette. Similarly, the eHLQ items were reordered to enhance the coherence of the vignette.

In subsequent validation iterations, feedback was generally positive, with individuals finding the text vignettes understandable and recognizable. However, they struggled more with areas where they rated themselves as limited or insufficient. Some participants mentioned difficulties with the questionnaire due to the lack of a “don’t know” option and noted that terms such as “insufficient” felt too academic and unrepresentative of their self-view. The term “digital services” was also revised to “digital health services” to clarify its meaning. Participants suggested that discrepancies in text vignette descriptions might stem from specific episodes rather than their general experiences, and some participants requested more precise wording to better reflect their experiences. During iterations and refinement based on feedback, the understandability and recognizability of the vignettes improved, with individuals having an overall positive view of the text vignettes after final refinement.

The clinicians had a generally positive view about the generated READHY text vignettes. Feedback emphasized the need for clarity in highlighting that the text vignettes were based on a PRO instrument. The length of the text vignettes had mixed reviews. Feedback suggested categorizing content into taxonomic groups. The language was too academic, and adjustments had to be made to align with the instrument.

Clinicians see the value of using the text vignettes at the population level, allowing for generalization and description of specific populations based on competencies and characteristics. However, the current format may not be suitable for individual-level use, as it offers a simplified representation for personalized interaction. On the basis of input received from all participants, the strings were refined. The refined text strings are presented in Table 3 (translated from Danish to English by the authors). In the context of this study, we have used gender pronouns, but they should be adjusted to ensure relevance and significance within the context and setting.

Part 3

There was a positive attitude among the clinicians and patients toward the text vignette format and this way of presenting and communicating PROs. The clinicians experienced being able to recognize patients in the text vignettes, and patients experienced being able to recognize themselves in their text vignettes. Although the text vignette format does not necessarily meet the specific needs, the textual presentation makes the information from PROs more accessible in an understandable way for both clinicians and patients.

There are different preferences for how dynamic the tool should be. Some prefer to select only specific dimensions, while others believe that the strength of the text vignettes comes from them providing the full picture insights and exposing possibly overlooked aspects. Clinicians who favor the text vignette suggest that color coding as a supplement to the text vignette would be helpful and that a schematic summary would help with readability, indicating that flexibility in the profile presentation is needed to accommodate different preferences. Some prefer text-based representations, while others find visual presentations more intuitive.

Clinicians may face language and comprehension challenges due to ambiguity in words and abstract concepts within the text vignettes. Ambiguity in words and concepts, such as “to some extent,” leaves clinicians uncertain about the severity of the patient’s problems. Abstract concepts such as “health” and “technology” also pose challenges in interpretation. The text vignettes highlight new angles in patients’ self-perception, health, motivation, and emotional distress, which clinicians find crucial.

Opinions differ on whether to highlight strengths or weaknesses. Some prefer insights into both aspects, while others prefer focusing solely on the weaknesses that are most likely to be approved. Clinicians acknowledge the value of using text vignettes at a population or group level for generalization but point out some limitations for individual-level use due to simplified representations. Emphasis on personal dialogue with patients remains crucial for addressing unresolved questions and determining personalized interactions.

From the patient’s viewpoint, there is self-recognition and understanding; however, engaging in discussions about text vignette representation proves challenging. It is essential to note that clinicians report based on their experience of interacting with patients, highlighting the dynamic nature of this interaction in understanding and interpreting the text vignettes. The clinician’s insights provide a valuable perspective for understanding the broader implications of text vignettes in a clinical setting.

Discussion

Principal Findings

This study presents a process for developing text vignettes based on PRO data, resulting in the creation of individual vignettes that incorporate all 13 scales of the READHY framework. The motivation for the development of these text vignettes was the challenges associated with presenting PRO data as numeric values or graphical representations, aiming to provide a clearer and more engaging way to present and communicate PRO information.

This findings of this study suggest an overall positive attitude toward the PRO data–informed text vignette format and this way of presenting and communicating PROs. Clinicians experienced being able to recognize patients in the text vignettes,

XSL•FO
RenderX

and the patient's experienced being able to recognize themselves in and understand the text vignettes describing themselves.

Considering the background emphasizing the challenges associated with graphical representations of PRO data, the findings suggest that PRO-informed text vignettes are understandable for clinicians and patients. While the text format may not perfectly align with all the needs and interests of clinicians and patients, it presents PRO data in a comprehendible manner, with the text vignettes presenting a recognizable description.

Patients' Perspective

Patients found elements of self-recognition in the text vignettes, although discussing their representation could be challenging. It is important to note that text vignettes also face challenges related to health literacy and differences in understanding, as highlighted in part 3. These challenges can pose significant barriers for individuals with low health literacy or those who cannot read. In such cases, regardless of the presentation format, additional support, such as reading the vignettes aloud, may be necessary. However, the written format generally makes the data more accessible and less complex.

Another potential challenge is that the threshold values used to select appropriate text strings may result in choices that are not recognized by the informants. For example, individuals scoring between 2.00 and 2.70 might not feel limited, or they may perceive issues in areas not fully captured by the items in a scale. This issue requires further exploration in future studies to determine whether scales can be used effectively or whether a focus on single items is more appropriate, particularly for those scoring at the extremes. This may be necessary as we work in the intersection of presenting data from psychometric valid scales reporting on latent variables and presenting numeric values as an interpretation of experiences. The patients' experiences and feelings may sometimes be undermined or misinterpreted in this process.

Clinicians' Perspective

The data-informed text vignettes add a candid dimension to the information, making it directly engaging and allowing for the capture of new perspectives on patients that clinicians would not otherwise have focused on, although not all perspectives are equally relevant. It is especially the aspects of experienced support and patients' own knowledge about health and illness that are important for clinicians to understand and gain perspective on. There are different preferences among clinicians regarding the format of the text vignettes; some prefer text-based representations, while others prefer visual presentations. Likewise, there are different preferences regarding how dynamic the text-based tool should be. Some experience a need to be able to select only specific dimensions, while others believe it is part of the strength of the vignettes that it presents the full picture and thus insight into possibly overlooked aspects. This indicates that there is a need for flexibility in the text vignette presentation to accommodate different preferences.

Clinical Relevance

Clinicians using text vignettes stress the importance of technology that effectively addresses practical and treatment-specific needs. It remains imperative that the information within text vignettes aligns with the treatment being offered.

Clinicians emphasize that the central focus should be on understanding the condition and enabling patients to lead fulfilling lives. Reading the text vignettes prompts clinicians to reflect on aspects that may have been previously overlooked, serving as a reminder of the critical need for clinical relevance in any work involving PROs. It underlines that for PROs, and indeed text vignettes, to realize its full potential in creating value, it must align with the clinical context and be relevant to clinical practice.

A More Straightforward Representation of PROs

In addressing some of the challenges with the quantitative representation of PROs, the use of text vignettes allows for a deeper understanding of PROs. Text vignettes recognize the complexities of patients' experiences and provide a broader perspective. This approach prevents reducing patients to just numerical data, offering instead a more comprehensive view of an individual's health. The text vignettes are presented in an understandable and consistent format, with transparency about how the collected information is applied. This transparency is crucial for patients' effective use of PROs [38]. By transforming complicated numerical data into a clearer and more coherent text format, text vignettes offer a direct representation that ensures patients and clinicians can grasp details without relying on prior knowledge of graphical presentations. This textual format encourages conversation, minimizes ambiguity, and fosters dialogue for a better understanding of individual experiences.

Promoting Dialogue for Mutual Understanding

A data-informed text vignette is not a universal solution, but rather an approach with both advantages and disadvantages that must be weighted and adapted to individual preferences and needs and that requires a more dynamic approach to meet needs. Recognizing these challenges suggests a need for meaningful conversations between patients and clinicians about aligning their understanding at a conceptual level. Such discussions offer a chance to clarify word meanings and ensure a common understanding of the patient's experiences. This approach is essential for accurate and meaningful communication between patients and clinicians, ultimately improving the quality of care and treatment. Clinicians and patients may have different perspectives on what the patient reports in the PRO instrument. An example is how HLQ scores were not perceived in the same way by patients and their physicians, with a disconcordance ranging between 20% and 44% in the 9 HLQ scales [14]. Translating the data into text vignettes may ease the conversation and help identify these disconcordances for other PRO data also, ease the alignment of expectations, and provide a common understanding of the patient perspective.

XSL•FO
RenderX

Bias Concern

Clinicians are generally receptive to text vignettes and the insights they provide. Many clinicians feel that the text vignettes offer a strong sense of the patients before any direct contact is made. However, clinicians also express concerns that the text vignette may make them biased in their encounter with the patient, which may affect their ability to understand and treat the patient objectively. It emphasizes the necessity of acquiring proficiency in tool use, particularly when presenting information in a text format. Being mindful of potential biases becomes central, especially in a context where the text vignette format might intensify the impact. This highlights the importance of a nuanced and skillful application of the tool, recognizing that biases are not exclusive to text vignette representation but should be carefully navigated, especially when conveyed in a confrontational textual manner.

Strengths and Limitations

A strength of this study lies in the stepwise process of creating a dataset using a validated instrument, followed by data triangulation. This process is based on iteratively developed text lines that can be combined into cohesive text vignettes, forming complete paragraphs. The cocreation with individuals, people living with a chronic condition, municipalities, hospital-based clinicians, and 1 general practitioner helps ensure the validity and meaningfulness of the proposed solution.

The number of participants in each of the 3 parts may be considered a limitation. In part 1, convenience sampling was used among participants active in a telehealth service and was limited by availability. We do not find this to be a problem for the presented results, as we were able to create 4 profiles and personas that are meaningful and can serve to illustrate the principles used as background for parts 2 and 3. The number of participants in part 2 was determined through concurrent evaluation during data sampling. When the inclusion of additional informants no longer contributed new information, the sampling process was considered complete. By including data from 2 distinct sociodemographic areas, we aimed to capture a range of perspectives. On the basis of these arguments, we found the number to have sufficient information power for a proof-of-concept study [39]. This is also supported by most of the participants finding the text vignettes understandable and recognizable.

In particular, in part 3, the number of patients is likely to be too small, but we have included this part to illustrate how clinicians who are familiar with the patients respond to the text vignettes describing them. The findings need to be assessed in this light. Moreover, the results may differ from those that will be obtained using PRO data instruments that are developed for clinical purposes, such as European Organisation For Research And Treatment Of Cancer [40], The World Health Organization-Five Well-Being Index [41], or European Quality of life–5 Dimensions [42].

Perspective

The study has used the READHY instrument to demonstrate how data-based text vignettes can help to understand patients and align expectations about what the data tell. During the field studies and in discussions afterward, we have received expressions of interest in setting up algorithms to convert other established PRO data results into text vignettes. This calls for abundant work in this field in collaboration with several PRO instrument owners and distributors, and we welcome collaboration in this field. It also calls for atomization programming interfaces that build on the proposed structures with filters based on cutoff values combined with generative artificial intelligence to refine the created text vignettes.

Conclusions

The study demonstrates how text vignettes can be developed using PRO instruments, with individual scales as input strings. This provides an opportunity to present numeric values in a text format that is understandable and recognizable to most patients and clinicians. Some clinicians prefer text vignettes to other forms of presentations and find them especially useful in establishing a better understanding of a patient before initial contact. However, language and the arrangement of text vignettes can present challenges, underscoring the need for adaptation to specific needs and clinician training to ensure accurate interpretation of the text vignettes. Different preferences for text vignette formats highlight the need for a more dynamic and adaptable tool that can cater to individual needs and preferences.

Acknowledgments

The authors would like to thank all participants for their contribution. The authors would like to specially thank Torsten Risør, Sine Rossen, Rikke Terp, Thyge Lynghøj Nielsen, and the PreCareKlinikken for providing feedback throughout the process and Mette Krog Andreasen and Morten Brandrup for facilitating access to informants.

The authors thank the European Union (EU) Horizon 2020 and all partners in Smart Inclusive Living Environments (SMILE) for making this work possible. This research was funded by the EU Horizon 2020 Research and Innovation Program under grant 101016848.

Abstract

Background: Health care institutions face high systemic risk due to the inherent uncertainty and complexity of their operations. This often leads to stressful incidents impacting the well-being of health care professionals, which can compromise the effectiveness of health care systems. Enhancing resilience among health care professionals is essential for maintaining high-quality care and ensuring patient safety. The role of middle managers is essential to ensure the response capacity of individuals and teams.

Objective: This study aims to develop a web-based intervention aimed at middle management to enhance individual, team, and organizational resilience.

Methods: An observational study was conducted in 3 phases: design, validation, and pilot study. The study was initiated in February 2022 and concluded in June 2023. Phase 1 involved designing the content for the web-based tool based on a comprehensive review of critical elements around resilience. Phase 2 included validation by an international panel of experts who reviewed the tool and rated it according to a structured grid. They were also encouraged to highlight strengths and areas for improvement. Phase 3 involved piloting the tool with health care professionals in Ecuador to refine the platform and assess its effectiveness. A total of 458 people were invited to participate through the Institutional Course on Continuous Improvement in Health Care Quality and Safety offered by the Ministry of Public Health of Ecuador.

Results: The tool, eResiliencia, was structured into 2 main blocks: individual and team resilience and organizational resilience. It included videos, images, PDFs, and links to dynamic graphics and additional texts. Furthermore, 13 (65%) of the 20 experts validated the tool, rating content clarity at an average of 4.5 (SD 0.7) and utility at an average of 4.7 (SD 0.5) out of 5. The average overall satisfaction was 9.3 (SD 0.6) out of 10 points, and feedback on improvements was implemented. A total of 362 health care professionals began the intervention, of which 218 (60.2%) completed preintervention and postintervention questionnaires, with significant knowledge increases (P<.001). Of the 362 health care professionals, 146 (40.3%) completed the satisfaction questionnaire, where overall satisfaction was rated at an average of 9.4 (SD 1.1) out of 10 points.

Conclusions: The eResiliencia web-based platform provides middle managers with resources to enhance resilience among their teams and their components, promoting better well-being and performance, even under highly stressful events. Future research should focus on long-term impacts and practical applications in diverse clinical settings.

resilience; health care professionals; web-based intervention; middle management; well-being; patient safety

Introduction

Systemic Risk

Health care institutions are considered high-reliability organizations due to the inherent systemic risk associated with the activities they conduct [1]. Uncertainty and complexity, inherent in health care delivery along with other factors, contribute to the occurrence of higher stressful incidents that sometimes result in harm (adverse events) [2]. Health care professionals are exposed almost daily to stressful situations that can deteriorate their occupational well-being, thus compromising the effectiveness of health care systems [3]. In addition, the impact and demands stemming from unexpected health outcomes and health care crises further exacerbate this situation. Ultimately, the post–COVID-19 pandemic period has underscored a reality that has always existed but has not been adequately addressed until now: the well-being of health care professionals is a necessary condition to ensure the effectiveness of health care systems and the quality of care [4].

Professional Well-Being

In clinical contexts, situations with the potential to deteriorate the well-being of professionals are varied. These situations can range from those related to patient safety, such as near-misses, poor prognoses, unexpected health outcomes, a patient's deteriorating condition, preventable and unavoidable adverse events, and the unexpected death of a patient, to those more associated with working conditions or structural factors. These include a lack of resources, high care pressure, elevated staff turnover, increased demand, violence against professionals, and moral injury. They can have an emotional impact on professionals, which affects their habits, practices, or clinical decisions [5]. When this behavior change occurs in the undesired direction, we may encounter defensive practices, burnout, or detachment that often entail assuming unnecessary risks for the patient and additional costs for the system [6,7].

Vicious Cycle

Even in the absence of behavioral change, the loss of professional well-being is accompanied by an exponential increase in the risk of human error in patient care, leading to lower performance and a deterioration in the quality of care provided to patients [8]. This worsening of outcomes can, in turn, contribute to the occurrence of new errors and safety incidents. Thus, we find workers in a vicious cycle where the loss of well-being, the inability to regain balance and face stressful situations, and the quality of care are intimately related [5,9]. Hence, preserving and enhancing the resilience of professionals is a key element in ensuring the proper functioning of health care systems, the quality of care, patient safety, and achieving better health outcomes [10].

Resilience

Resilience refers to the ability of individuals, teams, and organizations to adapt, recover, and grow in the face of stress, adversity, and challenging circumstances [11]. In the context of health care, it enables professionals to maintain their well-being and continue to provide high-quality care despite the inevitable challenges they encounter. This not only benefits the individuals themselves but also enhances the safety and effectiveness of care provided by health care teams [12].

Individual Differences

In addition to the inherent risk in health care activities, other cultural aspects can also be a source of distress for health care professionals and may even constitute a barrier to the process of recovering well-being once it has been compromised and are also directly related to values. From an individual perspective, health care professionals share a set of ideals focused on doing good and prioritizing the well-being of others. While these ideals are desirable for good performance, their rigid application in critical situations can intensify distress or hinder constructive coping and professional recovery [13].

Organizational Culture

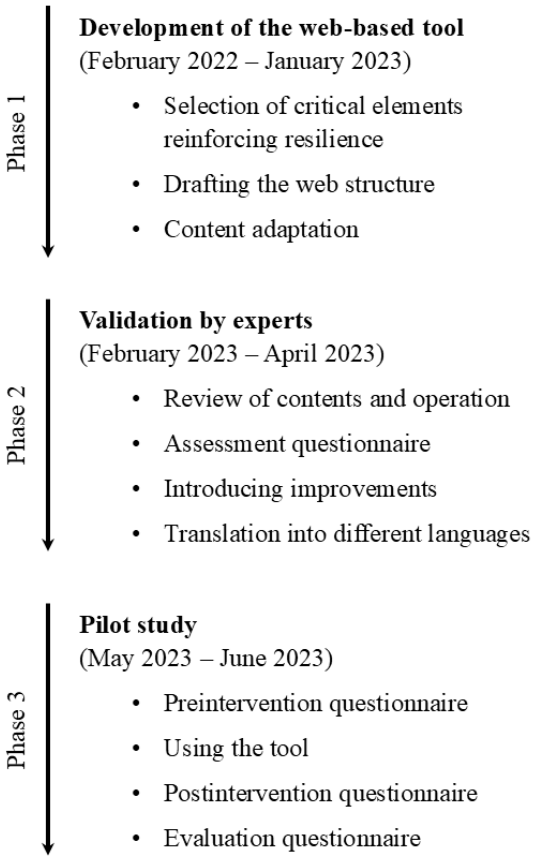
At the organizational level, the institution's culture plays a key role in determining how professionals feel, interpret, and cope with stressful situations. The prevailing professional culture in the health care sector is characterized by strong ideals of perfection that often lead to a negative and unconstructive view of human response, considering someone weak for asking for help or being unable to cope with a stressful situation. Understanding these causes allows for designing and implementing barriers that prevent or reduce the likelihood of succumbing to stressful situations occurring in the future.

Challenge

The World Health Organization has incorporated resilience in health care systems into the Global Patient Safety Action Plan 2021-2030 through strategy 2.4: providing a strong human factor and ergonomics-based perspective and contributing to strengthening the resilience of health care organizations and clinical practices [14]. This initiative aims to address a basic need for the proper functioning of health care systems, which is to take care of those who care.

We intend to address this need not only from a reactive approach when things go wrong but also by creating resilient teams and providing middle managers with tools to reinforce the resilience of professionals, teams, and the health care organization to ensure their ability to respond to critical situations. We believe that middle managers, due to their strategic position in the institution's structure, are key agents for the development of resilience at all levels; therefore, the materials of this project are specifically aimed at this group.

Methods



Study Design

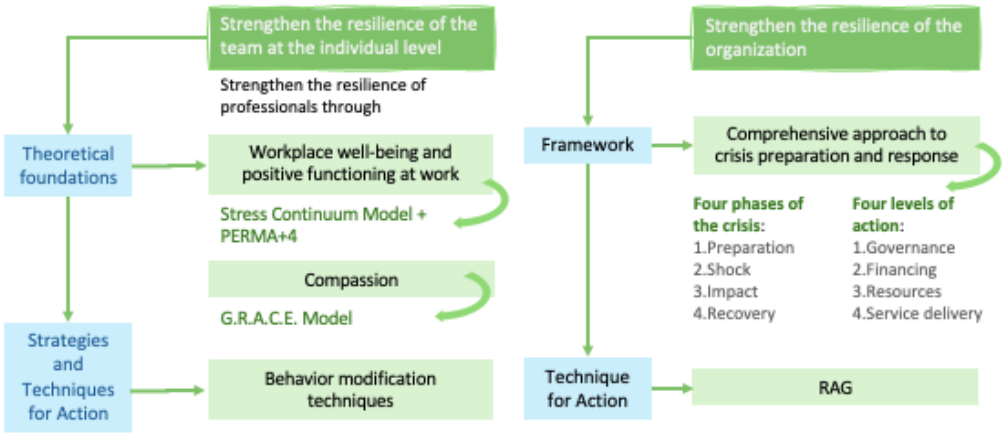
An observational study was developed in 3 phases: development of the web-based tool (phase 1), validation by experts (phase 2), and piloting with professionals (phase 3; Figure 1). Primary care and hospital were defined as usual settings for the new tool

XSL•FO
RenderX

named eResiliencia. The established 8 principles for learning tools that aim to support the translation of resilience into practice by Haraldseid-Driftland et al [15] were used. In this study, resilience in health care was defined as the capacity to adapt to challenges and changes at different system levels to maintain high-quality care [12].

Figure 1. Flowchart of project phases and steps.

The study was developed by a core group involving a multidisciplinary team supported by a panel of international experts in health administration, occupational safety, and patient safety. It was initiated in February 2022 and concluded in June 2023.



Phase 1: Development of the Web-Based Tool

To design the content for the web-based tool (phase 1), a comprehensive search of critical elements reinforcing resilience was conducted, culminating in a preliminary selection from among the most frequently cited elements. This included the revision of reviews and systematic reviews (after 2019) on the concept of resilience, experimental studies measuring the effectiveness of recent programs designed to enhance the resilience of health care professionals, and the content of different scales for measuring resilience. In particular, this search was aimed at identifying experiences and successful strategies [16].

The eResiliencia intervention is built on a robust theoretical framework that integrates principles of resilience, human behavior, and organizational adaptability to address the complex challenges faced by health care systems (Figure 2). This approach emphasizes strengthening resilience through the development of 5 essential traits: self-control, which involves regulating emotions and behavior under pressure; adaptability or the flexibility to adjust to changes and demands; optimism, characterized by a positive outlook and confidence in overcoming challenges; self-sufficiency, reflecting the ability to independently manage difficulties; and persistence, the sustained effort to persevere in the face of adversity.

XSL•FO
RenderX

Figure 2. eResiliencia theoretical framework. PERMA+4: PERMA+4 Well-Being model; RAG: Resilience Analysis Grid.

The intervention draws from the 5-tier model proposed by Seys et al [17], which combines preventive and supportive measures to build resilience. Levels 1 and 2 focus on proactive strategies such as prevention and self-care, while levels 3 to 5 offer structured peer and clinical support to address resilience at both individual and organizational levels. This multilevel approach ensures that resilience-building efforts are comprehensive and adaptable to the diverse contexts within health care settings.

eResiliencia operates across 3 interconnected levels: individual, team, and organizational. It uses both proactive and reactive strategies to enhance resilience. Proactive measures aim to build capacity before crises occur, using tools such as stress management models and workplace well-being frameworks. Reactive strategies focus on recovery and learning following critical events, ensuring that individuals and organizations can adapt effectively to challenges.

The intervention is informed by several evidence-based models, including the stress continuum model [18], which helps monitor and manage stress; the PERMA+4 Well-Being model [19], which promotes workplace well-being through its multidimensional framework; the G.R.A.C.E. model [20], which supports health care workers in cultivating compassion and managing burnout; and the Resilience Analysis Grid [21], which was applied to assess and enhance team response capacity in unexpected events. In addition, eResiliencia incorporates a set of behavior change techniques [22] designed to equip middle managers with targeted strategies for promoting workplace well-being. These techniques are tailored to the unique cultural and organizational contexts of health care systems, ensuring their relevance and practicality.

Following this, a second step involved drafting the web structure to accommodate the intended contents effectively. Subsequently, a process of content adaptation to the health care context ensued, wherein various support materials for the tool were developed. These materials underwent 2 rounds of internal review before arriving at version 1.0, ensuring their alignment with the intended objectives. The first version of the web platform was developed in Spanish and hosted on the Miguel Hernández University of Elche (Spain) servers, which comply with security requirements and regulations. A total of 11 months were spent to complete this phase, commencing in February 2022.

Phase 2: Validation by Experts

Version 1.0 underwent a review and validation process by an international panel of experts between February and April 2023. A total of 20 professionals integrated this panel, comprising 14 (70%) from Spain, 2 (10%) from Colombia, 1 (5%) from Argentina, 1 (5%) from Ecuador, 1 (5%) from Brazil, and 1 (5%) from Chile. The experts' identification was made using the snowball approach. All experts were informed of the pursued objective and the approximate time commitment and were requested voluntary, unpaid participation. Of the 20 professionals, 11 (55%) were women and 9 (45%) were men, and all met the criterion of a minimum of 10 years of professional experience. It was ensured that no personal evaluation would be disclosed, and communications with them were conducted via telephone or email.

Following a comprehensive examination of all contents and their structural organization, experts engaged were required to respond to a rubric designed to evaluate various aspects. This rubric used a scale ranging from 1 to 5 to assess the clarity of the content and its utility and applicability, grading from completely disagree to completely agree on whether the materials facilitated learning strategies to foster the resilience of professionals or teams under their purview, their likelihood to recommend the tool to other colleagues, and their intention to apply learned tools or strategies. In addition, experts were encouraged to identify strengths and areas for improvement and to rate their overall satisfaction with the web-based intervention and its contents on a scale from 1 to 10, where the higher the score, the greater the satisfaction. The level of agreement among evaluators was assessed to inform decisions regarding aspects requiring changes. All feedback and suggested improvements were meticulously implemented to enhance the quality of the content. Subsequently, the refined version of the tool was translated into English, Portuguese, and Valencian. Careful attention was given to ensuring equivalence across all versions through a process of back translation. Necessary adjustments were made to ensure the adequacy and coherence of the system across languages. An adaptation was also made to the idioms

XSL•FO
RenderX

and expressions commonly used in Latin American Spanish. This procedure also ensured that social and cultural aspects specific to each country were considered.

Phase 3: Pilot Study

From May 1 to June 30, 2023, a pilot study was conducted in a real setting in Ecuador. The participants' feedback served to refine the platform and the tool. A broader cohort of 458 health care professionals from Ecuador was invited to participate. They served as executives or managers in one of the country's public health care networks. This invitation was extended through the Institutional Course on Continuous Improvement in Health Care Quality and Safety offered by the Ministry of Public Health of Ecuador with the support of the Miguel Hernández University, Spain. The invitation was formally extended to all professionals from the management teams of public health care institutions in the country, including physicians, nurses, and other professional profiles. They assessed whether they wished to participate in this training, ensuring their data and performance were completely anonymized. Participants were required to complete a preintervention questionnaire at the moment of registration to access the contents of the web-based tool. This questionnaire comprised 20 questions assessing the knowledge areas to be addressed. In Multimedia Appendix 1, the topics addressed by each question can be consulted. After 7 days, a postintervention questionnaire containing the same questions was made available to assess content assimilation. Participants had the option to retake this postintervention questionnaire up to a maximum of 10 times, with a minimum score of 8 out of 10 required to qualify for a proficiency certificate. Following the completion of the postintervention questionnaire, participants were presented with an evaluation questionnaire consisting of the same questions posed to the experts during phase 2.

Data Analysis

In this study, both quantitative and qualitative analyses were conducted. The profile of participants who completed all phases of the iteration was compared with those who dropped out and did not finish to identify potential differences. For phase 2, descriptive analyses were performed on the rubric scores, and content analyses were conducted for open-ended responses. Fleiss κ was used to analyze the level of agreement among evaluators. The response options were recoded into 2 categories: "agree" (values 4 and 5) and "disagree" (values 1, 2, and 3), evaluating the overall agreement among experts across the 5 variables (clarity, utility, intention to recommend, intention to apply, and eResiliencia).

Similarly, in phase 3, the same analyses as in phase 2 were performed for the evaluation questionnaire. Descriptive statistics were conducted for both the preintervention and postintervention questionnaires. To assess differences between the means of such questionnaires, the Wilcoxon signed rank test was used. In addition, the McNemar statistic was calculated to compare the number of correct responses before and after the use of the web-based tool for each question. Qualitative analysis also considered the frequency of positive comments and improvement suggestions made by participants at the end of the structured survey. These comments, expressed in natural language, were categorized by 2 researchers (EG-H and IC) to facilitate their documentation. Finally, sociodemographic data were analyzed using descriptive statistics.

Ethical Considerations

In accordance with the Ecuadorian Ministerial Agreement AM00005-2022 and the Spanish Law on Biomedical Research (14/2007), studies conducted through anonymous surveys that do not collect health-related data are exempt from ethical review. This study was fully compliant with all regulatory standards for personal data protection. Ethical principles for medical research involving human participants included in the guidelines set by the Helsinki Declaration were followed. Informed consent for study participation was obtained at the time of registration on the platform, whereby individuals were required to select the corresponding checkbox, with instructions provided regarding the process for revoking their participation. No form of financial compensation was provided for participation.

Results

Phase 1: Development of the Web-Based Tool

A total of 42 documents were deemed relevant and were analyzed in depth to extract lessons learned and proposals for the design of eResiliencia (Table 1).

The working team outlined a presentation structure for eResiliencia and chose the most suitable appearance from several options. With the information gathered and the ideas from the working group itself, the first draft of the content was structured in the beta version of the website that hosts eResiliencia [59].

The content was divided into 2 main blocks (Figure 3), one aimed at building resilience at the individual and team levels, and another at the organizational level, preceded by a conceptual framework. Platform navigation was conducted through both the menu bar and the side panel (Figure 4). Within each block, there were subdivisions as shown in Table 2. In the tab dedicated to the conceptual framework, an explanation of the course context, an introduction to resilience, several examples of situations where it is crucial, and a section with definitions of the most relevant concepts of the course were provided. The first block, tools to strengthen resilience at the individual and team levels, offered the necessary strategies to enhance the resilience of team members at an individual level, placing particular emphasis on the importance of workplace well-being. Finally, the block on tools to reinforce resilience at the organizational level provided strategies to assess and achieve resilient institutions in the face of crises and unexpected events. In addition, a road map was included at the end of the course to aid in selecting the most useful strategies based on the objectives.

Table 2. Structure of the eResiliencia web-based platform.

Structure	Items
Framework	• Why this guideline? • Resilience components • Examples • Definitions
Individual level	• Stress Continuum Model • Enhancing resilience at the individual level • G.R.A.C.E. model • PERMA+4 Well-Being model for occupational wellness • Behavior change technique for building work-related well-being
Organizational level	• Enhancing resilience at the organizational level • Resilience Analysis Grid

In total, it comprised 17 videos, 11 figures and images, 4 PDF files, and references for further information expansion, among which downloadable materials or video, graph, and text links were also available. Upon accessing their personal account, users were provided with a section containing pertinent information regarding the platform's functionality, along with a video elucidating navigation and content. In addition, users had access to a support resource and the option to change their password.

Phase 2: Validation by Experts

Of the 20 experts, 13 (65%) assessed the tool and provided feedback. They rated the clarity of the content at an average of 4.5 (SD 0.7) and the utility and applicability at an average of 4.7 (SD 0.5), out of 5 in both cases. Regarding whether the materials facilitated learning strategies to foster the resilience of professionals or teams under their purview, 62% (8/13) of the experts indicated they *completely agree*, 31% (4/13) of the experts indicated they *agree*, and 8% (1/13) of the experts indicated they *completely disagree*. Regarding their likelihood to recommend the tool to other colleagues, 92% (12/13) of the experts responded *definitely yes*, and 8% (1/13) of the experts responded *probably yes*. The same results were obtained for their intention to apply learned tools or strategies. The level of agreement among experts for the combined set of the 5 evaluative variables of eResiliencia was 0.79 (95% CI 0.65-0.92).

Overall satisfaction was rated with an average of 9.3 (SD 0.6) out of 10 points. Some of the strengths highlighted were the chosen content and the ease of navigation and presentation of the web-based platform. In contrast, areas for improvement included making the videos more engaging and the possibility of incorporating practical exercises or a forum for participant interaction. As a suggestion, an introductory video of the content and the functionality of the web-based platform was included (Multimedia Appendix 2) [60]. The full list of comments made by experts is presented in Multimedia Appendix 3.

Phase 3: Pilot Study

Of the 458 professionals invited to participate, 362 (79%) registered on the platform. The preintervention and postintervention questionnaires of the pilot study were completed by 218 (60.2%) of these 362 health care professionals exercising leadership roles who began the intervention. Moreover, 146 (40.3%) health care professionals responded to the experience evaluation questionnaire.

Most of them were physicians (90/218, 41.3%) and nurses (59/218, 27.1%), with a mean experience of 10.3 (SD 8.8) years. Their primary work setting was primary care (113/218, 51.8%), hospital (79/218, 36.2%), quality area (9/218, 4.1%), or other management positions (7/218, 3.2%). The profile of those who did not complete the entire educational intervention was similar to those who did, with 42.4% (61/144 being physicians, 24.3% (35/144) being nurses, and 45.1% (65/144) working in primary care. Those who did not complete the intervention had slightly average experience, with 11.4 years compared with 10 years.

The scores obtained in the preintervention questionnaire averaged 42.0 (SD 16.6) of 100, while for the postintervention questionnaire, they averaged 74.7 (SD 22.7), with significant differences between them (P<.001; Z=–11.728). The increase in the percentage of correct answers for each question is represented in Table 3.

XSL•FO
RenderX

Table 3. Increase in percentage of correct answers for each question (n=218).

Questions[a]	Correct responses on the preintervention questionnaire, n (%)	Correct responses on the postintervention questionnaire, n (%)	Increase of correct answers (%)	McNemar test	*P* value
1	148 (67.9)	192 (88.1)	20.2	25.681	<.001
2	73 (33.5)	148 (67.9)	34.4	53.165	<.001
3	102 (46.8)	155 (71.1)	24.3	27.876	<.001
4	32 (14.7)	134 (61.5)	46.8	87.940	<.001
5	103 (47.2)	165 (75.7)	28.4	37.969	<.001
6	66 (30.3)	176 (80.7)	50.5	99.008	<.001
7	92 (42.2)	162 (74.3)	32.1	52.900	<.001
8	110 (50.5)	180 (82.6)	32.1	48.582	<.001
9	94 (43.1)	153 (70.2)	27.1	30.862	<.001
10	82 (37.6)	159 (72.9)	35.3	55.010	<.001
11	139 (63.8)	189 (86.7)	22.9	29.280	<.001
12	117 (53.7)	169 (77.5)	23.8	28.900	<.001
13	44 (20.2)	165 (75.7)	55.5	111.628	<.001
14	110 (50.5)	181 (83)	32.5	49.495	<.001
15	29 (13.3)	111 (50.9)	37.6	64.324	<.001
16	86 (39.4)	145 (66.5)	27.1	33.307	<.001
17	138 (63.3)	194 (89)	25.7	34.375	<.001
18	114 (52.3)	154 (70.6)	18.3	20.554	<.001
19	84 (38.5)	162 (74.3)	35.8	55.934	<.001
20	68 (31.2)	163 (74.8)	43.6	73.025	<.001

[a]Because this is active training, the questions have been masked to avoid spoilers. They are available upon reasonable request.

Moreover, 58.3% (127/218) of the health care professionals passed the postintervention questionnaire without requiring any retries. However, 14.2% (31/218) of the health care professionals needed 1 retry, 8.3% (18/218) needed 2 retries, 6% (13/218) needed 3 retries, and 3.7% (8/218) needed between 4 and 7 retries. Furthermore, 9.6% (21/218) of the health care professionals exhausted all 10 retry attempts without achieving the required score.

Regarding the perception of the 146 people who completed the evaluation questionnaire, the clarity of the content received an average score of 4.7 (SD 0.6) on a 1 to 5 scale, while the utility or applicability scored 4.8 (SD 0.5). The results of their opinion are depicted in Table 4.

Global satisfaction was rated 9.4 (SD 1.1) out of 10 points on average. Among the strengths underscored were the comprehensiveness of the content and the interesting techniques explained. Conversely, identified improvement areas consisted of incorporating more illustrative examples and providing downloadable materials.

[a]Not applicable.

Qualitative Analysis of Open-Ended Comments

Strengths

The most repeated topics among the strengths were the learning of new techniques or specific models (34/146, 23.3%), the web-based methodology that allowed access at any time (14/146, 9.6%), the organizational approach (10/146, 6.8%), the clarity of the content (9/146, 6.1%), stress management (6/146, 4.1%), and the examples provided (4/146, 2.7%).

Opportunities for Improvement

In terms of aspects to be improved, the incorporation of more examples (14/146, 9.6%) and the expansion of the content (14/146, 9.6%) were generally highlighted. In addition, improving the quality of the videos (12/146, 8.2%), including the possibility of interacting with other students in a more practical way (9/146, 6.2%), enabling downloadable content (9/146, 6.2%), reducing the length of the questionnaires (6/146, 4.1%), including web-based tutorials for resolving doubts with the teachers (5/146, 3.4%), and adding a progress bar to visualize the course as a whole (4/146, 2.7%) were emphasized.

Discussion

Principal Findings

Our developed web-based approach operates as a comprehensive tool designed primarily for middle managers, aiming to foster resilience at both individual and organizational levels within the staff at their charge. By using multimedia resources, this approach has been shown to enhance the knowledge about resilience of health care professionals across diverse fields and backgrounds.

eResiliencia was highly rated by the panel of experts regarding clarity and usefulness, indicating that the tool is perceived as comprehensible and relevant for application in professional contexts. High ratings were also obtained for the willingness to recommend the tool to colleagues and the intention to apply the learned strategies, demonstrating strong acceptance and confidence in the resource. For most (12/13, 92%) participants, the materials were potentially effective in strengthening team resilience, except for 1 (8%) expert who expressed complete disagreement. This highlights the need to consider diverse perspectives and possible improvements in adapting the content to various contexts. Nonetheless, overall satisfaction was high, with more than 9 points out of 10.

Implementing eResiliencia in Real-World Settings

The eResiliencia platform features a user-friendly interface, and in most cases, managerial staff possesses the necessary skills to use such digital tools effectively. However, some systemic limitations may impact its implementation. First, the increasing measures to prevent cyberattacks and data ransom incidents in health care institutions have led to stricter internet access controls, even in areas where connectivity was previously unrestricted. This decision may hinder access to eResiliencia within some organizations. In addition, in certain health care networks, managers lack the resources to access the platform outside their offices. Incorporating offline functionality could address these limitations and facilitate broader access to the platform.

Second, resistance from health care organizations, often rooted in established workflows or skepticism about the benefits of new interventions, represents a traditional barrier. In this case, the integration of eResiliencia was facilitated by embedding it within a national patient safety and quality training program aimed at launching a global institutional strengthening plan. A similar strategy could help overcome organizational resistance in other settings.

XSL•FO
RenderX

Third, ensuring flexibility and accessibility is essential to meet the diverse needs of users. The use of asynchronous learning options was key in this instance, allowing participants to decide when and how to engage with the platform. This flexibility significantly increases accessibility and is particularly relevant in environments with high workloads. However, allocating dedicated time during work hours could further enhance participation rates by reducing competing demands on participants' schedules.

Comparison With Prior Studies

It is known that health care professionals face stressful situations in their professional work. The frequency of burnout or the existence of defensive practices is also not uncommon. It is no surprise that the role of team leaders influences the team's ability to respond and recover after experiencing adverse situations [61]. The COVID-19 pandemic brought to the attention of managers, executives, and society in general concerns about the resilience capacity of these collectives, both at an individual and collective level, to face what has undoubtedly been the greatest global challenge for health care professionals. This study originates from that period and delves into both aspects, offering an easily accessible training format for those responsible for clinical teams. In this regard, it is based on the observation that most programs designed to increase resilience were developed to operate at the individual level and that it was necessary to create interventions focused on the work group [30].

eResiliencia incorporates agreed-upon resilience attributes [37] and skills that leaders must possess to strengthen their teams' resilience, which include self-efficacy, self-control, the ability to provide support and help, and learning from difficulties [62].

Uncertainty, resource shortages, constant protocol variations, the risk of infection and transmission, and critical decision-making with ethical implications, among other factors, were prevalent during the COVID-19 pandemic and contributed to fear, anxiety, stress, moral injury, or compassion fatigue among health care professionals [63,64]. These situations have highlighted the need to reconsider the role of middle management, as they must address the needs of their teams to face challenges. Therefore, their resilience is a crucial competence required for their work.

The scores obtained in this study by the professionals who underwent the training show that after the use of the tool, the results were better both overall and for each individual question. However, the preintervention questionnaire also revealed that participants' previous knowledge was relatively low in many areas, with correct response rates ranging from 13.3% (question 15; behavior change technique) to 67.9% (question 1; definition of resilience). This underscores the necessity and effectiveness of the educational intervention implemented. The greatest increases were in questions with initially low correct response rates (question 4, question 6, and question 13), suggesting the acquisition of new concepts. In contrast, questions such as question 1 and question 18, which initially had a higher percentage of correct responses, showed a less pronounced increase compared to those with lower initial performance. The increase in scores on the final questionnaire compared to the initial questionnaire is consistent with the findings of other studies, which show that both in-person [52,65-67] and on the web [50,68] interventions increase resilience capacity. In addition, it has been observed that they also protect the mental health of professionals [69].

Solutions to assist professionals were implemented in different countries and were similar, including the availability of psychological services, support hotlines, and websites with resource materials [70]. Focusing on tools available for Spanish speakers, an example is the digital platform and mobile app, Be+Against COVID, which was used in Argentina, Brazil, Colombia, Chile, Ecuador, and Spain [71].

Although middle managers have usually received training in occupational risk prevention and conflict management, many times there is a lack of specific and detailed training in fundamental aspects of team management and resilience. Traditionally, team management has focused on organizational and clinical aspects to ensure that patients' needs are adequately met. Nowadays, middle managers are expected to efficiently manage the resources of the professional teams they lead, particularly human talent, to adequately respond to health challenges.

Implications of Findings

In the postpandemic era, there is a growing consensus that among the functions of executives and middle managers (such as the organization of responses to care demands, task allocation, conflict management within teams, and the strengthening of teams to meet care demands effectively), there should be an emphasis on maintaining and strengthening the resilience capacity of their teams of professionals, because their ability to cope with highly stressful situations determines the quality of care provided and the outcomes for patients. This eResiliencia program follows this trend and takes a proactive approach by offering a framework for executives and middle managers to use some or all the resources to achieve this objective and prepare their team for everyday challenges and future crises.

Although most (197/218, 90.4%) of the participants were able to pass the training without any difficulties, some (21/218, 9.6%) individuals exhausted all reattempts without achieving the minimum required score. While these data suggest that the material and teaching methods are effective for most, it would be beneficial to delve into the reasons behind the difficulties faced by this small percentage to address and mitigate the problem.

Resilience training is presented as a crucial element in the professional development of middle managers in the health care sector. Promoting and reinforcing resilience is not only essential for the individual well-being of professionals but also strengthens the cohesion and effectiveness of the team as a whole. However, for this to be feasible, it is essential that clinical management evolves and provides effective tools to middle managers, facilitating resource management, including resilience training.

In this era, there is a growing consensus that the existing "find and fix" solutions should be replaced by those that are more forward-thinking [15]. Moreover, the organizational culture is

XSL•FO
RenderX

critical to ensuring patients receive adequate care and workers' resilience when things go wrong [72]. Health care organizations are evolving toward the principles of Safety II framework here [73], which involves recognizing the challenge of complexity and uncertainty in clinical practice to anticipate errors. Promoting the resilience of workers at both individual and team levels contributes to realizing the implementation of Safety II [74].

Fragmentation in the assignment of professionals poses a significant challenge to teamwork. Thus, cohesion among middle medical and nursing managers is essential to overcoming the barriers created by this fragmentation and fostering a more collaborative and efficient work environment. The training of middle managers in the health care organization must be a top-down strategy, driven by leadership. Health care executives must communicate these priorities to middle managers and provide the necessary support for implementation. Only through strong and consistent leadership from the upper echelons can we ensure that middle managers are equipped with the competencies required to effectively manage their teams and promote a resilient work environment.

The response rate indicates that 4 (40%) of the 10 professionals who registered on the platform were eventually not interested in the training on how to foster resilience in their teams and collaborators. This could be because they already possess the personal resources to tackle the task or because eResiliencia did not meet their expectations or failed to motivate them sufficiently. This aspect could be addressed, for example, with a more practical approach through group dynamics and cooperative tasks to generate greater interest and engagement, so participants can see a more direct application of the training tools.

Strengths

This study addresses the 5 key questions of a resilience study in the health care sector [75]. It proposes an alternative approach to individual-focused training by emphasizing the role of clinical team leaders and how to strengthen the resilience of their teams and team members.

Limitations

Although international experts share a common cultural background, they represent a group of Spanish-speaking countries. The generalization of content to other countries should not be done directly. Participants in the pilot study phase worked in various public health networks in Ecuador and took part in this experience as part of a quality and patient safety management course, which emphasized the need to move away from a blame culture. This aspect may have influenced their engagement with the eResiliencia content. Participants had a set amount of time to complete the training on the eResiliencia web-based platform. In a different self-directed learning context without this limitation, trainee behavior might be different. Because this is a study without a control group, the changes observed in participants' knowledge may not be exclusively attributable to eResiliencia. Finally, it should be noted that although the participants were enrolled in training organized by the Ministry of Public Health of Ecuador, it was emphasized that they could freely choose whether to complete the eResiliencia training and respond to the satisfaction survey. Answering the questionnaire did not provide any advantage and the responses were not disclosed, ensuring anonymity at all times, which was clearly communicated to the participants. This approach was taken to avoid a reporting bias.

Cultural Factors Influencing Resilience-Building Capacity

Ecuador's health care system is characterized by hierarchical structures and centralized decision-making, typical of high-power distance cultures. eResiliencia capitalizes on the influential role of middle managers, who act as intermediaries between upper management and frontline workers. By equipping middle managers with resilience-building tools, the intervention empowers them to cascade these strategies throughout their teams, reinforcing resilience at all levels of the organization. The networks engaged in this study operate with limited resources, requiring flexibility and improvisation to address challenges. eResiliencia provides structured yet adaptable strategies, offering tools for middle managers to tailor resilience-building efforts according to the specific needs and constraints of their teams. Although Ecuador faces challenges in long-term health care planning, eResiliencia introduces structured frameworks that emphasize proactive resilience building. These frameworks align with preventive measures to prepare health care professionals for crises, fostering a shift from reactive to proactive management.

Many of these aspects are common to countries in this region. However, the outcomes of eResiliencia in Asia, Europe, or North America are likely to differ significantly due to the cultural factors influencing resilience-building capacity. Cultural dimensions such as collectivism, power distance, and approaches to uncertainty, among others, play a crucial role in shaping how resilience strategies are developed and applied across different contexts.

Future Research

It is necessary to delve into a common definition of what is meant by resilience [11,75] and, by extension, the role of managers in the resilience of their team members. A critical aspect for future development involves the incorporation of mechanisms to monitor the utility and long-term impact of the knowledge acquired through the web-based tool, particularly considering the less optimistic data provided by some studies on nursing students [76]. In later phases, this intervention will be complemented by the development of improvement and action plans based on the application of the eResiliencia tools by health care teams and middle management interested in their centers. This will allow a more effective monitoring of the tool, its usefulness, and applicability. These approaches could also be extended to companies that provide home care, to train those who coordinate the work of informal caregivers in the home [77], in light of the growing caregiving economy. Finally, as these are preliminary data, this educational intervention should be tested in the context of other organizational models and diverse cultural settings to validate its effectiveness, acceptability, and utility.

XSL•FO
RenderX

Conclusions

The proposal to evaluate each professional, identify signs of stress, take appropriate measures, and manage team cohesion represents a training initiative that could be implemented clearly and explicitly. However, it is essential to first analyze the organizational context where the intervention will be applied and identify potential adjustments to improve its acceptability based on national and local organizational factors. This tailored approach ensures that the intervention aligns with the specific needs and characteristics of each setting, enhancing its effectiveness and relevance. This training would enable middle managers not only to manage conflicts but also to prevent them and foster a healthy and productive work environment. The developed tool proved to be well received by both the experts and the health care professionals who participated in this pilot phase.

Acknowledgments

The authors would like to acknowledge the experts who participated in the evaluation and validation of the web-based platform as well as all the participants from Ecuador who took part in the pilot study, thereby contributing to an improved experience with the platform. The authors also extend their gratitude to the National Directorate of Quality, Patient Safety, and Health Control of the Ministry of Public Health of Ecuador for their support and dissemination efforts in the initial recruitment process. Clara Pérez contributed to the statistical analyses.

The project was funded by Conselleria de Sanitat Universal i Salut Pública (Generalitat Valenciana, Spain) and the EU Operational Program of the European Regional Development Fund for the Valencian Community 2014-2020, within the framework of the Recovery Assistance for Cohesion and the Territories of Europe program, as the European Union’s response to the COVID-19 pandemic; Ser+ Contra COVID (UGP-21-408). The maintenance of the web-based platform is made possible by the funds allocated to the preparatory action in the UniSalut Program 2023 (subprogram ILISABIO, reference ILISABIO22_AP09). Throughout the execution of this study and composition of this manuscript, JJM benefited from an augmented research activity contract granted by the Carlos III Health Institute (reference INT22/00012).

Data Availability

The datasets generated analyzed during this study are available from the corresponding author on reasonable request. Topics addressed in each question are displayed in Multimedia Appendix 1.

Authors' Contributions

All the authors meet the International Committee of Medical Journal Editors criteria for authorship. JJM was responsible for the design of the study. JJM and IC conducted the search and the preliminary selection of contents related to resilience. IC and EGH drafted the web-based platform and developed the materials. JMD was responsible for the enrollment of people and the acquisition of data. DGT performed the statistical analysis and interpretation of the results. EGH developed the first version of the manuscript. All authors revised the paper critically for important intellectual content and read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Topics of the preintervention and postintervention questionnaire questions.

Abstract

Background: Web-based health courses providing lifestyle-related information can potentially increase knowledge, facilitate behavior change, and improve health outcomes for people living with multiple sclerosis (MS). Despite the low engagement with web-based programs by this population, few studies have evaluated factors influencing engagement. This study evaluated engagement with our 6-week lifestyle-related course (Multiple Sclerosis Online Course; MSOC) by participants enrolled in a large, international randomized controlled trial, as well as preliminary outcomes.

Objective: This study aimed to quantitatively assess engagement with the MSOC (the intervention course [IC] and standard-care course [SCC]), motivators of and barriers to participants' course completion, course satisfaction, engagement with the community forum, and intentions to implement lifestyle changes.

Methods: We collected data via a baseline survey before course commencement and an evaluation survey 1 month after the 6-week course. Course completers were queried on motivators of completion, course satisfaction, previous knowledge, forum participation, and intentions to adopt lifestyle changes. Noncompleters were queried on barriers to course completion. Differences between the 2 study arms were examined using chi-square and 2-tailed *t* tests. Multivariable linear regression models assessed factors (sociodemographic and course and health related) associated with participants' intentions to adopt lifestyle changes adjusting for baseline lifestyle factors. Moderation analyses were conducted to test group differences.

Results: Of the 857 participants, 442 (51.6%) completed the MSOC (IC: n=218, 49.3%; SCC: n=224, 50.7%), and 291 (34%) completed the evaluation survey (n=254, 87.3% course completers; n=37, 12.7% noncompleters). Key motivators of course completion included an interest in participating in MS research, optimizing health, course flexibility, and relevant and useful course content. Barriers to course completion included time constraints and technical issues. Most course completers rated the MSOC as "excellent/very good" (IC: 92/126, 73%; SCC: 78/128, 60.9%; *P*=.17). Engagement with the facilitator-led community forum was higher in the IC than in the SCC (56/126, 44.4% vs 32/128, 25%; *P*=.003). More IC completers versus SCC completers expressed their intention to adopt dietary changes (89/125, 71.2% vs 74/127, 58.3%; *P*=.04), increase their sun exposure (82/124, 66.1% vs 62/124, 50%; *P*=.01), supplement with omega-3 (84/125, 67.2% vs 60/126, 47.6%; *P*=.004), and practice meditation

XSL•FO
RenderX

(85/124, 68.5% vs 66/126, 52.4%; *P*=.009). Forum engagement, course satisfaction, new course content, and an interest in receiving additional course content were associated with intentions to adopt lifestyle changes across both study arms.

Conclusions: The web-based lifestyle IC provided new and satisfactory content and facilitated intentions to adopt lifestyle changes. Positive associations between engagement with the community forum and intentions to implement lifestyle changes and identifying barriers to completion such as time constraints provide important insights to inform the design of future digital health interventions for people living with MS and possibly other chronic conditions.

KEYWORDS

multiple sclerosis; randomized controlled trial; lifestyle; multimodal; digital intervention; Multiple Sclerosis Online Course; course engagement

Introduction

Background

Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system that affects almost 3 million people worldwide [1]. It is the most common cause of nontraumatic disability in young and middle-aged adults [2] and manifests with symptoms such as fatigue, depression, and anxiety, as well as reduced quality of life (QoL) [3,4].

Although treatments for MS such as disease-modifying therapies (DMTs) can ameliorate disease progression and reduce the risk of relapse (transient exacerbations of new or recurring neurological dysfunction) [5], people living with MS have expressed a strong interest in self-management strategies [6]. Self-management strategies, such as modification of lifestyle-related risk factors (eg, diet, exercise, and stress management), have been shown to be beneficial in managing MS-related symptoms and improving individuals' sense of control over their disease as an adjunct to pharmacological treatments [7-10]. More recently, web-based interventions have demonstrated effectiveness in promoting self-management strategies to improve MS-related knowledge, self-efficacy, and symptom management [11,12]. Web-based health interventions, particularly lifestyle-related ones, could improve accessibility issues and reduce barriers of geography and mobility, thereby increasing knowledge translation to people living with MS [12-15].

Despite the potential advantages of web-based health interventions for people living with MS in terms of availability and cost-effectiveness, these interventions have encountered issues related to high attrition [16,17] and low engagement rates [18]. Previous studies evaluating participation in web-based health-related courses for people living with MS have also focused primarily on course satisfaction [18], knowledge gain [18], and self-management of fatigue [11,12]. Few studies have comprehensively examined engagement (particularly course commencement and completion) with web-based health interventions to facilitate self-management strategies for people living with MS, including whether knowledge gain through interventions translates into changes in attitudes and lifestyle.

In addition, the influence of social support and interaction on the completion of self-paced web-based interventions for people living with MS remains unclear. While chat forums, online message groups, and web-based coaches have been found to increase course satisfaction [19], there is a noticeable gap in the literature regarding social engagement and the learning outcomes of web-based lifestyle interventions. Given the rapid shift toward web-based health care platforms and their potential benefits for people living with MS, studies exploring engagement with web-based interventions by populations with chronic illnesses such as MS remain a high priority.

We developed the Multiple Sclerosis Online Course (MSOC), a web-based program delivering evidence-based lifestyle recommendations for people living with MS with the aim of improving health and well-being outcomes in this population. After confirming the feasibility, acceptability, and learnability of the MSOC [14], a large randomized controlled trial (RCT) was designed and is currently being conducted to investigate the effectiveness of a multimodal lifestyle intervention course (IC) in improving health outcomes and QoL in people living with MS compared to a standard-care course (SCC) [15].

Objectives

This study aimed to evaluate engagement with the web-based lifestyle program, the MSOC, by RCT participants (an international cohort of people living with MS) and the impact of the MSOC in facilitating intentions to adopt lifestyle changes *after* participants were provided with access to the MSOC (IC or SCC; Textbox 1). This study used data collected from an evaluation survey 1 month after the delivery of the MSOC and specifically aimed to determine motivators of course completion, levels of course satisfaction, engagement with a facilitator-led community forum, and barriers to engagement among course noncompleters (Multimedia Appendix 1). In addition, we examined intentions to adopt lifestyle changes across the IC and SCC.

XSL•FO
RenderX

Textbox 1. A comparison of aspects of engagement with the Multiple Sclerosis Online Course across the intervention course and standard-care course in course completers and noncompleters.

Aspects examined among course completers
Motivators of course completion
Course satisfaction
Previous knowledge of course content
Participation in the facilitator-run community forum
Intention to adopt recommended lifestyle modifications
Sociodemographic and course- and health-related factors associated with participants' intention to adopt recommended lifestyle modifications
Aspects examined among course noncompleters
Barriers to course completion

Notably, this study complements our previously published quantitative study from the same RCT, which specifically aimed to determine sociodemographic, clinical, and lifestyle-related factors associated with course commencement and completion using participant baseline data [20]. That is, baseline data were collected before participants had access to the MSOC, whereas this study used data collected 1 month after the 6-week course. In another 2 *qualitative* studies from the same RCT, we examined how people living with MS (N=38 course completers) seek information online [21] and participants' perceptions of their MS and their perceived sense of control over their disease [22].

Overall, this study provides unique insights into factors influencing engagement and lifestyle change intentions and examines the role of course design elements such as facilitator-led forums. The study findings can be used to improve the design of future digital health interventions for people living with MS and potentially other chronic conditions.

Methods

Overview

In this ongoing RCT, the IC, based largely on information from the Overcoming MS lifestyle program [23], is being tested for its effectiveness in improving health outcomes in a large international cohort of people living with MS compared to the SCC, which provides general lifestyle recommendations from reputable MS websites, as described fully in the protocol paper [24] (Multimedia Appendices 2 and 3).

Enrolled participants (people living with MS recruited online from the United Kingdom and Ireland, North America, and Australia and New Zealand) were allocated to 1 of 2 courses using simple randomization: the IC or the SCC. The web-based courses were freely delivered worldwide in English via a laptop or PC connected to the internet. Course content was presented in videos, animations, text, and images and structured into seven modules covering the following topics: (1) introduction, (2) eating well (diet recommendations), (3) sunlight and vitamin D, (4) exercise, (5) meditation and the mind-body connection, (6) medication and family prevention, and (7) conclusion (Table S1 in Multimedia Appendix 4). Briefly, the 7 learning modules were delivered biweekly over 4 weeks followed by a 2-week catch-up period (total course length was 6 weeks). Each course also included a facilitator-led community forum.

In the feasibility RCT, while the MSOC was found to be both acceptable and useful by people living with MS, 45% of participants did not complete the course, and there was no engagement with the community forum [25]. As a result, facilitators and researchers were added to the community forum in the MSOC effectiveness RCT [24] to promote dialogue by introducing each module topic, promoting discussion within the module by asking questions related to the topic, and answering participants' questions with the intent of increasing engagement and, subsequently, course completion.

In total, 5 rounds of recruitment took place via international MS websites and social media: August 1, 2022, to September 12, 2022; October 19, 2022, to November 21, 2022; November 21, 2022, to December 31, 2022; March 27, 2023, to May 7, 2023; and July 24, 2023, to September 3, 2023.

Ethical Considerations

All participants provided informed consent for their data to be used for research. This study was approved by the University of Melbourne Human Research Ethics Subcommittee (ID: 22140). The trial was registered with the Australian New Zealand Clinical Trials Registry (ACTRN12621001605886). All methods were carried out in accordance with relevant guidelines and regulations. Participants were provided with a detailed plain-language statement explaining the study objectives, procedures, potential risks, and benefits. This study was administered and conducted solely by the Neuroepidemiology Unit at the Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, the University of Melbourne. The single-site nature of this study ensured that all participant data were securely stored in 1 location, on the University of Melbourne server. Participants did not receive monetary compensation for their involvement.

MSOC Completion

Course completion was defined as completing modules 1 to 6 of the MSOC as module 7 comprised a closing session and did not provide lifestyle-related information. Course noncompletion was defined as completing module 1 but failing to complete module 6. At the end of each run of the 6-week IC and SCC, all participants (including those who did not complete the

XSL•FO
RenderX

course) were emailed a voluntary postcourse evaluation survey to complete. Invited participants who did not complete the voluntary evaluation survey were then sent a further email reminder 2 weeks later.

Participant Sociodemographic and Health Characteristics

Participants submitted a baseline survey before course commencement via the online course platform. The baseline survey collected a range of sociodemographic characteristics (eg, sex, age, highest attained educational level, employment status, partnership status, and country of residence) and health data, including MS type (categorized into nonprogressive [benign or relapsing-remitting MS] and progressive [primary progressive, secondary progressive, or progressive-relapsing MS]); MS duration (in years), derived from the year of diagnosis and the year of survey completion; BMI, calculated from weight and height squared and categorized into underweight (<18.5 kg/m^2), normal weight (18.5-24.9 kg/m^2), overweight (25.0-29.9 kg/m^2), and obese (≥30.0 kg/m^2) according to World Health Organization guidelines; treated comorbidities queried via the Self-Administered Comorbidity Questionnaire and then dichotomized (≤1 or >1); DMT use (no or yes); and self-reported ongoing symptoms of relapse in the preceding 30 days (no or yes). Participants were also queried about whether they were taking medications for their MS.

Patient-Reported Outcome Measures

Fatigue was measured using the 9-item Fatigue Severity Scale, with mean Fatigue Severity Scale scores of >5 indicating clinically significant fatigue [26]. Disability was assessed using the Patient-Determined Disease Steps [27,28], a self-reported assessment of ambulatory disability that has been validated against the Expanded Disability Status Scale and is classified into 3 categories: normal or mild (0-2), moderate (3-5), and severe (6-8). The 14-item Hospital Anxiety and Depression Scale was used to assess anxiety and depressive symptoms [29,30]. This tool comprises 7 questions each for anxiety and depression rated on a Likert scale from 0 to 3 and has been validated in people living with MS [31]. Health-related QoL was assessed using the psychometrically validated Multiple Sclerosis Quality of Life–54 (MSQOL-54) instrument [32]. The Physical Health Composite and Mental Health Composite were derived from relevant subscales per the MSQOL-54 guidelines. Although minimal clinically important differences have not been established for the MSQOL-54 composite scores, differences of ≥5 points have previously been determined as the minimum clinically meaningful change in a health-related QoL measure [33,34].

Motivators of and Barriers to Course Completion

Participants completing either the IC or SCC (completers) were queried on motivating factors that facilitated course completion, with multiple-choice options offered: “Convenience/flexible time and location,” “Opportunity to participate in MS research,” “Topics that were relevant and/or important to me,” “The course was interesting,” “Connection and interaction with other people with MS,” “Engagement with facilitators,” “To optimize my health,” and “Other (specify in text).” Participants could select more than one response to this question.

Participants not completing either the IC or SCC (noncompleters) were asked to identify obstacles or issues they encountered that prevented course completion. Multiple-choice options offered included “Technical issues (e.g., computer, internet connection, website),” “Problems with navigating the modules,” “Lack of time or inability to schedule conveniently,” “Irrelevant/unimportant course content/topics,” “Low quality/attractiveness of course pages/videos/materials,” “Health related to MS,” “Other health issues,” “Family or work issues,” “Participation in another course or intervention,” “Did not receive reminder emails,” and “Other (specify in text).” Participants could select more than one response to this question.

Participants’ Levels of Satisfaction With the MSOC

Completers were queried regarding their satisfaction with the corresponding courses. This included two questions related to (1) overall course experience, measured on a 6-point Likert scale from “excellent” to “very poor” (responses were categorized into “Excellent/very good,” “Good/average,” and “Poor/very poor”); and (2) how likely they would be to recommend the course to a peer or family member with MS, measured on a 5-point Likert scale ranging from “Extremely likely” to “Extremely unlikely” (responses were categorized into “Extremely/Somewhat likely,” “Neither,” and “Extremely/Somewhat unlikely”).

Familiarity With the Course Content and Additional Information Seeking

Completers were asked to rate their familiarity with the course content before commencing the course using a 5-point Likert scale with options from “All of the content was new to me” to “I was familiar with all of the content.” Responses were categorized into “Familiar with most/all the content,” “Some of the content was new,” and “All/most of the content was new.”

Completers were also asked to select from a list of topics related to each module that they would like to receive additional information on (eg, “What is MS,” “Sunlight and vitamin D,” and “Exercise”; *yes* or *no*).

Community Forum Engagement

We assessed engagement with the facilitator-run community forum by querying completers on whether they participated in the forum during the course (yes or no) and, if so, whether they found the community forum beneficial (yes or no), with text options provided to expand on these responses.

Intention to Adopt Lifestyle Change Recommendations

To assess whether course engagement could facilitate lifestyle modification, completers were asked to rate their likelihood of adopting the lifestyle recommendations of the IC or SCC. The following question was asked for each topic or module: “As a result of taking the course, how likely are you to change the following lifestyle behaviour? (diet, smoking cessation, omega-3 supplementation, sun exposure or vitamin D supplementation, physical activity, meditation, and other stress reduction activities).” Responses were rated on a 5-point Likert scale: “extremely unlikely,” “moderately unlikely,” “neither,”

XSL•FO
RenderX

"moderately likely," and "extremely likely," resulting in a total score ranging from 0 to 5. Participants selected "not applicable" if they already adhered to the lifestyle recommendation (eg, nonsmoking).

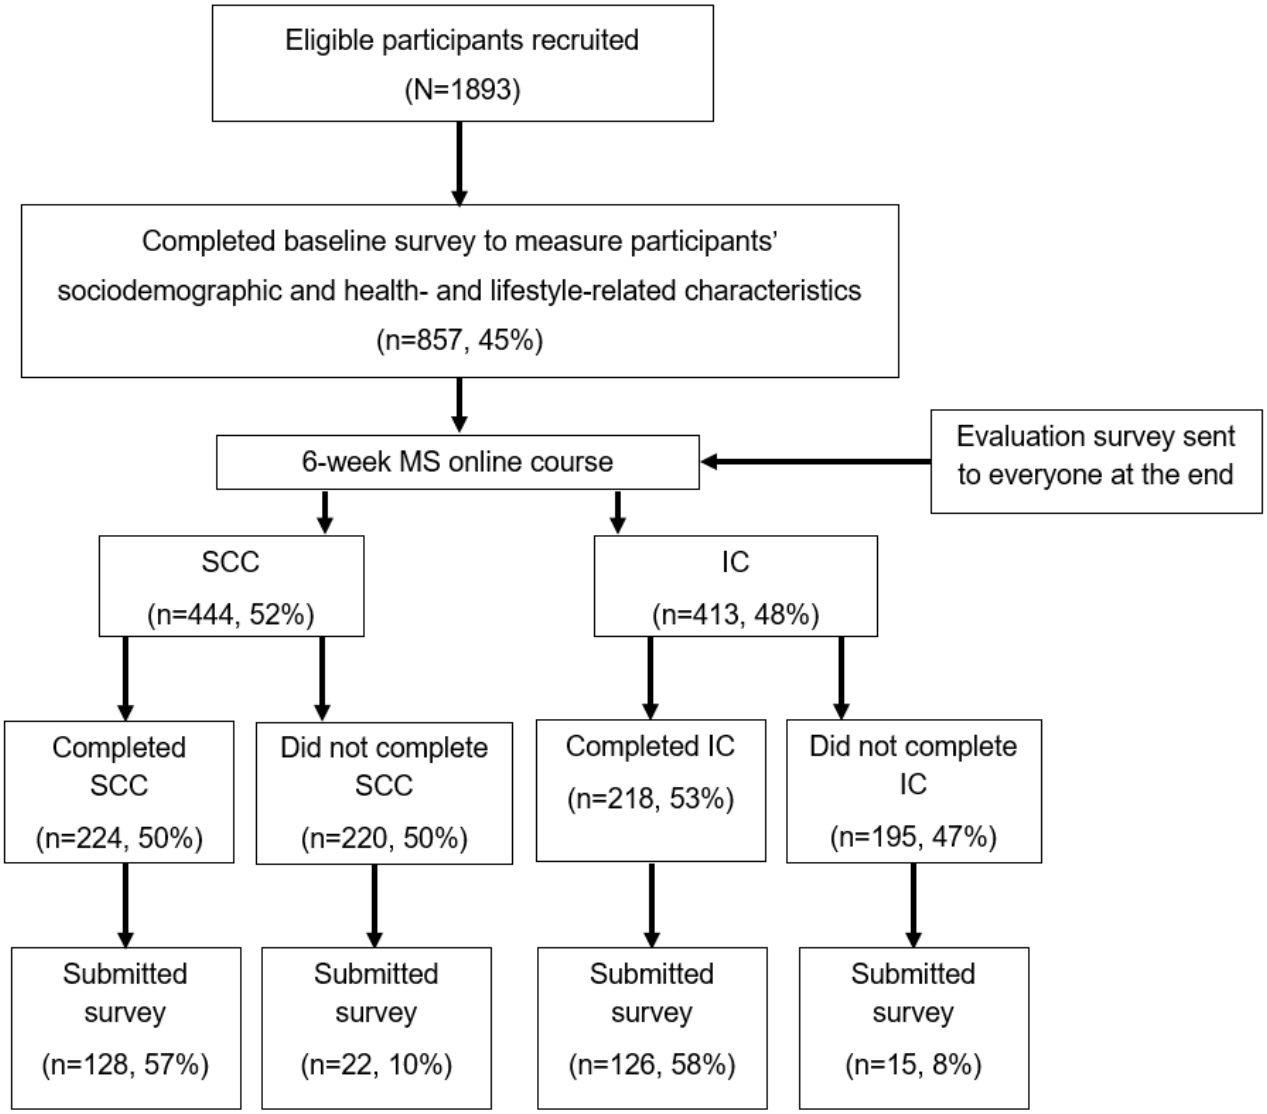
Statistical Analysis

Participant Characteristics and Group Engagement

Demographic characteristics of the study participants at baseline were examined as sample sizes and percentages (categorical variables) and means and SDs (continuous variables). Motivators of and barriers to course completion, course satisfaction levels, engagement with the community forum, interest in seeking additional information on course topics, and intention to adopt lifestyle recommendations of the IC and SCC were examined as percentages. Differences between the IC and SCC groups were assessed using the 2-tailed *t* test for continuous variables and chi-square tests for categorical variables.

Assessing Factors of Intention to Implement Lifestyle Changes

We examined whether participant- or course-related factors were associated with participants' intention to adopt individual lifestyle recommendations among course completers. Multivariate linear regression models were conducted to estimate adjusted regression coefficients and 95% CIs adjusting for baseline engagement with lifestyle recommendations and participation in another lifestyle or intervention program. To assess differences between the IC and SCC, we conducted moderation analyses by adding an interaction term (group × lifestyle behavior) to the regression models. All statistical analyses were conducted using Stata (version 17.0; StataCorp). Statistical significance was set at $P<.05$.



Results

Participant Characteristics

In total, 857 participants (aged ≥18 years with a confirmed clinical diagnosis of MS) enrolled in the MSOC effectiveness RCT and completed the baseline survey (IC: n=413, 48.2%; SCC: n=444, 51.8%; Figure 1). The analysis cohort comprised 291 participants (n=254, 87.3% course completers and n=37, 12.7% course noncompleters) who completed the baseline survey and postcourse evaluation survey.

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. IC: intervention course; MS: multiple sclerosis; SCC: standard-care course.

There were similar numbers of participants (141/291, 48.5% IC participants and 150/291, 51.5% SCC participants) across both study arms (Table 1). Participants were 87.6% (255/291) women, and the mean age was approximately 50 years (SCC: mean 50.6, SD 10.7 years; IC: mean 49.8, SD 11.5 years). On the basis of visual inspection alone, participants' sociodemographic characteristics appeared similar across both study arms except for BMI—the percentage of participants with obesity was lower in the IC (28/141, 19.9%) than in the SCC (48/150, 32%). A large proportion of participants held a university degree (187/291, 64.3%) and were partnered (210/291, 72.2%). Approximately half (141/291, 48.5%) of the participants were employed. The most frequent regions of residence were North America and Australia and New Zealand (Table S2 in Multimedia Appendix 4).

Most participants had nonprogressive MS types, and the mean time since diagnosis was approximately 10 years (SCC: mean 9.6, SD 8.43 years; IC: mean 10.0, SD 8.87 years). Approximately half of the participants reported no or mild disability (144/291, 49.5%) or clinically significant fatigue (159/291, 54.6%). On average, participants reported at least one comorbidity that was either physical or mental health–related. Approximately two-thirds of the participants reported symptoms of depression (183/291, 62.9%) and were taking medication to manage their MS (194/291, 66.7%), and 47.1% (137/291) had symptoms of anxiety within the normal range.

Motivation for and Barriers to Completion

Among the 857 participants who completed the baseline survey, course completion rates were 50.5% (224/444) for the SCC and 52.8% (218/413) for the IC (Figure 1). Among the course completers, 57.1% (128/224) and 57.8% (126/218) of SCC and IC participants, respectively, completed the postcourse evaluation survey (Table 2). The main motivation for course completion was similar between both groups regarding the "opportunity to participate in MS research" (SCC: 104/128, 81.3%; IC: 96/126, 76.2%). Other commonly reported motivators of course completion included "topics were relevant" (SCC: 88/128, 68.8%; IC: 89/126, 70.6%), "convenience/flexible time" (SCC: 88/128, 68.8%; IC: 83/126, 65.9%), "to optimize my health" (SCC: 77/128, 60.2%; IC: 86/126, 68.3%), and "the course was interesting" (SCC: 67/128, 52.3%; IC: 68/126, 54%). Less common motivators of completion were "connection and interaction with others" (SCC: 7/128, 5.5%; IC: 20/126, 15.9%) and "engagement with facilitators" (SCC: 8/128, 6.3%; IC: 14/126, 11.1%).

Of the 417 participants who did not complete the course, 37 (8.9%) completed the evaluation survey (22/222, 9.9% SCC noncompleters and 15/195, 7.7% IC noncompleters; Figure 1). Among noncompleters, the most commonly reported barriers to course completion were "lack of time or inability to schedule conveniently" (SCC: 9/22, 41%; IC: 7/15, 47%) and "technological issues" (SCC: 7/22, 32%; IC: 2/15, 13%). Other barriers to completion were "health issues" and "family or work-related issues," and low quality or attractiveness (ie, the course content lacked visual appeal or was not interesting) was reported by 14% (3/22) of SCC participants but no IC participants.

Participant Satisfaction

Most course completers were satisfied with the course across both study arms (78/128, 60.9% of SCC completers vs 92/126, 73% of IC completers rated the course as “excellent/very good,” and 48/128, 37.5% of SCC completers vs 32/126, 25.4% of IC completers rated it as “good/average”; Table 3). Less than 2% of completers across both study arms (SCC: 2/128, 1.6%; IC: 2/126, 1.6%) rated the course as “poor/very poor.” Most course completers (SCC: 106/128, 82.8%; IC: 113/126, 89.7%) were “extremely likely” or “somewhat likely” to recommend the course to friends or family members with MS, whereas approximately 4% (SCC: 5/128, 3.9%; IC: 5/126, 4%) were “extremely unlikely” or “somewhat unlikely” to recommend the course.

Familiarity With Course Content and Information Seeking

More SCC completers (102/128, 79.7%) compared with IC completers (87/126, 69%) were familiar with some or all the course content before taking the course, and only 3.1% (4/128) of SCC completers and 9.5% (12/126) of IC completers found that all or most of the course content was new (Table 3). When course completers were queried as to whether they would like to receive additional information on each course topic, the most common topics selected by ≥24% of SCC and IC completers were "diet," "physical activity (exercise)," "stress management," "medication and family prevention," and "review and consolidation" (Table 4). There was less interest in receiving additional information on "what is MS" (SCC: 12/128, 9.4%; IC: 16/125, 12.8%) and sun exposure (SCC: 24/128, 18.8%; IC: 17/125, 13.6%). Key topics of interest that SCC completers expressed greater interest in receiving additional information on than IC completers included physical activity (SCC: 49/128, 38.3%; IC: 30/125, 24%; $P=.01$) and "review and consolidation," which was part of the conclusion module (SCC: 63/128, 49.2%; IC: 32/125, 25.6%; $P<.001$).

Table 4. Topics that course completers would have liked additional information on[a].

Topic	SCC[b] (n=128), n (%)	IC[c] (n=125), n (%)
What is MS[d]	12 (9.4)	16 (12.8)
Diet	56 (43.8)	48 (38.4)
Sunlight and vitamin D	24 (18.8)	17 (13.6)
Physical activity	49 (38.3)	30 (24)[e]
Stress management	62 (48.4)	46 (36.8)
Medication and family prevention	41 (32)	32 (25.6)
Review and consolidation	63 (49.2)	32 (25.6)[f]

RenderX

Community Forum Engagement

A lower proportion of participants in the SCC (32/128, 25%) than in the IC (55/126, 43.7%) engaged with the community forum within the course. Furthermore, most completers who engaged with the forum found it useful (SCC: 23/32, 72%; IC: 44/55, 80%), with reasons including "appreciated the opportunity to gain insights from others' experiences," "highlighted the benefits of receiving answers to their questions," "provided valuable resources from facilitators," and "appreciated the ability to share their own perspective and experiences." In contrast, the 2 main reasons why completers did not find the forum useful included "the limited ability to directly reply to and engage with other course members" and "the low number of participants in the forums."

Participants' Intention to Make Lifestyle Modifications

A large proportion of IC and SCC completers intended to adopt lifestyle recommendations, particularly diet, sun exposure, physical activity, and stress management (Table 5). However, a smaller proportion of SCC versus IC completers were "extremely likely" or "moderately likely" to make changes in their diet based on the corresponding course content (74/128, 57.8% vs 89/125, 71.2%; *P*=.04). SCC completers were also less likely to increase their sun exposure (62/124, 50% vs 82/124, 66.1%; *P*=.01), supplement with omega-3 (60/126, 47.6% vs 84/125, 67.2%; *P*=.004), and practice meditation (66/126, 52.4% vs 85/124, 68.5%; *P*=.009). Of note, the SCC did not contain specific recommendations regarding sun exposure, omega-3 supplementation, or meditation practice (Table S1 in Multimedia Appendix 4).

Table 5. Intentions of participants in the intervention course (IC) and the standard-care course (SCC) to implement lifestyle changes.

Lifestyle change	SCC (n=128)[a], n (%)			IC (n=126)[b], n (%)			*P* value
	Extremely likely or moderately likely	Neither, extremely unlikely, or moderately unlikely	Not applicable	Extremely likely or moderately likely	Neither, extremely unlikely, or moderately unlikely	Not applicable

Factors Associated With Participants' Intentions for Lifestyle Modifications

Multivariate analysis found associations between several course-related factors and completers' intentions to adopt the lifestyle recommendations of each course (Table 6).

In particular, course satisfaction was associated with an intention to adopt vitamin D supplementation among SCC completers, whereas among IC completers, course satisfaction was associated with an intention to adopt dietary recommendations, vitamin D supplementation or sun exposure, and meditation practice. For example, IC completers who rated the course as "very good" or "excellent" had a 1.69-point (95% CI 0.24-3.13) higher intention to adopt a healthy diet due to the course. Engagement with the community forum, new course content, and seeking additional information on certain topics were also associated with intentions to change certain factors, with no group differences between the SCC and IC.

[a]We assessed associations between sociodemographic and course- and health-related factors and participants' intention to making changes in the healthy lifestyle behavior (range from 0=extremely unlikely to 4=extremely likely). Multiple linear regression models were used to estimate adjusted regression coefficients and 95% CIs adjusting for baseline lifestyle behaviors and involvement in other lifestyle interventions or programs. Differences between the SCC and IC were assessed using interaction analyses.

[b]aβ: adjusted regression coefficient.

[c]High satisfaction: participants who rated their overall satisfaction with the course as "very good" or "excellent."

[d]*P*<.05 between factors and intentions for lifestyle change within the SCC or IC.

[e] Group difference (*P*<.05) from SCC.

[f]*P*<.001 between factors and intentions for lifestyle change within the SCC or IC.

[g]*P*<.01 between factors and intentions for lifestyle change within the SCC or IC.

[h]Learning new content: participants who rated the course content as "most," "all," or "some" being new.

[i]MS: multiple sclerosis.

[j]DMT: disease-modifying therapy.

Sociodemographic factors associated with intentions for lifestyle modifications included age (being aged >54 years was associated with intentions to increase physical activity and supplement with omega-3, with the latter being significantly lower in SCC vs IC completers), employment status (being employed was associated with a higher intention to practice meditation among SCC completers and a lower intention among IC completers), educational level (a university degree was associated with a greater intention for diet changes and omega-3 supplementation among SCC vs IC completers).

Regarding health-related factors, longer MS duration (>15 years since diagnosis) was associated with a greater intention for dietary modifications and vitamin D supplementation among SCC versus IC completers. The use of DMTs and the presence of comorbidities were associated with intentions to adopt certain lifestyle modifications, with no significant differences between study arms.

Poorer participant-reported health outcomes at baseline were linked to higher intentions to adopt various lifestyle modifications, particularly among SCC completers (Table 7). Severe anxiety, depression and disability, and clinically significant fatigue were associated with greater intentions to adopt dietary modifications, vitamin D supplementation, increased sun exposure, and physical activity among SCC versus IC completers. However, higher physical and mental QoL was associated with lower intentions to modify vitamin D intake, omega-3 supplementation, and physical activity among SCC completers.

[a]We assessed associations between health outcomes and participants' intention of making changes to the healthy lifestyle behavior (range from 0=extremely unlikely to 4=extremely likely) in each course. Multiple linear regression models were used to estimate adjusted regression coefficients and 95% CIs adjusting for baseline lifestyle behaviors and involvement in other lifestyle interventions or programs. Differences between the SCC and IC were assessed using interaction analyses.

[b]aβ: adjusted regression coefficient.

[c]Hospital Anxiety and Depression Scale.

[d]*P*<.05 between health outcomes and intentions for lifestyle change within the SCC or IC.

[e] Group difference (*P*<.05) from SCC.

[f]*P*<.01 between health outcomes and intentions for lifestyle change within the SCC or IC.

[g]Clinically significant fatigue (Fatigue Severity Scale).

Discussion

Principal Findings

Despite the potential advantages of digital health interventions for people living with MS in terms of accessibility and cost-effectiveness, their engagement with web-based interventions is low [18]. This study comprehensively evaluated factors associated with engagement with a novel web-based lifestyle-related program, the MSOC, by people living with MS and examined short-term outcomes following course completion nested within the flagship RCT. Findings revealed that participants in both study groups (SCC and IC) found the course content interesting and useful and reported high levels of course satisfaction. Importantly, there was evidence that the course promoted intentions to implement lifestyle behavior changes, and key factors associated with these intentions were identified across both study arms. These findings provide new insights for designing and implementing web-based lifestyle interventions tailored to the MS community, addressing critical gaps in usability, engagement, and learnability of digital health solutions.

Course Completion

We observed completion rates of 23.3% (442/1893) for enrolled participants and 51.6% (442/857) among those who completed the baseline survey. These completion rates are noteworthy considering that participants were required to complete a 166-question baseline survey, and a previous scoping review reported 5% to 15% completion rates of health education massive open online courses (MOOCs) by the general population [35]. Given the documented desire of people living with MS to receive lifestyle-related information to improve their future health prospects [25], this may explain the higher rates of completion in this study. Similarly, this cohort enrolled in the RCT may represent a subgroup of highly motivated people living with MS.

Motivators of and Barriers to Completion

Primary factors contributing to course completion included the "opportunity to participate in MS research" and "to optimize my health." These findings align with those of the MSOC feasibility study [26], where many people living with MS reported that these factors were crucial to their engagement with the course. The intention of people living with MS to contribute to MS research is consistent with previous findings and represents one of the most common reasons why individuals engage in any research [27]. In addition, participants considered relevant course content and the flexibility to engage with the course in their own time as factors that influence course completion.

Primary barriers to completion were time constraints and technical issues. Other completion barriers included health-, family-, and work-related commitments. While MS-related studies examining noncompletion of web-based courses are limited, a recent mixed methods study of a 6-week MOOC called Understanding MS aimed at increasing understanding and awareness of MS also found that time constraints and MS-related symptoms were common completion barriers [36]. Other studies have also identified barriers to the uptake of web-based health interventions, such as older age, lower educational level, and MS symptoms [37].

Course Satisfaction, Familiarity, and Seeking of Additional Information

While course satisfaction was high across both study arms, satisfaction levels were higher in the IC arm than in the SCC arm (IC: 92/126, 73%; SCC: 78/128, 60.9%). Due to the quantitative nature of our evaluative study, we can only speculate why participants found the course satisfactory. Plausible reasons for high course satisfaction may be participants' strong interest in obtaining information on healthy lifestyle recommendations or self-management strategies to improve their future health prospects, as found in the qualitative studies of this trial, where participants expressed that they sought new knowledge to empower them to self-manage their MS [21,22].

The positive tone of the MSOC may have further contributed to the high satisfaction rates as this was found to be an important factor in the qualitative aspect of the MSOC feasibility RCT [38,39]. Similarly, "keep it positive" was 1 of the 3 core principles for developing the 6-week Understanding MS MOOC [40].

Participants in the SCC arm were more familiar with the course content and expressed greater interest in receiving additional lifestyle-related information than those in the IC. This is not surprising due to the SCC course content being sourced from publicly available MS society websites, whereas the content of the IC was novel for many IC participants. People living with chronic illnesses such as MS often exhibit a strong desire for new information to enhance their understanding and management of their condition [41]. Seeking additional information may reflect participants' motivation and engagement with digital health interventions aimed at disease self-management. Similarly, digital interventions for diabetes and rheumatoid arthritis have shown that reliable, professional guidance is particularly valued, especially by newly diagnosed individuals [42,43].

Interestingly, while the SCC provided information from readily available sources such as international MS websites, only a small proportion of participants (SCC: 2/128, 1.6%; IC: 2/126, 1.6%) were dissatisfied with the course, and a substantial proportion (SCC: 106/128, 82.8%; IC: 113/126, 89.7%) indicated that they would recommend the course to others. These findings are consistent with those of the MSOC feasibility study [39], where the MSOC was found to meet participants' expectations regardless of their familiarity with the course materials.

While new information that addresses knowledge gaps is critical for engaging participants in digital interventions, current findings suggest that even those familiar with the material can benefit when interventions provide fresh perspectives and dynamic delivery formats. Digital health interventions that offer updated, evidence-based content tailored to diverse participant needs—ranging from foundational knowledge for beginners to

XSL•FO
RenderX

advanced updates for experienced users—are likely to achieve higher satisfaction and engagement.

Community Forum Engagement

In the previous MSOC feasibility RCT, there was no engagement with the forum [39]. Although participants expressed positivity regarding the advantages of the forum in terms of connecting with other people with MS, they felt nervous and were reluctant to initiate discussions. This limitation was anticipated to potentially affect course completion as a pilot RCT of a web-based self-management program for fatigue for people living with MS found that lower interaction and support were associated with increased study dropout [12]. To address this issue in the current MSOC effectiveness RCT, a researcher facilitator was introduced into the community forum in each course. The facilitator, who was familiar with the evidence-based recommendations and course content, was responsible for initiating conversations, creating discussions, and answering participants' queries to encourage participant interaction and, ultimately, course completion. Subsequently, we found that 25% (32/128) and 43.7% (55/126) of participants in the SCC and IC study arms, respectively, engaged with the forum in this study.

Notably, the engagement with the facilitator-led community forum did not significantly improve course completion rates (IC: 218/413, 52.8%; SCC: 224/444, 50.5%) compared to the feasibility study (59% in the IC and 50% in the SCC). Furthermore, facilitators were cited as a motivating factor for course completion by only a small proportion of participants (SCC: 8/128, 6.3%; IC: 14/126, 11.1%), although limited forum engagement, with less than half of the participants actively taking part, likely constrained its impact on course completion. Key barriers to forum engagement identified by the participants included the inability to directly reply to one another (restricted to only replying in a group thread) and the small number of forum participants. As shown in previous digital health interventions, participants with neurological disorders particularly value emotional support from others with similar conditions [44]. Addressing these restrictions could create more opportunities for meaningful interaction and enhance the potential benefits of peer support in future iterations.

Interestingly, among those who did participate in the forum, most found it helpful (SCC: 23/32, 72%; IC: 44/55, 80%), particularly for accessing shared resources and gaining insights from others. These findings align with the findings of the 2 qualitative studies related to this RCT [21,22] and existing evidence [45] suggesting that participants are more likely to engage with digital health interventions that promote both social connectedness and information sharing.

Overall, while facilitator-led forums hold promise, the presence of a facilitator alone may not be sufficient to drive higher course completion rates. Introducing structured activities or prompts could further encourage engagement and foster dynamic conversations that extend beyond a small subset of participants.

Participants' Intentions to Undertake Lifestyle Modifications

The overarching aim of the MSOC was to improve QoL and health outcomes in people living with MS. Preliminary evaluation found that course completers across both study arms intended to initiate lifestyle modifications following the course. According to the theory of planned behavior [46], intentions serve as crucial predictors for behavior change, thereby providing support for the potential of the MSOC to encourage lifestyle modification in people living with MS. This will be assessed in detail by analyzing primary and secondary outcomes of the RCT at the 6-, 12-, 24-, and 30-month follow-ups.

Across both study arms, physical activity and stress reduction activities that did not include meditation practice were the most common lifestyle recommendations that participants intended to adopt. Notably, significantly more IC completers intended to increase their sun exposure, supplement with omega-3, and practice meditation than SCC completers. This finding was expected considering that no specific recommendations regarding these lifestyle modifications were provided in the SCC. In contrast, the SCC provided more general dietary information, emphasizing the importance of a balanced diet and providing information on the vast range of MS-related diets adopted by people living with MS.

A recent systematic review of web-based health education interventions found that most included studies focused on knowledge gain as the main outcome, whereas the impact of knowledge gain on other outcomes such as lifestyle modification was less clear [18]. However, the Understanding MS MOOC study did examine lifestyle modification in people living with MS 8 to 10 weeks after course completion and found that 43% to 52% of participants had made improvements in their diet quality, increased their physical activity, and initiated supplementation with vitamin D [47]. Of note, these modifications were observed despite only 1 of the 6 MOOC learning modules providing information on lifestyle-related risk factors. Collectively, the aforementioned study combined with our study findings demonstrates that web-based learning can potentially facilitate lifestyle modification in people living with MS. The findings are consistent with meta-analytic evidence of the effects of web-based lifestyle interventions in improving diet quality and increasing physical activity in survivors of cancer [48] and people with cardiovascular disease [49].

Factors Associated With Intentions to Undertake Lifestyle Modifications

Understanding factors that may influence individuals' experiences with web-based lifestyle interventions is important in optimizing the effectiveness of tailored programs. In this study, course-related factors were associated with participants' immediate learning outcomes. For instance, higher course satisfaction and an interest in seeking new information correlated with a greater intention to implement lifestyle modifications across both study arms, consistent with previous reports of links between knowledge gain and increased motivation [50].

Engagement with the forum was also associated with participants' intentions to change certain lifestyle behaviors,

XSL•FO
RenderX

consistent with previous study findings indicating that social connections made with peers during educational programs are important for engagement [51,52] and can mediate lifestyle changes [53]. In particular, a recent systematic review found that human support was a crucial component in the effectiveness of web-based behavior change interventions [19]. Furthermore, engagement with health care professionals in an MS-related face-to-face lifestyle program was found to increase participants' sense of control and agency in adopting lifestyle changes [52,54]. Overall, these results highlight the importance of facilitator-led community forums as integral components of digital health interventions. With tailored design and implementation, these features could be optimized to promote increased health-related knowledge and support lifestyle changes.

Of interest, a large proportion of SCC completers expressed their intention to change their lifestyle despite being familiar with the course content. Therefore, the SCC may have served to refresh or reinforce their existing knowledge. Engagement with information presented in a different setting or format (eg, animation and videos) may also have been a motivating factor for facilitating intentions for lifestyle changes. Alongside the observed high satisfaction levels, these results highlight the perceived value of the MSOC irrespective of participants' previous familiarity with the course materials, translating acquired or refreshed knowledge into motivational changes. This insight offers a key recommendation for future digital health design: developing modules that cater to both beginners and those with previous knowledge. For participants already familiar with the content, modules can serve as a refresher or provide new perspectives through web-based and visually engaging formats such as animations, videos, or quizzes.

Interestingly, other participant-related factors were also associated with intentions for lifestyle change. For instance, higher educational level was associated with lower intention for lifestyle change, consistent with studies indicating that participants with lower educational levels find course content more informative and applicable [17,55]. This highlights the importance of using clear, practical messaging and simplifying language and concepts to ensure accessibility for a broad audience. Disability was associated with an intention for diet change, vitamin D supplementation, and increased physical activity in the SCC but not in the IC. This may be attributed to the content of the SCC as it may not be possible for someone with a severe disability to adopt the restrictive diet or physical activity recommendations of the IC, especially if they rely on carers. As a result, it is important to consider course content and its applicability to people living with MS of all abilities.

In addition, SCC participants with severe mental health issues and lower QoL reported higher intentions to adopt lifestyle modifications. However, interestingly, our analysis of baseline characteristics and course completion in this RCT found that those with poor health status at baseline were less likely to complete the course [20]. While participants with poorer health may face physical or psychological challenges that reduce their likelihood of completing web-based courses, collectively, our results suggest that participants who complete web-based courses have a higher likelihood of implementing behavior change. Moreover, these findings suggest that future digital health interventions need to be designed to attempt to overcome course noncompletion, possibly by implementing tailored and motivational strategies such as progress tracking, personalized feedback, and interactive support tools to help overcome barriers to engagement to maximize the benefits of these programs.

Strengths and Limitations

This study sample represents a large and diverse international cohort of people living with MS, with characteristics similar to those of other international cohorts [7,37]. The findings expand on previously documented qualitative insights from this trial [21,22], providing a more comprehensive understanding of user experiences and engagement with web-based educational programs. The MSOC's utility as a web-based program demonstrates the potential of digital interventions to reach large, geographically diverse populations. This scalability is particularly beneficial for other chronic conditions for which health care access may be limited.

Various limitations should be considered. First, the study sample was restricted to RCT participants who completed the baseline and evaluation surveys. As research on web-based health interventions for chronic illnesses is likely to face challenges in recruiting and retaining participants [16,55], our study sample may be biased toward healthier individuals or those highly motivated to acquire lifestyle-related knowledge and adopt lifestyle changes. Second, while efforts were undertaken to recruit participants through various channels worldwide, this study also primarily involved participants from English-speaking countries with convenient internet able to access the recruitment sites. Consequently, the generalizability of the results may be limited, warranting caution in their interpretation. Third, the sample size of noncompleters across study arms may be considered small. This increases the risk of selection bias, potentially limiting the generalizability of the findings to a broader population of noncompleters. Nevertheless, identifying barriers to course completion, such as time limitations and technical and health-related issues, provides important insights for informing the development of web-based programs. For example, extending the course to >6 weeks may allow more participants to complete it, a strategy supported by findings from the Understanding MS MOOC study [36]. Other considerations may include presenting participants with incentives to complete the MSOC, such as completion certificates [56]. Furthermore, it is important to consider health disparities within the MS community to ensure that course content is appropriate for web-based interventions.

Conclusions

The evaluation of the MSOC in this study provided new and valuable insights for the development of future web-based programs for people living with MS. Participants expressed high levels of satisfaction with the MSOC and strong intentions to adopt lifestyle modifications, even among those already familiar with the course content. Notably, course completers with poorer health had stronger intentions to adopt recommended lifestyle changes upon completing the course, underscoring the potential value of web-based interventions among those most likely to benefit. Identifying motivators and

XSL•FO
RenderX

barriers to web-based course engagement could inform future course development to facilitate increased engagement and potentially achieve intervention objectives. Subsequent follow-up studies of the RCT's primary and secondary outcomes will examine the effectiveness of the MSOC intervention in supporting the adoption and maintenance of lifestyle changes and achieving the primary outcome of the study (clinically significant improvements in QoL). Overall, tailored, accessible, and innovative web-based interventions offer an important platform to assist people living with MS in self-managing their MS and related symptoms and potentially improving their future health prospects.

Acknowledgments

The authors express their sincere gratitude to all participants of the Multiple Sclerosis Online Course for their generous contribution of time and spirit. Their participation was invaluable, and without it, this study could not have been possible. They also acknowledge the role of their industry partner, JMAcreative, in the redevelopment of the courses. The authors extend special thanks to the project manager, Grace Suhartanto, for her support, guidance, and expertise in redesigning, testing, and implementing the courses. The authors also express their gratitude to the Overcoming MS charity (United Kingdom), who financially supported the technical development of the Multiple Sclerosis Online Course via JMAcreative. This work was supported by the Neuroepidemiology Unit at the University of Melbourne, which is funded by philanthropic donors.

Abstract

Background: Patients with long-term conditions, such as stroke, require regular follow-up visits to health care professionals to identify changes in symptoms. The digital previsit tool Strokehälsa (Strokehealth) has been designed to encourage individuals with stroke to reflect on stroke-related health concerns before a follow-up visit, thereby potentially enhancing their engagement during the visit. Strokehealth has previously been evaluated using a patient satisfaction survey (part 1), but there remains a need to further explore patients' perceptions and needs to optimize its functionality before broader implementation.

Objective: The overall aim was to attain deeper insights into patients' views and experiences of using the digital previsit tool Strokehealth before a follow-up visit. A secondary aim was to identify potential improvements to the tool based on these insights.

Methods: For this qualitative study, patients who had used Strokehealth version 1.0 before a follow-up visit were recruited through the previous survey between November 2020 and June 2021. Individual semistructured interviews were conducted, and data were analyzed using reflexive thematic analysis. Subsequent workshops were held with people with firsthand experiences of stroke, other stakeholders (including health professionals and researchers), and a web consultant to finalize decisions regarding adjustments to be implemented in Strokehealth version 2.0.

Results: Interviews were conducted with 33 participants (23 men and 10 women), with a median age of 67 (IQR 55-76) years. Analysis of the data regarding participants' experiences of using Strokehealth revealed three overarching themes: (1) a supporting tool for preparing dialogue and identifying needs, (2) how Strokehealth is introduced and communicated affects perceived usability, and (3) the wording and structure of Strokehealth influences the response process. The findings captured various aspects of receiving and using the digital previsit tool, highlighting its simplicity and purpose. Overall, Strokehealth was well received and contributed to a sense of being well cared for. Participants generally not only found Strokehealth easy to use but also shared suggestions on how to better address stroke-related issues, such as mental fatigue or pain. Examples of changes that have been implemented in Strokehealth version 2.0, based on participant feedback, include improved explanatory texts and expanded opportunities for free text.

Conclusions: The findings indicate that the freely available digital previsit tool Strokehealth was generally well received by patients with stroke who were scheduled for follow-up visits in outpatient settings.

stroke rehabilitation; post-stroke checklist; person-centered care; follow-up; eHealth; health literacy; patient engagement

Introduction

Health care systems are increasingly adopting digital support to address future challenges and to transition toward more person-centered care [1]. This shift has prompted a significant increase in the development and use of digital services and tools for self-care among community-dwelling people [2]. Advancements in medical care and improvements in health care services are leading to rising numbers of individuals living with conditions that require long-term care, such as stroke [3]. In patients with such conditions, a lack of adequate self-care or health care interventions can lead to serious consequences [3]. Continuous access to health care services is essential to ensure optimal self-management, psychological and emotional support [4,5], and treatment for patients, regardless of their condition [6]. The integration of digital technology can potentially enhance easy access to health care, patient engagement, and self-management [2,7]. However, individuals managing long-term conditions commonly show low eHealth literacy, potentially resulting in their exclusion from digital health resources [8]. Therefore, it is imperative that digital tools be tailored specifically for individuals with diverse health conditions and be designed with enhanced usability and accessibility.

Regular follow-up visits enable caregivers to identify potential health problems, detect symptom changes or worsening at an early stage, and take preventive actions to minimize their impact [9]. Follow-up visits also serve as opportunities to provide patients with support, education, and counseling regarding their condition, treatment options, and symptom management. This helps patients better understand their condition and empowers them to take a more active role in their health care. During follow-up visits, meaningful conversations can be facilitated using tools such as checklists or dialogue aids, for example, the Post Stroke Checklist [10]. However, patients have emphasized the importance of advance preparation to enhance engagement during discussions with health care professionals [11]. Such preparation can be achieved through previsit tools [12,13], which encourage patients to reflect in advance, and thereby make interactions with health care providers more efficient. Accordingly, a previsit tool for individuals with stroke—Strokehälsa ("Strokehealth"), based on the Post Stroke Checklist—was developed in a participatory co-design process with a patient partner, stakeholders, and a service designer [14]. The aim was to create a tool that would enable people—including those with various disabilities—to take an active part in their decision-making process by providing them with targeted questions and time to reflect on stroke-related concerns before their scheduled visit to an outpatient clinic specialized in stroke care [14]. Other previsit tools exist but most are designed to collect physical health data, such as blood glucose levels, or are highly comprehensive (eg, the stroke-related "Rehabkompassen" [15]), and require substantial time and effort from the user. In contrast, Strokehealth was designed to support reflection and communication, rather than extensive data collection.

In short, the content of Strokehealth and the procedure for its use in health care can be described as follows. First, the patient is introduced to Strokehealth version 1.0 through a brief introductory text before answering 14 questions (Multimedia Appendix 1) covering various health-related domains. Each question includes a short explanatory text to clarify and provide examples. To indicate any health concerns, the response choices are "yes," "no," or "choose not to answer." Upon completing Strokehealth, patients have the opportunity to provide additional open-ended comments or information before their scheduled visit. In addition, patients are offered further advisory information about stroke and self-management strategies, which is accessible via a clickable link. In clinical practice, health care providers send Strokehealth to patients via the Swedish national patient portal, prompting them by email or text message to log in and complete the tool. The health care provider—usually a stroke-specialized nurse—then has the option to review the patient's responses in advance and, if necessary, consult other professionals—for example, a physician or an occupational therapist—prior to the appointment, in order to proactively address the patient's concerns, although this step is optional.

In the development and evaluation of complex interventions, contextual factors—including organizational and local conditions—play a decisive role [16]. Therefore, Strokehealth was evaluated in a real-world setting involving patients who were discharged from a stroke unit and scheduled for follow-up visits. A previous study (part 1) was conducted using a web-based patient satisfaction survey, revealing that Strokehealth was perceived to provide a structured framework that facilitated the consideration of important issues in conjunction with health care visits [17]. A wide range of health problems was identified, and 56 out of 58 (96.6%) participants expressed confidence that Strokehealth effectively captured their health-related concerns. Analysis of free-text responses revealed that Strokehealth was viewed as a valuable tool for structured follow-up and was described as enabling increased patient engagement. Participants also noted that Strokehealth provided valuable information, offering enhanced insights into their condition and the available support. Suggestions for improvement included extended response options, the opportunity to develop one's answers, and clearer explanatory texts [17]. Sustainable development and implementation of the previsit tool require evaluating feasibility from different perspectives, especially from the patients' perspective as end users. Thus, it was considered necessary to conduct individual interviews to explore the participants' survey responses in depth and to allow them to elaborate on their suggestions for improvements. The present interview study is an important step in the development and evaluation of Strokehealth before its implementation in health care.

XSL•FO
RenderX

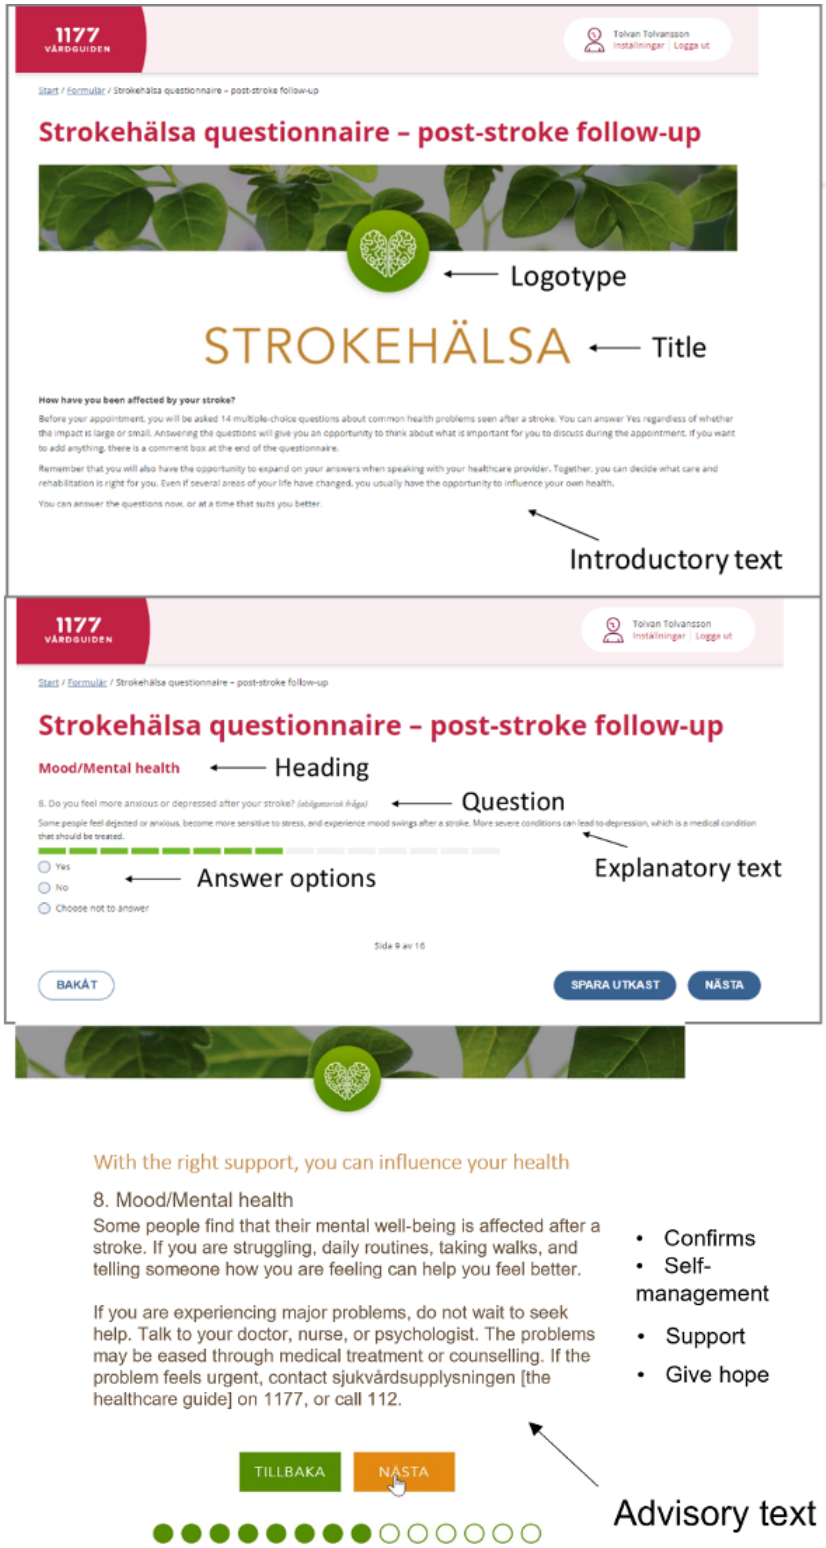
In this study, we aimed to gain deeper insights into patients' experiences with and views on using the Strokehealth digital previsit tool before follow-up visits. A secondary aim was to identify further ways to improve the previsit tool based on these findings.

Methods

Study Design

A qualitative study was conducted [18] as part of a larger research project aimed at developing and evaluating the Strokehealth previsit tool, using quantitative and qualitative methods and following the Medical Research Council framework [16]. The research paradigm guiding this study, as part of the larger project, is inspired by the principles of realistic evaluation based on scientific realism, in which various data sources are used in a pragmatic and flexible manner to explore "what works, for whom, under what circumstances?" [19]. This study involved the interpretative analysis of semistructured interviews to attain insights regarding how different contexts and mechanisms influence outcomes and to inform changes to the previsit tool. In this study, the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist was used to ensure explicit and comprehensive reporting (Multimedia Appendix 2) [20].

Ethical Considerations



Ethical approval was obtained from the Swedish Ethical Review Authority (556-17 and 2020-03324). After logging into the patient portal, patients were presented with information regarding the research project and asked whether they would consent to participate. Only those who provided informed consent were able to proceed with the survey (part 1) [17]. The introductory information made it clear that participation was voluntary and would not impact their medical treatment. No incentives were offered for participation. At the end of the survey, participants were asked a follow-up question about participating in an interview. All transcripts were anonymized before analysis and treated confidentially because they contained health-related information. Only the research team had access to the interview recordings, transcripts, and consent forms. No prior relationship was established between the researchers and participants before the interviews.

Setting and Participants

This study was conducted in the Västra Götaland region of Sweden. The study participants were community-dwelling individuals who had experienced a stroke, had recently used Strokehealth (Figure 1), completed a subsequent patient satisfaction survey, and volunteered to share their more in-depth experiences regarding the tool. Initial participant recruitment was performed consecutively between November 2020 and June 2021 from 3 hospitals in the region. The inclusion criteria were admission to a stroke unit, being scheduled for a follow-up visit to a stroke team nurse after hospital discharge, and having a personal account on the Swedish national patient portal. No exclusion criteria were set. Strokehealth was sent approximately 3 weeks to 3 months after discharge from the hospital, depending on the standard routines of the outpatient clinic.

XSL•FO
RenderX

Figure 1. A screenshot of the elements in the previsit tool Strokehälsa (English version; reproduced from Kjörk et al [14], which is published under Creative Commons Attribution 4.0 International License [21].

A web-based survey was sent to all patients who had used the tool (n=80). The survey was completed by 73% (58/80; 39 men; age: median 67, IQR 56-75 years). The survey included information about its purpose: to gain a better understanding of their experiences using the previsit tool Strokehealth in preparation for their follow-up visit, with a focus on its usability and functionality. At the end of the survey, respondents were asked whether they consented to future contact from the research team regarding a more in-depth interview. It was emphasized that the interviews would contribute to improving follow-up care supported by the tool. A total of 36 patients indicated their interest in further collaboration and were contacted via telephone by the last author (EKK), of whom 33 agreed to participate in individual interviews.

XSL•FO
RenderX

Data Collection

Data were collected using a semistructured interview guide, including questions about experiences and aspects of using Strokehealth (Multimedia Appendix 3). The interview guide was pilot-tested, and no adjustments were deemed necessary; therefore, the pilot interview was included in the present analysis. All interviews were conducted in Swedish over the telephone at prearranged dates and times. At the time of the interviews, only a few participants had completed their follow-up visits. No relationship had been established between the interviewer and the participants before the interviews. The participants' next of kin were allowed to be present and to participate when appropriate. During 2 interviews, a spouse was present for support.

All interviews were audio recorded. The study aims were repeated, and the participants orally confirmed their consent. To ensure high credibility, all interviews began with the same introduction, emphasizing the importance of the participants' experiences and viewpoints and that there were no right or wrong answers. Prompts such as "Could you elaborate on your thoughts?" were used. The duration of the interviews ranged from 8 to 40 minutes (median 24 minutes, IQR 21-28 minutes). All interviews were transcribed verbatim by a person who was not part of the study, using MS Word. The transcripts comprised 289 pages of single-spaced text. No member checks were conducted, and participants were not asked to provide feedback on the results.

Data Analysis

A reflexive thematic analysis [22] was conducted, aligning with an interpretivist paradigm that emphasizes understanding individuals' subjective experiences [18]. Reflexive thematic analysis was deemed an appropriate analytical approach based on the study's focus on the unique experiences of the patients who had used Strokehealth. Furthermore, reflexive thematic analysis entails a flexible process that facilitates the identification, analysis, and reporting of patterns of meaning within interview data [22]. In reflexive thematic analysis, both coding and theme development are flexible processes that evolve throughout the analysis. An inductive approach was used, that is, the analysis was data driven and based on the participants' subjective experiences. Analysis was performed by 2 authors (EKK and PP) using the NVivo software (version 12; Lumivero).

The analysis was performed using the 6-stage framework described by Braun and Clarke (Textbox 1) [22]. Throughout the analysis process, conscious reflections were made, and reflexive thematic analysis facilitated the authors' reflective engagement.

Textbox 1. The 6-stage framework of reflexive thematic analysis.

Stage 1. Both authors independently read and reread all transcripts to become familiar with the data.
Stage 2. Important features related to the research question were identified within the dataset and coded according to their content.
Stage 3. The codes were examined to identify significant patterns of meaning and clustered into potential themes and subthemes.
Stage 4. Themes and subthemes were reviewed against the dataset, and redefined in an iterative process, with continuous back-and-forth between the main texts and the codes.
Stage 5. The themes were analyzed in detail to refine their scope and focus, and informative names were assigned.
Stage 6. Analytical narrative and data extracts were contextualized in relation to existing literature, and the manuscript was produced.

After the completion of the analysis, some of the suggested changes that emerged from the interviews were implemented in Strokehealth, resulting in version 2.0. This process included consultation with members of the advisory board who were involved in the previous study [14]. In addition, a linguist reviewed the text to improve its clarity and structure. Finally, the proposed amendments to Strokehealth were discussed in formal decision-making workshops with the project's research team in collaboration with the patient partner. After the final decision workshop, adjustments to Strokehealth in the patient portal were made through close collaboration between EKK and a web designer. These workshops guided the final decisions about the design of Strokehealth and addressed issues such as clarifying the language by adding or removing text and answer options.

Research Team and Reflexivity

The interviews were conducted by EKK, a female who holds a PhD degree in occupational therapy and is a senior lecturer. She is an established researcher with previous experience in qualitative research and is well published in the fields of stroke rehabilitation and eHealth. Transcripts were cross-checked by PP, a female who holds a PhD degree in physical therapy. She is an assistant professor with previous experience in qualitative research and is well published in the fields of neurological rehabilitation and eHealth.

Results

Participants

The 33 study participants included 23 men and 10 women, with a median age of 67 (range 43-87) years (Table 1). Among these participants, 28 (85%) reported using the web multiple times per day, 3 (9%) reported using it weekly, and 2 (6%) reported using it once per year. Four participants (12%) received assistance in completing Strokehealth.

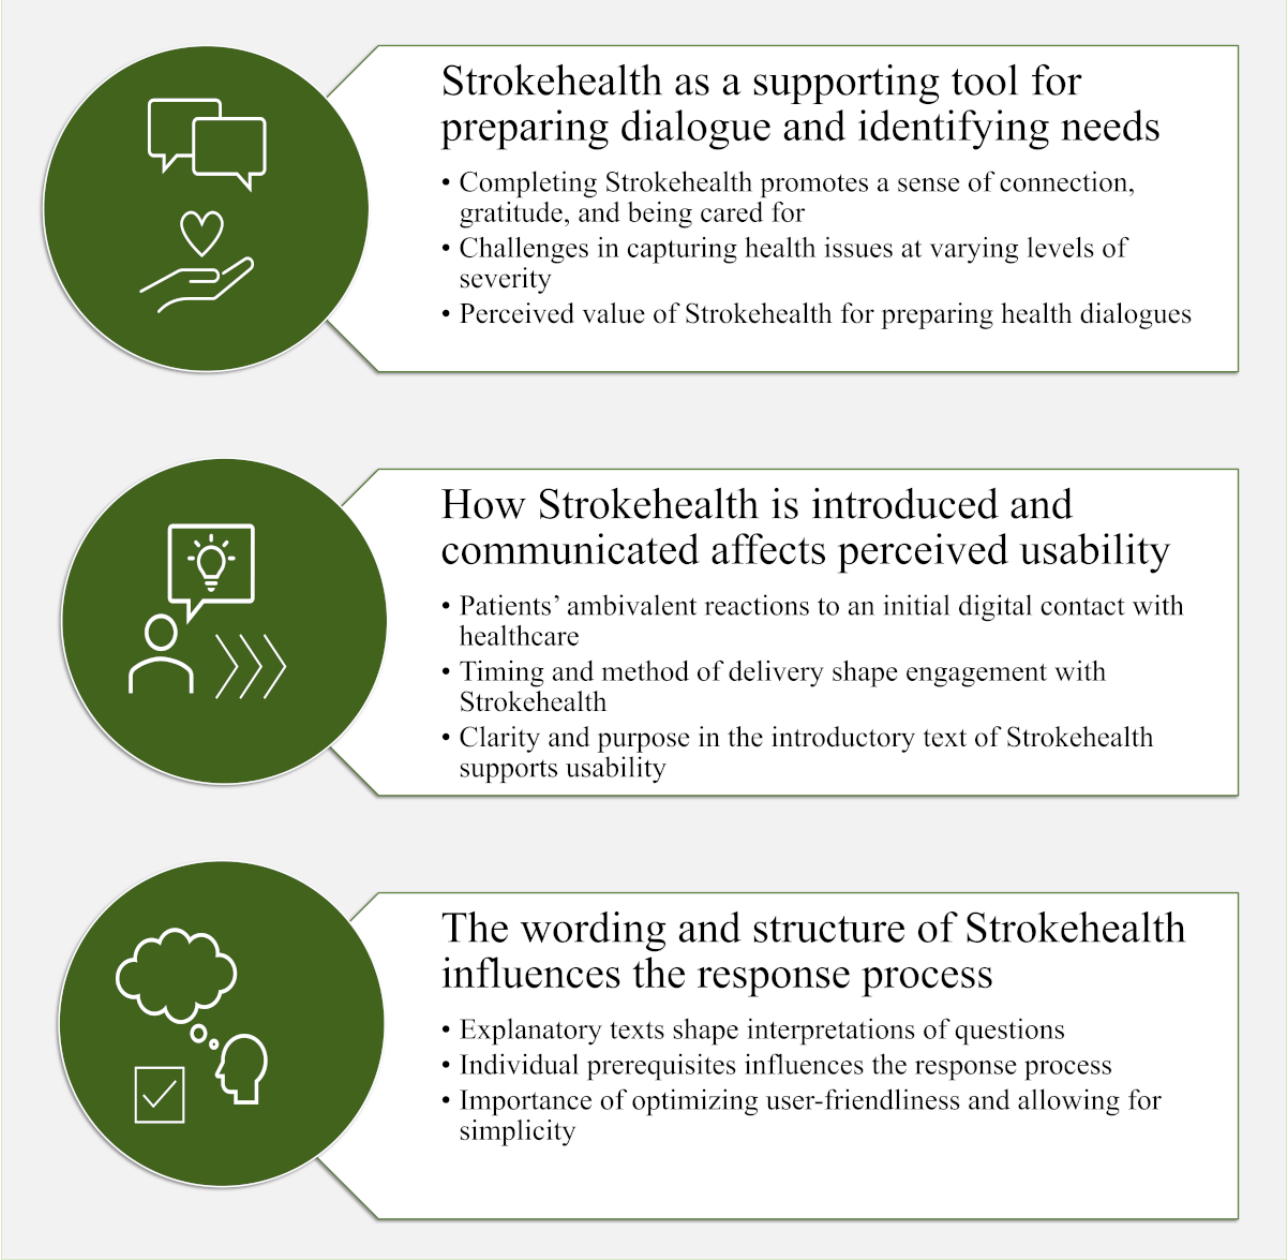
Intracerebral hemorrhage, n (%)	2 (6)
Previous stroke, n (%)	5 (15)
Stroke severity, NIHSS[b], median (minimum-maximum)	1 (0-7)
Stroke-related outcomes	
Length of hospital stay in days median (minimum-maximum)	5.5 (1-35)
Discharged to own home, n (%)	33 (100)

[a]Missing data: without assisted care in own home (n=1), independent (n=1).



[b]NIHSS: National Institutes of Health Stroke Scale; measured ≤24 hours of admission, normal values 0-42. Values are presented as numbers and valid percentages unless stated otherwise.

Themes Created Based on the Individual Interviews

The analysis resulted in the identification of 3 main themes, reflecting the participants' overall experiences with receiving and using the previsit tool before their planned follow-up visit to the nurse. The three main themes were as follows: (1) Strokehealth as a supporting tool for preparing dialogue and identifying needs, (2) how Strokehealth is introduced and communicated affects perceived usability, and (3) the wording and structure of Strokehealth influences the response process (Figure 2).

XSL•FO
RenderX

Figure 2. Themes and subthemes identified from interviews regarding the digital previsit tool Strokehealth.

Strokehealth as a Supporting Tool for Preparing Dialogue and Identifying Needs

This main theme represents aspects of how effectively Strokehealth captured the participants' health issues and how it was perceived in preparing patients for dialogue with health care professionals as well as family members.

Completing Strokehealth Promotes a Sense of Connection, Gratitude, and Being Cared for

The use of Strokehealth as preparation for a visit was perceived to contribute to the sense of being well cared for by health care. Some participants felt reassured by encountering familiar information within the tool, as this validated their existing knowledge and aligned with previous information received from health care providers. This recognition created a sense of connection and reassurance that they were not alone, and that experiencing such issues after a stroke was both expected and normal. Others expressed that the information provided within Strokehealth helped to fill knowledge gaps, supplemented their existing understanding, and brought a sense of hopefulness.

> Participant 2: It's really nice, what I'm looking at right now [advisory text]; it looks really good. It's short, concise, pleasant, and gives hope [laughs]. No, but I think so. I don't really have anything to object to. You can't do more than this, really. It looks nice, good, and informative. [Male, 61 years old]

Completing Strokehealth also evoked feelings of gratitude for being taken seriously by the health care system and for receiving good care. It provided participants with an opportunity to actively reflect on what it meant to have survived a stroke. They felt grateful for not being more severely affected by the stroke and for the confirmation that it could have been much worse, as they read about different problem areas—one question after another.

XSL•FO
RenderX

Challenges in Capturing Health Issues at Varying Levels of Severity

Most participants felt that the questions in Strokehealth were relevant and adequately addressed their health issues, including mental fatigue. However, individuals experiencing very mild symptoms perceived that the questions or the given examples did not fully capture their own experience. This prompted reflections on whether Strokehealth might be better suited for individuals with more severe strokes. One participant experiencing mild aphasia found that none of the questions adequately addressed this specific problem.

Participant 15: It also depends on what level I'm answering from. If I'm answering from an everyday perspective—can I go to the store, talk to my family and friends, participate in Teams meetings, or write messages, emails, or texts—then I have no problems. But if I want to do it at a higher level, workwise, maybe speak another language, and so on, then that's a completely different level, and perhaps a completely different answer to the question. [Male, 43 years old]

Another participant mentioned that none of the questions captured the challenges of everyday tasks that were previously effortless, such as emptying the dishwasher. Now, she had to consider each step while maintaining balance, which made the task exhausting. Participants suggested that more generous open-response areas would allow for detailed explanations of such issues. Participants also found that the questions in Strokehealth were insufficient to capture psychological factors, such as worrying thoughts about the future. They noted that the question related to this topic did not precisely reflect what participants wanted to express.

Perceived Value of Strokehealth for Preparing Health Dialogues

Participants found that completing Strokehealth not only helped them prepare for their follow-up visit but also provided them with a valuable opportunity to reflect on their situation and thoroughly consider their individual needs. They also felt that the tool helped make them aware of certain issues that might not have otherwise been addressed, such as their relationship with loved ones. Some participants even expressed that Strokehealth was valuable for explaining their problems to family members and highlighting common poststroke issues. They suggested that a previsit tool like Strokehealth could be beneficial for structuring and optimizing any health care visit that is often time-limited.

Participant 4: It makes things easier; it becomes like a preparation beforehand. I guess that's the case with all meetings—the more prepared you are, the better it is. If you know what it will be about and can reflect on it beforehand, it's always beneficial. So, I think that's a good thing. [Male, 58 years old]

Participants also reflected on the potential value to the staff if patients filled out Strokehealth, speculating that it might make the meeting more efficient. However, not everyone believed that Strokehealth was necessary; some felt confident about directly articulating their concerns and believed that the nurse was already informed about their problems.

Furthermore, Strokehealth also introduced new vocabulary that inspired them to seek further information in advance—for example, through search engines such as Google—to learn more about their condition and possible interventions. Consequently, this process of independently seeking information further enhanced their preparedness for the upcoming health care encounter.

How Strokehealth Is Introduced and Communicated Affects Perceived Usability

This main theme emphasizes that the way Strokehealth is introduced and communicated to patients plays a crucial role in how the tool is perceived and used. The analysis underscores the significance of offering patients various options for appointment preparation and enabling them to make active choices.

Patients' Ambivalent Reactions to an Initial Digital Contact With Health Care

Participants described different reactions upon receiving the digital notification, that is, a text message on their smartphone indicating that there is a form to complete (Strokehealth). Many participants who were already familiar with the patient portal became curious and felt confident that the short text message was sent from a trustworthy source. However, the meaning of the text message was not always clear to participants who had never previously received a notification from the patient portal. Some participants felt a sense of suspicion, thinking that an authority wanted to poke around in their private life or had concerns about the risk of fraud, as often reported in the media. In some cases, the sender (the nurse from the stroke team) would follow up with a telephone call. These verbal reminders increased patients' motivation to log in and complete Strokehealth. However, some participants mentioned that they would have preferred the initial contact after their stroke to be with a real person rather than an anonymous text message prompting them to answer questions using a digital tool, while others were fully content with the "digital-first" approach.

Participant 19: Well, I'm a bit critical and thinking like this—I was at the stroke unit about 14 days ago, and this is the first contact, about ten days later, that I receive from the healthcare side, and I find that a bit contradictory. On the one hand, maybe one would have wanted to talk to a person and not fill out a form because, after all, it's a transformative experience to have a stroke. [Male, 63 years old]

Participant 30: I felt that it's really good. I think all follow-up feels reassuring. It's very intense when it happens, and then the healthcare system kicks in, and suddenly, you're back home. I think all follow-up is good. And digital tools are totally fine, especially in combination with actually talking to someone, like in this case [Strokehealth combined with a dialogue with a nurse]. So, no, I'm in favor. [Male, 45 years old]

Several participants expressed that they would have preferred to be informed about Strokehealth during their hospital stay rather than only through a digital notification. However, they also acknowledged that this information might have been overlooked due to the many other concerns during their hospitalization.

XSL•FO
RenderX

Timing and Method of Delivery Shape Engagement With Strokehealth

Participants had various thoughts on how to personalize the process of when and how to complete Strokehealth. For instance, they reflected on the time span between hospital discharge and receipt of Strokehealth. It was generally considered that one needed some time to settle back home after discharge before the follow-up visit was scheduled and Strokehealth was delivered.

Participants also reflected on the timing of receiving the text message with a prompt to open the tool. Most considered the forenoon to be appropriate because they still had some of their often-limited energy left. If the message was sent during the night, the signal was likely to wake the recipient. Participants also emphasized that they wanted the flexibility to choose the most convenient time of day to engage with the tool. Approximately 1 week of preparation time was generally considered sufficient to allow participants to select the best time of day to engage with Strokehealth.

Participant 11: And then you could complete it at your own pace as well, you didn't have to rush through the questions, so it's quite nice, so yeah, I think it was a good thing, a really good thing. [Female, 53 years old]

Participants generally appreciated that they could log in and complete Strokehealth using a device of their own choice. The text was considered sufficiently visible on any device—including computers, tablets, and smartphones. However, the prompt to complete Strokehealth digitally caused stress for participants with less experience using technology. Additionally, the web-based system of the patient portal was perceived as difficult to navigate, adding to the digital stress. Some participants also experienced stress related to clicking the prompt to open Strokehealth and expressed concern about clicking the wrong button. However, once participants successfully managed to navigate the patient portal, most considered it easy to complete Strokehealth. For participants with severe technological issues, it was considered advantageous to have someone assist them. Additionally, some participants supported the idea of being able to choose between the digital previsit tool and a paper version on which they could make notes with a pen and then refer to during the follow-up visit.

Clarity and Purpose in the Introductory Text of Strokehealth Supports Usability

The participants' perception of the initial introductory text had an impact on their willingness to fill out Strokehealth. Most participants appreciated that the text was short and clear. Based on the contents of the introductory text, all participants clearly understood the purpose of answering the questions before their follow-up visit. Participants appreciated that the introductory text explicitly stated that there were only 14 questions, estimated to take a reasonable amount of time. Specific information that participants found helpful included that the answering process could be initiated at any preferred time and place and that the upcoming follow-up visit would provide an opportunity to elaborate on any of the indicated symptoms (ie, "yes" responses in Strokehealth).

Participant 25: Well, if it [the introductory text] says that your nurse will ask you about answers, so that you can explain how you have thought, then it makes you answer [the question]. Well, then I answer "yes" when it comes to swallowing because then I know that I can explain that later. And pain, I have that, but I can explain how much pain it is. [Female, 73 years old]

However, participants suggested providing the information that one could take a break at any point and making it clear that they could revisit and review their answers before submitting Strokehealth. On the other hand, participants expressed concerns that adding too much new information to the introductory text could impact readability.

Despite previous adjustments extending the introductory text, several participants did not notice the link to the advisory text at the end of the tool (or forgot it while answering the questions), suggesting a need for further improvements in future versions. Others acknowledged seeing the link to the advisory text but opted not to read it, either because they no longer had symptoms or because they believed that they had already received sufficient information.

The Wording and Structure of Strokehealth Influences the Response Process

This theme highlights how the linguistic formulation and structural design of Strokehealth affect users' understanding, interpretation, and response behavior. The response process was also perceived as dependent on individual prerequisites, highlighting the importance of how information is presented, the clarity of instructions, and the perceived user-friendliness of the interface.

Explanatory Texts Shape Interpretations of Questions

Most participants saw no disadvantages to the explanatory texts, and some even found them crucial for interpreting the questions and understanding their meaning. The provided contextual information—including various examples related to specific health issues—prompted participants to make new associations related to their own impairments. These reflections helped participants provide more accurate and informed answers to the questions. On the other hand, one participant expressed dissatisfaction with the comprehensive list of possible ailments in the explanatory text. He was concerned that selecting "yes" would inaccurately suggest that he experienced all listed ailments. Another participant noted that although some questions, for example, "Do you have more difficulty walking or moving safely after a stroke?" could include minor symptoms, such as slightly impaired balance, these symptoms were not mentioned within the explanatory text. He therefore found this question difficult to respond to.

Participants expressed overall satisfaction with the explanatory texts, finding them easy to comprehend. The texts were deemed concise and straightforward, and not disruptive when answering the questions. Participants emphasized the importance of maintaining simplicity and noted that excessive length could reduce response rates. However, participants identified certain problem areas that could benefit from more detailed explanations. For instance, participants found the question about pain difficult due to the complexity of the condition.

XSL•FO
RenderX

Participant 4: Perhaps the definition of pain is a bit subjective too. I don't have severe pain; it's more like a pressure sensation. But of course, that could also be considered pain, depending on how one defines pain—whether it's sharp pain, severe pain, discomfort, or something like that. I'm not sure if I would have answered 'pain' even though I had this slight discomfort. It didn't hurt; it's more of a discomfort if anything, especially if it's a milder sensation that doesn't feel like direct pain. [Male, 58 years old]

Not everyone felt a need to read the explanatory texts. Some participants chose to read the attached text only if the question sparked their interest in the topic, was unclear, or prompted deeper reflection on their remaining symptoms.

Participant 22: In those cases, my answer was obvious, I didn't read all of them thoroughly. I didn't go into the details or the fine print—I just moved on to the next one. I didn't read everything all the time; if the question was crystal clear to me, I just went to the next one without any comments. Yes, there were certain questions—not all of them—but some where I thought, "What the hell do they mean by that?" And of course, in those cases, I had to read more carefully to understand what it actually said. [Male, 65 years old]

Individual Prerequisites Influence the Response Process

During the interview, several participants reported experiencing communication or memory problems, including signs of aphasia. For many, these impairments impacted their ability to recall details, understand, and express their thoughts effectively within Strokehealth. Some participants mentioned that having a supportive spouse was advantageous when completing Strokehealth. Others mentioned that they answered the questions quickly, either due to their natural tendency to complete questionnaires quickly or because they were at work when the notification arrived. Responding rapidly may have reduced the time available for reflection on the questions; however, participants did not spontaneously raise this concern during the interviews.

Participant 6: It could be that I took a break from work when I did it, and maybe I felt like I didn't really have time to continue or look into it further, so I felt done. That's often how it feels—when I've completed a survey, I just want to get on with my life [laughs]. [Male, 46 years old]

Participants commonly mentioned the problem of fluctuating mental fatigue since their stroke. When participants experienced mental fatigue during their completion of Strokehealth, it influenced every answer. Participants felt that it was misleading to answer "yes" to questions about difficulties with activities of daily living if they were typically able to manage but were currently hindered by fatigue. They suggested including a specific question about fluctuating mental fatigue or adding a free-text area where participants could indicate "sometimes" instead of being limited to the binary "yes" or "no" responses. Another suggestion was to move the question about "life after stroke" from the bottom to the top of the tool, since that question was related to fatigue and hence impacted their responses to the subsequent questions. Notably, the presence of mental fatigue significantly affected participants' ability to focus during the response process. One participant described feeling mentally sluggish, as if their thoughts were moving "as slow as toffee." Accordingly, participants highlighted the need for flexibility to take breaks, without fear of losing previous responses.

Importance of Optimizing User-Friendliness and Allowing for Simplicity

Participants provided valuable insights regarding how to improve the tool's design to enhance the response process. Most participants found the structure, layout, and language of Strokehealth to be attractive, educational, and easy to comprehend. The number of questions, response options, wording, and sequencing of questions were all generally deemed user-friendly and straightforward. No language was considered offensive. In particular, participants with mild poststroke symptoms found the tool easy to navigate.

Regarding the response options, participants speculated that binary choices ("yes" or "no") might be insufficient, suggesting a need for more nuanced options.

Participant 6: I mean... I answered "yes" for those where I had even the slightest symptom. I did, yes. That's how I interpreted it: if I experienced even the slightest symptom, I would answer "yes," and if I didn't, I would answer "no."

Interviewer: So it wasn't hard for you to understand that this is how you should answer, at least?

Participant: No, no. But the feeling could still be that this "yes" might not convey the full truth. [Male, 46 years old]

Additionally, they emphasized the importance of providing a free-text area below each question to allow for personalized responses and improve user-friendliness. Participants felt that a single free-text area at the end of the tool was insufficient because they often wanted to specify directly after each question. The need for a free-text area was particularly evident after the question "Life after stroke," which was generally considered quite broad, with the ambition of capturing many aspects of importance.

Participant 2: I just think I would have liked to answer "yes," but then define it. I would want to specify right under that question... I would like to specify them a bit more, either by breaking that question into several or by allowing a free-text option right after, where you can specify what you mean. [Male, 61 years old]

Not all participants shared this perspective. Some found that the combination of the question itself and a single free-text area at the end was sufficient—especially if they found it challenging to write due to linguistic or motor impairments. Participants also reflected on the answer option "choose not to answer," which some viewed as somewhat peculiar, while others saw it as a "way out." No specific suggestions were made for alternative wording to enhance clarity, but some reflected that this response option could be supplemented with a free-text area to allow individuals to explain why they chose not to answer.

Participants appreciated that a summary appeared when they completed the response process before submitting Strokehealth.

XSL•FO
RenderX

Some suggested that the "submit" button should be made more prominent and visible. After submitting Strokehealth, it disappeared from the screen, which was seen as a disadvantage if someone wanted to review their answers before their follow-up visit. Similarly, it was suggested that it should be made easier to print the summary of their responses.

Development and Amendments to Version 2.0

Strokehealth was amended and altered based on the findings from the individual interviews and the theoretical framework—for example, aspects of person-centered care and health literacy (Multimedia Appendix 4). Several important changes were made in version 2.0, including a revision of the introductory text to better align with expressed preferences. Additionally, the answer options were extended to include a free-text box below each question and additional space in the general free-text box at the end of the tool. Moreover, the explanatory and advisory texts were improved to exhibit greater consistency in structure and content. These included confirming experiences, suggestions of what one can do by oneself (self-management), suggestions of potential interventions, and a prompt to seek support, if needed. Notably, the platform for the national portal has some limitations regarding layout options, predefined typography, and colors that cannot be changed.

Discussion

Principal Findings and Comparison With Prior Work

User Experience and Perceived Usefulness

The Strokehealth digital previsit tool, when used before a scheduled follow-up visit after stroke, was perceived as a supportive aid for facilitating dialogue and identifying patient needs. It was also considered to be useful and user-friendly. Themes identified from the interviews emphasized the importance of patient comprehension and motivation to initiate the response process. The real-world experiences captured in this qualitative study, combined with the findings from the initial patient satisfaction survey (part 1 [17]), provided the foundation for further improvements to the tool. While the initial survey provided useful data on general user satisfaction and perceived usability, the subsequent qualitative evaluation offered deeper insight into patients' experiences and contextual factors affecting their interaction with the tool. It captured emotional responses such as feeling acknowledged and supported, practical barriers related to digital literacy, and the need for more nuanced response options. These findings informed concrete improvements to the tool and highlighted the importance of considering patients' individual circumstances when implementing digital previsit tools in routine care. Based on user feedback, minor adjustments were recommended in version 2.0 to better support the follow-up process from initiation to identifying patient needs. Additionally, participants suggested greater flexibility in the timing and method of introducing Strokehealth to patients to enhance its accessibility and usability.

Supporting Patient Engagement and Self-Management

The current findings indicate that the information presented in Strokehealth fosters increased patient engagement and potentially supports meaningful dialogue with both health care professionals and family members. The stroke-specific information addresses common knowledge gaps that are often experienced by people with stroke and their families [4,23], especially after first-time strokes [24]. Participants reported that the information reassured them that their experiences were normal and, in some cases, motivated them to seek additional resources on the web or take health-related actions. Patients require relevant, concise, and easily accessible information to be able to make informed decisions and support their self-management [4,23,25]. The concise information within Strokehealth aims to foster shared responsibility for health—aligning with the broader health care shift toward self-management [26]; however, simply providing information is insufficient to elicit meaningful behavior changes without active patient engagement [25] or effective communication with health care providers [4]. Patient health engagement can be further encouraged by combining Strokehealth with a follow-up visit (whether on-demand or in-person) during which patients can revisit information and discuss it with health care professionals.

Self-Reflection and Response Design

Participants in this study emphasized the importance of self-reflection during the response process, highlighting various aspects of its significance. First, the response process encouraged participants to consider issues they might not have otherwise reflected upon. Somewhat surprisingly, participants also expressed that the response process fostered a sense of gratitude about not being more severely affected, as well as feeling cared for by the health care system, rather than abandoned—a sentiment that aligns with previous research findings [6]. Second, the self-reflections and responses were influenced by how participants interpreted the explanatory texts attached to each question. Most participants found these texts to be sufficient; however, some expressed that they did not fully address subtle impairments. Third, self-reflection was influenced by the design of the response options. Participants expressed their desire to provide more nuanced responses than were allowed by the binary response options, which reinforced findings from previous evaluations of the co-design process [14]. While this limitation was acknowledged, participants with firsthand experience of a stroke indicated that the response options were generally effective when complemented by a free-text area with sufficient space to record their reflections. Following the evaluation, restructuring the questions to include additional response options aimed at capturing milder symptoms was considered. However, overly complex or ambiguous questions could hinder engagement. Therefore, this approach was ultimately deemed to introduce unnecessary complexity, potentially compromising the goal of developing a user-friendly tool. Based on these insights, Strokehealth version 2.0 was modified to incorporate free-text areas below each question and revised text to better capture the nuances of patients' experiences and support the response process.

Accessibility and Digital Literacy

The present results suggest that Strokehealth can be accessible to a broad range of patients with stroke if choices are offered regarding when and how the tool is introduced. Some

XSL•FO
RenderX

participants described experiences of "digital stress" when navigating the patient portal, although 48 out of 58 participants (82%) used the web on a daily basis. This highlights the need for Strokehealth to be accessible to individuals with limited experience using digital tools. It is recommended that health care providers consider patients' eHealth literacy levels [27] and implement alternative communication methods as needed. For patients with limited digital literacy—including low digital skills, low confidence, or reluctance to use digital tools—health care providers could encourage seeking support from friends or family to alleviate digital anxiety. Our results indicate that some participants successfully completed the tool with support from spouses. Additionally, alternatives to the digital version should be readily available to help build patients' confidence in their ability to self-manage. Therefore, Strokehealth is also offered as a paper version [28], which can be sent by a health care professional to a patient who chooses not to interact with the patient portal after receiving the initial text message. Such efforts can improve accessibility and organizational health literacy, ultimately supporting patients in more effectively navigating the health care system [29].

Implementation Considerations

Importantly, evaluations of a digital health tool such as Strokehealth must consider not only the functionality of the tool itself but also the contextual factors [16] related to the follow-up process. Effective introduction is crucial for engaging patients in the proactive management of their health [30], including clear communication of the purpose of a notification and building trust in the sender [31]. In this study, the timing and method of delivery played a key role in engagement with the tool, with some participants initially questioning the legitimacy of the digital notification. Mentioning Strokehealth upon hospital discharge could raise awareness about the tool, enhance trust, and help patients perceive the follow-up process as seamless and integrated. Ideally, patients could be informed at the time of hospital discharge that they will later receive a digital previsit tool, once they have spent some time at home. This information should include the purpose of Strokehealth, and if they choose to opt out, a paper version could be offered at that later stage. Engagement was further influenced by factors such as fatigue and cognitive impairment, underscoring the need for well-timed notifications, ideally in the morning when patients' energy levels are higher. Strokehealth version 2.0 addresses these challenges by promoting flexibility, allowing patients to complete the tool at their convenience and to take control of their follow-up process.

Implications for Digitally Supported, Person-Centered Care

Our findings align with previous calls for digitally supported, person-centered care in long-term conditions such as stroke [1,2]. By providing insights into how patients experience the use of a digital previsit tool, this study contributes to the growing evidence base on how eHealth interventions can promote reflection, engagement, and preparedness ahead of follow-up visits.

Strengths and Limitations

This study involved patients who were consecutively recruited by the selected health care professionals; therefore, bias due to selection cannot be excluded. However, this sample—the majority of whom had a mild stroke—is representative of the Swedish population. The comprehensive description of the context and participants in this study, complemented by part 1 [17], supports the transferability of the findings to other organizations. In accordance with the co-design method, the researchers were involved in all parts of the design process [32,33], including the evaluation elements. However, the researchers' involvement could have made participants feel hesitant to express drawbacks, despite encouragement to openly share thoughts. Some of the interviews were relatively short in duration, which may have limited the depth of participants' responses. It is possible that conducting the interviews face-to-face, rather than by telephone, could have facilitated richer and more nuanced accounts by allowing for nonverbal communication and a more personal connection between the interviewer and the participant. Nevertheless, the critical feedback and rich data in this study demonstrate participants' willingness to share their experiences and contribute to improving the tool. To enhance reflexivity, reflections were systematically noted. Importantly, the researchers' preunderstanding is considered a factor that influences the data analysis and interpretation [34]. To ensure confirmability, the impact of this preunderstanding was considered throughout the analysis, together with continuous return to the coded data and transcripts in NVivo. Moreover, credibility was strengthened by conducting the interviews in a familiar environment, using a telephone interview. However, the use of the telephone could have influenced participant recruitment. Interviews were conducted by telephone due to the COVID-19 pandemic; however, this was found to be a surprisingly well-functioning method of collecting data in this sample.

The Strokehealth digital tool has now been tested within a clinical care pathway to assess whether patient needs and preferences are being appropriately addressed in accordance with prior recommendations [16]. Accordingly, Strokehealth has been implemented within the Swedish health care system, allowing health care professionals to access patient responses via the national patient portal prior to clinical visits. However, the broader implications and potential benefits from a health care system perspective warrant further exploration. Following guidelines for evaluating complex interventions, the next step would be to gather the perspectives of health care professionals to understand how Strokehealth could support them in the delivery of care. Together, our studies (parts 1 and 2) indicate that the tool's overarching purpose—to encourage reflection and preparation for a planned health care visit—remains broadly applicable among patients with stroke.

Conclusions

The digital previsit tool Strokehealth was generally well received, with participants describing it as supportive, easy to use, and valuable for fostering reflection and preparing for meaningful dialogue. Patients' feedback led to concrete refinements in Strokehealth version 2.0, including improved

XSL•FO
RenderX

explanatory texts, added flexibility in the timing and format of delivery, and expanded opportunities for free-text input. Importantly, the findings highlight that digital tools must account for individual circumstances, including eHealth literacy and cognitive or emotional challenges, in order to ensure equitable access. This study contributes to the evidence base for implementing person-centered, digitally supported follow-up care in stroke rehabilitation.

Acknowledgments

The authors sincerely appreciate the participation of individuals affected by stroke and their willingness to share their experiences. The authors also extend their gratitude to the health care professionals for managing the previsit tool alongside their regular duties. Furthermore, the authors would like to thank the members of the advisory board, the linguist, the web designers, and the patient partner and experts who participated in the decision workshops. This study was funded in part by grants from the Swedish state under an agreement among the Swedish government and the county councils, the ALF agreement (ALFGBG-965653); the Local Research and Development Board for Gothenburg and Södra Bohuslän (VGFOUGSB-76712); Sahlgrenska Hospitals Foundation (SU-892141 and SU-793481); the Swedish Stroke Association; the Swedish Neuro Association; an unconditional grant from Allergan; the Hjalmar Svenssons Foundation; Göteborg Foundation for Neurological Research; Rune and Ulla Amlövs Foundation; Per-Olof Ahls Foundation; John and Brit Wennerströms Foundation; the Innovation foundation at region Västra Götaland (VGRINN-968305); and the Greta and Einar Askers Foundation.

Abstract

Background: Ireland is ranked among the most disadvantageous European countries in terms of mental health challenges. Contrary to general health services that primarily focus on diagnosis and treatment, the mental health sector in Ireland deals with highly sensitive psychiatric case notes based on patient-doctor conversations. Such data, therefore, must be collected, analyzed, and stored with an approach customized specifically for psychiatry.

Objective: This study's objective involves examining the state of data handling practices in the Irish Mental Health Services (MHS), identifying the shortcomings regarding privacy, security, and usability of psychiatric case notes, and proposing an innovative technological solution that addresses most of the surfaced challenges.

Methods: The study was conducted using a comprehensive methodology. Our approach involved a thorough literature review, ethics approval, web-based surveys with mental health professionals as participants, interviews of psychiatrists, interactions with mental health organizations, analysis of inspection reports by the Ireland Mental Health Commission, and comparative evaluation of existing IT solutions. The thoroughness of our adopted research methodology instills confidence in the reliability and validity of our findings.

Results: Our study revealed outdated data management, heavy reliance on paperwork resulting in serious repercussions, parallel workload, alarmingly low readability of notes, and a nonviable setup that hinders research and analytical examination. Our survey reported an average score of 4.37 of 10 (SD 1.25) given by participants in terms of technology use. Regarding privacy measures, 75% (n=12) of participants mentioned that staff members are allowed to keep their phones while accessing psychiatric case notes. Similarly, 80% (n=13) of submissions highlighted that multiple staff members can access sensitive notes and patients' contact information. On the other hand, Mental Health Commission reports showed that their inspections are limited to evaluating physical privacy only. Regarding technological comparative analysis, we observed that conventional IT solutions are vulnerable against cyberattacks and fall short in addressing multiple challenges simultaneously. Therefore, an innovative convergence of different technologies is needed. Our research supports speech-to-text transcription for data collection, interactive artificial intelligence for data analysis, and permissioned blockchain for data storage and retrieval. Our survey participants also estimated the proposed solution to optimize their workload by an average of 35%.

Conclusions: Irish MHS seem to be handling psychiatric data under polycrisis circumstances; therefore, a single-dimensional digitization of records would not be sufficient in addressing the wide range of concerns. In addition to highlighting intertwined challenges in Irish psychiatry and validating the need for innovation in data handling practices in Irish MHS, this study culminated in the proposal of an innovative technological solution that offers a significant contribution to a considerably improved, efficient, and compliant service delivery in mental health care.

Introduction

Mental health care is a critical component of public health systems, playing a pivotal role in addressing the challenges of mental disorders and promoting overall well-being. The importance of mental health care extends beyond individual health outcomes, encompassing significant social and economic implications.

According to the third annual Mental State of the World (MSW) report, Ireland ranks among the countries with the lowest mental health score globally. Specifically, Ireland's Mental Health Quotient places it as the second worst in Europe, with the United Kingdom ranking worst, as shown in Table 1. Furthermore, Ireland is notable for having a significant proportion of respondents classified as distressed or struggling, ranging from 30% to 36% (Table 1). These findings were based on data collected from over 400,000 respondents across 64 countries in 2022, providing a comprehensive assessment of the mental well-being of included nations [1].

Table . Relevant statistics from the third annual Mental State of the World report 2022.

Countries	Mental health quotient score	Percentage of distressed population
Belgium	72.1	18.9
France	74.1	19
Spain	70.2	22.6
Germany	65.9	24.5
Ireland	56	30.4
United Kingdom	46.2	35.7

Another study conducted by scholars from Maynooth University, National College of Ireland, and Trinity College Dublin reveals that more than 40% of Irish adults experience a mental health disorder [2]. In terms of economic burden, mental health issues in Ireland are reported to be costing the country over 8.2 billion euros annually (a currency exchange rate of 1 EUR=US $1.1201 is applicable) [3]. As highlighted in the Organisation for Economic Co-operation and Development report from 2018, the cost of mental health problems accounts for 3.2% of Ireland's gross domestic product [4]. These financial implications underscore the urgency of addressing mental health challenges within the country and investing in robust mental health care infrastructure.

Mental health services (MHS) in Ireland are responsible for handling the sensitive and private data of patients, including their medical history, diagnoses, treatment plans, and personal information. When it comes to psychiatric data, the stakes get much higher. There have been several instances of mental health data breaches, abuses, and privacy violations within Ireland and across Europe, highlighting the need for improved security measures. With the growing reliance on digital health records, the risk of data-related threats continues to increase. In 2023 alone, European Union countries reported 309 major cybersecurity incidents in the health care sector, the highest among all critical sectors [5]. We have also listed some relevant incidents of data violations in Table 2.

XSL•FO
RenderX

Table . List of relevant data violation incidents.

Country	Incident	Year
France	Two French health care payment providers, Viamedis and Almerys, experienced data breaches affecting over 33 million people, exposing personal details and insurance information [6].	2024
Romania	A ransomware attack on Romania's health care management system has forced 100 hospitals to take their systems offline [7].	2024
Ireland	The Health Service Executive of Ireland experienced a serious ransomware cyberattack, which led to all its IT systems nationwide to be halted. The attackers demanded a ransom for not publishing private health data [8].	2021
Finland	A hack of psychotherapy records affected thousands of patients. Many of them reported instances of receiving emails with ransom demands paired with warning of disclosing their private conversations with the therapists [9].	2020
Ireland	A doctor was reported for the abuse of his patient's contact information by sending sexually motivated text messages [10].	2018
Ireland	Irish High Court ordered the suspension of a psychiatrist over allegations of sexual misconduct with vulnerable patients based on their mental health records [11].	2013

These incidents underscore the critical necessity of comprehending the deficiencies in data handling practices within Irish MHS and the pressing need to devise an appropriate solution that effectively addresses different concerns. Considering such challenges, it was important to evaluate different technological methods that are commonly adopted for securing psychiatric data and then compare those practices with the ones in Ireland MHS. When it comes to the state of technological advancements in psychiatry, the most common solutions are electronic health records (EHRs) and personal health records (PHRs). While EHRs and PHRs are useful solutions, they come with their own set of security risks [12,13]. Similarly, there is a wide range of technological solutions involving cloud, blockchain, and conventional databases that have been adopted by health care sector all over the world. eHealth or e-therapy is another recent form of counseling that has been arising during the last few years [14,15]. The World Psychiatry Association also promotes digital means in mental health care worldwide. Moreover, it has a dedicated working group on digitalization in mental health [16,17]. Since our research picked Ireland's MHS as a case study, we finalized our research objectives as follows:

- System insights: To gain insight into psychiatric procedures and evaluate how sensitive data are handled within the Irish mental health system.
- Stakeholders engagement: Interact and collaborate with different stakeholders, such as psychiatrists, psychologists, and mental health organizations. Document their concerns and establish a feedback loop.
- Technical proposal: Document the research findings and propose a solution that addresses the surfaced challenges after getting it validated by the stakeholders.

Furthermore, to validate and document the existing state of data handling practices in Irish MHS, this study makes a noteworthy research contribution toward technological advancement in the mental health care sector. Several methods were adopted to confirm the consistency of surfaced shortcomings. Moreover, different stakeholders of Irish MHS were engaged in research participation, public and patient involvement contribution, and critical analysis of proposed solutions. In addition to interacting with public MHS, the scope of this study was extended to relevant third-party organizations as well. Such a multifaceted approach helped us map out an innovative and novel technological solution based on consultations with the most pertinent stakeholders of the loop. This involves the convergence of different technologies, that is, speech-to-text transcription, artificial intelligence (AI), and permissioned blockchain. These technologies were selected for specific purposes with proper justifications, following an in-depth comparative evaluation against alternatives.

The remaining sections of this paper are organized as follows. The Methods section presents the methodology with pertinent details, involving interviews, surveys, third-party interactions, and technological evaluation. The Results section includes results and findings related to interviews, surveys, and descriptive comparative evaluation of different technologies. The Discussion section discusses a proposed solution, along with its applicability and novelty compared to the existing state. It also discusses the foreseen challenges and limitations of the presented work. The Conclusions section contains concluding remarks and future scope.

XSL•FO
RenderX

Methods

Study Design

An extensive mixed methodology was adopted to perform a thorough case study regarding existing data handling practices in Irish MHS. This research intends to document the current practices and propose an IT solution to further secure and improve existing service delivery or address any identified shortcomings. The following steps were taken for preliminary investigations, which led to the new technical proposal for Irish MHS.

Interviews With Psychiatrists

Detailed interviews were conducted with psychiatrists working in MHS in Ireland, that is, Galway, Dublin, Cavan, and Donegal. This helped us develop a basic understanding of the Irish psychiatry sector, its challenges, and any scope for improvement.

Case Notes in Psychiatry

It was brought to our knowledge that a large amount of paperwork is generated each day in the Irish MHS in the form of "case notes." Psychiatry case notes are used by doctors and nurses to plan, implement, and evaluate treatment for mental health patients. They are also used to track progress, exchange information among other health care practitioners, and ensure that care is being delivered safely, ethically, and effectively [18]. Furthermore, these notes are highly useful in the analysis of different cases. Clinicians often study these notes to identify what went wrong at what stage. Therefore, the authenticity and quality of psychiatry notes are of particular significance.

Reliance on Cognitive Abilities

Another aspect brought to our notice was that the existing practice relies on the human ability of a doctor to write down the conversation with a patient without skipping any important information. Such reliance on doctors' cognitive abilities results in a lack of uniformity regarding a patient's case record [19].

Moreover, a large percentage of these handwritten notes have quite a low readability. One of the psychiatrists claimed that 70% of the contents of psychiatric case notes are not readable. This is quite concerning, as this low-readability problem would also hinder the potential of research and analysis of such notes.

Legal Aspects

One interesting application of these psychiatry notes is connected to occasional legal matters. Evaluation of a suspect's mental vulnerability during criminal proceedings is quite common in Europe [20]. Under some circumstances, the solicitors are granted access to the psychiatry notes of a patient by the courts. The solicitors then use the documented conversation and assessments to establish their points whether in favor of proceedings or against it. This is quite a serious and sensitive domain. If we connect this application with the readability and uniformity challenges described earlier, those shortcomings could potentially manipulate or affect the outcome of a legal battle.

We came across a public example quoted by solicitor Sarah Grace in an interview to the RTE Upfront program in 2023 [21], which validated this aspect.

In her words: "In Ireland, in any sexual offence case, the therapy notes, or counseling records of the victims can be used against them to disprove what they are saying in trial."

She also pointed out that the entire defense team of solicitors as well as the accused can read those notes: "After the violation of your body, you also go through the violation of your privacy and dignity."

Technology Adoption

When it comes to the existing state of technology use in the Irish MHS, psychiatrists mentioned that so far, the technology has not actually helped them, instead, it has built a parallel system (paperwork+digital tasks) and increased the workload. As articulated by a psychiatrist:

> *Technology was supposed to REPLACE our workload, not ADD to it.*

A bit of variation was noticed in the extent of technology use among different MHS across Ireland. For example, unlike Cavan MHS, which relied largely on paperwork, the MHS in Letterkenny adopted a tool named T-Pro for the digital dictation of nursing notes, letters, and other documents [22]. Although this tool reduces time consumption in some specific tasks, it still does not replace the overall practice.

On the other hand, the digitization of mental health records should be considered beyond workload optimization, as it offers numerous benefits like enhanced case analysis and improved readability. Thus, workload reduction should be seen as an added advantage rather than a necessary requirement.

Patient-Doctor Equation

Psychiatrists also mentioned that several patients are not fully confident about the privacy of these notes. Some patients get uncomfortable, watching their clinician making notes about them while they are talking. They are, therefore, reluctant to share their thoughts freely, which hinders diagnosis. We also came across a similar observation made by psychiatrists in Switzerland [23], where the patients were worried about being judged or mistreated by medical staff if their report mentions their mental ailment. For some clinicians in the Irish MHS, this often results in maintaining 2 versions of notes, that is, an official version for the institution and a private version to keep track of highly confidential information related to their patients.

Quest for Solution

These insights put emphasis on the need for an automated technological solution to collect such sensitive data. The process should be automated to some extent, as asking doctors to replace "writing" with "typing" will only solve the readability issue. Still, it will not solve all the other challenges discussed earlier, that is, reliance on cognitive ability, workload, uncomfortable patients, authenticity, and uniformity.

We then asked, what if we record such treatment sessions (audio)? Although that could potentially solve many problems, we were informed that recording conversations would increase

XSL•FO
RenderX

the sensitivity of these data by multiple folds. This discussion then brought us to speech-to-text transcription as the most reasonable potential solution, which will be discussed later in this paper.

Community Engagement—Web-Based Survey

Overview

A web-based survey was also conducted to validate the preliminary findings and explore the respective scope of improvement. The target participants for our study were mental health practitioners working at Irish MHS, that is, psychiatrists, psychologists, psychiatric nurses, and senior consultants.

The inclusion criteria were mental health practitioners working at Irish MHS, who are involved in handling psychiatric case notes in any capacity.

A participant gets excluded if he or she is not a mental health practitioner or clinician, he or she has not experienced working in the Irish MHS, and he or she was not involved in handling mental health notes or patient's data.

Survey Sections

The survey comprised 9 sections, with 3 to 5 multiple-choice questions each. The questionnaire did not ask for any confidential information related to any institution. The summarized breakdown of the different sections of the survey is given below:

1. Participant's experience of working at Irish MHS (years).
2. Admission: Queries regarding the process of data handling during a patient's admission.
3. Treatment: Queries regarding the process of data handling during a patient's treatment.
4. Procedures: Data handling during an exchange of information between different departments.
5. Privacy and security: Measures in place to ensure privacy and security of the patient's data.
6. Technology: Extent of technology use and familiarity with modern digital practices.
7. Workload: Queries regarding the workload of patients on practitioners based on existing practices.
8. Assumed cases: Queries regarding participant's opinions about different assumed situations.
9. Suggestions: Submit any useful suggestion that could aid the research objectives.

Third-Party Interactions

Overview

In addition to evaluating the public and mainstream MHS in Ireland, we found it important to involve the insights from relevant third parties, such as government regulatory bodies for psychiatry and private sector. We had three reasons for this outreach: (1) to paint a bigger picture that involves diverse perspectives in the case study, so we may not miss out on something significant; (2) to check and ask around whether the shortcomings surfaced during our research have already been identified or documented by some other stakeholder or not; and (3) to go through the progress made by different players in psychiatry in case the solution we are looking for might already be in practice. And if yes, to what extent?

Brothers of Charity Services Galway

A local mental health organization named Brothers of Charity Services (BoCS) Galway is known among mental health clinicians for having quite advanced data management software. Upon our request for a demonstration, they were considerate enough to schedule a meeting with their IT team. Some important findings and insights are highlighted in the Results section.

Mental Health Commission

This study also involved interacting with Ireland's Mental Health Commission, which is responsible for promoting, encouraging, and fostering high standards and good practices in the delivery of MHS in Ireland [24]. They conduct annual inspections of MHS in Ireland and publish their reports [25]. Therefore, the Mental Health Commission's perspective was an obvious choice to be considered and included in this case study.

Technological Evaluation

Progressive digitization of all conventional processes and systems results in a constant generation of data at quite a rapid rate. All these data are produced, collected, processed, stored, and shared for various purposes. Many data science technologies are being adopted for health-related data handling. However, the areas of data security and privacy are not up to the mark yet [26]. We evaluated different IT solutions for mental health care data management and found that conventional data security practices are still prone to violations of different sorts.

Ethical Considerations

Before carrying out the survey and interviews, ethics approval was obtained from the research ethics committee of the University of Galway (2023.08.024). All participants signed a consent form and were well aware of their right to opt out at any stage. No financial compensation was offered or provided to the participants. The study does not involve confidential or sensitive data collection; instead, it entails validation of routine standard practice. It is important to note that any mental health patient data were not collected, stored, or used in the study.

Results

We have compiled results and findings from different components of the research methodology. It was interesting to notice how one problem was connected to many more.

Interview Findings

Overview

The key points from our interviews with mental health practitioners working in the Irish MHS have been summarized and listed as follows: excessive reliance on paperwork and physical privacy; in addition to record-keeping, psychiatry notes are quite useful in case analysis; psychiatry notes have occasional application in legal matters; handwritten notes have alarmingly low readability and uniformity; there is a dual system

XSL•FO
RenderX

in place, that is, paperwork and digital tasks; patients are often uncomfortable with this note-taking activity; patients are reluctant in sharing information to bypass the notes; patients often ask clinicians to skip some information to avoid stigma; and clinicians often maintain 2 versions of notes, that is, official and private.

Nonstatutory Services Report

Although BoCS's IT solution and dashboard were comprehensive and all-inclusive, it still lacked case note–specific data handling that we sought. However, it was quite an impressive system developed over 2 decades. This is why we picked it as a reference for our investigation regarding data handling practices in the private sector of Irish MHS. Here are some highlights:

- Around 2000 staff members use their IT solution referred to as "OLIS," that is, online information system.
- OLIS is not merely a mental health record management system, it is an extensive enterprise resource planning system with around 18 merged modules that support largely all aspects of their services. They have developed this IT system for over 20 years.
- Regarding security, the BoCS team mentioned that they have not experienced any serious cyberattack yet; however, they reported occasional phishing attacks.
- Their system does not store or manage psychiatry notes digitally. Instead, they have general fields for comments.

It is important to understand that if we remove the psychiatry notes aspect from the equation, mental health records would get the same treatment as general health records. Psychiatry notes are what make mental health records more sensitive and novel as compared to general health records.

Survey Findings

A total of 16 submissions by mental health professionals have been collected and analyzed. A breakdown of the participants' profiles is provided in Table 3.

Overall, the results confirm several concerns brought to our attention during the interviews. In one section, we asked all 16 participants to rank their Mental Health Department's processes out of 10 regarding IT use and modern digital practices. The distribution of responses was as follows: a total of 2 participants rated the processes at 7 of 10, a total of 4 participants gave a score of 5 of 10, a total of 6 participants rated them 4 of 10, and a total of 4 participants assigned a score of 3 of 10. The average score of the submissions is 4.37 of 10 (SD 1.25). This is alarming enough to establish the need for digitization. Moreover, some relevant findings regarding technology use, privacy measures, and workload at Irish MHS are shared in Tables 4-6, respectively.

Table . Survey participants' profile.

Profile	Values, n (%)[a]
Participants' role	
Nonconsultant hospital doctors	6 (40)
Senior psychiatrists	5 (30)
Psychiatric nurses	3 (20)
Health officers	2 (10)
Participants' role	
Working experience <5 years	50
Working experience >5 years	35
Working experience >10 years	15

[a]Percentages are rounded to the nearest tenth (10%).

Table . Survey findings regarding "technology use" at Irish Mental Health Services.

Question	Majority or average response	Values, n (%) [a]
How does a general physician usually refer a patient to your Mental Health Services?	General physician sends a letter by post.	15 (90)
What information is collected at the time of admission? Is that information stored electronically or just in a patient's paper file or folder?	Patient's identity, contact, and residence information are collected and stored both electronically and in paperwork.	12 (75)
When patients describe their private thoughts or mental challenges to a psychologist or psychiatrist, how is that information stored?	Notes on a paper-based chart or form.	15 (90)
To what extent, are the modern technology and digital practices being used by staff members regarding mental health records?	Staff members use technology to the extent of sending emails, faxes, and scans.	10 (65)

[a]Percentages are rounded to the nearest multiple of 5%.

XSL•FO
RenderX

Table . Survey findings regarding "privacy measures" at Irish Mental Health Services.

Question	Majority or average response	Values, n (%)[a]
How many staff members are involved in the process of discussing a patient's case?	5 to 10 including nonmedical support staff.	9 (60)
How often does a patient get assigned to alternative staff members, based on their availability, or shift timing?	50% split response between calling it a "routine practice" and "no such changes are made."	N/A[b]
Which staff members are authorized to access mental health patient files?	Any staff member can access files, if needed.	13 (80)
To what extent are the staff members aware of the privacy laws and how strict are the privacy policies?	All staff members are fully aware of GDPR[c] and relevant privacy laws, with repeated reminders or updates.	15 (90)
Are staff members allowed to keep or use their cell phones while they access patients' records or files?	Yes, staff members are allowed to keep cell phones.	12 (75)
Could assigned staff members access the contact information of an active patient being treated by them? That is, phone number and address.	Yes, assigned staff can access patient's contact information.	16 (100)

[a]Percentages are rounded to the nearest multiple of 5%.

[b]N/A: not applicable.

[c]GDPR: General Data Protection Regulation.

Table . Survey findings regarding "workload" at Irish Mental Health Services.

Question	Majority or average response	Values, n (%)[a]
On average, how many mental health patients does a psychiatrist or psychologist attend in a full working day?	5 - 10	11 (70)
On average, how many hours do psychiatrists or psychologists work in a full day (officially)?	7 - 9	15 (90)
On average, how much time is allocated for or consumed by each mental health patient? That is, consultation, diagnosis, report writing, and prescription.	30 minutes to 1 hour	13 (80)
On average, how early can a patient get an appointment with a psychiatrist or psychologist?	Wide range of responses; ranging between 2 days, a week, and a month.	N/A[b]

[a]Percentages are rounded to the nearest multiple of 5%.

[b]N/A: not applicable.

We shared a summarized version of the IT solution plan with our survey participants and asked them how much reduction in workload do they estimate if this plan gets implemented? Results are shown in Table 7.

From a different perspective, if we optimize the existing system, we can expect approximately 35% more patients to be accommodated each day. In our assessment, some improvements could be made by simple changes in the procedural protocols or policies, such as restricting the contact information to administrative staff only.

Table . Expected reduction in workload (survey results).

Range of reduction in workload	Participants, n
0%	0
10% - 25%	7
25% - 50%	4
50% - 60%	2
60% - 75%	3
>75%	0

Technological Evaluation Findings

The relevant use of technology was evaluated from 3 perspectives, that is, digitization of psychiatric case notes, the scope of AI, and data storage and retrieval.

Digitization of Psychiatric Case Notes

Overview

Numerous challenges pertaining to data handling practices in Irish MHS can be effectively addressed through the digitization of psychiatric case notes. However, certain limitations persist. These concerns encompass the human limitations associated with memory retention and the time-consuming nature of manual typing during patient sessions. In light of these usability considerations, we explored the implementation of a speech-to-text transcription approach. This approach involves facilitating psychiatrists with a speech-to-text transcription tool during mental health treatment sessions.

State of the Art

Several digital tools have been developed for the facilitation of note-taking process. Some well-known tools include Evernote, Microsoft OneNote, Google Keep, and Apple Notes [27]. Recent progress in this industry involves the development of several audio or video recording–based software that converts the audio or video input to text format. Some notables are T-Pro, CarePatron, VoiceBoxMD, Mentalyc, Athreon, Transcription City, Upheal, etc [22,28-33]. However, such tools rely on audio or video-recorded input, which has more serious implications of its own.

This leaves us with transcription tools that process live audio data to text form without storing the sound file. Most of the tools developed for this purpose are based on different speech-to-text application programming interfaces. Some notable speech-to-text application programming interfaces are being offered by Amazon, Assembly AI, Wav2Letter, DeepSpeech, SpeechBrain, JavaScript, IBM Watson, OpenAI, Google, Intel PyTorch, etc [34-43].

Scope of AI

Upon the successful transcription of the entire treatment session conversation between the psychiatrist and the mental health patient, we propose leveraging AI for two primary purposes: (1) to generate a summary of the treatment session and (2) to identify potential disorders and recommend appropriate treatment options.

AI has become an increasingly active area of research over the past few years in precision mental health care [44,45]. AI is expected to significantly improve psychotherapy research in the coming years. It has a lot of potential in predictive modeling [46]. Since we are dealing with the summarization of psychiatric treatment session, sentiment analysis of patient's statements could also be quite helpful in identifying various disorders. Sentiment analysis includes natural language processing, text analysis, and computational linguistics for identifying and extracting subjective information in source materials [47].

We propose a human-supervised, query-based summarization AI model for verifying factual consistency and identifying conflicts between source documents and a generated summary. Simply put, we would keep the psychiatrist or psychologist involved in the process to verify and direct the AI-generated content before submission.

During this research, we studied the shortcomings of unsupervised automatic speech recognition [48], which refers to the challenge of generating text transcriptions from raw speech during a conversation between a psychiatrist and a patient. Another interesting component is automatic text summarization, which is becoming quite important because of the large amount of textual content that grows exponentially on the internet and various archives [49]. Automatic text summarization approaches are either extractive, abstractive, or hybrid [50]. Moreover, these days, there is a need for summarizing text based on queries.

Data Storage and Retrieval

In response to the risks associated with EHRs and PHRs, more advanced IT solutions have been introduced. Cloud-based storage is another solution that has gained popularity in recent years. It allows for the secure storage and sharing of data over the internet [51]. Although cloud-based data handling is quite convenient and user-friendly, it could still make the records vulnerable to unauthorized access and loss of data [52].

This brought us to the doorsteps of blockchain technology, which is a decentralized digital ledger that stores data in a secure and tamper-proof manner [53]. Each block in the chain contains a timestamp and a cryptographic hash of the previous block, making it nearly impossible to alter or delete data without being detected.

Two well-known blockchain solutions were evaluated as potential platforms for our project, that is, Hyperledger Fabric and Ethereum [54]. We first compared these blockchain solutions in terms of the nature of their technology being decentralized or centralized. Although Ethereum can be categorized as decentralized and several security analysis tools have been developed for its smart contracts, they mostly have a command line interface with low usability [55]. Moreover, we found that using Ethereum could potentially violate the privacy of mental health records; therefore, Hyperledger Fabric seems more practical for us, as it is a private permissioned blockchain and is more suitable for private data [56].

Then, we compared these technologies based on their consensus mechanisms and how fast they achieve confirmations. This again resulted in Hyperledger Fabric being more appropriate because it has fewer confirmation nodes compared to Ethereum [57]. Finally, we differentiated Ethereum and Hyperledger Fabric based on throughput. This too ended in Hyperledger Fabric's favor, as it can process far more transactions per second compared to Ethereum [57].

Comparative Evaluation—Findings

We have categorized the findings of technological evaluation into 3 parent aspects, that is, data collection, data analysis, and data storage or retrieval. Table 8 describes what sort of solutions were available to us for each aspect of psychiatric data handling,

XSL•FO
RenderX

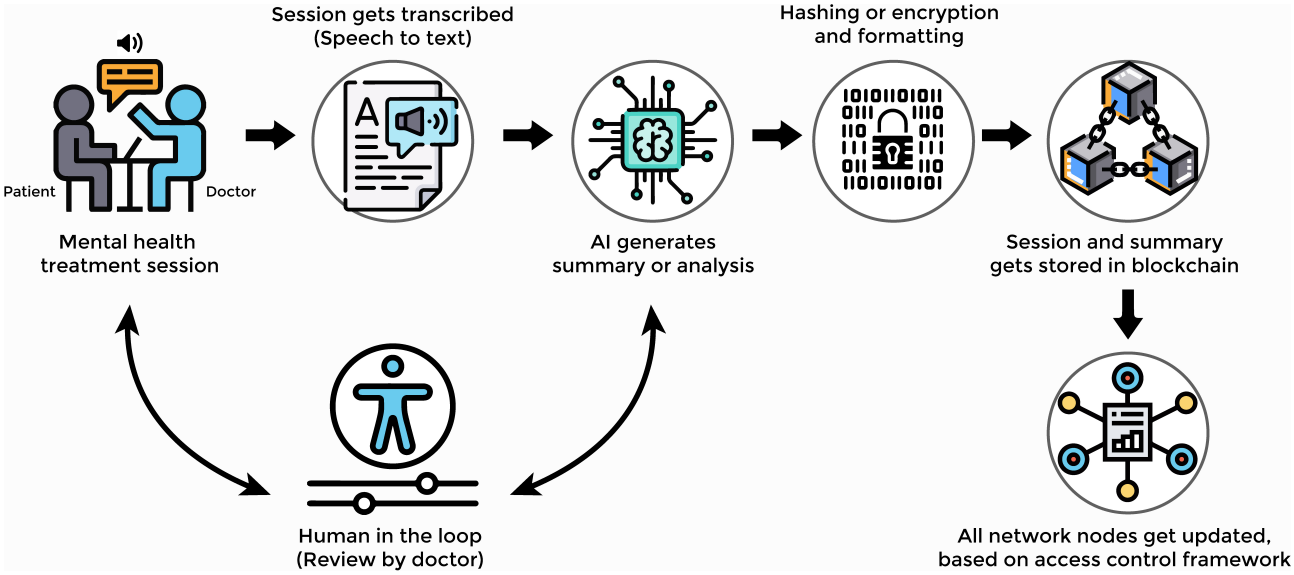
which ones did we choose, and what are the justifications of our choices or recommendations.

Table . Comparative evaluation of different existing technological solutions.

Data handling aspects	Available solutions	Suitable choice	Justification
Data collection	Handwritten notes, tools for typing notes (Evernote, OneNote, Google Keep, Apple Notes, etc), audio or video recording tools (Voice-BoxMD, T-Pro, Upheal, Mentalyc, Athreon, CarePatron, etc), speech-to-text transcription tools.	Speech-to-text transcription tools (OpenAI, Google API[a], JavaScript API, AWS transcribe, Assembly AI, Intel PyTorch, etc).	Digital note-taking tools would only resolve readability and digitization concerns. Whereas speech-to-text transcription would also resolve the workload, cognitive reliance, and patient reluctance concerns.
Data analysis	Multidisciplinary team meetings, written or typed reports and charts, statistical analysis tools, artificial intelligence (AI).	AI-enabled statistical analysis program with "Human in the Loop," trained with psychiatry-specific data for general statistics, identification of patterns, and recommendations.	With the exception of handwritten notes or charts, a convergence of all available solutions is needed. AI must be involved to reduce workload and facilitate the process of analysis, diagnosis, and treatment.
Data storage or retrieval	Patient folders with case notes in cabinets, scanned or typed files in PCs, conventional databases (SQL, etc), cloud (AWS, Google, etc), blockchain (Ethereum, Hyperledger Fabric, etc).	Permissioned blockchain with hashed storage. For example: Hyperledger Fabric.	Cabinet storage does not resolve any challenge. Conventional databases and cloud services are vulnerable against cyberattacks. Blockchain is secure, distributed, and tamper-proof, which would also address authenticity, in legal aspects.

[a]API: application programming interface.

Discussion



After compiling results and insights from our mixed methods, we started framing a technological solution and kept some psychiatrists in the loop to validate our technological proposals. This section summarizes the thought process behind reaching the proposed solution and how does it offer novelty.

Proposed Approach

The infographic overview of the proposed solution with its operations is given in Figure 1. If we further break the workflow into steps, it would be as follows:

- A mental health treatment session takes place, involving a patient and a doctor.
- During consultation, the conversation gets transcribed into digital text format.
- AI is then used to generate a summarized version or highlights of the treatment session. This step holds the potential to be advanced to probable diagnosis and treatment suggestions and insightful analysis by the AI tool.
- The AI-generated summary and analysis would then be reviewed by the doctor for any corrections or additions.
- Once approved by the doctor, the entire data would then get encrypted for security and hashed to reduce its size.
- The hashed data would then get stored to a permissioned blockchain.
- All nodes of the network would get updated based on an access control framework, that is, which staff members will have access to which sections of each patient record.

Figure 1. Overview of the proposed solution. AI: artificial intelligence.

XSL•FO
RenderX

Proposed Novelty

In Table 9, we have summarized 12 comparative aspects of the existing state of data handling practices in Irish MHS. It shows how our proposed solution would address, innovate, or improve each aspect.

Table . Comparative aspects between the current state and proposed solution.

Comparative aspects	Current state	Proposed solution
Digitization	Psychiatric case notes are largely based on paperwork in handwritten format.	Paperwork would get replaced by digitized psychiatric case notes.
Readability	Handwritten psychiatric case notes lack readability and hinder case study.	Digitized case notes would enable 100% readability and support the case study.
Cognitive reliance	Heavy reliance on the human ability to remember and write or type conversation.	Allows one to skip recalling or writing and focus on psychiatric evaluation instead.
Workload	Parallel workload (paperwork+digital tasks). If not write, one must type.	Speech-to-text transcription reduces workload and automates the note-making.
Expression reluctance	Note-writing makes patients reluctant and uncomfortable in sharing thoughts.	Automated transcription enables patients to feel comfortable while expressing.
Data storage	Patient's data and case are written in paper files and stored in cabinets.	Data would get stored in a permissioned blockchain in a hashed format.
Data privacy	Patient's contact data and case are explicitly described in files with stickers.	Data would be categorized in privacy terms and kept in encrypted format.
Access authorization	Unauthorized staff may access and read patient files and take photographs.	Role-based access authorization would be implemented using smart contracts.
Data tampering	Signatures are used for alteration in notes, with no digital tracking in place.	Blockchain would ensure data immutability and traceable digital footprints of all actions.
Data security	Outdated security measures for data storage and transfer, prone to cyberattacks.	Distributed yet semicentralized blockchain network would prevent cyberattacks.
Research and analysis	Handwritten notes obstruct the potential of research and psychiatric data analysis.	Digitized Psy-Notes enables psychiatric data analysis and diagnostic or treatment research.
Uniform data collection	Existing practice may result in variations in collected data by different doctors.	Transcribed treatment sessions would ensure uniformity in data for evaluation.

Challenges and Limitations

It is important to acknowledge that the initial phase of execution of such an advanced and reform-driven technological solution is not going to be a smooth process. Each aspect of this proposed plan would involve different sorts of challenges and demands, which are as follows: lack of familiarity with emerging technologies like blockchain and AI, training needs of the medical staff regarding the adopted technological solution, need for advanced usability and human-computer interaction standards, setting up the environment and distributed network of nodes, securing investment for a required equipment and routine maintenance, employment of skillful IT professionals for development and cybersecurity, employment of a dedicated research team for tracking progress and sharing insights, reliance on speech-to-text transcription tool for accommodating different Irish accents, the accuracy of the content generated by AI, integration of the proposed solution with existing systems, and amendments to the existing policies, where necessary, such as access control protocol.

The limitations related to AI and speech-to-text transcription were scaled down by adopting a human-in-the-loop approach. However, these technologies must be improved and upgraded over time to the extent where human involvement would be reduced to formality or validation. When it comes to blockchain applications, most people are concerned about the energy consumption associated with it. It is important to clarify that the energy-related drawbacks are related to those blockchain platforms that are based on a proof-of-work consensus mechanism. Our technological evaluation has recommended a permissioned blockchain platform, such as Hyperledger Fabric, which does not involve a proof-of-work mechanism.

Conclusions

Ireland's mental health challenges place it among the worst in Europe. This encouraged us to conduct a thorough case study regarding data handling practices in Irish MHS, in order to contribute toward an improved service delivery in the Irish psychiatry sector. We adopted a mixed methodology to collect data from various sources for comparative analysis and cross-validation. Our study involved literature review, interviews, web-based surveys, interaction with different organizations, analysis of some relevant inspection reports, comparative technological evaluation, and a feedback loop with stakeholders.

It was noteworthy that all results were complimenting and supporting each other. However, the list of surfaced shortcomings in Irish MHS from different aspects turned up way longer than our expectations. The main concerns highlighted by results included lack of digitization, reliance on

XSL•FO
RenderX

paperwork and doctors' cognitive abilities for writing case notes, low readability, reluctance of patients in sharing their thoughts due to confidentiality concerns, sensitive legal applications, data violations by the staff, and parallel workload.

Upon brainstorming and consultation, we finalized a solution that holds the potential to resolve multiple intertwined challenges collectively. It involves collecting psychiatric data using speech-to-text transcription, then performing analysis on it using AI, which upon doctor's review gets stored in a distributed permissioned blockchain in categorized and hashed format for retrieval based on access control rules. We shared our results and the respective proposed solution with psychiatrists working at Irish MHS, who estimated that it could reduce an average of 35% of their existing workload.

Although this proposed solution has some technical and practical challenges regarding development and usability, it is still innovative and worthy enough to be considered and executed, as it offers many positive implications. This is a novel convergence of different existing technologies that could get used smartly to address a wide range of flaws in the existing state of data handling in Irish MHS. Upon implementation, such a solution would not only facilitate the mental health practitioners in their diagnosis and treatment process but also optimize the workload and cost expenditure in the long term.

Acknowledgments

The authors would like to thank and acknowledge all mental health practitioners who facilitated their study with their participation and insightful feedback. Additionally, the authors appreciate the role played by organizations like the Mental Health Commission and the Brothers of Charity Services in shaping this case study. Finally, the authors recognize the resources and platform provided to the research team by the College of Science and Engineering and the School of Psychology in the University of Galway.

Abstract

Background: Mental health difficulties are increasing among Canadian postsecondary students, and many face barriers to accessing mental health care. Mobile health smartphone apps for mental health reduce common barriers to care and improve student mental health outcomes. However, students' engagement and use of mental health apps is low. Evaluating the usability and quality of mental health apps is essential not only for user engagement but also for safety and overall utility. Few mental health apps have undergone usability and quality evaluations, especially with measures explicitly designed for these apps. The JoyPop app is a resilience-building mental health app with evidence supporting its effectiveness for student mental health. It has yet to be evaluated using standardized measures of mental health app usability and quality, and the influence of usability and quality on use is unknown.

Objective: We evaluated the usability and quality of the JoyPop app and the predictive importance of usability and quality, compared to other relevant user characteristics, in predicting intentions to use the app in the future (usage intentions).

Methods: Participants (N=183) completed preapp measures assessing demographics and personality traits, then used the app for 1 week, and then completed postapp measures assessing the usability, quality, and use of the JoyPop app. Usability (overall; and subscales: ease of use, interface and satisfaction, and usefulness) and quality (objective, subjective, and perceived impact) were assessed with descriptive statistics. Multiple regression analyses tested the predictive importance of usability and quality on usage intentions after controlling for other user characteristics.

Results: Participants rated the JoyPop app's overall usability as "very good" (mean 5.63, SD 0.85). Participants rated the JoyPop app's overall objective quality as "excellent" (mean 4.06, SD 0.54). Subjective quality ratings were good, with many participants (135/183, 73.8%) indicating they would recommend the app to others. Participants rated the app as having a moderate and helpful impact on their mental health and coping skills (mean 3.48, SD 0.88). In each regression model, usability (β=.56, P<.001) and quality (β=.52, P<.001) were the strongest predictors and predicted usage intentions over and above other user characteristics.

Conclusions: Results align with prior research evaluating the JoyPop app and maintain that it is an engaging and high-quality mental health app that can support students. Findings provide important insight into the optimal design of mental health apps for students and inform adaptations to future iterations of the JoyPop app.

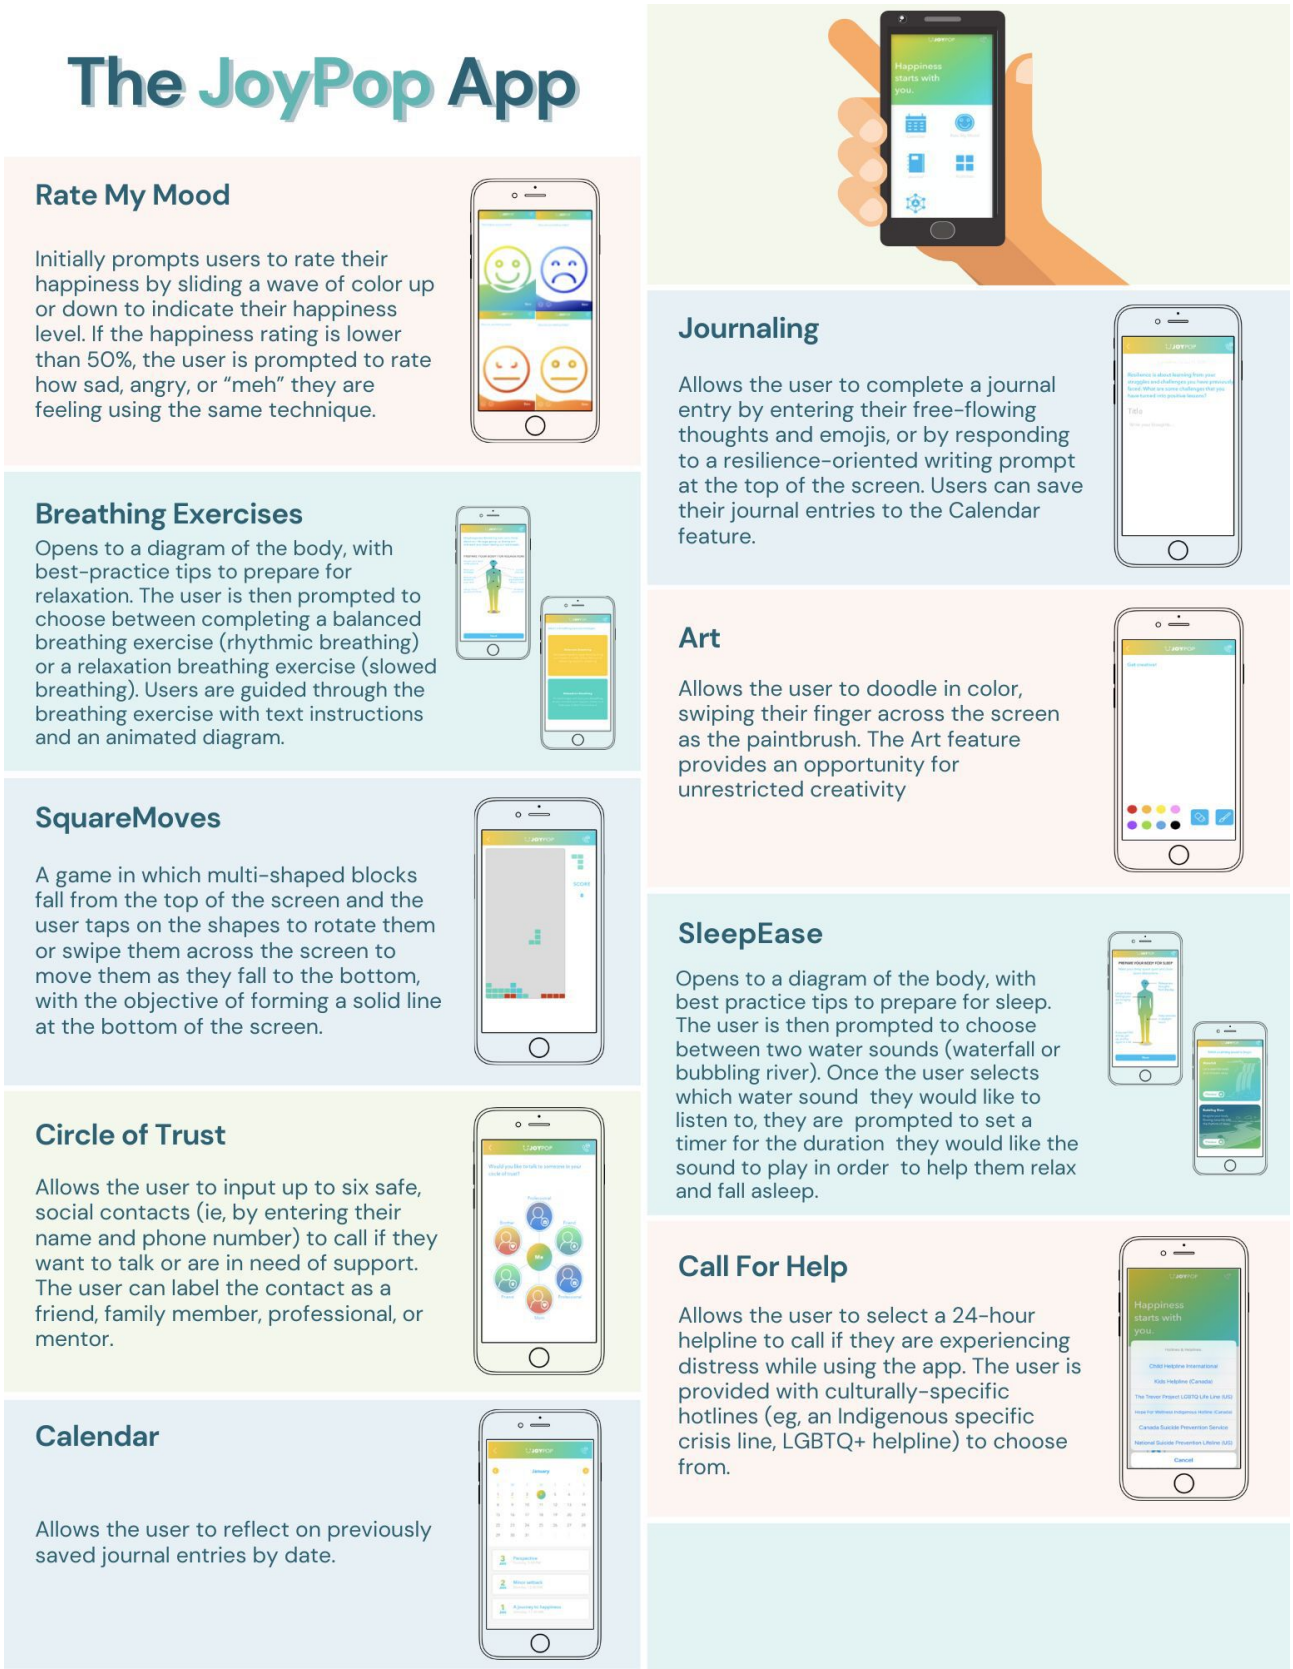
Introduction

Background

Mental health difficulties among Canadian postsecondary students are increasing [1-3]. Unaddressed mental health difficulties can exacerbate existing challenges and negatively impact academic and long-term health outcomes [4,5]. Concerningly, students face a multitude of barriers (eg, long wait times and financial constraints) to access mental health support [4,6], resulting in prolonged distress, difficulties for campus mental health services, and low future help-seeking behaviors [7,8]. Novel approaches that increase students' access to mental health support are needed [9,10].

Mobile health smartphone apps designed to improve mental health are promising tools to support students [10,11]. Mental health apps also expand service capacity, improve availability and access to support, and reduce stigma, cost, time, and travel-related barriers for students [12-14]. Mental health apps are especially promising for students because they use smartphones frequently and are open to using apps for

XSL•FO
RenderX



health-related reasons [15,16]. Research examining the effectiveness and efficacy of mental health apps among students shows that apps can improve well-being and reduce stress, depression, and anxiety [17,18].

The JoyPop App

The JoyPop app is a mental health app designed to improve resilience through evidence-based features that promote emotion regulation and adaptive coping among youths and emerging adults [19,20]. The JoyPop app was co-designed by youths, researchers, and service providers [20]. The app's transdiagnostic focus makes it a valuable addition to usual mental health supports and applicable to a diverse range of students [21,22]. The app is particularly relevant to students as many are undergoing critical life transitions, and timely interventions that promote resilience can have a long-lasting positive impact on well-being and mental health [23,24]. Details of each feature are provided in Figure 1, and the rationale for the inclusion of each feature is documented elsewhere [19,25].

XSL•FO
RenderX

Figure 1. Summary and highlights of features in the JoyPop app. LGBTQ+: lesbian, gay, bisexual, transgender, and queer.

There is an increasing multimethod evidence base supporting the effectiveness and value of the JoyPop app as a complement to mental health services across diverse users in clinical and nonclinical settings [19,25-29]. Among students, using the JoyPop app is associated with improved emotion regulation, improved depressive symptoms, and reduced stress [19,29]. Additionally, students perceive that the app improves emotion regulation and facilitates opportunities to implement adaptive coping skills [28]. Multiple randomized controlled trials (with students more generally [30] and with youths waiting for mental

XSL•FO
RenderX

health services [31]) evaluating the app's effectiveness in improving emotion regulation and mental health outcomes are ongoing.

Although evidence of a mental health app's effectiveness is essential, it does not guarantee users will engage with or enjoy their experience with an app [15,32]. Student engagement and long-term uptake of mental health apps are typically low [33-35] and can reduce the overall positive outcomes associated with app use [32,36]. Engagement, safety, and overall utility are affected by how usable an app is perceived to be and a user's perspective on the quality of an app [15,34,36]. Despite this, the majority of mental health apps available in major marketplaces have not undergone usability and quality evaluations [35,37,38].

Usability

Usability is defined as a "quality attribute that assesses how easy interfaces are to use" [39]. Evaluating mental health app usability can reveal factors (eg, functionality, feature usefulness, layout, and readability) that reduce engagement and use [35,36]. Mental health app usability studies show that students value mental health apps with a convenient and intuitive design, customization, anonymity, privacy, peer involvement, games, and options to access professional help [40,41].

Most studies assessing usability include measures designed for general technologies [42,43], such as the System Usability Scale [44]. Applying general technology usability measures to mental health apps can provide some valuable information, but they miss identifying factors unique to mobile health apps, such as limited computation power, security and privacy challenges, and characteristics associated with small screens and portable devices [43,45]. Measures designed specifically for apps, such as the Mobile Application Usability Questionnaire (MAUQ) [43], are rarely used [42,46]. Usability evaluations with validated and standardized measures developed for apps are recommended [43,46].

Quality

Evaluating the quality (eg, effectiveness, credibility, reliability, and safety) of mental health apps is also essential. Users are more likely to use a mental health app if it is provided by a credible source, positively impacts their mental health, and has evidence of safety and effectiveness [32]. Without proof of quality, users may rely on subjective star ratings, which can be inconsistent with an app's actual quality and clinical utility [47-49]. Claims of mental health app quality are not consistently assessed by regulatory bodies [49,50], and most apps lack evidence of quality and effectiveness, clinical input from professionals, and evidence-based features [51,52]. Poor-quality mental health apps can therefore pose significant risks to users, such as misdiagnosis, unknown side effects, and physical and mental harm [53].

Several resources are now available to locate, assess, and regulate the quality of mental health apps, such as app rating guidelines and platforms [37,54,55]. For example, the Mobile Health App Database (MHAD) rating platform provides quality ratings for a wide variety of mental health apps to help guide users and health care providers in selecting quality apps [54,56]. The Mobile Application Rating Scale (MARS) [49] is the most popular app rating guideline [42] and allows experts in mental health to rate apps based on quality indicators from health-related fields [49]. The user version of the Mobile Application Rating Scale (uMARS) is also available to help consumers without training and expertise to rate the quality of mobile health apps [55].

This Study

In this study, we aimed to (1) evaluate the usability and quality of the JoyPop app and (2) test the relative predictive importance of usability and quality on usage intentions, compared to other user characteristics. We used questionnaires explicitly designed to evaluate mobile health apps [42,46] to ensure that important facets of usability and quality unique to these apps were captured [43,57]. We chose age, gender, neuroticism, and agreeableness as relevant user characteristics based on past research highlighting their influence on mental health app use [58-61]. Because of the extensive literature highlighting the importance of usability and quality in mental health app use [32,37,45], we hypothesized that usability and quality would significantly predict JoyPop usage intentions over and above the other user characteristics.

Methods

Design

We used a 1-week prospective design to ensure students had sufficient time to use the app thereby facilitating more informed app evaluations.

Ethical Considerations

The study was reviewed and approved by the Lakehead University research ethics board (Romeo #1470023). All participants provided informed consent before beginning the study, were under no obligation to participate, and were free to withdraw at any time without penalty. All data were deidentified. We compensated participants for their time via cash or e-transfer or bonus points toward an eligible psychology course for completing part 1 and part 3 of the study (CAD $10 [US $7.28] or 1 bonus point for part 1, CAD $20 [US $14.57] or 1.5 bonus points for part 3).

Participants and Procedure

Participants were eligible for the study if they were students at Lakehead University who spoke and read fluently in English. We recruited students throughout the fall (2023) and winter (2024) terms (N=183). To increase the representativeness of our sample, we used multiple recruitment methods (eg, posters and class emails), had no exclusionary criteria based on student characteristics (eg, year of study), and provided refurbished iPhones with the JoyPop app for students who did not have a suitable device of their own. The study had 3 parts. In part 1, students attended an orientation session where they provided informed consent, learned about downloading and using the app, and completed preapp measures (ie, demographics and personality traits). In part 2, the research team reminded participants (via text or email) to use the app twice daily for 1

XSL•FO
RenderX

week. In part 3, participants were emailed or texted a link to complete postapp measures (ie, usability and quality).

Measures

Demographics

To describe the characteristics of the sample, we captured participant demographics (13 items) along with students' experience with mental health apps (5 items) by adapting items from prior questionnaires assessing technology experience [62,63]. We used the age and gender of participants as control variables in our analysis.

The Big Five Aspects Scale

We used the Big Five Aspects Scale (BFAS) [64] to gather information on participant personality traits. The BFAS consists of 100 items rated on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Participants rate their level of agreement with how well brief statements generally describe how they are. The BFAS provides scores for the traditional Big Five domains and 2 aspects for each domain. We used scores for the neuroticism and agreeableness domains as control variables in our analysis. The BFAS shows excellent internal consistency and test-retest reliability in postsecondary samples [64-66]. The internal consistency of domains used in this study was excellent (neuroticism, α=.9; agreeableness, α=.82).

MAUQ

The MAUQ [43] assesses the usability of mobile health apps. We used the 18-item standalone patient version of the MAUQ in this study as it best suits the context and design of the JoyPop app. Overall usability includes 3 subscales: ease of use (5 items), interface and satisfaction (7 items), and usefulness (6 items). Participants rate their level of agreement with brief statements on a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree). We calculated the overall usability score by computing the mean across all items. We derived subscale scores by computing the mean of scores for relevant subscale items. Higher scores indicate greater usability. Consistent with prior research [67,68], we used descriptors based on quartiles derived from a maximum possible score of 7 on the MAUQ scales to facilitate reporting and interpreting results: 0 - 1.75 (poor), 1.76 - 3.5 (moderate), 3.51 - 5.25 (good), and 5.26 - 7 (very good). The MAUQ has adequate psychometric properties across samples, including among postsecondary students [43]. The internal consistency of the overall scale score and subscale scores in this study was strong (overall scale, α=.92; ease of use, α=.79; interface and satisfaction, α=.86; usefulness, α=.85).

uMARS

The uMARS is a simple and reliable tool for end users to comprehensively evaluate mobile health app quality via indicators of objective and subjective quality, and perceived impact on a target health behavior [55]. We used the 27-item uMARS to evaluate the quality of the JoyPop app from the user's perspective. The 16-item "objective quality" scale of the uMARS allows users to rate app quality based on indicators derived from research and expert and clinician recommendations on a 5-point Likert scale ranging from 1 (inadequate) to 5 (excellent). The "objective quality" scale has 4 subscales: engagement (5 items), functionality (4 items), aesthetics (3 items), and information (4 items). We derived the overall and subscale scores by calculating the mean of relevant items (items rated as N/A were omitted). Based on item ratings and past research [69,70], we used descriptors for ranges of scores: 0 - 1 (inadequate), 1 - 2 (poor), 2 - 3 (acceptable), 3 - 4 (good), and 4 - 5 (excellent), to facilitate the interpretation of results and comparisons with other mental health apps. The overall scale and subscale scores have good psychometric properties [55]. The internal consistencies in this study were good (objective quality, α=.89; engagement, α=.77; functionality, α=.75; aesthetics, α=.78; information, α=.79).

The 4-item "subjective quality" subscale of the uMARS allows users to rate different indicators (eg, star ratings, whether it is worth recommending) of a mobile health app's subjective quality on a 5-point Likert scale ranging from 1 to 5 (anchors vary across questions). The 6-item "perceived impact" subscale of the uMARS allows users to rate its impact on user knowledge, awareness, intention to change, help-seeking, behavior change, and attitudes on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). This subscale was designed so that the wording of the items could be adapted to fit the function (eg, to impact mental health) of an app. We calculated the subjective quality and perceived impact subscale scores by calculating the mean of the relevant items (higher scores indicate stronger quality and impact). The subjective quality scale and perceived impact scale have good psychometric properties [55]. The internal consistency in this study was good (subjective quality, α=.79; perceived impact, α=.93).

Usage Intentions

We used an item ("How many times do you think you would use the JoyPop app in the next 12 months if it was relevant to you") from the subjective quality scale on the uMARS to assess participants' intentions to use the app in the future (usage intentions). Participants responded on a 5-point scale ranging from 1 (none) to 5 (>50 times). (Although we tracked the number of days participants used the app across the study period, we did not include this as our primary app use outcome variable as there was insufficient variation; that is, the majority of participants used the app every day; see descriptive results below.)

Statistical Analysis

We used SPSS (version 29, IBM Corporation) for the analyses. We calculated and examined the descriptive statistics for demographics and personality traits to characterize the sample. We calculated descriptive statistics for each scale and item of the MAUQ and uMARS to evaluate the usability and quality of the JoyPop app. To test our hypotheses that usability and quality would predict app use over and above other user characteristics, we conducted 2 multiple regression analyses. The first model included overall usability as a predictor; the second model included overall objective quality as a predictor. Both models included age, gender, agreeableness, and neuroticism as covariates. We included all predictors together for each model because our focus was to examine the relative importance of quality and usability in predicting use.

Results

User Characteristics

We present the characteristics of the sample in Table 1. On average, participants were aged 22.6 (SD 7.08; range 16 - 56) years. Most participants were women (150/183, 82%), White (100/183, 54.6%) or Black (33/183, 18%), full-time students (156/183, 85.2%), and in their first (81/183, 44.3%) or second (54/183, 29.5%) year of university. The majority of participants reported no current or past use of mental health apps (148/183, 80.9%), and most did not currently have a mental health app installed on their phones/devices (158/183, 86.3%). Among participants who used mental health apps in the past (35/183, 19.1%), most used them for 0 - 6 months (115/183, 62.8%). Descriptive statistics of relevant personality traits (ie, neuroticism: mean 3.18, SD 0.63; agreeableness: mean 4, SD 0.42) were consistent with prior research among students [64,66]. Most participants used the app every day of the study period (mean 4.69, SD 0.81).

Usability

Participants rated the JoyPop app's overall usability as "very good" (mean 5.63, SD 0.85; range 2.22 - 7), and 69.9% (128/183) of the sample had scores in the "very good" range. Participants rated the ease of using the app as "very good" (mean 6.37, SD 0.67; range 3.2 - 7), and 92.3% (169/183) of the sample reported scores in the "very good" range. Participants rated the interface and satisfaction with the app as "very good" (mean 5.7, SD 0.99; range 1.57 - 7), and 68.9% (126/183) had scores within the "very good" range. Participants rated the usefulness of the app as "good" (mean 4.93, SD 1.17; range 1.5 - 7), with 42.1% (77/183) of scores in the "good" range and 38.3% (70/183) of scores in the "very good" range. We found that all item scores (see Table 2) on the ease of use and interface and satisfaction subscales fell within the "very good" range, and all item scores on the usefulness subscale were in the "good" range.

Table . Means and SDs of MAUQ[a] subscale items.

Subscale items	Mean (SD)
Ease of use	
1. The app was easy to use.	6.58 (0.66)
2. It was easy for me to learn to use the app.	6.64 (0.55)
3. The navigation was consistent when moving between screens.	6.37 (0.94)
4. The interface of the app allowed me to use all the functions (such as entering information, responding to reminders, and viewing information) offered by the app.	6.32 (1.04)
5. Whenever I made a mistake using the app, I could recover easily and quickly.	5.96 (1.20)
Interface and satisfaction	
6. I like the interface of the app.	5.75 (1.23)
7. The information in the app was well organized, so I could easily find the information needed.	6.29 (0.92)
8. The app adequately acknowledged and provided information to let me know the progress of my action.	5.50 (1.45)
9. I feel comfortable using this app in social settings.	5.84 (1.24)
10. The amount of time involved in using this app has been fitting for me.	5.59 (1.42)
11. I would use this app again.	5.42 (1.50)
12. Overall, I am satisfied with this app.	5.55 (1.50)
Usefulness	
13. The app would be useful for my health and well-being.	5.19 (1.58)
14. The app improved my access to health care services.	4.63 (1.62)
15. The app helped me manage my health effectively.	4.52 (1.55)
16. This app has all the functions and capabilities I expected it to have.	4.85 (1.71)
17. I could use the app even when the internet connection was poor or not available.	5.16 (1.31)
18. This app provided an acceptable way to receive health care services, such as accessing educational materials, tracking my own activities, and performing self-assessments.	5.22 (1.45)

[a]MAUQ: Mobile Application Usability Questionnaire.

Quality

Participants rated the overall objective quality of the app as excellent (mean 4.06, SD 0.54; range 1.96 - 5), with 60.7% (111/183) of participants rating app quality as "excellent." Participants rated the app's functionality (mean 4.47, SD 0.52; range 2.75 - 5; 136/183, 74.3% in the "excellent range"), aesthetics (mean 4.17, SD 0.67; range 1 - 5; 101/183, 55.2% "excellent"; 41/183, 21.4% "good"), and information (range 1 - 5; 107/183, 58.5% "excellent"; 39/183, 21.3% "good") as "excellent." Participants rated the app's engagement as "good" (range 1 - 5; 74/183, 40.4% "good"; 34/183, 18.6% "excellent").

Regarding subjective quality (see Table 3), we found that many participants (144/183, 78.7%) would recommend the app to others. For our measure of app use, which asked how often participants would use the app in the next 12 months, 24% (44/183) reported 3 - 10 times, 42.1% (77/183) reported 10 - 50 times, and 19.1% (35/183) reported >50 times. Most participants (132/183, 72.1%) did not want to pay for the app. The most

XSL•FO
RenderX

frequent star rating of the app was 4 stars (92/183, 50.3%), followed by 3 stars (62/183, 33.9%).

Table . Means, SDs, and frequencies of "subjective quality" item responses (N=183).

Item and response options	Responses, n (%)	Responses, mean (SD)
Would you recommend the JoyPop app to people who might benefit from it?		3.69 (1.22)
Not at all; I would not recommend this app to anyone	7 (3.8)	
There are very few people I would recommend this app to	32 (17.5)	
Maybe, there are several people I would recommend this app to	33 (18)	
There are many people I would recommend this app to	49 (26.8)	
Definitely, I would recommend this app to everyone	62 (33.9)	
How many times do you think you would use the JoyPop app in the next 12 months if it was relevant to you?		3.55 (1.61)

1 to 2	8 (4.4)	
3 to 10	44 (24)	
10 to 50	77 (42.1)	
>50	35 (19.1)	
Would you pay for this app?		1.9 (0.98)
Definitely not	82 (44.8)	
Probably not	50 (27.3)	
Unsure	40 (21.9)	
Probably yes	9 (4.9)	
Definitely yes	2 (1.1)	
What is your overall (star) rating of the app?		3.54 (0.80)
One	3 (1.6)	
Two	13 (7.1)	
Three	62 (33.9)	
Four	92 (50.3)	
Five	13 (7.1)	

The overall perceived impact of the app on participants' mental health and coping skills (see Table 4) was moderate (mean 3.48, SD 0.88; range 1 - 5). Most participants rated the app as having a moderate impact (55/183, 30.1% of scores between ≥3 and <4) or a strong impact (45/183, 24.6% of scores ≥4). Many participants agreed or strongly agreed that the app had a positive impact on their awareness (107/183, 58.5%), behaviors (103/183, 56.3%), knowledge and understanding (103/183, 56.3%), intentions and motivation (106/183, 57.9%), and attitudes (100/183, 54.6%) related to mental health and coping skills. Most agreed or strongly agreed that the app had a helpful impact on their willingness to seek further help for mental health and coping skills if needed (115/183, 62.8%).

Usability, Quality, and Usage Intentions

We present the results of each regression model examining the relative predictive importance of usability and quality on usage intentions in Table 5. We found evidence of heteroskedasticity for age, so we used robust standard errors to obtain unbiased estimates of the regression coefficients. Our first regression model tested the predictive importance of usability on usage intentions. Age (β=.15; *P*=.008) and gender (β=.12; *P*=.04) were both significant and positive predictors of usage intentions. Neuroticism and agreeableness were not significant predictors of usage intentions. In line with our hypothesis, usability significantly and positively predicted usage intentions over and above other user characteristics, and usability was the strongest predictor in the model ($F_{5,177}$=15.69; *P*<.001; $R^2_{adjusted}$=0.29; β=.56; *P*<.001). Our second regression model tested the predictive importance of quality on usage intentions. Age was a significant and positive predictor of usage intentions (β=.17; *P*=.008). Gender, neuroticism, and agreeableness were not significant predictors of usage intentions. Consistent with our hypothesis, quality significantly and positively predicted usage intentions over and above other user characteristics and was the strongest predictor in the model ($F_{5,177}$=12.58; *P*<.001; $R^2_{adjusted}$=0.24; β=.52; *P*<.001).

Discussion

Usability and Quality of the JoyPop App

We evaluated the usability and quality of the JoyPop app and assessed their impact on intentions to use the app in the future after controlling for other user characteristics. Participants rated the overall usability as “very good” and all indicators comprising usability subscales were in the “good” to “very good” range. The cumulative evidence strongly supports that JoyPop app users are comfortable and satisfied with using it, find it easy to learn and use, and view it as a helpful tool to support mental health and well-being in different contexts (eg, clinical and academic settings) [25-28]. Usability ratings for the JoyPop app from this study are also similar to ratings of other popular mental health apps [71]. These findings will support organizations and consumers who are considering offering or using the JoyPop app.

Participants rated the JoyPop app’s overall objective quality, functionality, aesthetics, and quality of information as “excellent” and the app’s engagement as “good.” Results are consistent with past research on the JoyPop app, highlighting it as an engaging, high-quality mental health app with strong functionality, visual design, and helpful evidence-based content [25-28]. Results also indicate that the JoyPop app falls within the upper ranges for objective quality when compared to popular and research-supported mental health apps (eg, Calm, PTSD Coach, SuperBetter, and Destressify) rated by experts [54,72]. For example, across approximately 50 mental health apps rated using the MARS, the average objective quality was 3.54 (range 1.63 - 4.75) [54]. Among 19 popular research-supported mental health apps, the average objective quality score was 3.52 (SD 0.71), and average subscale scores were 3.98 (SD 0.82) for engagement, 3.42 (SD 0.80) for functionality, 3.23 (SD 0.90) for aesthetics, and 3.47 (SD 0.69) for information [72].

Response frequencies to items on the subjective quality scale also support the quality of the JoyPop app. Although these are subjective ratings, their importance is highlighted by the consistency between subjective consumer ratings of mental health apps and objective expert reviews of mental health apps [72]. Subjective quality results also showed that most participants would not pay for the app. This is not surprising, as research consistently shows that people are less likely to use apps that have associated costs [32,73]. Taken together, the high objective and subjective quality ratings of the JoyPop app across indicators of mobile health app quality, combined with its quality ratings compared to mental health apps reviewed by experts, strongly support its safety, credibility, helpfulness, and use for students. Future research will benefit from having experts evaluate the quality of the JoyPop app (eg, using the MARS) to validate this study’s findings and by compiling end-user quality evaluations of mental health apps to facilitate comparisons.

Finally, more than half of the participants perceived that the JoyPop app positively impacted their mental health and coping skills in all areas queried. This finding further supports the overall quality of the app. The broad range of areas impacted by the JoyPop app is consistent with past research demonstrating its effectiveness and benefits among diverse samples of users and supports its overall ability to deliver users an effective experience [19,25-29]. Results from rigorously controlled trials examining effectiveness are still needed. However, results on the app’s perceived impact on mental health and coping skills can delineate whether future outcomes are meaningful and impactful, provide researchers with an understanding of the potential mechanisms and reasons why the app might be

XSL•FO
RenderX

effective, and inform outcome measures that can be assessed in rigorously controlled trials (eg, measures of help-seeking and coping skills).

Influence of Usability and Quality on Usage Intentions

In our regression models, overall usability and objective quality were the strongest predictors of usage intentions and predicted usage intentions over and above age, gender, neuroticism, and agreeableness. Although we did not objectively measure app usage (eg, number of days used), behavioral intentions are a strong predictor of actual behavior, and user intentions are consistently shown to predict the use of digital health technologies [74-76]. Consequently, our results align with research demonstrating the substantial impact of quality and usability on engagement, long-term uptake, and use of mental health apps [32,35,37]. The importance of usability and quality in predicting participants' intentions to use the JoyPop app in the future, along with insight into indicators influencing its quality and usability, provides integral information for JoyPop and other mental health app development teams in optimal app design to improve user experience. An iterative process can be used in which development teams have users rate the usability and quality of the app, determine specific indicators requiring improvement, adapt the app based on these indicators, and then re-evaluate the usability and quality among similar populations.

Limitations

This study has some important limitations. First, we used a convenience sample primarily comprised of women, which may reduce the generalizability of results to men and the broader student population. However, the demographics and diversity of our sample help support the generalizability of the results to students because this study's demographics are similar to those found among students across Ontario [77]. Second, in our study, we requested that participants use the app twice a day over 7 days. This likely contributed to the limited variability in the number of days participants used the app and necessitated our use of a subjective measure of usage intention instead of actual use. To better capture objective usage metrics, studies conducted over longer periods without prompting participants to use the app are needed to establish the relative predictive importance of usability and quality on app use [57].

Conclusions

Mental health apps are promising tools for students' mental health. This study evaluated the usability and quality of a mental health app (JoyPop) designed to improve resilience while examining the relative predictive importance of usability and quality in predicting intentions to use the app in the future. Participants rated the JoyPop app as having "very good" usability. Participants rated the app as having high overall quality because of its "excellent" objective quality, good subjective quality, and helpful impact on their mental health and coping skills. After accounting for user characteristics, usability and quality were the strongest predictors of participants' intentions to use the JoyPop app in the future. Findings facilitate consistency and comparisons of mental health app usability and quality and contribute to the growing evidence base supporting the JoyPop app as an engaging and high-quality mental health app that can support students.

Conflicts of Interest

The senior author (AM) recently acquired intellectual property ownership rights for the JoyPop app (in June 2024). Prior to this time, intellectual property rights were owned by another researcher and institution. AM did not own any intellectual property rights when the study was developed, when data were collected, when data were analyzed, or when the initial draft of the manuscript was developed.

Abstract

Background: Patient portals are a crucial part of modern health care services, as they provide patients with access to their personal information and enable communication with health care professionals. The usability and usefulness of these portals are decisive factors in their adoption. There is a lack of previous research on the use of patient portals in occupational health care (OHC).

Objective: This study aims to examine patients' experiences with the usability and usefulness of OHC patient portals and to identify the factors that influence their perceived usability and usefulness.

Methods: A cross-sectional study was conducted through a web-based survey in April 2024 in Finland. Of the 3072 respondents, usability was assessed using 12 statements, and usefulness was evaluated with 9 statements. Responses were collected on a 5-point Likert scale. The survey also gathered respondents' background information, including age, gender, education, information and communication technology (ICT) skills, satisfaction, frequency of use, and data privacy concerns. Data analysis was performed using SPSS Statistics (version 29; IBM Corp), applying frequency analysis and a general linear model.

Results: The results showed that 75.1% (1895/2523) of respondents agreed that the portal was easy to learn and use, 70.5% (1774/2517) felt it supported collaboration with OHC, while 52.4% (1316/2511) reported that it provided a good overview of their work ability, and 35.5% (891/2505) felt it offered a good overview of their working conditions. The perceived usability of OHC patient portals was significantly associated with several factors in the adjusted model: fear of unauthorized access to data (F_4=4.49, P=.001, η^2=0.007), need for guidance (F_4=52.2, P<.001, η^2=0.080), frequency of use (F_1=34.3, P<.001, η^2=0.014), satisfaction with the portal (F_1=577.1, P<.001, η^2=0.193), perceived ICT skills (F_1=12.2, P<.001, η^2=0.005), and age (F_1=10.8, P<.001, η^2=0.004), with younger users (≤50 years) reporting better usability. Perceived usefulness was significantly influenced by frequency of use (F_1=9.80, P=.002, η^2=0.004) and satisfaction (F_1=548.0, P<.001, η^2=0.183), while other factors such as fear of unauthorized access (F_4=0.41, P=.80), need for guidance (F_4=1.52, P=.20), ICT skills, education, gender, and age were not statistically significant.

Conclusions: OHC patient portals must enhance their capacity to provide information on work ability and working conditions. Improved documentation of work-related hazards, risks, and workload factors in medical records is needed. These enhancements could raise patient awareness of work well-being factors.

(JMIR Hum Factors 2025;12:e73197) doi:10.2196/73197

KEYWORDS

patient portal; patient care; occupational health; work ability data; online questionnaire; Finland; descriptive statistics; general linear regression

Introduction

Generally, a patient portal is a website or mobile app that provides patients with access to their personal health information using a username and password. Through the portal, patients can view health records documented by health care professionals, such as prescribed medications, administered vaccinations, identified allergies, and laboratory test results. Additionally, the portal might enable secure communication with health care professionals [1-3].

Usability and usefulness are key factors in the adoption of patient portals [4-7]. Positive experiences are often associated with the portal's usability and useful features, such as the ability to request prescription renewals and view visit documentation [2,6,8]. Real-time access to information is also an essential aspect of a good user experience [5,6]. Some patients find portals easy to use and useful, while others encounter challenges due to complex interfaces [5,9], lack of user training [10], doubts about the portal's usefulness [11,12], and comprehensibility of medical terminology [8]. Concerns about security and privacy

XSL•FO
RenderX

[2,5,12,13] or lack of professional recommendations may also reduce willingness to use portals [1,14].

The impact of patient portal use on health outcomes has been variable. Some studies [15-17] have found no significant effect of portal use on health outcomes. Conversely, some studies have reported improvements in areas such as quality of care [18], health behavior [19], and understanding own health [5,20]. Many other studies indicate that patient portals enhance communication between patients and health care professionals and increase patient engagement in their own care [5,8,21]. Furthermore, patient portals have helped patients identify errors in their health records, enhancing patient safety [5,22,23].

My Kanta is the national patient portal accessible to all citizens in Finland, and citizens are widely using My Kanta, which allows them to view their medical records and prescriptions, as well as check laboratory and radiology results [24,25]. Alongside My Kanta, occupational health care (OHC) providers in Finland have developed patient portals for their clients [26], likely to strengthen customer relationships by offering their own portals [27].

In Finland, legislation mandates that all employers provide preventive OHC services to their employees to prevent work-related health issues and promote employees' health, safety, and work ability. In addition to the mandatory preventive services, employers also have the option to offer primary health care services at the general practitioner level. Thus, a significant user group for OHC portals consists of working-age patients, as around 91% of Finnish employees are covered by OHC services [28].

Similar to My Kanta, OHC patient portals are used to view medical records, prescriptions, vaccinations, and to check laboratory and radiology results. However, OHC portals, available as both a mobile app and a web service, expand on these functions by also allowing appointment booking, viewing sick leave certificates, and the designated OHC team, as well as enabling remote consultations and secure messaging [6,27].

Information in the portal is based on clinical data entered by OHC professionals and automatically transferred from the electronic health record system. This data is presented as read-only to patients. Additionally, patients are able to input their own health questionnaire responses, self-measurements, and treatment records from other health care providers. However, this patient-generated data is not visible to professionals without the patient's explicit consent. Access rights are clearly defined. Clinical data in the portal can be updated by OHC professionals, while patients are only able to manage their own entries. Furthermore, the portal does not display records from other health care providers, such as My Kanta [25].

A previous study has shown that in OHC, a significant amount of work ability data is generated through patient work [29], as a central objective of OHC is to prevent occupational illnesses and accidents, as well as to maintain and promote work ability [30].

Despite the significant role of patient portals in health care, there is a notable gap in research regarding the experiences of OHC patients with these portals. Only 1 study has explored the experiences of patients from a single OHC provider; however, the patients' ages ranged between 56 and 70 years, and the focus was on using patient portals for health promotion [3]. According to the study, patients were willing to use portals if the information is readily accessible and the functionalities are seamless.

Therefore, this study aims to examine the experiences of OHC patients concerning the usability and usefulness of patient portals. We are also interested in identifying the factors that influence the usability and perceived usefulness of these portals, thereby addressing the existing research gap.

The research questions (RQs) are:

RQ1: How do patients perceive the usability and usefulness of OHC patient portals?

RQ2: Which patient factors are associated with the usability and usefulness of OHC patient portals?

Methods

Participants and Data Collection

The study was conducted through an online survey in April 2024. Two organizations participated in the study: a trade union and a patient expert organization, both representing OHC patients. Each organization appointed a contact person who was responsible for distributing the survey. This contact person sent the survey link via email invitation to all members of their organization, with 2 reminders sent to encourage responses. Before the data collection phase, 5 individuals with experience using OHC patient portals reviewed the survey content for readability and comprehensibility. Their feedback was used to prepare the final version of the survey.

The email invitation to the potential respondents explained that this study aimed to gather insights into users' experiences with digital patient portals in OHC to help develop customer-oriented digital services. It also noted that the survey was part of a project by the Finnish Institute of Occupational Health, supported by the Finnish Work Environment Fund. Participation was voluntary, and the estimated survey completion time was provided. The invitation emphasized respondent anonymity, assuring that personal data and organizational affiliations would not be disclosed. It also mentioned that the results would be published in a scientific paper. Additionally, the invitation included contact information, a research information sheet, and a link to the project website.

A total of 3100 individuals completed the survey. Although the exact response rate could not be determined due to the lack of precise information on how many individuals received the survey (we estimated the size of this study's population to comprise approximately 46,000 individuals), it is known that 8372 people opened the survey link. Based on those who opened the link, the response rate can be estimated at approximately 37% (3100/8372).

XSL•FO
RenderX

Ethical Considerations

The Ethics Committee of the Finnish Institute of Occupational Health approved this study on March 1, 2024 (approval number ETR 022024, ID154008), and the study followed the Finnish research ethics practice. All procedures followed were per the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2000.

Participants were not asked to provide written consent for this study. In Finland, completing the survey is generally seen as an indication of consent to participate in the research and to permit the use of the data collected. Every participant received an official cover letter detailing this study's background, emphasizing that participation is entirely voluntary and anonymous, and noting that answering the questionnaire is considered informed consent to join this study. Also, the cover letter included the purpose of this study, the estimated time required to complete the survey, who the researchers are, the data collection methods, and the duration of data storage. The survey included a request for consent to use the responses for scientific research purposes. All responses were collected anonymously, and no identifying information was gathered. Data were stored securely as per institutional data protection policies to ensure participant privacy and confidentiality. Participants did not receive any compensation for their participation.

Measurements

Dependent Variables

The perceived usability of OHC patient portals was assessed using 12 statements developed per attributes of usability: learnability, efficiency, memorability, errors, and satisfaction [31]. The perceived usefulness of OHC patient portals was evaluated with 9 statements, which were based on researchers' experiences with OHC services and also used elements from the Technology Acceptance Model [32]. Responses to these statements were collected using a 5-point Likert scale, categorized as follows: "totally disagree," "somewhat disagree," "neither agree nor disagree," "somewhat agree," and "totally agree."

All survey variables that investigated the usability (12 statements) and usefulness (9 statements) of OHC patient portals were combined into 2 separate sum variables. Before forming these sum variables, the internal consistency of the items was assessed using the Cronbach α coefficient, resulting in values of 0.95 for the usability sum variable and 0.93 for the usefulness sum variable.

Independent Variables

The survey used in this study included questions on the respondents' background information: gender, age, education, information and communication technology (ICT) skills, satisfaction with OHC patient portals, frequency of use, a need for guidance, and fear of unauthorized persons seeing the data. These were used only in statistical analysis as adjustments.

For analyses, the variables were recoded to facilitate interpretation and enhance clarity. Gender was originally categorized as 1=female, 2=male, and 3=other, or do not want to say. For analysis purposes, these categories were recoded into 1=women and 2 - 3=other. Age was initially divided into 5 groups: 1=up to 30 years, 2=31 - 40 years, 3=41 - 50 years, 4=51 - 60 years, and 5=61 years or older. These were recoded into 2 categories: 1 - 3=50 years or younger and 4 - 5=51 years or older. Education was originally classified with response options of 1=basic education degree (primary school), 2=matriculation examination, 3=vocational college, 4=University or University of Applied Sciences, and 5=other. For analysis, these categories were retained except the "other" category, which was excluded. Perceived ICT skills were initially rated as 1=weak, 2=moderate, and 3=good and were recoded into 1=weak and 2 - 3=at least moderate for analysis. The satisfaction variable was originally measured using response options: 1=totally unsatisfied, 2=somewhat unsatisfied, 3=neither agree nor disagree, 4=somewhat satisfied, and 5=totally satisfied. These were recoded into 2 categories for analysis: 1 - 3=unsatisfied and 4 - 5=satisfied. Lastly, variables, need for guidance, and fear of unauthorized persons seeing the data were retained as per the originals. Additionally, the response option "neither agree nor disagree" is referred to as "neutral."

Data Analysis

The survey data were analyzed descriptively using frequency analysis in SPSS Statistics (version 29; IBM Corp) software. This study's respondent group consisted of a total of 3100 participants who answered at least 1 survey question. Of these, 639 reported regular use of the OHC patient portal, 1906 used it randomly, and 539 had never used it. Additionally, 16 did not respond to this question. The respondents' characteristic variables were described by the absolute (n) and relative (%) frequencies. The number of respondents varies depending on the background variable. No imputation was performed for missing data.

Before analyzing this study's data, participants who reported using the OHC patient portal were included. Respondents' (2545/3084) attitude statements regarding the perceived usability and perceived usefulness of OHC patient portals were described by the relative (%) frequencies (RQ1). However, the number of respondents varies because not all participants answered all attitude statements regarding usability and usefulness. Missing data was not imputed.

A general linear model (GLM) was used to examine the adjusted associations of respondent characteristics with the perceived usability and perceived usefulness of OHC patient portals (RQ2). In the GLM, only those respondents who reported using the patient portal were included in the analysis (2545/3084). The number of respondents varies because only those who both used the portal and responded to the relevant question were analyzed. Additionally, the differences between the crude and adjusted models arise because, in the adjusted model, only respondents who provided complete responses to all variables included in the model were analyzed. No imputation was performed for missing data. Descriptive statistics are presented alongside GLM results to aid interpretation of effect directions and group-level differences.

XSL•FO
RenderX

In the crude models, dichotomous variables were not treated as continuous to facilitate easier interpretation and comparison of differences. Using dichotomous variables in their original form allows for more straightforward analysis and clearer understanding of the results. In the adjusted model, dichotomous variables were treated as continuous covariates to enhance the model's stability. A model with numerous categorical variables could become unstable, leading to less reliable results.

Model selection was guided by a combination of theoretical relevance, model fit indices (eg, Akaike Information Criterion), and the principle of parsimony. Variables that did not improve model performance or interpretability were excluded, even if they were statistically significant in univariate analyses.

First, separate analyses (crude model) were conducted to examine the association of each independent variable with the dependent variable. Second, a fully adjusted multivariable model (adjusted model) was performed to measure the joint effects of all the statistically significant independent variables as covariates in the multivariable model. Collinearity diagnostics were performed, and variance inflation factor values were checked to ensure no significant multicollinearity was present among the independent variables. We chose a statistical significance level of <0.001 to apply a stricter criterion for assessing the significance of the results and to reduce the risk of false-positive results because of the large sample size. This helps to obtain more reliable and practically significant results.

Results

Characteristics of Respondents

Regular use of the OHC patient portal was reported by 20.7% (634/3060) of all respondents. A total of 23.3% (102/438) of men and 20.3% (528/2606) of women reported regular use. Among respondents aged 30 years or younger, 23.4% (22/94) reported regular use. Of those who were totally satisfied with the portal, 39.7% (95/239) reported regular use. Respondents with good ICT skills included 23.2% (264/1140) regular users. Among those who totally disagreed with concerns about unauthorized access, 31.2% (170/545) reported regular use. Additionally, 31.9% (273/855) respondents who did not feel a need for additional guidance reported regular use. Respondents' background characteristics are presented in Table 1.

[a]OHC: Occupational Health Care.

The Usability of OHC Patient Portals

According to the results, respondents most positively evaluated aspects related to learnability and ease of use. A large majority (1895/2523, 75.1%) felt that learning to use the patient portal was easy, and most (1861/2513, 74%) experienced the portal as easy to use. Additionally, many respondents (1875/2504, 75%) considered the text size in the portal easy to read. In contrast, the highest levels of disagreement were related to efficiency and user-centered design. Nearly 1 in 5 (451/2509, 18%) respondents disagreed that the portal allows them to quickly accomplish what they want, and 16% (399/2491) disagreed that user needs have been fully considered in the design of the portal. Figure 1 presents respondents' attitudes toward the usability of OHC patient portals, displayed as relative percentages (without decimals).

The analysis of the GLM assessed the impact of various factors on the usability of OHC patient portals. Satisfaction had the strongest association with the perceived usability of OHC patient portals. Need for guidance and frequency of use were also significantly associated, though to a lesser extent. Fear of unauthorized persons seeing the data, perceived ICT skills, and age were statistically significant but had small effects. The full results are presented in Table 2.

The Usefulness of OHC's Patient Portals

According to the results, the most positively received aspects of the OHC patient portal were its ability to facilitate easier contact with OHC and to support collaboration. A total of 70.1% (1765/2516) of respondents agreed that using the portal makes it easier to contact OHC, and 70.5% (1774/2517) believed that the portal supports their collaboration with OHC. In contrast, only 52.4% (1316/2511) of respondents felt that the portal provides a good overview of their work ability, and just 51.5% (1291/2505) felt that it supports them in improving it. Regarding working conditions, only 35.5% (891/2505) of respondents felt that the portal offers a good overview of their working conditions, and 39.9% (1000/2503) agreed that it provides information about how those conditions impact their health and work ability. Figure 2 presents respondents' attitudes toward the usefulness of OHC patient portals, displayed as relative percentages (without decimals).

According to the GLM analysis, satisfaction had the strongest association with the perceived usefulness of OHC patient portals. Frequency of use was also significantly associated with perceived usefulness, though to a lesser extent. The full results are presented in Table 3.

Discussion

Principal Findings

This study assessed the usability and usefulness of OHC patient portals using a survey. The analysis focused on respondents who reported using the portal either regularly or occasionally, excluding nonusers. Thus, the results reflect the experiences of actual OHC portal users.

Usability was generally rated positively: respondents highlighted ease of use, readability, and ease of learning as the most favorable aspects. Lower ratings were given to task completion speed and the extent to which user needs were considered in the portal's design. Age and ICT skills were statistically significant factors influencing usability ratings, with respondents aged 50 years or younger and those with strong ICT skills providing more positive assessments.

Usefulness received more mixed feedback: slightly more than half of the respondents felt the portal provided a good overview of their work ability, and just over a third considered it to offer a comprehensive view of their working conditions. Many respondents indicated that the portal did not sufficiently support them in improving their work ability or provide clear information on how working conditions might affect their health and work capacity. In contrast to usability, neither age nor ICT skills significantly influenced how useful the portal was perceived to be.

Additionally, user satisfaction with the OHC patient portal was strongly associated with both its perceived usability and usefulness, with regular users giving it significantly higher ratings than occasional users.

Comparison With Previous Studies

The findings of this study are consistent with previous research that has identified younger users and those with stronger digital skills as perceiving OHC digital services to be more user-friendly and intuitive [33]. Contrary to earlier studies that highlighted the significance of ICT skills, age, and gender in shaping perceptions of usefulness in digital health services [6,34,35], our study found that these factors did not significantly influence how users perceived the usefulness of digital health services. Moreover, the other studies suggest that both older [36] and younger users [37] generally find OHC patient portals useful, particularly for their clear overview of medical history and treatment plans. The results also showed that satisfied portal users valued its usability more, and those who used the portal regularly perceived its usability as better than occasional users. These results align with previous studies on user satisfaction [3,6,38].

Privacy concerns are a common issue with patient portals in Finland [12,13]. Despite these concerns, patients typically do not restrict the use or disclosure of their information [2]. Interestingly, users of OHC patient portals experience fewer privacy concerns (809/2960, 27.3%) compared to users of the national My Kanta portal (1265/3731, 33.9%) [12]. During the pandemic, privacy concerns among My Kanta users increased even more, with up to half of the respondents expressing concern (1923/3823, 50.3%) [13]. This topic warrants further examination, as patient portals are intended to serve as an essential tool for information exchange and communication between health care professionals and patients.

In this study, only slightly over half of the respondents felt that the portal gave a good overview of their work ability, while only a third found it provided a comprehensive view of their working conditions. Patients generally value access to personal health information [3], and when work-related data—such as the connection between diagnoses and occupational factors—is visible in the portal, it can increase awareness of occupational illnesses [39] and help patients understand how their work environment affects their health and work ability [40]. The patient data displayed in OHC patient portals originates from professionals' entries in the medical records. Previous studies

XSL•FO
RenderX

have found that work-related patient data is rarely documented, even when these issues are discussed with the patient [39,41,42].

Implications in Occupational Health

In OHC, work ability refers to an individual's capacity to perform their job, influenced by health, functional capacity, and working conditions [43,44]. OHC visits often focus on evaluating these aspects [45]. To enable OHC patient portals to provide access to this information, the documentation practices must be changed [46,47], particularly toward a more systematic recording of work-related patient data in medical records.

The observed lack of information on work ability and working conditions contrasts with the general expectation that digital services would improve access to information and increase users' awareness of their own situation [5,6]. When patients have access to information about the hazard, risk, and workload factors of their work and work environments, they can better understand the impact of working conditions on their well-being. This information could enable patients to make informed decisions to provide better opportunities to improve work ability, facilitate discussions with supervisors and OHC professionals on needs for work modifications, and promote the implementation of preventive measures.

To enhance the usability of OHC patient portals, it is important to ensure that the information they contain is comprehensive and easily understandable for patients, and that the portal's functions are useful to them. For example, the portal could remind users of upcoming periodic occupational health examinations or other job-related health tests, such as spirometry for those exposed to respiratory hazards in the workplace. Additionally, it could allow users to fill out symptom diaries to investigate symptom variation between work and nonwork periods, as well as exposure diaries to monitor the accumulation of exposure [48].

Work, working conditions, and work ability are central areas of OHC [30]. Additionally, OHC patient portals are widely available to many working citizens [28]. Future research should explore how these digital services can be developed to enhance collaboration between patients and OHC professionals.

Strengths and Limitations

This was a cross-sectional study that examined OHC patients' experiences with the usability and usefulness of patient portals, aiming to identify factors influencing these aspects and address existing research gaps. The theoretical framework of this study provided a solid foundation for designing the questionnaire and studying the usefulness and ease of use of OHC portals. Although the questionnaire used in this study was self-developed, its reliability is supported by the good Cronbach α values of the composite variables measuring usability and usefulness. This indicates that the questionnaire measured these concepts consistently and strengthens the reliability of the results. Thus, the research methods used in this study were well-suited and provided answers to the RQs while generating new information in line with the research objectives. However, this study has both strengths and limitations.

The strength of this study lies in its uniqueness. To our knowledge, no previous study has systematically assessed patient perceptions of the usability and usefulness of OHC patient portals. Another strength is the large sample size, which ensures a substantial number of observations for analysis and makes the data highly representative. This feature increases confidence in the accuracy and generalizability of the results. The third strength is its timeliness, considering the rapid growth of digital health services. Additionally, calculating the effect size was useful in this study as it provided an objective measure of the magnitude of observed differences. Effect size enabled comparisons between different variables and helped identify clinically significant associations.

The first limitation of this study is the dominant participation of 1 gender; thus, the sample is heavily skewed toward women (2606/3060, 85.2%). This gender imbalance may influence the results and limit the applicability of the findings to a broader population. Future research should aim for a more balanced gender representation to enhance generalizability.

Second, the sample likely includes individuals with higher digital literacy, as the survey was conducted online. This may result in an overrepresentation of participants who are comfortable with digital technologies, potentially excluding those with limited ICT skills. Consequently, the findings may not fully capture the experiences and perspectives of individuals with lower digital literacy.

The third limitation is that this study relies on self-reported data collection. However, certain valuable information can only be obtained through surveys, as was the case in this study. The fourth limitation is the lack of available information about the respondents. As participation in this study was anonymous, we do not know the characteristics of those who declined to participate or did not return the questionnaire. Moreover, despite the statistically significant results obtained in this study, caution should be exercised in interpreting the findings due to the low explanatory power of some results.

Conclusions

The ability of OHC patient portals to provide information on the work ability and the healthiness and safety of working conditions needs to be improved. In particular, more comprehensive documentation in medical records related to work-related hazards, risks, and workload factors is needed. This could strengthen the role of portals in promoting work ability and in preventing work-related illnesses and accidents, while also increasing patients' awareness of factors affecting work well-being. Furthermore, improving patient satisfaction with the usability and usefulness of OHC patient portals may lead to increased adoption of portals and, consequently, more equitable access to digital OHC services.

Abstract

Background: This study proposes an integrated approach to developing personalized health behavior change programs by combining personality traits and behavior types. Existing tools, such as Myers-Briggs Type Indicator (MBTI) and Dominance, Influence, Steadiness, and Conscientiousness (DISC), have limitations: MBTI reflects internal tendencies but lacks behavioral insights, while DISC highlights behavior but overlooks deeper personality aspects. To address these gaps, the study integrates MBTI and DISC to create a comprehensive profiling system.

Objective: The goal of this research is to design a novel profiling system that merges MBTI and DISC for personalized health management. This system aims to link personality traits with behavior patterns to enhance the effectiveness of tailored health behavior change programs.

Methods: The study involved 3 phases: administering MBTI and DISC tests to 130 participants to analyze correlations, developing an integrated survey for health behavior analysis, and testing its usability with 20 experts for validation.

Results: Significant correlations were observed between MBTI and DISC indicators, including a notable negative correlation between Thinking-Feeling (T/F) and Dominance (D), suggesting an inverse relationship between decision-making preferences and assertiveness. Usability testing results indicated high participant satisfaction, with an average SUS (System Usability Scale) score of 86.0. The SUS is a widely used questionnaire for measuring subjective assessments of usability. This score exceeded industry benchmarks for system usability. Expert evaluations further reinforced the system's practical applicability, highlighting its potential to enhance user engagement through personalized behavioral insights.

Conclusions: This study presents a combined MBTI and DISC profiling system, offering both theoretical insights and practical tools for health behavior change programs. Future research should validate its effectiveness with larger samples and explore broader applications in various health domains.

KEYWORDS

health behavior change; personalized programs; integrated profiling; personality types; Myers-Briggs Type Indicator; MBTI; Dominance, Influence, Steadiness, and Conscientiousness; DISC; personality assessment

Introduction

Overview

In modern society, health behavior change has become increasingly important. According to the World Health Organization, adopting healthy lifestyle habits is essential for preventing chronic diseases such as obesity and cardiovascular disorders, as well as for improving overall quality of life [1,2]. While health-promoting activities, such as exercise and dietary management, can yield positive outcomes, standardized approaches that fail to account for individual personality traits and behavioral tendencies often face limitations in sustainability and effectiveness [3,4]. For instance, the same exercise program may feel burdensome to individuals with introverted tendencies but serve as a motivating factor for those with extroverted traits [5,6].

XSL•FO
RenderX

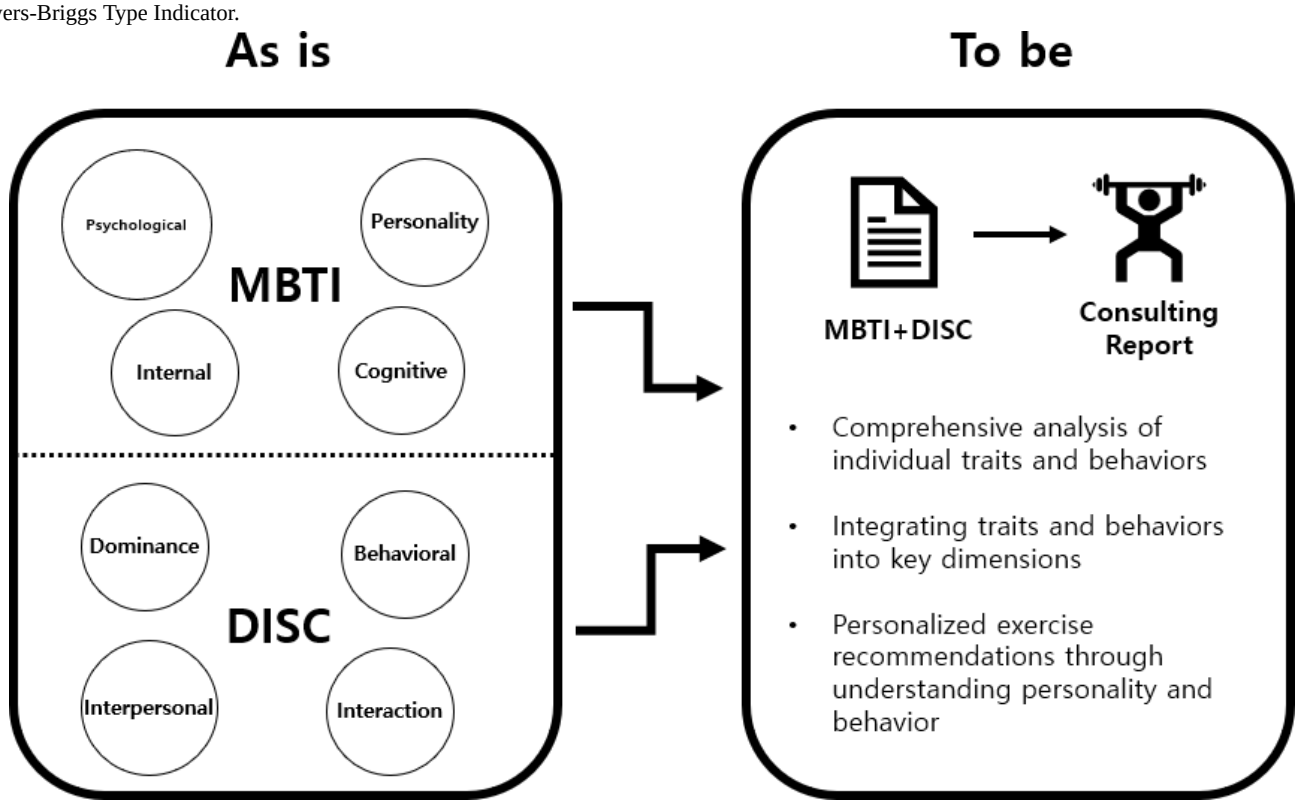
Several personality assessment models, including the Myers-Briggs Type Indicator (MBTI), Dominance, Influence, Steadiness, and Conscientiousness (DISC), Big Five, HEXACO, and Sixteen Personality Factor (16PF) Questionnaire, are widely used to analyze personality and behavior in fields such as psychology and health sciences. The MBTI categorizes personality into 16 types based on 4 dichotomies: Extraversion-Introversion, Sensing-Intuition, Thinking-Feeling, and Judging-Perceiving [7,8]. DISC focuses on 4 behavioral dimensions—Dominance, Influence, Steadiness, and Conscientiousness—emphasizing interpersonal interactions. The Big Five (OCEAN) assesses Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism, with Conscientiousness and Neuroticism predicting health regimen adherence and emotional barriers. HEXACO adds Honesty-Humility to similar dimensions, offering insights into ethical health decisions. The 16PF Questionnaire measures 16 factors, such as emotional stability, refining health intervention strategies. The MBTI provides cognitive insights through its 16 personality types but lacks behavioral specificity. DISC focuses on 4 behavioral dimensions, Dominance, Influence, Steadiness, and Conscientiousness, but overlooks deeper psychological motivations. The Big Five measures broad traits such as Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism, with Conscientiousness and Neuroticism predicting health regimen adherence and emotional barriers, yet it lacks detailed granularity. HEXACO adds Honesty-Humility, offering insights into ethical health decisions, but is less established. The 16PF Questionnaire refines health intervention strategies through 16 factors, such as emotional stability, but can be complex to administer.

We examined various analytical tools, and while each operates within its unique framework, no research has been identified that provides specialized solutions for complex and integrative domains, such as health behavior change programs [9].

This study proposes a novel approach that combines the strengths of MBTI and DISC to overcome these limitations. By integrating the analysis of individual personality traits and behavioral tendencies, the study aims to design personalized programs for health behavior change. Specifically, it seeks to identify correlations between the 2 tools and develop a methodology that maximizes the effectiveness of health behavior change programs, contributing both practical and academic value.

Literature Review on MBTI and DISC and Their Integration

The MBTI, developed in the 1940s by Catherine Cook Briggs and Isabel Briggs Myers, is a psychological tool designed to understand and explain individual personality types [10]. It categorizes personalities into 16 types based on cognitive preferences and information processing styles, using 4 dichotomies: Extraversion (E)–Introversion (I), Sensing (S)–Intuition (N), Thinking (T)–Feeling (F), and Judging (J)–Perceiving (P). MBTI is widely used to understand interpersonal relationships, decision-making styles, and job performance [10]. However, its focus on static personality classifications can limit its ability to reflect situational flexibility [9].



DISC, developed from the theories of William Moulton Marston in the 1920s, analyzes behavioral styles based on 4 dimensions: Dominance (D), Influence (I), Steadiness (S), and Compliance (C). It is especially effective in understanding interpersonal dynamics, improving teamwork, and managing workplace interactions [11]. While DISC excels in analyzing external behavior and interaction patterns, it lacks the depth to fully capture internal psychological factors [12].

Although MBTI emphasizes psychological preferences and DISC focuses on external behaviors, both tools are valuable for understanding individual tendencies [13]. Integrating their strengths allows for a comprehensive understanding of both psychological and behavioral dimensions. This integrated approach is particularly suited for addressing complex issues such as health behavior change, where both internal and external factors play critical roles [14].

Prior to initiating this study, we recognized that the cognitive insights of the MBTI and the behavioral analysis of DISC are essential for health behavior change programs. However, no related studies combining MBTI and DISC to analyze health consulting or behavior change were identified. Accordingly, this study proposes an integration of the 2 models, aiming to analyze correlations between their core dimensions and develop a novel profiling system tailored for designing personalized health behavior change programs (Figure 1).

XSL•FO
RenderX

Figure 1. The methodology for generating consulting reports integrates insights from both MBTI and DISC frameworks. The MBTI model contributes psychological, internal, and personality-based dimensions (eg, personality and cognitive preferences), while the DISC model incorporates behavioral traits such as dominance, interaction styles, and action-oriented tendencies. DISC: Dominance, Influence, Steadiness, and Conscientiousness; MBTI: Myers-Briggs Type Indicator.

Methods

Verification of the Correlation Between MBTI and DISC

The purpose of this study is to systematically verify the correlation between MBTI and DISC by administering both surveys to the same group of participants. Through this process, the research aims to establish a foundation for an integrated understanding of personality and behavior and to provide fundamental data for developing an integrated personality analysis model.

The correlation analysis between MBTI and DISC centers on clearly identifying the similarities and differences that each tool provides and proposing a new approach that can leverage the strengths and compensate for the weaknesses of both tools. This study also explores the possibility of overcoming the limitations of existing personality assessment tools and developing a more efficient and practical personality profiling system.

For this research, 4 elements were set as the main criteria: interpersonal relationships, information-gathering style, decision-making style, and planning tendency. These criteria were selected to evaluate the potential applicability of this approach to health behavior change strategies, such as exercise and diet coaching. For example, the Dominance (D) type in DISC is predicted to have a high correlation with the Extroversion (E) and Thinking (T) traits in MBTI, suggesting that it may be suitable for goal-oriented methods. Meanwhile, the Influence (I) type is associated with the Feeling (F) trait, indicating a preference for a more friendly and motivational approach.

This study investigated the correlation between MBTI and DISC by surveying 130 Korean students. Demographic data (eg, age and gender) of the participants were collected to strengthen the validity of personality trait analysis, with detailed results summarized in Table 1.

XSL•FO
RenderX

Table . Demographic analysis of the survey subjects.

Variables and categories	Frequency, n (%)
Year of birth	
2004-2000	100 (76.9)
1999 - 1990	19 (14.6)
1989 - 1980	11 (8.5)
Total	130 (100)
Sex	
Man	38 (29.2)
Woman	92 (70.8)
Total	130 (100)

To analyze personality types using MBTI and DISC, each tool's official survey was administered to ensure reliable responses from the students. Based on the survey results, this study examined the correlation between the 2 personality assessments and identified patterns in traits that appeared repeatedly. Graphs and charts were used to visualize these correlations and patterns, allowing for a clearer analysis of the relationship between MBTI and DISC.

Refinement of an Integrated Trait Analysis Methodology and Proposed Survey Items

The aim of this study is to develop an integrated personality analysis model that concisely and practically uses personality traits by examining the correlations between the 4 DISC types and the 16 MBTI types.

DISC categorizes human behavioral styles into 4 types: Dominance (D) for goal-oriented and challenging individuals; Influence (I) for optimistic and social people; Steadiness (S) for calm and patient individuals; and Conscientiousness (C) for analytical and logical thinkers.

MBTI explains psychological preferences in perceiving and judging the world through 4 dichotomies. The 'Attitude' (Extraversion/Introversion) dichotomy relates to how we engage with others during exercise; for instance, questions gauge if one easily socializes in new exercise groups (Extraversion) or prefers solitary workouts for focus (Introversion). The "Perceiving Function" (Sensing/Intuition) focuses on how we gather information when choosing an exercise, assessing a preference for detailed rules (Sensing) versus imagining overall potential (Intuition). The "Judging Function" (Thinking/Feeling) examines how we make exercise decisions, involving questions about prioritizing objective data (Thinking) versus considering emotional satisfaction (Feeling). Finally, "Lifestyle" (Judging/Perceiving) looks at how we plan exercise, determining whether one strictly adheres to plans (Judging) or prefers flexible, spontaneous changes (Perceiving).

Based on the key indicators of these existing tools, this study will categorize core traits into 3 - 8 types to design a model suitable for personalized coaching programs and behavior change strategies. We developed 40 survey items based on DISC and MBTI correlations, covering interpersonal relationships, information-gathering, decision-making, and planning tendencies, all adapted to specific contexts such as exercise and dieting. This survey will collect individual trait data, serving as a valuable source for designing customized health behavior programs.

Customer Health Care Profiling Application Based on Survey Items

An expert group of 20 was selected for analysis. This sample was chosen to evaluate the practicality and validity of the integrated trait analysis model. Based on the survey results, a profiling system was developed to provide tailored health care advice and personality descriptions suited to each customer's traits.

In developing the system, the 20 participants' data were used to review the validity of the integrated model and 2 experts were consulted to assess its practicality.

This system can be used in various health care settings such as hospitals, health and fitness centers, and wellness counseling services, with an emphasis on delivering services, products, and personalized coaching optimized for each individual's traits. For example, depending on the customer's personality type, the system can propose effective exercise plans, diet methods, and stress management strategies, providing professional and customized health management solutions.

Ethical Considerations

All information was collected anonymously. The data collected pertained to MBTI and DISC profiles, which are not individually identifiable and do not constitute sensitive personal information that could pinpoint individuals. At the time of the survey, participants were informed about the purpose of the study and their right to withdraw from participation at any time. Therefore, this study was deemed not to fall within the scope requiring institutional review board review. Specifically, this study was exempt from ethics review under Article 13(2) of the Enforcement Regulations of the Bioethics and Safety Act of Korea. This regulation exempts studies where researchers do not directly face identifiable individuals, and where "sensitive information" as defined by Article 23 of the Personal Information Protection Act is neither collected nor recorded.

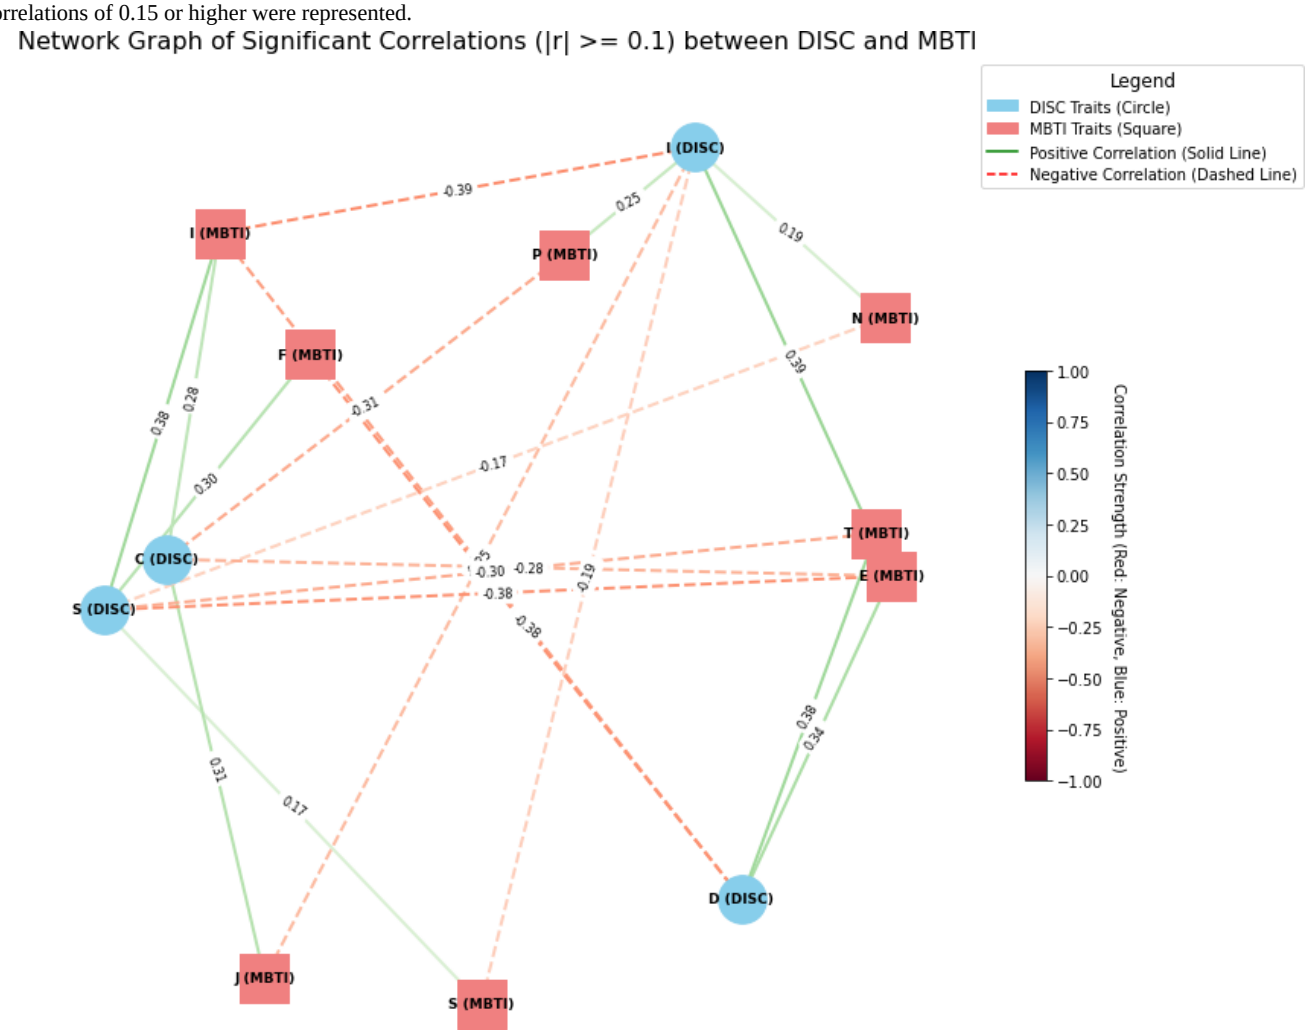
RenderX

Results

Analysis of the Correlation Between MBTI and DISC



The correlation analysis results for identifying the relationship between the 2 personality assessment tools, MBTI and DISC, are presented in Figures 2 and 3.

Figure 2. Summary of the analysis results of the correlation between MBTI and DISC, derived from the comparison table. Darker shades indicate stronger positive correlations and lighter shades represent stronger negative correlations. Only values with an absolute value of 0.15 or higher are displayed. DISC: Dominance, Influence, Steadiness, and Conscientiousness; MBTI: Myers-Briggs Type Indicator.

XSL•FO
RenderX

Figure 3. A network diagram of Myers-Briggs Type Indicator (MBTI)—comprising Extraversion (E)–Introversion (I), Sensing (S)–Intuition (N), Thinking (T)–Feeling (F), and Judging (J)–Perceiving (P)—and Dominance, Influence, Steadiness, and Conscientiousness (DISC) based on nodes and edges. Circles denote DISC and squares denote MBTI. Solid lines denote positive correlations and dashed lines denote negative correlations. Only correlations of 0.15 or higher were represented.

Through these findings, we aimed to determine the specific connections between MBTI's personality type indicators (E/I, N/S, T/F, P/J) and DISC's behavioral types (D, I, S, C), and to provide basic data for developing an integrated personality analysis model. The analysis was conducted using SPSS software (IBM Corp) and Pearson correlation coefficients were used to examine the relationships between the data. The sample consisted of 130 college and graduate students in their 20s and 30s.

First, both Extraversion (E) and Introversion (I) in MBTI showed significant correlations with all DISC types (D, I, S, C) (P<.001). Introversion (I) demonstrated positive relationships with Stability (S) and Conscientiousness (C), with a particularly stronger correlation with S (correlation coefficients 0.38, P<.001). In contrast, Extraversion (E) showed negative correlations with Dominance (D) and Influence (I), with a stronger negative correlation with I (correlation coefficients −0.38, P<.001).

Both Intuition (N) and Sensing (S) in MBTI showed significant correlations with Influence (I) and Stability (S) in DISC (P<.001). Intuition (N) had a weak negative correlation with Influence (I) (correlation coefficient −0.19, P=.03), whereas Sensing (S) had a weak positive correlation with Stability (S) (correlation coefficient 0.17, P<.04). Thinking (T) and Feeling (F) also exhibited significant relationships with Dominance (D) and Stability (S) in DISC (P<.001). Thinking (T) showed a strong negative correlation with Dominance (D) (correlation coefficient −0.38, P<.001), and Feeling (F) showed a positive correlation with Stability (S) (correlation coefficient 0.30, P<.001).

Finally, Perceiving (P) and Judging (J) in MBTI had significant correlations with Influence (I) and Conscientiousness (C) in DISC (P<.001). Perceiving (P) showed a negative relationship with Influence (I) (correlation coefficient −0.25, P<.001), while Judging (J) exhibited a positive relationship with Conscientiousness (C) (correlation coefficient 0.31, P<.001).

These results indicate that the correlation between MBTI and DISC is clearly evident in each type. For instance, according to the figure, MBTI's Introversion (I) had a strong positive relationship with DISC's Stability (S), while MBTI's Thinking (T) showed a strong negative relationship with DISC's Dominance (D). Despite MBTI and DISC each analyzing different aspects of personality—psychological preferences and behavioral patterns—these findings suggest that they can be mutually complementary.

Proposing an Integrated Trait Analysis Model and Developing Survey Items

The survey items were designed based on the DISC-MBTI correlation analysis results, narrowing down the classification into 4 types. A model was developed to categorize individuals into these 4 types, and the survey items were structured accordingly as Figure 4.

Based on the designed survey items, exercise prescriptions have been summarized in Table 2.

Figure 4. Type exploration and classification model based on MBTI-DISC. Considering the correlation between MBTI and DISC, 4 types (Relationship, Gather Information, Decision-Making, and Planning) were categorized. Clustering is represented using arrows. DISC: Dominance, Influence, Steadiness, and Conscientiousness; MBTI: Myers-Briggs Type Indicator.

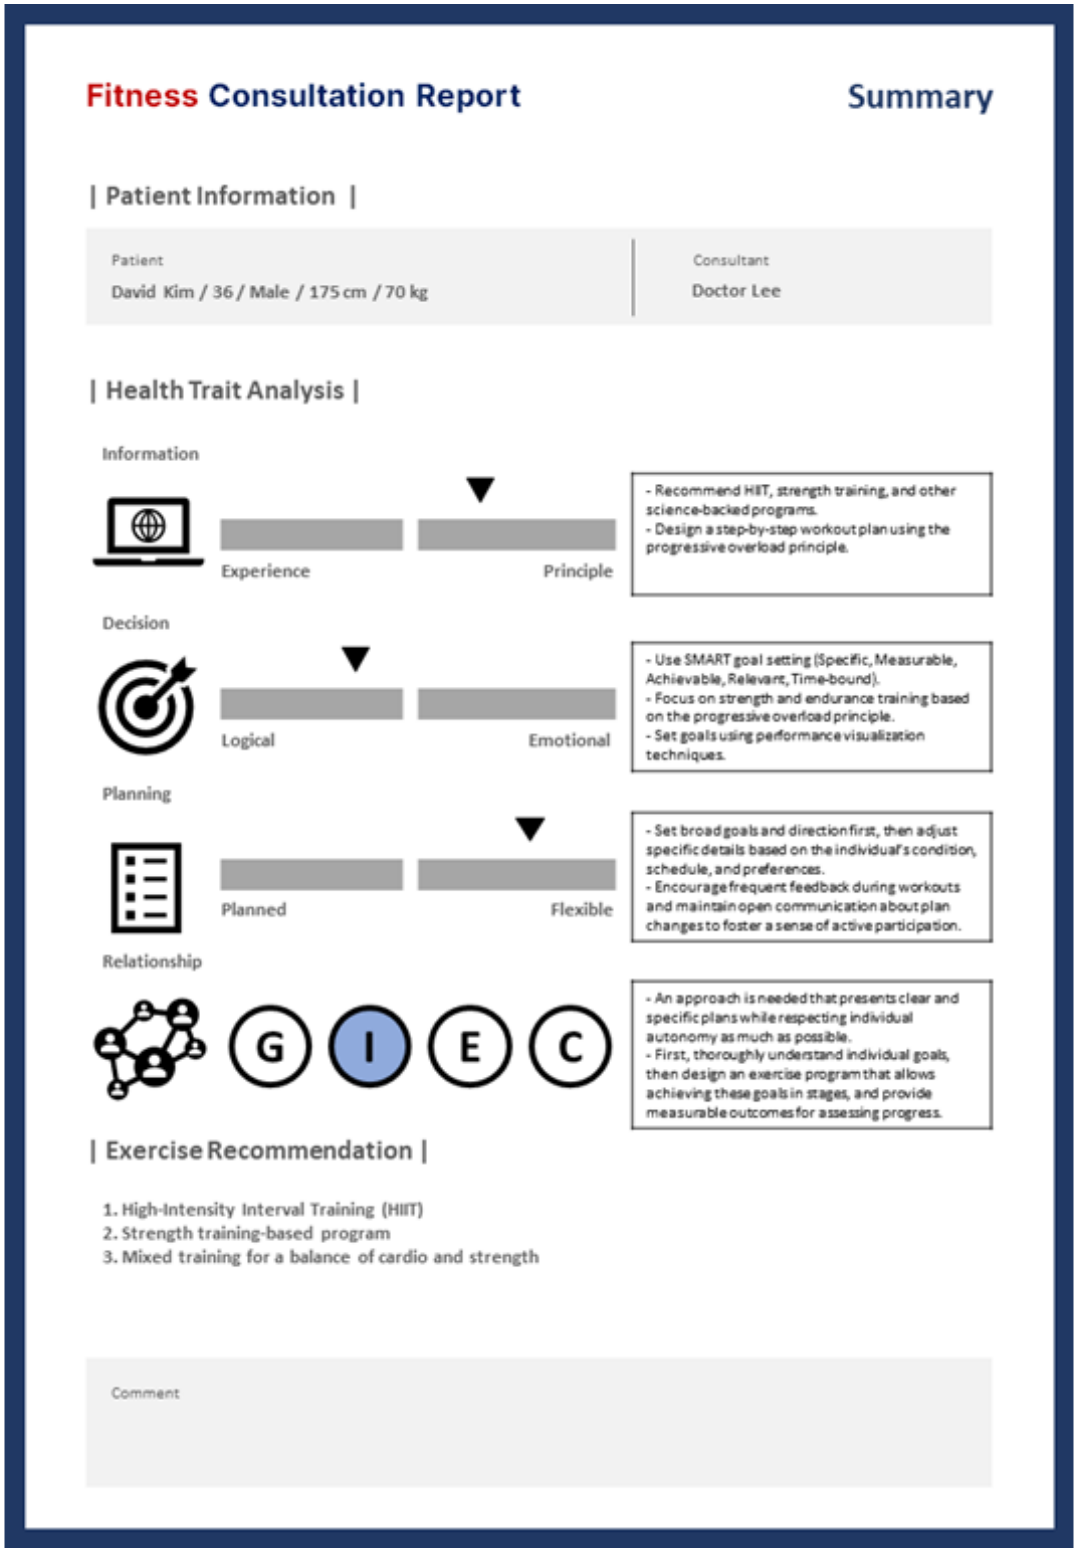
XSL•FO
RenderX

Table . Exercise prescription types based on the Myers-Briggs Type Indicator (MBTI)–Dominance, Influence, Steadiness, and Conscientiousness (DISC) survey. The table systematically classifies exercise prescription types by organizing them into key categories, including type, description, recommended exercises, and coaching strategies.

Categories and types	Description	Recommended exercises	Coaching, support, and planning strategies
Relationship			
Group-oriented	Finds motivation in activities with others, prefers social interaction.	Group fitness (Zumba, aerobics), team sports	Provide positive feedback, enhance collaboration with peers.
Individual-oriented	Prefers solo activities, focuses on achieving personal goals.	Solo running, gym equipment exercises	Emphasize individual performance, provide an independent environment.
Expert-dependent	Requires guidance and structured plans from trainers or experts, prefers systematic feedback.	Personal training, customized exercise plans	Offer professional, data-driven feedback.
Competition-oriented	Gains motivation through competition or performance comparison, values winning.	Competition-based sports (tennis, boxing, swimming)	Visualize performance comparisons with rivals, provide rewards for victories.
Gather information			
Experience-seeker	Chooses exercises based on reviews or others' experiences.	Trendy programs, popular classes	Provide review-based materials, emphasize user reviews and ratings.
Principle-seeker	Logically selects exercises based on scientific evidence and principles.	Systematic, structured exercise programs	Explain exercise effects and provide scientific data, offer professional resources.
Decision-making			
Logical goal-oriented	Sets specific goals and approaches exercise systematically to achieve them.	HIIT[a], strength training	Set performance-based goals, motivate with concrete data.
Emotion or relationship-oriented	Values emotional satisfaction or building relationships, prioritizes fun and experience.	Dance classes, group sports	Provide emotional support, foster positive relationship building.
Planning			
Structured or detail-oriented	Consistently follows a systematic and detailed plan.	Regular yoga, Pilates	Provide detailed schedules, set step-by-step goals.
Flexible and people-oriented	Adjusts plans flexibly according to circumstances, prefers interaction with others.	Trekking, diverse activity experiences	Emphasize autonomy, offer engaging and appealing options.

[a]HIIT: high-intensity interval training.

Based on the DISC-MBTI correlation analysis, the survey items were designed to narrow the classification down to 4 types. A model was then developed to categorize individuals into these 4 types, and corresponding survey items were created accordingly. Finally, the exercise prescriptions derived from these survey items are summarized.



In this study, we developed survey items to classify exercise tendencies by measuring individuals' relational tendencies. Each item assesses aspects such as the individual's level of activity, expression styles, and relationship preferences in interpersonal contexts. This approach identifies preferred environments and motivational factors during exercise. For the purposes of this study, we focused exclusively on methods for categorizing relationships with others during exercise.

Implementation and Validation of an Exercise Prescription Reporting Service

A practical profiling web application was implemented to input survey items and verify whether the results matched actual patient information. The web application was developed based on Flask and calculated the total scores by summing up the scores for each of the 4 survey items. The results of this process are presented in Figure 5.

XSL•FO
RenderX

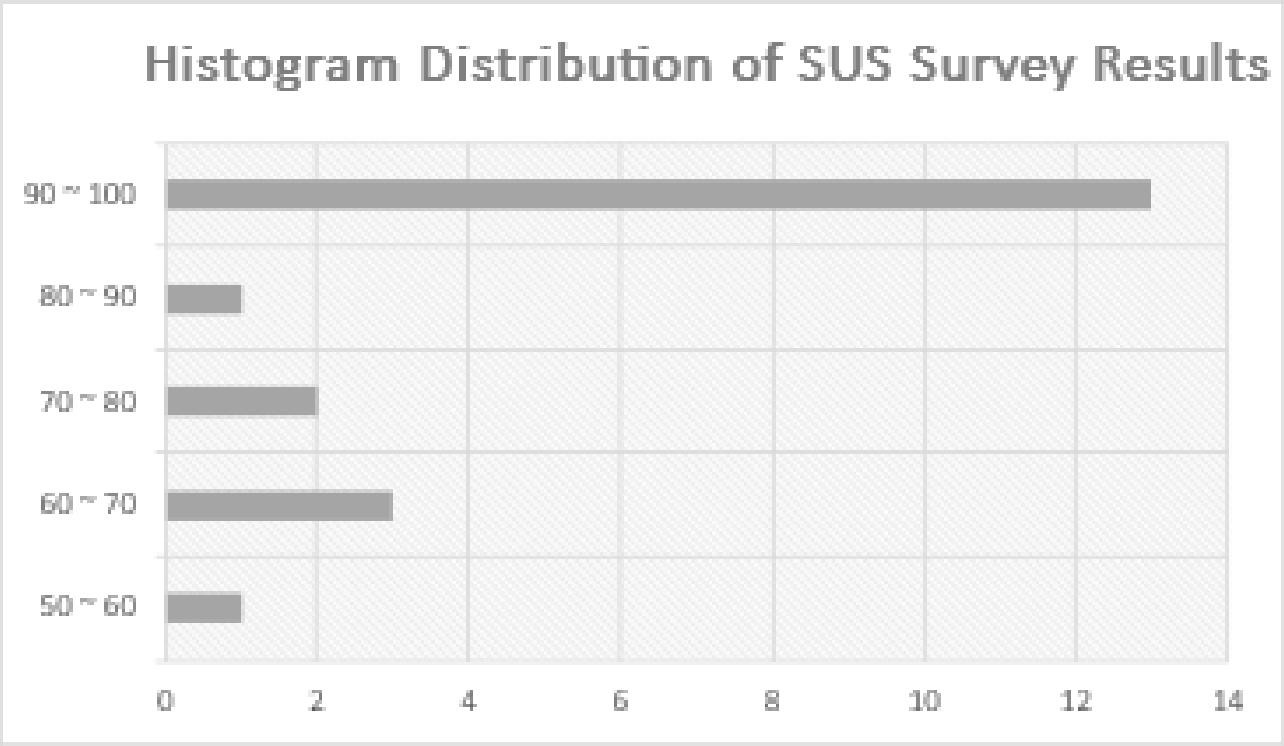
Figure 5. Example of an exercise prescription consulting report for 4 categories: relationship, information-gathering, decision-making, and planning.

A pilot test was conducted to validate the practicality and reliability of the proposed integrated trait analysis model. This process assessed whether the proposed profiling system effectively analyzed individuals' personality and behavioral traits and whether it could be practically used. The validation process consisted of a pilot test, result analysis and interpretation, and a practicality evaluation through expert interviews.

The pilot test involved applying the profiling system, developed based on MBTI and DISC survey data, to a group of 20 experts. The experts responded to the survey items, and the system analyzed their personality and behavioral types to generate customized profiling results. This process confirmed whether the profiling system could accurately classify and interpret types based on the survey data.

XSL•FO
RenderX

System Usability Scale Score Result for Prescription Reporting Service



To evaluate the usability of the proposed system, a System Usability Scale (SUS) assessment was conducted with 20 experts, as Table 3.

Table . Survey participants by occupation. The survey was primarily conducted with trainers, physical therapists, and professors.

Occupation	Participants, n
Trainer	8
Physical therapist	4
Exercise specialist	4
Professor in related fields	3
Aerobics instructor	1

The SUS, originally developed by Brooke [15], is a widely used and reliable tool for measuring system usability across various domains. The questionnaire consists of 10 items rated on a 5-point Likert scale, designed to assess both positive and negative aspects of usability. Odd-numbered items measure positive usability attributes (eg, ease of use and system integration), while even-numbered items measure negative usability attributes (eg, complexity and inconsistency). The standard scoring methodology was applied, where responses to odd-numbered items were adjusted by subtracting 1, and even-numbered items were adjusted by subtracting the response from 5. The final SUS score was computed by summing the adjusted values and multiplying by 2.5, following the established methodology described by Lewis and Sauro [16]. The resulting SUS score of 86.0 indicates a high level of usability and user satisfaction, as shown in Figure 6.

Figure 6. Histogram distribution of System Usability Scale (SUS) survey results. The majority of scores clustered in the 90 - 100 range, although a few respondents provided lower ratings.

Trainers, physical therapists, exercise specialists, professors in related fields, and aerobics instructors responded positively, highlighting that the system is intuitive, effectively integrates various functions, and is easy to navigate. In addition, participants across clinical, academic, and fitness backgrounds stressed that a highly personalized approach, tailored to individual user characteristics, is key to enhancing engagement and usability. Some experts, particularly trainers and exercise specialists, noted that the system has the potential to serve as an effective tool for continuous health care management by adapting to users' needs. However, some participants emphasized the need for more detailed exercise coaching programs and suggested conducting further real-world validation to ensure the system's effectiveness in practical settings. These findings, supported by feedback from professionals across diverse fields, including trainers, sports dance instructors, and professors, confirm the system's practical applicability and its potential for real-world implementation.

Discussion

Principal Results

This study identified the integrated correlation between MBTI and DISC, addressing the limitations of existing personality theories and enabling theoretical expansion. MBTI focuses on internal psychological preferences, while DISC emphasizes external behavioral patterns. By combining the strengths of these 2 tools, this study proposed a new analytical framework for comprehensively understanding individuals' personality and behavior.

The integrated trait analysis model, based on the correlation between MBTI and DISC, clarified the relationship between personality and behavioral types and validated its theoretical soundness through data-driven analysis. This research provides a new direction for personality analysis and behavior prediction studies in academic fields and serves as foundational data for future research.

In practical applications, this model can be used as a valuable tool for health care and health behavior change programs. For example, personalized health programs can be designed by optimizing exercise plans, diet strategies, and stress management techniques according to individual personality and behavioral types. For instance, individuals with DISC's Stability (S) and MBTI's Introversion (I) may benefit from quiet, structured exercise environments, whereas those with DISC's Influence (I) and MBTI's Extraversion (E) may thrive in sociable and dynamic activities.

In addition, the findings contribute to the development of personalized coaching programs that motivate behavior change based on a deep understanding of individual tendencies and behavior patterns. This system can be applied in diverse practical environments, such as hospitals, fitness centers, and counseling institutions, offering high user satisfaction while enhancing service quality.

Limitations

This study offers valuable insights into the correlation between MBTI and DISC, but it has several limitations. First, our sample size was limited to 130 Korean college and graduate students in their 20s and 30s, which may restrict the generalizability of our findings. The sample was also somewhat skewed toward female students and those born in the 2000s. The reliance on self-reported survey data also introduces potential biases, such as social desirability or self-perception. Future research should include larger, more diverse populations and incorporate additional data collection methods, like observational studies or third-party assessments.

We recognize that the cultural context of South Korea significantly influenced our survey results, particularly among the 20s demographic, which is sensitive to social norms. For example, Korea's collectivistic culture may modulate the expression of Extraversion (MBTI) and emphasize diligence for Conscientiousness (DISC C-type) or harmony for Steadiness (DISC S-type) in responses.

Furthermore, our study focused solely on MBTI and DISC. Integrating additional frameworks, such as the Big Five Personality Traits, could offer a more comprehensive understanding. The practical applications discussed, like healthcare and behavior change programs, also require further real-world validation to confirm their effectiveness. Finally, we simplified complex traits into 4 main categories for usability, potentially overlooking nuanced individual differences and not accounting for longitudinal changes in personality. Future studies should explore these dynamics and validate the profiling system in broader technological and organizational contexts.

Conclusions

In conclusion, this study successfully identified the integrated correlation between MBTI and DISC, combining their strengths to propose a novel analytical framework for understanding personality and behavior. By validating the integrated trait analysis model with data-driven methods, the research highlighted its potential to clarify the relationship between psychological preferences and behavioral patterns. This model offers both theoretical contributions to personality analysis and practical applications, such as personalized health behavior programs, which can optimize exercise plans, diet strategies, and stress management based on individual traits. While further validation in diverse settings is needed, the findings pave the way for future innovation in health care, counseling, and other fields that benefit from tailored behavior change strategies.

Abstract

Background: Clinical decision support systems are known to improve adherence to clinical practice guidelines and patient outcomes by providing clinicians with timely, accurate, and appropriate knowledge.

Objective: This study investigates the perceived usefulness and practical implementation of UpHill Route v3, a personalized digital care pathway (PDCP) system, in enhancing clinical decision-making and patient management across various clinical settings.

Methods: A mixed-methods retrospective study was conducted among medical doctors and nurses from four National Health System-Local Health Units in Portugal. Data were collected from May 2023 to April 2024. The primary data source was an anonymous questionnaire assessing health care professionals' perceptions of UpHill Route v3's usefulness using the Likert scale ranging from 0 (do not agree) to 10 (totally agree). Secondary analysis involved quantifying decisions across heart failure, multimorbidity, diabetes, and colorectal and breast cancer clinical pathways. These data were collected from user interactions with UpHill Route v3 as well as from its internal database. Descriptive and bivariate statistics were used to analyze the data.

Results: A total of 22 health care professionals with mean age 44.7 (SD 10.6) years, including 15 (68%) female participants and 9 (41%) physicians were included in the study. High ratings for adherence to clinical protocols, mean score 8.06 (SD 1.73); clinical decision support, mean score 8.05 (SD 1.73); patient care improvement, mean score 7.63 (SD 2.22); and confidence in patient management, mean score 8.26 (SD 1.56) were reported. Secondary analysis showed that across 3574 patients, 25,741 clinical decisions were informed, and 9254 actions were performed with the assistance of the PDCP tool.

Conclusions: The UpHill Route v3 PDCP tool is highly valued by health care professionals for its ability to support clinical decision-making and improve operational efficiency across various clinical settings. Our findings suggest that this tool can effectively bridge the gap between clinical guidelines and real-world practice.

care integration; clinical pathway; digital; heart failure

Introduction

Computerized clinical decision support systems (CDSS) are designed to enhance patient care by providing clinicians and patients with timely, accurate, and appropriate knowledge in the context of specific medical interactions or encounters. These systems have gained significant traction for their potential to improve adherence to clinical practice guidelines, bridging the gap between knowledge and its application in diverse clinical contexts [1,2]. Systematic reviews and studies have been conducted to evaluate the effectiveness of CDSS, showing that CDSS can lead to improvements in process adherence, thus leading to higher diagnosis accuracy and comprehensive disease management [3,4]. There are multiple types of CDSS. Traditional CDSS primarily offer static recommendations, whereas personalized CDSS integrates patient-specific data

XSL•FO
RenderX

from an electronic health record (EHR) to tailor clinical recommendations. Personalized digital care pathway (PDCP) represents a further advancement, extending CDSS capabilities beyond single encounters by ensuring continuity of care across multiple medical interactions. PDCP systems facilitate decision-making and action execution across multidisciplinary teams, while maintaining compliance with best practice protocols and continuously adapting based on patient-specific data. These systems have demonstrated benefits for patients, health care professionals (HCP), and institutions by contributing to improved service quality, workforce efficiency, and patient outcomes. This expands the scope of CDSS to the entire continuum of care, enabling the interaction among multiple multidisciplinary teams through a shared care pathway. [4,5].

PDCPs ensure that each HCP delivers tailored care aligned with standard protocols and guidelines, especially relevant for chronic conditions requiring frequent assessments and timely therapy adjustments across different contexts [6]. Current management strategies for chronic patient care typically rely on traditional methods such as face-to-face consultations, periodic monitoring, and manual documentation of patient records. Care plans are often manually developed based on clinical guidelines and personal clinical judgment, with minimal decision support integration. Most EHRs lack advanced decision support capabilities, decision characterisation, and patient communication features. Overall, current management strategies can be time-consuming and prone to variability in care delivery.

For example, CDSS have been shown to improve patient outcomes in heart failure management by enhancing monitoring, management, and optimization of therapies [7]. As more clinical practice guidelines emphasize the necessity of digital solutions for early disease detection and patient self-care [8], multidisciplinary chronic disease management programs powered by CDSS tools have yielded better quality of life, lower readmission rates, and reduced mortality [3]. Despite these benefits, there is a lack of evidence regarding the perceived usefulness of CDSS among HCPs using these systems and on the quantification and characterization of this usage on the number and types of decisions and actions usually performed by CDSS in chronic disease management [3,9].

This study hypothesizes that HCPs consider PDCPs, such as Uphill Route v3, to be more valuable than current management strategies for chronic patient management. As a PDCP and a subtype of CDSS, UpHill Route v3 aids medical decision-making and improves patient management by increasing compliance with locally validated clinical pathways. The software creates personalized care pathways by capturing patient health and demographic data from hospital EHRs, manual inputs by HCPs, or self-reported patient questionnaires (sent via text messages, web forms, or voice interaction capabilities). This approach further supports HCP clinical decisions and tasks throughout the clinical pathway. Thus, the main aim of this study was to characterize the perceived usefulness of a PDCP in chronic patient management. The secondary aim was to describe the number and types of decisions supported by the software, thus quantifying them as a proxy for the system's impact on decision support and patient management efficiency.

Methods

Study Design

This was a mixed-methods retrospective study, conducted to evaluate the usefulness of PDCP as a CDSS for HCPs. For the primary aim, qualitative data was collected through a questionnaire directed at HCPs using UpHill Route v3, to assess the perceived usefulness of PDCP and compare it with current management practices for chronic patient care. For the secondary aim, quantitative data on decisions and tasks performed during care pathways was retrieved from UpHill Route v3. This design allowed for a comprehensive understanding of the impact of UpHill Route v3 on clinical decision-making and patient management.

Setting

Medical doctors and nurses from four National Health System Local Health Units (LHUs) in Portugal, who were pilot-testing UpHill Route v3, were invited to participate. These professionals were trained in using UpHill Route v3 as part of the software implementation framework, as described in the software technical documentation and instructions for use. As part of the implementation process, clinical content embedded in the software was validated and approved, meaning that clinical leaders from the enrolled institutions approved the protocols reflected on the software.

The inclusion of patients in UpHill Route v3 was the exclusive responsibility of HCPs, who were instructed and trained to use the software in accordance with the technical documentation for noncritical patients in non-critical clinical settings.

The study encompassed the central, capital, and southern coastal regions of Portugal and conducted from May 2023 to April 2024. The LHUs—Litoral Alentejano, Amadora Sintra, Coimbra, and São José—serve a combined population of over 1.40 million people across 17,660 km². This vast region includes urban and suburban populations, and the clinical journeys in these four LHUs include heart failure, multimorbidity (ie, combined heart failure, chronic obstructive pulmonary disease, and diabetes), diabetes, and colorectal and breast cancer, which represent a diverse spectrum of chronic diseases with frequent acute care interventions.

Participants

To be eligible for this study, participants were required to be part of the HCP user base at the previously described health units that were pilot testing UpHill Route v3 in their daily practice and to have completed the training sessions in the proper use of the software. The instruction to use UpHill Route v3 only in noncritical settings was directly related to the targeted diseases, which were chronic or elective conditions integrated into predefined care pathways. The HCPs were briefed on the appropriate use of the system, and adherence to this criterion was monitored through participant feedback and usage data.

It is important to note that the device does not autonomously provide care to patients, and all the content and behavior are based on the locally validated clinical pathway. All participants

XSL•FO
RenderX

provided informed consent to be included in each care journey, ensuring their voluntary participation.

Endpoints and Variables

The primary aim was to study the perceived usefulness of this PDCP captured through a questionnaire administered to HCPs piloting UpHill Route v3. This questionnaire was developed so that the constructs under each question contributed to understanding the perceived usefulness of UpHill Route v3: (1) adherence to clinical protocols (ease of compliance with protocols; (2) clinical decision support (measure of recommendation relevance); (3) improvement in patient care (perceived value of the presented recommendations to the patient); (4) task management (time-saving benefits); and (5) confidence in patient management (reliability of support for delivery of exhaustive and proper care). Each question was answered using a Likert scale ranging from 0 to 10, indicating the participant's level of agreement with the presented component concerning PDCP usefulness. The questionnaire was written in Portuguese and distributed to participants via email. It is available in the supplementary materials (Multimedia Appendix 1).

The secondary aim was to describe the number and type of decisions supported by the software, by analyzing human-computer interactions made on the UpHill Route v3 graphical user interface. Decisions made with the support of the software are encapsulated in decision gateways, which are elements within UpHill Route v3 that prompt decision-making based on specific criteria. These criteria may be related to the patient's condition, signs and symptoms, or clinical results. Multimedia Appendix 2 represents an example interface for UpHill Route v3 graphical interface for the type 2 diabetes mellitus clinical pathway of a test patient. In this interface, HCPs are presented with patient-specific actions and decisions in the center panel. On the right panel, supportive complementary information related to the selected action or decision in the central panel is presented to the HCP. Data were collected from user interactions with UpHill Route v3, as well as from its internal database. Participants were characterized according to demographic variables (eg, sex, age) and years of clinical experience. Additionally, information on academic activity as a binary variable indicating whether participants were involved in academic roles alongside their clinical duties was collected.

Data Sources/Measurement

Primary objective data were collected through an online questionnaire. The questionnaire (in Portuguese) was delivered through Microsoft Forms and sent to the participants through email and are available in Multimedia Appendix 1. The analysis of the data was done using Microsoft Excel and STATA (version 14; StataCorp).

Secondary objective data were collected through queries from UpHill Route v3 internal database.

Data Processing Protocol

Data were collected from the software's database to describe the number and type of decisions supported by the software. The database recorded each option clicked on by the user for each pathway element. Then, these data were aggregated by pathway elements (ie, actions and decisions), each with a unique identification number. To analyze these elements and their selected options, queries on the database were performed, aggregating the same pathway element across all patient records.

Decisions were categorized into one of the ten clinical decision types as defined in the Decision Identification and Classification Taxonomy for Use in Medicine (DICTUM) [10]. These includes gathering additional information, evaluating test results, defining problems, drug-related decisions, therapeutic procedure-related decisions, legal and insurance-related decisions, contact-related decisions, advice, and precaution, setting treatment goals, and deferment.

Actions were categorized as clinical if assigned to nurses or physician profiles, or as nonclinical if assigned to administrative profiles. For example, clinical tasks included the recommendations to request a mandatory diagnostic test, while nonclinical tasks involved appointment scheduling. All data were aggregated by pathway elements, combining all the patient records without any identifiable patient variable.

Study Size

For the primary objective, all 48 potentially eligible HCPs who were actively piloting UpHill Route v3 at the time of study recruitment were invited via email to answer the questionnaire.

For the secondary objectives, internal data were retrieved anonymously for HCPs and patient data. Therefore, data from the activities of all 48 professionals was analyzed.

Statistical Methods

Descriptive statistics were used to summarize the demographic characteristics of the participants. Continuous variables were summarized with central tendency and dispersion measures, namely mean and standard deviation. Categorical variables were reported as relative and absolute frequencies. Bivariate analysis was conducted with a χ^2 test for categorical variables and a 2-tailed Student *t* test for continuous variables.

To address the primary objective, responses collected from the questionnaire were analyzed by calculating mean scores and measures of dispersion (standard deviation) for each question. Higher mean scores indicated greater perceived usefulness of UpHill Route v3, while low dispersion reflected stronger agreement among participants regarding the software's usefulness.

To address the secondary objective, we categorized and counted the types of decisions involving human-computer interaction, which were presented as absolute and relative frequencies. Additionally, we analyzed the tasks suggested by UpHill Route v3 within each care pathway, reporting these tasks as percentages.

Ethical Considerations

This research project was submitted and approved by NOVA Medical School under the main author's PhD research project "Characterizing uncertainty in decision making with complex multimorbidity patients," (No.108/2021/CEFCM) (Multimedia Appendix 3). The study involved secondary analysis of existing

XSL•FO
RenderX

data for which informed consent was obtained at the time of initial collection, and the original consent and institutional review board approval covered secondary analysis without requiring additional consent from the participants. All data used in this study were fully anonymized to ensure privacy and confidentiality. No compensation was provided to participants.

Results

A total of 22 participants answered the questionnaire (response rate, 46%). The mean age of the participants was 44.7 (SD 10.6) years, while mean years of experience was 20.6 (SD 11.0) years. Of the 22 participants, 15 (68%) were female; 9 (41%) were medical doctors, and the remaining 13 (59%) were nurses. Additionally, 2 (9%) of participants were involved in academic activities.

Bivariate analysis showed no significant associations between gender and medical doctor status (P=.30), gender and nurse status (P=.13), or gender and involvement in academic activities (P=.66). Similarly, t tests for continuous variables indicated no significant differences in age (P=.54) or years of experience (P=.44) between male and female participants.

Perceived Usefulness of UpHill Route V3

Participants rated the statement "UpHill Route v3 makes it easier to manage patients according to the clinical protocols of my institution" with a mean score of 8.06 (SD 1.73), a statement that aimed to assess the ability to easily comply with protocols. Focusing on clinical decision support, the statement "the UpHill Route v3 provides me with relevant clinical recommendations at the right time" received a mean score of 8.05 (SD 1.73). For the statement "the UpHill Route v3 helps me to improve my patient care", which evaluated the sense of patient care improvement, the mean score was 7.63 (SD 2.22). Finally, for confidence in patient management, "the UpHill Route v3 gives me more confidence that my patients are being properly cared for" received a mean score of 8.26 (SD 1.56). The results of the questionnaire are presented in Table 1.

Table . Results of the questionnaire applied to HCPs[a] to assess the perceived usefulness of the UpHill Route v3[b].

Question	Mean score (SD)
UpHill Route v3 makes it easier to manage patients according to the clinical protocols of my institution	8.06 (1.73)
The UpHill Route v3 provides me with relevant clinical recommendations at the right time	8.05 (1.73)
The UpHill Route v3 helps me to improve my patient care	7.63 (2.22)
The UpHill Route v3 gives me more confidence that my patients are being properly cared for	8.26 (1.56)

[a]HCP: health care practitioner.

[b]Responses collected from the questionnaire were analyzed by calculating mean scores and measures of dispersion (standard deviation) for each question using the Likert scale ranging from 0 (do not agree) to 10 (totally agree) indicated the participant's level of agreement with UpHill Route v3..

There were no significant differences in the perceptions of effectiveness of the UpHill Route v3 between physicians and nurses, as well as between genders.

Overall, the demographic characteristics or perceived usefulness of the UpHill Route v3 did not significantly differ based on gender or professional role (ie, medical doctor vs. nurse).

Decisions Supported by the Software

Data were collected from heart failure, diabetes, and cancer (colorectal and breast) care pathways across the four different institutions (ie, LHUs).

Forty-eight HCPs used UpHill Route for supporting decisions of a total of 3574 patients, with 25,741 decisions captured. HCPs answered 427 decision gateways, performed 9254 actions, and the system generated 2429 clinical notes. Overall, there were 37,534 activities (ie, sum of decisions, actions, and notes) performed in UpHill Route v3. These results are summarized in Table 2.

Table . Aggregated data of human-computer interactions across care pathways.

Local health unit (Care pathway)	Patients (n=3574)	Gateways (n=427)	Decisions (n=25,741)	Actions (n=9254)	Clinical notes (n=2429)	Total activities per pathway, n (activities per patient)
Litoral Alentejano (heart failure)	609	76	8249	2570	0	10,819 (19.5)
Litoral Alentejano (multimorbidity)	668	207	10,680	2350	0	13,030 (17.8)
Coimbra (colorectal cancer)	355	3	685	1356	0	2041 (5.8)
São José (colorectal cancer)	202	25	883	856	144	1883 (9.3)
São José (breast cancer)	223	32	878	1079	107	2064 (9.3)
Amadora/Sintra (diabetes)	1517	84	4466	1053	2178	7697 (5.1)
Total	—[a]	—	—	—	—	37,534 (10.5)

[a]Not applicable.

The Litoral Alentejano multimorbidity care pathway presented the highest number of activities per patient, with an average of 19.5 activities, followed by the Litoral Alentejano heart failure care pathway which exhibited a high level of clinical activity, with 17.8 activities per patient. São José colorectal and breast cancer pathways had an average of 9.3 activities per patient. Coimbra colorectal cancer and Amadora/Sintra diabetes care pathways averaged 5.8 and 5.1 activities per patient, respectively. Overall, the mean number of clinical activities per patient performed in the four health institutions using the UpHill Route v3 was 10.5.

As part of the secondary objective, the categorization of clinical decisions showed that the majority of decisions (9215/25,841, 35.7%) were related to “defining problem”, followed by “gathering additional information” (n=5759, 22.3%) and “treatment goal” (n=4845, 18.7%). The distribution of these decisions varied across different care pathways, with Litoral Alentejano multimorbidity and heart failure accounting for the largest proportions, representing 41.3% (n=10,678) and 31.9% (n=8251) of the total decisions, respectively. Other decision types, such as “contact-related” and “therapeutic procedure–related,” accounted for smaller proportions, 7.0% (n=1814) and 5.0% (n=1280), respectively. This distribution highlights the diverse range of decision types supported by UpHill Route v3, tailored to the specific needs of different clinical contexts. The results of the decision categorization, presented by clinical journey are summarized in Multimedia Appendices 4 and 5 .

While analyzing decision types, a total of 1814 (n=7.0%) decisions were found to be contact-related. These involved admitting or discharging patients, scheduling follow-ups, and referring patients to other parts of the health care system. There were 460 (1.8%) deferment decisions, which involved actively delaying or rejecting a decision on a problem presented by the patient. The highest number of decisions were defining-problem decisions, totaling 9215/25,841 (35.7%). These complex, interpretative assessments defined what the problem was, including diagnostic conclusions, evaluations of health status, etiological inferences, and prognostic judgments. A total of 1415 (5.5%) decisions were related to drug therapy, which involved starting, stopping, altering, or maintaining a drug regimen. There were 1053 (4.1%) decisions related to the evaluation of test results, involving simple, normative assessments of clinical findings and tests. A total of 5759 (22.3%) decisions were aimed at gathering additional information, which involved obtaining information from sources other than patient interviews, physical examinations, and patient charts. There were 1280 (5.0%) decisions related to therapeutic procedures; these involve planning, performing, or refraining from therapeutic interventions. A total of 4845 (18.7%) decisions were related to setting treatment goals, which involved defining specific objectives for patient care. The comprehensive details of each decision type’s categorization can be found in Multimedia Appendix 6.

Discussion

Principal Findings

This study evaluated the perceived usefulness and practical implementation of the UpHill Route v3 as a PDCP in various clinical settings. The primary outcome focused on the perceived usefulness of the system, as assessed by HCPs through a structured questionnaire. The results demonstrated high scores across multiple dimensions, including adherence to clinical protocols, clinical decision support, and confidence in patient management. Specifically, participants rated the system highly in the ease of adhering to clinical protocols by providing relevant clinical recommendations, demonstrating that HCPs perceive UpHill Route v3 as a valuable tool in clinical settings. Our analysis found no significant differences in the perceived usefulness of UpHill Route v3 between genders or professional roles (medical doctors vs nurses). This lack of disparity indicates that UpHill Route v3 is perceived to be equally beneficial across different demographic and professional groups within health care settings. Overall, this posits that the software with its

XSL•FO
RenderX

decision support capabilities proves valuable in adhering to clinical guidelines, providing relevant clinical guidance, enhancing patient care, and instilling confidence in the provided care.

The high scores across multiple dimensions of perceived usefulness indicate that HCPs find the UpHill Route v3 system valuable for clinical decision support. The system's ability to integrate clinical protocols and provide timely recommendations appears to enhance both clinical efficiency and the quality of patient care.

Concerning secondary outcomes, the data indicated significant usage of clinical activities being supported by UpHill Route v3, averaging 10.5 activities per patient. There were expected variations in clinical activities per patient across different care pathways. Litoral Alentejano multimorbidity and heart failure cases required the most activities per patient, suggesting highly complex pathways with numerous decision points. These care pathways naturally require more complex clinical activity for the management of these conditions. In contrast, Coimbra Colorectal Cancer and Amadora Sintra Diabetes involved fewer activities per patient, reflecting a more focused and shorter clinical pathway in those users. The distribution of decisions supported by UpHill Route v3 varied significantly, with defining–problem decisions and gathering additional information being the most common. This finding is consistent with the complex nature of clinical diagnostics and the need for comprehensive information gathering to inform clinical decisions in the follow-up phase of symptomatic chronic diseases such as heart failure or multimorbidity [11]. The system's ability to support these critical decision types highlights its relevance and utility in clinical practice. Overall, the categorization of decisions and tasks demonstrates the system's versatility in supporting various aspects of patient management, from diagnosis and treatment to follow-up care. These findings suggest that the UpHill Route v3 system can effectively bridge the gap between clinical guidelines and real-world practice, potentially leading to improved patient management.

The study's findings on UpHill Route v3 align with existing literature on the effectiveness of CDSS in healthcare [12]. Our findings emphasize the importance of CDSS, particularly PDCP, in providing timely and accurate decision support, through personalization and longitudinal continuity, which is crucial for clinicians in complex and dynamic environments [13]. This aligns with findings from multiple systematic reviews and studies. Although many CDSS enhance practitioner performance, evidence of their impact on patient outcomes remains limited and inconsistent, indicating a need for further research[14]. A recently published systematic review and meta-analysis focused on the primary prevention of cardiovascular disease demonstrated that CDSS were effective in improving blood pressure clinical target attainments. However, multilayered barriers affecting the uptake, longer-term use and active engagement from clinicians and patients may hinder their full potential in achieving other quality-of-care outcomes [15]. While digital care pathways have shown promise in optimizing the efficiency of care delivery, effective implementation requires training, resource allocation, support for information management, and optimizing alert algorithms to manage information overload [16,17].

The positive feedback on UpHill Route v3's decision support capabilities reinforces the concept that a PDCP as a CDSS can enhance clinical decision-making and patient management, and the subsequent step for PDCPs is likely to be task automation of predictable and mandatory tasks. Previous findings in the literature highlight its benefits. For instance, a systematic review by Jones et al [18] highlighted how task automation through CDSS can streamline workflows, reduce administrative burdens, and minimize human errors, allowing HCPs to focus more on direct patient care.

Future research should explore the long-term impacts of task automation on clinical outcomes and examine how the integration of PDCPs with other health care technologies can provide efficient orchestration of patient health care.

Several limitations and potential sources of bias need to be acknowledged in this study. First, only 22 HCPs replied to the questionnaire, a small number that may limit the generalizability of the findings, although they worked at multiple health care centers. Additionally, the study relied on self-reported data to assess the perceived usefulness of the system, which could be subject to response bias. Despite anonymization, participants may have provided favorable responses due to social desirability or perceived expectations of the study organizers. However, a strength of the study is the inclusion of aggregated data from diverse patient populations (eg, heart failure, diabetes, breast and colorectal cancer) across various clinical settings (ie, primary and secondary care) and contexts (ie, urban and rural).

Although all authors are affiliated with UpHill Health, S.A., the study design, data collection, and analysis were conducted using standardized methodologies to ensure objectivity. The findings were interpreted transparently and align with prior research on clinical decision support systems, reinforcing their validity.

While the study's findings are promising, the small sample size limits the generalization of the results. Future research should aim to include a larger and more diverse cohort across multiple health care settings (ie, various specialties and practice settings) and geographic regions to enhance external validity and applicability to broader clinical contexts. We speculate that variations in health care system infrastructure, clinical workflows, cultural factors, and user experience levels may influence the adoption and perceived effectiveness of PDCP.

Additionally, this study primarily focuses on short-term implementation outcomes. Future research should adopt a longitudinal approach to evaluate sustained adherence to protocols, patient outcomes, and cost efficiency, allowing for a more comprehensive assessment of the long-term impact of the UpHill Route v3 system on clinical outcomes and health care efficiency. Despite these limitations, the positive qualitative feedback and the objective quantitative interaction with the software by HCPs suggest that the UpHill Route v3 system is a valuable tool in various clinical settings, supporting decision-making and enhancing patient care.

XSL•FO
RenderX

Conclusion

This study demonstrates that HCPs highly value PDCPs as CDSSs for enhancing adherence to clinical protocols, providing timely recommendations, and improving patient care. The system showed significant activity, with several decisions supported across various clinical journeys and settings.

Despite the study's small sample size, the anonymous nature of the questionnaire and objective secondary outcome data provide robust evidence of the system's effectiveness across different clinical scenarios such as chronic, oncological, and surgical conditions. Further research with larger and more diverse populations is needed to confirm these findings and explore the system's long-term impact.

In summary, the PDCP systems support clinical decision-making and operational efficiency and promote the accurate execution of a wide range of clinical activities in patient management in health care settings.

Acknowledgments

This study was supported by UpHill, S.A., which provided funding as part of the main author's PhD studies. The funder's role was limited to facilitating the research activities and data collection. UpHill, S.A. was not involved in the study design, data analysis or interpretation, writing of the manuscript, or the decision to submit the article for publication.

Conflicts of Interest

All authors of this study are employees of UpHill, S.A. This affiliation may represent a potential conflict of interest. Efforts were made to ensure the study's design, data collection, analysis, and interpretation were conducted impartially and without undue influence from the author's employment status. The findings and conclusions presented in this manuscript are based on objective data and aim to contribute to the scientific understanding of clinical decision support systems.

Abstract

Background: The use of digital technologies, such as mobile apps, Zoom (Zoom Communications), virtual reality, and video games, to promote physical activity in individuals with autism spectrum disorder (ASD) has been increasing. However, there are no studies using ChatGPT (OpenAI), a popular tool in recent years, for promoting physical activity in children with ASD.

Objective: This study aimed to evaluate the feasibility and potential effectiveness of ChatGPT-delivered physical activity interventions in children with ASD.

Methods: A total of 26 families (parent-child dyads) participated in the study. Families were randomly assigned to an application group (n=13) and a control group (n=13). In the application group, parents implemented physical activities recommended by ChatGPT for their children with ASD. Data were collected using the Leisure Time Exercise Questionnaire (LTEQ) and a feasibility questionnaire.

Results: Parents reported that ChatGPT-delivered physical activities were a feasible intervention to increase physical activity levels in children with ASD. They also found the activity content suggested by ChatGPT to be interesting and useful. LTEQ measurements corroborated these findings, showing a significant increase in the physical activity levels of children in the intervention group after the intervention.

Conclusions: The results suggest that ChatGPT-delivered physical activities could be a promising intervention to enhance physical activity in children with ASD. Further investigation is warranted.

Introduction

Autism spectrum disorder (ASD) is a neurodevelopmental disorder that commonly emerges in early childhood and is characterized by the deficiencies in social interaction and communication skills and the restricted-repetitive behavioral patterns [1]. ASD negatively affects the behavioral, social, cognitive, and mental functions of children diagnosed with this disorder [2], as well as their physical activity levels [3]. Recent studies have revealed that children with ASD are less physically active than their typically developing peers [4], and that these children tend to lead sedentary lives [5]. Many individuals with disabilities, including children with ASD, spend a lot of time in sedentary behaviors such as watching television [6]. High levels of inactivity, a concern for all children, is an important issue to address since children with ASD have fewer opportunities to participate in physical activity [7,8].

Participation in physical activity provides many benefits to children with ASD in terms of physical and mental health [9-11]. Studies examining physical activities in children with ASD have revealed that physical activities can have a positive effect on manipulative and locomotor skills [12-14]. At the same time, some studies have found that physical activity helps increase the self-confidence and self-efficacy of children with ASD [10,14]. Furthermore, some studies have shown that stress and anxiety levels of children with ASD, who participate in physical activity, decrease [15] while their social and communication skills improve [16,17].

Despite the numerous health and social benefits of regular physical activity, there are many potential barriers that limit the participation of children with ASD in physical activity [9]. To explain the barriers that cause physical activity deficiencies in children with ASD, some studies focus on characteristic features of ASD, such as inadequate motor skills (joint flexibility, balance, speed, etc), biophysical behaviors (inattention and hyperactivity), and communication disorders [18-20]. Other studies have drawn attention to the limitations in the sustainability of current physical activity interventions for children with ASD [21]. Current physical activity interventions aimed at increasing the physical activity level of children with

XSL•FO
RenderX

ASD often require specialist support (teacher, medical clinician, or physiotherapist), costly specialized equipment, and unnatural environments (school, horse, pool, or equine therapy center, etc) [21]. In most cases, access to existing physical activity programs is limited to people living in areas where specialists provide services [22], and especially during global crises such as COVID-19 pandemic, children with ASD may have limited access to physical activity [3]. For this reason, it is stated that there is a need for an alternative physical activity presentation that children with ASD can do at home with their parents and reach a wider audience.

Recent studies have suggested that internet technologies, programs, and apps may have significant potential in promoting physical activity in children with ASD and creating a more sustainable physical activity presentation [21,23,24]. Among these apps, conversational agents using large language models (LLMs), which have recently become widely used worldwide, have attracted attention as powerful information search tools for children with ASD [25]. Their ability to produce contextually relevant and consistent text positions conversational agents using LLM as potential agents, especially for educational content [26]. Extensive information can be easily accessed anytime and anywhere by simply typing a query about individuals with ASD into conversational agents, usually exemplified by ChatGPT (OpenAI) [27,28]. Conversational agents using LLM provide useful information about daily living for individuals with ASD, such as daily tasks, personal care, and social interaction [29,30].

Although there are different conversational agents such as ChatGPT, BERT (Google), Cipherbot, and DeepSeek in the literature, it has been seen that ChatGPT is frequently used for children with ASD. These studies [31-35] included important information about application protocols and ChatGPT prompts. For this reason, this study used ChatGPT to deliver physical activities to parents of children with ASD. Released by OpenAI in November 2022, ChatGPT is an open AI language model that produces human-like responses to text-based prompts [36]. ChatGPT, which can run on a phone, tablet, or computer, can understand responses in a variety of languages, write stories of different types and lengths, summarize information in complex texts, provide explanations on various topics, and even refuse to respond to inappropriate prompts [37]. ChatGPT is also a highly advanced app in that it can provide a continuous dialogue by remembering what the user has said before in the conversation thread [38]. Although limited in number, studies [31-35] have revealed that ChatGPT can be a useful tool for improving the social skills of children with ASD or for providing information to parents about children with ASD. Although it is a new topic, there is no study evaluating the effectiveness and feasibility of ChatGPT-delivered physical activities in children with ASD. Considering this gap in the literature, the aim of this feasibility study was to examine the effectiveness and feasibility of ChatGPT-delivered physical activities to increase the physical activity level of children with ASD.

Methods

Study Design

This study was designed to evaluate the feasibility of ChatGPT-delivered physical activities to increase the physical activity level of children with ASD. A feasibility study examines whether an intervention is suitable for further testing [39] and allows the intervention procedure to be used in future studies [21]. The feasibility process of the study was based on previous studies that used feasibility measures to evaluate a web-based intervention [21,22,24,40-42] and consisted of 5 stages (Textbox 1).

Textbox 1. Feasibility process of ChatGPT-delivered physical activity.

- Stage 1 (assessment for participant eligibility): The researcher collaborated with a local special education and rehabilitation center in Ankara to recruit parents of children with autism spectrum disorder as participants.
- Stage 2 (ChatGPT training for parents): Parents attended three 40-minute training sessions that included information about ChatGPT and physical activity.
- Stage 3 (preintervention measurements): A week before the intervention, the physical activity level of children with autism spectrum disorder.
- Stage 4 (intervention [4 weeks]): Parents practiced the physical activities recommended by ChatGPT for 40 minutes, 3 days a week for 4 weeks.
- Stage 5 (postintervention measurements): A week after the intervention, the physical activity level of children with autism spectrum disorder and parents' opinions on ChatGPT-delivered physical activities were evaluated.

Participants

The participants of the study were recruited from Ankara province. The criterion sampling method was used in determining the participants [43]. Inclusion criteria were individuals agreeing to participate in the study voluntarily, having a child diagnosed with ASD according to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* criteria, and parents and children not having any health problems that prohibit physical activity. In line with these criteria, support was received from a special education and rehabilitation center to identify parents. With the permission of the director of the association, the primary researcher interviewed the participant candidates on the phone and explained the aim of the study and participation process to them. Consent forms were received from all parents who voluntarily participated in the study via email. A total of 26 parents (9 mothers and 17 fathers) and their children with ASD participated in the study. All parents filled out the demographic information form and physical activity questionnaire (pretest) before the intervention and the feasibility measures and physical activity questionnaire (posttest) after the intervention. The characteristics of the parents and their children with ASD are presented in Table 1.

Intervention

ChatGPT Training for Parents

In this study, parents played an important role by actively participating in ChatGPT-delivered physical activities and helping their children with ASD. Parental participation was an integral part of ChatGPT-delivered physical activities. To prepare parents for this role, the researcher conducted three 40-minute training sessions. Each session lasted until parents demonstrated proficiency. The first session focused on developing parents' skills in using ChatGPT. The researcher explained to parents how to download ChatGPT and how to get physical activity recommendations using ChatGPT. Then, the researcher asked all parents to give ChatGPT the following command: "Create a 4-week, 3-day, 40-minute physical activity program that can be implemented at home for my child who is…years old and has ASD." The researcher discussed the program created by ChatGPT with parents and told them to give the following command to ChatGPT for physical activities they did not understand: "What is…activity? Show me in detail." The researcher emphasized the importance of all parents using the commands suggested by the researcher in order to optimize the prompts. The second session included informing parents about the parts of a physical activity (warm-up, cool-down, and main part). The third session addressed strategies that parents can use when providing physical activity to children with ASD. These strategies generally included information about preparing children with ASD for physical activities (wearing sports clothes, social stories, and preview of activities and equipment), organizing the environment where physical activities will take place (safety, ventilation of the environment and sports pictures), including other members of the family in physical activities (parent and sibling participation), and reward is given. A special WhatsApp (Meta) group was created to answer parents' questions during the implementation of the ChatGPT-delivered physical activities. Parents' questions regarding the implementation of the physical activities and the use of the ChatGPT software were answered instantly via the WhatsApp

XSL•FO
RenderX

group. In addition, at the end of the daily physical activity session, parents chatted in the WhatsApp group to evaluate the effectiveness of the session and explore the experiences of other parents.

ChatGPT-Delivered Physical Activities

All parents, who completed the ChatGPT training, used ChatGPT-delivered physical activities to increase the physical activity levels of their children with ASD. One week before the intervention, the researcher asked each parent to give ChatGPT an appropriate command so that the physical activities were age-appropriate for children with ASD and could be easily carried out in the home environment. Although the content of ChatGPT varied, it generally suggested physical activities to parents consisting of 3 parts: warm-up, main part, and cool-down (Table 2). The researcher asked parents to ask ChatGPT again about the activities they did not understand about the activities suggested by ChatGPT until the intervention began. In addition, the researcher supported the parents by explaining the activities they did not understand in the WhatsApp group. The parents implemented the intervention for 40 minutes, 3 days a week for 4 weeks. The parents and the children with ASD participated in the activities together. During the implementation process, the researcher immediately answered the parents' questions about the activities and strategies in the WhatsApp group. In addition, at the end of the daily physical activity session, the parents chatted in the WhatsApp group to evaluate the effectiveness of the session and prepare them for the next session. In the interview, the researcher asked the parents questions about the extent to which physical activities were performed, who participated in physical activities, and what the benefits of physical activities were. In this way, the researcher tried to verify to what extent and how physical activities were carried out. All parents and children with ASD completed the 4-week intervention. The recommended physical activities in a typical week are shown in Table 2.

Table . Physical activities in a typical week recommended by ChatGPT.

Day and physical activity	Content
First day (movement and balance)	
Warming up (10 min)	Opening and closing the arms up and to the sides; slow walking with the knees pulled in; slow running in place.
Main exercise	
Balance line (5 min)	Draw a line on the ground and have your child walk along this line.
One leg on pillow (5 min)	Try to keep your balance on the pillow.
Rolling with ball (5 min)	Sit on the floor with your child and roll a large ball to each other.
Jumping (5 min)	Use a ring or cushion to bounce in and out.
Cooling down (10 min)	Slow walking and stretching movements (stretching the arms and stretching the legs).
Second day (coordination and movement)	
Warming up (10 min)	Stretching arms and legs; animal walks (bear walk, frog leap).
Main exercise	
Throwing and catching balls (10 min)	You and your child throw and catch a large ball to each other.
Rolling on the mat (5 min)	Rolling back and forth on a large cushion.
Imitation games (5 min)	Exercises of standing on one leg and finding balance while turning slightly.
Cooling down (10 min)	Slow breathing and yawning.
Third day (game day and free movement)	
Warming up (10 min)	Free dance and simple movements with rhythmic music.
Main exercise	
Balloon games (10 min)	Play a game with your child by holding balloons in the air.
Obstacle course (10 min)	Set up a simple track with cushions and chairs inside the house and have your child walk through the track (crawling, walking, and jumping).
Cooling down (10 min)	Slow paced walking and light stretching.

Data Collection

Overview

Data were obtained with the following 2 tools: (1) Feasibility Questionnaire and (2) Leisure Time Exercise Questionnaire (LTEQ). Measurements were made 1 week before and after the intervention. Data were collected via Google forms. The researcher shared the Google form links in the WhatsApp group and asked all parents to complete the forms in the links within 1 week. A personal information form was used to obtain

XSL•FO
RenderX

information about the demographic characteristics of parents (age, gender, and level of education) and children with ASD (age, gender, additional comorbidities, and number of people in the household).

Feasibility Questionnaire

Parents rated their ChatGPT-delivered physical activities via the Feasibility Questionnaire after the 4-week intervention. Questionnaire questions were designed considering previous studies investigating the physical activity level of children with ASD [3,21]. Questionnaire questions included the following: (1) how would you rate your overall experience with ChatGPT-delivered physical activities, (2) how interesting were the ChatGPT-delivered physical activities, (3) how beneficial were the ChatGPT-delivered physical activities for your child's physical activity level, and (4) to what extent did you learn about physical activity through ChatGPT? The Feasibility Questionnaire was rated on a 5-point Likert-type scale (very satisfied to not very satisfied, very to a little, very useful to not useful at all).

Leisure Time Exercise Questionnaire

To assess the physical activity level of children with ASD before and after the intervention, the researcher used the LTEQ developed by Godin and Shephard [44]. The LTEQ has been frequently used in previous studies [3,21,22,45-47] to determine the leisure time physical activity level of individuals with ASD. Memari et al [46] showed that the LTEQ has a good test-retest reliability score that can be used to determine the physical activity level of children with ASD. The questionnaire includes questions about at least 15 minutes of leisure time physical activity performed in the last 7 days and aims to determine the number of times of strenuous-intensity physical activities, moderate-intensity physical activities, and mild-intensity physical activities performed in the last week. To calculate the total score of the scale, high-intensity activities are multiplied by 9, moderate-intensity activities by 5, and light activities by 3, and all are added together. The formula is as follows: weekly leisure time activity score = (9 × strenuous intensity) + (5 × moderate intensity) + (3 × mild intensity). The calculated values are added up and generally evaluate the individual's leisure time activity. In this evaluation, scores of 24 and above are classified as "Active," 14 - 23 as "Moderately active," and 13 and below as "Not sufficiently active" [48]. The Turkish adaptation study of the LTEQ was conducted by Yerlisu-Lapa et al [49]. As a result of the exploratory factor analysis conducted to determine the factor structure of the questionnaire, the total correlations of the items were determined as 0.80, 0.76, and 0.65 for all 3 items, respectively, and it was found that 55% of the total variance was explained and gathered under a single factor. Test-retest reliability analysis yielded a Pearson correlation coefficient of r = 0.84 for the entire Leisure-Time Exercise Questionnaire (LTEQ), and 0.80, 0.76, and 0.72 for its vigorous, moderate, and mild intensity subscales, respectively. To assess equivalent form reliability, a comparison was made between the LTEQ and the International Physical Activity Questionnaire–Short Form (IPAQ-SF). The Spearman correlation coefficient for the relationship between the two forms was found to be ρ = 0.92, indicating a strong positive correlation [49].

Statistical Analysis

Descriptive statistics (mean, SD, percentage, and frequency) were used in the study for feasibility measurements, demographic information, and frequency of participation in physical activities. A 2-way mixed ANOVA (analysis of variance; 2 groups × 2 time points) was used to determine the effects of ChatGPT-delivered physical activities (from baseline to intervention) on the physical activity level of children with ASD. All these statistical processes were carried out with the SPSS package program (version 25.0; IBM Corp).

Ethical Considerations

The research was approved by the Bayburt University noninterventional clinical research ethics committee (number 209) on July 23, 2024. This study was approved by the Ethics Committee of Bayburt University (no. E-15604681-100-215816). Informed consent was obtained from the legal guardians of the participants. Participation was voluntary, and the participants had the right to withdraw from the study at any time. For secondary analyses using existing data with primary consent, the original consent or institutional review board approval covers secondary analyses without additional consent. Data have been anonymized and deidentified (pseudonyms were used in the study to protect the identities of the participants. Participant names were listed as P1, P2, P3, and so on. No financial compensation was given to the participants, but small symbolic rewards (stickers, reward cards, etc.) were given.

Results

Parental Opinions and Feedback on Feasibility of ChatGPT-Delivered Physical Activity

All parents expressed that they were very happy to participate in the ChatGPT-delivered physical activities. According to the parents, the ChatGPT-delivered physical activity content was interesting and very useful. Parents stated that the ChatGPT-delivered physical activities positively affected the physical activity levels of their children with ASD. Parents reported that they gained important information about physical activity through ChatGPT. In total, 92% (12/13) of the parents participated in the discussions in the WhatsApp group and shared pictures and videos of their children in the group.

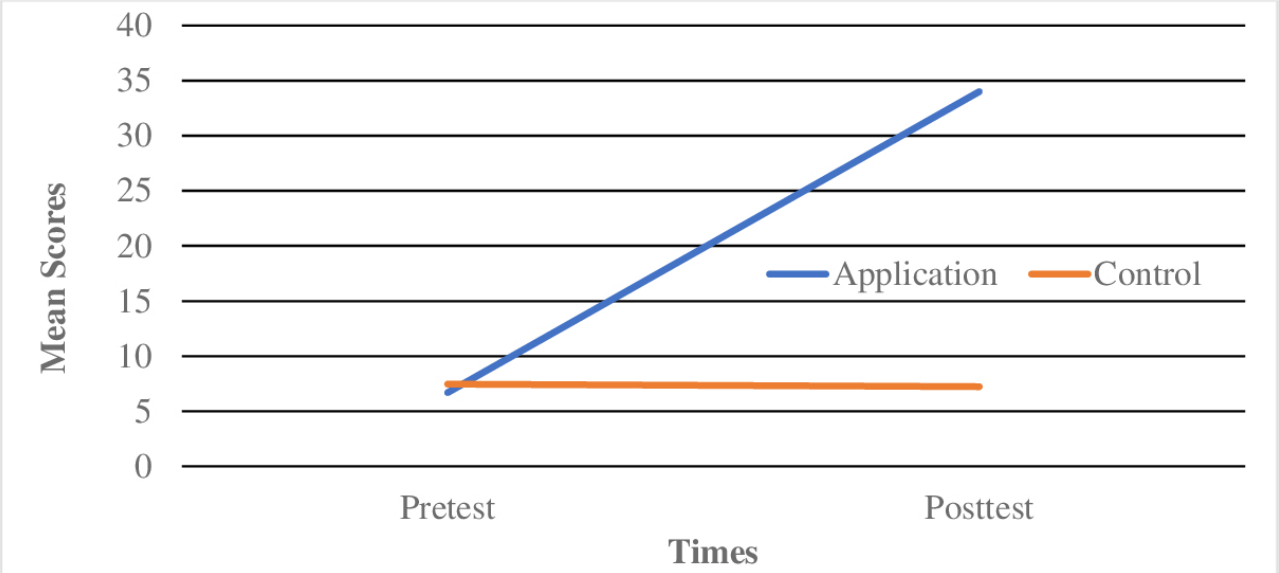
Physical Activity Level

In order to determine the effect of ChatGPT-delivered physical activities on the physical activity level of children with ASD, a 2-way mixed ANOVA (2 groups × 2 time points) test was performed (Table 3). While the mean physical activity score of children with ASD in the application group was 6.69 (not sufficiently active) before the intervention, their physical activity score increased to 34 (active) after the intervention. In contrast, while the mean physical activity score of children with ASD in the control group was 7.46 (not sufficiently active) before the intervention, their physical activity score decreased to 7.23 (not sufficiently active) after the intervention. Regarding the mean

XSL•FO
RenderX

physical activity scores, 2-way mixed ANOVA revealed a significant group effect ($F_{1, 24}$=108.769; P<.05, ηp^2=.819), a significant time effect ($F_{1, 24}$=341.333; P<.05, ηp^2=.934) and a significant group × time interaction ($F_{1, 24}$=353.069; P<.05, ηp^2=.936) on the physical activity level of the participants in the application and control groups.

Table . Analysis of variance results related to the pretest-posttest physical activity scores.



Source	Type III sum of squares	Mean square	*F* test (*df*)	*P* value	Partial eta squared (ηp^2)
Between-Subjects	9969.231				
Group (A/C)	2197.000	2197.000	108.769 (1, 24)	<.001[a]	.819
Error	484.769	20.199	—[b]	—	—
Within-subjects	5014.999				
Time (pretest-posttest)	2382.769	2382.769	341.333 (1, 24)	<.001[a]	.934
Time group	2464.692	2464.692	353.069 (1, 24)	<.001[a]	.936
Error	167.538	6.981	—	—	—

[a]Significant at P<.05.

[b]Not applicable.

Since ANOVA results reveal a significant group × time interaction, the adjusted Bonferroni value was used to determine whether there was a change in application and control groups over time. As reported in Figure 1, pair-wise comparisons revealed the significant increase in the preintervention physical activity scores of children with ASD in the application group compared with their postintervention physical activity scores (adjusted Bonferroni*: P*<.05, difference: +27.308); this was not the case in the control group (adjusted Bonferroni*: P*>.05, difference: −0.231).

Figure 1. Mean physical activity scores of the groups in preintervention and postintervention.

Discussion

Principal Findings

The aim of this study was to examine the effects of ChatGPT-delivered physical activity intervention on the physical activity level of children with ASD. The results revealed that there was a positive and significant increase in the physical activity level of children with ASD in the application group after ChatGPT-delivered physical activities compared with children with ASD in the control group. Current physical activity interventions that aim to increase the physical activity level of children with ASD generally include physical activity programs such as karate [50], swimming [51], summer camp [52], fitness [53], and therapeutic horseback riding [54]. Systematic reviews suggest that participation in existing physical activity programs has a positive effect on the developmental domains of children with ASD [10,12]. Despite these promising findings, there are some limitations in the sustainability of current physical activity interventions [24]. Current physical activity interventions are often disrupted due to dependency on professionals, unnatural environments, and high costs [21]. In most cases, access to current physical activity programs is limited to people living in

XSL•FO
RenderX

areas where professionals provide services [22]. In fact, in situations such as school closures due to COVID-19 pandemic, children with ASD have completely restricted access to physical activity [55]. Realizing this, researchers have recently begun to show interest in alternative physical activity interventions that can reach more people and that children with ASD can do at home with their families [3]. Various studies have been conducted on sustainable physical activity interventions, especially for children with ASD who cannot access physical activity [21,24,56]. The results of the studies revealed that physical activities provided remotely via WhatsApp and Facebook (Meta) are effective interventions to increase physical activity in children with ASD.

As seen in the literature, alternative physical activity interventions for children with ASD have been focused on social media platforms. Although it is a new topic, no study has been found using ChatGPT to improve the physical activity level of children with ASD. To our knowledge, this is the first study to evaluate the feasibility of ChatGPT-delivered physical activities to increase the physical activity level of children with ASD. In the study, it was taken into consideration that parents have a critical role in the participation of their children with ASD in physical activity [57,58], and parents assumed an important responsibility in the entire process. The parents who participated in the study reported that ChatGPT-delivered physical activities were a feasible and useful intervention to increase the physical activity level of children with ASD. Despite these positive findings, the parents did not understand some of the physical activity content in the WhatsApp group and consulted the researcher about the content. The researcher asked the parents to reprompt ChatGPT regarding the content they did not understand, and the problem was solved in this way. In conclusion, this study demonstrated that ChatGPT-delivered physical activities effectively increased the physical activity level of children with ASD. The findings provided preliminary evidence that ChatGPT-delivered physical activities could be an alternative physical activity that can be easily implemented in the home environment by parents.

Limitations of the Study

Although the study is a pioneering study examining the effectiveness of ChatGPT-delivered physical activities for children with ASD, it has some limitations. Since the study was conducted as a feasibility study, ChatGPT-delivered physical activities were implemented for only 4 weeks. In addition, a follow-up test was not conducted for the physical activity level of children with ASD. Therefore, it may be difficult to interpret the durability of the effects of ChatGPT-delivered physical activities on the physical activity level of children with ASD. Since the sample consisted of 26 families (parent and child dyads), the generalizability of the survey results regarding the physical activity level of children with ASD may be limited. ChatGPT training was organized to prepare the parents in the intervention group to implement physical activities. However, no interviews were conducted regarding the ChatGPT training to determine the perceived usefulness of this training. We relied on the self-report measures of the parents regarding the diagnoses and physical activity level of the children with ASD who participated in the study, did not make any observations, and excluded the perceptions of the children with ASD about the activity program.

Implications for Future Research

Future studies may use measurements such as those obtained via observation or pedometers, in addition to the LTEQ, to assess the physical activity levels of children with ASD during ChatGPT-delivered physical activities. This study does not provide any information on comparing ChatGPT-delivered physical activities with other physical activity programs. Future studies may compare the effects of ChatGPT-delivered and face-to-face physical activities. Future studies may include interviews with parents about the benefits of ChatGPT training organized for parents. We used ChatGPT version 4.0 in the study. Since this version only included verbal information, parents did not understand some of the content related to physical activity. Future studies may provide a more understandable process for parents by using different versions of ChatGPT that include image and video support. Furthermore, future studies can use different conversational agents such as BERT, Cipherbot, and DeepSeek to deliver physical activities to parents of children with ASD.

Acknowledgments

The author would like to thank the individuals with autism spectrum disorders and their parents who participated in the study. The author also expresses gratitude to the Special Education and Rehabilitation Center administrators and personnel for their trust, openness, and cooperation.

Data Availability

The participants of this study did not give written consent for their data to be shared publicly, so due to the sensitive nature of the research, supporting data are not available.

Authors' Contributions

UA contributed to conceptualization, data curation, formal analysis, investigation, methodology, project administration, resources, software, supervision, validation, visualization, writing – original draft, and writing – review and editing.

Abstract

Background: Colonoscopy is the standard diagnostic method for colorectal cancer. Patients usually receive written and verbal instructions for bowel preparation (BP) before the procedure. Failure to understand the importance of BP can lead to inadequate BP in 25%-30% of patients. The quality of BP impacts the success of colonoscopy in diagnostic yield and adenoma detection. We developed the "ColonClean" mobile health (mHealth) app for Android devices. It incorporates visual representations of dietary guidelines, steps for using bowel cleansing agents, and observations of the last bowel movement. We used the Technology Acceptance Model to investigate whether the use of the ColonClean mHealth app can improve users' attitudes and behaviors toward BP.

Objective: This study aims to validate the effectiveness of the ColonClean app in enhancing user behavior and improving BP, providing safe and cost-effective outpatient colonoscopy guidance.

Methods: This study uses a structured questionnaire to assess perceived usefulness, perceived ease of use, and users' attitudes and behaviors toward BP regarding the ColonClean mHealth app. A total of 40 outpatients who were physically and mentally healthy and proficient in Chinese were randomly chosen for this study. The data were analyzed using SPSS 25.0, and we used Pearson product-moment correlation and simple regression analysis to predict the perception of ColonClean.

Results: The results showed that 75% (30/40) of participants achieved an "excellent" or "good" level of BP according to the Aronchick Bowel Preparation Scale. Perceived usefulness and perceived ease of use of the ColonClean mHealth app were positively correlated with users' attitudes and behaviors (P<.05).

Conclusions: The ColonClean mHealth app serves as an educational reference and enhances the effectiveness of BP. Users expressed their willingness to use the app again in the future and recommend it to family and friends, highlighting its effectiveness as an educational guide for BP.

(JMIR Hum Factors 2025;12:e58479) doi:10.2196/58479

KEYWORDS

mobile health app; bowel preparation; nursing guidance; technology acceptance model; mHealth; mobile health

Introduction

Colorectal cancer (CRC) is the third most prevalent cancer and the second leading cause of cancer-related deaths worldwide [1-3]. Colonoscopy is the standard diagnostic method for colorectal cancer, and adequate bowel preparation (BP) is a necessary and crucial step to effectively examine the entire intestinal mucosa [4,5]. Currently, BP before colonoscopy is primarily provided by nurses through paper-based nursing instructions and oral explanations of relevant precautions [6,7]. This involves dietary restrictions and the use of bowel cleansing agents to remove feces from the colon and facilitate visual examination by physicians [8,9].

The explanations for BP are often lengthy, complex, and difficult to understand and remember. As a result, the proportion of inadequate BP ranges from 25% to 30% [10]. Poor BP could lead to 42% of adenomas and 27% of advanced adenomas not being diagnosed [11,12]. Inadequate BP also leads to a missed detection of 10.55% for sessile polyps [13], which can develop into CRC and are particularly difficult to identify as they lie flat on the mucosal layer of the colon [9]. Incomplete

XSL•FO
RenderX

colonoscopy increases the risk of cancer and requires repreparation, adding to health care resource costs [14-16].

The European Society of Gastrointestinal Endoscopy guidelines emphasize that good BP is essential for the diagnosis, treatment, and removal of tumors and precancerous lesions, as well as for the reduction of CRC incidence and its mortality rate. It ensures the quality, safety, and effectiveness of colonoscopy in the clinical examination environment. Adequate BP provides optimal visualization for physicians during the examination, facilitating the detection of polyps or other lesions [10,17].

During the COVID-19 pandemic in 2020, the need for a mobile health (mHealth) app became evident [18,19]. Currently, nursing instructions for BP mainly rely on paper-based materials accompanied by oral explanations, multimedia instruction CDs, or telephone interviews [20]. Using mobile apps can enhance patient education for bowel cleansing [21,22]. Therefore, our research team conducted a literature review and assessed current needs to design and build the "ColonClean" mHealth app for the Android operating system. The purpose of this study is to validate the effectiveness of the ColonClean mHealth app in enhancing users' attitudes and behaviors toward BP through the Technology Acceptance Model (TAM) by examining the correlations among perceived usefulness, perceived ease of use, usage attitudes, and actual usage behaviors. We aim for the ColonClean mHealth app to serve as a comprehensive and effective outpatient colonoscopy guidance tool, ultimately improving the effectiveness of BP.

Methods

Ethical Considerations

This study is an interventional investigation conducted in accordance with research ethics regulations. Approval from the Institutional Review Board of Taipei Veterans General Hospital was obtained prior to the commencement of the study (approval number 2021-10-007AC). The study was conducted from October 27, 2021, to December 31, 2022. Before enrolling participants, the purpose and details of the study were explained to them, and they provided informed consent by signing a consent form. Throughout the research process, all participants' privacy rights were strictly protected, and the collected data were used solely for research purposes. Participants were not compensated for their participation in this study.

Study Participants

G*Power 3.1.9.7 for Windows was used to analyze the questionnaire data, considering a power (1-β) of 0.8, α value of .05, a medium effect size of 0.3, and an estimated dropout rate of 20%. As a result, a sample size of 40 participants was determined. A total of 40 outpatients from the gastroenterology and endoscopy center of the medical center were recruited. The inclusion criteria were patients aged 20 years or older, recommended by physicians to undergo colonoscopy, without visual or hearing impairments, and without mental illnesses. After explaining the purpose and content of the study and obtaining written informed consent, paper-based nursing instructions were provided along with verbal explanations of ColonClean, and the BP was conducted. For easy access to ColonClean, the participants downloaded the ColonClean mHealth app on their mobile devices after scanning a QR code. The nursing instruction process involved 1-on-1 teaching, with an explanation lasting approximately 20 minutes in the independent waiting area outside the outpatient visit room. Each research participant was asked to submit feedback on their experience with ColonClean within 3 days of their colonoscopy.

mHealth App (ColonClean)

Individuals aged ≥50 years are the target group for CRC screening, making them the primary users of the ColonClean mHealth app. Considering the physiological and cognitive decline in older adults, it is crucial to design a user-friendly interface to avoid difficulties in usage. The interface design for older adults incorporates intuitive elements, clear and concise text, and straightforward operational steps [23]. Contrast colors were used for interface color schemes. The operational methods are simple and clear, with functions executed through clicks or straight-line swiping gestures [24,25]. All features were designed to operate within a single page, avoiding menu structures with more than 2 layers of information. This design reduces the psychological pressure on older adults, who may be afraid of making mistakes due to an unfamiliarity with technology; this allows them to focus and read the important information comfortably. Handwritten or voice inputs were preferred for filling in the forms. Clear return or cancel buttons were placed at the top or bottom of the screen. Considering the characteristics of the users, the emphasis was on interaction and feedback rather than simple page browsing to enhance the impression of BP.

The ColonClean mHealth app was developed using the Android 11 operating system due to its low development cost and popularity among the general public [26]. The user interface and content were designed using the Android app package, the Java programming language, and a built-in database.

The screen display of ColonClean is divided into 3 sections: top, middle, and bottom in a single-page layout for the main screen. The top section displays the "Examination Date and Time." The middle section features 6 key topics arranged in a zigzag pattern based on their importance. From left to right, these topics include "Dietary Guidelines," explaining the necessary dietary education starting 3 days before the examination as shown in Figure 1, and "Laxative Use," explaining the use of bowel cleansing medication. The "Fluid Intake" screen is for recording the amount of fluid consumed (Figure 2), while the "Stool Image Recognition" screen is for providing images to identify the type of the last bowel movement (Figure 3).

XSL•FO
RenderX

Figure 1. Representative images of “Dietary Options” in ColonClean.

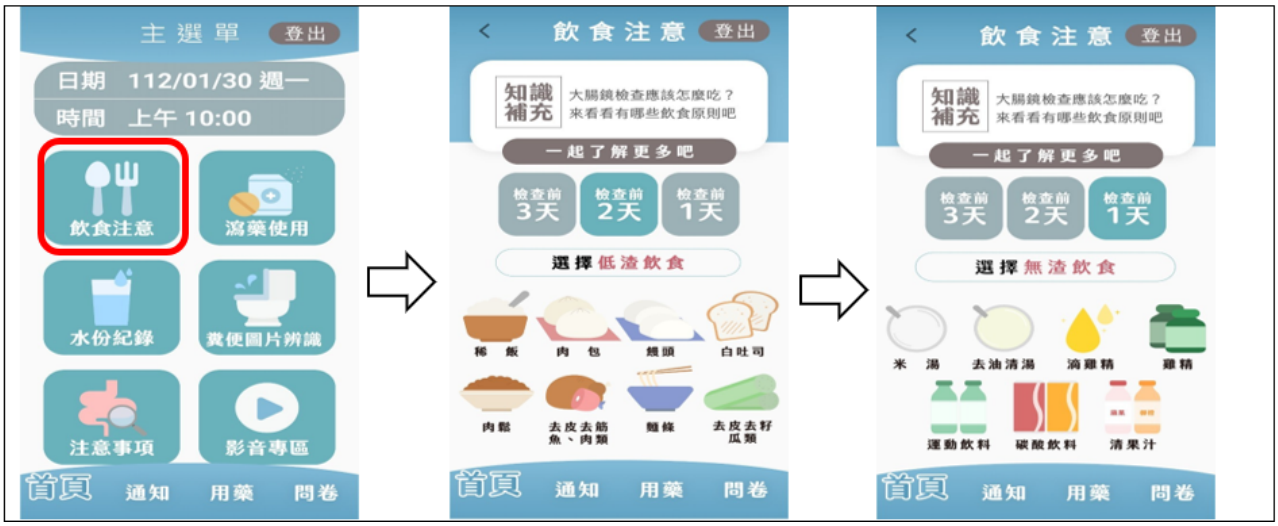

Figure 2. The “Hydration Intake Record” in ColonClean. Bowel preparation requires plenty of fluid intake to facilitate the passage of feces from the bowel.

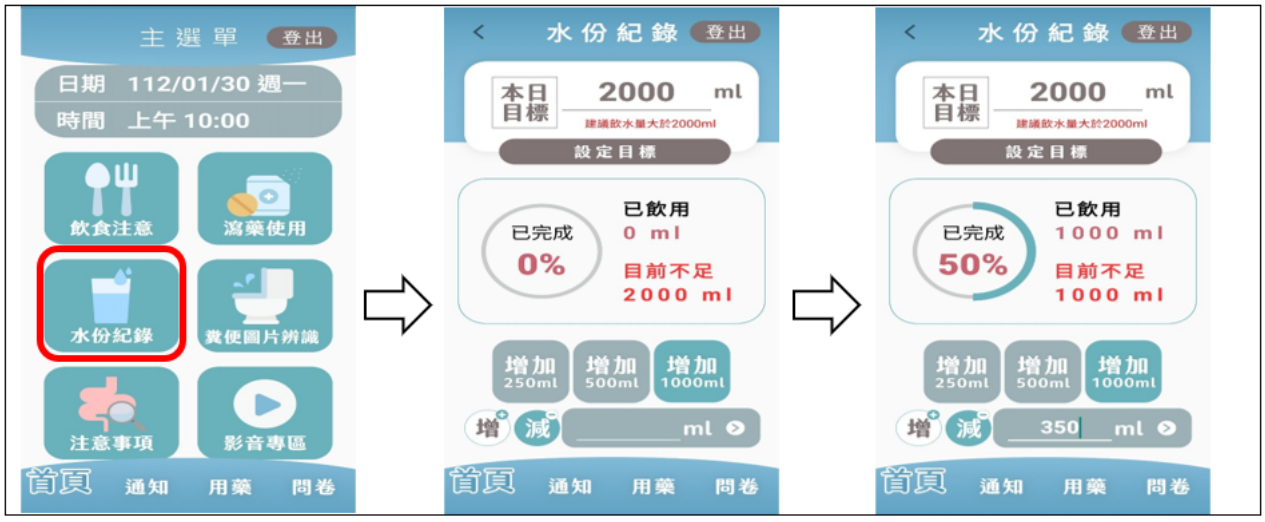

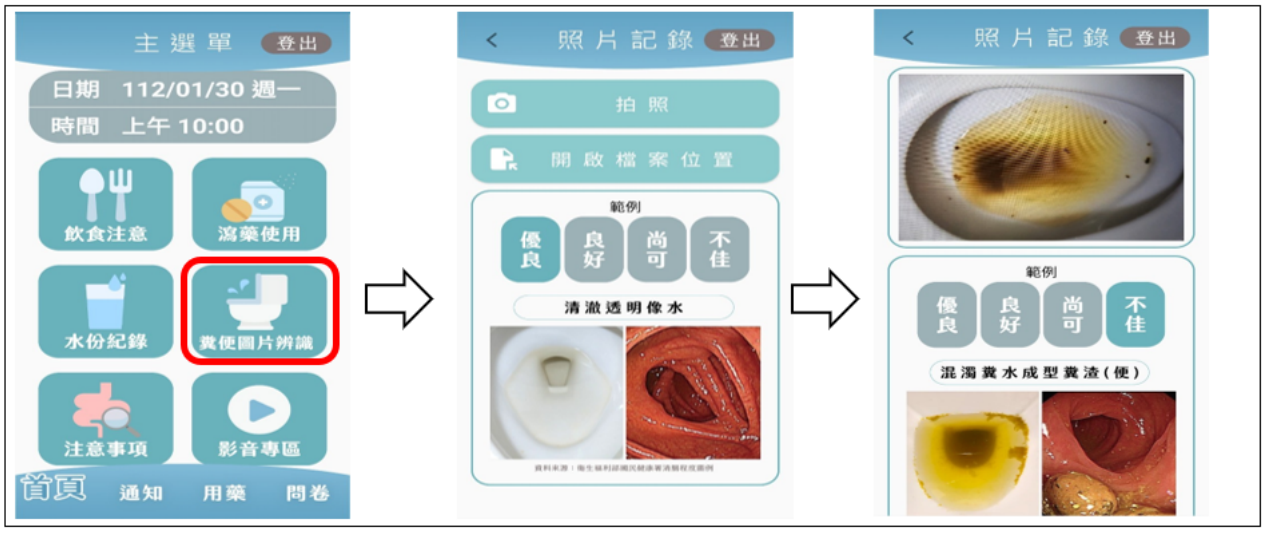

Figure 3. Images of the “Last Bowel Movement Type” section of ColonClean.

“Precautions” explains important points to keep in mind. The bottom section of the screen, from left to right, includes the “Home” button to return to the main screen; “Notifications,” which displays text messages; “Medication,” which provides

XSL•FO
RenderX

settings and modifications for regular medication or bowel cleansing agents; and "Questionnaire," which allows users to provide feedback on their experience using the ColonClean mHealth app.

The ColonClean app sent reminders and notifications to participants in the experimental group starting 3 days before their procedure. These notifications advised participants to begin dietary restrictions, such as avoiding high-fiber fruits and vegetables. Two days before the procedure, the app reminded users to switch to a low-residue diet, focusing on foods like congee or plain white noodles. The day before the procedure, the app prompted users to follow a clear liquid diet, including oil-free broth and sports drinks, and provided instructions on taking BP medications.

The app utilizes tap and swipe gestures for navigation; for user registration, it supports built-in Chinese phonetic input or handwriting recognition on mobile devices. The interface features a fresh color palette, primarily a warm lake green. Key information is highlighted in red, and unnecessary content is removed to offer concise summaries. Unique icons are designed as entry pointers to access relevant content. Tapping on an icon triggers entry into the main menu, which includes dietary guidance, instructions on using bowel cleansing agents (via images and videos), precautions for a colonoscopy, and fluid intake records, and provides references to the type of last bowel movement for understanding the differences compared to that during endoscopy. The design allows users to navigate intuitively, freely scrolling, tapping, and browsing related content between pages [27,28]. Push notifications are recommended to include instructions or prompts. Therefore, through push notifications, users are informed about relevant BP information to avoid any execution errors. Considering the user groups are middle-aged and older adults, complex actions are avoided. Instead, the key content is displayed directly in the push notification message. When a notification is received, users can click on the pushed message, which leads them to the relevant page with clear instructions or recommendations to view more detailed content. This approach reduces the chance of users misunderstanding the message. The user-centered push notification feature for BP steps enhances user engagement [29,30].

Aronchick Bowel Preparation Scale

After completing a colonoscopy, the physician submits a rating of the BP level using the Aronchick Bowel Preparation Scale (ABPS) in the endoscopy report system [1,31,32]. The ABPS is one of the most comprehensive and commonly used scales to describe the visualization of the colon and assess the percentage of stool covering the entire colon mucosa to explain the state of BP [33]. Based on this assessment, the adequacy of bowel cleansing is graded as excellent, good, fair, poor, or inadequate [11,33-35]. In Taiwan, domestic quality indicators for colonoscopy align with ABPS standards, targeting a 90% or above rating for both "excellent" and "good" categories. This ensures a high standard of care in colorectal screening, enhancing procedural accuracy and improving patient outcomes [36,37].

TAM

The TAM explains the behavior of users accepting new information technology in the field of computer technology [38]. Perceived usefulness and perceived ease of use affect users' attitudes toward adopting new technology, thereby influencing willingness and usage behavior. The perceived ease of use, perceived usefulness, attitudes, and behavior of outpatient endoscopy patients toward the ColonClean mHealth app were evaluated to assess their acceptance of using it. The questionnaire adopted a 5-point Likert scale. The 4 dimensions assessed by outpatient endoscopy patients after using ColonClean were perceived ease of use, perceived usefulness, attitudes, and usage behavior. The response options ranged from 1="strongly disagree," 2="disagree," 3="neutral," 4="agree," to 5="strongly agree." Higher scores indicated a higher level of agreement, while lower scores indicated a lower level of agreement. The questionnaire was initially developed based on literature references [39]. Three nursing informatics experts and scholars were then invited to evaluate the applicability and clarity of each question and to provide suggestions for improvement.

The Cronbach α coefficient was used to assess the internal consistency of the questionnaire items in this study. For the perceived usefulness dimension, consisting of 6 items, Cronbach α was 0.971. For the perceived ease of use dimension, consisting of 6 items, Cronbach α was 0.950. For the attitude dimension, consisting of 5 items, Cronbach α was 0.930. For the usage behavior dimension, consisting of 6 items, Cronbach α was 0.976. The questionnaire comprised a total of 23 items, and the Cronbach α coefficient for the scale was 0.986, indicating high internal consistency, meeting the requirement of a Cronbach α coefficient exceeding 0.7.

The structured questionnaire was designed and validated for reliability and validity by 3 nursing informatics experts. Participants accessed the questionnaire through a built-in link within the app, with the collected data stored in the backend management center for subsequent analysis.

Analysis

The data were analyzed using SPSS 25.0 (IBM Corp), with the utilization of the Pearson product-moment correlation and simple regression analysis to predict the perception of ColonClean.

Results

Demographic Characteristics

The demographic characteristics of the participants were as follows: 17 males (43%) and 23 females (58%); 27 participants aged ≥50 years (68%); and 35 participants with a high school/vocational education or above (88%).

ColonClean

After completing their colonoscopy, each research participant provided feedback on their experience with the ColonClean app within 3 days.. The feedback highlighted several key aspects of the app's design that contributed to user satisfaction and engagement:

XSL•FO
RenderX

- User-centered design: Participants appreciated the intuitive user interface, which maintained consistency in themes and main menu content. The clear and simple instructions, presented through a combination of text and visuals, facilitated user-friendly navigation. This consistency helped users feel more confident using the app.
- Examination date reminder: The feature displaying the examination date at the top of the main menu was well-received, as users felt it helped them stay organized and aware of the timing, potentially increasing compliance with preparation protocols.
- Graphic representations: Users found the unique graphic representations of dietary restrictions particularly helpful, as they enhanced understanding compared to traditional text descriptions. This visual approach was seen as effective in clarifying preexamination dietary options.
- Medication instructions: The clear, red-highlighted instructions for using bowel cleansing agents, along with drug images, dosage information, and timing, received positive feedback. Users appreciated the visual cues that simplified the medication process.
- Hydration tracking: Participants valued the hydration tracking feature, which encouraged them to monitor their water intake. Reminders to increase consumption when below recommended levels and positive feedback for meeting goals were highlighted as motivational elements that enhanced their commitment to the BP process.
- Bowel movement comparison: The option to take a photo of their last bowel movement and compare it with reference images was particularly beneficial. Users reported that this feature provided clarity on the required level of bowel cleanliness, enhancing their understanding of preparation requirements.
- Medication reminders and push notifications: The integration of medication reminders, particularly for chronic medications and anticoagulant discontinuation, was praised for preventing potential issues during the colonoscopy process. Users appreciated the timely push notifications that kept them informed about important tasks related to their preparation.

Overall, the research results indicated that users found the design of the ColonClean app effective in enhancing their understanding of and compliance with BP instructions. The app's focus on intuitive navigation, visual aids, and timely reminders contributed to a positive user experience, ultimately improving the effectiveness of BP for colonoscopy.

ABPS

After completing the colonoscopy, the BP level is reported by the endoscopist using the ABPS: 10 individuals (25%) achieved a "fair" level, 26 individuals (65%) achieved a "good" level, and 4 individuals (10%) achieved an "excellent" level. There were no cases of "poor" or insufficient preparation leading to interruption or inability to perform the examination.

TAM

Perceived Usefulness

The details of perceived usefulness are shown in Table 1.

Table . Perceived usefulness of the ColonClean app.

Perceived usefulness of the ColonClean app	Mean (SD)
Using ColonClean helps me quickly understand the tasks required for bowel preparation.	4.60 (0.59)
Using ColonClean provides easy access to relevant information about bowel preparation.	4.55 (0.68)
I believe that using ColonClean can improve the accuracy of my bowel preparation.	4.65 (0.53)
Using ColonClean enables me to effectively complete the required bowel preparation tasks.	4.65 (0.48)
ColonClean provides clear reminders about bowel preparation tasks, such as dietary restrictions and monitoring the type of my last bowel movement.	4.60 (0.59)
I find the educational information provided by ColonClean sufficient for completing my bowel preparation tasks.	4.65 (0.53)

The table presents users' perceptions of the usefulness of the ColonClean app in managing BP tasks. The mean scores, averaging around 4.62 of 5, suggest that users generally find the app very helpful. Below is an interpretation of the key findings:

- Understanding tasks (mean 4.60, SD 0.59): Users feel that the ColonClean app helps them quickly understand the requirements for BP, indicating clear and effective communication of instructions.
- Access to relevant information (mean 4.55, SD 0.68): The app is seen as a convenient tool for accessing important information about the preparation process. However, this metric has a slightly lower score, suggesting minor room for improvement in delivering information.
- Increased accuracy (mean 4.65, SD 0.53): Users believe that the app enhances the accuracy of their BP, reflecting a high level of trust in the app's guidance to meet medical standards.
- Effective completion of tasks (mean 4.65, SD 0.48): The app is viewed as highly effective in helping users complete BP tasks correctly, suggesting that it provides practical support throughout the process.

XSL•FO
RenderX

- Clear reminders (mean 4.60, SD 0.59): The app is viewed as highly effective in helping users complete BP tasks correctly, suggesting that it provides practical support throughout the process.
- Sufficient educational information (mean 4.65, SD 0.53): The app provides enough educational material for users to feel confident about completing their preparation, further supporting its educational role.

In summary, the ColonClean app was perceived as highly useful across various aspects of the BP process, with particularly strong scores for accuracy, task completion, and educational sufficiency. These results highlight the app's effectiveness in improving the user experience and promoting adherence to BP protocols.

Perceived Ease of Use

The details of perceived ease of use are shown in Table 2.

Table . Perceived ease of use of the ColonClean app.

Perceived ease of use of the ColonClean app	Mean (SD)
I think the interface design of ColonClean is clear and easy to understand.	4.63 (0.54)
I find the process of using ColonClean to be smooth.	4.63 (0.54)
It is easy to navigate and locate the desired functions in ColonClean.	4.63 (0.54)
I think the data presentation in ColonClean is quick and stable.	4.65 (0.58)
I find the font size in the ColonClean interface appropriate and easy to read.	4.53 (0.75)
The information provided by ColonClean makes it easier to understand the bowel preparation tasks.	4.68 (0.53)

Table 2 presents users' perceptions of the ease of use of the ColonClean app, highlighting their experiences with various interface features. The mean scores indicate a generally high level of satisfaction, with most ratings above 4.62 of 5, suggesting that users find the app intuitive and user-friendly. Below is an interpretation of the key findings:

- Clear interface (mean 4.63, SD 0.54): Users feel that the interface design is intuitive and user-friendly. This clarity in design is crucial for users' initial engagement with the app, suggesting that the developers prioritized usability.
- Smooth user experience (mean 4.63, SD 0.54): The app operates smoothly, without lag or issues, which is essential for encouraging continued use and satisfaction with digital health tools.
- Easy navigation (mean 4.63, SD 0.54): The ease of navigation suggests that users can quickly find the features they need, reducing frustration and enhancing overall satisfaction.
- Quick and stable data presentation (mean 4.65, SD 0.58): Users appreciate the app's rapid and reliable presentation of information. This reliability enhances user trust, which is particularly important in health care applications where accuracy is critical.
- Appropriate font size (mean 4.53, SD 0.75): Although the font size received a slightly lower rating, it still indicates that most users find it suitable. The slightly lower score suggests that some users might prefer larger text or different font styles, which could be an area for improvement.
- Enhanced understanding of BP (mean 4.68, SD 0.53): Users find that the information provided by ColonClean significantly aids their understanding of BP tasks, which is essential for ensuring compliance with medical procedures.

In summary, the high average scores across these metrics indicate that users generally find ColonClean to be an easy-to-use app that effectively supports BP. The highlighted areas demonstrate strengths in design, functionality, and educational support, with only minor adjustments needed in font size to further enhance the user experience. These findings suggest that ColonClean is a valuable tool for improving patient preparation and potentially contributing to better clinical outcomes.

Attitudes Toward Usage

The details of attitudes toward usage are shown in Table 3.

Table . Attitudes toward usage of the ColonClean app.

Attitudes toward usage of the ColonClean app	Mean (SD)
I believe ColonClean is an excellent choice for assisting with bowel preparation before an examination.	4.63 (0.54)
I am currently satisfied with the benefits provided by using ColonClean.	4.65 (0.53)
I would be willing to use ColonClean again in the future if I need to undergo bowel preparation.	4.63 (0.59)
I find the information provided by ColonClean to be very useful.	4.60 (0.59)
I prefer using ColonClean over paper-based nursing instructions (single sheets).	4.35 (0.77)

XSL•FO
RenderX

Table 3 summarizes users' attitudes toward the use of the ColonClean app, reflecting generally positive perceptions of its utility and effectiveness in assisting with BP tasks. The mean scores indicated a high level of satisfaction, with most ratings above 4.57 of 5, suggesting a strong endorsement of the app's features and benefits. Below is an interpretation of the key findings:

- Good choice for assistance (mean 4.63, SD 0.54): This high mean score reflects a strong consensus among users that ColonClean is an effective tool for supporting BP. The low SD suggests consistent agreement on its usefulness in this context.
- Satisfaction with benefits (mean 4.65, SD 0.53): Users' satisfaction indicates that the app meets their expectations and provides meaningful benefits during BP. The relatively low SD further shows that most users feel positively about the app's contributions.
- Willingness to use again (mean 4.63, SD 0.59): Users expressed a strong intention to use ColonClean for future BPs, suggesting that their initial positive experiences built trust in the app and that they see it as reliable.
- Usefulness of information (mean 4.60, SD 0.59): The perception that ColonClean provides highly useful information reinforces its role as a valuable educational resource, effectively aiding users in understanding the preparation process.
- Preference over paper instructions (mean 4.35, SD 0.77): Although users generally prefer ColonClean over traditional paper-based instructions, the slightly lower score and higher SD suggest that some users may still value printed materials or have mixed feelings about fully transitioning to digital formats. This variability presents an opportunity for further enhancements in the app's usability and content delivery.

In summary, the high mean scores (above 4.57) suggested that users had a positive attitude toward ColonClean, seeing it as an effective and beneficial tool for BP. The consistent responses (low SDs) indicated broad agreement among users on its usefulness. Meanwhile, the variation in preference over paper instructions may highlight areas for potential improvement. This feedback can guide future updates and enhancements to maximize user satisfaction and efficacy.

Usage Behavior

The details of usage behavior are shown in Table 4.

Table . Usage behavior of the ColonClean app.

Usage behavior of the ColonClean app	Mean (SD)
I am willing to use ColonClean as an aid for bowel preparation.	4.73 (0.45)
I am highly satisfied with the ability to access knowledge through ColonClean during bowel preparation.	4.70 (0.52)
I would recommend ColonClean to friends and family in the future.	4.63 (0.63)
I would use ColonClean to improve the effectiveness of bowel preparation.	4.70 (0.52)
I believe ColonClean provides useful information during the bowel preparation period.	4.68 (0.53)
Overall, I find using ColonClean to be satisfactory.	4.73 (0.51)

Table 4 summarizes the usage behavior of the ColonClean app and reveals overwhelmingly positive user sentiment. The overall mean score of 4.69 indicates high satisfaction with the experience of using ColonClean. This average score, combined with a relatively low SD (0.50), suggests a strong consensus among users regarding the app's effectiveness and utility. Below is an analysis of the meaning behind the scores:

- Willingness to use (mean 4.73, SD 0.45): The high mean score indicates that users are very inclined to use ColonClean as a supportive tool for BP. The low SD signifies that this sentiment is widely shared, suggesting strong confidence in the app's benefits.
- Satisfaction with knowledge access (mean 4.70, SD 0.52): Users expressed a high level of satisfaction with the knowledge accessible through the app during BP. This indicates that ColonClean effectively meets their informational needs, enhancing their preparation experience.
- Recommendation to others (mean 4.63, SD 0.63): The willingness to recommend ColonClean to friends and family reflects users' trust in the app's efficacy. Although this score remained positive, the slightly higher SD suggests some variability in users' willingness to recommend it, possibly due to differing experiences or expectations.
- Improvement of effectiveness (mean 4.70, SD 0.52): Users believed that ColonClean enhanced the effectiveness of their BP, reinforcing the app's perceived value as a helpful resource in the preparation process.
- Useful information obtained (mean 4.68, SD 0.53): The belief that the app provides useful information further underscores its utility as an educational tool. Users recognized that the app offers relevant guidance throughout the preparation period.
- Overall satisfaction (mean 4.73, SD 0.51): The high overall satisfaction score indicates that users felt positively about their experience with ColonClean. The consistency of this sentiment, reflected by the low SD, suggests that many users share a similar level of satisfaction.

In summary, the high mean scores across all categories reflect users' positive attitudes and satisfaction, underscoring ColonClean as a valuable tool for assisting with BP. The low SDs across most items indicate consistency in user experiences, suggesting that ColonClean effectively meets users' needs and

XSL•FO
RenderX

expectations. This feedback is critical for developers, as it reinforces the app's strengths and highlights areas where further enhancements could be beneficial.

Analysis

Pearson Correlation Coefficients

Pearson correlation coefficients were used to analyze the relationships among users' attitudes, perceived usefulness, perceived ease of use, and usage behavior of the ColonClean mHealth app (Table 5). The results indicated a significant positive correlation between users' attitudes and perceived usefulness (r_{38}=.907, P<.001), users' attitudes and perceived ease of use (r_{38}=.825, P<.001), users' attitudes and usage behavior (r_{38}=.835, P<.001), perceived usefulness and perceived ease of use (r_{38}=.894, P<.001), perceived usefulness and usage behavior (r_{38}=.933, P<.001), and perceived ease of use and usage behavior (r_{38}=.958, P<.001). Positive correlations were demonstrated between perceived usefulness and perceived ease of use, usage attitude, and usage behavior.

Table . Correlations among perceived usefulness, perceived ease of use, usage attitude, and usage behavior.

		Perceived usefulness	Perceived ease of use	Usage attitude	Usage behavior
Perceived usefulness					
	Pearson correlation analysis	1			
	Significance level (2-tailed)				
	Number	40			
Perceived ease of use					
	Pearson correlation analysis	0.894	1		
	Significance level (2-tailed)	<.001			
	Number	40	40		
Usage attitude					
	Pearson correlation analysis	0.907	0.825	1	
	Significance level (2-tailed)	<.001	<.001		
	Number	40	40	40	
Usage behavior					
	Pearson correlation analysis	0.933	0.958	0.835	1
	Significance level (2-tailed)	<.001	<.001	<.001	
	Number	40	40	40	40

Simple Regression Analysis

We used simple regression analysis to predict the correlation among the perceived usefulness, perceived ease of use, usage attitude, and usage behavior in the context of ColonClean. The correlation between perceived usefulness and usage attitude, with usage attitude as the criterion variable and perceived usefulness as the predictor variable, yielded B=0.907, t_{38}=13.3. This model explained 82.3% of the variance in usage attitude (R^2=0.823), and the test result with P<.001 indicated that perceived usefulness was a significant predictor variable for usage attitude. This suggests that when users perceive the app as providing substantial assistance, their attitude toward using it improves significantly. This highlights the importance of enhancing the app's practical functionality to foster a positive user experience. Similarly, the correlation between perceived usefulness and usage behavior, with usage behavior as the criterion variable and perceived usefulness as the predictor variable, resulted in B=0.933, t_{38}=16.0. This model explained 87.1% of the usage behavior (R^2=0.871), and the test result with P<.001 demonstrated that perceived usefulness significantly predicted usage behavior. When users believe that the app helps improve their preparation process, they are more likely to engage actively with it. The correlation between perceived ease of use and usage attitude, with usage attitude as the criterion variable and perceived ease of use as the predictor variable, resulted in B=0.825, t_{38}=9.0. This explained 68% of the variance in attitude toward use (R^2=0.68), with P<.001, indicating perceived ease of use as a significant predictor of attitude toward use. When users find the app easy to use, their attitude becomes more positive. This reflects their comfort and satisfaction during use, which in turn influences their willingness to engage with the

XSL•FO
RenderX

app. When determining the correlation between perceived ease of use and usage behavior, with usage behavior as the criterion variable and perceived ease of use as the predictor variable, the result was B=.958, t_{38}=20.5. This model explained 91.7% of the variance in usage behavior (R^2=.917), with P<.001, indicating that perceived ease of use significantly predicted usage behavior. When users perceive the app as easy to operate, they are more likely to engage actively. This underscores the importance of simplifying the app's interface and functionality to enhance user engagement and satisfaction.

In summary, the results indicate that both perceived usefulness and perceived ease of use have a significant positive impact on user attitudes and behaviors. This suggests that enhancing the perceived usefulness and ease of use of the ColonClean app during its design may encourage more positive user attitudes and behaviors, thereby improving health management outcomes. These findings not only validate the app's usability but also provide empirical support for future improvements.

Discussion

Principal Findings

Mobile health apps are increasingly used for illness prevention, education, and promoting healthy lifestyles [40]. However, the requirements for BP are often complex and challenging for patients to navigate and remember. To help outpatient colonoscopy patients adhere to dietary guidelines, manage bowel cleansing agents, and maintain regular medication schedules, push notifications were incorporated into the app's design. The app, protected under the patent titled "ColonClean Mobile Management System" (patent number M639094, Republic of China), features a user-centric interface that is both intuitive and visually appealing. The well-designed interface, content, push notifications, and multimedia section of the ColonClean mHealth app provide users with a convenient and helpful experience when using their mobile devices for health management. Users expressed their willingness to use the app again in the future and recommend it to family and friends, highlighting its effectiveness as an educational guide for BP.

User Attitudes and Preference for Paper-Based Instructions

Despite the overall positive reception of the ColonClean app, some users indicated a preference for paper-based instructions, as reflected in the lower mean score (mean 4.350.77) on this aspect. This finding aligns with existing literature suggesting that certain users may find physical formats more reliable or easier to reference than digital alternatives [41]. Factors contributing to this preference may include concerns about technology accessibility, device compatibility, or personal comfort with digital apps for health management.

Additionally, the preference for paper-based instructions may arise from a desire for tangible resources that can be easily annotated or highlighted [42]. Some users may feel that printed materials provide a more straightforward and immediate reference during the preparation process, particularly in situations where mobile devices are not accessible or convenient [43]. Therefore, while the digital format of the ColonClean app offers numerous advantages, such as interactivity and real-time updates, it is essential to recognize the value that traditional paper-based resources continue to hold for certain individuals.

Limitations and Recommendations

The ColonClean app operates on the Android system and functions as an mHealth app for mobile devices. However, it is important to note that during the acceptance process, instances may arise where individuals with non-Android operating systems or outdated device models are unable to be included in this study. Those unable to download ColonClean by scanning the QR code were excluded. It is advisable to consider optimizing future mHealth apps so that they can be integrated into mobile devices of various operating systems. This enhancement would contribute to more inclusive nursing guidance for BP, ensuring accessibility across platforms.

In the current era of smart health care, it is recommended to incorporate artificial intelligence recognition capabilities into the ColonClean app. Specifically, for the section where users capture images of their last bowel movement, artificial intelligence can automatically analyze and determine the quality of the stool, categorizing it as "excellent," "good," "fair," or "poor." This improvement would facilitate a more accurate assessment of the final bowel movement status. Furthermore, optimizing the ColonClean mHealth app for other individuals who require BP, such as those undergoing colorectal surgery or hospitalized patients preparing for colonoscopy, would ensure the successful completion of bowel cleansing.

Additionally, in light of the COVID-19 pandemic, when individuals undergoing screening needed to reschedule their appointments due to a positive diagnosis or being a close contact, or when they encountered issues like poor bowel movements, a consultation chat window was recommended as a future addition to address user inquiries and provide real-time solutions, thus maintaining user engagement and satisfaction. To ensure the continuity of examinations and achieve the objectives of examination, diagnosis, and treatment, it is crucial to minimize ineffective examinations or schedule cancellations that may impact individuals in need of these examinations. This approach aims to maintain a steady number of examinations and fulfill the purpose of providing necessary medical assessments and subsequent care.

Conclusions

In summary, while the ColonClean app shows promise in supporting BP, it is essential to recognize user attitudes toward traditional paper-based instructions. Enhancing the app with broader accessibility, artificial intelligence capabilities, and additional user support features could significantly improve its effectiveness and reach, ultimately contributing to better health outcomes for patients requiring BP.

Abstract

Background: Repeated applications of short-term dietary assessment instruments are recommended for estimating usual dietary intake. For this purpose, NutriDiary, a smartphone app for collecting weighed dietary records (WDRs) in the German population, was developed.

Objective: We aim to describe NutriDiary and evaluate its usability and acceptability.

Methods: NutriDiary was developed as a WDR, allowing users to enter food items via text search, barcode scanning, or free text entry. The sample for the evaluation study included 74 participants (n=51, 69% female, aged 18 - 64 years), including 27 (37.5%) experts and 47 (63.5%) laypersons (including n=22, 30%, nutrition students). Participants completed a 1-day WDR and entered a predefined sample meal (n=17 foods) the following day by using NutriDiary. An evaluation questionnaire was answered from which the system usability scale (SUS) score (0 - 100) was calculated. A backward selection procedure (PROC REG in SAS; SAS Institute) was used to identify potential predictors for the SUS score (age, sex, status [expert or laypersons], and operating system [iOS or Android]).

Results: The median SUS score of 75 (IQR 63 - 88) indicated good usability. Age was the only characteristic identified as a potential predictor for a lower SUS score (P<.001). The median completion time for an individual WDR was 35 (IQR 19 - 52) minutes. Older participants took longer to enter the data than younger ones (18 - 30 y: median 1.5, IQR 1.1 - 2.0 min/item vs 45 - 64 y: median 1.8, IQR 1.3 - 2.3 min/item). Most participants expressed a preference for NutriDiary over the traditional paper-based method.

Conclusions: Good usability and acceptability make NutriDiary promising for use in epidemiological studies.

dietary assessment; food record; barcode scanning; app; mobile phone

Introduction

Usual dietary intake, the long-term average daily intake of a nutrient or food**,** is the relevant exposure when studying diet-health relationships in nutritional epidemiology. To estimate usual dietary intake, repeated applications of short-term dietary assessment instruments are recommended [1]. Self-reported dietary intake is the most commonly used method in large-scale studies through its rapid and cost-effective use. Mostly, instruments such as 24-hour dietary recalls, food frequency questionnaires or dietary records (DRs) are used, with each of these methods having individual limitations and strengths [2]. Repeated use of these traditional dietary assessment instruments is costly and burdensome for both participants and researchers [3,4]. Innovative technologies such as web- or smartphone-based tools have the potential to facilitate self-reported dietary assessment by reducing the costs and time effort of data collection and postprocessing while achieving higher acceptance in study participants [5-7]. Smartphone technology seems particularly promising among those innovative approaches. First, smartphones are widely available to a large proportion of the population. According to a survey conducted in 2021, over 95% of people aged older than 13 years in Germany already use a smartphone [8]. Second, due to the advantage of portability and the fact that most people always carry their smartphone with them, smartphone-based tools are well suited for real-time recording of food intake [1]. Third, smartphone apps can facilitate food entry through the supplementary use of an

XSL•FO
RenderX

integrated barcode scanner or by using the camera function, which reduces the need to look up every food item in a database or enter it manually [9]. Nowadays, a large number of commercial nutrition apps for self-tracking or nutritional advice are freely available [10,11]. However, because of their limited scope and questionable quality of nutrient information, those apps tend to be unsuitable for dietary assessment in epidemiological studies [12,13]. Thus, several DR apps have been developed specifically for use in epidemiological studies. In a systematic review by König et al [14], 5 core assessment features to collect data on dietary intake in scientific studies by smartphone apps were identified: photo-based assessment, assessment of serving or portion sizes, free-text description of food intake, selection from a food database, and classification systems. These features are used either alone or in combination. Thereby, the combination of photo-based recording with free-text descriptions of the consumed foods or the joint use of a food database and the assessment of serving or portion sizes were the most popular methods [14].

To provide a digital alternative for paper-based dietary assessment in epidemiological studies, we developed NutriDiary, an app for conducting weighed dietary records (WDRs) with an integrated barcode scanner. This paper aims to describe the current version of NutriDiary and to report on its usability and acceptability in laypersons and experts.

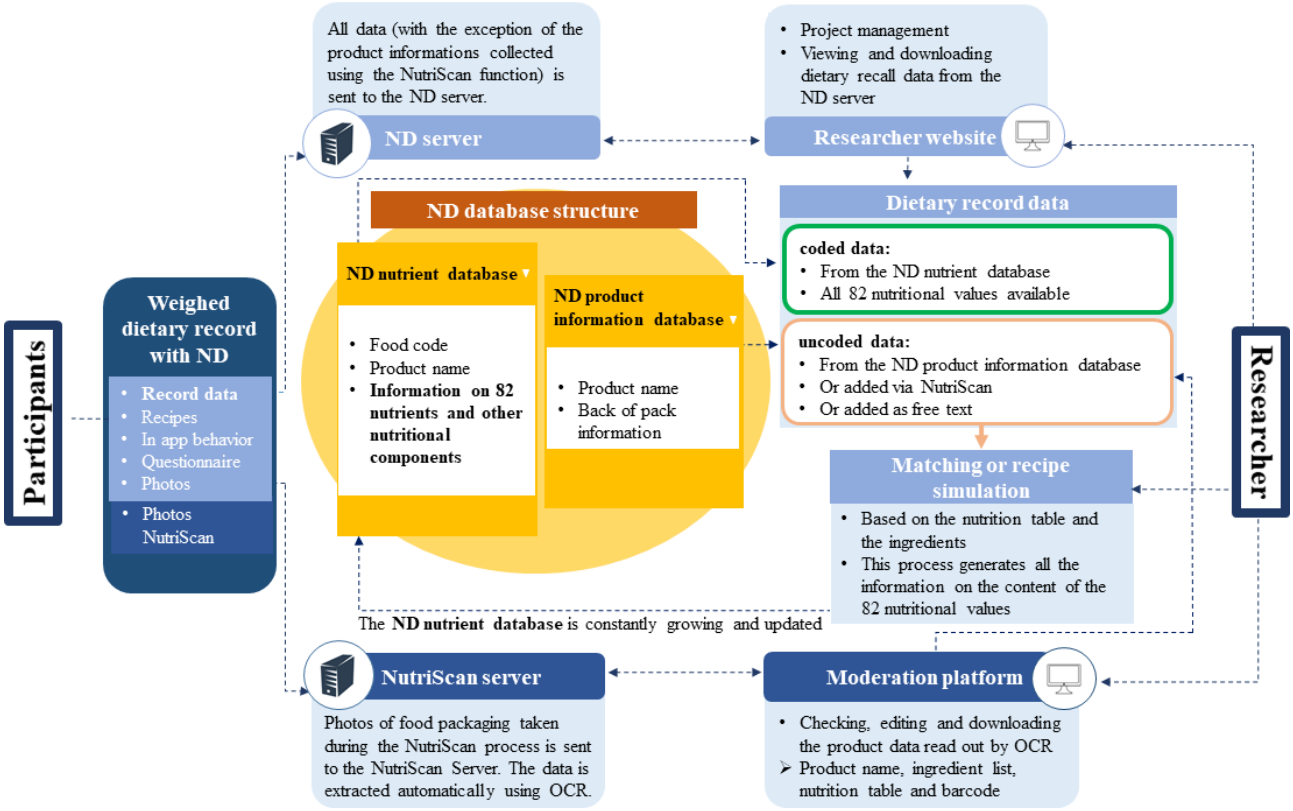
Methods

NutriDiary and the NutriDiary Database

Development and Functions of NutriDiary

NutriDiary was developed as a smartphone app to conduct WDRs within nutritional epidemiological studies. The app is available in common app stores and study participants (hereafter referred to as users) can use the app on their smartphones with personal login data (Figure 1A). Users can start their WDR after agreeing to the data protection regulations (Figure 1B). When entering a new eating occasion, users are initially asked to enter the date, time, and place of consumption (Figure 1C). Then, the app offers three ways to enter food, beverages, and supplements: (1) a text search and subsequent selection from the underlying database, (2) barcode scanning in the underlying database, or (3) free text entry.

Figure 1. The NutriDiary app (android version): (A) screen for entering access data, (B) welcome screen, and (C) food entry.



If a food item cannot be identified via barcode scanning, the user is guided through a standardized process for collecting all relevant product information (hereinafter referred to as the NutriScan process). Thereby, the user is asked to take photos of the brand and product name, the barcode, the ingredient list and the nutrient table following step-by-step instructions (Multimedia Appendix 1). This data is then sent to the NutriScan server and automatically read out using optical character reading. Researchers can access, edit, and download this data via a moderation platform. Based on the packaging information, dieticians can match detailed nutrient data from a similar product in the database or estimate detailed nutrient values by recipe simulation in order to continuously update and expand the underlying database (Figure 2). The recipe simulation is carried out manually using the list of ingredients and the nutritional table and is described in detail elsewhere [15]. Finally, users enter the weighed amount consumed, preparation method, and quantity of potential leftovers (Figure 1C). If weighing is not possible, users are provided with a range of specified options in the drop-down menu to select an estimated portion size, such

XSL•FO
RenderX

as teaspoon or slice. After all foods and beverages have been entered, users are redirected to the main screen, where all entered eating occasions are displayed for final review. To further ease the process of recording, NutriDiary offers some usability features. A recipe editor allows entry of custom recipes, which will be added to the user's personal databases. An integrated help mode provides immediate and problem-specific assistance to users by simply touching the screen element they need help with. In addition, the app includes a photo function for collecting information, for example, on meals consumed out-of-home and entered via free text. After finishing the WDR, data are submitted to a server of the University of Bonn (NutriDiary server, Figure 2). This server also provides an administration tool to researchers (researcher website) where scientific personnel can select project-specific settings, for example, study name, study duration or the number of recording days. The app also offers the option to integrate an individual questionnaire at the end of the recording period.

Figure 2. Overview of the data structure and data flow of the NutriDiary app; ND: NutriDiary; OCR: optical character reading.

Description of the NutriDiary Database

The complex database structure of NutriDiary is shown in Figure 2. It currently contains more than 150,000 items (approximately 25% are duplicates due to different packaging sizes and different barcodes) which come from various sources. The core database is divided into the NutriDiary nutrient database and the NutriDiary product information database. The basis of the NutriDiary nutrient database is an adaptation of the in-house food and nutrient database of the DONALD (Dortmund Nutritional and Anthropometric Longitudinally Designed) study named LEBTAB (LEBensmittelTABelle, food table) [15-17]. LEBTAB currently contains around 19,000 generic and branded food items (as of June 2023) with corresponding contents of energy, 82 nutrients, and other nutritional components. Data entries for generic foods are based predominantly on the German national standard food database "Bundeslebensmittelschlüssel" (version 3.02 [18]; Federal Ministry of Food and Agriculture). The energy and nutrient contents of branded foods are predominantly estimated by recipe simulation using labeled ingredients and declared nutrient contents [15,17]. When the participant enters a food item from the NutriDiary nutrient database, this item is automatically coded and the corresponding values for energy and 82 nutrients are available. To enhance user-friendliness and allow barcode scanning, additional branded food products and barcode information were added to the NutriDiary database structure by:

- requesting product information (product name, barcode, ingredient list, and nutrition table) from food manufacturers and others (Atrify [19], a subsidiary of GS1 Germany [1WorldSync] and DATA NatuRe eG [20], a cooperative to create a central data pool for organically produced foods) to set up the NutriDiary product information database, and
- adding barcode information of already included branded products to the NutriDiary nutrient database by searching in open databases such as Open Food Facts [21], codecheck [22] (Producto Check GmbH), and Open EAN/GTIN Database (European Article Number [EAN]/Global Trade Item Number [GTIN]) [23].

For the branded products obtained through step 1 (NutriDiary product information database), information only on the nutritional values indicated on the packaging (big 7) and the ingredient list are available (Figure 2). When a participant reports one of these products in a WDR, the trained dieticians

XSL•FO
RenderX

match extended nutrient values of an equivalent food from the NutriDiary nutrient database or carry out a recipe simulation as already mentioned above [15]. This step generates all 82 nutrients for these products and they are then transferred to the NutriDiary nutrient database, which is constantly growing.

The NutriDiary Evaluation Study

Study Design

A layperson and expert evaluation was conducted. Participants were asked to keep an individual WDR with NutriDiary for 1 day and to enter a predefined sample meal on the following day. The sample meal was identical for all participants and included 4 meals (breakfast, snack, lunch, and dinner) and was provided as a digital presentation sent to study participants via email. The sample meal comprised both, generic (n=15, presented as text) and branded food items (n=3, presented as pictures of the packaging including barcode), all labeled with a hypothetical quantity of consumption, preparation method, and type of entry (text entry vs barcode scanning). Participants were generally instructed to enter branded products via scanning the barcode. Further, 1 product was intentionally not available in both NutriDiary databases, requiring participants to complete the NutriScan process in order to add the food item to the record. Furthermore, participants were tasked to correct a logged entry and to enter a hypothetical leftover without further instructions but with reference to the NutriDiary website [24] to test whether the aids provided there (frequently asked questions and help videos) fulfill their purpose (ie, helping users to help themselves). After participants completed their WDR and entered the sample meal, they were asked to answer an app-integrated evaluation questionnaire on usability and acceptability of NutriDiary on day 3. As the WDRs were not analyzed at the nutrient level, no scales were handed out for weighing the food on day 1. The participants were asked to use scales from their households.

All participants were provided with a short video giving key instructions on how to use NutriDiary before starting the WDR. The video gave a brief overview of how to use the help mode, enter foods (via text search, barcode scanning, or free text entry) and navigate the recipe book. Furthermore, participants were informed about the NutriDiary website [24], where frequently asked questions and help videos for both, iOS and Android can be found. Beyond this, participants did not undergo any additional training in using the app.

Recruitment of This Study's Population

We aimed to recruit a minimum of 51 participants, based on the assumptions outlined by Lewis and Sauro [25]. This recommendation takes into account an SD of 17.7, which is typical for system usability scale (SUS) scores [25], and ensures sufficient precision to achieve a 95% CI with a margin of error of ±5 points. This study recruited both laypersons and experts. Experts (trained nutritionists with experience in the field of dietary assessment) were recruited via direct invitations (n=28). Laypersons (n=52) were recruited via oral advertisement in lectures, mailing, and personal contact by students studying nutrition and food science at the University of Bonn, and as part of a student project. The latter mainly targeted participants between 30 and 60 years of age (in the personal environment of the students and in 2 gyms) in order to increase the number of participants in middle age and older in the group of laypersons. All participants had to be fluent in the German language, have a functioning smartphone and a valid email address. Written informed consent from all participants was obtained before enrollment.

Usability and Acceptability Assessment

The questionnaire on usability and acceptability included 14 questions on 3 different categories (usability, acceptance, and technical issues). The usability of NutriDiary was assessed by using the SUS by Brooke [26,27], which allows for comparison between similar systems or products. In short, the SUS is a Likert scale consisting of 5 positive statements (odd-numbered) and 5 negative statements (even-numbered) to which respondents indicate their degree of agreement on a scale from 1 (strong disagreement) to 5 (strong agreement). For odd items, 1 is subtracted from the user response, and for even-numbered items, 5 is subtracted from the user response, added up and multiplied by 2.5 to convert the score ranging from 0 to 100, whereas higher scores indicate better usability. According to Bangor et al [28], an SUS score below 50 is considered as "not acceptable," a score between 50 - 70 years as "marginal," and a score above 70 as "acceptable" [28,29]. In our study, an appropriate German translation of the SUS developed by SAP usability professionals of a German software corporation (SAP SE; Systems, Applications & Products in Data Processing Societas Europaea) was used and integrated into the usability questionnaire [30].

Age and sex of the participants were assessed within the evaluation questionnaire. Status (expert or layperson) was already categorized during the recruitment process. Information on the operating system was automatically recorded when NutriDiary was used and sent to the server together with the questionnaire data. To find out whether participants would prefer the app to a traditional paper-based WDR, 2 additional questions in the same structure of the SUS were added. In order to assess technical problems participants were asked whether technical errors occurred (yes or no) and, if yes, to describe the error in more detail (free text entry).

Furthermore, in-app behavior of users was recorded and evaluated. The completion time for a WDR with NutriDiary was determined by using the activity protocol of the app, in which all actions were recorded and time-stamped. For this, the time of all input activities was summed up. Interruptions of more than 5 minutes were counted as breaks and excluded from summation. As the time effort of a WDR depends on the complexity of the meals and the number of foods eaten, the relative completion time (completion time divided by the number of items) was additionally calculated. Furthermore, the percentage of estimated household measurements was of interest as well as the percentage of automatically coded WDR entries.

Statistical Analyses

Results and participants' characteristics are presented as median with their lower IQRs for continuous variables or as relative frequencies (%) for categorical variables. A backward selection

XSL•FO
RenderX

procedure (PROC REG in SAS) was used to identify characteristics of participants that were potential predictors for the SUS score. The following variables were tested: sex (male or female), age (years), status (expert or layperson), and operating system (iOS or Android). All statistical analyses were conducted using SAS (version 9.4). The significance level was set at $P<.05$.

Ethical Considerations

All examinations were carried out with written informed consent from study participants. The NutriDiary evaluation study was approved by the Ethics Committee of the University of Bonn (project identification 445/23). All data collected in this study has been pseudonymized to protect participant privacy. No reimbursement was provided to participants for their involvement in this study.

Results

From overall 80 study participants, 74 (27 experts) completed the NutriDiary evaluation study according to this study protocol and answered the evaluation questionnaire (Table 1). Most participants were female (51/74, 69%) and younger than 30 years of age (41/74, 55%).

The overall age ranged from 18 to 64 years and the median age was 29 years (IQR 25 - 45). Overall, 54% (40/74) of the participants owned a smartphone with an iOS operating system. Table 2 shows the SUS score for NutriDiary for the total study sample and stratified by sex, age groups, status, and operating system. In the overall study sample, the SUS score for NutriDiary ranged from 43 to 100 (data not shown). The median SUS score of 75 (IQR 63 - 88) indicates a good usability of NutriDiary. The mean SUS score was 74 (SD 15; 95% CI 70-77; data not shown). The median SUS score was higher in women than in men (80, IQR 65 - 88, vs 70, IQR 55 - 78) and higher in the group of experts than in the group of laypersons (80, IQR 65 - 88 vs 73, IQR 58 - 88), with female laypersons having a higher SUS score than female experts (83, IQR 66 - 88 vs 80, IQR 60 - 85). Looking at the group of laypersons after excluding nutrition students (labeled in Tables 1 and 2 as “others,” median age 55, IQR 29 - 58, years), the median SUS score was 63 (IQR 50 - 73).

Table . Characteristics of study participants of the NutriDiary evaluation study (N=74).

	Total	Experts	Laypersons		
			Total	Nutrition students	Others
Participants, n (%)	74 (100)	27 (36.5)	47 (63.5)	22 (47)	25 (53)

Table . System usability scale (SUS) score for the NutriDiary app presented as median (IQR) values.

	Total		Women		Men	
	n	Median (IQR)	n	Median (IQR)	n	Median (IQR)
SUS score	74	75 (63 - 88)	51	80 (65 - 88)	23	70 (55 - 78)
Stratified by age group						
Age group 1: 18 -≤30 years	41	80 (70 - 88)	31	83 (70 - 88)	10	71 (63 - 85)
Age group 2: >30 -≤45 years	15	80 (68 - 90)	11	85 (65 - 93)	4	74 (70 - 78)
Age group 3: >45 - 65 years	18	58 (50 - 70)	9	58 (48 - 65)	9	65 (50 - 70)
Stratified by status						
Experts	27	80 (65 - 88)	23	80 (60 - 85)	4	83 (70 - 90)
Laypersons (total)	47	73 (58 - 88)	28	83 (66 - 88)	19	70 (55 - 73)
Nutrition students	22	85 (75 - 88)	19	88 (78 - 90)	3	73 (70 - 85)
Others	25	63 (50 - 73)	9	55 (48 - 65)	16	66 (53 - 73)
Stratified by operating system						
iOS	40	78 (65 - 88)	26	80 (68 - 90)	14	66 (55 - 73)
Android	34	74 (58 - 85)	25	75 (58 - 85)	9	73 (70 - 85)

Among the age groups 1 (18-≤30 y) and 2 (>30-≤45 y), the median SUS score was noticeably higher (80, IQR 70 - 88 and 80, IQR 68 - 90) than in age group 3 (58, IQR 50 - 70). The results of the backward selection procedure showed that age was the only characteristic identified as a potential predictor for the SUS score in the examined sample (P<.001).

Figure 3 shows the individual statements of the SUS questionnaire and a summary of the answers given by the 74 participants, presented as box plots. The figure shows that agreement tends to be high for the positive (odd-numbered) statements and tends to be low for the negative (even-numbered) statements, as is a prerequisite for a higher SUS score. Among the positive statements, the participants showed the lowest level of agreement with statement 1 “I think that I would like to use NutriDiary frequently.” For the negative statements, agreement was highest for statement 8 “I found NutriDiary very cumbersome to use.”

Figure 3. User rating (N=74) of the individual statements of the SUS evaluating the usability and acceptability of NutriDiary, shown as box plots. The dot represents the mean and the thick stripe the median. SUS: system usability scale.

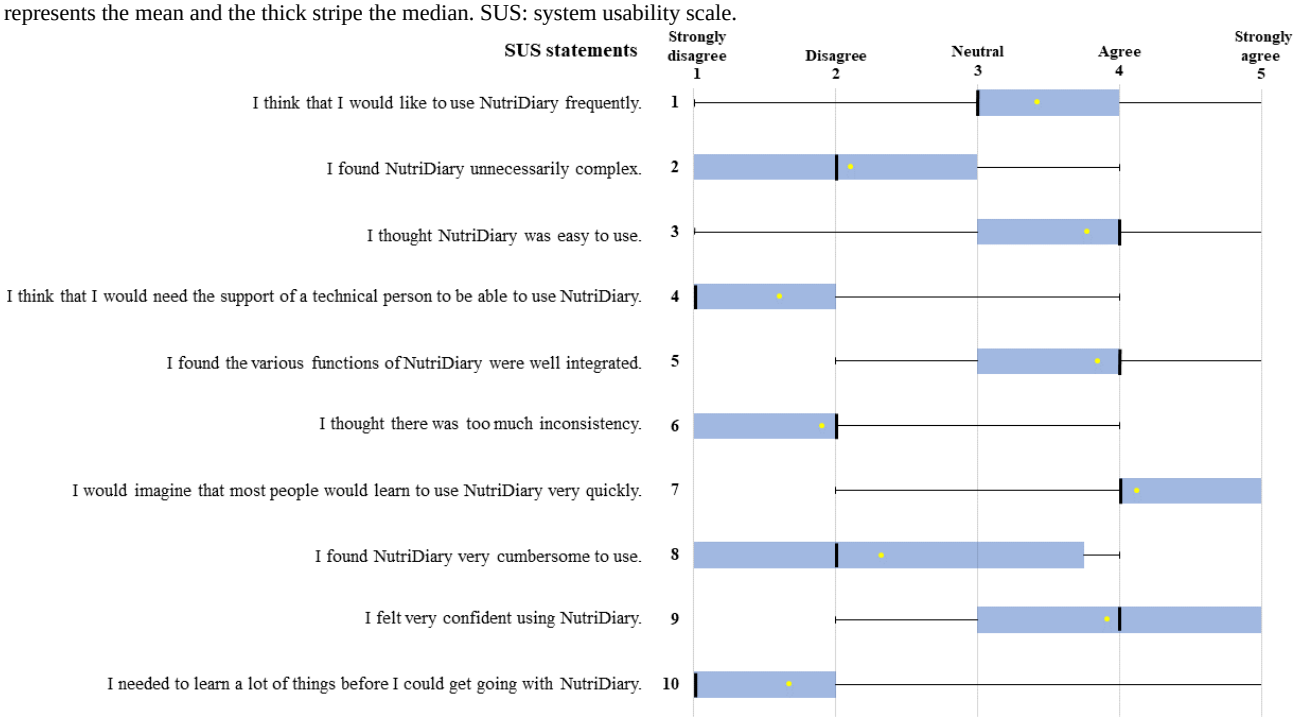

Table 3 shows the results of the evaluated in-app behavior logs and WDRs. The calculated median completion time for an individual WDR (day 1) with NutriDiary was 35 (IQR 19 - 52) minutes. Participants needed a median of 1.6 (IQR 1.2 - 2)

XSL•FO
RenderX

minutes to enter an item. This relative completion time was slightly higher in age group 3 (>45 - 63 y) compared to younger participants (1.8, IQR 1.3 - 2.3, min/item vs 1.5, IQR 1.1 - 2, min/item). The median time it took participants to enter the sample meal in NutriDiary on day 2 was 15 (IQR 12 - 18) minutes. The median relative completion time for entering the sample meal was 0.8 (IQR 0.7 - 0.9) min/item. Participants in age group 3 took slightly longer than younger participants. The median proportion of already coded items was 68% (IQR 55% - 82%) and the median proportion of estimated quantities (not weighed) was 8% (IQR 0% - 29%). Younger participants (age group 1) used more estimated household measurements instead of weighing than participants in age groups 2 and 3 (0% - 26%, 8% vs 0% - 31%, 7% and 0% - 23%, and 4%, respectively).

Table . Completion time and proportion of items already coded for the total sample (N=74) and stratified by age groups.

	Total	Age group 1: 18 - 30 y	Age group 2: 31 - 45 y	Age group 3: 46 - 65 y
Participants, n (%)	74 (100)	41 (55.4)	15 (20.3)	18 (24.3)
Number of entered items day 1[a]	21 (15 - 31)	22 (16 - 31)	21 (19 - 32)	21 (13 - 30)
Total completion time day 1 (min)[a]	35 (19 - 52)	35 (19 - 45)	44 (19 - 55)	36 (17 - 53)
Relative completion time day 1 (min/item)[a]	1.6 (1.2 - 2)	1.5 (1.1 - 2)	1.5 (1.1 - 2)	1.8 (1.3 - 2.3)
Total completion time sample meal (min)[a]	15 (12 - 18)	14 (11 - 17)	17 (11 - 19)	17 (13 - 23)
Relative completion time sample meal (min/item)[a]	0.8 (0.7 - 0.9)	0.8 (0.6 - 0.9)	0.9 (0.6 - 1.1)	0.9 (0.7 - 1.3)
Proportion of items already coded (%)[a]	68 (55 - 82)	63 (56 - 79)	77 (62 - 86)	71 (50 - 86)
Proportion of estimated household quantities (%)[a]	8 (0 - 29)	8 (0 - 26)	7 (0 - 31)	4 (0 - 23)

[a]Median (IQR).

In total, 24% (18/74) of the participants reported technical issues. In 2 cases, the app crashed, but could be reopened afterward and no data was lost. In 5 cases, participants stated that they had problems finding newly added products (this process is sometimes delayed in rare cases). Further, 4 participants reported that the selection from the drop-down menu did not work properly. In the remaining cases, participants described issues rather associated with this study design than with the technical functions of NutriDiary or gave general comments. For example, 4 participants reported that a barcode presented in the sample meal could not be scanned from the screen (probably due to varying screen-brightness and screen-resolution).

Overall, 85% (63/74) of the participants were able to enter the sample meal correctly. Of the 11 participants who made mistakes when entering the sample meal, 5 were in age group 1, 2 in age group 2, and 4 in age group 3, indicating that age did not affect the accuracy of data entry. In 2 cases, food items were missing. Further, 3 participants had difficulties in editing a WDR entry and entering hypothetical leftovers. Furthermore, 6 participants entered a different amount of food than that presented in the sample meal. When participants were asked whether they would prefer NutriDiary to the traditional paper method, a total of 77% (57/74) agreed. Only 9.5% (7/74) could imagine, that it would be easier to keep a WDR with pen-and-paper than to use NutriDiary (Multimedia Appendix 2).

Discussion

Principal Findings

To our knowledge, an app-based WDR system with barcode scanning function for scientific studies in Germany does not exist so far. The popularity and widespread use of smartphones make NutriDiary a promising alternative to the traditional pen-and-paper approach. Different ways for entering food items (text search, barcode scanning, and free text entry) and the NutriScan function enable users to record the products they consume in a very detailed manner. The digital data output has the potential to reduce the burden for researchers also. In this study, we evaluated NutriDiary in a convenience sample of experts and laypersons and found good usability and acceptability.

The median SUS score of 75 indicated good usability of NutriDiary. The SUS score has been developed as a means to measure the overall perceived usability of a system [26,27]. However, technology-based dietary assessment instruments for scientific purposes are very specific tools that are not designed for everyday use but to generate scientifically useful data. The collection of these data is often challenging for the participants. The first statement of the SUS questionnaire is “I think that I would like to use this system frequently.” This statement is unlikely to be agreed upon by many people in the case of a WDR due to the burden on participants by the method itself.

XSL•FO
RenderX

Nevertheless, the advantage of the SUS score is that it offers the possibility to compare systems used in the same context [27]. The median SUS score of 75 for NutriDiary (mean SUS score: 74, SD 15, for comparison) is comparable with SUS scores for other similar technology-based food records such as "METADIETA-web" (mean SUS score: 68, SD 15, n=26) [31], the "Eat and Track app" (mean SUS score: 69, n=15) [32] or the "Traqq app" (mean SUS score: 79, SD 15, n=22) [33].

Age has been discussed as a major limiting factor for the use of technology-based systems [29] or innovative dietary assessment instruments [31,34,35]. Consistently, the results of the backward selection procedure showed that age was identified as a potential predictor for a lower SUS score in the examined sample. Further, older participants took slightly longer to complete a WDR with NutriDiary than younger ones. Feasibility testing of the digital food record METADIETA-web by Vitale et al [31] also showed that the preference for using the digital tool instead of the traditional pen-and-paper method decreased with increasing age [31]. Older generations did not grow up with smartphones and computers and are therefore likely to be less intuitive with apps and web-based tools than younger generations. However, longer completion times could also be explained by higher accuracy in entering items and greater patience [36], which would be in line with the observation that older participants used fewer estimated household measurements instead of weighing than younger ones in our study (0% - 23%, 4% for age group 3 vs 0% - 31%, 7% and 0% - 26%, 8% for age group 2 and 1, respectively). Nevertheless, an understandable introduction to the use of the instrument might be particularly important in the group of older adults. For practical reasons, only an introductory video was sent out in this study. Our experience in training users to use the NutriDiary app shows that older people tend to ask more questions. This can only be addressed in a face-to-face conversation where it can be ensured that all relevant information is conveyed. Therefore, we recommend a personal introduction when using NutriDiary in epidemiological studies, if feasible.

The median SUS score was higher in women than in men and higher in the group of experts than in the group of laypersons. This may partly be explained by the fact that the proportion of older people was higher in men than in women and higher in the group of laypersons than in the group of experts. The group of laypersons also included students of nutritional science. Although this group certainly cannot be described as experts, the students may have some background knowledge that could have influenced the outcome. Whether this makes them more critical or less critical in their judgment remains questionable.

WDRs have the potential to provide the most accurate description of the types and amounts of the foods consumed over a specified period of time, but they are also considered to be one of the most burdensome and elaborate dietary assessment methods. When conducting a WDR, participants have to weigh and write down everything they eat and drink and always carry their kitchen scales, the record sheet, and a pen with them. This process is exhausting and time-consuming and requires a high level of cooperation from the participants [37]. The median completion time for conducting a WDR with NutriDiary was 35 minutes (1.6 min/item, Table 3) and can be rated as acceptable. When looking at the median relative completion time of the sample meal (here, the amount of the presented foods was predefined), it can be assumed that the single entering process (without weighing) takes around 0.8 minutes per item. This result suggests that weighing accounts for about half the completion time. Keeping this in mind, the single entering process is roughly comparable with the reported average completion time of other text-based DR apps, for example, with "My Meal Mate." Here, participants needed on average 22 minutes per day to complete a record with estimated (not weighed) portion sizes [38].

Whether the NutriDiary app significantly reduces the completion time compared to the traditional pen-and-paper method is questionable, because the digital version of a WDR does not change the fact that weighing is required for this dietary assessment method. However, NutriDiary offers some advantages that can make its use more attractive than the traditional method. First, most people always carry their smartphone with them and recording "on the go" is more practical than using pen-and-paper. Presumably, this makes it less likely that participants forget their records and need to add the meal at a later time. Second, features such as the recipe book and the barcode scanner can make recording easier, as frequently consumed food combinations and recipes can be stored and retrieved later, and consumed products can be added more easily. Furthermore, integrated standard household measurements make it easier to estimate the quantity if weighing is not possible, for example, when eating out of home. The photo function allows participants to add a photo of the meal, which can help the postprocessing. To figure out whether NutriDiary is more attractive to study participants than the traditional pen-and-paper method, we added 2 more questions to the SUS questionnaire (, Multimedia Appendix 2). The result clearly showed that the vast majority would prefer using the NutriDiary app instead of a paper-based food record. To avoid errors caused by application problems using technology-based instruments, an understandable introduction and information structure are necessary to prevent frustration and enable participants to help themselves quickly if they have difficulties. For this purpose, we designed a website where all information and support materials are centralized in 1 location [24].

When using traditional DRs in epidemiological studies, the postprocessing of the DRs is very time-consuming. The data needs to be digitized and manually coded by the study staff. In this study, 68% (IQR 55% - 82%) of the food entered in NutriDiary was already coded. Furthermore, the data was already available in digital form, suggesting less costs and time in data postprocessing, compared to the pen-and-paper method. NutriDiary was designed as an app for keeping WDRs, meaning that participants are asked to weigh all the food and drinks they consume. However, as experience showed that this is not always possible, the app also offers the choice of standard household measurements (eg, teaspoon, glass, or portion) to estimate the quantity in situations where weighing is not possible. Considering the burden of weighing all foods, this selection option might tempt participants to estimate rather than weigh. However, the proportion of estimated quantities was rather low and can be considered manageable in this study.

XSL•FO
RenderX

Within the development process of NutriDiary, building an appropriate food database structure and the collection, standardization, and integration of barcode and food packaging information to enable food entry via barcode scanning was one of the most challenging tasks. The underlying database determines the users' success in searching for food items and is essential for the functionality and accuracy of technology based, self-administered dietary assessment tools [3,39]. Therefore, we aimed to make the database as complete as possible. Due to a high number of available branded foods and the frequently changing food market, this is a major challenge [12,40-43]. According to the Food Federation Germany [44], there are more than 170,000 food products available on the German food market. Every year, about 40,000 new products are launched and just as many disappear [44]. It also happens that manufacturers change food recipes, which can also change the ingredient lists and nutritional values. These circumstances mean that the database needs to be constantly updated. To make this possible, the NutriScan function described above was developed and integrated. If the app is used regularly, the database is regularly updated with new products recorded by users.

Strengths and Limitations

The NutriDiary evaluation study had some strengths and limitations. As NutriDiary was developed for scientific use, practicing nutritionists were also recruited as experts. Although experts are not intended users of the app, their evaluation allows for a professional view of the usability of NutriDiary. Furthermore, experts decide on the use of the assessment instrument in scientific studies, which is why their opinion on usability is of particular importance in this context. To assess user-friendliness in older age groups as well, we specifically recruited older participants. However, this study population was not representative of the general German population. Most participants were female, young, and highly educated. This limited the generalizability of our results. Nevertheless, it is important to acknowledge that participants in epidemiological studies frequently possess a higher educational status compared to the general population. In addition, participants were aware of the purpose of this study, which was to evaluate the usability and acceptability of NutriDiary, making it difficult to assess the quality and transferability of the data on the completion time and proportion of items already coded. This study aimed to assess the usability and acceptability of NutriDiary and does not contain any data on the validity of the NutriDiary app. However, providing information on the app's validity and psychometric properties is a critical prerequisite for its effective application. Therefore, a validation study has already been initiated and will give insights into the validity and quality of the assessed nutritional data.

Conclusion

NutriDiary is the first smartphone based WDR app with integrated barcode scanning function for scientific purposes in Germany. The evaluation by experts and laypersons indicated an acceptable completion time, good usability and acceptability on the users' side, whereby younger experts and laypersons tended to rate the app better than older ones. Future research will give insights into the validity and feasibility of NutriDiary in different study populations.

Acknowledgments

The authors would like to thank all study participants for the provision of their data. Special thanks go to the students Sofie Frey, BSc, and Franziska Oidtmann, BSc, for their support with data collection. This work was supported by Diet-Body-Brain (DietBB) and the Competence Cluster in Nutrition Research funded by the Federal Ministry of Education and Research (FKZ: 01EA1410A).

Authors' Contributions

LK and UN did the conceptualization. IA, KB, JC, SAJK, LK, MEB, and UN developed the app. LK and MEB handled data curation and worked on the formal analyses. LK wrote the original draft. SAJK, MEB, UA, JC, IA, and UN reviewed and edited the writing. UN supervised the study.

Conflicts of Interest

The authors were involved in the development of the NutriDiary app.

Abstract

Background: Colonoscopies are vital for initial screening, follow-ups, surveillance of neoplasia, and assessing symptoms such as rectal bleeding. Successful colonoscopies require thorough colon preparation, but up to 25% fail due to poor preparation. This can lead to longer procedures, repeat colonoscopies, inconvenience, poorer health outcomes, and higher costs. eHealth tools can enhance bowel preparation and potentially reduce the need for repeat procedures.

Objective: This usability study aimed to identify strengths and weaknesses in a prototype companion app for colonoscopy examinations. The objective was to obtain in-depth insights into the app's usability, ease of use, and content comprehension, with the aim of refining the tool to effectively fulfill its intended purpose, guided by feedback from potential users.

Methods: From February to August 2024, we conducted a qualitative study using the think-aloud procedure. Each session involved 6 tasks and a semistructured interview to delve deeper into participants' task experiences. All think-aloud sessions and interviews were recorded. Quantitative usability questions were analyzed using Microsoft Excel, while qualitative data underwent coding and analysis based on thematic analysis principles.

Results: In total, 17 individuals, all smartphone users, participated in this study. Participants were recruited from 1 hospital, 1 private clinic, and 1 patient organization in Switzerland. The study found that participants rated the app's usability metrics positively, with an overall mean rating of ease of use at 4.29 (SD 0.59), usefulness at 4.53 (SD 0.72), and comprehensibility at 4.29 (SD 0.92). For the individual features, the mean ratings for ease of use were between 4 and 4.65, usefulness ranged from 4.35 to 4.82, and comprehensibility received ratings between 4.29 and 4.53, all measured on a 5-point scale, where 1 represented low agreement and 5 indicated high agreement. Additionally, 100% of participants indicated they will or may use the app if they require a colonoscopy examination. Participants highlighted the need for reminders and alerts in the week leading up to the colonoscopy, along with tailored content, simplified language, and visual aids.

Conclusions: The app prototype demonstrated favorable results with the majority of participants, and the testing process enabled the prompt identification and resolution of usability issues. The next phase will prioritize and assess potential improvements based on urgency and feasibility to guide a focused development plan. Usability testing highlighted features such as push notifications and personalized content as top priorities for participants, making them key areas for immediate attention. Moving forward, the app has the potential to function effectively as a companion app for colonoscopy examinations. To achieve this, further studies with a larger sample in real-world settings will be crucial.

Introduction

Background

Colonoscopies are widely recognized as the most reliable method for detecting colorectal issues; their effectiveness and safety hinge on the thoroughness of bowel preparation beforehand [1,2]. Ensuring adequate bowel preparation is crucial for achieving clear visualization of the colon's inner lining during the procedure. Poor bowel preparation is linked to risks such as missed significant lesions, procedural challenges, longer operation times, higher rates of interval colorectal cancers, and increased health care expenses [3]. However, a colonoscopy is an invasive procedure that demands extensive preparation. This includes taking a laxative, restricting food and liquid intake, and stopping certain medications in the week before the appointment.

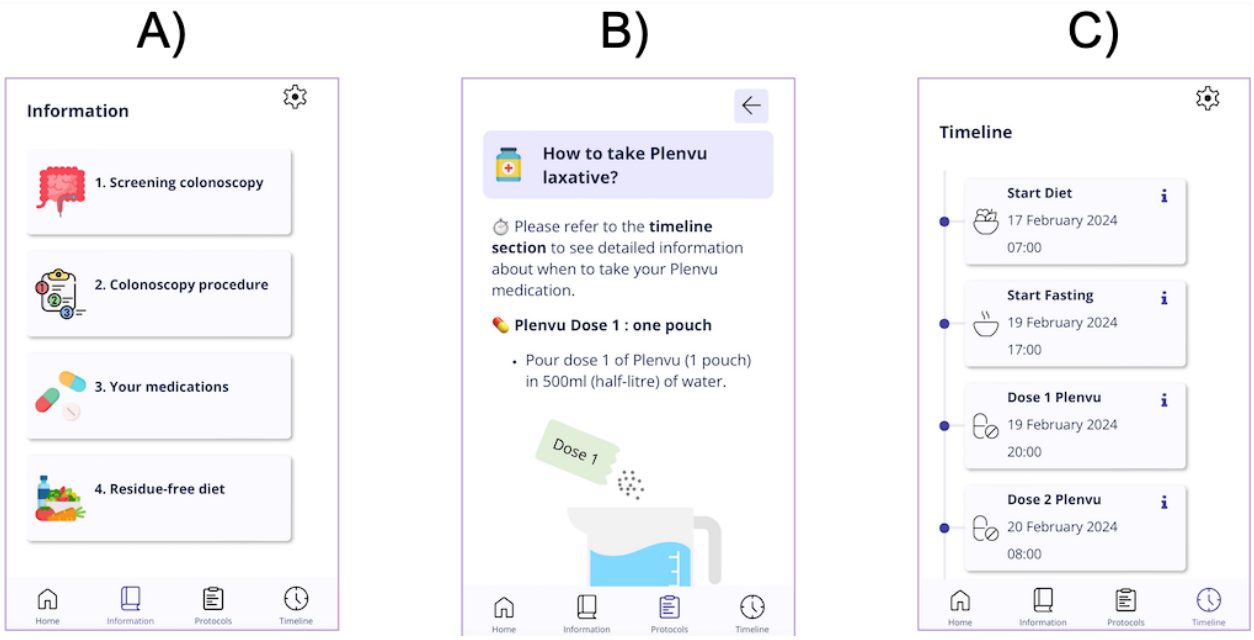
Research indicates that up to 11% of individuals miss their colonoscopy appointments [4,5], and among those who do attend, many have insufficient bowel preparation, hindering clear colonic visualization [6-12]. A recent study investigated the efficacy of various bowel preparation regimens (4L, 2L, and ≤1L) for colorectal cancer screening, focusing on key quality indicators such as bowel cleanliness, cecal intubation rate, adenoma detection rate, and polyp detection rate, all aligned with the performance standards set by the European Society of Gastrointestinal Endoscopy (ESGE) [13]. While all regimens met the ESGE's minimum quality thresholds, the adequacy of bowel preparation varied significantly between volumes [13]. Ultralow-volume preparations achieved an adequacy rate of 79%, notably lower than the 86.4% seen with high-volume preparations [13]. In particular, bowel preparation with sodium picosulfate and magnesium citrate (SPMC) and 1L polyethylene glycol with ascorbic acid (1L-PEGA) was adequate in only 75.2% and 82.9% of cases, respectively, highlighting the need for careful consideration when selecting a preparation method based on patient needs and procedural goals [13].

Misunderstanding dietary guidelines and cleansing instructions, along with noncompliance, significantly contributes to inadequate bowel preparation [14]. Ineffective bowel preparation can lead to several adverse outcomes, including reduced adenoma detection rates, extended procedure times, lower cecal intubation rates, increased electrocautery risks, and more frequent examination intervals [15,16]. To enhance patient adherence to colonoscopy procedures, various educational strategies have been used. Tools such as booklets, cartoons, and SMS text messaging have proven effective in increasing follow-up rates compared to standard care [17]. Furthermore, smartphone-based strategies have been developed to assist patients in preparing for colonoscopy [18-24]. Research indicates that these smartphone interventions generally lead to better outcomes, such as higher bowel cleansing quality scores, compared to usual care control groups [18-20,25,26]. However, there is limited evidence that these tools were designed with input from their intended users [27], which may reduce their effectiveness. Engaging potential users in the app development process is likely to enhance usability by ensuring the app's content and features match user needs and preferences [28-30].

Objectives

Considering that user research can significantly enhance a tool's adoption and adherence rates post launch [28], this usability study was conducted to pinpoint strengths and weaknesses in the prototype of a companion app for colonoscopy examinations and to provide detailed insights into its quality regarding usefulness, ease of use, and content comprehension. The goal is to refine the product based on evidence gathered from potential users, ensuring it meets its intended purpose effectively.

Methods



App Prototype

The health care technology company Gimini Biosciences SàRL is developing digital health solutions to empower patients undergoing complex medical interventions. Their mission is to ensure every patient has access to the necessary information for a successful medical examination.

The companion app for colonoscopy examinations, their first use case, features three main sections: (1) educational content about colonoscopy examinations; (2) digital protocols detailing diet, fasting, and laxative instructions; and (3) a personalized timeline based on the user's examination date and time to guide them on diet, fasting, and laxative schedules. Figure 1 illustrates the design of the prototype, showcasing these sections.

XSL•FO
RenderX

Figure 1. App prototype overview, including (A) patient information, (B) digital protocols, and (C) timeline and schedule.

Study Design

The study involved conducting a qualitative interview with each participant using the standardized think-aloud method [31], which is described in detail below. Participants were guided using a semistructured test script to articulate their cognitive process in real time while completing a list of predefined tasks. Similar to many qualitative studies, this research used purposive sampling to gather in-depth insights [32]. Participants were selected based on their capacity to offer detailed and firsthand insights into the research topic, ensuring they could effectively articulate their real-life experiences [32,33].

Participant Recruitment

The inclusion criteria covered individuals aged 40 - 65 years who use a smartphone, have undergone a colonoscopy examination, have access to Wi-Fi and email, are comfortable using teleconferencing tools (eg, Microsoft Teams), and are capable of screen-sharing during the testing session. Three institutions played a key role in recruiting participants: Clarunis (the University Digestive Health Care Center of St. Clara Hospital and University Hospital Basel), GGHA (Geneva Gastroenterology & Hepatology Associates SA), and EUPATI Switzerland (European Patients' Academy on Therapeutic Innovation).

Participants were directly approached and recruited by the collaborating institutions. Once a participant agreed to participate and signed the consent form, the respective institution forwarded the signed consent form along with the participant's contact details to the core research team at the University of Applied Sciences and Arts Northwest Switzerland (FHNW). From that point, the research team took over the coordination and management of the participant's involvement in the study.

Participants had the option to conduct the testing session in English, French, or German. The English version of the participant information sheet and consent form can be found in Multimedia Appendix 1. The information was also provided in both German and French, giving participants the freedom to select the language they felt most comfortable using, and the recruitment process spanned from February to July 2024. The researchers aimed to recruit a sufficient number of participants to achieve saturation, indicating that enough data had been collected when new information no longer provided additional insights [32,33].

Think-Aloud Procedure

The think-aloud method is extensively used in app development as a popular tool for assessing usability [34]. In a think-aloud test, participants are asked to use the system and verbalize their thoughts continuously as they navigate through the user interface. This technique allows researchers to gain deeper insights into user misconceptions, which often lead to practical recommendations for redesign: when users misunderstand design elements, those elements may require modification. It also sheds light on why users make incorrect assumptions about certain aspects of the design and why they find other parts intuitive. The method is used to make cognitive processes, which would otherwise remain implicit and unspoken, more visible. By having participants verbalize their thoughts while performing a task, researchers can gain insights into thought processes, decision-making strategies, and individual patterns of interpretation.

Participants evaluated a web-based prototype of the app. They were instructed to explore the prototype while vocalizing their actions and observations, and to offer feedback on features, navigation, and perceived usefulness as they interacted with it. Researchers reminded participants to maintain a continuous stream of thoughts when needed and observed their behavior throughout the test tasks. All sessions were recorded, capturing participants' screen interactions with the prototype. Detailed notes were taken during feedback sessions and stored using the research platform Tivian.

During each test session, participants were asked to complete 6 tasks, during which we observed their behavior and

XSL•FO
RenderX

interactions with the tool. Additionally, they provided subjective assessments for each task, evaluating its usefulness, ease of use, and comprehensibility of the content. Textbox 1 displays the list of tasks participants were required to complete during the test sessions. The English version of the complete test script can be found in Multimedia Appendix 2.

Textbox 1. The list of tasks participants were required to complete during the test sessions.

Task 1: Customization and language choice
Task 2: First screen tour
Task 3: Accessing and navigating the background information section
Task 4: Accessing and navigating the fasting and food instructions
Task 5: Accessing and navigating the laxative instructions
Task 6: Accessing and navigating the meal and exercise recommendations

The think-aloud test was designed to encompass every possible task a user might perform within the app, covering all available functions and interactions. By including all tasks, we ensured a thorough capture of user feedback across the app's entire functionality, providing a comprehensive assessment of the user experience. Below is a high-level summary of what each task involved:

- Task 1: Customization and language selection—In this task, participants were prompted to select their preferred language and adjust settings such as font size or content complexity, allowing them to personalize the app to their needs.
- Task 2: First screen tour—This task aimed to assess the intuitiveness of the app's initial screen, encouraging participants to reflect on the clarity of the navigation and their understanding of the content available in each section.
- Task 3: Exploring background information—Here, participants were guided to access and navigate the section on background information about the colonoscopy examination, supporting their understanding of the procedure as they prepared for their appointment.
- Task 4: Reviewing fasting and dietary instructions—This task directed participants to find and review guidelines on what they can and cannot eat before the examination, including details on when to begin the special diet and the required fasting period.
- Task 5: Reviewing laxative instructions—Participants were asked to locate and understand instructions on taking the laxative, including information on dosage timing for effective preparation.
- Task 6: Reviewing meal and exercise recommendations—This task involved participants exploring the app's suggestions for meals and exercises that could help them prepare optimally for the examination.

Analysis

After compiling all notes from the testing sessions, CJ, RM, and SS collectively reviewed and synthesized the findings. These were then presented to the app development team for discussion, focusing on identifying features and functions requiring modification. The data encompassed audio recordings of the think-aloud sessions, observations noted by CJ, RM, and SS, and responses to usability questions.

Quantitative usability data, such as user ratings of ease of use and usefulness of the different features, were aggregated and analyzed using Microsoft Excel for Mac 2021 (version 16.86) to compute totals, percentages, means, and standard deviations. Qualitative participant comments were translated into English as needed for coding purposes. NVivo version 1.7.2 (QSR International), a qualitative data analysis software, was used for coding and categorizing the qualitative data. The data underwent thematic analysis to capture the depth and the unique interpretative contributions of individual researchers [35]. To ensure coding reliability, the first 3 authors, who conducted testing sessions in 3 different languages, engaged in collaborative discussions. The initial codebook was organized around core eHealth app development components: user interface (including navigation and visual design), user experience design (such as personalization), functionality (including notifications and reminders), and patient engagement and support (such as educational content). Initial coding was carried out by the first author (CJ), followed by a review from RM. Any coding discrepancies were addressed through discussions with SS until a consensus was reached.

Ethical Considerations

The ethics committee of Northwest and Central Switzerland determined that ethics approval was not needed for this study, according to the Federal Act on Research Involving Human Beings, article 2, paragraph 1 (reference number Req-2023 - 01506). All participants were briefed about the research background and signed a consent form agreeing to participate. Participants did not receive payment but were offered the opportunity for early and free access to the app upon its launch.

Results

Sample Characteristics

In total, 17 participants from 4 institutions tested the app prototype (3 of them were pilot tests, 1 in each of the 3 test languages). Participants were mostly male (13/17, 76%) and aged 40 - 50 (8/17, 47%) years. The gender discrepancy among participants is largely due to recruitment challenges and the voluntary nature of the study. Since participation was optional, it may have led to a self-selection bias, where individuals more comfortable with technology or who have a specific interest in health applications were more likely to take part, resulting in a less balanced gender distribution among participants. Tests were conducted in German (6/17, 35%), French (6/17, 35%), and

XSL•FO
RenderX

English (5/17, 29%). Table 1 presents the demographics and characteristics of the sample.

Table . Sample characteristics (N=17).

Characteristic		Values, n (%)
Gender		
	Male	13 (76)
	Female	4 (24)
Age (years)		
	<40	1 (6)[a]
	40 - 50	8 (47)
	51 - 60	5 (29)
	>60	3 (18)
Language		
	German	6 (35)
	French	6 (35)
	English	5 (29)

Usability Metrics

Usability metrics are specific measurements used to evaluate a digital product's usability. These metrics typically assess how quickly users complete tasks, how often they make mistakes, and their overall satisfaction with the tool. By analyzing various usability metrics, we can gain a comprehensive understanding of the user's experience and the tool's overall usability.

During the testing sessions, we incorporated satisfaction metrics, which are subjective measures based on users' self-assessments. These metrics evaluated the ease of use, usefulness, and content comprehensibility of different sections of the app, as well as their overall impression of the app. Responses were rated on a Likert scale from 1 (low agreement) to 5 (high agreement). Table 2 provides an overview of these subjective measures for the various tasks and the app as a whole. Some measures were not applicable for certain tasks. For example, in task 1 (customization and language selection), there was no text content to assess for comprehensibility, so this measure is marked as N/A (not applicable) for that task. In task 2 (first screen tour), participants were only asked to reflect on whether the initial screen was intuitive, rather than completing an action. Therefore, measures such as ease of use, usefulness, and comprehensibility were not rated for this task.

XSL•FO
RenderX

Table . Subjective usability measures (N=17).

Task	Ease of use[a], mean (SD)	Usefulness[a], mean (SD)	Comprehensibility[a], mean (SD)
Task 1: Customization and language choice	4.41 (0.71)	4.35 (1.11)	N/A[b]
Task 2: First screen tour	N/A	N/A	N/A
Task 3: Accessing and navigating the background information section	4.41 (0.94)	4.76 (0.44)	4.53 (0.87)
Task 4: Accessing and navigating the fasting and food instructions	4 (1)	4.41 (0.87)	4.29 (0.99)
Task 5: Accessing and navigating the laxative instructions	4.53 (0.62)	4.82 (0.39)	4.35 (0.93)
Task 6: Accessing and navigating the meal and exercise recommendations	4.65 (0.7)	4.59 (0.62)	4.53 (0.8)
Overall satisfaction with the app as a whole	4.29 (0.59)	4.53 (0.72)	4.29 (0.92)

[a]User satisfaction of usability attributes was rated on a scale of 1 (low agreement) to 5 (high agreement).

[b]N/A: not applicable.

To provide a comprehensive assessment, test moderators also recorded observations on three additional usability metrics: (1) completion metrics (these measure whether users can successfully complete or partially complete tasks, indicating the tool's effectiveness); (2) duration metrics (these track the average time users take to perform a task, reflecting the design's complexity and the efficiency of user navigation); and (3) error metrics (these refer to actions users take that do not lead to the expected outcome, highlighting areas of confusion in the user interface or challenges with functionality). Table 3 presents an overview of these observed measures. Certain measures in this table were not applicable for task 2 (first screen tour), as participants were only asked to assess the intuitiveness of the initial screen rather than perform any specific action. As a result, metrics such as completion rate and error rate were not relevant for this task, since there was no actionable step for participants to complete or errors to quantify.

Table . Observed usability measures (N=17).

Task	Completion, n (%)	Error rate, n (%)	Duration (seconds), mean (SD)
Task 1: Customization and language choice	16 (94)	1 (6)	44.47 (32.39)
Task 2: First screen tour	N/A[a]	N/A	57.41 (45.94)
Task 3: Accessing and navigating the background information section	15 (88)	7 (41)	66.53 (46.32)
Task 4: Accessing and navigating the fasting and food instructions	16 (94)	7 (41)	75.41 (46.07)
Task 5: Accessing and navigating the laxative instructions	15 (88)	3 (18)	54.88 (47.89)
Task 6: Accessing and navigating the meal and exercise recommendations	17 (100)	3 (18)	56.76 (50.49)

[a]N/A: not applicable.

When asked if they would use the app for a colonoscopy examination once it becomes available, out of 17 participants, 14 (82%) said yes, 3 (18%) said maybe, and 0 (0%) said no.

Qualitative Feedback

Participants provided comments and qualitative feedback on the 6 tasks they performed during the test sessions. While their feedback concerning the comprehensibility of the content, the user-friendliness, and the general user benefits of the application was mostly positive, they also expressed some confusion about certain content or features. Additionally, they offered suggestions for improvements in areas such as design and visualization as well as user guidance to address the gaps or issues they identified in the prototype. Overall, participants stressed the importance of receiving reminders and alerts in the week leading up to their colonoscopy. They also preferred tailored content, simplified language, and visual aids to enhance their understanding. Table 4 summarizes their qualitative feedback, organized into 4 key themes: app content, design, guidance, and features. These themes collectively illustrate the

XSL•FO
RenderX

participants' preferences and priorities, providing valuable insights for the development and improvement of the application.

XSL•FO
RenderX

Table . Key themes that emerged from the thematic analysis of the qualitative feedback.

Themes and subthemes		Qualitative feedback
Content		
	Content accuracy	Participants expressed a need for greater accuracy in the app's content. Specifically, they suggested: • Allowing the selection of examination times down to the minute, rather than in 15-minute intervals. • Clearly stating that tea and hot drinks should not contain milk, as specified in the paper-based guidance. • Ensuring the app accurately reflects the strict fasting phase, as some participants experienced longer fasting periods than indicated.
	Content clarity	Some content has been found to be unclear or confusing. For instance: • The term "residue-free diet" may be difficult for laypeople to understand; "bowel cleansing" is suggested as a more straightforward alternative. • The term "protocols" is ambiguous, and "preparation" is recommended as a clearer option. • Instead of using the word "option" for meal examples, provide explicit examples to avoid misleading users into thinking these are the only choices available. • For dosage instructions, emphasize that the liquid should be consumed in sips rather than all at once. • The timeline entry "pickup medication" is unclear and potentially misleading; a more descriptive label is needed. • More information on physical exercise should be included, such as its effects and importance in the preparation process.
	Content completeness	It has been noted that certain content is currently lacking in the app, namely: • Expanded details on the colonoscopy procedure should be provided, with careful attention to wording. Starting the information section with cancer detection details can be perceived as alarming. It is essential to introduce the procedure in a reassuring manner, highlighting its benefits and emphasizing preventive care. • Information on the effects of laxatives. • Vegetarian menu options. • Post-colonoscopy care and potential adverse events. • Any assistance with laxative consumption would be greatly appreciated, as it can be quite unpleasant. For example, mixing the laxative with clear syrup to improve taste. Another tip is to sip water alternately with the laxative instead of consuming them sequentially, which can make the experience less difficult. Additional advice on making the process more manageable could include using a straw to drink the laxative or drinking tea beforehand to mitigate the salty taste.

XSL•FO
RenderX

Themes and subthemes		Qualitative feedback
	FAQs[a]	Participants have suggested including a section with FAQs to provide clear and concise answers to common concerns. Suggested questions include: • Why is a colonoscopy performed? Include an explanation of its purpose and benefits, and note any differences in the procedure or considerations for men and women. • Can I drive after taking the medication? • When can I resume a normal diet? • What are the advantages and disadvantages of various examination methods? Offer a comparison of different diagnostic options, such as stool examinations, to help users understand their relative benefits and limitations.
	Translation accuracy	A few minor translation inaccuracies have been identified: • “Dose 1” was incorrectly translated into German; the correct term is “Dosis.” • Under “fasting time,” “Untersuchung” is a more appropriate translation than “Prüfung.”
Design		

XSL•FO
RenderX

Themes and subthemes		Qualitative feedback
	Navigation clarity	Participants have proposed several improvements to enhance the clarity of the app's navigation. Suggested enhancements include: • Adjust the color scheme of the language selection navigation to make it more prominent. • The button for confirming language selection should be available in multiple languages. • Change the name of the navigation section labeled "Information" to better reflect that it pertains to the procedure rather than app-related information. • The back arrow should be made more prominent by increasing its size and repositioning it centrally for better visibility and ease of use. • There is uncertainty about the type of information the sections labeled "Protocols" and "Timeline" contain.
	Navigation structure	There were several suggestions to improve the app's navigation structure: • Increase the size of the customization icon and consider positioning it at the same level as the other main navigation icons to attract more attention. • Keep content concise and allow users to click for more detailed information when needed. • Display the timeline immediately after scheduling an appointment, as it is highly relevant. Ideally, place the timeline in the same section where laxative information is provided. • Clearly mark the section for taking the laxative in the protocol and integrate the "how" with the "when" to provide a comprehensive guide. • Distinguish and prioritize personalized content related to individual preparation for the colonoscopy from general informational content about the procedure, such as examination details and menu suggestions.
Guidance		

XSL•FO
RenderX

Themes and subthemes		Qualitative feedback
	Step-by-step guidance	Participants have reported some confusion and expressed a need for clearer guidance on navigating the app and understanding required actions. Specific recommendations include: • Add a note indicating that users can change the language and the date of their intervention, as this option is not immediately apparent. • Clearly explain why users need to enter their appointment details. • Provide a clear explanation of the next steps immediately after entering appointment information, as some users were unsure where to click. • Indicate that some content is customized based on the user's appointment time to clarify how the app personalizes information. • Include preliminary information about the general procedure at the start of the app, such as an overview page, to give users a better understanding of what to expect.
Features		
	Personalized notifications	Nearly all participants emphasized the critical need for personalized reminders and alerts, tailored to each patient based on the specific date and time of their colonoscopy appointment.
	Sharing and printing info	The importance of having the ability to print or share information directly from the app was emphasized.
	Tailored content	Participants noted that the app's capability to customize content for individual users makes it more favorable compared to other methods of information delivery, such as paper. Specific suggestions include: • Set the app to automatically select the language based on the user's browser settings. • Allow direct integration with the user's calendar for streamlined timeline management. • Ensure that the link directs users to the correct hospital right from the start. • Add the medical center's phone number or provide a direct link for users to easily contact the center.
	Visual aids	Participants recommended integrating visual aids to improve the clarity and comprehension of the information. Suggestions include: • Add illustrations to assist in understanding the content more easily. • Use visual cues to highlight the fasting time more prominently. • Present information about meal preparation and dishes in a more visual format, including photos of menu items. • Integrate photos and potentially a video to visually explain the procedure.

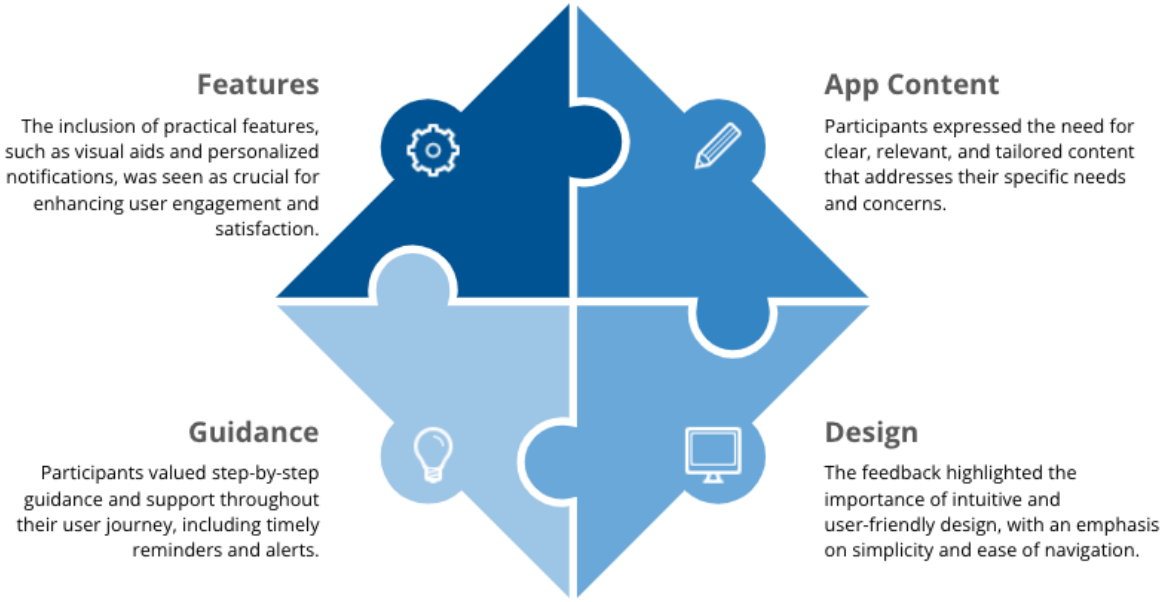
Discussion

Principal Findings and Implications for App Improvement

Our findings indicate that participants were generally willing to use the companion app for colonoscopy examinations and found it mostly useful and easy to navigate. Usability is crucial for implementation, as technologies that are user-friendly are more likely to be consistently used over time. This is why leading technology acceptance frameworks such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) emphasize ease of use and usefulness as key predictors for adopting new technologies [36,37]. The inclusion of subjective measures in assessments has been debated in the literature due to potential variability introduced by users' subjective views. Despite this challenge, many scholars advocate for the inclusion of subjective criteria, such as ease of use and visual appeal, because they are fundamental drivers of adoption [38-41]. Therefore, incorporating subjective criteria, such as perceived ease of use, into the testing process could enhance tool adherence and improve health outcomes [42]. However, it is important to recognize that moderating factors such as a person's age, education, and digital skills can influence their assessment of a technology's perceived ease of use and overall usefulness [38].

Although participants rated the app highly for both ease of use and usefulness, they also offered several suggestions for improvement. For instance, they recognized that preparing for a colonoscopy involves multiple complex steps during the week leading up to the appointment. They expressed a desire for the app to send timely reminders to guide users throughout the process, aligning with findings from previous similar research [27]. Reminders are likely crucial for the effectiveness of the app. In fact, a randomized controlled trial found that without reminders the app group had the same quality of bowel cleanliness as the control group [21]. Previous studies have demonstrated that personalized reminders and alerts enhance the adoption of electronic health technologies, effectively modifying various health behaviors [43].



The app content was generally well received for its clarity and ease of understanding. However, there were a few requests for improved clarity or accuracy in certain areas, as detailed in the Results section. Additionally, users identified some content gaps in the tested prototype. Specifically, they requested more comprehensive guidance on how to take the laxative and minimize the unpleasantness of the experience. Furthermore, there was a need for information addressing post-colonoscopy issues. This latter finding aligns with similar research; for instance, Sewitch et al [27] also highlighted the perceived importance of post-colonoscopy information among potential users. Their study similarly underscored the need for detailed guidance on what to expect and how to manage any subsequent issues after the procedure. This is especially pertinent considering that statistics reveal approximately 25% of patients experience a minor adverse event within 48 hours of a colonoscopy, and 0.5% encounter a serious adverse event within 30 days [44].

Participants indicated a need for more detailed, step-by-step guidance on using the app. They sought clear instructions on the use of entering specific information, such as their procedure date and time, and how to effectively use the app to prepare for their examination. This feedback aligns with the extensive literature emphasizing the importance of user training and guidance to enhance adoption rates [38]. Introducing an app tour with guided notes detailing each section, coupled with clear instructions on features such as adjusting font size, could greatly enhance the overall user experience. This initial guidance would make it easier for users to understand how to navigate the app and maximize its use right from the start. Research suggests that users' perception of ease of use can be significantly improved with high-quality training materials that guide them on how to effectively optimize these technologies [38,45,46].

Participants expressed a strong preference for more visual and interactive content, as well as a navigation design that prioritizes personalized information, such as the preparation timeline. They expressed a desire for information to be presented clearly at every stage of the colonoscopy preparation process. This feedback is consistent with previous research, which underscores the critical role of design elements and personalization in achieving successful patient adoption of digital health tools [38]. Several studies have specifically highlighted the importance of personalization. For example, a lack of customization options to meet individual needs can result in lower adoption rates or even abandonment of the tool [38,47]. Figure 2 provides a summary of our findings regarding user preferences for app design, content, features, and guidance. These insights will help boost the app's usability and functionality, ultimately improving user adoption.

XSL•FO
RenderX

Figure 2. Key areas for app improvement.

The next step will involve a thorough prioritization and impact assessment, where improvements according to urgency and feasibility will be ranked to guide a targeted development plan. For example, the usability testing results indicate that features such as push notifications and personalized content are top priorities for the participants. These will be addressed at the start of the next development cycle to ensure they are optimized before moving into real-world testing.

Limitations and Future Research

While the practical insights from participants regarding the app prototype were valuable and guided us in making important modifications, it is important to acknowledge several limitations. Using the think-aloud methodology, there is a potential for reporting bias where participants may shape their responses to align with perceived researcher expectations; additionally, participants might selectively verbalize thoughts that align with what they believe interviewers want to hear, known as social desirability bias [48]. To address these potential biases, moderators were trained to actively encourage participants to provide verbal feedback and to collect observational data. These observations were used alongside participants' subjective feedback during data analysis.

While the sample size of this study may appear small, previous research indicates that 80% - 90% of usability issues in websites and apps can be identified with 5 to 9 participants [49,50]. During the individual think-aloud sessions, recurring themes emerged, suggesting data saturation was achieved [32]. However, it is possible that additional participants could have uncovered different usability issues and provided diverse perspectives. Looking ahead, the app has promising potential as a companion for colonoscopy examinations. However, conducting larger-scale studies in real-world environments will be essential to validate and optimize its value and effectiveness.

Conclusions

Overall, participants expressed satisfaction with the app's usability. The think-aloud sessions provided real-time insights into the app's appeal, relevance, and use. Minor adjustments to the prototype's functionality were identified as necessary to enhance usability. Feedback and suggestions from participants have been integrated into the final app design. The initial findings from this usability study indicate that the app holds promising potential as a companion for colonoscopy examinations. This work establishes the foundation for further research to evaluate usability and feasibility among a larger, real-world population.

Acknowledgments

This study was sponsored by Innosuisse (Swiss Innovation Agency, grant 70325.1 INNO-ICT). The role of Innosuisse is to promote science-based innovation in the interests of industry and society in Switzerland. We extend our gratitude to the 3 institutions that were instrumental in recruiting the study participants: Clarunis (the University Digestive Health Care Center of St. Clara Hospital and University Hospital Basel), GGHA (Geneva Gastroenterology & Hepatology Associates SA), and EUPATI Switzerland (European Patients' Academy on Therapeutic Innovation).

Abstract

Background: Emergency and acute medicine doctors require easily accessible evidence-based information to safely manage a wide range of clinical presentations. The inability to find evidence-based local guidelines on the trust's intranet leads to information retrieval from the World Wide Web. Artificial intelligence (AI) has the potential to make evidence-based information retrieval faster and easier.

Objective: The aim of the study is to conduct a time-motion analysis, comparing cohorts of junior doctors using (1) an AI-supported search engine versus (2) the traditional hospital intranet. The study also aims to examine the impact of the AI-supported search engine on the duration of searches and workflow when seeking answers to clinical queries at the point of care.

Methods: This pre- and postobservational study was conducted in 2 phases. In the first phase, clinical information searches by 10 doctors caring for acutely unwell patients in acute medicine were observed during 10 working days. Based on these findings and input from a focus group of 14 clinicians, an AI-supported, context-sensitive search engine was implemented. In the second phase, clinical practice was observed for 10 doctors for an additional 10 working days using the new search engine.

Results: The hospital intranet group (n=10) had a median of 23 months of clinical experience, while the AI-supported search engine group (n=10) had a median of 54 months. Participants using the AI-supported engine conducted fewer searches. User satisfaction and query resolution rates were similar between the 2 phases. Searches with the AI-supported engine took 43 seconds longer on average. Clinicians rated the new app with a favorable Net Promoter Score of 20.

Conclusions: We report a successful feasibility pilot of an AI-driven search engine for clinical guidelines. Further development of the engine including the incorporation of large language models might improve accuracy and speed. More research is required to establish clinical impact in different user groups. Focusing on new staff at beginning of their post might be the most suitable study design.

Introduction

In making decisions about patient care, clinicians frequently are faced with queries and are often unable to retrieve answers to them in a timely fashion. A systematic review [1] estimates that the per-patient frequency of queries raised by clinicians ranges from 0.4 to 0.8 per patient and that about two-thirds of these queries are left unanswered. This picture has been fairly stable over time despite the broad availability of web-based evidence resources that can answer these questions. Unanswered

XSL•FO
RenderX

questions may lead to suboptimal patient care decisions and are missed opportunities for timely learning and practice improvement.

Medwise.ai is a solution codeveloped with Betsi Cadwaladr University Health Board), which helps clinicians find answers quickly from local guidelines and provide seamless and just-in-time access to high-quality evidence in the context of patient care decision-making in the clinical environment. A previous study [2] has demonstrated that smartphone apps can increase the speed to access guidelines when compared to using desktop computers. However, access to guidelines does not equate to finding answers to clinical questions quickly and effectively at the point of care. The Medwise.ai platform can collate local clinical guidelines and break them down into chunks of content that can be retrieved using natural language processing and information retrieval technologies as bite-sized answers for clinician's questions. We conducted a time-motion analysis, comparing cohorts of junior doctors using an artificial intelligence (AI)–supported search engine and the traditional hospital intranet, to examine the impact of the AI-supported search engine on participant time and workflow when seeking answers to clinical queries at the point of care. The secondary end points of our study were to assess whether effective question answering could lead to a better quality of work life and improve confidence in decision-making for the end user.

This study aimed (1) to gain user feedback for a novel context-specific proof-of-concept search engine and (2) to measure the time required to retrieve clinically relevant information with a novel engine compared to other search engines in the setting of hospital emergency care.

Methods

Study Design

We conducted a prospective direct pre- and postobservational pilot study in teams caring for medical emergency admissions examining the impact of access to Medwise.ai, a clinical query answering platform, versus information retrieval from guidelines saved on the hospital intranet using time-motion study methodology [3].

Study Setting

The study took place at the Ysbyty Gwynedd, Bangor. The Ysbyty Gwynedd is a district general hospital in North Wales with 550 beds covering all major specialties, including a dialysis unit and a 13-bedded critical care unit. Clinicians from 2 units in the hospital were recruited; the acute medical unit has 23 beds and is complemented by a same day emergency care unit for low-risk admissions.

Both units receive direct admissions from primary care and work closely with the emergency department (ED) to manage acute medical presentations. It is important to note that the traditional boundaries between emergency care and acute medicine have become less distinct in recent years due to increasing hospital overcrowding in the United Kingdom. While historically, patients were first seen in the ED by emergency physicians and then referred to the Acute Medical Unit for care by acute and general physicians, many acute and general medical teams now also work within the ED to manage the flow of acute medical patients.

During the day shift (8 AM to 8:30 PM), the on-call team consists of 4 doctors in training (a newly qualified foundation year 1 doctor, 2 core medical trainees with 1‐4 years of experience, and 1 medical registrar with 4 or more years of clinical experience and membership of the Royal College of Physicians) and an on-call consultant with a full specialist qualification. The sole task of the on-call team is the care of emergency admissions and emergencies of inpatients. Patients seen by doctors in training are subsequently reviewed by a consultant as part of the posttake ward round.

Intervention

Medwise.ai is a proof-of-concept search engine combining well-established information retrieval techniques with textual question answering and trained models that determine the best answer within a document. The search platform is available to the participating clinicians over a web app accessible via mobile web browser on both Android and iOS devices. Research staff trained the onboard clinicians and helped to install the Medwise.ai search on the participating clinicians' mobile devices ahead of observations.

Content development for Medwise.ai was informed by informal interviews (Multimedia Appendix 1) with staff and a single focus group, consisting of 14 participants, to identify relevant local guidelines and standard operating procedure documents to be included in the Medwise.ai platform, thus ensuring user buy-in and optimal functionality of the Medwise.ai platform. The local documents shared with Medwise.ai were in PDF or Microsoft Word format. It is important to note that searches using Medwise.ai were limited by the content available in the local repository; if the content did not exist within this repository, the AI would not be able to provide answers to queries. It should be noted that the underlying AI model's technical performance was not the focus of this study.

Research Procedure

A dedicated and trained member of the research team shadowed trainee doctors for 20 complete working days: observation days included 10 days without and 10 days with access to Medwise.ai. The 2 groups of participants were not matched for the hospital intranet versus AI-supported search engine using groups.

Doctors reviewed new admissions and conducted unscheduled reviews of previously admitted patients: the doctors were aware that they were observed, and written consent was taken prior to commencing the direct observation. The observed activity of doctors was entered into a work diary. For practical reasons, all observations were undertaken during office hours.

Sampling and Recruitment

The sample size was chosen pragmatically based on experience with previous time-motion studies [4]. Doctors working as part of the acute medical take throughout Ysbyty Gwynedd were recruited. To be included, participants had to be willing and able to give informed consent for participation in the study, be in possession of a smartphone to access web-based content, be permanent or locum staff, and be qualified as a doctor of any

XSL•FO
RenderX

grade. Participants had the right to withdraw from the study at any time. Participants received vouchers with a value of US $50 for participation in the study. Doctors who were only part of the clinical team for 4 hours or less were excluded from recruitment.

Candidates were approached by the principal investigator (CPS) or the dedicated research team member. Notification of the study was undertaken through existing WhatsApp groups and a Junior Doctors' Forum. Inclusion and exclusion criteria were identified during the initial screening.

Assessments

Participants' gender, specialty, grade, duration of work in their current post, and duration of clinical practice were recorded. Participants were shadowed for the duration of a shift but for a minimum of 6 hours per study day. Shadowing did not include times when doctors were consulting or examining patients.

Task duration for clinical queries was measured in minutes. Tasks were classified using a standardized list. Observed searches for information were classified by clinical content (diagnostic category, diagnostic pathway, treatment protocols, prognostication, scoring systems, normal values, and accessed data source). Confidence in decision-making was assessed at the end of each working day using a validated scale for self-assessment [5]. Confidence in decision-making and user satisfaction were measured using the Likert scale (How satisfied are you with the Medwise.ai product? On a Likert scale of 1-10) and the Net Promoter Score (NPS) [6] (How likely are you to recommend Medwise.ai to a friend or colleague?). NPS is a validated score that is used to measure user satisfaction. It is widely used in industry as a benchmark for comparing products within different industries. A positive NPS is considered as good, a score above 20 as favorable, and above 50 as excellent. Participants were also asked for suggestions for improvements of the platform.

Data Management and Statistics

Statistical analysis was primarily descriptive including key data items related to the frequency of clinical searches, the subject of such searches, the time taken for the searches, and graded feedback in relation to the app. Data were recorded on paper case report forms and subsequently transcribed into a Microsoft Excel database for further analysis. Data were anonymized through the removal of name, case report number, and age.

The comparison was made between the events during 10 observed shifts without the app and 10 observed shifts with the app. Diary data and data from questionnaires were analyzed using SPSS (IBM Corp). Kernel density plots were used to visualize the differences in observed task duration; Welch *t* test (2-tailed) was used to determine whether the apparent differences in distribution were likely to have occurred due to random chance or were due to a real difference in the mean task duration.

Given the sample size and the unknown baseline distribution of the variables in question, statistical comparison data from this study might inform subsequent power calculations for related research or a definitive trial.

Ethical Considerations

National Health Service (NHS) Research Ethics Review was not required as the study involved staff only as participants. The study was approved through Health and Care Research Wales and the Health Research Authority. No adverse events were anticipated. However, monitoring was in place in line with the sponsor safety reporting standard operating procedure. Data from focus group meetings were anonymized and deidentified. Written informed consent was given by all members of staff who were observed during the assessments. Participants were reimbursed with £50 (US $61.92) retail vouchers according to local regulations.

Results

Demographics and Baseline Characteristics

All assessments were undertaken between November 17, 2022, and February 8, 2023 (hospital intranet period) and July 6 and 27, 2023 (AI-supported search engine period).

The hospital intranet and AI-supported search engine groups both comprised 10 doctors each with 5 and 7 female doctors, respectively. The hospital intranet group had a median clinical experience of 23 months. Of these, 6.1 months were in their current specialty. The AI-supported search engine group had a median of 54 months of experience. Of these, 9.6 months were in their current specialty. No statistically significant differences between mean time in current specialty were observed between the groups (t=−1.01; 95% CI −11.4679 to 4.0179; P>.05).

Focus Group

The focus group was held on April 5, 2023, after the completion of the hospital intranet period. In total, 14 clinicians participated including foundation year 1 and 2 doctors, registrars, physician associates, and 3 consultant physicians. Participants were asked a list of prepared questions in relation to search habits, preferred information sources, and views about search engines (Multimedia Appendix 1).

Contributors discussed sources of information that they use for their clinical practice and recommended examples of web resources from other NHS organizations. Pros and cons of alternative models of information provision including share point sites were debated. Clinicians commented on the difficulties to find the right locally authorized resources in locations of the internet and intranet. On the other hand, they valued that Medwise.ai guidance is relevant for the organization in which the search is undertaken. Participants discussed their experience of using resources from other UK and international organizations if there is no identifiable local guidance for a topic. Doctors were concerned that Google searches might identify sources that contain misinformation. The challenge of identifying the right information in real time was described as crucial during the time pressures of acute and emergency care.

Descriptives

Overall, 67 searches were observed in the hospital intranet and 39 searches in the AI-supported search engine period. The mean number of clinical searches performed per shift was 6.7 (SD 3.43) in the hospital intranet group and 3.9 (SD 3.00) in the

XSL•FO
RenderX

AI-supported search engine group. Mobile phones were used for 40 of 67 (60%) searches in the hospital intranet group and 34 of 39 (85%) in the AI-supported search engine group. In the hospital intranet group, 11 searches were via Google. Other sources included apps, the British National Formulary, National Institute for Health and Care Excellence guidelines, and local guidelines. In the AI-supported search engine group, no search required Google.

Searches covered a large number of topics (Multimedia Appendices 2 and 3). The most commonly searched topics in both groups were medication-related (n=18 and n=10, respectively).

Participants in the AI-supported search engine group commented on the impact of Medwise.ai on workflow using free-text responses (Textbox 1).

Textbox 1. Free-text feedback provided by users collected at the end of observation.

"With more training [training of the AI system] this could be very helpful in speeding up carrying out jobs. Bit unfortunate study was carried out in final weeks of rotation, when doctors are the most comfortable with systems and need to search things very rarely" [Participant 1].

"Can see it has the potential to increase speed of doing jobs, thus means we see patients quicker" [Participant 2].

"May expediate time available for patient care if brings up more precise answers. When I know where to find the answers it is easier to go straight to the source" [Participant 3].

"As you get your answers under one second from hospital protocol, it saves time and helps you see more patients. also can provide more time for patient care rather than looking for protocol and guidelines in each app, it will be all in one. Highly recommended" [Participant 4].

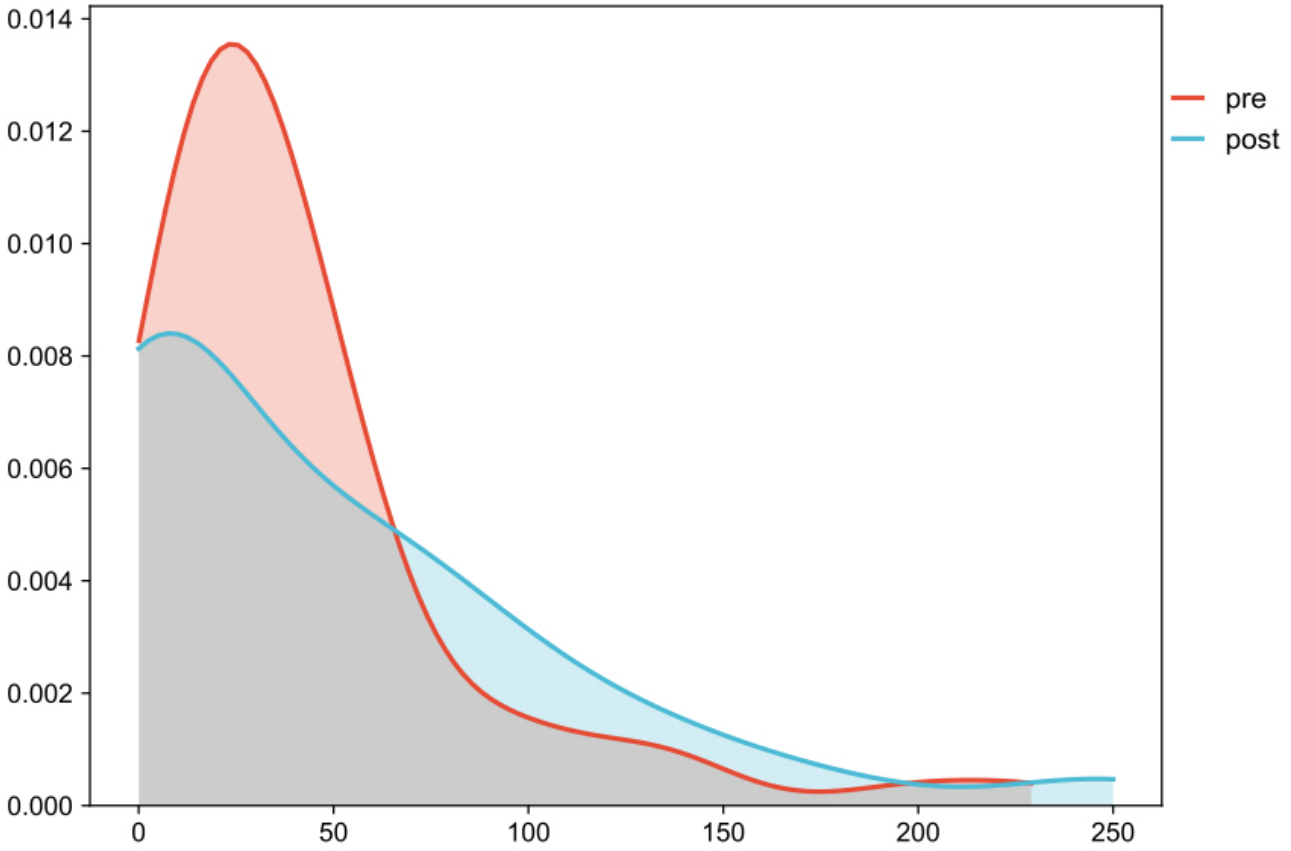
"Probably not much difference. Perhaps better used in GP. I think it would be more useful in GP. In hospital it is okay but not majorly useful. I think over all it would be a good idea. But I think I search for stuff more in GP. I think overall ED staff would use it most in hospital" [Participant 5].

"Easy availability of resources saves up time and causes less disruption to the flow of clerking. Easy access to BCU/local guidelines is very helpful as some of these are difficult to find on the intranet. Great idea; would be really helpful" [Participant 6].

"Will reduce search time for searching guidelines resulting in more time for patient care. And all in one place makes it easy to find [information]. I am surprised that I have not needed to access my phone/ the app as yet today as this is unusual. Would usually look at betsinet multiple times during a shift for electrolyte levels. I anticipate that this app would be useful" [Participant 7].

"Makes it easier to search for relevant guidelines/policies/pathways etc. Easy and quick to use. User friendly. Appears to work well for searches during work time. Quickly found everything I searched for" [Participant 8].

"Will help find relevant guidelines much more quickly, which will make work more efficient" [Participant 9].



"Directed me to mdcalc which I already use as an app. No impact on above criteria (workflow, number of patients seen and time for each patient). Would be more useful to have easy access to trust guidelines such as electrolyte imbalances and chest pain etc." [Participant 10].

Comparison of Groups

Comparison of the 2 groups revealed that searches in the hospital intranet group had shorter search times than in the AI-supported search engine group (41.4 vs 88.1 seconds, respectively; Welch t=4.06; 95% CI 20.30-59.09; P<0.05). The differences in the observed task duration are presented as Kernel density plots in Figure 1. There were no statistically significant differences between the groups with regard to user satisfaction (Welch t=0.75; 95% CI −1.2607 to 2.6607; P>.05) and likelihood of a search result solving the query (χ^2=2.2; 95% CI −3.24% to 27.45%; P>.05). Participants of the AI-supported search engine group were likely to recommend Medwise.ai to a friend or colleague as reflected in their NPS of 20 (40% promoters and 20% detractors).

XSL•FO
RenderX

Figure 1. Kernel plot of the duration of searches pre (hospital intranet) and post (artificial intelligence–supported search engine) phase.

Overall, the group using Medwise.ai spent longer searching for information, and their searches were not more likely to be successful compared to the usual information retrieval methods.

Discussion

What We Have Shown

To the best of our knowledge, this is the first study to evaluate the impact of an AI-based information retrieval system on clinical workflow in acute hospital care. The design and implementation of a clinical information search engine integrating intranet- and internet-based information resources using machine learning was feasible and well-received by participants.

Searches in this small sample were not faster, and there was no higher likelihood of a successful search result. Despite this, doctors believe Medwise.ai has the potential to improve efficiency and workflow in the future and hence highly recommended the digital tool to their colleagues.

Strength and Weaknesses

One of the strengths of our study is that it uses objective measures of efficiency including search times and search outcomes rather than relying on self-reported questionnaire data from users. This mitigates recall bias. Additionally, the free-text feedback from users provided useful insights in that it shows that despite Medwise.ai's limitations, the users were optimistic about its potential in the future and expressed views in favor of its implementation in clinical workflow, as evident in quotes in Textbox 1.

It is worth noting that no specific training in evidence searching was provided to the participants beyond what they would have received as part of their usual medical education. This lack of additional training could be seen as both a strength and a limitation of our study. On one hand, it reflects the real-world scenario where clinicians often rely on their existing search skills when using new tools. This approach allows for a more authentic assessment of the AI-supported search engine's usability and effectiveness in a clinical setting. On the other hand, it raises questions about whether targeted training in evidence searching or in using the new platform might have improved search efficiency and outcomes. The ideal search engine should require minimal introduction or training, but understanding its functionality could potentially enhance search yields. Future studies might consider comparing the performance of users with and without specific search training to better understand the impact of such preparation on the effectiveness of AI-supported search tools in clinical practice.

The initially unfamiliar user interface could have been a significant contributor to the longer search time. Additionally, the introduction of the AI-supported search engine occurred toward the end of the rotation when doctors were most confident about the processes and management of patients. Participants had spent an average of 8 months in their current specialty, throughout which they would have regularly used traditional information retrieval sources.

Our observations and user feedback highlighted several areas for potential improvement in future iterations of the AI-supported search engine. First, we recognized that the platform was initially developed for desktop use, but mobile

XSL•FO
RenderX

access emerged as the preferred method in the acute care setting. In response, the platform's developers are working on a mobile-first version, including dedicated iOS and Android apps, as well as access via a chatbot interface on WhatsApp. This adaptation aims to improve user experience and reduce search times. Additionally, we noted that the more experienced intervention group might have been less accustomed to new digital formats, potentially impacting their interaction with the novel interface. To address this, future iterations could incorporate more intuitive design elements and provide brief, targeted training to familiarize users with the system's capabilities.

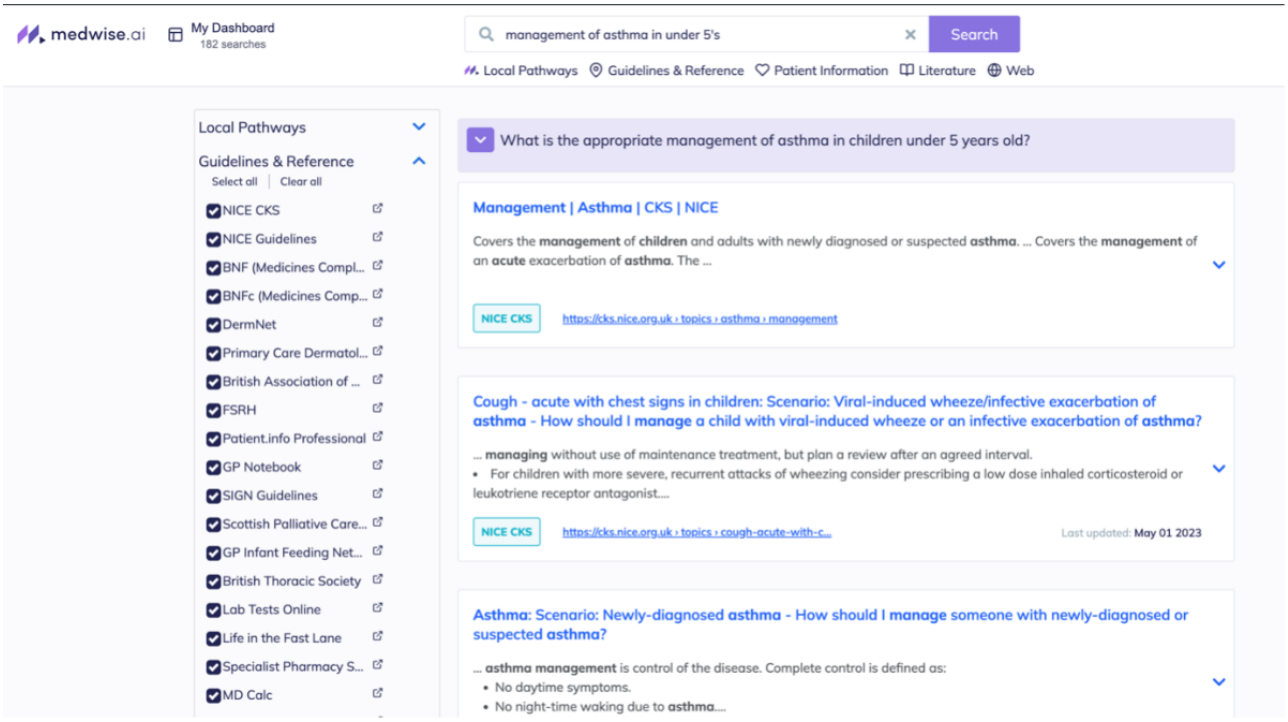
In our pilot, Medwise.ai was neither more nor less efficient, successful, or satisfying to users than traditional information retrieval sources. Searches using Medwise.ai were limited by the content available: if content did not exist within the local repository, then the AI will not be able to provide answers to queries. Finally, the local documents that were shared with Medwise.ai were in PDF or Microsoft Word format. Further development to transform these documents into more machine-readable formats with seamless integration with the search could further improve the performance of the Medwise.ai search engine. Like all AI-based tools, Medwise.ai's performance is contingent upon the quality and quantity of data used to train the tool. As the bank of searches builds up over time, Medwise.ai would be able to offer easier and faster access to reliable local guidelines.

The effectiveness of the search engine is dependent on the underlying AI models' performance. Although not a focus of this study, it is an area for future attention, particularly with the growing use of large language models.

What Others Have Shown

The NHS Long Term Workforce Plan [7] emphasizes the need to leverage the power of AI to improve efficiency and workflow. This case study is an example of a technological innovation to improve work efficiency with the end goal of improving patient care. It contributes to the literature focusing on evaluating the potential of AI-based technologies to improve service provision in the NHS [8-10].

Clinical Implications



The search engine was implemented successfully during this trial. With the clear hierarchy of information sources, Medwise.ai might represent a source that has higher utility for clinicians at the bedside than public search engines such as Google or Safari. While it has been hypothesized that AI could aid to bring clinical guidelines to routine consultations [11], clinical apps remain scarce [12]. Moreover, evidence suggesting a significant reliance on colleagues and internet websites for information retrieval during shifts makes a strong case for the need for easy-to-access evidence-based local guidelines [13].

Research Recommendations

Given the small sample size and the unknown baseline distribution of the variables in question, statistical comparison is expected to be of limited value. A larger study with randomization of doctors at the beginning of rotational posts might provide a more robust assessment. The authors believe that less experienced clinicians (foundation year 1 trainees or advanced nurse practitioners in their first year of practice) would rely heavily on digital information sources and would be equally unfamiliar with other information retrieval methods and might hence be the most suitable group to evaluate effects on decision-making, safety, and possible clinical impact. More recent developments in AI such as large language models have shown the ability to encode clinical knowledge and answer medical questions [14]. Integrating these into the Medwise.ai engine might improve accuracy and speed. In the proof-of-concept platform, a full-text, query-augmented, retrieval engine configured and tuned for medical searches was used (Figure 2). No large language models were used. Further research is needed to evaluate how the accuracy and performance of the proof-of-concept search engine could be improved by incorporating large language models into the engine.

XSL•FO
RenderX

Figure 2. An image of the platform's search reply.

Conclusions

Implementation of Medwise.ai was feasible. In this small pilot study of an AI-supported search engine, we did not demonstrate increased workflow efficiency, search success, or satisfaction when compared with searches using the traditional hospital intranet. However, doctors in training believed the solution has the potential to do so in the future and hence recommend its implementation in clinical workflow. With added source content and integration of the Medwise.ai search with the next generation of AI large language models, it is likely that more benefits will be realized.

Acknowledgments

Marie Latham-Jones and Lynne Grundy were instrumental in establishing the connection between Betsi Cadwaladr University Health Board and Medwise.ai. Laura Longshaw was the driving force behind the progress of this grant. Without her encyclopedic knowledge of research frameworks, forensic attention to detail, unmeasurable patience, and immense commitment, the authors would not have succeeded. Without Gareth Jones' contribution to the recruitment of participants in the artificial intelligence–supported search engine group, the study would not have been completed on time. A big thank you! The study was funded through an Innovate UK grant administered through Medwise with Betsi Cadwaladr University Health Board as a coapplicant (Innovate UK grant application 10023176).

Conflicts of Interest

HLKT, LRUP, and MP are employees of Medwise AI Limited. The authors have no other conflict of interest.

Multimedia Appendix 2
Clustered column chart showing the distribution of search categories in the hospital intranet period (control) and artificial intelligence–supported search engine period (intervention). "General calc" comprised of calculating medication doses and converting units of measurements. "Interpreting invx" meant finding information about the significance of specific findings on investigations including plain films, electrocardiographs, and blood results. "Medication" meant medication-related information, that is, dose, route of administration, and interactions. "Scoring systems" meant users calculating prognostic scores including Well score. "Staff contact" meant looking up bleep numbers for other members of the health care workforce. "Term" meant looking up specific definitions. "Treatment protocol" meant treatment pathways for conditions and presenting complaints.

Abstract

Background: Mobile health technologies have the potential to enhance the management, communication, and overall quality of life of patients with cancer. The MyPal project, using a participatory design approach, aims to provide palliative care support for patients with cancer through an electronic patient-reported outcomes eHealth platform.

Objective: This study aims to evaluate the usability and user experience of "MyPal for adults," a co-designed palliative care mobile app designed to support adults with cancer.

Methods: Representative users participated in a 4-step usability study using a "think-aloud" protocol, complemented with feature satisfaction, difficulty perceived, and design impression surveys along with a short, structured interview. Participants were also asked to provide quantitative feedback via the postuse System Usability Scale, User Experience Questionnaire, and Post-Study System Usability Questionnaire. The data were analyzed along the lines of the International Organization for Standardization (ISO) 9241‐210 framework.

Results: All participants found the intervention content useful, and they reported satisfactory usability, with a mean Post-Study System Usability Questionnaire score of 2.458 (SD 1.08) and a System Usability Scale score of 68.9. All aspects of the User Experience Questionnaire (attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty) surpassed usability quality benchmarks. The qualitative analysis identified 43 usability issues, primarily related to effectiveness and efficiency as defined in ISO 9241‐210.

Conclusions: In this study, we conducted a usability evaluation of the "MyPal for adults" app, a digital tool designed to enhance the palliative care experience. This approach identifies real-world usability issues, enabling iterative improvements in the eHealth platform's design. Our findings reveal a user-friendly interface and positive patient experiences. This study emphasizes the need to enhance mobile health platform usability, offering insights to improve digital palliative care.

Introduction

Background

Hematological malignancies (HMs) account for about 6.5% of global cancer cases, primarily affecting older individuals around 70 years old [1]. Patients with HMs often experience distressing symptoms, which can lead to a lower quality of life (QoL) [2]. Consequently, palliative care has emerged as a vital health care practice to enhance the QoL of individuals facing serious, life-limiting illnesses, regardless of age or disease stage [3].

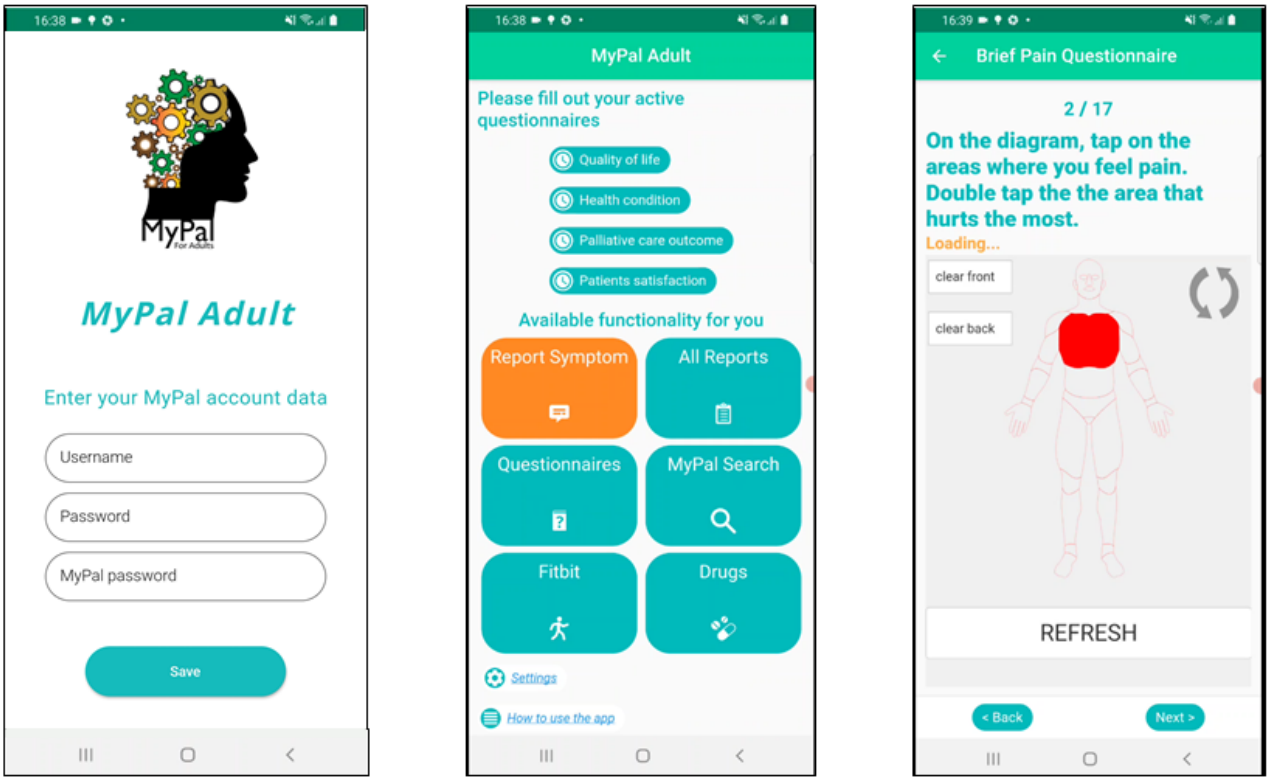
Effective palliative care relies on active patient-health care team communication, where electronic patient-reported outcome (ePRO) systems offer substantial promise [4,5]. These systems enable patients to report their health status, including personal evaluations, symptoms, psycho-emotional state, and adverse drug reactions via defined questionnaires. However, despite their potential to enhance patient care, the widespread integration of ePRO systems in routine health care and research remains limited [6].

XSL•FO
RenderX

Although smart device adoption in health care began increasing even before COVID-19 [7], enabling more direct dissemination of health information, complex interfaces often lead to app abandonment, especially among older users. The Google and Apple app stores offer around one million health-related apps, with approximately 300,000 in the mobile health (mHealth) category [8]. Despite this, mHealth app downloads are declining [9,10], raising concerns about their usability and acceptance, influenced by factors like privacy and usability [11].

To address these challenges, co-design approaches have gained interest [12]. Co-design involves collaborative efforts among researchers, designers, and end users who actively contribute to knowledge development, idea generation, and concept refinement [13]. This user-centered approach fosters a deeper understanding of user perspectives [14] and can optimize the development and usability of palliative care ePRO apps.

MyPal Project



MyPal [15], a collaborative H2020 research project funded by the European Commission, uses eHealth technologies to support adults and children with cancer through advanced patient-reported outcome systems. Its primary aim is to develop and clinically assess 2 new ePRO-based palliative care interventions for adults and children, along with their carers, and health care professionals (HCPs) to enhance their QoL [16], improve effective communication, and management of the disease. MyPal uses a user-centered, iterative methodology involving end users from the project's inception to design various platform components. The design of the MyPal platform and its features were aligned with the needs of patients receiving palliative care for hematologic malignancies, as identified through research conducted during the early stages of the MyPal project. These include symptom management tools (eg, pain and fatigue tracking and spontaneous symptom reporting), psychosocial support features such as customizable motivational messages and emotional well-being assessments via ePROs, and tools for personalized care planning allowing patients to set individual goals and preferences. In addition, the app facilitates advanced care planning discussions by providing educational resources that address both treatment and QoL considerations.

The MyPal platform for adult patients consists of a mobile app for the patient, a web app for the HCP, and tools for the administrator. MyPal also supports young patients (children and adolescents) and their careers in the CHILD study [17] with a serious game for patients, a mobile app for the carer, and a web app for HCPs. These interventions and their associated technologies are to be tested in a randomized clinical trial conducted across 5 countries (Greece, Germany, Italy, Sweden, and the Czech Republic).

This usability study focuses on the "MyPal for adults" app [18] which has an end goal to facilitate (1) better self-management of the HM disease symptoms, and (2) timely assessment of the reported symptoms or QoL deteriorations by treating HCPs. Technical components are demonstrated in an openly available video [19]. The MyPal adult platform includes a mobile app (Figure 1) that supports periodic and spontaneous reporting of physical and psycho-emotional symptoms, using standardized ePROs for periodic reporting and custom electronic forms for spontaneous reporting. These reports, along with the standardized ePRO data, are directly accessible to HCPs via their dedicated platform. HCPs can view reports, track the status of questionnaires for each patient, and be alerted to any symptoms that meet predefined thresholds, ensuring timely clinical intervention. The app also offers features such as medication management, where the patient can set reminders for dosage intake, an HCP-tailored disease, and health information search engine, personalized motivational messages that are sent to patients based on their needs collected via screener questionnaires at specific time points, and tracking of lifestyle parameters like physical activity and sleep quality. Additionally, "MyPal for adults" provides secondary supportive features that are optional for use, including an app tutorial, tech support chat, and contact information for local MyPal liaisons. Overall, the app is provided in 5 languages: Greek, Italian, Swedish, Czech, and English (only for demonstration).

XSL•FO
RenderX

Figure 1. The MyPal mobile app for adult patients: login page, home screen, and example question from the electronic patient-reported outcome module. The interface tested was in Greek; the version shown here is in English to facilitate clear communication of the app's design and functionality.

Objective

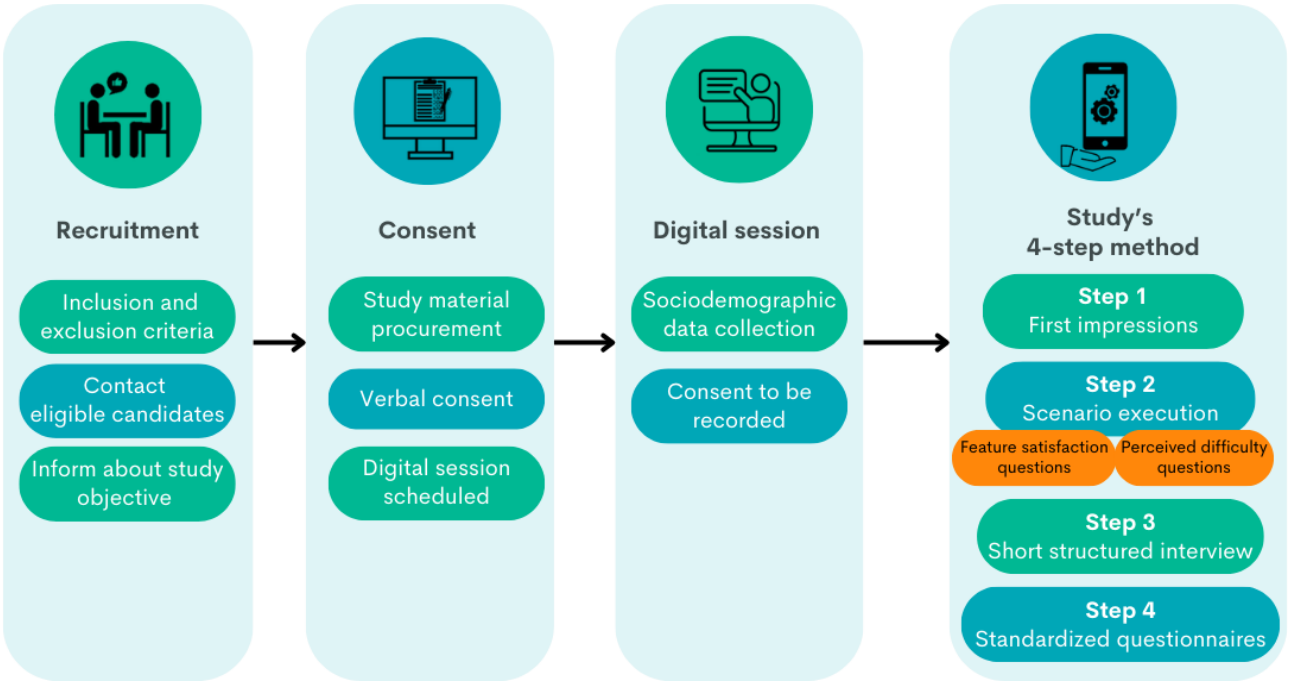
This study aims to evaluate the usability and user experience (UX) of a co-designed, midfidelity version of the "MyPal for adults" mobile app using a 4-step framework, focusing on assessing content, functionality, and barriers experienced by end users.

In that context, the research questions addressed are: Is "MyPal for adults" usable, comprehensible, satisfactory, and acceptable to end users? If not, what are the usability and satisfaction issues in terms of number, type, and severity as evaluated by patients?

Methods

Explorative Usability and UX Assessment

We chose an exploratory approach to assess usability and UX through a 4-step process, including a coaching "think-aloud" protocol [20], structured interviews, and follow-up usability and UX measuring questionnaires: the Post-Study Systems Usability Questionnaire (PSSUQ) [21], the System Usability Scale (SUS) [22] and the User Experience Questionnaire (UEQ) [23] known for their established effectiveness in the literature. This process simulated a patient's journey in the MyPal Adult intervention study, as described in its protocol [2] (Figure 2). Given the COVID-19 pandemic restrictions and the Greek National Health System's advisories against hospital visits, we conducted all assessments remotely using digital tools.



Usability, as per the ISO (International Organization for Standardization) usability framework (ISO 9241 - 210), is "the extent to which a product can be used by designated users to achieve specific goals with efficiency, effectiveness, and satisfaction, in a specific context use" [24]. The criteria of this framework are effectiveness, efficiency, satisfaction, and context of use. Typically, the concept of usability also covers comprehensibility, learnability, functionality (operability), attractiveness, appropriateness recognizability, accessibility, user error protection, and interface aesthetics [25].

As described in ISO 9241 - 210, effectiveness is the accuracy and completeness with which users achieve specified goals, such as symptom reporting. Efficiency refers to the resources used in relation to the results achieved, like the time needed to report a symptom. Satisfaction is defined as the "extent to which the user's physical, cognitive, and emotional responses that result from the use of a system, product, or service meet the user's needs and expectations" [24].

UX is defined as "user's perceptions and responses that result from the use or anticipated use of a system, product, or service." [26]. Good UX not only contributes to higher work motivation and performance but can also affect the well-being of users [27]. Achieving acceptable UX or usability requires systematic evaluation and iterative design adjustments as the app matures [28].

XSL•FO
RenderX

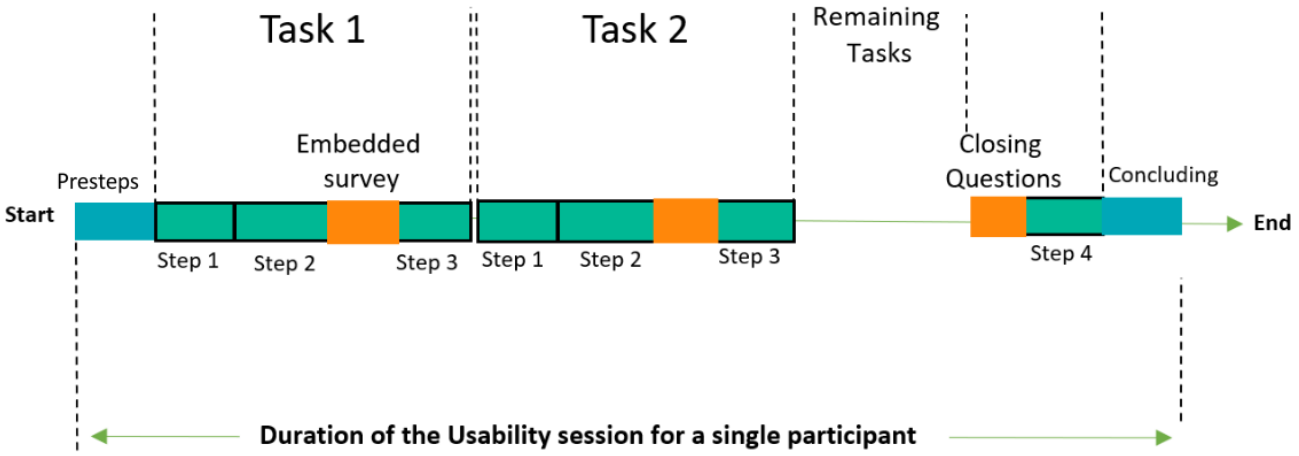
Figure 2. Participant journey in the usability study.

Participant Recruitment

Participants for this study were recruited through nonprobability methods, a mix of purposive sampling to target relevant participants, and convenience sampling to address recruitment challenges during the COVID-19 pandemic. They were recruited based on predefined inclusion criteria in the project's randomized clinical trial protocol [2]. Indicatively, adults (18 years or older) diagnosed with hematologic cancer, who were scheduled to receive or had previously been exposed to any line of treatment, and were users of an internet-connected device (smartphone or tablet). Exclusion criteria included patients requiring immediate referral for specialized palliative care or with a life expectancy of less than 3 months. To this end, given our institution's close collaboration with ELLOK (Greek Federation of Cancer Patients), members were contacted via telephone and email, facilitated by MyPal's clinical liaisons, ensuring the participation of members who are patients with hematologic cancer. Finally, since ELLOK had previously procured volunteers to consult on and test earlier prototypes, we added an exclusion criterion stating that no participant should have had any prior experience interfacing with the midfidelity app in focus. This exclusion criterion was added to ensure that all participants would be "naïve" users, that is, users who have no training or experience with the app, as would be the case for a patient enrolling in the MyPal study.

To address the recruitment difficulties posed by the pandemic and in consultation with our clinical liaisons, the inclusion criteria were expanded to include individuals with other chronic diseases sharing care needs similar to hematologic cancer (eg, autoimmune skin conditions and chronic pulmonary diseases) and recent hospital visits in the last 6 months were also planned to be included as a countermeasure.

Data Collection



Global Process

In alignment with the MyPal Adult intervention study protocol, interested and eligible candidates were informed about this usability study objective and the MyPal project goal, its technologies, and their functionalities, and provided with a detailed informational sheet and contact details for any inquiries. The consent process was also conducted remotely using digital tools due to the COVID-19 pandemic restrictions. After confirming their participation in this usability study, they were emailed with every material a patient joining the MyPal Adult intervention study would receive, specifically the link to download the app, a user manual, and a quick-start guide, offering a summary of the project's goal and the platform capabilities. They were also asked to confirm the appointment for the usability session. Verbal consent was obtained once more by the moderator of the usability study prior to the session initiation.

Each participant completed a single 55- to 70-minute teleconference session, following a structured task-based use scenario (Figure 3). The moderator used a PC with a webcam and the Zoom (Zoom Communications, Inc) platform to record facial expressions and facilitate the sharing of the mobile device screen. Participants were asked to install the Zoom app on their smartphones and laptops prior to the session to enable screen sharing from their smartphones and record facial and vocal interactions via their laptops. For the app testing, participants used their own Android devices; however, the research team had a backup Android device available if needed.

XSL•FO
RenderX

Figure 3. Step sequence in a single think-aloud session.

Preparatory Steps

At the beginning of each session, participants provided sociodemographic information, including age and sex. They also answered 2 multiple-choice questions about their smartphone skills, based on their comfort level and experience with using smartphone apps, including frequency of use, ability to navigate apps, and familiarity with mobile technology in general, and 3 questions on smartphone app use (Multimedia Appendix 1). Following the introduction, the usability study's context, task completion logic (described in the task "scenario" in Multimedia Appendix 2), and the "think-aloud" process were explained in detail. An example task was also presented to familiarize participants with the "think-aloud" method.

Step 1: First Impressions

During the task "scenario" execution, participants navigated to various functionalities' screens. The moderator inquired about the screens' general eye-catching attributes and the users' initial impressions. For each screen, 2 questions were posed: (question 1.1) "What is your initial impression of this screen?" and (question 1.2) "How do you rate the design and information organization?" To gain more detailed insights, a third question was added for each screen (question 1.3): "What actions do you think you can perform on this screen?"

Step 2: Task "Scenario" With an Embedded Survey for Satisfaction and Perceived Difficulty

The second step involved executing tasks within the "scenario," where participants were encouraged to think aloud to identify usability issues, aligning with the "think-aloud" protocol. The "scenario" included in total of 16 tasks (Multimedia Appendix 2). Some of the tasks included multiple-choice questions in the 5-Likert and 7-Likert scale [29], to gather quantitative data on perceived difficulty and satisfaction with specific functionalities. While the satisfaction questions were inquired for every feature in the app, (mainly focusing on modules and elements regarded as important early on in the design ideations), the perceived difficulty questions were more targeted. Difficulty-perceived questions were only inquired during tasks that had performed poorly based on the results of prior assessment procedures (validation, rehearsal testing) within the MyPal project. In accordance with the "think-aloud" protocol, moderators worked with participants during task execution, meaning they would intervene to prompt participants to verbalize their thoughts, or "think-aloud." When a participant struggled with a task, the moderator noted it down and provided guidance. If participants repeatedly encountered issues with a specific action leading to task failure, moderators inquired about the problem's nature to capture participant perceptions and experiences.

Participants' verbalizations about their preferences or dislikes regarding the PROs content were not considered, as it was not the study's purpose. Nonetheless, participants were encouraged to voice their thoughts while going through the content to uncover potential user interface (UI) inconsistencies.

Step 3: Short Structured Interview

After completing the final task in the "scenario," participants were given the opportunity to add anything to their responses regarding feature satisfaction from step 2 and to address any follow-up questions related to the usability evaluation and overall UX. Additionally, 3 extra questions were posed as part of the structured interview following the last task of the "scenario:" (question 3.1) "How do you perceive the secondary complementary supportive features? Would you use them?" (question 3.2) "What would be your first action with this app?" and (question 3.3) "Do you feel the app expects something from you?"

Step 4: Standardized Questionnaires

Before concluding each session, quantitative feedback was gathered from participants using a set of well-established and validated questionnaires. These included the SUS, a 10-item questionnaire rated on a 5-point Likert scale ranging from Strongly Disagree to Strongly Agree, which assesses the overall usability of a system [22]. The UEQ measures 6 distinct dimensions of UX—attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty—using a 7-point semantic differential scale [23]. Finally, the PSSUQ, which is rated on a 7-point scale from Strongly Disagree to Strongly Agree, evaluates user satisfaction with system usability, covering areas such as task ease, efficiency, and interface quality [21]. Participants were then given the option to submit either only the PSSUQ or all 3 questionnaires.

XSL•FO
RenderX

Data Analysis

Steps 1 and 3 ("first impression" and "short, structured interviews") underwent inductive thematic analysis [30], involving transcription and translation of all participant responses into English, along with the calculation of standardized questionnaire scores. In step 2 (task "scenarios"), a deductive analysis aligned with the ISO framework categories was performed [30].

Ethical Considerations

The study received ethical approval from the Bioethical Committee of the Center for Research and Technology Hellas (ETH.COM-61). The study involved human participants and adhered to institutional and ethical guidelines for research involving human participants. Informed consent was obtained from all participants after they were provided with clear information regarding the purpose of the study, procedures involved, data handling, and their right to withdraw at any time without penalty. No waiver of consent was applied. Privacy and confidentiality were maintained throughout the study. All data collected were fully anonymized before analysis, and no personally identifiable information was stored or used in reporting. Any potential identifiers in screenshots or visual material were removed or blurred. Participants did not receive any form of remuneration or compensation for their participation in the study.

Results

Participant Demographics

A total of 9 participants took part in the usability and UX testing. They were recruited from 3 regions in Greece—Thessaloniki, Karditsa, and Heraklion—for feasibility and proximity reasons. The study group included 4 individuals with chronic lymphocytic leukemia (CLL), 2 senior citizens, and 3 adult representative users afflicted by a range of chronic ailments. The gender distribution was balanced, with 4 (44%) women and 5 (56%) men. Participants' ages ranged from 27 to 68 years old, with a mean age of 49.1 (SD 13.6) years, and a median of 17 (IQR 42-59) years. Regarding smartphone skills, participants self-reported varying levels of proficiency: 1 (11%) participant reported poor skills, 2 (22%) participants reported low skills, 2 (22%) participants had medium skills, 1 (11%) participant had high skills, and 3 (33%) participants considered their skills to be perfect. In terms of prior experience with similar apps, 2 (22%) participants had used health-related apps before, while the majority of participants (7/9, 78%) had no previous experience (Table 1).

Table . Participants' sociodemographic data.

Characteristics	Value (N=9)
Gender, n (%)	
Female	4 (44)
Male	5 (56)
Age (years), mean (SD)	49.1 (13.6)
Smartphone skills, n (%)	
Poor skills	1 (11)
Low skills	2 (22)
Medium skills	2 (22)
High skills	1 (11)
Perfect skills	3 (33)
Prior experience with similar apps, n (%)	
Yes	2 (22)
No	7 (78)
Participant's diagnosis, n (%)	
CLL[a]	4 (44)
Chronic arthritis	1 (11)
COPD[b]	3 (33)
HS[c] stage 3	1 (11)

[a]CLL: chronic lymphocytic leukemia.

[b]COPD: chronic obstructive pulmonary disease.

[c]HS: hidradenitis suppurativa.

Participants' Feedback

Step 1: First Impressions

Overview

This section presents the results from open-ended questions gathered during the first impressions collection step, translated into English. Each participant is referenced by an assigned ID (eg, P1 and P2). The analysis of these initial impressions is based on themes that emerged during the inductive thematic analysis.

Question 1.1: "What Is Your Initial Impression of This Screen?"

Every functionality and screen received a positive first impression. No one expressed any major dislikes or was annoyed by something particular in the design. The only negative comment was about the app's icon:

> *I don't particularly like that the icon's portraying a human head that is black like it is burned. Also, the gears appearing like they are inside the head makes me cringe a little bit.* [P4]

Question 1.2: "How Do You Rate the Design and Information Organization?"

As question 1.2 significantly overlapped with question 1.1, participants had already developed an impression of each screen's design by the time question 1.1 was posed. All participants neutrally accepted every screen in each functionality, with minor feedback primarily related to button placement and text entry field colors.

When analyzing participant responses, 2 distinct user groups emerged: young users (25-35 years of age) and senior users (45-70 years of age). While younger participants desired a more modern app design, they found the app's current design very user-friendly.

> *It would be very good if there was an additional UI with a more modern design, like with a side menu etc but I guess this would be more helpful with older patients as well. I don't really mind it as long as it proves easy-to-use and useful. Which I guess it will ... at least it seems that way.* [P8]

The color palette of the app and the simplicity of the design were very much appreciated by the more senior users.

> *I really like the colors, they are quite soothing, and give me the "health care" vibe. Everything seems quite simple and straightforward.* [P2]

Question 1.3: "What Actions Do You Think You Can Perform on This Screen?"

The main purpose of this question was to determine if the context of use for each functionality was evident from the screen's appearance and whether the action-probing screens were distinguishable from the informing and data-viewing screens. Almost all participants correctly identified the main purpose of each screen, except for one participant (P9), who was a senior patient with limited technology experience.

> *I understand that the purpose of this screen is to help me manage my disease. I guess it will ask me somehow about my medication. Can I speak to it? I don't understand how to do this or what to do.* [P9]

Step 2: Task "Scenario" With an Embedded Survey on Satisfaction and Perceived Difficulty

We identified 43 problems in the task "scenarios," which were classified according to the categories defined as part of the ISO 9241‐210 framework. The task can be found in Multimedia Appendix 2. Most problems (10/43, 23%) occurred during questionnaire submission at task 3. Other tasks with notable problems were drug entry (5/43, 12%) and reminder setting in the drug module (8/43, 19%) at tasks 11 and 12, respectively.

Table 2 presents the problems mapped to the main categories defined by the ISO usability framework, an example for each, and the transcript or description of the observation. It also presents the task where the problems occurred and the type of the problem. Some tasks could not be completed because of programming errors or bugs. When problems were caused by programming errors, they were classified as N/A (not applicable) in each ISO framework category and the task was considered failed. In those cases, a screenshot was displayed of the broken feature to enable the continuation of the study.

About 30% (13/43) were classified as "effectiveness" and took place mainly at the "add a drug" task, where users were asked to log their medication. A total of 23% (10/43) were classified as "efficiency" and occurred mainly at the registration process during the baseline filling-out questionnaire mainly affected by the repetition of text at each step of the registration process. In the MyPal Adult intervention study, prior to the "MyPal for adults" app's regular use, a baseline data collection is taking place immediately after logging into the app for the first time, as part of the app's registration process. The registration process was a relatively new feature, that was not thoroughly tested prior to this study, and problems were expected. It is presented in a step-by-step manner guiding the user to complete all baseline questionnaires and configure app initial settings. In addition, a notable efficiency issue was related to task 16, and the time needed to locate the emergency contact number of the local liaison team in the app. A smaller portion (9/43, 21%) related to "satisfaction" and was mainly noticed in the medication reminder setting task, which was perceived as overly complex by most participants, hindering their satisfaction with it. Two problems were classified as context of use. These problems were identified by a single participant, and both could be explained by the fact that this participant was a senior user, not experienced with mobile apps. The problems coded as the context of use included the following: (1) the participant tried to use the MyPal patient-tailored disease-related information search engine to "ask a question" (expecting a chat function) to the clinicians and (2) the size of some UI elements, that is, the module buttons, text displayed. Finally, 21% (9/43) of the problems were classified as N/A and were related to technical issues, such as software bugs or errors, that were outside the scope of usability-related classifications (effectiveness, efficiency, etc). These technical issues arose from system updates occurring during the usability testing and could not be

XSL•FO
RenderX

classified according to the ISO usability framework. Most of these problems occurred mainly in the Fitbit module when attempting to view the sleep data, setting drug reminders, and accessing the patient-tailored disease-related information search engine.

In Figures 4 and 5, we present the results of the feature satisfaction and perceived difficulty questionnaires which complemented the usability task "scenario." The question formulation can be also found in Multimedia Appendix 2.

As shown in the figures, most of the functionalities of the app were rated as satisfactory and easy to use. However, the medication reminder feature stood out as overly complex for some participants, leaving a portion either unsatisfied or indifferent. Another noteworthy observation concerns the questionnaire module. While most participants found it generally satisfactory, they struggled to locate it quickly, suggesting the need for a more intuitive or descriptive heading. Regarding the ePROs and questionnaires overall (including personalization surveys and symptom reporting), some dissatisfaction and difficulty were noted, largely due to efficiency issues. These stemmed from repetitive text at each question and high question volume, which impacted the UX, and even had some participants thinking it was a technical bug with the system.

Table . Problems with the app, classified according to the International Organization for Standardization framework.

ISO[a] categories	Problems (n=43), n (%)	"Scenario" section and task number (example)	Verbalization or observation (example)	Problem detected (example)
Effectiveness	13 (30)	App registration process (task 2)	"So, I can see here the clinics communication information, so I guess I tap on next"	Setting up the notification timing choice was not visually clear and as a result the participant did not notice it and moved on.
Efficiency	10 (23)	Custom personalization surveys and ePROs[b] impression (task 3)	"Why are the same texts repeated? Wouldn't it be better to have them all grouped so the texts wouldn't have to be repeated?"	There are a lot of seemingly repeated questions in a questionnaire, where only a small phrase would change, and all the other wordings would stay the same.
Satisfaction	9 (21)	Login and initial settings (task 1)	"Is this normal, or is it a bug? In any case it should not be like that"	Password needs to be protected. When the passwords are entered, they could be hiding with asterisks.
Context of use	2 (5)	Patient tailored disease-related information search engine (task 14)	Participant is entering a question directed to his clinicians	The participant did not understand that this is a search engine.
N/A[c]	9 (21)	Fitbit Module (task 9)	"It doesn't work. I am pressing the button but I cannot see my sleep data"	There is a technical issue with a specific button, the participant cannot watch his sleep data.

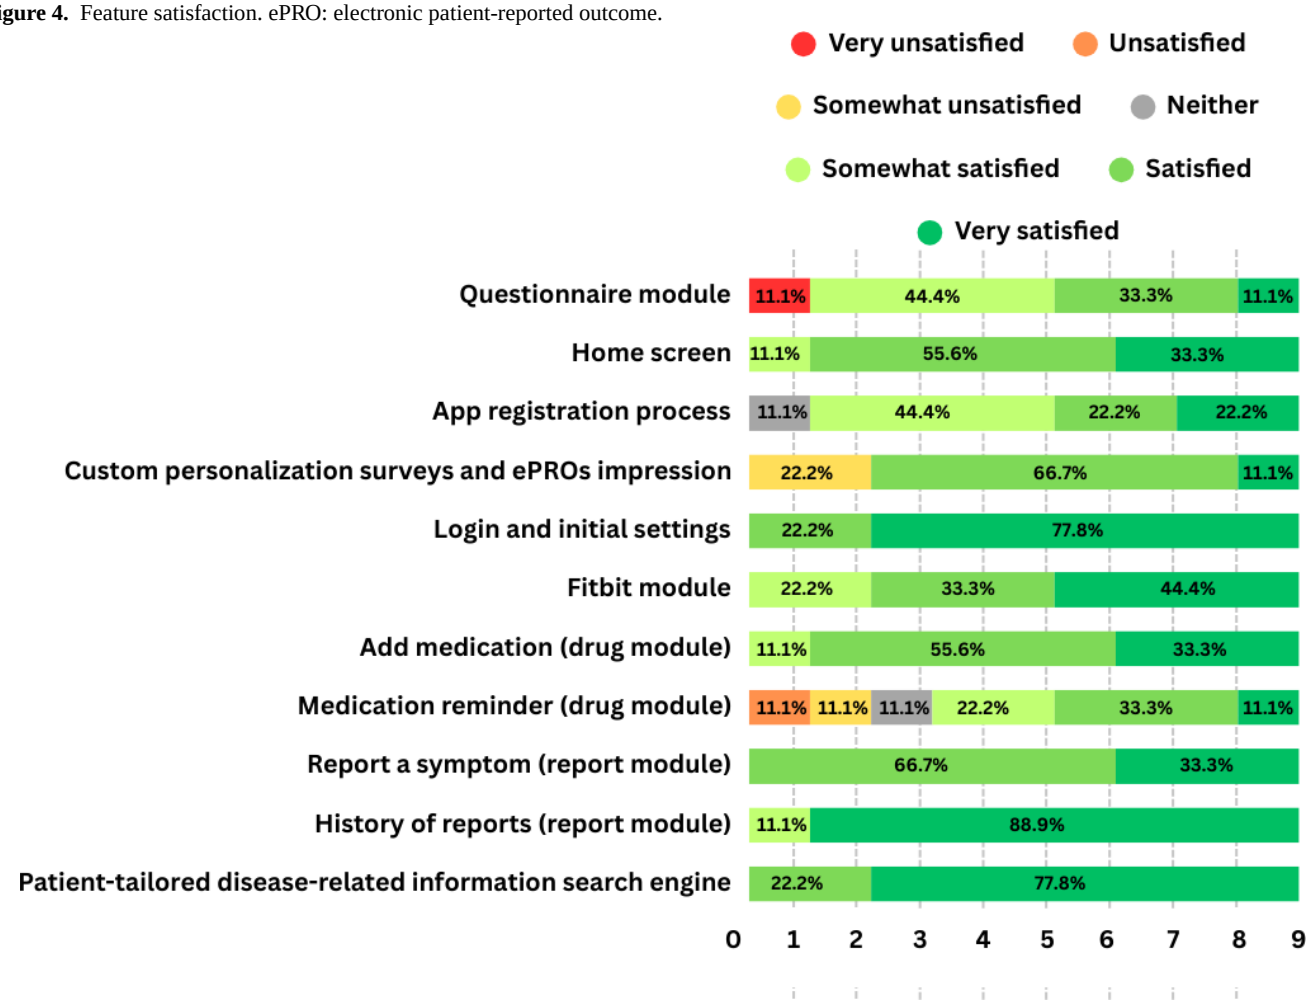
[a]ISO: International Organization for Standardization.

[b]ePRO: electronic patient-reported outcome.

[c]N/A: not applicable.

XSL•FO
RenderX

Figure 4. Feature satisfaction. ePRO: electronic patient-reported outcome.



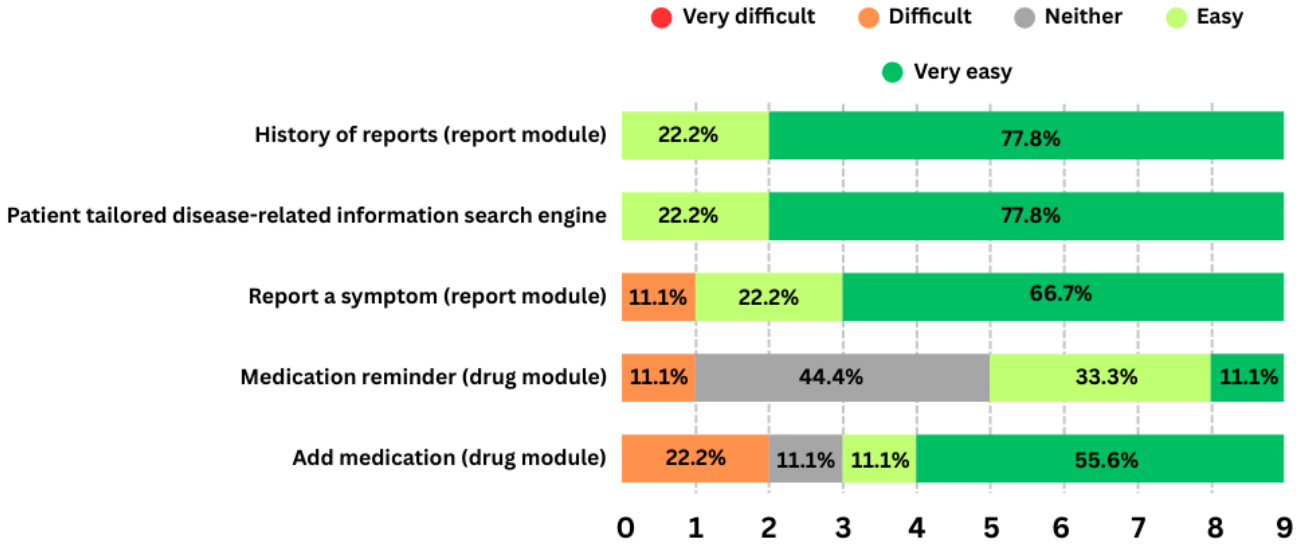


Figure 5. Task difficulty.

Step 3: Short Structured Interview

This section presents the results from the open-ended questions, translated into English, collected during the structured interview process that followed the task-based "scenario."

Question 3.1: "How Do You Perceive the Secondary Complementary Supportive Features? Would You Use Them?"

All participants expressed their willingness to use every complementary supportive feature. The tech support chat was very appreciated, as well as the app's manual.

XSL•FO
RenderX

> *I really like the fact that the manual of the app is in the home screen and so easily accessed.* [P3]
>
> *I really appreciate the chatting service for technical support. I feel like I could do this.* [P7]

Question 3.2: "What Would Be Your First Action With This App?"

This question aimed to determine if participants would prioritize pending questionnaires. However, participants' responses were inconclusive regarding this objective because all users, being new to the app, expressed a desire to explore and become familiar with it instead of immediately focusing on the active pending questionnaires.

> *I would like to familiarize myself with the app at first. I would just browse through everything and start playing with it, I guess.* [P8]
>
> *I would most likely first enter my medications and set reminders for them. Then I would probably report something retrospectively.* [P2]

Only 2 users expressed the desire to first navigate to the questionnaire module or the questionnaire pending list so they can verify they have completed everything is expected from them:

> *I guess first step is to familiarize myself with the app and make sure that I have reported everything I must since I can see in the pending list that there are a few questionnaires available for me.* [P4]
>
> *Well, I am a gadget geek so I would want to explore the whole app. But first I would navigate to the questionnaire module to make sure everything is set.* [P1]

Question 3.3: "Do You Feel the App Expects Something From You?"

This was a follow-up to question 2, ensuring that pending questionnaires were clear to all users. All participants except one did not grasp the main purpose of the pending questionnaire list on the home screen. The participant who understood its purpose admitted it was not obvious and required guidance from the moderator.

> *Yes, of course it is expecting me to answer these pending questionnaires displayed in this list. But I have to say if you had not asked me before I would not notice it right away. I would eventually but not right away.* [P5]

Step 4: Standardized Questionnaires

Following every session, the participants were asked to submit a follow-up questionnaire that included the postuse SUS, the UEQ, and the PSSUQ. All participants submitted every questionnaire. The mean scores of each questionnaire are presented in Table 3.

XSL•FO
RenderX

Table . Poststudy standardized questionnaire scores.

Standardized questionnaires	Value
PSSUQ[a,b]	
SYSUSE[c] score, mean (SD)	2.14 (0.74)
INFOQUAL[d] score, mean (SD)	2.70 (1.09)
INTERQUAL[e] score, mean (SD)	2.77 (1.48)
Overall PSSUQ score, mean (SD)	2.46 (1.08)
SUS[f,g] score	68.9
UEQ[h,i] means, mean (SD)	
Attractiveness	1.667 (0.574)
Perspicuity	1.444 (0.728)
Efficiency	1.500 (0.671)
Dependability	1.361 (0.6)
Stimulation	1.528 (0.52)
Novelty	1.306 (0.825)

[a]PSSUQ: Post-Study System Usability Questionnaire.

[b]Scale: 1=strongly agree or best score to 7=strongly disagree or worst score.

[c]SYSUSE: System Usefulness.

[d]INFOQUAL: Information Quality.

[e]INTERQUAL: Interface Quality.

[g]Scale: 0=worst usability to 100=best usability.

[h]UEQ: User Experience Questionnaire.

[i]Scale: –3=worst to +3=best.

Discussion

Principal Results and Findings

This study assesses the usability and UX of the "MyPal for adults" app in the early phases of the MyPal project. Results from the usability test yielded a marginally positive SUS score of 68.9, as per Brooke [22]. UX results were favorable, as evidenced by UEQ means and user feedback. PSSUQ also showed a positive outcome (mean 2.46, SD 1.08), with higher ratings for usefulness compared to information quality and UI. While all quantitative data indicated an acceptable score, a closer examination of participant responses revealed the primary issues with the app. User feedback emphasized the importance of tailoring specific interface elements, such as wording changes (eg, "Questionnaires" to "My Questionnaires"). Additionally, technical bugs in 2 features and repetitive text in ePRO screens reduced satisfaction and utility. Furthermore, certain functions, particularly the Medication module, were seen as overly complex, requiring refinement to enhance ease of use. Despite these challenges, users expressed a desire to engage with the app and appreciated its potential once they became familiar with its features.

Findings from step 1 confirm that all participants found the presented information comprehensible, with a clear organization of information. However, participants made numerous proposals, suggesting a potential need for a more personalized interface that accounts for age-related preferences. Older users appreciated the app's simplicity, while younger users preferred a more modern and visually engaging design. The feedback primarily focused on button placement, header wording, and contextual text. Given that these differences between age groups were consistently observed throughout the study, a dual-tiered UI could provide an effective solution. Such an approach would allow users to choose between a more visually appealing, modern interface and a minimalist, straightforward design better suited for older adults or those less familiar with technology. This tailored UI could help mitigate issues related to horizontal comprehension and ensure that every module's screen has its purpose understood by all participants.

Findings from step 2 revealed more major issues in the drug reminders and emergency contact detail modules compared to the minor issues found with the app's core functionality, the ePRO submission, which mainly related to wording and information displayed refinements. Participants found the medication reminder function confusing and overly complex and indicated they were unlikely to use it. Interestingly enough, during the "think-aloud" part of the study, most participants also dismissed this as an issue by pointing out that they already have a system and keep a medication log with reminders in place, making this feature possibly redundant. Locating emergency contact information was challenging for all participants, which in an emergency situation, could prove vital.

XSL•FO
RenderX

Participants suggested a more obvious approach, where the information can be found at the top of the home screen, which arguably could hinder usability by limiting the available screen to essential app functionalities and should be further explored. Additionally, 2 modules faced technical problems: (1) the search engine module and (2) the activity data display in the Fitbit module. The search engine module experienced unexpected bugs because the study was conducted on the development server, while the Fitbit module had difficulties connecting to the Fitbit server during the project's early development phase.

In general, based on the questionnaire results, the participant's attitude, and our overall impression and experience of the usability study, participants enjoyed using the app, and in many cases, they complemented their feedback with suggestions for UI-related details and expressed concerns about module titles or text. For instance, "Questionnaires" could be improved to "My Questionnaires" to clarify its purpose. An interesting realization was the importance of translating paper-based PROs into digital "ePROs" successfully. Unlike paper-based PROs presented on a single sheet, ePROs in the "MyPal for adults" app had individual screens for each question, leading to perceived information redundancy and concerns about falsely perceived technical issues. Participants also raised concerns about HCPs' ability to respond promptly to MyPal reports due to their busy schedules, which could affect the UX of patients, aligning with previous research on chronic pain monitoring [31].

Findings from step 3 indicate that participants were eager to explore and familiarize themselves with the app before engaging with specific tasks, such as completing pending questionnaires, an encouraging sign of positive anticipation for using the system. Additionally, many expressed a desire to explore the app, set up medication reminders, and retrospectively report symptoms. The accessibility of the app's manual was highly appreciated, especially by more senior participants, who also were positively surprised, and even relieved, when they realized the app had its own tech support functionality. Further investigation revealed that senior users anticipated complex background computations, and the availability of tech support reassured them. One of the app's core functionalities, facilitating ePRO submissions, was supported by in-app reminders and notifications, as well as a list of pending ePROs prominently displayed on the home screen to draw users' attention upon opening the app. While some participants quickly identified the pending questionnaire list, others required additional guidance, underscoring the need for clearer design cues or onboarding processes to ensure critical tasks were not missed.

Finally, the importance of iteration in the development cycle must be highlighted since all participants had problems with the presentation of the ePROs, and almost all participants but one missed the pending list of questionnaires, present on the home screen of the app. Although this could in part be attributed to the actual question which was formulated in a way to not betray its purpose, the fact that it was missed completely by almost every participant (all but one) suggests that a redesign of the app following the principles of UX is needed.

Challenges and Limitations

Study limitations include programming errors that interrupted tasks and potentially led to the loss of usability information. These errors endured due to concurrent bug fixes conducted alongside the study. The scheduling challenges related to usability testing caused by COVID-19, compounded by the Greek National Health System's discouragement of hospital visits, resulted in significant delays. Consequently, participants faced programming errors that impeded their ability to complete tasks without issue.

Beyond these limitations, the main challenges were related to the study participants. The purposive sampling method used in this study, while suitable for targeting specific user groups, does introduce inherent selection bias. Participants were chosen based on their medical conditions and alignment with clinical trial inclusion criteria. This limits the generalizability of our findings to the broader population but remains relevant to the specific user group we studied. Furthermore, the nature of usability testing and the absence of blinding may have influenced participant feedback, as users were aware they were interacting with the MyPal app. We aimed to mitigate this by simulating real-world use cases via a use scenario, where users would receive a thorough briefing during onboarding, conducted by a recruiter physician to explain the functionalities of the app. We also encouraged participants to provide candid and constructive feedback throughout the process.

Additionally, the participants had a very diverse level of smartphone skills which along with the age variation, posed a limitation. Age is a determining factor in the use of mobile app products, especially considering neurodegenerative conditions that affect older individuals may significantly impact dexterity, and thus navigation. While the study did not focus on participants with such conditions, the age range of 27 to 68 years presents its own challenges. However, the median of 17 (IQR 42-59) years suggests that the majority of participants were within a relatively concentrated age group, minimizing the impact of an extensive age gap.

Finally, participant recruitment was arduous due to the constraints imposed by the COVID-19 pandemic. Initially targeting users with hematologic malignancies and more specifically CLL or myelodysplastic syndrome, recruitment difficulties led to a shift toward enlisting senior patients coping with other chronic diseases that necessitate periodic hospital visits. While the original objective was to secure 10 - 15 participants, the study ultimately included 9 participants. Faulkner [32] has demonstrated that groups of 10 users can identify an average of 95% of usability problems, mitigating concerns regarding sample size. It is worth noting that the study's findings possess limited generalizability but can be partially applied to self-management mHealth systems using ePROs within the context of palliative cancer care, with a focus on a dedicated mobile app tailored for patients with cancer.

Comparison With Prior Work and Future Directions

Our usability evaluation of the "MyPal for adults" app demonstrates its potential to improve patient-provider communication, supporting the broader scope of palliative care

XSL•FO
RenderX

for patients managing chronic illnesses. Comparing our findings with prior research in the field of eHealth apps for palliative care, several key insights emerge. First, this study aligns with previous research that emphasizes the potential of eHealth apps to improve communication between patients and HCPs in palliative care settings [33]. Through the MyPal app, participants in this study reported improved channels for information exchange, empowering them to actively participate in their care decisions. This echoes findings from related studies [33,34], which have also highlighted how eHealth apps can bridge the communication gap in palliative care, providing a convenient and accessible platform for patients to engage with their health care providers.

While our usability evaluation yielded positive outcomes, it is important to note that, similar to much of the prior work in this field [33], this study primarily involved testing, feasibility assessments, and acceptability studies on relatively small patient populations. A comprehensive evaluation that can impact patient outcomes, including symptom management, QoL, and overall satisfaction with care, necessitates the execution of rigorous clinical trials [35]. This phase of assessment represents the final critical stage in establishing the app's effectiveness and suitability for integration into palliative care practices, as is the plan with the "MyPal for adults" app.

Future research should aim to broaden the use of the MyPal app to include a more diverse range of patients in palliative care. Additionally, the integration of the app with existing health care systems is crucial to enhance its functionality, providing HCPs with real-time patient data and enabling better care coordination. Finally, ongoing development efforts should prioritize a user-centric design approach, incorporating input and feedback from both patients and health care providers to maintain the app's intuitiveness, accessibility, and alignment with evolving user needs.

Conclusions

This usability study assessed the "MyPal for adults" app with a diverse user group, including individuals with chronic diseases, and patients with CLL. Participants generally had positive initial impressions of the app's design and organization, though some preferred a more modern interface. Although certain modules posed usability challenges, the ePRO modules were well-received. However, enhancing learnability, personalization, and addressing technical issues in some tasks is essential. This study emphasizes the importance of iterative, user-centered development to improve the app's usability and UX. Notably, older users favored simplicity, while younger users sought a contemporary design, indicating room for age-specific improvements. Given the app's role in palliative cancer care, effective ePRO implementation and thoughtful translation of paper-based PROs into digital formats are critical. Ensuring timely health care provider responses to patient reports is vital. These findings offer valuable insights for refining the MyPal app and may inform other self-management mHealth systems in palliative cancer care.

Acknowledgments

This work was partly funded by the MyPal project which has received funding from the European Union's Horizon 2020 research and innovation program under grant 825872 [15]. The authors express their sincere gratitude to ELLOK (Greek Federation of Cancer Patients) for their invaluable assistance in granting access to members for study participation. Special thanks go to Dr Christina Karamanidou for her significant role in participant recruitment and for establishing a communication pathway with ELLOK.

Authors' Contributions

PB led the study design, authored the primary text, and conducted the research. PN contributed to the study's conceptualization and provided critical manuscript revisions. PA offered manuscript edits and supported PB throughout the study.

Conflicts of Interest

Abstract

Background: Research supports the use of mobile phone apps to promote medication adherence, but the use of and satisfaction with these apps among medically underserved patients with chronic illnesses remain unclear.

Objective: This study reports on the overall use of and satisfaction with a medication adherence app (Medisafe) in a medically underserved population.

Methods: Medically underserved adults who received care for one or more chronic illnesses at a federally qualified health center (FQHC) were randomized to an intervention group in a larger randomized controlled trial and used the app for 1 month (n=30), after which they completed a web-based survey. Objective data on app usage were provided as secondary data by the app company.

Results: The participants were very satisfied with the app, with all participants (30/30, 100%) somewhat or strongly agreeing that they would recommend the app to family and friends. Participants strongly agreed (28/30, 93%) that the reminders helped them remember to take their medications at the correct time each day, and they (28/30, 93%) found the app easy to use. Additional features accessed by some included educational features and the adherence report. Participants noted the helpfulness of having a medication list on their phones, and some used it during medication reconciliation at doctor visits. Use of the Medfriend feature, which alerts a social support person if a medication is missed, was low (n=2), but those who used it were very positive about the feature.

Conclusions: A commercially available medication adherence app was found to be useful by participants, and they were satisfied with the app and the additional features provided. The use of medication adherence mobile phone apps has the potential to positively influence chronic disease management in a medically underserved population on a large scale.

Introduction

Background

Medication adherence is vital for those with chronic illnesses who require long-term medication therapies to maintain optimal health. For example, medication adherence and persistence with high blood pressure medications are known to significantly decrease the risk of both cardiac events and stroke [1,2]. In those with type 2 diabetes, medication adherence with hypoglycemics reduces microvascular complications [3]. Unfortunately, the burden of chronic diseases is increasing, with an estimated 60% of adults in the United States having 1 chronic disease and 40% having 2 or more chronic diseases [4]. The growth of chronic disease burden coupled with a lack of medication adherence is associated with increased health care expenditures due to increased demands on health care resources [5,6] and poor health outcomes such as worsening disease status and even death [5]. The economic impact of low medication adherence is estimated to cost the US health care system between US $100 billion and $290 billion annually [5-8].

Medication adherence is therefore particularly important in medically underserved populations who seek care at federally qualified health centers (FQHCs). These centers serve communities and populations with a demonstrable unmet need for health services [9]. These centers are reporting growth in more complex patient populations because their patients have higher rates of chronic conditions and social risk factors associated with poorer health outcomes [10]. Additionally, lower rates of medication adherence are seen in lower socioeconomic populations [11,12] and those with multiple chronic conditions [13]. The reasons for this are influenced by social determinants of health and the material and social conditions in which people live [14]. Adverse social determinants of health are associated with lower medication adherence [15].

Mobile health (mHealth) interventions, defined as the use of mobile wireless technologies for public health [16], have been cited as a potential way to reduce health disparities among chronically ill and medically underserved populations [17,18]. However, despite the promise of these technologies, researchers indicate that mHealth interventions remain understudied in medically underserved populations [17,18]. This is true of medication adherence apps, which can support patients in adhering to their medications through reminders, medication educational information, adherence data, and social support. Studies have shown mixed results for the interest in mobile phone interventions in vulnerable populations [18,19]. Furthermore, research testing commercially available apps to manage chronic disease in a racially and ethnically diverse sample found that the usability of the tested apps in this population was suboptimal [20]. Understanding and gathering detailed data from diverse perspectives regarding the user experience of medication adherence apps will provide important information that is needed to support wider implementation.

A recent meta-analysis of the effectiveness of mobile apps on medication adherence in adults with chronic illnesses found that medication adherence mobile apps, which are designed to be used across a range of multiple chronic health conditions, remain underexplored [21]. This meta-analysis reported that in general, patients have a high acceptance of medication apps, but none of the studies analyzed included medically underserved populations [21]. Eight studies have demonstrated increased medication adherence with the use of medication adherence apps [22-29], but only 3 of these were conducted in low-income medically underserved populations [27-29]. Two of those studies in underserved populations were focused on hypertension [27,28], and the other included hypertension and type 2 diabetes and was a post hoc analysis of a digital health offering using a cluster-randomized design [29]. Only 1 of these studies, conducted in an urban low-income population with hypertension, obtained satisfaction information on the intervention [28]. Satisfaction with the app was high, and most participants felt they would use the app or a similar program in the future. Participants agreed that the app made it easier to keep track of their medications and that having a medication list on their phone made it easier to take care of themselves. More detailed feedback from the participants or information on which features of the app were used was not gathered [28].

A high-quality, free, commercially available smartphone medication adherence app called Medisafe supports patients in adhering to their medication regimen across disease states [30]. It uses a variety of advanced features, such as daily reminders, which can be snoozed, rescheduled, and marked as taken or missed; medication educational information in the form of medication cards and videos; an interaction checker; customizable refill reminders; adherence reports; and the ability to designate a social support person to be notified if a medication is skipped [23]. A randomized controlled trial (RCT) mixed methods evaluation in patients with coronary artery disease examined the efficacy [23] and the utility, acceptability, and engagement [31] of the Medisafe app. This study was conducted in a large urban tertiary hospital in Sydney, Australia and did not focus on a medically underserved population. In addition to improving self-reported medication adherence, overall utility was rated positively, with participants indicating that having their medication list on their phone and receiving timed reminders were useful. Most participants engaged with the app and its features; found the app acceptable, convenient, and easy to use; planned to continue using the app; and would recommend it to a family member or friend [31].

A qualitative study explored the potential benefits and barriers of using a mobile medication app in a medically underserved population in the United States [18]. The researchers found that patients were willing to try smartphone apps but expressed concerns about affordability, the technology being too complicated, not keeping phones with them all the time, and not being able to use all the features [18]. That study exposed a knowledge gap regarding the perceptions and user experiences of medically underserved patients with chronic illnesses who use free commercially available medication adherence apps.

Purpose

To address the knowledge gaps, a larger RCT investigating the efficacy of the Medisafe app (reported elsewhere) [32] was performed for evaluating the overall use and satisfaction of patients with a variety of chronic illnesses in a medically

XSL•FO
RenderX

underserved population in an FQHC in the United States. The efficacy portion of the RCT found significant improvements in both medication adherence (Cohen *d*=0.52; *P*=.01) and medication self-efficacy (Cohen *d*=0.43; *P*=.04) for participants assigned to use the app compared to the usual care group [32]. As part of this RCT, participants assigned to the intervention arm provided feedback and usage data regarding their experience using the Medisafe app [32]. This manuscript presents the summaries of the perceptions of patients enrolled in the intervention arm of the RCT regarding the usefulness of and satisfaction with the app features after 1 month of use. Given the improvements observed in medication adherence and self-efficacy, understanding patients perceived usefulness and satisfaction with the app is important to address potential barriers for uptake and use in larger medically underserved patient populations who often receive care for chronic illnesses in FQHCs.

Methods

Setting and Recruitment

Participants were recruited from November 2021 through June 2022 from an outpatient adult medicine department in an FQHC in the northeastern United States. The inclusion criteria for the RCT study were as follows: (1) adults aged 18 years or older, (2) having the ability to speak and understand English, (3) personally owning and using an Android smartphone (version 5.0 or above and at least 88 MB of phone space) or iOS smartphone (version 13 or later and at least 165 MB of phone space), and (4) taking at least one medication for a chronic condition based on the computerized medical record at the health center. Patients were excluded if they: (1) were already using a medication reminder app or other electronic reminder system such as phone alarms, (2) owned a smartphone not capable of downloading the app, (3) had a diagnosis of severe dementia or serious mental illness, or (4) were otherwise unable to use a mobile phone or the medication reminder software either physically or cognitively. For this study, only those participants who were randomized to the intervention group and used the Medisafe app were invited to participate in the survey.

Recruitment involved an informational flyer, a referral form from clinicians at the health center, and in-person recruitment. The flyer and referral forms were available to clinicians, staff, and patients in the FQHC offices and at the reception desk. The form contained study information, the contact information of the principal investigator (PI), and a place for patients interested in participation to provide their contact information. The form also contained a section for health care providers (HCPs) to refer potential patients and a section for their signature to verify that the patient's medications listed in the electronic health record were correct and current. The PI (CH) conducted in-person recruitment at the FQHC on multiple days per week and worked with clinic staff to identify potentially eligible patients. Although a convenience sample was used (ie, patients visiting the clinic on any given day), the risk of selection bias was reduced by using the aforementioned 2-prong approach to identify eligible patients for recruitment, inviting all patients meeting the eligibility criteria to participate, and using random assignment to either the intervention or control group. The 2 groups were not statistically different [32]. The PI approached eligible patients at the end of the health center visit to inform them of the study. Once the PI confirmed participant eligibility and obtained informed consent, participants were randomized to either the intervention or control group. Additional details of study procedures for the RCT have been previously published [32].

Statistical Analysis

Based on a preliminary efficacy study for the RCT [33], a total sample of 60 participants was estimated to enable the detection of differences between the groups with Cohen *d* effect values of 0.6-0.7 (80% power; α=.05) for the quantitative study variables [32]. As 30 participants were randomized to the app intervention group, their usage and satisfaction data are presented in this manuscript. Descriptive statistics and frequency distributions were used to describe the sample and determine if the data were normally distributed. Qualitative participant responses were transcribed into an Excel spreadsheet, and the content was coded and summarized as themes by the researcher (CH) and PhD faculty advisor (DPS).

Ethical Considerations

This research was approved by the Vanderbilt University Institutional Review Board (IRB #211409) and is registered with ClinicalTrials.gov (NCT05098743). All participants received a copy of the consent form. Based on participant preference, informed consent was completed as either an IRB-approved e-consent form or a hard copy. The consent form contained a privacy and confidentiality protection description ensuring that all study data are deidentified. Participants received a US $25 gift card after completion of the baseline survey and a US $35 gift card after completion of the follow-up survey.

Medisafe App Intervention

The Medisafe app is a Health Insurance Portability and Accountability Act (HIPAA) compliant medication adherence app that is available at no cost in the iTunes and Google app stores. In previous studies, Medisafe was ranked highly among medication reminder apps [30,34]. The Medisafe app provides interactive and customizable daily timed reminders to reinforce medication taking at a set time every day through a push notification, equivalent to an alarm or text message. The reminders can be snoozed, rescheduled, or marked as taken or skipped, and they are repeated a total of 3 times in 10-minute intervals if the participant does not mark the medication dose. Additional features include educational information in the form of a medication database that includes written and video content [30]. The written content is in the form of a medication card, which Medisafe terms a leaflet, and it reviews what the medicine is used for, medication interactions, what to do if the user misses a dose, what the user should watch for, possible side effects, how it should be used, and where to store the medication. Some medications also have video content, consisting of a brief clip of an HCP reviewing the most important considerations when taking the medication, which can be viewed on tapping the information icon. There is also an interactions tab that lists possible interactions with the medications or food/alcohol.

XSL•FO
RenderX

Lastly, there is an interaction checker where participants can check for interactions between their medications. The app also has a Medfriend feature, which allows participants to designate a family member or friend as their support person. The Medfriend feature will alert the designated Medfriend who can provide peer support and additional reminders through text messages, emails, or a telephone call if the patient misses a dose. The language mode of the app can be switched, if desired, to multiple foreign languages, including Spanish.

The PI helped consented participants set up the app using a copy of the patient's medication list extracted from the electronic health record. The PI also reviewed how participants could access and edit their medications; access medication educational content; and indicate when a medication was taken, skipped, or rescheduled. The PI reviewed with participants additional app features such as Medfriend, medication interaction checking, adherence reports, and refill reminders. Participants were also shown how to access the help and support section in the app. Following the app set up, the PI provided previously developed educational materials as a take-home resource. These materials, specific to either an iPhone or Android smartphone, included a laminated "quick tips" card with short instructions on the reviewed features and how to access them. Additional detailed instructions on how to use the app were printed in a question-and-answer format and distributed to participants.

Data Collection and Study Procedures

All study data were collected using observation, a REDCap web-based survey, and secondary data provided by the app company and were obtained using a data-sharing agreement between institutions. REDCap is a secure web-based software platform designed to support data capture for research studies [35,36]. Following consent, all participants completed the baseline study survey. Those randomized to the intervention group also completed a survey at study end to obtain feedback on the app, including usability and satisfaction.

Observation

While setting up the app for the intervention group, the PI completed a study-specific observational behavioral checklist. The purpose of the checklist was to inform the researchers if participants had difficulty setting up the app and how long it took them to do so. The checklist included documenting whether the participant had difficulty visualizing the app and had difficulty with dexterity while setting up the app, and mentioning the number of times the participant's input of medications needed to be corrected. The length of time in minutes from starting the download of the app to completing app set up and reviewing the app was also documented.

Survey

After 1 month, based on preference, participants completed the follow-up survey online, by phone, or in-person at the health center. Participants who did not complete the follow-up survey within 10 days of the 1-month follow-up date received 2 reminders via phone, email, or text message.

Measures

The end-of-study survey included 11 questions that assessed satisfaction and usability using a 5-point Likert scale with responses ranging from "strongly disagree" to "strongly agree." The survey questions were developed and pilot tested before use [33]. Seven of the first 11 questions were developed by Santo et al [31] and were used with permission in this study, while the remaining 4 were developed by the researchers. Six additional questions asked about the use of additional features such as the educational information, Medfriend feature, interaction checker, adherence report, refill reminder, and additional morning reminder of the Medisafe app. These questions asked participants whether they used a given feature, and if they did, whether they found the feature useful. There were open-text response options available to elicit qualitative data from the app participants such as how a feature helped them manage their medications and what they found most useful about the feature. The remainder of the survey included 6 general use questions previously developed and pilot tested, 4 of which were "Yes/No" questions (eg, did you use the refill reminder and did you have technical issues with the smartphone app?). The remaining 2 questions assessed how often medication reminders were received each day and which language the participant used.

Secondary Data

Deidentified usage data were obtained from the Medisafe company at study completion. Medisafe provided the PI with objective user interactions with the Medisafe app, such as whether educational information in the form of a leaflet was accessed by participants and whether the Medfriend feature was used.

Analysis

Descriptive statistics and frequency distributions were used to describe the sample and determine if the data were normally distributed. Open-ended survey question responses were imported into an Excel (Microsoft Corp) spreadsheet, and the content was coded and summarized as themes by the researcher (CH) and the PhD faculty advisor (DPS). This approach was taken given the short, free-text, and limited responses received. Since the qualitative data came from the open-ended survey responses, data collection was based on sample size rather than data saturation.

Results

Participant Characteristics

Complete details are included in Table 1, and information can also be found in the app efficacy manuscript [32]. A flowchart of study participants in the main RCT can be found in Figure 1. The median age of the 30 participants using the app was 53.5 years (IQR 37-76 years). Most participants in the intervention group were non-White (23/29, 79%). Races/ethnicities were as follows: Asian (5/29, 17%), Black or African American (10/29, 35%), Hispanic/Latino (4/29, 14%), Native American or Alaska Native (1/29, 3%), and other (3/29, 10%). More than 75% of the participants had government insurance (25/30, 83%), and a small number of participants were uninsured (2/30, 7%). Brief

XSL•FO
RenderX

health literacy scores were generally high (median 12.0 of a possible score of 15, IQR 5-15). Slightly more than half of the participants (16/29, 55%) reported that it was either very or somewhat difficult to pay their monthly bills. The most common chronic illness was hypertension (22/30, 73%), followed by hyperlipidemia (19/30, 63%) and type 2 diabetes (14/30, 47%). Most participants (25/30, 83.3%) had 2 or more chronic illnesses.

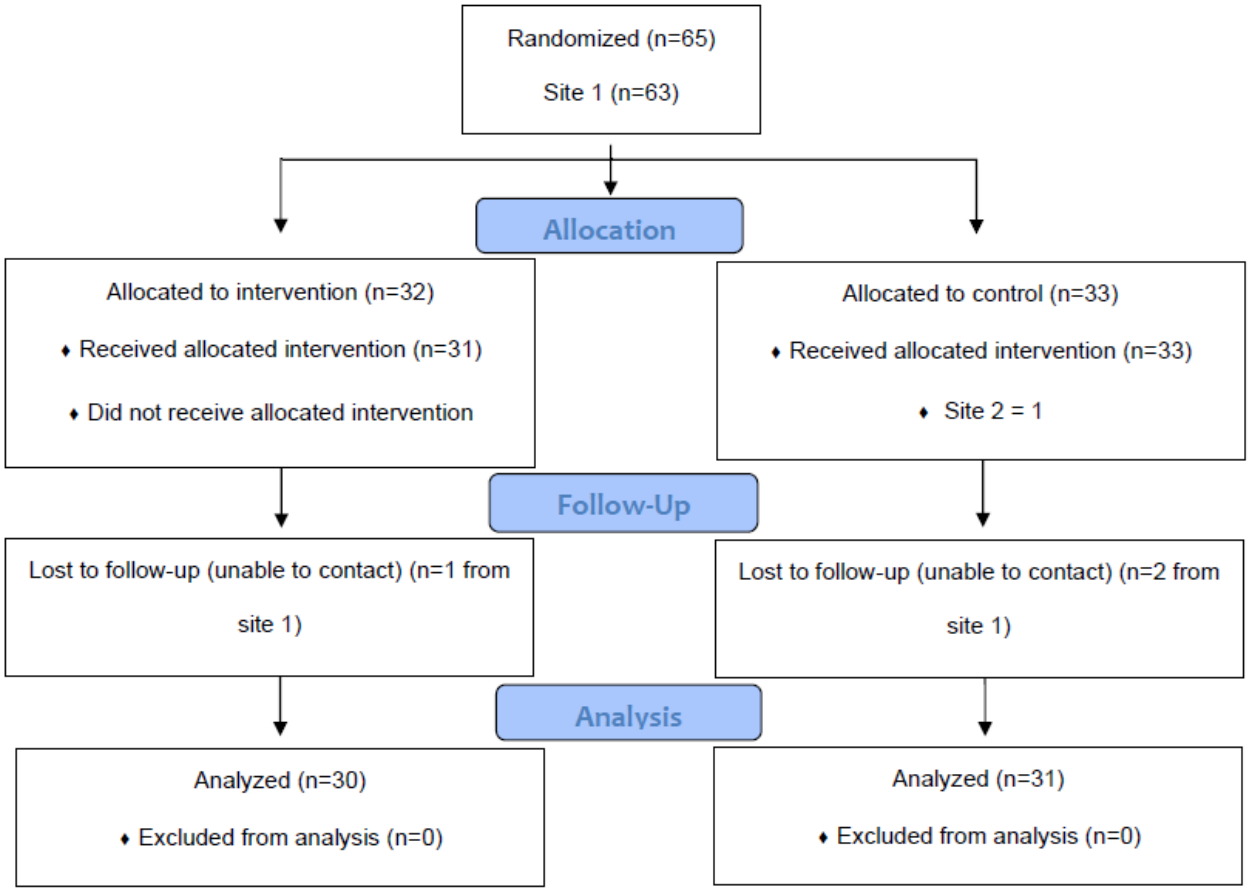

Table 1. Sociodemographic characteristics of the participants using the app.

Characteristic	Value, n (%)
Race/ethnicity (N=29)	
Asian	5 (17)

XSL•FO
RenderX

Figure 1. Flowchart of study participants in the larger randomized controlled trial of the efficacy of the app intervention.

Behavioral Observations While Setting Up the App

During app set up, some participants (4/30, 13%) expressed difficulty visualizing the app owing to the unavailability of their eyeglasses, which they stated were either in their car or left at home. No participants had difficulty with dexterity while setting up the app, and the median time it took from starting the app download to completing the set up and reviewing the app was 15 minutes (IQR 10.0-25.0; minimum 10, maximum 30 minutes). The majority of participants (21/30, 70%) did not need to be corrected when they entered the medications. However, 4 (13%) were corrected by the researcher once, 3 (10%) were corrected twice, and 2 (7%) were corrected thrice. Patients were corrected when they spelled the medication name incorrectly, chose the incorrect medication dose, or set an incorrect time for the reminder.

Satisfaction and Utility

Summaries of the participants' reports of satisfaction are presented in Table 2.

Most participants (27/30, 90%) strongly agreed that they liked the app design, while most (25/30, 83%) strongly agreed that it was useful to have their medication list on their smartphone. Some participants (2/30, 7%) mentioned the usefulness of the app when seeing other HCPs to indicate the medications they were taking during medication reconciliation. Furthermore, a large proportion of participants (28/30, 93%) strongly agreed that the reminders helped them to remember to take their medications at the correct time each day. The majority of participants strongly agreed that the app was easy to use (27/30, 90%) and convenient (28/30, 93%) and that they would continue using the app (26/30, 87%). A small number of participants (2/30, 7%) somewhat agreed that they would continue using the app. It is important to note that some participants (2/30, 7%) strongly disagreed that they would continue using the app, because they found the reminders annoying. All the participants (30/30, 100%) somewhat agreed or strongly agreed that they would recommend the app to family and friends.

Somewhat agree	2 (7)
Strongly agree	28 (93)

The 2 participants (10%) who were dissatisfied with the app described the reasons why. One said:

> *It is annoying when you get a reminder and you are in the middle of doing your work. This is not for everybody. I work on the computer and on my cell phone and it is very distracting to receive the reminder in the middle of working on something. It might be better for someone who doesn't have as much going on. I find it very distracting.*

The other participant had technical difficulties but blamed it on the type of phone they had:

> *The bug thing with the notification alarms was a problem. I have an android - a cheap phone. My phones get destroyed because of the type of work I do.*

Use of Educational Information

Almost half of the participants (12/30, 40%), self-reported accessing educational information. To the contrary, objective usage data from Medisafe indicated that only 3 participants (10%) accessed the educational content, which was defined as cards termed “leaflets” or videos. According to Medisafe, this was done for a total of 14 medications. Additionally, Medisafe reported that only 1 participant accessed 4 different videos and 1 leaflet, 1 participant accessed 1 leaflet, and 1 participant accessed 6 different videos and 2 leaflets. Although not all participants actually accessed the information, those who reported accessing the educational information (12/12, 100%) found the information useful. When asked about how they used the educational information in the app, the participants reported learning about the side effects of the medications (6/12, 50%), reported that it was helpful for general knowledge (4/12, 33%), and mentioned using it to learn more about medication and food interactions (2/12, 17%).

Medfriend Feature

Based on usage data from Medisafe, only 1 participant (3%) used the Medfriend feature. That participant was very positive about the feature and reported that her husband would call her to say, “Are you taking your medicines?” She stated:

> *It gets him involved. It makes him recognize that I need support and I need to take the medicine. It makes me know he loves me.*

Another participant self-reported using the Medfriend feature, but there was no indication of use in the Medisafe data. The participant reported that when her husband was notified, he would send a text about her forgetting her medications and she would remember to take them. Those who did not use the Medfriend option were asked, “who might that person be for you?” Among those who responded (18/30, 60%), the top 3 most common responses were their sibling (4/18, 22%), their child (4/18, 22%), and their husband or wife (4/18, 22%).

Interaction Checker

All participants who used the interaction checker (5/30, 17%) agreed that it was useful. One participant reported that 2 of the medications she had been taking together should be taken separately and stated, “It was a lifesaver!” The other 4 participants expressed an appreciation for being able to have access to this type of information. The use of the interaction checker was distinct from the educational content and could not be verified in the Medisafe data as Medisafe does not register or track the use of the interaction checker.

Adherence Reports and Reminders

Participants (8/30, 27%) who checked their adherence report agreed it was useful. The adherence report provided them with a history of their daily missed and taken medications as well as a weekly adherence percentage based on what they reported when marking medication reminders in the app. Participants reported experiencing positive reinforcement for adhering to their medications through the adherence report, mentioned the affirmation they received when they saw a high percentage of adherence, and reported appreciating the positive reinforcement as useful. Some participants (2/30, 7%) mentioned that it incentivized them to reach higher levels of adherence.

Slightly less than half of the participants (13/30, 43%) received reminders to take their medications 2 times a day, while around one-third (9/30, 30%) received reminders 3 or more times a day. Reminders were generally well received:

> *I like the reminder. The shaking of the pill bottle helps me. Sometimes I will wake up at night and remember hearing the shaking pill bottle that day and I will get out of bed and check if I took my pills that day. I might be cooking with the grandkids and the first reminder goes off. I might ignore it but with the second reminder I might put the bottles on the counter so I can remember.*

Three participants (15%) mentioned the app’s helpfulness, particularly for those who have multiple chronic illnesses and take multiple medications.

> *This app was a lifesaver. I take a lot of different medication so sometimes I forget whether I took the*

XSL•FO
RenderX

> *medication or not. I can check the app to see if I took it or not.*

One of those 3 participants commented as follows:

> *It is perfect for people who have multiple illnesses and take a lot of different medications. I take eight different medications a day.*

Most of the participants (27/30, 90%) did not use the refill reminder. In their comments, a number of participants said they received automatic refill reminders from their pharmacy and therefore did not need this feature of the app. All participants (30/30, 100%) used the app in English, and the majority (24/30, 80%) did not make any changes, such as changing the time of a reminder, removing or adding a medication, or changing the medication dose in the app. Many participants (13/30, 43%) said they would use the app to manage someone else's medications.

Technical Difficulties Using the App

Some participants (4/30, 13%) mentioned they had technical difficulties. Of those who reported difficulties, 3 (75%) needed to allow notifications from the app to hear the reminders. Another user mentioned that they had to tap the "take all" icon a number of times before it registered and suggested that it should be made bigger or be more centrally placed. Participants gave additional feedback about the app when asked (20/30, 67%). In this section, participants (7/20, 35%) specifically mentioned liking the reminder.

> *It was really nice to hear that shaking sound. It was fun.*

Some participants (2/20, 10%) reported that the snooze function was particularly helpful when they were away from home.

> *The snooze option is helpful to use when I am out and don't have my medications. When I come back home it reminds me so I remember to take it.*

Social Support

The 2 participants (7%) who self-reported using the Medfriend feature were very enthusiastic.

> *It's a great app and I love it. My husband is on it for his meds and I am his Medfriend. I am also going to get my mother hooked up on it.*

The other participant shared her thoughts about the feature, highlighting her increased feelings of self-efficacy and social support.

> *This app is about being a team player. You are able to help me and I am able to help you. I can now say "I did it" "I can do this." This is a good app. I can't see anyone who is interested in their health not using this app. Since being introduced to this app I know that it is there for me.*

Discussion

Principal Findings

As part of an RCT using the Medisafe medication adherence app in a medically underserved population with a variety of chronic illnesses, behavioral observations on app use and satisfaction and usage data were gathered from participants in the intervention arm of the study and the Medisafe company. The quantitative RCT results (reported elsewhere) [32] found significant improvements in both medication adherence and medication self-efficacy for participants who used the app. The portion of the RCT presented in this manuscript, which collected behavioral observations and satisfaction and usage data from the intervention arm, identified that participants were satisfied with the app and found it useful. Even though the use of the additional features was generally low, those who used them found them useful. Most participants did not need help setting up the app. An important strength of this RCT is that it explored patients' perceptions of the usefulness of the app and their satisfaction with the app and therefore fills an important knowledge gap. This was done by collecting both quantitative and qualitative data through open-response questions, which gave voice to the perspectives of a low-income racially and ethnically diverse sample of adults with chronic illnesses receiving care in an FQHC [17,18]. As FQHCs are reporting a growth in the rates of treating complex chronic conditions [10] and there are lower rates of medication adherence among populations with lower socioeconomic status and those with multiple conditions [37], the implementation of tools to enhance medication adherence is imperative. Understanding the user experience with the Medisafe mobile app demonstrated that wider-scale use of the Medisafe app is feasible in a low-income population with multiple chronic illnesses. Systematic literature reviews have pointed out a gap in implementation studies of mobile app interventions in this population [38]. This study addressed an important knowledge gap by demonstrating that the use of a commercially available free medication adherence app is a viable option for medically underserved adult patients with chronic diseases.

Prior research found that medically underserved patients expressed reluctance about paying for a medication adherence app [18]. While not directly addressed in this study, some participants anecdotally asked before enrolling in the study if they would need to pay for the app, and when told it was free, they expressed interest in participating. This underscores the importance of not having patients incur additional costs for the technology and was a strength of this intervention.

Most participants were able to set up the app with minimal assistance, with a median duration time of 15 minutes during the behavioral observation. It is important to note that 30% of the participants needed to be corrected 1-3 times when setting up the app, thus pointing to the importance of helping some patients set up the app initially and checking that the medications are entered accurately. This highlights a difficulty with individuals setting up the app. Although not implemented in this study, another option is to import medications from other databases, such as Apple Health, or a pharmacy directly. This may shorten the time it takes to set up the app. Once the app is set up properly, in addition to HCPs assisting patients, the help and support page and the company contact could serve as a resource for patients.

Survey data indicated that satisfaction with the app was high, with most patients strongly agreeing it was easy to use. All

XSL•FO
RenderX

intervention group participants (30/30, 100%) strongly agreed that they would recommend the app to family or friends. This was higher than the proportion in the study by Santo et al [31], which used Medisafe and found that 78.6% of patients with coronary heart disease would recommend it [31], and the study by Anglada-Martinez et al [24], which used a similar app and found that 71.4% of patients receiving treatment for hypertension, dyslipidemia, heart failure, or HIV would recommend it [24]. Both these studies were, however, conducted outside of the United States. It may be that Americans are more familiar with app technologies and feel more comfortable recommending apps to others.

Qualitative research conducted in a medically underserved population with chronic illness regarding the use of medication adherence apps found that technical issues and complexity were concerns when setting up and using these apps [18]. One study involving a medication adherence app similar to Medisafe indicated that 50% of participants reported problems receiving reminders [24]. The Medisafe app used in this study is a commercially available app with high-quality assessment ratings [30,39], and in this study, technical issues were rare. The most common issue was not receiving the reminders until the participant allowed notifications from the app in their phone settings. No participants expressed that the app was technically complex, which was previously cited as a concern in this population but was not an issue in this study [18]. One participant had ongoing technical issues receiving reminders. These findings suggest that the Medisafe app can be implemented in this population from a technology standpoint, and participants did not find it difficult to use.

Similar to other studies involving the Medisafe app, feedback results point to receiving timed medication reminders as the most used aspect of the app [31]. Furthermore, feedback regarding the app aligns with the findings of other studies linking medication reminders with medication adherence [22,25,28,29]. Participants found the snooze function of the reminder helpful when they were not home to take their medications and used this function as a reminder to take their medications when they got home. The snooze function therefore was an important component of the app when participants experienced disruptions in their routines, such as being away from their medications. The findings also align with a previous study in a medically underserved population where participants indicated that disruptions in their daily routines negatively affected their medication adherence [18]. This study demonstrated that patients used the reminder feature when available, and the majority of patients found it helpful in improving medication adherence. The 1 participant who was bothered by the reminders used his phone for work and found the reminders distracting if he was using his phone for work purposes. The reminders predominantly targeted the phenomenon of forgetting, which has been found by a study to be the most likely cause of reported nonadherence in low-income uninsured patients with multiple chronic illnesses [13].

Research has shown that both patient knowledge of medications and their satisfaction with the information provided about their medications can improve medication adherence [40]. There was a discrepancy between the data reported by Medisafe and the number of participants who self-reported accessing educational information. Although the reason for this discrepancy is not clear, several possibilities exist. First, participants could have overstated the use of educational features. Another potential reason might be related to the specific data Medisafe defines as educational data. Medisafe does not collect data on the use of the interaction tracker or the “For You” tab at the bottom of the app and only collects data if a participant clicks on the educational leaflet and opens it up. In contrast, participants might have perceived content under the “For You” tab and drug interaction materials or videos as educational materials, resulting in a discrepancy between patient self-reported data and Medisafe data regarding accessing educational content. The feedback received demonstrated that participants who reported accessing the educational information (less than half) were very positive about doing so. The educational information was found to be useful for learning about side effects and food and medication interactions. Because individuals have different preferences for the amount of medication information they receive and the way that information is delivered [41], the modularity of the Medisafe app is useful to facilitate patient education in a practical and less burdensome way. The information is available at the patient’s fingertips and can be accessed as frequently as needed to learn what they want at their convenience. The educational app feature is also advantageous to HCPs as it alleviates some of the burden and time commitment associated with educating patients about their medications.

Social support has been found to have a positive effect on medication adherence [42-44]. Studies deploying digital technologies in the form of web-based online communities to provide social support have generally demonstrated that they can support people emotionally, socially, practically, and politically [45]. However, using technology to provide social support has not been studied in the context of a commercially available medication adherence mobile app. This study addressed this gap by studying social support via a commercially available app in the context of medication adherence. The Medisafe app offers social support in the form of Medfriend, and this is the first known study to incorporate this feature as part of the study intervention. Some studies have pointed out that online social support networks for those with specific chronic illnesses lessened the burden on relationships with family and friends, who are referred to as “offline” support persons [45,46]. However, despite asking and offering to demonstrate how to set up the Medfriend feature, usage of the Medfriend feature was very low. This study did not gather information on why participants chose not to set up the Medfriend feature, and this is a limitation of the study. It may have been because this feature was seen as too burdensome by the patients or their support people, most of whom were identified as family members. Patients might have avoided using Medfriend due to confidentiality concerns associated with this feature, which entails giving access to the user’s medication list, as many participants (13/30, 43%) were willing to use the app to manage someone else’s medications but chose not to share their own medication information. Another challenge regarding the Medfriend feature was that there was a discrepancy between Medisafe data and self-reported data on the use of the Medfriend feature. Despite the aforementioned concerns, the 2

XSL•FO
RenderX

participants who reported using the Medfriend feature were satisfied with it as they perceived that the app fostered social support. To further explore the social support feature of the app, research on dyads who use the app to manage the medications of family members might shed new light on the phenomenon of incorporating social support into mobile apps. By studying a subset of the population, including patients and their caregivers, the social support feature may be used more frequently. If the confidentiality of medication lists proves to be a barrier, a feature that dissociates specific medications from the reminder might address that concern. Support persons could receive a general text that their online Medfriend has not taken their medications without sharing details on the specific medications.

Participants reported that having a list of medications on their phone was beneficial, which was also noted in a population of patients with coronary heart disease who used the Medisafe app in Australia [31]. When managing chronic illnesses, patients are often referred outside of the FQHC setting or require hospitalization to receive care. Some participants mentioned using the phone medication list for medication reconciliation when seeing other HCPs. This finding is in contrast to that of another study of patients presenting to an emergency department setting, which found that emergency department patients rarely used their mobile phones to share their medication list during medication reconciliation [47]. Medication reconciliation can be facilitated through the adoption of these technologies. HCPs in both primary care and tertiary care settings should suggest and support patients with implementing researched medication adherence mobile apps. The sample of this study included many patients with multiple chronic conditions. These participants appreciated the ability of the app to work across multiple chronic illnesses and its helpfulness when taking multiple medications. This finding underscores the importance of advocating for the use of medication adherence apps like Medisafe, which can work across a range of illnesses and medications and can be easily adjusted when medications change over the disease trajectory. Additionally, participants who used the adherence report felt that it provided positive reinforcement and was an incentive to reach higher levels of adherence. Similar to what has been reported in other studies, a majority of participants reported not using the refill reminder because they already received text alerts from their pharmacy, which they found helpful [18]. When HCPs select apps for patients to enhance their medication adherence, careful attention to app features and evaluation of existing research findings, such as the findings of this study, are important.

Limitations

This study had several limitations. First, the study duration of 1 month does not provide insights regarding long-term patient satisfaction and continued use of app features, which are important aspects of chronic disease management. Though this study found high satisfaction and usability of the app during the first month of use, future studies should evaluate the role of time in app usage and satisfaction. Medisafe data and self-reported data showed that the uptake of educational information and the Medfriend social support feature was low. There was an unresolved discrepancy in the number of participants who reported accessing educational information and the actual usage identified from the Medisafe data. The discrepancy might be because Medisafe data only captured if the leaflet was accessed. Patients may have perceived accessing educational information as clicking the interaction button or clicking the “For You” tab at the bottom of the app, which Medisafe data did not capture. This can be clarified in the future by a more detailed definition of what constitutes the educational features of the app. Incorporating interviews to clarify subsequent survey results would strengthen future research studies. Another limitation of the study is that we did not gather participants’ inputs about why they chose not to use the Medfriend feature. Therefore, this study cannot speak about the potential benefits of this feature. Finally, although the app can be used in several languages and many patients who seek care at FQHCs speak a primary language other than English [48], the researchers were not able to incorporate multiple languages into the study protocol.

Future Research

FQHCs and primary care settings working with adults who are chronically ill should consider medication adherence mobile phone apps as acceptable and practical tools to support medication adherence. Future studies could include a larger sample, consider the use of the available provider portal, and consider the experiences of both providers and patients. Cost analysis could be performed, and hospitalization rates and long-term usage and health outcomes over time could be studied. This study was for a 30-day period, but a study with a longer duration is necessary to see if the use of the app is sustained over time. In this study, only 2 participants reported barriers to using the app, and a larger long-term study could further explore barriers to sustained use and strategies for maintaining engagement in this population. Future research should use mixed methods to provide insights into app modification, the nature of barriers to use, and how app features, such as the Medfriend feature, could more easily be implemented among patients who might benefit the most from such features. As uptake of the additional features of the app, such as educational information and the Medfriend option, was low in this study, future research using larger datasets could explore what types of patients chose to use specific features and why they did. We purposefully did not require certain features to be used because we wanted to organically discover which features were most often used, if any.

Studying the usability of the app and its associated effects in ethnic populations in various languages is an important area of future research as community health centers serve a large number of patients with limited English proficiency [48].

Conclusion

This study demonstrated that the medication adherence app is a useful, convenient, and feasible intervention in an FQHC setting. The various features of this app positively influenced the medication-taking behaviors of adults with one or more chronic illnesses. Participants were satisfied with the app and the features they chose to use. Reminders were viewed as helpful by the majority of participants. The medication list feature was particularly useful for patients who had multiple chronic

XSL•FO
RenderX

conditions and saw multiple providers, and some used it to facilitate medication reconciliation. The findings of this study have important clinical implications, as clinicians can recommend the use of medication adherence apps as tools to provide support in adhering to medication regimens and as additional tools to use during medication reconciliation.

Acknowledgments

We would like to extend our gratitude to the leadership and staff of the health center and the participants who made this work possible. Support for this study was provided by the Vanderbilt Institute for Clinical and Translational Research (VICTR) #VR56076, Student Achievement Research Award (SARA), and VICTR #VR60349. The research study was also supported by CTSA award UL1TR002243 from the National Center for Advancing Translational Sciences. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the National Center for Advancing Translational Sciences of the National Institutes of Health.

Abstract

Background: Perinatal nurses are increasingly encountering patients who have engaged in perinatal substance use (PSU). Despite growing evidence demonstrating the need to reduce nurses' stigmatizing attitudes toward PSU, limited interventions are available to target these attitudes and support behavior change, especially those reflecting the overwhelming evidence that education alone is insufficient to change practice behavior. Arts-based interventions are associated with increasing nursing empathy, changing patient attitudes, improving reflective practice, and decreasing stigma. We adapted ArtSpective for PSU—a previously evaluated, in-person, arts-based intervention to reduce stigma toward PSU among perinatal nurses—into an interactive, digital, and responsive platform that facilitates intervention delivery asynchronously.

Objective: This study aimed to evaluate the usability, acceptability, and feasibility of the interactive, responsive platform version of ArtSpective for PSU. Our goal was to elicit the strengths and weaknesses of the responsive platform by evaluating the user experience to identify strategies to overcome them.

Methods: This study used a mixed methods approach to explore the platform's usability, user experience, and acceptability as an intervention to address stigma and implicit bias related to PSU. Theatre testing was used to qualitatively assess usability and acceptability perspectives with nurses and experts; a modified version of the previously validated 8-item Abbreviated Acceptability Rating Profile was used for quantitative assessment. Quantitative data for acceptability and satisfaction were analyzed using descriptive statistics. All qualitative data were analyzed iteratively using an inductive framework analysis approach.

Results: Overall, 21 nurses and 4 experts in stigma, implicit bias, and instructional design completed theatre-testing sessions. The mean duration of interviews was 31.92 (SD 11.32) minutes for nurses and 40.73 (SD 8.57) minutes for experts. All participants indicated that they found the digital adaptation of the intervention to be highly acceptable, with mean acceptability items ranging

XSL•FO
RenderX

from 5.0 (SD 1.0) to 5.5 (SD 0.6) on a 1-6 agreement scale. Nurses reported high satisfaction with the platform, with mean satisfaction items ranging from 5.14 (SD 0.56) to 5.29 (SD 0.63) on a 1-6 agreement scale. In total, 1797 interview segments were coded from the theatre-testing sessions with 4 major themes: appearance, navigation, characterization, and overall platform, and 16 subthemes were identified. Consistent with the quantitative findings, the results were positive overall, with participants expressing high satisfaction related to the platform's appearance, the ease with which they could navigate the various modules, engagement, clarity of the presentation, and feasibility of being completed asynchronously.

Conclusions: Developing and evaluating the usability of a digital adaptation of ArtSpective for PSU resulted in strong support for the usability, acceptability, and satisfaction of the program. It also provided insight into key aspects related to acceptability and usability that should be considered when designing a digital adaptation of an arts-based intervention for health care providers.

Introduction

Background

Stigmatizing attitudes among nurses who treat patients with perinatal substance use (PSU) [1-7] is a major barrier to the implementation of evidence-based practices for maternally provided care (ie, breastfeeding and skin-to-skin contact) that improve infant outcomes; decrease symptom severity; and reduce pharmacologic treatment, length of stay, and costs [8-18]. Despite growing evidence that demonstrates the need to reduce nurses' stigmatizing attitudes toward PSU [17-20], limited interventions are available that target these attitudes and support behavior change among nurses. Interventions that have been studied use didactics to increase awareness about the need to reduce stigma and increase compassion [20]. However, these interventions do not reflect the overwhelming evidence that education alone is not sufficient to change practice behavior [21,22] and that stigmatized attitudes may prevent the application of education to individual practice [23]. Evidence-based interventions targeting stigmatizing attitudinal change are necessary to empower nurses to effectively reduce biases and judgments toward PSU and care for these patients.

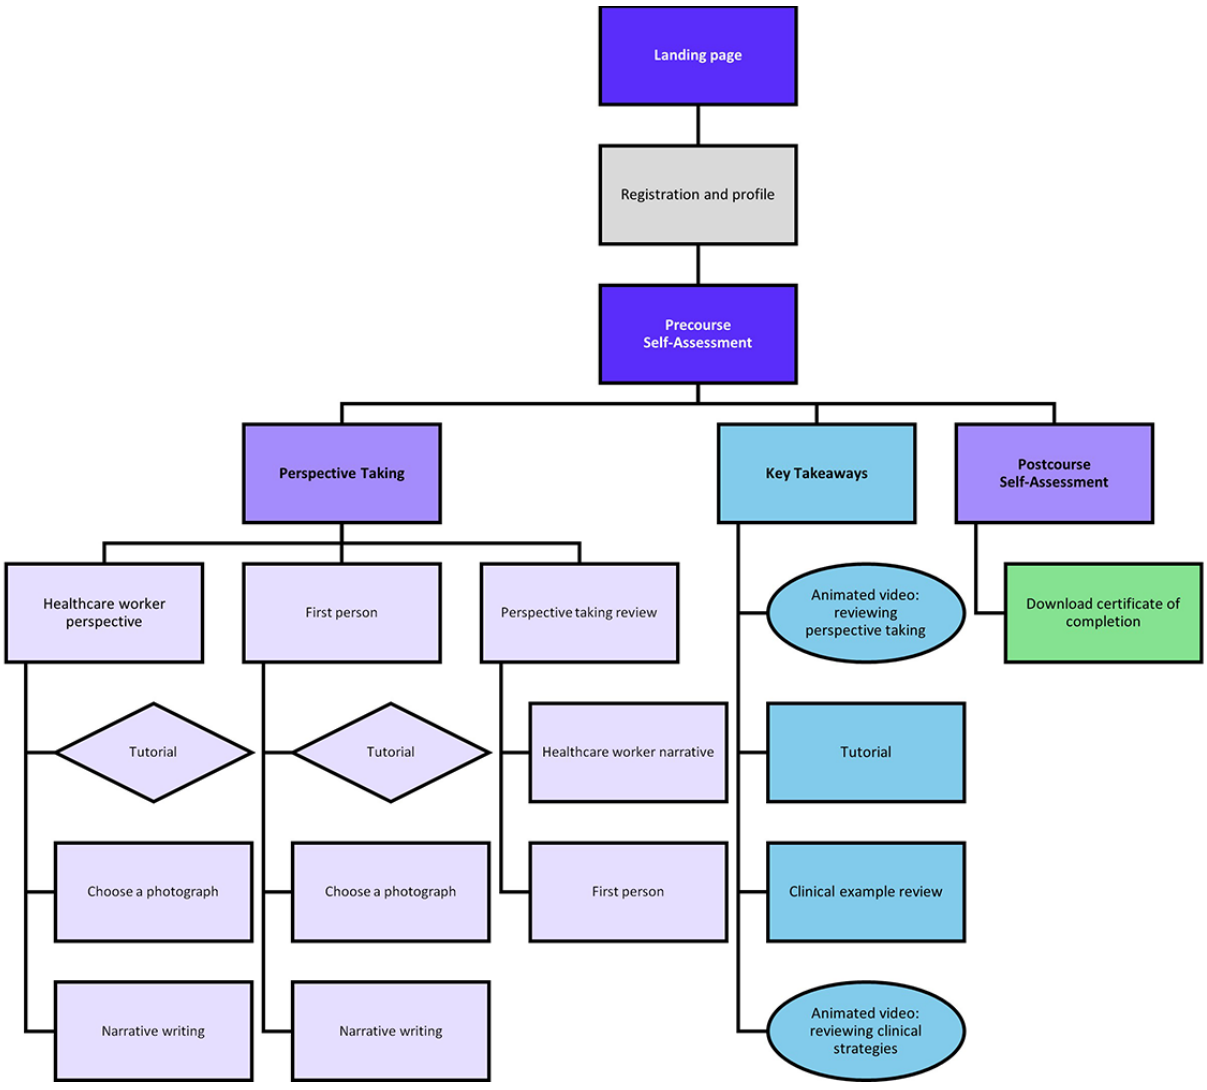
One of the key weaknesses of traditional interventions in addressing stigma is that they are generally structured around passive learning and focus on knowledge deficits rather than intervening on stigma itself [24]. In contrast, increasing research demonstrates how arts-based interventions improve clinical skills and communication between health care providers, especially for stigmatized attitudes [25]. Arts-based pedagogy is associated with increasing nursing empathy, changing stigmatized attitudes toward patients, and improving reflective practice [26]. Photography and digital storytelling have been demonstrated to decrease stigma and increase provider willingness to help patients affected by substance use disorder [27]. In addition, creative storytelling has been effectively used to improve clinician attitudes toward persons with dementia, a highly stigmatized population [28].

ArtSpective for PSU: An Arts-Based Intervention

Overview

Based on existing evidence of efficacy for arts-based interventions to improve clinician attitudes toward stigmatized patient populations [29,30], we developed ArtSpective for PSU to facilitate perspective taking and change attitudes toward PSU among nurses to facilitate their engagement with mothers and promote evidence-based practice that is not impeded by biases and stigma. ArtSpective for PSU was initially designed as a synchronous intervention that is delivered in one 60-minute session to a small group of nurses through live videoconference [24,31-33]. The intervention is grounded in art pedagogy previously used by art museum educators and facilitates a perspective-taking exercise using curated fine-art photographs and guided narrative storytelling. Participants are shown images and instructed to select two to interact with for the intervention. Selected images use a documentary photographic style characterized by ambiguity in subject matter, which enables participants to write two short creative narratives from two different perspectives (one perspective per image): (1) the perspective of a subject in the photograph and (2) the outside perspective of the nurse. Perspective taking is described as taking the point of view of another person within the other's context. This is grounded in evidence that this type of contextualization is associated with taking actions and exerting behaviors to alleviate distress and improve outcomes [34]. Participants spend time discussing their narratives with partners during the synchronous session after writing a narrative about the photographs they reviewed. They also engage in facilitated dialogue related to the perspective-taking attitudes elicited during their participation. These conversations enabled participants to compare their responses to the photographs and notice when their interpretations displayed biased attitudes.

While participants previously reported high demand, satisfaction, and efficacy with the synchronous version of ArtSpective for PSU [24], they identified key barriers to scaling the intervention across hospitals and health systems, given its synchronous and in-person modality. These barriers are consistent with several implementation barriers that prevent engagement with arts-based interventions, including fluctuation



XSL•FO
RenderX

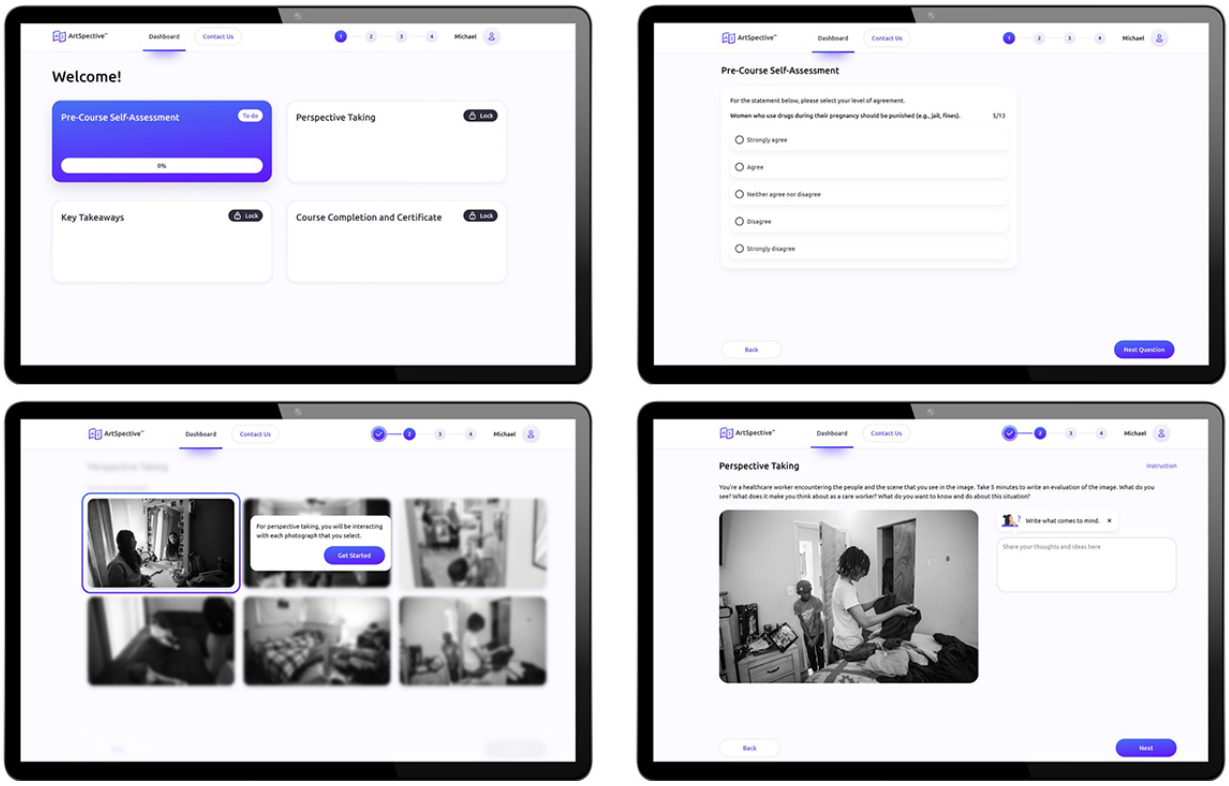
in participation, skepticism of efficacy, and obstacles related to delivery, especially in person [35]. Given these barriers, we adapted ArtSpective for PSU into an interactive, responsive platform that facilitates the delivery of the intervention asynchronously. Responsive platforms and digital delivery of interventions have been demonstrated to improve uptake and overcome implementation barriers related to scalability, especially for interventions designed for nurses [36-42].

Design and Development of Digital Intervention

A multidisciplinary team, including experts in nursing, labor and delivery, health informatics, health communication, and implementation science, developed the interactive responsive platform. Before developing the platform, we conducted 2 focus groups related to the synchronous version of the intervention (n=11) to identify specific requirements for the interactive, responsive platform. Participants noted the need for the adapted intervention to (1) take less time to complete, (2) allow for self-pacing, and (3) be delivered asynchronously [24]. Partnering with a public health communications firm, the synchronous intervention components were adapted into an interactive, responsive platform optimized for desktop, smartphone, or tablet interface. The platform incorporated electronic art exhibits and facilitation materials consisting of a 30-minute, web-based session that nurses could complete asynchronously (Figure 1). The platform design is grounded in the user experience design methodology, which is anchored in principles related to understanding users, user participation throughout the process of development, user-centered evaluation, iteration, a reflection of the entire user experience, and a multidisciplinary perspective to design and development [43,44]. The overall design is guided by Material 3, an iteration of Google Material Design, an open-source adaptable system of guidelines, components, and tools that support best practices of user interface design [45]. The platform also uses structured headings, alternative text descriptions, bold fonts, high-contrast color combinations, and captions to ensure accessibility across all users.

Figure 1. ArtSpective for perinatal substance use (PSU) platform structure.

Before the study's launch, the research team and health communications firm developed an interactive prototype of the digital adaptation of ArtSpective for PSU in Figma (Adobe). A panel of experts with extensive experience in perinatal nursing, PSU, art pedagogy, implementation science, and user interface and experience design examined all prototype elements in an iterative process as part of a heuristic evaluation. This process consisted of identifying platform functionalities individually



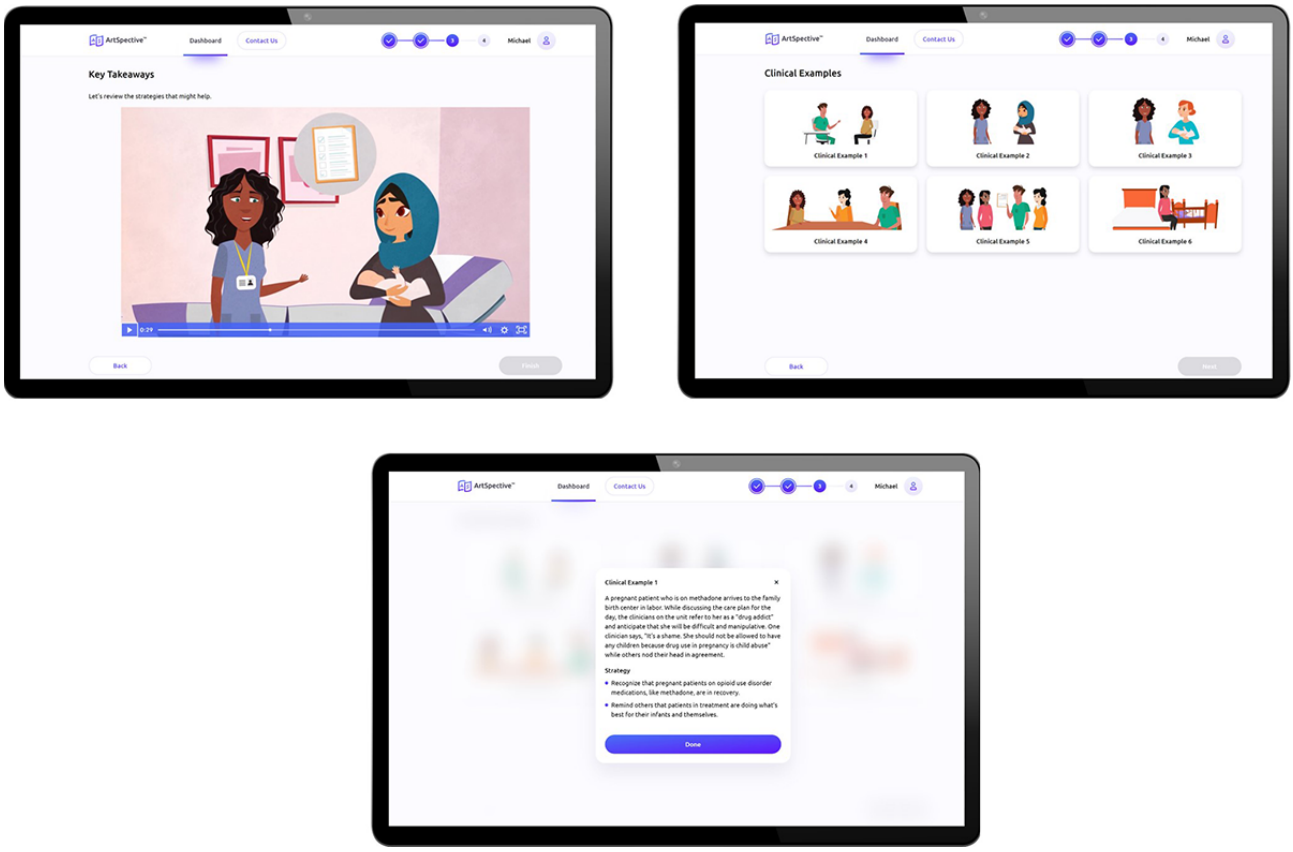
XSL•FO
RenderX

based on the list of heuristics for usable interfaces [46,47]. The health communications firm iteratively refined the prototype as user interface issues were identified.

Platform Flow

At the platform launch, users are asked to register for an account or log into their existing account. Following account creation, users complete a series of demographic questions as part of creating their profile. Once a profile has been completed, the user lands on a dashboard with the four core modules that comprise the intervention: (1) *Pre-Course Self-Assessment*, (2) *Perspective Taking*, (3) *Key Takeaways*, and (4) *Course Completion and Certificate*. Modules are displayed as symmetrical cards with large rounding on each card. Small, rounded badges are included on each module card to indicate if it has a status of "To Do," "Locked," or "Completed." Navigation is contained at the top of the interface, along with a module progress bar that uses numbers and colors to indicate progression through the platform (Figure 2).

Figure 2. Sample of the dashboard, along with the Pre-Course Self-Assessment and Perspective Taking modules, in the adapted intervention.



In the Perspective Taking module (Figure 2), participants are presented with 6 rounded symmetrical cards containing photographs to select from for the exercise. Before choosing a photograph, the user is prompted to complete a brief guided tutorial and then prompted to imagine that they are a health care worker encountering the scene they see in the image and directed to type a message into a textbox consisting of an evaluation of the image from their health care worker perspective. Following this, the participant is presented with the same 6 photographs (the first photograph they chose has a reduced opacity to indicate that it can no longer be selected). The participant is prompted to type a message into a different textbox that evaluates the second image from their personal perspective. After entering their messages, the participant sees each photograph they chose and can read the messages they typed without editing them.

In the Key Takeaways module (Figure 3), participants watch a 1-minute animated video depicting the perspective flipping exercise through the actions of animated characters, exploring how to limit assumptions in patient care through the lens of how the participant's health-care-worker perspective may have been different from their personal perspective in the exercise. After watching the video, participants review 6 rounded symmetrical cards that contain clinical examples and strategies illustrated with the characters from the animated video and watch a 90-second video articulating the core clinical examples and techniques that users reviewed in the previous phase to reinforce the content. On average, participants spend 10 minutes engaging with this module.

XSL•FO
RenderX

Figure 3. Sample of the video displayed in the Key Takeaways module and the Clinical Examples page presented in the adapted intervention.

Before evaluating the effectiveness of a digital adaptation, it is critical to examine its use and sustainability [48,49], including usability, acceptability, and feasibility with end users. Usability is characterized by how well specific users achieve a predetermined goal with efficiency and satisfaction in a particular context [50]. Acceptability relates to how end users think and feel about a digital intervention, while feasibility relates to how well it can be deployed with end users [51-53].

Purpose

This study aimed to evaluate the usability, acceptability, and feasibility of the interactive, responsive platform version of ArtSpective for PSU—designed to deliver an adapted version of the in-person, arts-based, perspective-taking intervention to improve nurses' stigmatizing attitudes toward PSU—following a mixed methods approach. Our goal was to elicit the strengths and weaknesses of the responsive platform by evaluating the user experience to identify strategies that overcome the weaknesses.

Methods

Study Design

The evaluation of the platform's usability, acceptability, and feasibility followed a mixed methods approach, combining target user experience evaluation facilitated through Zoom (Zoom Communications) videoconference and a validated measure of acceptability.

Procedure

Study Population and Recruitment

A purposive sample of nurses was invited to participate through an email sent to all nurses meeting eligibility criteria employed by a large, urban academic medical center in Chicago with high rates of birthing individuals with opioid use disorder and infants with neonatal opioid withdrawal syndrome. This was followed by snowball sampling in both community hospitals and academic health centers in Michigan and Chicago. Inclusion criteria consisted of (1) being credentialed as a registered nurse, (2) actively practicing in a perinatal unit (labor, postpartum, and neonatal intensive care unit), and (3) being at least 18 years old. In addition, a convenience sample of experts in instructional design, stigma, and implicit bias was recruited to participate. The target sample size was 24 nurses and 4 experts.

Methodology

We used theatre testing to qualitatively explore nurses' and experts' usability and acceptability perspectives. Theatre testing is a methodology that is integrated into the Assessment Decision Administration Production Topical Experts-Integration Training Testing (ADAPT-ITT) model and designed to facilitate the adaptation of evidence-based interventions [54]. It is a type of pretesting methodology that has been previously used to test messaging, such as television or print advertisements, with a key target demographic [55]. Participants who reflect the intended audience of the intervention are asked to respond to a demonstration of an intervention and answer questions designed to elicit their reactions to it [54]. A key strength of this methodology is its ability to rapidly gather feedback about a

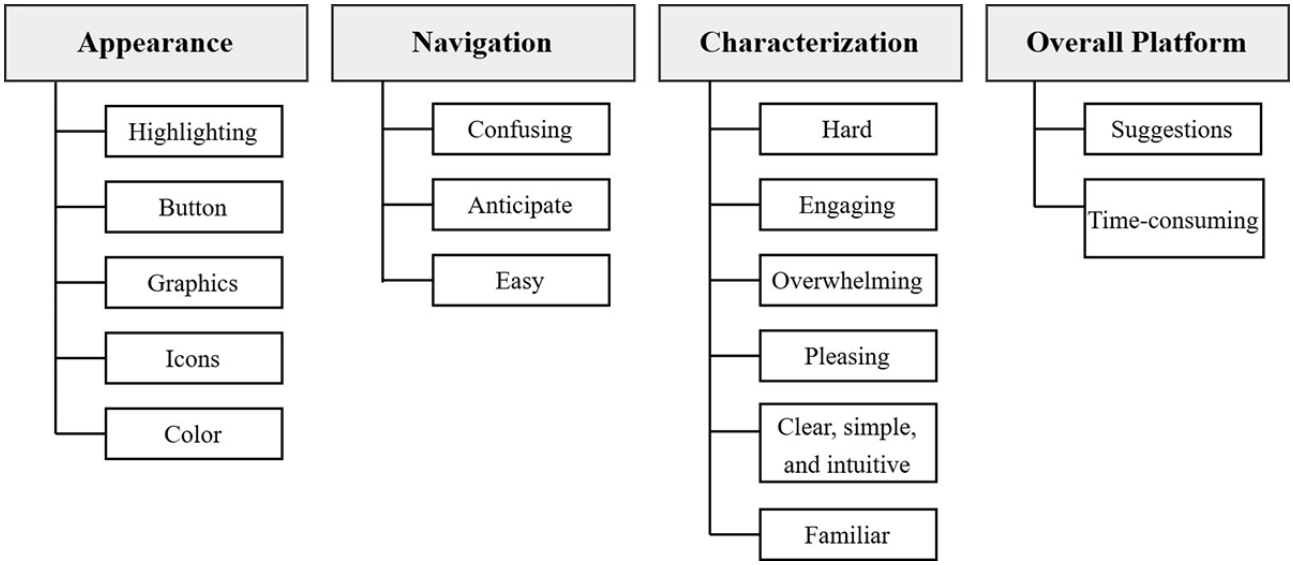
XSL•FO
RenderX

prototype that reflects the intervention as end users would experience it. We modified the 8-item Abbreviated Acceptability Rating Profile (AARP) [56], a previously validated and widely used acceptability instrument, for quantitative acceptability assessment. The abbreviated nature of the instrument was designed to overcome barriers related to time-intensiveness. Modifications to the AARP for this study included specific references to perinatal substance. We complemented the instrument with a separate stand-alone set of 5 items related to satisfaction that were used previously when conducting concept testing of the synchronous intervention [24].

Theatre testing for qualitative evaluation provides a deeper understanding of users' perspectives on interface and platform design and individual user experience. Simultaneously, the quantitative data derived from the validated scale and our supplemental satisfaction questions provide precise measurements of acceptability and feasibility among nurses and experts. The goal was to explore both the usability and user experience of the platform and its acceptability and feasibility as an intervention to address stigma and implicit bias related to the treatment of PSU.

Data Collection

A total of 2 research team members (MR and CS) designed the theatre-testing session interview guide, which was piloted for presentation and clarity of information and workflow (Multimedia Appendix 1). MR (male) has a PhD and MPH. He is a clinical assistant professor with experience and training in implementation science and provider behavior change. CS (male) has a PhD, MSN, and RN. He is an assistant professor with training and experience in implementation science and care for vulnerable populations, including individuals with PSU and postpartum women. This study is reported according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines (Multimedia Appendix 2) [57]. Participants were invited by email to individual sessions facilitated through Zoom videoconference and were informed that the researchers leading the study were developing a new platform to promote a behavior change intervention. Sessions lasted between 30 and 45 minutes between December 2022 and October 2023. Each session was conducted by one of two analysts on the research team (YG) who have extensive expertise in qualitative interviewing and have clinical experience caring for patients with substance use disorder. The analysts did not share their assumptions or motivations for facilitating the study with participants. The study procedure was explained to participants after they had logged into the Zoom session, and participants were informed that the interview would be video recorded and transcribed. Interviewers used the screen-sharing feature in Zoom to display the interactive prototype and clicked through the screens and prompts. To understand participant reactions to the platform, the concurrent think-aloud method was used by asking participants to verbalize what they noticed or did not understand [58]. No training or contextualization of the prototype were offered before the interview began to avoid biases related to preparation. Participants were given minimal assistance in understanding what was displayed, and interviewers only interjected with contextual information to encourage them to continue reflecting on what they saw. Following the demonstration, the interviewer debriefed each participant, using a semistructured interview guide that assessed overall user experience, design of the content in the platform, and ease of navigation, and performed a brief retrospective analysis of issues that participants noted during the demonstration [59]. Participants also completed a questionnaire using Qualtrics XM hosted at the University of Michigan that included questions about demographics, the AARP, and stand-alone satisfaction questions.



Nonparticipants did not attend the sessions, and no relationship with participants was established before they engaged with the study. No repeated interviews were conducted, and no field notes were taken. Sessions were recorded through Zoom Recordings, pseudonymized, and transcribed verbatim. Transcripts were not returned to participants for their review. Data were transcribed by Rev. Data were analyzed in MAXQDA (version 22.8.0; VERBI GmbH), a computer-assisted qualitative data analysis software. The research team met after 21 interviews with nurses to discuss data saturation and information power. Since no new themes emerged in later interviews, the research team concluded that information power had been reached, and no additional interviews were required. In addition, following the 4 interviews with experts, the research team met separately to discuss information power and concluded that since all 4 experts had provided similar feedback, information power had been reached.

Data Analysis

All data, including pilot sessions, were included in the final data analysis. Pilot sessions were included, as no changes were made to the interview guide or protocol after the pilot sessions were conducted. We conducted separate quantitative and qualitative data analyses. All quantitative data regarding acceptability and satisfaction were checked for completeness, and analyses were performed using descriptive statistics (mean, SD, frequency, and percentage) to describe demographic characteristics, responses to the modified AARP, and satisfaction items. All qualitative data were analyzed iteratively, using an inductive framework analysis approach [60]. Three multidisciplinary research team members with backgrounds in implementation science, perinatal nursing, and qualitative research methods (MR, YG, and MM) read the transcripts to inductively identify initial sets of codes. The team then met to discuss codes and map them to a coding schema, resulting in a codebook based on overarching themes. In addition, 2 research team members (YG and MM) independently coded segments in each transcript, meeting regularly with the entire research team to discuss discrepancies and refine or modify the codebook as necessary. This resulted in an iteratively developed, more detailed codebook. All themes were organized into major themes and subthemes that reflected quotes from the interview transcripts (Figure 4). Participants did not provide feedback on the findings.

Figure 4. Overview of overall themes and subthemes.

Ethical Considerations

The study was deemed exempt by the University of Michigan institutional review board (HUM00223937). Informed consent was obtained from all participants. Data have been deidentified. Participants received a US $30 cash card for their time.

Results

Overview

A total of 21 nurses and 4 experts completed theatre-testing sessions. No participants refused to participate. The mean duration of interviews was 31.92 (SD 11.32) minutes for nurses and 40.73 (SD 8.57) minutes for experts. Table 1 shows the demographic data of the participants. The majority of participants identified as female (22/25, 88%), and nearly half (12/25, 48%) of the participants were between 18 and 34 years old. Nearly half (10/21, 48%) of nurses practiced in the neonatal intensive care unit. Years of experience among nurses were equally divided across the three categories (<5, 5-10, and >10 years).

Quantitative Measures

All participants indicated that they found the digital adaptation of the intervention to be highly acceptable, with mean acceptability items ranging from 5.0 (SD 1.0) to 5.5 (SD 0.6) on a 1-6 agreement scale (Table 2). Nurses reported high satisfaction with the platform, with mean satisfaction items ranging from 5.14 (SD 0.56) to 5.29 (SD 0.63) on the same agreement scale (Table 3). Of note, after completing the intervention, participants recognized the severity of clinician stigma toward PSU; they recognized the intervention is needed to better understand and demonstrate compassion for mothers and infants affected by PSU.

XSL•FO
RenderX

Table 2. Acceptability of the intervention among all participants using the Abbreviated Acceptability Rating Profile (N=25).

Item	Score[a], mean (SD)
This is an acceptable program for addressing clinician stigma towards perinatal substance use.	5.20 (0.57)
This program should be effective in reducing clinician stigma towards perinatal substance use.	5.04 (0.79)
Clinician stigma toward perinatal substance use is severe enough to justify this program.	5.54 (0.64)
I would recommend this program to others.	5.00 (1.00)
This program would not have bad side effects on the clinician participant.	5.50 (0.65)
I liked this program.	5.00 (1.00)
This program is a good way to handle clinician stigma toward perinatal substance use.	5.08 (0.74)
Overall, the program would help clinicians.	5.24 (0.59)

[a]Items were rated on a 1- to 6-point agreement scale, with higher scores indicating greater levels of acceptability.

Table 3. Nurses' satisfaction with the intervention (n=21).

Item	Score[a], mean (SD)
The overall program was beneficial to me.	5.14 (0.56)
After completing the program, I have a better understanding of compassion for mothers and infants affected by perinatal substance use.	5.29 (0.63)
After completing the program, I have a better understanding of maternal agency related to caring for mothers and infants affected by perinatal substance use.	5.14 (0.64)
Because of this program, I will be more compassionate to mothers and infants affected by perinatal substance use.	5.25 (0.54)
This program was unique, unlike other training about stigma toward perinatal substance use.	5.19 (0.66)

[a]Items were rated on a 1- to 6-point agreement scale, with higher scores indicating greater satisfaction.

Qualitative Measures

Interviews and Themes

A total of 1797 interview segments were coded from the theatre testing sessions. A total of 4 major themes and 16 subthemes were identified. Major themes included appearance, navigation, characterization, and overall platform. A summary of themes is contained in Figure 4.

Appearance

The first major theme was related to the appearance of the platform and different aspects of the visual user experience and design. We identified five subthemes of appearance: (1) highlighting, (2) buttons, (3) graphics, (4) icons, and (5) color. Participants reflected on how highlighting was used in the navigation bar to indicate progression, module completion, and photograph selection during the Perspective Taking module. They observed that highlighted buttons helped them with navigation. They also noted that highlighting in the navigation bar provided a clear indication of their progression and appreciated the use of visual elements to denote locked or unlocked modules, noting the strength of the visual design of the platform. Participants frequently compared it with other training modules where highlighting as a visual cue was not present, which led to a lack of motivation by the user to complete a different training.

> *…the next button is literally highlighted when you're next and it literally walks you right through it and I think that's super important for courses like this because sometimes it's not easy, people are going to give up and just get right through it and not even complete it as they're supposed to.* [Participant 107]

Participants also appreciated that highlighting related to locked photos was used during the Perspective Taking module to help them know where to go next.

Participants noted the use of buttons throughout the platform and how they served as visual cues for navigation. They noticed that illuminating the buttons and giving them specific colors provided the signal to move to the next step.

> *I liked the visual reminders and cues, having the little padlock sign that's not where you are now. Good use of color and contrast for the buttons to say next or completed.* [Participant 106]

The "Next" button also encouraged them not to give up before completing the course. They also mentioned that the modal window containing a blue button with a check mark helped them to know that the course had concluded and that they could download a certificate of completion. Overall, the buttons served as visual cues for the participants, and the colors made them easy to understand.

XSL•FO
RenderX

Participants observed the strengths of how the text was formatted and sized, the arrangement of content, the use of animated characters, and photography. While most participants noted specific strengths related to monochromatic colors for all graphical elements, some participants pointed out that this seemed like too much of one color, making it more difficult to find specific elements.

> *I would maybe emphasize the woman as a different color. It's like the numbers are that color, the Continue button is that color and the woman is that color. I feel like it's a little overload on that color.* [Participant 119]

One suggestion they made was that the characters in the Key Takeaways module could be easier to understand if they were in full color. In addition, participants commented that the colorization of the graphics helped them understand what was coming next.

Most participants found the typography and the design of iconography and color made it easier to navigate overall. However, some noted that the overwhelming use of blue icons, buttons, and graphics made it difficult to see where to click next. Participants also indicated that icons in the menu choices helped to prompt them on what they needed to complete. They commented that the checkmarks (once completed) that appeared next to each clinical example in the Key Takeaways module helped clarify what needed to be reviewed before they could continue.

> *The same screen as before, just the first one has a checkbox now, so I would assume to continue through until they all get a checkbox. And currently the finish is grayed out, so I assume I still have something to do on the screen before I can move on.* [Participant 111]

Participants also noted that check mark icons in the menu choices helped guide them on what was completed and what still needed to be reviewed. The participants generally found the icons helpful and appealing, especially when combined with bolding and bulleted list formatting.

> *I think definitely the usability of this was a lot more simpler. I feel like other courses that I've taken, it's a little bit outdated and it's a little bit harder to navigate. I like big fonts and all this stuff. It's just nice. It's like bubbles and push, click, next, get started. That was really nice.* [Participant 103]

Finally, some participants observed that using the large checkmark icon at the end of the training was unclear, noting that they were unsure whether to save the certificate of completion or view it. However, they also mentioned that since the only choice was to click on the page, it led them to download the certificate, which clarified the user experience.

Overall, participants commented that the lavender color was a calming element in the platform. They also found the white background and blue colors appealing. Participants mentioned that the color scheme helped them to navigate, pointing out that the grayed-out objects that appeared not to be clickable helped to indicate how the platform progressed. They also noted their satisfaction with how the colored buttons guided participants to click through the different parts of each module.

> *I think the content is pretty calming, giving the lavender colors and just the very light design in general. There isn't too much going on, on the page, so it's not very distractive, and I could see where my tasks are.* [Participant 102]

Although some participants stated that there was too much blue and purple, others felt that a similar color was helpful for consistent navigation. In general, participants remarked that the consistent blue color for all the buttons made it clear where to click next and helped them know how to navigate.

Navigation

The second major theme was related to the user experience surrounding the platform's navigation and how users were able to interpret navigational elements. We identified three subthemes of navigation: (1) confusing, (2) anticipate, and (3) easy.

Overall, participants remarked that the platform was not confusing. However, some participants commented that tutorial features were overly prescriptive, which confused them about whether they were still in the tutorial or were supposed to begin their reflection in the Perspective Taking module.

> *I will say there were times I wasn't exactly sure if I had completed something, or I guess I should say some things were somewhat repetitive, like when I click the picture and then it pops up again and then it goes away, but then I have to click it again. That was kind of the only thing.* [Participant 117]

Participants reported that they knew what to do after each step and that the platform's visual cues helped them anticipate the next step. Overall, they observed that the step-by-step process, including check marks to indicate what was completed, the "Next" buttons that were illuminated when they were activated, and the grayed-out imagery to indicate what could not be selected, helped to guide them on what they needed to do next.

> *Think it was pretty easy to navigate, because once you complete something, it shows you that you've completed it. What else you need to do, there's buttons that says you need to do that. And once you complete a task, the next button or the finish button illuminates, then I feel that's your clue that you could move on.* [Participant 101]

Participants described the visual cues as being very helpful in making navigation easy. They also observed that the signup and log-in features were simple and easy to navigate.

> *…literally for each section, it would explain what the section is, and then in order to continue, you would have to either fill something out, or click the highlighted button.* [Participant 102]

Characterization

The third major theme was related to how participants characterized the platform across engagement, clarity, familiarity, and difficulty. We identified six subthemes of

XSL•FO
RenderX

characterization: (1) hard; (2) engaging; (3) overwhelming; (4) pleasing; (5) clear, simple, and intuitive; and (6) familiar.

There were very few instances of participants indicating difficulty, except for the requirement that they would need to respond to questions about substance use when they might not remember a case related to substance use in their caseload. Participants also noted that if they had personal experience with substance use, it would be more difficult to actively participate.

> *I also don't have any personal or family relationships with people with substance use. So I think in that sense, I don't... I wouldn't have as much hesitation or maybe nervousness in going through this module versus somebody who does have a personal experience. It might be a little challenging, perhaps.* [Participant 105]

Participants noted that one of the most engaging aspects of the platform was knowing in advance how many scenarios there would be during the Perspective Taking module and not being able to skip around in the platform.

> *I really liked the format of this. I've done quite a few modules in the last few months, and I wish they all looked like this because I think sometimes the ones that are just you're going through an automatic voiced PowerPoint and then you have a knowledge check every so often can just really drag you down. Anything that allows for more thoughtful learning I think is good. Yeah, I liked it a lot.* [Participant 108]

They were also very receptive to the active learning format that allowed them to practice a skill instead of reviewing didactic material. In addition, they found the activities on the platform incredibly engaging since they related to a topic they were already familiar with.

> *I think a lot of them are rather mundane and bleak and you just feel like, oh, I have to do another module. But this one was just intriguing. I think a lot of that was because of the uniqueness of it. So it didn't make me feel like, oh, geez, another module I have to do. It kept my interest.* [Participant 121]

A common observation among participants was that the monochromatic color scheme sometimes felt overwhelming to process. However, they reflected that this was modulated by the different photographs used. When presented with the Perspective Taking module, some participants also noted that the task of writing a narrative in 5 minutes felt like a significant task that may not be achievable. Finally, some participants shared that the number of "Next" and "Continue" buttons during the tutorials seemed overwhelming.

> *In the tutorial, a lot set up the same. I do feel like this one, there was a lot of "Hit the 'Next' button," and then "Hit the 'Continue' button," whereas if you just hit the "Next" button, could you not... Could you do without some of the "Next," and then "Next," again, button. It seemed like you had to hit the "Next" button at that end a lot. And I was like, I feel like that's redundant. If you hit the "Next" button, you should just be done.* [Participant 112]

There was high satisfaction with the platform layout, presentation clarity, and information flow, and the participants noted that the use of material design principles caused the platform to be visually pleasant.

> *I think the content is pretty calming, giving the lavender colors and just the very light design in general. There isn't too much going on the page, so it's not very distractive, and I could see where my tasks are.* [Participant 101]

Participants also noted that instructions and guidance were unambiguous and made progressing through the different modules easy. They were especially satisfied with how the design allowed them to see the difference between the writing activities in the Perspective Taking module and the didactic material in the Key Takeaways module. There was consensus on the dashboard's clarity about how to progress through the platform, and participants found the signup and sign-in flow to be very intuitive and accessible.

> *There's four distinct sections. They kind of go in an order. Once you finish one, it highlights that you're supposed to move on to the next. So there's not really any way to get kind of lost.* [Participant 105]

Participants noted that the Key Takeaways module structure that used cards, modal windows, and short video segments was clearly organized and easy to follow.

Finally, participants consistently reported that the format was very familiar and similar to other courses they had taken.

> *It reminds me of kind of the courses that we have to take in the hospital when we have to renew or look at our continuing education. It has kind of that similar feel.* [Participant 115]

Overall Platform

The fourth major theme was related to participant observations about the entire platform experience, with a particular focus on their suggestions for improvements and how they would characterize the time commitment required to complete the platform activities. We identified two subthemes: (1) suggestions and (2) time-consuming.

Participants suggested that during sign-up and profile creation, the platform should not request a profile picture, as this is too personal for an educational module connected to their workplace.

> *The profile picture thing, unless it was like pre-selected profile pictures, but I think it would just be kind of funny also if you were just doing an education module for them to ask for a profile picture.* [Participant 116]

In the Pre-Course Self-Assessment module, participants noted that it would be helpful if they were given more notice that they would be prompted to share their personal perspective as part of the training, which may be something not all nurses want to do. During the Perspective Taking module, participant suggestions included reducing the length of the tutorial to avoid redundancy, making the visuals more explicit about what role

XSL•FO
RenderX

they were assuming in each of the narrative writing steps, retaining instructions from one screen to the next to help recall what to do, and adding more arrows and icons to help with users who are less experienced with web-based platforms. In addition, participants suggested some improvements to the exercise that was being facilitated asynchronously in this module. This included a desire to learn other participants' perspectives and eliminate the review of their narratives after they wrote them, since they could not be edited. In the Key Takeaways module, participants suggested that the clinical examples and strategies could be separated more clearly to deliver more independent information. They also thought that these could be more consolidated to help participants remember them.

> *It might be nice if you were like, here, read this clinical example and then click a button and you say, actually, here's the strategies that we recommend for this situation, instead of just having it all on one page. If you separate those, it might be more clear to people this situation actually did not go well. Here's what we want to promote.* [Participant 106]

Finally, some participants suggested that the platform be more explicit about available subtitles for videos so that users who do not have headphones could still review the video content. In the Course Completion and Certificate module, participants suggested that the platform include an instrument that assesses competency related to the learning before providing a certificate, as well as a presentation of statistics and background data about maternal substance use, so that participants could carry more issue-related content with them after participating.

Very few participants noted that the platform was too time-intensive after completing the application session during the interview. Those participants who did observe this aspect said that when using the platform, they might need to take a break after the perspective-taking exercise before proceeding to the Key Takeaways module, since the perspective-taking exercise required writing, and the Key Takeaways module required listening and reading. Even though the total amount of time for the whole session was approximately 30-45 minutes (interview and application session together), they thought that taking a break between the two modules might be helpful.

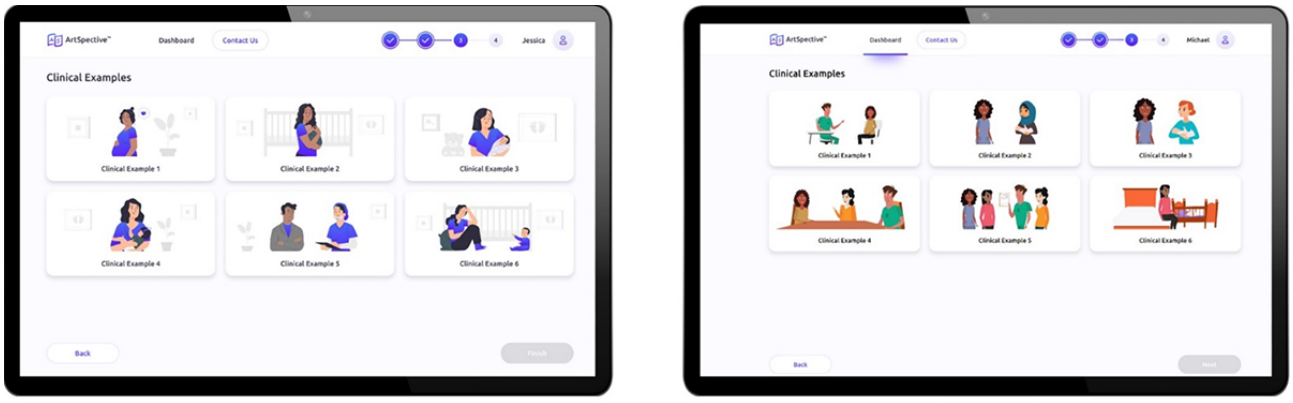
> *...I see a few key takeaways, but by this point I'd probably take a two-minute break or five-minute break only because that perspective taking took a lot of my mental capacity, so I'll probably just rest and, I don't know, refresh my mind for a couple minutes. Then, I'll go ahead and press the key takeaway.* [Participant 103]

Discussion

Principal Findings

In this study, we evaluated the initial usability, acceptability, and feasibility of the interactive, responsive platform version of ArtSpective for PSU—an adapted version of an arts-based synchronous intervention designed to improve nurses' stigmatizing attitudes toward PSU—following a mixed methods approach. We engaged 21 perinatal nurses and 4 experts in instructional design, stigma, and implicit bias to participate in theatre-testing sessions where they qualitatively assessed the usability of the platform and quantitatively assessed acceptability. This mixed methods approach has been extensively used to evaluate usability [61-64] and is consistent with previous work that uses theatre testing to gather feedback on an intervention from a specific group of users [65-67].

The results from the theatre testing sessions were positive overall, with participants expressing high satisfaction with the appearance of the platform, the ease with which they were able to navigate the various modules, their engagement in the platform, the clarity of the presentation, and its feasibility to be completed asynchronously by perinatal nurses. These findings were consistent with the quantitative acceptability measures and complementary satisfaction items. Using a mixed methods approach provided a more holistic assessment of the platform's different usability, acceptability, and feasibility aspects among perinatal nurses and experts.



Furthermore, while quantitative and qualitative analyses indicated high acceptability and satisfaction, the theatre-testing sessions allowed for more granular data on platform usability. The use of theatre testing as a modality for conducting this type of evaluation also provided a more accessible method for practicing nurses to participate as it did not require them to allocate more significant time to engage in task-oriented usability testing, overcoming barriers related to engaging health care providers in this type of study [68-70] and engaging far more than the 5 participants that are minimally adequate to identifying more basic usability challenges [71]. Furthermore, an important implication of using theatre testing in this way is that we could collect granular usability data without investing fully in a developed platform. This provided for a more cost-effective development process that allowed developers to incorporate target user feedback before the final development of the platform.

In designing an interactive, responsive platform for perinatal nurses, we observed that while having a monochromatic color scheme consistent with material design principles may be helpful, it might also make it more difficult for nurses to discern differences. As a result, one of the updates made to the platform before development included changing the color scheme of illustrated characters in the Key Takeaways module from monochromatic to full color (Figure 5). In addition, while evidence related to effective asynchronous module instructional design recommends robust tutorials to guide participants [72,73], we observed that too many instructions could lead to more confusion and frustration. Therefore, future tutorial integration into interactive, responsive platforms for health care providers should be highly targeted and aligned with only the most essential information. This could be integrated through tooltips or info buttons that allow users to select which aspects of the platform they need more help clarifying. At the same time, our findings demonstrate that while an asynchronous platform may facilitate engagement in an intervention among health care providers, it must facilitate rapid content completion without sacrificing meaningful comprehension and overall effectiveness. Our findings indicate that achieving this goal requires a dynamic and modern design that also balances graphical and verbal cues

XSL•FO
RenderX

with a similar structure to other training platforms that allows users to recognize that the material is consistent with different pieces of training and, therefore, gain trust with users so that they are willing to engage in completing the intervention with a high degree of fidelity to each step.

Figure 5. Platform screens before and after the completion of theatre-testing sessions: (A) the original Clinical Examples screen with monochromatic characters and (B) the updated screen with full-color characters aligned with the animated videos.

A B

Comparison With Previous Work

Our findings related to acceptability and satisfaction were consistent with those related to our previous work, demonstrating satisfaction with the intervention [24]. This supports our conclusion that the platform addressed some of the dissatisfaction points identified in the previous study of the synchronous intervention, which illuminated the need for an asynchronous version of the intervention that would not compromise satisfaction overall among nurses.

Limitations

Our study is not without limitations. First, while we achieved information power after recruiting 21 perinatal nurses, 28% (7/25) of participants identified as either African American or Asian, and 88% (22/25) identified as female. While these demographics are somewhat representative of the perinatal nursing field, our results related to the usability of an interactive, responsive platform outside of the perinatal specialty might be more generalizable with a different group of participants. Furthermore, all participants were from two states in the Midwest, which may not be generalizable to providers in other regions of the United States. Second, although a larger sample of experts may have offered additional feedback, the sample included in this study was conveniently selected, represented multiple disciplines with varied expertise, and the research team concluded that information power was reached after receiving very similar feedback from all 4 experts being interviewed. Third, while theatre testing was an effective approach to gathering input from target users, we could not incorporate task-specific analyses into the sessions, as the theatre-testing approach is oriented around the presentation of the prototype. This enabled our study to include more nurses, but a task-oriented analysis, where we could compute a severity score for different issues encountered, may have allowed us to further augment our findings [74-76]. Fourth, while the validity and reliability of the AARP scale have been previously demonstrated [56], we did not have a sample large enough to evaluate the reliability of the AARP or the individual satisfaction items in our study. However, these items were administered primarily to pragmatically assess acceptability and satisfaction overall to inform future usability testing of the developed platform. Finally, since we were presenting a prototype of the intervention, not all features were fully implemented. For example, users reviewed a desktop version of the platform even though it was designed responsively. The decision to only review the desktop version was motivated by study feasibility. A prototype that switches between desktop and mobile formats may have confused participants as they went through the various modules. One alternative would be to review a separate mobile prototype. However, that would introduce feasibility challenges related to how much time perinatal nurses could allocate to participate in the study. To overcome these limitations, future studies might stratify participants into two groups where one group engages in theatre testing with a desktop-oriented prototype and the second group reviews a mobile prototype.

Conclusions

Developing and evaluating the usability of a digital adaptation of ArtSpective for PSU provided insight into key aspects related to usability, acceptability, and feasibility that should be considered when creating a digital adaptation of an arts-based intervention for health care providers. Overall, theatre-testing sessions identified key strengths and weaknesses of the prototype and provided opportunities to refine the platform's design before engaging in more costly development. Nurses and experts found the platform acceptable and were highly satisfied with its design and features. Future studies could evaluate the efficacy of the fully developed platform among practicing perinatal nurses and inform further refinements of the platform to ensure that health care providers in other specialties can engage with the intervention asynchronously.

Abstract

Background: As the prevalence of mild cognitive impairment (MCI) among older adults increases, so does the need to enhance social participation and cognitive functions through innovative interventions. Digital storytelling in group settings holds potential not only to foster social connections but also to integrate with traditional in-person activities, leveraging both for greater impact.

Objective: This study aimed to evaluate the feasibility of the Huiyou app in supporting group-based storytelling activities, aiming to enhance social participation for people with MCI. We focused on the app's ability to improve storytelling goal attainment, social connectedness, self-efficacy, and subjective happiness, comparing these outcomes between the experimental and control groups.

Methods: We randomly assigned 20 participants with MCI to either an intervention group or a control group, engaging them in the use of the Huiyou digital storytelling app over 4 weekly sessions of 45 minutes each. We measured outcomes through the Assessment of Life Habits questionnaire (77 items), particularly outdoor activities and interpersonal relationships; the Social Connectedness Scale–Revised (20 items); the General Self-Efficacy Scale (10 items), focusing on coping self-efficacy; and the Subjective Well-Being Scale (SWBS; 20 items), with a special emphasis on self-acceptance.

Results: The sample had an average age of 69.7 (SD 3.21) years, with no significant (P=.23) baseline differences between groups in age, sex, or educational background. Cognitive function, assessed via the Montreal Cognitive Assessment–Chinese questionnaire, also showed no significant differences at baseline (P=.20). Specifically, significant enhancements in the outdoor activity (mean value difference 0.171, SD 0.353; Cohen d=1.046; P=.03) and interpersonal adaptation experience subscales of the SWBS (mean value difference 0.167, SD 0.247; Cohen d=1.290; P=.01) were noted. Notably, storytelling performance improved markedly, evidenced by increases in story sharing duration and complexity. Although overall improvements in Assessment of Life Habits (P=.14), Social Connectedness Scale–Revised (P=.59), and Subjective Well-Being Scale (P=.26) scores were not statistically significant, the large effect sizes observed suggest potential benefits of the Huiyou app that might be obscured by the study's small sample size.

Conclusions: This study indicates that the Huiyou mobile storytelling app is feasible to enhance social participation and specific aspects of social functioning such as interpersonal adaptation for people with MCI. Despite the lack of significant changes in overall scores for key scales, observed effect sizes highlight a positive trend that merits further investigation. These results advocate for the continuation of digital intervention development to improve quality of life and social integration for individuals with MCI.

Introduction

Background

People with mild cognitive impairment (MCI) face significant challenges in daily life due to cognitive deficits and emotional changes that reduce their ability to function socially [1]. Cognitive decline is closely linked to decreased social activities, with behavioral symptoms and social-cognitive deficits often leading to poor maintenance of social networks and difficulties using everyday technology [2,3]. Memory loss further undermines feelings of security and autonomy, often resulting in frustration and anxiety [4]. Despite these challenges, maintaining high-level social participation is crucial for people with MCI as it has been shown to prevent or slow down cognitive decline, improve quality of life, and reduce social isolation and loneliness [5-8]. Despite this, people with MCI often experience reduced social connections and activities, which are fundamental to social participation [9,10]. Conversely, limited social engagement can lead to further cognitive decline and increased isolation [11,12]. However, multiple barriers, including the subtle nature of MCI-related social decline, often impede participation in social activities. In response, various interventions have been developed to support social participation for people with MCI. Technology-based interventions, supported by modern technologies such as cameras, internet communication, and speech-to-text tools, have shown promise in enhancing social participation for people with MCI. These interventions include cognitive rehabilitation programs, educational tools, telecommunication systems, social robots, and self-management systems, all designed to improve social engagement and quality of life [13-15]. While some studies suggest that these interventions have outcomes comparable to those of traditional treatments, such as in the quality of social interactions [16], they offer the advantage of expanding care from hospitals to homes, reducing therapists' workload and enabling remote treatment [17]. Recent studies have demonstrated that patients engaging in digital technology–based serious game interventions experience notable improvements across multiple domains, including global cognitive function, executive function, attention, mood (notably reductions in depression), and activities of daily living, compared to those undergoing traditional rehabilitation or receiving standard medical care [18]. Given this context, digital storytelling interventions, which combine the benefits of technology with the therapeutic power of narrative, hold particular potential to further enhance social participation and cognitive engagement among individuals with MCI.

Digital storytelling is a powerful tool for enhancing cognitive engagement and fostering social connections, particularly among older adults with MCI. Engaging in storytelling requires individuals to recall past experiences, organize their thoughts, and articulate them coherently [19], which stimulates essential cognitive processes such as memory recall, attention, and language skills. For those with MCI, this activity offers a structured yet creative outlet for mental engagement, helping maintain and even improve cognitive functions that are often challenged by the condition [20]. In addition, storytelling fosters social connections by creating opportunities for individuals to share their personal narratives with others whether in person or through digital platforms [21]. Recent developments such as time travel tours have made digital storytelling more accessible to older adults by enabling them to create and share location-based narratives through a conversational web interface without requiring advanced technical skills [22]. This exchange of stories not only builds empathy, understanding, and a sense of community but also combats the social isolation that frequently accompanies cognitive decline [23]. When older adults share their stories in a group setting, they reinforce their own memories while contributing to the collective memory of the group, further strengthening social bonds [24]. As an intervention, digital storytelling uniquely addresses the cognitive and social challenges faced by people with MCI by combining the therapeutic benefits of storytelling with the accessibility and engagement potential of digital tools. This dual focus on cognitive engagement and social connection makes digital storytelling a valuable approach for improving the overall well-being of older adults with MCI, providing them with a meaningful way to connect with others and exercise their cognitive abilities.

Prior Work

Technology-based storytelling interventions involve recalling previous actions, events, and feelings using physical prompts (ie, photographs, household items, music, and audio recordings). Such prompts are now commonly stored and presented digitally [25]. However, there is some evidence, albeit not conclusive, suggesting that storytelling interventions or reminiscence therapy for dementia yield no significant effect on quality of life immediately following the intervention period when compared to a control group (no treatment; see the study by Wood [26]). In reviews of storytelling interventions and apps aimed at enhancing social participation among people with MCI [19,27], we identified 4 key themes: capture memory, saving memory, memory retrieval, and sharing. These themes represent the core aspects of the interventions, focusing on how individuals can record, store, recall, and share their personal experiences. These elements collectively contribute to the effectiveness of technology-based storytelling interventions.

Various digital storytelling applications are designed to assist older adults, particularly those with MCI or dementia, in enhancing their mood and increasing social engagement [28]. The main features for generating materials across these applications include the ability to upload personalized content such as photos, videos, and music [29]. Some applications offer additional capabilities such as selecting auto-play intervals [30], adding tags [31], or creating dynamic timelines [29]. For memory retrieval, features include auto-playing photos and videos, viewing materials on timelines, and using virtual reality to project realistic images [32]. Some applications support a

XSL•FO
RenderX

random display of materials to trigger reminiscence [33]. Story sharing capabilities vary, with some applications enabling sharing through smartphones, tablets, or dedicated platforms [34,35]. These features often include options to share edited storybooks, personal videos, or narrated slideshows with family, friends, or broader networks [25,30]. Additional features frequently involve creating structured stories, using prewritten scripts, integrating multimedia content, and supporting administrative activities such as tagging and organizing materials [36].

The platforms for these applications are primarily smartphones and tablets [32], with some using laptops, computers, or virtual reality devices [37]. The impact on social participation includes improving mood, increasing social interactions, enhancing subjective well-being, and fostering closer ties with friends and family [30]. However, specific outcomes vary, and not all applications provide detailed results on social participation. Overall, these digital storytelling applications demonstrate significant potential for enhancing social engagement and emotional well-being among older adults with cognitive impairments.

Digital storytelling interventions offer a promising avenue for enhancing social participation among people with MCI, but they also face significant barriers and limitations. One major issue is that most interventions target individual relationships rather than broader community-based connections [8,38], which can limit the social impact and scope of interaction. This focus on personal relationships might support social connections within families but does not necessarily encourage engagement with the wider community or strangers, which is essential for comprehensive social participation. Another barrier involves the difficulty that people with MCI often encounter with commercial digital storytelling applications [39]. These applications frequently require a level of digital literacy that can be challenging for this group even after training sessions. As a result, many interventions rely on caregivers or trained volunteers to help develop and share stories, which may not be sustainable or widely accessible [29,40]. This indicates a need for user-friendly applications designed to accommodate the specific needs and capabilities of people with MCI, reducing the learning curve and associated resource demands. There is a research gap in developing customized software that caters specifically to the usability needs of people with MCI [41,42]. The addition of group elements to digital storytelling can enhance engagement and foster a sense of community [43], yet current digital storytelling tools focus on individual experiences, not collaborative storytelling [30,44]. Privacy concerns also emerge when sharing stories with broader audiences [43,45]. While sharing personal stories online can create new connections and engagement, it also poses risks of exposing sensitive information or triggering unfavorable reactions from a wider audience. This necessitates careful consideration of privacy and safeguarding measures when designing digital storytelling interventions. Moreover, most studies use the basic versions of the interventions or applications, but few studies have been conducted as randomized controlled trials to measure the efficacy of the interventions or applications [19]. Recent international research underscores the potential of digital health interventions in supporting individuals with MCI. A systematic review and meta-analysis by Di Lorito et al [46] found that such interventions can produce positive effects on cognitive abilities among people with MCI and dementia. Furthermore, Karakose et al [47] conducted a comprehensive bibliometric and science mapping analysis, revealing the evolving landscape of digital addiction research, which is pertinent to understanding user engagement with digital health tools. These findings highlight the importance of integrating international perspectives to inform the development and implementation of digital storytelling applications such as Huiyou.

The Huiyou App

To bridge these research gaps, we co-designed an app, 会友 (Huiyou, derived from the pinyin pronunciation, which means “meeting new friends” in Chinese), with therapists and people with MCI [48]. It is inspired by a classic quote from Confucius in the *Analects*: “A gentleman seeks friendship through literature and reinforces goodness through friendship.” This statement emphasizes the idea that individuals cultivate friendships through literary exchange and support virtue through companionship. The name reflects a positive vision of fostering social connections through literature, friendship, and benevolence. Users can leverage technological means through the software to expand their social circles, facilitating deeper communication and connections with others. The name embodies the social nature of the software and its goal of promoting friendship. Huiyou effectively stores memories from daily life and encourages people with MCI to reminisce and discuss favorable memories with new friends. Huiyou has 2 main features: supporting people with MCI to conduct self-reflection daily (preparing materials using cues) on certain topics and facilitating group memory retrieval (presenting a story and promoting a discussion with group members). In addition, Huiyou uniquely integrates structured outdoor activities with digital storytelling to reinforce physical engagement alongside cognitive and social interaction. The 2 innovative aspects of Huiyou are embedded memory retrieval for capturing daily life and its ability to collect recent, valuable memories. The intervention design also deliberately combines self-generated memory prompts with shared group discussions to maximize both personal reflection and collective participation. Another feature is combined self-reflection and group reflection to enhance social interaction during the discussion in addition to sharing and participating in social activities outside the home. A previous publication provides more details about the design of Huiyou [48].

Study Objectives

This study contributes theoretically by advancing the understanding of digital storytelling to enhance social participation and emotional well-being for people with MCI. Empirically, it delivers one of the first pilot evaluations of a co-designed, culturally adapted mobile storytelling app for community-dwelling older adults with MCI in China. The integration of storytelling with structured outdoor engagement provides a practical model for accessible, technology-supported interventions in low-resource settings. This experimental study aimed to investigate the feasibility of the Huiyou digital

XSL•FO
RenderX

storytelling intervention for people with MCI. We hypothesized that (1) the Huiyou intervention would significantly enhance social participation among individuals with MCI, as evidenced by improved quantitative measures of social participation outcomes; and (2) the intervention would facilitate the achievement of predefined social participation goals, with quantitative assessments confirming goal attainment.

Methods

Ethical Considerations

Ethics Review Approvals or Exemptions

Ethics approval for this study was granted by the Swinburne University of Technology Human Research Ethics Committee (approval number 20226525-11105; September 26, 2022). The study was conducted in accordance with the principles of the Declaration of Helsinki. The study protocol was also published in advance [49].

Informed Consent

Informed consent was obtained from all participants prior to their involvement in the study. For participants with mild cognitive impairment (MCI), consent was obtained with the support of a formal or informal caregiver. Participants were also asked to articulate their reasons for participation to confirm understanding and willingness. Trained research assistants provided step-by-step guidance throughout each session, addressing confusion or distress in real time. Participants were continuously monitored for signs of cognitive overload or discomfort, with immediate support provided as needed.

Privacy and Confidentiality

All data were anonymized using participant ID codes, and no personally identifiable information was collected or stored. Data were securely stored on encrypted servers with access restricted to authorized research personnel. No identifiable images or personal data of participants are presented in this manuscript.

Compensation Details

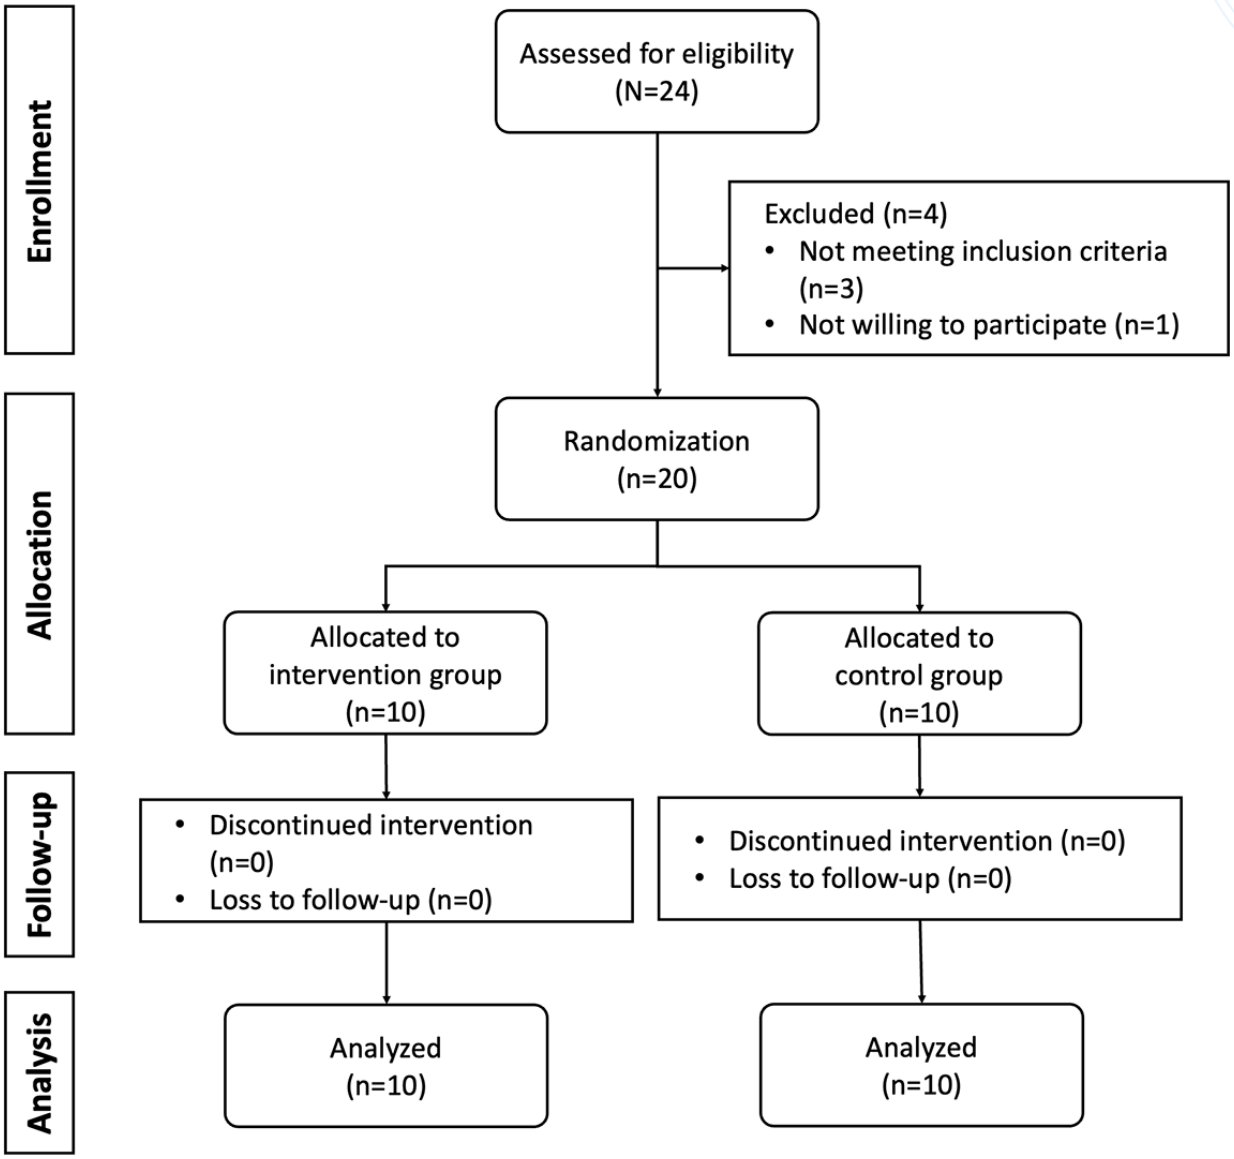
No financial or material compensation was provided to participants. Participation was entirely voluntary, and support was offered to ensure a safe and respectful experience.

Study Design and Procedure

We conducted a 4-week experimental study with a waitlist control group to assess the impact of the Huiyou app on people with MCI (see Multimedia Appendix 1 for the CONSORT checklist). The randomization sequence for participant allocation was computer generated and managed through a Microsoft Excel spreadsheet. As this study involved active participation in the experimental activities, it was designed as a single-blind experiment. The experiment was conducted in 2 batches, with the second batch serving as a supplemental recruitment due to some participants' limited availability.

This study commenced with the installation and learning of the Huiyou software, along with pretesting, on December 18, 2023. The intervention period spanned the second to the fifth week, with posttesting conducted at the end of the fifth week and some participants opting for testing in the sixth week. The intervention sessions took place at the Jing Shi Psychology Centre Meeting Room in Tiantongyuan, Tongzhou District, Beijing.

After each intervention session, the theme for the following week was announced, with the first week's theme disclosed after the pretest. A WeChat group was established to facilitate the convenient communication of activity information and scheduling adjustments. Participants had the flexibility to upload the necessary materials for their stories through the Huiyou app at any time, including photos and videos.



Recruitment

Recruitment for this study commenced in September 2023 and concluded in December 2023. We initiated participant selection by prescreening people with MCI from previous studies. Our collaboration with the Jing Shi Psychology Centre was pivotal in reaching out to potential participants. The center provided these individuals with detailed information about the study, including providing informed consent forms and an overview of the activities involved. A total of 20 participants enrolled in the study, with 10 (50%) randomized to the experimental group and 10 (50%) to the control group (Figure 1). The communication between the participants and staff in the partner institution before the formal research was aimed at gauging their interest in participating in our research. In addition, the center assisted in the recruitment process by conducting screenings of people with MCI using the Montreal Cognitive Assessment–Chinese (MoCA-C) questionnaire [50]. This meticulous and collaborative approach ensured that we recruited participants who met the study criteria and were well informed and motivated enough to contribute to our research on improving the lives of people with MCI. Participants were asked to complete the scales within a week.

The inclusion criteria for recruiting people with MCI were being clinically diagnosed with MCI using the MoCA-C screening tool, residing in community-dwelling complexes in Beijing, being aged ≥65 years, and having no significant visual or hearing impairments. In addition, participants were required to have adequate reading skills, especially for digital interfaces. Exclusion criteria were in place for individuals who had neurological conditions such as stroke or brain injury as these could affect daily functioning and impact study outcomes.

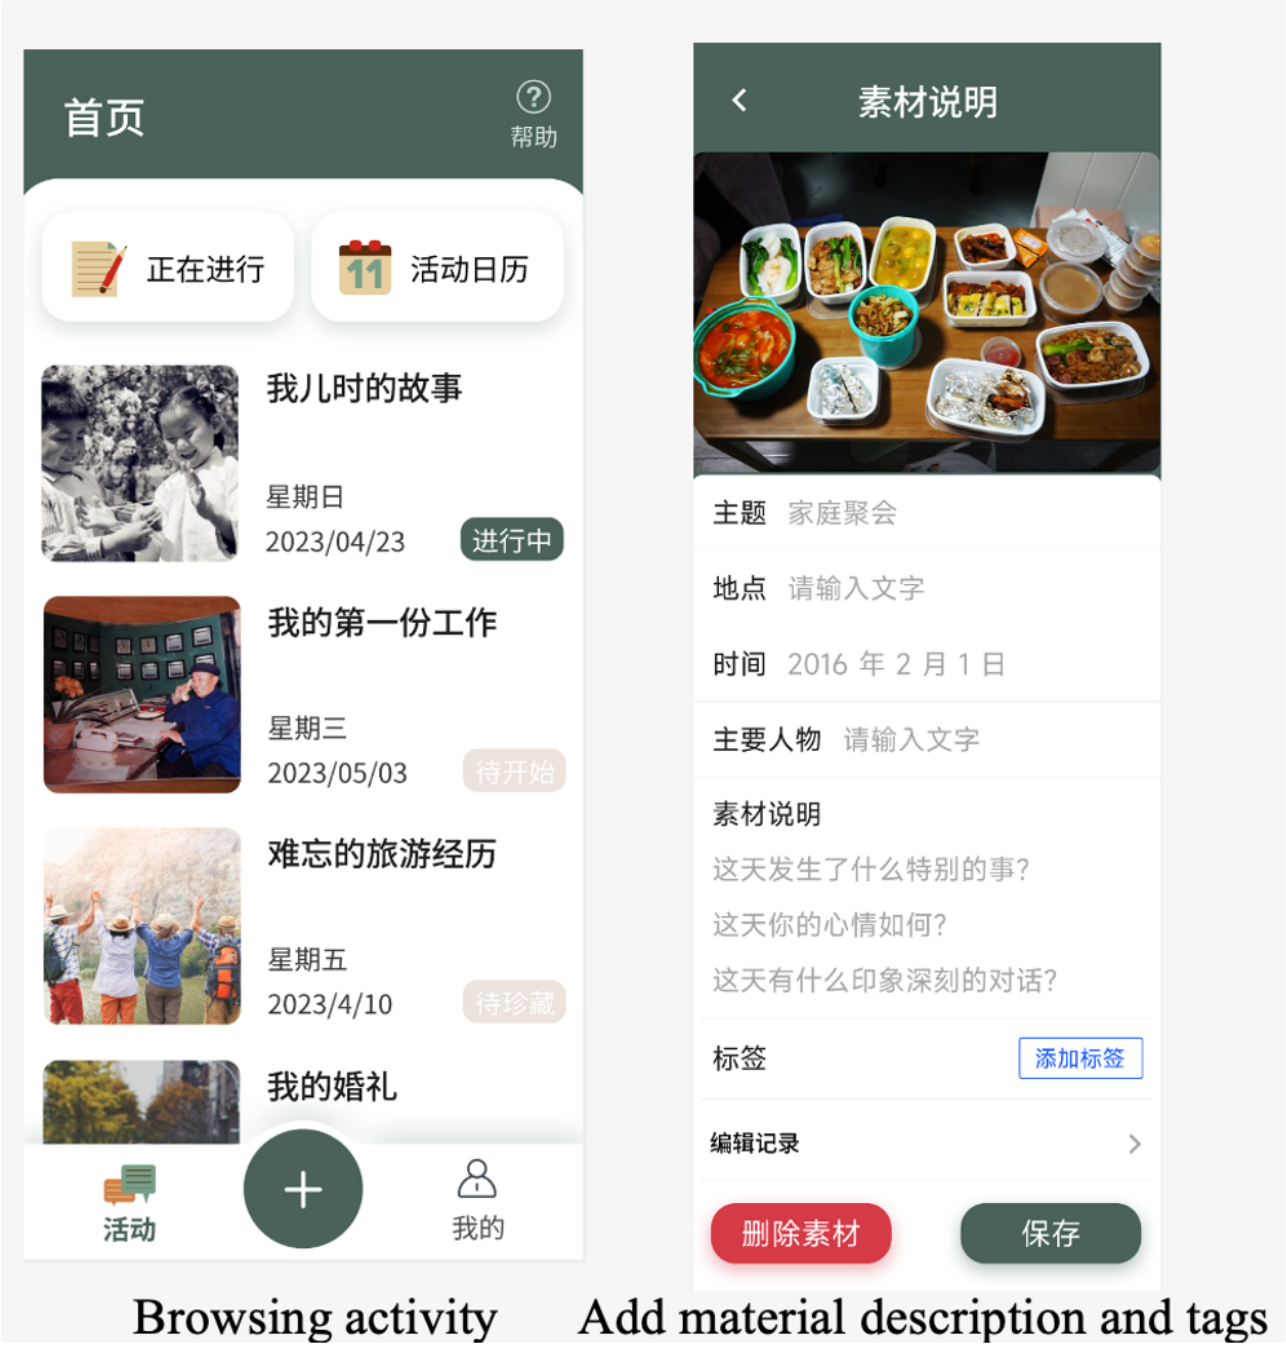
Intervention: Huiyou Group



Huiyou is an Android-based mobile app designed to support digital storytelling co-designed with therapists and people with MCI [48]. Participants engage with weekly activity themes, where they are prompted to prepare and upload photos or videos relevant to 1 of 3 selected themes. Users can also edit keywords and categorize them for better organization. Once an activity begins, participants are grouped into small teams of 3 to 4 members for a storytelling session. A tablet serves as the interface for the storyteller, displaying prepared keywords to aid in their narrative, whereas a computer screen acts as the display terminal for the audience. Currently, owing to technical constraints, the display technology is managed through Keynote (Apple Inc), with researchers predownloading and processing materials to ensure smooth playback. Participants are given approximately 30 minutes before each activity to prepare their materials. The sessions are held weekly, with the timing determined by each group through discussions before each activity. Goal assessments are conducted at the end of the second and fourth weeks, with detailed records kept of goal completion, notes, and the duration of each story shared.

Figures 2 and 3 illustrate various functionalities of the Huiyou mobile app designed to enhance user interaction and memory recording. The workflow of Huiyou is as follows. Participants sign up for topics of interest, and we assist them in scheduling a sharing time. Huiyou assigns 3 missions, providing several guiding questions to help participants think about and prepare their materials in advance. During preparation, participants can type in memos and tips. During the sharing session, the pictures are displayed to group members, and participants can refer to their memos. This process ultimately creates a shared storytelling memory. The co-design and usability study of Huiyou provides a more detailed description of the app [48]. The first screenshot in Figure 2 shows the Browsing Activity page, offering a user-friendly interface for users to navigate through different activities seamlessly. The second screenshot in Figure 2 highlights the functionality for users to add material descriptions and tags, enabling them to organize and categorize their entries for better accessibility and management. The first

XSL•FO
RenderX

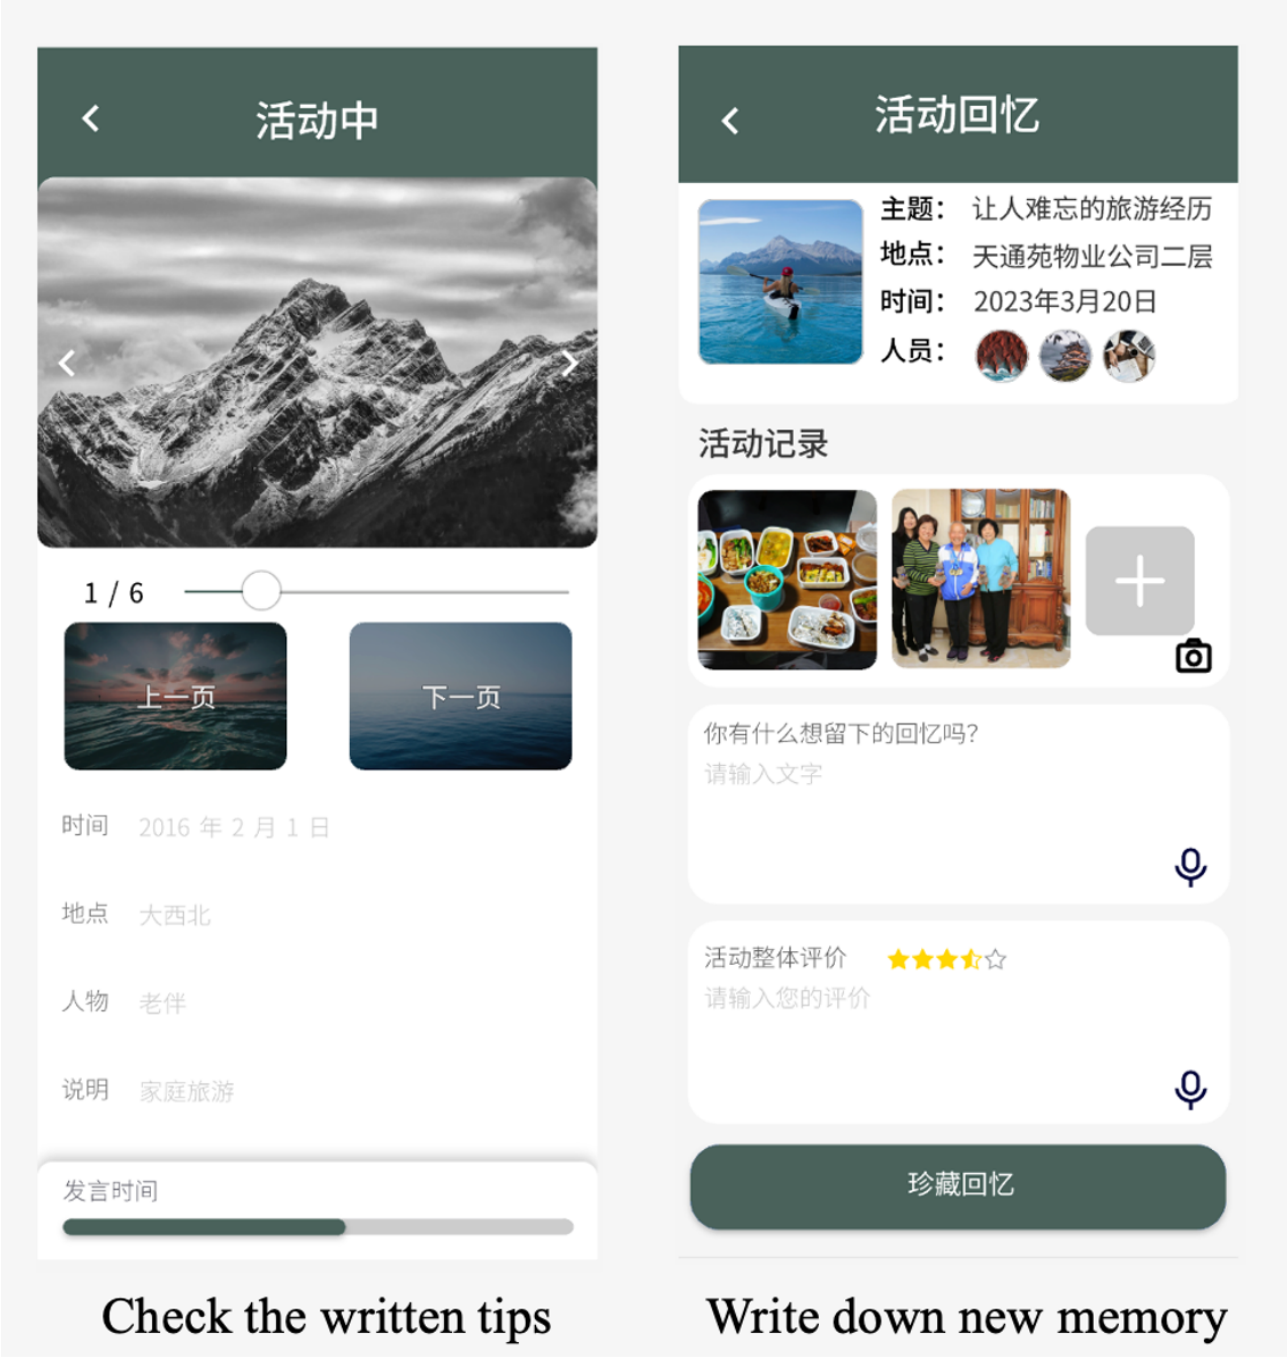


image in Figure 3 shows the Check the Written Tips section, where users can access practical advice on using the app effectively. Finally, the Write Down New Memory feature, which provides a structured format for users to document new memories with prompts and text fields to guide detailed recollections, is shown in the second screenshot of Figure 3.

Figure 2. Screenshots of Huiyou—memory collection.

XSL•FO
RenderX

Figure 3. Screenshots of Huiyou—story sharing.

Waitlist Control Group

The participants in the waitlist control group were involved in all evaluations at the beginning (T0) and end (T1) of the study. After completing the final evaluation (T1), they were offered the opportunity to learn about the Huiyou program, which they could potentially use in future research. This arrangement ensured that all participants received equal information about the program's features and potential benefits, although they did not use the program during the study period [49].

Measures

Assessments were completed at community locations in Beijing, China, at baseline (T0) and 4 weeks (T1). Baseline participant characteristics included age, sex, educational level, and MoCA-C score. This paper summarizes the assessments for social participation (Assessment of Life Habits [LIFE-H]; 77 items), social connectedness (Social Connectedness Scale–Revised [SCS-R]; 20 items), self-efficacy (General Self-Efficacy Scale [GSES]; 10 items), and subjective sense of happiness (Subjective Well-Being Scale [SWBS]; 20 items), as Table 1 shows. Further details of the study design can be found in the protocol paper [49].

XSL•FO
RenderX

Table 1. Study assessments and outcome measures, which were conducted on all participants at baseline and after 4 weeks.

Assessment	Outcome
Social participation	• The LIFE-H[a] (77 items): indoor activity, outdoor activity, interpersonal relationships, community life, and amusement and recreation
Goal attainment of storytelling	• Duration of story sharing • Number of key events in the story • Number of photos collected • Number of notes made on the photos
Social connectedness	• SCS-R[b] (20 items)
Self-efficacy	• GSES[c] (10 items): action self-efficacy and coping self-efficacy
Subjective sense of happiness	• SWBS[d] (20 items): interpersonal adaptation experience, mental health experience, family atmosphere experience, psychological balance experience, physical health experience, target value experience, social confidence experience, growth and progress experience, contented and abundant experience, and self-acceptance experience

[a]LIFE-H: Assessment of Life Habits.

[b]SCS-R: Social Connectedness Scale–Revised.

[c]GSES: General Self-Efficacy Scale.

[d]SWBS: Subjective Well-Being Scale.

All the scales used have validated Chinese versions, and we used these versions in this study. Social participation was evaluated using the Chinese version of the LIFE-H, a validated and reliable self-report questionnaire comprising 77 items [51]. This instrument assesses various aspects of daily living, including indoor activities, outdoor activities, interpersonal relationships, community life, and amusement and recreation. Goal attainment in storytelling was measured by recording several key metrics: the duration of story sharing, the number of key events included in each story, the number of photos collected, and the number of annotations made on these photos. Participants set baseline targets on a 10-point scale before commencing the activity and revisited these targets during the second and fourth weeks of the intervention to track progress and achievement [52]. Social connectedness was assessed using the SCS-R, a 20-item, well-established self-report questionnaire known for its validity and reliability in measuring individuals' sense of belonging and connection to others [53]. Self-efficacy levels were measured using the GSES, a validated 10-item questionnaire that evaluates both action self-efficacy and coping self-efficacy, reflecting the participants' confidence in managing and executing tasks as well as handling challenging situations effectively [54,55]. The subjective sense of happiness was evaluated using the SWBS, another reliable and valid self-report instrument consisting of 20 items. This scale captures a wide range of experiences related to well-being, including interpersonal adaptation, mental health, family atmosphere, psychological balance, physical health, goal achievement, social confidence, personal growth, contentment, and self-acceptance [56]. Interpersonal adaptation is the process of adjusting one's behavior and communication style to better fit in with others in social interaction [53].

In addition to the structured quantitative assessments, qualitative observations were conducted during the field-testing sessions to capture participants' engagement and social interaction patterns. Researchers took brief field notes after each session, documenting participants' verbal and nonverbal responses, interactions, and levels of engagement. These observations were intended to supplement the quantitative findings by offering contextual insights into the participants' experiences with the intervention [57]. A full systematic analysis of these qualitative data was outside the scope of this paper and has been reported separately in a companion article focusing specifically on the qualitative findings. In this paper, qualitative observations are referred to selectively to support the interpretation of key quantitative outcomes.

Statistical Analysis

Quantitative data analysis was conducted in the JASP software [58]. The analysis focused on key metrics related to the digital storytelling intervention: duration of story sharing, number of key events in the story, number of photos collected, and number of notes made on the photos. Participants submitted subjective reports at 3 junctures: baseline, the 2-week follow-up, and the 4-week follow-up. For each metric, we followed the Bangor Goal-Setting Interview Manual [52] to calculate the mean and variance of and changes in the outcomes reported by participants in addition to objective measures such as the actual duration of story sharing, the total photos collected, and the tally of notes made. To standardize the scoring across various metrics, a normalization method was applied: the maximum number of photos (n=9) was set as a perfect score of 10, with each participant's count proportionately scaled. Similarly, for the duration of story sharing and the number of notes, the highest recorded value was established as the benchmark for a full score of 10, with other values adjusted accordingly. Regarding the number of key events in the story, following transcription, our research team conducted a quantitative assessment to enumerate significant narrative elements within each shared story. Finally, to attain a comprehensive insight into the participants'

XSL•FO
RenderX

experiences and the intervention's impact, thematic coding was applied to analyze the data from the concluding user interviews.

To evaluate the intervention's impact, we calculated a standardized change rate for each outcome measure:

This calculation standardizes each participant's change relative to their baseline, providing a more sensitive measure of group differences. Independent *t* tests were conducted in JASP to compare these change rates between the intervention and control groups, with *P* values and effect sizes with 95% CIs reported. An α level of .05 was set for all 2-tailed tests. No interim analyses or stopping rules were applied, as the trial involved a small sample and posed minimal risk to participants. Participants and facilitators were not blinded due to the nature of the intervention. However, outcome assessors and data analysts were blinded by using coded group labels and de-identified data.

All randomized participants (N=20) were included in the final analysis and analyzed in the groups to which they were originally assigned, following an intention-to-treat approach. No participants were lost to follow-up. Minor missing data identified during data checking were subsequently completed through verification with source records, and no imputation was required. No subgroup or sensitivity analyses were prespecified or conducted, given the exploratory nature of the study. Harms were described narratively, as no adverse events were reported.

Harms Assessment

Given the non-invasive and low-risk nature of the digital storytelling intervention, no formal adverse event monitoring was implemented. Harms were defined broadly as any negative physical, emotional, or psychological responses associated with participation in the intervention. These were assessed non-systematically through participant self-reports and informal observations made by facilitators during and after each session. No adverse events or participant-reported harms were observed or reported throughout the trial.

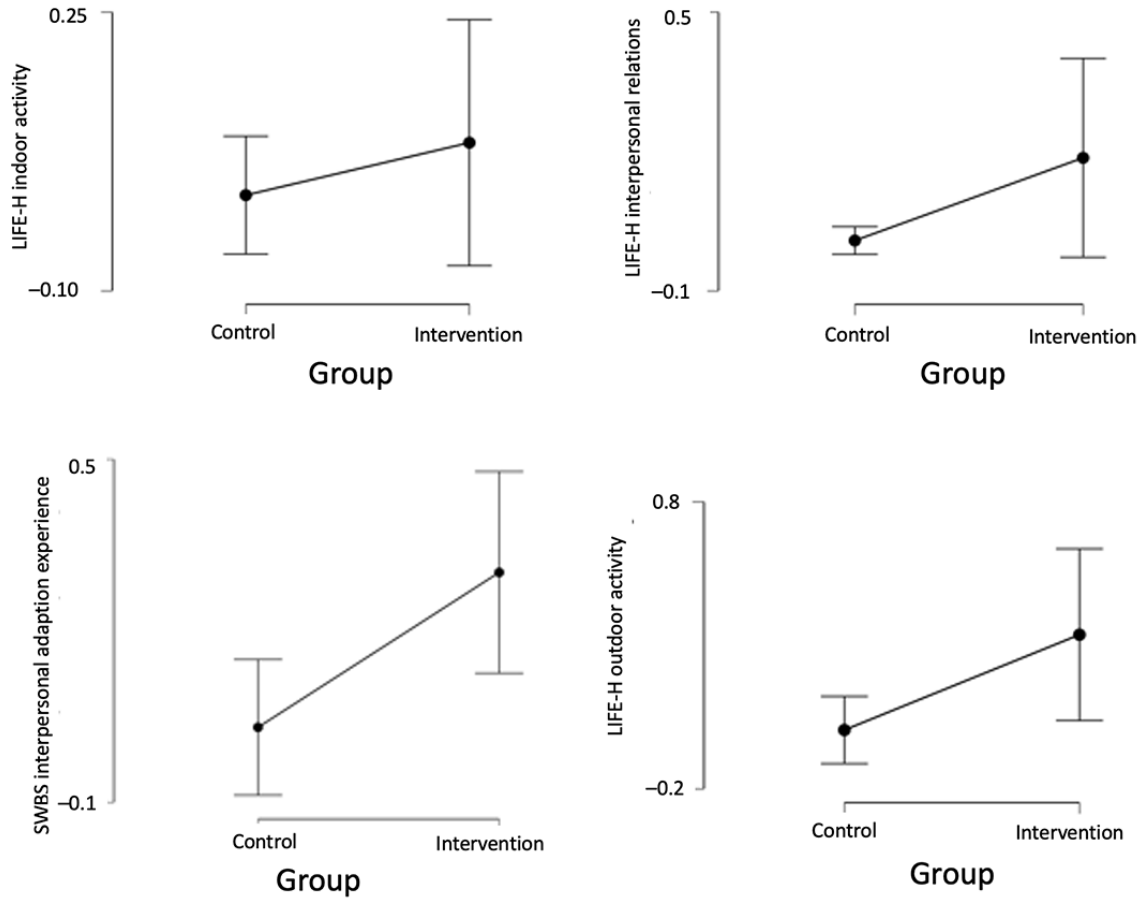
Results

Sample Characteristics

A total of 20 participants were recruited and randomly assigned to either the intervention group or the waitlist control group (n=10, 50% per group). Demographic and cognitive assessments showed no significant differences between the groups, supporting the randomization protocol (Table 2). Participants were randomly assigned to the intervention or control group in a 1:1 ratio using simple randomization. The allocation sequence was generated by an independent researcher using Excel's RAND function and implemented via sequentially numbered, opaque, sealed envelopes. The personnel responsible for enrolling participants and assigning interventions did not have access to the allocation sequence, ensuring allocation concealment. Specifically, the difference in age was not statistically significant (*P*=.23), nor were differences in sex distribution (*P*=.29), educational attainment (*P*=.41), or MoCA-Ca scores (*P*=.20). Participants averaged 69.7 (SD 3.21) years of age, with no significant difference between groups (mean 68.80, SD 2.61 in the intervention group vs mean 70.60, SD 3.49 in the waitlist control group; *P*=.23). Most participants (16/20, 80%) were female, with sex distribution consistent across groups (*P*=.29). Educational levels and cognitive function (assessed using the MoCA-C) did not significantly differ between groups (*P*>.05 in all cases).

Table 2. Sample characteristics overall and by treatment condition (N=20).

Characteristic	Total	Intervention (n=10)	Waitlist control (n=10)	*P* value
Age (y), mean (SD; range)	69.7 (3.21; 65-76)	68.80 (2.61; 65-76)	70.60 (3.49; 65-74)	.23
Sex, n (%)				.29
Male	4 (20)	1 (10)	3 (30)	
Female	16 (80)	9 (90)	7 (70)	
Educational level, n (%)				.41
University	4 (20)	2 (20)	2 (20)	
High school	7 (35)	5 (50)	2 (20)	
Middle school	9 (45)	3 (30)	6 (60)	
MoCA-C[a] score, mean (SD)	23.25 (1.51)	23.7 (1.19)	22.8 (1.66)	.20



[a]MoCA-C: Montreal Cognitive Assessment–Chinese version.

Intervention Impact Analysis

According to statistical comparisons of change rates across key outcome measures (Multimedia Appendix 2), significant improvements were observed in outdoor activity on the LIFE-H (t_{18}=2.339; Cohen *d*=1.046; *P*=.03) and in interpersonal adaptation experience on the SWBS (t_{18}=2.884; Cohen *d*=1.290; *P*=.01), indicating that the intervention effectively enhanced participants' engagement in outdoor activities and interpersonal adaptation. In other measures, such as indoor activity on the LIFE-H (*P*=.40) and the GSES (*P*=.98), slight but nonsignificant improvements were noted. Figure 4 illustrates the change rates across outcome measures, with clear improvements for outdoor activity and interpersonal adaptation, whereas other measures showed overlapping trends, consistent with the nonsignificant *t* test results.

XSL•FO
RenderX

Figure 4. Selected outcome measure change rates—intervention versus control group. LIFE-H: Assessment of Life Habits; SWBS: Subjective Well-Being Scale.

Effect of Huiyou

To assess specific domains of social participation and subjective well-being, we used the LIFE-H, SCS-R, GSES, and SWBS. Pre- and postintervention *t* tests were conducted to compare group differences (Multimedia Appendix 3). Most measures showed no significant baseline differences between the experimental and control groups, confirming initial equivalence. Specifically, baseline comparisons showed no significant group differences in general LIFE-H (*P*=.14), indoor activity (*P*=.40), outdoor activity (*P*=.03), interpersonal relationships (*P*=.08), community life (*P*=.81), SCS-R (*P*=.59), GSES total (*P*=.98), action self-efficacy (*P*=.39), coping self-efficacy (*P*=.14), SWBS total (*P*=.26), interpersonal adaptation (*P*=.01), mental health (*P*=.42), family atmosphere (*P*=.41), psychological balance (*P*=.22), physical health (*P*=.21), target value (*P*=.21), social confidence (*P*=.46), and contented and abundant experience (*P*=.70). However, a significant baseline difference was observed in the self-acceptance experience on the SWBS, where a baseline difference (*P*=.007) was noted and considered in subsequent analyses.

Table 3 presents descriptive statistics for improvement rates across study measures. For LIFE-H categories, average improvement rates ranged from 0.045 (SD 0.156; general) to 0.171 (SD 0.353; outdoor activities), reflecting varied enhancements in daily living habits. The SCS-R showed a mean improvement of 0.098 (SD 0.192). Mental health experience on the SWBS demonstrated the largest variability (mean 0.448, SD 1.12; range −0.222 to 5), indicating individual differences in postintervention outcomes. Other subjective well-being domains, including interpersonal adaptation (mean 0.167, SD 0.247; *P*=.01) and psychological balance (mean 0.313, SD 0.514; *P*=.22), also showed positive trends; however, these results were not statistically significant.

Multimedia Appendix 2 shows the effect sizes (Cohen *d*) of improvement rates across various outcome measures, visually highlighting the magnitude of changes observed between the intervention and control groups. The red dashed line at 0.80 indicates the threshold for a large effect. As shown, interpersonal adaptation experience and outdoor activity demonstrated large effect sizes (Cohen *d*=1.29 and 1.05, respectively), suggesting substantial improvements attributable to the intervention. Several other outcomes, including overall LIFE-H, SCS-R, and SWBS scores, showed medium to small effects, whereas a few measures exhibited minimal or negative effects. This visual summary supports the interpretation that, while the intervention had varied impacts, it significantly enhanced certain aspects of social participation and well-being in people with MCI.

The remaining variables, including different facets of life habits (LIFE-H), general self-efficacy (GSES), social connectedness (SCS-R), and various dimensions of subjective well-being

XSL•FO
RenderX

(SWBS), did not show statistically significant changes. Small to moderate effect sizes were observed, suggesting that, while certain domains such as outdoor activity and interpersonal adaptation showed meaningful improvements, other areas such as community life, self-efficacy, and overall subjective well-being exhibited minimal to no change.

Table 3. Descriptive statistics and improvement rates in study measures.

	Improvement rate, mean (SD; range)	*t* test (*df*)	*P* value	Cohen *d*
LIFE-H[a] general	0.045 (0.156; −0.273 to 0.597)	1.566 (18)	.14	0.701
Indoor activity	0.053 (0.168; −0.181 to 0.653)	0.87 (18)	.40	0.389
Outdoor activity	0.171 (0.353; −0.2 to 1.414)	2.339 (18)	.03	1.046

[d]SWBS: Subjective Well-Being Scale.

Goal Attainment of Digital Storytelling

Table 4 presents the goal attainment ratings at baseline and the 2- and 4-week follow-ups, alongside statistical comparisons across various measures related to digital storytelling activities among participants. The measures include the duration of story sharing, the number of key events in the story, the number of photos collected, and the number of notes made on the photos, each assessed through participant and objective ratings. At baseline, the duration of story sharing was rated at an average of 4.8 (SD 1.23), which increased to 9.2 (SD 0.79) at the 4-week follow-up. Similarly, the number of key events showed an increase from a baseline rating of 5.5 (SD 1.35) to 9.5 (SD 0.528), and the number of photos collected rose from an initial 5.2 (SD 1.39) to 9.7 (SD 0.48). Finally, the number of notes made on the photos increased from 5.2 (SD 0.92) to 9.7 (SD 0.48). These results demonstrate a significant improvement in all measured aspects of digital storytelling activities, reflecting enhanced participant engagement, storytelling complexity, and interaction with digital content over the course of the study.

Table 4 presents the mean attainment and changes in story sharing duration, number of key events, number of photos collected, and notes on the photos at baseline and the 2- and 4-week follow-ups among 50% (10/20) of the participants in the intervention group. The table illustrates a clear improvement in participants' performance from the initial assessment to subsequent follow-ups. Substantial improvements were observed across all digital storytelling performance metrics, including longer storytelling durations, greater number of key events, more photos collected, and more notes recorded.

XSL•FO
RenderX

Table 4. Goal attainment ratings at baseline and the 2- and 4-week follow-ups and statistical comparisons.

Measure	Participant rating (1-10), mean (SD)			Researcher rating (1-10), mean (SD)
	Baseline (T0)	2 wk	4 wk (T1)	
Duration of story sharing	4.8 (1.23)	8.7 (1.34)	9.2 (0.79)	6.8 (1.93)
Number of key events in the story	5.5 (1.35)	8.4 (1.43)	9.5 (0.53)	5.7 (1.06)
Number of photos collected	5.2 (1.39)	8.6 (1.26)	9.7 (0.48)	7.3 (1.49)
Number of notes on the photos	5.2 (0.92)	8.3 (1.77)	9.7 (0.48)	7.3 (1.49)

In addition to the quantitative findings, qualitative observations during the field-testing phase highlighted noticeable changes in participants' engagement and interaction patterns. Initially, several participants appeared hesitant to share their stories; however, by the third and fourth sessions, many became more active, showing greater willingness to discuss personal memories and respond to others' narratives. Emotional expressions such as laughter, nostalgia, and mutual encouragement were frequently observed during group discussions. For example, one participant shared the following—"We chatted away, made new friends. Without this activity, I wouldn't have met everyone, you know" (group 1; P1)—reflecting the social bonds that developed through the sessions. Another participant remarked the following—"I am very interested in this activity as it is a completely new experience for me. I have never done anything like it before" (group 2; P1)—highlighting the novelty and engagement stimulated by the Huiyou app.

Most participants also demonstrated increasing independence in navigating Huiyou, requiring less assistance over time. One participant expressed the following:

> *I managed to do everything by myself and didn't ask for help from anyone.* [Group 1; P2]

Furthermore, the intervention appeared to strengthen interpersonal relationships beyond the sessions, with a participant noting the following:

> *I've had more interactions with my husband now; we reminisce about the old times together.* [Group 1; P3]

These observations provide supplementary evidence of improved social connectedness, storytelling engagement, and digital competency among participants with MCI.

No subgroup or sensitivity analyses were prespecified or conducted in this study. Given the small sample size and the exploratory nature of the trial, the analysis was limited to evaluating primary and secondary outcomes at the group level.

No harms or unintended events were reported in either the intervention or waitlist control group throughout the study period. Participants did not report any emotional distress, discomfort, or adverse reactions related to the digital storytelling sessions or study procedures. Facilitators also did not observe any concerning behaviors or incidents during intervention delivery.

Discussion

Principal Findings

The principal findings of this pilot randomized controlled trial investigating the effects of the mobile storytelling app Huiyou on social participation and storytelling ability among people with MCI are compelling. This study demonstrated that the experimental group, which engaged with the Huiyou app, exhibited a significant improvement in outdoor activities compared to the control group. This was reflected by a Cohen *d* value of 1.046, indicating a large effect size, suggesting that the intervention significantly increased the frequency and possibly the quality of outdoor social interactions among participants. In addition, there was a significant enhancement in interpersonal adaptation experiences, with a Cohen *d* of 1.290, also indicating a substantial effect. However, although there were strong effects observed for the LIFE-H total score, SCS-R total score, SWBS total score, interpersonal relationships, psychological balance experience, physical health experience, and target value experience, these improvements did not reach statistical significance. This may be due to the small sample size.

Despite the lack of statistically significant changes across all measures, the large effect sizes observed suggest meaningful improvements that warrant further investigation. These findings underscore the potential value of the Huiyou app in enhancing social participation among individuals with MCI but also suggest that larger-scale studies are necessary to fully assess the app's impact. The intervention effectively increased the duration of story sharing, the number of key events detailed in the stories, the volume of photos collected, and the number of notes made on these photos. These improvements indicate an increase not only in participant engagement but also in the complexity and richness of the narratives shared by the participants. This multifaceted enhancement highlights the efficacy of the intervention in enhancing participants' storytelling skills and their overall experience with the digital platform. It reflects a broader impact on their engagement and the quality of their interactions. This improvement suggests that the intervention successfully boosted participants' ability to adapt to social interactions, enhancing their social integration and reducing feelings of isolation. These outcomes underline the potential of tailored digital storytelling interventions to enrich social engagement and overall quality of life for people with MCI.

Comparison With Prior Work

Social Participation and Storytelling Engagement

In our discussion regarding the Huiyou intervention, we noted a significant increase in outdoor activities after the intervention, echoing the findings of Ryu and Heo [59]. They noted a positive correlation between life satisfaction and physical activities, suggesting the various benefits of outdoor engagement. The significant improvement in outdoor activities observed in the experimental group of this study compared to the control group highlights that the intervention led to increased participation in these activities by older individuals. The strong effect size (Cohen *d*=1.046) indicates a substantial impact of the intervention, demonstrating its effectiveness in enhancing outdoor activity among participants. This notable increase not only supports the efficacy of our intervention but also suggests that engaging in outdoor activities could be particularly beneficial for improving the overall well-being and social engagement of people with MCI. This finding is crucial for developing future interventions aimed at increasing physical activity and social interactions in this population. Our structured weekly meet-ups as part of the intervention encouraged active participation in the external environment, as highlighted in the study by Ryu and Heo [59]. Their research expands on this connection by linking outdoor engagement not only to physical and psychological well-being but also to increased life satisfaction and health perception. This indicates that the intervention's impact on outdoor activities extends beyond immediate physical benefits, potentially influencing overall life satisfaction and health perception among participants, thus underlining the vital role of structured outdoor activities in improving quality of life for people with MCI. Furthermore, the holistic advantages of outdoor activities, bolstered by structured interventions, encompass physical health, optimism, and cultural engagement. This comprehensive approach to wellness emphasizes the importance of environmental factors in promoting outdoor activities, alongside the findings of Ryu and Heo [59] and Chang [60]. These studies highlight the multifaceted value of outdoor engagement in promoting health and well-being among people with MCI and stress the importance of both structured interventions and supportive environments in enhancing outdoor activity participation. The prototype developed in this study played a significant role in enhancing outdoor activities, particularly reflected in the notable differences in LIFE-H outdoor activity scores after the intervention. This aligns with existing research indicating the significant benefits of structured outdoor interventions, particularly those conducted in natural settings, for enhancing the physical and mental health of older adults. These studies highlight that such interventions can lead to improved physical activity, reduced stress, and better overall well-being [61]. These findings suggest that similar programs focusing on outdoor activities could be valuable in various contexts to promote a healthier lifestyle and greater social engagement. Specifically, rehabilitation programs that incorporate outdoor mobility have shown success in increasing activity levels, outdoor mobility, and endurance for older adults recovering from illness or injury. This suggests that incorporating structured outdoor activities into rehabilitation or wellness programs can have a notable impact on improving both physical endurance and quality of life for people with MCI [62]. Coming out of the room is a preliminary step toward engaging in outdoor activities. It is a crucial aspect of encouraging physical activity and social interaction, especially for people with MCI. By fostering a motivation to leave the room, interventions can lay the groundwork for enhanced outdoor activity, leading to improved health outcomes and overall well-being. Given this understanding, it is important to design interventions that address the barriers that may prevent individuals from coming out of their rooms. This might involve creating structured programs that are appealing and easily accessible, offering social incentives, and providing support to overcome potential anxiety or hesitation. Such efforts can increase the likelihood of engaging in outdoor activities, which in turn can lead to better physical health and more social connection.

Our findings on the Huiyou app underscore its substantial positive effects on interpersonal adaptation among participants with MCI. The significant improvement in interpersonal adaptation experience, highlighted by activities such as generating and sharing material, aligns with existing research on psychological interventions for MCI or dementia [63]. The intervention notably increased participants' scores compared to those in the control group, which suggests that the digital storytelling approach not only enhances interpersonal skills but also supports people with MCI in adapting more effectively to social interactions. The strong effect size (Cohen *d*=1.290) emphasizes the impact of the intervention, illustrating its potential to significantly improve social adaptability in individuals with MCI. These findings advocate for the integration of storytelling elements into interventions as a powerful mechanism to enhance social capabilities and address some cognitive impairments associated with social challenges. Interventions that focus on building social connections and promoting social participation have been shown to improve interpersonal adaptation and reduce feelings of isolation [64]. Technology-based interventions such as digital applications that support reminiscence activities can further enhance memory recall and strengthen social interactions [20]. This aligns with our findings that the "generate material" phase, involving the searching and sharing of photos, facilitated increased interactions with friends and family, thereby improving social bonds.

Furthermore, Bentley et al [37] highlighted the importance of connecting with places to strengthen social contact, promoting a unified system with friends and family to share places and stories. This concept dovetails with our findings, wherein participants engaged in deeper reminiscence with their spouses to recall more detailed memories. This process not only nurtured more positive interactions but also effectively reduced negative exchanges, highlighting the value of digital storytelling interventions in cultivating meaningful interpersonal relationships. The convergence of our results illustrates the multifaceted impact of digital storytelling interventions on enhancing social interaction and communication. Through facilitating the creation and sharing of content, such interventions promote active social participation and

XSL•FO
RenderX

reminiscence, contributing to improved interpersonal relationships among participants and their social circles.

Moreover, the study's intricate assessment of digital storytelling activities revealed considerable improvements in engagement, complexity of storytelling, and interaction with digital content, marking a significant stride in enhancing participants' quality of life. Digital storytelling interventions offer several benefits for older adults, including promoting mental health, building meaningful community connections, achieving digital literacy, mitigating negative ageism, and enhancing intellectual ability [65]. In addition, we found that these interventions can support self-expression and language expression, providing a platform for older adults to share their stories, which encourages active communication and engagement with others. By engaging in digital storytelling interventions, older adults can develop new skills, build social networks, and gain a sense of accomplishment, contributing to improved overall well-being. Given these observations, incorporating digital storytelling into rehabilitation and engagement programs could effectively improve participants' quality of life through enhanced interaction and complexity in storytelling while also strengthening social engagement and psychological well-being. The Huiyou app notably enhanced participants' storytelling engagement, as evidenced by increased narrative complexity and more active interaction with digital content. The structured sessions and targeted prompts encouraged deeper reflection and participation in storytelling activities. Furthermore, the process of generating and sharing stories fostered richer social interactions within participants' networks, highlighting a positive potential toward improved social connectedness. Complementary structured outdoor activities also contributed to significant improvements in outdoor activity engagement, supporting both physical and psychological well-being. Overall, the findings suggest that structured interventions integrating digital storytelling, social participation, and outdoor activities can meaningfully enhance quality of life and social well-being for people with MCI. Although a detailed qualitative analysis is reported separately, key observations during the intervention reinforce the quantitative results. The progressive increase in storytelling engagement, emotional sharing, and group interaction suggests that Huiyou successfully fostered a supportive social environment for people with MCI. These behavior changes align with previous research emphasizing the role of peer interaction and shared memory activities in promoting social participation. Furthermore, the gradual improvement in participants' digital literacy and confidence with the app underscores the potential for appropriately designed technology to support autonomy and reduce technology-related anxiety among older adults with cognitive impairment.

Self-Efficacy and Measurement Challenges

Our study examined the lack of significant changes in self-efficacy among older adults engaging in physical and social activities. It shed light on several critical factors that merit consideration. First, the intervention's duration was a potential factor influencing these outcomes. Existing literature supports the notion that short-term interventions may not be sufficiently impactful to alter self-efficacy levels significantly, particularly in older adults who may have long-held beliefs about their capabilities [66]. Self-efficacy develops and is influenced over time through mastery experiences, vicarious experiences, verbal persuasion, and interpretations of physiological and emotional states [67]. Consequently, the relatively brief span of our intervention might not have provided ample opportunities for these processes to effectuate a meaningful change in self-efficacy levels. Second, the challenge of detecting significant changes in self-efficacy is compounded by the high baseline self-efficacy scores observed among participants and the possible insensitivity of the measurement tools used. This observation aligns with findings of other studies that highlight the difficulty in measuring subtle shifts in self-efficacy among populations with already high levels of this construct [66,68]. The necessity for more refined measurement tools is emphasized, suggesting a need for instruments that can discern minor yet impactful changes in self-efficacy. Such tools would enable a more accurate assessment of intervention effects, particularly in contexts in which initial self-efficacy levels are high. Third, the stress associated with participation in activities represents another critical consideration. Our findings indicate that stress may undermine self-efficacy beliefs, resonating with previous research indicating that stress and anxiety can negatively impact one's confidence in performing future activities [69,70]. This means that incorporating strategies within interventions is crucial to managing stress and enhancing psychological resilience among participants. Thus, tailoring interventions to account for initial psychological states and using stress management techniques could be pivotal in supporting and possibly improving self-efficacy beliefs.

Given the cognitive and linguistic difficulties among people with MCI [71-73], measurement tools such as the SCS-R should be simplified for accurate evaluation. The linguistic complexity of some measurement tools, particularly the double-negative phrasing found in items of the SCS-R, may have posed cognitive challenges for participants with MCI. While this limitation was acknowledged, future research should pilot simplified or adapted versions of such instruments that are validated for populations with cognitive impairment to ensure accuracy and comprehension. Given these considerations, there is a pressing need for more straightforward or positively framed items in future studies, especially when assessing populations with cognitive impairments such as MCI. Simplifying the language used in measurement tools not only accommodates the cognitive profiles of these populations but also enhances the reliability and accuracy of the data collected.

While not all measures showed significant changes, certain areas such as physical health and self-acceptance exhibited positive trends toward improvement. This observation suggests that prototype-based interventions could contribute to a broader impact on these outcomes. Studies have shown that outdoor physical activity interventions in green and blue spaces can improve health outcomes, including well-being, mood, and physical performance [74]. Although our study indicated that structured activities play a pivotal role in enhancing outdoor activity engagement, the scope of these findings suggests the need for more extensive studies to validate these trends and determine the potential for these interventions to improve health outcomes across a wider range of indicators [75].

XSL•FO
RenderX

The results from the digital storytelling intervention suggest that further exploration in this field could lead to improved strategies for enhancing social participation and quality of life for people with MCI. The success of these interventions underscores the need to develop innovative approaches that effectively address the unique challenges faced by people with MCI.

Limitations

Primarily, the pilot nature of this study, with 10 participants in both the intervention and control groups, serves as a foundational step, limiting the generalizability of our findings. The modest sample size also restricts our ability to detect significant differences across some outcome measures, underscoring the need for expanded research to validate these initial results in a future study. This study was conducted as a pilot trial to explore the feasibility and preliminary effects of a digital storytelling intervention for people with MCI. Although the study received ethical approval from the relevant institutional review board, it was not prospectively registered. At the time of initiation, trial registration was not required for minimal-risk behavioral interventions under institutional policy. We acknowledge the absence of prospective registration as a limitation and recommend that future confirmatory trials undergo prospective trial registration in accordance with best practices. Given the pilot nature of this study (N=20), the statistical power was limited, and the findings should be interpreted with caution. However, the promising trends observed in this preliminary investigation justify the design and implementation of a larger, fully powered randomized controlled trial to validate the intervention's effectiveness and enhance generalizability to a broader population of people with MCI. Although randomization was used, a notable baseline difference in self-acceptance scores (SWBS) was observed between groups. This may have introduced bias into postintervention comparisons related to this variable. Future studies should consider stratified randomization or statistical adjustment to better control for such baseline differences. Concerning the sex distribution, our study observed a lower participation rate among men. Rather than reflecting a bias in recruitment or willingness to participate, this trend aligns with broader observations that, in China, men tend to engage less in collective activities compared to women. This aspect provides a cultural context to our findings and suggests avenues for further exploration into sex dynamics in social participation. A crucial point of consideration is the nature of the participants recruited through institutions, who tended to be more active or had previously engaged with psychological services. This selection bias suggests that the intervention's preliminary findings may not fully represent the broader population of older individuals with MCI, particularly those who are less active. Recognizing this, there is a pronounced need for future studies to delve into the intervention's effects on a more diverse and possibly less active older adult cohort, ensuring a comprehensive understanding of the intervention's benefits across varying levels of initial activity and engagement. Addressing feasibility concerns, the potential commuting barriers highlighted the importance of local community engagement in facilitating participation. Organizing activities within participants' communities could enhance the intervention's accessibility and reduce logistical barriers to participation. We could also use an online platform for digital storytelling to support participants who live far away from the group members.

Moreover, the scalability of the Huiyou intervention requires careful consideration. Technical barriers such as digital literacy gaps among older adults, limited access to compatible devices, and challenges in maintaining user engagement over time could hinder broader implementation. Contextual challenges, particularly in low- and middle-income settings, include resource constraints and insufficient community infrastructure to support ongoing group activities. These considerations are crucial for ensuring that digital storytelling interventions such as Huiyou can be effectively scaled to benefit wider populations of people with MCI.

Conclusions

The Huiyou intervention has shown promising effects on the well-being of people with MCI, significantly enhancing outdoor activities and interpersonal adaptation experiences. Notable improvements were observed in participants' engagement with digital storytelling, contributing to more complex narrative constructions. Consistent with existing research, these outdoor activities were found to contribute to both physical and psychological health, potentially affecting overall life satisfaction. Enhanced social connections were facilitated through digital content sharing, boosting interpersonal relationships. However, improvements in self-efficacy were limited, suggesting challenges in enhancing this area through short-term interventions, particularly given the cognitive limitations associated with MCI. These findings underline the importance of developing suitable measurement tools that can capture nuanced changes in this population.

Although most outcome measures did not reach statistical significance, the large effect sizes observed in outdoor activity and interpersonal adaptation outcomes suggest promising intervention potential. Given the limited sample size, these findings should be interpreted as preliminary, highlighting the need for further research using larger randomized controlled trials to substantiate and extend these early results. This study underscores the potential for digital interventions to improve quality of life for people with MCI and suggests a need for accessible and user-friendly digital platforms tailored to their specific needs. Future studies should expand on these findings by examining the intervention's effectiveness across a more diverse and larger population to fully leverage digital tools in supporting individuals with MCI.

Acknowledgments

The authors would like to extend their thanks to all the staff, people with mild cognitive impairment, carers, and therapists who contributed to this project. They also sincerely thank student researchers Mingyang Zhang, Lingjie Wu, and Lingjun Liu for their assistance in organizing the activities and collecting the data. In addition, they are grateful to Yuan Fang for helping double-check the data analysis and ensuring its quality. No funding was received for this research.

Data Availability

Due to ethical considerations and data protection policies regarding vulnerable populations, including older adults with mild cognitive impairment (MCI), the deidentified participant data, data dictionary, and statistical code are not available for external sharing. Access is strictly limited to the research team as approved by the institutional ethics committee, and will not be granted to other researchers or institutions.

Abstract

Background: Out-of-hospital cardiac arrests (OHCAs) are a leading cause of death worldwide, yet first responder apps can significantly improve outcomes by mobilizing citizens to perform cardiopulmonary resuscitation before professional help arrives. Despite their importance, limited research has examined the psychological and behavioral factors that influence individuals' willingness to adopt these apps.

Objective: Given that first responder app use involves elements of both technology adoption and preventive health behavior, it is essential to examine this behavior from multiple theoretical perspectives. Building on the unified theory of acceptance and use of technology (UTAUT) and health belief model (HBM), this study therefore developed an integrative framework to explain which behavioral determinants and demographic and health-related factors drive an individual's willingness to install a first responder app for OHCA.

Methods: We conducted a web-based cross-sectional survey (N=3660; mean age 49.95, SD 16.75 years; n=1909, 52.2% women) in June 2024 among Belgian adults. Behavioral determinants (UTAUT and HBM constructs), demographic (eg, age), and health-related (eg, cardiopulmonary resuscitation training experience) variables were measured using (multi-item) scales. Willingness to install the app served as the outcome variable. We developed a structural equation model using the *Lavaan* package in R and specified regression paths, on the one hand, between the behavioral determinants and willingness to install the app, and on the other hand, between the demographic and health-related factors and the behavioral determinants. Additionally, we conducted multiple group analyses to examine the moderating role of demographic and health-related factors on the relationships between the behavioral determinants and the willingness to install the app.

Results: Our results revealed that 2 UTAUT variables (ie, facilitating conditions: β=.07; *P*=.003 and social influence: β=.16; *P*<.001) and 3 HBM variables (ie, perceived susceptibility: β=.06; *P*=.003, perceived barriers: β=–.29; *P*<.001, and perceived benefits: β=.38; *P*<.001) were associated with willingness to install a first responder app for OHCA. Additionally, most demographic and health-related factors were indirectly related to willingness via behavioral determinants, with age being the sole moderator.

XSL•FO
RenderX

Specifically, a negative association between perceived severity and willingness was only observed among older adults. In addition, the positive relationship between perceived benefits and willingness was stronger for older adults compared to younger ones.

Conclusions: Overall, the results of this study have both theoretical and practical implications. Theoretically, this study finds its relevance in extending the UTAUT and HBM to altruistic mobile health apps and advancing our understanding of technology adoption in health contexts. Practically, the study's findings could inform real-life health campaigns aimed at enhancing citizen participation in first responder systems.

Introduction

Background

With the widespread use of mobile phones, the potential of technology to improve health outcomes has significantly increased [1]. Many people, for example, use their mobile devices to install apps for medical and public health practices, better known as mobile health (mHealth) [2]. Most of these apps enable users to monitor their health by, for instance, tracking their steps or creating personalized diet plans [3,4]. Additionally, besides promoting self-tracking, some mHealth apps can also be used to enhance the health of others and benefit society overall. Examples of such altruistic mHealth apps include contact tracing apps (CTAs), used during the recent COVID-19 pandemic [5], and first responder apps.

First responder apps alert and mobilize trained citizens to provide first aid in emergency situations, such as experiencing an out-of-hospital cardiac arrest (OHCA) [6]. Experiencing an OHCA is a leading cause of death worldwide [7], and in order to tackle this public health problem, early recognition of an OHCA and responding quickly to the situation are crucial. The use of a first responder app could thus be critical in this case, as citizens can be alerted to provide cardiopulmonary resuscitation (CPR) before the arrival of professional medical help, thereby ensuring a higher chance of survival [6,8]. However, despite the significant value of these apps, little is still known about their integration within societies for 2 reasons. First, these apps offer health benefits for others but not directly for users themselves, thereby leaving a gap in our understanding of users' motivations behind adopting these altruistic apps. Second, first responder apps for OHCA differ substantially from other mHealth apps, as they are not designed for frequent use. Once installed, users are only required to engage with the app when they receive a notification requesting assistance for someone experiencing a cardiac arrest. As such, given this infrequent use, it is crucial to understand individuals' willingness to install first responder apps for OHCA in order to promote the adoption of such apps in society.

Therefore, this study aims to contribute to the literature by defining which behavioral and individual factors play a role in citizens' willingness to install a first responder app for OHCA. Given that first responder app use involves elements of both technology adoption and preventive health behavior, it is essential to examine this behavior from multiple theoretical perspectives, including the unified theory of acceptance and use of technology (UTAUT) [9] and the health belief model (HBM) [10]. Based on these theories, we will develop an integrated framework to explain the behavioral determinants that drive individuals' willingness to install altruistic mHealth apps, that is, first responder apps for OHCA. Additionally, demographic and health variables will be examined to provide a comprehensive understanding of factors driving adoption willingness.

Technology Perspective: UTAUT

To address the technology-related aspect of first responder app adoption, the study builds on the UTAUT model [9], a commonly used theoretical model for predicting the adoption of new technologies. The model consists of 4 key behavioral determinants of technology adoption: performance expectancy (ie, perceived effectiveness of the technology), effort expectancy (ie, the degree of ease associated with using the technology), social influence (ie, descriptive and injunctive norms), and facilitating conditions (ie, resources available that make it easier to adopt the new technology, such as internet access and owning a smartphone).

Given that this model integrates elements from various models and theories related to technology acceptance, it has been used frequently in the past to explain the adoption of apps that require frequent and consistent interaction, such as mobile banking apps [11], health monitoring apps [12,13], or travel apps [14]. Moreover, besides these frequently used apps, UTAUT has also been successful in explaining the adoption of CTAs [5,15-18]. Studies, for example, found that users were more inclined to install CTAs when they perceived the app as effective [5,17,18] and easy to use [18]. Additionally, social influence [16] and facilitating conditions, like smartphone ownership [19], were crucial predictors of CTA adoption. The study by Walrave et al [19], for example, showed that not owning a smartphone was one of the main reasons for not using a CTA.

These studies on CTAs, in turn, offer a relevant comparison for our study, as these apps, similar to first responder apps for OHCA, benefit public health and involve passive use (ie, only interacting when receiving a notification). Based on their insights, it is thus reasonable to assume that the factors outlined in the UTAUT model could also serve as effective predictors for the willingness to install a first responder app for OHCA—an app that is characterized by its altruistic nature, focus on immediate action, and infrequent use. In line with the prototype

XSL•FO
RenderX

willingness model [20], we focus on willingness to install a first responder app rather than behavioral intention or actual use, since no such app currently exists in Belgium, thus making those measures less feasible at this stage. Building on the UTAUT model, this study therefore extends the literature by forming the following hypotheses:

- Hypothesis 1—Performance expectancy is positively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 2—Effort expectancy is negatively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 3—Facilitating conditions are positively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 4—Social influence is positively associated with the willingness to install a first responder app for OHCA.

Health Perspective: HBM

When installing a first responder app, individuals are not merely installing new software but are committing to potentially performing life-saving actions, that is, providing CPR to someone experiencing a cardiac arrest. Relying solely on a technological perspective, such as the UTAUT model, would therefore be insufficient to fully understand an individual's willingness to install a first responder app for OHCA. Logically, this decision requires consideration of the health-related implications and responsibilities associated with the app's use. Therefore, in addition to examining first responder app adoption through the lens of technology acceptance, it is essential to apply a health behavior change model to better understand the factors influencing the adoption of a first responder app for OHCA.

To do so, we will integrate the HBM [21], which is a widely recognized framework for understanding health-related behavior. The HBM suggests that individuals' decisions to take health actions are influenced by 5 different factors: perceived susceptibility (ie, belief in the risk of experiencing a health problem), perceived severity (ie, belief in the seriousness of the health problem), self-efficacy (ie, confidence in performing the health behavior), perceived benefits (ie, factors that facilitate the health behavior), and perceived barriers (ie, factors that hinder the health behavior). In this context, a perceived benefit might be personal relevance [22], while a potential barrier could include privacy concerns [23]. Self-efficacy was later added as the fifth variable [21].

The model is often used to explain health behaviors aimed at protecting or improving one's own health, such as condom use [24], or using mobile apps for managing chronic diseases [25]. However, limited research has explored the effectiveness of the HBM in predicting altruistic health behavior like providing CPR. Unlike self-beneficial behaviors, installing a first responder app, and thus committing oneself to potentially performing CPR, is a health behavior that only benefits another individual (ie, person experiencing a cardiac arrest). Several studies have examined the application of the HBM in the context of CTA adoption, which can also be considered an altruistic health behavior, as its primary goal is to minimize the spread of COVID-19. These studies indicate that self-efficacy, perceived barriers, and perceived benefits are the most significant predictors of adoption [18,26]. For instance, participants were more inclined to install the app when they felt confident in using it, recognized its benefits, and perceived fewer barriers to its adoption. While perceived severity and susceptibility have not consistently predicted adoption in studies on CTAs, they have shown positive associations with preventive health behaviors, such as mask-wearing [27].

Despite these insights related to CTAs, research on first responder apps and the determinants outlined in the HBM is limited. Still, building on findings from previous studies, the HBM likely also applies to the adoption of first responder apps for OHCA. For instance, as these apps can prevent severe outcomes, such as death or brain injury [28], individuals who perceive OHCA as a severe health risk may be more willing to install the app to be able to prevent such serious consequences. In addition, perceived susceptibility may influence willingness by heightening awareness of the app's necessity in addressing a widespread health risk in society. Furthermore, because of the similar altruistic and preventive nature of CTAs, we can expect that self-efficacy and perceived benefits may positively influence the willingness to install a first responder app, while perceived barriers may negatively influence it.

Building on these insights, this study therefore aims to provide an extensive overview of how the variables of the HBM can explain the willingness to install a first responder app for OHCA. Based on current literature on mHealth apps and preventive health behavior, we propose the following hypotheses:

- Hypothesis 5—Self-efficacy is positively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 6—Perceived susceptibility is positively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 7—Perceived severity is positively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 8—Perceived barriers are negatively associated with the willingness to install a first responder app for OHCA.
- Hypothesis 9—Perceived benefits are positively associated with the willingness to install a first responder app for OHCA.

Influential Factors

Apart from the previously mentioned direct determinants of first responder app adoption, the HBM also identified a number of indirect factors affecting health behavior, including demographic factors and prior contact with the health problem [10]. Other health behavior change models such as the theory of planned behavior [29] and social cognitive theory [30] also emphasize the importance of demographic (eg, age, gender, and socioeconomic status [SES]) and social context variables in shaping individuals' beliefs, attitudes, and social norms. Moreover, these theoretical propositions have also been confirmed in empirical research as, for example, older people

XSL•FO
RenderX

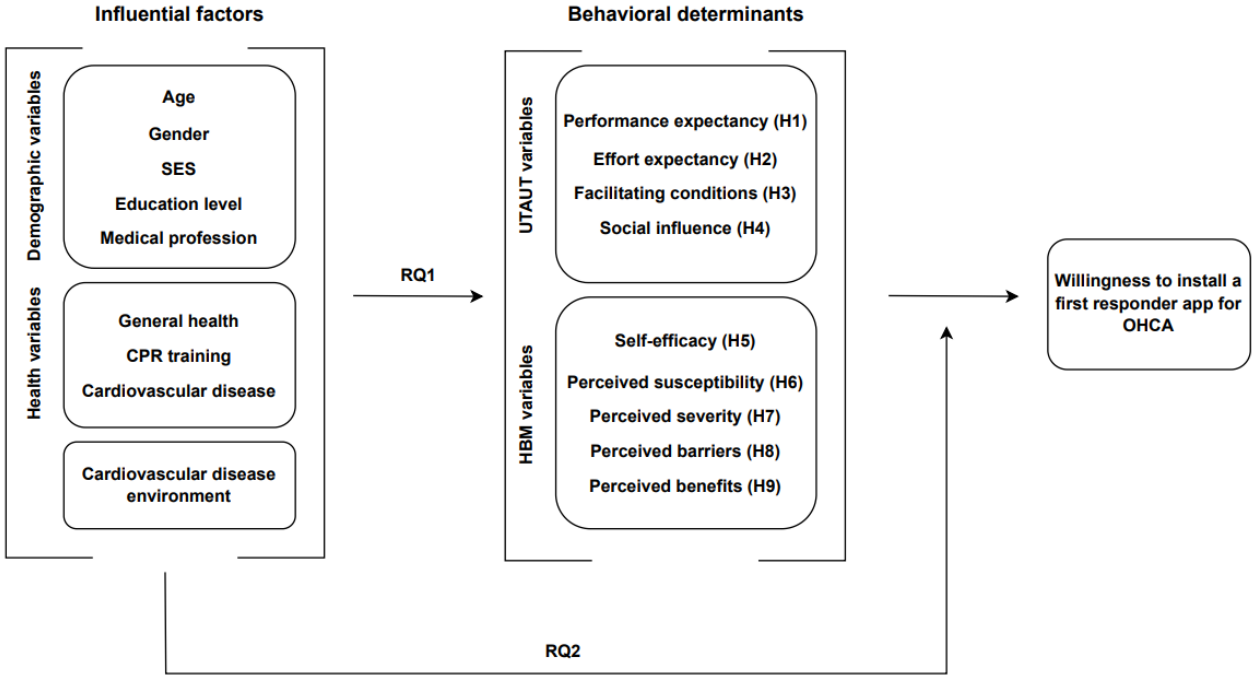
tend to perceive health issues, such as COVID-19, as more severe [31].

Along with demographic variables, practicing a medical profession may also play a significant role in installing a first responder app for OHCA. Individuals working in the medical sector could, for example, perceive greater benefits from using such an app, as it can improve patient outcomes through bystander CPR [6,8]. Consequently, their perceived barriers to installing the app and expectations regarding its effectiveness may also be shaped by their professional experience and familiarity with emergency medical care.

In addition, as installing a first responder app for OHCA is a health-related behavior, the general health status of an individual and other relevant health variables should also be taken into account. First, given that CPR training significantly enhances the willingness to provide CPR [32,33], we could assume that trained individuals will be more likely to install a first responder app for OHCA, potentially via various behavioral determinants such as increased self-efficacy and perceived benefits. Second, the HBM highlights the relevance of prior contact with a health problem as a factor that can increase perceived susceptibility and severity, thereby influencing behavior [10]. In this study, having a cardiovascular disease and, therefore, an increased change of experiencing a cardiac arrest can be a relevant factor. Finally, indirect contact with health issues, such as having a family member or close acquaintance with a cardiovascular disease, could also affect individuals' perceptions and decisions to adopt health-related behaviors like installing a first responder app for OHCA.

Since relationships between these influential factors (ie, demographic and health variables) and behavioral determinants of first responder app adoption have not been tested before, we pose the following research question (RQ):

- RQ1—Do demographic and health variables influence the behavioral determinants of willingness to install a first responder app for OHCA (performance expectancy, effort expectancy, social influence, facilitating conditions, self-efficacy, perceived severity, perceived susceptibility, perceived barriers, and perceived benefits)?



In addition to examining the variables mentioned earlier as predictors, it may be valuable to explore their potential moderating role. In the UTAUT model, gender and age already moderate the relationships between the key determinants and technology adoption [9,34]. For example, the relationship between performance expectancy and the intention to adopt a technology was stronger for men and young people, but the opposite was found for the other determinants [9,35]. Additionally, empirical research indicates that an individual's education level moderates relationships between certain UTAUT variables (ie, performance expectancy and social influence) and individuals' willingness to adopt new software [36]. This suggests that similar effects could be found for other demographic and health-related variables in the context of first responder OHCA apps. As there are again a limited amount of studies that investigated these moderations, we will examine the following RQ:

- RQ2—Do demographic and health variables moderate the relationships between the behavioral determinants (performance expectancy, effort expectancy, social influence, facilitating conditions, self-efficacy, perceived severity, perceived susceptibility, perceived barriers, and perceived benefits) and individuals' willingness to install a first responder app for OHCA?

Overall, to fully understand the willingness to install a first responder app for OHCA, this study will evaluate a self-developed integrative framework that incorporates determinants from the UTAUT and HBM, along with additional influential factors that are particularly relevant to this context (Figure 1).

RenderX

Figure 1. Conceptual framework of understanding and predicting willingness to install a first responder app for OHCA. Arrows indicate hypothesized associations based on theory and do not imply a causal relationship due to the cross-sectional design. CPR: cardiopulmonary resuscitation; H: hypothesis; HBM: health belief model; OHCA: out-of-hospital cardiac arrest; RQ: research question; SES: socioeconomic status; UTAUT: unified theory of acceptance and use of technology.

Methods

Study Design, Setting, and Participants

To test our hypotheses and address our RQs, we conducted a cross-sectional survey in June 2024 among a representative sample of Belgian adults. Participants were recruited out of a large national panel managed by a research agency, which ensured representativeness based on key sociodemographic characteristics, including gender, age, education level, and region of residence. Using quota sampling, the agency, with help from the researchers, actively monitored sample composition and adjusted invitations during data collection (eg, targeting underrepresented age groups). Eligible participants were individuals aged 18 years or older residing in Belgium. Respondents were asked to fill in a web-based Qualtrics questionnaire in Dutch or French, given the bilingual nature of the country.

Ethical Considerations

The study received ethics approval from the Social and Societal Ethics Committee of the KU Leuven (G-2024-7825). At the beginning of the survey, participants were informed about the study's objectives, procedures, their right to opt out at any time, and the confidentiality of their data, and were required to provide informed consent before continuing. Given the web-based procedure, the involved researchers were available via email to answer questions and solve practical and logistic issues. As compensation, participants received digital points from the research agency that recruited them, which could be redeemed for cash or donated to charity. To ensure privacy and confidentiality, all data were collected anonymously, with no personal identifiable information recorded, and were used solely for research purposes. In addition, the data were kept on a secure server.

Study Size

Of the initial 3908 respondents, only those who completed more than the sociodemographic section of the questionnaire were included (n=3752). After removing 92 ineligible cases (underage, duplicate responses, or lack of consent), the final sample was 3660 participants, with a mean age of 49.95 (SD 16.75) years; 52.2% (n=1909) were women. The sample included 2205 Dutch-speaking and 1455 French-speaking respondents. Education levels varied, with 1.6% (n=58) having no formal education, 3.9% (n=144) primary, 36% (n=1319) secondary, 28.9% (n=1058) bachelor, 26.5% (n=971) master, and 3% (n=110) PhD. SES was assessed using the MacArthur Scale of Subjective Social Status [37]: 4% (n=149) low SES (scores 1-3), 70.3% (n=2576) medium SES (scores 4-7), and 25.5% (n=935) high SES (scores 8-10). Health-related data showed that 10.1% (n=369) worked as medical professionals, 58.8% (n=2153) had CPR training, 15.4% (n=564) had cardiovascular disease, and 30.4% (n=1113) knew someone with cardiovascular disease.

Assessments and Data Sources

Demographic Variables

Respondents' gender (1=man, 2=woman, and 3=other), year of birth, education level (1=no degree, 2=primary school degree, 3=secondary school degree, 4=bachelor degree, 5=master degree, and 6=PhD), and subjective SES were questioned [37]. Respondents were also asked if they practice a medical profession (1=yes and 0=no).

XSL•FO
RenderX

Health Variables

We asked respondents whether they had ever followed a CPR training (1=yes and 0=no) and whether they (1=yes and 0=no) or people in their surroundings (1=yes and 0=no) experienced a cardiovascular disease. Additionally, general health was measured with an adapted version of the Linear Analogue Scale [38]. Respondents had to indicate their general health condition on a scale from 1=worst to 100=best. On average, participants scored 71.11 (SD 18.05), suggesting that the overall health of our sample was good.

Willingness to Install a First Responder App for OHCA

To measure participants' willingness to install a first responder app for OHCA, participants first received an explanation of what is meant with a first responder app. They were told that a first responder app for OHCA is a mobile app that alerts and mobilizes volunteer citizens to provide first aid to someone experiencing a cardiac arrest. Additionally, we explained the different features of the app (eg, location-based technology), the goal of the app, and that such an app is currently being set up in Belgium. Next, we asked respondents if they ever heard of a first responder app (n=458, 13.5% heard of a first responder app) and to indicate on a 5-point Likert scale (1=totally disagree to 5=totally agree) to what extent the following statement applied to them: "If a first responder app for OHCA is available in Belgium, I am willing to install it." The mean score of 3.64 (SD 1.03) indicates a moderately high willingness to install the app.

Behavioral Determinants

UTAUT Determinants

Performance Expectancy

Based on the definition given by Venkatesh et al [9], performance expectancy was measured by a self-developed scale that asked respondents to indicate on a 5-point Likert scale (1=totally disagree to 5=totally agree) to what extent the following 2 statements applied to them: "This first responder app is an effective app for saving individuals experiencing a cardiac arrest" and "This first responder app would ensure that fewer people die from a cardiac arrest." In these statements, this refers to the particular first responder app for OHCA in Belgium that is being set up. We found a high correlation between the 2 items (r=0.75; P<.001) and merged them together in 1 variable. On average, participants scored 3.90 (SD 0.78), indicating a strong positive perception of the app's effectiveness.

Effort Expectancy

This was assessed using a 5-point Likert scale (1=totally disagree to 5=totally agree) item adapted from van der Waal et al [18], asking participants to rate the statement, "I think it will cost me a lot of time and energy to install this first responder app." The average score was 2.06 (SD 1.05), indicating that most participants found the app easy to install.

Facilitating Conditions

Facilitating conditions were measured with a 5-point Likert scale (1=totally disagree to 5=totally agree) item based on van der Waal et al [18], asking participants to rate the statement, "I have a smartphone with internet access, allowing me to install this first responder app." The mean score of 4.04 (SD 1.08) indicates high smartphone ownership and internet access among respondents.

Social Influence

Social influence was surveyed by measuring both injunctive and descriptive norms. We developed 2 items based on the definitions of Rimal and Real [39]. Injunctive norms were measured by asking respondents to indicate on a 5-point Likert scale (from 1=totally disagree to 5=totally agree) to what extent the following statement applied to them: "Most people in my environment would have a positive attitude toward this first responder app." Descriptive norms were measured by: "Most people in my environment would install this first responder app, if this app would be available in Belgium," and were evaluated on a 5-point Likert scale. Both norms were combined in social influences, as they were correlated (r=0.65; P<.001). With an average score of 3.28 (SD 0.78), the results indicate that social influences were moderately strong, meaning that the participants believed a fair number of people in their environment would install the first responder app and have a positive attitude toward it.

HBM Determinants

Self-Efficacy

A self-developed scale based on the definition of Bandura [30] asked respondents to indicate on a 5-point Likert scale (from 1=totally disagree to 5=totally agree) to what extent the following 2 statements applied to them: "It seems difficult to install this first responder app" and "I would be able to install this first responder app if I wanted to." The first item was recoded for analysis and then merged with the second item into 1 construct, as there was a significant correlation between the 2 items (r=0.45; P<.001). Participants scored high on self-efficacy (mean 3.92, SD 0.87), suggesting that they feel confident in their ability to successfully install a first responder app.

Perceived Susceptibility of an OHCA

Perceived susceptibility was assessed on both personal and societal levels using self-developed items based on El-Toukhy [40]. Respondents rated their own risk (personal perceived susceptibility) and the average person's risk (societal perceived susceptibility) of experiencing a cardiac arrest on a 5-point Likert scale (1=very low to 5=very high). Personal and societal susceptibility were correlated (r=0.56; P<.001) and combined into one measure with a mean of 2.90 (SD 0.64), indicating a moderate perceived susceptibility of an OHCA.

Perceived Severity of an OHCA

To measure respondents' perceived severity of an OHCA on a personal and societal level, a self-developed scale adapted from El-Toukhy [40] asked them to indicate on a 5-point Likert scale (from 1=totally disagree to 5=totally agree) to what extent the following 2 statements applied to them: "I believe that if I experience a cardiac arrest, it could have serious consequences for me" and "I believe that if someone experiences a cardiac arrest, it can have serious consequences for that person." The items, personal and societal perceived severity, respectively,

XSL•FO
RenderX

correlated with each other (r=0.71; P<.001), and a mean score was calculated by averaging the 2 items. On average, participants perceived an OHCA as very severe (mean 4.45, SD 0.74).

Perceived Barriers

Based on technology and health behavior literature [19,21,41], we created 14 different items that reflected various barriers that respondents could experience while installing a first responder app (Multimedia Appendix 1). Examples of these barriers included phone-related issues, digital difficulties, privacy violations, and credibility of the app. Respondents had to indicate on a 5-point Likert scale (from 1=totally disagree to 5=totally agree) to what extent the statements applied to them (eg, "I would not install this first responder app because I am afraid my privacy will not be guaranteed."). A manifest variable was created by summing the scores of all 14 items (range 14-70). Consequently, a low score on this variable indicates that a participant experiences few barriers, while a high score suggests that a participant encounters many barriers when it comes to installing a first responder app for OHCA. On average, participants scored 29.75 (SD 10.70), indicating that they generally did not feel substantially hindered in their ability to install the app.

Perceived Benefits

For perceived benefits, we developed 5 items that reflected various benefits respondents could perceive about installing a first responder app for OHCA (Multimedia Appendix 1), based on previous studies on altruistic health apps and providing CPR [22,32,42]. We measured benefits like personal relevance and altruistic satisfaction. Respondents had to indicate on a 5-point Likert scale (from 1=totally disagree to 5=totally agree) to what extent the statements applied to them (eg, "I would install this first responder app because it is my duty to help people."). A manifest variable was formed by adding the scores from all 5 items, resulting in a possible range of 5 to 25. A lower score on this variable reflects fewer perceived benefits, while a higher score indicates more benefits related to installing a first responder app. The average participant score was 18.17 (SD 3.47), suggesting that most respondents saw the app as advantageous.

Data Analysis

After data cleaning, reliability indices (Multimedia Appendix 2), descriptive statistics (Multimedia Appendix 3), and zero-order correlations (Multimedia Appendix 3) were calculated. Then, we developed a structural equation model (SEM) using the *Lavaan* package in R (R Foundation for Statistical Computing) to test the hypotheses and address the RQs.

All variables with 2 items were entered as latent variables, while single-item variables were entered as manifest variables. Subsequently, we specified the regression paths, which were drawn between the behavioral determinants (ie, performance expectancy [hypothesis 1], effort expectancy [hypothesis 2], facilitating conditions [hypothesis 3], social influence [hypothesis 4], self-efficacy [hypothesis 5], perceived susceptibility [hypothesis 6], perceived severity [hypothesis 7], perceived barriers [hypothesis 8], and perceived benefits [hypothesis 9]; independent variables) and the willingness to install a first responder app for OHCA (ie, dependent variable) to answer our 9 hypotheses. Additionally, to examine RQ1, paths were specified between the behavioral determinants as dependent variables and the influential factors (ie, demographic and health-related variables) as independent variables.

To explore RQ2 and examine the moderating role of the influential factors on the relationships between the behavioral determinants and the willingness to install a first responder app for OHCA, multiple group analyses were conducted. We created groups based on the median for age, SES, general health, and education. For age, we compared younger and older participants; for SES, we compared low and high SES groups; for health, we compared poor and good health; and for education, we compared lower and higher educational attainment. Gender was recoded as a dichotomous variable, as the group of 11 participants who selected "other" was too small for meaningful analysis; these responses were therefore treated as missing values. The variables for medical profession, CPR training, cardiovascular disease, and cardiovascular disease in one's environment were also dichotomous, meaning that participants were already divided into 2 distinct groups for each variable. The constrained model (ie, the model in which the paths of the behavioral determinants to willingness were specified to be the same across groups) was then compared with an unconstrained model (ie, the model in which the paths of the behavioral determinants to willingness were allowed to differ across groups), and a chi-square difference test was conducted to assess whether the model fit differed significantly between the groups.

The following indices were used to assess the model fit: chi-square/degrees of freedom, Comparative Fit Index, Tucker-Lewis Index, root mean square error of approximation (RMSEA), 90% CI for RMSEA, and standardized root mean square residual. The overall hypothesized model indicated an acceptable fit (χ^2_{95}=1230.8; P<.001; RMSEA=0.060; 90% CI 0.057-0.063; Comparative Fit Index=0.950; Tucker-Lewis Index=0.874; standardized root mean square residual=0.030). Although the chi-square (df) statistic and corresponding P value are reported, they were not used as the primary criterion for model acceptance or rejection, given that reliance on chi-square (df) alone can be overly restrictive in many research contexts. The study was preregistered on the Open Science Framework after data collection but before data analysis. The preregistration included the hypotheses and a detailed analysis plan (including model specifications, exclusion criteria, and handling of missing data). Additionally, an anonymized and cleaned version of the dataset and R code are available on Open Science Framework to enhance transparency and reproducibility of the analyses.

Results

Relations Between Behavioral Determinants and Willingness to Install a First Responder App for OHCA

Parameter estimates can be found in Table 1. First, regarding hypothesis 1 on the association between performance expectancy and willingness to install a first responder app for OHCA, we

XSL•FO
RenderX

found no significant relationship between the 2 variables. Hypothesis 2 was also rejected, as we did not find a significant association between effort expectancy and willingness to install a first responder app for OHCA. For hypothesis 3, we found that more facilitating conditions were related to a higher willingness to install a first responder app for OHCA, which consequently confirms the hypothesis. In addition, social influence positively predicted willingness to install a first responder app for OHCA, thus confirming hypothesis 4. However, there were no significant associations between willingness to install a first responder app for OHCA, self-efficacy (hypothesis 5), and perceived severity (hypothesis 7), thus refuting hypothesis 5 and hypothesis 7. Perceived susceptibility on the other hand was positively related with the willingness to install a first responder app for OHCA, confirming hypothesis 6. Finally, the strongest associations with willingness to install a first responder app for OHCA occurred for perceived barriers (hypothesis 8) and perceived benefits (hypothesis 9), confirming hypothesis 8 and hypothesis 9.

Table 1. Parameter estimates of the structural equation model: relations between behavioral determinants and willingness to install a first responder app (FRA) for out-of-hospital cardiac arrest[a].

Demographic Variables

The results showed that practicing a medical profession was positively related to effort expectancy, perceived susceptibility, perceived barriers, and benefits but negatively with facilitating conditions, self-efficacy, and perceived severity (Table 2). Age was positively associated with performance expectancy, effort expectancy, and perceived susceptibility but negatively with facilitating conditions, social influences, and self-efficacy. Furthermore, education level correlated with 6 of the 9 behavioral determinants: negatively with effort expectancy, perceived susceptibility, and perceived barriers and positively with facilitating conditions, self-efficacy, and perceived severity. Gender was only positively related to self-efficacy and negatively related to perceived barriers. This means that men had higher levels of self-efficacy and women perceived more barriers to install a first responder app for OHCA. Finally, we found positive relationships between SES and facilitating conditions and social influences, whereas SES was negatively correlated with perceived susceptibility (Table 2).

Health Variables

General health proved to be an important variable, as the higher participants rated their health, the higher they scored on performance expectancy, facilitating conditions, self-efficacy, and perceived benefits, but the lower they scored on perceived susceptibility and barriers. Moreover, having done a CPR training was also positively related to 5 behavioral determinants (ie, performance expectancy, facilitating conditions, self-efficacy, perceived severity, and perceived benefits) but negatively with effort expectancy and perceived barriers. Surprisingly, we found no significant associations between any of the behavioral determinants and experiencing a cardiovascular disease oneself. Knowing someone in your close environment who is experiencing a cardiovascular disease, on the other hand, increased perceived susceptibility and perceived benefits of a first responder app for OHCA (Table 3).

We also explored the indirect relationships between the influential factors and willingness to install the app through the behavioral determinants. Only a limited number of these relationships were significant. Multimedia Appendix 4 reports the estimates.

The Moderating Role of the Influential Factors

Regarding RQ2, multiple group analyses were performed to examine potential moderating effects of the demographic and health variables (Table 4). Age was the only significant moderator in the SEM, with the chi-square difference test indicating a significant difference between the fits of the constrained and unconstrained model ($\Delta\chi^2_9$=23.690; *P*=.005). The post hoc tests revealed that age differences were only present for 2 relations within the model (Table 5). First, perceived severity was differently related to willingness to install a first responder app for OHCA. For young adults, there was no significant relation (β=.028; *P*=.49), and for older adults, there was a negative relationship (β=–.072; *P*=.03). Thus, for older people perceiving a cardiac arrest as severe related negatively to willingness to install the app. In addition, the association between perceived benefits and willingness to install a first responder app for OHCA was significantly stronger for older people (β=.123; *P*<.001) compared to younger people (β=.092; *P*<.001) .

Discussion

Overview

OHCAs are one of the leading causes of death worldwide, impacting approximately 350,000 people annually in Europe [7]. With survival rates ranging from 5% to 25% [7], first responder apps for OHCAs offer a vital solution to increase survival rates by mobilizing volunteer citizens to provide CPR in emergency situations. However, despite the emergence of these apps, little is still known about their adoption processes. Building on a comprehensive framework that integrates the UTAUT model, the HBM, and other contextual variables, this study therefore contributes to the literature by examining which factors influence citizens' willingness to install a first responder app for OHCA. While this framework suggests meaningful relationships between the variables studied, it is important to note that these are correlational and do not imply causality due to the cross-sectional nature of the study.

Main Findings Related to Hypotheses

This study offers partial evidence for the use of UTAUT determinants in understanding the adoption of first responder apps for OHCA, expanding our insights into how the model applies to altruistic mHealth apps. Specifically, only facilitating conditions (hypothesis 3) and social influence (hypothesis 4) were positively related to willingness to install a first responder app for OHCA, whereas performance and effort expectancy were not. First, aligning with facilitating conditions in studies on CTAs [18,19], people with internet and smartphone access were more willing to install a first responder app for OHCA, which is unsurprising given that these conditions are essential for installing and using a first responder app [19]. In addition, individuals who perceived more positive descriptive and injunctive norms were more willing to install a first responder

XSL•FO
RenderX

app for OHCA. This aligns with a systematic review on CTAs showing that social influence is one of the most significant predictors of novel app adoption [16]. Moreover, research shows that social influence is a crucial predictor of the intention to perform bystander CPR [43], which may also help clarify the relationship observed in this study.

Performance (hypothesis 1) and effort expectancy (hypothesis 2) were not significantly associated with willingness to install a first responder app for OHCA. While previous studies on CTAs and other health apps have reported mixed results for effort expectancy [5,18,44], performance expectancy has been classified as a strong predictor [13,15,17,18]. These insignificant findings in this study could be attributed to the fact that the first responder app has not yet been implemented in Belgium, thus making it hard for individuals to estimate the app's effectiveness (performance expectancy) and ease of use (effort expectancy) based solely on the brief description provided.

Regarding the HBM determinants, we identified 3 significant relationships (ie, perceived susceptibility, barriers, and benefits) with willingness to install a first responder app for OHCA. First, even though mixed findings occurred for perceived susceptibility in mHealth app literature [18,25,45], this variable was a significant predictor for the willingness to install a first responder app (hypothesis 6). This indicates that individuals who perceive themselves to be at a higher risk of experiencing a cardiac arrest are more inclined to adopt the app. Consequently, their personal risk assessment likely influences their perception of the app's importance in society. In addition, perceived barriers (hypothesis 8) and benefits (hypothesis 9) were significantly associated with willingness to install a first responder app for OHCA, with barriers negatively and benefits positively relating to willingness. In other words, the more barriers participants perceived, the less likely they were to install the app, while those who saw more benefits were more inclined to install. These findings align with previous research on health app adoption and bystander CPR, where barriers such as usability issues or privacy concerns [19,21,22,41], and perceived benefits like personal relevance and altruistic satisfaction [21,31,42], have been shown to be key predictors. Interestingly, perceived barriers and benefits emerged as the strongest predictors, highlighting their critical role in users' willingness to install a first responder app for OHCA.

Finally, there was no significant relationship between self-efficacy (hypothesis 5) or perceived severity (hypothesis 7) and willingness to install a first responder app for OHCA. The absence of a link with self-efficacy is surprising, as it contradicts studies on CTAs [18,26] and other mHealth technologies [46,47], where self-efficacy often emerged as a strong predictor, sometimes even the strongest. One possible explanation could lie in the difference between technology-related and health-related self-efficacy. In health research, self-efficacy often involves confidence in performing complex behaviors, like CPR. As such, it may not be self-efficacy related to feeling able to install the app, which can be fairly simple, but rather self-efficacy related to feeling capable of providing CPR if alerted, which may predict individuals' willingness to install the app. This study only measured technology-related self-efficacy, which might explain the absence of a significant link in the findings. Future studies should explicitly differentiate between technology-related and health-related self-efficacy to clarify their respective roles in shaping willingness to adopt first responder apps. Additionally, mixed results regarding perceived severity have been reported in the literature [18,48], suggesting variability in its influence across different health behaviors. In the context of first responder apps for OHCA, the lack of a significant relationship might be explained by the psychological and physical distance associated with such emergencies. Although citizens recognize that OHCA is a severe, life-threatening condition, they may perceive it as happening outside of their immediate, familiar environment and therefore do not feel a personal sense of responsibility. This feeling of detachment might lessen their willingness to install a first responder app.

Main Findings Related to RQs

We formulated 2 RQs to explore influential factors that may affect the behavioral determinants of willingness to install a first responder app for OHCA and to examine the potential moderating effects of these factors on the relationships between the determinants and willingness. As expected, age proved to be a significant variable for 2 main reasons. First, it was associated with 6 of the 9 behavioral determinants. Second, it was the only moderating factor in the model. More specifically, there was an age difference in the relation between perceived severity and willingness: no significant link was found for adults younger than 50 years of age, while a negative association was observed for those older than 50 years. Older adults who viewed cardiac arrest as severe were thus less willing to install a first responder app for OHCA. This finding is surprising; yet, it may suggest that older adults, who often have a more skeptical attitude toward technology [49], may associate severe medical emergencies with the need for professional intervention rather than assistance from lay responders. This perception could reduce their confidence in the app's usefulness or appropriateness. Alternatively, they may feel less personally capable or comfortable engaging with the app, especially in high-stakes situations. While these interpretations remain speculative, they highlight the need for further research into how age-related attitudes toward technology and emergency care shape the willingness to install health apps. Additionally, there was an age difference in the relationship between perceived benefits and willingness, with a stronger positive relation identified among older adults. The stronger positive relationship may indicate that older people, unlike digital natives, require clearer and more substantial advantages before they are willing to adopt new technologies. This aligns with Rogers' diffusion of innovations theory [50], which suggests that individuals assess the relative advantages and disadvantages of an innovation before deciding to adopt it. Moreover, it is in line with the UTAUT model that says that all relationships except for performance expectancy are stronger for older people [9,35].

In accordance with the HBM [10], also other demographic variables such as gender, SES, and education level were related to several of the behavioral determinants, and in that way indirectly to willingness to install a first responder app for OHCA. For example, younger people and men experienced more self-efficacy, which aligns with existing research on

XSL•FO
RenderX

technology-related self-efficacy [51,52], and people with a lower SES perceived themselves and their environment as more susceptible to a cardiac arrest. This relationship is logical, as general health showed a strong correlation with SES.

Health variables, although often not included within behavior change models [10,29], seemed to play a meaningful role. First of all, medical professionals perceived greater benefits of a first responder app for OHCA than those outside the medical field, which aligns with expectations, given the app's potential to improve patient outcomes [6]. However, they also reported more barriers, lower self-efficacy, higher effort expectancy, and lower scores on facilitating conditions and perceived severity. This pattern of results, where medical professionals score lower on multiple variables associated with willingness to install the app, may be attributed to several factors. First, they may be less technology-savvy or more resistant to health care digitalization, a trend supported by previous research [53]. Second, their familiarity with the consequences of a cardiac arrest could reduce the perceived severity, as the nature of their work may lead them to view a cardiac arrest as a more routine, manageable event. Third, they may have reservations about the general public's ability to provide effective CPR, leading to greater skepticism toward the app's effectiveness in nonprofessional hands. This skepticism may be unfounded, as individuals trained in CPR scored higher across 7 of the 9 behavioral determinants in this study, highlighting the potential benefits of promoting CPR training among the general public in first responder app adoption.

Furthermore, the general health status of individuals affected the majority of the behavioral determinants, but surprisingly, this was not the case for having cardiovascular disease. This is in contrast with the HBM, which states that prior experience or direct contact with a health issue typically influences perceptions and attitudes toward related health behaviors [10]. Indeed, one would assume that individuals with a cardiovascular disease, given their increased susceptibility to a cardiac arrest, would perceive themselves as more at risk and potentially recognize greater benefits in a first responder app for OHCA. Although we did find individual correlations between having a cardiovascular disease and several determinants (eg, positively related to effort expectancy, perceived susceptibility, and perceived barriers), their significance diminished when tested within the full model. Given the cross-sectional nature of our study, making it impossible to make claims about directionality, longitudinal research is needed to further clarify these correlations. On the contrary, knowing people in your environment who have a cardiovascular disease heightened individuals' awareness of personal risk and ensured more perceived benefits of a first responder app for OHCA.

Limitations

This study has several limitations that should be considered when interpreting the findings. First, as mentioned, the use of a cross-sectional survey design limits the ability to establish causal relationships. The relationships observed in the study should be interpreted as correlational, rather than causal. For example, while our model posits that social influence increases individuals' willingness to install a first responder app, it is also plausible that individuals who are already willing to install such an app subsequently develop stronger descriptive and injunctive norm perceptions. To further explore the directional effects and how all constructs within the model influence each other over time, future research should consider using longitudinal or experimental methodologies.

Second, many behavioral determinants were assessed with only 1 or 2 items, rather than more complex, multidimensional scales. This approach was intentional to minimize participant burden and was supported by literature in applied survey research and health psychology, which suggests that single-item measures can be as valid and reliable as their multifaceted counterparts [54]. However, we did not validate the single-item measures in our study, and future research is, therefore, recommended to validate these measures and compare them with multi-item scales to assess whether they perform equally well. This is particularly important, given that some single-item measures (eg, effort expectancy) targeted only specific facets of the constructs rather than capturing them in their entirety.

Third, while the study benefited from a large sample, the use of a web-based survey panel may have introduced self-selection biases. Individuals who join such panels and choose to participate in a CPR-related survey may be more technology-savvy and health-conscious than the general population. This could have led to an over- or underestimation of certain beliefs or attitudes toward the app. For instance, participants may have reported a higher willingness to install the app, as technology-savvy individuals may be more comfortable downloading and using health apps compared to the general public. Future studies should, therefore, consider using alternative or mixed method recruitment strategies, such as random digit dialing or community-based sampling, to validate the results in more diverse and representative populations.

Finally, as there is no existing first responder app for OHCA in Belgium, the study could not measure behavioral intention or actual app use, which is typically measured in studies applying models like UTAUT or the HBM. As a result, we were unable to determine whether participants' stated willingness would translate into real-world behavior. Additionally, the use of self-reported willingness to install the app may have been subjected to social desirability bias. For example, participants may have overstated their willingness to install the app to appear socially responsible or helpful, especially given the focus on emergency health situations. This intention-behavior gap is well documented in health behavior research and highlights an important limitation of the study. Future research should replicate this work in countries where such apps are already in use to examine whether the identified determinants also predict actual behaviors, such as installation rates, retention over time, and the frequency of CPR interventions triggered by the app.

Implications and Future Research

The findings of this study have both theoretical and practical implications. Theoretically, it finds its relevance in extending the UTAUT and HBM to altruistic mHealth apps that require active involvement, which has not been done before. Moreover, this study contributes to the field by developing a comprehensive

XSL•FO
RenderX

framework that also integrates relevant demographic and health variables, offering a more nuanced understanding of the factors influencing the first responder app for OHCA adoption. Practically, this study was conducted in Belgium, which is a country that currently lacks an established first responder system. As such, the knowledge provided by the study provides practical guidance regarding how to convince citizens in Belgium to participate in the first responder system that health care professionals are currently deploying. Building on this, future research could further enhance these efforts by designing and testing health messages in an experimental setting based on the key determinants of willingness to install a first responder app that we identified in this study. In that way, subsequent studies can refine communication strategies for real-life campaigns. Additionally, it would be valuable to replicate the proposed model in countries where first responder apps for OHCA are already available. Such studies could examine actual adoption behaviors and compare the model's applicability across different contexts.

This study provides an important first step in mapping the behavioral, demographic, and health-related factors of the Belgian population that influence the willingness to install a first responder app for OHCA. By identifying key behavioral determinants, such as social influence and perceived barriers or benefits, and other sociodemographic and health-related factors, we offer actionable insights that governments can use to shape implementation strategies. For example, campaigns could emphasize the app's societal benefits and social norms around helping others while also addressing privacy or usability concerns. Additionally, app developers may draw on these insights to design a more accessible and user-friendly first responder app for OHCA. Our findings also point to the need for tailored messaging, as one-size-fits-all communication strategies may not be effective for the entire Belgian population. For instance, older adults may respond differently to a message focused on a certain behavioral determinant than younger adults, suggesting that future research should explore how best to adapt outreach efforts to diverse groups. Future efforts to roll out such technology should be grounded in this type of population-informed research, ensuring that interventions are aligned with what people value and what might hold them back.

Acknowledgments

Generative artificial intelligence (ChatGPT) was used to improve the language and clarity of certain sections, as all authors are nonnative English speakers. However, it was not used to generate original content, ideas, or code. This work was supported by grants from Interne Fondsen KU Leuven (Internal Funds KU Leuven; CITSC/24/012). Abstract

Background: Breast cancer treatment, particularly during the perioperative period, is often accompanied by significant psychological distress, including anxiety and uncertainty. Mobile health (mHealth) interventions have emerged as promising tools to provide timely psychosocial support through convenient, flexible, and personalized platforms. While research has explored the use of mHealth in breast cancer prevention, care management, and survivorship, few studies have examined patients' experiences with mobile interventions during the perioperative phase of breast cancer treatment.

Objective: This study aimed to explore the experiences of patients with breast cancer using iCareBreast, a mobile app designed to provide perioperative guidance and psychosocial support.

Methods: A qualitative approach was used to explore participant experiences. A total of 13 English- or Chinese-speaking participants from the intervention group of a clinical study were recruited via purposive sampling between April 2021 and February 2022. Semistructured individual phone interviews were conducted, audio-recorded, and transcribed verbatim. Thematic analysis was performed to identify key patterns of experience, focusing on usability, emotional impact, perceived value, and areas for future improvement.

Results: Overall, 4 main themes and 11 subthemes emerged from this study: (1) navigating the app with confidence and comfort, (2) making sense of treatment through relevant and evolving content, (3) finding emotional anchors in a time of uncertainty, and (4) advocating for broader use and continued motivation. Participants found the app user-friendly and appreciated its structure and locally relevant content, which helped reduce anxiety and enhance surgical preparedness. Features such as deep breathing exercises, motivational quotes, survivor stories, mindfulness practices, and peer support links offered emotional comfort and a sense of companionship. Participants strongly advocated for more personalized and adaptive content aligned with their treatment type and recovery progress. They also emphasized the value of interactive elements, such as video demonstrations and accessing messaging functions, to support sustained engagement. Many expressed the need for extended support throughout the adjuvant treatment phases, including chemotherapy and radiotherapy.

Conclusions: The iCareBreast app was perceived as a supportive tool during the perioperative period, helping patients navigate both informational and emotional challenges. However, the findings underscore the importance of extending content across the treatment continuum and enhancing personalization and interactivity. mHealth interventions should be responsive to patients'

XSL•FO

evolving needs and integrated into clinical care pathways to provide timely, comprehensive, tailored, and ongoing support for women with breast cancer.

KEYWORDS

breast cancer; mobile health; psychosocial intervention; participant experience; qualitative study

Introduction

Background

Breast cancer is one of the most prevalent cancers among women worldwide and remains the leading cause of cancer diagnosis and mortality in Singapore [1,2]. Despite advancements in treatment, patients frequently experience heightened anxiety, depression, and uncertainty as they navigate surgical procedures and recovery [3-5]. Psychological distress affects approximately 50% of patients with breast cancer and is closely linked to factors such as short time since diagnosis, being in the preoperative phase, and concerns about body image [6]. Preoperative depressive symptoms are particularly concerning, with rates as high as 39% among patients undergoing mastectomy or lumpectomy, particularly in Asian countries [7]. These statistics highlight the significant psychological challenges faced by women during the perioperative period.

In addition to emotional distress, many patients report unmet information needs during the active treatment phase. During treatment preparation, patients often seek detailed explanations about the treatment plan and procedures, whereas their focus shifts to managing side effects and understanding long-term outcomes during treatment [8]. Supportive and goal-oriented strategies before surgery, including psychosocial interventions, have been shown to effectively reduce stress and improve the quality of life for patients with breast cancer [9-11]. These findings underscore the critical importance of comprehensive psychosocial support in addressing psychological distress and unmet information needs, ultimately improving outcomes during the perioperative period.

Traditional face-to-face psychosocial support mechanisms may not always be sufficient and convenient to meet the needs of patients with breast cancer, particularly during the brief and emotionally intense period from diagnosis to surgery. Mobile health (mHealth) interventions have emerged as innovative solutions that offer timely psychosocial support through accessible digital platforms. These interventions leverage flexibility, convenience, and cost-effectiveness to deliver personalized care. Research highlights mHealth's value across breast cancer care, including prevention, early detection, care management, and survivorship. Through interactive features such as pictures, audios, videos, and tracking diaries, these platforms provide educational resources, monitor health, promote lifestyle changes, facilitate emotional support, and enable communication with health care professionals (HCPs) [12]. Despite their potential, psychosocial interventions specifically targeting patients with breast cancer during the perioperative period are limited, particularly those delivered through mHealth or eHealth platforms. Furthermore, there is a limited understanding of patients' preferences for such solutions [13]. To address this gap, we developed an innovative e-supportive care mobile app, iCareBreast, designed for patients with breast cancer undergoing surgery. On the basis of the self-efficacy theory proposed by Bandura [14], the app aims to enhance patients' self-efficacy in perioperative care while addressing their specific needs during this critical period.

Objectives

Understanding participant experiences with these technologies is essential for uncovering the mechanisms behind their impact, optimizing their design to better meet patients' needs, and guiding future implementation [13,15]. This process evaluation focused on exploring the experiences of patients with breast cancer who used the iCareBreast mobile app, designed to deliver care support during their surgical journey. By gathering qualitative insights into each component of the app, the evaluation aimed to identify user experience, focusing on usability, strengths, weaknesses, and suggestions for future improvements. These insights are critical for refining the app and ensuring that it effectively addresses patients' needs, ultimately enhancing their perioperative care experience.

Methods

Study Design and Participants

This descriptive qualitative study is a follow-up to a randomized controlled trial (ClinicalTrials.gov ID NCT04172350) [16] that evaluated the effectiveness of iCareBreast, a mobile-based perioperative care program, on various health outcomes in improving perioperative self-efficacy, anxiety, depression, fatigue, health-related quality of life, and perioperative care satisfaction among women undergoing breast surgery in a public hospital in Singapore. The randomized controlled trial enrolled 123 women with early-stage breast cancer, randomized to either the iCareBreast intervention group (n=62) or the control group (n=61). While no statistically significant differences were found between the groups for most health outcomes, participants in the iCareBreast group reported higher perioperative care satisfaction.

All participants received standard multidisciplinary preoperative care, including consultations with a breast surgeon. The number and duration of consultations varied depending on case complexity and individual patient concerns. Patients were typically referred to a breast care nurse (BCN), who served as a nurse navigator providing education, emotional support, and care coordination. A short hospital stay (1-2 days) following breast-conserving surgery or mastectomy was typically required to ensure adequate pain control, postoperative monitoring, and wound care education. Postoperative follow-up appointments were scheduled with the breast surgeon. Medical social workers

XSL•FO
RenderX

were available, and referrals were made based on clinical judgment and patient-specific needs. In addition to standard care, participants in the intervention group used the iCareBreast app daily at home.

iCareBreast e-Support Care Program

The iCareBreast app was an interactive tool designed to guide and support patients through their perioperative journey. Tailored to each patient's surgery date, the app provided daily guidance and information over a 29-day period (14 days before surgery, the day of surgery, and 14 days after surgery). Aiming to enhance care management and patient engagement for both surgery preparation and recovery, iCareBreast included 4 main functions: educational content, perioperative care guidance, psychological support, and social support.

The educational components covered presurgery and postsurgery topics relevant to breast cancer, such as anatomy, treatment options, and anesthesia. The perioperative care included preoperative preparation, day-of-surgery guidance, and postoperative care guidance on wound and drain management, pain control, infection monitoring, physiotherapy, and discharge planning. The psychosocial support component provided daily motivational quotes, mindfulness exercises, and stories from breast cancer survivors, along with a summary of breast cancer support networks available in Singapore. In addition, participants could ask questions through the app's messaging system, with responses provided by HCPs and researchers within 24 hours.

The iCareBreast app was downloaded from the Google Play Store (for Android) or the Apple App Store (for iOS), available in participants' preferred language—either English or Mandarin. A unique activation code was used for login, ensuring confidentiality and preventing cross-group contamination. Further details have been published elsewhere [16].

Recruitment

Purposive sampling was used to select participants from the intervention group, categorized by age groups (21-49, 50-64, and ≥65 years), to ensure representation across different levels of technology competency. Participants in the intervention group were purposely invited to the interview phase at the same time they were enrolled in the main study. Interviews were conducted 2 weeks after surgery (immediately following the intervention) until data saturation was reached, which occurred with the 10th participant. Three additional patients with breast cancer were interviewed to confirm that no new information emerged, resulting in a total of 13 participants enrolled. All participants were informed that participation in the interview was optional and would not impact their involvement in the main study. They were also informed that the interviews would take approximately 10 to 20 minutes and would be audio-recorded.

Data Collection

All semistructured interviews were conducted via phone calls during the COVID-19 period (from April 2021 to February 2022). Interviews lasted an average of 20 minutes, with duration ranging from 12 to 32 minutes. An interview guide was developed to facilitate discussions about participants' experiences using the app, focusing on usability, strengths, weaknesses, and suggestions for future improvements.

Approximately 2 weeks after surgery, when participants had just completed their app use, a female research assistant who had no prior contact with participants trained in qualitative interviewing conducted individual phone interviews at mutually convenient times for both the interviewer and participants. The interview guide (Multimedia Appendix 1) was developed by an academic expert specializing in eHealth interventions, with another academic expert providing feedback on content clarity. A total of 10 interviews were conducted in English, and the remaining 3 in Mandarin. The Mandarin interviews were transcribed verbatim, then back translated into English by the same bilingual research assistant and verified for accuracy by another bilingual team member. Field notes were also taken to capture nonverbal cues (such as crying or laughing) to supplement the transcripts.

Data Analysis

Data were analyzed following the 6 phases of thematic analysis described by Braun and Clarke [17]. This approach enabled us to explore and interpret patterns of meaning across the dataset, with an emphasis on understanding participants' experiences and perspectives rather than counting specific responses. All interviews were transcribed verbatim by the same interviewer (research assistant) and cross-checked for accuracy by another team member. Data were analyzed concurrently with collection using inductive thematic analysis [17]. Two independent coders immersed themselves in the transcripts, repeatedly reading them. Codes were developed inductively from the data, and themes were shaped based on the depth and recurrence of meaning both within and across interviews. Initial coding was conducted independently by both coders line-by-line in the raw Microsoft Word documents, after which the codes were transferred to XMind Zen software to develop themes and subthemes related to participant experience [17,18]. A thematic map illustrating the connections between themes and subthemes was created after a third researcher reviewed and harmonized the findings [17]. Study rigor and reliability were maintained through prolonged engagement, peer debriefing, and by taking an audit trail and field notes [19]. Study finding was reported according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist (Multimedia Appendix 2) [20].

Ethical Considerations

Ethics approval was obtained from the SingHealth Centralised Institutional Review Board (reference number 2019/2632). In accordance with the principles of the Helsinki Declaration, the participants were fully informed about the study, given ample time for consideration, and assured of their voluntary participation and right to withdraw at any time. All participants provided informed consent, and their identities were anonymized. They were then randomly assigned to either the intervention or control group. No compensation was provided to the participants.

Results

Participant Demographics

A total of 13 participants were interviewed for this study, all of whom were women with breast cancer undergoing breast surgery. The mean age was 58.5 (SD 11.8) years, with an age range of 35 to 73 years. Overall, 31% (4/13) of the participants were aged 21 to 49 years, 31% (4/13) were aged 50 to 64 years, and the remaining 38% (5/13) were aged ≥65 years. The average hospital stay was 2.85 days. Of the 13 participants, most were Chinese (n=11, 85%), with 1 (8%) Malay and 1 (8%) from another ethnicity. All participants identified as religious believers. Just more than half of the participants (11/13, 85%) received a polytechnic-level education or less; 46% (6/13) were currently employed, and 46% (6/13) had an income of more than SGD 3000 (approximately US $2243). Overall, 62% (8/13) of the participants underwent mastectomy, including 3 who received immediate reconstruction. Furthermore, 31% (4/13) of the participants underwent lumpectomy, with one receiving immediate postlumpectomy reconstruction. Approximately half of the participants (6/13, 46%) received adjuvant treatment (chemotherapy or radiotherapy) after surgery during the study period. Other sociodemographic and clinical characteristics of the participants are provided in Table 1.

[a]Extended coordination of postdischarge care due to no immediate home support.

Overview

Overall, 4 main themes and 11 subthemes emerged from the thematic analysis: navigating the app with confidence and comfort, making sense of treatment through relevant and evolving content, finding emotional anchors in a time of uncertainty, and advocating for broader use and continued motivation. A summary of the themes and subthemes is provided in Figure 1.

Figure 1. User experience thematic map for the iCareBreast app, showing 4 main themes and 11 subthemes.

Theme 1: Navigating the App With Confidence and Comfort

Subtheme 1.1: Simple, Familiar, and Easy to Use

Participants generally found the app easy to use and navigate, with a clean layout that suited users across ages, including older adults. While the content was released daily, the app's flexibility allowed them to preview upcoming content and catch up on any information from previous days that they may have missed. In addition, participants appreciated the daily app reminders, which helped engage them in completing their daily tasks consistently:

> *Simple, convenient. Also, there was no need to enter this, enter that, switch here and there.* [P5]

> *Yeah I appreciate the ah availability of the information before the actual day has passed.* [P1]

Subtheme 1.2: Technical Glitches and Physical Limitations

While most had a smooth experience of using the app, several users encountered login problems or faced issues such as the app hanging. However, these issues were quickly resolved by our technical support team in Finland, who developed the app and provided technical assistance throughout the study period. A few participants also noted that they were physically too unwell to use the app on the day of surgery and during the initial days after surgery, as they needed to remain in bed and focus on recovery:

> *That day there are some login technical issues. But then your colleague is setting it up. But then after that, this is no more issue.* [P12]

Subtheme 1.3: Preferences for How Support Is Delivered

Some participants missed out on using the in-app messaging feature due to its location or unfamiliarity, suggesting that making it more visually prominent would help them easily ask questions and receive support without needing to contact hospital staff. Others, particularly older users, preferred direct phone calls for urgent concerns. They noted that this feature is more appropriate for nonurgent issues. Many felt that shorter video-based instructions, particularly for physiotherapy or muscle relaxation exercises, would be easier to follow and maintain interest than written or static images:

> *I forgot to use, because it (messaging feature) was not part of the main interface, I think the design of that part was build it within the setting.* [P4]

> *I don't know if it itself as a reminder to the patients. But my therapy is simple so I will remember after a*

XSL•FO
RenderX

> *few times you see, that I don't need to see every, but if I keep seeing every day I will like I feel like boring...a video format will be good, because we can follow like an instructor that we can follow.* [P12]

Theme 2: Making Sense of Treatment Through Relevant and Evolving Content

Subtheme 2.1: Feeling Prepared and Reassured Before Surgery

Participants found the surgical guidance within the app clear and helpful, particularly as it walked newly diagnosed patients with breast cancer through the process step by step. Knowing what to expect for breast cancer and surgical procedures reduced uncertainty and helped them mentally prepared for surgery. The app's detailed knowledge on postoperative expectations and postsurgery care such as pain management, wound care, and lymphedema prevention was particularly valuable:

> *I feel self-prepared (for surgery). Uh, I know what's going to happen. what will happen. How am I going to accept it and take care of it.* [P9]

Subtheme 2.2: A Reliable Source in a Sea of Misinformation

Many participants felt that the content provided in the app was trustworthy and Singapore-relevant source of information. Many appreciated not having to seek additional resources, such as Google searches, which they found overwhelming or sometimes confusing. The volume and complexity of information shared during clinical visits often left them feeling overwhelmed and more likely to forget important details. Many participants appreciated that they could refer back to the app whenever needed, finding it a helpful resource to reinforce what they had learned during clinic visits:

> *Yeah, in fact this software is specifically for the patient at the hospital in Singapore, I think the content of the app is may more rigorous than my own online searching.* [P1]

> *So someone like me I need to refer to the app to refresh my memory. I'll go back to the apps again and see the exercise (physiotherapy) and all those posted on the app lah.* [P11]

Subtheme 2.3: The Need for Continued Support Beyond Surgery

Several users felt the iCareBreast content ended too soon, particularly as new symptoms or emotional challenges often arose later. They expressed a strong desire to extend the app's content to include the subsequent adjuvant treatment phase, with a particular emphasis on chemotherapy. They suggested adding information on different types of chemotherapy, side effect management, and ongoing recovery support to better prepare patients for this stage. Some participants also expressed interest in educational resources on radiotherapy, similar to the surgery-related guidance, covering topics such as types of radiation, key precautions, and postradiation care:

> *For me, the first 14 days were fine; my wound healed well, no pain, nothing unusual. But after the 14 days (end of app using), the pain started, and there was some discharge. Additional information could be helpful.* [P7]

> *Because like for me, the treatment after the surgery I think at least I have to go 9 more months of treatment so I think it would be helpful if we expand using the application after the surgery.* [P8]

Subtheme 2.4: Desire for Contents That Fits Personal Condition and Recovery

Some participants felt that, while the app provided general information, it lacked in-depth detail information based on their surgery type, treatment plan, or recovery stages. Participants felt that the app should adapt to their progress and treatment stages, with features such as adjusting physiotherapy exercises as they recover to provide more personalized support. They also hope for more guidance on nutrition, exercise, and long-term self-care as they progress in recovery:

> *Some people need chemotherapy and so on, so I think it would be great if it was added, it would be continuous for the patient. Because of this disease its treatment is relatively long…patient will just choose to see the content that relevant will be a long-term help for them.* [P1]

> *Additionally, this kind of information for faster recovery, like diet, I believe will be helpful, because I was trying to search if there's any in the app, I couldn't find much.* [P3]

Theme 3: Finding Emotional Anchors in a Time of Uncertainty

Subtheme 3.1: Calming Anxiety Through Daily Guidance

Many participants reported that the app's day-to-day guidance and recovery tips gave them a clearer sense of what to expect, helping to reduce anxiety and alleviate doubts. The amount of daily information in the app also made them feel less overwhelmed. After practicing the provided deep breathing exercises or mindfulness practices, participants felt less pain and pressure, more relaxed, and experienced improved sleep quality:

> *The daily updates on what would happen each day, like meeting the anesthetist and what they would do. It helped me know what to expect, so I didn't feel panicked.* [P7]

Subtheme 3.2: Feeling Supported, Connected, and Uplifted

The app served as a supportive emotional companion, helping participants feel cared for and less alone. They experienced a sense of connection, encouragement, hope, and optimism when reading stories from breast cancer survivors, realizing that many others had been through similar experiences. However, participants suggested adding more diverse breast cancer survivors' stories to strengthen this emotional support aspect. They also appreciated the peer group resources provided, which allowed them to seek additional support and participate in more activities. In addition, participants reported feeling more focused, hopeful, and motivated to think positively and appreciate the present, inspired by the app's motivational quotes and mindfulness practices. They suggested that adding more

XSL•FO
RenderX

mindfulness practice videos would further enhance these benefits:

> *Yeah, I think it can introduce two people (breast cancer survivors' story) a week, that make you feel there are a lot of people who are recovering... A kind of more encouragement.* [P2]

> *The app helped me a lot. One day, when I was feeling down, especially on Chinese New Year's Day, I was very negative. Then, I saw content in the app that talked about people in Africa who don't have food and children in other places who suffer from diseases. It reminded me to be grateful, and it completely changed my outlook. I stopped being resentful and started communicating better with my family.* [P13]

Theme 4: Advocating for Broader Use and Continued Motivation

Subtheme 4.1: A Resource Worth Recommending

Nearly all participants recommend the app to others in similar situations. They saw it as a valuable support tool that made a difference in both practical and emotional aspects of their recovery:

> *Yes, if others need something like this for the long term, I think I would recommend them to use.* [P10]

Subtheme 4.2: Encouragement to Stay Engaged

Participants expressed a desire for the app to provide ongoing motivational content to help them feel supported. Continued emotional support and inspiration were seen as key to encouraging long-term use of the app throughout their recovery:

> *We have this disease, diagnosis has been extremely scared, it is difficult to sleep. Have this thing (APP) is also a kind of encouragement, good. Isn't it? If the app keeps giving me encouragement, confidence, of course I will continue using. Otherwise, if recurrence happen and the app content would be forgotten for a long time.* [P6]

Discussion

Principal Findings

This qualitative study explored how women with breast cancer experienced and engaged with a mobile perioperative support app during the breast cancer perioperative period. Through thematic analysis of interviews with 13 users, 4 key themes were identified, highlighting how the app supported users in navigating their surgery treatment journey, making sense of medical information, managing emotional challenges, and suggesting its potential beyond surgery.

The findings indicate that participants generally felt confident using the iCareBreast app due to its user-friendly interface and smooth navigation across both iOS and Android platforms. The app delivered daily content tailored to each user's surgery date, which helped manage the information flow during an already emotionally overwhelming period. Participants valued this gradual delivery, noting it prevented the overload often experienced during clinic visits or conversations with others. The app's flexibility was another key strength. Users appreciated being able to catch up on missed information if they enrolled late, and some users found it helpful to preview upcoming content if desired. Daily app reminders were seen as helpful prompts that supported consistent engagement, particularly by older users who also appreciated the app's straightforward design. These features underscore the importance of designing digital tools that accommodate varying levels of digital literacy. A few users reported occasional app hang-ups or encountered login difficulties, particularly during scheduled app updates timed according to Finland's time zone, where the iCareBreast app was developed and maintained, which inadvertently affected users in Singapore. These technical challenges were quickly addressed, ensuring minimal disruption to the participants.

Research consistently highlights that patients with breast cancer experience distress and anxiety during the perioperative phase due to uncertainty about what to expect, lack of health-related information, and concerns about unexpected surgical outcomes [21]. These emotional states can exacerbate feelings of being overwhelmed by the overwhelming volume of information provided during hospital visits [22,23]. Our study findings supported this observation. Many participants reported relying on the iCareBreast app to recall guidance from physicians or physiotherapists. This reliance underscores a communication gap that contributes to heightened distress early in the perioperative journey [21]. Although preoperative education and surgery-related information have been shown to reduce anxiety, improve knowledge, and enhance satisfaction, particularly when delivered in person [23], limited consultation time and the fast-paced nature of clinical care often restrict such opportunities. In this context, digital tools such as mobile apps can play a valuable role in supplementing patient education. Participants in our study noted that the iCareBreast mobile app helped in addressing their doubts. They appreciated its trustworthy, locally relevant content, which they described as more accessible and less overwhelming than online searches, which were often confusing or inconsistent. For many users, the app served as a reassuring and structured source of support during the perioperative phase.

Participants described the app as a source of emotional comfort and companionship during a time of uncertainty. Features such as deep breathing exercises, mindfulness practices, daily motivational quotes, breast cancer survivor stories, and links to peer support groups were seen as helpful in reducing feelings of isolation, enhancing focus, and increasing hope. These findings align with the self-efficacy theory proposed by Bandura [14] and the social support components, which guided the conceptual framework of the app's content. The integration of practical knowledge with psychosocial support appeared to mitigate uncertainty-related anxiety and contributed to a more reassuring perioperative experience [21]. However, several participants expressed a desire for a greater variety of mindfulness videos and a wider selection of survivor stories. They felt that expanding these elements would offer additional encouragement, strengthen their sense of hope, and help them stay focused on the present. At the time of the study, the app included 3 survivor stories and 5 short mindfulness practices, which participants found limited. Enhancing this content may

XSL•FO
RenderX

deepen the emotional support provided and increase the app's impact on psychological well-being during the perioperative period [24].

At the same time, our findings point to areas for future development. Participants expressed a strong desire for the app's content and motivational support to extend beyond the perioperative period, encompassing the adjuvant treatment phase, including chemotherapy and radiotherapy. They also highlighted the value of content addressing long-term needs, such as practical advice on nutrition and strategies for maintaining overall health. Many participants noted that their informational and emotional needs evolved significantly approximately 2 weeks after surgery, when discussions about further treatments typically began during follow-up consultations. These findings underscore the importance of providing continuous education and psychosocial support across the entire cancer treatment trajectory [25]. Expanding the app to support active treatment phases could enhance patient engagement, improve preparedness, and help reduce the anxiety associated with uncertainty. To achieve this, the content should align closely with the patient's treatment progress and individual care plans. In addition, HCPs play a critical role in ensuring the ongoing and timely delivery of support that reflects each patient's evolving needs.

In addition to extended support, participants expressed the need for more detailed and personalized information tailored to their specific type of surgery, treatment plans, and recovery process. They noted that personalized physiotherapy exercise and in-depth explanations of treatment options would enhance the app's relevance to their individual experiences. This need for personalized information and care has also been emphasized in previous studies, which report that the complexity of breast cancer treatments, including various combinations of surgery, chemotherapy, radiotherapy, and hormonal therapies, creates a significant demand for individualized support [26]. To address these needs, future app iterations could incorporate features such as an initial intake assessment to identify individual treatment types, algorithms designed to tailor recommendations based on individual treatment plans, and interactive tools for progress monitoring [27-29]. These enhancements would enable the app to remain adaptable and relevant, providing patients with timely and personalized support as patients navigate the complexities of their breast cancer treatment.

In addition, participants expressed a preference for an interactive and engaging format. While the current app includes a messaging feature that allows participants to post nonurgent concerns related to breast cancer surgery, it was underused. Several participants mentioned that this feature was hidden within the settings, making them either unaware of its availability or prone to forgetting to use it. Others acknowledged its usefulness as an alternative means of communicating with HCPs but noted that its use was limited to nonurgent matters, and some preferred speaking with HCPs directly through a phone call. Importantly, many participants favored video content, particularly for deep breathing and physiotherapy exercises, because they found visual demonstrations easier to follow and more confidence building than text or image-based instructions. These findings highlight the need for mHealth interventions to prioritize interactive features to support long-term patient engagement. Future research delivering interventions via mHealth platforms should explore the integration of additional interactive components, such as enhanced video-based content, user-friendly messaging systems, and real-time feedback mechanisms. By aligning with patient preferences, such features have the potential to engage users more actively with digital health tools [30]. Aligning app design with patient preferences and use behaviors could increase engagement, enhance satisfaction with care, and contribute to improved health outcomes over time [13,27].

Recommendations for Future Clinical Practices and Research

This study highlights the significant emotional burden faced by patients with breast cancer in the perioperative period. Many participants experienced heightened anxiety and distress due to the uncertainty of surgery and its potential outcomes. During this time, patients often felt overwhelmed by the volume and complexity of information provided by HCPs. The challenges are compounded by the short window between surgical decision-making and the procedure itself-often just a few days, depending on hospital scheduling and clinical urgency. This limited time frame can make it difficult for patients to process their diagnosis, seek clarification, or access psychosocial support, particularly as preoperative consultations are typically brief and infrequent. In light of these findings, HCPs, particularly BCNs, play a proactive role in regularly assessing and addressing patients' informational, emotional, and psychosocial needs, particularly during the preoperative period. Early introduction of supportive resources, including digital tools, can help patients better prepare for surgery and reduce feelings of uncertainty. After surgery, as patients often transition quickly into adjuvant treatment, ongoing support remains crucial. BCNs play a vital role in maintaining ongoing communication and providing emotional support to help patients cope with the evolving demands of treatment and recovery.

Future research should focus on qualitative studies to explore patients' experiences and support needs throughout the continuum of care, from the waiting period for diagnosis, the period of diagnosis to surgery, and the transition into postsurgical and adjuvant treatment. Such studies could provide valuable insights into how mHealth interventions can be optimized to benefit more patients by extending their use period and tailoring support to address patients' evolving needs at each stage of their treatment journey. Further development of mHealth solutions should prioritize personalization, such as tailoring content based on individual treatment plans and recovery stages, to improve relevance and user engagement. Adding interactive elements such as real-time messaging and video demonstrations can make the app more engaging and easier to use. By designing features based on patients' preferences, future versions of the app could play a stronger role in supporting better health outcomes and making oncological care feel more personalized and responsive.

Study Strengths and Limitations

A key strength of this study was its use of mHealth technology to support patients with breast cancer during the perioperative

XSL•FO
RenderX

period, a phase often marked by high anxiety and limited access to psychosocial support. The iCareBreast app provided timely, accessible, and structured guidance, which was particularly valuable during the COVID-19 pandemic when traditional face-to-face support was not feasible. This study is one of the few that specifically explores user experiences with mHealth, specifically during the perioperative phase of breast cancer care—a phase with limited research focus and unmet patient needs. It offers valuable practical recommendations for future psychosocial or educational interventions using mHealth and provides insights into enhancing patient engagement with mHealth solutions in clinical practice.

However, this study has several limitations. First, participants were restricted to those who were technologically proficient and willing to provide feedback, potentially limiting the generalizability of the findings to the broader population of patients with breast cancer. In addition, the perspectives primarily reflect those of older adults, with a mean participant age of approximately 58.5 years, which may not fully capture the age-specific perspectives of younger patients with breast cancer. Furthermore, as with other qualitative studies, reliance on self-reported data may introduce recall bias.

Conclusions

In conclusion, this study provides valuable insights into participants' experiences using a mobile perioperative support app and highlights the evolving nature of their informational, emotional, and psychosocial needs throughout the early treatment journey. Participants found the app to be a helpful and accessible resource that enhanced their preparedness for surgery, reduced anxiety, and offered emotional reassurance. However, their feedback also revealed a strong need for extended, personalized, and interactive support beyond the immediate postoperative period. These findings underscore the importance of designing patient-centered mHealth interventions that align with the dynamic realities of cancer care. Future iterations should prioritize content continuity, personalization, and engagement strategies to ensure long-term engagement across the treatment continuum. Such enhancements hold promise for improving patients' experience, emotional well-being, and long-term outcomes in breast cancer care.

Acknowledgments

The authors would like to thank all the participants for their valuable contributions to this study. The authors would also like to thank the administrative staff and nursing team at KK Women's and Children's Hospital, Singapore, for their logistical support. The authors are grateful to Buddy Healthcare Ltd Oy for their role in developing the iCareBreast app and providing technical support throughout the study. This research work was funded by the Business Finland (grant 203/31/2018).

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

YP was primarily responsible for data collection and drafting the manuscript. HH contributed to the study conceptualization, supervised the study as the main supervisor, provided administrative and material support, guided the intervention development, and participated in both drafting and critically reviewing the manuscript. MP contributed to the study as a cosupervisor, providing guidance on intervention development and supporting manuscript preparation and funding acquisition. SHL served as cosupervisor, overseeing the study, obtaining ethics approval, contributing to the intervention development, and assisting with manuscript preparation. All authors have contributed significantly and agree with the content of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Remote patient monitoring (RPM) has the potential to reduce in-clinic visits and promote proactive and preventive care for patients with chronic diseases in primary care. However, a decentralized approach to RPM in a primary health care (PHC) setting has not met stakeholders' expectations regarding scalability. This study introduces a centralized virtual ward (CVW)–led RPM, utilizing a multidisciplinary team approach to monitor patients with chronic diseases by clinicians who do not belong to the patients' PHC center.

Objective: This study aimed to gain a better understanding of patients' perceptions of CVW-led RPM for managing chronic diseases in a PHC setting.

Methods: In-depth interviews were conducted with 22 patients with chronic diseases enrolled at a PHC center in Stockholm, Sweden. The RPM project ran between October 2018 and April 2019 and included a total of 395 patients. Interviews followed a semistructured interview guide and were analyzed using qualitative content analysis.

Results: Primary care patients with chronic diseases expressed that their contact with the CVW felt impersonal but at the same time secure and accessible. They noted a lack of coordination and communication between the clinicians of the CVW and their PHC providers. Captured data resulted in 1 overarching theme "Sense of security and accessibility, but impersonal and uncoordinated" based on 5 categories: sense of security, care and self-care, accessibility, quality of care, and communication.

Conclusions: Our findings suggest that by addressing patients' needs for new organizational routines for patient-caregiver communication, RPM via centralized virtual wards can better realize the potential of this technology.

chronic disease; patients perception; primary care; qualitative study; remote patient monitoring; remote sensing technology; telemedicine

Introduction

Background

The future of health care needs a shift from reactive to proactive and preventive care to reduce the rising global burden of diseases [1]. The World Health Organization defines primary health care (PHC) as "a key process in the health system that supports first-contact, accessible, continued, comprehensive, and coordinated patient-focused care" [2]. A fundamental philosophy of PHC has been to deliver continuity of care to achieve positive patient experiences, greater patient satisfaction, increased treatment adherence, and improved patient outcomes [3].

Globally, PHC is facing numerous challenges, including rising costs, increased public demand for convenience, and technological advances driving personalized health care [4]. New models of health care delivery, including centralized coordination among providers, have been suggested to improve care quality and reduce hospitalizations [5]. Novel digital solutions may enable new forms of interventions and activities that address these challenges [6].

Remote patient monitoring (RPM) is a technology that allows health care providers to monitor, evaluate, and manage patient-reported health data through a remote interface. The collected data are transmitted to the health care provider for clinical review, care management, and patient education [7,8]. RPM enables clinical interventions performed by medical staff

XSL•FO
RenderX

who monitor health data, communicate with the patient, and make decisions as a part of the treatment [9].

A plethora of studies indicate that patients with chronic diseases perceive RPM as improving their access to care [10], sense of security [11,12], engagement [13], and disease-specific knowledge [14]. RPM also supports better clinical assessment [15,16], promotes better relationship-based continuity [17], and improves self-management [18]. However, recent studies have identified a lack of competence regarding the use of RPM in clinical care [19]. Also, given the resource constraints and time pressures in PHC, it can be challenging to introduce new tasks such as continuous monitoring of health data.

Virtual wards were first introduced in PHC in 2005, targeting individuals with a very high risk of future emergency hospitalization [20]. The intention was to use multidisciplinary teams and the daily routines of a hospital ward to provide health care in the community [21,22]. A community virtual ward project targeting older adults with complex health care and social care needs resulted in a reduction of emergency department visits and hospital admissions [23]. A centralized health information strategy in the PHC sector has fostered data-driven decision-making, improving the transparency of workflow and preventative care [24].

Combining the virtual ward concept with RPM could potentially offer a more feasible approach to implementing RPM in PHC. The prediction of prior work around CVW and RPM highlights the importance of care coordination and leverages the full range of health care skills within the system to promote patient-centered care [25]. Consequently, it encourages greater patient autonomy and self-management and provides a sense of reassurance [26]. The introduction of CVW models for monitoring patients with COVID-19 during the pandemic may have transformed patients' experiences of care, making the measurement of patient experience increasingly vital for building a strong, person-centered health care system [27].

Problem Statement

Despite growing interest among stakeholders, the implementation of RPM in PHC remains limited [28]. Patients support sharing their health data but are concerned about data privacy, security, and management [29]. Clinicians see the benefit of having access to more reported health data but are concerned about increased workload due to the volume of transferred health data [30]. Clinicians also worry that the modernization of health care might lead to a decline in continuity of care [31,32] and reduced patient safety [33]. A major concern among PHC professionals regarding the use of RPM is increased workload due to the transfer of a large amount of data and an increased number of requests from caretakers [34-36]. Health care managers have seen telemonitoring as a means for cost reduction. However, due to increased workload and the cost of technology, managers believed that service centralization would reduce the level of clinician involvement in frontline, resulting in cost savings [32].

A key distinction of the centralized virtual ward (CVW)–led RPM model compared to the traditional in-clinic RPM is that the CVW multidisciplinary care team solely focuses on digital patient interactions based on patient vitals transferred via the RPM platform. The CVW-led RPM team can therefore continuously monitor incoming patient data and interact with the patients without interruptions related to in-clinic workload. This allows the CVW-led RPM model to conduct the monitoring of chronic patients from several clinics, which could therefore address patient and clinician concerns and make the implementation of RPM in PHC more feasible according to health managers' consideration.

The novelty of this study is the examination of the patients' perception of CVW-led RPM in a PHC setting. To our knowledge, there are no previous publications on this topic.

Objective

The objective of this study was to explore patients' perceptions of CVW-led RPM for managing their chronic diseases in a PHC setting.

Methods

Study Overview

In this qualitative study, semistructured in-depth interviews were conducted with participants of a digital health intervention, in a Swedish PHC setting. This study is reported in accordance with the Consolidated Criteria for Reporting Qualitative Research checklist [37].

Centralized Virtual Ward

A private Swedish health care provider, with multiple PHC practices across the country, collaborated with researchers from Karolinska Institutet to establish a CVW-led RPM project at a PHC center in Stockholm. This project was initiated to evaluate the effects of a centralized model of RPM compared to the health care providers' previous experience of piloting an on-site RPM project, where patients sent their vitals to and communicated with their ordinary clinicians at the PHC.

To establish the CVW-led RPM project, an RPM platform provider was contracted by the health care provider. A specialist doctor in family medicine, 2 specialist district nurses, and an information technology assistant worked part-time at the CVW. All clinical staff at the collaborating PHC were informed about the project. In addition, 2 doctors and 3 nurses from the PHC received training and were given access to the RPM platform for monitoring and communicating with patients during the entire project period.

After the project was launched, the CVW team monitored patient data to detect early signs of deterioration. Elevated vital signs resulted in asynchronous patient contact initiated by the CVW via the platform. Based on the transmitted patient data, medical staff at the CVW were able to personalize treatment plans and make medication adjustments digitally. When signs of deterioration indicated that the participants needed a physical examination, the staff at the patients' PHC center were alerted by the CVW.

The CVW clinicians received training in digital communication with patients but did not conduct any physical examinations

XSL•FO
RenderX

during the intervention. Further details of the intervention are available in previously published papers [38,39].

Remote Patient Monitoring Project

The PHC staff created a list of eligible participants for the project enlisted at the PHC by using a database extraction tool (MedRave) [40], connected to its electronic health records. A flyer with written information about the intervention was mailed to the candidates. The flyer contained an email address and instructions on how to express interest in participating in the project. The information about the project was posted at the PHC center. PHC staff gave information to eligible candidates about the intervention during physical visits. CVW staff phoned the candidates who showed interest in participating in the intervention and gave further information about the project and assessed eligibility.

The inclusion criteria to the CVW-led RPM project were age above 18 years, being fluent in the Swedish language, having access to a smart device with the iOS operating system and internet access, and having one or more of the following chronic conditions: hypertension, chronic heart failure, type 2 diabetes, chronic obstructive pulmonary disease, anxiety, and mild depression. Pregnant women and patients with other psychiatric conditions were excluded. In total, 395 participants were enrolled during the first 3 months of the project. At the time of enrollment, 153 participants gave their written consent to be contacted about further research. The project started in October 2018 and ended after 6 months at the end of March 2019.

All the participants were scheduled for introductory group information sessions at the PHC (6-10 participants per session). The CVW enrolled the participants into the platform and decided on a monitoring plan for each participant based on their chronic disease(s). An information technology assistant from the RPM platform provider helped the participants to download an iOS app into their smartphone device and paired the app to the selected noninvasive sensor(s) via Bluetooth. The participants received verbal and written instructions on how to share their vitals (blood pressure, weight, sleep rhythm, step count), track their vitals, fill out forms, receive standardized information, and communicate asynchronously by chat or synchronously via prebooked video appointments with the CVW.

The participants were able to transmit health data or respond to questionnaires without restrictions in time or place. Vitals and answers to questionnaires were transferred via the participants' apps to a secure cloud server.

Recruitment of Study Participants

All 153 RPM project participants who consented to be contacted were invited by the last author (MT) via email (including 1 reminder) to receive information about this qualitative study. A total of 21 (13 female) patients responded to the invitation and accepted to be interviewed. The number of participants at each process stage for the recruitment to the in-depth interviews is presented in Table 1.

Table . Process stage for in-depth interviews.

Process stage	Number of participants
In the RPM[a] intervention	395
Agreed to be contacted for qualitative study information	153
Agreed to be interviewed	22
Completed the interview	22

[a]RPM: remote patient monitoring.

Data Collection

Due to the COVID-19 pandemic, the in-depth interviews were conducted digitally via the Zoom communication platform [41] and audio-recorded after the participants' verbal consent. Only the interviewer and the participant were present during the individual interview.

Interview Guide

A semistructured interview guide was designed to attain an in-depth understanding of participants' perception about the interaction with the CVW team. A pilot interview with 1 person not included in this study was performed by the first author (AJ, PhD student, M.D, specialist in family medicine, male). The final interview guide was approved by all the authors (Multimedia Appendix 1).

Between March and May 2021, 22 in-depth interviews were conducted. Each interview ranged between 45 and 90 minutes. An external research assistant (female) with previous experience in qualitative methods, without any affiliation to the participants, conducted the interviews after initial training in the semistructured interview guide and with the guidance of the last author of this study (MT, associate professor in family medicine; female).

Data Analysis

All interviews were recorded and transcribed verbatim. Data analysis was conducted in Swedish. The principles of qualitative content analysis were conducted according to Graneheim and Lundman [42]. A basic inductive content analysis process was applied [43]. The first and last authors selected meaningful phrases and sentences independently. The second step was to condense them to meaning units, and the third step was to set open codes on the manifest level to avoid interpretation and abstraction at the coding stage. The condensing of meaning units into codes was revised during physical meetings in discussions between the first and second authors, and after agreement, a new clustering of codes was conducted if needed. This ensured a common understanding and a reduction in the number of codes before aggregating these into subcategories

XSL•FO
RenderX

and categories. The strength of this method is that during the categorizations, the authors are going back to the original statements several times. After the coding and categorization described above, all the authors discussed the results and developed the overall theme (Textbox 1).

Textbox 1. Examples of meaning units, condensed meaning units, and codes.

Quote

"I take my blood pressure a number of times a week, then I get someone who reviews these values and thinks whether it's good or bad simply. So far, all the values have been satisfactory all the time, so it's that you feel calm, and you know that someone is checking it."

Meaning unit

I take my blood pressure and feel reassured that someone is checking and thinking whether it is good or bad.

Condensed meaning unit

I feel reassured.

Code

Someone is keeping track and is watching.

Ethical Considerations

This study was approved by the Regional Ethical Review board in Stockholm, with 2 amendments (Dnr 2018-625-31/5; 2018/1717 - 32; 2020 - 01890). An email with study information and a consent form was sent to the participants prior to the interview. All the participants gave written informed consent before they were scheduled for an in-depth interview, and oral informed consent was recorded verbally at the start of the interview. To ensure participant anonymity, the participants' identification was replaced by a unique identification number. This number was used to match the participants and their transcripts and to report participant quotations in this study. The participants did not receive any compensation for being interviewed.

The first author (AJ) was clinically active at the pilot PHC 1 year prior to the launch of the project. Thus, he did not participate in the data collection to avoid bias.

Results

Demographics

The 22 interviewed participants had a mean age of 61.2 years (SD 11.2; range 40-78 years of age). Most (n=13, 59%) participants were women. They had predominantly 1 medical condition (n=15, 68%), where 19 (86%) of these participants had hypertension. No participant was diagnosed with more than 3 medical conditions. In comparison to the CVW-led RPM project, the 385 participants had a mean age of 58 years, with 62.3% (n=240) being female participants. The participant characteristics of this study are listed in Table 2.

XSL•FO
RenderX

Table . Participant characteristics (n=22) with 1 or more chronic conditions.

Characteristics	Participants, n (%)
Age (y)	
40 - 49	4 (18)
50 - 59	5 (23)
60 - 69	8 (36)
70 - 79	5 (23)
Sex	
Female	13 (59)
Male	9 (41)
Medical condition	
Hypertension	19 (86)
Diabetes	6 (27)
Mental disorder	3 (14)
Congestive heart failure	1 (5)
Chronic obstructive pulmonary disease	1 (5)
Number of medical conditions	
One	15 (68)
Two	5 (23)
Three	2 (9)

Overall Theme

The following theme was constructed: “Sense of security and accessibility, but impersonal and uncoordinated” based on 5 categories: sense of security, care and self-care, accessibility, quality of care, and communication (Textbox 2).

Textbox 2. Subcategories, categories, and themes from content analysis. CVW: centralized virtual ward; PHC: primary health care.

Theme: Sense of security and accessibility, but impersonal and uncoordinated.

- Sense of security
  - Self-control
  - Care relationship between CVW and the patient
- Care and self-care
  - Care utilization at the PHC
  - Health awareness
- Accessibility
  - Care not dependent on space and time
- Quality of care
  - Basis for making health care decisions
  - Proactive care
- Communication
  - Participant communication with the CVW team
  - Lack of coordination between CVW team and other caregivers at the physical center

XSL•FO
RenderX

Sense of Security

A higher number of transferred vitals and correspondence with the CVW at signs of deterioration strengthened the patients' sense of security. The patients experienced that the CVW reacted promptly to deviating vital signs. Seeing that their vitals were stable induced a sense of security, which reduced their worries about a potential major medical event. Prompt actions taken by the CVW at signs of deterioration built further trust. The participants expressed that the CVW cared about them. A recurring argument for sense of security was the interaction with a trusted health care professional who gave clinical feedback:

> *Then you know that there is someone who cares, there is someone who sees my values every day which my regular doctor does not do. Then I feel safer, then there is a reason why I do this every morning.* [Participant 9]

The participants regarded their collected vitals as evidence when they interacted with health care professionals. They used this evidence to present their case when having a physical contact at their PHC. The clinicians' access to collected vitals and medical records gave a historical perspective, which gave the patients an elevated sense of security as illustrated:

> *What is positive is that it feels like there is a history all the time that you can keep track of, what it looks like for me… it feels like there is a history to see in a completely different way, which gives security…* [Participant 12]

RPM with interactions by the CVW sheds light on the importance of feeling safe as expressed by the following participant:

> *Now you start to realize that it is incredibly important that you feel safe, important for your health and the feeling of… well if something happens, yes, then I know.* [Participant 13]

Care and Self-Care

Continuous reporting of vitals gave the participants insights into their underlying condition and the symptom related to their chronic diseases. Discussing deviating vitals with the CVW enhanced their understanding about the causes of deterioration. Health awareness resulted in patients taking steps toward active lifestyle changes. Motivation for tracking vitals increased as it gave better insights about their condition, as 1 participant described:

> *… say that I had gone to the health centre every other month or quarterly and taken my blood pressure there, then I had not thought about the times between each visit that you may have felt bad and that it may have been because the blood pressure had been too high. Now it was very easy when you feel a little strange, this does not feel good, well then, I can take the blood pressure and then I have better understanding of how I feel right then and how it feels to have this high blood pressure.* [Participant 20]

Feedback on the collected vitals and being monitored also motivated some participants to take further steps toward active lifestyle changes, as expressed by the following participant:

> *Yes, but it is with this that I have started to move a lot more, it has really motivated me to do not just walking but also other physical activity like with swimming and cycling and things like that, there have really been changes there.* [Participant 3]

Insights about the correlation between lifestyle choices and the stability of vitals were generated in the dialogue between the participants and the CVW. These insights motivated the participants to change harmful lifestyle behaviors. The participants sensed that the CVW tried to improve their health outcomes by working both reactively and preventively. One participant described an aha feeling:

> *Just that feeling that it was nice that someone has an ambition to make it possible for me as a patient to improve. A little aha-feeling… It felt like someone cared, like "now we'll do good before it gets too bad," so that was positive.* [Participant 1]

Accessibility

The participants expressed that they refrained from contacting the PHC for what they perceive as bagatelle symptoms because they want other patients with greater medical needs to have access to care. This mindset might lead to deteriorating symptoms that might result in unnecessary complications. The RPM platform reduced thresholds for asking questions about their chronic condition, which enhanced the participants' sense of accessibility to the CVW compared to the medical staff at the PHC center as expressed:

> *I contact healthcare when I need to. If I had a question that was important to me, but that I wouldn't call the regular health centre about.…When I can write that easily, maybe I'll reach out to them more often if I have questions or such…. Usually, I don't do that; I go to the doctor when I am really unwell…* [Participant 16]

The participants were able to travel with their noninvasive sensors and contact the CVW to follow up on their vitals. This opened a new dimension of accessibility to health care for some participants who had been restricted from traveling:

> *A benefit is that you are not tied to sitting at home; even when I travel, I have the blood pressure monitor with me, and I can take those readings, which can also be used for monitoring.* [Participant 6]

Quality of Care

The difference between the number of data points collected by traditional health care versus RPM via the CVW raised new perspectives. The participants reflected that the collection of additional data points could result in better decision-making by the health care staff:

> *The staff I have contact with have significantly better information available once I contact them.* [Participant 9]

XSL•FO
RenderX

A higher frequency of data transfer by sharing of vital measurements leads to a better basis for medical decision-making for the CVW according to patients' experiences. They found that continuous control of vital signs allows both patients and clinicians to detect signs of deterioration. This allows clinicians to adjust treatment plans more stringently to stabilize patients' vitals. Medical adjustment made based on only 1 measurement is not as reliable as those made based on a higher frequency of measurements according to the following participants:

> *…it became more quantitative data of course because it felt like the case became more, it became a better basis in the continued care…* [Participant 20]

> *To go to the healthcare centre and do a measurement at some point in the year does not actually say much more than what it is right then. I think it is good to have some continuous measurements, partly it is a security to get information if there is something that seems strange.* [Participant 9]

To be reminded of reporting values was expressed as feeling that "someone taps on the shoulders." This proactiveness of the CVW was more appreciated than the traditional way of contacts from the health care center.

> *…if I did not leave my daily vital measures they contacted me. The healthcare centre does not do this in the same way, but it is this part that I appreciate, that there is someone who taps you on the shoulder and says that now is the time to leave some vital measures.* [Participant 19]

Communication

This category includes the communication between the CVW, the participants, and the PHC staff. A communication plan was established for participant referrals from the CVW to the PHC. The CVW was being seen as a quite separate entity, and some participants mentioned that it was not important where the CVW was located physically. The ease of use of the app, including the CVW response through the asynchronous channel, was expressed as faster, easier, and simpler compared with the communication channels with the PHC center:

> *…if they are in the healthcare centre or if they are sitting elsewhere, I have no idea and I do not care so much either. It does not matter to me.* [Participant 6]

> *Much simpler. Much faster response, much easier…Yes, I have much more communication with the healthcare now than I had before…* [Participant 4]

The participants identified that the clinicians at the PHC did not have access to their collected RPM data. In addition, the general practitioners were not interested in getting the information regarding the collected vitals. The lack of communication and collaboration between the PHC personnel and the CVW was mentioned by some participants:

> *I can't quite understand if this team collaborates, or to what extent they cooperate with the healthcare centre, or if they are updating them on the values that I submit.* [Participant 19]

> *But I don't know if that's the case; it doesn't seem like it when I've wanted to show my values to the doctors. There was a female doctor, and she said, 'That's not for us.'* [Participant 5]

The asynchronous communication, in combination with the standardized automatic replies and notifications sent to the participants, was described as impersonal:

> *So, it feels safe although it is quite impersonal, I would say.* [Participant 22]

> *Yes, it's not the same staff that I have contact with anymore; it could be random people reaching out who I don't really know who they are, so it becomes more anonymous that way…It becomes impersonal that way.* [Participant 11]

The participants noticed that there was a lack of coordination between the CVW and the PHC center. Also, some participants wished that their efforts of vital submissions would result in better transparency and utilization of health data between the patients, the CVW, and the PHC center. There was a sense of disappointment that the PHC staff did not have access to their health data through the platform and that they felt rejected when they tried to show their data to the health care personnel at the PHC center. One participant expressed lack of coordination as follows:

> *I lacked some natural spin-offs such as my general practitioner or others that I met with would be informed and kept track of this. But they seemed unaware that I was connected to this system.* [Participant 1]

Discussion

Principal Findings

The unique contribution of this study lies in exploring patients' perspective of CVW-led RPM in a PHC setting, bringing a new dimension into the field of RPM in comparison to on-site RPM by the PHC staff. A principal finding of this study was that the participants did not mind that the CVW staff did not belong to their ordinary PHC. The qualitative data highlight the participants' appreciation for engaged, accessible, and well-prepared CVW staff rather than an attachment to their PHC clinician. The participants experienced similar benefits of RPM as the traditional model of RPM, such as enhanced sense of security [12], improved accessibility [18], positive effects on self-care [44], better quality of care [45], and the need for improvement in communication between the patients and the staff [17,46]. In addition, this study underscores the challenge of data transfer and communication between the CVW staff and the PHC staff. The main theme of this study represents the main result: *Sense of security and accessibility, but impersonal and uncoordinated*.

Interpretation of Findings

The participants valued the CVW-led RPM in terms of staff medical competence, availability, and prompt feedback in

XSL•FO
RenderX

comparison to their regular clinical contact. This indicates that patients' trust can be earned through virtual interactions, even with unfamiliar health care staff. In this case, the CVW was able to earn the participants' trust by following a set of protocols to monitor incoming data to detect the signs of deterioration and reacted promptly by reaching out to the individual.

Similarly, Walker et al [17] found that RPM participants reported an increased sense of safety when clinicians responded to clinical signs of deterioration. A sense of safety is defined as an internal sense—an intrinsic state based on faith and trust in oneself and others [47]. The capacity for the RPM system to operate safely lies in the possibility of understanding a participant's symptoms and health behaviors. A sense of safety also relates to participants' ability to process health data and awareness that the health care professionals continuously monitored their data [12]. Although a false sense of security was not mentioned by the participants, one could argue that there is a potential risk for a false sense of security as an extended outcome of organizational and workflow challenges that arise during the introduction of new ways of working, as described in the literature [48] .

The automated response in the patient application gave a sense that someone was constantly monitoring their vitals. But the dismissal of RPM data by some individual clinicians at the PHC upon physical visits may have contributed to the participants' experience of uncoordinated care. However, the communication gaps need further investigation.

A higher number of interactions with the CVW with a faster response rate compared to their usual care at the PHC prompted a sense of accessibility to care. Access to asynchronous communication and data visualization by the RPM application gave the participants a new perspective regarding the accessibility and continuity of care. Previous studies have described that improved accessibility increases the chance of getting medical attention [49], resulting in the avoidance of hospitalization [50-52]. Hall et al [10] also describe that patients' access to technology can aid in the development of effective health behavior interventions. The ability to share vitals from the convenience of their residence at any time of the day resulted in the sense that they had better accessibility to the CVW than to their PHC center. By eliminating confinements of time and space, their interactions with the CVW felt more adequate since they were able to ask specific questions about their underlying health conditions. The participants sensed that the answers provided by the CVW were based on facts from the collected health data. This interpretation is consistent with prior findings that patient trust increases when health data are accurate and complete [53]. Improved accessibility also reduced the threshold for help-seeking behavior from the participants. In turn, the effects of continuous interactions between the participants and the CVW in combination with the prompt response rate from the CVW enhanced their sense of continuity of care. The combination of accessibility to care and sense of continuity of care became the driving factors for their sense of security.

Previous studies found that future care models of chronic disease management will shift toward self-care facilitated by digital technology, social support, and clinical expertise [54]. Self-care is based on long-term adaptations of lifestyle behaviors with adherence to preventive or therapeutic regimens with the potential of improving health outcomes [55]. The cornerstone in self-care is collaborative care between the patient and the health care provider and individual education in disease management [56,57]. Several studies indicate that RPM empowers patients by enhancing their motivation to adhere to the treatment plan, understanding of their chronic condition, and ability to follow their vitals [17,58]. The participants of this study described enhanced knowledge about their chronic condition, awareness and understanding of deviating vitals, and adherence to long-term lifestyle changes. The collection of vitals from the comfort of their residence enhanced the sense of measurement accuracy. In line with previous findings [59], we found that the collection of vitals is a major key for allowing patients to actively share their personal health data. By observing the longitudinal trends of their vitals, the participants gained a better understanding of the effects of their lifestyle choices, resulting in deeper insights into their chronic condition. As described by Quinn et al [60], patient-gathered health data allow the patients to better understand their disease process, monitor their symptoms, and feel connected to their health care provider. These insights, with their ability to discuss their observations with the CVW, evolved in revising their health goals, leading to self-knowledge that was used for better self-care.

Stavropoulou et al [61] describe the quality of care as "holistic care, addressing all patient needs with competency and aiming for the best patient outcomes". The participants expressed confidence in the CVW's ability to detect deterioration signs based on health data trends. A common notion among the participants was that a higher frequency of shared vitals resulted in a better basis for medical decision-making, resulting in higher quality of care in comparison to annual checks made at the PHC center. The participants anticipated a reduced risk of deterioration because the CVW reacted to deviated vitals and applied preventive measures for restoring the participants' health to achieve better health outcomes. However, 1 area of consideration regarding longitudinal collection of health data at a high frequency is the ethical aspects concerning boundaries of confidentiality and the clinician's access to vast amounts of data [62]. The participants in this study did not express concerns regarding compliance to data regulatory frameworks for protecting their data privacy.

The inclusion criteria requiring participants to have access to iOS smart devices and sufficient digital literacy have excluded less tech-savvy individuals or those from lower socioeconomic backgrounds. This selection bias potentially limits the generalizability of the findings to broader patient populations, consistent with prior research highlighting digital divides in remote health monitoring uptake [29].

This study identifies that clear organizational routines and communication strategies between patients, CVWs, and their PHC center are crucial for gaining patient confidence in a CVW-led RPM setting. Several participants expressed a sense of uncoordinated health care due to a lack of work routines for sharing information between the CVW and the PHC center. While RPM facilitates continuous data collection and clinical oversight, our findings highlight persistent communication gaps

XSL•FO
RenderX

between the CVW and patients' primary care providers, which may hinder integrated care delivery. Addressing these collaborative barriers is critical to realizing the full potential of CVW-led RPM. Setting clear goal-oriented communication strategy between caregivers and patients can increase the success rate for establishing RPM [63,64]. This finding might also be relevant to setting up a CVW-led RPM within PHC settings. Our participants appreciated the ability to communicate with the CVW without being confined to the opening hours of the PHC center. Although they appreciated the better accessibility to the CVW, they argued that the asynchronous way of communication felt impersonal. This impersonal sentiment can be due to the transactional nature of digital care with fewer nonverbal cues and limited opportunities for nuanced empathy that can hinder traditional elements of small talk, creating a sense of anonymity and the decreased opportunities for emotional and social support in comparison to standard clinical visits. Despite this limitation, enhanced patient agency, transparency, and collaborative goal-setting, all supported by CWV-led RPM, can foster a sense of partnership and engagement, thereby mitigating feelings of isolation.

Previous studies describe that an increased number of communications require new work routines for the health care personnel [58] and that there is a continuous need for improvement in the communication between the patients and the staff [17,46]. Our findings suggest that clear communication strategies and work routines could reduce the perception of impersonal interactions from the participants' perspective.

Despite advancements in RPM technology after the COVID-19 pandemic, there are still barriers for scalability of RPM in PHC settings [19], making the findings of this study relevant to understanding these challenges and potentials of CVW-led RPM.

Strengths and Limitations

To support trustworthiness [42], we described each phase of our study methodology from data collection, analysis of data, and interpretation. The credibility [42] of the results has been validated by internal considerations regarding the reliability and accuracy in every process of this study. To improve the reliability of the study data, clear coding rules were applied so that each researcher could independently interpret the data. The trustworthiness and credibility of the study were also strengthened by providing detailed contextual information, conducting member checks, and performing a pilot study before data collection.

A primary limitation of this study was the lack of patient involvement in the design process. The limitation to data collection correlates to the recruitment of participants to the RPM project where patients who lacked access to an iOS smart device were excluded. This reduced the potential number of candidates with a lower socioeconomic background. An additional limitation of this study is the lack of information about the participants' digital literacy and experience of using iOS smart devices. However, all the participants included in this study had access to iOS smart devices, and they received instructions for how to use the RPM app prior to getting connected to the CVW for sharing their vitals. To ensure dependability [65] on data collection, the participants were required to be fluent in the Swedish language. In addition, a semistructured interview guide was used to enhance dependability. This study did not explore the importance of how the underlying disease impacted the patient's perception of the CVW-led RPM. Such aspects need to be further investigated in further research.

Transferability [65] was assured by describing the study setting, methods, and time frames for the collection of data. Despite the fact that the pool of the participants may not represent all the participants of this RPM project, we recognize that there is a strength in the large sample size contributing to data collection. Since some participants had left the RPM project 18 months prior to being interviewed, recall bias may have been introduced. In addition, the duration of participation in the project varied among the participants, which might have affected their view and understanding of the organizational structure and the strengths and limitations of the project.

To obtain confirmability [65], the research team audited the results and discussed the analysis repeatedly. Research reflexivity was maintained through continuous dialogues within the research team regarding personal biases that might affect data interpretation. The final strength of the study material is the inclusion of various points of view from participants as well as the research team, which is required in qualitative studies.

Conclusion

Patient perceptions of a CVW-led RPM of chronic diseases in PHC could be condensed to a "Sense of security and accessibility, but impersonal and uncoordinated," with 5 underlying categories: sense of security, care and self-care, accessibility, quality of care, and communication. This study reveals the following learnings from a patient perspective regarding CVW-led RPM: sense of security due to the health care staffs' prompt reaction on signs of health deterioration, improved motivation for care and self-care, sense of accessibility to health care staff, and enhanced quality of care.

Our findings suggest that by addressing patients' needs for new organizational routines for patient-caregiver communication, RPM via centralized virtual wards can better realize the potential of this technology.

Future research is needed to explore the health care personnel's perceptions regarding their interactions between the CVW and PHC.

Acknowledgments

We would like to thank all the participants of this study who shared their experiences of the project. Without them, this study would not have been possible. We would also like to thank the research assistant Emma Hedberg Rundgren for conducting the

Abstract

Background: Palliative care supports individuals with incurable, life-threatening illnesses, focusing on symptom management and quality of life. Access to timely care, including essential medications, is often limited, particularly in rural areas, leading to gaps in home-based care. Digital health technologies, including drone-based delivery systems, have the potential to address such logistical challenges. For these technologies to be effective, they must be adapted to the specific needs of patients and caregivers, which often differ from general health care contexts, especially in remote areas.

Objective: This study aimed to identify user needs and requirements for a drone-based medication delivery system designed to supplement traditional courier services in palliative care. The study also sought to explore practical considerations for integrating drones into home-based care workflows, with the goal of informing both technical design and clinical applicability.

Methods: We conducted 1 focus group (FG) and 4 semistructured individual interviews with family caregivers involved in home-based palliative care. Participants were recruited via local palliative care services in rural regions. The discussions focused on experiences with palliative care, medication logistics, needs, expectations, and concerns regarding drone-assisted delivery. Interviews and the FG were audio-recorded, transcribed, and analyzed using structured qualitative content analysis.

Results: A total of 10 caregivers participated (mean age 68.6, SD 12.3 years) in this study. Six participants took part in the FG and 4 participants were part of individually conducted interviews. Caregivers frequently reported long travel distances to obtain medications, sometimes leaving patients unattended and noting medication shortages, especially in the afternoons and on weekends. Participants highlighted the potential of drones to supplement existing courier services during periods of high demand. At the same time, caregivers expressed concerns about limited technical skills, particularly regarding mobile apps for ordering deliveries, and emphasized the need for simple, user-friendly systems.

Conclusions: These findings reveal logistical gaps in palliative care medication supply and design requirements for drone-based delivery systems. There is a clear demand for faster, more reliable access to essential medication, especially during evenings and weekends. Whether drone-assisted delivery can reduce hospitalizations and support patients' wishes to remain at home warrants further research. Specialized outpatient palliative care teams are central to eHealth adoption, providing technical guidance, emotional support, and confidence in using new technologies. Their involvement in communication and training is critical. Strengthening digital health literacy requires individual training and structural adjustments to meet the needs of older caregivers and those with limited digital affinity. Concerns about losing personal interaction remain significant; digital tools should complement, not replace, face-to-face care. Timely medication access could reduce caregiver stress and improve quality of life by supporting symptom control at home. To foster acceptance, caregivers need hands-on experience. Future studies should test drone delivery in real-world settings, addressing technological, psychological, and social factors.

Introduction

Over the past decades, most developed countries have seen declining mortality rates [1,2]. This increase in life expectancy is accompanied by a rise in chronic and incurable diseases, especially in old age, such as cardiovascular conditions, cancer, and diabetes. The end of life is often marked by enduring and heavy symptom burdens, prompting the development of specialized palliative care to support patients and families in leading a self-determined life and maintaining quality of life [3,4].

Most palliative patients prefer to remain in their familiar home environment. While 76% wish to spend their final days at home, only about 20% actually do, with nearly half dying unplanned in hospital settings [5]. The care setting significantly impacts quality of life; patients at home generally experience better outcomes than those in institutional settings [6].

As the number of terminally ill people increases, home care becomes more reliant on family caregivers. The level of support required varies depending on the illness [7]. This puts a tremendous amount of pressure on family caregivers, as they are often unable to cope with the stressful situation and may feel helpless in the face of the situation [3,8]. In this regard, it was indicated that the pattern of enduring in the social, psychological, physical, and spiritual domains at certain time points (diagnosis, return to home, recurrence, and terminal stage) is similar between patients and their caregivers, which is mainly influenced by the nature of the disease and the availability of professional care [3,9,10]. This implies that the needs of patients and caregivers should be addressed in parallel, as these key time points are identical for patients and caregivers [3,9].

Palliative care aims primarily at minimizing pain to preserve patients' dignity and life quality, which also positively affects caregivers' well-being [11,12]. Fast and flexible symptom management is crucial and often requires rapid medication adjustments by caregivers or specialized outpatient palliative care (SOPC) teams [13]. The inability to respond quickly and adjust necessary medication can jeopardize home care and lead to unwanted hospital admissions and a deterioration in the patient's and caregivers' quality of life. In other words, it is crucial to ensure rapid and direct access to essential medicines that improve quality of life, especially in rural areas.

In this context, drones may offer value by significantly improving delivery response times in health services [14]. Drones are increasingly applied in health care and medicine, particularly in areas such as public health, disaster response, telemedicine, and medical logistics [15]. In the context of medical transport, drones are used to deliver medications (eg, vaccines, pharmaceuticals), blood products, organs, defibrillators, and other essential medical equipment [15-20]. These medical drones offer substantial advantages for health care, including faster emergency response times, improved access to medical services in remote or hard-to-reach regions, and enhanced clinical outcomes, such as increased survival rates [14,21-23]. Compared with helicopters, drones offer a more cost-effective solution for transporting medical supplies. Their utility is especially pronounced in regions with challenging terrains such as mountains, deserts, or forests, in areas with limited road access, over long distances, or in locations impacted by large-scale natural disasters [18,19,24]. Overall, drones hold significant promise for improving health care delivery in such contexts [18]. Despite their considerable potential in health care, the adoption and effectiveness of drones are influenced by technological, organizational, and environmental factors (TOE barriers) [14,25,26]. In Germany and many other countries, structural and regulatory conditions, such as undefined legal frameworks and operational guidelines, currently limit the use of drones to research projects and prototype testing [14,27]. Most existing projects on medical drones have been conducted in Africa, where regulatory conditions are comparatively more flexible than in Europe or North America [27,28]. However, findings from African contexts cannot be directly generalized to European settings [29]. Among the factors affecting drone usage, usability, and design consistently emerge as the most critical. In addition, users' limited skills, negative perceptions of the technology, and the relative immaturity of drone systems pose significant barriers to broader adoption [14,25,26].

Despite increasing interest in drone-based medication delivery, robust evidence on its impact in real-world health care logistics remains limited. Most existing studies have focused on single scenarios [20,21,23,30-32] or relied on simulations [33,34], and thus have not been conducted in real-world settings. To date, 1 study covered the entire development process, from the initial app prototypes to the complete ordering and delivery workflow using an ordering app and drone over densely populated areas in Germany [35]. In particular, to our knowledge, no study has investigated drone-based medication delivery in the real-world context of palliative care, a setting characterized by complex symptom management, urgent medication needs, and a high reliance on family caregivers. Consequently, it remains unclear whether drones could meaningfully improve medication logistics, support care networks, or enhance symptom management and quality of life in outpatient or inpatient palliative care. To address these gaps, the present study is embedded within the PalliDrone project, which aims to co-create and evaluate a drone-based medication delivery system for palliative care [36,37]. The PalliDrone project comprises multiple intervention components (T0–T3), encompassing medical and nursing strategies. It will assess the usefulness, effectiveness, and benefits of drone delivery compared to conventional courier services, treating it as a complex health intervention [38]. In this context, the present study focuses on identifying user needs, potential benefits, and practical requirements for integration into existing palliative care processes. Specifically, the research objectives are:

1. To explore the needs, expectations, and concerns of family caregivers regarding drone-based medication delivery in palliative care.
2. To assess how drone delivery could alleviate burdens on caregivers and support timely access to essential medications.
3. To identify practical and organizational factors that may facilitate or hinder the implementation of drone-based medication logistics in real-world palliative care settings.

XSL•FO
RenderX

In this study, we aim to explore the practical requirements, opportunities, and challenges associated with drone-based medication delivery in palliative care for family caregivers. Specifically, the study seeks to inform both the technical readiness of a user-centered drone delivery system and its potential integration into clinical workflows. By assessing user needs, expectations, and concerns, the study provides insights that are relevant for the development of the drone system itself as well as for its safe, effective, and feasible use in routine palliative care practice. This dual focus ensures that the intervention addresses both technological feasibility and clinical applicability.

Methods

Overview

This study adheres to the COREQ (Consolidated Criteria for Reporting Qualitative Research) to enhance transparency, credibility, and completeness in qualitative reporting. A completed COREQ checklist is provided in Checklist 1. The COREQ checklist was used as a guiding framework during the preparation and reporting stages. Before data collection, the checklist was instrumental in informing the study design, ensuring that all pertinent aspects—including the composition and reflexivity of the research team, participant selection strategy, and detailed data collection procedures—were meticulously planned and documented in advance. During the process of manuscript development, the COREQ items were systematically reviewed to verify that each relevant element was transparently reported in the Methods and Results sections. This process ensured completeness and facilitated reproducibility.

Setting and Sampling

The focus group (FG) and interviews included family caregivers selected through purposive sampling. The sampling was used, with participants being purposively recruited to ensure a diverse range of experiences relevant to the study's objective. The selection of participants was conducted by the SOPC teams of the "Anhaltische Hospiz- und Palliativgesellschaft" in Dessau-Roßlau, Germany, and the "Leipziger Palliativgesellschaft" in Torgau, Germany. Participants were approached by telephone or via email. The SOPC teams identified potential participants who met the inclusion criterion of having provided care for a palliative patient within the past 6 months in rural regions. Within this sample, variation in relationship to the patient (spouse and other relative) and gender was sought to capture a range of perspectives. Although the data collection process did not entail the application of formal stratification criteria, such as age, caregiving burden, or technology literacy, the SOPC teams were encouraged to extend invitations to individuals with a range of backgrounds, thereby fostering heterogeneity in the ensuing discussions. Group effects were minimized, and no strict exclusion criteria were applied, reflecting the open, cocreative nature of the development process. There was no relationship to participants before the study.

Materials

A German-language FG and interview guide was developed through a systematic, multistage process informed by qualitative research principles rooted in a constructivist paradigm by AL and FF [30,39]. This method was chosen due to existing theoretical assumptions, with the aim of exploring a wide range of perspectives rather than reaching consensus. The guide focused on eliciting argumentative patterns, that is, the reasoning and justification underlying participants' views, rather than collecting biographical narratives [40]. The stepwise procedure (collecting, checking, sorting, and subsuming) ensured systematic coverage of relevant themes while maintaining openness to emergent issues [39]. First, potentially relevant questions were collected without concern for their final usability (collecting). Next, the questions were evaluated against qualitative guideline criteria (checking). Then, the content was sorted into thematic areas (sorting). Finally, these were subsumed into question blocks, each beginning with an open introductory question. The sequence of these blocks was also determined (subsuming). Critical review and feedback were provided by PJ, MG, and members of the PalliDrone project team (peer group). Feedback aimed to assess the clarity and relevance of items. No fixed instructions were given, and the guide was refined after each feedback round.

In terms of content, the guide development was informed by established models of technology acceptance, particularly the technology acceptance model (TAM 1 - 3) [41-43]. TAM proposes that technology adoption is primarily driven by perceived usefulness and perceived ease of use, complemented in later extensions by factors such as social, cognitive, and psychological factors. These factors collectively shape the intention to use. The Technology Usage Inventory expands upon the traditional technology acceptance factors of the TAM, such as perceived usability, usefulness, immersion, and accessibility (technology-specific), by incorporating key psychological constructs, including interest, curiosity, technology-related anxiety, and skepticism [44,45]. The guide built on these theoretical foundations and on instruments from previous research on cocreative development of drone-assisted delivery and mobile app [30]. Thus, the final guide includes four categories: (1) processes and problem situations in palliative care (is-state), (2) specification of the process flow and communication (usability), (3) possibilities for realizing technical integration (usefulness), and (4) concerns regarding the implementation and integration (concerns). The guide began with a narrative stimulus (description) to initiate the conversation, followed by open-ended thematic question blocks. These were built on previous responses (immanent) and introduced new themes (exmanent). Transitions between blocks were deliberately soft to encourage storytelling. Evaluative questions were asked at the end. The complete FG and interview guide is available in Multimedia Appendix 1.

Data Collection

All FG and interview discussions were conducted in German. The FG was conducted at "Leipziger Palliativgesellschaft" in Torgau, Germany. With the help of the "Anhalt-Hospiz Dessau", interviews were conducted at the homes of caregivers. Two

XSL•FO
RenderX

moderators (M) guided both formats: M1 (AL, female, research associate, experienced in mixed methods) actively led the sessions using an inductive questioning approach (starting with immanent before exmanent questions), while M2 (FF, female, postdoc, experienced in FG and interviews) remained more passive and managed the input setting. M1 moderated the discussion, asked questions, and encouraged participants to elaborate, drawing out a range of views. M2 documented interactions, atmosphere, and key statements through an ad-hoc protocol, which was later made available for participants to verify the accuracy of their contributions. Before the data collection, M1 received interview training from M2. Both moderators were familiar with the subject matter and guided their actions using the principle of "methodological understanding of others" [46].

At the beginning of each session, moderators introduced themselves and explained the procedure. A detailed overview of drone-based medication delivery was presented, followed by an open discussion about possible applications in palliative care. Participants reflected on urgency, expected relief for caregivers, and situations where traditional courier delivery would suffice.

Sessions were audio-recorded. Data validation was ensured through member checking. Participants received summaries of their respective FG discussions or interviews and were invited to provide feedback or corrections. This process helped to confirm the accuracy and credibility of the data while respecting participants' time and availability.

Participants were informed in writing and verbally about the recording and their right to withdraw consent at any time.

The FG lasted about 90 minutes; interviews lasted around 30 minutes, depending on the situation. In interviews, 1 member of the SOPC team was present, and in the FG, 2 members were present. This was done deliberately to provide emotional support for participants, given that recruitment targeted caregivers within 6 months of bereavement, which could evoke distress.

Data Analyses

All collected statements during the FG and interviews were repeated and discussed with participants. All participants confirmed for correctness. The participants' responses were transcribed and coded by 1 researcher in German (AL). Transcripts were not returned to participants. A simple transcription system was used, that is, only manifest content was analyzed [47,48]. The data analysis was conducted according to the content analysis method from Elo and Kyngäs [47] and was coded using a deductive approach moving from general to specific [49]. All data were coded with the MAXQDA 2022 program (VERBI Software GmbH). The unit of analysis (event) was defined as words and as one or several sentences that contain one theme of the guideline-based questions [50]. Thus, aspects that would fit the matrix were chosen from the data. The categories were formed along the guideline-based question complexes [30,44] (see Table 1).

To validate the concept, a second researcher (FF), familiar with the analyses, independently coded 20% of the transcripts to calculate the interrater reliability. In case of discrepancies, discussions were held between the 2 researchers until a consensus was reached. Cohen Kappa was computed for all variables [51]. The interrater reliability was $\kappa=0.71$ ($P<.001$) with a substantial agreement [51,52].

For reporting purposes, illustrative quotes and examples were translated into English. Translations were iteratively cross-checked by FF and AL of the research team to ensure that the original meaning, tone, and context were preserved.

Table . Structured analysis matrix showing the categorization of caregiver statements collected during focus groups and interviews. The study explored perspectives on drone-based medication delivery among family caregivers of recently deceased palliative patients (within 6 months) in rural areas in Germany, in 2024.

No.	Category	Definition	Example
1	Is-state	Describes the initial situation and current state of problems and work procedures in palliative care as well as the competence in handling medical apps and drones	—[a]
1.1	Work procedure	Describes the current work flow in palliative care	“We always plan for a week and adjust it every day, depending on what we need.”
1.2	Problems	Describes current problems in palliative care that justify the usefulness of the technology	“So we have to speed things up so that we can do all this.”
1.3	Competence	Describes the current level of knowledge and skills in handling medical apps and drones	“Well, I have no experience. Sometimes you see one flying and it’s a bit easy.”
2	Usability	Describes the necessities or conditions for the comprehensibility, application, and usability of the technology	—
2.1	Realization options	Describes different implementation options for the drone, app, and the general process	“It would really be more interesting for rural areas, where there is a bit more space and people have their yard.”
2.2	Communication	Describes the necessities or conditions for the communication of the technology	"I could imagine that. But then it has to be quick. Because when I call, I’m on a house call and a normal patient, I want to prescribe an antibiotic. It’s the weekend, Saturday if you like, I need it on duty today if you like and then I call. Then it’s really a matter of a minute and I don’t stay in this house call forever. And then I think it has to happen within five minutes.”
2.3	Drone process	Describes the necessities or conditions/characteristics of the process of technology	“If you are logged in, you will see all patients. When I log in, I also see all patients.”
2.4	Ordering	Describes the necessities or conditions for the ordering of medication	“But that’s basically just triggering the prescription. I could also call. I think in this case it’s quite practical via this app. Triggering the prescription.”
2.5	Delivery	Describes the necessities or conditions for the transfer of medication	“For example: It should be dropped off right here on the meadow, or somewhere up ahead. And when the person of SOPC team, triggers the order, they can decide: Delivery here or to the customer. And the caregiver can only decide: Delivery to my home.”
3	Usefulness	Describes the advantages, the benefits of the technology	"We’ve had it once or twice now, we had a ward round with the doctor. She wanted to inject a medication, but we didn’t have it there. It would be good to say, I need this now. It’ll be there in 10 min.”

XSL•FO
RenderX

No.	Category	Definition	Example
4	Concerns	Describes the dangers, the risk, the complications, the disadvantages, the difficulties that the technology brings with it	"I think there are problems with the fact that the patients we look after can't do that at all. [...] So I say, if you're there as a nurse yourself and you have the app on your duty phone, it may all work. You can use it, but the patients we look after, I'd say 70, 80 percent of them, can't do that. And they're not mobile either, they're immobile, they can't even go out the door. I think that's actually the big problem."

[a]Not available.

Ethical Considerations

The PalliDrone project was reviewed and approved by the Ethics Committee of Martin-Luther-University Halle-Wittenberg (case number 2024‐038, date of approval April 18, 2024) for the conduct of the PalliDrone study. All participants gave their informed written consent before the FG and semistructured interviews and were informed about the procedure, the general aim, and the reasons for the discussion or interview. Participants were informed of their right to withdraw at any time without any consequences. For participants who were approached for qualitative interviews following recent bereavement, special care was taken to ensure they had the opportunity to ask questions and receive adequate explanations before consenting. All data were anonymized before analysis. All personal identifiers (eg, names and locations) were removed during transcription. Transcripts and coded data were stored on secure, password-protected servers accessible only to the research team. Participants did not receive financial compensation for their participation but were offered reimbursement of travel expenses where applicable. No identifiable images or other identifying information about participants are presented in this manuscript or in the supplementary materials.

Results

Characteristics of Caregivers

Between June and July 2024, we collected data from 10 participants. Six participants took part in the FG, and 4 participants were part of individually conducted interviews. No one dropped out during the discussions or interviews. All caregivers (n=10; mean age 68.6, SD 12.3) lacked knowledge and skills in using drones, and only 30% (3/10) were familiar with using medication apps. Of the 10 participants, 30% (n=3) care for their relatives while they are still working. Additional findings are reported in Table 2.

Table . Demographic characteristics of study participants, including age, gender, technology competence, and education (N=10). Participants were family caregivers of recently deceased palliative patients (within 6 months) in rural areas in Germany.

Characteristic	Value
Age, mean (SD)	68.60 (12.29)
Age range (years)	49‐84
Gender, n	
Female	8
Male	2
Drone competence, n	0
Medication app competence, n	3
Professional active, n	3
Secondary school, n	6
High school, n	3
Profession degree, n	5
University degree, n	5

Qualitative Content Analyses

Overview

Is-State

With 80 - 81 utterances, talking about their daily lives and problems was the most reported topic during the interviews and FG. However, all participants reported that they worked well with the SOPC.

> *[…] I've already called at night when he gets his pain attacks again, […] it's wonderful, they [SOPC] were always available.*

Some of the participants reported that they had little or no technical experience (competence), did not own a tablet or smartphone, and therefore could not imagine ordering medication via app and drone. Technical difficulties or poor network coverage in rural areas are barriers to the use of drone-based medication delivery (problems). In particular, those who reported no problems with medication delivery said they did not see the point of having medication delivered by drone. While some of the caregivers stated that the medication delivery with the courier service has been good so far, most of the participants reported problems with long errands for medication and transportation tickets. One of the biggest difficulties is leaving their relatives alone for too long:

> *You come home and he's lying down again because he tried to get up and he couldn't. But those are situations where you're really pushing yourself to the limit. I could see [the drone] really taking the pressure off.*

They mentioned that home delivery may be a relief in any case.

Another major problem mentioned was delivery bottlenecks during evenings and weekends. One woman described the problem this way:

> *I also took over the final care of my uncle. He had lung cancer. And he was taken out of the hospital without medication. He was screaming in pain. I had an aunt who was completely overwhelmed. […] I got in the car and drove to the next town. Friday night. Pharmacies closed. No pharmacy available. […] We just didn't have the medicine. […] in the morning we had the same problem. It's a small town, but the pharmacy had been closed for three months because the owner was sick. So we had to go back to the next bigger town. Same problem. Who should I send? My aunt couldn't have made it. […] I was really lucky that the doctor came by chance, his family doctor, and they knew each other privately. She said I'll stay here until you get back and I drove myself. But that's where the problems start. If I had a drone, a lot of things would have been easier for me.*

In addition, many caregivers have little family support, are often older adults, are no longer able to drive, or have to travel long distances, making it difficult to provide care and obtain medications. The lack of time available to general practitioners was also mentioned as a problem.

Another mentioned problem was the e-prescription. A key issue with e-prescriptions is delayed availability; pharmacies often cannot access all medications immediately after the chip card is inserted, as updates may take additional time.

Usability

Participants emphasized that the delivery process should be clear and as simple as possible. Since caregivers often need more than just medication—such as transport tickets—they suggested drones could also deliver important documents. Generally, they found it difficult to imagine ordering medication via an app and drone but appreciated the idea of centralizing all information: "because then you only have one point of contact." Most participants could only envision drone delivery being useful in rural areas.

In terms of communication, participants stressed the importance of direct contact with SOPC services, especially for consultations:

> *And there are also side effects from these medications. That's the case when you have palliative care and questions quickly arise.*

They would be more willing to use an app if it enabled phone communication with general practitioners, SOPC teams, and pharmacies. A chat function was dismissed as too impersonal and lacking advisory value. One participant with a caregiver who spoke limited German suggested the app should support multiple languages.

Some participants preferred that the SOPC team initiate medication orders through the app, with individual orders placed only if necessary. They also valued having a choice between courier and drone delivery.

Regarding logistics, caregivers suggested that "the nursing service should be involved" and that medication be delivered directly to the SOPC service. While most found it hard to visualize the drone process, "find it hard to imagine how such a drone would work," they could imagine choosing half-hour delivery time slots and having "an alternative" between courier or drone.

Usefulness

Although usefulness was in sum the category with the lowest statements, it was the category with the most agreement that drones would be useful in "emergency situation where they're panicking or something," in rural areas, "over the weekend," or in situations where the relatives have to be left alone:

> *My husband was very ill at the time, he always said when I had to go away […]: Don't leave me alone. There was no one there […]. It's all such a problem […] so with the drone, that's a good thing.*

Concerns

Participants encounter a range of challenges when delivering medications via drone. These include adverse weather conditions, inadequate network infrastructure, dead spots in remote areas, malfunctioning technology, and users who are unable to operate the technology. In addition, data protection concerns and escalating costs for users further compound the

XSL•FO
RenderX

challenges. Notably, the primary concern among participants pertains to technical issues with the drone, such as its ability to reach its destination and its reliability. There is also a fear that "the drone may crash."

The participants expressed concerns that the introduction of drone-based medication delivery systems might result in a diminution of human interaction with pharmaceutical services:

> *I can well imagine that if someone is alone at home and then only has a telephone, they no longer have any relationship with other people. That's why I think it's very important for me, […] that there is [...] personal contact, with the doctor or, as is the case with palliative care, that human closeness is not lost.*

This is accompanied by "the concern that if you take advantage of this, you might get one less home visit."

Another concern raised was the logistics of medication delivery by drone if "people […] live in a new building, three floors up, are single, old, over 80 and even older, then the drone comes and drops the medicine in front of the door, downstairs, who's going to fetch it?"

This concern was further compounded by the possibility that the delivery would be made to a lower floor, necessitating the retrieval of the medicine by someone else, like children or pets. The participants expressed uncertainty regarding the procedural mechanisms involved in the administration of medication delivered by drone. Specifically, there was a lack of clarity concerning the necessity of signature authentication in such circumstances, given the assumption that the delivery would be formalized through the usage of a signature.

Discussion

Principal Findings

This study aimed to explore the practical requirements, opportunities, and challenges associated with drone-based medication delivery in palliative care for family caregivers by addressing their needs, relief, and requirements. FG and interview results revealed that family caregivers face challenges in assessing the usefulness of drone delivery, largely due to unfamiliarity with such technologies and generally low eHealth literacy [53]. Caregivers highlighted frequent delays in medication access, especially during evenings and weekends, which often led to emergency interventions and increased stress. They expressed a need for reliable and fast delivery solutions that operate beyond regular hours, while emphasizing the importance of maintaining human contact and trusted communication channels, particularly with SOPC teams.

Needs, Expectations, and Concerns of Family Caregivers Regarding Drone-Based Medication Delivery in Palliative Care

This study revealed that family caregivers face persistent challenges in accessing medications in a timely manner, particularly during evenings and weekends. These delivery gaps often result in emergency interventions or unplanned hospital admissions, increasing stress and contradicting patients' wishes to remain at home [5,6]. Such problems are especially acute during early stages of palliative care, before SOPC teams are established [3,8-10]. This highlights the need for a reliable, fast delivery system that operates even during off-hours, where conventional courier services may fail. Studies in rural medicine and emergency supply delivery have demonstrated drones' ability to overcome logistical and geographic barriers and reduce delivery times, especially in areas with limited infrastructure [15-24,32]. For example, the usage of drones for the delivery of defibrillators has led to a notable enhancement in accessibility to essential lifesaving equipment [21-23,32]. Consistent with the findings of our study, these investigations underscore the value of drones as a useful addition to existing logistics, rather than a replacement. They demonstrate the potential of drones to facilitate access to critical medical supplies through faster delivery [54]. However, there is a paucity of studies that have used drones within the framework of a living lab design to substantiate their effectiveness and practicality within a particular context. Moreover, palliative care differs from emergency contexts in its ongoing, sensitive care relationships where continuity and human interaction are paramount.

However, the family caregivers also highlighted a limited familiarity with drones and generally low eHealth literacy, making it difficult to assess the usefulness of the technology. The technological gap makes it difficult to assess what caregivers truly need in this context. This gap necessitates empowering both individuals through skill development and adapting social and technical infrastructures accordingly, because digital health literacy is an interplay between user competence, system readiness, and their interaction [55]. At the same time, the likelihood of requiring palliative care increases with age, raising concerns about a mismatch between technical competence and care needs. Although the most common palliative care services are symptom management (88%) and psychological support (81%), which often require face-to-face contact, eHealth can complement traditional support to some extent [56]. However, concerns regarding a potential loss of trusted human contact, particularly with SOPC teams, privacy risks, and the possibility that digital ordering systems could exclude those with limited technical competence were faced in this context. These concerns align with previous studies reporting that palliative care users value face-to-face relationships and clear communication as part of care delivery [53,57]. This indicates that the loss of human connection is a key concern, mirroring previous research [31,53,58]. Given disparities in access to palliative care globally, alternative delivery models that help patients and families communicate needs are essential [59]. This is particularly important for family caregivers, who frequently report feelings of helplessness in managing complex care situations [8,60].

Drone-Assisted Delivery as a Relief for Family Caregivers

Despite these concerns, caregivers acknowledged the potential benefits of drones, especially for logistical relief and emergency access. Participants described how delivery delays often required them to travel long distances to pharmacies, leaving patients unattended. These situations were particularly stressful for older adult caregivers, many of whom had limited mobility or transport options [61,62]. A reliable drone delivery system was

XSL•FO
RenderX

perceived as potentially reducing such logistical burdens by shortening delivery times and enabling rapid response during urgent situations, especially in rural or poorly connected areas [15-24,32]. Although most participants had no previous experience with drones, they acknowledged that faster access to medication could improve symptom control and help maintain patient comfort, which in turn might reduce caregivers' stress levels. Previous studies have demonstrated strong links between patient well-being and caregiver quality of life [3,7,10,62,63]. Managing pain effectively is a priority in palliative care, and fears related to pain, particularly fear of patients dying in pain, can exacerbate caregiver distress [63]. Faster access to medications via drones could reduce these fears and feelings of helplessness [21-23,32]. However, these anticipated benefits remain hypothetical and require further empirical testing in real-world palliative care contexts.

Practical and Organizational Factors for Implementation of Drone-Assisted Delivery

Several conditions emerged as critical for successful implementation. Integration into established SOPC workflows was considered essential to maintain trusted communication channels and ensure that drones complemented rather than replaced conventional courier services [53,57]. Strengthening collaboration with SOPC teams is crucial, as caregivers view these professionals as trusted partners for both emotional and technical support. Participants emphasized that the ordering process should be as clear and simple as possible, ideally with the SOPC team initiating medication orders and individual orders placed only when necessary. They valued having a single point of contact for all medication-related information (eg, within the app) and suggested that drones could also transport essential documents, such as transport tickets. Direct communication options, particularly via telephone, with SOPC teams, general practitioners, and pharmacies were seen as indispensable, while chat functions were dismissed as impersonal and lacking advisory value. Direct communication was also the most important aspect of the cocreative process for developing a delivery app for drone-assisted systems [31]. However, in the present study, participants were, on average, 18 years older (mean age 68.6,SD 12.3) and preferred not to communicate with the SOPC via app or chat. Moreover, multilingual app interfaces were recommended to accommodate caregivers with limited German proficiency.

In terms of logistics, caregivers expressed a preference for having the option to choose between courier and drone delivery, with flexible time slots (eg, 30-minute windows) for urgent deliveries. Involving nursing services and enabling direct delivery to SOPC facilities were seen as beneficial. While many participants found it difficult to imagine the operational aspects of drones, they recognized their potential for rural areas with limited infrastructure.

Environmental and technical challenges, such as weather conditions, potential mechanical failure, and flight range limitations, were viewed as possible constraints. Data protection, noise disturbance, and regulatory and liability issues were additional concerns that would need to be resolved before deployment [26,31]. Moreover, unequal access to necessary digital tools could exacerbate disparities among caregivers and patients from different socio-economic or geographic backgrounds [31]. These findings highlight that technological readiness alone is insufficient; social, infrastructural, and regulatory readiness must also be addressed before implementation [25,55].

Study Limitations

Although the sample reflects typical age and gender distributions, it is not representative due to the small number of participants. The recruitment process, conducted by SOPC staff, may have introduced a positive selection bias. Caregivers with an established trust relationship with the SOPC teams may have been more inclined to participate and potentially more open to innovative care concepts, including drone delivery. This could have led to an overrepresentation of participants who were generally supportive of new interventions. We also note that such participants may have been more motivated to engage in research activities, which could have influenced the generally positive reception of the concept. While drones in medical delivery were largely unknown to all participants, reducing the likelihood that only technology enthusiasts were included, clear rejections of drone use were rare. However, limited knowledge restricted the depth of the discussion. Nevertheless, data saturation can be assumed, as previous studies have also shown low awareness of drones in health care, likely due to the novelty of the technology and lack of discourse [31]. Despite this, the discussions revealed a clear need for drone delivery, particularly through the detailed accounts of caregivers' challenges. This supports the relevance of the topic, even with limited previous knowledge. Another limitation concerns the presence of SOPC team members during data collection, one in the interviews and 2 in the focus group. Their involvement was intended to provide emotional support for participants, who were within 6 months of bereavement. However, the SPOC involvement may have introduced social desirability bias, as SOPC staff were also involved in recruitment. Participants might have felt inclined to provide answers they believed aligned with SOPC expectations. To minimize this risk, SOPC staff did not actively contribute to the discussions, and all facilitation was conducted by the research team. However, the possibility that their presence influenced participants' responses cannot be fully excluded. All FGs were conducted in German; to preserve meaning, translations were cross-checked. Minor linguistic shifts were adjusted through a process of iterative translation.

Clinical Implications

This study reveals several clinical implications. First, integrating eHealth can help ensure timely medication supply during critical care gaps, such as evenings and weekends. Drone-based delivery could reduce unnecessary hospitalizations and support patients' preference to remain at home. Second, SOPC teams play a central role in facilitating eHealth use. Caregivers view them as essential for technical guidance, emotional support, and confidence in using new technologies. Their involvement in training and communication is therefore crucial. Third, strengthening digital health literacy should be a structural task. The study shows that a lack of eHealth literacy is a key obstacle to accepting and effectively using drone-based health care

XSL•FO
RenderX

solutions. Therefore, empowerment measures should focus not only on individual training but also on structural adjustments that better adapt technological offerings to the abilities and needs of target groups, such as older relatives and people with little affinity for technology. Fourth, technology must not replace human connection. Concerns about losing personal interaction in palliative care remain significant. Digital tools should complement in-person care and include communication features that maintain links with SOPC teams. Fifth, improving the quality of life through faster access to medication may ease pain and reduce caregiver stress. Drone delivery may help close critical supply gaps, a potential that future research should explore further. Ultimately, to foster acceptance, caregivers need hands-on experience with drone-based services to understand their practical value.

Conclusions

This study highlights both opportunities and challenges in implementing drone-based medication delivery in palliative care. Caregivers perceived drones as a promising solution for timely access to essential medication, particularly during critical care gaps such as evenings and weekends. It remains open for further research whether the integration of eHealth solutions like drone-assisted delivery could help reduce unnecessary hospitalizations to support patients' preference to remain at home. Successful adoption; however, requires more than technical feasibility. Low digital health literacy, especially among older caregivers, remains a key barrier. Effective eHealth must align with users' abilities, offering simple interfaces and integration into trusted systems like SOPC teams, who play a central role in providing technical guidance, emotional support, and confidence in new technologies. Their involvement in both communication and training processes is therefore critical for successful adoption. Strengthening digital health literacy should be addressed not only through individual training but also via structural adjustments that better adapt technology to the needs of older caregivers and those with limited affinity for digital tools.

Improving timely medication access could also reduce caregiver stress and improve patients' quality of life by supporting symptom control at home, which remains open for further research. Ultimately, to foster acceptance, caregivers need hands-on experience with drone-based services to understand their practical value. Future research should focus on real-world testing in living lab environments, evaluating feasibility, effectiveness, and integration into existing clinical workflows while ensuring that technological, psychological, and social needs are equally addressed.

Acknowledgments

We would like to thank the PalliDrone team for the exchange and discussion of the focus group guide and for evaluating the results of focus groups. A special thank you goes out to the "Leipziger Palliativgesellschaft" in Torgau, Germany, and the "Anhalt-Hospiz Dessau" for their help with participant recruitment. Generative artificial intelligence (DeepL Write) was used solely to assist in reviewing and improving the correctness of some English-language expressions in the manuscript. All content, interpretation of data, and conclusions were fully authored and verified by the study team. We acknowledge the financial support of the Open Access Publication Fund of Martin-Luther-University Halle-Wittenberg. This research was funded by the Federal Ministry of Education and Research Germany through the "TDG—Translational Region for Digitalized Healthcare" project 03WIR3128A. PJ received this funding. The funder had no involvement in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

Abstract

Background: Latinas are one of the largest and fastest-growing female ethnic groups in the United States and have high levels of physical inactivity and sedentary behavior (SB), contributing to a disproportionate burden of chronic health conditions. An ecological momentary assessment (EMA) involves the use of smartphone-based data collected in real time to assess health behaviors and outcomes.

Objective: We examined the feasibility, validity, and acceptability of an EMA protocol assessing physical activity (PA) and SB in Latina adults.

Methods: For 7 days, 67 Latinas (average age 39 years, SD = 13.6; n=37, 55.2% earning less than US $50,000/year; n=53, 79.1% foreign-born; and n=49, 73.1% of Mexican or Mexican American origin) completed a signal-contingent EMA protocol with 3 prompts per day and wore an ActiGraph GT3X accelerometer to measure levels of PA and SB. EMA prompts inquired about current behavior, feelings, beliefs, social conditions, and contexts.

Results: Latinas completed 69.7% (892/1279) of EMA prompts. They were more likely to respond to EMA prompts when engaged in more SB (odds ratio [OR] 1.04, 95% CI 1.01-1.06) and less light-intensity PA (OR 0.97, 95% CI 0.94-0.99) in the 30 minutes around the prompt. Accelerometer data validated self-reported occasions of PA and SB via EMA. The majority of participants (>70%) were satisfied with the protocol and expressed interest in participating in future studies.

Conclusions: EMA is a feasible, valid, and acceptable methodology for capturing movement behaviors among Latinas, which can provide insights into the antecedents and consequences of these behaviors in their daily lives.

KEYWORDS

experience sampling; ambulatory assessment; Hispanic; physical activity; exercise; sitting; accelerometer; women

Introduction

Latina or Hispanic adult women (hereafter, “Latinas”) are one of the largest, fastest-growing female ethnic groups in the United States and engage in lower levels of physical activity (PA) compared to Latino men and non-Latina women [1,2]. Recent estimates suggest that one-third of Latinas in the United States report no moderate-to-vigorous-intensity physical activity (MVPA; outside of work), the highest of any racial or ethnic group [3]. Conversely, Latinas tend to engage in more light-intensity physical activity (LPA) and less sedentary behavior (SB) compared to their White and Black counterparts [4,5]. The unique movement behavior profiles among Latinas likely result from unique barriers and facilitators that Latinas encounter in their daily lives. Yet, our understanding of Latinas’ engagement in movement behaviors (ie, MVPA, LPA, and SB) and determinants of those behaviors in naturalistic settings is limited, hampering efforts to effectively intervene [6]. Therefore, it is not surprising that Latinas in the United States experience disproportionately high rates of chronic conditions closely linked to low levels of MVPA such as diabetes, hypertension, obesity, and certain cancers.

The ecological momentary assessment (EMA) has increased in popularity over the last 15 years in PA research as a methodological approach to better capture health behaviors and their determinants as they occur in daily life [7]. Specifically, EMA is a real-time data capture methodology designed to intensively and repeatedly assess participants’ behaviors,

XSL•FO
RenderX

experiences, feelings, and contexts surrounding a phenomenon of interest [8]. Such an approach can improve ecological validity and reduce recall errors [9], ultimately improving our understanding of when, where, with whom, and why movement behaviors occur.

Despite the potential advantages of this methodological approach, no studies have explicitly evaluated the feasibility, validity, and acceptability of EMA to capture movement behaviors in Latinas. Latinas are likely to face unique barriers to participation in research involving methodologies such as EMA given documented issues related to lack of trust in research, limited rapport with research staff, and cultural insensitivity of research to the unique values, traditions, and beliefs of the Latino/a community [10,11]. Other issues associated with broader research participation among Latinas include concerns about immigration or undocumented status, lack of access to Spanish-speaking staff or interpreters, and lack of childcare [10,11].

Therefore, there is a need to establish the feasibility, validity, and acceptability of a smartphone-based EMA study to assess movement behaviors in Latinas. In this study, we examined the feasibility, validity, and acceptability of a 7-day EMA protocol assessing PA and SB. To determine feasibility, we examined rates of compliance with elements of the study protocol (ie, EMA, accelerometer wear time). EMA studies across a variety of designs, samples, and research fields have reported an average compliance with EMA protocols of 79% [12]. However, given that EMA studies focused on movement behaviors in other samples of minoritized women have reported lower compliance [13] balanced with the need to capture representative and ecologically valid data on participants' daily experiences, we deemed a compliance rate of 70% to be acceptable. We also examined measurement reactivity to determine whether accelerometer-derived behavioral data were affected or changed because of answering the EMA prompts. With respect to validity, we investigated the degree to which EMA-reported behaviors corresponded with the amount of MVPA, LPA, and SB captured by the accelerometer over that same time. To our knowledge, we are not aware of any studies that have investigated compliance with, potential reactivity to, or validity of EMA reports with regard to LPA; however, given the unique movement behavior profiles of Latinas with high amounts of LPA and accumulating evidence regarding the health benefits of LPA [3-5,14], this is an important question to investigate. Finally, to establish acceptability, we used end-of-study feedback on specific elements of the study. This formative research is crucial for enhancing our understanding of the factors influencing movement behaviors and for developing personally tailored and context-sensitive movement-related interventions for Latinas.

Methods

Participants and Recruitment

Latinas living in Guilford County, North Carolina, and surrounding counties were recruited for participation in this study. Recruitment was done primarily through community centers serving predominantly Latina/o populations. Through conversations with community partners, effective methods for recruitment were identified. Print materials were placed at community locations. Further, announcements were made and recruitment tables with staff were present at specific community events (eg, English as a second language classes, soccer games, and family services). Community partners also communicated information about the study to organization patrons. Women were eligible if they were aged ≥18 years, self-identified as Latina or Hispanic, and had no limitations that would prevent engaging in PA. If women did not speak and read English or Spanish, were pregnant, or were unwilling to use their personal smartphone for the study, they were deemed ineligible to participate. We hired and trained bilingual, bicultural research staff to recruit, enroll, and check in with participants over the course of the study.

Procedures

Following eligibility screening, Latinas attended the introductory training session (day 1) at one of three community locations. At the training session, a research staff member provided a broad overview of the study (eg, procedures, risks or benefits, and compensation). After the overview, individuals were asked to review the consent form (written in English) and sign to indicate their willingness to participate in the study. Research staff indicated that they could read the consent form to participants, if desired. Although we did not collect specific records of whether participants read the consent themselves or had the staff member read it to them, based on anecdotal staff reports, most participants read the consent form themselves. Research staff were available to answer any questions individuals had. Once participants consented, they completed a baseline questionnaire to provide basic demographic and health information. Participants were also familiarized with an accelerometer, which was to be worn on the hip during all waking hours unless they were showering, bathing, or swimming. Research staff also provided more details on the EMA study procedures during the training session and assisted participants in downloading the smartphone app, LifeData, onto their personal smartphones. The app delivered the signal-contingent EMA protocol. The EMA protocol delivered a questionnaire at a random time within three 2-hour windows (ie, morning: 6:30-8:30 AM; afternoon: 12-2 PM; evening: 6-8 PM). The EMA surveys took 2 - 3 minutes to complete, and participants could receive between 29 and 35 items at each prompt depending on participant responses at the time of the prompt (eg, if they were at work and if they were alone). Screenshots of all EMA items can be found in Figure S1 in Multimedia Appendix 1. When reviewing the EMA items during the training sessions, as well as at the beginning of each EMA prompt, participants were presented with definitions of key constructs to help orient participants to what was meant by specific terms that appeared in the questions. For instance, participants were provided a definition of physical activity that aligned with MVPA (eg, moderate to hard physical effort and breathing harder than normal). The EMA protocol was available in English and Spanish and continued for 7 consecutive days.

After the delivery of an EMA prompt, participants had 30 minutes to answer the EMA. After 30 minutes, if the EMA prompt was still unanswered, the questionnaire became

XSL•FO
RenderX

inaccessible and was counted as missing. Research staff monitored compliance in real time and contacted all participants 2‐3 days into the EMA protocol to check in and address any issues related to questionnaire delivery, compliance, etc.

Following the 7-day study period, participants returned the study equipment at a community location and were compensated for their time. Community locations were also compensated for granting the research team space to meet with participants. Finally, participants were asked to complete a brief questionnaire to gather feedback about their experience in the study.

Measures

EMA-Reported Physical Activity and Sedentary Behavior

At each EMA prompt, participants were asked "What were you doing just before the phone went off?" and were given the option to select all responses that were applicable (eg, watching television or movies; using a computer, tablet, or phone; physical activity or exercise; running errands; and household chores [15-17]; see Multimedia Appendix 1 for a complete list of response options). Given our interest to determine the validity between self-reported PA and device-measured PA, occasions in which participants selected "physical activity/exercise" at the time of the prompt were classified as currently engaged in PA at that occasion. Responses were coded so that occasions in which PA was not reported were the reference (coded as 0) and occasions in which PA was reported were the comparison (coded as 1). Aside from occasions where participants reported engaging in "physical activity/exercise," they were asked if they were sitting while doing their current activity. We classified participants as engaging in SB at the time of the prompt if they reported sitting while doing their current activity. Responses were coded so that occasions where sitting was not reported were the reference (coded as 0) and occasions where sitting was reported were the comparison (coded as 1). Regardless of whether participants indicated they were currently engaged in PA or SB, they were not asked to report the duration of their current PA or SB.

Device-Based Physical Activity and Sedentary Behavior

The ActiGraph GT3X-BT accelerometer measured participants' PA and SB. Data from this device were downloaded in 30-second epochs, and movement behaviors were operationalized as minutes of MVPA (ie, ≥2020 counts/minute), LPA (ie, 100‐2019 counts/minute), and SB (<100 counts/minute) [18,19]. Time stamps from the device and EMA questionnaires were used to pair the 2 data sources and create windows of accelerometer data before, after, or around the EMA prompt. Movement behavior data accumulated in the 15 minutes before, 15 minutes after, or 30-minute window around (ie, ±15 minutes) the EMA prompt was used in analyses. Nonwear time was determined based on consecutive minutes of 0 activity counts [19]. Time intervals in which valid wear time amounted to at least half of the interval were considered valid and included in the analysis (eg, ≥7.5 minutes of wear in the 15 minutes before the prompt).

Time

We created variables representing the time of day and day of the week EMA prompts were delivered. EMA prompts delivered between 6:30 and 8:30 AM were classified as morning prompts, 12 and 2 PM as afternoon prompts, and 6 and 8 PM as evening prompts. Prompts delivered from Monday to Friday were classified as weekday prompts, and prompts delivered on Saturday and Sunday were classified as weekend prompts. Finally, an EMA prompt number variable (ranging between 1 and 21, as this is the maximum number of prompts that could be delivered as part of the study) was created to account for time in study.

Demographic, Family, Work, Social, and Structural Determinants

During the introductory training session, participants completed a baseline questionnaire that assessed demographic and health information including age, nativity, and self-reported health. Although not relevant to the aims of this manuscript, at each EMA prompt, participants reported on family, work, and social conditions and potential stressors they were experiencing. Latinas' geographic location at the time of the prompt was also recorded at each EMA prompt.

Study Feedback

At the end of the study, participants provided their perceptions of study procedures, their overall experience, and their willingness to complete smartphone-based or accelerometer-related study procedures in future studies. Items and response options are provided in the Results section.

Data Analysis

Our analytic approach was informed by previous work investigating the feasibility and validity of EMA in PA-related research in other populations [15-17]. As an intensive longitudinal study, we fit a series of multilevel models to account for the nested structure of our data (ie, observations nested within people) to investigate the aims previously defined [20,21]. Descriptive statistics and frequencies were calculated to describe compliance (ie, total answered prompts completed divided by total delivered prompts).

To determine if engagement in movement behaviors influenced the likelihood of completing an EMA prompt, we fit a series of multilevel logistic regression models. More specifically, these models examined if engaging in movement behaviors (ie, MVPA, LPA, and SB in the 30-minute window [±15 minutes] around the EMA prompt) as well as temporal (ie, time of day, day of week, and time in study) or demographic factors (ie, age, preferred language, self-reported health, nativity status, and employment status) influenced whether or not an EMA prompt was completed. EMA prompts were dummy coded (ie, prompts completed were coded as 1; prompts not completed were coded as 0). Prompts were considered not completed if a participant did not open the EMA questionnaire within 30 minutes of delivery or the prompt was answered but the participant did not answer all questions included in the EMA questionnaire (ie, did not provide complete data at the EMA prompt).

XSL•FO
RenderX

The next set of models examined whether the time spent engaging in PA (or SB) in the 15-minute window before the EMA prompt differed from the time spent engaging in PA (or SB) in the 15-minute window after the EMA prompt. This is relevant as it provides insights into whether the EMA prompt resulted in any reactivity (or changes in PA or SB as a result of being prompted about their movement behaviors) [22,23]. We created a dummy-coded variable representing the 15 minutes prior ("window"=0) and after the EMA prompt ("window"=1) to examine its association with MVPA, LPA, and SB (one movement behavior per model).

Our final set of models examined criterion validity. We fit multilevel linear regression models to determine associations between EMA-reported PA and SB and accelerometer-derived PA and SB, respectively. We used EMA-reported PA (or SB) at the time of the prompt as the main predictor to determine associations with accelerometer-derived MVPA, LPA, or SB (one movement behavior per model). For all models in which MVPA was the outcome, model results were consistent regardless of using raw or transformed MVPA variables, so we opted to use raw MVPA values to aid in the interpretability of findings.

Based on a priori selection of covariates and prior studies, we adjusted all multilevel models for time and day of the prompt, time in study (ie, EMA prompt number), age (grand mean centered), employment status (dummy coded), language of questionnaire (dummy coded), nativity (dummy coded), and self-reported health (eg, [3,5,6,12,15,23-25]). Previous simulation studies indicate that having at least 50 units at the high order level (in our case, participants at level 2) with between 5 and 30 observations per unit (in our case, we averaged 10 valid observations per participant) is sufficient to generate accurate unstandardized coefficient and standard error estimates [26]. Quantitative analyses were conducted in Stata v. 18 and SAS v9.4.

Lastly, to establish acceptability, we evaluated reports of satisfaction with, convenience of, and disruptions due to study participation. In addition to Likert items assessing acceptability, participants were given the opportunity to provide additional feedback via an open-ended question. Only one-third (23/67, 34.3%) of the participants responded to the open-ended question, and responses were brief, with an average length of 10 words. Therefore, we did not conduct a formal qualitative analysis but highlighted quotes to represent common responses across respondents.

Ethical Considerations

All study procedures were approved by the University of North Carolina at Greensboro's institutional review board (IRB FY22-483). Written informed consent was obtained from all individual participants included in the study. Several measures were implemented to ensure participant privacy and confidentiality, including meeting with participants in private or secluded areas at community locations, using ID numbers to link participant data, and storing electronic or paper records in secure locations. Participants could earn up to US $50 in gift cards: US $20 for attending the introductory session and US $30 for completing the EMA and accelerometer protocol (not prorated based on compliance).

Results

Participant Characteristics and Completion of EMA Prompts and Accelerometer Wear

A total of 67 Latinas completed the study. Table 1 displays the demographic characteristics of study participants. Participants were, on average, 39 years of age (SD = 13.6). About half of the sample met physical activity guidelines and indicated they were from households earning less than US $50,000 per year. Approximately three-quarters (53/67, 79.1%) of the sample were foreign-born. Similarly, about three-quarters (49/67, 73.1%) of the sample were identified as Mexican or Mexican American.

Sedentary behavior (minutes), mean (SD)	
Device-based assessment (15 minutes prior to EMA prompt)	9.32 (4.21)

[a]MVPA: moderate to vigorous intensity physical activity.

[b]EMA: ecological momentary assessment.

There were 1279 EMA prompts delivered across all participants. Of the EMA prompts delivered, participants answered 927 (72.5%) EMA prompts and completed 892 (69.7%, range: 5% - 100%) EMA prompts. On approximately two-thirds of occasions, participants had valid actigraphy data in the 15 minutes before (n=842, 65.8%) or 15 minutes after (n=860, 67.2%) the EMA prompt. Frequencies and descriptive statistics for EMA-reported and device-based movement behaviors are displayed in Table 1.

Factors Influencing Compliance With Study Procedures

Table 2 displays associations between demographic, temporal, and behavioral factors and compliance. There was no difference in odds of participants completing the EMA prompt (vs not) depending on the amount of MVPA engaged in in the 30-minute window around the EMA prompt (P>.05). However, Latinas were more likely to complete an EMA prompt if they engaged in more SB (odds ratio [OR] 1.04, 95% CI 1.01-1.06) and less LPA (OR 0.97, 95% CI 0.94-0.99) in the 30-minute window around the EMA prompt.

XSL•FO
RenderX

[a]EMA: ecological momentary assessment.

[b]All models were based on 67 participants with 850 observations.

[c]MVPA: moderate to vigorous intensity physical activity.

[d]OR: odds ratio.

[e]LPA: light intensity physical activity.

[f]SB: sedentary behavior.

[g]$P<.05$.

Latinas were more likely to complete an EMA prompt in the afternoon, evening, and weekend compared to mornings and weekdays (except for the model with LPA predicting compliance). Participants were also more likely to complete an EMA prompt as participants received more notifications in the study (ie, time went on in the study). There was no difference in odds of completing an EMA prompt by between-person demographic factors (eg, age).

Potential Reactivity to EMA Prompts

Latinas engaged in significantly more SB in the 15 minutes following the EMA prompt (*B*=0.49, SE 0.21, *P*=.02; mean 9.56, SD 4.14 minutes) compared to the 15 minutes before the prompt (mean 9.07, SD 4.34 minutes). However, there was no difference in MVPA (*B*=−0.04, SE 0.07; *P*=.54) or LPA (*B*=−0.3, SE 0.19; *P*=.11) in the 15 minutes before the EMA prompt compared to the 15 minutes after the EMA prompt (data not shown in table).

Criterion Validity of EMA Responses

Table 3 displays results from models investigating the extent to which there was agreement between device-based movement behaviors and EMA reports of PA and SB. Latinas who self-reported engaging in PA at the time of the prompt averaged 3.6 more minutes of device-based MVPA (*B*=3.60, 95% CI 2.75 - 4.45) and 2.32 more minutes of LPA (*B*=2.32, 95% CI 0.17-4.61) relative to occasions when Latinas did not report being physically active at the time of the prompt. Further, device-based assessments of SB corresponded with self-reported behavior via EMA. At the time of the prompt, Latinas averaged 4.11 more minutes of device-based SB in the 30-minute window (ie, ±15 minutes) on occasions when they reported sitting at the time of the prompt relative to occasions when they did not report sitting at the time of the prompt (*B*=4.11, 95% CI 3.10-5.11).

Adjusting for covariates may overfit models. Another set of unadjusted multilevel models was tested to determine correspondence between EMA-reported and device-based behaviors. Results did not differ substantially from the adjusted results presented in Table 3 regarding agreement between EMA-reported and device-based behaviors. Output from unadjusted multilevel models is in Multimedia Appendix 2.

Acceptability

As indicated in Table 4, most participants (48/66, 72.7%) were satisfied with the study. More than half of the participants indicated that the length of the questionnaires was reasonable (ie, 37/66, 56.1% strongly disagreed or disagreed that the EMA questionnaires took too much time to complete). There were mixed responses regarding the convenience of the timing of EMA prompts (ie, 21/66, 31.8% agreed or strongly agreed prompts were delivered at a convenient time; 15/66, 22.7% disagreed or strongly disagreed). One participant noted in open-ended comments about the study: "Sometimes questionnaires were too early, or I was busy with my kids, and I couldn't answer." Another participant indicated a preference for more time before EMA prompts became inaccessible, with one participant noting that they would have liked to "get more than 30 minutes to answer [the EMA prompt]." Most participants indicated that the preferred number of EMA prompts per day was 3 (52/66, 78.8%) and study days was 7 (53/66, 80.3%). Though in open-ended responses, some participants reported the desire for EMA questionnaires to take less time to complete. Nearly half of the participants indicated that the accelerometer was not a nuisance to wear (29/66, 43.9%) or were neutral about wearing it (18/66, 27.3%), while 28.8% (19/66) indicated it was a nuisance to wear. More than four-fifths (56/66, 84.8%) of the sample indicated that they were satisfied with the compensation provided for completing the study.

Discussion

EMA can provide novel insights into the prediction and modeling of movement-related behaviors as it captures phenomena of interest in real-time and real-world environments. However, such a methodology is only useful and informative if participants are willing to comply with study procedures and the data collected through this method are valid. To our knowledge, this study is the first to investigate Latinas' willingness, compliance, and accuracy in reports of behaviors in an EMA protocol designed to assess movement-related behaviors. We found that among a sample of emerging to midlife Latinas of Mexican or Mexican American origin and born outside of the United States, these women were willing to engage in and comply with the EMA research, demonstrated strong agreement in reporting engagement in PA and SB when compared to device-based measures, and, overall, had positive perceptions of the study procedures. This study provides encouraging findings for future EMA research with Latinas to better understand and intervene on movement-related behaviors.

Latinas demonstrated acceptable levels of compliance with the EMA protocol, answering approximately 72.5% (927/1279) and completing 69.7% (892/1279) of EMA prompts in this study. Across a variety of research designs, samples, and disciplines, the average compliance with an EMA protocol is approximately 79% [12]. Compared to EMA studies of movement behaviors exclusively among samples of women, compliance rates documented in this study were similar [27,28] or better than previous research [13]. Some of the PA EMA studies among women have implemented strategies to entice EMA compliance by offering additional compensation based on the percentage of EMA prompts answered [27,29]. However, Wrzus and Neubauer [12] found that compliance did not differ if EMA studies used incentives dependent on answering minimum percentage of prompts compared to incentives without compliance reinforcement. It appears the main compliance issue women in our study expressed was the convenience of EMA prompts (eg, timing). Further design considerations regarding EMA prompts among Latinas may be warranted.

Rates of activity monitor nonwear documented in this study were surprising, considering that participants generally reported that it was not a nuisance to wear the activity monitor. Commercial wearable devices may be more advantageous than research-grade devices as commercial devices tend to be water-resistant, comfortable to wear, and stylish, all of which can promote continuous wear with limited reasons for device removal. However, researchers should weigh the pros and cons of using commercially available devices for research purposes [30].

Our findings suggest that the likelihood of completing an EMA prompt increases significantly if Latinas are engaged in higher levels of SB and less LPA around the time of the prompt. Previous EMA studies have similarly documented that rates of compliance are improved if a participant is engaged in high levels of SB around the EMA prompt and that engagement in MVPA around the EMA was unrelated to compliance [16,17]. Other PA EMA studies have documented compliance differences based on concurrent engagement in MVPA (particularly driven by vigorous intensity PA) [15,31], but we did not observe such differences in compliance. This may be due to the relatively low levels of MVPA in our study sample. We did, however, find that engaging in more LPA around the prompt decreased the likelihood of completing an EMA prompt. Engaging in higher levels of LPA may reflect a general busyness of daily life among women, which may explain poorer compliance at those times.

One concern with EMA protocols is that they can potentially induce measurement reactivity (ie, changes in a construct because of intensively assessing it) [22,23]. Our finding that Latinas sat for significantly more time immediately following the EMA prompt as compared to immediately before the EMA prompt aligns with previous findings [15]. Of note, estimates in our study suggest that the difference in SB before and after the EMA prompt was approximately 30 seconds. This volume of change in SB may not have practical implications for Latinas' health. Further, neither MVPA nor LPA significantly changed among Latinas because of completing the EMA prompt, aligning with previous work [15,23]. In general, findings from this study are promising as they suggest that completing an EMA prompt does not induce meaningful reactivity in PA or SB behaviors among Latinas.

Regarding the validity of EMA to assess PA and SB, on occasions when Latinas reported engaging in PA or SB via EMA, actigraphy-derived measures of those behaviors were greater than when those behaviors were not reported via EMA. Importantly, actigraph-derived MVPA increased by nearly 4

XSL•FO
RenderX

minutes when Latinas reported engaging in PA at the EMA prompt, but LPA only increased by about 2 minutes. This suggests that Latinas accurately differentiated between intensities of PA as they were instructed during the introductory training session and reminded at the beginning of each EMA prompt. Given the relatively low prevalence of MVPA in the ±15-minute window around the EMA prompt across all observations (mean 0.96, SD 2.87 minutes), the increase of nearly 4 minutes of device-based PA when PA was reported at the prompt indicates that participant reports were consistent with the behavioral engagement. The agreement between EMA-reported and device-based movement behaviors is consistent with findings from studies involving diverse samples of emerging, midlife, and older adults. These studies have shown increases of 2-4 minutes in device-based PA on occasions when PA was reported through EMA prompts, compared to occasions when it was not [15-17,32]. Ultimately, these findings indicate that Latinas accurately report their current movement behaviors through EMA.

Finally, the overall positive perceptions of the EMA study indicate that this type of smartphone-based study design is acceptable to assess movement behaviors in a sample of Latinas that have immigrated to the United States. Based on participants' feedback, further refining ways to minimize study demands and improve the convenience of study procedures would be advantageous. Additional strategies such as customizing to participants' sleep and wake time schedules or allowing more time to complete the EMA prompt could address issues of convenience. Lengthening the available window in which Latinas can respond to an EMA prompt may help limit potential burden. However, when deciding whether to lengthen the availability of the EMA questionnaire, researchers should weigh the potential benefits and costs of such a decision considering the phenomenon of interest they are interested in capturing. Finally, considerations around the number of items and time to complete at each EMA questionnaire may be necessary. Some EMA studies have reduced the number of items in EMA prompts, while also providing variety in the constructs assessed, by randomizing items so that only a portion of constructs are assessed at each EMA prompt [15,33]. Though such design considerations may only be applicable in studies with a larger number of EMA prompts within days or more days of assessment to ensure that all constructs are adequately captured to reflect the changing contexts of daily life.

Strengths of this study include the rigorous interrogation of factors that may influence potential feasibility and validity of a movement behavior EMA protocol among a socially vulnerable population of Latinas. However, study limitations should be noted. Although simulation studies indicate that in intensive longitudinal study samples of more than 50 participants with assessments within participants can generate reliable fixed and random estimates as well as standard errors [26], our sample size was relatively small (N=67), which may limit the generalizability of findings. Additionally, we obtained a larger percentage of Latinas meeting PA guidelines compared to national averages. Further, most of our sample identified as Mexican or Mexican American and was born outside of the United States. There may be important differences in terms of feasibility, validity, and acceptability depending on Hispanic origin and nativity status. Relatedly, we did not take height and weight measurements to determine participants' Body Mass Index (BMI). Some studies have indicated differences in EMA compliance by BMI [15]. Examining differences in compliance by BMI is an important direction for future EMA research among Latinas. With respect to our study design, because a random, signal-contingent prompting schedule was used, it is likely that not all bouts of PA and SB were captured. Further, EMA items did not assess the duration or intensity of PA or SB.

The findings from our study indicate that EMA methods are a feasible, valid, and acceptable approach to use with Latinas to understand PA and SB. Although some strategies may need to be implemented in future work to enhance compliance with smartphone and accelerometer-based study procedures, our study provides timely, new evidence that EMA can be effectively used among Latinas to capture movement behaviors. Latinas represent a vulnerable and understudied population in PA research. Using EMA in such a group can shed new light on the antecedents and consequences of movement behaviors, leading to new intervention targets delivered in the context of Latinas' daily lives. The findings from this study represent an essential first step in that process.

Acknowledgments

This research was supported by a Faculty Research Grant, Office of Research and Engagement, University of North Carolina at Greensboro. The authors would also like to thank Ashley Banegas, MPH, for her assistance with recruitment and data collection.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Health messages are integral to smoking cessation interventions. Common approaches to health message development include expert-crafted messages and audience-generated messages, which produce messages that can be monotonic, didactic, and limited in number. We introduce an alternative approach to health message development that relies on user-generated content available on open-content platforms as a source of health messages.

Objective: We examined the acceptability of user-generated content curated from Twitter (subsequently rebranded X) as a source of health support messages in a newly developed smoking cessation mobile intervention called Quit Journey and the optimal timing and frequency with which health messages can be deployed to support app users in real time.

Methods: A total of 12 semistructured focus groups were held with 38 young adults with low socioeconomic status who smoked cigarettes, wanted to quit, and were aged 18 to 29 years. Focus groups were held virtually on GoTo Meeting, audio recorded, and transcribed verbatim. Deductive thematic analysis was used, with themes based on 5 constructs from the second unified theory of acceptance and use of technology (ie, effort expectancy, facilitating conditions, hedonic motivation, performance expectancy, and social influence) and negative, neutral, and positive sentiment.

Results: Participants perceived user-generated content positively (56/108, 51.9% of the quotes) and focused on their perceived usefulness (37/108, 34.3% of the quotes). User-generated content was perceived as authentic, nonrepetitive support from people with similar real-life experiences. Negative or sarcastic user-generated content elicited negative reactions from participants. Participants preferred receiving 3 or fewer daily messages, ideally before cravings. Suggestions focused on the need to screen user-generated content before its inclusion in the app library and allow app users to customize message frequency and timing.

Conclusions: User-generated content was deemed an acceptable source of health messages. This content can improve the efficacy and effectiveness of smoking cessation interventions by increasing their pool of unique messages that may be better received and more persuasive than expert-curated content. User-generated content can be used to curate health messages for all medical conditions and behaviors with relevant publicly available online content for integration in behavioral interventions given its high volume, brevity, and narrative-like nature. Future research is needed to investigate the effects of user-generated content on health behaviors and identify the theoretical mechanisms for these effects.

Introduction

Health messaging is integral to smoking cessation efforts, including behavioral interventions [1,2]. Effective health messages are understandable; informative; engaging; and, most importantly, capable of inducing behavior change [3]. Despite the importance of health messages to behavioral interventions, the process of health message development is “commonly

XSL•FO
RenderX

hidden within a black box" [4]. The most common is a top-down approach to message development, where interventions include expert-crafted health messages that embody clinical or expert guidelines, determinants of behavior change as outlined in theoretical frameworks (eg, health belief model, theory of planned behavior, and elaboration likelihood model), message tactics (eg, gain framed and narratives), and approaches (eg, targeting and tailoring) [3]. Alternatively, target populations have been involved in developing health messages in a bottom-up approach, although this approach is less frequently used [5]. We propose a different approach, where health messages are curated from online open-content sources for use in smoking cessation interventions.

There are limitations to current approaches to health message development. Expert-constructed messages can be perceived as dry, didactic, or unrelatable and can be met with persuasion resistance from audiences [6,7]. Target population–constructed messages can be difficult to generate, especially at scale. Both approaches to message development generate a finite number of messages that are recycled over the course of an intervention. Message repetitiveness can result in message fatigue, which leads to unfavorable message attitudes and reduced message effectiveness, credibility, and behavioral intentions [8,9]. This is particularly important given the need for a substantial pool of candidate messages to cover the extended treatment times of smoking cessation interventions, which usually last 4 to 6 weeks (and often require multiple quit attempts), and the need for personalized message content and intensity under adaptive interventions [10,11].

Web 2.0 and social media platforms have an endless reservoir of user-generated health content owing to their active users, including 2 billion for Instagram and 600 million for Twitter (subsequently rebranded X) [12]. User-generated content is defined as "content [that] is created or produced by the general public rather than by paid professionals and primarily distributed on the internet" [13]. There is evidence suggesting that people turn to online platforms, including social media, for health purposes. For instance, health discussion forums, social media platforms, and crowdsourcing platforms have user-generated smoking cessation content [14,15]. In 2018, a total of 70.14% of Americans used digital means to access health information, whereas 14.02% shared health information via social media platforms [16]. However, research on Web 2.0 and social media platforms has been limited to examining tobacco advertising and audience-targeting strategies and their associations with tobacco use behaviors [17-19]; analyzing opinions and attitudes regarding tobacco products and the viability of predicting user behavior based on online media posts [20-23]; and, finally, engaging with and disseminating antitobacco messaging and cessation interventions [14,24-26].

User-generated content remains a practically untapped resource for persuasive health messaging. There is evidence suggesting that users trust content created by those going through similar experiences [27]. User-generated online content is also akin to unscripted peer-to-peer communication, which is typically conversational and can include narrative elements or storytelling. These content characteristics can induce behavior change through various mechanisms, such as reducing counterarguments and facilitating role-modeling of the behavior [28-31]. For example, peer messages have been associated with greater engagement with tobacco interventions compared to expert messages [32], whereas emotional and personal testimonials have been associated with greater quitting among individuals with low and middle socioeconomic status (SES) who smoke than among those with high SES [33].

In this study, we explored reactions to the potential of user-generated content as a source of support messages in a smoking cessation intervention [34] called Quit Journey that targets individuals with low SES who smoke cigarettes. The app will feature an on-demand message library and just-in-time support messages to be sent to users when they are at risk of a lapse or relapse. These messages will be drawn from Twitter, a microblogging platform. As target audiences' reactions to health messages are critical determinants of their effectiveness [3,35], we gauged the acceptance of the use of Twitter messages for cessation support in Quit Journey among young adults with low SES who smoked and their opinions on the frequency and timing of the just-in-time support messages. This study was part of the preparation phase of the multiphase optimization strategy for the development and evaluation of Quit Journey [36,37].

Methods

Ethical Considerations

The National Institutes of Health institutional review board exempted this study on October 11, 2019, under category 2, research that only includes interactions involving educational tests, survey procedures, interview procedures, or observation of public behavior (title 45 of the Code of Federal Regulations, part 46.10(d)(2)), and category 3, research involving benign behavioral interventions (title 45 of the Code of Federal Regulations, part 46.10(d)(3)). ICF International's institutional review board exempted this study on November 19, 2019, under category 2 and approved an amendment on February 26, 2020. All participants verbally consented to take part in the study. Participants received US $150 as compensation. Participants were assigned numeric identification numbers that were used during the focus group discussions and in the transcripts.

Participants and Recruitment

We partnered with UserWorks, Inc, to recruit a convenience sample of 38 young adults with low SES who smoked. Individuals with low SES are a priority for smoking cessation efforts, with high prevalence of cigarette smoking among adults with low incomes (18.3%) and those without a high school diploma or who passed the General Educational Development test (20.1% and 30.7%, respectively) [38].

Eligibility criteria included being aged 18 to 29 years; having a low SES, as evidenced by being neither a 4-year college graduate nor a college enrollee [39-41]; being a current smoker who smoked at least 100 cigarettes in their lifetime and reported smoking every day or some days; willingness to quit within 6 months; not currently using any smoking cessation aids or noncigarette combustible tobacco products; being a smartphone owner; and speaking English. Recruitment took place between January 2020 and April 2020. The sample size was deemed

XSL•FO
RenderX

sufficient to achieve data saturation, and none of the participants withdrew from the study [42,43]. The 32-item COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist can be found in Table S1 in Multimedia Appendix 1 [44].

Procedures

We conducted 12 virtual focus groups lasting approximately 1.5 hours each on GoTo Meeting using a topic guide informed by the second unified theory of acceptance and use of technology (Multimedia Appendix 1) [45,46]. In this paper, we focus solely on Quit Journey's message library and just-in-time support feature, which are under development. The moderator described the concept behind the on-demand message library and just-in-time support feature in 8 focus groups and presented mock app pages with placeholder messages and 5 sample tweets in 4 focus groups. For example, one sample tweet read the following:

> *...after seeing a smokers teeth now im glad I haven't touched a cig in months!!*

All sample tweets can be found in Note S1 in Multimedia Appendix 1. In total, 31.6% (12/38) of the participants were involved in 2 focus groups, one in which the moderator presented the concept behind utilizing user-generated content in Quit Journey and one in which the moderator presented app mock pages with placeholder user-generated content. Our work on perceptions of smoking cessation apps and of Quit Journey and its individual features has been published elsewhere [47-51; Wakeman M, unpublished data, April 2025].

We conducted dry runs to ensure that the sessions ended on time. TG, a male user experience strategist, moderated the discussions. EL, a female strategic communications and marketing project director, was a backup moderator and recorded notes. TG, EL, and SE-T were the only nonparticipants present during the focus group discussions, and none had a previous relationship with the participants. Participants were informed that the moderators were unaffiliated with the research group that commissioned the study. The focus groups were audio recorded and auto-transcribed by GoTo Meeting. Three members of our staff verified these transcripts against the audio files. Transcripts and findings were not returned to participants for feedback.

Analysis

We adopted a deductive thematic approach to data analysis [52]. After an initial review of the transcripts, we developed codes and corresponding themes based on 5 constructs from the second unified theory of acceptance and use of technology: effort expectancy, facilitating conditions, hedonic motivation, performance expectancy, and social influence [45,46]. Furthermore, we coded the transcripts for negative, neutral, and positive sentiment; design concepts; suggestions for improvement; and Quit Journey app features [49-51]. Briefly, effort and performance expectancies were defined as "perceived ease or effortfulness" and "perceived usefulness or helpfulness" of mobile apps and their features, respectively. Facilitating conditions were defined as "factors that can aid or impede [their] uptake or use," whereas social influence referred to "perceived importance of significant others' recommendations and approval" in considering use of mobile apps and their features. Hedonic motivation was defined as "perceived fun, pleasure, or enjoyment (or lack thereof) associated with [their] use." Negative and positive sentiment captured statements that indicated "a sense of disapproval, criticism, or skepticism" or "a sense of approval, praise, or certainty" about mobile apps, respectively. Neutral sentiment captured remarks that "did not have positive or negative tone, contained equal number of positive- and negative-toned remarks, or were conditional in nature." The design concept code captured statements related to the visual depiction and aesthetics of mobile apps or their features. Finally, the suggestion code captured statements that were "concerned with improvements, modifications, or adjustments" to mobile apps or their features, whereas the app feature code captured the Quit Journey app feature being discussed (eg, carbon monoxide tracking; Wakeman M, unpublished data, April 2025) [47-51]. Quotes that did not fit under a technology acceptance construct but still conveyed a particular sentiment were coded as "not applicable."

We introduced new codes if the content in the transcripts did not fit the predefined ones. In coding the transcripts, we applied the predominant theme in each quote even if it was not mentioned explicitly (ie, in response to a moderator's question). When one theme was contingent on another, we coded the quote for the underpinning theme. We followed a multicoding approach where multiple domains (eg, technology acceptance and sentiment) could be applied to a single quote but only 1 code could be selected from each domain (eg, negative, neutral, or positive).

MW and LT independently coded the focus group transcripts. Using the ATLAS.ti qualitative software (version 8; ATLAS.ti Scientific Software Development GmbH), we calculated 2 intercoder agreement measures: the Krippendorff c-alpha and Krippendorff cu-alpha. The first, a measure of separating relevant and irrelevant content (ie, whether coders identified texts of similar locations and lengths), was 0.82 [53]. The second, a metric related to semantic domain reliability (ie, whether coders coded for the presence or absence of groups of related themes), was 0.66 for technology acceptance, 0.70 for sentiment, and 0.94 for app features [53]. MW, LT, and SE-T discussed discrepancies and resolved them.

Results

Overview

Sample characteristics are shown in Table 1, and detailed participant characteristics can be found in Table S2 in Multimedia Appendix 1.

XSL•FO

Table . Participant characteristics (N=38) [47-51].

Characteristics	Participants, n (%)
Sex	
Female	20 (52.6)
Male	18 (47.4)
Race and/or ethnicity	
American Indian or Alaska Native	1 (2.6)
Asian, Native Hawaiian, or Pacific Islander	3 (7.9)
Black or African American	11 (28.9)
Hispanic or Latino	6 (15.8)
White	16 (42.1)
Mixed	1 (2.6)
Highest level of education	
Lower than high school	3 (7.9)
High school graduate	10 (26.3)
High school equivalent	3 (7.9)
Some college, no degree	18 (47.4)
2-year associate degree	4 (10.5)
Smoking frequency	
Every day	30 (78.9)
Some days	8 (21.1)
Quit time frame	
7 days	11 (28.9)
30 days	22 (57.9)
6 months	5 (13.2)
Smartphone operating system	
Android	21 (55.3)
iOS	17 (44.7)

User-generated content was an acceptable source of smoking cessation support messages. Of 108 extracted quotes, roughly half (n=56, 51.9%) reflected a positive sentiment (Table 2). Discussions largely focused on performance expectancy (n=37, 34.3%), followed by effort expectancy (n=7, 6.5%), hedonic motivation (n=7, 6.5%), and facilitating conditions (n=1, 0.9%). All quotes appear verbatim in Tables S3 and S4 in Multimedia Appendix 1.

Table . Distribution of the number of quotes by technology acceptance and sentiment toward the user-generated message library. Column totals add up to 100% within each theme, whereas overall row totals add up to 100% across a semantic domain (N=108).

Technology acceptance domain	Sentiment, n/N (%)			Total, n/N (%)
	Negative	Neutral	Positive	
Effort expectancy	1/7 (14.3)	0 (0)	6/7 (85.7)	7/108 (6.5)
Facilitating conditions	0 (0)	1/1 (100)	0 (0)	1/108 (0.9)
Hedonic motivation	0 (0)	3/7 (42.9)	4/7 (57.1)	7/108 (6.5)
Performance expectancy	9/37 (24.3)	3/37 (8.1)	25/37 (67.6)	37/108 (34.3)
Social influence	0 (0)	0 (0)	0 (0)	0 (0)
Not applicable	19/56 (33.9)	16/56 (28.6)	21/56 (37.5)	56/108 (51.9)
Total	29/108 (26.9)	23/108 (21.3)	56/108 (51.9)	108/108/ (100)

XSL•FO
RenderX

Performance Expectancy

Most quotes on the usefulness of user-generated content for smoking cessation (25/37, 67.6%) overlapped with positive sentiment. Reasons for its perceived usefulness included providing nonrepetitive, authentic content from people "going through the same thing as you" (P35). User-generated content was also seen as a validation of the intended audiences' emotions and experiences while imparting a sense of community and social support:

> *I know I get annoyed when...something that's...giving you motivational quotes and it'll just start like repeating them because they only have a few.* [P11]

> *Yeah, I feel like it'd be very motivating to have that sense of community [from the tweets] and to see it working in real-time and kind of have that push to be inspired to keep going, if you see actual people getting benefits from it.* [P10]

Participants emphasized the benefits of knowing the experiences of others, which could improve their self-efficacy and motivation to quit:

> *I think [the tweets] would be super helpful for people.... The community who have ended up quitting smoking, I think it would be super helpful to see what they have to say and what they think about it after the fact. So, yeah, I like that a lot.* [P08]

> *I think it's nice to have a personal touch and [the tweet] gives the user a reminder that it's possible to achieve the outcome you're wanting and...there's proof from other people that have been able to overcome the...addiction that we're all trying to kick.... There are key points that I can see in some of these [example tweets] that I'm thinking to myself are applicable to me and concerns that I have. So, it's just another reminder and incentive and...positive reinforcement that I think is a great idea.* [P14]

Quotes with a negative sentiment (9/37, 24.3%) captured skepticism about the relevance of others' success stories or their motivating impact on individual participants' quit journeys:

> *I just don't think that...reading what other people are doing...is like helpful to me and...if I'm quitting smoking, I don't care if someone else...is a "proud owner of a tobacco free body," right. Like, there's lots of people who don't smoke. But...that's not my journey.* [P11]

Negative sentiment also reflected participants' reactions to sample tweets that were perceived as sarcastic or ironic in tone or those that referenced the adverse health effects of smoking:

> *I don't like the first [example tweet], because I feel like that would just make me feel bad, especially if like my teeth are already yellow from smoking.... If you're...struggling and then someone else is, like, "Oh, yay." Like, you know, "I'm doing so well and blah blah blah," and...that can make you feel kind of...bad. And then...if you feel that you might just start smoking more because you're like, what's the point, I'm a failure.* [P11]

Other Technology Acceptance Themes

Participants perceived Quit Journey's tweet-based message library as both easy and fun to use. Quotes reflecting effort expectancy, or the perceived ease of using the message library, and hedonic motivation, or the perceived enjoyment of using the message library, were generally positive (6/7, 85.7% and 4/7, 57.1%, respectively):

> *I think it will be fun [to include tweets].* [P16]

Discussions rarely focused on conditions that could facilitate or impede the use of a Twitter-based message library or just-in-time support messages. For example, one participant had no privacy concerns, noting that they would be comfortable with the app collecting their ratings of messages to personalize message content as the app learned their preferences.

Suggestions

An additional 105 quotes focused on participants' suggestions related to message content, timing, and frequency. First, to maintain the authenticity of user-generated content (ie, ensuring that app users know that the messages were authored by real people), participants suggested that messages be attributed to the poster's name, Twitter handle, or online platform. Others suggested that the app's library maintain the visual presentation of Twitter messages to signal the messages' authenticity. Finally, participants suggested that the tweets should be unedited or unaltered, including emojis and any spelling or grammatical errors unless they jeopardized the meaning of the message. If edited, it should be minimal to aid comprehension:

> *If you're going to have [tweets], yeah, it's better to know that it's from a real person than like a computer-generated thing.* [P11]

> *Just mention the name of the platform the messages are from but exclude the name of the people who posted. Keep them anonymous.* [P06]

> *We use social media a lot, we do a lot of misspelling, we miss punctuations, and all of that stuff. So...if that is gonna be coming from an actual person...you want to show...not just the good, but the ugly too [in the tweets], you know not everyone can spell.* [P16]

Participants emphasized that sarcastic, ironic, or negative tweets should not be included in the app's message library:

> *I would just be cautious with what [Twitter] messages you use.... But I like the idea, like, getting a notification. Maybe...every day or twice a day or something that has something kind of inspirational to help you. But...I think it's...really a matter of choosing ones...that are all positive.* [P05]

Regarding push messages, participants suggested tailoring the messages based on age, smoking behavior, and ratings of previous messages, among other factors. Furthermore, participants emphasized the importance of being able to customize the timing and frequency of notifications. For example, although feedback was mixed, most participants preferred to receive support messages before a craving occurred.

XSL•FO
RenderX

Participants suggested that they would be receptive to 1 to 10 messages per day, with 3 messages per day being the most common:

> *I guess [I would prefer to receive messages] before, or during the craving, because if it comes afterwards, then you probably already smoked one.* [P10]

> *So, in my opinion, it would be that if you're making a really good progress, the less [tweets] that you may need, or it can be the opposite...if you're doing really good, more [tweets].... I don't know. I think maybe start off three a day—morning, noon, night.* [P16]

> *I feel like [the tweets are] really personal and probably even could like learn me in a way where if I'm having...a bad day or...there's certain times where I feel like I need a little more support then.... Just to kind of like throw it at me and then if I have to change it then I will change it, you know?* [P02]

Discussion

Principal Findings

This study showed that user-generated content was an acceptable source of support messages in Quit Journey, a smoking cessation intervention targeting individuals with low SES who smoke. The perceived usefulness of user-generated content reflected core characteristics of effective health messaging, including their brevity, relatedness to target populations, and narrative-like nature, while avoiding pitfalls common to expert-designed messages, such as monotony, repetitiveness, and didacticism [3,6]. Suggestions to improve user-generated content for use in Quit Journey's message library and just-in-time support feature included refraining from overly negative or sarcastically toned messages and tailoring the messages to users' characteristics, time-varying needs, and message preferences [3]. Cumulatively, these results suggest that we can leverage user-generated content to build Quit Journey's message library. More broadly, user-generated content marks a departure from the limited number of top-down, expert-designed messages commonly used in health interventions, which can be subject to persuasion resistance and message fatigue [8,9]. Moreover, the use of user-generated content exponentially increases the pool of candidate messages, which allows for the tailoring of message content, frequency, and timing to users' needs. This is particularly true for technology-based smoking cessation interventions, where the capture of time-varying psychological, physiological, and contextual factors is increasingly feasible [54,55]. Our proposed approach of relying on user-generated content is applicable to practically all health conditions and behaviors with relevant publicly available online content, including addictive and lifestyle behaviors [56,57].

Comparison to Prior Work

User-generated content includes elements of effective health messages, including its brevity and narrative-like nature, which can improve message persuasiveness and effectiveness in promoting behavior change [30,31]. Indeed, our participants attributed the usefulness of user-generated content to its realism and role-modeling from others who have attempted to quit, successfully or otherwise. For example, one participant noted their aversion to "computer-generated" messages (P11), whereas another noted how these messages could improve self-efficacy, saying that "if someone else can do it, maybe...you can do it too" (P21). These positive perceptions may also reflect involvement with message creators and trust in the health information provided as personal stories by those perceived to be similar to them and with firsthand experiences [27,29,58]. Evidence shows that peer messages and emotional and narrative content have been used to effectively treat nicotine dependence and are associated with greater engagement with tobacco cessation interventions [32,59]. Notably, tweets are similar in length to SMS text messages, which have proven successful as smoking cessation interventions [60]. While user-generated content has been shown to influence nonhealth decision-making (eg, purchasing decisions) [61,62], future research should examine its persuasive effect on health behaviors, identify mechanisms of its effect (eg, self-efficacy and perceived norms), and compare its effectiveness to other content generation approaches (eg, expert-crafted messages and artificial intelligence conversational agents or chatbots [63]).

Open-source content negates message fatigue associated with message repetition [8,9]. A typical smoking cessation intervention is 6 to 8 weeks long and includes a fixed number of support messages (eg, the National Cancer Institute's SMS text messaging intervention SmokefreeTXT) [64]. An intervention recipient is bound to receive the same messages during the intervention once they have exhausted the number of messages dedicated to a particular purpose (eg, craving support). Furthermore, individuals who smoke often attempt to quit several times before they are successful [65]. This means that they will be exposed to the same messages if they reset their quit day or re-enroll in an intervention. Additionally, tailoring messages to individuals' characteristics and time-varying factors as they undergo an intervention quickly becomes a challenge [66]. This could be one of the reasons why many smoking cessation interventions use only basic tailoring strategies (eg, addressing an intervention recipient by their name) [67]. A large pool of candidate smoking-related messages curated from Twitter or other platforms can facilitate tailoring of intervention message content.

Our results show that the appeal of user-generated content as a source of cessation support messages was dependent on message content and attributes. Participants generally preferred positive messages over those perceived as sarcastic or ironic, consistent with previous research [68]. Furthermore, perceptions were mixed on messages that focused on the adverse health effects of smoking. These discussions reflect debates on the use of fear appeals (ie, messages that include a threat) and gain- versus loss-framed messages (ie, messages that emphasize benefits of compliance with message recommendations or losses associated with noncompliance, respectively) in health interventions [69,70]. There is evidence suggesting that fear appeals can be effective in promoting smoking cessation [71-73], including among individuals with low SES who smoke [2]. It is noteworthy that the persuasiveness of a message depends on various factors, such as the behavior in question (eg, one time vs repeated and prevention vs detection), audience

XSL•FO
RenderX

characteristics (eg, readiness for change), and other message elements (eg, inclusion of self-efficacy statements). For example, evidence shows that gain-framed messages can be slightly more effective in promoting some preventive behaviors, including smoking cessation [74,75]. Additionally, there are unintended and ethical consequences of fear appeals and loss-framed messages and questions about their long-term effects on behavior [76]. Taken together, feedback from our participants and existing literature suggests a need to identify the underlying theoretical concepts conveyed in user-generated messages and investigate the effect of different types of user-generated messages on behavioral outcomes at various stages of a smoking cessation intervention.

Participants' suggestions centered on message attribution and content and the frequency and timing of push messages. They emphasized the appeal of attributing the messages in Quit Journey to their actual authors. This is consistent with research showing that message source can increase trust and operate as a cue to persuasion and attitude change [27,77]. Relatedly, participants noted the need for the messages to be authentic and human-authored, suggesting that the tweets retain their conversational tones and even grammatical errors. Finally, participants emphasized the need to tailor message content to personal and dynamic factors [66,78,79]. For instance, participants suggested several tailoring factors, including cravings, mood, and stage of quitting. Furthermore, participants suggested that, on average, they would be open to receiving up to 3 daily push notifications but preferred to have the ability to customize the frequency and timing of these messages. While these requests are common [80], they defeat the purpose of just-in-time support [10]. A compromise could be to allow users some control over the number of daily messages they want to receive and giving them options to customize other aspects of the intervention (eg, app aesthetics).

Strengths and Limitations

To our knowledge, our approach to curating publicly available user-generated content in a smoking cessation mobile intervention (and in health interventions generally) is the first of its kind [22,54]. In this study, we demonstrated initial acceptance of this approach among the target population of our smoking cessation intervention, Quit Journey. Study strengths include a diverse group of participants, with no more than 50% being from one race and/or ethnicity. Limitations include the reliance on educational level as a sole indicator for SES [39-41]. The focus groups were held virtually due to the COVID-19 pandemic, which may have impacted engagement in discussions. Additionally, the pandemic had mixed effects on smoking behaviors [81], which consequently could have affected participants' perceptions of our smoking cessation mobile app and its components, including the proposed user-generated message library to support smoking cessation. Participants were only shown 5 example tweets, which were not representative of the wide range of smoking-related tweets that could have elicited different reactions from participants. Furthermore, because the message library and just-in-time support features of Quit Journey were still under development, participants were presented with mock pages with placeholder messages. Participants were not representative of all individuals who smoke, such as older individuals, some of whom may not be as receptive to social media content as the young adults in our study [82]. Finally, due to scheduling conflicts, focus groups had unequal numbers of participants.

Conclusions

This study provided evidence of the acceptability of user-generated content as a source of support messages in smoking cessation interventions. Implementing this new approach to developing health messages requires additional research to select and evaluate user-generated content with the target audience before these messages are integrated into a behavioral intervention. Although we focused on smoking cessation, our proposed approach to health message development can be applied to other health conditions and risky behaviors to accommodate increasing needs for content-diverse, relatable, and short messages that can support individual users and their dynamic needs during behavior change.

Acknowledgments

ICF International's services for this study were performed under the support of the National Institute on Minority Health and Health Disparities through contract 75N91019F00132 with the National Cancer Institute. The National Cancer Institute had no input on the development of Quit Journey or its features or on study conceptualization or data analysis and interpretation. The efforts of MW, LT, and SE-T have been supported by the Division of Intramural Research of the National Institute on Minority Health and Health Disparities. Charmaine Chan, Kristyn Kamke, and Zahra Ansari reviewed the transcripts against the audio files. Rahaf Zaza extracted quotes in an exploratory phase of the analysis.

Funding

This research is supported (in part) by the Intramural Research Program of the National Institutes of Health (NIH; ZIAMD000011). The contributions of the NIH authors are considered works of the United States Government. The findings and conclusions presented in this paper are those of the authors and do not necessarily reflect the views of the NIH or the US Department of Health and Human Services.

Data Availability

All data generated or analyzed during this study are included in this published paper and its supplementary information files.

Abstract

Background: In rural Australia, geographical isolation, limited resources, and complex health care navigation create significant barriers to mental health care access. Mental health care professionals and organizations often work in segregation, exacerbating existing barriers. Digital technology provides an opportunity to improve communication between providers and streamline workflows while supporting a diverse range of consumers.

Objective: This co-design study aimed to identify rural community needs and explore digital solutions to enhance mental health service delivery pathways.

Methods: Using a design-thinking methodology, we conducted focus groups and workshops with 17 participants (7 consumers and caregivers and 10 health care professionals) from a rural region to understand mental health service needs, systemic challenges, and design potential digital solutions. Thematic analysis followed a grounded theory approach, involving systematic coding and theme development through an iterative consensus process.

Results: Access to mental health care emerged as the central theme. Rural community participants reported strong community connections but faced challenges, including limited technological innovation and substantial travel burdens. Health care professionals highlighted critical systemic pressures: underresourcing, overwhelmed clinicians with extensive waitlists, and complex referral processes. Both groups identified overlapping barriers in service limitations and system navigation. During the design phase, we developed personas capturing consumer and health care professional experiences and conceptualized an integrated digital solution comprising a health care professional dashboard and a consumer-facing app with caregiver access to enhance service coordination.

Conclusions: The study demonstrated strong stakeholder support for implementing an integrated digital solution to enhance rural mental health service delivery. Further research is required to build upon the solution prior to testing, optimizing, and scaling.

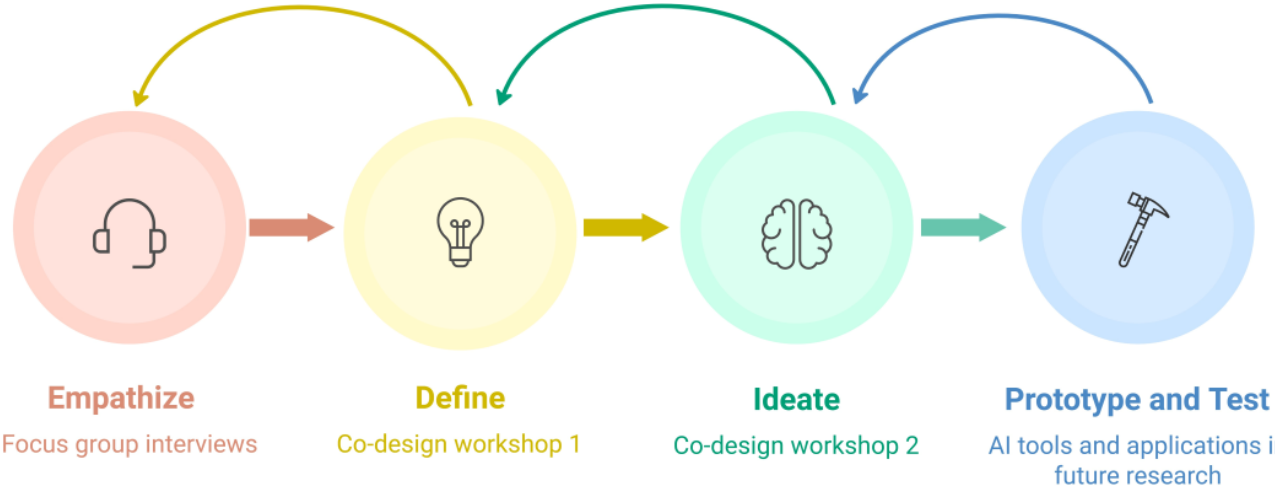
Introduction

Mental health burden has significant economic and social impacts [1], particularly in rural areas [2,3], which typically have fewer trained professionals, limited services, and less service innovations compared to metropolitan areas [3-6]. In Australia, 7 million rural residents face substantial barriers to mental health care access. These obstacles include fewer resources, limitations in technology, lack of knowledge of services, distance to services, and a deficiency in culturally sensitive practices [7], with complex and often ineffective treatment pathways [3].

General practitioners (GPs), as the primary contact for mental health support [8,9], face considerable challenges when connecting patients with appropriate mental health care, primarily due to time constraints in determining suitable referrals and limited availability of services in rural communities [10,11]. Adding to the complexity, service availability, fee structure, and communication methods vary between providers and change frequently, reflecting poor integration between services. This exacerbates the problem caused by inefficiencies and complexities in the health care system, decreasing the efficiency of care provision and inadvertently resulting in potentially less effective care [2].

The Australian government has provided the Initial Assessment and Referral Decision Support Tool (IAR-DST), a clinical decision support tool to assist with mental health care level determination. While IAR-DST determines care need, clinicians require additional support to rapidly identify suitable local providers and optimize referral processes [12]. Without such support, rural GPs may struggle to initiate the right referral on their first attempt where limited service availability already constrains their options. This may lead to rework, delayed treatment, and patient disengagement [13]. Moreover, many rural Australian people forgo seeking support altogether due to the difficulties in accessing GPs, so the importance of getting the referral processes right on the first attempt is even more imperative [10].

Digital referral platforms could augment existing assessment tools by automating provider matching and streamlining referral workflows [14]. Such systems show promise in reducing administrative load while supporting culturally and linguistically diverse consumers, for example, through better matching of services and more informed options [15]. However, their utility in rural Australian settings remains unexplored. Awareness of the needs and context of the community, what resources are available, and how their systems operate is invaluable [5,8]. Thus, to explore whether this could be a useful strategy, the community in which it would be implemented must be involved in the co-design process.



The primary aim of this formative study was to explore digital solutions for mental health care referral pathways in a rural community using participatory and human-centered design-thinking methods. Specifically, this study explored if the rural community wants a digital solution for mental health referral pathways, how it would be useful, and who would benefit.

Methods

Study Design

Participatory and human-centered design-thinking methodologies informed the structure and approach for all participant activities (Figure 1). Design-thinking methodology is an iterative, user-centric process that aims to create a solution that is desirable, feasible, and viable [16] to end users, stakeholders, and the supporting infrastructure. Accordingly, consumers' and health care professionals' lived experiences, preferences, and needs are prioritized to develop a technological solution to improve referral efficiencies in rural communities.

Figure 1. Participatory and human-centered design-thinking methodologies (adapted from NNGroup: Design thinking 101). AI: artificial intelligence.

Design-Thinking Methodology

Design-thinking phases were reflected in the study design:

1. Empathize: Semistructured focus groups with consumers and health care professionals to develop a deep understanding of the rural community needs.

XSL•FO
RenderX

2. Define: A workshop to start the co-design process with combined consumer and health care professional input to prioritize the pain points in the mental health care system.
3. Ideate: A second workshop with consumers and health care professionals to brainstorm possible solutions.

Setting

The study took place in the Riverland, South Australia, which is a small, rural region with a high level of rurality (Modified Monash Model 5), which entails considerable geographical remoteness and smaller population sizes. The Riverland area represents a typical low-resourced and low socioeconomic rural context with a Socio-Economic Indexes for Areas score of 996.8, indicating a level of socioeconomic conditions that falls below the national average.

Participants

Consumers were recruited through researcher and clinician networks and included those with lived experience of mental health issues and formal or informal caregivers of people who experienced mental health issues. To be eligible to participate, consumers needed to be 18 years of age or older and have interacted with a health service regarding their mental health, or the mental health of a person they cared for, within the past 24 months. Health care professionals were recruited using purposeful sampling. Those who worked in the Riverland region in South Australia and had experience working with mental health consumers in the previous 24 months were invited to participate. The services approached included all public health sites, private mental health services, nongovernment organizations (NGO), charities, and Aboriginal services. Prospective participants were contacted via email or telephone and informed of the nature and purpose of the study, prior to consenting.

Ethical Considerations

This project was approved by the Department of Health and Wellbeing Ethics Committee (2023/HRE00227) and the Aboriginal Health and Research Ethics Committee (04-23-1104). All participants provided written consent prior to their inclusion in the study and were remunerated for their time according to South Australian Health Department guidelines. Participants' data were deidentified and stored on a secure electronic server.

Data Collection

Data collection occurred from June to September 2024.

Empathize: Focus Groups

All focus groups followed a semistructured format as provided in Multimedia Appendix 1. Consumers (n=7 - 10) participated in two 90-minute, face-to-face focus group discussions that were facilitated by experienced coinvestigators (KP and SL), including a lived experience representative (SL). The first session explored past experiences with mental health care and expectations of mental health management. The second focus group discussion explored current digital engagement behaviors and willingness to explore digital solutions. Health care professionals (n=7 - 10) participated in two 60-minute focus group discussions conducted on the web (via Microsoft Teams) with the same facilitators. The first session explored the coordination of care and navigation across the mental health system. The second focus group discussion centered on experiences with technology as a solution and willingness to explore further a digital solution.

Following the completion of the focus group interviews, all participants were invited to participate in two 3-hour face-to-face design workshops. The workshop was facilitated by 2 external design-thinking experts. A consumer representative from a consumer and caregiver mental ill-health advocacy group (SL) and members of the research team with a background in psychology or focus group research assisted (KB, AEM, and AMS). All face-to-face focus groups and workshops were held in a local hospital meeting room.

Define: Design Workshop 1

Participants were asked to choose from consumer scenarios presented (as outlined in the Results section). For each scenario, consumers and health care professionals worked together in groups (n=4 - 6) to map the key interactions that happen along the consumer mental health "journey." Following the mapping process, these interactions and timelines were discussed with the entire group to fill in any gaps and highlight barriers in the system (pain points).

Ideate: Design Workshop 2

Key journey moments across the scenarios in workshop 1 were prioritized for conversation in workshop 2. Using these "key moments," the room was split into 2 groups (1 group of consumers and 1 group of health care professionals). Each group discussed the pain points in the referral pathways and identified possible technological solutions. Following these small group discussions, the core pain points and technological solutions were discussed with the entire group. Following on from earlier conversations, participants were provided with a scope to focus on interactions between using mobile phone apps and health care professional–facing dashboards.

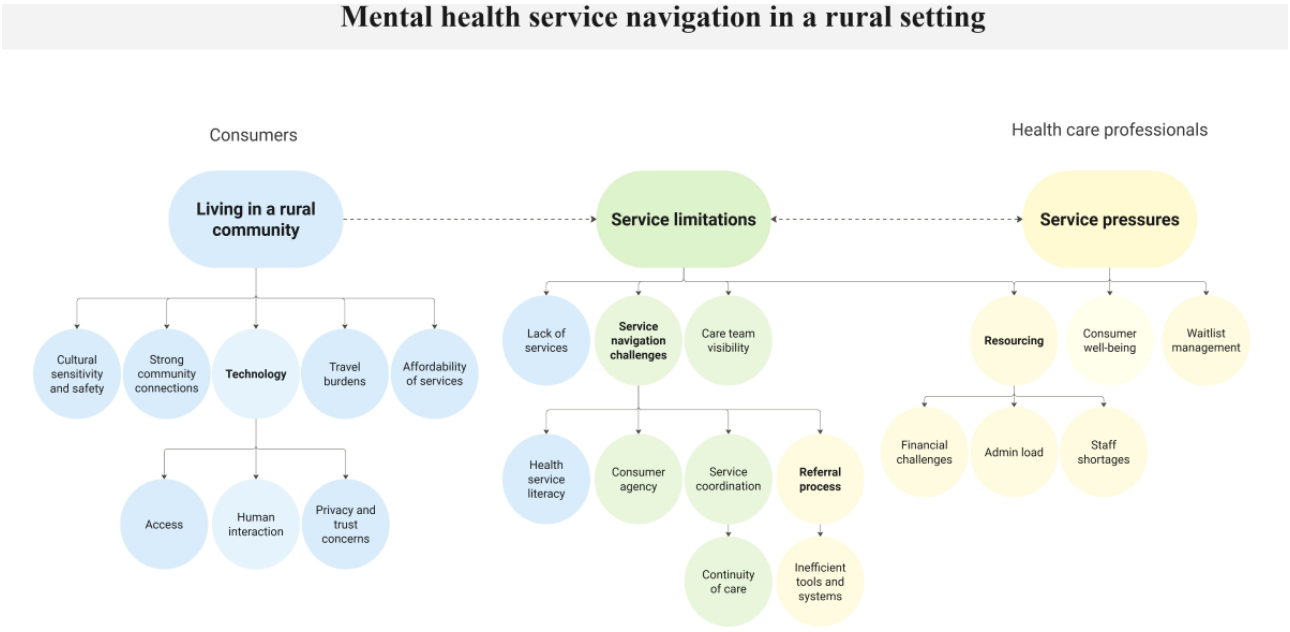
Data Analysis

Focus groups were recorded, transcribed, and deidentified. Field notes were written by AMS and KB. Data were thematically coded using qualitative analysis software NVivo (version 14; Lumivero), guided by a grounded theory approach. The thematic coding process was managed by AMS and KB, in discussion with AEM, BP, and SL. Open coding was performed by AMS and checked for accuracy by KB, with any discrepancies discussed and resolved through consensus. Axial and selective coding were subsequently conducted by AEM, AMS, BP, KB, and SL [17]. Saturation of data was discussed (ie, no new themes were being generated by the data). Themes and subthemes were finalized by AEM, AMS, BP, KB, and SL. This study followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) reporting guidelines, ensuring transparency in reporting researcher reflexivity, study design, and data analysis (Checklist 1) [18].

The iterative process of design-thinking methodology was implemented throughout the study, with data collected and analyzed in each phase to advise the next phases of data collection. Participants were provided with a verbal summary

XSL•FO
RenderX

of previous session content, at the commencement of the session, and given the chance to comment or provide correction. Preliminary analyses of the focus groups were discussed with the research team, and external user-experience designers advised on the planning of co-design workshop 1. Participant outputs were digitally collated, and user personas were developed. User personas are a fictional representation of real-life users who share common characteristics, behaviors, goals, and pain points [19,20]. This effectively narrows down the intended users of the platforms and creates a more targeted approach, reflecting the "define" stage of the design-thinking process. Moreover, it creates a more detailed representation of the consumers to inform effective and targeted design decisions while maintaining the anonymity of the real study participants and reflecting their experiences accurately. Insights from co-design workshop 2 were similarly digitized and analyzed to identify key themes, which were then grouped to uncover opportunities. These opportunities were mapped back to the user personas to ensure that the solutions created serve the user.



Results

Overview

A total of 7 consumers and 10 health care professionals participated in focus groups and design workshops. In total, 10 consumers were contacted; 2 were unavailable, 1 did not attend, providing no notice, and 7 participated in at least 1 focus group or workshop. A total of 15 health professionals or organizations were contacted. In total, 3 professionals were unavailable, 2 did not return contact, and 10 attended a minimum of 1 focus group or workshop. Health care professionals included a psychiatrist, GPs (n=2), a clinical psychologist in private practice, NGOs and nonprofit managers (n=2), mental health nurses (n=2), and an Aboriginal nurse unit manager. Of the consumers, 5 had experienced a mental health issue, and 2 cared for someone with a mental health issue in the previous 24 months. One of the 2 Aboriginal consumers was an Aboriginal Elder.

The unifying theme identified across consumer and health care professional focus groups was "access to mental health care in a rural community." A coding tree displays an overview of the main themes and subthemes identified from the focus group discussion (Figure 2), with example quotes provided in Table 1.

Figure 2. Coding tree of the main themes and subthemes identified from the focus group discussions.

XSL•FO
RenderX

Table . Themes and subthemes from focus groups.

Themes and subthemes	Quotes
Theme 1: living in a rural community (consumer identified)	
1.1. Cultural sensitivity and safety	• "I heard a whisper, they're getting a morgue up here. I don't know how true this is. But they want to know how to make it culturally appropriate. So they're getting someone from Adelaide to come up here to tell us" [Consumer 2].
1.2. Strong community connections	• "We are just one really, really big family" [Consumer 4—in relation to community group members in the Riverland].
1.3. Travel burdens	• "Sometimes it's transport because that's terrible up here" [Consumer 1—assisting people with mental health support].
1.4. Affordability of services	• "Clients don't have money to pay to see a GP" [Health care professional 1].
1.5 Technology	
1.5.1. Access	• "But I'm happy to use my phone. Get my SMSs when I've got appointments, they text me say your appointment" [Consumer 4]. • "A lot of people who use our services don't have smart phones. Or if they do, they have very limited capabilities and often don't have access to internet" [Health care professional 2]. • "I don't know how to use a computer. But I know how to use my phone" [Consumer 4].
1.5.2. Human interaction	• "I'd rather stand in a line at a grocery store rather than using the checkout because I like face-to-face contact" [Consumer 3—regarding worries about using technology]. • "The least human interaction I can have sometimes, the better. If my social battery is full, empty actually, I'll opt for that" [Consumer 5 regarding a fuel app that allows users to pay from their phone at the bowser].
1.5.3. Privacy and trust concerns	• "Could this not just be—instead of, 'How's your Wednesday been? Let's write this. What are your good thoughts, bad thoughts, gratitudes. Something to work on tomorrow.' Instead of it being so invasive, could it not be a basic K10 every three weeks? Or just a check-in every so often to see how you're travelling, instead of being an every single day thing" [Consumer 5].
Theme 2: service limitations (consumer and health care professional identified)	
2.1. Lack of services	• "Up here, if you need to get referred onto any specialist service, like a psychiatrist or a psychologist. They're just not available and you just can't make an appointment with one" [Consumer 1]. • "Specialist services not being available in Riverland" [Health care professional 6—in relation to the biggest pressure point they face in the Riverland with mental health services].
2.2. Care team visibility	• "It would be helpful to know who is part of this client's care team" [Health care professional 1].
2.3. Service navigation challenges	
2.3.1. Health service literacy	• "I'm still not aware of all the services here or what's available" [Consumer 3].
2.3.2. Consumer agency	• "The person's got to make a choice. It has to be their choice" [Consumer 1]. • "Some sort of system that would involve the client, so that information that was being shared was accessible by the client and was maybe even directed by the client" [Health care professional 1].

XSL•FO
RenderX

Themes and subthemes	Quotes
2.3.3. Service coordination	• "It would be really helpful in terms of me then, if I could somehow use that system to communicate with their GP or other people in their team" [Health care professional 5].
2.3.3.1. Continuity of care	• "Not getting your own GP when you want to go and see the doctor" [Consumer 4].
2.3.4. Referral process	• "When you look at how many services are in town, I don't know what they all are. I don't know who's referred people to whom" [Consumer 1]. • "Yes and if they require an actual official referral" [Consumer 5 in response to Consumer 1].
2.3.4.1. Inefficient tools and systems	• "Depending on the GP, I find it varying levels of useful" [Health care professional 5—addressing referrals they receive from general practitioners]. • "The other thing is that when the clinician who's assessing the patient at the intake, if that assessment is just limited to a tool or is too superficial or is mostly looking at past records. Especially for risk assessment, then usually they get it wrong" [Health care professional 6].
Theme 3: service pressures (health care professional identified)	
3.1. Consumer well-being	• "A lot of clients are completely disengaged with mental health services, despite them being significantly unwell" [Health care professional 2]. • "I think it would be beneficial for lots of family and carers to be involved and have access to the apps, because they're obviously usually the first to know when people are deteriorating. It gives them resources too, how to navigate the step model of care for their person" [Health care professional 1].
3.2. Waitlist management	• "I find waitlist management really hard, because it's impossible for me to predict how long someone's going to need services for" [Health care professional 5].
3.3. Resourcing	• "This hospital's constantly bed blocked now. I work closely with [psychiatrist] and the on-call psychiatrist to determine whether community treatment would be more beneficial" [Health care professional 3].
3.3.1. Financial challenges	• "Or finances which is obviously what [Health care professional 6] has sort of alluded to as well" [Health care professional 4—in response to the biggest mental health service challenges faced].
3.3.2. Admin load	• "It's another administrative job that nobody wants to do" [Health care professional 1].
3.3.3. Staff shortages	• "Recruitment and retention of staff is a big one" [Health care professional 4—in response to the biggest mental health service challenges faced].

Empathize: Focus Groups

Overview

Consumer insights were primarily shaped by the experience of living in a rural community. Such experiences were underpinned by the effects of geographical isolation and lower population densities, often resulting in service limitations. These limitations may, in turn, stem from broader service pressures faced by health care professionals such as staff shortages and a lack of resources, contributing to the unique challenges faced by rural communities in accessing mental health care.

Living in a Rural Community

In spite of the challenges faced, consumers living in rural settings had strong community connections, describing themselves as "one really, really big family" (Consumer 4), feeling a sense of pride in residing in the country. Aboriginal participants echoed these sentiments by having support networks to care for those with mental health issues. Regardless of strong community connections, trust in health care systems was varied, with Aboriginal participants less likely to trust in health care systems. As an Aboriginal Elder observed: "That's where it's

XSL•FO
RenderX

different for Aboriginal people. The health system was where they stole kids" (Consumer 2).

Historically, Aboriginal people in Australia have faced systemic discrimination [21], leading to distrust in the health care system, underscoring the importance of cultural safety and sensitivity when developing the technological solution. Distrust in health care systems may also extend to distrust in technological products issued by these systems, as corroborated by consumers, regardless of Aboriginality. Lacking cultural and rural appropriateness, privacy, and data mishandling concerns may contribute to this varied trust.

When asked regarding the general experience of using digital technology tools, consumers raised concerns about accessibility, as some were unable to afford smartphones, phone credit, or had limited digital literacy.

Consumers reinforced that rural mental health services were harder to access due to affordability or geographic location, often requiring numerous visits to metropolitan Adelaide for specialist services. Of the services that were available in the Riverland, most were said to have long wait times, or consumers were not aware of their existence.

Service Limitations and Potential Solutions

Health care professionals and consumers voiced that available mental health services were hard to find and difficult to navigate for consumers in rural areas. Despite being a lifelong resident in the Riverland, a consumer was "still not aware of all the services here or what's available" (Consumer 1), and another reinforced that it would be helpful to "create some kind of a roadmap to the services" (Consumer 5). This lack of health service literacy may be a by-product of ineffective communication and coordination between mental health services, GPs, and hospital services. Participants identified that effectively increasing interservice communication can lead to a better continuity of care, improving mental health outcomes for patients.

Care team visibility and effective communication may assist in avoiding duplication of services, as "there's a lot of overservicing that happens in [the mental healthcare] space" (Health care professional 1), thus reducing workloads and service limitations. Consumers suggested that this may empower and encourage them to actively participate in their care while reducing the risk of confusion and misunderstanding. Consumers felt strongly regarding patient choice, having the necessary information to make an informed decision regarding their care. In this respect, the role of the caregiver was also emphasized by both consumers and health care professionals, as caregivers can advocate for patients when they cannot do so themselves. Caregivers are also "usually the first to know when [patients] are deteriorating" (Health care professional 1). Health care professionals respectively advocated for the consumers, valuing the importance of care "directed by the client" (Health care professional 1) and sharing information with the consumers.

Service Pressures and Potential Solutions

The predominant challenges and frustrations for health care professionals were categorized under the central theme of service pressures. Services were impacted by limited resource availability, which included a lack of finances for infrastructure and increased administrative loads due to staff shortages and attrition.

Most mental health services in the Riverland were characterized by prolonged waiting periods for patients, as providers were overburdened. Methods for the management of waitlists varied between health care providers. Participants suggested that if consumers were able to inform the health care service of their symptoms improving or worsening, health care professionals would be able to reprioritize consumers and better manage waitlists.

While both consumers and health care professionals agreed that displaying waitlists in the technology tool would be quite helpful, services would struggle to update waitlists regularly, as it would be the "first thing that slips when practices get busy" (Health care professional 1).

Health care professionals unanimously agreed that referral processes between services were underoptimized and "siloed" (Consumer 1), significantly impacting service delivery. Each service used varied processes and systems for referral and interservice communication, and most relied on inefficient and archaic tools such as fax machines: "It can actually delay consumer care because the fax might not be working, or got rejected" (Health care professional 3).

All health care professionals except 1 were unfamiliar with the IAR-DST, preferring practical, more familiar tools that allow flexibility in clinical judgment. Clinician discrepancies in tool use were often not visible to other health care professionals, impacting the efficiency of the referral process. In a similar vein, out-of-date waitlists and service directories place pressure on GPs to efficiently refer patients. For developing the technological solution, health care professionals prioritized consumer advocacy and recognized the importance of addressing consumer pain points in improving service provision.

Define: Design Workshop 1

Overview

Workshop 1 was conducted with mixed groups of health care professionals and consumers. Based on the preliminary insights from focus groups in the empathize stage, the following consumer scenarios were developed.

1. An older person living alone in an isolated rural location with limited family support, moderate mental health challenges, and no internet access.
2. A young adult living and working in town with severe mental health challenges requiring frequent journeys between metro services and rural community support services.
3. A single parent with mild mental health challenges living rurally and accessing GP and NGO supports.
4. A young person attending a rural high school, accessing services and supports following an acute mental health admission at the local hospital.
5. A farmer living on a rural property, experiencing isolation and hesitant to seek support for his mental health challenges.

XSL•FO
RenderX

Participants chose scenarios 1, 2, and 3 for the journey mapping exercise. Each step of the consumer journey was mapped with the current channel that the consumer engages in, the value of this interaction, the software capabilities to replace or augment, the value that could be added from this augmentation, and the outcome for the consumer.

Scenario 1

An older person living alone in an isolated rural location with limited family support, moderate mental health challenges, and no internet access.

The role of the caregiver was particularly stressed in this scenario due to the consumer's limited access to technology. All participants agreed that the caregivers should be given access to the technological solution at the discretion of the consumer. The caregiver will thus be able to facilitate consumer care through the digital tool.

Community support groups, or another trusted person, were proposed to facilitate mental health care support for consumers when a caregiver was unavailable. This was particularly pertinent for some Aboriginal consumers and those of a lower socioeconomic status, who may lack smartphones or internet access. Conversely, SMS text messaging through basic mobile phones appeared to be more readily available and accepted across the population. By incorporating an SMS text messaging feature into a clinician platform, accessibility may be enhanced for individuals with limited technological literacy or low socioeconomic backgrounds.

Scenario 2

A young adult living and working in town with severe mental health challenges requiring frequent journeys between metro services and rural community support services.

Current channels for patient-mental health service interactions were identified to be initial care visits (GP, hospital admissions, and community mental health groups), crisis services, specialized services, telehealth appointments, potential police contact, and ongoing support groups. Participants valued positive relational interactions in these channels, specifically feeling safe, respected, and avoiding behavioral stereotyping from decision makers such as law enforcement and doctors, as it can lead to inappropriate care.

Consumers and health care professionals reiterated that navigating the health care system with available services was overwhelming and confusing. Moreover, health care professionals acknowledged that patient handovers were inadequate, particularly between metropolitan and rural services. To address this, real-time information sharing, such as discharge summaries between services in the dashboard, was suggested.

Trust and privacy issues were identified as potential concerns for the clinician dashboard and consumer app. Both consumers and health care professionals emphasized the importance of data encryption to protect the transfer of sensitive patient data between services. Including the consumer in the care team ecosystem was suggested to entrust the consumer with handling of their own information, giving the ability to share or unshare data with selected providers.

Scenario 3

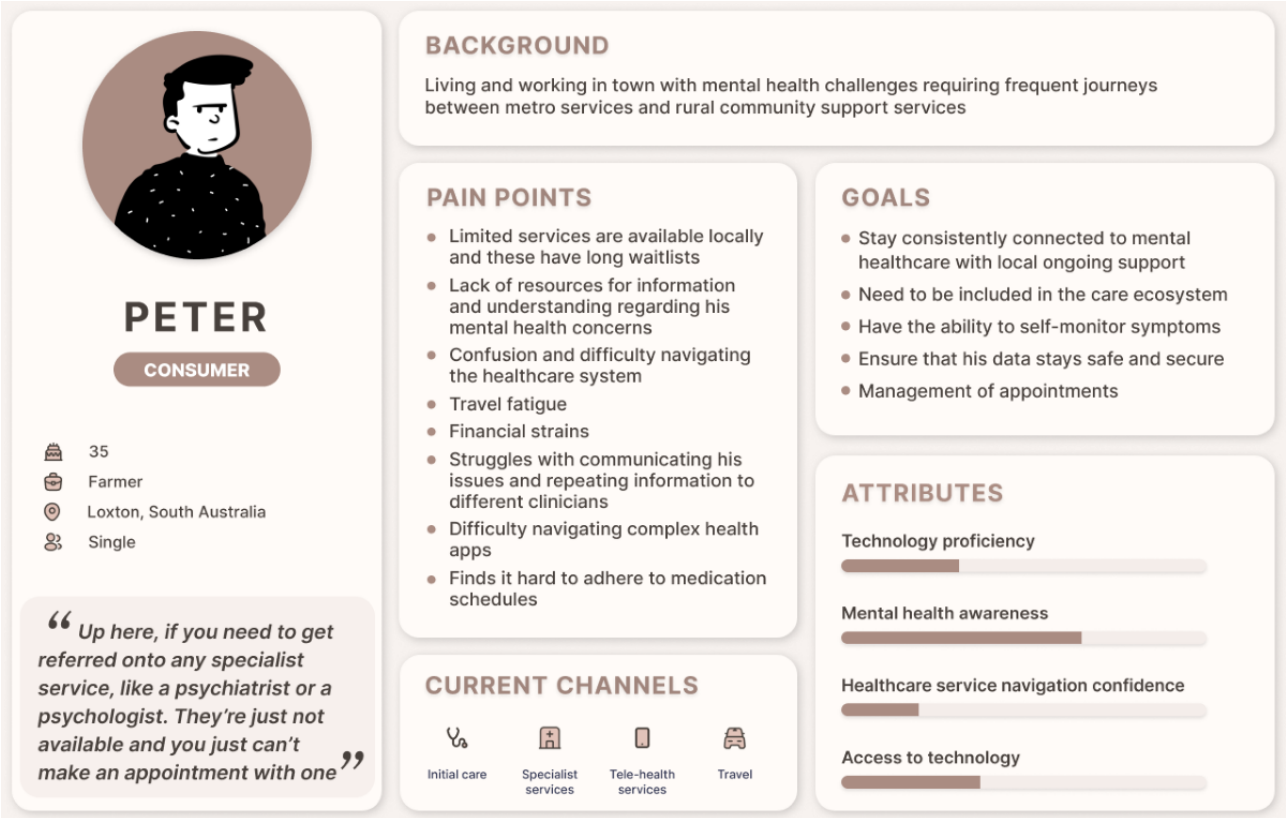
A single parent with mild mental health challenges living rurally and accessing GP and NGO supports.

Participants reaffirmed that navigating the available services in the Riverland was overwhelming, advocating for a centralized directory of services in the digital tool with customization specific to the user and their mental health requirements. The potential user in this scenario was presumed to have hectic schedules, leading to missed appointments or medications. To combat this, participants proposed the software to embed a medication and appointment management system that consolidates and integrates the user's existing apps to prevent software fatigue.

User Personas

Informed by the insights derived from the 3 scenarios, the following user personas were developed (Figures 3 and 4): "Anna," a health care professional persona, and "Peter," a consumer persona.

Health care professional persona "Anna" was structured around a GP, as this is often the initial point of contact for mental health care in Australia [22]. One of the biggest challenges in mental health care quoted by a clinician (Health care professional 6) was the lack of specialist services in the Riverland. Health care provider bottlenecks and frustrations presented previously are consolidated under pain points: inefficient referral processes, lack of communication between services, underresourcing, and difficulties in maintaining patient well-being. The desired outcome for Anna is to ultimately improve patient care by coordinating with other services effectively. The attribute scale displays Anna as proficient in technology, care coordination as poor, service navigation confidence as moderate, and time management as poor. Technological channels for providing care entail electronic health record systems and general practice software, telehealth services, and patient communication through mobile devices and email.



Consumer persona "Peter" was framed around scenario 2. Similar to health care professionals, access and availability of specialist services were quoted to be a pressure point by a consumer (Consumer 1). An amalgamation of consumer issues raised in focus groups and scenarios and pain points underscores rural access issues such as service access, long waitlists, and service navigation. Peter envisions more consumer-driven care and better support throughout his mental health care journey. The attribute scale presents technology proficiency as low, mental health awareness as moderate to high, health service navigation as poor, and access to technology as moderate. Peter's current channels for accessing care include a GP for primary care, traveling for specialist services, and telehealth services for potential ongoing care.

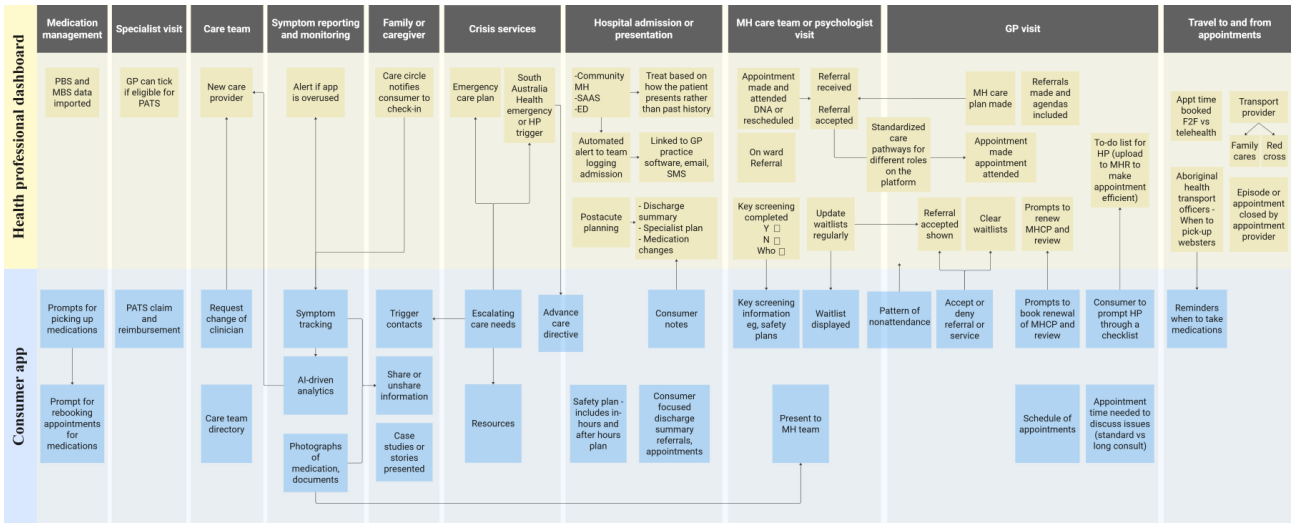
Figure 3. Health care professional persona “Anna”.

Figure 4. Consumer persona “Peter”.



Ideate: Design Workshop 2

The content of the personas was used to guide participant discussions in workshop 2 and ensure that consumer and health care professional goals were kept central, and ideated solutions were addressing respective pain points.

XSL•FO
RenderX

Co-design workshop 2 iteratively revised bottlenecks in prior phases and generated possible solutions through an interaction map between the proposed clinician dashboard and consumer app (Figure 5). An overarching theme of "communication" was identified across the clinician and consumer journey. It was considered essential for health care professionals to be able to easily communicate with each other, and for the consumer's journey to be easily visible, within the constraints of privacy and confidentiality. Health care professionals articulated the desire for consumer-specific information (eg, referrals made to other agencies) as well as generic organization information (eg, requirements for valid referrals), relevant to the consumer they are seeing, to be made clearly accessible. Likewise, communication was a key aspect of consumer agency, both for consumers being aware of their options and being able to communicate required information to their health provider, even if that was prompted via an app and discussed in a session. Participants also provided personal reflections of the study and its aim, ultimately affirming their support for a consumer-facing app and a health care professional–facing dashboard.

Figure 5. Interaction map outlining communication pathways within and between a health professional dashboard and consumer app. AI: artificial intelligence; DNA: did not attend; ED: emergency department; F2F: face to face; GP: general practitioner; HP: health care professional; MBS: Medicare benefits schedule; MH: mental health; MHCP: Mental Health Care Plan; MHR: My Heath Record; PATS: patient assistance transport scheme; PBS: pharmaceutical benefits scheme; SAAS: South Australia Ambulance Service.

Prototype and Test

Low-fidelity prototypes were developed by the research team based on ideated solutions and re-evaluated using the personas. These displayed key interactions between the consumer app and the health care professional dashboard. The main features will be applied and tested in the future include but are not limited to the connectivity between platforms used by different providers, self-assessment and patient assessment tools that are required for referral and monitoring processes, medication management, social network building, transport, and telehealth options.

Discussion

Principal Findings

The core purpose of this study was to initiate co-designing a digital platform with consumers and health care professionals, which may enhance referral processes and service navigation in rural mental health care. Three core themes emerged, which include (1) consumers identifying that "living in a rural community" has both positive aspects (strong community bonds) and negative challenges (access to technology and innovation); (2) health care professionals highlighting "service pressures" such as waitlists, consumer well-being, and resourcing; and finally, (3) both consumers and health care professionals identifying "service limitations," such as navigation challenges and issues around an inefficient referral process. The human-centered technological solution that was explored in the workshops highlights the need for "communication" to integrate the consumer, caregiver, and providers, marking a critical step toward optimizing rural mental health care.

In this study, consumers highlighted both challenges and positive aspects of living in a rural community. Struggles included limited access to mental health services, often requiring travel to metropolitan locations for necessary care. Despite these challenges, rural consumers were often mentioned to be supported by dedicated caregivers and benefited from strong community bonds, especially among the Aboriginal population. These findings are consistent with prior studies [7] that identified barriers such as limited resources and distance to services while also highlighting the importance of person-centered and collaborative care. Thus, a key implication for future iterations of the prototype is to integrate community-based support systems to reduce strain caused by remoteness. Participants in this study further mentioned the importance of integrating other health services and community groups into the platform. While this is important for delivering a holistic service, it is outside the scope of this study and requires further investigation of limitations such as data sharing barriers. Future research could explore opportunities to integrate health services, providing additional support to consumers.

Rural health care professionals in this study faced pressures of underresourcing and access challenges. Similar to previous research [23], this resulted in mental health care systems that

XSL•FO
RenderX

were overly complex, impacting health care professionals in coordinating care and consumers in navigating the required care. Our study showed that both providers and consumers deemed the current referral processes to be inefficient due to a lack of care coordination and limited communication between services, exacerbated by existing rural service limitations [7]. Participants in this study supported the view that a dashboard for health care professionals could address these referral inefficiencies by integrating referral tracking, communication tools, and standardizing or displaying referral processes for various services. Participants also agreed that a consumer-facing app complements the dashboard by offering consumers the agency to input information for their care team and displaying real-time service updates. An app could also allow for a consumer-nominated, trusted community member to access particular information, for example, appointment times. Thus, transport to appointments could be facilitated if the consumer is unable to take themselves. Although the digital platform may not directly resolve resource constraints, it is likely to reduce administrative loads for health care professionals, enhance care coordination, and provide a more consumer-centered approach to mental health care by improving the accessibility of services for consumers [24]. This could also afford a flow-on effect, whereby practitioner burnout is decreased and retention is improved. In particular, in rural locations where GPs take on a high proportion of mental health cases, easy, appropriate referral could reduce compassion fatigue and burnout [8].

Prior studies have explored the use of digital platforms to improve service navigation [15] and potentially improve communication among providers [25,26]. However, these platforms did not integrate well with existing infrastructure used by clinicians; thus, they resisted uptake [27]. Furthermore, many of these solutions were designed for urban settings and do not resolve the challenges faced by rural consumers and providers. Rural Australia, compared to metropolitan areas, has fewer public mental health systems [28] but a higher prevalence of private organizations that often operate in isolation. The health care professional dashboard could enable communication with these private organizations and public systems, facilitating care coordination. Thus, this study distinguished itself by its focus on a rural community. This uniquely positioned the study to co-design a platform to improve rural mental health referral pathways. Due to the location, there were fewer services to coordinate than a metropolitan region; yet, the population could benefit substantially from a platform that decreases the sometimes wastefully siloed service provision and enhances communication between service providers, consumers, and their care teams.

Strengths and Limitations

A key strength of this study lies in its participatory approach, engaging both consumers and health care professionals in the design process, ensuring that the digital platforms developed are grounded in real-world experiences [29] and tailored to the unique challenges of rural mental health care. By using design-thinking methodology, the prototyped solutions are human-centric, contextually relevant, and functional [16]. The percentage of Aboriginal participants employed in this study was representative of the community demographics; however, further in-depth Aboriginal input is needed prior to implementing the solution. This study was also limited by its total number of participants. While this is reflective of a pilot study, it may also limit the generalizability of the findings to broader contexts; thus, future studies with a greater number of participants are necessary to further prototype the provider platform and consumer-facing app in continued consultation with end users. This includes testing the feasibility and acceptability and determining which cohorts would benefit most. Furthermore, the solution should be tested in other rural Australian regions to assess scalability.

Conclusions

The proposed human-centered technological solution aims to integrate the consumer, the caregiver, and the provider, marking a critical step toward optimizing rural mental health care. The co-design process empowered consumers to actively engage in their mental health care journey while suggesting options to streamline system inefficiencies for overburdened clinicians. Ultimately, this platform may not only improve patient well-being and satisfaction but also boost the morale and retention of rural mental health professionals—a critical factor in addressing the current workforce shortage. Importantly, designing a solution in collaboration with rural communities may help to ensure a trusted, sustainable, and scalable implementation [29] in the future.

Acknowledgments

The authors acknowledge the contributions of DC, who passed away before the publication of this manuscript. The study was produced with the financial and other support of the Health Translation SA (HTSA) Medical Research Future Fund Catalyst Grant Scheme, led by HTSA, and supported by The Hospital Research Foundation Group.

Authors' Contributions

KB and AEM were involved in the conceptualization, methodology, data collection, data analysis, and writing the manuscript. Abstract

Background: There is an increased focus on involving members of the public in health research. These types of groups, such as "health consumer groups," bring different expertise to inform the design of a research study. There is a growing general concern about older adults' acceptance and use of technologies. This becomes critical when it involves health care services.

Objective: To understand the use of social robots among older adults, it is prudent to gauge stakeholders' perspectives on optimal research design. In line with the philosophy of the "triple helix model," researchers sought the expertise and guidance of a health consumer group.

Methods: Researchers recruited an expert health consumer group for this study. This included 5 participants from an 8-member panel. Semistructured interviews were conducted. Each interviewee was introduced to visual stimuli of assistive technologies, older adults, and social robots. Subsequently, they were asked for their perspectives on what they viewed and to provide guidance on how to best design upcoming research on these phenomena.

Results: Key themes were derived from the interview transcripts with the health consumer group members. Findings include panel members' advice and guidance on explaining the research aims to technology-averse older adults, approaching data collection from this demographic, and, finally, their perceptions of the appearance of social robots.

Conclusions: The advice and guidance of this expert health consumer, in tandem with researchers and industry partners, substantially aid in advancing research efforts toward social robot use among technology-averse older adults in Australia. This research provides vital information, including how best to approach data collection about social robots from this demographic.

Introduction

Health Consumer Groups

A health consumer group, also called the consumer council, is a platform that brings together community members to provide health care–related consumer views, opinions, and experiences to help guide research projects and to disseminate research findings among the community [1]. A "consumer" is a receiver or a potential receiver of health care services. However, other terms are also used to describe health care recipients, laypersons, users, service users, patients, and clients [2].

There is an increased focus on involving differing perspectives from the public domain in developing health-specific interventions [3]. This involvement of public representatives enables a broad range of differing ideas, perspectives, and resolutions to be brought forward [1]. Such public involvement is advocated for governing boards [4], social care [5], and consumer research [6]. It is recognized that the expertise of members of the public is unique and is different from possessing professional skills [7]. Consequently, this enables various stakeholders in the health care sphere to have their perspectives incorporated, enabling health care professionals to design and implement effective strategies [1]. While the use of "expert opinion" in health research is common [4], there is now a more significant push to increase the involvement of patients and the public in health research [8]. Public participation in health research refers to research conducted with or by the public rather than to, about, or for them [8]. Consumer and community participation in health care is well-recognized [9]. However, the case for public involvement in health research has, over the years, become more widespread [9].

Health consumer groups in the Australian health care networks are commonplace. Ordinarily, they comprise ex-health care professionals, retired professionals who worked adjacent to the health care sector, and stakeholders with a wealth of experience with the health care sector throughout their lives [1].

XSL•FO
RenderX

Subsequently, their perspectives are vital, as they offer an outside view of issues occurring within the health care sector, which may need to be seen or recognized by professionals [1].

Rationale for Using Health Consumer Groups in Research

Social robot research among older adults in an Australian context is still emerging within the literature. Australia's older adults are particularly hesitant and resistant to newer forms of technology, which pose expected barriers to the acceptance and use of social robots by Australia's older adults in a clinical setting [10,11]. Enabling outside perspectives, such as those of members of a health consumer group, allows researchers to access valuable information regarding potential causes of these barriers. Theoretical, political, and ethical reasons are given in favor of public involvement with research. Theoretically, according to World Health Organization guidelines, there is a difference between disease and illness. A disease is a "physiological and clinical abnormality" [12]. On the other hand, an illness is a persistent sickness and is a "more subjective concept related to personal experience of a disease" [12]. Research studies require the expertise of professionals and input from "experts" who may have witnessed and experienced living through a medical condition.

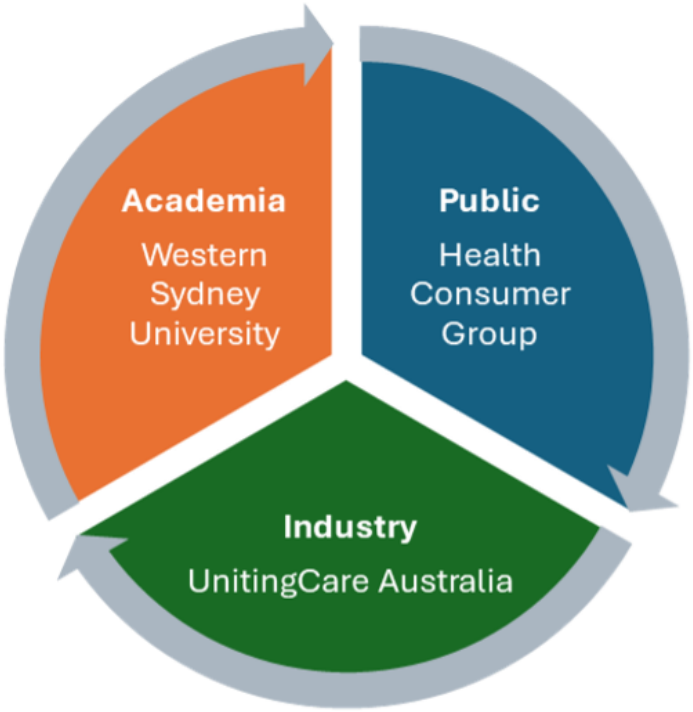
The political argument for involving the public members in health research is based on the premise that, as citizens and taxpayers, individuals who use health care services have the right to influence research funded through public monies [13]. Finally, the traditional model of a passive patient and an active doctor is no longer valid. Similar to the ethical obligation of health to involve patients in service delivery [2], there is a growing call for community input in research conducted within those communities.

Roles Played by Members of Health Consumer Groups

Members of health consumer groups play a critical role in ensuring clinically relevant research is being undertaken. Health group members are essential in identifying priority areas for research. They can identify research gaps from a layperson's perspective [13]. First, consumer participation helps determine the type of information communities need [13]. Second, they can help with the design and development of innovations. Next, they can help recruit relevant participants for research studies [8]. Finally, members of a health consumer group can ensure that the information produced is in a format and language that is easily comprehensible [13].

Limitations of Health Consumer Groups

There are challenges in using health consumer groups for exploratory research. First, as a preselected group, the perspectives of the consumer group members may not be representative of opinions held by the entire demographic or community [14]. Second, the size of the consumer group plays a crucial role in the depth of the discussion conducted in qualitative research [14]. If a consumer group is too large and the resources of researchers are spread too thin, the engagement can become disorganized, difficult to manage, and lead to inadequate data collection [15]. If the consumer group is too small, the scope of information could be further limited [15]. Finally, there is a chance of misunderstanding some of the technical information and jargon [15]. Not all health consumer group members are health care professionals. This may create knowledge deficits or misunderstandings and can lead to misconceptions about the research, interventions, policies, or practices discussed within the interview processes [14].



Triple Helix Model

The triple helix model (Figure 1) inspired the use of a health consumer group for this study. First proposed by Etzkowitz and Leydesdorff [16], the "triple helix model" (Figure 1) initially referred to the interactions among higher education, government, and industry to encourage economic, social, and cultural development in a region. Each component of the helix model plays a commensurate role in fostering economic, social, and cultural development [17]. For example, higher education focuses on research and the dissemination of innovation, industry on the production of goods and services, and the government or the public on serving the interests of people, including legislative and regulatory mechanisms that encourage and foster the diffusion of innovation into a population [17].

The triple helix model has mainly been used to improve the innovation process [16]. However, this study uses an "end-user enriched triple helix" approach [18], which considers the end-users' perspective. Innovations do not occur spontaneously; in fact, understanding the user's perceptions and interacting with them is critical to the success of a technological innovation [19]. The lack of input from users may lead to missed opportunities. The use of the triple helix model is based on the premise that involving the end users and adopting a participatory approach would lead to a more effective innovation development process. As older adults are the logical end users [18] of such technologies as social robots in the aged care sector, the triple helix model provides an essential apparatus to include their perspectives in the research process while incorporating academic and industry interests [17].

Social Robots and Older Adults

Assistive technology use among older adults is commonplace. Assistive technologies are ordinarily used to improve the quality of life of older adults by overcoming a physical or cognitive deficit [20]. Newer forms of assistive technology, such as social robots, have been deployed among older adults in a range of contexts with demonstrable effectiveness (Figure 2A). Social robots are machines equipped with a degree of artificial intelligence and human-like mechanics that can mimic or replicate a human interaction with a user [20]. These interactions include companionship, gameplay, touch, eye movement, handshaking, hugging, greetings, verbal interactions, and recognizing cues (Figure 2B). In the aged care sphere, where the number of older adults is increasing, and the number of care staff is declining, social robots can provide valuable supplements to care practices, social interactions, connectedness, and subsequent improvements in the quality of life for older adults (Figure 2B) [21,22].

Primarily, research on social robots among older adults has focused on mimicking social interactions and providing companionship (Figure 2B) [23,24]. As demonstrated by Khosla et al [25], interactions between social robots and older adults in care were associated with significant improvements in observed states of well-being among residents. This is reinforced by Ge and Schleimer [26], whose analysis of older adults' use and acceptance of social robots demonstrated a marked improvement in general well-being. The benefits of social robots to older adults in care transcend social interactions and companionship. Consistent with Fasola and Mataric [27] and Kyong et al [28], deploying a socially assistive robot to assist in exercise routines has been shown to provide positive motivation and outcomes for older adults in care settings. Socially assistive robots can also motivate older adults to engage in physical activities (Figure 2A). According to Macis et al [29], the deployment of a socially assistive robot into a residential aged care facility motivated residents to try and maintain a daily stretching and tai chi routine. Pharmacological disbursement is another area where socially assistive robots have been deployed effectively. According to Smarr et al [30], reminders to take medications and management systems for pharmacology by socially assistive robots in care facilities have produced positive outcomes and a greater level of compliance.

Studies show that the use of social robots can improve the quality of life; however, acceptance of the technology is a key barrier in Australia [31]. To better explore and understand this phenomenon, researchers contend that it is important to seek broader contextual information from differing players in the health care sphere, such as assessing the acceptance of the technology by a health consumer group. This would aid in overcoming these barriers in Australia. In addition, Australia has an aging population, and it is expected that the proportion of Australians aged 65 and older will represent 21% - 23% of the population in 2066. As mentioned above, with a major shortage of health care workers in Australia, the social robots in aged care present an opportunity to fulfill this gap. Thus, understanding the adoption of social robots in aged care in Australia has become a national priority.

Research Objectives

Social robot research among older adults in an Australian context is still in its infancy. Research using a health consumer group in designing an academic study with older adults and social robots is limited. Before testing social robots as an intervention among older adults in a clinical aged care setting, it is prudent to gauge the perceptions of an expert health consumer group. Subsequently, the objective of this research is to apply the triple helix model of innovation to seek guidance from a health consumer group to aid research efforts in the adoption of social robots among older adults.

Methods

Participant Recruitment

UnitingCare Australia recommended the research team contact the Sydney Partnership for Health, Education, Research and Enterprise for advice on this study. An element of the Sydney Partnership for Health, Education, Research and Enterprise is the Age and Aging Clinical Academic Group (AAA CAG), which acts as an expert health consumer panel related to aged care [1]. The work of the AAA CAG is to guide and inform research, policy, practice, and support assistive technology use to further healthy aging and independent living for Australia's aged population [1]. The AAA CAG consists of 8 members, many of whom have worked within, adjacent to, or have extensive experience in the Australian health care sector. People who worked in AAA and CAG formed the population of the study. To reduce bias, each person was invited to participate in the study. Therefore, the participants were selected randomly from the population.

Participant Information

Overall, 5 members of AAA CAG were interviewed, of whom 3 were deselected due to lack of interest, age, and time constraints. Of the 5 interviewed members, 3 were males and 2 were females between the ages of 66 and 73 years. Overall, 2 were from non–English-speaking backgrounds (non-ESB) and 3 were from English-speaking backgrounds (ESB; Table 1.

Table . Participant demographic information.

Participant number	Age (years)	Sex	Language background
P1	73	Male	Non–English speaking
P2	66	Male	English speaking
P3	73	Female	English speaking
P4	72	Female	Non–English speaking
P5	66	Male	English speaking

Participant Interviews

Semistructured interviews were conducted with each member via Zoom (Zoom Communications, Inc.). Participants were asked background questions from a preselected pool about their perceptions and experiences with assistive technologies. Visual stimuli, including images and short video clips about social robots and older adults, were used to give the participants an insight into this novel technology. Examples included images of a social robot leading a seated physiotherapy routine to older residents in a care facility. Similarly, a BBC YouTube clip of an independently living older man interacting with PEPPER, a social robot, was also used in the interview process. This was designed to mirror past studies that have also used videos and visual stimuli to demonstrate the capability of robots [32,33]. Finally, researchers asked participants for their opinions, feelings, and perceptions regarding the use of social robots in a research project with older adults. Each interview lasted approximately 45 minutes, and audio recordings were taken using Zoom. Professional transcriptions of each recording were

XSL•FO
RenderX

generated using Notta AI software (Notta Inc.), and each participant was deidentified and provided with a participant number (P1-P5). Manual content analysis was conducted on each transcription. Transcripts were read and reread manually to ensure maximum retention.

Data Analysis

The initial content analysis was inductive, following the guidelines of Braun and Clarke [34,35]. This involved familiarization with the data by reading and rereading the interview transcripts. During this process, the researchers identified and reviewed initial codes, which were later grouped into themes. The themes were subsequently confirmed through meetings with the research team and deductively grouped using the protocols developed by the Australian Clinical Trials Alliance. Three key themes emerged across the 5 interviews with members of the health consumer panel.

Ethical Considerations

Ethics approval was sought from the Western Sydney Human Research Ethics Committee, which approved application H15666 to seek information from the AAA CAG. As the study involved an expert consumer panel, who is involved with aged care in an ancillary capacity, its ethics classification was a low-negligible risk. The AAA CAG meets monthly to discuss various research projects, technologies, interventions, policies, and practices currently within the health care sector. As part of the recruitment process, the authors of this paper were asked to present their research study via a Zoom meeting to all AAA CAG panel members. The chair of AAA CAG permitted the research team to contact each interested member for interviews by providing each member's email address. Interviews, rather than a focus group discussion, were preferred. Interviews ensured that all members were free to voice their opinions without hesitation. Each participant met the inclusion criteria: a member of the AAA CAG, above 65 years of age, willingness and availability to participate in the study, and some experience with aged care consumer products. After the preselection phase, researchers distributed participant information sheets, consent forms, and other informational materials to members who indicated interest in participating. Informed consent was obtained prior to conducting interviews. All participants were deidentified and any identifiable information was obscured within this research and held by researchers only. Gift cards in the amount of $50 were distributed to each participant for their participation in this project.

Results

Overview

This section outlines the main themes that emerged as the researchers analyzed the transcripts. In line with previous research on engaging consumers and communities [36], we focused on identifying topics that provided guidelines for researchers on how to use social robots with older adults. Participants' quotes are presented with the following information: participant identification number, gender, age, and language background (ESB or non-ESB).

Communicating the Research Aim to Tech-Averse Participants

Researchers may find communicating the interview's research aims to the participants easy and straightforward. However, it can be a challenge with some population segments. Older adults could be skeptical about new technologies, including social robots. Not surprisingly, some may hold opposing views even about standard assistive technologies.

> … *my mother-in-law - an elderly lady-had to be convinced to get a walking stick and get it fitted properly as well. She said she didn't need it, but she does.* [P3, Female, 73 years, ESB]

Hesitation to use tools or equipment by older adults appears to be shared across different backgrounds and demographics:

> … *it's nothing to do with education. It's to do with a mindset [of this age group]*. [P4, Female, 72 years, non-ESB]

One research participant was particularly vocal about the need to explain the research aims to older adults:

> … *the biggest thing that I can see is to be able to communicate, talk to them [participants]*. [P1, Male, 73 years, non-ESB]

The same participant offered advice, stating:

> *Initially, they might [resist], but when they can see the benefits of it, I don't think there will be any resistance [to the research project]*.

Panel members of this consumer health group reiterated that undertaking human-robot interaction research is meaningful if older adults are convinced about its benefits. As mentioned by a non–English-speaking panel member:

> *Initially, they might [resist], but when they can see the benefits of it, I don't think there will be any resistance...* [P1, Male, 73 years, non-ESB.]

A suggestion on how to communicate the research aims of a social robot project to older adults highlighted the role of family members:

> *If there was a family member or carer involved and they also were accepting and recommending [involvement in the research project], I think yes... that would certainly get through the first barrier.* [P5, Male, 66 years, ESB]

Data Collection Methods With Older Adults

The consumer health panel members advised researchers on collecting data from older adults. The participants' overarching opinions were "direct" questions and "face-to-face" interviews. The research team also received advice on involving "health professionals" and "family members" during the data collection phase. One panel member (P1, male, 73 years, ESB) warned the research team against using videos to communicate the idea of a social robot. Despite older adults' generally known aversion to technology, this English-speaking male participant strongly advocated for a direct interaction of the robot with older research participants.

XSL•FO
RenderX

Appearance of the Social Robot

The research team also sought advice on the robot's appearance. Two members of the consumer panel had previously been exposed to humanoids:

> *...In Paris, in 2017, ... this little white machine came up and was talking to us in English.* [P3, Female, 73 years, ESB]

Another participant revealed the introduction of a baby seal, Paro, at his previous workplace. These panel members did not find the social robot "scary." Such participants quickly commented that this may not be the case with the average older adult who would interact with the humanoid for the first time:

> *Look..., it goes back to that idea of dystopian...it's sort of big brotherish.* [P5, Male, 66 years, ESB]

Another panel member (P4, female, 72 years, non-ESB) stated that while the robot's image was "acceptable"… "the eyes could be more friendly." This participant also hesitated about the robot's look:

> *The expression,..., the expression, yeah...* [P4, Female, 72 years, non-ESB]

Interestingly, another female participant (P3, 73 years, ESB) appreciated the "feminine form" of the robot and that it was "not confronting with the height and size."

Discussion

Principal Findings

In this section, we highlight 3 key themes identified from the data analysis. We also highlight the managerial implications of the results for each theme. The primary aim of this paper was to seek advice and guidelines from members of a health consumer group regarding human-robot interaction research with older adults. Such advice becomes even more critical when the consensus is that a participant group is vulnerable [37]. There is a general concern about older adults' vulnerability to technology, especially regarding their security and privacy [38].

Key Theme 1: Communicating the Research Aim to Tech-Averse Participants

The first theme that emerged from our analysis was the importance of explaining the aims of a research project to an anxious participant group. Previous researchers [39] have already acknowledged that conducting research with older adults presents challenges; however, the most identified challenges center around obtaining consent and ensuring privacy during interviews. The discussion with the health consumer group revealed that presenting the research topic to tech-averse participants, such as older adults, could hinder gaining cooperation for interviews and discussions [40]. The results demonstrate that demographic variables have little role to play in older adults' attitudes toward technology. Researchers working on tech-related topics should involve family members, peers, or other familiar clinicians to ensure smooth participation in the research project. Furthermore, identifying an opinion leader within the group and encouraging them to use technology will have a positive impact on the group's adoption of the technology. This snowball effect will be more powerful than trying to convince everyone to adopt the technology. In addition, to encourage tech-averse participants to adopt the technology, consistent messaging about its benefits is required. For example, "the robot can help with my exercise routine" and "the robot exercise routine is entertaining and fun." Highlighting the health and entertainment benefits is more likely to reduce resistance to technology. Furthermore, it is also important to change the mindset; for example, a 30-minute robot tai chi exercise as part of their daily routine could help change their mindset. Robots delivering these exercises daily can help older individuals change their daily behavior and change their mindset toward regular exercise.

Key Theme 2: Data Collection Methods With Older Adults

Another commonly discussed topic with the health consumer group focused on data collection methods. Despite increasing evidence of older adults' comfort in using the internet [41], our panel of experts felt that the best way to collect data was face-to-face, allowing older adults to interact directly with a social robot. While it may not be feasible to "house" the robot for extended periods at a facility [42], the findings suggest short-term interactions in a safe environment would be an ideal way to introduce older adults to humanoids. For example, short 30-minute robot-driven exercises daily would work better than 2 - 3 hours of activity. The findings also indicate that effective communication between the robot and the individual is critical in the adoption of the robot. Older individuals would find it difficult to communicate with the robot if it were at the house for only 1 - 2 days. Thus, having the robot for several weeks or months in the house would help older individuals learn to communicate with the robot more effectively. This would also help change the "mindset" toward being more active and exercising.

Key Theme 3: Appearance of the Social Robot

Finally, the health consumer group provided mixed feedback on the robot's appearance and features. Recent studies [43] have found that older adults label the robot as "friendly." However, it could be that some of these studies used smaller types of robots in their projects. Other researchers [44] have reported older adults' dislike for a machine that tries to look like a human—a fake human. Our results demonstrate the need for further research in this area. It is necessary to consider users' needs by investigating them in greater detail. At this stage, the results show conflicting arguments from the health consumer group. For example, some preferred robots with eyes that were more friendly. However, they did not like the expressions of the robot. Other participants highlighted that the feminine features of the robot made it look less confrontational. While these findings are limited to a few participants, it is clear that the personalization and customization of robot features are necessary to enhance adoption. It was interesting to find that the adoption of the robot depends on the individual's preferences for the robot's features. However, academic research in this area is limited, and future studies should investigate the personalization and the personification of robots.

XSL•FO
RenderX

Limitations and Future Studies

Several essential caveats deserve comment. First, this research study was conducted with an 8-member health consumer group, resulting in a small sample size for interviews. Next, our study considered only one type of social robot—Pepper. It is quite possible that a different robot type may have resulted in different opinions by the participants. Finally, it is important to consider the presence of bias in participant responses due to their values and attitudes toward robots. The industry partner (UnitingCare Research) recommended future research to focus on the health consumer group. This would provide a standard unit of analysis in future studies, and it provides researchers with a standard research process to compare against. One of the key learnings from the study is that when you are recruiting participants for the health consumer group, it is important to vet the participants. Future studies should develop a vetting process for the health consumer group. This would help future studies have a standardized selection process and help researchers compare the results more accurately. Furthermore, the study was limited to the qualitative methodology, and future studies should validate the findings using empirical modeling.

As this research is the foundation for future studies, including social robots and older adults, the results highlight how best to approach studying this phenomenon. Future studies should consider these recommendations to effectively design social robot interventions among older adults in the Australian aged care context. However, the findings are limited to the Australian aged care context, and future researchers should explore different cultural backgrounds. For example, in the Middle East, religion is at the core of their livelihood, and therefore, the way individuals interact with the robot may differ substantially from that of older Australian adults. The Japanese are more likely to adopt the robot; thus, future researchers may compare whether culture impacts the adoption process. Comparisons between these contexts are important to understand the factors driving robot adoption. These findings could be used to advise future studies in aged care.

Conclusions

Health consumer groups are vital health care stakeholders, whose experiences, perspectives, concerns, and recommendations form the basis for designing robust interventions to improve the quality of life for specific demographics through products and services. After being pretested among an expert health care consumer panel by the authors, the findings of this study should provide confidence to another element of the triple helix model: industry. However, as mentioned in the limitations of this study, social robot research among older adults in Australia is still emerging. This study represents nascent exploratory research that requires further testing. The authors, in conjunction with industry partners, recommend field testing of social robots among older adults to assess their acceptance and use, as they are the intended end users of the technology.

Abstract

Background: Cigarette smoking is a leading cause of preventable morbidity and mortality worldwide. Women who smoke face greater health risks than men, including higher rates of cardiovascular disease and more pronounced declines in lung function. Despite this, women experience lower success rates with conventional smoking cessation treatments, due in part to unique sex- and gender-related factors influencing smoking behavior and barriers to quitting. Digital health tools, such as mobile health apps, offer a promising avenue for delivering accessible, tailored smoking cessation support to women.

Objective: This study evaluated the acceptability and feasibility of the "My Change Plan–Women" (MCP-W) app, a gender-specific smoking cessation mobile health intervention co-designed with women who smoke, clinicians, and researchers, to address women's unique needs in smoking cessation.

Methods: We conducted a single-group, prospective, sequential mixed methods study with 30 women who smoke in Ontario, Canada. Participants used the MCP-W app for 28 days. Acceptability was defined as ≥50% of participants endorsing "agree" or "strongly agree" to the statement "using the app is likely to help me make changes to my smoking habits." Feasibility was defined as ≥50% of participants using the app for 7 or more days during the trial period. Quantitative data on acceptability, smoking behavior, and motivation to quit were collected at baseline and follow-up via REDCap (Research Electronic Data Capture) surveys. App usage metrics were captured through Google Analytics. Semistructured interviews explored participants' experiences using the app and were thematically analyzed using the theoretical framework of acceptability.

Results: At follow-up, 37% (11/30; 95% CI 21%-56%) of participants rated the MCP-W app as acceptable, falling below the predefined threshold (≥50%) and indicating that the intervention "needs further work." Feasibility criteria were met, with 60% (18/30) of participants using the app for 7 or more days. Notably, acceptability was higher among those who used the app for more than 14 days (7/11, 64%) compared with those with lower usage (4/19, 21%). Average daily cigarette consumption decreased from 16.4 to 14.6 cigarettes, and the number of participants reporting at least 1 smoke-free day in the previous week increased from 7% (2/27) to 22% (6/27). Qualitative findings revealed that women with higher motivation to quit found the app more

XSL•FO
RenderX

helpful, particularly its behavior change tools (eg, cigarette tracking and identifying triggers) and gender-specific content. However, women facing stress, mental health challenges, or low readiness found it harder to engage. Participants suggested enhancements including customizable reminders, more interactive content, and live or artificial intelligence–based emotional support.

Conclusions: The MCP-W app is a feasible intervention for delivering gender-specific smoking cessation support. However, its acceptability was limited to a third of users with high levels of motivation. Improvements to interactivity and support features may enhance its relevance and uptake among women with complex barriers to quitting.

Introduction

Cigarette smoking is one of the leading risk factors of morbidity and mortality globally contributing to the development of cancers, lung diseases, and heart diseases [1]. While the prevalence of smoking among women in some Western countries may be reducing overall, the rate of decline is slowing, and the contribution of smoking to deaths among women is increasing [2,3]. Smoking causes more harm in women compared with men. Relative to men, women who smoke have higher rates of cardiovascular events and experience greater decline in lung function as a result of smoking [4]. When trying to quit smoking to protect their health, women experience less success than men when offered evidence-based smoking cessation treatment. The disparity can be partly attributed to sex- and gender-related factors affecting motives for smoking and barriers to quitting, which are rarely addressed in treatment. This highlights the need for smoking cessation programs to take into account the unique needs of women and incorporate them into treatment.

Various sex- and gender-related factors affect smoking and quitting behaviors among women. Cosgrove et al [5] found differences between the effect of nicotine on the dopaminergic pathway in the brains of men and women, where men showed a greater dopamine response to smoking than women. This suggests that men smoke for the pleasurable effects of nicotine, whereas smoking has additional drivers in women. Others theorized that stressful life experiences in women become a conditioned cue for smoking (ie, sociopharmacology) [6]. This theory is backed by evidence of high smoking rates among women facing material hardship, domestic violence, mental illness, and lone parenting. Biological factors, as well as diverse social and psychological factors (ie, sex- and gender-related factors), contribute to a greater difficulty in smoking cessation among women relative to men [4,7-11]. Previous work suggests a number of unique challenges experienced by women in quitting, including using smoking to cope with stress or manage emotions and control weight by suppressing their appetite [12]. Behavioral interventions that focus explicitly on the unique experiences of women trying to quit could improve smoking cessation success [11].

Mobile health (mHealth) technology, such as smartphone apps, can deliver smoking cessation treatment to wider populations in a more cost-effective manner [12-16]. For greater effectiveness, mobile app content can be tailored to address the unique smoking cessation needs of women. Indeed, 4 apps dedicated to helping women reduce or quit smoking have been identified in a systematic review of the literature [13]; 2 of them focus on women who are pregnant [17,18], 1 on modifying multiple health behaviors among women [19], and 1 for Chilean women using which sends motivational messages and strategies to women to reduce or quit smoking [20]. This trend is encouraging, but there is room for further work focused on a wider, more general population of women who smoke.

The "My Change Plan–Women" (MCP-W) app is one such additional mHealth intervention. The original version of the app, My Change Plan (MCP), was developed to support the smoking cessation efforts of patients enrolled in the Smoking Treatment for Ontario Patients (STOP) program and was a digital evolution of a paper-based booklet, also called "My Change Plan" [21,22]. The MCP app provides evidence-based behavioral change techniques to support tobacco reduction and cessation that can be helpful for both women and men in developing their quit plan. The quit plan includes goal setting, identifying smoking triggers, and developing coping strategies which are grounded in theory [23-25]. It allows users to track their cigarettes and cravings and evaluate financial savings from reducing or quitting smoking. It also provides evidence-based information in the app's library about smoking cessation medications, local supports for smoking cessation (eg, smoker's helpline), and the impact of physical activity, nutrition, stress, and sleep on smoking and smoking cessation. The MCP app has been available for iPhone (Apple Inc) and Android (Google) smartphones, in their respective app stores, for over 5 years. The MCP-W app retains MCP gender-neutral content and complements it with women-specific content that focuses on women's unique motives for smoking and the barriers to quitting they experience. The women-specific content is delivered through 4 animation videos embedded in the app, and testimonials from women who smoked are included in the app's library. The animated videos focus on women-specific motives for smoking, challenges faced by women when trying to quit, and strategies that have helped women overcome them. The testimonials include quotes from women on topics such as "desire to quit," "quit strategies," "quit struggles," and "encouragement."

The women-specific version of this app, the MCP-W app, was co-designed in collaboration with women who smoke (ie, patient partners) and a multidisciplinary team of researchers and

XSL•FO
RenderX

clinicians with expertise in tobacco addiction, implementation science, sex and gender science, women's health, public health, and app development [26]. The MCP-W app was based on motivational interviewing. This is a counseling method aimed to promote behavioral change in a compassionate and nonjudgmental manner [27]. It respects women's autonomy to make changes to their smoking at their own pace, when they feel ready, and does not pressure them into quitting by using scare or shame tactics.

The MCP-W app was developed between July 2022 and August 2023, and a testable version was finalized in January 2024. The aim of this study is to test whether women who smoke find the MCP-W app to be an acceptable tool for the delivery of gender-informed smoking cessation support, and whether the MCP-W app can feasibly deliver this content.

Methods

Study Design and Setting

We conducted a single-group, prospective, sequential mixed methods study to test the acceptability and feasibility of the MCP-W app at the Center for Addiction and Mental Health (CAMH) INTREPID Lab in Toronto, Ontario, Canada. A comprehensive protocol of this study was published previously [26].

Participant Recruitment and Study Procedures

Purposive sampling was conducted between February and May 2024 to recruit 30 women participants who smoked cigarettes to test the MCP-W app. The study recruitment flyer was shared through monthly presentations to STOP clinicians, who provide smoking cessation treatment in primary care clinics across Ontario, Canada. In addition, recruitment flyers were provided to health care practitioners at the Nicotine Dependence Clinic at CAMH and posted on the CAMH research boards across campus. Furthermore, past treatment-seeking individuals (STOP program participants), who agreed to participate in future research studies, were contacted about the study.

Women who expressed interest in participation were screened for eligibility over the telephone. We included women between 25 and 65 years of age, who smoked at least 5 tobacco cigarettes per day, owned a smartphone, had continuous internet access, and had experience using smartphone apps. Those who did not feel comfortable using smartphone apps, or were pregnant, breastfeeding, or trying to become pregnant in the next 3 months were ineligible to participate. Individuals with severe general or mental health conditions that could interfere with study participation were also excluded. This criterion was assessed during the eligibility screening and applied to those unable to complete study procedures due to a physical or mental illness (eg, current hospitalization). Eligible participants provided informed consent over WebEx (Cisco Systems), a secure online platform to conduct videoconference meetings, after a discussion of the study procedures, risks, benefits, and rights as a study participant. During this WebEx meeting, participants also completed the baseline survey (Multimedia Appendices 1 and 2) through a unique REDCap (Research Electronic Data Capture) survey link sent by email, where they provided information about their sociodemographic characteristics, acceptability of the app, smoking behaviors, smoke-free days in the past week, and their motivation to quit smoking. They downloaded the MCP-W app (either an Android or an iPhone version) and were provided a brief demonstration of the various app features.

Participants were granted access to the app for a period of 28 days. After the 28-day trial completion, participants were sent an automatic email through REDCap with a follow-up survey. The follow-up survey asked participants about the acceptability of the app, smoking behaviors, smoke-free days in the past week, motivation to quit smoking, the usability of the app using the System Usability Scale (SUS) [28], and how likely they were to recommend the app to others (Multimedia Appendices 2 and 3). In addition, participants were invited to schedule the follow-up semistructured WebEx interview about their experiences using the app. Interviews were conducted by a research staff member who did not have any previous relationship with the participants. The interview guide consisted of questions about the app based on the 7 constructs of the theoretical framework of acceptability (TFA; ie, affective attitude, burden, ethicality, intervention coherence, opportunity costs, perceived effectiveness, and self-efficacy) [29], as well as additional questions about barriers to quitting smoking, the app's helpfulness in quitting smoking, and strategies to make the app helpful for women from diverse backgrounds (Multimedia Appendix 4). The interview lasted for an average of 34 (SD 11, range 18 - 62) minutes. The interviews were automatically transcribed by the WebEx Assistant Software. Research staff members reviewed, cleaned, and verified the transcripts for accuracy.

Data Analysis

Primary Outcomes

The primary outcomes for the study included acceptability and feasibility of the app. Acceptability of the app was measured by asking the question "using the app is likely to help me make changes to my smoking habits" at baseline and follow-up surveys, which could be answered on a 5-point Likert scale from "strongly agree" to "strongly disagree." The proportion of participants endorsing "agree" or "strongly agree" was calculated. The app would be considered "acceptable" if the majority (≥50%) of participants rate it as such. Similarly, if 26% to 50% reported the app as acceptable, then it would be deemed "needs further work"; otherwise, it would be deemed "unacceptable" if the proportion was 25% or lower. Nonresponse values were imputed to "do not agree" since low study participation most likely indicated low acceptability of the app.

Feasibility of the app was assessed using Google Analytics data. Participants were assigned unique log-in IDs and the number of times they accessed the app and clicked on the videos was collected using Google Analytics. The app would be considered "feasible" if the proportion of participants who accessed the app for 7 days or more out of 28 days was 50% or more, "needs further work" if 26% to 49% , and "not feasible" if 25% or less. Since the Google Analytics data was available for all participants, there was no missing data on feasibility measures. The binomial 95% CIs were calculated to assess precision of

XSL•FO
RenderX

estimates, but the decision about acceptability and feasibility rested on point estimates.

Secondary and Tertiary Outcomes

The secondary outcome measures consisted of participants' motivation to quit smoking. Changes in mean scores of motivation from baseline to follow-up were calculated for each of the 3 validated subscales: "importance," "commitment," and "ability" [30]. Participants rated the following statements: (1) it is important for me to change my smoking habits, (2) I am trying to change my smoking habits, and (3) I could change my smoking habits, using a Likert scale where 1=definitely not, 2=probably not, 3=maybe, 4=probably, and 5=definitely.

The tertiary outcomes consisted of smoking behavior metrics including change in the number of cigarettes smoked daily and the number of smoke-free days in the last 7 days. Quantitative data was analyzed using Stata v.16 (StataCorp). Based on the observed distribution, we used McNemar tests for binary outcomes, exact Wilcoxon signed-rank tests for paired ordinal data, and negative binomial regression for cigarettes per day. Demographic data were analyzed descriptively.

Qualitative Data Analysis

A deductive analysis approach was used to analyze the qualitative data [31]. Using Microsoft Excel, the interview data elicited from the 26 participants were organized into categories based on the 7 TFA constructs and 2 additional questions asked in the interview guide. KM read and reread all transcripts to become familiar with and code the data. AG and OM reviewed the transcripts and the extracted and coded data to ensure accuracy and consistency. KM, OM, and AG met weekly to discuss and refine the codes. Coded data were structured into themes and relevant quotes were selected to support themes and subthemes.

Ethical Considerations

The study was approved by the CAMH Research Ethics Board (#122/2023). Participants provided informed consent via WebEx (Cisco Systems). Participants were provided an honorarium of CAD $30 (a currency exchange rate of US $1=CAD $1.33796 was applicable at the time of data collection) for completing the baseline survey and an additional CAD $30 for completing the posttrial interview. No identifying information about the participants has been included in this manuscript.

Results

Characteristics of Study Participants

A total of 383 women were contacted about the study (369 from the STOP program and 16 from other sources), out of which 55 women expressed interest and were screened for eligibility. Of the total, 49 women were found to be eligible, out of which 32 women provided informed consent and completed the baseline survey. Furthermore, 30 women were able to download the app, and 2 women could not do so due to technical issues, 27 completed the follow-up survey, and 26 completed the interview (3 participants were lost to follow-up). The baseline demographic data of the 30 participants are described in Table 1.

XSL•FO

[b]Data collected in Canadian dollars. A currency exchange rate of US $1=CAD $1.33796 was applicable at the time of data collection.

[c]COPD: chronic obstructive pulmonary disease.

Primary Outcome Measures

Acceptability of the MCP-W App

Following the 28-day trial period, participants responded to the following question: "Please indicate how much you agree or disagree with the following statement: Using the app is likely to help me make changes to my smoking habits." In total, 11 out of 30 (37%, 95% CI 21%-56%) participants endorsed "agree or strongly agree." This result did not reach our predefined threshold for acceptability (≥50%), but landed in the "needs further work" range (26% - 49%). We assessed the acceptability of the intervention before and following the 28-day trial, in which the proportion of participants endorsing "agree or strongly agree" decreased from 43% (13/30) before using the app to 37% (11/30) at follow-up; however, this decrease was not statistically significant (Table 2).

Table . Primary, secondary, and tertiary outcome measures.

Outcome measures	Baseline	Follow-up	*P* value
Primary outcome			
Acceptability[a], n (%)			.09
Agree or strongly agree	13 (43)	11 (37)	
Neutral, disagree, or strongly disagree	14 (47)	16 (53)	
Secondary outcome			
Motivation[b], mean (SD)			
Importance	4.7 (0.6)	4.7 (0.6)	>.99
Commitment	4.6 (0.7)	4.5 (0.7)	.22
Ability	4.1 (0.9)	3.7 (1.0)	.40
Tertiary outcomes			
Cigarettes smoked per day[b], mean (SD)	16.4 (7.5)	14.6 (7.0)	.01
1 or more smoke-free days in the last 7 days[b], n (%)	2 (7)	6 (22)	.01

[a]Acceptability was measured on a 5-point Likert scale using the question: "Using the app is likely to help me make changes to my smoking habits."

[b]Data from 27 participants who completed the follow up survey.

Feasibility of the MCP-W App

Based on the Google Analytics data, 18 (60%, 95% CI 41%-77%) participants used the app for 7 or more days, which fulfilled the 50% feasibility criteria. Furthermore, 14 (47%) participants used the app for 1 - 7 days, 5 (17%) used it for 8 - 14 days, 3 (10%) for 15 - 21 days, and 8 (27%) for 22 - 28 days. Based on the number of days the MCP-W app was used, the proportion of participants who found the app acceptable was 14% (2/14; 1 - 7 days), 40% (2/5; 8 - 14 days), 67% (1/3; 15 - 22 days), and 63% (3/8; 22 - 28 days; Multimedia Appendix 5). There was a statistically significant correlation between the number of days the app was used and agreement with the acceptability of the app (P<.001).

Secondary and Tertiary Outcome Measures

Motivation to Quit

Participants had a high level of motivation with respect to "importance" of quitting smoking (mean score of 4.7, SD 0.6), and it did not significantly change from baseline to follow-up. There were no statistically significant changes in the "commitment" and "ability" measures (Table 2).

XSL•FO
RenderX

Smoking Behaviors

The number of cigarettes smoked per day significantly reduced from a mean of 16.4 (SD 7.5) cigarettes at baseline to a mean of 14.6 (SD 7.5) cigarettes at follow-up. The number of participants endorsing 1 or more smoke-free days in the last 7 days significantly increased from 2 (7%) at baseline to 6 (22%) at follow-up (Table 2). Based on the number of days the MCP-W app was used, the proportion of participants who reported a smoke-free day in the last 7 days at follow-up was 0% (1 - 7 days), 20% (8 - 14 days), 100% (15 - 22 days), and 25% (22 - 28 days). Furthermore, 1 participant reported quitting smoking at follow-up.

System Usability

The mean total score of the SUS was 70.2 (SD 12). The mean score of the response for the question "How likely are you to recommend this app to others?" was 6 (SD 2.0; on a scale of 0 to 10).

Qualitative Inquiry Into the Acceptability and Feasibility of the MCP-W App

Table 3 summarizes key themes and insights from qualitative inquiry with MCP-W participants.

Table . Summary of key themes and insights from qualitative results.

Theme	Subthemes or key insights	Supporting quotes
Motivation and readiness to quit	• App more useful for those highly motivated or ready to quit • Lower readiness linked to lower engagement	• "I was pretty motivated... that gave me a definitive start date." [ID 27] • "I'm not there yet... the app helped …but I think you have to be a 100% ready." [ID 01]
Barriers to quitting smoking	• Stress, mental health, daily hardships • Habitual use and nicotine addiction • Social contexts and emotional triggers	• "The more stressed I am, the more I smoke..." [ID 19] • "It's really hard to quit... the brain always makes excuses to get it" [ID 28]
Helpful app features	• Cigarette tracking increased awareness • Trigger identification and coping strategies • Resource library, visual feedback (savings, graphs, progress) • Gender-specific content resonated with users	• "...just reminding me to get outside and…do something other than just …smoking..." [ID 11] • "Everything they were talking about (in the videos) is how I felt..." [ID 18]
Features in need of improvement	• Burden of frequent tracking/logging • Usability issues (eg, journal entries, notifications) • Desire for more interactivity and real-life testimonials	• "It just seemed like the app wanted me to go into it every time..." [ID 07] • "I would like to get more like a free open option to write stuff down" [ID 19]
Desire for additional support	• Suggestions for live support or artificial intelligence–based chat features • App more effective when paired with counseling or pharmacotherapy	• "A live connection... someone like ...a sponsor." [ID 14] • "Maybe they should be starting that (medication) already before they use the app, so they already have a jump start, so to speak" [ID 29]

Motivation and Readiness to Quit Smoking

We found that participants' motivation and readiness to quit smoking influenced the acceptability and feasibility of the MCP-W app. More than half (n=16) of all participants interviewed mentioned that they were motivated to quit smoking. The app was seen as a helpful tool particularly for those highly motivated to quit. Some doubted the app's utility for women with lower levels of motivation or readiness.

> *Well, right now for my journey, I'm at a point where I know - I know I've got to quit smoking for my health, for my family's health, but mainly for mine just because I'm getting older I smoked for so long. Um, here's my cough…* [ID 03]

> *Well, I was pretty motivated when you first contacted me, so I think that's what helped [quit] was with the trial starting that that gave me a definitive start date or an end date, I should say.* [ID 27]

> *And I'm so tired of smoking, I don't want to smoke anymore. But I'm not there yet. I don't think, cause, I mean, I could analyze my smoking and I could, you know, the app helped me with that and, and figure it out and the triggers and… But, I think you have to be a 100% ready.* [ID 01]

Participants who mentioned that they were motivated and ready to quit smoking appeared to find the MCP-W app feasible, which they demonstrated by engaging with the MCP-W app longer than participants who mentioned they were not as motivated or ready. For example, one of the following

XSL•FO
RenderX

participants who was ready to quit used the MCP-W app for 29 days compared with the other participant who was not ready and only used the MCP-W app for 14 days.

> *But I'm determined right now with this app… It like with the full 29 days I've been using the app so far…* [ID 31]

> *I feel like, I have no motivation or willpower or something, and I'm just not making real changes here. So this is just kind of like, maybe it'll help other women, but not me.* [ID 16]

Some participants felt that the app is of most use to women who are ready to quit. Since they did not feel ready, it was less relevant to their needs.

> *If I was further into this stage of quitting smoking or wanting to quit smoking, it would definitely - it would help me. I just - I'm not there yet, so it was easy for me to not-not use the app, to not look at it. Right?* [ID 03]

> *I think that if somebody is ready, that it would be a valuable tool. It would be like an accountability tool… So I think I would be a good candidate for that if and when I was ready, I was just not ready…* [ID 32]

Participants cited numerous barriers to quitting smoking, some related to gender and others to the nature of the tobacco addiction including daily stressors (eg, employment, housing, finance, and relationships; n=16), the addictive nature of nicotine (eg, lifelong habit and hard to give up; n=14), boredom or nonstructured daily routine (n=4), social smoking (eg, with partners, friends, and work colleagues or managers; n=3), and mental health challenges (eg, depression; n=3).

> *The more stressed I am, the more I smoke, so, stress is a big trigger. I think when you're looking at, like, certainly me being a single mom, everything's on me to do all the time. So, I think quitting smoking would be a lot easier if I wasn't so stressed out all the time.* [ID 19]

> *I think that I would not have to love nicotine. Or I think that I would not have ever had to start smoking… But personally, I just don't think, once a person starts and once their brain like becomes addicted to nicotine, it's, it's really hard to quit cause the brain always makes excuses to get it.* [ID 28]

Some participants mentioned that the tailored content in the app was helpful to overcome gender-specific barriers to quitting.

> *I was able to cut out a few cigarettes when I'm walking to the bus stop. I made a conscious effort, because I thought, oh, that is what I really could skip. Um, most of my problem is that it is habit. I think the reasons why we smoke and when we're smoking, when you see it [in the MCP-W app], it really hits home. It's like, wow.* [ID 02]

> *I think since I've started using this [MCP-W app], I have reduced. So proud of that, um. It's just a matter of reducing to nothing.* [ID 10]

> *So, it actually made me think about that in retrospect of where I've been and what I've been doing and even just reminding me to get outside and go and do something other than just sitting here smoking. Just seeing that sheer number and volume day by day, helped me cut back. By the end of the month, it helped me cut back probably 10 to 11 cigarettes per day.* [ID 11]

MCP-W App Features That Were Helpful

Participants provided additional insights about the acceptability and feasibility of the MCP-W app. Factors that facilitated the acceptability and feasibility of the MCP-W app included the available tools and resources, for example, the feature of tracking the number of cigarettes they smoked. Participants (n=15) mention this feature helped them become more aware of the number of cigarettes they were smoking and held them accountable for changing their behavior (n=6). When tracking their cigarettes, they also became more aware of their smoking triggers such as emotions, places, and people they were with (n=10).

> *I like the idea that when I did use it, that it would ask me my, my attitude or who I was smoking with, which then if I used it properly, then it would trigger to when I am actually smoking. And then it would make me more aware of where I need to maybe change my surroundings or the urge to smoke.* [ID 04]

Participants mentioned that identifying their triggers and recording their coping strategies was helpful (n=15).

> *I did like the survey where you could put your motivations for quitting, how many you smoked a day, what to do, what are your triggers, how you could alleviate those stresses… when you think about it beforehand, so that when you're in the moment, you're able to go back to that app, look at it and say, "Okay, I said I would do this."* [ID 23]

Participants thought that the library feature provided helpful information about resources on quitting smoking, medications, such as nicotine replacement therapy, managing weight when quitting, and so on (n=14).

> *The library section had quite a bit of information as well with different smoking cessation medications and different supports and things like that that are very helpful.* [ID 25]

Other features found helpful by participants included visualizing their smoking through progress graphs (n=7), receiving notifications about reduction in number of cigarettes (n=6), and feedback about money saved (n=4).

> *I liked the notifications. So, when it said to me, like, you've smoked, you know, so many cigarettes less this morning than you did yesterday, that was kind of like a pat in the back moment for me.* [ID 01]

A number of participants provided feedback on the gender-specific content embedded in the app. In total, 9 participants mentioned the topics depicted in the videos and testimonials tailored to women who smoke resonated with them

XSL•FO
RenderX

and 5 mentioned that the videos motivated them or provided them information they did not know.

> *You know, I was reading the testimonials of people and it's, it's real people and you, you know, you can relate to them and then it just gives you more motivation to want to quit smoking.* [ID 04]

> *I think every video hit home, because everything they were talking about is how I felt or how I feel, right? So it kind of, that reminded me of like my own personal journey as well. So there was a lot of things in those videos that was just totally me.* [ID 18]

MCP-W App Features That Needed Improvement

Using the app requires a time commitment which was perceived as a burden to some. Half the participants (n=13) mentioned they found it difficult to find time or forgot to track every cigarette they smoked, and several (n=12) mentioned they needed reminders to log their cigarettes, with some specifying the need for customizable reminders 2 or 3 times a day. Indeed, 5 participants mentioned that women with children would have difficulty logging their cigarettes multiple times a day every day. Furthermore, 4 participants also reported logging factors associated with every cigarette was too tedious.

> *It just seemed like the app wanted me to go into it every time I had a cigarette and I just don't have that kind of time or resources to do that, especially while I'm at work - and like if you've got a young mom or anything like that, there's no way they could do that. Like, it'd be better if we could go in a couple of times a day and just pinpoint on a timeline when we had cigarettes.* [ID 07]

Some participants described functionality and design issues with key features of the MCP-W app that may have affected the usability. For example, some participants mentioned the journal did not allow independent entries (n=7), clicking on notifications did not open the app (n=2), or logging previous cigarettes did not allow logging the factors associated with them (n=4).

> *My journal part… I couldn't enter anything… I think it would be really beneficial if we can write things like 'Today really sucks and I'm really struggling with quitting smoking"… I would like to get more like a free open option to write stuff down.* [ID 19]

> *Sometimes I noticed on my phone, I'd get a notification pop up. And then I'd click on it, but it never said anything. So, I don't know if there were some problems with that.* [ID 10]

A few participants (n=5) wished for the MCP-W app to be more engaging in order to maintain participants' interest over time. Participants suggested that the MCP-W app should include interactive activities (ie, gamification) or dynamic content to keep interest levels high (n=8).

> *Maybe that's a good time to have something integrated into the app, like a game to play…* [ID 19]

> *Because there was not a true engagement. At the end of the day an app, it passes the excitement like a movie or like a show, like anything. It passes the time. So if there's no more like new things or like more engagement you will lose just interest naturally, I think…* [ID 22]

In total, 15 participants acknowledged that the app contains both gender-specific and gender-neutral content. Furthermore, 2 suggested that the library could be improved by including more gender-related information such as hormonal influences on smoking. They also preferred human actors in the videos as opposed to the animated characters (n=9), with additional success stories and strategies to overcome challenges to quit (n=6).

> *I think having a section to deal with hormones would be very beneficial like… things have changed drastically for me there, going through menopause… So, I think having that information involved, so you can take a closer look at yourself, because hormones trigger everything in your life, really.* [ID 11]

> *Oh, maybe, like real people (in the videos) would be nice and also maybe people who have been successful in what worked the best for them.* [ID 28]

A few participants (n=6) mentioned that they would like to have a feature that allows the user to connect to a support person or artificial intelligence (AI)–based chatbot for more personalized support.

> *A live connection where you can phone somebody and speak to them live. And not for psychological, like, not a psychiatrist or psychologist, but just someone, like, what do they call-a sponsor?* [ID 14]

> *I think in terms of quitting and smoking, you need more live support, that's one. But like I mentioned before, I think if it had like a chat open or linked to other participants that shared the experience, like, "Okay, how are you doing this day."* [ID 22]

Overall, participants (n=5) mentioned that the app can be a helpful tool, particularly when it is combined with other types of support such as behavioral counseling or smoking cessation medication, rather than a stand-alone solution.

> *Well, it did [help] on the few days that I had, for whatever reason, fewer smokes than other days. I think it did tell me like something like "You didn't have a cigarette this morning"… I think I'm stuck in some personal issues right now that that make it hard. I think you have to already be committed to doing something seriously and not have a lot of extraneous problems that are gonna defeat you before you even get started. Maybe somebody should already be starting patches or have a bunch of the other, you know, whether it's that medication, you know, pills or whatever they are, or other things. Maybe they should be starting that already before they use the app, so they already have a jump start, so to speak. Otherwise, just jumping into the app, it's really hard to just change everything without more, more of a push.* [ID 29]

XSL•FO
RenderX

In summary, participants' motivation and readiness to quit smoking significantly influenced the acceptability and feasibility of the MCP-W app. Women motivated to quit found the app helpful for tracking smoking behaviors, identifying triggers, and providing gender-specific resources. However, individuals with lower readiness to quit engaged less with the app. Participants recommended improvements, such as providing additional success stories of women, enhanced interactivity (eg, gamification), and personal coaching options. While the app could be beneficial, especially when paired with other cessation tools, it was not perceived as a stand-alone solution, particularly for individuals who face significant barriers to quitting.

Discussion

Principal Findings

In this study, we aimed to test the acceptability and feasibility of a gender-specific app for smoking cessation among women who smoke using a mixed method approach. Our study found that the MCP-W app was acceptable to slightly more than a third of women, with 37% (11/30) endorsing it as a helpful tool that can support their smoking cessation needs. As such, it did not meet the a priori acceptability criteria (>50%). Nonetheless, the app met feasibility criteria, with 60% (18/30) of participants using it for 7 or more days. The finding that the MCP-W app did not meet the predefined threshold for acceptability (only 11/30, 37% of participants rated the app as likely to help with smoking cessation) has important implications for future scalability and deployment. This result suggests that without additional support or enhancements, the MCP-W app in its current form may not be suitable as a stand-alone tool for a broad population of women who smoke. Instead, the app may be most useful for a subset of women who are already highly motivated to quit. This emphasizes the need for further development work to improve engagement and relevance, particularly for women exhibiting ambivalence about quitting. Future iterations of the app may benefit from incorporating more dynamic features (eg, personalized reminders, gamification, or peer support options) and tailoring content based on users' readiness to change.

The proportion of participants needed to consider the app acceptable (50%) was not met; however, the proportion of participants who used the app more frequently (more than 14 d) found it acceptable (7/11, 64%), as compared with the proportion of participants (4/19, 21%) who found it acceptable but used the app less frequently (14 d or less). The significant correlation between acceptability and feasibility of an app could be bidirectional, representing the increased acceptability of the app resulting in more use or conversely, as users engage with the app for longer, they find it more helpful. Previous research has found a similar correlation between acceptability and feasibility, even though they have been recognized as separate constructs [32,33]. In addition, the proportion of participants who mentioned they would find the MCP-W app acceptable at baseline was 43% (13/30), demonstrating their low pre-existing beliefs about the app's ability to help them make changes to their smoking. Research has shown that pre-existing beliefs about effectiveness can affect engagement with digital health interventions, for example, perceiving technology as distracting is linked with lower use metrics [34]. There may be a need for more education and awareness about the potential helpfulness of digital health interventions among women who are trying to reduce or quit smoking.

MCP-W use was associated with a positive change in participant smoking behaviors. The average number of daily cigarettes reduced from 16.4 to 14.6, and more women reported that they attempted to quit after using the MCP-W compared with baseline (6 vs 2). The latter was more pronounced in women who used the app more versus less than 14 days. This is an encouraging finding, although it should be interpreted with caution given that our study did not have a control group. This finding is consistent with other reports from digital interventions for smoking cessation [13,35] that speak to the potential effectiveness of digital health tools to support individuals in quitting. Our sample included women with a high level of motivation for quitting, which did not change significantly across the study timeline. Women rated the importance of quitting smoking as 4.7/5 at both baseline and follow-up. However, their perceived "ability" to quit smoking, measured by the statement "I could change my smoking habits (reduce or quit)" decreased in a nonsignificant way from 4.1/5 to 3.7/6. Since many women reported tracking their cigarettes and reducing during the trial, it is possible that these actions crystalized the challenges they face in their day-to-day lives, thus rating their ability to quit as lower.

Women's attitudes toward quitting were closely linked with whether they rated the MCP-W app as acceptable and the relative intensity of their use of the app (feasibility). Despite the majority of women reporting high motivation for quitting for common reasons, such as improving one's health, saving money, and for their families or children, many felt they were not ready to make this change. Lack of readiness was centered around life stressors such as material hardship, interpersonal conflict, lone parenting, mental illness, and medical problems. Dealing with the above was prioritized, and quitting smoking was left to be dealt with in the future, when life circumstances would change. This notion is consistent with the previous literature on women and smoking [7]. This explains, in part, why some women did not find the app acceptable. The app cannot directly change difficult life circumstances but is aimed at strengthening women's resilience in light of them. It is possible that combining the use of the app with support from cessation counselors could provide women with clarity regarding the individual barriers they face and guide them to develop helpful strategies to overcome those barriers [36].

The MCP-W app contained evidence-based gender-neutral behavior change techniques meant to facilitate change via goal setting, tracking daily cigarettes, and identifying triggers for smoking [23]. Most women found these techniques helpful. This is consistent with previous research on effective features that are recommended for use in smoking cessation apps [13]. However, in our study, women who were not ready to quit tended to put less effort into these behavioral tasks (ie, logging smoked cigarettes and identifying smoking triggers), compared with women who were ready to quit. Some women also commented on the efforts needed to enter information into the

XSL•FO
RenderX

app (ie, goal setting and tracking), and felt it was a big task, particularly from women with very little free time, like single mothers. It is possible that newer technologies will be able to make these tasks less tedious and easier to perform. For example, voice to app features, where you do not need to enter information manually to your device but use a voice command to do so (eg, "MCP-W, record I just smoked one cigarette in my car as I am driving back from work"). Voice-activated app functions are widely used today [37] and should be explored in the future as a method to reduce the burden of tracking a target behavior.

The MCP-W app contained gender-specific components including 4 animation videos and testimonials from women who quit smoking. The majority of women appreciated the tailored content and felt they could relate to the challenges expressed by other women. They sense that others sharing your struggles and understanding you is considered a key tenet of peer-supported activities in addiction recovery [38]. In addition, seeing other women succeed in quitting smoking may also improve one's self-efficacy of quitting as suggested by the social cognitive theory [39]. It could also help reduce the stigma and shame that is associated with smoking that is known to undermine cessation treatment seeking in some women [40]. It is possible that this will provide women with future gains of increased readiness to ask health care providers and family members for cessation support instead of smoking in secret or denying their smoking [41].

Overall, several participants who described themselves as motivated and ready to quit reported using the behavioral tools in the app with greater engagement. This helped them identify triggers for smoking and come up with alternatives to smoking in these situations. Other participants wished for live support to address challenges, such as chronic medical conditions or mental illness, that come in the way of quitting. This support is most likely to be achieved through interactive counseling by a human or agent. Nonetheless, our results suggest that the MCP-W could be helpful to a subset of women who are willing to use the app in line with their strong commitment to quitting. These findings also indicate that future research should consider stratifying or targeting participants based on motivation and readiness to quit, as well as testing the MCP-W app as part of a blended intervention model (eg, combined with counseling or pharmacotherapy). For example, for women who struggle to engage with the app due to life challenges and low motivation for quitting, a live counseling alternative could be doubly helpful. First, it provides ongoing encouragement and emotional support, and second, it solves problems like how to overcome specific barriers in one's life, such as having a smoking male partner. Alternately, some women felt that the support could be delivered using a virtual agent such as an AI-based chatbot counselor. Given the advances in the use of AI technologies in health care and the early success of smoking cessation chatbots [35], this is an avenue for scalable low-cost support that should be tested in the future.

Strengths and Limitations

The strengths of the study include the co-development of gender-specific content for a smoking cessation app by collaborating with patient partners and subject matter experts [42]. In addition, the use of mixed methods ensured that we captured in-depth contextual information about the quantitative findings of the app's acceptability and feasibility using qualitative data from the interviews [43]. However, most of the participants in this study were treatment-seeking individuals that reported continuing to smoke at the end of a treatment course with the STOP program. This represents a selection bias toward individuals with treatment resistance, which could limit generalizability to women who smoke in the general population [44]. In addition, the study sample size was small and nonparametric tests had to be conducted to explore the acceptability and feasibility. We also acknowledge that the study sample primarily consisted of middle-aged women with higher levels of education, which may limit the generalizability of our findings to younger individuals or those experiencing socioeconomic disadvantage. However, this was an exploratory study, and the attrition rate of participants was low, which allowed us to conduct appropriate statistical analyses.

Conclusions

The MCP-W app could serve as a valuable tool to support women in their journey to quit smoking. By delivering gender-specific smoking cessation content through a pre-existing gender-neutral platform, the app addresses unique needs. The acceptability and feasibility of the app are closely linked to the motivation and readiness of the woman attempting to quit. Improvements such as incorporating interactive features and offering additional personalized support could enhance its relevance. Feedback from participants highlighted the app's most helpful features, providing valuable insights. These findings underscore not only the current value of the MCP-W app but also its potential to evolve through continuous improvement, leading to greater effectiveness in women-focused smoking cessation interventions.

Acknowledgments

The authors wish to acknowledge the Center for Addiction and Mental Health (CAMH) Information Management Group for programming the My Change Plan–Women app, those contributing to the development of the animation videos—Mathangee Lingam, Darrelle Carpentier, Sophia Alcasabas, Adina Coriou—and patient partners Natasha Jaczek, Jung No, Lesley Quair, Mirabelle Infante, and Susan Haney involved in the development of the app content. Abstract

Background: Incorporating serious games and advancements in information and communication technologies into physical rehabilitation can substantially enhance the process, provide unique benefits, and improve its effectiveness and efficiency. While recent literature highlights various game-based interventions for physical rehabilitation, there is a lack of comprehensive guidance on how to design and develop systems that effectively address the actual needs of therapists, practitioners, and individuals with physical disabilities.

Objective: The objective of this study was to explore the intentions, needs, and desires of therapists and other practitioners, as well as to examine the factors and determinants influencing the effectiveness and efficacy of game-based physical rehabilitation, since therapists and other health care practitioners play crucial roles in both patient recovery and the establishment of an effective game-based therapy.

Methods: A design science approach was adopted to achieve this research objective. A focus group of 27 participants was conducted to gather feedback, identify user needs, and understand the requirements for game-based physical rehabilitation. The participants first tested commercially available games and then evaluated mock-ups of the proposed game prototypes.

Results: This study provides essential design insights and guidelines for designers and researchers, focusing on the practical needs and requirements of game-based physical rehabilitation systems.
